Abstract. During the last decades, the methods for intuitive task level programming of robots have become a fundamental point of interest for industrial application. The paper in hand presents SkiROS (Skill-based Robot Operating System) a novel software architecture based on the skills paradigm. The skill paradigm has already been used and tested within the FP7 project TAPAS, and we are going to use it in several new FP7 projects (CARLOS, STAMINA, ACAT). It facilitates task-level programming of mobile manipulators by providing the robot with a set of movement primitives, skills and tasks. This hierarchy brings many advantages, where the most relevant is the separation of control in the layers of hardware abstraction (proxy), multi-sensory control (primitive), object-level abstraction (skill) and planning (task). The definition and the clear division in different abstraction levels allows the implementation of a flexible, highly modular system for the development of cognitive robot tasks.

Keywords: Mobile manipulation, Software architecture, Task-level programming

1 Project idea and objectives

The task-level programming is a way of programming a robot on an abstract level. This promises to decrease the amount of competences necessary to deal with complex robots and it is a powerful way to speed up the programming process and the code reuse. This is realized creating an abstraction which hide the complexity of the lower layers and allows to focus on the task itself. Task-level programming specifies what the robot should do in terms of actions on the objects involved in the task and not necessarily to the full extent how it should be achieved.

In earlier papers [1, 4] we defined tasks as a sequence of skills where the skills provide the atomic programming blocks that a) unify sensing and robot action for
interaction with the environment [4] and b) are motivated by human intuition [1]. The skills are comparable to the manipulation primitive nets, described best in [2]. These nets are sequences of manipulation primitives, with simple decisions based on the outcome of each single manipulation primitive in the net. In these nets each manipulation primitive needs its own explicitly specified parameters, e.g., a specific force or velocity in a specific direction. This, however, makes this particular implementation unsuitable for robotics novices in a factory hall. Instead, our skills propose a method for specifying only high-level parameters, while low-level parameter for the lower level primitives are mostly inferred through reasoning. This also brings the skill names more close to human intuition, e.g., ”pick” and ”place”.

The research on tiered robotic architectures started in ’80 [3], and still no standard exists. A major research effort to form a generalized robot middleware is the Robotic Operating System (ROS) [6] where there are some projects in the similar direction as SkiROS. Two examples are moveIT [7] and ROSco [5]. The former is focused on industrial manipulators and embed some good tools, like collision-detection, arm motion planning and execution, etc. ROSco is focused on home environment robots, it is based on ”behaviors”, which are Hierarchical Finite State Machine (HFSM) composed of generic, parameterized building blocks. [5]

SkiROS aims to create a system capable of extending the capabilities of moveIT with high level ones similar to those realized within ROSco. In that sense, the final objective of SkiROS is to give us a flexible platform, integrating the state of the art in the task-level programming. It will be used as a tool to make research and aims to go beyond the state of the art in terms of robustness, sustainability and execution speed.

The main structure of SkiROS is illustrated in Figure 1. It is divided into 4 layers, each one with separate interfaces for specific usage and development. This structure allows the development of key features and algorithms as independent

![Diagram of SkiROS layers](image_url)

**Fig. 1.** The proposed layers in SkiROS, with the related concerns. The Device Layer realizes the hardware abstraction, the Primitive Layer merges the hardware control with sensors feedback. The Skill Layer realizes a concatenation of primitive device properties, based only on semantic information. Finally, the Task Layer plans the skill sequence to achieve the final goal.
plugins in a modular way without interfering with the rest of the core system. Thus, the sharing, reuse and collaborative development of further plugins will be an straightforward task.

2 ROS benefit for the project

*SkiROS* targets an ambitious goal which shares some of its main functionalities with ROS. In particular:

- ROS interprocess communication structure (topics, services and actions), a fundamental feature to modularize the system.
- ROS pluginlib to easily insert new functionalities in the system layers meanwhile decouple them from the system itself. Note that the use of pluginlib bind us, for now, to code entirely in C++.
- ROS drivers to interact with sensors.
- URDF/SRDF standard to describe the robot structure.
- Rviz and Gazebo used to visualize and/or simulate robot environments.
- ROS moveIT package offering many fundamental functionalities in the pick-place pipeline.
- ROS-industrial package offers drivers for industrial arms and grippers.

3 Contribution to ROS-I

The contribution of *SkiROS* to ROS-industrial is a trailblazing investigation of the first ROS architecture capable to allow easy and independent implementation/use of functionalities on different levels of abstraction, from hardware control to complex tasks. In particular it will:

- Bring forward the hardware abstraction standard already started for arms, but not for other devices.
- Investigate a primitive standard, where can be realized different constrained and sensor-based control strategies and sensor data analysis.
- Investigate skill standard to realize a reliable concatenation of primitives using semantic information.
- Investigate a task-planning system.

The system is going to extensively used and validated into real industrial environment in terms of robustness, sustainability and intuitiveness within at least three European projects, *CARLOS, STAMINA* and *ACAT*.

4 Use cases

*SkiROS* will target numerous use-cases in several projects. Some of them identified within the *STAMINA* project are presented below:
– Use-Case 1: De-palletizing, pick objects placed with a rough order in a container.
– Use-Case 2: Bin-picking, pick objects randomly placed into a container.
– Use-Case 3: Kitting, collecting the components into a joint kit.

The use-cases require the robot to fetch the right parts from different types storage, pallets and containers, and place them into the kits. This should be accompanied with a built-in quality check of the parts. This require skills such as bin-picking, navigation, inspection and placing. Based on the use-case specs provided the robot should be able to find out autonomously how it can solve the task, ideally without the need of additional programming.

STAMINA address the call ICT-2013.2.2 "Robotics use cases & Accompanying measures project" and it is a 3 years length project.

5 Conclusion and future works

In this paper we briefly presented our task-level programming paradigm, based on skills. The skill based system has already been used and tested extensively in the context of industrial settings of the EU FP7 Project TAPAS [4]. It was a robust system, which simplified the task planning of mobile manipulators and while its general performance can be considered adequate, there is plenty of room for improvements. As a consequence, we have now started developing a reference implementation under the name SkiROS, a robot software architecture tailored for the specific needs of industrial projects, which implements the skill paradigm with a modular and flexible way. Its main characteristic is the realization of complex robotic applications including multi-robot cooperation and integration of sensors in a plethora of robot operations. It will allow to develop, compile, share and use code easier, on every layer of abstraction.
