Model Reduction of Linear Switched Systems by Restricting Discrete Dynamics

Mert Baştuğ1,2, Mihály Petreczky2, Rafael Wisniewski1 and John Leth1

Abstract—We present a procedure for reducing the number of continuous states of discrete-time linear switched systems, such that the reduced system has the same behavior as the original system for a subset of switching sequences. The proposed method is expected to be useful for abstraction based control synthesis methods for hybrid systems.

I. INTRODUCTION

A discrete-time linear switched system [11], [18] (abbreviated by DTLSS) is a discrete-time hybrid system of the form

\[
\begin{align*}
\Sigma \left\{ \begin{array}{l}
x(t+1) = A_{\sigma(t)} x(t) + B_{\sigma(t)} u(t) \\
y(t) = C_{\sigma(t)} x(t),
\end{array} \right. \quad x(0) = x_0
\end{align*}
\]

where \( x(t) \in \mathbb{R}^n \) is the continuous state, \( y(t) \in \mathbb{R}^p \) the continuous output, \( u(t) \in \mathbb{R}^m \) the continuous input, \( \sigma(t) \in Q = \{1, \ldots, D\} \), \( D > 0 \) is the discrete state (switching signal), \( A_q, B_q, C_q \) are matrices of suitable dimension for \( q \in Q \). A more rigorous definition of DTLSSs will be presented later on. For the purposes of this paper, \( u(t) \) and \( \sigma(t) \) will be viewed as externally generated signals.

Contribution of the paper: Consider a discrete-time linear switched system \( \Sigma \) of the form (1), and a set \( L \) which describes the admissible set of switching sequences. In this paper, we will present an algorithm for computing another DTLSS

\[
\tilde{\Sigma} \left\{ \begin{align*}
\tilde{x}(t+1) &= \tilde{A}_{\sigma(t)} \tilde{x}(t) + \tilde{B}_{\sigma(t)} u(t) \\
\tilde{y}(t) &= \tilde{C}_{\sigma(t)} \tilde{x}(t)
\end{align*} \right. \quad \tilde{x}(0) = \tilde{x}_0
\]

such that for any switching sequence \( \sigma(0) \cdots \sigma(t) = q_0 \cdots q_t \in L \) and continuous inputs \( u(0), \ldots, u(t-1) \), the output at time \( t \) of (1) equals the output of (2), i.e., \( y(t) = \tilde{y}(t) \) and the number of state variables of (2) is smaller than that of (1). In short, for any sequence of discrete states from \( L \), the input-output behaviors of \( \Sigma \) and \( \tilde{\Sigma} \) coincide and the size of \( \tilde{\Sigma} \) is smaller.

Motivation: Realistic plant models of industrial interest tend to be quite large and in general, the smaller is the plant model, the smaller is the resulting controller and the computational complexity of the control synthesis or verification algorithm. This is especially apparent for hybrid systems, since in this case, the computational complexity of control or verification algorithms is often exponential in the number of continuous states [19]. The particular model reduction problem formulated in this paper was motivated by the observation that in many instances, we are interested in the behavior of the model only for certain switching sequences.

DTLSSs with switching constraints occur naturally in a large number of applications. Such systems arise for example when the supervisory logic of the switching law is (partially) fixed. Note that verification or control synthesis of DTLSSs can be computationally demanding, especially if the properties or control objectives of interest are discrete [5]. The results of the paper could be useful for verification or control of such systems, if the properties of interest or the control objectives depend only on the input-output behavior. In this case, we could replace the original DTLSS \( \Sigma \) by the reduced order DTLSS \( \tilde{\Sigma} \) whose input-output behavior for all the admissible switching sequences coincides with that of \( \Sigma \). We can then perform verification or control synthesis for \( \tilde{\Sigma} \) instead of \( \Sigma \). If \( \tilde{\Sigma} \) satisfies the desired input-output properties, then so does \( \Sigma \). The same applies for piecewise-affine hybrid systems, which can be modelled as a feedback interconnection of a linear switched system of the form (1) with a discrete event generator \( \phi \) which generates the next discrete state based on the past discrete states and past outputs [6], [20]. Likewise, assume that it is desired to design a control law for \( \Sigma \) which ensures that the switching signal generated by the closed-loop system belongs to a certain prefix closed set \( L \). Such problems arise in various settings for hybrid systems [19]. Again, this problem is solvable for \( \Sigma \) if and only if it is solvable for \( \tilde{\Sigma} \), and the controller which solves this problem for \( \tilde{\Sigma} \) also solves it for \( \Sigma \).

Related work: Results on realization theory of linear switched systems with constrained switching appeared in [14]. However, [14] does not yield a model reduction algorithm, see Remark 1 in [2] for a detailed discussion. The algorithm presented in this paper bears a close resemblance to the moment matching method of [1], but its result and its scope of application are different. The subject of model reduction for hybrid and switched systems was addressed in several papers [3], [23], [12], [4], [8], [21], [22], [7], [9], [10], [13], [17]. However, none of them deals with the problem addressed in this paper.

Outline: In Section II, we fix the notation and terminology of the paper. In Section III, we present the formal definition and main properties of DTLSSs. In Section IV we give the precise problem statement. In Section V, we recall the con-
cept of Markov parameters, and we present the fundamental
theorem and corollaries which form the basis of the model
reduction by moment matching procedure. The algorithm
itself is stated in Section VI in detail. Finally, in Section
VII the algorithm is illustrated on a numerical example.

II. PRELIMINARIES: NOTATION AND TERMINOLOGY

Denote by $\mathbb{N}$ the set of natural numbers including 0.
Consider a non-empty set $Q$ which will be called the
alphabet. Denote by $Q^*$ the set of finite sequences of
elements of $Q$. The elements of $Q^*$ are called strings or
words over $Q$, and any set $L \subseteq Q^*$ is called a language over
$Q$. Each non-empty word $w$ is of the form $w = q_1q_2 \cdots q_k$
for some $q_1, q_2, \ldots, q_k \in Q$, $k > 0$. In the following, if a
word $w$ is stated as $w = q_1q_2 \cdots q_k$, it will be assumed that
$q_1, q_2, \ldots, q_k \in Q$. The element $q_i$ is called the $i$th letter of
$w$, for $i = 1, 2, \ldots, k$ and $k$ is called the length of $w$.
The empty sequence (word) is denoted by $\varepsilon$. The length
of word $w$ is denoted by $|w|$; specifically, $|\varepsilon| = 0$. The set
of non-empty words is denoted by $Q^+$, i.e., $Q^+ = Q^\prime \setminus \{\varepsilon\}$. The set of words of length $k \in \mathbb{N}$ is denoted by $Q^k$.
The concatenation of word $w \in Q^*$ with $v \in Q^*$ is denoted
by $wv$; if $v = v_1v_2 \cdots v_k$, and $w = w_1w_2 \cdots w_m$, $k > 0$, $m > 0$, then
$wv = v_1v_2 \cdots v_kw_1w_2 \cdots w_m$. If $v = \varepsilon$, then $wv = w$; if $w = \varepsilon$, then $wv = v$.

If $Q$ has a finite number of elements, say $D$, it will be
identified with its index set, that is $Q = \{1, 2, \ldots, D\}.

III. LINEAR SWITCHED SYSTEMS

In this section, we present the formal definition of linear
switched systems and recall a number of relevant definitions.
We follow the presentation of [14], [16].

Definition 1 (DTLSS): A discrete-time linear switched
system (DTLSS) is a tuple
$$\Sigma = (p, m, n, Q, \{ (A_q, B_q, C_q) | q \in Q \}, x_0)$$
(3)
where $Q = \{1, \ldots, D\}$, $D > 0$, called the set of discrete
modes, $A_q \in \mathbb{R}^{n \times n}$, $B_q \in \mathbb{R}^{n \times m}$, $C_q \in \mathbb{R}^{p \times n}$ are the matrices
of the linear system in mode $q \in Q$, and $x_0$ is the initial state.
The number $n$ is called the dimension (order) of $\Sigma$ and will
sometimes be denoted by $\dim(\Sigma)$.

Notation 1: In the sequel, we use the following notation and
termination: The state space $X = \mathbb{R}^n$, the output
space $Y = \mathbb{R}^p$, and the input space $U = \mathbb{R}^m$. We will write
$U^+ \times Q^+ = \{(u, \sigma) | u \in U^+ \times Q^+ \}$, $|u| = |\sigma|$, and $\sigma(t)$ for the
$t$th element $q_t$ of a sequence $\sigma = q_1q_2 \cdots q_{|\sigma|} \in Q^+$ (the
same comment applies to the elements of $U^+, X^+$ and $Y^+$).

Throughout the paper, $\Sigma$ denotes a DTLSS of the form
(1).

Definition 2 (Solution): A solution of the DTLSS $\Sigma$ at the
initial state $x_0 \in X$ and relative to the pair $(u, \sigma) \in U^+ \times Q^+$
is a pair $(x, y) \in X^+ \times Y^+$, $|x| = |\sigma| + 1$, $|y| = |\sigma|$ satisfying
$$x(t+1) = A_{\sigma(t)}x(t) + B_{\sigma(t)}u(t), \quad x(0) = x_0$$
$$y(t) = C_{\sigma(t)}x(t),$$
for $t = 0, 1, \ldots, |\sigma| - 1$.
We shall call $u$ the control input, $\sigma$ the switching sequence,
$x$ the state trajectory, and $y$ the output trajectory. Note that
the pair $(u, \sigma) \in U^+ \times Q^+$ can be considered as an input to
the DTLSS.

Definition 3 (Input-state and input-output maps): The
input-state map $X_{\Sigma, x_0}$ and input-output map $Y_{\Sigma, x_0}$ for the
DTLSS $\Sigma$, induced by the initial state $x_0 \in X$, are the maps
$$U^+ \times Q^+ \rightarrow X^+; (u, \sigma) \mapsto X_{\Sigma, x_0}(u, \sigma) = x,$$
$$U^+ \times Q^+ \rightarrow Y^+; (u, \sigma) \mapsto Y_{\Sigma, x_0}(u, \sigma) = y,$$
where $(x, y)$ is the solution of $\Sigma$ at $x_0$ relative to $(u, \sigma)$.

Next, we present the basic system theoretic concepts for
DTLSSs. The input-output behavior of a DTLSS realization
can be formalized as a map
$$f : U^+ \times Q^+ \rightarrow Y^+.$$ (5)
The value $f(u, \sigma)$ represents the output of the underlying
(black-box) system. This system may or may not admit a
description by a DTLSS. Next, we define when a DTLSS
describes (realizes) a map of the form (5).

The DTLSS $\Sigma$ of the form (1) is a realization of an input-
output map $f$ of the form (5), if $f$ is the input-output map of
$\Sigma$ which corresponds to some initial state $x_0$, i.e., $f = Y_{\Sigma, x_0}$.
The map $Y_{\Sigma, x_0}$ will be referred to as the input-output map of
$\Sigma$, and it will be denoted by $Y_{\Sigma}$. The following discussion is
valid only for realizable input-output maps.

We say that the DTLSSs $\Sigma_1$ and $\Sigma_2$ are equivalent if $Y_{\Sigma_1} = Y_{\Sigma_2}$.
The DTLSS $\Sigma_m$ is said to be a minimal realization of
$f$, if $\Sigma_m$ is a realization of $f$, and for any DTLSS $\Sigma$ such
that $\Sigma$ is a realization of $f$, $\dim(\Sigma_m) \leq \dim(\Sigma)$. In [14], it is
stated that a DTLSS realization $\Sigma$ is minimal if and only
if it is span-reachable and observable. See [14] for detailed
definitions of span-reachability and observability for LSSs.

IV. MODEL REDUCTION BY RESTRICTING THE SET
OF ADMISSIBLE SEQUENCES OF DISCRETE MODES

In this section, we state formally the problem of restricting
the discrete dynamics of the DTLSS .

Definition 4: A non-deterministic finite state automaton
(NDFA) is a tuple $\mathcal{A} = (S, Q, \{ -q(t) \}_{t \in Q}, F, x_0)$ such that
1) $S$ is the finite state set,
2) $F \subseteq S$ is the set of accepting (final) states,
3) $-q(t) \subseteq S \times S$ is the state transition relation labelled by
$q \in Q$.
4) $x_0 \in S$ is the initial state.

For every $v \in Q^*$, define $-v$ inductively as follows:
$-v = \{(s, s) | s \in S\}$ and $-qv = \{(s_1, s_2) \in S \times S | \exists s_3 \in S : (s_1, s_3) \in -v \text{ and } (s_3, s_2) \in -q(t)\}$ for all $q \in Q$. We denote
the fact $(s_1, s_2) \in -v$, by $s_1 \rightarrow_v s_2$. Define the language $L(\mathcal{A})$ accepted by $\mathcal{A}$ as
$$L(\mathcal{A}) = \{ v \in Q^* | \exists s \in F : s_0 \rightarrow_v s \}.$$ Recall that a language $L \subseteq Q^*$ is regular, if there exists an
NDFA $\mathcal{A}$ such that $L = L(\mathcal{A})$. In this case, we say that $\mathcal{A}$
accepts or generates $L$. We say that $\mathcal{A}$ is co-reachable, if
from any state a final state can be reached, i.e., for any $s \in S,$
there exists $v \in Q^*$ and $s_f \in F$ such that $s \rightarrow s_f$. It is well-known that if $A^0$ accepts $L$, then we can always compute an N DFA $A_{co-r}$ from $A^0$ such that $A_{co-r}$ accepts $L$ and it is co-reachable. Hence, without loss of generality, in this paper we will consider only co-reachable NDFA.

**Definition 5 (Realization and L-equivalence):** Consider an input-output map $f$ and a DT LSS $\Sigma$. Let $L \subseteq Q^*$. We will say that $\Sigma$ is an $L$-realization of $f$, if for every $u \in U^+$, and every $\sigma \in L$ such that $|\sigma| = |u|$, $Y_\Sigma(u, \sigma)(|\sigma| - 1) = f(u, \sigma)(|\sigma| - 1)$,

\[
Y_\Sigma(u, \sigma)(|\sigma| - 1) = f(u, \sigma)(|\sigma| - 1),
\]

i.e., the final value of $Y_\Sigma$ and $f$ agrees for all $(u, \sigma) \in U^+ \times L$, $|\sigma| = |u|$. Note that a $Q^+$-realization is precisely a realization. We will say that two DT LSS $\Sigma_1$ and $\Sigma_2$ are $L$-equivalent, if $\Sigma_2$ is an $L$-realization of $Y_{\Sigma_1}$ (or equivalently if $\Sigma_1$ is an $L$-realization of $Y_{\Sigma_2}$).

**Problem 1 (Model reduction preserving L-equivalence):** Consider a minimal DT LSS $\Sigma$ and let $L \subseteq Q^+$ be a regular language. Find a DT LSS $\mathcal{\Sigma}$ such that $\dim(\mathcal{\Sigma}) < \dim(\Sigma)$ and, $\Sigma$ and $\mathcal{\Sigma}$ are $L$-equivalent.

V.MODEL REDUCTION ALGORITHM: PRELIMINARIES

In order to present the model reduction algorithm and its proof of correctness, we need to recall the following definitions from [15].

**Definition 6 (Convolution representation):** The input-output map $f$ has a generalized convolution representation (abbreviated as GCR), if there exist maps $S^f_0 : Q^+ \rightarrow \mathbb{R}^r$, $S^f : Q^+ \rightarrow \mathbb{R}^{p \times m}$, such that $S^f(q) = 0$ if $q \in Q$ and $f(u, \sigma)(t) = S^f_0(q_0q_1 \cdots q_t) + \sum_{k=0}^{t-1} S^f(q_kq_{k+1} \cdots q_t)u_k$

for all $(u, \sigma) \in U^+ \times Q^+$, $0 \leq t \leq |\sigma| - 1$ with $\sigma = q_0q_1 \cdots q_{|\sigma|-1}$.

By a slight abuse of the terminology adopted in [15], we will call the maps $\{S^f, S^f_0\}$ the Markov parameters of $f$. Notice that if $f$ has a GCR, then the Markov-parameters of $f$ determine $f$ uniquely. In other words, the Markov-parameters of $f$ and $g$ are equal if and only if $f$ and $g$ are the same input-output map, i.e. $S^f_0 = S^g_0$ and $S^f = S^g$ if and only if $f = g$.

In the sequel, we will use the fact that Markov parameters can be expressed via the matrices of a space-representation. In order to present this relationship, we introduce the following notation.

**Notation 2:** Let $w = q_1q_2 \cdots q_k \in Q^*$, $k > 0$ and $A_{q_i} \in \mathbb{R}^{n \times i}$, $i = 1, \cdots, k$. Then the matrix $A_w$ is defined as

\[
A_w = A_{q_1}A_{q_2} \cdots A_{q_k}.
\]

If $w = \varepsilon$, then $A_{\varepsilon}$ is the identity matrix.

**Lemma 1 ([15]):** The map $f$ is realized by the DT LSS $\Sigma$ if and only if $f$ has a GCR and for all $v \in Q^*$, $q_0q \in Q$,

\[
S^f(q_0qv) = C_qA_vB_{q_0} \quad \text{and} \quad S^f_0(qv) = C_qA_vx_0.
\]

We will extend Lemma 1 to characterize the fact that $\Sigma$ is a realization of $f$ in terms of Markov parameters. To this end, we need the following notation.

**Notation 3 (Prefix and suffix of L):** Let the prefix $(L)_<$ and suffix $(L)_>$ of a language $L$ be defined as follows: $(L)_< = \{s \in Q^* \mid \exists w \in Q : sw \in L\}$, and $(L)_> = \{s \in Q^* \mid \exists w \in Q : ws \in L\}$. In addition, let the 1-prefix $(L)_1$ and 1-suffix $(L)_1$ of a language $L$ be defined as follows: $(L)_1 = \{s \in Q^1 \mid \exists q \in Q : sq \in L\}$ and $(L)_1 = \{s \in Q^1 \mid \exists q \in Q : qs \in L\}$. A language $L$ is said to be prefix (resp. suffix) closed if $(L)_1 = L$ (resp. $(L)_1 = L$).

See [2] for an example which further illustrates this notation. Note that if $L$ is regular, then so are $(L)_<$, $(L)_>$, $(L)_1$, $(L)$. Moreover NDFA accepting these languages can easily be computed from an N DFA which accepts $L$.

The proof of Lemma 1 can be extended to prove the following result, which will be central for our further analysis.

**Lemma 2:** Assume $f$ has a GCR. The DT LSS $\Sigma$ is an $L$-realization of $f$, if and only if for all $v \in Q^*$, $q_0q \in Q$

\[
\begin{align*}
q_0vq & \in (L)_1 \implies S^f_0(qv) = C_qA_vx_0, \\
q_0vq & \in (L)_1 \implies S^f(q_0qv) = C_qA_vB_{q_0}.
\end{align*}
\]

Lemma 1 implies the following important corollary.

**Corollary 1:** $\Sigma$ is $L$-equivalent to $\hat{\Sigma} = (p, m, r, Q, \{\hat{A}_{q_1}B_{q_2}\} \hat{C}_{q} \hat{q} \in Q, \hat{x}_0)$ if and only if

(i) $\forall q \in Q, v \in Q^* : q \in L \implies C_qA_vx_0 = \hat{C}_{q}\hat{A}_{\hat{q}}\hat{x}_0$,

(ii) $\forall q_0q \in Q, v \in Q^* : q_0q \in (L) \implies C_qA_vB_{q_0} = \hat{C}_{q}\hat{A}_{\hat{q}}\hat{B}_{\hat{q}_0}$.

That is, in order to find a DT LSS $\hat{\Sigma}$ which is an $L$-equivalent realization of $\Sigma$, it is sufficient to find a DT LSS $\hat{\Sigma}$ which satisfies parts (i) and (ii) of Corollary 1. Intuitively, the conditions (i) and (ii) mean that certain Markov parameters of the input-output maps of $\Sigma$ match the corresponding Markov parameters of the input-output map of $\hat{\Sigma}$. Note that $L$ need not be finite, and hence we might have to match an infinite number of Markov parameters. Relying on the intuition of [1], the matching of the Markov parameters can be achieved either by restricting $\Sigma$ to the set of all states which are reachable along switching sequences from $L$, or by eliminating those states which are not observable for switching sequences from $L$. Remarkably, these two approaches are each other's dual.

Below we will formalize this intuition. To this end we use the following notation.

**Notation 4:** In the sequel, the image and kernel of a real matrix $M$ are denoted by $\text{im}(M)$ and $\ker(M)$ respectively. In addition, the $n \times n$ identity matrix is denoted by $I_n$.

**Definition 7 (L-reachability space):** For a DT LSS $\Sigma$ and $L \subseteq Q^*$, define the $L$-reachability space $\mathcal{R}_L(\Sigma)$ as follows:

\[
\mathcal{R}_L(\Sigma) = \text{span}\{A_{x_0}x_v \mid v \in Q^*, v \in ((L)_1)\} \cup \{\text{im}(A_{v_1}B_{q_0}) \mid v \in Q^*, q_0v_0v \in ((L)_1)\}.
\]

Whenever $\Sigma$ is clear from the context, we will denote $\mathcal{R}_L(\Sigma)$ by $\mathcal{R}_L$.

Recall that according to Notation 3

\[
((L)_1)_< = \{s \in Q^* \mid \exists v_1 \in Q^* : sv_1q \in L\},

((L)_1)_> = \{s \in Q^* \mid \exists v_1, v_2 \in Q^* : v_1sv_2q \notin L\}.
\]
Intuitively, the $L$-reachability space $\mathcal{R}_L(\Sigma)$ of a DTLSS $\Sigma$ is the space consisting of all the states $x \in X$ which are reachable from $x_0$ with some continuous input and some switching sequence from $L$. It follows from [14], [18] that $\Sigma$ is span-reachable if and only if $\dim(\mathcal{R}_L(\Sigma)) = n$.

Definition 8 (L-unobservability subspace): For a DTLSS $\Sigma$, and $L \subseteq Q^*$, define the $L$-unobservability subspace as

$$\mathcal{O}_L(\Sigma) = \bigcap_{v \in Q^*, q \in Q, v \in L} \ker(C_qA_v).$$

If $\Sigma$ is clear from the context, we will denote $\mathcal{O}_L(\Sigma)$ by $\mathcal{O}_L$. Recall that according to Notation 3,

$$s(L) = \{s \in Q^* | \exists v \in Q^*: vs \in L\}. \tag{13}$$

Intuitively, the $L$-unobservability space $\mathcal{O}_L(\Sigma)$ is the set of all those states which remain unobservable under switching sequences from $L$.

From [18], it follows that $\Sigma$ is observable if and only if $\mathcal{O}_L = \{0\}$. Note that $L$-unobservability space is not defined in a totally “symmetric” way to the $L$-reachability space, i.e., subscript of the intersection sign in Equation (12) is not $vq$, $s(L)$.

VI. MODEL REDUCTION ALGORITHM

In this section, we present an algorithm (Algorithm 3) for solving Problem 1. The proposed algorithm relies on computing the matrices $P$ and $W$ which satisfy the conditions of Lemma 3 and Lemma 4 respectively. In order to compute these matrices, we will formulate alternative definitions of $L$-reachability/unobservability spaces. To this end, for matrices $G.H$ of suitable dimensions and for a regular language $K \subseteq Q^*$ define the sets $\mathcal{R}_K(G)$ and $\mathcal{O}_K(G)$ as follows:

$$\mathcal{R}_K(G) = \text{span}\{\im(A_vG) | v \in K\}$$

$$\mathcal{O}_K(H) = \bigcap_{v \in K} \ker(HA_v).$$

Then the $L$-reachability space of $\Sigma$ can be written as

$$\mathcal{R}_L = \mathcal{R}_{(L)_1}(x_0) + \sum_{q \in Q} \mathcal{R}_{(q\{K\})}(B_q), \tag{14}$$

where $((L)_1)_s$ is defined as in (11), and

$$q(K) = \{s \in Q^* | \exists v_1, v_2 \in Q^*, q = v_1v_2 \in L\}. \tag{15}$$

In (14), + and $\sum$ denote sums of subspaces, i.e. if $\mathcal{W}, \mathcal{V}$ are two linear subspaces of $\mathbb{R}^n$, then $\mathcal{W} + \mathcal{V} = \{a + b | a \in \mathcal{W}, b \in \mathcal{V}\}$. Similarly, if $\{\mathcal{W}_i\}_{i \in I}$ is a finite family of linear subspaces of $\mathbb{R}^n$, then $\sum_{i \in I} \mathcal{W}_i = \{\sum_{i \in I} a_i | a_i \in \mathcal{W}_i, i \in I\}$.

The $L$-unobservability space can be written as

$$\mathcal{O}_L = \bigcap_{q \in Q} \mathcal{O}_{(q\{K\})}(C_q). \tag{16}$$

where

$$K^q = \{s \in Q^* | \exists v \in Q^*, vsq \in L\}. \tag{17}$$

Note that if $L$ is regular, then $q(K)$ and $K^q$, $q \in Q$, and $((L)_1)_s$ are also regular and NDFA’s accepting $q(K)$, $K^q$, $q \in Q$, and $((L)_1)_s$, can easily be computed from a NDFA accepting $L$. From (14) and (16) it follows that in order to compute the matrix $P$ in Lemma 3 or $W$ in Lemma 4, it is enough to compute representations of the subspaces $\mathcal{R}_K(G)$ and $\mathcal{O}_K(H)$ for various choices of $K$, $G$ and $H$. The corresponding algorithms are presented in Algorithm 1 and Algorithm 2. There, we used the following notation.

Notation 5 (orth): For a matrix $M$, $\text{orth}(M)$ denotes the matrix $U$ whose columns form an orthogonal basis of $\im(M)$.

Lemma 5 (Correctness of Algorithm 1 – Algorithm 2): Algorithm 1 computes $\mathcal{R}_K(G)$ and Algorithm 2 computes $\mathcal{O}_K(H)$.

Proof: See [2].

Notice that the computational complexities of Algorithm 1 and Algorithm 2 are polynomial in $n$, even though the spaces of $\mathcal{R}_L$ (resp. $\mathcal{O}_L$) might be generated by images (resp. kernels) of exponentially many matrices.

Using Algorithm 1 and 2, we can state Algorithm 3 for solving Problem 1. The matrices $P$ and $W$ computed in Algorithm 3 satisfy the conditions of Lemma 3 and Lemma 4 respectively. Lemma 3 – 4 then imply the following corollary.

Corollary 2 (Correctness of Algorithm 3): The LSS $\Sigma$ returned by Algorithm 3 is a solution of Problem 1, i.e. $\Sigma$ is $L$-equivalent to $\Sigma$ and $\dim(\Sigma) \leq \dim(\Sigma)$.
Algorithm 1 Calculate a matrix representation of $\mathcal{O}_K(G)$.
Inputs: $(\{A_q\}_{q \in Q}, G)$ and $\mathcal{A} = (S, \{\rightarrow_q\}_{q \in Q}, F, s_0)$ such that $L(\mathcal{A}) = K, F = \{s_1, \ldots, s_k\}$, $k \geq 1$ and $\mathcal{A}$ is co-reachable. 
Outputs: $\hat{P} \in \mathbb{R}^{n \times n}$ such that $\hat{P}^T \hat{P} = I$, rank($\hat{P}$) = $\hat{r}$, $\text{im}(\hat{P}) = A_{\hat{r}}(G)$.

1: $\forall s \in S, \forall f : P_s := 0$.
2: $P_{s_0} := \text{orth}(G)$.
3: $\text{flag} := 0$.
4: while $\text{flag} = 0$ do
5: $\forall s \in S \land p^\text{old} := P_s$
6: $\forall s \in S$ do
7: $W_s := P_s.$
8: for $q \in Q, s' \in S : s \rightarrow_q s'$ do
9: $W_q := \begin{bmatrix} W_q \ A_q p^\text{old} \end{bmatrix}$
10: end for
11: $P_s := \text{orth}(W_s)$
12: end for
13: if $\forall s \in S : \text{rank}(P_s) = \text{rank}(p^\text{old})$ then
14: $\text{flag} := 1$.
15: end if
16: end while
17: return $\hat{P} = \text{orth}(\{P_{s_1}, \ldots, P_{s_k}\})$.

Algorithm 2 Calculate a matrix representation of $\mathcal{O}_K(H)$.
Inputs: $(\{A_q\}_{q \in Q}, H)$ and $\mathcal{A} = (S, \{\rightarrow_q\}_{q \in Q}, F, s_0)$ such that $L(\mathcal{A}) = K, F = \{s_1, \ldots, s_k\}$, $k \geq 1$ and $\mathcal{A}$ is co-reachable.
Outputs: $\tilde{W} \in \mathbb{R}^{n \times n}$ such that $\tilde{W}^T = I$, rank($\tilde{W}$) = $\tilde{r}$, $\text{ker}(\tilde{W}) = A_{\tilde{r}}(H)$.

1: $\forall s \in S, \forall f : W_s := 0$.
2: $\forall s \in F : W_s := \text{orth}(H^T)$.
3: $\text{flag} := 0$.
4: while $\text{flag} = 0$ do
5: $\forall s \in S \land p^\text{old} := W_s$
6: $\forall s \in S$ do
7: $P_s := W_s.$
8: for $q \in Q, s' \in S : s \rightarrow_q s'$ do
9: $P_s := \begin{bmatrix} P_s \ W_q^\text{old} A_q \end{bmatrix}$
10: end for
11: $W_s := \text{orth}(P_s^T)$
12: end for
13: if $\forall s \in S : \text{rank}(W_s) = \text{rank}(p^\text{old})$ then
14: $\text{flag} := 1$.
15: end if
16: end while
17: return $\tilde{W} = W_{s_0}$.

Algorithm 3 Reduction for DTLSSs
Inputs: $\Sigma = (p, m, n, Q, \{A_q, B_q, C_q\}_{q \in Q})$ and $\mathcal{A} = (S, \{\rightarrow_q\}_{q \in Q}, F, s_0)$ such that $L(\mathcal{A}) = L, F = \{s_1, \ldots, s_k\}$, $k \geq 1$ and $\mathcal{A}$ is co-reachable.
Output: $\tilde{\Sigma} = (p, m, r, Q, \{\tilde{A}_q, \tilde{B}_q, \tilde{C}_q\}_{q \in Q})$.

1: Compute a co-reachable NDFA $\mathcal{A}_q$ from $\mathcal{A}_q$ such that $L(\mathcal{A}_q) = (L(1))_s$, where $(L(1))_s$ is as in (11).
2: Use Algorithm 1 with inputs $(\{A_q\}_{q \in Q}, x_0)$ and NDFA $\mathcal{A}_q$. Store the output $\hat{P}$ as $P_{s_0} := \hat{P}$.
3: for $q \in Q$ do
4: Compute a co-reachable NDFA $\mathcal{A}_{q, q}$ from $\mathcal{A}_q$ such that $L(\mathcal{A}_{q, q}) = q(K)$, where $q(K)$ is as in (15).
5: Use Algorithm 1 with inputs $(\{A_q\}_{q \in Q}, B_q)$ and NDFA $\mathcal{A}_{q, q}$. Store the output $\tilde{P}$ as $P_{s_0} := \tilde{P}$.
6: end for
7: $P := \text{orth}(\{P_{s_0}, P_1 \cdots P_D\})$
8: for $q \in Q$ do
9: Compute a co-reachable NDFA $\mathcal{A}_{q, q}$ from $\mathcal{A}_q$, such that $L(\mathcal{A}_{q, q}) = (K)q$, where $(K)q$ is as in (17).
10: Use Algorithm 2 with inputs $(\{A_q\}_{q \in Q}, C_q)$ and NDFA $\mathcal{A}_{q, q}$. Store the output $\tilde{W}$ as $W_{s_0} := \tilde{W}$.
11: end for
12: $\tilde{W}^T := \text{orth}(\{\tilde{W}_1^T, \ldots, \tilde{W}_n^T\})$
13: if $\text{rank}(P) < \text{rank}(\tilde{W})$ then
14: Let $r = \text{rank}(P), P^{-1}$ be a left inverse of $P$ and set
$\tilde{A}_q = P^{-1} A_q P, \tilde{C}_q = C_q P, \tilde{B}_q = P^{-1} B_q, x_0 = P^{-1} x_0$.
15: end if
16: if $\text{rank}(P) < \text{rank}(\tilde{W})$ then
17: Let $r = \text{rank}(W)$ and let $W^{-1}$ be a right inverse of $W$. Set
$\tilde{A}_q = W A_q W^{-1}, \tilde{C}_q = C_q W^{-1}, \tilde{B}_q = W B_q, x_0 = W x_0$.
18: end if
19: return $\tilde{\Sigma} = (p, m, r, Q, \{\tilde{A}_q, \tilde{B}_q, \tilde{C}_q\}_{q \in Q})$.

Observe that the language $L$ accepted by the NDFA $\mathcal{A}$ is the set $L = \{12, 12312, \ldots\}$ and it can also be represented by the regular expression $L = (123)^*12$. As stated in Definition 4, the labels of the edges represent the discrete mode indices of the DTSSL. The model reduction procedure is applied to the single input - single output (SISO) DTSSL $\Sigma$ of order $n = 7$ with $Q = \{1, 2, 3\}$ and

- $A_1 = [[0, 1, 0, 0, 0, 0, 0]; \text{randn}(6, 7)]$
- $A_2 = [[\text{randn}(2, 7); [0, 0, 0, 0, 0, 0, 0]; \text{randn}(4, 7)]$
- $A_3 = [[\text{randn}(1, 7); [0, 0, 1, 0, 0, 0, 0]; \text{randn}(5, 7)]$
- $B_1 = \text{randn}(7, 1), B_2 = \text{randn}(7, 1), B_3 = \text{randn}(7, 1)$
- $C_1 = \text{randn}(1, 7), C_2 = [1, 0, 0, 0, 0, 0, 0], C_3 = \text{randn}(1, 7)$.

Applying Algorithm 3 to this DTSSL whose admissible switching sequences are generated by this NDFA, yields a reduced order system $\overline{\Sigma}$ of order $r = 3$, whose output values are the same as the original system $\Sigma$ for the instances when the NDFA reaches a final state. Note that this corresponds precisely to an $L$-realization in the sense of Definition 5 (the last outputs of $\Sigma$ and $\overline{\Sigma}$ are the same for all the switching sequences generated by the governing NDFA, i.e., for all

VII. NUMERICAL EXAMPLE

In this section, the model reduction method for DTSSLs with restricted discrete dynamics will be illustrated by a numerical example. The data used for the example and corresponding MATLAB code are available from https://kom.au.dk/~merth/. The example specifically illustrates the use of Lemma 4 and Algorithm 3. For an example where Lemma 3 is used, see [2]. The NDFA which generates the set of admissible switching sequences is defined as the tuple $\mathcal{A} = (S, \{\rightarrow_q\}_{q \in Q}, F, s_0)$ where $S = \{s_0, s_1, s_2\}, \rightarrow_1 = \{(s_0, s_1)\}, \rightarrow_2 = \{(s_1, s_2)\}, \rightarrow_3 = \{(s_2, s_0)\}$ and $F = \{s_1\}$. 

$A_1 = [[0, 1, 0, 0, 0, 0, 0]; \text{randn}(6, 7)]$
$A_2 = [[\text{randn}(2, 7); [0, 0, 0, 0, 0, 0, 0]; \text{randn}(4, 7)]$
$A_3 = [[\text{randn}(1, 7); [0, 0, 1, 0, 0, 0, 0]; \text{randn}(5, 7)]$
$B_1 = \text{randn}(7, 1), B_2 = \text{randn}(7, 1), B_3 = \text{randn}(7, 1)$
$C_1 = \text{randn}(1, 7), C_2 = [1, 0, 0, 0, 0, 0, 0], C_3 = \text{randn}(1, 7)$.
\sigma \in L(\mathcal{A}) \). In this example, the algorithm makes use of Lemma 4 and constructs the \( W \) matrix. The matrix \( W \in \mathbb{R}^{r \times n} \) computed is \( W = \begin{bmatrix} I_{1} & 0 \end{bmatrix} \). The outputs of \( \Sigma \) and \( \bar{\Sigma} \) for the switching sequence (18) of length 11 generated by the NDFA \( \mathcal{A} \) are given in Figure 1 for comparison.

\[
\sigma = 12312312312
\]  

(18)

Note that the resulting DTLSS is merely an \( L \)-realization of \( \Sigma \) and nothing more, i.e., its output coincides with the output of \( \Sigma \) for only the instances corresponding to the final states of the NDFA, see Remark 3 in [2] for further discussion. This fact is visible from Figure 1, where it can be seen that output corresponding to the final state \( s_f \) of the NDFA coincides for \( \Sigma \) and \( \bar{\Sigma} \) (Observe that for all switching sequences generated by \( \mathcal{A} \) ending with the label 2, the output values of \( \Sigma \) and \( \bar{\Sigma} \) are the same). The input sequence of length 11 used in the simulation is generated by the function \texttt{randn}. Finally, note that the DTLSS \( \Sigma \) is minimal [2] (note that the definition of minimality for linear switched systems are made by considering all possible switching sequences in \( Q^* \) [15]), whereas for the switching sequences restricted by the NDFA \( \mathcal{A} \), it turns out 4 states are disposable in this case. In fact, this is the main idea of the paper.

VIII. CONCLUSIONS

A model reduction method for discrete time linear switched systems whose discrete dynamics are restricted by switching sequences comprising a regular language is presented. The method is essentially a moment matching type of model reduction method, which focuses on matching the Markov parameters of a DTLSS related to the specific switching sequences generated by a nondeterministic finite state automaton. Possible future research directions include expanding the method for continuous time case, and approximating the input/output behavior of the original system rather than exactly matching it, and formulating the presented algorithms in terms of bisimulation instead of input-output equivalence.
