Results: Of 47 subjects, 27 were male and 20 female. Subjects’ mean age was 60 years old. Demographics included 26/47 (55%) African Americans, 7/47 (15%) Hispanics, 12/47 (26%) Caucasians and 2/47 (4%) Asian. Ninety-six % of patients (45/47) had been seen by a physician within the past year, and had been told their kidney function was poor. Eighty-three % of patients (39/47) were referred to a nephrologist. Thirty-six % patients saw a nephrologist and, of those patients, only 13 patients were referred to a surgeon for access. Of the patients who saw a nephrologist, twenty two % (6/28) did not follow through with access placement secondary to noncompliance. Thus, of 47 patients starting hemodialysis with a catheter, only 7 had actually seen a surgeon for access placement. The largest drop off in the continuum of care of the patient is between seeing the nephrologist and seeing the surgeon. Since half of the patients surveyed received care elsewhere, it indicates this finding is not unique to our institution.

Conclusions: There are numerous points in the path to arteriovenous access where attrition occurs. Nephrologists and primary care physicians must oversee proper follow up and follow through to assure successful access placement. In our study, we found that there is a big attrition point from nephrology to surgery referral. A coordinator to help follow up patients or a joint clinic are options to improve this problematic step.

FR-P0720

The Association of Overhydration Status with Megafistulas in End-Stage Renal Disease Patients on Hemodialysis Mihaly T. Tapolcai, Maria Faludi, Melinda Forr, András Tisler, Tibor Fulop, Klara Berta. Dept of Dialysis, Semmelweis Medical Care Semmelweis Univ, Budapest, Hungary; Nephrology, Semmelweis Univ, Budapest, Hungary; Nephrology, Univ of Mississippi, Jackson, MS.

Background: Megafistulas are tortuous dilated fistulas that fold upon themselves and become visible on the arm and shoulders all the way to the clavicle. They may exacerbate low cardiac output, as well as represent a problematic dilatation of the dialysis access. We sought to investigate the association of bioimpedance apparatus (BCM) measured extracellular fluid volume overhydration (OHV) and the presence of megafistulas.

Methods: In a cross sectional study we compared the pre-dialysis BCM-measured OHV% in 12 prevalent chronic dialysis patients with megafistulas (MEGA) who had negative angiographies with that of 52 control dialysis patients (CONTR).

Results: 10/12 MEGA patients had OHV% >16% as compared to 20/52 CONTR patients (Chi square p = 0.02).

**Megafistula and Overhydration**

![Graph showing degree of overhydration vs. megafistulas](image)

The degree of OHV% was 20.2 ± 7.4% among the MEGA vs. 14.4 ± 7.1% in the CONTR group (Student t p = 0.01), representing 4.2 ± 3.2 vs 2.8 ± 1.6 L of excess fluid (p = 0.03). MEGA patients took an average of 1.7 ± 1.4 vs. 0.8 ± 0.8 (p = 0.002) antihypertensive medications compared to the CONTR patients yet their blood pressure was 156/91 vs 141/78 mmHg (p = 0.03/0.0001). We found no difference in fistula vintage, body mass index, age, inflammatory markers, diabetes status or diuretic use. The odds ratio of overhydration being associated with a megafistula is 5.3 (p = 0.01).

Conclusions: There is an association of BCM-measured overhydrated clinical state with the presence of megafistulas; either as an increased volume capacitance or as a potential cause.

FR-P0721

The Observation of the Tunneled Cuffed Catheter Insertion Through Right Innominate Vein in Hemodialysis Patient Yanhuang Feng, Tianlei Cui, Peng Fu. Div of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.

Background: The routine vascular access for hemodialysis is often available due to thrombosis and occlusion after frequent cannulation, which leads to an increase in cost and difficulty of catheterization or recanalization. Further catheterization may accelerate the exhaustion of vascular resources. We inserted cuff catheter through right innominate vein in patients with thrombosis or occlusion of right internal jugular vein and subclavian vein so as to preserve precious vascular access at other parts of body. Here we report our observation of right innominate vein catheterization.

Methods: We enrolled patients who had been receiving regular HD in our center and to whom catheter cannot be inserted due to thrombosis or occlusion of internal jugular vein and subclavian vein. We performed cuff catheter insertion by puncturing right innominate vein in 8 patients and recorded their clinical features, lesion position, and efficacy of the treatment.

Results: Among the 8 cases, where mean age is 67.6 years (range from 54-78), 3 of them are male and 5 are female. All the patients received central venous catheterization for more than 2 times, with median time of having a catheter for 36 months. The vascular ultrasound and CTA reveals that all of them suffered thrombosis or occlusion of right internal jugular vein and subclavian vein. By puncturing right innominate vein, all the patients’ vascular accesses have been successfully established, with the end of cuff catheter located in the right atrium, superior vena cava (SVC) or SVC/ right atrial junction. No obvious discomfort has been reported, nor did complications such as hematoma and pneumothorax recorded. The mean follow-up period lasts for 12 months, all vascular access of these cases are patent.

Conclusions: For HD patients with limited vascular resources such as thrombosis or occlusion of right internal jugular vein and subclavian vein, the application of tunneled cuffed venous catheter through innominate vein has been proved to be safe and effective. It could preserve vascular access by bypassing the stenotic lesion internal jugular vein or subclavian vein, and reduce the incidence of vascular access exhaustion.

FR-P0722

Tunneled Hemodialysis Catheter and Hemodialysis Outcomes Vedran Pasara, Mladen Knotek. Dept of Medicine, Renal Div, Univ of Zagreb, Merkur Hospital, Zagreb, Croatia.

Background: Studies have reported that tunneled dialysis catheter (TDC) is associated with inferior hemodialysis (HD) patient (pt) survival, as compared to arteriovenous fistula (AVF). Since many cofactors may also affect survival of HD pts, it is unclear whether the risk for the worse survival arises from TDC per se, or from associated conditions. Therefore, the aim of this study was to determine the long-term outcome of HD patients, with respect to vascular access (VA).

Methods: This retrospective case-control study included all 156 TDC with 57 AVF from 2010 to 2012 at Clinical Hospital Merkur. Control group consisted of 97 pts dialyzed through AVF. The groups were matched according to dialysis unit and time of VA placement. The site of choice for the placement of TDC was right jugular vein. Kaplan-Meier analysis with log-rank test was used to assess pt survival. A multivariate Cox regression analysis was used to determine independent variables associated with the pt survival.

Results: Cumulative one-year survival of pts who were dialyzed exclusively through TDC was 86.4 % and of those who were dialyzed exclusively through AVF the survival was 97.1 % (p<0.002). In a multivariate Cox regression analysis, male sex and older age were independently negatively associated with the survival of HD pts, while shorter duration of HD before the creation of the observed VA, hypertension renal disease and glomerulonephritis were positively associated with survival. TDC turned to be an independent negative risk factor for survival of HD pts (HR 23.037, 95% CI 6.221-85.308).

Carpal Tunnel Syndrome Is Associated with Arteriovenous Fistula in Hemodialysis Patients

Il Young Kim,1 Min Jung Kim,1 Joon Hui Kim,1 Dong Won Lee,2 Soo Bong Lee,1 Su Min Park,1 Jong Man Park,2 Woo Jin Jung,2 Sang Heon Song,2 Eun Young Seong,2 Harin Rhee,2 Ihm Soo Kwak.2 1Internal Medicine, Pusan National Univ Yangsan Hospital, Yangsan, Republic of Korea; 2Internal Medicine, Pusan National Univ Hospital, Busan, Republic of Korea.

Background: Carpal tunnel syndrome (CTS) is associated with various systemic diseases such as rheumatoid arthritis, hypothyroidism, peripheral neuropathy and diabetes mellitus (DM). In hemodialysis patients, several factors can contribute to CTS, including amyloid deposition, generalized fluid retention, increased synovial volume, edema around the nerve, and an ischemic or ‘steal’ effect distal to a dialysis access. This study aimed to evaluate the influence of arteriovenous fistula (AVF) dysfunction on the development of CTS.

Methods: The study included 43 patients (23 male & 20 female) on maintenance hemodialysis via AVF and 97 healthy controls. The median nerves of study population were examined by ultrasonography. Cross-sectional area (CSA) of the median nerve was measured at the distal wrist (CSA-D), and proximal forearm (CSA-P), and wrist-to-forearm ratio (WFR; CSA-P/CSA-D) was calculated for each hand. We also investigated the history of percutaneous transluminal angioplasty (PTA) in them.

Results: The mean age of hemodialysis patients was 60.4 ± 16.0 years. The mean duration on hemodialysis was 48.3 ± 39.6 months. The WFRs in hemodialysis patients were higher than those in healthy controls (1.37 ± 0.45 vs. 1.21 ± 0.25, P < 0.05). The hands with AVF (n = 43) showed higher WFR than those without AVF (n = 43) in hemodialysis patients (1.35 ± 0.47 vs. 1.25 ± 0.26, P < 0.05). The WFRs in patients with a history of PTA were higher than those in patients without a history of PTA (1.46 ± 0.56 vs. 1.23 ± 0.32, P < 0.05).

Conclusions: In maintenance hemodialysis patients, WFR of median nerve was significantly increased in the hand with AVF. Moreover, development of CTS was related not only to AVF itself, but also to AVF function.

FR-PO724

Factors Affecting Patency of Haemodialysis Arterio-Venous Fistulae and Grafts

Ayesha Iritang-Ali, Salman Ahmed, Nicola Ding, Joseph Russell, Nihil Chitalia, Maggi Steele, Hannah R. Wilson, David Makanjuola. Renal Unit, St. Helier Hospital, Carshalton, United Kingdom.

Background: Arterio-venous fistulae (AVF) are the preferred access for haemodialysis (HD), and where these cannot be created, arterio-venous grafts (AVGs) are the next best option. AVFs/AVGs however, not uncommonly fail to mature. The causes of this are varied, but loss of patency due to thrombosis and/or significant stenoses are major causes. We investigated the factors affecting patency of AVFs/AVGs in order to identify whether there were any characteristics which were predictive of this.

Methods: All AVFs/AVGs created in our unit between 2006 and 2014 were reviewed. Reasons for loss of primary patency were obtained from the dialysis access database. Characteristics reviewed were age, gender, co-morbidity score, diabetes status and site of AVF. Patients were grouped as follows: patency <30 days, patency <90 days, patency >90 days and patency >365 days.

Results: There were 1897(1) AVFs and 251(2) AVGs created. 649 (34.2%) of AVFs were lower arm, all the AVGs were upper arm, or lower limb. 1346 (62%) were male. The main reasons for AVF loss were clotted/stenosed vessels in 76% of cases. There was no association between ethnicity or gender with regard to patency rates. Other variables are shown in table 1.

Conclusions: We did not find any definite predictive factors for loss of primary patency in the variables we studied. In particular, co-morbidity score, age and diabetes showed no association with poorer outcomes. There is quite a significant ‘drop off’ in primary patency at 12 months. In the majority of cases, this was due to thrombosis of the HD access. This highlights the importance of close surveillance, as measures to maintain patency (surgical or radiological) are more likely to be required in this period.

FR-PO725

Drug-Eluting Stents versus Bare-Metal Stents During Percutaneous Coronary Intervention in Patients on Dialysis

Tara I. Chang,1 Maria E. Montez-Rath,1 Mark A. Hlatky,1 Wolfgang C. Winkelmayer.2 1Stanford; 2Baylor College of Medicine.

Background: In patients undergoing percutaneous coronary intervention (PCI), drug-eluting stents (DES) reduce the need for repeat revascularization (RR) compared with bare-metal stents (BMS). The effects on death and MI are more controversial, with mixed results from observational studies and generally null results from clinical trials. However, few previous studies have focused patients with end-stage renal disease (ESRD). We compared the effectiveness of DES with BMS in a representative cohort of US patients on dialysis.

Methods: Using the US Renal Data System, we identified 36,117 patients on dialysis with Medicare Parts A+B who had PCI with stenting after DES became available in the US (4/23/03 – 12/31/10). We used propensity-score matching (PSM) and inverse probability of treatment weighting (IPTW) with Cox regression to examine the association of DES versus BMS on the following 1-year outcomes: death, death or MI, and death, MI or RR. Due to concerns about residual indication bias, we conducted a second, temporal analysis that leveraged the large changes in the prevalence of DES use during three distinct eras: Transitional (4/23/03 – 6/30/04); Liberal (7/1/04 – 12/31/06); and Selective (1/1/07 – 12/31/10).

Results: In the PSM and IPTW analyses, DES was associated with lower risks of all three outcomes compared with BMS.

Eleven Year Trends in Myocardial Infarction and Stroke in the Incident and Prevalent Dialysis Populations

**Background:** Myocardial infarction (MI) and cerebrovascular (CVA) events are highly prevalent in the chronic dialysis population. We aimed to quantify the annual incidence and trends of MI and CVA events from 2004 to 2014 in a large dialysis population.

**Methods:** We analyzed 600,000 patients receiving chronic dialysis from a large dialysis provider from January 2004 to December 2014. For each calendar year, we calculated the incidence of MI and CVA (event per 100 patient-years) identified by ICD9 code for the population in the first 120 days of chronic dialysis (incident period) and in the subsequent period after the first 120 days (prevalent period). Linear regression was used to quantify statistically significant trends in MI and CVA rate of the eleven year period.

**Results:** Over an eleven year period in the incident population, the mean incidence of MI and CVA was 3.3 and 3.2 events per 100 patient years respectively. Among the prevalent population, the mean incidence of MI and CVA was 1.9 and 1.8 events per 100 patient years respectively. Using linear regression models, the incidence of MI and CVA was found to decrease by 0.14 (p<0.05) and 0.11 (p=0.0009) per year among incident patients. Similarly, the incidence of MI and CVA was found to decrease by 0.06 (p=0.0007) and 0.10 (p<0.0001) per year among prevalent patients. See Figure 1.

**Conclusions:** Both MI and CVA rates are decreasing among incident and prevalent dialysis populations over the past eleven years.

---

FR-PO727

Relationship of Ticagrelor Dose and Platelet Reactivity in Patients with End Stage Renal Disease on Hemodialysis

**Background:** In our previous study, ticagrelor has superiority on platelet inhibition than clopidogrel in patients with end stage renal disease (ESRD) on hemodialysis (HD). One study compared two doses of ticagrelor (90 or 60mg) and placebo, reported that ticagrelor significantly reduced the risk of cardiovascular death, MI, or stroke and increased the risk of bleeding. The rate of bleeding is more frequent in 90mg group. We hypothesized there was some relationship between ticagrelor dose and platelet inhibition. We investigated efficacy and safety of standard and low dose ticagrelor, and clopidogrel in ESRD patients on HD.

**Methods:** In a single-center, prospective, randomized study, 50 ESRD patients were randomly assigned to receive clopidogrel (75mg once daily), standard dose ticagrelor (90mg twice daily) or low dose ticagrelor (90mg once daily) for 14-days. Platelet function assessment which included transmittance aggregometry, and VerifyNow TM P2Y12 assay were then used to serially measure. Maximal platelet aggregation (MPA), inhibition of platelet aggregation (IPA), and P2Y12 reaction units (PRUs) were evaluated. Results: Baseline characteristics, and concomitant medication of three groups were not significantly different. The standard dose ticagrelor showed significant lower MPA and higher IPA as compared with clopidogrel at 1.5 and 48 hours, and 14-days after (p<0.05). Low dose ticagrelor showed significant lower MPA and higher IPA at 48 hours after (p<0.001). Although there was no statistical significance, after 1,48hours and 14-days revealed lower MPA and higher IPA, as compared with clopidogrel. There was no significant difference between two ticagrelor doses. Two doses of ticagrelor showed significant lower PRUs, as compared with clopidogrel (p<0.001). 2 patients of standard dose ticagrelor and 1 patient of clopidogrel discontinued study because of bleeding. There was no bleeding in low dose ticagrelor.

**Conclusions:** Low dose ticagrelor may result in greater platelet inhibition than clopidogrel in ESRD patients on HD. Further studies with large number and various doses of medicine are needed.
**FR-PO731**

**Temporal Trends in Myocardial Infarction Incidence and 30-Day Mortality in U.S. Dialysis Patients**

**Background:** Acute myocardial infarction (MI) is a catastrophic event in dialysis pts. Few data exist on current MI hospitalization rates. We assessed trends in type of MI (ST-elevation MI [STEMI], non-ST-elevation MI [NSTEMI], and unclassifiable MI [other]), demographics, and death rates by type of MI in 2005-2011.**

**Methods:** Using Medicare claims data, we created yearly cohorts of dialysis pts point prevalent on January 1 of each year 2005-2011. We assessed STEMI, NSTEMI, and other MI hospitalization rates, and calculated annualized 30-day death rates following MI.

**Results:** In 2005 there were 10,275 NSTEMI, 1,892 STEMI, and 1,918 other MI vs 2011 16,235 NSTEMI, 1,269 STEMI, and 1,634 other MI. Demographics: mean age 67; 5% < 45, and 6% > 84 yr; 47% female; 48% white, 32% black; 55% ESRD from DM. While overall MI rate increased slightly from 2005-2011 (80.1/1,000 PY in 2005 vs 91.2 in 2011), STEMI and other MI decreased by 44% and 29% respectively, while NSTEMI increased by 31%. Short term mortality was relatively unchanged for NSTEMI (295 deaths/1000 PY), increased slightly for STEMI (495/1000 PY in 2005 to 565/1000 PY in 2011), and was highest following other MI (881/1000 PY in 2005 and 915/1000 PY in 2011).

**Conclusions:** In the recent treatment era there has been little change in either rates of overall MI hospitalization or 30-day mortality. The increase in NSTEMI rates may be due to greater utilization of more sensitive cardiac biomarkers (cardiac troponins) for MI diagnosis. MI remains a catastrophic event for dialysis pts. Aggressive interventions to reduce the burden of ischemic heart disease and to improve its prognosis in dialysis pts are warranted.

**FR-PO732**

**Risk of Acute Coronary Events and Coronary Interventions for Overweight and Obese Patients versus Normal Weight Patients Undergoing Dialysis – A National Study**

**Background:** Although elevated body mass index (BMI) is associated with increased risk of cardiovascular events in the general population, it is suggested that the converse may hold true for patients on dialysis.**

**Methods:** We tested this hypothesis in a national cohort of 1,072,737 incident Medicare-eligible US patients, who began dialysis between 5/1995 and 12/2008. Hospitalizations attributed to first myocardial infarction (MI) (ICD 9 codes: 410) and major coronary interventions (coronary angioplasty, stent, and coronary bypass surgery) following first MI were obtained from the US Renal Data System. Multivariable Cox regression compared hazard ratios [HR] of MI and subsequent coronary interventions among BMI categories.

**Results:** The adjusted HR of MI was highest for underweight patients and lowest for morbidly obese patients, decreasing significantly with increasing BMI category. Overweight patients were significantly more likely to receive a coronary intervention post-MI compared to normal weight individuals but this benefit did not extend to morbidly obese or underweight patients.

**Conclusions:** In contrast to the general population, higher BMI is associated with lower risk of major coronary events in US dialysis patients suggesting a protective effect. Furthermore, access to coronary interventions following a major coronary event is not equal across BMI categories.

**FR-PO733**

**Propensity-Based Comparison of Haemodialysis and Peritoneal Dialysis with Risk of Haemorrhagic and Ischaemic Stroke Among New Dialysis Patients**

**Background:** The risk of stroke is between 6-10 fold higher in dialysis patients compared to the general population. It is hypothesised that the choice of dialysis modality at initiation may influence the risk of stroke.**

**Methods:** We tested this hypothesis in a national cohort of 1,097,747 US patients (n=86,168 on PD) who were Medicare eligible and began dialysis between 5/1995 to12/2010 and followed until 9/2011. Hospitalizations attributed to first Haemorrhagic Stroke (H-CVA) and Ischaemic stroke (I-CVA) were obtained from the US Renal Data System files and merged with data from the medical evidence, treatment history and mortality files. Multivariable Cox regression compared the hazards ratio [HR] of H-CVA and I-CVA for PD versus HD with a propensity-matched intent-to-treat (ITT) approach and as-treated analysis. Patients were censored at transplantation, death, recovery of kidney function, or end of study (Sept 2011). Approval was received from University Hospitals Ethics Committee.

**Results:** The adjusted PD/HD HRs for first hospitalized H-CVA using the intent-to-treat model was 0.89 (0.83-0.95) and this decreased from 0.73 (0.61-0.87) in the period 1995-1998 to 0.64 (0.51-0.80) in the period 2007-2010. In contrast, overall HRs for I-CVA were 1.15 (1.12-1.18) and this decreased from 1.20 (1.13-1.27) in the period 1995-1998 to 1.06 (0.97-1.15) in the period 2007-2010. The as-treated model suggested more favourable outcomes for H-CVA with overall HR of 0.61 (0.57-0.67) and for I-CVA with a HR 0.96 (0.89-1.03) in 2007-2010 period. Patients who switched from PD to HD or HD to PD had significantly higher HR of H-CVA, while patients who switched from PD to HD had higher HR of I-CVA.

**Conclusions:** PD and HD contribute differentially to the overall risk of I-CVA and H-CVA among new dialysis patients. While PD is similar to HD with regard to hazards of I-CVA, it appears to protect against the hazard of H-CVA. These associations should be taken into consideration when choosing treatment options for new dialysis patients.

FR-P0734

Predictors of Sudden Cardiac Death in Hemodialysis Patients with and without Previous Arrhythmia – Results from a Multinational Cohort Viviane Calice-Silva,1 Stephen Thijssen,2 Xiaolong Ye,2 Aileen Grassmann,3 Daniele Marchel,2 Bernard J. Canaud,2 Peter Kotanko,1 Pedro Recuerto-Filho.1 1Pontifícia Univ Católica do Pará, Brazil; 2Renal Research Inst; 3 Fresenius Medical Care, Germany.

Background: Cardiac dysfunction, rapid electrolyte shifts and high ultrafiltration rates during hemodialysis (HD) are associated with increased vulnerability to arrhythmogenic events. Patients with previous arrhythmia (ARR) are at a higher risk of sudden cardiac death (SCD – Herzog et al, 2011). Our aim was to analyze predictors of SCD in HD patients with and without previous ARR.

Methods: Incident HD patients from the Monitoring Dialysis Outcomes (MONDO) cohort who received in-center treatment between 1/2006-12/2011 and survived at least 90 days on HD were included and followed until 12/2012. Causes of death were classified as SCD according ICD-10/ICD-9. Patients with comorbidity or prior hospitalization due to ARR and/or ARR predisposition were identified. Cox proportional hazard models were constructed to explore associations between baseline parameters and SCD.

Results: We studied 19,129 patients (16 countries). 7,538 patients with complete data were included in the models, 613 died of SCD. Mean age 62.7±15.5 years, 58.1% male, 48.4% diabetics. Age, ischemic heart disease, albumin, serum sodium, interdialytic weight gain in % of post-HD weight and pre-HD-systolic blood pressure were identified as predictors of death in both subgroups. Distinct predictors are shown below.

Conclusions: Despite the small sample size, some predictors of SCD seem to differ depending on the presence or absence of arrhythmia history or predisposition. These findings may assist the identification of patients at high risk for SCD. Further studies have to be done to corroborate these results.

FR-P0735

The Risks of Acute Health Events After Incident Atrial Fibrillation in Older Hemodialysis Patients Medha Ary1, Benjamin A. Goldstein,2 Mark A. Hlatky,3 Nisha Bansal,3 Alan S. Go, Wolfgang C. Winkelcmaier,1 Baylor College of Medicine, Houston, TX; 2Duke Univ, Durham, NC; 3Stanford Univ, Palo Alto, CA; 4Univ of Washington, Seattle, WA; 5Kaiser Permanente Northern California, Oakland, CA.

Background: Limited data exist about whether incident atrial fibrillation/flutter (AF) impacts the risks of major acute health events in patients with ESRD undergoing hemodialysis (HD).

Methods: From the US Renal Data System, we studied older (≥67 years) adults with ≥2 years of uninterrupted Medicare A+B coverage before starting HD (2006-11) and no known AF prior to ESRD. Incident AF was ascertained from ICD-9 diagnosis codes (427.3x) in inpatient claims. We used extended Cox regression adjusted for sociodemographic characteristics and key comorbidities to estimate hazard ratios (HR [95% confidence interval]) for death, ischemic stroke, myocardial infarction (MI), and hip fracture (as a negative control outcome). AF was treated as a time-varying covariate, with time since first AF diagnosis further categorized as ≤10, 11-30, 31-90, and >90 days. Patients were censored at time of kidney transplant or end of data (12/31/2011).

Results: We identified 85,377 eligible HD patients; 16.7% developed incident AF and 58.2% died during follow-up. Incident AF was associated with higher adjusted mortality: 8-fold higher during the first 30 days (HR=8.2 [7.9-8.6]), 4-fold higher between 31-90 days (HR=4.2 [4.0-4.4]), and 2-fold higher beyond 90 days after AF diagnosis (HR=2.2 [2.1-2.2]). Incident AF also increased the adjusted rate of ischemic stroke 1.5-2.5-fold during the first 30 days (HR=2.1 [1.6-2.7]), 31-90 days (HR=2.5 [2.0-3.0]), and beyond 90 days (HR=1.5 [1.3-1.7]). Quantitatively similar findings were obtained for MI. However, the adjusted rate of hip fracture was only marginally increased following AF diagnosis (≈30 days: 1.0 [1.0-1.6]; 31-90 days: 1.1 [1.0-1.3]; >90 days: 1.2 [1.1-1.4]). All associations were attenuated when requiring incident AF to be indicated as principal discharge diagnosis.

Conclusions: While AF was independently associated with higher risks of ischemic stroke, MI, and hip fracture in older ESRD patients on HD, it was more strongly associated with excess all-cause mortality.

The CRASH-ILR Study: Half a Million Hours of Continuous ECG Monitoring in a Hemodialysis Population Robert Lewis,1 Darren Green,2 Philip A. Kalra,3 Donah Zachariah,3 Paul Kalra,3 Paul R. Roberts.4 1Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom; 2Salford Royal NHS Trust, Salford, United Kingdom; 3Royal Bournemouth Hospital, Bournemouth, United Kingdom; 4Southampton Univ Hospitals Trust, Southampton, United Kingdom.

Background: Sudden cardiac death (SCD) may cause ≥25% of all hemodialysis (HD) patient deaths. Multiple potential mechanisms may contribute to the risk of life-threatening arrhythmias in this population. The CardioRenal Arrhythmia Study in Hemodialysis has continuously monitored patients using an Implantable Loop Recorder (ILR) for more than 500,000 hours.

Methods: 30 patients (60% male) aged 67±12 years on established HD for 39±44 months with varied etiology of CKD (diabetes 37%, hypertension 23%) and ejection fraction of 56±8% were implanted with a Reveal XT ILR (Medtronic, MN, USA). Patients transmitted data at each HD session and were asked to activate their ILR if symptomatic with palpitations, dizziness or syncope.

Results: Patients were monitored for an average of 17,810±8,108 hours performing 94±92 transmissions. 6 patients (20%) died during the study. The final arrhythmia was VF in 2 patients and agonal bradycardia in 3. One patient died from SCD 2 weeks after device explantation due to infection. All 3 bradycardic deaths occurred in patients during end-of-life care. 1 VF death occurred during a GI bleed: the other was unheralded. A surviving patient received a biventricular pacemaker for 2:1 block detected by ILR. Atrial arrhythmias (AA) were noted in 7 (25%), 4(13%) of which were incident. 1 patient had asymptomatic sustained VT managed with antiarrhythmic drugs. Frequent ectopy was recorded in 2 patients. There were 19 symptomatic activations in 6 patients all corresponding to sinus rhythm (or AA in cases of permanent AF). 6 patients had device explantation, 4 after renal transplantation and 2 due to device infection.

Conclusions: CRASH-ILR is the longest ILR follow up in HD patients to date and provides new insights into arrhythmia and SCD. Arrhythmias occurred in 15% (50%) of the study population. Mortality was high, but this was due to SCD as an expected end-of-life event in 5 of 6 patients.

FR-P0737

Revisiting Ultrafiltration Rate (UFR), Treatment Time (TT) and Mortality in Thrice Weekly Hemodialysis Jennifer L. Bragg-Gresham, Brett W. Platter, Debabrata Ray, Yi Li, Rajiv Saran. KECC, Univ of Michigan, Ann Arbor; MI.

Background: UFR and TT are two potentially modifiable practices for improving outcomes in HD. UFR > 13 ml/kg/hour has been associated with higher mortality. We re-examined this association, focusing on the effect of higher UFR at TT ≥ 4 hours, as longer TT has been claimed to be ‘protective’, even though TT >4 hours is logistically difficult to implement in the prevailing US practice setting.

Methods: Using recently available national data from CROWNWeb (CW), we analyzed 10,699 adults on thrice-weekly, in-center HD. Baseline CW data was extracted from June 2012. Patients were followed through December 31, 2013. Cox regression was used to examine the association between UFR (calculated as the intradialytic weight loss / TT and expressed in ml/kg post HD-weight/hr) and mortality, adjusting for demographics, co-morbidities, dialysis vintage, intradialytic weight gain (IDWG) and dialysis dose (Kt/V), stratified by TT. Average follow-up was approx 1 year.

Results: Individuals receiving TT ≥ 240 were younger, more likely to be black and male, and had larger BMI. In both strata of TT (< 240 and ≥ 240) those patients with UFR > 13 tended to be younger, non-black race, have a lower BMI, longer HD vintage, higher Kt/V and higher IDWG than patients with UFR < 13. Congestive heart failure was more prevalent in patients with UFR ≥ 13 regardless of TT. In both strata of TT, patients with a UFR > 13 had higher hazard of mortality, with a larger risk found in those with TT ≥ 240.

Funding: NIDDK Support

Conclusions: A higher UFR (>13) was associated with higher mortality irrespective of TT category. The association was surprisingly strong among those receiving longer TT. In the US, longer TT is prescribed in order to achieve small solute targets (confounding-by-indication) and not necessarily to lower the UFR, as high UFR is a consequence of high IDWG and the average shorter TT.

Sudden Death and Dialysate Potassium in Hemodialysis: Results from the Dialysis Outcomes and Practices Pattern Study (DOPPS)

Angelo Karavolas, 1 Jarcy Zee, 1 Steven M. Brunelli, 1 Len A. Usuytay, 2 Daniel E. Weiner, 1 Franklin W. Maddux, 3 Allen R. Nisseness, 4 David C. Mendelsonsohn, 5 Michel Y. Jadoul, 6 Friedrick K. Port, 1 Bruce M. Robinson, 7 Francesca Trentori, 1 Air Research Collaborative for Health, Ann Arbor, MI; 1 DaVita Clinical Research, Minneapolis, MN; 2 FMCNA, Waltham, MA; 3 Tufts Medical Center, Boston, MA; 1 DaVita Healthcare Partners, Inc., El Segundo, CA; 4 Humbor Regional Hospital, Toronto, Canada; 7 Unive Catholique de Louvain, Belgium

Background: Sudden death (SD) is common in hemodialysis (HD) patients. We investigated trends in dialysate (DK) and pre-dialysis serum (SK) potassium across the Dialysis Outcomes and Practices Pattern Study (DOPPS) phases 1-5 (1996-2015) and evaluated whether the risk of SD is higher with lower DK.

Methods: 67,263 patients in 21 countries were studied. Instrumental variable methods were used to model the effect of DK on SK. Adjusted Cox regression was used to test the associations of baseline DK and SK with all-cause death, and an arrhythmia composite (AC) of SD or arrhythmia-related hospitalization.

Results: In the US, DK and SK (mEq/L) have been stable over time (70% DK=2, 25% DK=3; mean±SD SK=4.7±0.7). In Europe, DK has increased (currently 15% DK=1-1.5, 45% DK=2-3, 33% DK=3) while mean SK has decreased from 5.2 to 4.9. SK was only 0.08 mEq/L higher per 1 mEq/L higher DK. SK ≥ 6 (ref 4.5-4.9) was associated with death (HR=1.12, 95% CI: 1.05-1.19) and AC (HR=1.17, 1.04-1.33). Compared to DK=2, DK=3; mean (AC) of SD or arrhythmia-related hospitalization.

Conclusions: The risk of incident AK among patients on HD is increased after a stroke, MI, or hip fracture. Risks were highest in the first 90 days after the event, and remained elevated >90 days after an ischemic stroke or MI, but not after a hip fracture.

Arrhythmias as a Potential Cause of Dizziness and Syncpe in Patients with End-Stage Renal Disease

Kati Kaartinen, 1 Jani Ahvonen, 2 Seppo Ojansen, 2 Joonas Markku Rautavaara, 1 Olle Anttonen, 3 Tuomas Kerola, 1 Kati Vaaraniemi, 1 Marja H. Miettinen, 1 Juhani Koistinen, 4 Atte Atikosuo, 5 Tuomo Nieminen. 1 Dept of Nephrology, Helsinki Univ Central Hospital, Helsinki, Finland; 2 Dept of Nephrology, Päijät-Häme Central Hospital, Lahti, Finland; 3 Dept of Nephrology, Central Hospital of Central Finland, Jyväskylä, Finland; 4 Dept of Cardiology, Vaasa Central Hospital, Vaasa, Finland; 5 Dept of Internal Medicine, Univ of Helsinki, Helsinki, Finland.

Background: It is unknown how often arrhythmias underlie dizziness and syncpe in end-stage renal disease. We launched a study to implant subcutaneous loop recorders for their estimation.

Methods: Data is shown for 40 patients (62.4±8.2 years [mean±SD], range 39 to 78 y, 26 M) with stage 4 or 5 renal failure and F-to-F of ≥ 2 months. Main kidney diseases were diabetic (18), polycystic disease (8) and chronic glomerulonephritis (6). One patient was pre-dialytic, five had peritoneal dialysis, and rest were on hemodialysis. Median time since the start of dialysis was 1.6 years. Seven patients (18%) had either chronic or paroxysmal atrial fibrillation (AF) prior to the implantation of the recorder, being in line with published data.

Results: During the F-to-F of 14±7 months, recorder revealed bradyarrhythmia in six (15%) patients with an R-R arrest >5.0 sec with a max. of 9.0 sec; two patients with symptoms thus far received a pacemaker. AF occurred in 21 (53%) patients. The median time to detect new AF was 235 days. Four patients (10%) had non-sustained ventricular tachycardia unknown before the recorder data.

Conclusions: Arrhythmias are more typical than estimated in patients with severe kidney disease. Particularly, symptomatic bradycardia is relatively common and can be easily treated with a pacemaker. AF is three times more common than known before. These findings may change diagnostics and treatment of dizziness in these patients.

Acute Health Events and the Risk of Incident Atrial Fibrillation in Older Patients Undergoing Maintenance Hemodialysis

Medha Airy, 1 Benjamin A. Goldstein, 2 Mark A. Hlatky, 1 Alan S. Go, 3 Nisha Bansal, 2 Wolfgang C. Winkelmlayer, 1 Baylor College of Medicine, Houston, TX; 2 Duke Univ, Durham, NC; 3 Stanford Univ, Palo Alto, CA; 4 Kaiser Permanente Northern California, Oakland, CA; 5 Univ of Washington, Seattle, WA.

Background: Acute health events might increase the risk of developing atrial fibrillation (AF). We examined the incidence of new onset AF relative to several acute events in patients with ESRD initiating hemodialysis (HD).

Methods: From the USRDS, we studied older (67+ years) patients with 2 years of Medicare A&B coverage prior to initiating HD (2006-11) who had no documented diagnosis of AF, or claims indicating ischemic stroke, myocardial infarction (MI), or hip fracture prior to ESRD. We used time-varying Cox regression to estimate adjusted hazard ratios for incident AF relative to the acute events of interest, adjusted for socio-demographics and baseline comorbidities. The incidence of AF after either an acute MI, or hip fracture was modeled in time-varying fashion, during the periods of 0-30, 30-90, and >90 days after the acute event. Patients were censored at kidney transplantation or end of database (12/31/2011).

Conclusions: Arrhythmias are more typical than estimated in patients with severe kidney disease. Particularly, symptomatic bradycardia is relatively common and can be easily treated with a pacemaker. AF is three times more common than known before. These findings may change diagnostics and treatment of dizziness in these patients.

Blood Pressure and Risk of Cardiovascular Events Among Hemodialysis Patients: The CRIC Study

Nisha Bansal, 1 Charles E. McCulloch, 2 Feng Lin, 2 Cassianne Robinson-Cohen, 1 Mahboob Rahman, 1 John W. Kusek, 4 Amanda Hyre Anderson, 1 Raymond R. Townsend, 1 Jackson T. Wright, 1 Alan S. Go, 2 Arnold B. Alper, 5 Radhakrishna Reddy Kallem, 1 Chi-yanth Hsu, 1 UW; 6 UCSF; 7 U/H; 8 NIDDK; 9 UPenn; 10 Case Western; 11 KPNC; 12 Tulane.

Background: Among hemodialysis (HD) patients, previous studies have reported a U-shaped association between systolic blood pressure (SBP) and risk of mortality. However, the shape of the association between SBP and risk of cardiovascular events (CVD) is not well characterized.

Methods: We studied participants on HD in the Chronic Renal Insufficiency Study (CRIC). SBP was measured at the dialysis unit (“dialysis-unit SBP”, N=803) and at the CRIC study visit (“out-of-dialysis-unit SBP”, N=326). We studied the association of SBP

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conversely, the association between out-of-dialysis-unit-SBP was linear, with the highest quartile having greater than 2-fold risk of CVD than the lowest quartile.

Conclusions: Among HD patients, the association of SBP measured in the dialysis unit with CVD is U-shaped, while the association of SBP measured outside the dialysis unit with CVD is linear, similar to what has been reported for mortality (Bansal et al., Hypertension 2015). Targeting SBP measured outside the dialysis unit may improve CVD outcomes in HD patients.

title

Choosing the Right Analysis of Repeated Events for Clinical Trials in Dialysis

George Tomlinson, Stephanie Dixon, Amit X. Garg, Charmaine E. Lok. Medicine, Toronto General Hospital, Toronto, ON, Canada; 1ICES-KDT; London Health Sciences Centre.

Background: Cardiovascular (CV) events are a leading cause of morbidity and mortality in hemodialysis (HD) patients. There is a paucity of randomized clinical trials (RCT) in nephrology and fewer positive ones, perhaps due to incorrect choice of endpoints or inadequate power. We simulated RCTs with repeated CV events and competing non-CV death to determine how different analytic methods affected study power (sample size).

Methods: We simulated 1000 RCTs of 1100 patients, with frequency and timing of CV events (CV death, MI, stroke, PVD, CV revascularization, and leg amputation) based on real observations in an Ontario HD administrative cohort (n=9647) from 2004-2011. In simulations, patients were randomized to placebo or a treatment with a known effect and censored at 4 years or non-CV death. We analyzed this data with 1) a Cox model for time to first event, 2) a model with non-CV death as a competing risk, 3) a negative binomial (NB) model and 4) several adaptations of the Cox model for repeated events (e.g., Wei, Lin and Weissfeld, WLW). To check for 2 potential problems (finding a difference when there was none and missing a true difference), we ran simulations in 2 scenarios: 1) with zero treatment effect, we calculated the false positive rate; 2) when the treatment delayed CV event by 33%, we calculated the true positive rate (power) based on the 1000 simulations.

Results: In the source (real) data, 45% of patients had >2 CV events; the overall CV event rate was 0.26/yr. When there was no effect of treatment, the NB model had a false positive rate of 11%; for all other models, it was the expected 5%. For the time to first event, competing risk and the WLW marginal Cox model, power was similar (72%) and notably higher than for the remaining Cox-type models (52%-61%).

Conclusions: The WLW Cox model for repeated events was as powerful as models for time to first event but has the advantage of assessing the impact on all (repeated) events a patient experiences. This highlights the importance of choosing the appropriate analytic method when designing a clinical trial in HD patients to maximize the likelihood of both a positive and a meaningful result.

Routine Predialysis Measurements of Systolic Blood Pressure Are Higher Than Predialysis Standardized Measurements of Systolic Blood Pressure

Dana Miskulin, Jennifer J. Gassman, David W. Ploth, Manisha Jambh, Lavinia A. Negrea, Mahboob Rahnam, Ronald Schrader, Susan Paine, Philip Zagger, Tiffa; UNM; DCI; Cleveland Clinic; MUSC; Unio of Pittsburgh; Case Western.

Background: Measurement of systolic blood pressure (SBP) in the dialysis unit does not follow American Heart Association recommendations. We determined the differences between predialysis SBP (SBP) measured in routine practice versus a standardized procedure.

Methods: The Blood Pressure in Dialysis Study is a pilot, multicenter, randomized clinical trial that assesses treatment of hypertensive HD patients to two BP targets. Measurement of predialysis SBP is done after 5 minutes rest, 3 readings 1 minute apart, with attention to cuff size, placement and patient positioning. We compared the 2-week averaged routine predialysis SBP (RDUSBP) taken immediately prior to enrollment with the 2-week averaged predialysis standardized SBP (SDUSBP) in the first 2 weeks of baseline. The within subject variability in SBP, (s

Results: We studied 186 patients. The week averaged RDUSBP was a mean (SD) 10.3 (16.6) mm Hg higher than 2 week averaged SDUSBP (p<0.001).

The RDUSBP was ± 5 mm Hg of the SDUSBP in 20% of patients, 6-15 mm Hg higher in 30%, 15-25 mm Hg higher in 17%, >25 mm Hg higher in 17% and >5 lower in 16%. Estimating treatment effect, for RDUSBP (15.7) and SDUSBP (19.6) were not significantly different, (p<0.99). Differences between RDUSBP and SDUSBP tended to be greatest among those with a high body mass index.

Conclusions: SDUSBP were, on average, 10 mm Hg lower than RDUSBP measured in the dialysis unit. Reliance on routine BP measurements may lead to overtreating hypertensive HD patients. More attention to the measurement of BP in dialysis unit is needed.

Funding: NIDDK Support, Pharmaceutical Company Support - Dialysis Clinic, Inc.
Comparison of Central and Peripheral Blood Pressure in Predicting Cardiovascular Surrogates in Patients with End-Stage Renal Disease

**Background:** Hypertension is an established cardiovascular (CV) risk factor and is closely related with mortality in end-stage renal disease (ESRD) patients. Recent studies have demonstrated that central blood pressure (cBP) is a significant predictor of CV disease in the dialysis population, because cBP reflects the hardening conditions of the coronary and cerebral arteries and vascular damage. Therefore, we investigated the association between cBP and CV surrogates compared with peripheral blood pressure (pBP) in patients with ESRD.

**Methods:** A cohort of 92 ESRD patients from the Cardiovascular and Metabolic Disease Etiology Research Center between November 2013 and February 2015 was selected. cBP was measured by Sphygmocor noninvasively. CV surrogates were determined by carotid intima-media thickness, pulse wave velocity (PWV) and left ventricular mass index (LVMI). Linear regression analysis and Steiger’s Z test were used to compare predictive utility of cBP and pBP for CV surrogates.

**Results:** The mean age was 53.2 years and 52 (56.5%) were male. Mean systolic cBP (eSBP) and central pulse pressure (cPP) was 140.2±28.9 and 57.1±22.8 mmHg. Mean systolic pBP (pSBP) and peripheral pulse pressure (pPP) was 145±25.8 and 65.8±22.2 mmHg. There was an independent association of eSBP and pSBP with PWV (β=0.408, P<0.01; β=0.322; P=0.001) and LVMI (β=0.370, P=0.001; β=0.382, P=0.001). cPP and pPP also were independently associated with PWV (β=0.381, P<0.001; β=0.353, P=0.001) and LVMI (β=0.411; P<0.001; β=0.497; P<0.001) after adjustment for confounding factors. However, there were no significant differences in the predictive value of cSBP and pSBP for estimating PWV (adjusted R², 0.494 vs. 0.431, P=0.07) and LVMI (adj R², 0.215 vs. 0.220, P=0.885). No significant difference was found for cPP and pPP for predicting PWV (adj R², 0.451 vs. 0.429, P=0.546) and LVMI (adj R², 0.220 vs. 0.265, P=0.320).

**Conclusions:** Although cBP values were closely associated with CV surrogates, these values did not provide additional information beyond pBP in predicting CV risk in patients with ESRD.

**FR-P0743**

Early Mortality in Hemodialysis Patients Anticoagulated for Atrial Fibrillation

**Background:** Atrial fibrillation (AF) is prevalent in the Hemodialysis (HD) population and portends a high mortality rate. AF also causes embolic stroke and is treated with lifelong oral anticoagulation (OAT). We have previously shown early increased mortality in HD patients receiving OAT without significant stroke reduction (JASN, 25:609A, 2014). It is unclear why OAT increased early mortality in these patients. To address this question, we queried the USRDS for unique risk factors for mortality in this cohort.

**Methods:** All incident adult HD cases from the USRDS for 2005-2008 were queried for demographics, access type, risk factors before dialysis, and mortality. Data were derived from ICD9 and CPT codes, or Form 2728. Proportional hazards models were used to estimate the hazard ratio (HR) for death within 90 days.

**Results:** 34,522 incident HD patients with AF were identified, 6664 (19.3%) of whom died within 90 days of the initiation of dialysis. For the entire group, demographics showed: 83.1% Caucasian, mean age 57.4 years (SD=9.0), and 41.5% female. When controlling for diabetes, cardiomyopathy TIA, pulmonary hypertension, aortic stenosis, CHF, MI, cancer, obesity, cardiac device, age and access type the HR for death in the OAT group was 1.10 (95% CI 1.04 - 1.16). The 1-, 2- and 3-month mortality rates were 6%, 83.1% Caucasian, mean age 75.4 years (SD=9.0), and 41.5% female. When controlling for demographics, access type, risk factors before dialysis, and mortality. Data were derived from ICD9 and CPT codes, or Form 2728. Proportional hazards models were used to estimate the hazard ratio (HR) for death within 90 days.

**Conclusions:** OAT therapy in HD patients with AF may contribute to the increased death rate observed during the first 90 days of dialysis, but not apparently due to bleeding. We speculate that OAT use may be associated with non-hemorrhagic complications that may lead to increased mortality in the HD population. Defining this level of clinical detail is beyond the scope of an administrative dataset like the USRDS. Future studies addressing non-hemorrhagic effects of OAT may provide new insights on possible causes of early mortality in these patients.

**FR-P0746**

Reduced Temperature Hemodialysis Augments Dialysis Induced Improvement of Cardiac High Energy Phosphate Levels

**Background:** Reduced temperature hemodialysis was significantly associated with increased PWV (36.5°C/64.5°C/66°C vs. 35.0°C; R²=0.03). At both temperatures, hemodialysis was significantly associated with increased mean LV ejection fraction (36.5°C/cp 64.5°C/66°C post 70.9±6.8% vs. 0.002;35.0°C/cp 69.0±6.1% post 72.4±6.3% vs. P<0.01). P<0.05 was highly significant compared with basal condition (P<0.01) and reduced temperature hemodialysis (P=0.03: ). Mean increase in P<0.05 was higher after reduced temperature compared to normothermic hemodialysis (+51.5% vs +74.1% respectively).

**Risk Grading by CHADS2_Vasc Score Is Useful in Non-Dialysis Subjects with Atrial Fibrillation while It Is Not Useful in Dialysis Patients Because of Their Very High CHADS2_Vasc Scores**

**Background:** Whether CHADS2_Vasc score is useful for predicting the risk of outcomes has not been sufficiently examined in dialysis patients with AF. **Methods:** Two prospective studies of 1,109 dialysis patients (AF group (n=35); non-AF group (n=1,074)) and 26,469 community dwellers (AF group (n=25,058); non-AF group (n=411)) living in the same area were conducted. Subjects were subdivided into four groups according to CHADS2_Vasc score (G1: CHADS2_Vasc score = 0; G2: score = 2; G3: score = 3; G4: score = 4). Crude mortality rates of all-cause and cardiovascular death and crude incidence rates of stroke (per 1000 person-years) were estimated in each group.

**Results:** Results were shown in the table.
Conclusions: CHA2DS2_Vasc score is useful for predicting the risk of outcomes in non-dialysis subjects with AF and dialysis subjects without AF. Dialysis patients with AF already had very high scores and the risk grading by CHA2DS2_Vasc score is not useful.

Post Stroke In-Hospital Disability Deterioration and Mortality of Community-Onset Stroke in Patients with and without End-Stage Renal Disease

Tomoko Usui,1 Norio Hanafusa,2 Hideo Yasunaga,1 Masao Mi Nakaku,1
1Dept of Hemodialysis and Apheresis, The Univ of Tokyo Hospital, Japan; 2Dept of Clinical Epidemiology and Health Economics, School of Public Health, the Univ of Tokyo, Japan.

Background: Increasing evidence suggests that end-stage renal disease is associated with higher risk and severity of cerebrovascular disease. However, the risk factors for post stroke disability and mortality is not clear. We examined the association between risk factors including dialysis treatment and disability deterioration and mortality during hospital stay of community-onset stroke.

Methods: The Japanese Diagnosis Procedure Combination database includes administrative claims and discharge abstract data of about 50% of all acute-care inpatients in Japan. Using this database, we extracted data of inpatients age >20 years old, admitted within 3 days after community-onset stroke between July 2010 and March 2013. Disability level was divided into modified Rankin Scale (mRS) 0-1, 2-3, 4-5, and 6 (death). Disability deterioration was defined as an increase in disability level. The odds ratio (OR) for in-hospital disability deterioration and mortality was calculated using a logistic regression model.

Results: Out of 438,569 patients, 7,633 (1.7%) had dialysis therapy. The median length of stay was 24 and 20 days for patients with and without dialysis, respectively. During the hospital stay, there were 101,024 (23.0%) disability deterioration and 46,029 (10.5%) death. The patients with dialysis had higher rate of disability deterioration (26.7%) and mortality (13.0%) compared to those without. After adjustment with age, gender, BMI, mRS, Activities of Daily Living, smoking habits, hypertension, diabetes, dyslipidemia, atrial fibrillation, coronary heart disease, heart failure, peripheral arterial disease, cerebrovascular complications, antipatelet, anticoagulant, and thrombolytic medications, multivariate-adjusted ORs of dialysis for deterioration of disability was 1.57 (95%CI 1.48-1.66) and in-hospital mortality was 1.72 (95%CI 1.59-1.86).

Conclusions: Dialysis treatment was an independent risk factor for in-hospital disability deterioration and mortality of community-onset stroke.

FR-PO750

Proportion of Treatments with Low Systolic Blood Pressure and Short Term Mortality in Incident Hemodialysis Patients

Dusan Maddux,1 John W. Larkin,1 Danqing Xu,2 Len A. Usyvat,1 Frank van der Sande,1 Jeroen Kooman,3 Peter Kottonko,4 Franklin W. Maddux.1 1Medical Office, Fresenius Medical Care North America, Waltham, MA; 2Univ of California at Santa Barbara, Santa Barbara, CA; 3Maastricht Univ Medical Centre, Maastricht, Limburg, Netherlands; 4Research Inst, New York, NY.

Background: Prior studies have associated low mean predialysis systolic blood pressures (preSBP) with increased 120 day risk for mortality in incident hemodialysis (iHD) patients (Maddux et al., ASN 2014). This study aimed to investigate how the percent (%) of low mean preSBP during the prior weeks’ hemodialysis (HD) treatments affects the short term risk of mortality in iHD patients.

Methods: For this study, 56,525 iHD patients at Fresenius Medical Care North America (FMCNA) clinics were investigated from 1/1/2004 to 12/31/2010. From the first date of outpatient chronic dialysis (FDD), the % of the prior weeks’ mean preSBP <110 mmHg was calculated for the first 4 months of HD. Mortality risk in the following week (7 days) was analyzed by the % of the prior week’s mean preSBP <110 mmHg at weeks 2, 4, 6, 12, and 16 from FDD.

Results: We observed that the short term risk for mortality in the following week increases in iHD patients as the % of the prior week’s mean preSBP <110 mmHg increases at weeks 2, 4, and 6 from the FDD; the risk for mortality was found to be the greatest at week 2 and was slightly reduced by week 6. Conversely, by week 12 and 16 from FDD, the % of the prior week’s mean preSBP <110 mmHg was not found to be related with the risk of mortality in the next week.

Conclusions: This study demonstrates that increases in the % of low mean preSBP during the prior weeks’ hemodialysis (HD) treatments is associated with heightened short term risks of mortality during the first 6 weeks of iHD, but not during weeks 12 and 16 from the FDD.

FR-PO751

The Possibility of Faster Progression of Brain Atrophy in Patients on Peritoneal Dialysis Compared with Hemodialysis

Kazuhiko Tsu ruya,1 Hitoshi Yoshida,1 Takanari Kitazono,2 1Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 2Dept of Medicine and Clinical Sciences, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.

Background: Brain atrophy has been reported in chronic kidney disease (CKD) patients, especially in hemodialysis (HD) patients. Recently, we reported faster decline in normalized gray matter volume (GMV) in peritoneal dialysis (PD) patients compared with non-dialysis-dependent CKD (ND) (Tsuruya, et al. Am J Kidney Dis, 2015). However, it has not been reported on the comparison of the progression rate of brain atrophy between PD and HD patients. In the present study, we compared it among PD, HD, and ND patients.

Methods: A total of 151 patients of 38 PD patients aged 60 ± 12 years (men 23, diabetes 11), 24 HD patients aged 64 ± 6 years (men 18, diabetes 9), and 89 ND patients (CKD stage 3a, 34; stage 3b, 31; stages 4-5, 24) were recruited and underwent MRI scanning at baseline and after two years. T1-weighted MRI images were analyzed with statistical parametric mapping software. Total gray matter, total white matter, and cerebrospinal fluid were segmented and each volume was quantified. Normalized GMV was calculated as percentage of intracranial volume to normalize for head size variability. We compared the annual change in normalized GMV among CKD stages.

Results: Annual change in normalized GMV was significantly higher in PD patients than other CKD patients. This finding remained significant even after adjustment for potential confounding factors.

Conclusions: Progression of brain atrophy is significantly higher in PD patients than other CKD patients including HD patients, independent of age, gender, diabetes, and blood pressure level.
FR-PO752

In Centre Nocturnal Haemodialysis: Improving Outcomes and Experience for Patients
Matthew P.M. Graham-Brown, Darren Robert Churchward, Alice C. Smith, Richard J. Baines, James O. Burton, John Wills Renal Unit, Univ Hospitals of Leicester, Leicester, United Kingdom; Dept of Infection, Immunity and Inflammation, Univ of Leicester, Leicester, United Kingdom.

Background: Extended periods of haemodialysis (HD) improve patient outcomes. Home HD schedules can deliver extended dialysis, but there are patient and physician related barriers that make home therapies impossible for many. We explored in centre nocturnal HD (INHD) as a method of offering extended periods of HD to patients unsuitable for home therapy.

Methods: Ten prevalent HD patients switched from standard HD (3x4 hours) to INHD (3x5 hours) for four months. Mean ultrafiltration (UF) volumes (L), relative UF rates (ml/kg/hour) and absolute UF rates (ml/hour) were calculated. Additional, biochemical and haematological data, data on dialysis adequacy and blood pressure control were collected. Changes in quality of life (QoL) were assessed using SF12, EQ-5D and the Hospital Anxiety and Depression Score (HADS) questionnaires.

Results: Seven patients completed four months of INHD. Mean dialysis time per session was 355 minutes (SD±34.92). Mean total UF volume increased from 2.0±0.5L to 2.6±3.4L (p=0.02), but there was a reduction in absolute mean UF rates from 513±121ml/hour on standard dialysis, to 356±66 ml/hour on INHD (p=0.03) and a decrease in mean relative UF rates from 6.5±1.7ml/kg/hr to 4.6±1.6ml/kg/hr (p=0.03). Adequacy measured by urea reduction ratio improved from 72±2% to 80±3% (p<0.001), with a trend towards improved phosphate control to within therapeutic targets, from 1.7±0.6mmol/L to 1.2±0.2mmol/L (p=0.08). In addition, there were improvements in all QoL scores. Mean EQ-5D visual analogue score improved from 48.16±9.2 to 72±13.2 (p=0.003). Mean HADS anxiety score decreased from 9±5.83 to 3.57±3.04 (p=0.03). SF12 physical component score improved from 31.3±3.32 to 41.69±10.19 (p=0.005).

Conclusions: Despite an increase in total UF volume, extended INHD led to an overall reduction in UF rate that has been shown to abrogate HD induced cardiac injury. Other physiological benefits included improved urea clearance and better phosphate control. There were also significant improvements in patient QoL measures over four months.

FR-PO753

Association of Multiple Strokes on Mortality in Incident Hemodialysis Patients: An Application of Multistate Model to Determine Transition Probabilities
James B. Wetmore, Jonathan D. Mahnkopf, Milind A. Phadnis.
1Medicine, Div of Nephrology, Hennepin County Medical Center, Minneapolis, MN; 2Biostatistics, Univ of Kansas Medical Center, Kansas City, KS.

Background: Little is known about the effect of multiple, or subsequent, ischemic strokes in patients receiving dialysis.

Methods: A retrospective cohort study of incident hemodialysis patients with Medicare Parts A and B coverage who had experienced a first ischemic stroke was performed. A multistate model with Cox proportional hazards was used to predict transition probabilities from first ischemic stroke to subsequent stroke or to death. Demographic and clinical factors associated with the respective transition probabilities were determined.

Results: Overall, 12,054 individuals (mean age 69.7 years, 41.3% male, 53.0% Caucasian and 34.0% African-American) experienced a first stroke. Female sex was associated with an increased risk of having a subsequent stroke (adjusted hazard ratio 1.37, 95% confidence intervals 1.20 – 1.56, P < 0.0001), African-Americans, as compared to Caucasians, had lower likelihood of dying after a first stroke (0.81, 0.77 – 0.85, P < 0.0001). A subsequent stroke trended towards having a higher likelihood of transitioning to death compared to a first new stroke on dialysis (1.72, 0.96 – 3.09, P = 0.071). The probability of transitioning to a subsequent stroke increased over the first 6 months, peaked at approximately 12 months, then declined steadily over time (Figure). When a subsequent stroke occurs at 24 months, probability of survival dropped >15%, in absolute terms, from 0.254 to 0.096, with substantial drops observed at subsequent time points such that the probability of survival was more than halved.

Conclusions: Likelihood of subsequent ischemic stroke and of survival in dialysis patients appears to vary by sex and race.

FR-PO754

Electrocardiographic Manifestation in End-Stage Renal Disease Patients with Different Renal Replacement Treatment
Thasinas Dissayabutra, Eiji Kusano, 1Biochemistry, Chulalongkorn Univ, Pathumwan, Bangkok, Thailand; 2Internal Medicine, Div of Nephrology, Jichi Medical Univ, Shimotsuke, Tochigi, Japan.

Background: End-stage renal disease commonly coexists with certain type of cardiovascular diseases, partially reflects the burden of cardiac in uremic state and dialysis methods. Hemodynamic changes are different between predialysis state, hemodialysis (HD), peritoneal dialysis (PD) and post-kidney transplant (Post-KT) patients. This study aimed to investigate the cardiac disorders using electrocardiographic (ECG) features between each stage of CKD patients, including HD, PD and Post-KT.

Methods: ECG records were analyzed retrospectively in 974 participants, including (a) 48 Early CKD (CKD stage 1-2), (b) 188 Advanced CKD (CKD stage 3, 4 and 5), (c) 567 Hemodialysis (HD), (d) 112 chronic ambulatory peritoneal dialysis (PD) and (d) 59 post-kidney transplant (KT) patients. ECGs were analyzed by two examiners for major ECG abnormalities.

Results: A few ECG abnormalities were observed in Early CKD, but highly frequent QTc prolongation and first degree atrio-ventricular block (AVB) were detected in Advanced CKD. PD patients developed more left ventricular hypertrophy (LVH) and premature ventricular contraction than HD counterparts.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

536A
Conclusions: Prolonged QTc, first-degree AVB, LVH and PVC were prevalent in ESRD and dependent on renal replacement therapy method. The physicians should be cautious and promptly treat to the fatal arrhythmias.

The Relation Between Sclerostin, Peripheral Vascular Calcification, and Cardiovascular Events in ESRD Patients Young Ja Na, Sang Yoon Lim, Myung-gyu Kim, Sang-Kyung Jo, Won-Yong Cho. Nephrology, Korea Univ Hospital, Seoul.

Background: Sclerostin, a negative regulator of Wnt signaling pathway produced by osteocyte, is a potent regulator of bone metabolism and a novel candidate for the bone vascular axis in chronic kidney disease patients. Although sclerostin is known as an inhibitor of vascular calcification, recent studies demonstrated conflicting results about the association between sclerostin and cardiovascular events or mortality. In this study we tested the association between sclerostin, peripheral vascular calcification, and cardiovascular events in end stage renal disease (ESRD) patient starting peritoneal dialysis.

Methods: In this prospective study, we included 45 ESRD patients admitted to Korea University Anam Hospital for starting peritoneal dialysis. Circulating sclerostin level was measured in all patients before the start of peritoneal dialysis. Simple vascular calcification score (SVCS) was measured using plain radiographic films of both hands and the pelvis. Median follow up period was 36 months.

Results: Higher sclerostin level was associated with male sex, diabetes mellitus, higher left ventricle (LV) mass index, and lower LV fractional shortening in univariate analysis. ESRD patients with severe vascular calcification (SVCS ≥3) had significantly higher prevalence of diabetes mellitus. They had higher pulse wave velocity, alkaline phosphatase, and lower cholesterol levels, LV fractional shortening and in multivariate analysis, the presence of diabetes mellitus (OR, 44.59, p=0.023), lower cholesterol levels (OR, 0.94, p=0.032) were independent risk factors predicting severe vascular calcifications. In multivariate Cox regression model, higher pulse wave velocity (HR 1.63, p=0.028) was a significant predictor for cardiovascular events. In addition higher sclerostin group (HR 9.82, p=0.094) and lower albumin levels (HR 0.25, p=0.081) display a strong tendency of increased cardiovascular events.

Conclusions: This study showed the possible important role of sclerostin in the development of vascular calcification and cardiovascular events in PD patients. Longer term follow up with larger sample size will be needed to clarify this issue.

FR-PO756

Use of Anticoagulants in Patients with Atrial Fibrillation and End Stage Renal Disease: A Study of Real World Data Lloyd P. Haskell,1 Chris Knoll,2 Patrick Ryan,3 Zhong Yuan.1 1Cardiovascular, Janssen R and D, Raritan, NJ; 2Epidemiology, Janssen R and D, Raritan, NJ; 3Epidemiology, Janssen R and D, Titusville, NJ.

Background: End stage renal disease (ESRD) in patients with atrial fibrillation (AF) is a significant cause of morbidity and mortality. While these patients are at high risk for stroke, there are limited data with respect to use of anticoagulants in clinical practice and current guidelines are not clear on how to manage them.

Methods: US-based, four large healthcare databases (Truven MarketScan Commercial Claims/Encounters [CCAE], Medicare Supplemental [MDCR], Medicaid [MDCD] and Optum Clininformatics [Optum]) were used to establish cohorts of patients with AF and ESRD, who were identified using ICD-9 codes. The first encounter with evidence of both conditions during the inception period of 2010-2012 was the index date; patients must have had at least 1 year enrolment prior to and after the index date to be eligible for the study. The use of anticoagulants was examined during the follow-up period.

Results: Table 1 shows patient demographics and use of anticoagulants by data source. As expected, the privately-insured patient populations (CCAE and Optum) as well as the Medicaid population (MDCD) were younger as compared with the Medicare eligible (MDCR). Across study cohorts, approximately 37% to 40% of patients with AF and ESRD received at least one dispensing of warfarin, with the exception of the Medicaid population (14%). About 3% to 4% of patients (except for Medicaid) received at least one dispensing of novel oral anticoagulant therapy (rivaroxaban, apixaban, or dabigatran).

Table 1: Use of Anticoagulants in Patients with AF and ESRD

Conclusions: Less than 40% of patients with AF and ESRD received anticoagulant therapy. As these are high risk patients, anticoagulant therapy may be underutilized. Further research is necessary to investigate clinical outcomes associated with anticoagulation in these patients.

FR-PO757

Factors Determining Changes in Mortality Rates in Incident Hemodialysis Patients Jochen G. Raimann,1 Len A. Usvyat,2 Dugan Maddux,2 Jeroen Kooman,3 Frank van der Sande,3 Kevin Chan,2 Franklin W. Maddux,2 Peter Kotanko.1,4 1Renal Research Inst; 2 Fresenius Medical Care North America; 3 Maastricht Univ Medical Centre; 4 Icahn School of Medicine at Mount Sinai.

Background: The higher risk of death for incident hemodialysis (HD) patients decreases during the first year (Chan, 2011). Next to vintage, risk is also affected by patient characteristics and the evolution of clinical and laboratory parameters. We analyzed how mortality rates change in different age groups, levels of albumin, in black and white, and in diabetic and non-diabetic patients after HD initiation.

Methods: We analyzed patients commencing HD in Fresenius Medical Care North America clinics between 1/1/2005 and 11/30/2014. We calculated proportions of patients dying from all causes in diurnal intervals starting with the first day on HD up to 1000 days. Only patients who had their first outpatient treatment on day 1 of their first ever HD were analyzed. We analyzed differences in mortality in the following strata: a) age groups (<40, between 40 and 65, and >65 years), b) serum albumin greater and below 3.8 g/dL, c) black and white; and d) diabetic and non-diabetic patients. We fitted penalized B-splines with 95% CIs through all available daily rates.

Results: We studied 334,880 patients. For all groups, mortality rates dropped within the first year. There were differences between groups of age, albumin and between white and black patients, but none between diabetic and non-diabetic patients.

Conclusions: Mortality rates decrease substantially once patients initiate HD. After approximately one year on HD, mortality remains consistent in all groups, but remains lower for those with higher albumin, younger age and black race. Diabetes appears to not affect mortality. Since only patients starting in an outpatient setting were included, selection bias may apply differently to the patient groups.

FR-PO759

Survival in Elderly on Dialysis and Impact of Institutionalization Amarpali Brar, David Kau, Moto O. Salliu, Mary C. Mallappallil. Renal, SUNY Downstate, Brooklyn, NY.

Background: We hypothesized that in the very elderly dialysis patients in the United States, institutionalization in nursing homes would increase mortality in addition to age alone.

Methods: Data was obtained from the U.S. Renal Data System. Incident dialysis patients from 2001 to 2008 above the age of 70 were included. Follow-up period was from incident dialysis date to either death or last follow up on September 30, 2009. Patients above 70 were categorized into four groups according to age as 70-75 years, 76-80 years, 81-85 years, greater than 85 years and further divided into institutionalized and non-institutionalized.

Results: A total of 349,440 patients were identified above the age of 70 years at the time of initiation of dialysis. Major causes of end stage renal disease were diabetes, hypertension, glomerulonephritis, cystic kidney disease, and urological causes. Mean survival for non institutionalised patients was 3.15 ± 0.01 years for those between 70-75 years of age, 2.55±0.01 years for 76-80 years of age, 2.12±0.01 years for 81-85 years of age and 1.64:±0.01 years for those above 85 years at the time of initiation of dialysis respectively. For institutionalized patients, mean survival was significantly lower, 1.71±0.03 years for 70-75 years old, 1.44±0.02 years for 75-80 years old, 1.25±0.02 years for 81-85 years old and more than 85 years and 1.04±0.02 for > 85 years age group, p<0.001. The oldest group in non-institutionalized over the age of 85 years had a similar survival as the institutionalized ESRD patients 70-75 years old.

Conclusions: There was increased mortality in institutionalized elderly patients as compared to non institutionalised elderly patients in the same age group. Keeping with the increased frailty and decreased benefits of therapies in the very elderly especially in those with additional co-morbidities besides age, palliative and end of life care should be considered.

FR-PO760

Geriatric Nutritional Risk Index Is a Simple Predictor of Mortality in Chronic Hemodialysis Patients Kosaku Nitta, Ken Tsuchiya. Dept of Medicine, Kidney Center, Tokyo Women’s Medical Univ, Shinjuku-ku, Tokyo, Japan.

Background: Malnutrition is common in hemodialysis (HD) patients, and it is associated with increasing risk of mortality. The geriatric nutritional risk index (GNRI) has been developed as a tool to assess the nutritional risk. The aim of the present study was to examine the reliability of the GNRI as a mortality predictor in a Japanese HD cohort.

Methods: We prospectively examined the GNRI of 332 maintenance HD patients aged 40-49, 50-59, 60-69, ≥ 70 years of age. The patients were further divided into quartiles (Q) according to GNRI values (Q1: <91.6, Q2: 91.7-97.0, Q3: 97.1-102.2, Q4: >102.3). Predictors for all-cause mortality were examined using Kaplan-Meier and Cox proportional-hazards analyses.

Results: The GNRI presented a normal distribution. During the follow-up period of 36 months, a total of 76 patients died. The overall mortality at the end of the 3-year observational period was 22.3 %. At the 3-year follow-up period, Kaplan-Meier survival rates for all-cause mortality were 72.3%, 79.3%, 84.9%, and 92.6% in Q1, Q2, Q3, and Q4, respectively (p = 0.0067). Multivariate Cox proportional-hazards analysis demonstrated that the GNRI was a significant predictor of adjusted all-cause mortality (HR 0.958; CI 0.929–0.9, p = 0.001).

Conclusions: The results of the present study demonstrate that the GNRI is a strong predictor of overall mortality in HD patients. However, cardiovascular mortality was not associated with GNRI values, and it did not differ among the GNRI quartiles. The GNRI score can be considered a simple and reliable marker of predictor for mortality risk in Japanese HD patients.

FR-PO761

Frailty and Clinical Outcomes in Chronic Dialysis Patients Dong Ho Yang,1 Eun jung Ko,1 Hye yun Jeong.1 1Internal Medicine, CHA Bundang Medical Center, Seongnam, Republic of Korea; 2Internal Medicine, CHA Gumi Medical Center, Gumi, Republic of Korea.

Background: Frailty is a biological syndrome of decreased reserve and resistance to stressors and is independently associated with mortality and hospitalization in the general population. We investigated the relationship between frailty and clinical outcomes in chronic dialysis patients.

Methods: In this prospective study, 1,658 patients receiving chronic dialysis were enrolled. Chronic dialysis was defined as dialysis for more than 6 months. Of the 1,658 patients, 1,255 received hemodialysis. The remainder received peritoneal dialysis. Fried’s criteria for frailty as modified by Woods et al. was used. A trained interviewer asked study participants about 5 frailty phenotypes (slowness, weakness, exhaustion, shrinking, and physical inactivity) using the RAND 36-item Short Form.

Results: The mean age was 55.2±11.9, and 55.2% were male. Overall, 577 (34.8 %) patients met the study definition of frailty. Another 755 (45.7%) patients were pre-frail. Table 1 shows the prevalence of frailty and its components by age group. During the 30-month follow-up period, 607 patients (79 non-frail, 249 pre-frail, and 279 frail) were hospitalized; and 87 patients (10 non-frail, 24 pre-frail, and 53 frail) died (P<0.001). Frailty was strongly associated with hospitalization (adjusted hazard ratio [HR] 1.80, 95% CI 1.4 to 2.3) and mortality (HR 2.37, 95% CI 1.11 to 5.0) in multivariate analysis. The relationship between frailty and hospitalization was strongest among patients age 40 to 49, with a HR of 3.02 (95% CI 1.48 to 6.20).

Conclusions: We found a high prevalence of frailty in chronic dialysis patients across all age groups. The risk of hospitalization and mortality in the 30-month follow-up period significantly increased in frail chronic dialysis patients.
FR-PO763

1- and 2-Year Mortality Prediction Models for Patients Starting Chronic Dialysis
Mikko Haapio,1 Jaakko Helve,1 Carola Gronhagen-Riska,1,2 Patrik Finne,1,2 1Nephrology, Univ of Helsinki and Helsinki Univ Hospital, Helsinki, Finland; 2Finnish Registry for Kidney Diseases, Helsinki, Finland.

Background: Mortality risk of patients with end-stage renal disease (ESRD) is highly elevated compared to patients without ESRD. Taking into account our limited nephrological care resources and the simultaneously increasing number of ESRD patients there is a great need for means of mortality risk estimation to assist both in individualized patient care as well as in sound use of resources. Some mortality prediction models already exist, but many have shown a lack of comprehensiveness in data or in patient recruitment in their development.

Methods: Our objective was to design a prediction model for 1- and 2-year all-cause mortality in patients starting chronic renal replacement therapy. In addition, we aimed to build an easy-to-apply model consisting of only a few variables. We used the comprehensive data of the Finnish Registry for Kidney Diseases with complete coverage of Finnish ESRD patients. Model training group included all incident adult patients who started chronic dialysis in Finland from 1 January 2000 to 31 December 2008 (n=4335). The external validation cohort consisted of all those who started dialysis from 1 January 2009 to 31 December 2012 (n=1768). Prediction algorithms for 1- and 2-year mortality were developed using multivariate logistic regression with stepwise selection of variables. Our primary analyses included 32 variables, from which the most important ones were selected.

Results: Both final prognostic models, including only 6-7 variables, showed adequate discrimination (c-statistic 0.77 and 0.74 for 1- and 2-year mortality, respectively). Because of a significantly lower mortality in the newer (validation) cohort, both models somewhat overestimated mortality risk.

Conclusions: Mortality prediction algorithms could be more widely implemented into clinical treatment-planning of ESRD patients. Our prediction models perform sufficiently and are convenient to use, and could assist in individualized risk-stratification and, furthermore, in equal and fair sharing of limited health care resources.

FR-PO764

Comorbidity Burden at Dialysis Initiation and Mortality: A Retrospective Cohort Study
Alywn Titus Gomez,1 Bryce A. Kibed,1 Talal A. Alfaadhel,2 Brenda Hemmelgarn,3 Karthik T. Tennukore,1 1Medical, Dalhousie Univ, Halifax, NS, Canada; 2Medicine, Univ of Toronto, Toronto, ON, Canada; 3Medicine, Univ of Calgary, Calgary, AL, Canada.

Background: Contemporary assessments of the validity and prognostic value of comorbidity indices in dialysis are lacking. We sought to assess the validity of two comorbidity indices used for dialysis patients and to determine if a high degree of comorbidity was associated with mortality.

Methods: We conducted a retrospective cohort study of incident chronic dialysis patients in a tertiary care institute from 2006-2013. The Charlson Comorbidity Index (CCI) and End-Stage Renal Disease Comorbidity Index (ESRD-CI) were calculated in all patients at dialysis initiation. These indices combine individual medical conditions into an overall score. Comorbid conditions were ascertained using electronic records. The primary outcome was all-cause mortality.

Results: The cohort consisted of 771 patients. Most were male (62%) and Caucasian (91%). Patients had a high prevalence of diabetes (48%) and history of myocardial infarction (31%). The c-index was 0.61 for the CCI, and 0.63 for the ESRD-CI. In an adjusted analysis, ESRD-CI scores of 4, 5 and ≥6 were associated with a similar mortality risk (Table 1). There was a small increased mortality risk for CCI scores of 4, 5 and ≥6.

Conclusions: The CCI and ESRD-CI had a limited ability to discriminate risk of death for incident dialysis patients. Although a higher comorbidity burden was associated with mortality, increases in index scores did not considerably change the risk of death.

*Adjusted for age, sex, race, cause of end-stage renal disease, type of dialysis (hemodialysis or peritoneal dialysis), estimated GFR, albumin, phosphate and hemoglobin

FR-PO765

Cumulative Risk of Death in Propensity-Matched Incident Dialysis Patients: A Nationwide Prospective Multicenter Cohort Study in Korea
Hee-Yeon Jung,1 Sukyung Lee,1 Ji-Young Choi,1 Se-Hee Yoon,2 Jung-Hee Cho,1 Sun-Hee Park,1 Chan-Duck Kim,1 Yong-Lim Kim.1 1Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; 2Internal Medicine, Konkuk Univ, Danjeon, Republic of Korea.

Background: Our previous study reported the superior outcome of peritoneal dialysis (PD) than hemodialysis (HD) in the early dialysis period. This study investigated the impact of dialysis modality after the early period of incident dialysis patients.

Methods: Incident dialysis patients were enrolled from Korean nationwide prospective cohort from September 2008 to December 2013. The patients were stratified by modality at day 90 after the first dialysis or the modality at dialysis initiation if death occurred prior. The survival of PD and HD patients were compared by propensity score matching analysis. Relative risk of death was estimated using the cumulative hazard ratio from the stratified Cox proportional hazard model adjusted for residual confounding.

Results: A total of 1348 patients were matched from 2658 incident dialysis patients with mean follow-up of 29.9 ± 14.1 months. All clinical parameters including baseline residual renal function were comparable between PD and HD patients. The cumulative risk of death was significantly lower in PD than HD from 6 months after dialysis initiation. The cumulative hazard ratio for death was 0.70 (95% confidence interval [CI] 0.41-0.98) at one year for PD compared with matched HD and 0.68 (95% CI 0.46-0.90) at two years. The cumulative survival probability was higher in PD patients for up to 3.5 years on dialysis, with no difference after the period.

Conclusions: Overall survival in maintenance dialysis patients favored PD in the early period of dialysis and the survival advantage lasted to 3-5 years after initiation of dialysis. However, PD and HD patients had similar survival outcomes thereafter.

FR-PO766

Inflammation and Fluid Overload a Complex Interaction: Results from the International MONDO Initiative
Marijke J.E. Dekker,1 Len A. Usvyat,2 Daniele Marcelli,1 Frank van der Sande,3 Constantijn Konings,1 Peter Kotanko,2 Jeroen Kooman.3 1Catharina Hospital Eindhoven; 2Renal Research Inst; 3Fresenius Medical Care; 4Maastricht Univ Medical Center.

Background: In hemodialysis (HD) patients, the presence of inflammation or fluid overload (FO) is associated with increased mortality. The combined presence of these two is associated with even a greater risk of death. This study aims to unravel the temporal relationship between fluid status alterations and inflammation.

Methods: We conducted a longitudinal study (baseline and follow-up 3 months each) in a European subset of the MONDO-Initiative. Fluid status was assessed by multifrequency bioimpedance and inflammation by C-reactive protein (CRP). We divided patients into 4 groups based on fluid- and inflammation status. FO was defined as overhydration above >2.5L. Inflammation was defined as CRP >10mg/L.

Results: We included 5954 patients (56.1% male, age 63 years, vintage 5.1 years). At baseline inflammation and FO were jointly present in 1092 (18.3%) patients. 141 (11.8%) developed inflammation during follow up. Of the 1192 (20%) patients with inflammation but with normal fluid status at baseline, 111 (10.2%) had FO during follow up. Inflammation at baseline predicted FO during follow up (odds ratio(OR) 1.2095% CI 1.05-1.37)). Likewise, FO during baseline predicted inflammation during follow up (OR 1.30 95% CI 1.15-1.47)). However, in a minor of patients the presence of FO and/or inflammation appears to be a relatively stable condition. The presence of both inflammation and FO during baseline was associated with an increased mortality risk compared to the absence of both.

Conclusions: FO and inflammation are associated in prevalent HD patients. FO is a predictor for inflammation and vice-versa inflammation predicts FO. The combined presence of FO and inflammation is associated with poor survival.

**Blood Volume Analysis as a Guide for Dry Weight Determination in Chronic Hemodialysis Patients**

**Line Malha,1,2,3 Hassan Fattah,1 Frank Modersitzki,1 David S. Goldfarb,1,2,4**

**Background:** Volume overload and depletion both lead to high morbidity and mortality. Achieving euvolemia is a challenge in patients with end stage kidney disease (ESKD) on hemodialysis (HD). Blood volume analysis (BVA) uses radio labeled albumin to determine intravascular blood volume (BV). The measured BV is compared to an ideal BV (validated in healthy controls). We hypothesized that BVA could be used in HD to evaluate the adequacy of the current clinically prescribed “estimated dry weight” (EDW) and to titrate EDW in order to improve overall dry weight status. We were also interested in the reproducibility of BVA results in ESKD. This is the first longitudinal study of BVA in HD patients.

**Methods:** 12 adults on chronic HD were recruited; 10 completed the study. BVA (Daxor, Norwood, MA) was used to measure BV at baseline. EDW was kept the same if the patient was deemed to be euvoicmic by BVA otherwise, the prescribed EDW was changed with the aim that measured BV would match ideal BV. A second BVA measurement was done 1-3 months later in order to measure BV again.

**Results:** Based on BVA, 6/10 patients were euvoicmic at baseline and 5/10 were euvoicmic at the second measurement. When comparing patients who had their prescribed EDW changed after the initial BVA to those who did not, both groups had similar differences between measured and ideal BV (P=0.75). BV values were unchanged at the second measurement (P=0.34) and there was no linear correlation between BV change and initial EDW change (r=0.04).

**Conclusions:** This pilot study is the first longitudinal measurement of BVA in HD patients. It revealed that changing weight did not proportionally change intravascular BV. BV remained stable for 1-3 months. BVA may not be helpful in clinically stable HD patients but studies on patients with hemodynamic instability and uncertain volume status are needed.

Funding: Pharmaceutical Company Support - Daxor provided BVA equipment and supplies but was not involved in study design or execution and did not participate in the analysis of data or preparation of the manuscript.

**FR-PO768**

**Effects of Physician Payment Reform on Provision of Home Dialysis**

**Kevin E. Erickson,1 Wolfgang C. Winkelmayer,1,2 Glenn Matthew Chertow,1,2 Jay Bhattacharya,1**

**Background:** Patients with end-stage renal disease can receive dialysis at home or in-center. In 2004 the Centers for Medicare and Medicaid Services reformed physician payment for in-center hemodialysis care from a capitated to a tiered fee-for-service model, augmenting physician payment for frequent in-center visits. We evaluated whether payment reform influenced dialysis modality assignment.

**Methods:** Using a national cohort of patients starting dialysis in the US in the three years before and after payment reform, we conducted difference-in-difference analyses comparing patients with Traditional Medicare coverage (who were affected by the policy) to others with Medicare Advantage (who were unaffected by the policy). We also examined whether the policy had a more pronounced influence on dialysis modality assignment in areas with lower costs of home vs. in-center dialysis.

**Results:** Patients with Traditional Medicare coverage experienced a 12% (95% CI, 2% to 21%) reduction in home dialysis use following payment reform compared to patients with Medicare Advantage. Patients living in areas with larger dialysis facilities (where payment reform had made in-center hemodialysis comparatively more lucrative for physicians) experienced a 16% (95% CI, 8% to 23%) reduction in home dialysis use following payment reform compared to patients living in areas with smaller facilities (where payment reform made in-center hemodialysis comparatively less lucrative for physicians).

**Conclusions:** National physician payment reform intended to improve the quality of dialysis care resulted in fewer patients receiving home dialysis. This highlights a major failure of the policy and the importance of considering unintended consequences of future physician payment reform efforts.

**Characteristics and Outcomes Amongst Patients Who Switch Dialysis Provider**

**Scott Reule,1 Paul E. Drawz, Robert N. Foley. Dept of Medicine, Univ of Minnesota, Minneapolis, MN.**

**Background:** Associations between provider switch and inferior clinical outcome have been demonstrated in primary care settings. It is plausible that similar associations extend into those on renal replacement therapy (RRT) as nephrology care often extends beyond that of RRT management alone. There is a paucity of literature available describing the characteristics and outcomes amongst those whom switch dialysis provider.

**Methods:** Using USRDS data, a change in provider will be defined to the presence of any non-continuous facility codes while receiving maintenance RRT. As patients transitioning to maintenance RRT may experience early adverse outcomes, only those patients having initiated RRT with a vintage of at least 1 year were included in the analysis. Means and proportions were calculated for continuous and categorical variables, respectively. Logistic regression was used for adjusted comparisons with adjustments for baseline demographic characteristic including age, sex, and race. All estimates with p-value < 0.05 were considered significant.

**Results:** Applying these criteria, a total of 187,510 (9.1%) of prevalent patients requiring RRT were identified as having changed provider at least once. The mean age of those who have changed provider (vs. no change) was 41.3 years (vs. 57.3 years), 57% were male (vs. 55.1%), 51.3% were white (vs. 49.1%), diabetes as comorbidity in 29.9% (vs. 21.1%), and 23% were < 65 years of age at initiation (vs. 7.95%). Risk of death was lower in those who change provider (OR 0.69; CI 0.68 – 0.70) and odds were higher for both listing for (OR 2.9; CI 2.9 – 3.0) and receipt of renal transplantation (OR 4.1; CI 4.0-4.2).

**Conclusions:** Patients who switch dialysis providers constitute a distinct population of patients who are younger and lack comorbid conditions frequently observed in those on dialysis. Compared to those who do not switch providers, those who switch are more likely to be listed for and receive renal transplant.

**FR-PO770**

**Effects of Sildenafil in Dialysis Patients with Erectile Dysfunction: A Systematic Review and Meta-Analysis**

**Anaawin Sanzuanque,1,2 Sikarin Upala,1,2 Internal Medicine, Bassett Medical Center and Columbia Univ College of Physicians and Surgeons, Cooperstown, NY;1 Preventive and Social Medicine, Faculty of Medicine Sirivaj Hospital, Mahidol Univ, Bangkok, Thailand.**

**Background:** Erectile dysfunction (ED) is prevalent in dialysis patients. Sildenafil, a PDE-5 inhibitor, has been shown to be very effective against ED in general population. However, there is some evidence that dialysis patients are resistant to sildenafil treatment. We performed this meta-analysis to evaluate efficacy of sildenafil in dialysis patients with ED compared with control.

**Methods:** We comprehensively searched the databases of MEDLINE, EMBASE, and Cochrane Databases. The inclusion criteria were published RCT comparing sildenafil therapy to placebo or controls on ED in patients with dialysis. The primary outcome was change in International Index of Erectile Function (IIEF) score. The diagnosis of ED was confirmed with a score of ≥ 21 or less in IIEF.

**Results:** From 153 full-text articles, 3 studies involving 153 dialysis patients were included in the meta-analysis. All included studies were RCT comparing sildenafil with active control in either hemodialysis or peritoneal dialysis patients. A meta-analysis using fixed-effects model was performed. Those who received sildenafil had a significant improvement in IIEF score with a MD of 10.48 (95% CI: 9.96 to 11.00, p-value<0.01).

**Conclusions:** This is the first meta-analysis to show that sildenafil is effective in dialysis patients with erectile dysfunction compared with control. Further study comparing other benefits and side effects of PDE-5 inhibitor in dialysis patients should be conducted.

**FR-PO771**

**Validation of Screening Questionnaires for Sleep Apnea in Hemodialysis Patients**

**Farahnah Yousaf,1 Mitesh K. Patel, Saw H. Mu, Alla Goldberg, Chaim Charytan, Bruce S. Spinowitz, New York Hospital Queens.**

**Background:** Sleep apnea hypopnea syndrome (SAHS) is common in end stage renal disease (ESRD). We investigated the validity of Berlin and STOP-BANG questionnaires against nocturnal oximetry in identifying high risk hemodialysis patients for SAHS.

**Methods:** After obtaining local IRB approval, adult hemodialysis patients who were undergoing regular chronic hemodialysis for at least 3 months were consented and asked to complete Berlin and STOP-BANG questionnaires. Nocturnal oximetry from hemodialysis night using Pulsox 300i wristwatch was also completed. The saturation recordings were downloaded and analyzed using Profox software. The first hour of recording was deleted in effect as saturation recording period from sleep time only. Saturation data were also excluded from analysis. Oxygen desaturation index (ODI) was defined as the number of desaturations ≥ 3% from baseline lasting ≥ 10 seconds, per hour. Sensitivity, specificity, positive and negative predictive values were calculated for the Berlin and STOP-BANG questionnaires.

**Results:** Twenty HD patients (11 males and 9 females) aged 54 ± 5.8 years had a mean body mass index of 25.5 ± 6.7 kg/m² and neck circumference of 38.4 ± 5.8 cm.

**Conclusions:** This is the first meta-analysis to show that sildenafil is effective in dialysis patients with erectile dysfunction compared with control. Further study comparing other benefits and side effects of PDE-5 inhibitor in dialysis patients should be conducted.

**FR-PO772**

**Validation of Screening Questionnaires for Sleep Apnea in Hemodialysis Population**

**Erickson F,1 Modersitzki F,2 Wolfrum H,2 Tschander C,1 Winkelmayer WC.1 Preventive and Social Medicine, Faculty of Medicine, Stanford Univ, Palo Alto, CA;2 Medicine, Baylor College of Medicine, Houston, TX.**

**Background:** Sleep apnea hypopnea syndrome (SAHS) is common in end stage renal disease population. Reliable screening tools for SAHS in ESRD population are limited.

**Methods:** Both Berlin and STOP-BANG questionnaires lack specificity to be utilized in this setting. The inclusion criteria were published RCT comparing sildenafil therapy to placebo or controls on ED in patients with dialysis. The primary outcome was change in International Index of Erectile Function (IIEF) score. The diagnosis of SAHS was confirmed with a score of ≥ 21 or less in IIEF.

**Results:** From 153 full-text articles, 3 studies involving 153 dialysis patients were included in the meta-analysis. All included studies were RCT comparing sildenafil with active control in either hemodialysis or peritoneal dialysis patients. A meta-analysis using fixed-effects model was performed. Those who received sildenafil had a significant improvement in IIEF score with a MD of 10.48 (95% CI: 9.96 to 11.00, p-value<0.01).

**Conclusions:** This is the first meta-analysis to show that sildenafil is effective in dialysis patients with erectile dysfunction compared with control. Further study comparing other benefits and side effects of PDE-5 inhibitor in dialysis patients should be conducted.

Moderate to Severe Nocturnal Hypoxemia and Executive Dysfunction in Patients Undergoing Maintenance Hemodialysis Farahnaz Youssaf, Mitsesh K. Patel, Chaim Charytan, Alla Goldberg, Bruce S. Spinowitz. New York Hospital Queens.

Background: Nocturnal hypoxemia and executive dysfunction is common in end stage renal disease. We investigated the impact of moderate to severe nocturnal hypoxemia on executive function in patients undergoing maintenance hemodialysis.

Methods: Following local IRB approval, adult hemodialysis patients were consented to complete 1 night of nocturnal oximetry using Pulsiox 300T wristwatch. The first hour of recording was deleted in efforts to capture oximetry reading from sleep time only. Oxygen desaturation index (ODI) was defined as the number of desaturations ≥ 3% from baseline lasting ≥ 10 seconds per hour. Trail making tests A and B were also completed during dialysis session. Trail making test A and B performance was compared using t-test in patients with ODI < 15 versus those with ODI ≥ 15. Executive dysfunction was defined as trail making A and B completion time > 75 seconds and 180 seconds, respectively.

Results: Nine of 20 patients aged 45 ± 12 years with a mean body mass index (BMI) of 23 ± 3 kg/m² and neck circumference of 35 ± 4 cm had ODI < 15. The remaining eleven patients aged 60 ± 12 years with a mean BMI of 28 ± 5 kg/m² and neck circumference of 41 ± 6 cm had ODI ≥ 15. Patients with ODI ≥ 15 took significantly longer (77 ± 34 sec) to complete trail making test A versus patients with ODI < 15 (45 ± 23 sec). Five of 11 (45%) patients with ODI ≥ 15 required > 75 seconds to complete trail making test A compared to only 1 patient out of 9 (11%) with ODI < 15. Mean duration for completion of trail making B test was also longer in patients with ODI ≥ 15 (157 ± 87 seconds) compared to ODI < 15 (117 ± 67 seconds) [p<0.03]. Two of 11 patients with ODI ≥ 15 and 2 of 9 patients with ODI < 15 required > 180 seconds to complete trail making test B.

Conclusions: Patients with ODI < 15 performed better on trail making test A, were younger with a smaller BMI and neck circumference, compared to those with ODI ≥ 15. Additional research is warranted to confirm these findings. Whether treatment of moderate to severe nocturnal hypoxemia may slow or prevent executive decline in patients undergoing maintenance hemodialysis remains to be determined.

FR-PO773
Indoxyl Sulfate (Indican) and Sleep Disorders in Hemodialysis Patients: The Retained Solutes Outcomes and Clinical Studies (ROSCO) Study Yunnuo Zhu,1 Tanushree Banerjee,1 Tariq Shafi,2 Timothy W. Meyer,2 Michael L. Melamed,3 Thomas H. Hostetter,4 Neil R. Powe,51 UCSF; 2JHU; 3Stanford; 4Albert Einstein; 5Case Medical Center.

Background: Although sleep disorders are common in dialysis patients, the pathophysiology of sleep disturbance is unclear. Protein-bound solutes inadequately removed during dialysis may contribute to sleep disorders.

Methods: We examined the association of total and free levels of IS with sleep disorder in 1,241 prevalent dialysis patients from the HEMO study. IS levels were measured using mass spectroscopy and modeled as tertiles. Sleep disorder was assessed using a 5-level categorical question in the Short Form (36) Health Survey. We used ordinal logistic regression to assess the relation of IS with sleep disorder, adjusting for confounders including age, race, gender, ICED score, body mass index, diabetes, congestive heart failure, serum albumin, creatinine, and phosphate levels. The lowest tertile of IS was the reference group. Effect modification was tested for IS levels with Kt/V and gastrointestinal (GI) disease (due to IS’s GI origin).

Results: Patients were on average 57.5 years old, 62.8% were black, and 43.2% were male. There was a significant association between increasing tertiles of free IS and more severe sleep disorder in both unadjusted [OR 1.44 (95% CI: 1.1-1.89)] and adjusted models [1.78 (1.24-2.58)]. There was effect modification by Kt/V (p=0.03) but none by GI disease (p=0.17). Similar results were observed with total IS and sleep disorder [2.09 (1.37-3.19)]. Stratified analyses by Kt/V did not show an association between higher tertiles of free IS and sleep disorder in the high Kt/V group [0.72 (0.45-1.14)]. However greater odds of sleep disorder with higher tertile of IS were noted in the low Kt/V group. This relation was also present for total IS; those with low Kt/V had greater odds of sleep disorder with the highest total IS tertile [2.11 (1.29-3.45)] but not with the high Kt/V group [0.91 (0.61-1.35)].

Conclusions: Higher levels of IS are significantly associated with sleep disorder. Patients with a lower dialysis dose may be more susceptible. Further research on whether removal of IS improves sleep outcomes is needed.

FR-PO774
Quantifying Physical Activity Levels and Sleep in Hemodialysis Patients Using a Commerially-Available Activity Tracker Maggie Han,1 Schanel Williams,1 Anna Meyring-Wosten,1 Viviane Callico-Silva,2 Melissa Mendoza,1 Hanjie Zhang,1 Xiaoling Ye,1 Tariq Shafi,2 Deborah S. Evans,1 Deborah A. Benner.1 1DAVita HealthCare Partners Inc, Denver, CO; 2Apex Health Innovations, Simi Valley, CA.

Background: Unemployment rates are high among dialysis patients; a 2011 study found approximately 71% of working-age dialysis patients are unemployed.1 Another study found that dialysis negatively impacts employment status and has the largest effect between dialysis years 1 and 2.2 We examined whether prolonged dialysis (dialysis vintage) affects employment status.

Methods: Dialysis vintage data and mean age were obtained from a sample of 16,069 employed patients from a large dialysis organization (Nov 2014-April 2015). Employment status was defined as regular full-time (35 hrs/ wk), regular part-time (<35 hrs/wk), and per diem (≤24 hrs/wk).

Results: Regular full-time employed patients were older (52.6 yrs) than part-time (49.1 yrs) and per diem (49.0 yrs) patients. Employment status was highest among all patients for all categories of employment during year 1 of dialysis (35.7%) and dropped significantly by year 2 (14.4%) [Table]. Employment status continued to drop as vintage
Conclusions: Our study found that dialysis vintage negatively impacts employment status and has the largest effect between years 1 and 2. Further study is needed to reveal if a similar rate of increase toward this threshold exists. It appears that these patients should alert dialysis staff that support and intervention may be needed to help patients employed. References: 1) Muehler RJ et al. Clin J Am Soc Nephrol. 2011;6(3):489-496. 2) van Manen JG et al. Peri Dial Int. 2001;21(6):595-601.

Provider Visit Frequency During Hemodialysis and Its Effect on End Stage Renal Disease Comorbidities
Juan E. Echeverri, Joslyn Wiley, Hazem Abu Grara, Rene Armando Garcia, Alberto J. Sabucedo, Marco A. Ladino-Avellaneda. Div of Nephrology, Miami VA Medical Center/Univ of Miami, FL.

Background: In the United States, patients with End Stage Renal Disease (ESRD) on hemodialysis visit their Nephrologist one to four times per month during their dialysis sessions. Medicare reimbursement policy encourages frequent provider visits for patients on ESRD on hemodialysis. We believe that increasing the number of face-to-face provider visits improves the care and clinical outcomes of comorbidities related to ESRD (hypertension, hyperphosphatemia, and hyperkalemia). Methods: We used a Pre and Post-test pilot study design to evaluate the effect on laboratory measurements and blood pressure by increasing the frequency of Nephrologist face-to-face visits at the Miami VA Medical Center. Seventeen patients that were evaluated during a period of six months were included in the analysis. In the initial three months, the patients were evaluated four times per month (usual care). The number of face-to-face visits was increased to eight times per month (or twice weekly) for the following three months. Results: A paired-sample t-test was conducted to compare the mean systolic blood pressure measure before and after the intervention. Additional provider face-to-face visits per month were associated with a significant difference in the systolic blood pressure before and after the intervention (p = 0.004, t=3.303, Mean=8.235, and Standard Deviation=16). In addition, we found improvement of the phosphorus levels with a difference that was statistically significant (p = 0.028, t=2.419, Mean=5.512, and Standard Deviation=16). Patients reported increased perceived quality of care when they had the opportunity of seeing the Nephrologist more frequently.

Conclusions: Hypertension and electrolyte abnormalities are known risk factors that increase morbidity and mortality in patients with End Stage Renal Disease. Adherence to medications may improve in patients on Hemodialysis therapy. Increasing the number of visits per month with the Nephrologist during Hemodialysis sessions increases adherence to a renal diet, medication use and patient satisfaction.

FR-PO779

Response Rate of Hepatitis B Virus Vaccination in Various Stages of Chronic Kidney Disease
So Mi Kim, Eun kyong Lee, Yun Jung Oh. Div of Nephrology, Dept of Internal Medicine, Jeju National Univ Hospital, Jejudo, Republic of Korea; Dip of Nephrology, Dept of Internal Medicine, Dankook Univ Hospital, Cheonan, Chungnam, Republic of Korea; Div of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Jejudo, Republic of Korea.

Background: Although hepatitis B virus (HBV) vaccination is recommended for all dialysis patients, the response rate of HBV vaccination in dialysis patients is very low. Therefore, we tried to investigate the necessity of early HBV vaccination in pre-dialysis patients analyzing the response rate of vaccination in various stages of chronic kidney disease (CKD).

Methods: A total of 87 patients in 3 different stages of CKD was enrolled in this study. Patients in stage 3 (n=30) and 4 (n=28) were received the HBV vaccine as standardized schedule, consisting of 1 mL of the recombinant vaccine, Hepavax-gene TF at 0, 1, and 6 months. And then, the patients with stage 5 (n=29) were received the same vaccine for dosing doses at 0, 1, 2, 3, 4, 5, and 6 months. Three months after each of the last vaccination, serum level of Anti-HBs was measured in all patients.

Results: There was no significant difference in baseline characteristics including age, sex, presence of DM among the 3 groups. The overall seroconversion rate after vaccination was 79.4%. The seroconversion rate was significantly higher in patients with stage 3 than other patients (stage 3: 94%, stage 4: 79%, stage 5: 66%, p<0.01). Analyzing based on dialysis, seroconversion rate was also significantly higher in pre-dialysis patients than in dialysis patients (pre-dialysis group: 86%, dialysis group: 65%, p=0.02). There was no significant factor to contribute seroconversion in multivariate analysis.

Conclusions: Our study showed the high seroconversion rate after HBV vaccination in CKD patients with stage 3 and pre-dialysis. Therefore, the HBV vaccination should be considered in early CKD stages.

FR-PO780

Outbreaks of Hepatitis C Infection Infected Reported in U.S. Hemodialysis Facilities, 2008-2014

Background: Hepatitis C virus (HCV) infection is more prevalent among hemodialysis (HD) patients than the general population. HCV transmission in dialysis units may contribute, and is difficult to detect due to lack of symptoms and systematic screening. We summarized HCV outbreaks reported to CDC to characterize their frequency and factors contributing to transmission in HD facilities.

Methods: We defined a healthcare-associated outbreak as '2 new HCV infections (positive anti-HCV; E1 year after negative anti-HCV, or positive anti-HCV with acute hepatitis) in the same facility.' We reviewed outbreaks in 2008-2014 reported to CDC. For HD unit outbreaks, we summarized type of facility, number of new cases, number of patients notified for HCV testing, infection control lapses identified, and results of HCV molecular testing. Infection control transmission was confirmed if there was epidemiological and molecular evidence of transmission.

Results: During 2008–2014, 22 outbreaks of HCV infection in healthcare settings were reported to CDC; 11 (50%) of these outbreaks occurred in outpatient HD clinics. Seventy-nine (median 4, range 2–21) new HCV infections were identified. More than 1,800 HD patients were notified and screened for HCV in outbreaks facilities. Infractivity HCV transmission was confirmed in all 11 outbreaks. New cases had treatment time and location overlap with their HCV-infected source patient. For 9 outbreaks, lapses in infection control were identified, including environmental disinfection (8), hand hygiene (5), and injectable

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

542A
medication handling (3), separation of clean and contaminated workspaces (2), and vascular access care (1). Multiple lapses were identified in 7 outbreaks. No specific infection control lapses were identified at the time of the investigation in 2 outbreaks. 

Conclusions: Outpatient hemodialysis clinics remain a common setting for healthcare-related HCV outbreaks. Infection control lapses were frequently identified in reported outbreaks. Rigorous adherence to recommended infection control practices is needed to protect patients and prevent future outbreaks in this setting.

FR-PO781
Influenza and Outcomes in ESRD Patients David T. Gilbertson,1 Anne C. Beaubrun,2 Kenneth J. Rothman,1 Jiannong Liu,1 Brian D. Bradbury,1 Akhtar Ashfaq,1 Charles A. Herzog,2 Allan J. Collins,1 Chronic Disease Research Group, MMRF;3 Ctr for Observational Rsrch, Amgen;4 RTI Health Solutions.

Background: Yearly influenza vaccination is recommended for all ESRD patients, due to a high risk of influenza-related complications. Through the CDC’s Outpatient Illness Surveillance, information on patient visits to health care providers for influenza-like illness (ILI) is collected. These data give estimates of the percent of all OP visits that are for presumed influenza, and give national information on timing and severity of each influenza season. We assessed the association between CDC ILI data and outcomes in ESRD patients.

Methods: We aggregated weekly ILI data from 2000-2012 to monthly, and calculated the monthly number of deaths and hospitalizations among US ESRD patients during the same time period. Using time series decomposition, we subtracted out seasonal and trend components from both series, and computed correlations between the ILI and mortality/hospitalization data.

Results:

The figure displays deaths and ILI data after removing seasonal and trend components. There were 2 influenza seasons (2003-2004 and 2009-2010) during this time period where the peak was at the end of the calendar year (early in the influenza season) instead of at the beginning of the next calendar year. Similar “early” peaks are seen in deaths among ESRD patients. There is also correlation between other peaks and valleys of the ILI data and ESRD deaths; correlation coefficient = 0.63. Correlations were also calculated with cause-specific hospitalizations: 0.69 for ILI-influenza/pneumonia; 0.42 for ILI-any infection; 0.16 for ILI-MI; and 0.02 for ILI-stroke.

Conclusions: The association between ILI and outcomes in ESRD patients is strong. While influenza vaccination rates among ESRD patients have improved over the last decade, the overall rate is still below 70%, suggesting room for further improvement.

FR-PO782
The Burden of Pneumonia in Patients Receiving Dialysis: Incidence, Case Fatality, and Costs to Medicare Scott Sibbel,1 Reiko Sato,2 Abigail Hunt,1 Wendy Tureume,1 Steven M. Brunelli,1 David V. Kshirsagar,1 Diane Reams, Magdalene M. Assimon, Anne Mobley Butler, Jennifer E. Flythe, M. Alan Brookhart. Univ of North Carolina at Chapel Hill.

Background: End-stage renal disease patients receiving dialysis are at particular risk for infection. We assessed the clinical and economic burden of pneumonia in a population of Medicare-enrolled ESRD patients with respect to incidence and case fatality rates, rates of all-cause hospitalization, and costs.

Methods: Patients included in the analysis received dialysis between 01 Jan 2009 and 31 Dec 2011, and were enrolled in Medicare Parts A and B. Pneumonia episodes were identified from institutional and supplier claims. Patients were considered at-risk from the first date of Medicare coverage and were censored from the analysis upon transplant, withdrawal from dialysis, recovery of renal function or death. Linear mixed effects models were used to assess hospitalization rates and costs over the 3 months prior to and 12 months following a pneumonia diagnosis.

Results: The pneumonia incidence rate for the study period was 21.4 events/100 patient-years with the majority of episodes (90.1%) requiring inpatient treatment. The 30-day case fatality rate was 10.7%; case fatality rates were higher for older patients and for pneumonia requiring inpatient treatment (11.2%). All-cause hospitalization rates were greater in the month of the pneumonia episode vs month -3 prior to diagnosis (IRR, 4.61; 95%CI: 4.46, 4.76) and remained higher than baseline over the 1-year follow-up period. Mean per patient per month costs were $10,976 (95% CI: $10,717, $11,275) higher in the month of the index episode compared to month -3, largely driven by increased inpatient costs, and remained elevated through end of follow-up.

Conclusions: Pneumonia episodes are frequent among ESRD patients and result in hospital admissions and greater overall costs to Medicare (~$20,000 incremental) over the following year.

Opioid Use Associates with Infection Related Morbidity and Mortality in Hemodialysis Patients Abhijit V. Kshirsagar, Diane Reams, Magdalene M. Assimon, Anne Mobley Butler, Jennifer E. Flythe, M. Alan Brookhart. Univ of North Carolina at Chapel Hill.

Background: Opiates are frequently prescribed for pain in the US hemodialysis (HD) population but have intrinsic properties that increase risk of infection, a common cause of morbidity and mortality for patients. Data regarding the association of opioids with infection are lacking.

Methods: We conducted a retrospective cohort study using data from a large national dialysis provider linked with the United States Renal Data System and Medicare Part D (2006-2010). We used a new user design – comparing only new users of opioids to new users of prescription non-steroidal anti-inflammatory drugs (NSAIDS) to address confounding, as well as excluding patients with cancer, use of hospice services, or use of > 1 opiate. We assessed treatment effects on infection-related morbidity and mortality using inverse probability of treatment weighted Kaplan-Meier methods, adjusting for many comorbidity, lab, and clinical variables.

Results: 5,113 patients met entry requirements, of which 3,439 (67.3%) received an opioid. Relative to new NSAID users, new opioid users had similar baseline laboratory values, but were slightly younger, and had a higher prevalence of comorbidities, including recent infections (8.7% vs 6.8%), diabetes (52.3% vs 49.3%), and chronic obstructive pulmonary disease (COPD), 17% vs 12.2%. After multivariable adjustment, we observed an elevated risk of 90-day infection-related hospitalization, (Risk Difference (RD) 2.5/100 patient-years) for recent infections (8.7% vs 6.8%), diabetes (52.3% vs 49.3%), and chronic obstructive pulmonary disease (COPD), 17% vs 12.2%. After multivariable adjustment, we observed an elevated risk of 90-day infection-related hospitalization, (Risk Difference (RD) 2.5/100 patient-years) for recent infections (8.7% vs 6.8%), diabetes (52.3% vs 49.3%), and chronic obstructive pulmonary disease (COPD), 17% vs 12.2%.

Conclusions: We found that opioids were associated with increased risk of infection-related outcomes in the dialysis population.
Conclusions: Our results suggest that opioid initiation increases the short-term risk of infection-related morbidity and mortality among HD patients.

A Retrospective Review of the Two-Step Tuberculin Skin Test in Manitoba’s Dialysis Population

Rukhsana A. Foster,1,2 Thomas W. Ferguson,1 Claudio Rigatto,1 Navdeep Tangri,1 Blake R. Lerner,1 Reid Whitlock,3 Paul Komenda,3
Community Health Sciences, Univ of Manitoba, Winnipeg, MB, Canada; 3Medicine, Univ of Manitoba, Winnipeg, MB, Canada.

Background: Reactivation of latent Mycobacterium Tuberculosis (LTB) is a health concern in patients on dialysis due to their immunosuppressed state. The most frequently used test for LTBI screening in this population is the Tuberculin Skin Test (TST). The diagnostic accuracy (sensitivity and specificity) and clinical utility of the TST in a contemporary North American dialysis population is unknown.

Methods: We performed a retrospective cohort study of 483 hemodialysis and peritoneal dialysis patients across 4 dialysis units. All patients received a two-step TST and subsequent treatment if positive. We then linked the cohort with the Manitoba Health TB Registry to ascertain if treatment was received for LTBI.

Results: Of 483 patients, 406 were two-step TST positive (84%). Patients with a BCG vaccination were more likely to test positive (50 vs. 34%, p = 0.07). Using a diagnostic gold standard of an abnormal chest X-ray as a proxy for LTBI, the TST has limited diagnostic and clinical utility for LTBI screening in this population.

Conclusions: The TST is limited and diagnostic utility for LTBI screening in patients on dialysis. Further research into the diagnostic accuracy of interferon-gamma release assays, and a revision of TST screening guidelines in patients on dialysis should be considered.

FR-PO785

Reliability and Construct Validity of the Coping Strategy Inventory-Short Form in Hemodialysis (HD) Patients in 13 Countries in the Dialysis Outcomes and Practice Patterns Study (DOPPS)

Elodie Speyer,1 Hal Morgenstern,1 Yasuaki Hayashino,1 Peter G. Kerr,1 Hugh C. Rayner,1 Reid Whitlock,1
1Arbor Research Collaborative for Health; 2University of Michigan; 3Teurion Hospital; 4Monash Health & Monash Univ; 5Birmingham Heartlands Hospital.

Background: In international studies, questionnaires are often translated into several languages without consideration of cultural and linguistic differences that may compromise the reliability and validity of survey instruments, especially those measuring psychosocial factors. The Coping Strategies Inventory-Short Form (CSI-SF) is a 16-item questionnaire, developed in English, and previously validated in US cardiac failure patients. It is scored by calculating 4 scales (each with 4 items) to measure 4 different coping strategies. The aim was to assess and construct validity of the CSI-SF in HD patients across 13 countries.

Methods: The CSI-SF was self-administered to HD patients across 13 countries in 9 languages in DOPPS 4 (2009-11). Cronbach’s alpha was used to assess internal consistence. Exploratory and confirmatory factor analyses were used to assess the factor structure of the CSI-SF by country and language.

Results: 6,656 HD patients completed the CSI-SF and were included in this analysis (55% male; median age 63, range: 18-96 yrs). Using the English version in 4 countries and the Swedish version, we found good internal consistence (α=0.63-0.77) for 3 of the 4 scales; the 4th scale was internally consistent if two items were dropped. In these countries, both types of factor analyses indicated a factor structure perfectly consistent with these same 4 scales. In the 8 other non-English versions, results were very different: internal consistence was lower for the 4 scales; no country showed an exploratory factor structure similar to that found previously, nor was the 4-factor structure confirmed with factor analysis.

Conclusions: The CSI-SF is reliable for measuring coping in HD patients in English and other English versions, as tested in the DOPPS. The importance of coping for predicting outcomes in HD patients can now be described in these countries. More research is needed for measuring coping strategies in other countries and languages.

FR-PO786

Associations Among Psychosocial/Medical Factors and Quality of Life in Hemodialysis Patients with End-Stage Renal Disease

Gumwoo Kang, Internal Medicine, Catholic Univ of Daegu School of Medicine, Daegu, Korea.

Background: Patients with end-stage renal disease (ESRD) have a significant impairment in quality of life (QoL). Most previous studies have focused on medical factors mainly. However, quality of life can also be affected by psychosocial problems in the circumstances of chronic illness. The aim of this study was to identify the associations among psychosocial factors, medical factors and QoL in hemodialysis (HD) patients.

Methods: The study included 101 patients with ESRD who were undergoing HD (mean age 57.1 ± 2.1 years). Psychosocial factors were evaluated using the Hospital Anxiety and Depression Scale (HADS), Multidimensional Scale of Perceived Social Support, Montreal Cognitive Assessment and Pittsburgh Sleep Quality Index. In addition, for evaluating caregivers’ burden in part of psychosocial factors, HADS and Zarit Burden Interview of main caregivers were administered. We also accessed medical factors (Kt/V and urea reduction ratio, etc.) with laboratory results (body mass index, albumin, hemoglobin, etc.). The QoL was evaluated using WHO Quality of Life-BREF (WHOQOL-BREF). Canonical correlation analysis was used to investigate the patterns of associations.

Results: The canonical correlation between psychosocial factor and QoL was 0.49. The first canonical correlation was 0.67 (p = 0.001) and the second was 0.519 (p = 0.006). However, the canonical correlation between medical factor and QoL was not significant (p = 0.586). The second canonical correlation was 0.713.

Conclusions: The QoL of patients with ESRD was not associated with medical factor, but psychosocial factor in canonical correlation analysis. This finding may suggest that medical workers should recognize and treat psychosocial problems as well as clinical problems. We also would like to emphasize the comprehensive approach with cooperation between psychiatrists and nephrologists for improvement of QoL in ESRD patients.

FR-PO787

Longitudinal Associations of Dietary Protein and Energy Intake with Protein-Energy Wasting Syndrome in Hemodialysis Patients

Chiara Regazzoni,1,2 Xin Tian,1,2 Xiaorui Chen,1,2 Xiaowei Sun,1,2 Dan Zhu,1,2 Tomir Gur,3 Yvonne de Zwaan,2,4
1University of Glasgow; 2Robert Gordon University, UK; 3University of Utah; 4VA SLC, VA Denver.

Background: The associations of baseline dietary protein intake (DIPI) (<0.6 g/kg/d) and low dietary energy intake (DEI) (<25 kcal/kg/day) are included in the definition of protein-energy wasting (PEW) syndrome. Therefore, we aimed to examine the longitudinal associations of baseline DIPI and DEI with PEW syndrome (defined by modified criteria that excludes dietary variables) at 1 year of follow-up in 1480 MHD pts in the HEMO Study.

Methods: DIPI and DEI were obtained by 24-h dietary recall. PEW syndrome at month 12 was defined as the presence of 2 out of the 3 criteria: serum chemistry (albumin by BCP method < 3.5 g/dl or cholesterol < 100 mg/dl), body weight (BMI < 23 kg/m² or wt loss > 10% over 1 yr), and muscle mass (mid-arm muscle circumference 10% or more than the 50th percentile of reference population). PEW syndrome at month 12 was related to baseline DIPI and DEI in logistic regression models.

Results: 17.4% had PEW at month 12. The prevalence of PEW syndrome at month 12 by baseline DIPI and DEI quartiles are summarized in the figure.

The associations of baseline DIPI and DEI with PEW syndrome at month 12 in logistic regression models are summarized in table.
Associations of baseline DPI or DEI with the presence of PEW syndrome at month 12*  

<table>
<thead>
<tr>

<td>0.30 (0.22, 0.41)</td>
</tr>
</tbody>
</table>

*Each cell represents a separate logistic regression model, 1 Adjusted for demographics, ESRD duration, Kt/V group, race group, smoking and alcohol use, 2Adjusted for above plus diabetes, CAD, CVD, PVD, CHF and arrhythmia.

Conclusions: The contrarian finding of lower risk of PEW in those with low DEI and DPI could reflect mathematical coupling (as both DEI and DPI include body wt in the denominator and those with PEW have lower body wt).

FR-PO788

PEW Syndrome, Inflammation and Mortality in Hemodialysis Patients  
Sri Sri Beddu, Xiaoxiu Chen, Wei, E. Boucher, Dominique Ferrari, Kalani L. Raphael, Tom Greene, Michel Chonchol.

Background: The term ‘malnutrition-inflammation complex syndrome’ implies that malnutrition and inflammation are tightly interlinked. Therefore, we examined whether the mortality associations of markers of inflammation and protein-energy wasting syndrome (PEW) are attenuated by each other in 906 maintenance hemodialysis (MHD) patients in the HEMO Study, a multi-center RCT that examined the effects of dialysis dose and dialyzer flux on mortality.

Methods: High sensitivity Creative Protein (hsCRP), tumor necrosis factor (TNF)-a and interleukin (IL)-6 were measured in the month 12 stored samples. Weight loss was estimated from baseline and month 12 post-dialysis weights and hence, PEW syndrome at month 12 was defined as the presence of 2 out of 3 criteria: serum chemistry (albumin by nephelometry < 3.5 g/dl or cholesterol < 100 mg/dl), body weight (BMI < 23 kg/m^2 or wt loss > 10% from baseline), and muscle mass (mid-arm muscle circumference 10% or more than the 50th percentile of reference population). Cox models were used to relate month 12 PEW syndrome and hsCRP, TNF-a and IL-6 with subsequent mortality.

Results: Mean age was 57 ± 14 yrs, 45% were women. 67% were black. PEW syndrome was present in 17.4% at month 12. Median (IQR) serum hsCRP was 6.3 (2.6-16.4) mg/L, IL-6 3.3 (2.0-7.6) pg/ml, and TNF-a 31.2 (21.3-46.1) pg/ml. There were 388 deaths over 2189 years of follow-up. PEW syndrome had 2 fold higher risk of mortality which was only marginally attenuated by adjustment for markers of inflammation (table). CRP and IL-6 were associated with higher mortality risk independent of PEW. TNF-a was not associated with mortality.

<table>
<thead>
<tr>
<th></th>
<th>Model 1*</th>
</tr>
</thead>
<tbody>
<tr>
<td>PEW syndrome</td>
<td>2.22 (1.78, 2.76)</td>

</tr>
<tr>
<td>Each doubling of IL-6 -</td>
<td>1.13 (1.00, 1.18)</td>
</tr>
</tbody>
</table>

Conclusions: PEW and inflammation are independent predictors of mortality. These results suggest PEW and inflammation might not be tightly interlinked.

Funding: NIDDK Support

FR-PO790

Association of Pre-Transplant Dialysis Modality and Post-Transplant Outcomes: A Meta-Analysis  
Emily Joachim, Ali I. Gardezi, Suddheer Mudugunti, Sana Waheed, Jung-Im Shin, Brad C. Astor, Micaiah R. Chau.

Background: Patients who undergo dialysis prior to renal transplant have overall worse outcomes than patients who receive a preemptive transplant. However, individual studies give conflicting results regarding whether post-transplant outcomes differ based on pre-transplant dialysis modality (peritoneal dialysis (PD) versus hemodialysis (HD)).

Methods: We searched English-language literature from January 1, 1980 through August 31, 2014, national conference proceedings and reference lists of all included studies. We used combinations of terms related to dialysis (hemodialysis, peritoneal dialysis, or renal replacement therapy), kidney transplant and outcomes. Studies were included if they measured post-transplant patient mortality for both pre-transplant HD and PD. Studies were excluded if they were not in English or if they included pediatric patients.

Results: A total of 15 studies reported five-year patient mortality. These included 166,531 patients on HD and 51,980 patients on PD pre-transplant. The pooled hazard ratio for five-year patient mortality after renal transplant was 0.91 (CI 0.85-0.97) in favor of pre-transplant PD over HD (p<0.006).

Conclusions: Distance is an important factor in patient decision-making when initiating PD, particularly for those living farther away from commonly offered HD services. Analyses of treatment selection must appropriately model distance to reflect logistics of treatment options and service availability to patients.

Funding: NIDDK Support, Other U.S. Government Support

FR-PO790

Impacts of Geographic Distance on Peritoneal Dialysis (PD) Utilization: Refining Models of Treatment Selection  

Background: Proximity to dialysis services may ease patient travel burden. Different frequency of visits to dialysis facilities and resulting differences in travel distance may affect patients’ selection of hemodialysis (HD) versus PD. PD has historically been less commonly available in dialysis facilities and less commonly used than HD. We refine methods of prior research to reassess the relationship between patients’ distance to dialysis care and modality choice to better reflect the conditions of patients’ choice set of providers’ location (absolute distance) and available services (relative distance).

Methods: Retrospective cohort of 70,131 patients initiating dialysis and 4,795 dialysis facilities in 2006 using USRDS data. The primary outcome was patient PD use. Independent variables included absolute distance from patients’ home to nearest HD facility, relative distance dichotomized as the nearest PD facility closer or same distance as nearest HD facility, and their interaction. Logistic regression was used to model distance on PD use, controlling for patient and market factors.

Results: 9% of new dialysis patients used PD in 2006. There was a positive, non-linear relationship between absolute distance to closest HD services and PD use (p=0.006). In terms of relative distance, odds of PD increased if a PD facility was closer or the same distance as the nearest HD facility (p=0.006). The interaction of absolute and relative distance was not significant.

There was moderate heterogeneity among these studies (I^2=41.4%, p=0.05). Six studies included an adjusted risk ratio (RR); the pooled RR for these studies was 0.89 (CI 0.82-0.97) in favor of PD (p=0.006). There was significant heterogeneity among these six studies (I^2=72.7%, p=0.003).

Conclusions: Based on these results, pre-transplant peritoneal dialysis is associated with better post-transplant survival at five years compared to hemodialysis. Further work should explore potential reasons for this difference and compare additional outcomes such as graft survival, delayed graft function and rejection.

Impact of Poverty and Health Care Insurance on Pre-End Stage Renal Disease Care in Dialysis Patients

Robert Nee,1 Lawrence Agodoa,2 Kevin C. Abbott,1 Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; 1NIDDK, National Insts of Health, Bethesda, MD.

Background: Access to nephrology care prior to end-stage renal disease (ESRD) is significantly associated with lower rates of morbidity and mortality. We assessed the association of area and individual-level indicators of poverty and types of health care insurance on pre-ESRD care provided by nephrologists.

Methods: In this retrospective cohort study using the United States Renal Data System database, we identified 739,537 patients initiated on maintenance dialysis from January 1, 2007 through December 31, 2012. We assessed the Medicare-Medicaid dual eligibility status as an indicator of individual-level poverty and ZIP code-level median household income (MHI) data obtained from the 2010 United States Census. We conducted multivariable logistic regression of pre-ESRD care as the outcome variable, as reported on the Centers for Medicare and Medicaid Services Form 2728.

Results: The proportions of dual-eligible and non-dual eligible patients who had pre-ESRD care were 53.06% and 61.82%, respectively (p<0.001). Dual-eligibility was associated with significantly lower likelihood of pre-ESRD care (adjusted odds ratio [aOR] 0.83, 95% confidence interval [CI] 0.82-0.84). Patients in the lowest area-level MHI quintile had an aOR 0.89 (95% CI 0.88-0.90) compared to those in higher quintile levels. Both African American (AA) and Hispanic patients were significantly less likely to have pre-ESRD care (aOR 0.85, 95% CI 0.84-0.86 and aOR 0.71, 95% CI 0.70-0.72, respectively). Interaction terms for dual eligibility and AA race and Hispanic ethnicity were significant (p<0.001 and p=0.002, respectively).

Conclusions: Individual and area level measures of poverty were independently associated with lower likelihood of pre-ESRD care. Efforts to improve pre-ESRD nephrology care may require focusing on the poor and minority groups. [Disclaimer: The views expressed in this paper are those of the authors and do not reflect the official policy of the Department of the Army, Department of the Navy, Department of Defense, or the United States government.]

Prevalence and Development of the Charlson Comorbidity Scoring System for Korean Incident Peritoneal Dialysis Patients

Hyunjoeon Cho,1 Myoung-Hee Kim,1 Seung Seok Han,1 Jae Yoon Park,1 Hyunjoo Ryu,1 Hye Jin Kim,1 Dong-Ryeol Ryu,1 Haejong Lee,1 Jung Pyo Lee,1 Chun Soo Lim,4 Kook-Hwan Oh,1 Kwon Wook Joo,1 Won Su Kim,1 Dong Ki Kim.1 Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; 2Dental Hygiene, College of Health Science, Eulji Univ, Gyeonggi-do, Korea; 3Internal Medicine and Ewha Medical Research Inst, School of Medicine, Ewha Womans Univ, Seoul, Korea; 4Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea.

Background: The Charlson Comorbidity Index (CCI) has widely used for predicting mortality and adjusting as a confounder in statistical analyses. However, the CCI remains disputed as an index to be applied to ESRD populations because the CCI was developed for general population. In this study, we modified the CCI and developed a modified Charlson comorbidity index in incident peritoneal dialysis patients (mCCI-IPD) to improve risk stratification for mortality.

Methods: The mCCI-IPD was developed based on 7,606 Koreans who received their first peritoneal dialysis treatment between 2005 and 2008. Data were obtained from the Korean Health Insurance dataset. The mCCI-IPD score was the sum of the weights which were assigned to individual comorbidities according to their relative prognostic significance determined by multivariate Cox proportional hazards model. The modified index was validated in an independent prospective cohort (n=664).

Results: The Cox proportional hazards model showed that the CCI comorbidities except ulcers, peripheral vascular disease, dementia and connective tissue disease significantly predicted mortality. Thus, the mCCI-IPD included 11 comorbidities with re-assigned severity weights. In the validation cohort, the CCI and the mCCI-IPD were correlated with mortality. However, the analyses using continuous net reclassification improvement revealed that the mCCI-IPD improved net mortality risk reclassification by 30.8% (95% CI, 7.6-54.1; P<0.009) relative to the CCI.

Conclusions: The mCCI-IPD performed the better risk stratification for mortality in incident peritoneal dialysis patients than the CCI. It suggests that the mCCI-IPD may be a preferred tool for clinical study of peritoneal dialysis patients.

Diabetes, Black Race, Female: Risk Factors for Hospitalization After Dialysis Start in a Nationwide Cohort Sample

LaTonya J. Hickson,1-2 Bjorg Thorsteinsdottir,3-4 Priya Ramar,1 Jordan K. Rosedahl,1 Cynthia S. Crowson,2 Robert C. Albright,1 Nana-Hawa Yayeh Jones,1 Rozalina G. McCoy,2 Suzanne M. Norby,1 Andrew D. Rule,1 Amy W. Williams,1 Nilay D. Shah,1 Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 2Mayo Clinic Kern Center for the Science of Health Care Delivery, Mayo Clinic; 3Primary Care IM, Mayo Clinic; 4Pediatrics, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Young dialysis patients have a high frequency of hospitalizations and readmissions. Multiple factors likely contribute to this occurrence, but have not been fully elucidated.

Methods: Young, incident dialysis patients aged 20-44 years included in the US Renal Data System with first dialysis service in 2005-2011. Multivariable multinomial logistic regression models examined associations and interactions between baseline predictors and hospitalizations through claims in the first 3-15 months; all p-values <0.05.

Results: For 46,895 patients (mean age: 36; 58% male; 46% black, 48% white, 4% Asian, 2% other race, 41% with diabetes, 23% with Charlson score ≥4) mean hospitalization rate was 2.3 per year. Subgroups for low to high utilizers included: 0 (46%), >0-4 (25%), >4-10 (20%) and >10 (10%) per year. Compared to the 0 hospitalization group, the >10 group had more females (48% vs 39%), more blacks (51% vs 45%), fewer Asians (2% vs 5%), more diabetics (52% vs 34%), more with Charlson score ≥4 (41% vs 14%). Diabetes were more likely to be high utilizers (odds ratio [OR]: 1.98 (1.84, 2.14) adjusting for age (OR:1.30(1.23,1.37) per 10 year decrease; sex (OR:1.23 (1.15,1.32) females vs males), black race (OR:1.24(1.16,1.34) blacks vs whites). Charlson ≥4 were also more likely to be high utilizers (OR: 7.00(6.75, 7.84) vs Charlson score 0-1), with higher comorbid females having nearly twice the risk as highly comorbid males (OR: 12.62 x 6.23, interaction p<0.001) when compared to low comorbid males.

Conclusions: Hospitalizations are frequent among young incident dialysis patients, particularly among diabetics, blacks, females, and those with multiple comorbidities. Further investigation into socioeconomic factors and causes of hospitalizations is needed to clarify these findings for targeted interventions.

Does Race Affect the Cause of Mortality in End Stage Kidney Disease?

Background: Cardiovascular disease accounts for 50% of mortality in end-stage kidney disease (ESKD). Caucasians (C) are more likely to die from cardiovascular disease, infection and withdrawal compared to Afro-Caribbean’s (AC). Little is known about the causes of mortality for Indo-Asian (IA) patients; with the rise in diabetes mellitus (DM) it is inevitable that more patients from IA backgrounds will get ESKD. We aim to investigate whether there are any differences in causes of mortality based on race.

Methods: We performed a single center, prospective, observational study. Electronic case notes were used to extract data to include cause of death, age of initiation of RRT, age of death, dialysis vintage (DV), gender and presence of DM. Patients were excluded if RRT was less than 90 days, or if they were transplanted.

Results: In total 3431 patients commenced RRT during the study period, 802 patients died, 364 were C, 259 IA and 178 were AC. There were no significant differences between the groups for age at initiation, DV, and age of death. Significantly fewer IA died during the follow up period compared to C (p<0.0001) and AC (p<0.0001). More IA and AC were diabetic (p<0.0001). Cardiovascular deaths were more common in C and AC patients compared to those of IA race (p<0.0001). IA had higher sepsis related deaths when compared C or AC (p<0.0001).

Conclusions: Despite the increased prevalence in DM, IA patients do not have worse survival outcomes or cardiovascular deaths compared to C and AC. We believe that the elevated sepsis related mortality in IA patients is secondary to the higher prevalence of diabetes. This data enables stratifying management therapies dependent on race and may help in designing cardiovascular end points trials in racially diverse group of patients.

Association of Dialysis Provider Assignment with Early Dialysis Mortality in U.S. Veterans: A Transition of Care in CKD Study

Eleni Strege, Melissa Soochoi, Connie Rhee, Vanessa A. Ravel, Joline L.T. Chen, Jenny Jing, Csaba P. Kovesdy, Kamary Kalantar-Zadeh, UC Irvine; UTHSC.

Background: Mortality is high during the first months after initiating kidney replacement therapy including in U.S. veterans. Only 10% of veterans receive dialysis therapy in a Veterans Administration (VA) based dialysis clinic and the majority of veterans are assigned to non-VA centers and dialysis chains.

Methods: We examined all-cause mortality during the 3, 6, 12 and 24 month period after transition in a cohort of 52,158 US veterans who transitioned to ESRD over 4 years (10/2007-9/2011) and the association of dialysis provider assignment. Baseline provider was determined by facility information and divided into 5 categories: DaVita(DV), Fresenius(NR), Other Chain(OC), Non-Chain(NC), and VA. Associations were examined in Cox proportional hazard models and adjusted for age, gender, race, ethnicity, initial vascular access and primary cause of ESRD.

Results: Upon dialysis transition, patients were 70+12 yrs old, 6% female, 25% African-American, 19% initially used AV fistula and 42% had diabetes as the cause of ESRD. At baseline, 24%, 28%, 13%, 21%, and 10% of veterans received treatment at DV, FR, OC, NC, and VA facilities, respectively. Over the first 3, 6, 12 and 24 mos after transition, 5489(11%), 9283(18%), 14339(27%) and 21697(42%) veterans died, respectively (Figure left). Compared to patients initiating treatment at the VA, all patients receiving treatment at other facilities had higher risk of mortality through all periods of follow-up, after adjusting for case mix covariates (Figure right).

Conclusions: Veterans transitioning to dialysis treatment in a VA based hospital dialysis center have the best survival over the first 2 years of follow up. Whether the better survival of VA dialysis care is from selection bias versus true superior care in the VA system warrants additional studies.

FR-PO796

Time-Varying Racial/Ethnic Differences in Mortality After Initiation of Dialysis in U.S. Dialysis Patients

Guofen Yan, Keith C. Norris, Alison J. Yu, Tom Greene, Jenny Z. Ma, Wei Yu, Alfred K. Cheung, Univ of Virginia; UCLA; Univ of Southern California; Univ of Utah.

Background: While survival advantage for African Americans (AAs) and Hispanics, compared to Whites, has been observed for decades, our understanding of the mechanism is still incomplete. Using national dialysis patients, we examined whether this survival advantage exists across the entire course of ESRD or just within a certain time interval after initiation of dialysis.

Methods: The study included 1,255,640 adult incident dialysis patients between 1995 and 2010 in the USRDS. We calculated age-specific hazard ratios (HRs) of death for AAs and Hispanics vs. Whites, adjusted for covariates, for every 6-month interval in the first 4 years of dialysis and for the period thereafter.

Results: For each age group above 40 years (Table), lower risk of death for AAs than Whites (HR<1) did not vary greatly across these time intervals. In contrast, in each age group under 40 years, the HR for AAs vs. Whites evolved over time, which was highest in the first year, declined in the second year, and reached stable over time. Hispanics exhibited lower mortality risks in all age groups that remained relatively constant over time (not shown).

Table. Adjusted HRs for AAs vs. Whites

<table>

<td>0.76</td>
</tr>
<tr>
<td>&gt;80</td>
<td>0.84</td>
</tr>
</tbody>
</table>

Note: most of these HRs were significant at p<0.05

Conclusions: AAs over 40 years old and Hispanics of all ages have uniformly lower risks of death than Whites across the course of ESRD. For younger AAs, conversely, their higher-mortality risk period is limited to the first two years of dialysis. Further studies to delineate the factors responsible for excessive mortality associated with racial subgroups will improve care for all dialysis patients.

FR-PO797

Real Threat of ESRD in China: A Ten-Year Experience from Nanjing 3 Million Insurance Covered Population

Yun-Chen Han, Ling Sun, Han-Ming Huang, Kun Ling Ma, Bei Wang, Bi-Cheng Liu, Zhongda Hospital, Southeast University; Nanjing, Jiangsu, China; Nanjing Municipal Human Resources and Social Security Bureau, Nanjing, Jiangsu, China; Southeast Univ School of Public Health, Nanjing, Jiangsu, China.

Background: In the past decade, Chinese government has made great efforts to provide an affordable and equitable access to renal replacement therapy (RRT) for most of ESRD patients. Here we analyzed the ten years registry data of 3 million Nanjing Urban Employee Basic Medical Insurance (UEBMI) covered population and firstly provided the epidemiological data about ESRD in this developing country.

Methods: Using the electric registry system of UEBMI, we included all subjects insured by UEBMI in Nanjing from 2005 to 2014, and identified subjects who developed ESRD in this cohort. The prevalence and incidence of ESRD was analyzed based on this unique data system.

Results: During the 10-year period, the incidence rate of ESRD in UEBMI cohort in Nanjing gradually declined from 289.3ppm in 2005 to 218.8ppm in 2014. However, the prevalence rate increased steadily from 891.7ppm in 2005 to 1228.6ppm in 2014. The annual mortality rate declined from 138 per 1000 patient-years in 2005 to 97.8 per 1000 patient-years in 2014. Long-term survival rate of ESRD fluctuated during the past decade, with 1-year survival rate ranging from 85.1% to 91.7%, 3-year survival rate from 69.9% to 78.3% and 5-year survival rate from 58% to 65.4%.

Conclusions: This study firstly provided an epidemiological data about ESRD based on the complete electric registry data system in large population in China. Due to the lack of a national complete registry data system, the real burden of ESRD in China is still unclear. Nanjing is one of the biggest cities in China. Our present study based on the ten years complete electric registry data system provided a convincing data about the real threat of ESRD in China. According to this study, we estimated that China will probably have over 1.5 million ESRD patients in the near future with the establishment of improved healthcare system. It is therefore utmost important for both medical communities and government to take active measures to control this coming disaster.

An Evaluation of Completeness of Monthly Clinical Data in CROWNWeb, a New Data Source for the United States Renal Data System

Valarie B. Ashby, Lingqun Liu, Xizhao Li, Tempie H. Shearon, Bruce M. Robinson, Douglas E. Schaubel, Yi Li, Rajiv Saras, Univ of Michigan, Ann Arbor; Mi; Arbor Research Collaborative for Health, Ann Arbor, Mi.

Background: CROWNWeb (CW) is a web-based system which collects administrative and clinical data from all Medicare-certified dialysis facilities in the US. It includes patient admission, tracking, and discharge information, CMS forms, and clinical data elements, and is not limited to Medicare patients. Monthly clinical data submission began in May 2012.

Methods: Monthly clinical data were only available to the USRDS through administrative claims for Medicare patients.

Results: The percentages of patients with CW data (any, high) are shown below. All measures had an increase in reporting from 2013 to 2014. High-level reporting in 2014 ranged from 75% (Hemodialysis (HD) Kt/V) to 90% (vascular access type). For all measures, reporting was higher for HD than PD patients, for adults than children, and for peritoneal dialysis (versus without) diabetes as cause of ESRD. 72% of HD patients had high-level reporting for all 5 HD measures. 70% of PD patients had high-level reporting for all 5 PD measures.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents only recommends presenting author.

547A
Conclusions: CW is now an integral part of the USRDS. Our study suggests a generally high and increasing proportion of completeness of clinical components in CW. These data will enhance the value of the USRDS database for researchers in coming years.

Funding: NIDDK Support

FR-PO799

Facility Size and Impact of Extreme Measure Values on DFC Star Ratings

Christopher J. Harvey,1 Claudia Dahlerus,1 Zezhi (zac) Zhang,1 Joseph M. Messana,1 Ji Zhu,1 Cindy Liao,1 Natalie Scholz,1 K. A. Wisniewski,1 Richard Hirth,1 Elena K. Balovenkov,2 Joel S. Andrassy,3 Yi Li.1 Biostatistics, Kidney Epidemiology and Cost Center, Univ of Michigan, Ann Arbor, MI;2 Centers for Medicare and Medicaid Services.

Background: In 2015 CMS implemented star ratings for dialysis facilities to make it easier for consumers to compare dialysis facilities by providing a summary of each facility’s performance on a set of 9 DFC quality measures. Our study compares two scoring approaches to the star rating to assess the impact of each on controlling outlying measure values with regard to facility size.

Methods: Fixed percentiles are applied to assign 10% of facilities 1-star or 5-stars based on performance. 2013 data were extracted from the 2015 January DFC file. Probit ranking and z-score transformation were applied to the DFC measures to develop an overall score and final star rating. We compared the final distribution of star ratings for each approach and assessed impact on smaller facilities. We represent the rating by number of patients in each facility contributing to the hospitalization measure, and split ~6000 facilities into groups of ~100 and calculated percentage of each star rating in each group.

Results: Use of original measure values and z-scores allowed skewed measures to highly influence the ratings, but preserved original measure distributions. Probit ranking resulted in giving more 5-star ratings to smaller facilities and z-scored approach resulted in assigning more 1-star and 5-star ratings to smaller facilities (Figure 1).

Figure 1: Distribution of Star Ratings by Facility Size

FR-PO800

P11 as Marker and Vitamin D as Treatment Option in Depression in Maintenance Dialysis Patients

Background: Depression is a disabling condition impairing all aspects of human functions. The serotonin system has been implicated in the pathophysiology of depression. Recently, as a member of the S100 family of proteins, P11 is known to have relation to functions. The serotonin system has been implicated in the pathophysiology of depression.

Methods: As a single center cross-sectional study, we examined the peripheral blood mononuclear cells P11 mRNA, IL-6, TNF-α, 25-hydroxycholecalciferol (25-(OH)D3) of patients with hemodialysis (HD, N=27), peritoneal dialysis (PD, N=39) and healthy group (N=7). Groups were divided by presence of depressive mood and categorized by severity of depressed mood via Beck Depression Inventory (BDI).

Results: In non-depressive group (BDI<10), the mean means of P11 were high in HD group (5.51 ± 7.0 (HD, N=15) vs. 1.39 ± 0.33 (PD, N=11) and 2.29 ± 0.37 (control, N=7), p < 0.05). The mean IL-6 levels were low in control group (4.31 ± 1.34 pg/mL (HD) and 7.53 ± 1.39 pg/mL (PD) vs. 2.23 ± 0.49 pg/mL (control), p < 0.05). The mean TNF-α levels were low in control group (4.31 ± 0.26 pg/mL (HD) and 4.15 ± 0.25 pg/mL (PD) vs. 1.85 ± 0.53 pg/mL (control), p < 0.05) respectively. In depressive group (BDI>10), P11 levels showed relationships with depression severity in peritoneal dialysis group ( spearman rho=0.2, p <0.09).

In hemodialysis group, 25-(OH)D3 level was lower in depressive group (11.98 ± 3.8 vs. 7.5 ± 2.7, p < 0.05), but there was no difference in peritoneal dialysis group (6.3 ± 3.3 vs. 7.4 ± 7.1, p =0.55).

Conclusions: By diagnostic tool, P11 can be used in peritoneal dialysis group as a depression marker despite taking the effect of inflammation into consideration, but not in hemodialysis group. As other treatment option, 25-(OH)D3 can be used in hemodialysis group for depression management, but not in peritoneal dialysis group.

FR-PO803
Anti-Platelet Factor 4 Antibodies: A One HIT Wonder
Suzanne H. Forbes, Sean Platton, Michael K. Almond, Neil Ashman, Laura Green, Nephrology, Royal London Hospital; Haematology, Royal London Hospital; Nephrology, Southend Hospital.

Background: Hemodialysis (HD) patients are exposed to regular anticoagulation, usually unfractionated heparin (UFH) or low-molecular weight heparin (LMWH). For standard HD (4 hrs, 3 days/week) this equates 26 full days exposure/y. Recently there was interest in the presence of heparin induced thrombocytopenia (HIT) in HD, and the causative anti-platelet factor 4 (PF4) antibody. There are several publications suggesting the presence of the antibody, without the clinical syndrome of HIT, is present in up to 25% HD patients, and may be an independent risk factor for cardiovascular and vascular access morbidity.

Methods: We looked for HIT antibodies in 2 prevalent HD cohorts, one with UFH, one LMWH (i.e. line lock sodium citrate). We tested serum for anti-PF4 antibodies using several established tests; STic Expert® (IgG-specific exclusion test), Diamed (particle gel immuno-assay), polyclonal IgG/A/M ELISA, IgG-specific ELISA.

Results: We included 127 patients: 60 receiving tinzaparin, 61 receiving UFH and 6 heparin-free. Serum samples were taken at the start of a standard HD session. The average duration on dialysis was 3.4 years. Results of the various tests are shown.

Only 1 patient tested antibody positive (OD 0.5) in the LMWH group. Platelet count and reactivity (as measured by TEG) in the UFH and LMWH group did not differ but the STic Expert positive/negative groups, the UFH LMWH groups, or those with higher or lower tertiles of ELISA OD.

Conclusions: Despite the previously reported concern over the presence of HIT antibodies in HD patients, we comprehensively show here no evidence of antibody positivity in HD patients. Exclusion tests such as STic Expert are not useful in these patients.

FR-PO804
Upper Gastrointestinal Bleeding Among Dialysis Patients in an Endemic Area for Chronic Liver Disease: Taiwan National Cohort Study
Chih-Chiang Chien, Chien-Ya Hung, Chih Hwa Univ of Medical Technology, Tainan, Taiwan; Chi Mei Medical Center, Tainan, Taiwan.

Background: End-stage renal disease (ESRD) and chronic liver disease (CLD) both increase the risk for upper gastrointestinal (UGI) bleeding. The prevalence of ESRD and CLD are high in Taiwan. The aim of this study was to evaluate the incidence, risk factors, and categories of UGI bleeding in ESRD dialysis patients.

Methods: Using Taiwan’s National Health Insurance research database, we enrolled 42,457 incident ESRD dialysis patients who began dialysis between 1999 and 2004. The patients were followed until death, dialysis cessation, or 31 December 2008. Cumulative incidence of UGI bleeding after initiation of dialysis was calculated using Kaplan-Meier methods. Predictors for UGI bleeding were determined using Cox models.

Results: During the follow-up period, 5,528 patients had a UGI bleeding. Male, elderly, receiving hemodialysis (HD) and patient with comorbidities had a higher rate of UGI bleeding. The 1-, 3-, 5- and 7-year cumulative incidence rate of UGI bleeding were 9.8%, 21%, 25.3% and 28% in patients with liver cirrhosis (LC) on HD, 5.8%, 16.2%, 22.2% and 24.4% in patients with LC on PD, 3.7%, 9.2%, 13.2% and 16.4% in patients without LC on HD, and 2.1%, 5.5%, 8.2% and 10.4% in patients without LC on PD (log-rank: p < 0.001). After multivariate adjustment, prior gastrointestinal bleeding (HR 1.731, 95% CI, 1.651-1.834), LC (1.682, 95% CI, 1.524-1.856), alcoholism liver disease (1.536, 95% CI, 1.635-1.834), and receiving HD (1.316, 95% CI, 1.153-1.502) were independently risks for UGI bleeding in ESRD dialysis patient. Gastric ulcers were found to be the most common source of bleeding (50.3%), while bleeding resulting from a gastroduodenal ulcer was least frequent.

Conclusions: ESRD dialysis patients had a higher risk for UGI bleeding, especially those with prior gastrointestinal bleeding, LC, and alcoholism liver disease. In addition, receiving HD is a strong predictor for UGI bleeding. More attention should be paid to select dialysis modality, especially in high risk patients.

FR-PO805
Palmitoylethanolamide Is a Promising Potential Therapeutic Target for Increasing High Density Lipoprotein Cholesterol Levels
Hamid Moradi, Miki Igarashi, Melissa Soooho, Elani Streja, Hamid M. Said, Moti L. Kashyap, Daniele Piomelli, Kamyar Kalantar-Zadeh, UC Irvine; VA Long Beach.

Background: End stage renal disease (ESRD) is associated with significant increased risk of cardiovascular (CV) mortality. High density lipoprotein (HDL) deficiency and dysfunction is a major contributor to CV disease in ESRD. Strategies aimed at improving HDL level and function are crucial in improving CV outcomes. Palmitoylethanolamide (PEA) is an anti-inflammatory lipid derived mediator that activates PPARalpha nuclear transcription factor. We hypothesized that serum PEA will correlate with HDL and PEA can increase HDL via activation of apoA1/Apo(Al-Apo) expression.

Methods: Serum PEA concentration was determined in 50 patients on maintenance hemodialysis (MHD) using LC/MS technology and correlated with clinical laboratory indices including a lipid panel. Liver cells (Hepatoma cell line HepG2) were exposed to various concentrations of PEA in vitro for 24 hours and subsequently mRNA expression of ApoA1, the major protein component of HDL, was measured using real-time PCR.

Results: Serum PEA concentrations strongly correlated with serum HDL levels in MHD patients (r=0.57, p <0.0001). PEA also correlates with total cholesterol (r=0.36, p<0.009) however not with LDL or triglycerides. In the in-vitro studies, PEA at a concentration of 60 micromolar and 120 micromolar was increased ApoA1 expression significantly in HepG2 cells after 24 hours.

Conclusions: For the first time we report that serum PEA concentrations strongly correlate with serum HDL concentrations in MHD patients. Involvement of PEA in HDL production is confirmed in in-vitro studies where incubation of liver cell in PEA resulted in increased ApoA1 expression. These novel findings indicate that PEA may be a promising therapeutic target in HDL deficiency treatment associated with not just ESRD but any proatherosclerotic condition.

Funding: NIDDK Support

FR-PO806
Arachidonoylglycerol, a Major Activator of the Endocannabinoid System, Is Significantly Increased in Patients with Kidney Disease
Hamid Moradi, Miki Igarashi, Melissa Soooho, Elani Streja, Connie Rhee, Hamid M. Said, Moti L. Kashyap, Norstatola D. Vaziri, Daniele Piomelli, Kamyar Kalantar-Zadeh, UC Irvine; VA Long Beach.

Background: Chronic kidney disease (CKD) is associated with oxidative stress and inflammation. There is evidence that cannabinoid 1 receptor activation leads to increased oxidative stress and inflammation. We previously showed that 2-arachidonoylglycerol (2-AG), one of the main activators of the endocannabinoid system, is significantly increased in the kidney of animals with ischemia-reperfusion (IR) injury. We hypothesized that serum 2-AG levels will be significantly elevated in CKD patients.

Methods: Serum concentrations of AG were determined in 21 healthy controls, 50 randomly assigned age and gender matched patients on maintenance hemodialysis (MHD), 13 patients on peritoneal dialysis (PD) and 6 patients with CKD stage IV using LC/MS technology. In MHD patients, serum levels of AG were correlated with various laboratory indices.

Results: Serum levels of 1-AG and 2-AG were significantly and incrementally increased with 2-AG compared to healthy controls. MHD patients had the highest AG levels which positively and significantly correlated with number of treatments per week (r=0.47, p=0.008), AST/ALT (r=0.5, p=0.001), platelet count (r=0.40, p=0.010), ferritin (r=0.36, p=0.016) and negatively with HDL cholesterol (r=-0.43, p=0.04).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Conclusions: For the first time we report that serum AG concentrations are significantly increased in CKD patients. These novel findings are in line with our report on IR acute kidney injury and with a recent study which showed that in an oxidative stress setting, monoacylglycerol lipase, an enzyme responsible for AG breakdown is inhibited leading to increased levels. Moreover, the substantial increase in MHD patients is intriguing given association of MHD with increased oxidative stress, inflammation and platelet activation.

Funding: NIDDK Support

FR-PO807
Newly Launched Cellulose Tri-Acetate Membrane with Asymmetric Structure Dramatically Improves Peripheral Circulation and Hemodynamic Stability During Hemodialysis
Ikuto Masakane, Tabuki Hospital, Nephrology, Yamagata, Japan.

Background: The most important concern about the biocompatibility of dialysis membrane is the activation of platelets and it would lead hemodynamic instability during dialysis session. The newly launched CTA with asymmetric thick structure (ATA) was produced in order to reduce stimulant property to platelets and the rapid reduction of the serum levels of small urmic solutes by thickening the membrane. We evaluated the solute removal performance and biocompatibility of ATA.

Methods: Seven chronic hemodialysis patients were enrolled to the current study. The conventional CTA was used for the first 4 months and ATA was used for the next 4 months. We evaluated the solute removal property by the clearance of urea, beta2 microglobulin (B2MG) and removed amount of alpha1 microglobulin (a1mG) and albumin loss in spent dialysate. The biocompatibility was evaluated by changes in WBC and platelet count, IL-6, Pentorexine-3 (PTX-3) and high sensitive CRP (hsCRP). The peripheral circulation was estimated by the Skin Perfusion Pressure (SPP) by PAD-3000® (Kaneka Medix, Osaka, Japan). Intra-dialytic hemodynamic stability was evaluated by arterial blood pressure and subjective feelings of the patients.

Results: The clearance of Urea was significantly reduced through dialysis session in both groups but the B2MG clearance was maintained only in ATA. The total removed amount of A1mG was significantly higher in ATA than CTA. The platelet count didn’t change in ATA during dialysis session but significantly decreased in CTA. WBC counts, IL-6, PTX-3, hs CRP in both groups didn’t change. The systolic blood pressure and frequency of intra-dialytic hypotension were not different in both groups whereas some of the patients felt post-dialytic fatigue improved in ATA. SPP was maintained during dialysis session in ATA but deteriorated in CTA.

Conclusions: The new ATA membrane could reduce the activation of platelets and maintain the peripheral circulation during a dialysis sessions and the time-dependent deterioration of solute removal. The new ATA membrane may improve the QOL and prognosis of chronic dialysis patients.

FR-PO808
Mathematical Modeling of Fluid Transport in Peritoneal Cavity
Fansan Zhu,1 Samer R. Abbas,2 Roxana M. Bologa,2 Aurelita Lanto,2 Peter Kotanko,2,1 Nathan W. Levin.1 1Renal Research Inst, New York, NY; 2Rogosin Inst, New York, NY; 1Icahn School of Medicine at Mount Sinai, New York, NY.

Background: The current standard method (peritoneal equilibration test (PET)) is used to obtain transport characteristics of the peritoneal membrane for creatinine, urea and electrolytes, but not for fluid volume. Consequently, ultrafiltration profiles are difficult to obtain because the weight difference between the inlet and outlet dialysate show only net removal during PD. The aim of this study was to investigate whether the rate of change in fluid (Vf) in peritoneal cavity and body tissue fluid volume (Vb) can be simulated with a two compartment model.

Methods: Segmental bioposmance was continuously monitored in ten PD patients to provide Vf during standard PET in the clinical unit (Zhu, et al. Am J Kidney Dis, 2003). Vf was measured with whole body bioposmance technique (Hydra 4200). A two compartment model of Vf and Vb (Fig. 1(a)) was established (Eq.1-Eq.4). Two transport coefficients: k1 and k2 represent the rate of fluid shift from Vf to Vb by reabsorption and from Vb to Vf , driven by the glucose gradient. k1 and k2 were estimated by best fitting with the actual measurements based on the Marquardt-Levenberg algorithm.

Results: Parameter estimation was successful (residuals=0.01) in all but one patient, who experienced technical problems during the measurements. Fig. 1 (b) shows change in Vf and Vb, during standard PET simulation in a patient. K2 correlated inversely with the initial tissue fluid volume Vb (k2=-0.0002* Vb +0.0024, R2=0.46, p<0.05).

Conclusions: This model describes dynamics of fluid transport during PD treatment. K1 and k2 reflect the characteristics of peritoneal membrane in individual patient. The relationship of K2 and Vb suggests that fluid status could be a factor in ultrafiltration,which could be helpful in clinical practice.

FR-PO809
Linagliptin Ameliorated Methyglyoxal-Induced Peritoneal Fibrosis in Mice
Takuo Nagai, Shigehiro Doi, Ayumu Nakashima, Takao Masaki. Dept of Nephrology, Hiroshino Univ Hospital, Hiroshima, Japan.

Background: Recent studies have reported that methyglyoxal (MGO) was increased in peritoneal dialysis patients, playing an important role in the development of peritoneal fibrosis. On the other hand, linagliptin, a dipeptidyl peptiase-4 (DPP-4) inhibitor, exhibits beneficial effects in diabetes patients independent of blood glucose concentration. In this study, we examined whether linagliptin suppressed MGO-induced peritoneal fibrosis in mice.

Methods: Male C57BL/6 mice were divided into three groups: a vehicle group, an MGO injection group, or an MGO injection plus linagliptin group (n=6 per group). Peritoneal fibrosis was induced by a daily intraperitoneal injection of saline containing 40 mmol/L MGO for 21 days. Saline was given in the vehicle group. Linagliptin was administered at a dose of 10 mg/kg by oral gavage once a day.

Results: Immunohistochemical staining revealed that linagliptin suppressed the expression of α-smooth muscle actin and fibroblast-specific protein-1, the deposition of collagen 1 and collagen 3 and infiltration of macrophages (F4/80). In addition, linagliptin reduced TGF-β1 concentration in peritoneal fluid of MGO-treated mice. Peritoneal equilibration tests showed improvement of peritoneal function in mice receiving linagliptin treatment.

Conclusions: These results suggest that oral administration of linagliptin ameliorated MGO-induced peritoneal fibrosis.

Funding: Private Foundation Support

FR-PO810
Addition of Alanyl-Glutamine to Dialysis Fluid Restores Peritoneal Cellular Stress Responses – A Randomized Controlled First-in-Man Trial
Andreas Vychytil,1 Klaus Kratochwill,2,1 Michael Boehm,2 Rebecca Herzog,2 Katharina Gruber,1 Anton Lichtenauer,2 Lilian Kuster,3 Dagmar Csacsiuch,1 Andreas Gleiss,1 Martin Bilban,3 Seth L. Alper,1 Christoph Aufricht.1 1Medical Univ of Vienna, Vienna, Austria; 2Zytoprotec GmbH, Vienna, Austria; 3Beth Israel Deaconess Med. Cit, Harvard Medical School, MA.

Background: Peritoneal dialysis (PD) fluid cytotoxicity and intermittent bacterial infection contribute to membrane failure and peritonitis in PD patients. Recent meta-analyses revealed no significant influence of newer biocompatible PD fluids on peritonitis rate or peritoneal membrane function, but glutamine addition to standard PD fluids has shown cytoprotective effects both in vitro and in vivo.

Methods: In this open-label randomized controlled cross-over phase I/II trial (NCT01353638), 20 stable PD patients each underwent two 4 h peritoneal equilibration tests with glucose-based PD fluids supplemented with or lacking 8 mM alananyl-glutamine ( Ala(αGl)n), and separated by a 4 week washout phase. Effects of AlaGln on peritoneal inflammation and stimulated cytokine release were also tested in a mouse model of PD-associated peritonitis.

Results: Intraperitoneal (IP) exposure to Ala(αGl)n-supplemented PD fluid increased dialysate [glutamine] more rapidly (at 2 h mean 0.55-0.71 mM, p<0.05) and increased heat shock protein expression in peritoneal effluent cells (median 2.12-3.20, p<0.05), but did not alter peritoneal ultrafiltration, small solute transport, cell counts, or biomarkers. AlaGln increased ex vivo LPS-stimulated TNF-α release (effect C1 60-100 pg/mL, p<0.001) and, in patients with previous peritonitis, decreased dialysate [IL-8] (effect C1 0.1-4.3, p<0.05).

IP A/G also reduced inflammation and enhanced cytokine release in the mouse model. No adverse effects of AlaGln were noted.

Dipeptide Alanyl-Glutamine Protects from Peritoneal Fibrosis and Attenuates IL-17 Dependent Pathways During Peritoneal Dialysis

Evelina Ferrantelli,
Georgios Liappas,
Marc Vila cuenca,
Robert H.j. Beelen,
Manuel Lopez-Cabrera.

**Background:** Peritoneal dialysis (PD) is complicated by chronic inflammation and progressive parietal membrane damage. Alanyl-Glutamine (Ala-Gln), a stable dipeptide commonly used in parenteral nutrition, has immunomodulatory effects and improved resistance of mesothelial cells to PD fluids. Recently, IL-17 was identified as novel player in PD induced peritoneal damage. In this study we investigated if intraperitoneal Ala-Gln administration confers protection against peritoneal damage by modulating IL-17 expression in uremic rodent PD models.

**Methods:** Uremic Peritoneal Dialysis Rat Model

**Results:** Supplementation of PD fluid with Ala-Gln resulted in reduced peritoneal thickness (70.90 ± 13.45 vs 16.23 ± 0.70, P < 0.001), ASMA expression and angiogenesis. Addition of Ala-Gln also showed attenuation of PD induced IL-17 mediated pathways, reflected by substantial reduction normalisation of peritoneal levels of IL-17 (32.35 ± 13.32 vs 7.99 ± 1.59, P < 0.001), TGfβ, IL-6 and ROR(γ). Moreover, repeated exposure of the Ala-Gln treated group to recombined IL-17 increased peritoneal fibrosis which was however restored upon IL-17 neutralization.

**Conclusions:** These results suggest that intraperitoneal administration of Ala-Gln ameliorates PD induced peritoneal damage at least in part by modulating IL-17 expression. Therefore, this evidence paves into investigations whether Ala-Gln could be a potential strategy to ameliorate peritoneal deterioration during PD.

MicroRNA Expression Profiling in Peritoneal Fibrosis

Yoshiyuki Morishita,
Daisuke Nagata.

**Background:** Peritoneal fibrosis (PF) is an intractable complication leading to peritoneal membrane failure in peritoneal dialysis (PD). The aim of this study was to identify the microRNAs (miRNAs) involved in PF.

**Methods:** miRNA screen was performed using microarray analysis in peritoneal tissue of PF patients. miRNA expression was induced by intraperitoneally injection of PD fluid containing methylglyoxal (MGO). The expression level of identified miRNAs of serum and drained dialysate were evaluated using qRT-PCR.

**Results:** The initial profiling study identified 6 miRNAs (miRNA-21-5p, miRNA-221-3p, miRNA-223-3p, miRNA-142-3p, miRNA-327 and miRNA-34a-5p) increased more than two fold and no miRNA decreased less than half in peritoneum tissue of PF patients compared with control rats. Among them, serum level of miRNA-21-5p (D/P Cr –r=0.44, p<0.01; D/D0 glucose –r=0.43, p<0.01), miRNA-327 (D/P Cr –r=0.48, p<0.01; D/D0 glucose –r=0.50, p<0.01) and miRNA-221-3p (D/P Cr –r=0.50, p<0.01; D/D0 glucose –r=0.50, p<0.01) and drained dialysate level of miRNA-221-3p (D/P Cr –r=0.52, p<0.01; D/D0 glucose –r=0.46, p<0.01) and miRNA-34a-5p (D/P Cr –r=0.44, p<0.01; D/D0 glucose –r=0.48, p<0.01) were significantly correlated with peritoneal membrane functions in PD patients. Anti-miRNA-21-LNA significantly inhibited miRNA-21-5p expression in peritoneum of PF mice. It also inhibited peritoneal fibrosis thickening and maintained better peritoneal membrane functions. It significantly increased PPAR-α expression in peritoneum of PF mice.

**Conclusions:** The results of present study suggested several miRNAs involved in PF, and they may be used as the novel diagnosis biomarkers and therapeutic targets for PF.

Nanoparticles of Lipids Associated with Paclitaxel as an Alternative Strategy to Block Peritoneal Fibrosis

Filipe M. Silva,
Rafael Pepineli,
Elerson Costalonga,
Irene L. Noronha.

**Background:** PF is a progressive peritoneal membrane damage and is the main limitation for the long term use of PD. 3-4% of PD patients develop PF, which is a major complication leading to hospitalization, increased costs, and loss of mediated peritoneal dialysis (PD) treatment. Advances in nanotechnology enabled drug release systems that can provide the release of an active drug in the target tissue. Nanoparticles similar to LDL were developed, linked to Paclitaxel (NanoPACL), an antiproliferative drug. NanoPACL have the ability to bind to LDL receptors present on the cell surface, particularly in immune-inflammatory sites. The aim of this study was to analyze the effect of NanoPACL administration in an experimental model of PF.

**Methods:** PF was induced in Wistar rats by daily IP injections of chlorhexidine gluconate (CG) at 0.1% during 15 days. Animals (n=20) were divided into 4 groups: Control, NanoPACL, Paclitaxel and NanoPACL+Paclitaxel. Nanoparticles without Paclitaxel, via IP; NanoPACL, PF rats treated with NanoPACL (4mg/kg every 3 days, via IP). Euthanasia was performed on day 30. Peritoneal thickness and function, immunohistochemistry and qPCR were analyzed.

**Results:** NanoPACL significantly reduced peritoneal thickness, α-SMA expression and cell proliferation compared with control groups. Treatment with NanoPACL decreased TGF-β and Smad 3 mRNA expression and preserved peritoneal membrane function characterized by preservation of UF and reduced mass transfer of glucose (MTG).

Vitamin D Receptor Activator (VDRA) Attenuates Epithelial-to-Mesenchymal Transition (EMT) via Modulation of NADPH Oxidase (NOX) Activity and Mitochondrial Dysfunction in Human Peritoneal Mesothelial Cells (HPMC)  

Duk-Hee Kang, Juyeon Ko, Eun sun Ryu, Hyun-yon Jung, Shina Lee, Dong-Ryeol Ryu, Seung-Jung Kim, Kyu Bok Choi. Dept of Internal Medicine, Ewha Womans Univ School of Medicine, Seoul, Republic of Korea.

Background: EMT is known as a key mechanism of peritoneal fibrosis in peritoneal dialysis. Oxidative stress induced by NOX and mitochondrial dysfunction is one of the mechanisms responsible for EMT. Paricalcitol, a selective VDRA, is known to exert anti-fibrotic effect organ fibrosis, however there are no studies about the role of paricalcitol on peritoneal fibrosis. We investigated whether paricalcitol imposed any effect on TGFβ1-induced EMT of HPMC with an exploration of mechanism of anti-fibrotic effect of paricalcitol in terms of modulation of oxidative stress.

Methods: EMT was evaluated by morphological changes of HPMCs and the expressions of E-cadherin and α-smooth muscle actin. Intracellular ROS was analyzed by measuring NOX activity, NOX mRNA expressions with DCF-DA and MitoSox stained. Activation of Erk1/2, p38 MAPK, nuclear translocation of β-catenin and snail expression were assessed by western blotting and immunocytochemistry. Effect of paricalcitol on ROS generation and EMT was analyzed in HPMC exposed to TGFβ1.

Results: TGFβ1 (1mg/ml) induced EMT of HPMCs with an increase in ROS generation and NOX activity from 30 minutes, and mitochondrial ROS production from 6 hours. TGFβ1 also increased the phosphorylation of Erk and p38 MAPK from 1 hour, which was followed by nuclear translocation of β-catenin and snail up-regulation in HPMC. Paricalcitol (50nM) ameliorated TGFβ1-induced EMT in HPMC, which was associated with a decrease in both NOX- and mitochondria-mediated ROS production. TGFβ1-induced EMT was partially alleviated by N-acetyl cysteine (5mM) or apocynin (100μM), which was further inhibited by an addition of rotenone (1μM) or paricalcitol.

Conclusions: One of the VDRAs, paricalcitol, ameliorated TGFβ1-induced EMT of HPMCs by a decrease in ROS generation in HPMCs. Anti-oxidant effect of paricalcitol seems to be related to the direct inhibition of NOX and mitochondria-mediated ROS production.

Adenosine Monophosphate-Activated Protein Kinase Inhibitor (AMPAK) Agonist Attenuated Epithelial-to-Mesenchymal Transition (EMT) of Mesothelium and Peritoneal Fibrosis via an Amelioration of Oxidative Stress  

Duk-Hee Kang, Juyeon Ko, Eun sun Ryu, Hyun-yon Jung, Shina Lee, Dong-Ryeol Ryu, Seung-Jung Kim, Kyu Bok Choi, Sun-Hee Park, Yong-Lim Kim. Dept of Internal Medicine, Ewha Womans Univ School of Medicine, Seoul, Republic of Korea; Kyungpook National Univ School of Medicine, Daegu, Republic of Korea.

Background: Phenotype transition of peritoneum has been regarded as an early mechanism of peritoneal fibrosis. Meformin, one of the AMPK agonists, has recently received a new attention due to an inhibitory effect on EMT of cancer cells. We investigated whether meformin imposed any effect on EMT of HPMC with an exploration of cellular mechanism for anti-fibrotic effect of meformin.

Methods: EMT was evaluated by morphological changes and the expressions of E-cadherin and α-SMA after stimulation of TGFβ1 (1ng/ml). ROS generation was analyzed by measuring NOX activity, NOX mRNA expressions, and MitoSox stained. Activation of Smad2/3, MAPK, nuclear translocation of β-catenin and snail expression were also assessed. Animal model of peritoneal dialysis (PD) was established by daily infusion of HGP-induced PD animal model, Twist and YB-1 were also up-regulated and a transformed fibroblastic phenotype of HPMCs was found stimulated by high glucose (HG, 60mmol/L).

Results: TGFβ1-induced EMT of HPMC was ameliorated by meformin. TGFβ1 increased ROS generation and NOX activity from 30 min, and mitochondrial ROS production from 6 hrs. TGFβ1 increased the phosphorylation of Smad2/3 and MAPK, which was followed by nuclear translocation of β-catenin and snail up-regulation. Meformin ameliorated ROS production, the activation of Smad2/3 and MAPK, and snail expression. In PD model, meformin decreased peritoneal thickness and EMT with an increase in ratio of E-cadherin to oxidized glutathione and superoxide dismutase activity. Meformin also decreased the expression of nitrosyrrine in peritoneum and 8-OhdG in dialysate.

Conclusions: AMPK may play a role in preservation of peritoneal function by protecting the peritoneum from phenotype transition and fibrosis via an amelioration of oxidative stress.

Twist Accelerates Human Peritoneal Mesothelial Cells Proliferation and Fibrosis by Regulating YB-1  

Liije He. Dept of Nephrology, Xijing Hospital, Xi’an, China.

Background: We have previously shown that E-box–binding transcription factor Twist is overexpressed in high glucose damage of human peritoneal mesothelial cells (HPMCs) and is involved in peritoneal membrane (PM) fibrosis in vitro. Here, we further identify its precise function related to peritoneal membranes (PM) fibrosis.

Methods: We have previously shown that E-box–binding transcription factor Twist is overexpressed in high glucose damage of human peritoneal mesothelial cells (HPMCs) and is involved in peritoneal membrane (PM) fibrosis in vitro. Here, we further identify its precise function related to peritoneal membranes (PM) fibrosis.

Results: Here, up-regulated expression and activation of Twist and YB-1 were found in HPMCs under extensive periods of PM fibrosis ex vivo. In immortal HPMCs and in HG-induced PD animal model, Twist and YB-1 were also up-regulated and a transformed fibroblastic phenotype of HPMCs was found stimulated by high glucose (HG, 60mmol/L).

Conclusions: One of the VDRAs, paricalcitol, ameliorated TGFβ1-induced EMT of HPMC, which was associated with a decrease in both NOX- and mitochondria-mediated ROS production. TGFβ1-induced EMT was partially alleviated by N-acetyl cysteine (5mM) or apocynin (100μM), which was further inhibited by an addition of rotenone (1μM) or paricalcitol.

Conclusions: Our data suggested that activation of Twist/YB-1 pathway might contribute to the growth retardation of HPMCs and the progressive PM fibrosis during PD.

FR-PO818

The Expression of miRNA200a in Peritoneal Dialysis Associated Peritoneal Fibrosis  

Xin Wei. Nephrology Dept, The First Affiliated Hospital of Nanchang Univ, Nan Chang, China.

Background: Peritoneal fibrosis (PF) is an almost invariable consequence of peritoneal dialysis (PD), which is an established alternative for the replacement therapy of end-stage renal disease. We know that miR-200a belong to miR-200 family, which is closely related to a variety of fibrotic diseases.However, the role of miR-200a in peritoneal fibrosis is largely unknown.

Methods: The peritoneal fibrosis mouse model associated with PD was established by intraperitoneal injection of lipopolysaccharide + 4.25% peritoneal dialysate. The expression of miRNA was detected by microarray. The expression of miRNA profiles between fibrotic and normal peritoneal tissues was compared (n=3 in each group). The differentially expressed miRNA (miR-200a) was validated by real-time PCR in larger sample size cohorts (n=15). The expressions of miR-200a were also detected in the epithelial-mesenchymal transition (EMT) process of peritoneal mesothelium cells.

Results: In mice model of PD, peritoneal tissue was markedly thickened and with a massive extracellular matrix accumulation. By miRNA microarray analysis, miR-200a was significantly down regulated (3.31 folds change, P<0.05) in fibrotic peritoneal tissue. The down-regulated expression level of miR-200a was also validated by real-time PCR in larger cohorts (P<0.05). Then, the expression level of miR-200a was detected in the EMT process of human peritoneal mesothelium cells. During the process of TGFβ-1 induced EMT, miR-200a was significantly down-regulated compared with the control (P<0.05)

Effects of Astragaloside IV against the TGF-β-Induced Epithelial-to-Mesenchymal Transition in Peritoneal Mesothelial Cells by Promoting Smad7 Expression

Lu Zhang,1,2 Zhenghong Li,1 Weiming He,3 Lingdong Xu,2 Jing Wang,1 Jun Shi,1 Meixing Sheng,1 1The First Clinical Medical College, Nanjing Univ of Chinese Medicine, Nanjing, Jiangsu Province, China; 2Renal Div, Jiangsu Province Hospital of Chinese Medicine, Nanjing, Jiangsu Province, China; 3Jiangsu Province Academy of Traditional Chinese Medicine, Nanjing, Jiangsu Province, China.

Background: To investigate the effect of Astragaloside IV (AS-IV) on the regulation of the TGF-β1 Smad signaling pathway in mesothelial cells with an epithelial-to-mesenchymal transition (EMT).

Methods: EMT of human peritoneal mesothelial cells (HMrSV5) was induced using 2 ng/ml TGF-β1. Cells were randomly divided into a vehicle group, a vehicle group with AS-IV, a TGF-β1-treated group, and a TGF-β1-treated group receiving varied doses of AS-IV or NAC. Real-time quantitative PCR and western blot were used to detect the expression of genes and proteins associated with the TGF-β1/Smad signaling pathway and EMT. DCFH-DA was used to detect the generation of ROS in HMrSV5 cells, and a transwell migration assay was used to verify the capacity of AS-IV to inhibit EMT in HMrSV5 cells. Lentivirus were used as carriers for the overexpression or knockdown of the Smad7 gene.

Results: Expression levels of E-cadherin (epithelial marker) were decreased and vimentin, α-SMA (EMT markers) and collagen I (extracellular matrix protein) phospho-Smad2/3, Smad1 and Smad2 were increased significantly in the TGF-β1-treated HMrSV5 cells. AS-IV was associated with downregulated expression of vimentin and phospho-Smad2/3 in a dose-dependent manner, while the expression of Smad7 increased. Silenced or forced expression of Smad7 verified its role in the inhibitory effect of AS-IV on TGF-β1-induced EMT in HMrSV5 cells.

Conclusions: AS-IV effectively promotes the upregulation of Smad7 in the TGF-β1/Smad signaling pathway during the EMT of HMrSV5 cells, indicating its potential therapeutic effect for the control of PF.

FR-PO821
Extracellular Vesicles in Peritoneal Effluent

Deirisa Lopes Barreto,1 Anita N. Boing,2 Rienk Nieuwland,2 Anita Groostraat,2 Raymond T. Krediet,1 1Nephrology, AMC-UvA, Netherlands; 2Clinical Chemistry.

Background: Continuous and long-term exposure to peritoneal dialysis (PD) solutions induces constant low-grade inflammation and remodeling of peritoneal membrane morphology. Although the biochemical composition of peritoneal effluent offers the opportunity to explore the peritoneal membrane status in a simple and non-invasive manner, to date no clinically useful effluent biomarker has been identified that reflects the peritoneal membrane integrity sufficiently. As human body fluids contain extracellular vesicles (EVs), which are now believed to provide novel biomarkers for diseases, we investigated the presence of EVs in peritoneal effluent.

Methods: Peritoneal effluent of a short-term PD patient was collected from a regular dialysis dwell. After centrifugation, aliquots of cell-free effluent were frozen in liquid nitrogen and stored at -80°C until analysis. EVs were isolated by size exclusion chromatography. Thereafter, transmission electron microscopy (TEM) and flow cytometry (comprising markers for epithelial and mesothelial cells, leucocytes, platelets and erythrocytes) were used to detect the presence of single EVs.

Results: EVs and liposomes were identified by TEM and flow cytometry. EVs exhibited their characteristic cup shape. The majority of EVs had a mean diameter <100nm, and were present in similar amounts as in human plasma. Most EVs originate from epithelial and mesothelial cells. Moreover, EVs stained positive for leucocyte antigens, mesothelin and cancer antigen 125.

Conclusions: This is the first study to demonstrate the presence of EVs in human peritoneal effluent. Furthermore, the cellular origin of most peritoneal EVs is established.

miR-200a Negatively Regulates TGF-β1-Induced Peritoneal Mesothelial Cell Epithelial-Mesenchymal Transition by Targeting ZEB1 and ZEB2 Expression

Xin Wei, Guojun Hao, Qinkai Chen. Nephrology Dept, The First Affiliated Hospital of Nanchang Univ, Nan Chang, China.

Background: Peritoneal fibrosis (PF) is an almost invariable consequence of peritoneal dialysis (PD), which is an established alternative for the replacement therapy of end-stage renal disease. In our previous study, we found that the expression level of miR-200a were down-regulated in fibrotic peritoneum and the epithelial-mesenchymal transition (EMT) process of peritoneal mesothelial cell. However, the role of miR-200a in EMT of peritoneal mesothelial cell and peritoneal fibrosis is largely unknown.

Methods: Human peritoneal mesothelial cell line (HMVSV5) was cultured in the presence or absence of TGF-β1. The protein expression levels of EMT index and E-box-binding homeobox (ZEB) 1/2 were determined by western blot. The level of miR-200a was determined by real-time PCR. miR-200a mimic or inhibitor and it negative control RNA were transfected into HMVSV5 cells using Lipofectamine 2000.

Results: We found that miR-200a mimic can attenuated TGF-β1 induced peritoneal mesothelial cell EMT and synthesis of extracellular matrix. It was also demonstrated that the miR-200a was responsible for protecting peritoneal mesothelial cells from mesenchymal transition by targeting suppression of ZEB1/2.

Conclusions: The results suggested that miR-200a may not only be a useful biomarker of EMT in ovarian cancer, but also of potential therapeutic value in peritoneal fibrosis.

Funding: Government Support - Non-U.S.

FR-PO823

Identification and Functional Characterization of Human Peritoneal Fibroblast Subsets According to the Expression of CD90/Thy-1

Edyta Kawałk, András Rudolf, Maria Bartosova, Rusan Catar, Janusz Witowski, Duska Dragun, Achim Joerres, Claus P. Schmitt. 1Dept of Nephrology and Medical Intensive Care, Charité-Universitätsmedizin Berlin, Berlin, Germany; 2Dep of Pathophysiology and Clinical Immunology, Poznan Univ of Medical Sciences, Poznan, Poland; 3Center for Pediatric and Adolescent Medicine, Universitätssklinikum Heidelberg, Heidelberg, Germany.

Background: The exact origin of myofibroblasts in PD-associated peritoneal fibrosis is unknown. Lineage tracing studies suggest that resident submesothelial fibroblasts may be their major precursors. Here, we set out to identify HPFB subsets in human peritoneum and examined co-expression of CD90/Thy-1 with markers of the myofibroblastic phenotype.

Methods: HPFB were isolated from omentum, purified and then separated (MACS) into CD90/Thy-1+ and CD90/Thy-1- populations for assessment of myofibroblastic markers:

- qPCR, immunofluorescence, and ELISAs. Moreover, the presence of FSP-1+ and CD90/Thy-1+ fibroblasts was studied by immunofluorescence in peritoneal biopsies of 12 PD, 5 uremic patients, and 8 healthy controls.

Results: Cells positive for FSP-1+ and CD90/Thy-1- were absent in healthy controls, but were detectable in uremic and PD patients. In those, the majority (>95%) of FSP-1+ HPFB were also CD90/Thy-1+. In vitro studies showed that CD90/Thy-1+ HPFB had a 1.2-fold higher proliferation rate (MTT assay; n=12, p<0.05) than CD90/Thy-1-. Expression of myofibroblastic markers in CD90/Thy-1- cells was significantly higher with α-SMA, collagen-1 and TGF-β1 being increased (2.5-, 1.6- and 1.8-fold, respectively; n=13, p<0.05).

Conclusions: The vast majority of FSP-1+ HPFB detected in the peritoneum of uremic and PD patients expressed CD90/Thy-1+. In contrast, this phenotype was not detected in normal peritoneum. In vitro studies demonstrated increased expression of myofibroblastic markers in CD90/Thy-1+ HPFB. These cells may thus contribute to peritoneal fibrosis which often develops in patients during chronic PD.

FR-PO824

Innovative Index to Follow the Peritoneal Infections and for Monitoring the Recovery Process After Peritonitis

Grazia Maria Virzi, Sabrina Milan manani, Alessandra Brocca, Massimo de Cal, Ilaria Tantillo, Carlo Crepaldi, Claudio Ronco. Nephrology, San Bortolo Hospital-IRRI.

Background: Cell-free DNA is present in the peritoneal effluent of stable PD patients, but there is no data on cDNA in case of peritonitis. We investigated the variation of peritoneal cDNA (pcDNA) levels in PD-related peritonitis.

Methods: We enrolled 53 PD patients: 30 without any history of systemic inflammation and peritonitis in the last 3 months (groupA) and 23 with acute peritonitis (groupB). PcdNA were quantified by Real-Time PCR. Peritoneal samples on day 1-3-10-30 and until the 120th from the start of peritonitis were collected for WBC counts and pcdNA evaluation in group B.

Results: Quantitative analysis of pcdNA showed significantly higher levels in groupB compared with groupA (p<0.01), similarly as WBC. PcdNA showed significantly higher levels in groupB on day 1-3-10 and 30 compared with groupA (p<0.05). A significant correlation was observed between pcdNA level and WBC on day1 (rho=0.89) and day3 (rho=0.5) both p<0.05. No statistically significant correlation was observed on day10 and 30. In groupB, pcdNA tends to progressively decrease. From this decreasing curve, we estimated that 49 days are necessary to reach the value of 31 GE/ml (75percetile in groupA) and 63 days to reach 31 GE/ml (median). We observed a new rapid increase of cDNA level (consistent with WBC) in 5 relapsing patients, at the first day of relapsing peritonitis.

Conclusions: pcDNA increased in peritoneal effluent in PD-relatetd peritonitis and tended to progressively decrease in relation with membrane repair process. Peritoneal cDNA could be a new method to determine acute damage and an inverse index of repair process. PcdNA could help to evaluate functional and structural integrity of peritoneal membrane and to follow the evolution of infections during peritonitis.

FR-PO825

The Role of Cell-Free DNA for Management in PD-Related Peritonitis

Grazia Maria Virzi, Sabrina Milan manani, Alessandra Brocca, Massimo de Cal, Ilaria Tantillo, Carlo Crepaldi, Claudio Ronco. Nephrology, San Bortolo Hospital-IRRI.

Background: Peritonitis and exit site infections are the major complications of PD, and remains the major cause of switch from HD. In this study, we investigated the role of peritoneal cell-free DNA (cDNA) and its association with peritonitis.

Methods: We enrolled 23 PD patients with peritonitis and without any history of systemic inflammation (14 male, mean age: 68±16yrs). cDNA were extracted and quantified in peritoneal effluent by Real Time PCR for β-globin gene.

Results: All patients were treated and clinically recovered from peritonitis in 13 5.5 days. 18/23 patients had a first episode of peritonitis and responded to first-line antibiotics (65% Gram+, 22% Gram- and 13% sterile), whereas 5/23 had a relapsing episode of peritonitis (responded to other course of intra-peritoneal antibiotics). There...
There was no difference in cDNA levels between Gram^+^ (Gram-positives) patients with single episode and relapsing peritonitis, but there was a significantly difference in cDNA between PD patients with positive and negative outcomes (n=4), defined as death (p=0.05). cDNA showed significantly higher levels in 3 patients required catheter removal (p=0.05). There was no difference in cDNA levels between PD patients with a negative history of previous peritonitis (n=3) and PD patients with a positive history (n=20) (p=0.48). There was no statistically significant correlation between cDNA and number of previous peritonitis (r=0.13, p=0.55).

Conclusions: This pilot study provided substantial basis for further investigations of molecular mechanisms of peritoneal injury and potential clinical application of cDNA. cDNA could provide some additional information about patient’s outcome and management. These results can be considered hypothesis generating, and stimulate further exploration of a prognostic and predictive role of cDNA in PD-related peritonitis.

FR-PO826
Epimorphin Expressions in Mice Model of Peritoneal Fibrosis
Munchun Yamada, Takashi Oda, Shuhei Komatsu, Taito Oshima, Tadasu Kojima, Yasuyu Sudo, Tomohiro Tomiyasu, Noriko Yoshikawa, Masaharu Yoshida, Nephrology, Hachioji Medical Center of Tokyo Medical Univ, Hachioji, Tokyo, Japan.

Background: Long-term peritoneal dialysis induces peritoneal fibrosis in submesothelial area. Epimorphin is a mesenchymal protein that regulates epithelial morphogenesis through epithelial-mesenchymal interactions, has recently attracted attention as an important modulator of tissue repair. We previously reported that epimorphin was involved in the repair of fibrosis in mice (Lab Invest 2010). In this study, we evaluated the epimorphin expressions in the peritoneal fibrosis mice model.

Methods: Peritoneal fibrosis was induced by the injection of 0.1% chlorhexidine gluconate in 15% ethanol and 85% normal saline (CG-injected mice) into peritoneal cavity of 10-week-old male C57Bl6 mice every other day. Control mice received glucose lactate-based NPDS (PD) and the same NPDS with dissolved H+ (HPD). Peritoneal tissues were subjected to morphological analysis including Masson’s Trichrome staining. Epimorphin expressions were assessed by IF staining for epimorphin. PMCs were assessed by Masson’s Trichrome staining and IF staining for epimorphin.

Results: In CG-injected mice, the marked thickening of the submesothelial compact zone was shown in Masson’s trichrome staining. IF staining for epimorphin was positive in the submesothelial area corresponding to the fibrotic area. Epimorphin staining was significantly stronger than that in control mice. Such an increase in epimorphin expression was confirmed by and real-time RT-PCR (n=5, p<0.05 vs control).

Conclusions: Our results showed that L-PDF induced apoptosis by importing lactate via MCT-1 in HPMCs, and suggest that B-PDF improved biocompatibility by inhibiting mesothelial cell apoptosis.

FR-PO827
Peritoneal Mesothelial Cells (PMCs) Injury Induced by Neutral Peritoneal Dialysis Solution (NPDS) and Its Amelioration by Molecular Hydrogen (H+), Lijie He, Shiren Sun, Dept of Nephrology, Xijing Hospital, Xi’an, Shaanxi, China.

Background: PMCs play pivotal roles in suppression of peritoneal fibrosis, adhesion, and bacterial infection in PD therapy. It is reported that histological changes of peritoneum and incidence of encapsulating peritoneal sclerosis, have been decreased by NPDS introduction. However, meta-analysis did not show superiority of NPDS in incidence of bacterial peritonitis, suggesting bio-incompatibility of current NPDS. H+ has anti-oxidative effects in biological way, and its clinical application has been studied. The present study aims to examine PMC injury by NPDS, and its ameliorating effect of H+.

Methods: Male SD rats (n=24) were divided into three groups: control (Con), 2.5% glucose lactate-based NPDS (PD), and the same NPDS with dissolved H+ (400 ppm) (HPD). The latter two groups were given NPDS or H2-NPDS intraperitoneally for 10-day 20 mL once a day. Peritoneal tissues were subjected to morphological analysis including immunohistochecmistry (cytokeratin, vimentin, proliferation, Ki67 and apoptosis, M30 cytodeath), and PMCs obtained to gene analysis by real time PCR, and microarray assay.

Results: The collagen thickness increased in PD and HPD, however, there were significant changes in stainings of vimentin, M30 cytodeath, and Ki67 in PD as compared to Con. There was no change in PD. In gene cluster analysis, there were changes by 8.7% in whole gene expression between PD and Con, and 3.7% changes between PD and HPD. In PCR, no difference was found in Epithelial-Mesenchymal Transition (Snail, TGF-β, ASMA) among the groups, while wound healing (MMP9, CTGF, Fibronectin, FAK), cytokines (IL1b, TNFα, IL6) were decreased in PD as compared to Con, but no changes in HPD.

Conclusions: This pilot study provided substantial basis for further investigations of molecular mechanisms of peritoneal injury and potential clinical application of cDNA. cDNA could provide some additional information about patient’s outcome and management. These results can be considered hypothesis generating, and stimulate further exploration of a prognostic and predictive role of cDNA in PD-related peritonitis.

FR-PO828
Bicarbonate-Buffered Peritoneal Dialysis Solution Suppresses Lactate-Induced Apoptosis via Monocarboxylate Transporter-1 in Human Peritoneal Mesothelial Cells
Akiko Kuma, Tetsu Miyamoto, Ryota Serino, Yumi Furuno, Yoko Fujimoto, Hiromichi Ueno, Yutaka Otsuji, Masahito Tamura. Dept of Nephrology, Univ of Occupational and Environmental Health, Kitakyushu, Japan.

Background: Long-term peritoneal dialysis is associated with functional and structural alterations of the peritoneal membrane. Lactate-buffered peritoneal dialysis fluid (L-PDF) has impaired biocompatibility due to the presence of supra-physiological levels of lactate. Although bicarbonate-buffered PDF (B-PDF) has been developed, its biocompatibility remains unclear. Here, we investigated the effects of L- or B-PDF on cell viability and apoptosis in cultured human peritoneal mesothelial cells (HPMCs), focusing on monocarboxylate transporters (MCT).

Methods: HPMCs were cultured in media containing 10% fetal bovine serum and L-PDF with 1.5% glucose (L1), 2.5% glucose (L2), B-PDF with 1.5% glucose (B1) or 2.5% glucose (B2), or no PD (control). Cell viability and apoptosis were determined using the WST-1 and TUNEL assays, respectively. The percentage of MCT-1 and -4 on lactate-induced apoptosis were evaluated by siRNA transfection for MCT-1 and -4.

Results: Cell viability was significantly decreased in cells incubated with L1 (12±2.2%, control–100%) and L2 (2±1.1%), compared with B1 (74±2.5%) and B2 (72±2.5%) after 72 h incubation. Apoptotic cells were also increased in L1 (69±1.6%), L2 (73±8.5%) when compared with B1 (3±0%) and B2 (4±1%). MCT-1 and -4 protein and mRNA expression levels, examined by Western blotting and real-time PCR, were similar in all cells. Protein expression levels of MCT-1 and -4 were almost completely diminished after transfection of siRNA for MCT-1 and -4, respectively. MCT-1 siRNA increased the levels of cell viability by 3.2–3.7-fold and decreased the amount of apoptotic cells from 64±8% to 47±4% in cells treated with L1 for 72 h. Interestingly, MCT-4 siRNA had no effect on cell viability and apoptosis.

Conclusions: Our results showed that L-PDF induced apoptosis by importing lactate via MCT-1 in HPMCs, and suggest that B-PDF improved biocompatibility by inhibiting mesothelial cell apoptosis.

FR-PO829
MiRNA-143/145 Gene Cluster Enhances Cell Deformation and Fibrosis of Human Peritoneal Mesothelial Cells via Modulating TPA4
Bicarbonate-Buffered Peritoneal Dialysis Solution Suppresses Lactate-Induced Apoptosis via Monocarboxylate Transporter-1 in Human Peritoneal Mesothelial Cells
Lijie He, Shiren Sun. Dept of Nephrology, Xijing Hospital, Xi’an, Shaanxi, China.

Background: In this study, we work for the function and mechanism of miR-143/145 gene cluster in human peritoneal mesothelial cells (HPMCs), which were used as possible triggers for peritoneal membrane fibrosis.

Methods: To investigate if miR-143/145 gene cluster could promote PM fibrosis, all these immortal HPMCs were characterized by fibrosis related markers and tested the expression of miRNA-143/145 cluster and tropomyosin4 (TPM4) by real-time PCR or Western blot. We also used PD dialysis rat model to observe the response of PM to miR-143/145 gene cluster and their possible target.

Results: Here, we found that miR-143/145 gene cluster, which are examined to be highly expressed in HG-induced HPMCs (HG, 60 mmol/L) and in PD animal model. TPM4 were found significantly lower expression in HG-induced HPMCs. So our study showed that HG-induced HPMCs expressed miR-143/145 gene cluster and their possible target. 

Conclusions: Our data suggested that miR-143/145 gene cluster pathway might contribute to the cell deformation of HPMCs and the progressive PM fibrosis during PD.

Mitochondrial DNA Copy Number Is Associated with Peritoneal Dialysis Failure in Younger and Metabolically Healthier Peritoneal Dialysis Patients

Jae Eun Um,1 Jong Hyun Jhee,2 Kyoung Sook Park,2 Chang-Yun Yoon,2 Mi Jung Lee,1 Jong Tak Park,1 Shin-Wook Kang,1 Tae-Hyun Yoo1,2

1Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea; 2Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Insulin resistance and inflammation are known to be closely related to adverse outcomes in peritoneal dialysis (PD) patients. Recently, mitochondrial function has been reported to play a key role in glucose metabolism as well as systemic inflammation in various populations. However, the clinical consequences of mitochondrial function in PD patients are not well known. Therefore, this study was aimed to investigate the relationship of mitochondrial DNA (mtDNA) copy number and clinical outcome in PD patients.

Methods: A total of 120 prevalent PD patients were recruited. mtDNA copy number was counted by a PCR based method. Primary outcome was PD catheter removal due to ultrafiltration failure. Metabolic syndrome was defined using the Modified National Cholesterol Education Program (Adult Treatment Panel III) criteria. Cox proportional hazard analysis was performed to determine the independent association of mtDNA copy number with primary outcome.

Results: The mean age was 52.3 years and 52 patients (42.5%) were male. The mean mtDNA copy number was 29.1±14.9. During a mean follow-up duration of 59.4±39.3 months, primary outcome was observed in 54 patients (45.0%). There were no significant differences in baseline characteristics between non-PD and PD failure group except for serum adiponection levels (20.5±7.3 vs. 17.5±7.3 mg/mL, P=0.028). mtDNA copy number was significantly associated with PD failure in multivariate Cox analysis (hazard ratio (HR)=0.995, 95% confidence interval (CI)=0.976-1.015, P=0.634). However, a subgroup analysis revealed that mtDNA copy number was an independent predictor of PD failure in patients younger than 55 years without metabolic syndrome (HR=0.819, 95% CI=0.692-0.970, P=0.020) after adjustment for confounding factors.

Conclusions: mtDNA copy number may be associated with ultrafiltration failure in younger and metabolically healthier patients treated with PD.

IL-6 Induces VEGF Production by Human Peritoneal Mesothelial Cells During Peritonitis Through SP4-Mediated Trans-Signaling with sIL-6R

Rusan Catar1, Janusz Witowski2,1, Nan Zhu3, Christian Luecht3, Achim Joerres2

1Nephrology and Medical Intensive Care, Charité-Universitätsmedizin Berlin, Berlin, Germany; 2Pathophysiology, Poznan Unive of Medical Sciences, Poznan, Poland.

Background: Vascular endothelial growth factor (VEGF) has been implicated in peritoneal angiogenesis and membrane remodelling in peritoneal dialysis (PD). Human peritoneal mesothelial cells (HPMC) have been identified as a major source of VEGF in the peritoneum. However, the exact mechanism of VEGF induction in HPMC is unclear. Since IL-6 concentrations in the drained dialysate correlate with VEGF levels, the link between the two has been suggested. While HPMC do not bear classical IL-6 receptor, they can respond to IL-6 trans-signalling that involves soluble IL-6 receptor (sIL-6R).

Methods: HPMC were isolated from normal omentum. Dialysate effluent was obtained from stable PD patients and during peritonitis. VEGF mRNA and protein levels were measured by RT-qPCR and ELISA, respectively. The involvement of transcriptional factors was assessed by EMSA, transient transfections with VEGF promoter constructs, and siRNA silencing.

Results: IL-6 and sIL-6R alone had no effect on VEGF release by HPMC. However, the exposure to IL-6+sIL-6R resulted in a time- and dose-dependent induction of VEGF mRNA and protein. The combination of IL-6+sIL-6R activated the VEGF promoter region that contained high affinity binding sites for the transcription factor SP4. Specific mutation of the SP4 binding site eliminated VEGF promoter activation. In turn, the induction of SP4 was controlled by ST2. Exposure of HPMC to dexamethasone efficiently obtained during acute peritonitis and containing increased levels of IL-6 and sIL-6R resulted in a dose-dependent VEGF induction. This effect was significantly attenuated in cells treated with siRNAs for either SP4 or ST2.

Conclusions: Dialysate IL-6 and sIL-6R act through the trans-signalling pathway controlled by the STAT3-SP4 axis to up-regulate mesothelial VEGF production during peritonitis.

IF NMR Based Metabolome Can Predict Relapsing Peritonitis and Differentiate Bacterial and Fungal Peritonitis as Well

Narayan Prasad1, Raj K. Sharma1, Amit Gupta1, Dinesh Kumar1

1Nephrology and Renal Transplantation, SGPGIMS, Lucknow, UP, India; 2CBMR.

Background: Conventional culture methods for microbes are inherently slow and inefficient. Treatment of bacterial (BP) and fungal peritonitis (FP) are different and quick differentiation is needed. Presently, there is no biomarker to predict relapsing peritonitis (RP). Bacteria and fungi may have different metabolome as one is prokaryotic and other eukaryotic.

Methods: Five unused PD fluid, 13 effluent from normal PD and 45 effluents from 15 patients (at baseline, 1 week and 2 weeks of therapy) with BP including 3 who relapsed and 3 FP were included. Half of each was subjected to total and differential WBC count and culture; and half was frozen at -80°C for NMR analysis. BP and FP was diagnosed based on identification of organism. RP was defined as per standard definition. High Resolution NMR spectra were recorded at 291 K on a Bruker Avance III 800 MHz spectrometer. Standard 1D 1H NMR spectra were acquired using the Carr–Purcell–Meiboom–Gill (CPMG) pulse sequence. To confirm the assignment of marker peak, two-dimensional (2D) 1H-1H COSY and HH-13C HSQC spectra were also acquired.

Results: Five unused and 13 normal PD effluents after 6 hours of dwell did not show any marker peak at NMR spectra at 0.67 ppm while 15 cases of BP showed marker peak; however marker peak disappeared after resolution of peritonitis at 1 week and 2 weeks of antibacterial therapy except for 3 cases who relapsed in whom marker peak was persisting despite absence of clinical peritonitis. The 3 cases of FP did not show any such marker peak differentiating it from BP. Marker signal represent trans-methylene protons of cyclopropene ring moiety as reported earlier and depicted in Figure 1.

Conclusions: The cyclopropane signal at 0.67 ppm can be marker signal to differentiate BP and FP and persistence of this signal at 2 weeks after clinical resolution of peritonitis predicts RP.
CVD. Increased intact parathyroid hormone and FGF-23 levels are associated with the progression of parenchymal fibrosis in peritoneal dialysis (PD) patient. N-acetylcysteine (NAC) acts on atherosclerosis and also improves the endothelial functions. This study was designed to evaluate the correlation between FGF-23, endothelial dysfunction and markers of inflammation in chronic PD patients and to evaluate the effect of three months of treatment with NAC in these parameters.

Methods: All patients underwent Doppler studies to assess endothelial function by the flow mediated dilatation (FMD) of the brachial artery and carotid arterial intima media thickness (CIMT). Brachial artery was imaged during reactive hyperemia (endothelium-dependent) and during a glyceryl trinitrate dilatation (nitrergic-mediated dilatation, NMD, endothelium-independent) in all PD patients. NAC was given in the dose of 1200 mg in two divided doses for a period of three months. The associations between different parameter were analyzed using Spearman correlation. All patients were repeated after three months of therapy with NAC.

Results: A total of 73 chronic PD patients were enrolled in this study. FGF-23 showed strong positive correlation with serum homocysteine level ($r=0.90, P<0.001$), hsCRP ($R=0.977, P<0.001$), Endothelium Dependent Dilatation (EEDD) ($r=0.968, P<0.001$) and CIMT ($r=0.994, P<0.001$), but negatively correlated with Endothelium Independent Dilatation and Vitamin D level. All these parameters including FGF-23, hsCRP, homocysteine, CIMT and EDD were significantly reduced after three months of therapy with NAC.

Conclusions: FGF-23 correlated well with inflammatory markers and endothelial function. With three months of therapy, NAC significantly reduces the CIMT, inflammatory markers and improves the endothelial function in chronic PD patients.

FR-PO835
SRF Enhances Cell Adhesion, Migration and Peritoneal Fibrosis via Modulating miRNA-199a/214 Cluster in Human Peritoneal Mesothelial Cells Li Jie He, Shiren Sun. Dept of Nephrology, Xijing Hospital, Xi’an, Shaanxi, China.

Background: Our previous work showed that serum response factor (SRF) was involved in fibrosis of peritoneal membrane, but the exact underlying mechanism were still unclear. Here we further study the role of miR-199a/214 cluster and the relationship of SRF in peritoneal fibrosis.

Methods: We isolated HPMCs from the effluents of end-stage renal disease (ESRD) patients with peritoneal dialysis (PD), and also used PD dialysis rats model to observe the response of PM to miR-199a/214 cluster and the predicted target CDH1 and CLDN2.

Results: In this study, we found that miR-199a-5p/214 cluster, which was examined to be highly expressed in HG-induced HPMCs by real time PCR, was directly regulated by SRF after HG stimulation. All these HG induced immortal HPMCs became scatter, have the migration ability, lost cell-cell adhesion, and characterized by phenotype markers. The overexpression of SRF in peritoneal fibrosis. Gefitinib treatment abrogated increased phosphorylation of EGFR, inhibited overproduction of transforming growth factor-$\beta 1$ and multiple proinflammatory cytokines and the accumulation of macrophages to the injured peritoneum. Moreover, gefitinib significantly reduced peritoneal increase of CD31 (+) blood vessels and vascular endothelial growth factor (+) cells after injury.

Conclusions: These results demonstrate that EGFR contributes to peritoneal fibrosis, inflammation and angiogenesis and suggest that EGFR inhibitors may have therapeutic potential in peritoneal fibrosis.

FR-PO837
Effects of Alanyl-Glutamine Addition in Peritoneal Dialysis Fluid on Peritoneal Immune Modulation – A Pilot Clinical Trial Klaus Khorntschull, 1,2 Rebecca Herzog, 1,2 Manoj K. Bhasin, 1 Seth L. Alper, 3 Andreas Vychytil, 4 Christoph Aufricht. 1 Medical Univ of Vienna, Vienna, Austria; 2 Zytoprotec GmbH, Vienna, Austria; 3 Beth Israel Deaconess Med. Ctr., Harvard Medical School, Boston, MA.

Background: Low peritoneal glutamine levels may contribute to reduced immune defense and increased inflammation in the peritoneal cavity. As a pilot clinical trial, PD patients were treated with PD fluid supplemented with 8 mM alanyl-glutamine (AlaGlN) and the effect on peritoneal cell immuno-competence was studied by functional assays and transcriptomics using RNA-sequencing (RNAseq) and microRNA (miRNA) profiling of cells derived from PD effluents.

Methods: In an open-label, randomized, crossover clinical trial at the Medical University of Vienna (EudraCT-2012-00404-36), 6 stable PD patients received either standard PD fluid (Physionol-40 3.86%, Baxter) or AlaGlN-supplemented PD fluid for an overnight dwell followed by a 4 h peritoneal equilibration test. Cytokine release from effluents of treated effluent was assessed as a measure of immuno-competence. Cells were also analyzed by RNAseq (TruSeq Single-end miRNA, Illumina) and miRNA microarray analysis (Affymetrix) using an integrated bioinformatics workflow developed in the Bhasin Lab.

Results: AlaGlN treatment significantly increased cytokine release following ex-vivo stimulation, consistent with restoration of previously suppressed peritoneal immunocompetence. Peritoneal effluent cell transcripts of 9,797 genes were identified. Unsupervised clustering and principal component analysis revealed partial separation between patients. Supervised analysis using the paired approach identified 13 differentially expressed miRNAs and 41 differentially expressed genes with $>1.5$-fold change ($P<0.01$). Functional enrichment analysis of these genes indicated pathways linked to immune response and modulation.

Conclusions: In summary, AlaGlN-mediated improvement in peritoneal leukocyte immuno-competence was correlated with changes in peritoneal leukocyte transcriptome status in well-documented clinical samples. To strengthen these promising data, larger numbers of patients will be treated with AlaGlN for a prolonged period in an international multi-center RCT.

FR-PO838
Choice of Dialysis Modality for Children with End Stage Renal Disease Julien Hospes, 1,2 Cecile Couderc. 1,2 Pediatric Nephrology, Robert Debre Hospital, Paris, France; 3REIN Registry, Agence de la Biomédecine, La Plaine Saint Denis, France.

Background: Despite many studies that aim to assess the best modality of dialysis, results remain conflicting both in adults and in children. This lack of medical evidence leads commentators to emphasize the importance of patients’ choice in the decision process. Thus, we try to assess factors that impact the choice of the dialysis modality in children and to determine which from medical factors, center practices or patients’ wishes plays the major role.

Methods: All incident patients <20 years old at start of dialysis, recorded in the French ESRD registry between 2002 and 2013 were included. We used multivariate hierarchical logistic regression models to study patients and centers characteristics associated with the probability of starting with peritoneal dialysis (PD). The effect of centers was assessed by including centers as a random effect.

Results: Among 806 patients treated in 177 centers, 601 (74.6%) started with hemodialysis (HD) and 205 (25.4%) with PD. A higher probability of PD was found in younger children while starting HD was associated with a low use of PD. Low and high educational level of the town of residence were both associated with less probability of PD when compared with average educational level. There was a significant variability between centers, that was not explained by patients’ case-mix. Being treated in specialized pediatric centers was associated with less probability of PD, while the probability of PD was proportional to the rate of PD in the center.

Conclusions: Although little evidence exists to favor a dialysis modality over the other in children, HD remains the predominant modality in France. PD is still mostly offered to the ‘old’ patient or to ‘uncooperative’ children while it remains understudied in patients starting RRT in emergency. However, we found that besides medical factors, centers practices play a major role in the choice of dialysis modality. This raise concerns about the place left to patients’ and families’ choices and to what extend doctors may influence the final decision. Further pediatric studies focusing on children and parent’s wishes are needed in order to provide cares as close as possible to there expectations.
FR-PO839
Clinical Course of Children Born with Chronic Kidney Disease – A Single Centre Experience
Christina Taylan,1 Bernd Hoppe,2 Eva Maria Haffner,2 Lutz Thorsten Weber.1 1Pediatric Nephrology, Univ Hospital of Cologne, Cologne, Germany; 2Pediatric Nephrology, Univ Hospital of Bonn, Bonn, Germany.

Background: The number of babies born alive suffering from chronic kidney disease (CKD) is constantly increasing.

Methods: We analyzed the outcome of infants with CKD and renal replacement therapy (RRT) treated within their first year of life. Between 2007 and 2013 17 infants (11 male; 6 female) developed end-stage renal disease resulting in RRT in our department.

Results: All of them received peritoneal dialysis (PD) initially at a median age of 34 [1-334] d. During follow-up 10 children underwent renal transplantation (RTx), 1 child was still on PD at last follow-up, 1 child had to go back to hemodialysis after graft loss and 2 had a recovery of renal function. 3 out of 17 children died during the PD period. Causes of death were severe sepsis twice and one cerebral bleeding. The mean GFR at last follow-up (22.6±7.3 years) of patients who underwent RTx was 105±28 ml/min/1.73 m². The mean age at transplantation was 29.2±14.3 months. Mental development was measured by Mental Developmental Index T1 (Bayley Scales of infant development BSID-II) at an average age of 12 [9-16] months and showed developmental delay at the motor, mental and behaviour rating scale. At time of transplantation 6/10 infants had tube feeding, 9/10 were <3. percentiles of height, 3/10 were <3. percentile of body weight.

Conclusions: RRT started in the first year of life was associated with reasonable outcome and should be offered to all infants with end stage renal disease. It is, however, associated with a high risk of developmental delay. This work emphasizes the great demands made on an interdisciplinary team of pediatric nephrologists, psychologists and social workers.

FR-PO840
Altered Myogenesis and Oxidative Stress in a Rat Model of Chronic Kidney Disease
Keith A. Sigastris,1 Neal X. Chen,2 Jason M. Organ,3 Kalissa O’Neill,4 Sharon M. Moe,5,4 1Dept Physical Therapy, Indiana Univ, Indianapolis, IN; 2Div of Nephrology, Indiana Univ, Indianapolis, IN; 3Dept of Anatomy, Indiana Univ, Indianapolis, IN; 4VAMC, Indianapolis, IN.

Background: Skeletal muscle atrophy and impaired muscle function are associated with lower quality of life, and greater disability and mortality risk in those with chronic kidney disease (CKD). However, the pathogenesis of atrophy is unknown.

Methods: We used a slowly, progressively, naturally occurring, CKD rat model (Cy-rat) and its normal littermate (NL). At 35 weeks, we tested muscle strength, sacrificed and collected tissues and blood. RNA and protein were isolated from skeletal muscle and real time PCR and western blot performed.

Results: CKD rats developed sarcopenia evident by reduced cross sectional area (p<0.05), increased connective tissue deposition on histology (p<0.05), and impaired strength (p<0.05). Strength was defined as the maximal amount of force produced during maximal, electrically stimulated dorsiflexion. These findings of atrophy can be explained by reduced regeneration, increased catabolism, or differentiation of muscle stem cells toward myofibroblasts. By PCR, there was increased activation and differentiation of muscle stem cells (reduced Pax-7, increased MyoD and myogenin (p<0.05)) and increased proteolytic markers (Atrogin-1 and MuRF-1 (p<0.05)). Fibrosis may be enhanced via decreased miR-29b (p<0.05) and increased Wnt5a (p<0.01). Finally myostatin was increased in blood (p<0.05). Strength was defined as the maximal amount of force produced during maximum, electrically stimulated dorsiflexion. Time PCR and western blot performed.

Conclusions: It is possible that the deregulation of TLR2 and TLR4 expression on leukocytes may be caused by uremic toxins in CKD population. Besides, the high workers may be related to inflammatory mechanisms in uremic patients.

FR-PO841
Can Calcitriol and Calcidiol to Regulate Toll Like Receptors 7, 9 Expression and IL-6 and IFN-γ Expression on Lymphocytes Incubated with Uremic Serum? Maria Dalboni,1,2,3 Danilo Takashi Aoike,4,5 1,2Nephrology, Univ Fed of Sao Paulo, Sao Paulo, Brazil; 3Medicine, Tufts-New England Medical Center, Boston; 4Medicine, Univ Nove de Julho, Sao Paulo, Brazil.

Background: VD deficiency is highly prevalent among patients in all stages of CKD. Studies have reported that the Vitamin D deficiency is associated with mortality and morbidity in CKD patients and may modulate TLRs that are involved in inflammatory responses. Thus, the purpose was evaluate the effect of cholecalciferol on IL-6, IFN-γ expression on lymphocytes B and T in patients on dialysis with vitamin D hypovitaminosis.

Methods: In a randomized, placebo-controlled, double-blind study, we investigated the effect of cholecalciferol (100,000 UI once per week or placebo) for 3 months, in patients on chronic dialysis, who had nutritional vitamin D deficiency. The 25(OH)D detection was performed by immunoenzyme and 25(OH)D, IFN-γ, TNF-α, IL-10, VDR, CYP27 and CYP24 expression by flow cytometry on lymphocytes B and T.

Results: After 3 months of treatment, Cholecalciferol increased 25(OH)D levels (16.0±5.4 vs 42.8±13.06 p<0.01) and reduced IFN-γ levels (525.3 (128-1775) vs 484.8 (262-7250) p<0.001), but have no effect on TLR7 and TLR9 expression. However, 25(OH)D increased expression of TLR7 (305±78 vs 252±45 p<0.01) and TLR9 (1864±700 vs 548±370 p<0.001 and CYP24 (264±136 vs 200±86 p<0.01) and increased of VDR (730±360 vs 965±440 p=0.006) and CYP27 (245±38 vs 442±380 p=0.04) expression.

Conclusions: Cholecalciferol treatment in CKD patients showed to be efficient to correct hipovitaminosis D. In addition, we observed impact of 25(OH)D, repletion on expression of the TLR7, TLR9, IFN-γ and improve of regulatory mechanisms.
associated with intracellular production of vitamin D on lymphocytes from CKD patients. These results suggest that novel treatment play an important role on TLRs expression as an anti-inflammatory and that this may contributed to a better systemic inflammation response in CKD patients.

FR-PO844
The Effect of Selenium Deficiency on Thyroid Hormone and Cardiovascular Diseases in Hemodialysis Patients  So Mi Kim,1 Eun Kyong Lee,2 Yun Jung Oh,3 Ja Soon Kim,4 1Div of Nephrology, Dept of Internal Medicine, Jeju National Univ Hospital, Jeju National Univ School of Medicine, Jeju, Jejudo, Republic of Korea; 2Div of Nephrology, Dept of Internal Medicine, Dankook Univ Hospital, Cheonan, Chungnam, Republic of Korea; 3Div of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Jejudo; 4Div of Nephrology, Dept of Internal Medicine, Incheon sarung Hospital, Incheon, Kyongkido, Republic of Korea.

Background: Selenium deficiency is known to associate with impairment of thyroid hormone and cardiovascular diseases such as ischemic heart disease (IHD), cardiomyopathy or sudden death. In hemodialysis (HD) patients, various causes may contribute to selenium deficiency, including malabsorption, alteration of metabolism, and removal through dialysis itself. Therefore, we tried to investigate the effect of selenium deficiency on thyroid hormone and cardiovascular diseases in HD patients.

Methods: This cross-sectional study enrolled 83 HD patients. They were divided into two groups based on serum selenium levels: 62 patients were normal level and 22 patients were low level. Then, thyroid hormones such as TSH, free T4 were measured. And cardiovascular diseases, including IHD, heart failure or cardiomyopathy, were evaluated.

Results: Thyroid hormone impairment, including hypothyroidism and subclinical hypothyroidism, showed higher tendency in selenium deficient group than that in non-selenium deficient group. (27.5% vs 10% P=0.06) The prevalence of IHD was significantly higher in selenium deficient group than that in the non-selenium deficient group. (59% vs 21%, P=0.04) But there was no difference in heart failure and cardiomyopathy. The patients with thyroid hormone impairment showed high prevalence of IHD, and the coincidence of thyroid hormone impairment and IHD was also significantly higher than that in selenium deficient group than that in non-selenium deficient group. (18% vs 4%, P=0.014).

Conclusions: This study showed the significant high prevalence of thyroid hormone impairment and IHD in HD patients with selenium deficiency. Selenium deficiency may be affect heart disease, associating with thyroid hormone impairment.

FR-PO845
Associations of Prelude (Pre-ESRD) BMI and Weight Change with Early Dialysis Mortality Among U.S. Veterans: A Transition of Care in CKD Study Flani Strega,1 Melissa Soodoo,1 Joline L.T. Chen,2 Amanda R. Torторici,1 Jennie Jing,1 Danh V. Nguyen,1 Csaba P. Kovessy,1 Kamyar Kalantar-Zadeh,3 1UC Irvine; 2UTHSC.

Background: In end stage renal disease (ESRD) lower body mass index (BMI) portends a higher risk of mortality while obesity is protective, the so-called obesity paradox. However, the association of BMI and change in BMI over time in the pre-ESRD period and early post-ESRD mortality is unknown. We hypothesized that lower and decreasing BMI prior to transition to ESRD may be associated with higher early dialysis death.

Methods: In a cohort of 22,716 US veterans who transitioned to dialysis between 10/2007 and 9/2011 with available BMI values within the last 2 year prelude period (prior to transition to ESRD), we adjusted for age, sex, race, ethnicity, cause of ESRD, and region. In the models of BMI slope, we also adjusted for BMI level at the time of transition.

Results: The mean±SD age was 69±11 yrs, 27% were African-American, 7% Hispanic, and 49% diabetic. There was a reverse I-shaped association between BMI and mortality, where patients with BMI <27 kg/m² were at higher risk of death (Figure A). When examining changes in weight over the 2-year prelude there was a U-shaped association where patients with little to no change in BMI (-1 to +1 kg/m² per year) exhibited the best survival (Figure B).

Conclusions: Among veterans transitioning to dialysis, obese patients and those patients with little to no weight change in the last 2 years prior to ESRD have the greatest survival in the first 3 months post transition. Weight change in late stages of pre-dialysis CKD, possibly due to uremic wasting and fluid gain, portend poor outcomes, and could be used to identify at-risk patients.

Funding: NIDDK Support

FR-PO846
Nutritional Assessment for Incident Dialysis Patients Kurt Masakane,1 Yuya Sakai,1 Miho Suzuki,1 Yubaki Hospital, Nephrology, Yamagata, Japan; 2Yubaki Hospital, Dept of Health and Nutrition.

Background: Nutritional status is one of the most powerful predictors of patient survival in chronic dialysis patients especially in elderly. It is generally accepted that aging itself is one of the risk factors of malnutrition. Recently the patients who started dialysis have become older and older as the average age of incident dialysis patients in Japan is nearly 70 years old. It is very meaningful to evaluate the status of malnutrition in new elderly dialysis patients, its time-course and to establish strategies for preventing progression of malnutrition.

Methods: The nutritional status of 257 incident dialysis patients in YHG was retrospectively evaluated by MIS. The nutritional status on 37 patients out of the 257 patients has been followed for 3 years. The “malnutrition” was diagnosed as “moderate-severe” in MIS and fullfill of the diagnosis of PEW. Patients greater than 75 years old were categorized as Elder and patients under 75 years old as Non-elder. The statistical significane of time-dependent changes in nutritional status was evaluated by paired-T test.

Results: The prevalence of malnutrition at the point of dialysis initiation by MIS in average was 7%, 12% in Elder and 5% in Non-elder. The nutritional status had been improved in the non-elder but not in the elderly. The lean body mass had decreased in the first year of dialysis vintages in both groups and had remained the same in the following 2 years. Body mass fat had increased consistently for 3 years in non-elderly. It had increased for the first 2 years but had began to decrease in the third year in the elderly. Protein and energy intake per ideal body weight were lower in elderly dialysis patients.

Conclusions: Malnutrition in elderly dialysis patients was often accompanied by the initiation of chronic dialysis therapy and would gradually develop in the maintenance period. In order to protect the progression of malnutrition several proposals were addressed as the proper timing of the initiation of dialysis before the deterioration of daily activities; nutritional education for sufficient energy and protein intake, exercise education and sufficient dialysis prescription with biocompatible dialysis membranes.

FR-PO847
Uric Acid Is a Determinant of Glomerular Filtration Rate in Inflammatory Conditions Suad Ma Hannawi, Issa AL Salmi, Medicine, The Ministry of Health, Dubai, United Arab Emirates; The Renal Medicine Dept, The Royal Hospital, Muscat, Oman.

Background: The presence of gout or a baseline serum uric acid in the upper range are possibly stronger predictors of first CV events than some traditional CV risk factors or parameters of inflammation. Presence study analysis UA determinants in relation to GFR.

Methods: Patients attending the only centre of MOH in Dubai were studied during their OPD and Laboratory visit from Jan 2014 till Dec 2014. Many laboratory tests including UA were performed. MDRD formula was used to get eGFR. Simple statistical and regression models were performed. Variables that normally distributed being log transformed.

Results: 79 (88.6%,11.4%) were recruited with mean age46.14(3.4) years. Mean UA was 249.8 (84.4, eGFR137.1(50.5)(59.6,306.1).

Regression analysis found a negative relationship between UA and GFR (P<0.001,-0.004,-0.002) and positive relationship between uric acid and age (p=0.032, 0.001-0.011), urea (p=0.001,0.041-0.137), microalbuminuria (p=0.046,0.000-0.001), microalbumin/cr (p=0.001,0.031-0.013), SBP(P=0.025,0.001-0.014), age at DX RA (p=0.028,0.001-0.010), monocyte% (p=0.009,0.013-0.088), monocyte count (p=0.003,0.015-0.776) TG (p=0.034,0.009-0.231), but also negative with cholesterol (p=0.033,-0.148,-0.007).

Uric acid multiple model has maintained a strong correlation with eGFR (p<0.005), monocyte count (0.009), cholesterol (p=0.007),microalbuminuria(0.01), after adjustment for all the above mentioned variables.

Conclusions: UA is determined by eGFR and other renal parameters in inflammatory condition. On the other hand, uric acid increase the risk of renal impairment and CVD in inflammatory condition. Thus, uric acid level might be an elemental key factor that result in high renal and CV associated morbidity and mortality in the inflammatory diseases. UA is a powerful independent predictor of prevalent renal dysfunction but was also a significant predictor of progression of renal disease. UA may not be just an innocent bystander but may be an active player in the pathogenesis of renal disease by causing endothelial dysfunction, intravascular renal disease and renal impairment in inflammatory conditions.

FR-PO848
Does Nutritional Status and Serum Electrolytes Change when Dialysis Patients Reduce Their Fluid Overload? Penny Faith Sheppard,1 Suzette Thompson,2 Laura Rosales,1 Nathan W. Levin,1 Peter Kotanko,1 Fansan Zhu,1 1Renal Research Inst, New York, NY; 2Fresenius Vascular Care, New York, NY.

Background: Electrolyte balance between the intracellular (ICV) and extracellular (ECV) fluid compartment is essential in the control of normal physiological functions. Nutritional status is mainly reflected by ICV. In hemodialysis (HD) patients the relationship between control and management of fluid balance is not completely understood. We aimed to evaluated whether the degree of reduction of fluid overload affects the measurement of ICV, and concentrations of serum albumin (Alb), sodium, potassium, and calcium.

Methods: Fifty six HD patients were studied. At baseline (BL), the fluid status was evaluated by calf bioimpedance spectroscopy (cBiS). If patient’s dry weight (DW) was not reached by criteria of cBiS DW, the post target weight was gradually reduced (Zhu et al, 2015/ JASN). Then, Patients were divided into two group: one group reduced fluid overload (POD) and the other group didn’t (NONPOD). The analysis were performed with paired T test and ANOVA test with post hoc, respectively. The paired T test was used to compare the pre and post treatment as well as different groups.

Results: The between group of two groups are statistically significant for all variables. After treatment, the ICV level, sodium, potassium, calcium concentration increased significantly, respectively P<0.05. The ECV level increased in both groups, respectively P<0.05.

Conclusions: The reduction of fluid overload is associated with increase of ICV and decreased in ECV, which may affect heart disease, associating with thyroid hormone impairment. Selenium deficiency may be affect heart disease, associating with thyroid hormone impairment.
Physiol Meas, 29:S530-S516, 2008). At six months follow up, the patients either reached DW or did not (NDW) due to difficulty in prolonging treatment time. ECV and ICV, weight, and systolic blood pressure (SBP) were measured pre and post HD. Comparison of all parameters between BL and follow up were made using student t test.

Results: Thirty one patients reached DW and 25 did not. Weight and ECV were significantly reduced during follow up. However, ICV, electrolytes and Alb concentrations did not change between different fluid statuses. Post HD SBP significantly decreased from BL to the end of the study in DW but not in NDW groups.

Conclusions: Although extracellular fluid (ECV) was largely reduced, the ICV and serum concentrations of sodium, potassium, and calcium did not differ significantly. This implies that there is no fluid or mass shift from ICV to ECV, suggesting over all isotonic removal of sodium and that nutritional status is not changed by attainment of dry weight.

Trends in Weight Change During the First Two Years of Transition to Hemodialysis Treatment

Vivian Ngo,1 Elani Strejfa,1 Anna Mathew,2 Tae Hee Kim,1 Yoshitsugu Obi,1 Connie Rhe1,3 Csaba P. Kovedy,2 Kamyar Kalantar-Zadeh,1 UC Irvine; Hofstra North Shore LIJ Health System; UTBSC.

Background: Some hemodialysis patients may undergo rapid weight loss in the first few months of starting dialysis, but the nature of this trend has not yet been characterized in large nationally representative studies. We hypothesized the trajectory of weight change during the first 24 months of hemodialysis therapy may differ by baseline body mass index (BMI).

Methods: We examined percent post-dialysis weight (kg) change from baseline in 37,759 incident hemodialysis patients who initiated dialysis in a large US dialysis organization in calendar years 2007-2011 and who survived the first 2 years of hemodialysis. Trends of percent weight change over time were analyzed using crude and case-mix adjusted mixed effects models. Baseline BMI was categorized into 8 categories (<18.5, 18.5-20, 20-23, 23-25, 25-30, 30-35, 35-40, >40) kg/m2).

Results: Patients were 60±14 years old, 64% diabetics, 44% female, and had an average starting weight of 82±22 kilograms. Patients reached a nadir of weight at the 5th month of dialysis with an average 2% weight loss from baseline. At 14 months, patients' weight had not reached a nadir and lost approximately 6% of their weight by the 24th month. Obese patients (BMI >40) did not reach a nadir and lost approximately 6% of their weight by the 24th month.

Conclusions: Baseline BMI can affect the trajectory of weight change over the first two years in hemodialysis patients. Further studies are needed to better understand the cause of these differences and their impact on clinical outcomes.

FR-PO850

Significance of Renal Autonomic Nerves in the Reduction of Body Weight by SGLT2 Inhibitors

Aika Hagiwara, Kazutoshi Miyashita, Masaaki Sato, Hiroyuki Inoue, Kentaro Fujii, Masanori Tamaki, Hiroshi Itoh. Nephrology, Endocrinology and Metabolism, School of Medicine, Keio Univ, Shinjuku, Tokyo, Japan.

Background: Sodium-glucose co-transporter (SGLT) 2 inhibitors decrease not only serum glucose level but also body weight significantly. Similarly, it is reported that renal denervation (RDN) decreases body weight, in addition to blood pressure. The urinary glucose might have a relationship with sympathetic activation that controls body weight, however, the relationship has not been elucidated.

Methods: The present study examined the roles for renal autonomic nerves in the weight reduction by SGLT2 inhibitors through performing RDN on mice fed on a high-fat diet. The C57BL/6 mice fed on a high-fat diet were divided into 4 groups; control group, RDN group, SGLT2 inhibitor group and SGLT2 inhibitor with RDN group. The body weight, glucose tolerance, tissue weights, tissue hormone sensitive lipase (HSL) activity and noradrenaline concentration were examined. The SGLT2 inhibitor (tobiglitazin 50 mg/ kg pellet) was administered to mice from 8 weeks old mixing it in the high-fat diet (60 Kcal% fat). RDN was performed at 7 weeks old by surgically stripping the renal arteries and coating the vessels with a solution of 10% phenol in ethanol.

Results: The body weight at 16 weeks old significantly decreased in the SGLT2 inhibitor group. In that group, the catecholamine levels in subcutaneousfat and the activity of HSL which was measured by the phosphorylation level were increased. On the other hand, RDN with SGLT2 inhibitor group significantly weakened the degree of the reduction of body weight by the SGLT2 inhibitor associated with suppression of the catecholamine levels and the activity of HSL in the adipose tissue. In RDN without SGLT2 inhibitor group, the body weight significantly decreased; however, HSL in the adipose tissue was not activated.

Conclusions: These results indicate that HSL activation in the adipose tissue mediated by the renal autonomic nerves was involved in the mechanism of weight reduction by SGLT2 inhibitors. The renal autonomic nerves were suggested to have a role in the control of tissue HSL activity and body weight.

FR-PO851

The Combination of Walking Exercise and Branched Chain Amino Acid Recovered Response of Protein Synthesis in Low Protein Diet Fed Chronic Kidney Disease Model Rats

Background: Low protein diet (LPD) protects progression of renal injury in patients with chronic kidney disease (CKD). However, LPD may accelerate muscle wasting in these patients. The exercise and branched chain amino acid (BCAA) are known to increase the muscle synthesis by activating mTOR signaling pathway. The aim of this study is to investigate whether walking exercise and BCAA would increase muscle protein synthesis in LPD fed CKD (5/6 nephrectomized) rats.

Methods: CKD rats were fed LPD or LPD fortified with BCAA diet (BD), and about half of the each group were loaded with the walking exercise (7 weeks of treadmill, 15 min/m, 1 hour/day, 5 days/week). After 7 weeks, the kidney and the soleus muscle were collected to evaluate the renal fibrosis and the muscle protein synthesis, respectively.

Results: The renal fibrosis and fibrosis were not different between LPD and BD fed CKD rats, and the walking exercise did not accelerate renal damage in both LPD and BD fed CKD groups. The walking exercise increased the phosphorylation of p70S6kinase, a biomarker of mammalian target of rapamycin complex 1 activity, in soleus muscle of LPD and BD fed CKD rats. However, the phosphorylation of p70S6kinase was lower in LPD fed CKD rats when compared with sham-operated groups and BD fed CKD group.

Conclusions: CKD reduces activation of muscle protein synthesis. Combination of walking exercise and BCAA recovered the muscle protein synthesis in CKD rats. These results suggest combination of walking exercise and BCAA may be beneficial to improve the muscle protein synthesis in CKD.

Unacyl-Ghrelin: A Key Molecule in Uraemic Cachexia in Children and Adult Patients

Alice Monzani,1 Michela Perrone,2 Sara Testa,1 Fabio Paulliolonga,2 Silvia Consolo,2 Gianlugi Ardissoni,2 Francesca Tel,2 Marta Lepore,2 Stefani Rotondo,2 Antonietta Biasuzzi,2 Luciana Ghio,2 Gianni Bona,2 Alberto Edefonti,2 Div of Pediatrics, Univ del Piemonte Orientale, Novara, Italy; 2Pediatric Nephrology Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy.

Background: Cachexia and poor growth are common in children with chronic kidney disease (CKD). Several mechanisms are involved, including loss of appetite and poor food intake. Unacyl-ghrelin (UAG) is known to produce an inhibitory effect on feeding. We measured UAG levels in children and adolescents with CKD stage II-IV on conservator treatment (CKD-CT), on haemodialysis (CKD-HD) and after transplantation (Tx), compared with children and adolescents without CKD (CK). We measured also plasma ghrelin (Ghrl) levels in the same subjects and GFR was calculated by Schwartz formula. Weight, height and bicipital, tricipital, subcapacular and suprailliac folds were measured, and BMI z-score, fat-mass and fat-free mass pro body weight (FM/BW and FFM/BW, respectively) were calculated.

Visceral Fat Area Is Associated with Renal and Cardiac Function in a Population with Normal or Mildly Impaired Renal Function
Sung Jin Kim,1 Yunju Nam,1 Hyeon Seok Hwang,1 Seok Joon Shin.1,2 Hye Eun Yoon.1,2 1Internal Medicine, The Catholic Univ of Korea, Seoul, Korea; 2Internal Medicine, Incheon St. Mary’s Hospital, Incheon, Korea.

Background: Visceral fat is involved in the development of metabolic and cardiovascular diseases. This study was to evaluate the association between visceral fat area (VFA) and renal and cardiac function and arterial stiffness in a population with normal or mildly impaired renal function.

Methods: This cross-sectional study included 719 middle-aged adults who underwent a voluntary health check-up program. Participants with estimated glomerular filtration rate or mildly impaired renal function. A Pearson correlation coefficient was determined between VFA and uric acid, HOMA-IR, total body fat, and visceral fat. Results: Across the tertiles of VFA, there was a significant trend for decline in eGFR (P=0.001), increase in baPWV (P=0.001) and left ventricular mass index (P<0.001), and decrease in the ratio of early mitral inflow velocity to peak mitral annulus velocity (E/E’; P<0.001), increase in baPWV (P<0.001) and left ventricular mass index (LVMi, P<0.001), and E/E’ (P=0.01, 95% confidence interval [CI] -0.11 – -0.01, P=0.02), LVMi (β = 0.08, 95% CI 0.06 – 0.10, P<0.001), and baPWV (r = 0.28, P<0.001), LVMi (r = 0.31, P<0.001), and E/E’ (r = 0.21, P<0.001). In multivariate analysis, VFA was linearly associated with eGFR (β = -0.06, 95% confidence interval [CI] -0.11 – -0.01, P=0.02), LVMi (β = 0.08, 95% CI 0.06 – 0.10, P=0.001), and E/E’ (β = 0.01, 95% CI 0.006 – 0.19, P=0.001), after adjustments for cardiovascular risk factors. In contrast, total body fat was not associated with eGFR.

Conclusions: VFA is associated with renal and cardiac function in middle-aged adults with normal or mildly impaired renal function. Measuring VFA may predict risks of renal and cardiac diseases.

Serum Ferritin <70 µg/L Predicts Functional Iron Deficiency in Patients with Chronic Kidney Disease Neha Garg, Miralalini Kotru, Om Prakash Kalra, Meera Sikka. Pathology, UCMS and GTBH, Delhi, New Delhi, India.

Background: Chronic Kidney Disease (CKD) is a major public health problem with anemia occurring early in the course of disease. Its most common cause is erythropoietin deficiency which can be effectively treated with erythropoietin stimulating agents. However most of the patients do not respond adequately due to development of Functional Iron Deficiency (FID). The current diagnostic criteria for FID as recommended by KDOQI 2006 tend to miss the diagnosis of FID. The study was conducted to explore the role of hsCRP and Interleukin-6 (IL-6) along with Serum Ferritin (SF) in improving the efficacy of this criteria.

Methods: 77 clinically diagnosed patients of CKD (Stage 3, 4 and 5) of either sex, age >18 years with Hb <11 g/dL were included in the study. Complete clinical history and physical examination was done. Complete hemogram with peripheral smear, serum iron, total iron binding capacity, Transferrin Saturation (TSAT), SF, transferrin receptors (TfR), hsCRP, IL-6, ESR were estimated.

Results: stIB/log ferritin (taken as gold standard) detected 31/77 patients as having iron deficient erythropoiesis. Out of these 31 patients, 12 patients had SF <12 µg/L indicating absent iron stores. Remaining 19 patients had SF in these. TSAT <20% and SF <100 µg/L detected FID in only 2 patients with a sensitivity of 6.45%. SF at a cut-off <70 µg/L showed the best sensitivity (83.87%) and specificity (73.91%) in detecting FID in these patients. Another 2 patients were missed in this group as who were missed FID cases who were missed by hsCRP. In the absence of raised hsCRP, SF <70 µg/L had very good sensitivity (100%). However, in the presence of raised hsCRP sensitivity was reduced (79.16%).

Conclusions: TSAT <20% and SF <100 µg/L had a sensitivity of only 6.45%. However, SF <70 µg/L emerged as the most sensitive and specific in identification of iron deficient erythropoiesis. SF <12 µg/L - SF <70 µg/L was able to identify 14/19 cases of FID. Also hsCRP could be used to stratify the CKD group in which FID could be detected with high sensitivity and specificity.

Chronic Inflammation Is Associated with Poor Clinical Outcomes Independent of Mineral Metabolism Abnormalities in the HEMO Study
Anna Jeanette Jovanovich,1,2 Eugene J. Nuccio,2 Alfred K. Cheung,3 Tom Greene,1 Michel Chonchol,2 Kristen L. Nowak,2 1Denver VA Medical Center; 2University of Colorado Denver; 3VA Salt Lake City, Utah.

Background: Epidemiological studies show a high prevalence of chronic inflammation, vitamin D deficiency, and fibroblast growth factor 23 (FGF23) excess in hemodialysis patients. Whether the relationships of high circulating C-reactive protein (CRP) and interleukin-6 (IL-6) with all-cause mortality and cardiac and infectious events are attenuated in the presence of circulating markers of mineral metabolism is unknown.

Methods: We studied the association of inflammatory markers (CRP and IL-6) with all-cause mortality, and cardiac and infectious hospitalizations and deaths among 1340 subjects from the Effect of Dialysis and Membrane Flux in Maintenance Hemodialysis (HEMO) trial. Cox regression models adjusted for important confounding variables: demographics, comorbidities, Kt/V, dialyzer, smoking, albumin, and mineral metabolism markers including serum calcium, phosphorus, intact parathyroid hormone, 25-hydroxyvitamin D, 1,25-dihydroxyvitamin D, and FGF23.

Results: Mean age was 58±14 years, 56% were female, and 63% were black. Median (IQR) CRP and IL-6 levels were 6.1 (2.6-15.2) µg/mL and 3.2 (1.7-6.9) pg/mL, respectively. Over mean 2.8 years follow-up, there were 582 deaths, 514 cardiovascular events, and 499 infectious events. Among subjects with levels in the highest quartile compared to the lowest quartile, both CRP and IL-6 were significantly associated with all-cause mortality in adjusted analyses, odds ratio (OR) 1.96 (95% CI, 1.27-3.02) and 1.51 (95% CI, 1.02-2.33), respectively. However, only CRP, was associated with cardiovascular disease events (OR 1.90, 95% CI, 1.04-3.44) and infectious events (OR 3.84; 95% CI, 1.37-10.74) among subjects with levels in the highest quartile compared to the lowest quartile.

Conclusions: CRP and IL-6, were significantly associated with all-cause mortality independent of mineral metabolism abnormalities. Only CRP was significantly associated with cardiovascular disease and infectious disease events independent of mineral metabolism abnormalities among subjects in the HEMO trial.

Assessment of Protein-Energy Wasting: Comparing a New PEW Score and the MIS in Chronic HD Patients
Camiel LM de Roij van Zuidewijn,1 Muriel P. Grooteman,2 Peter J. Blankesmit,3 Menso Jan Nubé,1 Pieter M. Ter Wee,1 1Nephrology, UU Medisch Centrum, Amsterdam, Netherlands; 2Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands.

Background: the assessment of protein-energy wasting, a syndrome of decreased body protein and energy fuels, remains debated. Recently, a French group introduced a new PEW score, encompassing BMI, serum creatinine, pNPA and serum albumin. In a cohort of chronic hemodialysis patients, we compared the predictive value of this score with the Malnutrition Inflammation Score (MIS) using all-cause mortality as end point. Furthermore, we investigated which of these scores correlates best with quality of life (QOL).

Methods: from data of the CONvective TRAnsport STudy (CONTRAST), the new PEW score and the MIS were determined at baseline. QOL was measured with the Kidney Disease QOL-Short Form 36, which results in 2 general and 12 kidney-disease specific domains of QOL. Discrimination and calibration for mortality were tested by Cox regression models adjusted for important confounding variables: demographics, comorbidities, Kt/V, dialyzer, smoking, albumin, mineral metabolism markers including serum calcium, phosphorus, intact parathyroid hormone, 25-hydroxyvitamin D, 1,25-dihydroxyvitamin D, and FGF23.

Results: 489 out of 714 patients were analyzed. 183 died during follow-up (mean 3.7±1.7 years). Discrimination for mortality was higher for MIS than the new PEW score (Harrell’s C statistic 68.0 (95% CI 65.7-69.8) and 61.0 (95%CI 59.0-63.3), respectively). Furthermore, mortality calibration was adequate for MIS (p=0.65), but not for the new PEW score (p<0.05). Lastly, MIS correlated with 13 domains of QOL (p<0.12), whereas the new PEW score only correlated with the physical component score (p=0.18).

Conclusions: both the MIS and the new PEW discriminate for mortality, but the MIS performs better. Furthermore, only the MIS is properly calibrated. Third, the MIS correlates with more QOL domains with higher correlation coefficients. Therefore, we conclude that MIS is preferred over the new PEW score in assessing PEW.

FR-PO857

Change in MIS Over 1 Year Is Not Associated with Mortality in Chronic Hemodialysis Patients
Camiel LM de Roij van Zuidewijn,1 Muriel P. Grooteman,1 Menso Jan Nubé,1 Peter J. Blankesmit,3 Pieter M. Ter Wee,1 1Nephrology, UU Medisch Centrum, Amsterdam, Netherlands; 2Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands.

Background: protein-energy wasting, a state of decreased body protein and energy fuels, has been associated with increased mortality as measured by the Malnutrition Inflammation Score (MIS), a composite, clinical, nutrition-related score. Longitudinal data on this score, however, are limited. We checked whether a change in MIS over 1 year of follow-up is associated with mortality.

Methods: data from CONTRAST were used, a well-defined cohort of end-stage kidney disease patients. Patients were selected for analysis if MIS was available at baseline (M0) and at 12 months (M12). Delta (Δ) MIS was calculated as MIS (M12) – MIS (M0). As the
association between ΔMIS and mortality was not linear; patients were divided into quartiles of ΔMIS. Cox proportional hazards models, crude and adjusted for potential confounders, were used to calculate hazard ratios (HRs) of patients with severe deteriorating MIS (increase >2 points), mild deteriorating MIS (increase of 1 or 2 points), stable MIS versus patients with an improving MIS.

Results: 404 patients were available for analysis. Mean age was 63.0±13.5 and 62.4% were male. During follow-up (median 3.1 years), 135 patients died. Median ΔMIS was 1.0 (IQR -1.0 to 3.0). Survival curves are shown in fig. 1. HR of patients with a mild deteriorating or stable MIS versus patients with an improving MIS was 0.85 (95%CI 0.53-1.39) and 0.97 (95%CI 0.56-1.67), respectively; for patients with a severe deteriorating MIS, HR was 1.63 (95%CI 1.02-2.51). After correction for age, sex, dialysis vintage and dialysis modality, this association did not remain significant (p=0.1).

Conclusions: a change in MIS over 1 year is not associated with mortality in a multivariable survival analysis.

FR-PO858
Soluble CD14, a Marker of Endotoxemia, Associates with Survival and Cardiovascular Disease in CKD Patients
Ruben Poesen,1 Ian Barrows,1 Ali Ramezani,2 Pieter Evenepoel,3 Kathi Claessens,4 Bjorn Meijers,5 Dominic S. Raj,2 *Nephrology, Univ Hospitals Leuven, Belgium; 1Renal Diseases and Hypertension, George Washington Univ.

Background: CKD goes along with gut microbial dysbiosis and gut barrier dysfunction, possibly contributing to endotoxin translocation. Subsequent binding of endotoxin to toll-like receptor-4 and its co-receptor CD14 activates the innate immune system. As half-life of systemic endotoxin is very short, soluble CD14 (sCD14) has been proposed as better marker of endotoxin exposure. Whether sCD14 relates to adverse outcome in CKD patients not yet on dialysis is unknown.

Methods: We performed a prospective study in CKD patients stage 1-5. Plasma sCD14 was determined with ELISA. Determinants of sCD14 were examined with regression analysis. The relationship between sCD14, survival and cardiovascular disease was determined using Cox proportional hazard analysis.

Results: 495 CKD patients were followed from 2005 until 2010. Median plasma level of sCD14 was 11.6 μM (IQR 5.7–21.8). We observed a highly significant inverse correlation between sCD14 and serum TMAO (rho -0.71, P < 0.0001). During follow-up, we noted a total of 51 deaths and 75 cardiovascular events. In univariate Cox proportional hazard analysis, sCD14 was a significant predictor of mortality (HR 1.521 (1.183 – 1.956), P < 0.0001) and cardiovascular disease (HR 1.570 (1.283 – 1.921), P < 0.0001). However, significance was lost after adjustment for eGFR for overall mortality (HR 1.126 (0.795–1.647), P=0.10).

Conclusions: Serum levels of TMAO rise in parallel to a declining renal function and further analysis of 24h urine samples is ongoing to elucidate its renal handling. In this European cohort of CKD patients, we were not able to find an association between TMAO and adverse outcome that is beyond renal function, which is in contrast to previous observations in US populations, both general and CKD. This may question the validity of TMAO as a universal biomarker for cardiovascular disease, possibly due to population-specific differences in diet and/or microbial metabolism.

FR-PO860
Microbiota Derived Phenylacetylglutamine Associates with Survival and Cardiovascular Disease in CKD Patients
Ruben Poesen, Pieter Evenepoel, Bjorn Meijers. Nephrology, Univ Hospitals Leuven, Belgium.

Background: Lately, there is increasing interest in gut microbiota derived uremic retention solutes as driving force behind adverse outcome in CKD. Both p-cresyl sulfate and indoxyl sulfate are considered representatives of this group, also commonly referred as to protein-bound solutes due to their high protein binding and dependence on active tubular secretion for renal clearance. Phenylacetylglutamine is another microbial metabolite subjected to high tubular secretion, although protein binding is rather low. We questioned whether this solute also relates to adverse outcome in CKD patients not yet on dialysis.

Methods: We performed a prospective study in CKD patients stage 1-5. Serum levels of phenylacetylglutamine were determined using LC-MS. Correlation between eGFR and serum phenylacetylglutamine was explored using Spearman’s rank correlation analysis. The relationship between phenylacetylglutamine, survival and cardiovascular disease was examined using Cox proportional hazard analysis.

Results: 488 CKD patients were followed from November 2005 until December 2010. Median serum level of TMAO was 11.6 μM (IQR 5.7–21.8). We observed a highly significant inverse correlation between eGFR and serum TMAO (rho -0.71, P < 0.0001). During follow-up, we noted a total of 51 deaths and 75 cardiovascular events. In univariate Cox proportional hazard analysis, TMAO was a significant predictor of mortality (HR 1.521 (1.183 – 1.956), P < 0.0001) and cardiovascular disease (HR 1.570 (1.283 – 1.921), P < 0.0001). However, significance was lost after adjustment for eGFR for overall mortality (HR 1.126 (0.795 – 1.647), P=0.10).

Conclusions: Serum levels of TMAO rise in parallel to a declining renal function and further analysis of 24h urine samples is ongoing to elucidate its renal handling. In this European cohort of CKD patients, we were not able to find an association between TMAO and adverse outcome that is beyond renal function, which is in contrast to previous observations in US populations, both general and CKD. This may question the validity of TMAO as a universal biomarker for cardiovascular disease, possibly due to population-specific differences in diet and/or microbial metabolism.
FR-PO861
Sarcopenia Among Prevalent Hemodialysis Patients: Weighing the Evidence

Piyawan Kittisukulnam,1 Juan Jesus Carrero,2 Glenn Matthew Chertow,2 George A. Kaysen,4 Kirsten L. Johansen,1 1UCSF; 2Karolinska Inst; 3Stanford Univ; 4UC Davis.

Background: There is no consensus on the best way to define sarcopenia in ESRD. Use of muscle/height (H) is suggested by geriatric societies but may underestimate sarcopenia, particularly in the setting of excess adiposity. We compared three definitions of sarcopenia in a prevalent HD cohort.

Methods: ACTIVE/ADIPOSE enrolled HD patients from San Francisco and Atlanta from 6/09 to 8/11. Bioelectrical impedance spectroscopy was performed before a midweek dialysis session (n=645), and total-body muscle mass was estimated using an equation containing age, sex, body weight (BW), and intracranial water. We defined sarcopenia as muscle mass ≥2SD below sex-specific means for adults 18-49 y from NHANES data indexed to Ht, %BW, and body surface area (BSA) by DuBois formula. We compared the prevalence of low muscle mass among the three methods and assessed their correlation with handgrip strength.

Results: Mean age was 57±14 years, 41% were women, 61% black. The prevalence of sarcopenia was 8% by muscle/Ht, 25% by muscle/%BW and 32% by muscle/BSA. Most sarcopenic patients by muscle/BSA had normal muscle mass, while >50% of sarcopenic patients by %BW were obese. Almost none of the overweight or obese patients were identified as sarcopenic by muscle/Ht.

Conclusions: The imbalance in gut microbiota associated with alterations in colonic epithelium contributes to the accumulation of gut-derived uremic toxins in chronic kidney disease (CKD) patients. Therapeutic strategies like probiotic supplementation may modulate the gut microbiota and reduce the toxins levels. It is known that the effect of probiotics' supplementation on indoxyl sulfa levels in non-dialysis CKD patients.

Methods: This double-blind, placebo-controlled trial, 29 non-dialysis CKD patients were recruited. Patients were randomized to receive probiotic (1 capsule, containing 30 billion of colony forming units - S. thermophilus, L. acidophilus, and B. longum, n=17) or placebo (n=12) for 3 months. IS plasma levels were quantified by HPLC, calprotectin and protein C reactive were analyzed by immunoenzymatic assay. Five patients in probiotic group and three in placebo were lost to follow-up.

Results: Plasma IS increased significantly in patients who received probiotics whereas the other parameters did not change.

Underline represents presenting author.
rats. The overall bacterial community composition was compared according to the UniFrac distance metric among control rats, CKD rats, and CKD + AST-120 rats. A principal coordinate analysis plot revealed clustering of each group. We identified the intestinal microbiome containing tryptophanase and/or tyrosine phenol-lyase gene in the genome sequences from NCBI bacterial genome. These enzymes metabolize tryptophan to indole and tyrosine to phenol, respectively.

Conclusions: Our data suggest that UT production is not only the cause of uremic symptoms but also correlated with a subset of indigenous gut microbes and affects the composition of gut microbiota.

FR-PO865

Association of Urine Volume at the Start of Dialysis and Subsequent Changes in Serum Albumin Level in Incident Hemodialysis Patients Rieko Furuichi,1 Yoshitsugu Obi,1 Connie Rhee,1 Steven M. Brunelli,2 Joline L.T. Chen,1 Anna Mathew,1 Tae Hee Kim,1 Elani Streja,4 Csaba P. Kovásvy,4 Kamyr Kalantar-Zadeh,1 1UC Irvine; 2Davita Clin Research; 3Hofstra North Shore-LIJ Health System; 4UTHSC.

Background: Previous studies have shown that low serum albumin (Alb) levels are associated with higher mortality in hemodialysis (HD) patients. While serum Alb is a critical inflammatory and nutritional marker, low Alb may also result from albuminuria. It is unknown if a change in serum Alb over time is due to the loss of residual kidney function. While data on urine Alb was unavailable, we hypothesized that higher urine volume (UV) correlated with a decrease in Alb.

Methods: Among 38,504 incident HD patients receiving care from a large dialysis organization from 2007-2011, we examined serum albumin level trajectory over 5 years (divided into 20 patient quarters) across five strata of baseline UV: <300, 300-<600, 600-<900, 900-<1200, >1200 mL. The association between baseline UV and serum albumin trend was examined using mixed effects models with adjustment for gender, age, race, kidney disease, and insurance type.

Results: Patients were 62±15 years old, 38% female, 28% black, and 46% diabetic. Higher baseline UV was incrementally associated with higher Alb levels across strata: 3.44±0.48g/dL, 3.50±0.46g/dL, 3.57±0.44g/dL, 3.59±0.45g/dL, and 3.65±0.46g/dL respectively. [Figure] Serum Alb increased over the first 6 patient quarters (18 months) on dialysis and then stabilized. Patients with higher UV not only had a higher baseline serum Alb level, but also maintained a higher serum Alb level over follow-up.

Conclusions: Higher baseline UV appears to be associated with sustained higher serum Alb levels over time. Improvement in hypoalbuminemia as a result of transition to dialysis therapy appears to be independent of residual kidney function and may suggest an inherent advantage of dialysis initiation.

Individual Variation of Hippuric Acid and P-Cresyl Sulfate Plasma Levels Correlate with Variation of Intestinal Microbial Phyletypes in Hemodialysis Patients Greet Lrl Glorieux,1 Sara Vieira-Silva,2 Sunny Elloot,1 Eva Schepers,1 Annemieke Dhondt,1 Raymond C. Vanholder,1 Jeroen Raes,2 Geert Huys,2 Marie Joossens,2 Renal Div, Ghent Univ Hospital, Gent, Belgium; 3Microbiology and Immunology, KULeuven, Leuven, Belgium; 4Microbiology, Ghent Univ, Gent, Belgium.

Background: In chronic kidney disease (CKD), a myriad of metabolites accumulate in the circulation. A substantial part is generated by intestinal microbota. We hypothesize that there is a link between plasma levels of these uremic metabolites and the composition of the intestinal microbiota.

Methods: Over 4 months, up to 8 consecutive plasma and fecal samples from 16 hemodialysis patients (14M/2F, 74±10y; vintage 43±30mo) were collected. Uremic metabolites were quantified by UPLC. Fecal microbial DNA was amplified for 16S DNA (V4 hypervariable region) sequencing (Illumina MiSeq). After quality and chimera filtering (UCHIME) data was rarefied to 10,000 reads/sample and taxonomically annotated (RDP).

Conclusions: Gut microbiota in HD patients were significantly different compared to healthy controls (p<0.05). Many HD associated features were correlated with specific intestinal bacteria, such as bifidobacteria and eubacteria. The differences were neither in the microbial community detection nor in the microbial community composition.

Decreased Vitamin K Intake in Italian Hemodialysis Patients Maria Fusaro,1 Claudia D’Alessandro,1 Marrianna Noale,1 Giovanni T rippi,1 Lucia Bonfante,2 Nicola Veronese,1 Irene Santinello,3 Sabina Zambon,1 Sandro Giannini,4 Maurizio Gallieni,2 Adarnasius Cupitoni.1 1CRN - Padua, Italy; 2Div of Nephrology Dept of Clinical and Experimental Medicine, Univ of Pisa, 3Nephrology Unit, Univ of Padua; 4CNR-IFC Clin. Epid. and Physiopathol. of Renal Dis. and Hypert. of Reggio Calabria; 5Clinica Medica 1, Univ of Padua, Italy; 6Univ of Padova; Dialysis Unit St Carlo, Milan, Italy.

Background: Vitamin K is involved in the production of Bone and Matrix GlA Proteins (BGP and MGP, respectively), regulating bone and vascular health. We carried out a pilot study to evaluate vitamin K intake in hemodialysis (HD) patients.

Methods: We measured vitamin K1 intake (7-day food record) in 78 Italian hemodialysis patients (48 M, 30 F) compared to intake in 39 healthy adults (28 M, 11 F).

Results: HD patients had a mean (± SD) age of 62.8±15.9 years, median dialytic age of 97 months, mean BMI of 25.4±4.5 Kg/m2. Mean serum levels of interest for CKD-MBD were: Ca 9 mg/dL, P 4.3 mg/dL, PTH 231.5 pg/mL, ALP 81.5 U/l. Control group mean age was 64.1±13.9 years. HD patients had a significantly lower intake of vitamin K1 compared to controls (see Table). We also evaluated and compared between HD patients and controls the intake of other fat soluble vitamins and of nutrients closely associated with bone and mineral disorders in CKD patients (see table). All were decreased in HD patients.

Conclusions: This vitamin K intake study is the first carried out on Italian diet. We found a decreased intake of Vitamin K1 in HD patients. This finding supports the hypothesis of supplementing vitamin K1 for the prevention of vascular calcifications and bone disorders in HD patients. Benefits of vitamin K1 supplementation should be proved by a randomized trial.

Association of Geriatric Nutrition Risk Index with Body Fluid Composition, Renal Adverse Outcomes and Mortality in Patients with Chronic Kidney Disease Rekbin Tai, Yasushi Ohashli, Shbosuke Aoki, Shizuka Kobayashi, Osamu Akizawa, Ken Sakai. Dept of Nephrology, School of Medicine, Faculty of Medicine, Toho Univ, Tokyo, Japan.

Background: Decreased body stores of protein and energy fuels may express by the geriatric nutritional risk index (GNRI) consisting of body mass index (BMI) and serum albumin levels. We studied the association of the GNRI with body fluid composition, renal adverse outcomes and all-cause mortality in patients with chronic kidney disease (CKD).

Methods: Body fluid composition was measured in 306 patients with CKD from 2005 to 2014 and was separated into three components—(a) free water mass consisting of fluid, fat, and minerals, (b) intracellular water (ICW) content, and (c) extracellular water (ECW) content. Patients were categorized according to tertiles of GNRI levels. Of those, 275 patients were followed until March 2015. The adverse renal outcomes were defined by a decline of 50% or more from baseline glomerular filtration rate or initiation of renal replacement therapy.

Results: Patients with the lower tertiles of the GNRI levels were more likely to be higher age, have a lower BMI, diastolic blood pressure, serum albumin, hemoglobin, glomerular filtration rate, and proteinuria (P < 0.05). In the body fluid composition, those tended to have lower free water mass (r = 0.73, P < 0.001) and the ratio of extracellular water to
intracellular water (r = 0.37, P < 0.001). Compared with patients with the middle tertile of the GNRI levels during a median 2.5-year follow-up, the lowest tertile of the GNRI levels had higher mortality (6.8 vs. 1.7 per 100 patient-years, P < 0.001), but had no worse adverse renal outcomes (16.5 vs. 9.0 per 100 patient-years, P = 0.08). In multivariate analysis, the lower GNRI levels independently remained as a risk factor for all-cause mortality (hazard ratio, 3.16; 95% CI, 1.30–8.84; P < 0.001).

Conclusions: The GNRI may be a simple and useful tool for predicting the risk of mortality even in CKD population including patients with massive proteinuria. These findings emphasize the importance of adequate body stores of protein and energy fuels in patients with CKD.

FR-PO869
A Novel Index for Estimation of Sarcopenia Mass Using Biomarkers of Kidney Function: Sarcopenia Index
Kianoush Banazi-Kashani,1,2 Lucie Kukralova,3 Erin N. Frazee,4 Rahul Kashyap,5
1. Div of Nephrology and Hypertension, Dept of Internal Medicine, Mayo Clinic, Rochester, MN; 2. Div of Pulmonary and Critical Care, Dept of Internal Medicine, Mayo Clinic, Rochester, MN; 3. Faculty of Medicine in Hradec Kralove, Charles Univ, Prague, Czech Republic; 4. Dept of Pharmacy, Mayo Clinic, Rochester, MN.

Background: Sarcopenia is associated with poor patients’ outcomes in Intensive Care Unit (ICU). Tools to evaluate sarcopenia are DXA scan, CT and MRI, which may not be feasible for critically ill patients. We hypothesize a novel index which can be used as a surrogate for sarcopenia among ICU patients.

Methods: This is a secondary analysis of prospectively enrolled critically ill patients. Adult ICU patients (>18 years) with shock, sepsis, use of IV antibiotics and contrast media exposure, in 24 hours of enrollment, intra-abdominal hypertension or severe Trauma were included. We excluded patients with pre-existing acute kidney injury, pregnancy, and kidney transplant, or those who were on dialysis or were moribund. We measures paraspinal muscle surface area at L3 level, using Slice-O-Matic software (TomoVision®; Magog, Canada). Sarcopenia Index (SI) was calculated as [Serum Creatinine (Scr) X 100] / [Paraspinal Muscle Surface Area] X 100.

Results: A total of 226 patients met the inclusion criteria. Among these, 110 patients who had abdominal CT within ± 4 weeks of their index ICU admission were included in the final analysis. The median age (IQR) was 67 (57–77) years and 59 (54%) were male. SI and Paraspinal Muscle Surface Area were found to be statistically correlated (R² = 0.26, p < 0.0001).

Conclusions: SI has a fair correlation with gold standard in critically ill patients. This index would be a surrogate for sarcopenia for patients who cannot tolerate transfer to imaging testing.

FR-PO870
Association with Activities of Daily Living and Geriatric Nutritional Risk Index
Healthy Liver Foundation, Tokyo, Japan; 2. Dept. of Medical Informatics, Tokyo Medical and Dental University, Tokyo, Japan; 3. Dept. of Internal Medicine, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan.

Background: Protein energy wasting (PEW) is a typical status of Malnutrition seems to be a prevalent complication in end-stage renal disease (ESRD), and is associated with poor prognosis. We previously reported that Geriatric Nutritional Risk Index (GNRI) is useful for a prevalent complication in end-stage renal disease (ESRD), and is associated with poor prognosis. We previously reported that Geriatric Nutritional Risk Index (GNRI) is useful for predicting the risk of mortality in HD patients.

Methods: This is a secondary analysis of prospectively enrolled critically ill patients. Adult ICU patients (>18 years) with shock, sepsis, use of IV antibiotics and contrast media exposure, in 24 hours of enrollment, intra-abdominal hypertension or severe Trauma were included. We excluded patients with pre-existing acute kidney injury, pregnancy, and kidney transplant, or those who were on dialysis or were moribund. We measures paraspinal muscle surface area at L3 level, using Slice-O-Matic software (TomoVision®; Magog, Canada). Sarcopenia Index (SI) was calculated as [Serum Creatinine (Scr) X 100] / [Paraspinal Muscle Surface Area] X 100.

Results: A total of 226 patients met the inclusion criteria. Among these, 110 patients who had abdominal CT within ± 4 weeks of their index ICU admission were included in the final analysis. The median age (IQR) was 67 (57–77) years and 59 (54%) were male. SI and Paraspinal Muscle Surface Area were found to be statistically correlated (R² = 0.26, p < 0.0001).

Conclusions: SI has a fair correlation with gold standard in critically ill patients. This index would be a surrogate for sarcopenia for patients who cannot tolerate transfer to imaging testing.
epithelial cytotoxicity. Note: MgT has significantly lower GI-effects (bleating and diarrhea) than other Mg formulations. These results warrant further in vivo and clinical studies to investigate the beneficial role of MgT in protecting against cisplatin-AKI.

**Impact of Uremic Serum on the Barrier Function and Inflammation in Human Colonocytes**  
Laila Santos Andrade,1 Maria Dalboni,2 Jose Tarcisio Giffoni,2 Caren Cristina Grabulosa,2 Lilian Cuppari,2,3 *1 Nutrition Education Program, Federal Univ of São Paulo, São Paulo, Brazil; 2 Medicine, Div of Nephrology, Federal Univ of São Paulo, São Paulo, Brazil.

**Background:** In chronic kidney disease (CKD) it has been suggested that alterations of the gut are associated with inflammatory state and uremic toxicity. Studies suggest that uremia may impair the intestinal barrier function, by promoting increased intestinal permeability. In this study we aimed to evaluate the in vitro effect of uremic serum on the transepithelial electrical resistance (TER), inflammation and apoptosis in the intestinal epithelial cells.

**Methods:** Pools of serum were prepared from blood samples from patients maintained on hemodialysis (Pre-HD and Post-HD), and of patients with CKD stage 4 (NND-CKD). A pool of serum form healthy individuals served as control (CTL). When the TER exceeding 1,000 Ω cm² was reached, the T84 cells were incubated for 24 h in medium containing 10% pool of serum from each group. At the conclusion of the incubation period, the TER was measured again and the following parameters were determined by flow cytometry: expression of toll-like receptor (TLR), production of reactive oxygen species (ROS) and apoptosis. TNF-α and IL-6 in the culture supernatant was determined by ELISA. A total of nine experiments were performed.

**Results:** No differences among groups were found regarding TER (p=0.443), apoptosis (p=0.751), ROS (p=0.999), expression of TLR-2 (p=0.493), TLR-4 (p=0.418) and TLR-9 (p=0.937) and secretion of TNF-α (p=0.438). IL-6 secretion was higher (p<0.001) by cells incubated with post-HD pool (2.07±0.53 pg/ml) when compared with cells incubated with CTL pool (0.67±0.35), NND-CKD (0.61±0.53) and pre-HD (0.11±0.45).

**Conclusions:** The results obtained from this model suggest that uremic serum per se does not seem to impair the integrity of intestinal epithelial cells. The increased IL-6 secretion in post-HD condition may be a consequence of pro-inflammatory stimulus of the dialysis process.

**Prediction of One-Year Mortality and Hospitalization Risk Using Nutritional Indicators and Their Trajectories in a Large Prevalent Hemodialysis Cohort**  
Michelle M.Y. Wong,1 Stephan Thijsse,2 Yuedong Wang,2 Len A. Usuy,1 Qingqing Xiao,1 Peter Kotanko,1 Franklin W. Maddux,3  
1 Renal Research Inst; 2 Univ of California - Santa Barbara; 3 Fresenius Medical Care North America.

**Background:** Existing nutritional scores developed in the hemodialysis (HD) population do not consider temporal trajectories of nutritional parameters. We aimed to develop predictive models for mortality and hospitalization using readily available nutritional indicators and their rates of change.

**Methods:** Using retrospective data from a large US HD provider, a cohort with HD vintage ≥1 year (N=21,082 and N=23,384 in mortality and hospitalization analyses, respectively) was randomly split 2:1:1 for model development, testing and validation. Parameters included demographics, nutritional/inflammation parameters, and slopes of all continuous variables over 6 months. Follow-up period was January-December 2012. Performance of generalized linear models and generalized additive models (GAM) was evaluated with area-under-the-curve (AUC), sensitivity and specificity.

**Results:** For both mortality and hospitalization prediction, GAM performed best. The best mortality model included neutrophil:lymphocyte ratio (NLR) slope, serum bicarbonate slope, albumin, creatinine, age, sex and vintage (AUC 0.85, 95% CI 0.83-0.86; sensitivity 0.70; specificity 0.83). The best hospitalization model included NLR slope, albumin, congestive heart failure, serum bicarbonate slope, creatinine, serum phosphate slope, vintage, diabetes, serum phosphate, volume of urea distribution, age and enPCR (AUC 0.70, 95% CI 0.62-0.79; sensitivity 0.41; specificity 0.88).

**Conclusions:** We developed novel and accurate predictive models for mortality and hospitalization using nutritional indicators and their slopes over time. Future studies are needed to assess if its application can improve nutritional intervention allocation and outcomes in HD patients.

**Funding:** Pharmaceutical Company Support - Renal Research Institute

**Extracellular Fluid/Intracellular Fluid (ECF/ICF) Volume Ratio Is A Novel Risk Indicator of Death and Highly Related to Malnutrition-Inflammation-Arteriosclerosis (MIA) Complex in Hemodialysis (HD) Patients**  
Eunjung Kim, Soyon Rhee, Jiwon Ryu, Hee Jung Jeon, Jungsung Noh, Ja-Ryong Koo. Nephrology, Hallym Univ Hospital, Dongtan/Seoul, Korea.

**Background:** Fluid overload and malnutrition are well recognized risk factors contributing to the high mortality in HD patients. Recent studies suggest pathophysiological link between fluid overload and malnutrition as a part of MIA complex. Because the ECF and ICF volume can represent fluid volume and nutritional status respectively, ECF/ICF ratio could be defined as a novel integrated marker reflecting both fluid overload and malnutrition. Accordingly we investigated the relationship of ECF/ICF ratio to survival in the context of MIA complex in chronic HD patients.

**Methods:** 77 HD patients (age 53±13 year, diabetes 38%) were prospectively enrolled. ECF/ICF volume was measured by multi-frequency bioimpedance analysis. Nutrition, inflammation, arteriosclerosis and volume status were measured by serum albumin, C-reactive protein (CRP), pulse wave velocity (PWV) and serum B-type natriuretic peptide (BNP) respectively.

**Results:** Mean ECF/ICF ratio was 0.56±0.06 and cut-off value for maximum discrimination of survival was 0.57 by ROC curve. As compared with low ECF/ICF group (ratio<0.57, 58%), high ECF/ICF group (ratio>0.57, 42%) had higher all-cause mortality, CRP, PWV, BNP and lower serum albumin level. During the 5-year follow-up, 24 all-cause death occurred (18 in high ECF/ICF group versus 6 in low ECF/ICF group, log rank P<0.001). In Cox analysis adjusted for age, diabetes, BP and cardiac function, the ECF/ICF ratio was an independent predictors of all-cause death (HR=1.25, 95% CI=1.01-1.54, per 0.01 in ECF/ICF ratio) and nullify the effect of MIA component and volume marker on survival. The degree of malnutrition (albumin), inflammation (CRP), arteriosclerosis (PWV) and fluid overload (BNP) were correlated well with ECF/ICF ratio.

**Conclusions:** Chronic HD patient with high ECF/ICF ratio is not only fluid overloaded but malnourished and have stiff artery with more inflammation. As a novel integrated marker of fluid overload and malnutrition, ECF/ICF ratio is highly related to MIA complex and a major risk indicator of death in chronic HD patients.

**FR-PO876**

**Weight Gain After Listing Independently Predicts Pre-Transplant Sensitization Status**  
Prithika Shrivastava,1 Krista L. Lentine,2 Ankit Sakhija,1 Fidel Barrantes,1 Diane M. Cibrik,1 Yihung Huang,1 Abhijit S. Naik,1  
1 Univ of Michigan; 2 Saint Louis Univ; 3 Renal Medical Associates, NM.

**Background:** Non-allodonnue stimuli such as infections, vaccinations and pro-inflammatory events cause sensitization to HLA antibodies and increased panel reactive antibodies. Obesity is recognized as an inflammatory state. Given relationship between obesity and inflammation we speculated that weight gain on the waitlist may increase sensitization status at the time of transplantation.

**Methods:** Using national data from the Organ Procurement and Transplantation Network we identified first time kidney only transplant recipients, aged 18-70, transplanted between January 1,2009 and June 30,2013. Previous non-renal transplants were excluded. A calculated panel reactive antibody of 20% or more at the time of transplant was considered to be “sensitized”. Using a priori chosen variables we performed a logistic regression model with sensitized status at time of transplantation as the dependent variable and change in BMI from listing to transplantation, BMI at transplant, recipient age, prior sensitization status, prior pregnancy, dialysis time and race as independent variables.
Results: Among 55,894 patients transplant recipients. 39.45 % were female of which 67.32% were previously pregnant. Overall 15.12% had received prior blood transfusions. Mean BMI at waiting list and transplantation was similar at 28.4± 5.5 kg/m². Greater than 50 % patients with BMI ≥ 30 kg/m² at listing had an increased their BMI by time of transplantation,while ≤50 % patients in BMI<30 kg/m² had lost weight. A 1-unit increase in BMI was associated with an increased risk of being sensitized.
aOR:1.01 (1.01-1.02). Other independent predictors included prior transplantation aOR:1.25 (1.18-1.33), AA race aOR:1.26 (1.19-1.32), pregnancy aOR:3.32 (3.04-3.63), dialysis time aOR:1.23 (1.11-1.14).

Conclusions: The majority of obese patients gain weight on the waitlist. We identified weight gain on the waiting list to be associated with a small but statistically significant increase in odds of being sensitized. Further studies are needed to determine the impact of malnutrition-inflammation complex on pretransplant sensitization.

FR-PO877
High Salt Diet Impairs the Immune Defense against Uropathogenic Escherichia coli in Murine Pyelonephritis
Katarzyna Jobin, Katharina Hochheiser, Maike Giesing, Christian Kurts.
Inst of Experimental Immunology, Univ of Bonn, Bonn, Germany.

Background: Recent studies demonstrated that NaCl stimulates immune responses, for example by promoting Th17 cells differentiation, macrophage recruitment into tissues and pro-inflammatory cytokine release from epithelial cell lines. Specifically, high salt diet (HSD) exacerbated experimental autoimmune encephalomyelitis and improved immune defense against L. major infection. Little is known about the influence of HSD on anti-microbial responses in the kidney – an organ with extremely high sodium chloride concentration.

Methods: Wild type female mice were given normal salt diet (NSD) or HSD one week prior to infection with uropathogenic E. coli into the bladder resulting in pyelonephritis development. 20 h after the infection, kidneys were harvested and analyzed for CFU and immune cell subsets by flow cytometry.

Results: HSD exacerbated pyelonephritis as measured by CFU. Additionally, in kidney medullas of mice fed HSD the number of PMNs, Ly6c^- macrophages and NK cells was significantly decreased in comparison with NSD fed mice. Although PMNs from mice given HSD produced more ROS than PMNs from mice on NSD, in vitro studies demonstrated that less mediatory PMNs from mice fed HSD than NSD were able to perform phagocytosis.

Conclusions: Contrary to the expectations, HSD worsened experimental pyelonephritis, possibly through affecting immune cell activation and/or migration into the kidney medulla. This finding may be of clinical significance and, if confirmed in human studies, decreasing salt intake during bladder infection or pyelonephritis could support antibiotic therapy. Further studies are needed to elucidate the immune mechanisms underlying the negative effect of HSD on pyelonephritis.

 Gut Microbiota Lactobacillus Protects against the Progression of Renal Impairment Through the Modulation of TLR2-Mediated Gut Barrier Stability in Rats
Ayumi Yoshifuku, Shu Wakino, Junichiro Irie, Takaya Tajima, Kazuhiro Hasegawa, Hirobumi Tokuyama, Hiroshi Itoh.
Keio Univ, Japan.

Background: Gut microbiota has been shown to have some role in the pathogenesis of various diseases and previous study demonstrated that Lactobacillus(Lact) decreased in number in CKD. In this study, we elucidated the significance of Lact in the pathogenesis of CKD.

Methods: Six-week-old spontaneously hypertensive rats (SHR) were rendered CKD by 5/6th nephrectomy (Nx). The SHR were divided into three groups; sham-operated SHR (SHR), SHR with Nx (Nx) and Nx given Lact (Nx+Lact). After 12 weeks, biochemical parameters, urinary protein excretion, IL-6, histological changes in the kidney, and molecular changes of tight junctions and TLR2 expression were explored. Furthermore, the changes of total renal protein and tissue were evaluated. The expressions of colon tight junction proteins were examined by immunoblotting.

Results: The gut flora analysis revealed that the decrease in Lact in Nx, which was restored in Nx+Lact. However, fecal uromic toxins did not show significant changes. Both serum indoxylsulfate and IL-6 increased in Nx. These increases were ameliorated in Nx+Lact. The decreases in the tight junction proteins Occludin and ZO-1 as well as in TLR2 in Nx were mitigated by Lact. In the pseudourease-free condition, Lact decreased the urinary protein excretion. In caco-2 cells, the downregulations of Occludin and ZO-1 by indole were ameliorated by Lact. OxPAPC inhibited the Lact-induced restoration of these tight junctions.

Conclusions: The supplementation of Lact improves the gut environment through the activation of TLR2 pathway. This improvement would contribute to the decrease in systemic uromic toxin levels, systemic inflammation and urinary protein excretion. This probiotic therapy can provide novel therapeutic strategy against the progression of CKD.

Nutrition Analysis Mobile Application in Patients with Chronic Kidney Disease

Chavakrit Krittanawong,1 Sakkarin Chirapongsatham,2,3 Zhen Wang,4 Hua Ann Jenny Lu.4 1. Div of Cardiovascular Disease, Mayo Clinic, Rochester, MN; 2. Div of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN; 3. Div of Gastroenterology, Dept of Medicine, Phramongkutklao Hospital and College of Medicine, Royal Thai Army, Bangkok, Thailand; 4. Dept of Healthcare Policy and Research, Mayo Clinic, Rochester, MN; 5. Div of Nephrology, Massachusetts General Hospital and Harvard Medical School, Boston, MA.

Background: While mobile phone applications have become increasingly important in the last decade, few eating healthy mobile applications exist for patients. Yet in their daily lives, patients on a restricted diet often lack instant access to health information with regards to the food that is in front of them. It is there therefore an objective of this pilot project to introduce a device that patients can utilize to overcome such problems.

Methods: The nutrition analysis application is named “GoFoody Project” and primarily consists of two functions: a scanning system and a recommendation system.

Results: The first major component of this invention is the food scanning and recognition process, which is comprised of two sub-processes: a food recognition and a barcode scanning. In the photo recognition, the user can take a picture of food and send it to the cloud database for further processing, regardless of their location. Second, the recommendation system compares the patient’s medical profile with their consumptions records in order to make health and dietary suggestions.

Conclusions: Over the next few years, we anticipated that this invention will be popular in grocery stores such as Walmart, Target, etc. We plan to demonstrate our invention to the healthcare industry by using the example of computer vision technology and cloud database.

Lipoxin A₄, Attenuates Obesity-Induced Adipose Inflammation and Associated Liver and Kidney Disease

Emma Borgoson,1 Kumar Sharma,2 Catherine Godson.3 1. Center for Renal Translational Medicine, Inst for Metabolomic Medicine, UC San Diego, San Diego, CA; 2. Diabetes Complications Research Centre, Conway Inst, Univ College Dublin, Dublin, Ireland.

Background: Visceral obesity and adipose inflammation is considered a driving force of systemic disease, e.g. chronic kidney disease (CKD). Inflammatory resolution is actively regulated by specialized pro-resolving mediators (SPMs), including the lipid LXA₄. Impairment of SPMs may underlie development of obesity-related pathology. Here we explored the therapeutic potential of LXA₄ in experimental obesity-induced systemic disease, e.g. liver cirrhosis and CKD.

Methods: C57BL/6 or Adiponectin-/- mice were fed a standard (10% fat) or high fat (60% fat) diet for 12 weeks. LXA₄ (5ng/g) and benzo-LXA₄ analogue (1.7 ng/g) were given as intravenous therapeutics i.p. 3 times weekly, between wk 5-12. Furthermore, omental adipose tissue biopsies were isolated from obese (BMI 35-50) bariatric surgery patients (n=4). Adipose explants were incubated with vehicle or LXA₄ (1 nM) for 6h at 37°C, and leukocytes were characterized by flow cytometry.

Results: Obesity caused distinct pathologies, including impaired glucose-tolerance, adipose inflammation, fatty liver and CKD. Lipoxins attenuated obesity-induced CKD; reducing glomerular expansion, mesangial matrix and urinary H2O2. Furthermore, LXA₄ reduced liver weight, serum alanine-aminotransferase and hepatic triglycerides. LXA₄ decreased obesity-induced adipose inflammation, attenuating TNF-α and CD14+ M1 macrophages (MΦs), while restoring CD206+ M2-MΦs and increasing Annexin-A1. Lipoxins did not affect renal or hepatic MΦs, suggesting protection occurred via attenuation of adipose inflammation. Lipoxins restored adipose expression of autophagy markers LC3-II and p62. LX-mediated protection was demonstrable in adiponectin-/- mice, suggesting that the mechanism was adiponectin independent. The ongoing clinical studies are characterizing whether Lipoxins promote an M1-to-M2 MΦ phenotype shift in human omental adipose tissue.

Conclusions: In conclusion, Lipoxins protect against obesity-induced systemic disease and these data support a novel therapeutic paradigm for treating obesity and associated CKD.

Prevalence of Protein-Energy Wasting Syndrome and Its Association with Anemia, Erythropoietin Resistance, Overhydration and Body Composition in Hemodialysis Patients

Carlos Adrián Chávez-Mendoza,1 José Luis Ortega Vargas, Jorge Osvaldo Montes Riveras, Ricardo Correa-Rotter, Olymka Vega-Vega.2 1. Nephrology and Mineral Metabolism, National Inst of Medical Science and Nutrition Salvador Zubirán, Mexico City, Mexico.

Background: The prevalence of protein-energy wasting syndrome (PEW) in Mexican hemodialysis (HD) patients is unknown. Accordingly, there is no information on which clinical, biochemical, quality of life (QL), and body composition (BC) variables are associated or predictive PEW in this population.

Methods: Observational comparative study that included 191 prevalent HD patients. BC was determined by BIS employing (BCM,Fresenius®), QL was measured with KDOQI and presence of PEW according to ISRN criteria.

Results: General characteristics are shown in Figure 1, prevalence of PEW was 22%(n=41). No differences between groups (with or without PEW) were present in age, Charlson index, number and type of drugs employed, time on dialysis, vascular access, history of PD or kidney transplant and hospitalization days in the last year. PEW patients had a higher prevalence of DM(p<0.04), lower Hb(p<0.006) and higher EPO requirement(p<0.04) despite similar iron reserves. In terms of BC, PEW patients had more overhydration (OH) and higher extracellular water (ECW), and lower lean and fat tissue indexes (TLT,FTI). Surprisingly, QL indicators were not different between groups. In a Cox multivariate logistic regression model analysis, predictors of PEW were: degree OH(OR 3.2,95% CI 1.2-8.3,p=0.001), and ECW(OR 0.51,95% CI 0.22-0.89,p<0.01).

Efficacy of Nutrition Counseling on Protein Intake Restriction in Chronic Kidney Disease Patients – Niigata Part of SOFT-J (Study on Regional Variation of FROM-J Intervention by JSN) 

**Background:** Low adherence is frequently observed in patients with chronic kidney disease (CKD) who are following a diet therapy. This study evaluated the efficacy of nutrition counseling focused on protein restriction for CKD patients in clinics by national registered dieticians using iPad and textbook used in FROM-J (Frontier of Renal Outcome Modification in Japan) study, aiming at promoting relationship between home doctor and nephrologist.

**Methods:** 47 patients with CKD stage 3 (eGFR 30-59 ml/min/1.73m²), age 40-85 were recruited. Nutrition counseling was conducted once for 30 min by national registered dieticians using iPad and textbooks in clinics without any dietician in the staff. Optimal protein and energy intake were prescribed as 0.9 g/kg/day and 25-30 kcal/kg/day, respectively. The amount of protein intake was estimated from dietary records and by 24 hours urine collection before and 2 months after counseling (pre/post, respectively).

**Results:** All patients recorded their daily diets, 24/7 provided 24 hours urine collections. Counseling significantly decreased protein intake (record pre 1.10 ±0.23 g/kg/day post 1.00 ±0.26 p<0.001, urine pre 1.02±0.29 post 0.91±0.22 p=0.04). Although energy intake slightly decreased (record pre 31.9±6.4 kcal/kg/day post 30.1±5.2 p=0.03), this was not below the prescribed optimal calories. Salt intake decreased in recorded data but not in urine data (record pre 8.4±2.8 g/day post 7.6±1.7 p<0.03, urine pre 9.0±4.2 post 9.1±4.4 p<0.86, respectively). There was no significant difference in body mass index, eGFR, HbA1c (diabetic patients), LDL cholesterol, uric acid and blood pressure.

**Conclusions:** iPad and textbook counseling by dieticians is effective in reducing protein intake without compromising necessary caloric requirements, even in clinics without regular nephrologist or dietary staff. Informational technology may be an effective method of delivering on-demand nutritional counseling that can directly benefit patient care.

**Activin B Has a Functional Role in Hepcidin Induction by Inflammation**

**Background:** Induction of the iron regulatory hormone hepcidin contributes to the anemia of chronic kidney disease by restricting iron availability. Bone morphoepoetic protein 6 (BMP6) signaling is a central transcriptional regulator of hepcidin. Recently, the transforming growth factor-β (TGF-β)/BMP superfamily member Activin B was implicated in hepcidin induction by inflammation via noncanonical SMAD1/5/8 signaling, but its mechanism of action and functional significance in vivo remain uncertain.

**Methods:** Hesp3 cells and primary hepatocytes were treated with Activin B, BMP6, or Activin A, without or with siRNA knockdown of Activin/BMP pathway components, and were tested for SMAD2/3 versus SMAD1/5/8 phosphorylation and hepcidin expression. Liver Activin B expression was measured and the effect of the Activin inhibitor follistatin-315 was examined in multiple rodent models of anemia of inflammation.

**Results:** Activin B, but not Activin A, stimulated SMAD1/5/8 signaling and hepcidin expression in liver cells to a similar degree ascanonical SMAD2/3 signaling, and with similar timecourse of peak and kinetics of induction. Activin B-induced hepcidin expression was blocked by the Activin type II receptors ACVR2A and ACVR2B, noncanonical BMP type 1 receptors ALK2 and ALK3, and SMAD5. The co-receptor homologulin (HV) bound directly to Activin B and facilitated Activin B-SMAD1/5/8 signaling. Activin B-SMAD1/5/8 signaling occurred selectively in hepatocyte-derived cells and was not enabled by HV in other cell types. Liver Activin B mRNA expression was increased in multiple rodent models of inflammation associated with increased hepcidin and hypoferrernia. Follistatin-315 had no effect on basal hepcidin expression, but blunted hepcidin induction by inflammation in mice.

**Conclusions:** Our data elucidate a novel mechanism for noncanonical SMAD activation by BMP/TGF-β superfamily members, and support a functional role for Activin B in hepatic induction of inflammation in vivo. Targeting the Activin B-hepcidin pathway may lead to new therapies for anemia of inflammation including the anemia of chronic kidney disease.

**Effects of a Very Low Protein Diet Supplemented with Amino and Keto Acids on Skeletal Muscle Protein Synthesis and Degradation in Patients with Chronic Kidney Disease**

**Background:** Chronic kidney disease (CKD) is characterized by progressive loss of muscle mass, an effect which could be accelerated by low (LPD) and very low protein diets (VLPD), even if essential amino/keto analogue (AA/KA) supplements are used. However, to the best of our knowledge, skeletal muscle protein metabolism adapts to a supplemented VLPD in CKD patients is still unexplored.

**Methods:** To determine the muscle responses to a supplemented VLPD (0.45 g/kg +0.1 g/kg AA/KA, 35 kcal/kg), as compared to a standard LPD (0.55 g/kg 35 kcal/kg), we subjected patients who reached the primary end-point.

**Results:** All patients recorded their daily diets, 24/7 provided 24 hours urine collections. Counseling significantly decreased protein intake (record pre 1.10 ±0.23 g/kg/day post 1.00 ±0.26 p<0.001, urine pre 1.02±0.29 post 0.91±0.22 p=0.04). Although energy intake slightly decreased (record pre 31.9±6.4 kcal/kg/day post 30.1±5.2 p=0.03), this was not below the prescribed optimal calories. Salt intake decreased in recorded data but not in urine data (record pre 8.4±2.8 g/day post 7.6±1.7 p<0.03, urine pre 9.0±4.2 post 9.1±4.4 p<0.86, respectively). There was no significant difference in body mass index, eGFR, HbA1c (diabetic patients), LDL cholesterol, uric acid and blood pressure.

**Conclusions:** iPad and textbook counseling by dieticians is effective in reducing protein intake without compromising necessary caloric requirements, even in clinics without regular nephrologist or dietary staff. Informational technology may be an effective method of delivering on-demand nutritional counseling that can directly benefit patient care.

**Risk of Anemia and Blood Transfusion following Reduction of Maximum ESA Doses**

**Background:** The cost of providing erythropoietin stimulating agents (ESAs) for renal patients is currently covered in the province of Alberta, Canada. Due to the high costs associated with therapy, the provincial funding agency reduced the maximum weekly ESA dose by 50%. We sought to determine the clinical impact of this policy change on the risk of severe anemia (hemoglobin [HGB] <90 g/L) and transfusions.

**Methods:** All patients in the Southern Alberta Renal Program with a HGB >90g/L and receiving more than darbepoetin 75ug/wk or epoetin 15000 units/wk were reduced to an equivalent of darbepoetin 75ug/wk in September 2013. Serum HGB, iron stores, serum albumin, and parathyroid hormone assessed at baseline, 3 months, and at 6 months (end of study). Blood transfusion data was extracted from provincial electronic records. Patients were returned to a higher ESA dose when the HGB declined to <90g/L. We performed Kaplan-Meier analysis and multivariable regression analysis to calculate the median time to a drop in HGB level to <90g/L (primary outcome) and the receipt of blood transfusions (secondary outcome) following ESA dose reduction. ESA doses were re-established in people who reached the primary end-point.

**Results:** Patients (mean age 61±16 years) met the inclusion criteria. The majority of patients were treated with hemodialysis (75%) and received darbepoetin (81%). The mean baseline darbepoetin dose (or equivalent for those treated with epoetin) was 110±26ug/wk; mean baseline HGB was 106±12g/L. A HGB of 90g/L was reached in 50% of the cohort by 4.1 months (median 1.8 months, IQR 0.4-2.8 months). Blood transfusions occurred in 15% of the cohort during the study and 12% in preceding 3 months (p=0.77). In multivariate analysis, only higher baseline HGB levels were associated with reduced hazard of a drop in HGB to <90g/L. Baseline ESA dose magnitude, and baseline iron stores was not independently associated with our primary outcome.

**Conclusions:** HGB declines below 90 g/L. In about four months following ESA dose reduction. The short-term risk of blood transfusion remains similar. The clinical and economic implications of this policy remain to be determined.

**FR-P090**

**Association of Moderate Ascorbic Acid Supplementation with Plasma Ascorbic Acid and Oxalate Levels in Prevalemt Hemodialysis Patients**

**Background:** Ascorbic acid (AA) supplementation may improve anemia in hemodialysis (HD) patients. Oxalate (Ox), an AA-metabolite, is excreted in the urine and is also removed during HD. When the plasma Ox concentration (plasma [Ox]) reaches 30 µM, Ox may deposit pathologically in organs. Moderate oral AA supplementation—up to 100 mg of AA/day—is often prescribed to HD patients. Of concern, patients who received earlier forms of HD could develop pre-HD Ox levels of 30 µM or higher when taking this moderate AA dose. We hypothesized that moderate AA use is not associated with an increase in pre-HD plasma [Ox] when patients receive high-flux HD.

**Methods:** In 2011, we surveyed outpatients on HD regarding AA supplement use. Pre-HD AA and Ox levels were measured. The treatment group consisted of patients who took moderate AA for more than 4 months. Control patients were patients who did not take moderate AA for more than 4 months.

**Results:** There were no difference in pre-HD plasma [Ox] (mean±SD) between the treatment and the control groups, 21.9±10.1 µM vs. 20.6±10.6 µM, respectively (P=0.42). Median plasma AA concentration was 47.2 µM (IQR 24.6-63.8) in the treatment group and 15.8 µM (IQR 8.5-67) in the control group, (P=0.001).

Chronic Kidney Disease Is Associated with Altered Muscle Mitochondrial Energies by Functional MR Spectroscopy and Optical Spectroscopy

Baback Roshanraza,1 Bryan R. Kestenbaum,2 Jorge Gamboa,3 Jonathan Himmelfarb,1 Ian H. De Boer,4 Kevin Conley.1 1Medicine, Kidney Research Inst - Univ Washington, Seattle, WA; 2Vanderbilt Univ, Nashville, TN.

Background: Exercise intolerance and muscle weakness are frequent clinical complications of CKD associated with adverse health outcomes, yet the pathophysiology underlying these conditions is poorly understood.

Methods: Cross-sectional study of in vivo muscle mitochondrial energetics using 31P Magnetic Resonance Spectroscopy and optical spectroscopy (MRS/OS) in 12 subjects with non-diabetic CKD (eGFR<60) and 26 controls. 31P MRS and OS were performed on the hand muscle under controlled ischemia. ATPflux (ATPase rate) was measured from hand muscle using Body Composition Monitor (Fresenius). The primary outcome was the coupling efficiency of mitochondrial oxidative phosphorylation ATP production (ATPflux) per unit of oxygen consumed (O2 uptake) or P/O ratio. Grip strength and timed up and go were assessed. Pearson’s correlation coefficient was calculated for univariable associations. We used multivariable linear regression adjusting for age.

Results: Mean age of CKD patients was 53±13yrs. Physical performance of the CKD group was no different from predicted normal values. Mean P/O values were 1.46±0.3 vs. 1.45±0.3 in controls. Correlation of P/O ratio age (r=-0.42), followed by eGFR (r=0.32). In contrast to controls, patients with CKD had higher O2 uptake (P=0.03) without concomitant change in ATPase rate.

Conclusions: Application of non-invasive tools reveals that CKD is associated with greater muscle O2 uptake reflecting uncoupling of oxidative phosphorylation. These results suggest altered mitochondrial respiration in skeletal muscle of patients with CKD prior to dialysis.

Improving Outcomes with Nutrition in Older People with Advanced Chronic Kidney Disease – Baseline Data from a Pilot Randomised Controlled Trial

Lisa Johansson,1 Mary Hickson,2 Edwina A. Brown.3 1Nutrition and Dietetics, Imperial College Healthcare NHS Trust, London, United Kingdom; 2Imperial Kidney and Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom.

Background: It is difficult to determine when to start dialysis in older people as creatinine and eGFR can be misleading. Dialysis start is often determined by weight loss, symptoms, potassium and fluid overload, all of which are potentially modifiable with nutrition. This pilot RCT aims to determine whether dietary interventions can result in improved patient outcomes, including time to dialysis, in older people with advanced chronic kidney disease (CKD).

Methods: Patients ≥65 years, with eGFR 10-20mls/min were randomised to an observational or intervention group (greater dietary input). Data will be collected every 6 months for up to 2 years: nutritional status (Subjective Global Assessment), symptoms (Palliative Outcome Scale – Symptoms Renal), function (6 metre walk gait speed test and Jamar handgrip dynamometer) and fluid overload using Body Composition Monitor (Fresenius).

Results: 80 patients were recruited, baseline data presented. The 2 groups have statistically similar baseline demographic and clinical characteristics. Overall, 30% have malnutrition of which 58% are overweight/obese. 28% have nutritionally relevant potentially uraemic symptoms (nausea, vomiting and/or poor appetite). Fluid overload (>2L) was observed in 22% of those that were assessed (n=58).

Conclusions: There is a high prevalence of indications for dietary interventions within older people with advanced CKD at baseline which may positively affect outcomes within two years.

Funding: Government Support - Non-U.S.
High Protein Intake in Relation to Incident End-Stage Renal Disease (ESRD) Among Blacks and Whites in the Southern Community Cohort Study (SCCS) - Rakesh Malhotra, Edmond Kato Kabagambe, Kerri L. Cavanaugh, William J. Blot, Tafat Alp Ikizler, Loren Lipworth. Vanderbilt Univ Medical Center.

Background: Dietary composition could contribute in part to observed racial disparities in ESRD incidence. Diabetes, a major risk factor for ESRD, may lead to differences in dietary intake and metabolism. We examined whether protein intake is associated with ESRD risk and whether the association varies by race and diabetes.

Methods: We conducted a nested case-control study of ESRD within the SCCS, a prospective study of low income blacks and whites in the southeastern US (2002-2009). Through 2012, 1,074 incident ESRD cases were ascertained by linkage with the USRDS, and matched to 3,230 controls on age, sex, and race. A validated food frequency questionnaire was administered at baseline. Odds ratios (OR) and 95% confidence intervals (CI) for ESRD were computed in relation to protein intake, expressed as daily % of total energy intake and modeled in 1 standard deviation (SD) increments in unconditional logistic regression models stratified by race and diabetes. ORs were adjusted for age, sex, BMI, education, income, hypertension, total energy intake and % energy from saturated and polyunsaturated fat.

Results: Median daily % energy intake from protein were higher among whites than blacks and those with vs without diabetes, but differences between ESRD cases and controls were small (15.9 and 15.7%, respectively, for blacks with diabetes, 14.6 and 14.6% for blacks without diabetes, 16.6 and 16.4% for whites with diabetes, and 15.1 and 15.1% for whites without diabetes). For a 1 SD (3.17%) increase in daily % energy intake from protein, adjusted ORs (95% CI) for ESRD were 1.18 (1.05-1.34) for blacks with diabetes, 1.06 (0.93-1.21) for blacks without diabetes, 0.89 (0.61-1.30) for whites with diabetes and 1.00 (0.74-1.33) for whites without diabetes.

Conclusions: Our results raise the possibility that among blacks with diabetes, a diet higher in protein is associated with increased incidence of ESRD. If confirmed, future studies might examine contributors leading to adverse outcomes associated with high protein intake in this subpopulation.

Background: The intestinal microbial flora consists of diverse bacterial species that inhabit the gastrointestinal tract. These bacteria are integral to the ontology and regulation of the immune system, and maintenance of intestinal homeostasis. In the chronic kidney diseases, changes of the intestinal bacterial flora have been reported, which contribute to nutritional disorder, systemic or local inflammation, and the uremic toxin production. Phosphate promotes a bacterial growth. So, by phosphate adsorption, intestinal bacterial flora may be changed. We examined whether phosphorus adsorption with lanthanum carbonate could change intestinal bacterial flora in renal failure mice.

Methods: We used 5 weeks old male ICR-derived glomerulonephritis (ICGN) mice (n=10) for renal failure group and ICR mice (n=10) for control group. Each group mice were fed with standard diet or diet supplemented with 3% lanthanum carbonate for 10 weeks. Gene expression patterns of a whole bacterial flora in the intestine were analyzed. LogTLR4 protein content in muscle (~4-fold increase vs. controls p<0.05). LogTLR4 protein content in muscle (~4-fold increase vs. controls p<0.05).

High-Fat Diet Induces the Production of IKKβ by Macrophages to Promote Nephropathy - Xin Wan, Binbin Pan, Changchun Cao.

Background: The NF-κB activation may participate in lipid nephropathy which may be regulated by inhibitor kappa B kinase epsilon (IKKε). To investigate the role of IKKε in this process, mice experiment was performed.

Methods: Mice were grouped into wild-type or with normal fat diet (WN), 2 wild-type with high fat diet (WH), 3 IKKε knockout with normal fat diet (KN), 4 IKKε knockout with high fat diet (KH). Renal function, lipid, histological changes and tubular proliferation were analysed. IL-1β, TNF-β, p50 and p65 were determined by western blot. NF-κB level was tested by EMSA. Expression of IKKε was evaluated via immunohistochemistry and immunofluorescence.

Results: Cystatin C levels were significantly higher in WH group than others. Staining with hematoxylin-eosin revealed that tubular lesions in WH group (3.53 ± 0.21) were more severe than in WN group (0.32 ± 0.11). By Immunohistochemistry, WH group exhibited marked macrophages infiltration than WN, KN and KH groups. Western blot showed significant increase of IL-1β, TNF-β and marked increment in the expression of NF-κB pathway components consists of p50 and p65 in WH group, while these increases were blocked in KN and KH groups. Furthermore, NF-κB level in WH group was higher than other groups. WH group exhibited remarkable macrophages infiltration than other groups by Immunofluorescence. Immunohistochemistry showed remarkable increases in the expression of IKKε in the WH group compared with other groups. Immunofluorescence analysis demonstrated that the expression of IKKε was located around macrophages.

Randomized, Double-Blind, Crossover Clinical Trial on Oral Rice Endosperm Protein Supplementation to Patients on Maintenance Hemodialysis Michihiro Hosojima,1 Hisaki Shimada,2 Shigeru Miyazaki,2 Yoshitsugu Obi,1 Hazuki Kondo,3 Mikio Fujii,4 Reiko Watanabe,4 Shoji Kuwahara,1 Ryohei Kaseda,1 Ichici Narita,1 Yoshiki Suzuki,1 Motomi Kadowaki,1 Akihiko Saito.5 1Dept of Clin Nutr Sci, Niigata Univ, Japan; 2Shinrakku-en Hospital, Japan; 3Univ of California; 4Kameda Seika Co., Ltd., Japan; 5Dept of Niigata Prefecture, Japan; 6Dept of Clin Nephrol & Rheumatol, Niigata Univ, Japan; 7Health Administr Center Div, Niigata Univ, Japan; 8Faculty of Agriculture, Niigata Univ, Japan.

Background: Protein-energy wasting, a state of metabolic and nutritional derangements, is an important risk factor that affects outcomes of patients with CKD, particularly in ones with ESRD and on maintenance dialysis (MHD). Purified rice endosperm protein (REP) contains less phosphorus (150 mg/100g) compared with soybean (787 mg/100g) and casein (737 mg/100g) proteins, and may improve nutritional status without imposing further metabolic derangements.

Methods: We carried out a randomized, double-blind, placebo-controlled, cross-over study to evaluate the effect of REP supplementation (5 g day−1 × 4 weeks) on nutritional and metabolic status in 50 MHD patients (UMIN000010876). The primary outcome was the change in urea kinetic-based normalized protein nitrogen appearance (nPNA), an indicator of protein intake in MHD patients. The inclusion criteria were: (1) nPNA < 1.2 g/kg/day; (2) serum albumin concentration ≤ 3.6 mg/dl; (3) body mass index 19 kg/m² and < 23 kg/m²; (4) ≤ 5% variation in dry weight during the period of preceding 6 months; and (5) duration of MHD ≥ 2 years.

Results: By intention-to-treat analyses, REP increased nPNA by 0.07 (95%CI, 0.03-0.11) g/kg/day compared with placebo, whereas Dserum phosphorus concentration was not significantly different between the groups (0.18 (95%CI, -0.23 to 0.58) mg/dl). REP did not show significant effects on other nutritional parameters. Per-protocol analyses yielded similar results. There were no specific complications associated with the REP supplementation.

Conclusions: Purified REP may be useful for dietary supplementation in MHD patients. Further studies are warranted to evaluate its long-term or high-dose efficacy.

Association of Serum Phosphate Levels and Mortality Risk in Patients with Chronic Kidney Disease: A Systematic Review and Meta-Analysis Anawin,1,2 Sikaran Utpila,1,2 1Internal Medicine, Bassett Medical Center and Columbia Univ College of Physicians & Surgeons, Cooperstown, NY; 2Preventive and Social Medicine, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand.

Background: Abnormalities of serum phosphate are associated with increased risk for mortality in end stage renal disease (ESRD) or dialysis patients. Use of phosphate binders has shown to reduce risk of mortality in these population and is recommended in several guidelines. However, there is still controversy on the management of serum phosphate in patients with chronic kidney disease (CKD). This meta-analysis evaluated the impact of serum phosphate on mortality in patients with CKD not requiring dialysis.

Methods: We comprehensively searched the databases of MEDLINE, EMBASE, and Cochrane Databases. The inclusion criteria were published RCT and prospective cohort studies assessing effects of high serum phosphate (compared to normal range) and a 1-mg/dl increase in phosphorus level in patients with CKD (eGFR < 60 ml/min/1.73 m²). We excluded ESRD, dialysis, or renal transplant patients. The primary outcome was risk of all-cause mortality. We used hazard ratio (HR) or risk ratio (RR) in the multivariate model as an effect estimate.

Results: From 15 full-text articles, five studies involving 6,536 patients were included in the meta-analysis. All were prospective cohort studies of CKD stage 3 or 4 patients. There was an increase all-cause mortality risk in higher phosphorus levels (HR = 1.36, 95% CI: 1.24 to 1.49, p=0.001, I²=0%) compared with normal phosphorus levels. A 1-mg/dl increase in serum phosphate also increases mortality risk with HR=1.23 (95% CI: 1.14-1.34, p<0.01, I²=0%).

Conclusions: Elevated serum phosphate levels were independently associated with increased mortality risk among patients with CKD. Randomized controlled trials are needed to assess the benefits of using phosphate lowering therapy in patients with CKD before developing ESRD or dialysis.

Serum Phosphorus Levels prior to Transition to Dialysis and Early Dialysis Mortality Among U.S. Veterans: A Transition of Care in CKD Study Amanda R. Tortorici,1 Yoshitsugu Obi,1 Melissa Soohoo,1 Connie Rhee,1 Elani Streja,1 Jennie Jing,1 Rajiv Saran,2 Bruce M. Robinson,2 Yi Li,2 Danh V. Nguyen,1 Keith C. Norris,1 Csaba P. Kovedsy,3 Kamyar Kalantar-Zadeh.1 1UC Irvine; 2UM-KECC; 3UCLA; 4UTHSC.

Background: Previous studies have shown that higher phosphorous (Phos) levels were monotonically associated with higher risk of death in patients with chronic kidney disease and end-stage renal disease (ESRD). The impact of the pre-ESRD Phos levels on early post-ESRD mortality is not known.

Methods: In US veterans who transitioned to dialysis between 10/2007 and 9/2011, we identified 10,724 patients with available Phos measurements within the last 6 months pre-ESRD (prior to transition). We examined the association of Phos (averaged over 6 months) as a continuous predictor of all-cause mortality within the first 3 months post transition, using restricted cubic spline analysis and Cox models adjusted for age, sex, race, ethnicity, cause of ESRD, and region of residence.

Results: The median SD age of the cohort was 66±11 years, among whom 34% were African-American, 8% were Hispanic, and 52% had diabetes listed as their primary cause of ESRD. We observed a reverse J-shaped association between pre-ESRD Phos and 3-month post-ESRD mortality risk. Patients with Phos levels <4.7 mg/dl had a higher risk of mortality, and patients with Phos levels >9.0 mg/dl trended towards a higher risk of mortality as well. However, patients with Phos levels between 4.7 and 7.2 mg/dl demonstrated lower mortality risk.

Conclusions: Among veterans transitioning to dialysis, both lower and higher Phos levels were associated with higher risk of early post-ESRD mortality, while patients with Phos levels between 4.7 to 7.2 mg/dl had the lowest risk of mortality. Further studies are needed to determine if using dietary and medication interventions to attain this Phos range confers higher survival in this population.
FR-PO901
The Comparison of Serum Calcium, Phosphorus and Intact Parathyroid Hormone Between Peritoneal Dialysis Patients and Hemodialysis Patients
Guisen Li, Li Wang. Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chengdu, Sichuan, China.

Background: In this study, we compared the serum calcium, phosphorus and intact parathyroid hormone between peritoneal dialysis patients and hemodialysis patients to study the difference in MBD biochemical variables between PD and HD.

Methods: 507 patients were enrolled from July 1, 2014 to December 31, 2014, including 148 patients received peritoneal dialysis and 359 patients received hemodialysis patients (HD) more than 3 months. Basic clinical information, data of dialysis, serum calcium, phosphorus and iPTH levels were collected in all patients, and comparative analysis was carried out based on those information.

Results: The age and the dialysis vintage was significantly higher in HD group than in the PD group (P < 0.001). Serum phosphorus was lower, percentage of phosphorus in target was higher and percentage of calcium in target was lower (P = 0.271) in PD group than in HD group (P<0.001). The serum phosphorus levels of PD patients with peritoneal transport characteristics or high average transport were much lower than those with low transport or low average transport (P = 0.0167). The levels of serum phosphorus (P < 0.001), iPTH (P < 0.0167) and alkaline phosphatase (P=0.001) were much lower in women with PD than those with RRF<2ml/min. The levels of serum calcium (P < 0.01), corrected calcium (P<0.01), phosphorus (P = 0.025), iPTH (P<0.001) and alkaline phosphatase (P<0.01) were much lower in patients with urine volume >1000ml/d than those <1000ml/d. There was a negative correlation between RRF and serum phosphorus (r=-0.291, P < 0.001) and iPTH (r=-0.271, <0.01) in PD group. The weekly total Kt/V (r=-0.201, P < 0.019) and weekly total creatinine clearance (CeC (r=-0.407, P<0.001) negatively related to serum phosphorus. The Ccr (r=-0.241, P < 0.01) negatively correlated with serum iPTH.

Conclusions: The serum levels of phosphorus is lower and the percentage of achieving target of phosphorus is higher in PD patients than HD patients. The peritoneal high transport characteristics, RRF>2ml/min, urine volume >1000ml/d and the nutrition status have obvious influence on the serum phosphorus and iPTH levels in PD patients.

FR-PO902
Increased Risk of Cerebral Hemorrhage in Hemodialysis Patients with Hyperphosphatemia: The Q-Cohort Study
Shunsuke Yamada,1 Masanori Tokumoto,1 Masatomo Taniguchi,1 Takanari Kitazono,1 Kazuhiko Tsuruya,2 1Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; 2Integrated Therapy for Chronic Kidney Disease, Kyushu Univ, Fukuoka, Japan; 3Internal Medicine, Fukuoka Dental College, Fukuoka, Japan.

Background: Mounting evidences have shown that hyperphosphatemia, an established component of CKD-MBD, accelerates cardiovascular disorders in dialysis patients. However, previous studies did not separately determine the effects of hyperphosphatemia on the onset of cerebrovascular disorders and cardiovascular disorders in dialysis patients.

Methods: The present study is an observational study consisting of 3431 outpatients undergoing hemodialysis. The associations between the baseline serum phosphate (Pi) level and the onset of cerebral bleeding and infarction were examined. Independent variable was serum Pi level. Dependent variable was the onset of cerebral hemorrhage and infarction. Age, sex, diabetes mellitus, history ofcardiovascular events, diastolic vintage, KtV for urea, systolic blood pressure, hemoglobin, serum levels of calcium, parathyroid hormone, albumin, alkaline phosphatase, creatinine, and C-reactive protein, and use of vitamin D and Pi-binder were used as covariates. Cox proportional hazard model was used for analyses. All statistical analysis was conducted by JMP11.2 (SAS institute).

Results: The mean age of the examined population was 63.7±12.8 years, female was 41%, and the proportion of diabetes mellitus was 29%. Mean serum levels of calcium, Pi, and intact parathyroid hormone were 9.1±0.76 mg/dL, 4.92±1.12 mg/dL, 168±210 mg/dL, respectively. During the mean observational period of 3.1 years, 77 patients newly developed brain hemorrhage and 140 developed brain infarction. Hyperphosphatemia (Pi≥6 mg/dL) did not increase the risk of brain infarction, but increased the risk of brain hemorrhage by 2.2 fold, compared with the target Pi range (3.5£Pi<6.0 mg/dL), even after adjustment for the potential confounders.

Conclusions: Hyperphosphatemia is closely associated with the onset of cerebral hemorrhage but not with cerebral infarction. Our results highlight the importance of Pi management in the prevention of cerebral hemorrhage in dialysis patients.

FR-PO903
Development and Evaluation of Novel Correction Equations for Serum Calcium Concentrations in Hemodialysis Patients
Yoshitsugu Obi,1 Wei Ling Lau,1 Elaní Streja,1 Connie Rhee,1 Steven M. Brunelli,2 Csaba P. Kovédy,3 Kamyar Kalantar-Zadeh,2, 1UC Irvine; 2DaVita Clinical Research; 3UTHSC.

Background: Ionized calcium (iCa), but not total calcium (tCa), is the physiologically relevant component of blood calcium. However, these measurements correlate poorly in hemodialysis patients even after correction for serum albumin, which may be partly explained by electrolyte and acid-base derangements in this population.

Methods: In 1,366 patients who initiated conventional HD over four years (1/2007-12/2010), we identified 6,830 iCa measurements where serum albumin, tCa, sodium, chloride, phosphorus, and bicarbonate were measured simultaneously. We randomly divided patients into a derivation set (n=681) or a validation set (n=685) to develop and evaluate new correction equations for serum iCa concentrations by comparing correlation r and Bayesian information criterion (BIC) in linear regression analysis as well as receiver operating characteristic (ROC) curves for hypercalcemia determined by iCa (<5.28 mg/dL).

Results: Albumin was associated with iCa, but its coefficient was -0.15, not -0.8 as shown in the conventional correction equation. Furthermore, albumin-corrected iCa showed lower correlation than uncorrected iCa with tCa (r=0.69 and 0.76, respectively). Two equations were developed from the derivation set as follows; [EQ1] 1.1*iCa – 0.12*(phosphorus + 1) and [EQ2] 1.1*iCa – 0.08*(anion gap – 2). In the validation set, EQ1 and EQ2, compared to the conventional correction by albumin, showed better correlation with iCa (<0.78 and 0.80, respectively), lower BIC (96% and 92%, respectively), and higher area under the ROC curve for Ca-defined hypercalcemia (P<0.01 for both).

Conclusions: Novel correction equations for iCa show better association with iCa and hypercalcemia evaluated by iCa. Its clinical usefulness needs to be evaluated in further studies.

Relationship Between Dietary Phosphorus Intake and Protein and Energy Intakes in Hemodialysis Patients
David E. St-Jules,1 David S. Goldfarb,2,3 Mary Lou Pompeii,1 Kathleen Woolf,1 Kamyar Kalantar-Zadeh,2 Mary A. Sevick,1 1NYU School of Medicine; 2NY Harbor VA Medical Center; 3NYU Langone Medical Center; *NYU Steinhardt; *UCLA School of Public Health.

Background: Excess dietary phosphorus may contribute to mineral and bone disorders in hemodialysis (HD) patients. However, many high phosphorus foods are also important sources of dietary protein, which raises concerns that phosphorus restriction may compromise protein status.

Methods: We conducted a cross-sectional study of 190 African American and white men and women on intermittent HD for >3 months. Dietary data were collected by three 24-hour recalls, which were analyzed using NDSR®. Only participants who completed all three recalls and reported intakes ≥500 kcal/d were included (n=137).

Results: Dietary phosphorus and protein were highly correlated (R=0.73). Based on linear regression, a 1,000 mg/d phosphorus restriction would provide about 78 g protein/d or 1.1 g protein/kg/d for a 70-kg person. When adjusting for energy intake, the association of dietary phosphorus and protein was far less apparent (R=0.42). Further, the highest phosphorus intake was about two times greater than the lowest phosphorus intake for each energy and protein intake level (500 kcal and 5% of kcal increments), reaching 600 mg/d for some groups.

Figure 1. Ranges in reported dietary phosphorus intake of hemodialysis patients in relation to daily energy and protein intake in the Balance/Wise study (n=137)

Proportion of Daily Dietary Calories from Protein: Intake

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

**Conclusions:** Although dietary phosphorus and protein are highly correlated, this relationship appears to be driven in part by the amount of Calories consumed. Moreover, phosphorus intake ranges widely within energy and protein intake increments, suggesting that reductions in dietary phosphorus may be achieved in many HD patients without compromising the protein status.

**Background:** High phosphorus levels are associated with increased cardiovascular and all-cause mortality but phosphorus control continues to be a challenge amongst dialysis patients. In this study, we conducted a survey to assess phosphorus control and identify barriers to phosphorus control in patients receiving dialysis at Loyola outpatient dialysis unit.

**Methods:** The study consisted of 17 question survey evaluating patients knowledge and understanding of phosphorus control, self care practices and social support as potential barriers to phosphorus control. Patients were approached during dialysis to participate. Objective patient data and laboratory data was collected from electronic medical records. Study was approved by Loyola IRB.

**Results:** Of the 99 eligible subjects, 57 completed the survey. Mean age of the participants was 62 years, 52% were males and 75% were African Americans. Patients were categorized into uncontrolled (phosphorus >5.5 mg/dL) and controlled phosphorus group. The two groups had similar demographics, co-morbidities, dialysis adequacy and medication pill burden. Approximately 80% of patients with uncontrolled phosphorus were aware of normal phosphorus levels in dialysis patients, complications associated with high phosphorus and identified majority of foods with high phosphorus compared to 53% 43% and 57% in the controlled phosphorus group, respectively. Patients with uncontrolled phosphorus frequently identified cheating on diet and missed medication dose as reasons for lack of phosphorus control. There was no difference among the two groups relative to social support or self-care practices. 75% patient in controlled and 55% in uncontrolled group were interested in learning more about phosphorus control.

**Conclusions:** Patients with uncontrolled phosphorus had significantly greater knowledge and understanding of phosphorus control. While continued education of patients regarding phosphorus control is important, qualitative research to study patients’ behavioral aspects is needed to better understand barriers to phosphorus control.

**FR-PO906 Use of a Simple, Widely Available Laboratory Test to Quantify and Explain Variation in Phosphorus Levels in Beverages**

Elizabeth J. Lindley, David Francis Keane,1 Tracey Ying,2 John W. Macd. Agar,3 Gunnar H. Heine,4 Juergen Geisel,3 1Leeds Teaching Hospitals NHS Trust, United Kingdom; 2Geelong Hospital, Australia; 3Saarland Univ Medical Centre, Germany.

**Background:** Restriction of dietary phosphorus (P) is essential in the management of hyperphosphataemia in CKD. Beers and wines contain inorganic P that is readily absorbed but data on these beverages, and less well-known soft drinks, is difficult to obtain. An assay used routinely in hospital laboratories has been validated for measurement of P in a range of beverages (Lindley, J Ren Nutr 2014) enabling renal unit staff to compile information on locally sourced products and investigate variation between brands.

**Methods:** Beverages were processed as if they were urine samples and tested using the standard phosphomolybdate assay. 12 beers popular in the German Saarland were tested to find out if lower P brands could be identified. 10 wines from a micro-winery in New South Wales containing little or no di-ammonium phosphate (DAP, a widely-used yeast nutrient) were compared with 8 Australian wines from UK supermarkets. Classic Coca-Cola, which is strictly regulated world-wide, was used to check agreement between analysers in different countries.

**Results:** The P content of alcoholic beers in the Saarland selection varied from 12 to 27 mg/dL. There was no association between P and alcohol level. P levels in the non-alcoholic beers tested to date were 9 and 18 mg/dL. DAP-free white wines contained 6 to 8 mg/dL. P varied from 14 to 20 mg/dL. DAP increased the P level by about 2 mg/dL, for every 100 mg/mL added to the wine must. Much higher P levels in the supermarket wines (up to 31 mg/dL) suggest routine addition of 500 to 700 mg/L DAP.

**Conclusions:** Phytic acid in cereal grains and grape pips provides P for the seedlings. Inorganic phosphorus is released from this indigestible molecule by the enzyme phytase during malting (sprouting) and fermentation. Biological variation, differences in production that affect the breakdown of phytic acid and addition of DAP contribute to the wide range of P content in beer and wines. Until appropriate labelling becomes mandatory, tables of measured P content by brand could help patients trying to restrict their P intake.

**Funding:** Government Support - Non-U.S.
Serum phosphate in the two groups

Conclusions: 1. Statistically significant separation in serum phosphate was achieved between the two groups (fig 1) with no apparent increase in secondary hyperparathyroidism. 3 patients in the HRG commenced Cinacalcet during the course of the study because serum PTH > 1200ng/dL. 2. As expected, LRG had a significantly larger pill burden than the HRG, with 20 patients in the LRG taking 9 or more binder pills. 3. Despite increased pill burden, albumin levels were not different between groups. 4. Crude mortality 4 times higher in the HRG.

Efficacy and Safety of PT20: A Novel Iron-Based Phosphate Binder

Geoffrey A. Block, George G. Hon, Nuno Faria, Jonathan Powell.

Background: PT20, a novel iron based phosphate binder (P-binder), has been specifically engineered with adpic acid substitution to improve phosphate binding capacity and affinity of ferric oxides. PT20 has shown high binding affinity for phosphate in preclinical studies.

Methods: Patients were on hemodialysis with serum phosphate (P) levels between 4.0 and 8.0mg/dL plus serum ferritin levels <1000 mg/dL at their screening visit. All patients were then washed out of previous P-binders and required to have an increase in serum P of at least 1.0 mg/dL to enter study. 153 subjects were randomized to either 400mg, 800mg, 1600mg, 3200mg PT20 or placebo, each taken TID with meals for 28 days. Doses were not modified during the treatment period. Primary end point was change in serum P from Baseline to Day 29. Secondary endpoints assessed safety as well as haematological parameters.

Results: PT20 treatment significantly reduced serum P levels and demonstrated a dose response effect (ITT population; p<0.001). All dose groups showed a reduction in mean serum P levels greater than placebo. Mean reduction in P over the 28 days was (mg/dL) 1.36 / 3200mg; 1.29 / 1600mg; 0.59 / 800mg; 0.40 / 400mg and 0.17 / Placebo dose.

Mean serum P levels greater than placebo. Mean reduction in P over the 28 days was (mg/dL) 1.36 / 3200mg; 1.29 / 1600mg; 0.59 / 800mg; 0.40 / 400mg and 0.17 / Placebo dose.

Conclusion: PT20 treatment significantly reduced serum P levels and demonstrated a dose response effect (ITT population; p<0.001). All dose groups showed a reduction in mean serum P levels greater than placebo. Mean reduction in P over the 28 days was (mg/dL) 1.36 / 3200mg; 1.29 / 1600mg; 0.59 / 800mg; 0.40 / 400mg and 0.17 / Placebo dose.

Phase III Study to Investigate the Long-Term Efficacy, Safety, and Tolerability of PA21 (Sucroferric Oxyhydroxide) in Japanese Hemodialysis Patients with Hyperphosphatemia

Fumihiko Koiwa, Masafumi Fukagawa, Keitaro Yokoyama, Tadao Akizawa, Akira Terao.

Background: PA21 (sucroferric oxyhydroxide: SFOH) after 52-weeks of treatment in Japanese hemodialysis (HD) patients with hyperphosphatemia.

Methods: In total, 161 patients were treated with SFOH (750–3000 mg/day; starting dose 750 mg/day; available as 250 mg and 500 mg tablets). SFOH was administered at Week 0, after treatment with any prior phosphate binders had been discontinued. Doses of SFOH were titrated to maintain predefined serum phosphorus (sP) concentrations of 3.5–6.0 mg/dL.

Results: Mean sP concentrations decreased from 5.46 mg/dL at Week 0 to 5.00 mg/dL at the last evaluation. Mean sP concentrations were maintained within the target range of 3.5–6.0 mg/dL throughout the 52-weeks treatment period. The average number of SFOH tablets was 3.3 tablets/day, and the average dose of SFOH was 1.141 mg/day./

Conclusion: SFOH demonstrated a sustained sP-lowering effect 52-weeks of treatment in Japanese HD patients, and was associated with a low pill burden and good tolerability.

FR-PO912

Improved Serum Phosphorus Control and Decreased Phosphate Binder Pill Burden Amongst African American Hemodialysis Patients Taking Sucroferric Oxyhydroxide

Linda H. Fiscietto, Lin Ma, Vidhya Parameswaran, Claude Mullon, Franklin W. Maddux, Robert J. Kossman.

Background: A retrospective database study was conducted on the real-world effectiveness of sucroferric oxyhydroxide (SO) in controlling serum phosphorus (sP) among hemodialysis (HD) patients (pts). This analysis focuses on the subset of patients who self-reported race as Black or African American.

Methods: All patients were classified as part of standard care at FMCNA clinics and had ≥1 sP measured during SO use. Changes in sP, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and phosphate binder pills per day (PDD) were assessed 3-months before (baseline; BL) and 3-months during SO treatment (SO-TX).

Results: On average, pts (n=1015) were 51 years old with a dialysis vintage of 5.2 years and hyperphosphatemia (BL sP=6.93 mg/dL). BL phosphate binder used were: sevelamer (32.1%), calcium acetate (26.3%), calcium carbonate (4.7%), lanthanum (7.2%), calcium citrate (6.4%) and no PB specified (5.5%). As shown in Figure, pts in-range for sP concentrations at Week 0 as a covariate, P = 0.09. The average number of SFOH tablets was 3.3 tablets/day, and the average dose of SFOH was 1.141 mg/day. Overall, the incidence of adverse events and adverse drug reactions was 94.4% and 32.9%, respectively. Frequently observed adverse drug reactions were diarrhea (22.4%) and constipation (2.5%); no severe diarrhea or constipation was reported. Despite slight increases in serum Ferritin and transferrin saturation, no clinical signs of iron accumulation or overload were observed at 52 weeks.

Conclusion: SFOH demonstrated a sustained sP-lowering effect 52-weeks of treatment in Japanese HD patients, and was associated with a low pill burden and good tolerability.

Real-World Use of Sucroferric Oxxyydroxide in Hemodialysis Patients: Changes in Serum Phosphorus Control and Phosphate Binder Pill Burden

Linda H. Ficociello, Lin Ma, Vidhya Parameswaran, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann.
Freensius Medical Care North America (FMCNA), Waltham, MA.

Background: Approximately 40% of US dialysis patients (pts) do not achieve serum phosphorus (sPhos) goals (US-DOPPS Practice Monitor, 4/2015). This retrospective database analysis assessed the real-world effectiveness of sucroferric oxxyydroxide (SO) to control sPhos in hemodialysis (HD) pts.

Methods: In-center HD pts prescribed SO as part of routine clinical practice at FMCNA clinics with ≥1 sPhos during SO use were included. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and phosphate binder (PB) pills per day (PPD) were assessed. Pts were assessed at baseline and 3 and 3 months during SO treatment (follow-up).

Results: On average, pts (n=3151) were 54 years old with 4.3 years dialysis vintage and hyperphosphatemia (baseline sPhos = 6.94 mg/dl). PB prescribed at baseline were: sevelamer (47%), calcium acetate (26%), calcium carbonate (6%), lanthanum (7%), other (23% Pb). Pb in with in-range sPhos (3.5-5.5 mg/dl) increased from 13 to 20.4% (57% increase). Mean sPhos (6.94 to 6.73 mg/dl, p<0.001) and mean sCa (9.21 to 9.18 mg/dl, p=0.003) decreased significantly. iPTH changed minimally.

Conclusions: In a cohort of African American hemodialysis patients prescribed sucroferric oxxyydroxide, a 57% increase in patients with in-range (3.5-5.5 mg/dl) serum phosphorus (p<0.001) along with a decrease in pill burden (4.8 fewer pills, p<0.001) was observed.

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America.
Conclusions: These results suggest that hyperphosphatemia affects aortic gene expression linked to oxidative stress and inflammation, and that the adverse cardiovascular effects of high serum Pi may be prevented by oral treatment with the phosphate binder VS-505.

FR-PO916

Fractional Excretion of Phosphate Misrepresents Hormonal Effects on Phosphate Reabsorption in Chronic Kidney Disease
Kenneth R. Phelps,
Darius Mason,
Sun J. Kang

Background: The serum P concentration ([P]u) is the sum of Ecr/Cr and TRcr/Cr, where Ecr/Cr and TRcr, are rates of urinary excretion and tubular reabsorption of P per volume of filtrate. Ecr/Cr is proportional to filtrate [P] in the cortical distal nephron ([P]c); we have argued that [PTH] correlates with Ecr/Cr, for this reason in CKD. Fractional excretion of [P] (FEcr), usually calculated as ([P]c)[P]c/(Ecr/Cr)[P]c, also equals 1/(1 + (TRcr/Ecr/Cr)). Since Ecr equals influx of [P]c, the second expression shows that both I and TR determine FEcr. We hypothesized that FEcr correlates with [PTH] and [FGF23] in CKD because I affects all 3 variables.

Methods: We measured fasting [cr], [P]c, [PTH] (1-84 Scantibodies and intact [FGF23]) (Immuntotics) in 30 patients with stages 3-4 CKD. We calculated Ecr/Cr, as [P]c/[Ecr/Cr], TRcr, as [P]c/(Ecr/Cr)[P]c, and FEcr as [P]c/[P]c.[P]c. We performed simple linear regressions as in the table and a multilinear regression of FEcr on [PTH] and [FGF23] did not result from effects of the hormones on TRcr.

Results: FEcr correlated directly with [PTH] and [FGF23] in CKD because I affects all 3 variables. In Bijvoet’s infusion studies, linear regressions as in the table and a multilinear regression of FEcr on [PTH] and [FGF23] did not result from effects of the hormones on TRcr.

Conclusions: FEcr is unrelated to [PTH] and [FGF23] even though both hormones reduce P reabsorption. Although FEcr varied inversely with TRcr/Cr correlations of FEcr with [PTH] and [FGF23] did not show any effect on FEcr, and therefore did not reflect quantitative relationships between hormone concentrations and P reabsorption. The correlations occurred because FEcr and TRcr were correlated with Ecr/Cr. FEcr should not be used to relate P reabsorption to hormones in CKD.

Attributes of the Walton-Bijvoet Nomogram at Normal and Reduced Glomerular Filtration Rate
Kenneth R. Phelps,
Darius Mason,
Sun J. Kang

Background: The serum P concentration ([P]) is the sum of Ecr/Cr and TRcr/Cr (urinary excretion and tubular reabsorption of P per volume of filtrate). In Bijvoet’s infusion studies, observed TRcr/Cr equaled maximum TRcr/Cr (Tm/GFR) at fasting fractional P excretion (FEcr) > 20%, as FEcr fell, (Tm/GFR) – TRcr/Cr rose. These observations were incorporated into a nomogram that derives Tmcr from [P]c and FEcr. Although the nomogram was based on data obtained at GFR > 40 mL/min, it is used to assess P reabsorption in CKD.

We examined this practice.

Methods: We collected fasting morning serum (s) and urine (u) from 30 patients with stages 3-4 CKD and 28 controls with MDRD eGFR > 60. We calculated Ecr/Cr, as [P]c/[cr], TRcr, as [P]c, Ecr, and FEcr as [P]c/[cr].[cr]. After ascertaining Tmcr/GFR from [P]c, we determined Ecr/Cr, TRcr/Cr, and FEcr/Cr. We performed group comparisons with the Mann-Whitney U test.

Results: In CKD, Ecr/Cr and FEcr were higher, and eGFR, TRcr/GFR, (Tmcr/GFR)/(TRcr/GFR), (TRcr/GFR)(Ecr/Cr), (Tmcr/GFR – TRcr/Cr), and (Tmcr/GFR)/(TRcr)(Ecr/Cr) were lower than in controls. In [P], was not different in the 2 groups. In CKD, FEcr was > 20% in 27/30 patients; mean (Tmcr/GFR – TRcr/Cr) and (Tmcr/GFR)/(TRcr)(Ecr/Cr) approximated 0 and 1, respectively.

Conclusions: The Walton-Bijvoet nomogram is accurate but unnecessary if (TRcr/Ecr/Cr) < 4. In this circumstance, Tmcr/GFR = TRcr/Cr – [P]c – Ecr/Cr, whether Ecr/Cr is increased by P influx or low Ccr. Use of the nomogram and calculation of TRcr/Cr, require the same variables. In CKD, the nomogram is accurate but unnecessary if (TRcr/Ecr/Cr) < 4.

Role of KHSRP and Pin1 in Mediating the Parathyroid Hormone Response in the Proximal Tubule
Rebecca Murray,
Michael Merchant,
Syed J. Khundmiri,
Barbara Clark,
Eleanor D. Lederer

Background: Parathyroid hormone (PTH) regulates the type IIa sodium-phosphate cotransporter (Npt2a), the major regulated proximal tubule phosphate transporter. In both the protein and mRNA level. We previously identified KHSRP as a PTH-responsive phospho-protein that binds Npt2a mRNA and may mediate its degradation. Pin1, a pep-tidyl-prolyl isomerase, is the upstream regulator of KHSRP function and localization.

Methods: We phosphorylated Pin1 binds KHSRP, promoting KHSRP phosphorylation and maintaining its cytosolic localization. We hypothesize that PTH stimulates Npt2a mRNA destabilization through PKA-mediated phosphorylation of Pin1.

Results: A 24-hr increase in Pin1 phosphorylation. IP of KHSRP followed by immunoblot for Pin1 showed that Pin1 associates with KHSRP under basal conditions, but not following 24-hr PTH or 8-hr treatment. Pre-treatment with H-89 blocked the PTH/8-Brc-induced dissociation. 24-hr PTH did not alter total expression of KHSRP, but stimulated its translocation to the nucleus.

Conclusions: We conclude that PTH-mediated destabilization of Npt2a mRNA likely involves PKA-mediated regulation of Pin1 and KHSRP activity. Funding provided by VA to EDL.

Phosphate Depletion-Induced Metabolic Acidosis and Alkali Urine May Be Caused by Inappropriate Stimulation of Apical Cl/HC× Exchanger (Pendrin) in Mouse Kidney Type B Intercalated Cells (IC-B)
Yukiko Yasuoka,
Tomomi Oshima,
Yuuichi Sato,
Hiroshi Nonoughi,
Katsumasa Kawahara

Background: Mice treated with a low phosphate (P) diet can maintain normal levels of plasma P concentration via stimulation of bone reabsorption, but show hypercalcemia, hypercalciuria, and hypophosphatemia. Usually, the Ca-sensing receptor (CaSR) was found to be localized in the basolateral membrane of IC-B as well as in the thick ascending limb of Henle’s loop (Yasuoka et al, 2014). This study was aimed to determine whether hypercalcemia and/or hypercalciuria affect urine pH as expected in mice treated with either dietary P depletor or CaCl2-loading.

Methods: C57Bl/6J mice (10 wks, male) were divided into three groups: (1) normal diet (1% P, n=6), (2) low-P, (LP) diet (0.02% P, n=4), (3) CaCl2-loading (1% P, +1% Ca (CaCl2), n=6). All diets contain 1% Ca (CaCl2). On day 7, a 24-hr urine, blood, and kidney samples were collected.

Results: Serum and urinary Ca were markedly and significantly increased in the LP and CaCl2 groups [serum, 9.1 and 8.9 mg/dl; and urine, 2,400 and 2,140 μg/day], compared with control [serum, 7.6 mg/dl; urine, 105 μg/day]. Although serum pH decreased significantly and specifically to 7.25 and 7.20 in both groups, pH of the urine decreased to 5.6 (P < 0.05) in the CaCl2 group and, surprisingly, increased to 7.4 (P < 0.05) in the LP group (control, serum pH 7.35; urine pH 6.3). Kidney histology and immunohistochemistry showed that

*Values are mean (SEM). P > 0.01 for all other comparisons.

Conclusions: FEcr is > 20% at (TRcr/Ecr/Cr) < 4. In this circumstance, Tmcr/GFR = TRcr/Cr – [P]c – Ecr/Cr, whether Ecr/Cr is increased by P influx or low Ccr. Use of the nomogram and calculation of TRcr/Cr, require the same variables. In CKD, the nomogram is accurate but unnecessary if (TRcr/Ecr/Cr) < 4.

the IC-A-cell height and basolateral Cl⁻/HCO₃⁻ exchanger type 1 (AE1) staining significantly increased in the CaCl₂ group, whereas the IC-B-cell height and apical Pendrin and basolateral AE4/6 staining significantly increased in the LP group.

**Conclusions:** P₂-depletion induced metabolic acidosis may be due to imbalanced urinary alkalization and acid absorption caused by inappropriate stimulation of Pendrin and AE4 through the hypercalcemia-induced activation of the basolateral CaSR in IC-B.

MUC1 Increases Renal Calcium Channel TRPV5 Activity to Enhance Calcium Reabsorption in a Galectin-3 Dependent Fashion

Mingzhu Nie, 1 Zhufeng Yang, 1 Jie Liu, 1 Denise K. Marciano, 2 Manoj S. Bal, 3 Pediatrics, UTSW Medical Center, Dallas, TX; 1Internal Medicine, UTSW Medical Center, Dallas, TX.

**Background:** MUC1 (MUC1) mutations cause autosomal dominant tubulo-interstitial kidney disease (ADTKD-MUC1), a condition similar to a nephropathy caused by Uromodulin (UMOD) mutations (ADTKD-UMOD). We previously showed that UOMD may protect against calcium-containing kidney stones by increasing TRPV5 cell surface abundance and tubular calcium reabsorption, which may decrease the risk of urinary supersaturation. The role of MUC1 in kidney is unclear. As UOMD and MUC1 share characteristics regarding disease phenotype, protein function, and structure, we examined the hypothesis that MUC1 enhances TRPV5 channel activity.

**Methods:** We expressed TRPV5 and MUC1 variants in HEK293 cells and studied TRPV5 current density by whole-cell patch-clamp recording.

**Results:** MUC1 coexpressed with TRPV5 resulted in a higher TRPV5 current density compared to mutant MUC1-C or control. MUC1 increased TRPV5 current density when applied extracellularly and required TRPV5 N-glycan for upregulation. Immunofluorescence imaging showed apical MUC1 expression along the distal nephron which is compatible with TRPV5 regulation in DCT. To test if MUC1 affects TRPV5 endocytosis, we tested if MUC1 upregulates TRPV5 in caveolin-1 deficient fibroblasts, as TRPV5 undergoes endocytosis via caveolin-1. While MUC1 alone had no effect, cotransfection of recombinant caveolin-1 with MUC1 restored TRPV5 upregulation by MUC1. The extracellular domain of MUC1 contains variable number tandem repeats (VNTRs) which bind galectin-3, a lectin involved in lattice formation of channels. Using galectin-3 siRNA, we identified galectin-3 as a prerequisite for TRPV5 upregulation by MUC1. This was confirmed by the inability of MUC1 lacking VNTR to upregulate TRPV5. In urine samples of patients with calcium-containing kidney stones we found less urinary MUC1 compared to control individuals.

**Conclusions:** MUC1 upregulates TRPV5 by extracellular lattice formation with TRPV5 N-glycan via galectin-3 which impairs TRPV5 channel endocytosis. These data are consistent with MUC1 contributing to protection against calcium-containing kidney stones.

NCC Activity Modulation as a Mechanism for PTH Regulation of DCT Calcium Transport

Benjamin S. Ko, 1 Robert S. Hoover, 2 Dept of Medicine, Univ of Chicago, Chicago, IL; 2Dept of Medicine, Emory Univ, Atlanta, GA.

**Background:** The distal convoluted tubule (DCT) is a major site of both calcium and sodium transport. While altered DCT calcium handling is not required for thiazide-induced hypocalciuria, studies have documented increased DCT calcium reabsorption in response to thiazide administration. This suggests that DCT sodium transport does affect DCT calcium transport, while thiazide-induced hypocalciuria is due to a proximal effect, modulation of NCC activity may affect DCT calcium transport by TRPV5. Since parathyroid hormone (PTH) is known to increase TRPV5 activity and decrease NCC activity, we theorized that decreased NCC-mediated sodium reabsorption may contribute to the enhanced TRPV5 calcium transport, and while thiazide induced hypocalciuria is due to a proximal effect, modulation of NCC mediated sodium reabsorption may contribute to the enhanced TRPV5 calcium transport by PTH from a 45% increase (6.0 ±0.2 to 8.7 ±0.3 nmol/mg/min, n=4, p<0.01 compared to control) as well as a 20% increase (6.1 ±0.7 to 7.3 ±0.2 nmol/mg/min, n=4, p<0.01 compared to non-targeting treated groups)). Inhibition of PKC and PKA, the known pathways by which PTH acts upon TRPV5, resulted in further attenuation of the PTH effect.

**Conclusions:** Here, through the use of a cell model with native NCC and TRPV5 activity, we report that modulation of NCC activity does indeed contribute to the TRPV5 response to PTH, implying a role for hormonal modulation of NCC activity in distal calcium handling. Further study is needed to determine the mechanism for these findings.

How Disruption of Distal Neprhon Salt Reabsorption Causes Calcium Wasting, Tubule Calcification and Skeletal Changes

Sharon L. Barone, 1,2 Jie Xu, 1 Nayan Varasteh kia, 1 Saeed Alshahrani, 1 Marybeth Brooks, 1 Kamyar A. Zahedi, 1,2 Manoocher Soleimani, 1,2 1Internal Medicine, Univ of Cincinnati, Cincinnati, OH; 2Research Services, Veterans Affairs Medical Center, Cincinnati, OH.

**Background:** Carbonic anhydrase II/sodium chloride co-transporter (NCC) and pendrin/NCC double knockout mice (dKO) develop salt wasting and are growth retarded. We propose that the disruption of sodium and chloride reabsorption in these mice causes phosphate and calcium wasting and leads to bone and skeletal anomalies.

**Methods:** Renal alterations that lead to distorted calcium and phosphate reabsorption and contribute to tubular calcification and growth retardation in the dKO mice were examined.

**Results:** dKO mice are volume depleted, exhibit kidney hyperperfusion, and have increased urinary calcium and phosphate excretion. These mice also exhibit skeletal anomalies and osteopenia and develop tubular calcium phosphate deposits. Parathyroid hormone (PTH) and fibroblast growth factor-23 (FGF-23) levels are normal in dKO mice. The urinary content of prostatic glandin E2 (PGE2) is significantly elevated, along with the expression of microsomal prostaglandin E synthase 1, while the sodium phosphate transporter IIa (NaPi-IIa) is downregulated, in the kidneys of dKO mice. qRT-PCR analyses revealed that the expression levels of NCC2 variants A and F were reduced while NCC2-B levels are increased in dKO animals. The latter changes lead to decreased NKCC2 activity in the medullary thick limb and increased calcium excretion, while NaPi-IIa downregulation reduces the reabsorption of phosphate in the proximal tubules. Placement of dKO mice on a high calcium diet or indomethacin corrected the above abnormalities. These results show an important role for salt wasting and dehydrogenase-induced PGE2 synthesis in renal calcium and phosphate excretion as well as in bone calcium mobilization.

**Conclusions:** Our studies suggest the presence of PGE2-mediated pathways, which are responsible for the response to PTH and VDI, to contribute to distal and volume contraction and independent of sodium and calcium wasting. PTH and FGF-23 activity can lead to anomalous mobilization and excretion of calcium and phosphate, and ultimately lead to skeletal abnormalities and growth retardation.

Hypercalcemia-Induced Natriuresis Is Mediated by Endothelin-1 (ET-1) and TGF-β in the NCC Knockout Mice

**Background:** Acute hypercalcemia commonly increases urinary sodium and water excretions. We previously showed that targeting the calcium receptor CaSR does not affect sodium transport in the renal tubule (Loupy, et al., JCI, 2012), suggesting that the natriuretic effect of hypercalcemia does not involve CaSR. Since hypercalcemia increases the renal expression of ET-1, we tested if ET-1 mediates the natriuretic effect of hypercalcemia.

**Methods:** Forty-two 8 week-old, male C57Bl86 mice were studied. Osmostat minipumps were implanted to infuse PTH1-34 and maintain the concentration of PTH to normal range throughout the experiment. Hypercalcemia was induced by the oral administration of dihydroxytachysterol (DHT; 7.5mg/kg food/day). Eighteen mice were treated with an ET-1 receptor antagonist, macitentan (Maci, 27mg/kg BW/day), with or without DHT. Eight mice were treated with DHT for 3 day with cromakalim (Croma, 50mg/kg BW/day, intraperitoneal) alone or with the combination of hypercalcemia (5.0/1 vs 2.4/0.1 mmol/L control mice) and exhibited increased water and sodium excretion as compared to control mice (2.0 ± 0.1 vs 1.4 ± 0.1 mL/day and 46 ± 4 vs 36 ± 2 mmol Na+/mmol creatinine, respectively, p<0.01 for both). Mice treated with Maci+DHT had similar levels of hypercalcemia-induced natriuresis as mice treated with DHT only. However, mice treated with Maci+DHT showed no increase in urinary sodium excretion. Mice treated with Maci only were similar to control mice. A 3-4 fold increase in the renal level of ET-1 mRNA was observed in mice treated with DHT and Maci+DHT.

**Conclusions:** Hypercalcemia increases the renal production of ET-1, which is likely responsible for the increase of urinary sodium excretion. In contrast, ET-1 is not involved in hypercalcemia-induced polyuria.

Methods: Primary human umbilical vein endothelial cells (HUVECs) were serum starved and treated with an intracellular buffer and preincubated with reverse-mode (Ca2+-influx) NCX1 inhibitors SN-6 or SEAO4000 and the general NCX1 inhibitor ORM-10103. NCX1 protein was knocked down using siRNA. ERK1/2 activation was determined by western blot. [Ca2+]i was measured in ECs loaded with the fluorescent Ca2+ indicator Fluo-4/NGW.

Results: We observed a significant increase (>2-fold; p=0.024) in the plasma of ERK1/2 pathway and extracellular Ca2+ was required for activation. Furthermore, inhibitors of reverse-mode NCX suppressed IS-induced activation of ERK1/2 in a time- and dose-dependent manner and attenuated IS-induced Ca2+ transients. Knock-out of NCX1 (the main NCX isoform in HUVECs) by siRNA confirmed the pharmacological data.

Conclusions: We propose that Ca2+-influx through reverse-mode NCX is required for IS-induced ERK1/2 activation. Given the known role of ERK1/2 activation in the expression of pro-inflammatory molecules such as COX-2 and VCAM-1 in ECs, reverse-mode NCX could be a novel target for improving endothelial function in CKD.

Chronic Kidney Disease Impairs Myocardial Perfusion and Disturbs Calcium/Calcium Handling Melinda Verkaik,1, 2 Marjetten Oranje,1 Desiree Abdurrahim,1 Pieter M. Ter Wee,1 Etto C. Ertinga,1 Marc G. Vervloet,1 1 Dept of Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; 2 Dept of Physiology, Inst of Cardiovascular Research ICAr-UU, VU Univ Medical Center, Amsterdam, Netherlands; 2 Biomedical NMR, Dept of Biomedical Engineering, Eindhoven Univ of Technology, Eindhoven, Netherlands; On behalf of the NIGRAM Consortium.

Background: The molecular and microcirculatory changes that may underlie the increased prevalence of heart failure and cardiac mortality in CKD are ill-defined. We hypothesized that IS directly impairs both myocardial perfusion and disturbed cardiac diastolic and systolic function due to disturbed calcium fluxes across the myocardial sarcoplasmatic reticulum.

Methods: Eight week old C57Bl/6J mice were subjected to partial nephrectomy (5/6Nx) or sham-surgery, and after 6 weeks mice were subjected to myocardial contrast echocardiography (MCE) to test myocardial perfusion. Cardiac function was assessed using Cine MRI. In single intact cardiomyocytes diastolic and systolic function, as well as intracellular Ca2+ transients were measured by fura-2 loaded cardiomyocytes.

Results: No difference was found between groups for heart weights over tibia length, neither for ejection fraction, cardiac output, end diastolic and systolic volume, and E/A ratio. The molecular and microcirculatory changes that may underlie the increased prevalence of heart failure and cardiac mortality in CKD are ill-defined. We hypothesized that IS directly impairs both myocardial perfusion and disturbed cardiac diastolic and systolic function due to disturbed calcium fluxes across the myocardial sarcoplasmatic reticulum.

Conclusions: CKD compromises both myocardial microvascular perfusion reserve, and systolic and diastolic function in cardiomyocytes. Calcium fluxes across the sarcoplasmic are disturbed, due to a reduced amount of phosphorylated phospholamban, which activates the sarcoplasmic reticulum Ca2+ channel SERCA.

FR-PO926
Recessive Mutations in SLC34A1 (NaPi-IIa) as a Cause of Idiopathic Infantile Hypocalcemia Karl P. Schlingmann,1 Birgitta Kranz,1 Martin Kaufmann,1 Elisabeth A.M. Cornelissen,1 René J. Bindels,1 Asaf Vivante;1 Robert L. De Vries,1 Elithan N. L. Verkaik,1 1 Dept of Physiology, Inst of Cardiovascular Research ICAr-UU, VU Univ Medical Center, Amsterdam, Netherlands; 2 Biomedical NMR, Dept of Biomedical Engineering, Eindhoven Univ of Technology, Eindhoven, Netherlands; On behalf of the NIGRAM Consortium.

Background: Infantile hypocalcemia (IHH) is characterized by severe hypocalcemia with failure to thrive, vomiting, dehydration, and nephrocalcinosis. Initially mutations in CYP24A1 encoding the vitamin D catabolizing enzyme 25-hydroxyvitamin D2-24-hydroxylation were discovered that lead to an accumulation of active 1,25(OH)2D and subsequent hypocalcemia and hypercalciuria.

Methods: In a subset of IHH patients without mutations in CYP24A1 we now performed a positional candidate gene approach in order to identify a second IHH gene locus. Results: We identified a shared homozygous interval on chromosome 5q35 with a maximum LOD score of 6.91. The sequence analysis of SLC34A1 encoding proximal-tubular sodium-phosphate co-transporter NaPi-IIa revealed recessive mutations in the 4 index cases as well as in 18 additional sporadic IHH patients. The clinical reevaluation revealed renal phosphate wasting but no signs of rickets. Functional studies of mutated NaPi-IIa in Xenopus oocytes and OK cells demonstrated a disturbed membrane trafficking as well as a loss of phosphate transport activity. The reexamination of Slc34a1 knockout mice highlighted the critical role of phosphate depletion and FGF-23 suppression. In affected patients, clinical and laboratory findings persist after omitting vitamin D prophylaxis but rapidly respond to phosphate supplementation.

Conclusions: Therefore, an early differentiation between CYP24A1 (24-hydroxylation) and SLC34A1 (NaPi-IIa) defects appears crucial for a effective therapy in children with IHH.

FR-PO927
Identification of SLC41A3 as a Novel Player in Renal Magnesium Homeostasis Jeroen H.F. De Baati, Anke Lameris, René J. Bindels, Joost Hoenderop. Dept of Physiology, Radboud Univ Medical Center, Nijmegen, Netherlands.

Background: Hypomagnesemia is a common clinical cause of muscle cramps, epilepsy and cardiac arrhythmias. In the distal convoluted tubule (DCT) of the kidney, transcellular reabsorption of Mg2+ regulates the body Mg2+ balance by determining the final urinary Mg2+ excretion. In the DCT, Mg2+ is reabsorbed from the pro-urine via the apical Mg2+ channel TRPM6. Until now, the basolateral Mg2+ extrusion mechanism in DCT is still unknown, but recent findings suggest that proteins of the SLC41A family may contribute to cellular Mg2+ extrusion. The aim of this study was, therefore, to investigate the role of SLC41A3 Mg2+ homeostasis using the Slc41a3 knockout mouse.

Methods: The Slc41a3 knockout mice were studied by serum and urinary electrolyte analysis. To determine the effect of Slc41a3 on intestinal Mg2+ absorption, the Mg2+ absorption capacity was measured using the stable [112Mg] isotope.

Results: Tissue expression screening was performed by RT-PCR, showing that Slc41a3 is the only SLC41 isoform with enriched expression in DCT compared to other segments in the kidney. Interestingly, serum and urinary electrolyte determinations demonstrated that Slc41a3 knockout mice suffer from hypomagnesemia due to renal Mg2+ wasting. Serum and urinary Na+, K+ and Ca2+ levels were not affected. Mg2+ uptake was similar in wild type and knockout mouse, although Slc41a3 knockout animals exhibited increased intestinal expression of Mg2+ transporters Trpm6 and Slc41a1. Remarkably, 10% of the Slc41a3 knockout mice developed severe unilateral hydropnephrosis, as demonstrated by the presence of transitional epithelium lining the fluid cavity. Feeding the Slc41a3 knockout mice a low Mg2+ diet may have instigated the formation of hydropnephrosis.

Conclusions: In conclusion, SLc41A3 was established as a new important factor for renal Mg2+ handling, suggesting that Slc41a3 is the basolateral Mg2+ extrusion mechanism in DCT. These mice provide the first mouse model with isolated hypomagnesemia, without concomitant electrolyte disturbances. In the future, SLc41A3 mutations should be considered in patients with unilateral hydropnephrosis and/or hypomagnesemia.

FR-PO928
Diuretic Inulin Supplementation Stimulates Magnesium Absorption in Patients with Proton Pump Induced Hypomagnesemia Jeroen H.F. De Baati,1 Mark Wilhelm Hess,2 Joost Hoenderop,2 Joost P.H. Drenth,3 René J. Bindels,3 1 Dept of Physiology, Radboud Univ Medical Center, Nijmegen, Netherlands; 2 Dept of Gastroenterology, Radboud Univ Medical Center, Nijmegen, Netherlands.

Background: Hypomagnesemia is a common and severe side effect of patients using proton pump inhibitors (PPI). For the first time we provide a successful alternative for oral Mg2+ supplementation. Methods: This clinical trial prospectively determined serum Mg2+ concentrations in 133 patients using PPIs. Under maintenance of PPIs, eleven identified cases of PPI-induced hypomagnesemia were exposed to 2 repetitive dietary suppletions with inulin for 14 days was washed out and compared to 10 healthy non-PPI users. The primary endpoint was serum Mg2+. Secondary endpoints were serum Ca2+, K+, and Na+ levels.

Results: Hypomagnesemia is present in 13% of the study population. Dietary supplementation with inulin significantly enhanced mean serum Mg2+ levels by +0.1 mmol/L in patients and Ca2+ by +0.1 mmol/L in healthy controls. Moreover, in patients with PPIH concomitant treatment effects were observed for serum Ca2+ (+ 0.09 mmol/L) and serum K+ (+ 0.07 mmol/L), no effects were seen on serum Na+. Patients with PPIH had adequately renal excretion of Mg2+ and Ca2+, which increased due to inulin following increases in serum levels. Additionally, two SNPs in TRPM6 (rs3770425 and c.2274024A) were identified that cause a 4.75 times higher risk to develop hypomagnesemia.

Conclusions: Inulin fibers are a promising prebiotic treatment strategy to treat intestinal- and renal-caused hypomagnesemia. For the first time we provide a successful alternative for oral Mg2+ supplementation.

Funding: Government Support - Non-U.S.

FR-PO929
The Distal Convoluted Tubule Plays a Key Role in Tacrolimus-Induced Hypomagnesemia and Hypercalcemia Rebecca A. Laerle,1 Sabina K. Jelen,2 Chao-Ling Yang,1 Joost Hoenderop,2 René J. Bindels,2 David H. Ellison,1 1 Div of Nephrology & Hypertension, Oregon Health and Science Univ, Portland, OR; 2 Radboud Inst for Molecular Life Sciences, Radboud Univ Medical Center, Nijmegen, Netherlands; 3 Renal Section, Portland VA Medical Center, Portland, OR.

Background: The immunosuppressive drug tacrolimus, used to prevent graft rejection, often leads to hypomagnesemia and can also cause hypercalcemia. A decrease in renal Mg2+ and Ca2+ reabsorption is thought to be involved, but the molecular mechanisms are unclear. Tacrolimus requires a binding partner, FKBP12, to inhibit its canonical target, calcineurin. We generated a mouse model in which FKBP12 can be deleted along the whole body.

Results: We found that the distal convoluted tubule (DCT) was knockdown using siRNA. ERK1/2 activation was determined by western blot. 

Conclusions: Therefore, an early differentiation between CYP24A1 (24-hydroxylation) and SLC34A1 (NaPi-IIa) defects appears crucial for a effective therapy in children with IHH.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

580A
neprin (KS-FKBPI2). We then tested if either FKBPI2 disruption or calcineurin inhibition alleviated the nephrotoxic effects on the mRNA abundance of renal ion transport proteins leading to hypomagnesemia and hypercalciuria.

**Methods:** KS-FKBPI2 mice were generated using an inducible CRE/LOX system driven by the Pax8 promoter. Mice were treated with doxycycline (KS-FKBPI2) or vehicle (control). Mice were fed a high phosphate diet (3%) for 24 days on plasma [Mg^2+], urinary Ca^2+ excretion, and mRNA abundance of renal proteins involved in ion transport using metabolic cages, colorimetric assays and qRT-PCR.

**Results:** As expected, tacrolimus caused hypomagnesemia and hypercalciuria in control mice, which was not the case in KS-FKBPI2 mice. Compared to KS-FKBPI2 mice, tacrolimus reduced the mRNA abundance of proteins involved in Mg^2+ and Ca^2+ transport by the distal convoluted tubule (DCT) including, TRPM6, calbindin-28K and the Sodium Calcium Exchanger-1. In contrast, tacrolimus had no effect in KS-FKBPI2 mice (p<0.05 for all comparisons). The abundance of mRNA encoding Claudin 16 and 19, thick ascending limb (TAL) proteins involved in Mg^2+ and Ca^2+ handling, were not affected by tacrolimus treatment in either group.

**Conclusions:** Tacrolimus reduces the abundance of mRNA encoding proteins involved in Mg^2+ and Ca^2+ transport by the DCT. These effects require FKBPI2, suggesting that calcineurin inhibition is essential. The results show that the DCT plays a key role in these troubling side effects.

**1 Physiology, Radboud Univ Medical Center, Nijmegen, Netherlands; 2Nephrology, Univ of Utah, Salt Lake City, UT; 3Pathology, Univ of Utah, Salt Lake City, UT.

**Background:** The transient receptor potential melastatin type 6 (TRPM6) epithelial channel participates in Mg^2+ reabsorption in the distal convoluted tubule. Using patch clamp, cell surface biotinylation and Total Internal Reflection Fluorescence (TIRF) live cell imaging of transfected HEK293 cells, TRPM6 channel activity was measured.

**Results:** Urinary Mg^2+ excretion was increased (~1.7-fold) in AC3 deleted mice compared to controls where as serum Mg^2+ concentrations were not different. Renal TRPM6 mRNA levels were increased by ~3-fold, Mg^2+ excretion was increased by ~2-fold in AC3 deleted mice. Serum Mg^2+ was significantly lower in AC3 deleted animals for 7 days on the low Mg^2+ diet compared to the control animals. In HEK293 cells, it was demonstrated that cAMP signaling rapidly potentiates the activity of TRPM6 by promoting its accumulation at the plasma membrane and by increasing its single channel conductance. Comparison of electrophysiological data between the phosphorylation-deficient S1252A and phosphomimetic S1252D mutants suggests that phosphorylation at this intracellular residue participates in the observed stimulation of channel activity.

**Conclusions:** These data support a physiologically relevant magnesiumotropic role of cAMP signaling in the direct stimulation of Mg^2+ transport in the kidney membrane trafficking and function of TRPM6 ion channels in the distal convoluted tubule.

**Renal Handling of Magnesium in Individuals on Long Term Proton Pump Inhibitor Therapy** 

**Saubhik Sural**, 

**Nephrology, Peerless Hospital & B K Roy Research Centre, Kolkata, West Bengal, India.

**Background:** Proton Pump Inhibitors (PPI) are a group of very commonly used medication. Recently the US-FDA has issued warning regarding the risk of high serum magnesium are associated with an increased risk of SCD. Although serum magnesium levels showed a negative correlation with the duration of PPI therapy (r = 0.502; p < 0.01). The FE—Mg of the PPI group is significantly reduced suggesting increased renal conservation of magnesium in order to maintain near normal serum levels.

**Conclusions:** Compensatory renal conservation of Mg occurs in long term PPI receiving patients. Thus if patients with impaired renal handling of Mg (diabetes; CKD or those on diuretics) receive long term PPI therapy they might possibly be at a greater risk of clinically significant hypomagnesemia.

**1Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan; 2Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.

**Background:** We have recently reported that the risk of progression of CKD associated with high serum phosphate (P) was significantly attenuated in patients who had higher serum magnesium (Mg) levels (Kidney International in press), although the causality remains unclear. Here we studied whether Mg protects against kidney injury induced by P overload.

**Methods:** Eight-week-old C57BL6 mice underwent uninephrectomy and were divided into 4 groups: 1. high P (1.25% P)-normal Mg (0.05% Mg) diet; 2. high P (1.25%) -low Mg (0.005% Mg) diet, 3. low P (0.2%) -normal Mg (0.05% Mg) diet; 4. low P (0.25%) -low Mg (0.005% Mg) diet. Twenty-four-hour urine samples were collected for the measurement of daily urinary excretion of P. After 6 weeks of dietary intervention, mice were sacrificed and kidney tissues were harvested for histological analysis and mRNA quantification.

**Results:** Mice fed with the high P-low Mg diet showed severe tubular injury, interstitial fibrosis, and a marked accumulation of F4/80 positive cells in the interstitium; these changes were largely attenuated in mice in the high P-normal Mg diet group. Creatinine clearance in the high P-low Mg diet group was significantly lower than that in the high P-high Mg diet group (0.04±0.02 vs 0.27±0.14; p<0.05). Both TGF-β/Smad and TNF-α mRNA expression levels in the whole kidney were upregulated in the high P-low Mg diet group compared with those in the high P-normal Mg diet group. No histological evidence of kidney injury was found in both of the low P groups. Since urinary P excretion in the high P-low Mg diet group was equivalent (at 3 weeks) to or even lower (at 6 weeks) than that in the high P-normal Mg diet group, it is unlikely that the exacerbation of kidney injury in the high P-low Mg diet group was owing to an increased intestinal absorption of P.

**Conclusions:** Low Mg diet aggravates phosphate-induced kidney injury. Mg may be beneficial to reduce the phosphate toxicity to the kidney.

**1Epidemiology, Erasmus MC, Univ Medical Center Rotterdam, Rotterdam, Netherlands; 2Internal Medicine, Erasmus MC, Univ Medical Center Rotterdam, Rotterdam, Netherlands.

**Background:** Low serum magnesium has been associated with cardiovascular disease (CVD) mortality in population-based studies. However, results are conflicting and it remains unclear if this effect is mediated by an effect on atherosclerosis or heart rhythm.

**Methods:** We examined the relationship between serum magnesium and CVD mortality in 9,820 participants aged ≥ 45 years from the population-based Rotterdam Study. We used multivariable-adjusted Cox proportional hazard regression models and divided serum magnesium into quartiles, with the second and third quartile combined as reference group.

**Results:** During a median follow-up of 8.7 years, 780 participants died of CVD, including 431 deaths from coronary heart disease (CHD) and 217 sudden cardiac deaths (SCD). Low serum magnesium (0.80 mmol/L) was associated with an increased CVD mortality risk (HR 1.25, 95%CI 1.10-1.41) and SCD (HR 1.68, 95%CI 1.20-2.37). Low serum magnesium was associated with an increased QT-interval, due to a strong effect on heart rate (RR interval -7.7 ms, 95%CI -14.7 to -0.7), but additional adjustment for heart rate did not change the association with SCD. Low serum magnesium was associated with increased intima media thickness (0.01 mm, 95%CI 0.004-0.020), and this explained part of the effect of magnesium on CVD mortality. Notable, high serum magnesium (≥ 0.89 mmol/L) was also associated with an increased risk of death from SCD (HR 1.50, 95%CI 1.05-2.16), but reduced risk of death from CHD (HR 0.64, 95%CI 0.43-0.95).

**Conclusions:** Low serum magnesium is associated with an increased risk of death from SCD, which is partly explained by an effect on atherosclerosis. Both low and high serum magnesium are associated with an increased risk of SCD. Although serum magnesium strongly affects heart rate, this did not explain the relationship between serum magnesium and SCD.
FR-PO934
Oral Magnesium Supplementation Improves Serum Calcium Propensity in Chronic Kidney Disease Stage 3-4
Jain B. Bressendorff, Ditte Hansen, Morten Schou, Andreas Pasch, Matthias Bachtler, Lisbet Brandt.
1 Dept of Cardiology, Nephrology and Endocrinology, North Zealand Hospital, Hillerød, Denmark; 2 Dept of Medicine, Div of Nephrology, Roshilde Hospital, Roskilde, Denmark; 3 Dept of Clinical Chemistry, Univ Hospital Bern (Inselspital), Bern, Switzerland; 4 Dept of Clinical Research, Univ of Bern, Bern, Switzerland.

Background: In previous experimental studies of chronic kidney disease (CKD) magnesium has been shown to improve vascular calcification. Serum calcium propension was measured using the T50 analysis which has been shown to predict all-cause mortality among patients with chronic kidney disease (CKD) stage 3-4.

Methods: In a proof-of-concept randomized placebo-controlled double-blinded trial of placebo versus slow-release magnesium oxide at two different doses (360 mg daily or 360 mg twice daily) for eight weeks in 34 subjects with CKD stage 3-4 and plasma magnesium <0.82 mmol/L, T50 was measured to examine whether magnesium supplementation affects serum calcification propensity.

Results: In subjects randomized to magnesium 360 mg twice daily (n = 11) plasma magnesium increased by 0.11 mmol/L (confidence interval: 0.05 - 0.17, p = 0.003) and T50 increased by 40 minutes (confidence interval: 18 - 63, p = 0.003) after eight weeks of treatment (Figure 1), while there were no changes in plasma phosphate, calcium or parathyroid hormone. There were no significant changes in T50 in the placebo (n = 12) or magnesium 360 mg once daily (n = 11) groups.

Conclusions: Oral magnesium oxide 360 mg twice daily improves serum calcification propensity in CKD stage 3-4 after eight weeks of treatment. Larger, long-term trials are needed to assess whether this translates into reductions in vascular calcification (e.g. coronary artery calcium score or pulse wave velocity) and cardiovascular endpoints.

FR-PO935
The Novel NaPi-IIb Inhibitor ASP3325 Does Not Mitigate Hyper-phosphatemia in Chronic Kidney Disease Patients on Hemodialysis
Tobias F. Larsen, Chiasso Kameoka, Ikumi Nakajo, Yuta Tanishi, Satoshi Yoshida, Tadao Akizawa, Ronald Alfonso Smulders, Astellas Pharma Europe BV, Leiden, Netherlands; 1 Astellas Pharma Inc., Tokyo, Japan; 2 Dept of Nephrology, Showa Univ School of Medicine, Tokyo, Japan.

Background: The sodium-dependent phosphate co-transporter type 2b (NaPi-IIb) is considered an important mediator of active inorganic phosphate (Pi) absorption and therefore recognized as a target molecule for treatment of hyperphosphatemia. We evaluated the pharmacological characteristics of ASP3325, a novel NaPi-IIb inhibitor being developed to treat hyperphosphatemia in chronic kidney disease (CKD).

Methods: The inhibition ratio of P-Pi uptake during ASP3325 (0.03-1000 nmol/L) treatment was measured in HEK293 cells stably expressing rat or human NaPi-IIb. To assess the competitive inhibition of NaPi-IIb to intestinal Pi absorption, ASP3325 and 32P-Pi were orally administered in sequence, and then serum 32P-Pi levels were measured. For normal rats, an ASP3325 containing-diet was provided for three days and the rate of Pi excretion in urine was measured on the final day. For rats with adenine-induced renal failure, an ASP3325 containing-diet was provided for two weeks after which plasma levels of phosphorus were measured.

Results: ASP3325 inhibited 32P-Pi uptake with an IC50 value of 7.0 mmol/L in HEK293 cells expressing human NaPi-IIb and an IC50 value of 88 mmol/L in HEK293 cells expressing rat NaPi-IIb. In normal rats, oral administration of ASP3325 at 1 and 3 mg/kg significantly reduced the area under the concentration curve of serum 32P-Pi levels from 0 to 30 min post oral administration. ASP3325 (0.001%-0.01%) reduced urinary Pi excretion dose-proportionally, and treated with 0.01% ASP3325 reduced excretion by 31.2% compared to vehicle (P=0.01). In rat with adenine-induced renal failure, ASP3325 (0.001%-0.01%) exhibited a dose-related reduction in plasma levels of phosphorus. Following two weeks of treatment, plasma level of phosphorus in the vehicle-treated group was 11.43 ± 0.66 mg/dL, and in the 0.01% ASP3325-treated group was 6.61 ± 0.47 mg/dL (P=0.01).

Conclusions: ASP3325 inhibited NaPi-IIb-mediated Pi transport and decreased plasma levels of phosphorus in rats with renal failure as well as urinary Pi excretion in normal rats. ASP3325 might therefore be a novel candidate for the treatment of hyperphosphatemia in humans.

FR-PO936
Novel NaPi-IIb Inhibitor ASP3325 Inhibits Phosphate Absorption in Intestine and Reduces Plasma Phosphorus Level in Rats with Renal Failure
Kazuhiro Terai, Yoshiharu Tomura, Showa University, Tokyo, Japan.

Background: The sodium-dependent phosphate co-transporter type 2b (NaPi-IIb) is considered an important mediator of intestinal inorganic phosphate (Pi) absorption and therefore recognized as a target molecule for treatment of hyperphosphatemia. We evaluated the pharmacological characteristics of ASP3325, a novel NaPi-IIb inhibitor being developed to treat hyperphosphatemia in chronic kidney disease (CKD).

Methods: The inhibition ratio of P-Pi uptake during ASP3325 (0.03-1000 nmol/L) treatment was measured in HEK293 cells stably expressing rat or human NaPi-IIb. To assess the competitive inhibition of NaPi-IIb to intestinal Pi absorption, ASP3325 and 32P-Pi were orally administered in sequence, and then serum 32P-Pi levels were measured. For normal rats, an ASP3325 containing-diet was provided for three days and the rate of Pi excretion in urine was measured on the final day. For rats with adenine-induced renal failure, an ASP3325 containing-diet was provided for two weeks after which plasma levels of phosphorus were measured.

Results: ASP3325 inhibited 32P-Pi uptake with an IC50 value of 7.0 mmol/L in HEK293 cells expressing human NaPi-IIb and an IC50 value of 88 mmol/L in HEK293 cells expressing rat NaPi-IIb. In normal rats, oral administration of ASP3325 at 1 and 3 mg/kg significantly reduced the area under the concentration curve of serum 32P-Pi levels from 0 to 30 min post oral administration. ASP3325 (0.001%-0.01%) reduced urinary Pi excretion dose-proportionally, and treated with 0.01% ASP3325 reduced excretion by 31.2% compared to vehicle (P=0.01). In rat with adenine-induced renal failure, ASP3325 (0.001%-0.01%) exhibited a dose-related reduction in plasma levels of phosphorus. Following two weeks of treatment, plasma level of phosphorus in the vehicle-treated group was 11.43 ± 0.66 mg/dL, and in the 0.01% ASP3325-treated group was 6.61 ± 0.47 mg/dL (P=0.01).

Conclusions: ASP3325 inhibited NaPi-IIb-mediated Pi transport and decreased plasma levels of phosphorus in rats with renal failure as well as urinary Pi excretion in normal rats. ASP3325 might therefore be a novel candidate for the treatment of hyperphosphatemia in humans.

FR-PO937
Statin Therapy Reduces Phosphate Levels in Dialysis Patients: Results from the Epidemiological Vitamin K Italian Study (VIKI Study)
Maria Fusaro, Sandro Giannini, Marianna Noale, Giovanni Tripipi, Piergiorgio Messa, Andrea Aghi, Nicola Veronesi, Maurizio Gallieni, Sabina Zambon, CNR, Padua; 2 Univ of Padua; 3 Ospedale Maggiore Policlinico, Milan; 4 CNR, Reggio Calabria; 5 San Carlo Borromeo, Milan.

Background: Statin therapy is the mainstay approach to reduce VC and prevent CV events in patients with dyslipidemia. The aim of this study was to investigate an association between statin therapy and plasma phosphate levels in patients on hemodialysis recruited in the VIKI Study.

Methods: The VIKI Study is a multicenter, cross-sectional study in 387 CKD patients on hemodialysis from 18 hospitals in Italy. We determined plasma levels of vitamin 25(OH)D, vitamin K, osteocalcin (bone-Glia-Protein or BGP), matrix-Glia-protein (MGP) and routine biochemistry. Assessment of VC was centralized (Witteman’s method: by measuring the length of calcific deposits along the anterior and posterior wall of the aorta). Plasma phosphate levels were dichotomized according to the median value (≥4.6 vs <4.6 mg/dL).

Results: 33% of the VIKI Study population (n=126) was on statin therapy. Patients on simvastatin had significantly lower HDL cholesterol (meanSD: 40.4±11.1 vs 43.5±13.4 mg/dL, p=0.0473) and higher plasma triglyceride levels (median: 164.0 vs 142.0 mg/dL, p=0.0041) compared to those not on statin. Plasma phosphate levels were significantly lower in patients on statin therapy (4.57±1.2 vs 4.86±1.33 mg/dL, p=0.0365). The analysis of the vitamin K components showed that patients on statin therapy had higher plasma MK7 levels (median: 1.16 vs 0.84 ng/mL, p=0.0241), while concentrations of vitamin 25(OH)D were significantly reduced (median: 26.0 vs 30.7 ng/mL, p=0.0198). In a multivariate analysis adjusted for BMI, angina, LDL, BGP and antibiotics, statin therapy was significantly associated with lower plasma phosphate levels (OR 0.61, 95%CI 0.38-0.98, p=0.0411), while BMI (OR 1.06, 95%CI 1.01-1.12, p=0.0250) and serum BGP levels ≥ 182 mcg/L (OR 1.58, 95%CI 1.01-2.48, p=0.0472) were associated with higher phosphate concentrations.

Conclusions: To our knowledge this is the first evidence of an association between statin therapy and reduced plasma phosphate levels in CKD patients.

Epidemiology of Kidney Stone Disease in Icelandic Children 1985-2013
Solborg E. Ingvarsdottr, Olafur S. Indridason, Runolfur Palsson, Vidar O. Edvardsson, Children’s Medical Center, Landspitali – The National Univ Hospital of Iceland; Div of Nephrology, Landspitali – The National Univ Hospital of Iceland, Faculty of Medicine, Univ of Iceland, Reykjavik, NA, Iceland.

Background: The aim of the study was to examine time trends in the prevalence and incidence of kidney stone disease in Icelandic children and adolescents over the past 3 decades.

Methods: Computerized databases of all major hospitals and medical imaging centers in Iceland covering the years 1985 to 2013, were searched for ICD, radiology and surgical procedure codes indicative of kidney stones for subjects aged 0-18 years of age. Incidence was calculated for the time periods 1985-1989, 1990-1994, 1995-1999, 2000-2004, 2005-2009 and 2010-2013, based on population information for Icelandic children in these years. Prevalence was calculated for the years 1999-2013.

Results: From 1985 to 2013, there were 186 incident patients, 110 (59%) of whom were female. Median (range) age at diagnosis was 15.0 (2.1-17.9) years. The annual incidence increased from a mean of 3.7/100,000 in the first 5 years to 11.0/100,000 in the years 1995-2004, but decreased thereafter and was 7.8/100,000 in 2010-2013. This trend was more pronounced in boys, for whom the incidence was 4.7/100,000 in the first time period, 11.0/100,000 during 2000-2004 and only 2.4/100,000 in 2010-2013. The incidence for girls increased from 2.7/100,000 in the first time period to 14.2/100,000 in 1995-1999 and has since then leveled off and was 13.6/100,000 in 2010-2013. The mean annual prevalence of kidney stone disease in 1999-2013 was 44/100,000 for boys and 51/100,000 for girls.

Conclusions: The incidence rise observed and current incidence of kidney stones in Icelandic children is similar to that recently reported in the USA. A significant incidence increase was observed for females in the early 1990’s but this did not trend downwards in boys and remained stable in girls. These trends can not be adequately explained and warrant further study.

Kidney Stone Recurrence in Icelandic Children
Solborg E. Ingvarsdottr, Olafur S. Indridason, Runolfur Palsson, Vidar O. Edvardsson, Children’s Medical Center; Div of Nephrology, Landspitali – The National Univ Hospital of Iceland; Faculty of Medicine, Univ of Iceland, Reykjavik, Iceland.

Background: The 5-year recurrence rate of kidney stones in adults is in the range of 30-50%. No population-based data are available on the recurrence of childhood kidney stone disease. The purpose of this study was to examine the recurrence rate of stone disease in Icelandic children.

Methods: Patients were identified by searching computerized databases of all the major hospitals and the only freestanding radiology clinic in Iceland for diagnostic, radiology and surgical codes indicating kidney stones in 1985-2013. We subsequently examined medical records of patients with kidney stone disease for information on stone recurrence. A recurrent stone event was defined as radiologic signs of a new stone or a new episode of flank pain and hematuria. The Kaplan-Meier method was used to assess stone-free survival and the log-rank test to compare groups.

Results: We identified 186 children with stone disease during the study period. There were 76 boys with a median (range) age of 14.6 (0.2-17.9) years and 110 girls aged 15.4 (8.1-17.9) years. The follow-up time was 13.0 (0-36) years. A total of 67 children (37%) experienced a second stone event, at a median of 1.9 (0.9-18.9) years after the initial diagnosis. The recurrence rate was 26%, 35%, 41% and 46% after 5, 10, 15 and 20 years of follow-up, respectively. There was no significant difference in recurrence rate between boys and girls (p=0.24) and those aged under and over 13 years at diagnosis (p=0.56), but a significant difference between patients diagnosed in 1985-1994, 1995-2004 and 2005-2013 was observed, with a 5-year recurrence rate of 9%, 24% and 8% respectively (p=0.002).

Conclusions: In our population-based pediatric study, the recurrence rate of kidney stones is similar to that reported in adults. Further, the rate of recurrence appears to be increasing as has recently been reported for the incidence of childhood stone disease. Increased recurrence rate may be related to improved diagnosis and documentation of stone events and/or environmental factors affecting urinary lithogenicity.

Funding: Government Support - Non-U.S.

Medical records of patients with kidney stone disease for information on stone recurrence. Assessment of Health-Related Quality of Life (HRQoL) in Rare Kidney Stone Formers (RKSF)
Frank Modularitz, Alicia Meck, David S. Goldfarb, Medicine, New York Univ School of Medicine, New York, NY; Medicine, Mayo Clinic, Rochester, MN.

Background: Assessment of HRQoL in RKSF is important for following disease course and evaluating treatments. We previously showed that SF with cystinuria reported lower SF than non-cystinuric subjects 5.5 years ago. We now report on population-based assessment of HRQoL in the Rare Kidney Stone Consortium (RKSC) Registries, to be followed prospectively.

Methods: Patients were enrolled from 3 RKSC registries: primary hyperoxaluria (PH), cystinuria and Dent disease. In adults, HRQoL is measured using the SF-36v2 and in children the SF-10. Participants chose between online assessment or paper-based questionnaire. Results are calculated as norm-based scores (NBS) based on US Standard Population = 50.

Results: 280 participants were enrolled; 200 adults, 80 children; 163 males, 118 females. Mean age was 34 years: for adults 44y and children 10y. 189 adults and 68 children were included in the baseline analysis: PH: 145, cystinuria: 71, Dent: 41. Domain scores for children are presented without cystinuria (n=10). For all participants, SF-36 NBS and summary scores for adults are below 50, except for the domain Physical Functioning (mean = 51.2). The lowest total domain score was in General Health with 45.8 ± 11.8. Adult and significantly different results in Role-Physical, Bodily Pain, Vitality, Social Functioning, Mental Health and Mental Component Score based on disorder. The lowest score was found in cystinuria for General Health (mean = 43.9). The summary scores for Physical Health (PHS) and Psychosocial (PSS) in children were 47.4 ± 14.2 and 51.80 ± 9.6 with

Supplemental Calcium Increases the Growth Rate of Renal Calculi in Stone Formers

Christopher J. Loftus, Josephine Velovetz, Alexander Chaftoff, Jennifer C. Hu, Carol Swetlik, Joseph Roy Abraham, Manoj Monga, Juan C. Calle. Glickman Urology and Nephrology Inst, Cleveland Clinic, Cleveland, OH.

Background: Though dietary calcium is associated with a decreased risk of stone formation, post-menopausal women supplemented with calcium have an increased risk of urinary tract stones. Prior studies have examined the effect of supplemental calcium on the risk of passing symptomatic stones but its role in the pathogenesis of stone formation is not clear.

Methods: We retrospectively identified 6059 patients with a history of urolithiasis. Eligible patients had 2 or more CT scans greater than 30 days but less than 2 years apart during the time of the stone event. For those on no supplementation, the most recent urine sample was used. Of these, 626 patients met the criteria: 195 on calcium, 127 on vitamin D only, and 104 on none. Patients on calcium received 46mg/d of 2703IU vitamin D3/d or 5607IU D2/d and patients on vitamin D only received 3085 IU D3/d or 6296 IU D2/d. Urine calcium was calculated as the sum of the maximum of all stones on CT, and rate of stone growth was calculated by the change in consecutive stone burdens divided by the elapsed time between scans.

Results: Stone composition was similar among all groups: 65.5% calcium oxalate, 20.0% calcium phosphate, and 11.8% uric acid. Stone formation rate in mm/year: standard deviation was 7.8±10.8 for calcium group, 3.3±11.4 for vitamin D, and 4.49±13.8 for none. Those supplemented with calcium had a higher rate of stone formation than those supplemented with vitamin D or none, p<0.01. Serum calcium was statistically significant when controlling for serum PTH and calcium on multiple logistic regression. BMI, gender, age and dose of calcium were not significantly associated with stone formation rate while dose of vitamin D had an inverse association, p=0.0490.

Conclusions: Supplementation with calcium was associated with a significant increase in stone growth rate in stone formers. Vitamin D supplementation showed no added risk and may potentially have a protective effect. Though the pathophysiology is unclear, these data suggest patients at risk of stone formation should be cautious of supplementation use.

FR-PO944
Effects of Calcium and Vitamin D Supplementation on Known Stone Formers

Felicity T. Enders, John R. Asplin, Deepa A. Malieckal, David S. Goldfarb. Internal Medicine, Div of Nephrology, NY Harbor VA Healthcare System, New York, NY; Internal Medicine, Div of Nephrology, New York Univ School of Medicine, New York, NY; *Internal Medicine, Div of Nephrology, NY Harbor VA Healthcare System, New York, NY; †Health Sciences Research, Div of Biomedical Statistics & Informatics, Mayo Clinic, Rochester, MN; ‡Liholink Corp, Chicago, IL.

Background: While high dietary calcium has protective effects against kidney stone formation, the effect of supplementation with calcium and vitamin D on the risk of kidney stone formation remains unclear. Post-menopausal women supplemented with calcium have an increased risk of urinary tract stones; however, there is conflicting evidence for the effects of supplementation on urinary excretion of calcium.

Methods: We identified 6059 patients with a history of urolithiasis by CT scan, 2061 of which had 24-hour urine collections before and after starting supplementation. For patients on no supplementation, the most recent urine was used. A total of 1486 patients were supplemented with calcium, 417 with vitamin D only, and 158 with no supplementation. Patients on calcium received an average of 600mg/d of 2702IU vitamin D3/d or 5678IU D2/d and patients on vitamin D only received 3005IU D3/d or 6307IU D2/d.

Results: Stone composition did not differ among groups: 70.0% calcium oxalate, 16.6% calcium phosphate, and 10.8% uric acid stones. There was a significant decrease in urinary calcium excretion in patients supplemented with calcium (p=0.021) and vitamin D (p=0.011) and significant decreases in urinary oxalate in those supplemented with calcium (p=0.0001) and vitamin D (p=0.0001). No differences were seen in the amount of change between supplemented groups for any urinary excretion values.

The table shows changes from baseline. Among all groups, higher serum calcium was associated with higher urinary calcium excretion (p=0.0001); higher serum calcium (p=0.0007)and vitamin D (p=0.026) were associated with lower oxalate excretion.

Conclusions: Both calcium and vitamin D supplementation decreased urinary calcium excretion. High serum calcium and vitamin D was associated with higher urinary calcium excretion in both men and women.

FR-PO945
Tolvaptan Therapy Effectively Decreases Urinary Calcium Oxalate, Calcium Phosphate, and Uric Acid Supersaturations in Stone Formers

Wisit Cheungpasitporn, Stephen B. Erickson, Andrew D. Rule, Felicity T. Enders, John C. Lieske. †Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; ‡Dept of Health Sciences Research, Mayo Clinic, Rochester, MN.

Background: Drinking large amounts of fluids is universally recommended for urinary stone prevention but can be difficult to do for many stone formers. Tolvaptan, a V2 receptor antagonist, blocks water reabsorption in the collecting duct. This in turn should increase serum osmolality and stimulate thirst. The net effect should be lower supersaturation of stone forming salts, but this has not been proven.

Methods: This double blind, randomized, placebo-controlled, crossover study was conducted in 21 adult calcium urinary stone formers, stratified as major calcium oxalate (CaOx, n=10) or calcium phosphate (CaP, n=11). Patients were randomized to receive tolvaptan 45 mg/day or placebo for week 1, followed by washout week 2, and then crossover to drug or placebo for week 3. The 24 hr urine volume and chemistries were assessed at the end of week 1 and week 3.

Results: Tolvaptan versus placebo decreased urinary calcium oxalate (204±96 vs 529±213 mOsm/kg, P<0.0001) and increased urinary volume (4.8±12.9 vs 1.8±0.9 L, P<0.0001). However, the majority of urinary salt excretion rates (mg/24 hrs) including sodium and calcium did not significantly change. Thus, urinary CaOx SS (-0.01±1.1 vs 0.95±0.87, P<0.001) and CaP SS (-1.6±17 vs -0.13±1.02, P=0.001) both decreased. Urinary Uric Acid (UA) SS also fell (-2.05±0.45 vs -5.24±3.12, P=0.03). The tolvaptan treatment effect on urinary supersaturation did not differ between CaOx and CaP stone types (P=0.05 for all interactions). Serum sodium increased slightly while on tolvaptan (142±3 vs 141±2 mEq/L, P=0.01).

Conclusions: Use of tolvaptan increased urinary volume but did not appreciably change daily excretion of urinary constituents. The net effect was thus a fall in CaOx, CaP and UA SS. This study highlights the dramatic benefit increased free water ingestion alone can have on urinary supersaturation. Use of tolvaptan or other V2 receptor antagonists could be a useful strategy for selected stone formers not responsive to intensive dietary and/or behavioral counseling.

Claudin-14 Gene Polymorphisms May Regulate Urine Calcium Excretion
Teresa Ariccia-Calegari, Marco Simonini, Lorenza Macrina, Paolo Manunta, Donatella Spotti, Giuseppe Vezzoli, Nephrology and Dialysis Unit, San Raffaele Scientific Inst, Milan, Italy.

Background: Claudins are a family of proteins that form paracellular calcium channels in tight junctions and may thus regulate tubular permeability to divalent cations. Claudin-14 is expressed in the ascending limb of Henle’s loop and inhibits calcium reabsorption. A previous GWA showed that two polymorphisms (SNPs) of CLDN14 (rs219778 and rs219781) were associated with kidney stones and calcium excretion in an Iceland population. The present study is aimed to explore the effect of CLDN14 SNPs on calcium excretion.

Methods: We have performed a retrospective study on 380 hypertensive patients never treated with antihypertensive drugs. These patients underwent a saline load test (i.v. infusion of NaCl 0.9% 2 litres in 2 hours) to evaluate sodium sensitivity. Kidney stones in their clinical history was ascertained by interview. Calcium was measured in 24-h urine and oxalate excretion was obtained from the GWA data.

Results: Kidney stones were reported by 9.3% of patients. No association was found between CLDN14 SNPs and stones. As previously observed, rs219778 was associated with kidney stones and calcium excretion in an Iceland population. The most significant association occurred with rs219778 (GG 5.62 ± 2.49, GA 4.86 ± 3.67, AA 3.67 ± 2.82, p = 0.0001). The association with calcium excretion was also observed when calcium excretion after saline load was considered (considering rs219755: AA 3.10 ± 0.36, GA 3.12 ± 0.21, GG 0.75 ± 0.51, p = 0.0008).

Conclusions: The CLDN14 genotype is associated with calcium excretion. This association is observed even after saline load test, a well known stimulus to urinary calcium excretion. Minor alleles of these SNPs could cause a reduction of calcium excretion and could be protective against kidney stones and hypercalciuria. The lack of association among stones and CLDN14 SNPs could be due to the method used to identify stone formers.

Independent Effect of Blood Glucose Level on Urinary Citrate and pH
Majuran Periniam,1 Erin Bakshis Ware,1,2 Jennifer Smith,1 Stephen T. Turner,1 Sharon R. Kardia,9 John C. Lieske,1,2 1Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 2Laboratory Medicine, Mayo Clinic, Rochester, MN; Dept of Epidemiology, School of Public Health, Univ of Michigan, Ann Arbor, MI; 3Inst for Social Research, Univ of Michigan, Ann Arbor, MI.

Background: Urinary citrate is an important kidney stone inhibitor and its excretion is influenced by systemic acid base status and diet. However, the effects of demographies and other factors on urinary citrate excretion are not well defined, including the independent influence of blood glucose.

Methods: Twenty-four hour urine samples were collected from non-Hispanic white sibships in Rochester, MN. Height, weight, blood pressure, blood glucose, serum creatinine and cystatin C were measured. Diet was assessed using the Viocare food frequency questionnaire. The effects of blood glucose, demographics and diet on urinary citrate excretion, urine pH and net gastrointestinal (GI) alkali absorption were evaluated in bivariate and multivariable models, plus interaction models that included age, sex, and weight.

Results: Samples were available from 709 individuals (mean age 66±9 years). In general urine citrate and urine pH correlated positively with higher net alkali absorption (p<0.0001). Urine pH was higher in women for any given net alkali absorption value, but not after adjustment for covariates. In multivariable models urinary pH decreased with higher serum creatinine, blood glucose, dietary protein and increased with dietary potassium. Meanwhile, in multivariable models urinary citrate increased with age, weight, eGFR, urine pH and increased with loop diuretic and thiazide use. Association of urinary citrate and age was influenced by blood glucose (p<0.01).

Conclusions: In our study urinary citrate and pH correlated positively with net GI alkali absorption. Blood glucose had independent effects on urine pH and urinary citrate. This study provides the first evidence that blood glucose could influence stone risk independent of urinary pH and urine citrate crystallization. These observations could provide new insights into the association of obesity and urinary stone disease.

Renal Oxalate Secretion Reduces Risk of Systemic Oxalosis in Primary Hyperoxaluria
Irshad A. Bhoj1, Kristin C. Mara, Felicity T. Enders, Ramila A. Mehta, John C. Lieske, Dawn S. Milliner, Nephrology and Hypertension, Mayo Clinic, Rochester, MN.

Background: Primary Hyperoxaluria (PH) is a rare genetic disease causing high hepatic production of oxalate. Renal excretion of oxalate keeps plasma oxalate (Pox) controlled but leads to stones and often ESRD. Systemic oxalosis occurs when GFR is reduced and Pox rises above the supersaturation threshold (approximately 45 mmol/L). Renal handling of oxalate in relation to GFR is poorly understood.

Methods: 16 patients ≥ 12 years without ESRD were identified from the Rare Kidney Stone Consortium registry. We used the most recent simultaneous Pox, serum creatinine and 24 hour urine oxalate (Uox). Net oxalate secretion (Sox) equals Uox-eGFR×Pox. Proximal tubular oxalate (PTox) is Uox corrected for creatinine and estimated proximal tubule water absorption, eGFR is by CKD-EPI (adults) or modified Schwarz (adolescents).

Results: 45 patients were identified (37 PH-1; 5 PH-2; 7 PH-3). Median age was 23.2 (IQR: 16.7, 32.9) and eGFR was 66.1 mL/min/BSA (54.8, 80.8). Pox, Sox and Uox rose sharply when eGFR fell below 45 mL/min. Similar results were seen in eGFR groups. PTox and Pox increased proportionally (p<0.001).

Conclusions: Compensation for high oxalate production in PH is maintained through CKD stage 3a. Higher PTox in CKD stage 3b may accelerate proximal tubular CaOx crystallization. Risk for systemic oxalosis is low until at least CKD stage 4.

FR-PO950
Effect of Antibiotic Treatment on Oxalobacter formigenes Colonization

Background: Kidney stones are a disease of worldwide prevalence with significant public health implications. About 60-80% of stones are composed of calcium oxalate (CaOx). Hyperoxaluria is a major risk factor. Oxalobacter formigenes (OF), a member of the normal gastric microbiota plays a major role in net colonic oxalate absorption and secretion. We now report OF colonization rates in a young healthy population, the stability of colonization, and the effects of antibiotic treatment on OF colonization.

Methods: We followed 64 healthy subjects tested for Helicobacter pylori (HP), who were stratified with antibiotics (Amoxicillin and clarithromycin for 2 weeks) for HP eradication. Using species-specific PCR, we tested for OF colonization at baseline and at follow-up.

Results: Of the 64 subjects (MF: 24/40; mean age 25.0 ± 5.5y) tested for OF, 25 (32%) subjects were positive at baseline. Subject to HP elimination, 6 became OF-negative at 6 weeks, only 2 reverted to positive at week 24, and 4 patients remained negative at follow up (Mean 21.0 ± 6wks). Of 16 untreated positive people, 12 (75%) remained positive at follow up (Mean 18.8 ± 7.7wks), but of 26 untreated negative subjects, only 6 (23%) were positive at follow up (mean 19.7 ± 6.6wks), significantly fewer than the untreated positives (p=0.001 by Fisher exact test).

Conclusions: We conclude that OF status remains stable over a follow-up period of several months, with antibiotics suppressing colonization in the majority of people in the short term. The differential long-term effect of antibiotics on OF colonization and its effect on urinary oxalate excretion, will be important to evaluate.

FR-PO951
Identification of Calcium-Oxalate Binding Proteins in Human Urine That Prevent Crystal Adhesion: An In Vitro Model of Kidney Stone Formation
Scott C. Norcott, J. Feng, F. Koenig, Quixin Guo, Katelynn H. Moor, Paul F. Austin. Dept of Surgery, Div of Urology, Washington St, Louis, MO.

Background: There are limited therapeutic options for the treatment of stone disease and about 50% of patients experience at least one recurrence. Existing treatment protocols focus on altering urine concentrations, which presents challenges due to the idiosyncratic nature of many stones and the variety of underlying factors. In this study, we examine the hypothesis that there are naturally occurring urinary proteins capable of binding calcium oxalate crystals, promoting their clearance, and preventing stone formation. Elucidating these interactions may provide novel therapies.

Methods: Calcium oxalate monohydrate (COM) crystals and fluorescently-labeled derivatives (COM-FITC) were synthesized in vitro. Stone formation was modeled in vitro by assessing the FITC-COM crystals to confluent monolayers of inner medullary collecting duct (IMCD) epithelial cells. Affinity chromatography was used to isolate COM-binding proteins from human urine.

Results: COM and COM-FITC crystals synthesized in vitro exhibited the typical prismatic morphology of urinary crystals. Incubation of IMCD cells with COM-FITC crystals resulted in rapid binding to the cell surface with high affinity. The addition of urinary proteins purified from human urine inhibited COM-FITC binding by 76.2%. Furthermore, urinary proteins inhibited the growth of COM crystals in free solution by 63.7%. In using this affinity chromatography to isolate COM-binding proteins, we found that this technique may facilitate the design of peptide-based therapies that prevent crystal adhesion and stone formation, as well as the development of diagnostic biomarkers that stratify patients and guide treatment decisions in at-risk populations.

Hydroxyapatite Induces Tolerance in Primary Human Monocytes Exposed to Calcium Oxalate Crystals
Benjamin Canales,1 Paul R. Dominguez Gutierrez,2 Sergei Kusmartsev,1 Katherine M. Lowney,1 Ammon B. Peck,2 Scott A. Koenig,3 Qiusha Guo,1 Katelynn H. Moore,3 and Paul F. Austin.1

Background: Although most crystal deposits within tissue produce inflammation, renal interstitial hydroxyapatite deposits do not, accumulating as Randall’s plaque. To further explore this lack of response, we investigated the effect of oxalate, hydroxyapatite, and combination of both on time dependent, immunological responses in human THP-1 (monocyte) cells, the precursors to tissue macrophages.

Methods: Using 1 mg/ml LPS and untreated as positive and negative controls, THP-1 cells were exposed to varying concentrations of soluble potassium oxalate (KOx) or CaOx and treated (10, 100, and 1000 ug/ml). In addition, a group of primary human monocytes were pre-treated with 100 ug/ml of HA or CaOx followed by secondary treatment with 100 ug/ml HA, 100 ug/ml CaOx, and 1 mg/ml LPS. THP-1 cells were collected at 2, 4, and 8 hours after various treatments, and RNA was analyzed by quantitative real time PCR.

Results: Pre-exposed THP-1 cells responded strongly at baseline, demonstrating marked suppression of TNFα, IL-1β, IL-8, and IL-10 secretion. However, at 4 hours, a dose depended response was observed at 100 ug/ml LPS exposure of human monocytes to HA had little effect on cytokine response to subsequent CAOx and LPS exposure; however, pre-exposure to CAOx followed by HA negated all further cytokine production.

Conclusions: In our human monocyte model, the order of CAOx and HA exposure affects myosin response. HA neither stimulates cytokine production nor inhibits demonstrated production when pre-exposing monocytes prior to CAOx exposure. Pre-exposed CAOx monocytes, however, had decreased cytokine and chemokine expression when secondarily treated with HA. This tolerance mechanism may partially explain the lack of papillary inflammation in the pathogenesis of Randall’s plaque.

FR-PO953
A Low Sodium Diet Inhibits Stone Formation in Genetic Hypercalciuric Stone-Forming Rats
Benjamin S. Scott1

Background: About 60–80% of stones are composed of calcium oxalate (CaOx) and about 50% of patients experience at least one recurrence. Existing treatment protocols on urinary oxalate excretion, will be important to evaluate. We conclude that of dietary Na restriction reduces kidney stone formation, we utilized 101 generation genetic hypercalciuric stone-forming (GHS) rats fed either a low (LNa, 0.05%) or normal (NNa, 0.4%) Na diet for 18 weeks. Urine was collected at 6 wk intervals; a mean was determined for each analyte and then an overall 18 w week mean calculated. Radiographic analysis for stone formation was done at 18 wks.

Results: As anticipated, the decreased mean uNa (NNa=2.48±0.3 mmol/24h; LNa=0.9±0.2 mmol/24h) and uCa (NNa=2.65±0.13 mmol/24h; LNa=1.9±0.06, p<0.001) in the LNa group resulted in significantly lower overall mean uCa was lower with LNa than NNa (NNa=17.3±3.5 mg/dL; LNa=15.2±0.5, p<0.01) as was u phosphate (P) (NNa=16.5±0.6 mg/dL; LNa=13.8±0.4, p<0.001). Urine oxalate (Ox) and citrate (C) increased in LNa, citrate and volume did not differ with diet Nna. There were no significant differences in a u NaP characterization with respect to CaOx or CaOx. Serum Ca was significantly increased with LNa (NNa=10.9±0.1 mg/dL; LNa=11.4±0.1, p<0.01) while there were no differences in urine P, PTH or FGF23. Radiographic analysis of kidneys demonstrated a significant decrease in calcification with LNa (calcification scores with a range of 0-3: NNa=1.4±0.15; LNa=0.5±0.12, p<0.001).

Conclusions: Thus a low Na diet reduced uCa and stone formation in GHS rats even though urine supersaturation was not altered. These data, in a genetic model of hyperoxaluria and stone formation, lend support to the use of dietary Na restriction to prevent recurrent Ca nephrolithiasis.

FR-PO954
Ethylene Glycol Induced Hyperoxaluria in Rats: A Transcriptional Study

Background: Hyperoxaluria, if remains undiagnosed, can cause renal injury and inflammation leading to a number of diseases including advanced stages of renal failure. In order to look into the different pathways and molecular mechanisms involved in the kidneys of hyperoxaluric rats, we performed genome wide analysis of differentially expressed genes in the kidneys of rats fed ethylene glycol (EG).

Methods: Male rats were divided into two groups. Rats in one group were fed normal diet and the other group diet supplemented with 1.25% EG. Urinary assays were done at different time intervals and after 14 and 28 days rats were euthanized, kidneys explanted and total RNA extracted for micro array analysis using Agilent 8 x 60k single color arrays. Data was analyzed using bio-conductor Limma (Linear models for micro array analysis) package using R. Gene ontology (GO) and KEGG pathway analyses were also performed. Immunohistochemical (IHC) and Eosin and Hematoxylin (E & H) staining was also done for highly significant genes.

Results: All rats became hyperoxaluric from day 7 and had crystal deposition at different time intervals. Urinary LDH, sodium and creatinine were significantly different in the EG group as compared to the control. There was significant expression of different genes encoding for macromolecular modulators such as osteopontin (OPN), monocye chemoattractant protein-1 (MCP-1), lipocalin 2 (Lcn-2), fibroin (Fn-1), clusterin (CLU) and kidney injury molecule-1 (KIM-1) along with nicotine amide dinucleotide phosphate (NADPH) oxidase-4 (NOX-4) and glutathione peroxidase (Gpx-2). Gene analysis showed 17 and differentially expressed pathways for day 14 and day 28 respectively.

Conclusions: Results highlight that the EG treated rats showed heavy deposition of crystals and there were 15 pathways that were common between day 14 and day 28 giving a deep insight into the molecular mechanisms and pathways activated in hyperoxaluric rats.

Sucrose and Thiosulfate Competitively Inhibit Oxalate Transport via a Drosophila Prestin (dPrestin, dSIC26α)-Dependent Mechanism Greg M. Landry,1,2,3 Taku Hira,1,4 Jacob B. Anderson,1 Christopher Joseph roel Gallo,1 Michael Francis Romero,1,2,3,5 Physiology and Biomedical Engineering, Mayo Clinic College of Medicine, Rochester, MN; Nephropathy and Hypertension, Mayo Clinic College of Medicine, Rochester, MN; O’Brien Urology Research Center, Mayo Clinic College of Medicine, Rochester, MN.

Background: Nephrolithiasis affects approximately 12% of men and 6% of women in industrialized countries with the majority of stones being composed of calcium oxalate (CaOx).

Methods: Using Drosophila melanogaster as a robust and translatable model of CaOx nephrolithiasis, we studied the effects of sucrose and thiosulfate on oxalate transport, and subsequent CaOx crystal formation, as a proof of principle in providing a nidus to identify new therapeutic interventions.

Results: Results indicate that dPrestin transports thiosulfate with a much higher affinity than sucrose (dPrestin sucrose Kₚₒₓ = 8.65 ± 3.87 mM compared to dPrestin thiosulfate Kₚₒₓ = 0.23 ± 0.03 mM). Additionally, both sucrose (48 h) and thiosulfate (24 and 48 h) were effective at decreasing Malpighian tubule CaOx crystallization with the opposite results observed at 48 h in Malpighian tubules where dPrestin was not expressing a role indicating differentiation for cell-specific dPrestin in luminal oxalate transport.

Conclusions: Given the higher affinity of thiosulfate for dPrestin when compared to those which are reported for oxalate (dPrestin average Kᵢₚₒₓ for oxalate = 0.87 ± 0.16 mM and for thiosulfate = 0.22 ± 0.03 mM), we have concluded that the ability of thiosulfate to act as a competitive inhibitor of oxalate at the transporter level, specifically dPrestin, may explain the regulatory role in CaOx stabilization seen in the absence of thiosulfate. Overall, our findings predict that thiosulfate or oxalate-mimics may be effective as therapeutic competitive inhibitors of CaOx crystallization.

FR-PO956

Background: C3 glomerulopathy (C3G) is a progressive form of glomerulonephritis (GN) characterized by antibodies associated with abnormalities in regulation of the alternative pathway (AP) of complement. Mice with deficiency of factor H (Cfh⁻/⁻), a negative AP regulator, are an established experimental model of C3G in which abundant complement C3 accumulates along the glomerular basement membrane.

Methods: We examined the spontaneous renal phenotype in Cfh⁻/⁻ mice with and without accompanying deficiency of complement receptor 3 (CR3), the main receptor for iC3b. We performed accelerated serum nephrotoxic nephritis (ANTN) in CR3-deficient mice, accompanying CR3 deficiency was associated with significantly increased albuminuria, glomerular hypercellularity and macrophage influx, and mortality. We performed bone marrow transplantation experiments in Cfh⁻/⁻ recipients indicated that the protective effect of CR3 was dependent on BM-derived cells. ANTN produced severe, significant increased albuminuria, glomerular hypercellularity and macrophage influx, and mortality. Bone marrow (BM) transplantation experiments in C3G patients, which do not score in the standard C3NeF assay. Here we compare how 50-80% of C3G patients. Notably also autoantibodies but lack C3Nef. Some C3 convertase antibodies deregulate the C3 convertase and additional C3 convertase inhibition.

Results: Among the 34 C3G patients, 19 patients were identified with autoantibodies which bind to the C3 convertase, but lack C3Nef. 15 patients were identified C3NeF positive according to the binding to the C3 convertase, high titer (HT) and low titer (LT) antibodies were identified among isolated autoantibodies from all 34 C3G patients. HT as well as LT antibodies strongly activated the C5 convertase and enhanced C5a generation. Interestingly all antibodies bound to the C3 convertase, but only HT and not LT antibodies complement C5 convertase activity. The HT but not the LT antibodies increased C3 convertase assembly, stabilized the convertase and increased C3a generation.

Conclusions: Two classes, HT and LT, of complement C3 convertase binding autoantibodies were identified in C3NeF-positive and negative C3G patients. These antibodies deregulate complement by two different mechanisms: HT antibodies activate complement on the C3- and C5 convertase levels, while LT antibodies activate only on C5 convertase level. We speculate that these functional different autoimmune forms explain responder and non-responder types to therapeutic C5 inhibitors.

FR-PO959

Autoimmune C3 Glomerulopathy: Can Complement Inhibiting Drugs Reduce Complement Activation by C3 Convertase Autoantibodies? Friederike Sophie Schulze,1 Fei Zhao,1 Giuseppe Remuzzi,2 Marina Noris,3 Christine Skerka,1 Peter F. Zipfel,1,3 Hans Knoll Inst, Jena; 1Mario Negri Inst for Pharmacological Research, Bergamo; 1Friedrich Schiller Univ, Jena.

Background: C3 glomerulopathy is a severe kidney disorder that is caused by deregulation of the alternative complement pathway. Pathways are important in the development of new autoantibodies cause complement deregulation and how complement inhibitors affect the action of these autoantibodies.

Methods: IgGs were purified from patients with C3 convertase antibodies lacking C3NeF (n=19) and also from C3NeF+ patients (n= 15). These purified IgGs were tested for their impact on complement activity and the effect of soluble CR1 (sCR1) and Eculizumab was examined by ELISA, Western blot and complement activation assays.

Results: C3 convertase antibodies from patients lacking C3NeF deregulated complement only in the absence of autoantibodies stabilized the C3 convertase and all activated the terminal complement pathway. C3NeFs activated complement in a related manner. In probes with C3 convertase antibodies sCR1 did inhibit excessive complement activity. Also Eculizumab prevented antibody mediated complement activation. Both inhibitors blocked C3NeF-mediated complement deregulation in a related manner. For some probes from either C3NeF+ or C3NeF- patients a higher dose of sCR1 was necessary to affect C3 convertase activity.

Conclusions: A subgroup of C3G patients present with C3 convertase-binding antibodies but lack C3NeF. Some C3 convertase antibodies deregulate the C3 convertase and all stabilize the C5 convertase. The complement inhibitors sCR1 and Eculizumab reduced complement activity. Patients with antibodies causing only excessive C5 convertase activity may benefit from Eculizumab, whereas patients with excessive C3 convertase may require additional C3 convertase inhibitors.

FR-PO957

Two Autoimmune Forms of C3-Glomerulopathy Are Defined by Complement Convertases Deregulating Autoantibodies Christine Skerka,1 Fei Zhao,1 Giuseppe Remuzzi,2 Rossella Piras,2 Peter F. Zipfel,1,3 Dept of Infection Biology, Leibniz Inst for Natural Product Research and Infection Biology, Jena, Germany; 3Laboratory of Immunology and Genetics of Transplantation and Rare Diseases, IRCCS- Istituto di Ricerche Farmacologiche, Bergamo, Italy; 1Friedrich Schiller Univ, Jena, Germany.

Background: In C3Glomerulopathy (C3G) defective complement activation on level of the C3 convertase is caused by mutations in genes coding for complement components and or regulators as well as by autoantibodies. C3 nephritic factor (C3NeF) has been reported in 50-80% of C3G patients. Notably also autoantibodies to C3b and Factor B were identified in C3G patients, which do not score in the standard C3NeF assay. Here we compare how the new C3 convertase reacting antibodies and also C3NeF affect complement regulation on the level of the C3- and the C5 convertases.

Respiratory Syncytial Virus May Exacerbate Kidney Damage in IgA Nephropathy Through C3a/C5aR and C5a/C5aR Signaling Amplifying the Effects of Th17 Cells Xiaozhao Li,1 Xinyue Hu,2 Ting Meng,3 Juntao Feng,2 Qiaoling Zhou.1 1Dept of Nephrology, Xiangya Hospital of Central South Univ, Changsha, Hunan, China; 2Dept of Clinical Laboratory, Xiangya Hospital, Central South Univ, Changsha, Hunan, China.

Background: The exacerbation of IgA nephropathy (IgAN) is related to respiratory tract infection with respiratory syncytial virus (RSV), but the mechanism is unknown. In this study we investigated the role of complement activation products C3a and C5a (C3aR and C5aR) in response to the effect of T-helper 17 (Th17) cells in the pathogenesis of IgAN associated with RSV.

Methods: IgA nephropathy was induced in BALB/c mice with lipopolysaccharide, carbon tetrachloride and bovine serum albumin. Then the mice were sensitized with C3aR-Antigen (C3aRA) and C5aR-Antigen (C5aRA) respectively and infected with respiratory syncytial virus (RSV) in sequence. Urine Albumin-Creatinine ratio and sediments were measured. The pathological changes in kidney and lung tissues were observed under microscopy. C3aR and C5aR proteins in kidney tissue were examined by immunohistochemical staining. Th17 cell regulatory T cells (Tregs) in kidneys were tested by flow cytometry. C3a-C5a, IL-17A, IL-6 and IL-21, IL-22 in the kidneys were detected by ELISA.

Results: The IgAN mice had albuminuria and microscopic hematuria, renal mesangial proliferation and C3a deposition, high electron dense deposition in glomerular mesangial region, decreased frequency of Tregs, increased frequency of Th17 and Th17-Treg ratio. Furthermore, C3a, C5a, C3aR, C5aR and Th17-related cytokines IL-17A, IL-6 and IL-21 were all increased in the kidneys of IgAN mice. Compared with IgAN mice, the manifestations in RSV-IgAN mice were more severe, but alleviated in C3aR-treated groups and C5aR-treated groups respectively.

Funding: Government Support - Non-U.S.
Conclusions: RSV infections may exacerbate kidney damage in IgAN through C3a/C3aR signaling amplifying the Effects of Th17 Cells. The first two authors contributed equally to this work.

Functional Glomerular Deceleration Accelerating Factor Induction by Heme: Role of HO-1
Maria Detours, Giouli Makri, Vasileios Atsalas, Pu Diann, Elias A. Lianos.
1 Medicine, Univ of Athens, Greece; 2 Medicine, Rutgers Biomedical and Health Sciences, NJ.

Background: In hemolytic disorders and glomerular injury associated with hematuria intraglomerular free heme increases and may activate the alternative complement (C)-pathway. Rat glomeruli express deceleration factor (DAF) in glomerular epithelial cells (GEC). We assessed whether heme upregulates glomerular DAF to minimize C activation and explored underlying mechanisms.

Methods: hmox1-/- and hmox1 +/+ rats were generated by Zinc Finger Nuclease (ZNF)-mediated HO-1 gene disruption and rats with GEC targeted HO-1 overexpression (GEC-hmox1) by Sleeping Beauty Transposon mediated transgenesis using a nephrit promoter. Wild-type (WT) or hmox1 +/+ , hmox1-/- or GEC-hmox1 glomeruli were treated for 18 h with heme (hemin, FePP) or non-iron porphyrins with opposite effects on HO activity: 1) HO inducers, Cobalt (CoPP) and the non-metal protoporphyrin IX (PPIX) and 2) HO inhibitors: Zinc (ZnPP), Tin (SnPP) protoporphyrins, Tin (SnMP) and Chromium (CrMP) mesoporphyrins. C3b deposition in glomeruli was triggered by exposure to 10% rat serum. DAF, HO-1 and C3b levels were assessed by western blotting or Real-time PCR. HO enzyme activity was measured by standard methods.

Results: Constitutive DAF (mRNA and protein) decreased in both hmox1 -/- and hmox1 +/+ and increased in GEC-hmox1 glomeruli. Heme, at concentrations encountered in hemolytic disorders (50-400 µM), increased DAF expression in WT glomeruli. This effect was attenuated in both hmox1 -/- and hmox1 +/+ and augmented in GEC-hmox1 glomeruli. Heme-mediated DAF induction in hmox1 +/+ glomeruli persisted despite complete HO-1 absence. Of the non-Fe porphyrins, CoPP, ZnPP and PPIX increased DAF and HO-1. SnPP induced DAF but not HO-1. SnMP and CrMP had no effect on either heme. Tin or SnPP-mediated DAF induction reduced C3b deposition. This was reversed by PI-PLC which removed membrane bound DAF.

Conclusions: HO-1 regulates constitutive DAF expression and heme-mediated DAF induction. The latter is independent of metal moiety and HO enzyme activity, requires the porphyrin ring and may also occur via a HO-1 independent mechanism. DAF induction by heme is functional and attenuates C-activation.

Complement Activation Impairs Endothelial Cell Migration – Possible Role in TMA Pathogenesis
Magdalena Riedl, Daniel Schlhamer, Fred G. Pluthero, Walter H. Kahr, Christoph Licht.
Cell Biology Program, The Hospital for Sick Children, Toronto, ON, Canada.

Background: Cell migration is a key requirement in multiple physiological scenarios including angiogenesis and endothelial cell repair. Thrombotic microangiopathy (TMA) is characterized by endothelial cell (EC) activation and injury, in atypical hemolytic urticemic syndrome caused by complement activation on ECs. We hypothesized that EC injury in aHUS was at least in part – caused by complement-mediated inhibition of cell migration. Methods: To test this hypothesis blood outgrowth ECs were exposed to complement by blocking EC surface regulators (CD46, CD55, CD59) and incubating ECs with 50% normal human serum (NHS; complement active). Heat inactivated serum (HIS; complement inactive), C5-depleted serum (terminal pathway inactive) and media served as controls.

Results: Wound healing assay in fluidic conditions (wound infliction via trypsin/EDTA) showed within 1.5 h a wound area decrease to 62.5±1.5% when perfused with media. Subsequent (1.5h) HIS perfusion allowed for further wound area reduction to 38±6.5%, similar to C5-depleted serum (46±5%). In contrast, exposure to complement (NHS) inhibited further wound closure (wound area 63±7%, p<0.05). The proliferation rate (% BsdU+ positive cells after 2 h) was similar between controls and complement-exposed ECs (20±2 vs. 21.1±3%), and no apoptosis or necrosis was detected within a 30min - 4h observation period (Annexin V, live dead aque dye). However, we demonstrated an instantaneous but transient cell membrane perfusion, suggesting a role for PIP3 signaling in impaired cell migration leading to EC injury and defective EC repair – findings extending our current concept of TMA pathogenesis.

Conclusions: Our data suggest that sublethal EC complement exposure results in impaired cell migration leading to EC injury and defective EC repair – findings extending our current concept of TMA pathogenesis.

FR-PO962

Uncommon Features in Antibody Binding Sites of Human Anti-Glomerular Basement Membrane Autoantibodies
Mary H. Foster, Elizabeth Sarah Buckley, Amy G. Clark.
Medicine, Duke Univ Medical Center and Durham VAMC, Durham, NC.

Background: Detection of pathogenic anti-α3(IV)NC1 collagen autoAb in the serum or kidneys is required for diagnosis of anti-GBM nephritis and Goodpasture Syndrome, yet little is known about the origin and structure of human anti-α2/α3/α4 in these diseases. The heterogeneity of serum Ig, lack of ready access to kidney tissues in patients, and inability to reproduce complex immunological microenvironments in vitro present formidable barriers. Humanized models provide a novel platform to circumvent these obstacles.

Methods: We generated Hu-HSC mice by injection of human CD34+ hematopoietic stem cells into immunodeficient NOD-scid-gamma hosts. Mice with an established human immune system (mean blood chimerism 15.0±15.9% at 3 mons post-injection) were immunized twice with α3(IV)NC1 collagen prior to tissue harvest. Human C amplified EBV transformed using Cpe oligos and kinase inhibitors, screened for antigen binding, electrophoresed with a human heterohybridoma, and subcloned. The mAb sequences were determined using PCR of cDNA with published primer panels and analyzed using IMGT/TV-QUEST.

Results: Sequence analysis of 6 non-clonally related human anti-α3(IV)NC1 mAb revealed skewed gene use and unusual motifs in the critical HCDR3 that is predominantly responsible for antigen binding. 4 of 6 (67%) human mAb are encoded by an IgH J6 allele, the extended sequence of which enriches for aromatic tyrosine residues in HCDR3. The HCDR3 are exceptionally long, with mean length 26.4 amino acids (a.a.) compared to average human HCDR3 of 15.2 a.a., and include hydrophobic motifs, an autoimmune signature uncommon in Ig repertoires of healthy individuals and of unimmunized Hu-HSC mice. Similar motifs were observed in murine anti-α3(IV)NC1 mAb, despite substantial species differences in Ig gene loci and a.a. composition.

Conclusions: Our results suggest that binding of α3(IV)NC1 collagen by human anti-GBM autoAb requires unusual structural motifs that can access recessed hydrophobic epitopes and that are normally excluded from the healthy human immune repertoire. Similar motifs in man and mouse suggest origins by convergent selection.

Antigenicity Alteration of Deglycosylated Myeloperoxidase
Juntao Yu, Zhuo Cui, Minghui Zhao.
1 Academy for Advanced Interdisciplinary Studies, Peking Univ, Beijing, China; 2 Renal Div, Peking Univ First Hospital, Beijing, China.

Background: Myeloperoxidase (MPO) is a kind of enzyme located in the azurophilic granules of neutrophils, which is the most common target antigen of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) in Chinese patients. Native MPO possesses five N-glycans at positions 323, 355, 381, 483 and 729. The alteration of MPO antigenicity after deglycosylation of these glycans is not elucidated.

Methods: We prepared deglycosylated MPOs via glycosidases based on commercial human-derived intact MPO, and then detected the antigenicity of deglycosylated MPOs in 40 patients with anti-glomerular basement membrane (GBM) disease without MPO-ANCAs.

Results: We found antibodies against deglycosylated MPOs existed in patients with antigranulocyte disease. 12/40 (30%) patients were positive for MPO treated with PNGase F naked MPO without hydrocarbon side-chain. 12 (30%) patients were positive for MPO treated with Endo H (MPO with one GluNac only). Antibody against the intact native MPO was not detectable in all these patients. Furthermore, clinical analysis presented that the deglycosylated antibodies against deglycosylated MPOs were positively associated with renal dysfunction. The plasma levels of antibodies against naked MPO without glycan were positively correlated with the concentrations of serum creatinine (P<0.006, R=−0.178). The plasma levels of antibodies against MPO with one GluNac only were also positively correlated with the concentrations of serum creatinine (P=0.002, R=−0.234).

Conclusions: The existence of patients’ antibodies towards deglycosylated MPO first discovered the new epitope exposure of MPO after the loss of hydrocarbon side-chain, explicating the possible reasons for antigenicity alteration, and then prompting some clinical significance of these antibodies.

Autoantibodies to a Cryptic Myeloperoxidase-Specific Immunodominant Epitope Correlate with Disease Activity in Patients with MPO-ANCA Vasculitis
UNC Kidney Center; Univ of North Carolina, Chapel Hill, NC.

Background: ANCA vasculitis is commonly characterized by polyclonal autoantibody reactivity to one of two autoantigens, proteinase 3 (PR3) and/or myeloperoxidase (MPO). ANCA positivity has been observed in patients with active and quiescent disease. A subset of MPO-ANCA in many patients recognizes a cryptic epitope which is normally buried within MPO suggesting that this epitope may be exposed by mechanisms that are not yet understood. We assessed human anti-KV reactive longevity in a large cohort of patients with MPO-ANCA vasculitis to better understand the temporal association of the anti-ANCA antibody response.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

Reror
Methods: Serum, plasma, and extensive clinical data from patients with ANCA vasculitis were prospectively collected every 3 months. A highly sensitive and specific indirect ELISA using KIV peptide was developed to longitudinally screen patient samples for reactivity over their disease course. To minimize non-specific antibody signal, reactivity to a scrambled peptide of the same amino acid composition was also measured. A positive signal was defined as two standard deviations above the healthy control mean (HC n=85).

Results: Of 67 patients with MPO-ANCA vasculitis, 28 were positive for human anti-KIV autoantibodies at least once during their disease course spanning an average follow-up of 3.3 years. The majority of these patients displayed positivity during initial stages of disease, while others exhibited a persistence of reactivity. Further structural analysis of autoantibody binding to native MPO confirmed this peptide to be a cryptic epitope.

Conclusions: These findings suggest that conformational changes in MPO that expose this cryptic epitope may be important in the pathogenesis of the MPO-ANCA vasculitis and may provide insight into the etiology of this disease. Furthermore, this assay could help to more clearly define temporal disease activity.

An Anti-GBM Autoantibody Gene Contributes Risk to Distinct Auto-Collagen Responses
Amy G. Clark, Inge M. Wormi-Schudel, Mary H. Foster.
Medicine, Duke Univ Medical Center and Durham VAMC, Durham, NC.

Background: The mechanism by which anti-GBM nephritis is initiated and regulated remains an enigma. Recent studies indicate that anti-GBM patients’ serum IgG react with multiple collagen chains and with atypical alpha3(V)NC1 epitopes, and that diverse marine anti-collagen antibodies auto-antigenically linked. We examined these relationships in a novel autoantib IgG transgenic model expressing a human GBM gene at low frequency in adult mice but enriched in anti-GBM IgG and arthrogryphic anti-collagen II IgG.

Methods: Mice expressing an IgK-encoding kappa light chain Tg were bred with mice expressing a collagen II alpha1 chain. Both anti-collagen and anti-alpha3(V)NC1 collagen I antibodies were detected by western blot, dot blot, and ELISA and characterized by their ability to react in situ with anti-GBM antigens. We assessed the contribution of anti-alpha3(V)NC1 antibodies to the development of collagen I and II autoantibodies by assessing serum samples from Tg mice versus wild type controls.

Results: Differences in collagen II and III reactivity were observed with anti-collagen II antibodies being stronger than those anti-collagen III. Anti-alpha3(V)NC1 collagen I antibodies were present in both Tg and non-Tg mice, but were more strongly expressed in Tg mice. These results suggest that anti-collagen II antibodies are regulated by the absence of anti-collagen III autoantibodies.

Conclusions: Our results demonstrate the potential of this transgenic model to study the role of distinct autoantibody responses in the development of anti-GBM nephritis.

FR-P0966
Autoantibodies Target Multiple Epitopes in THSD7A in Primary Membranous Nephropathy
Hong Ma, David J. Salant, Laurence H. Beck.
Medicine, Renal Section, Boston Univ Medical Center, Boston, MA.

Background: Thrombospondin type-1 domain-containing 7A (THSD7A) is a large type 1 transmembrane glycoprotein expressed by the podocyte. It serves as the in situ antigen in a subset of primary membranous nephropathy patients. Its extracellular domain consists of a regularly repeating structure composed of thrombospondin type-1 and F-spondin repeats, as well as a highly basic region. We sought to investigate the location(s) of the humoral epitopes targeted by anti-THSD7A antibodies in membranous nephropathy.

Methods: N- and C-terminal truncation mutants of THSD7A, as well as constructs comprising single or multiple adjacent domains, were expressed in HEK293T cells. Reactivity with human autoantibodies was assessed by western blot, dot blot, and immunoprecipitation.

Results: Patient sera displayed varying degrees of reactivity to these recombinant constructs, with most sera reacting with 2 or more distinct domains in the more C-terminal, extracellular domain of the molecule. A subset of sera recognized an additional epitope in the N-terminal portion of the molecule. Reactivity with the larger constructs, such as THSD7A serially truncated from the N- or C-terminus, was stronger than that against constructs composed of 1 to 4 adjacent domains, and could be detected by western blot, dot blot, and immunoprecipitation.

Conclusions: As in PLA2R associated membranous nephropathy, the humoral response to the target antigen THSD7A involves multiple epitopes within the molecule. Reactivity with autoantibody appears to depend on the conformation of an extended THSD7A extracellular region. Further analysis of additional anti-THSD7A positive sera will help to define the epitopes within the molecule, underlie the pathogenesis of this autoimmune disease, and identify potential targets for novel therapeutic strategies.

Intramolecular Epitope Spreading in Phospholipase A2 Receptor, in IMN Patient En Route to End-Stage Renal Disease
Michael Shvey, Ira Kurtz, Quansheng Zhu, Miguel Fernando Palma Diaz, PC. Pham, Phat H. Duong, Liyao Kao, Douglas Yao, Ira Kurtz, Quansheng Zhu.
Medicine, Univ of California, Los Angeles, Los Angeles, CA; Pathology, Univ of California, Los Angeles, Los Angeles, CA.

Background: Clinical studies have established that over 70% of patients with idiopathic membranous nephropathy (IMN) possess high levels of circulating autoimmune antibodies targeting phospholipase A2 receptor (PLA2R) in the glomerular visceral epithelial cells. Our recent studies demonstrated that over 70% of IMN patients are circulating autoantibodies that target PLA2R triggering immune complexes formation in situ and deposition in the glomerular subepithelial spaces. The immunodominant epitope in PLA2R was recently located to the extreme N-terminus of the receptor encompassing the THSD1-C3 region. In the rat model of MN, epitope spreading was detected in the antigenic protein, megalin that is correlated with the disease progresses. Whether epitope spreading occurs in human IMN and its relationship to disease progresses is unclear.

Methods: Serum samples from biopsy-proven IMN patients were collected and screened for anti-PLA2R antibodies using Western-blot and epitope-specific ELISA assays. The reaction of autoantibody and PLA2R protein was further analyzed using immunoprecipitation and immunoblotting assays.

Results: Western-blot analysis using patient sera against full-length PLA2R or the dominant epitope region indicated that, 3 of the 12 serum samples that were positive with anti-PLA2R autoantibodies failed to recognize the dominant epitope protein. Further test of these 3 samples against a series of truncated PLA2R extracellular domains on Western-blot demonstrated that the autoantibodies bind strongly to the Cys-R-FnII-CTLD1-3 region of PLA2R. Interestingly, serial analysis of sera from a patient with worsening proteinuria showed, that the autoantibodies first recognized the Cys-R-FnII-CTLD1-3 region and then spread to the CysR-FnII-CTLD1 region, suggesting epitope spreading is associated with the disease progresses.

Conclusions: Our results demonstrate for the first time that intramolecular epitope spreading occurs in PLA2R in IMN. This finding supports the important role of the dominant epitope in IMN pathogenesis and disease progresses.

FR-P0968
Demonstration of a High Titer Low Affinity Anti-PLA2R Autoantibody in an IMN Patient En Route to End-Stage Renal Disease
Scott E. Wenderoff, Adisaq Suwanichkul.
Pediatrics, Baylor College of Medicine, Houston, TX.

Background: Circulating immune complexes (IC) deposit in the glomeruli of the kidney in many autoimmune diseases, leading to proliferative glomerulonephritis. IC binding can promote proliferation or induce apoptosis in human macrovascular EnCs.

Conclusions: As in PLA2R associated membranous nephropathy, the humoral response to the target antigen THSD7A involves multiple epitopes within the molecule. Reactivity with autoantibody appears to dependent on the conformation of an extended THSD7A
Kidney diseases.

Methods: Renal ENCs were cultured from C57BL/6 mice and primary human glomerular ENCs were obtained commercially. Cells were treated with heat aggregated IgG (anti-β2m) or IC. Quantitative RT-PCR was used to measure mRNA levels of TNF superfamily members. A cellular ELISA was used to assess TRAIL protein expression on ENCs. Apoptosis was assessed using annexin V and H2AX phosphorylation, and caspase 3 activity assays, as well as TUNEL staining. In vivo findings were validated in a renal inflammatory mouse model of acute IC kidney injury.

Results: TRAIL mRNA expression is up-regulated by renal endothelial cells in vitro in the presence of IC binding and in vivo. Membrane TRAIL expression on ENCs also increases after treatment with IC in a dose dependent manner. Receptors for TRAIL, DR5, DR4, and the receptor for TRAIL-R1 (TRAIL-R1) are expressed by ENCs at RNA and protein levels. Using XTT cell proliferation assays, there is a modest decrease in EnC metabolism or proliferation after treatment with IC. Caspase 3 activity and DNA double strand breaks were both increased in cultured ENCs after treatment with IC in a dose dependent manner. Results were similar for both murine and human glomerular ENCs.

Conclusions: Results suggest that IC binding to glomerular ENCs in vitro is pro-apoptotic. Several TNF superfamily members known to promote apoptosis and their receptors are also up-regulated on ENCs treated with IC. Targeting TRAIL binding to DR5 and its downstream signaling pathways may reduce EnC activation or injury in IC kidney diseases.

Paired Immunoglobulin-Like Type2 Receptor α (PILRα) Negatively Regulates Immune Complex-Mediated Glomerulonephritis

Yutaka Suigaya, Naotake Tsuboi, Yutaka Kaminura, Shoichi Maruyama, Seichi Matsuo. Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.

Background: PILRα expressed mainly on macrophages, dendritic cells and granulocytes, has been described for its regulatory functions for leukocyte β2 integrin activation in acute inflammation including LPS-induced endotox shock model. Here, we investigated roles of PILRα in immune complex (IC)-mediated glomerulonephritis.

Methods: IC-mediated glomerulonephritis was induced by intravenous administration of nephrotic serum (NTS) after pre-conditioning with rabbit IgG in C57BL/6 (WT) and PILRα−/− mice. Functional analysis for renal injury was performed by urine albumin and serum creatinine (creatinine) concentrations at day 7, 14 and 21. Diseased kidneys from both mouse strains were harvested for histology, renal leukocyte infiltrates by flow cytometry and renal cytokine profiles by ELISA after induction of NTS glomerulonephritis. In vitro, α4β7 integrin-dependent neutrophil adhesion on IC was evaluated in both mouse strains.

Results: BUN and Cr concentrations were significantly elevated in PILRα−/− mice compared to wild type mice at day 14 and day 21 and those were highly associated with deteriorated proteinuria. In histological analysis, glomerular damages, corroborated with both glomerular PAS deposits and glomerular crescent formation, were more severe in PILRα−/− mice at day 21 (p<0.05). Moreover, glomerular neutrophil accumulation was remarkably observed in PILRα−/− mice compared to WT mice at day 21. In addition, total infiltration of Ly6G+ neutrophils, F4/80+ macrophages and CD3+CD4+ T cells in whole kidneys were increased in PILRα−/− mice than WT mice at day 14 and day 21. Renal pro-inflammatory cytokine production for IL-1β and IL-6 on day 7, 14 and 21 also demonstrated severe renal inflammation in PILRα−/− mice. In vitro, PILRα−/− deficient neutrophils showed enhanced adhesion and spreading on IC compared to WT.

Conclusions: PILRα−/− deficiency resulted in deteriorated renal damage in mouse IC-mediated glomerulonephritis compared to WT mice, indicating that PILRα negatively regulates IC-mediated leukocyte recruitment by inhibition of α4β7 integrin activation.

FR-PO971

Role of Interferon Regulatory Factor 5 and Toll-Like Receptor 7 in Immune Complex Glomerulonephritis

Yuri Cohen-Bayan, Barry K. Horne, Yao Xie, Prachi Shukla, Ian R. Rifkin, Ramon G. Bonegio. Renal Section, Boston Univ Medical Center, Boston, MA.

Background: Immune-complex glomerulonephritis (ICGN) is a common cause of glomerular inflammation characterized by in situ formation of immune complexes and activation of the complement cascade. Interferon regulatory factor 5 (IRF5) is a transcription factor acting downstream of toll-like receptors 7 (TLR7) to trigger an inflammatory response. Recent genetic studies have associated systemic lupus erythematosus (SLE), and other autoimmune syndromes with gain-of-function polymorphisms in the IRF5 gene. We therefore hypothesized that deletion of IRF5 or TLR7 would ameliorate ICGN.

Methods: We induced nephritic nephropathy using an endotoxin-free IgG1 fraction of sheep nephritic serum (SNS) in FgRiBv−/− mice that either express (Control) or do not express IRF5 (IRF5−/− or TLR7−/−). During the first five days following tail-vein injection of NTS, at a time when the heterologous antibody response peaked, we euthanized the mice and compared histology, albuminuria, renal immune cell infiltration and renal cytokine expression.

Results: The control mice developed severe glomerulonephritis characterized by massive albuminuria, prominent kidney mononuclear cell infiltration and presence of crescents or necrosis in 28±6% of glomeruli. In contrast, TLR7−/− and IRF5−/− developed significantly less severe disease with crescents/necrosis in only 6±2% of glomeruli (p<0.01), and significantly decreased monoclonal cell infiltration (including both patrolling and infiltrating monocytes). IRF5−/− mice showed a similar pattern in the control and IRF5−/−KO, but not in the IRF5−/−KO mice. Therefore, TLR7-independent pathways downstream of TLR7 is responsible for the proteinuria. Consequently, we conclude that the TLR7/IRF7 pathway may represent a novel therapeutic target for the control of glomerular inflammation.

Therapeutic TLR9 Inhibition Prevents the Establishment of Anti Myeloperoxidase Autoimmunity and the Development of Glomerulonephritis in Mice with Established Autoimmunity

Sharon Lee Ford, A. Richard Khine, Stephen R. Holtsworht, Toshiki Kano, Satoshi Horikoshi, Yusuke Suzuki. Div of Nephrology, Dept of Internal Medicine, Juntendo Univ School of Medicine, Bunkyo-ku, Tokyo, Japan.

Background: We have shown TLR9 ligations enhances anti-myeloperoxidase (MPO) autoimmunity (AI) and glomerulonephritis (GN) through dendritic cell (DC) activation. We assessed therapeutic TLR9 inhibition on both the development of anti-MPO AI induced through DC vaccination and subsequent development of GN by TLR9 responsive innate effector cells.

Methods: Injection of MPO/Freud’s Adjuvant or transfer of MPO/CpG (TLR9 ligand) pulsed bone marrow derived DCs established anti-MPO AI. To stimulate effector cells, intraperitoneal (IP) CpG or MPO/Freud’s Adjuvant was injected after inducing anti-MPO AI, triggering renal glomerulonephritis and anti-glomerular basement membrane glomerulonephritis (GN).

Results: TLR9 signaling was inhibited with an inhibitory oligodeoxynucleotide before both induction of AI and triggering renal injury.

Results: Mice receiving MPO/CpG/DCs + IP CpG compared to MPO/CpG/DCs + IP CpG (Control) developed heightened immune responses (cells/spleen: 5.4±6 vs 6.1±5.1×10^6, p<0.05) and renal injury (area:3.1±7 vs 11±3μm²/L, p<0.05; abnormal glomeruli:93±3 vs 15±3%, p<0.001) confirming effector cell TLR9 ligand is required for disease induction and a target for therapeutic inhibition. TLR9 inhibition prevented MPO/CA induced systemic and MPO/autoimmunity measured by MPO specific dermal DTH swelling (2.6±18.6±3Dmm, p<0.05) and decreased frequency of MPO stimulated IL-17A producing cells (6±1 vs 21±3cells, p<0.01) compared to control. TLR9 inhibition prevented IL-17A driven mice in receiving MPO/CpG/DCs (DTTH:3.2±3 vs 18.6±3Dmm, p<0.001, IL-17A:21±6 vs 3±0.9, p<0.001) and significantly decreased mononuclear cell infiltration (including both patrolling and infiltrating monocytes) when given to mice with established anti-MPO AI compared to control (DTTH:3±1 vs 13±4mm footpad swelling, p<0.05, area:26±1 vs 34±3μm²/L, p<0.05; abnormal glomeruli:43±9 vs 79±5%, p<0.01).

Conclusions: Therapeutic TLR9 inhibition prevents the development of anti-MPO AI and is a therapeutic option to prevent the development of renal injury once anti-MPO AI is established.

FR-PO973

TLR9 Activation Aggravates Murine IgA Nephropathy; Possible Role of BAFF Mediated Pathway

Yuko Makita, Hitoshi Suzuki, Akiko Takahata, Toshiki Kanato, Satoshi Horikoshi, Yusuke Suzuki. Div of Nephrology, Dept of Internal Medicine, Juntendo Univ School of Medicine, Bunkyo-ku, Tokyo, Japan.

Background: Contribution of Toll like receptors (TLRs) which play a key role in the innate immune system has been discussed in the pathogenesis of IgAN. We recently demonstrated that TLR9 is importantly involved in progression of kidney injuries in IgAN prone mice. On the other hand, role of B cell activating factor (BAFF) is discussed in the pathogenesis of human IgAN. Present study examined the contribution of BAFF in the TLR9 mediated progression of IgAN using IgAN prone mice.

Methods: Commercially available quiescent IgAN prone mice (ddY mice) at 4 weeks of age were used for this study. They were divided into two groups with (n=8) or without (n=8) TLR9 ligand (CpG-ODN) for 12 weeks. Renal histological lesions and serum levels of IgA, IgG and IgA-IgG immune complexes (IC) were evaluated at 16 weeks of age. Serum levels of aberrantly glycosylated IgA was measured by the binding of Sambucus nigra bark lectin and Ricinus communis agglutinin I. Splenic expressions of TLR9, MyD88, BAFF and its receptor (TACI) were also quantitatively evaluated.

Results: CpG-ODN treated, but not non-treated mice, showed mesangial deposition of IgA, IgG and IgA-IgG immune complexes (IC) were evaluated at 16 weeks of age. Serum levels of aberrantly glycosylated IgA was measured by the binding of Sambucus nigra bark lectin and Ricinus communis agglutinin I. Splenic expressions of TLR9, MyD88, BAFF and its receptor (TACI) were also quantitatively evaluated.

Conclusions: Present study indicated that TLR9 activation exacerbates murine IgAN via increase of aberrantly glycosylated IgA and nephritogenic IC. In addition, present findings also suggested that TLR9 mediated BAFF expression may be involved in the nephritogenic IgA and IC production.
FR-PO974

Key Role of Apoptosis Inhibitor of Macrophage in Phlogenic Action of Glomerular Nephritogenic IgA in IgA Nephropathy

Akiko Takahata,1 Kento Kitada,2 Chieko Nogi,3 Satoko Arai,4 Yuko Makita,5 Hitoshi Suzuki,6 Junichiro Nakata,6 Satoshi Horikoshi,3 Toru Miyazaki,6 Yusuke Suzuki.1

1Div of Nephrology, Dept of Internal Medicine, Juntendo Univ School of Medicine, Bunkyo-ku, Tokyo, Japan; 2Laboratory of Molecular Biomedicine for Pathogenesis, Center for Disease Biology and Integrative Medicine, Faculty of Medicine, The Univ of Tokyo, Bunkyo-ku, Tokyo, Japan.

Background: Apoptosis inhibitor of macrophage (AIM), a protein mainly produced by macrophages, has been reported to be related to autoimmune diseases as well as arteriosclerosis.

Methods: We evaluated the role of AIM in IgA nephropathy (IgAN) using IgAN prone mice, grouped ddY (gddY) (J Am Soc Nephrol.2012;3:1364-74). Serum of gddY mice was injected to AIMKO and wild-type (WT) mice, and proteinuria and glomerular depositions were evaluated over time. In addition, nephritogenic IgA, produced by gddY splenic B cells hybridomas, was injected to AIMKO and WT to perform the same evaluation.

Results: We found excessive expression of AIM in gddY, which were co-localized with glomerular IgA. Glomerular IgA depositions were observed in AIMKO and WT 2h after the injections of gddY serum and purified nephritogenic IgA. The depositions were cleared soon thereafter in WT but later in KO after being accumulated. However, proteinuria was not noticed in WT, but noticed in KO. Moreover, CD45 soon thereafter in WT but later in KO after being accumulated. However, proteinuria was not noticed in WT, but noticed in KO. Moreover, CD45 was accumulated by CD45-negative cells by IgA1-secretive cells by IgA1-secretive patients. Our study defines how these signaling pathways influence IgA1 O-glycosylation.

Methods: IgA1-secretating cells from IgAN patients and healthy controls (HC) were stimulated with IL-6/LOF/OSM with or without JAK-STAK inhibitors. Gd-IgA1 levels were determined by lectin ELISA. Cell lysates from IgAN and HC cells were analyzed by global tyrosine-kinome profiling using PamStation®12 platform and Western blotting. The role of STAT3 or STAT1 in mediating IL-6/LOF/OSM, signaling was confirmed by siRNA knock-down (k/d).

Results: siRNA k/d of STAT3 and STAT1 reduced production of Gd-IgA1 in IgAN cells induced by IL-6 and LOF/OSM, respectively. A specific inhibitor of JAK/STAT signaling reduced IL-6/LOF-enhanced production of Gd-IgA1, but only in IgAN cells. Global tyrosine-kinome profiling identified nine target peptides that were selectively inhibited by the tested JAK/STAT inhibitor in the IgAN cell lysates. Bioinformatics analyses and pathway mapping identified abnormal signaling in JAK/STAT and MAPK cascades as the highest ranked pathway.

Conclusions: IL-6/LOF/OSM cytokines enhanced production of Gd-IgA1 via over-activating JAK/STAT pathways in IgAN cells. Global tyrosine kinome profiling validated this finding and also indicated participation of MAPK. Elucidating the mechanisms of abnormal signaling associated with Gd-IgA1 production in IgAN-secreting cells may provide new targets for treatment of IgAN.

Expression of Mesangial Tissue Transglutaminase Is Independent of Abrerrantly Glycosylated IgA in Patients with IgA Nephropathy

Akihiro Kato,1 Kazuo Takahashi,2 Tomohiro Mizuno,1 Stacy D. Hall,1 Akiko Takahata,1 Yuki Yuzawa,1 Fujita Health Univ School of Medicine, Toyoyake, Aichi, Japan; 2/meiio Uni, Nagaraya, Aichi, Japan; 3Univ of Alabama at Birmingham, Birmingham, AL; 4Fujita Health Univ School of Health Sciences, Toyoyake, Aichi, Japan; 5Nagoya Univ Graduate School of Pharmaceutical Sciences, Nagaraya, Aichi, Japan.

Background: It has been reported that tissue transglutaminase (TG2) is essential for mesangial deposition of IgA1 and development of mesangial inflammation in a mouse model of IgA nephropathy (IgAN). We have shown that some IgAN patients have an active form of TG2 in the mesangial area and that mesangial TG2 activity is associated with elevated proteinuria and proliferation of mesangial cells (MC). The impact of aberrantly glycosylated IgA1 on mesangial TG2 expression merits investigation, as circulating immune complexes, including those containing aberrantly glycosylated IgA1, are deposited in the mesangium in IgAN.

Methods: To understand the role of mesangial TG2 in IgAN, expression of TG2 in cultured MC stimulated by sera from IgAN patients with mesangial TG2 activity (IgAN-TG2A), IgAN patients without mesangial TG2 activity (IgAN-TG2N), disease controls (DC), or healthy controls (HC) were assessed. Expression of TG2 in MC stimulated by purified serum IgA1 or enzymatically deglycosylated IgA1 was also assessed. Furthermore, we characterized hinge-region (HR) O-glycosylation profiles of serum IgA1 from IgAN-TG2A and IgAN-TG2N using high-resolution mass spectrometry.

Results: MC stimulated with sera from IgAN-TG2A showed more binding of IgA1 and expressed more TG2 than those stimulated with sera from IgAN-TG2N, DC, or HC (P>0.01). Mass spectrometry analysis identified 13 IgA1 HR O-glycosylomics with up to 3 galactose-deficient glycans. The number of galactose-deficient glycans was not significantly different between IgA1 from IgAN-TG2A and IgA1 from IgAN-TG2N (0.76 vs. 0.79 mol/HR). Enzymatically deglycosylated IgA1 did not change TG2 expression on MC compared to IgA1 from HC.

Conclusions: Sera from IgAN patients enhanced mesangial TG2 expression. Aberrantly glycosylated IgA1 alone was insufficient to increase TG2 expression by MC.

FR-PO979
ACNA Disease Patients Demonstrate a Higher Frequency of CD33+ Myeloid Cells with Variable Suppressive Abilities. Meghan E. Free, Katie Stember, Julie Anne G. McGregor, J. Charles Jennette, Ronald J. Falk, Maureen Su. 1UNC Kidney Center, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; 2Pathology and Laboratory Medicine, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; 3Pediatrics, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.

Background: Myeloid-derived suppressor cells (MDSCs), or CD33+ myeloid cells, have been extensively studied in cancer as potent suppressors of T cell activation. Regulatory T cells do not control T cell proliferation in patients with ANCA disease as an alternative suppressive mechanism.

Methods: Analyses were performed using flow cytometry on peripheral blood mononuclear cells (PBMC) from 63 patients stained with relevant antibodies. Suppressor potential of CD33+ myeloid cells was assessed with a standard T cell suppression assay.

Results: Flow cytometric analysis of PBMCs revealed an increased population of lineage negative, HLA-DR negative, CD11bhigh and CD33+ myeloid cells in patients with ACNA disease compared to healthy controls (mean 2.72% versus 0.18% of PBMCs). This CD33+ myeloid cell population also contained MPO and PR3. Suppression assays utilizing patient CD33+ myeloid cells and autologous T cells have demonstrated variable suppressive capacities with the majority of patients exhibiting modest (30-60%) suppression.

Conclusions: CD33+ myeloid cells are increased in patients with ACNA disease and represent a potential source of T cell suppression not previously investigated. Intriguingly, the patients who demonstrated the highest frequency of CD33+ myeloid cells were those who had sequentially received rituximab and cyclophosphamide.

FR-PO980
Endothelial NF-κB Induction by ACNA-Activated Neutrophils. Mira Choi, 1Adrian Schreiber, 2Claudia Eulebenberg, 2Ralph Kettritz, 3Claus Scheidereit. 1Dept of Nephrology, Charite, Berlin, ECR; 2Charite, Berlin, Germany; 3Experimental and Clinical Research Center (ECRC), Berlin, Germany.

Background: Activation of the NF-κB/Rel family and subsequent transcriptional upregulation of inflammatory mediators plays a central role in vascular diseases. ACNA vasculitis is an inflammatory condition where ACNA-activated neutrophils (PMN) interact with the endothelium resulting in necrotizing vasculitis. We hypothesized that ACNA-activated PMN promote endothelial NF-κB and vascular inflammation.

Methods: NF-κB activation was assessed by IkBα degradation, EMSA, RT-PCR and IHC. NF-κB was studied in renal tissue from mice with ACNA-induced NGN, ACNA-stimulated PMN and endothelial cells.

Results: In kidney extracts from mice in which we had induced anti-MPO Ab-mediated NCGN, we observed a significant correlation between the percentage of crescents and NF-κB activity by EMSA (R²=0.72, n=20). Similar correlations were found for crescents and upregulation of the NF-κB dependent genes TNFa and IkBα. In renal biopsies from patients with ACNA-induced NCGN, we observed strong phospho-p65 staining in the glomerular convolute. Regarding the importance of PMN-EC interactions in ACNA vasculitis, we studied NF-κB activation in PMN and ECs in vitro. Low-dose TNFa priming resulted in a significant increase in NF-κB activity in EC when co-incubated with mAb-stimulated PMN and observed significant IkBα degradation in EC (n=10). We confirmed this with human ACNA preparations. Cell-free PMN supernatants were sufficient for endothelial NF-κB activation indicating that direct cell-cell contact was not required. Consequences of endothelial NF-κB activation were the upregulation of endothelial TNFa and IL-6 mRNA and its release as cytokines into the supernatant, which lead to increased recruitment and adhesion of new PMN.

Conclusions: Renal NF-κB activation and NCGN severity were closely correlated. Our in vitro data demonstrate that ACNA-activated PMN induce endothelial NF-κB activity thereby promoting vascular inflammation by recruiting more PMN. Inducing endothelial NF-κB may help limiting the ACNA-mediated damage.

Ubiquitin C-Terminal Hydrolase-L1 Controls Dendritic Cell Cross Priming of the CD8+ T Cell Response. Anna Reinicke, 1Malte Mühlig, 1Pina Schmucker, 2Tim Otto, 2Christian Kurts, 1Hans-willli Mittrücker, 2Catherine Meyer-Schewig. 1Nephrology, III. Medical Clinic, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; 2Immunology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Background: Ubiquitin C-terminal Hydrolase-L1 (UCH-L1) is a central deubiquitinating enzyme of the ubiquitin proteasomal system. UCH-L1 is thought to regulate the pool of ubiquitin. Within the kidney, UCH-L1 is de novo expressed in glomerular podocytes in human and rodent glomerulonephritis. Mice with constitutive UCH-L1 deficiency exhibit an exacerbated course of immune-complex nephritis suggesting that UCH-L1 deficiency may alter the ability to generate effective renal immune responses. The current study was undertaken to identify the origin of renal tubulo-interstitial UCH-L1-expressing cells, 2. To analyze the response of UCH-L1-deficient mice to a bacterial infection, 3. To analyze the role of UCH-L1 in dendritic cells (DCs). Method: Constitutive UCH-L1-deficient mice were generated by Cre-Lox technology. The immunologic phenotype was investigated by challenging UCH-L1-deficient mice with Listeria monocytogenes. Cross presentation and cross priming assays were performed in vitro and in vivo. The DC phenotype was assessed in naive and stimulated DCs by FACS, Western, protemal and deubiquitinate-based activity assays, and real-time PCR.

Results: UCH-L1 is expressed in DCs isolated from kidney and spleen, and in bone-marrow derived cultured DCs. UCH-L1 expression in bmDCs is regulated by IFN-γ and LPS. UCH-L1 activity is upregulated by LPS stimulation while other deubiquitinating enzymes down-regulate their activity in the absence of UCH-L1. DCs are specially equipped to cross present antigen to stimulate a CD8+ T cell response. Cross-presentation of cell-associated antigen in UCH-L1-deficient DCs is significantly reduced in vitro and in vivo while activation of a CD4+ T cell response is unaffected. Finally, exposure to L. monocytogenes results in a significantly decreased generation of antigen-specific CD8+ T cells.

Conclusions: We describe a hitherto unrecognized role for UCH-L1 in controlling CD8+ T cell activation by DCs.

CD103+ Dendritic Cells Elicit CD8+ T Cell Responses to Accelerate Kidney Injury in Adiriamycin Nephropathy. Qiao Cao, 1Qing Li, 1Xin M. Wang, 2Chenguang Wang, 1Yuan Min Wang, 2Stephen L. Alexander, 1Yiping Wang, 2Bijan C. Harris. 1Centre for Transplant and Renal Research, Westmead Millennium Inst for Medical Research, The Univ of Sydney, Sydney, NSW, Australia; 2Flow Cytometry Facility, Westmead Millennium Inst for Medical Research, The Univ of Sydney, Sydney, NSW, Australia; 3Centre for Kidney Research, Children's Hospital at Westmead, Sydney, NSW, Australia.

Background: CD103+ dendritic cells (DCs) in non-lymphoid organs exhibit two main types of function, namely maintaining tolerance by induction of regulatory T cells and protecting against tissue infection through activation of CD8+ T cells. However, the characteristics and functions of CD103+ DCs in kidney remain unclear.

Methods: Adiriamycin nephropathy (AN) was induced in BALB/c mice. The distribution, phenotype and function of kidney CD103+ DCs were assessed in normal and AN mice. CD103+ DCs were depleted by neutralizing CD103-saporin (SAP) antibody in AN mice to examine their role in vivo.

Results: In the present study, we showed that CD103+ DCs are one of four subpopulations of renal mononuclear phagocytes in normal kidney; they expressed DC-markers CD103 and CD86, but down regulation of VDR. Podocytes in renal cortical sections of Tg26 mice displayed enhanced expression of SNAIL and down regulation of VDR. NF-κB and NF-κB237 displayed upregulation of SNAIL but down regulation of VDR. HIV-IPs displayed H3K4 trimethylation at SNAIL promoter and enhanced expression of histone deacetylase (HDAC) 1, DNA methyl transferase (Dnmt) 3b. IP studies revealed the association of HDAC1, Dnmt3b, Dnmt1, and mSin3A with the SNAIL, VDR agonts, HDAC inhibitor, and demethylating agents alone could not reverse NF-κB expression optimally, but could do so, when used in combination. In summary, SNAIL recruits multiple chromatin enzymes to form a repressor complexes that down regulate VDR expression in HIV milieu. To upregulate VDR optimally, reversal of VDR expression is needed.

Conclusions: SNAIL recruits multiple chromatin enzymes to form a repressor complexes that down regulate VDR expression in HIV milieu. To upregulate VDR optimally, reversal of VDR expression is needed.

Advanced Glycation End Products Induced the Imbalance Between Th17 and Treg Cells via RAGE Pathway in Diabetic Nephropathy. Yanlin Zhang, Ao Cheng. Dept of Nephrology, The First Affiliated Hospital of Xiamen Univ, Xiamen, Fujian, China.

Background: There was imbalance of Th17/Treg cells in patients with diabetic nephropathy, but the mechanism was still unclear. Advanced glycation products (AGEs) often accumulated in the patients with diabetic nephropathy. The main purpose of this experiment is to explore whether AGEs can cause the imbalance of Th17/Treg cells through RAGE signaling pathway.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
592A
Methods: (1) Recruitment of 20 healthy adults and 40 diabetic nephropathy patients of CKD stages 3 to 5. AGEs content of CD4+ T cells/ Th17 cells/ Treg cells to verify the correlation. (2) Prepared AGE-HSA in vitro and isolated the initial CD4+ T cells from healthy volunteers peripheral blood to explore the effect of AGE-HSA on the differentiation of initial CD4+ T cell: AGE-HSA with different dose and time stimulated initial CD4+ T cells, or for RAGE neutralization, blocking and to detect the ratio of Th17 cell and Treg cells by flow cytometry and determine the expression mRNA of RORgt and Foxp3, and the expression of mRNA and protein of STAT3 and HIF-1α.

Results: In patients with diabetic nephropathy, there is accumulation of AGEs and increasing of Th17 cells and the reduction of Treg cells. The ratio of Th17 cells and Treg cell is imbalance (increase in the proportion). There was a positive correlation between the concentration of AGEs and ratio of Th17 cells and Treg cells; (2) The AGE-HSA in a dose dependent manner inhibited the CD4+ T cells differentiation to Th17 cells, or for RAGE neutralization, blocking RAGE could mitigate this effect; (3) AGE-HSA increased the expression of RORgt in the initial CD4+ T cells, but no effect on Foxp3. After blocking RAGE, it could inhibits the expression of RORgt induced by AGE-HSA; (4) the expression of STAT3 and HIF-1α was raised in the initial CD4+ T cells induced by AGE-HSA, while blocking RAGE, expression of STAT3 and HIF-1α. induced by AGE-HSA was inhibited.

Conclusions: In patients with diabetic nephropathy, there was positively correlated between the content of AGEs and the proportion of Th17 cells and Treg cells, and AGE-HSA of STAT3 and HIF-1α. induced by AGE-HSA was inhibited.

Histological injury in the biTreg 5 months showed severe proliferative glomerulonephritis in pristane injected wild type mice. As one possible explanation for the improved outcome, we found that biTregs from wild type mice produced less inflammatory cytokines. Studies in a model of acute crescentic glomerulonephritis demonstrated that activation of RORgt in the kidney is imbalance (increase in the proportion). There was a positive correlation between the content of AGEs and the proportion of Th17 cells and Treg cells, and AGE-HSA of STAT3 and HIF-1α. induced by AGE-HSA was inhibited.

Conclusions: In patients with diabetic nephropathy, there was positively correlated between the content of AGEs and the proportion of Th17 cells and Treg cells, and AGE-HSA of STAT3 and HIF-1α. induced by AGE-HSA was inhibited.

FR-P0984

Background: We recently characterized Foxp3+ regulatory T cells, co-expressing the Th17 characteristic transcription factor RORγt, as an independent and bi-functional T-cell lineage (biTregs). biTregs secrete both, anti-inflammatory (IL-10, IL-35), but also pro-inflammatory (IL-17) cytokines. Studies in a model of acute crescentic glomerulonephritis suggest that pro-inflammatory biTreg functions are mediated by RORγt. This is of high clinical relevance, since multiple RORgt blocking agents are currently under development.

Methods: Systemic lupus erythematosus (SLE)-Pristane in biTregγ+/mice.

Results: Time course analyses showed increasing infiltration of biTregs into kidneys of pristane injected mice with a maximum at around 5 months. Subsequently percentages decreased and were back to baseline at 8 months. To study the functional role of RORγt in biTregs, Foxp3γ- x RORCγ- mice were generated (biTregγ-). Renal histology at 8 months showed severe proliferative glomerulonephritis in pristane injected wild type mice. Histological injury in the biTregγ- group, in contrast, was significantly ameliorated.

Conclusions: Depletion of Tregs with anti-CD25 antibodies abrogated the beneficial effects of IL-2C treatment. Significant recovery of all 3 activation subsets occurred 3 months post-rituximab treatment. Using ROC curve analysis, activatedCD154+CD45RA- CD4+ T cells (P<0.01) were upregulated in responders (75.7±1.2%). IFN-γ+CD8+ T cells were similarly decreased in responders (73.6±1.2%) and non-responders (72.6±1.1%) (p=0.005) and controls (72.6±1.25%). IL-2+CD8+ subs were lower in responders (24.0±14%) compared to non-responders (44.2±15%) (p=0.007) and controls (63.1±5%) (p=0.03). Significant recovery of all 3 activation subsets occurred 3 months post-rituximab treatment.

Conclusions: We have identified prognostic markers which define a subset of FSGS patients bearing an immunological signature representing hyperresponsiveness to T-cell stimulation, with good response to rituximab therapy.

FR-P0987

Cytokine Profiling in Rituximab-Treated Pediatric Focal Segmental Glomerulosclerotic Nephrotic Patients Wee Song Yeo, Chang-Yien Chan, Hui Kim Yap. Pediatrics, Yong Loo Lin School of Medicine, National Univ of Singapore, Singapore, Singapore.

Background: Focal segmental glomerulosclerosis (FGS) is the most common histological pattern seen in pediatric steroid-dependent and steroid-resistant nephrotic patients. In recent years, rituximab is increasingly used in nephrotic patients who have failed therapy with conventional immunosuppressants. This study aimed to examine the cytokine profile in rituximab-treated pediatric FSGS nephrotic patients and elucidate the cytokine profile differences between responders and non-responders.

Methods: We study population consisted of 13 pediatric FSGS patients who underwent rituximab therapy. Plasma cytokine profiling was performed on each of these patients utilizing multiplexed Luminex® Cytokine Human 27-plex assay pre- and post-rituximab therapy.

Results: Five (38%) of the patients responded to rituximab, defined as having achieved complete resolution of proteinuria accompanied by cessation of prednisolone and calcineurin inhibitors within 3 months. All patients in the study demonstrated an increase in plasma interferon-gamma-inducible protein (IP)-10 levels post-rituximab therapy (554.3±62.4 pg/ml (pre) vs 793.4±125.5 pg/ml (post), p<0.008). Comparing the cytokine profile between responders and non-responders, responders demonstrated a positive mean-fold change in macrophage inflammatory protein (MIP)-1α, in contrast to non-responders which demonstrated a negative mean fold change (0.23±0.16 vs -0.17±0.08, p=0.04). There were, otherwise, no noted significant differences in the other cytokines i.e. pre- (post-rituximab and ii) between responders and non-responders.

Conclusions: Our study results suggest the development of a pro-inflammatory state in our patients post-rituximab therapy. The increase in plasma IP-10 in patient post-rituximab may account for the phenomenon of rituximab-associated colitis. The finding of increased plasma IP-10 in responders compared to non-responders is novel. Further mechanistic studies are required to ascertain the role of MIP-1α in the mechanism of action of rituximab.

Gut-Kidney Axis in the Pathogenesis of IgA Nephropathy
Gabriella Lauriero,1 Eustachio Montemurro,1 Maria De Angelis,2 Valentina Maranzano,1 Lucia Vannini,1 Loreto Gesudalio.1
1DETO-Nephrology Unit, Univ of Bari, Italy; 2DISSA, Univ of Bari, Italy; 3Dept of Agricultural and Food Sciences, Univ of Bologna, Italy.

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis worldwide. It is characterized by deposition of deoxyribonucleated IgA1 and IgA antibodies in the glomeruli and its pathogenesis is only partially defined. Intestinal microbiota could be involved in IgAN, as suggested by the observation that B-cell activation factor (BAFF) transgenic mice had high levels of aberrantly glycosylated serum IgA, the presence of commensal flora and the circulation of corresponding specific IgA antibodies being essential for the development of IgA deposits. BAFF is an important regulator of B cell maturation, survival and function. The aim of the study was to analyze the role played by gut kidney axis in the pathogenesis of IgAN.

Methods: 16 healthy controls (HC) and 32 IgA patients (16 non-progressors - NP and 16 progressors - P) were included in the study. Serum creatinine, estimated Glomerular Filtration Rate, 24h-proteinuria and histological descriptions following Oxford Classification (MEST score) were analyzed. Gut microbiota, urinary and fecal metabolome of all subjects were characterized by 16S sequencing, Biochrom 30 series amino acid analyzer and gas-chromatography mass spectrometry/solid-phase microextraction (GC-MS/SPME).

Results: Serum BAFF levels were positively correlated with 24h-proteinuria (**P <0.01 P vs HC). IgAN patients with histological grade at diagnosis M1, E1, S1 and T1 had significantly higher levels of serum BAFF than HC. Moreover, serum BAFF levels were positively correlated with 24h-proteinuria (r=0.47, **P <0.0069) and with the levels of fecal phenolic metabolites (r=0.61, ***P <0.0003).

Conclusions: Gut kidney axis might play an important role in the pathogenesis of IgAN.

Intestinal Macrophages Polarized to Activation of Pro-Inflammatory and Had Dysfunction of Phagocytosis Leading to Aggravate Microinflammation and Assist Bacterial Translocation as Carrier in Uremia Rats
Lingshuang Sun, Hongli Jiang, Hua Liu, Meng Wei. Dialysis Dept of Nephrology Hospital, First Affiliated Hospital of Medicine School.

Background: This study investigated whether intestinal macrophages are related to low-grade inflammation and bacterial translocation (BT) during uremia, and whether probiotics can alter the macrophage activity.

Methods: Male Sprague-Dawley rats were randomly divided into 3 treatment groups: sham, uremia (untreated), and uremia + probiotic. The expression of cell surface antigen CD11a (a.k.a., lymphocyte function-associated antigen 1 [LFA1]), inducible nitric oxide synthase (iNOS), ICAM1, and TGF-β were analyzed by immunohistochemistry. Gene and protein expression of early growth response protein 1 (EGR1) and TLR4 in intestinal specimens were determined. Density of labeled macrophages and tracer bacteria in intestinal and extraintestinal tissues were examined by immunofluorescent microscopy, and macrophage micromorphology were examined by transmission electron microscopy. In addition, the intestinal LPS levels were measured. Intestinal uremia exhibited significantly high intensity of expression of iNOS, ICAM1, and TGF-β staining. Gene and protein expression levels of intestinal TLR4 and EGR1 were also highest in this group. Intestinal segments of uremic rats exhibited high density and broad distribution of tracer bacteria and macrophages. Intestinal macrophages in untreated rats showed fewer cytoplasmic protrusions and pseudopodia. Administration of probiotics resulted in restoration of macrophage classic activation and phagocytosis that was associated with a reduction in BT.

Conclusions: In the uremic state, intestinal macrophages are polarized toward a proinflammatory phenotype that results in low-grade inflammation. Abnormal intestinal macrophage activation and impaired phagocytic function are associated with increased BT. Probiotics may reduce BT by enhancing phagocytosis of intestinal macrophages.

FR-P0990
Linking PI3K/AKT Signaling to RNase 7 Production and Urinary Tract Sterility
Tad Eichler, Robert Easterling, Brian Becknell, John David Spencer. The Research Inst at Nationwide Children’s, Columbus, OH.

Background: Antimicrobial peptides (AP) play a role in shielding the uroepithelium from uropathogenic E. coli (UPEC). We have identified RNase 7 (RNase 7) as a potent, epithelial-derived AP that is secreted by the bladder uroepithelium and renal intercalated cells. RN7 serves as an immune sensor for the uroepithelium from UPEC. Currently, there is a limited understanding of the mechanisms that regulate RN7 production, and if disrupted RN7 production increases UTI risk. Using a chemical inhibitors transcriptome PCR array, we identified the PI3K/AKT pathway as a unique regulator of RN7. Here, we confirm that PI3K/AKT regulates RN7 expression and relate changes in RN7 to UTI pathogenesis.

Methods: To evaluate the role of PI3K/AKT in regulating RN7, we treated primary human renal epithelial cells (REC) with insulin, a known PI3K agonist and/or insulin+wortmannin (wort), a PI3K/AKT inhibitor. PI3K/AKT activation was confirmed by Western blot. qRT-PCR and ELISA quantitated RN7. UPEC growth in urine inoculated with and/or insulin+wort was measured.

Results: Insulin-dependent phosphorylation of the PI3K/AKT in RFC was detected by 1hr. Insulin induced RN7 gene expression and protein expression 3-fold (25.23±3.51ng/mL vs 0.05±0.06 ng/mL). RN7 induction was abolished with wort, confirming PI3K/AKT involvement in RN7 production. Media from insulin treated RFC suppressed UPEC growth compared to media from RFC pretreated with wort or vehicle control, suggesting that PI3K/AKT and RN7 is involved in UTI pathogenesis. Urinary RN7 levels were significantly higher during disease flare compared to levels during remission. Serum LPS level correlated with acetate level (r=0.52, **P <0.01). Renal LBP, GPR-41 and GPR-43 expression showed markedly increased in nephritis patients compared to healthy controls, and was predominantly detected in the tubulo-interstitium, associated with inflammatory cell infiltration, fibrosis and tubular atrophy. LBP, GPR-41 and GPR-43 expression showed similar staining intensities and localization in patients with nephritis and those with non-glomerulus diseases.

Conclusions: Our data suggest that acetate and LPS may be involved in the pathogenesis of lupus nephritis and non-glomerulus diseases.

Funding: NIDDK Support

FR-P0991
Serum Acetate and Lipopolysaccharide Levels Correlate with Disease Activity in Patients With Lupus Nephritis
Daniel Tak Mao Chang, Ping Lung Chan, Qing Zhang, Yin Yi Au, Desmond Y.H. Yap, Mel Chau, Susan Yung. Dept of Medicine, The Univ of Hong Kong, Hong Kong.

Background: Lupus nephritis is a severe manifestation of systemic lupus erythematosus and is associated with poor prognosis. The gut microbiota has been implicated in the etiology of autoimmune diseases. Bacterial products from the gut may enter the circulation and induce inflammatory responses. Acetate is a short chain fatty acid (SCFA) produced by gut microbiota and lipopolysaccharide (LPS) is a component of the outer wall of Gram-negative bacteria. We measured serum acetate and LPS levels and intra-renal expression of their cell surface receptors in lupus nephritis patients to investigate the potential relationship between gut microbiota and lupus nephritis pathogenesis.

Methods: Serum acetate and LPS levels were measured in patients with biopsy-proven severe proliferative lupus nephritis, patients with non-lupus glomerular diseases and healthy controls (n=50 for each group). Intra-renal expression of LPS-binding protein (LBP) and GPR-41 and GPR-43 (SCFA receptors) was also examined.

Results: Serum acetate and LPS levels were significantly higher in patients with lupus nephritis compared to levels in patients with non-lupus renal diseases (P<0.05, for both) and healthy subjects (P<0.01, for both). In lupus nephritis patients, serum acetate and LPS levels were significantly higher during disease flare (P=0.04 and P=0.0015 respectively compared to levels during remission). Serum LPS level correlated with acetate level (r=0.52, P=0.0001), and inversely correlated with that of IgG (r=−0.61, P=0.01). Renal LBP, GPR-41 and GPR-43 expression was markedly increased in lupus nephritis patients compared to healthy controls, and was predominantly detected in the tubulo-interstitium, associated with inflammatory cell infiltration, fibrosis and tubular atrophy. LBP, GPR-41 and GPR-43 expression showed similar staining intensities and localization in patients with lupus nephritis and those with non-lupus renal diseases.

Conclusions: We propose that acetate may be involved in the pathogenesis of lupus nephritis and non-glomerulus diseases.

Funding: Government Support - Non-U.S.

Noninvasive Assessment of Macrophage Activation in Experimental Glomerulonephritis Using Optical Imaging with Near-Infrared Light as a Surrogate of Disease Activity
Sebastian Braehler, Dongyue Huang, Matthew David Cheung, Walter J. Akers, Alfred Hyoungjui Kim. Washington Univ School of Medicine, St. Louis, MO.

Background: Glomerulonephritis (GN) represents a major cause of morbidity & mortality. The standard for diagnosing GN is through renal biopsy, but this is not performed uniformly across many centers. There is an unmet need to identify a noninvasive approach for detecting disease activity in patients with GN. Recent advances in deep tissue imaging using probes detected by near-infrared (NIR) wavelengths have enabled the noninvasive probing of biologic activity. Macrophage infiltration of the kidney is observed in early GN and once activated, express the cysteine protease cathepsin B. Thus, renal macrophage activation can be assessed by detecting urinary RNase7 levels that reflect macrophage infiltration.

Methods: RNase7 was induced in 129 mice by nephrotoxic serum (NTS) delivered intravenously. RNase7 induction was assessed using albumin ELISA & chromogenic creatinine assay. H&E and PAS stained slides of mouse kidneys were observed using light microscopy. Presence of renal macrophages was confirmed using FACS. NIR optical imaging of anesthetized mice was performed following IV administration of a cleavable fluorophore for imaging macrophages. We performed serial urinary RNase7 levels to monitor macrophage infiltration.

Results: In mice with uninflamed kidneys, we confirmed the paucity of renal macrophages. Accordingly, there was minimal renal fluorescence signal as determined by renal fluorescence intensity signal in NTS mice compared to control mice.
FR-PO993  
Improved Tissue Clearing and 2-Photon Imaging of Mouse Kidneys Reveals Immune Cell Architecture in Nephrotic Nephritis  
Matthew David Cheung, Dongyue Huang, Alfred Hyongjui Kim.  
Background: Tissue clearing approaches such as CLARITY renders tissue transparent, and in combination with two-photon microscopy, enables microscopic visualization deep internal structures in unaltered organs. These cutting edge approaches have drastically improved the understanding of cellular circuits in the brain. However, application of this approach has only recently been described for the kidney. Here, we clear mouse kidneys to better understand the immune cell architecture following induction of nephrotic nephritis (NTN) using a modified lipid removal approach that also worked for human kidney fragments.  
Methods: 129 mice were injected intravenously with nephrotic serum to induce NTN. Mice were perfused with an acrylamide monomer solution to form the basis of the hydrogel. Lipid removal was accomplished using 8% sodium dodecyl sulfate (SDS). An acrylamide solution was used to quench light absorbing heme in red blood cells trapped within the tissue. Cleared mouse kidneys were stained with antibodies specific for B cells, T cells, macrophages, and dendritic cells (DCs). Human kidney fragments were incubated in acrylamide monomer solution then cleared as mentioned above. Cleared tissue was imaged using two-photon microscopy.

Results: Compared to previously published protocols, perfusion of acrylamide monomers into mice significantly accelerated the tissue clearing process. Enhanced tissue clearing was observed when we incubated kidneys in aminoalcohols. We observed vast networks of lymphocytes, macrophages, and DCs cleared NTN kidneys compared to DC-deficient control kidneys. Human kidneys also were cleared using this approach, and we noted DC networks in healthy donor controls.

Conclusions: We identified a new protocol that enhanced and accelerated tissue clearing in mouse and human kidneys. Using this approach, we found elaborate networks of lymphocytes and monocyte-derived cells in NTN mouse kidneys. We also observed DC networks in healthy human donor fragments. These data demonstrate the utility of tissue clearing in evaluating cellular architecture in mouse and human kidneys.

Natural IgM Mediates Ischemic AKI  
Lindsey R. Goetz, Jennifer Laskowski, 1 Brandon Renner, 1 Rachel A. Woolaver, 1 Liudmila Kulik, 2 Kazue Takahashi, 3 Matthew C. Pickering, 1 Joshua M. Thurman.  
Background: Glomerular IgM deposition occurs in numerous “non-immunologic” kidney diseases and has been shown in chemical and inflammatory models of injury. We recently demonstrated that complement activation within the kidney leads to neo-epitope formation. Because the alternative complement pathway is activated in renal ischemia reperfusion (IR) injury, we hypothesized that complement activation during renal IR generates neo-epitopes recognized by natural IgM antibodies that then exacerbate inflammatory injury.

Methods: To investigate this hypothesis, we used a 24 minute IR model. Results: We first subjected soluble IgM deficient (sIgM) mice to renal IR and found a trend toward less severe injury in these mice vs. wild type (wt) controls (mean BUN of 135 ± 39 [SD] and 152 ± 26 mg/dL, respectively; n ≥ 7, p = NS). To accentuate complement activation in this model, we then exposed mice heterozygous for complement regulatory protein factor H (B6/±) to the same IR protocol and found that the B6/± mice sustained worse renal injury and had greater glomerular IgM deposition than wt controls (mean BUN of 114 ± 46 and 63 ± 48 mg/dL, respectively; n ≥ 14, p = 0.009 and mean glomerular IgM RFUs of 44 ± 7 and 22 ± 7, respectively; n ≥ 8, p = 0.0002). To further evaluate IgM pathogenicity, we induced IR injury in mice deficient in both factor H and IgM (B6/± IgM-) and noted a trend toward attenuation of renal injury in the B6/± vs. B6/± mice (mean BUN of 106 ± 69 and 127 ± 52 mg/dL, respectively; n ≥ 7, p = NS) with data collection ongoing.

Conclusions: These data suggest that natural IgM contributes to ischemic renal injury by binding neo-epitopes generated during complement activation in the kidney. This adds to a growing body of evidence suggesting a common final pathway of IgM-mediated glomerular injury in a variety of “non-immunologic” renal disorders and offers a novel therapeutic target for the treatment of these diseases.

FR-PO995  
Activation of Toll-Like Receptor 2 in the Pathogenesis of Contrast-Induced Nephropathy  
Kristina Angela Rathnem, 1 Altuf-M Khan, 1 Federico Jose Teran, 1 Kathleen S. Hering-Smith, 1 Eric E. Simon, 2 Vecchi Batuman, 2 Medicine, Nephrology & Hypertension, Tulane Univ, School of Medicine, New Orleans, LA; 1, 2 SVHCS, New Orleans, LA.

Background: Innate immunity mediated by Toll-like receptors (TLRs) is involved in the pathophysiology of contrast-induced nephropathy (CIN). We studied the expression of TLRs and associated molecules in CIN using human renal proximal tubule epithelial cells (RPTECs) and aged diabetic (db/db) mice.  
Methods: We cultured RPTECs in normal (5mM) or high (35mM) glucose media for 24 h and then exposed them to nonionic (iodixanol or iohexol) and ionic (Urografin) contrast media (CM) at a dose of 25–100 mg iodine/ml for another 24 h. Then we cleaved the same media. 24-wk-old male db/db mice were given nonionic CM i.v. (3 g of iodine/kg bw) after 24 h water deprivation. All mice were sacrificed 24 h after CM injection.

Results: The mRNA expressions of TLR2 increased by 2.5 fold (p < 0.05), TICAM-1 by 1.7 fold (p < 0.05) in RPTECs exposed to iohexol compared to untreated RPTECs in a dose-dependent fashion. RPTECs in high glucose for 48 h and exposed to ioxanol showed significantly increased apoptosis compared to RPTECs in normal glucose. 24-wk-old db/db mice became obese, polyuric, glucosuric, ketonuric, and had increased GFR, systolic blood pressure, urine NGAL, and renal tubular damage compared to nondiabetic (db/m) control mice. 24 h after iohexol injection, db/db mice showed a significant decrease in GFR, metabolic acidosis and significant increases in serum creatinine, urine and kidney KIM-1 levels and kidney damage histologically compared to control db/d mice. After iohexol administration, the mRNA level of TLR2 was significantly increased by 2.4 fold (p < 0.01) in kidney compared to control but there was no change in TLR4 expression. The expression of CD11b and CD68 were also significantly upregulated in kidney.

Conclusions: High glucose RPTECs and diabetic (db/db) mice are vulnerable to CIN. Innate immunity mediated by TLR2 plays a major role in the pathogenesis of CIN as demonstrated by in vitro and in vivo studies. TLR2 may prove to be a promising drug target for the development of new therapeutics against CIN.

Heparanase Deficiency Improves Renal Function During Experimental Glomerulonephritis  
Marileen Garson, 1 Marinell Benner, 1 Henry Dijkman, 1 Jinxing Li, 1 Ton J. Rabolink, 1 Israël Vladovský, 2 Jo H.M. Berden, 1 Angelique Roep, 1 Michael Elkin, 3 Joris A. Smits, 1, 3 Centre for Complement and Inflammation Research, Imperial College London, London, United Kingdom.

Background: Heparanase (HPSE), a heparan sulfate (HS)-specific endoglucuronidase, mediates the onset of proteinuria and renal damage during experimental diabetic nephropathy. Glomerular HPSE expression is increased in the majority of proteinuric diseases. The exact role of HPSE in the development of other inflammatory glomerular diseases is still unknown.

Methods: Here, we evaluated the role of HPSE in two models of experimental glomerulonephritis, being a murine basement membrane and lipopolysaccharide (LPS)-induced glomerulonephritis, in wild type (WT) and HPSE-deficient mice.

Results: Induction of experimental glomerulonephritis led to an increased HPSE expression in WT mice, which was associated with a decreased glomerular HS expression and albuminuria. Albuminuria was reduced in the HPSE-deficient mice in both models, which was accompanied by a better renal function and less renal damage. Notably, glomerular HS expression was preserved in the HPSE-deficient mice. Glomerular leukocyte and macrophage influx was reduced in the HPSE-deficient mice, which was accompanied by a reduced expression of both Th1 and Th2 cytokines. In vivo, tumor necrosis factor (TNF)-α and LPS directly induced HPSE expression and increased transendothelial albumin passage in a HPSE-dependent manner.

Conclusions: Our study shows that HPSE deficiency ameliorates proteinuria and renal damage in experimental glomerulonephritis by preserving glomerular HS expression, and reducing leukocyte and macrophage influx, and by affecting the local cytokine milieu.

FR-PO997  
Iron Chelation as a Novel Renoprotective Strategy in Lupus Nephritis  
Erika L. Boessen, 1 Cellular & Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE.

Background: Poorly liganded iron damages tissue via several mechanisms. Multiple iron homeostasis proteins have been proposed as urinary biomarkers of lupus nephritis, and we have previously found that renal tissue iron levels are increased in the (NZBxNZW)F1 mouse model of lupus nephritis. Anemia is also common in lupus patients. Together, these data suggest that dysregulation of body iron homeostasis may occur in lupus. This pilot data suggests that dysregulated body iron homeostasis affects hematological parameters.

IKK2 Inhibition Inhibits the Initiation, but Aggravates the Progression of the Disease in a Mouse Model of Lupus Nephritis. 

Miki Yatabe,1,2,3 Chihiro Nishimura,2 Tetsuhiro Kato,4 Ryo Kubo,4 Takanori Maruo,4 Michihiro Horiuchi,4 Takeshi Yamazaki,4 Takeshi Okada,4 Masaki Matsuzaki,4 Masayasu Mutoh,4 Shoko Yamanaka,4 Masahiro Takahashi,5 Masato Kato,2,6 Masahito Kato,2,7 Akiko Ito,2,8 Toshio Kishimoto,2,9 Minoru Sato,2,10 Takeshi Ozaki,2,11 Masayuki Yonezawa,1,2,3

**Background:** The NF-kB transcription factor family facilitates the activation of dendritic cells (DC) and CD4+ T helper (Th) cells, which are important for protective adaptive immunity. Inappropriate activation of these immune cells may cause inflammatory disease, and NF-kB inhibitors are promising candidate drugs.

**Methods:** Here, we investigated whether inhibiting the NF-kB component IKK2 can attenuate crescentic glomerulonephritis, a severe DC- and Th-cell dependent kidney disease by induction of the passive and the accelerated NTN mouse model.

**Results:** Prophylactic pharmacological IKK2 inhibition reduced DC activation, Th cell activation and ameliorated glomerulonephritis in mice. However, therapeutic IKK2 inhibition during ongoing disease, which is relevant for clinical situations, unexpectedly aggravated the nephritogenic immune response and disease symptoms. This resulted from systemic loss of regulatory T cells (Tregs), which have been previously shown to protect against crescentic glomerulonephritis and which require IKK2 as well.

**Conclusions:** In conclusion, although IKK2 inhibition can suppress the induction of nephritogenic immune responses in vivo, it may aggravate such responses in clinically relevant situations, because it also impairs Treg, and thereby unleashes pre-existing nephritogenic responses. Our findings argue against using IKK2 inhibitors in chronic glomerulonephritis, and perhaps also in other immune-mediated diseases.

Transfused M2 Macrophages Ameliorate Renal Injury in Murine Nephrotoxic Serum Nephritis. 

Qiuna Du,1 Naotake Tsutobi,1 Yutaka Sugiyama,1 Seichi Matsuo,1 Shoichi Maruyama.1 Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan.

**Background:** Glomerular leukocyte infiltration is a hallmark of glomerulonephritis. In addition to the effector roles of glomerular macrophages (M2a) for tissue injury, recent studies found involvement of alternatively activated macrophages (M2b Mø) in resolution of kidney inflammation. The aim of this study is to directly assess the potential of M2b Mø to protect against renal injury in murine nephrotoxic serum (NTS) nephritis.

**Methods:** Bone marrow (BM)-derived Mø and mouse iPS-derived Mø were obtained under the stimulation of IL-4/IL-13 to differentiate M2b Mø with high expression of arginase-1 and IL-10. M2b Mø were co-cultured with vehicle-treated mice (median onset of albuminuria 39 and 32 weeks, respectively).

Liver iron concentration was significantly lower in deferiprone-treated mice than vehicle-treated mice, consistent with effective iron chelation. Renal cortical and outer medullary iron concentrations were not significantly different between groups. Unexpectedly, hematocrit was significantly improved by treatment with deferiprone (48% increase versus 39% increase in vehicle-treated mice; P<0.01), whereas red cell hemoglobin and plasma non-heme iron concentrations were not different between groups.

**Conclusions:** Our pilot data suggest that iron chelation may delay the onset of albuminuria in a mouse model of lupus nephritis without adversely affecting hematological parameters.

A Randomized Multicomponent Intervention to Reduce Disparities in Transplant Referral: Results from the RaDIANT Community Study

Rachel E. Patzer,1 Leighann Sauls,2 Jennifer C. Gander,3 Laura Plantinga,4 Sudeshna Paul,1 Eric M. Gibney,1 Laura L. Mulloy,5 Stephen O.Pastan,1 Emory Univ; 1Southeastern Kidney Council, 1Piedmont Hospital; 1Georgia Regents Univ.

**Background:** The Reducing Disparities In Access to kidney transplantation (RaDIANT) Community Study is a dialysis facility-level randomized clinical trial to test the effectiveness of a multicomponent intervention in improving kidney transplant (KTx) referral and reducing racial disparities in referral in Georgia.

**Methods:** In 2013, 134 dialysis facilities were randomized to receive either usual KTx education (n=67) or a multicomponent intervention conducted by, consisting of KT education and engagement activities targeting dialysis facility leadership, staff, and patients (n=67) over 12 months. Paired t tests, overall and by race [white and African-American (AA)], were used to compare referral at 9 months of intervention vs. baseline, in intervention and control facilities.

**Results:** Facilities that received the intervention had a greater absolute increase in referral over 9 months than facilities that performed usual KTx education (+7.8% vs. -2.5%).
A total of 51 of the 67 (76.1%) intervention facilities improved their percentage of patients referred for KTxs over the 9 month study period. Intervention vs. control facilities had a greater increase in referral among AA (+7.3% vs. -2.5%) than white (+0.4% vs. -1.2%) patients over 9 months. Among the 26 dialysis facilities that had an AA vs. white racial disparity in referral at baseline, 69.2% no longer had a racial disparity in referrals by 9 months.

Conclusions: Data from RaDIANT Community Study intervention facilities suggest that a large, randomized, quality improvement program among dialysis facilities in GA may improve KTxs access. Availability of data after 12 months of the intervention will allow final assessment of the effectiveness of the intervention.

FR-PO1002
Association of Neighborhood Poverty and Living Donor Kidney Transplant Rates by Race
Douglas Scott Keith, Angie G. Nishio-Lucar, Gayle M. Vranic
Medicine, Univ of Virginia, Charlottesville, VA.

Background: Despite a growing shortage of deceased donor kidneys in the US, living donation (LD) rates have declined steadily since 2004. We sought to understand the impact of candidate socioeconomic environment on living donation rates.

Methods: We identified all candidates listed for kidney or kidney pancreas transplant in the SRTR database from 2000-2010. Data was linked to US census data on median income of candidate zip code. Neighborhood poverty was defined as neighborhoods with median income below $25,000.

Results: Neighborhood poverty was associated with lower LD rates for all racial and ethnic groups. Overall LD rates were highest among Caucasians and lowest among AA. Efforts should be made to remove financial disincentives to living donation to address racial and socioeconomic disparities in access to the life-saving treatment of transplant.

FR-PO1003
Deceased Donor Renal Transplant eGFR at Six Months Has Improved in the Last 13 Years in Spite of Declining Donor Quality
Douglas Scott Keith, Gayle M. Vranic, Angie G. Nishio-Lucar
Medicine, Univ of Virginia, Charlottesville, VA.

Background: Deceased donor quality has declined in the last decade but long-term graft outcomes are improving. We sought to analyze the trend in graft function at six months post-transplant in relation to this improvement.

Methods: All adult deceased donor kidney transplant recipients with at least six months graft survival recorded in the SRTR database between 2000 and 2012 were analyzed. The CKD EPI eGFR was determined based on the patient characteristics and serum creatinine at six months post-transplant. KDPI of the donors was also calculated. Linear regression was used to determine the effect of covariates on eGFR.

Results: 111,678 deceased donor recipients were identified. 4918 (4.4%) recipients with no six month creatinine time record were excluded. The median eGFR improved from 54.5 ml/min./1.72m2 in 2000 to 58.9 in 2012 (p=0.001) while the median KDPI increased from 41% to 46%(p=0.001). The use of tacrolimus/mycophenolate derivative also increased from 33.1% to 89.8%. Every 10 unit increase in KDPI resulted in a 3 ml/min./1.72m2 decline in eGFR.

FR-PO1004
Recipient Age and KDPI Are the Most Potent Predictors of Early Acute Rejection in Deceased Donor Kidney Transplantation
Douglas Scott Keith, Gayle M. Vranic, Angie G. Nishio-Lucar
Medicine, Univ of Virginia, Charlottesville, VA.

Background: The rate of acute rejection in first six months after deceased donor kidney transplant is now under 10% in the modern era of immunosuppression. We sought to determine the factors predictive of acute rejection in this era.

Methods: All recipients transplanted between 2001 and 2012 in the SRTR database were included in the analysis. Logistic regression was performed to determine the odds ratio of acute rejection in the first six months adjusting for multiple covariates.

Results: The acute rejection rate was 7.1% during the study period. KDPI and recipient age were the most important factors influencing rejection rates with recipients under 30 years old having a rate of rejection more than double that of recipients 60 years or older and recipients receiving donor kidneys with a KDPI over 90% having a 2 fold increase in rejection rate over those receiving a kidney with a KDPI less than 30%.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
No vascular complications, rejection or allograft loss was noted. All of the donors were aged 0 to 5 years of age. Younger age and low weight of the donors did not adversely affect our results. The average serum creatinine remains at 0.89 to date. Kidney size 0.3 to 1.2 cm on average at 3-6 months in follow up. There were no perioperative complications, allograft failure, rejection, vascular complications or recurrence of the primary disease. The average serum creatinine remains at 0.89 to date.

Conclusions: KDPI and recipient age are the most important factors associated with rejection. Risk stratification for donor recipient pairs based on age and KDPI should be considered when determining induction and maintenance immunosuppression needs.

The only factors in the KDPI determination associated with rejection were donor age, donor hypertension, HCV seropositivity, and black donor race, with age accounting for most of the effect.

Conclusions: KDPI and recipient age are the most important factors associated with rejection. Risk stratification for donor recipient pairs based on age and KDPI should be considered when determining induction and maintenance immunosuppression needs.

FR-PO1005

Transplantation of Cadaveric Kidneys from Infants and Toddlers into Adults in the Era of Extreme Donor Shortage

Jimena A. Blandon, Nader Najafian, Neerja Agrawal,
Nephrology, Cleveland Clinic Florida, Weston, FL; Nephrology, Cleveland Clinic Florida, Weston, FL; Nephrology, Cleveland Clinic Florida, Weston, FL.

Background: Kidney transplantation is the treatment of choice for patients with ESRD. The number of patients in the waiting list for a deceased donor kidney transplant continues to increase. In this era of extreme donor shortage we present our experience with transplantation of cadaveric kidneys from infant and toddler into adult recipients.

Methods: This was a retrospective study of twelve adult deceased donor kidney transplant recipients from pediatric donors ages 0-5 years. Medical records were reviewed from visits previous to transplantation to the most recent follow up after transplant.

Results: Twelve consecutive adult patients were transplanted with pediatric en bloc kidneys from donors 0-5 years between February 2014 to February 2015. Ten of the donors were standard criteria brain death (DBD) and two were donors with cardiac death (DCD), KDPI scores ranged from 47 to 87%, donor age from 6 months to 5 years, weight 6 to 15 Kg. Recipients were equally distributed by gender, average age 56 years, mean BMI 22. All patients were followed in average 6 months to 1 year. In the early post transplant period 9 recipients were noted to have glaucosuria with normal blood glucose and mild metabolic acidosis. These findings were noted on average up to 3 to 6 months after transplant and resolved thereafter. Nine patients had follow up renal ultrasound with finding of increase in kidney size 0.3 to 1.2 cm on average at 3-6 months in follow up. There were no perioperative complications, allograft failure, rejection, vascular complications or recurrence of the primary disease. The average serum creatinine remains at 0.89 to date.

Conclusions: We report excellent outcomes after adult kidney transplant from cadaveric donors aged 0 to 5 years of age. Younger age and low weight of the donors did not adversely affect our results. No vascular complications, rejection or allograft loss was noted. All of our patients have excellent allograft function 6-12 months post transplant.

FR-PO1006

The Role of Dobutamine Stress Echo in Identifying Cardiac Ischaemia, Cardiovascular Events and Role of Subsequent Cardiac Angiography

Maria Ventura, Robin Ramphul, Sami Firooz, Juan Carlos Kaski, Rajan Sharma, Debasish Banerjee, Renal and Cardiology Depts, St. George’s Univ Hospitals NHS Foundation Trust.

Background: Dobutamine Stress Echo (DSE) is an established method of identifying cardiovascular (CV) risk in patients undergoing kidney transplantation, however the role of coronary angiography (CA) is not clear. The aim of this study was to investigate the role of DSE and CA in predicting cardiac ischaemia and CV events in this population.

Conclusions: DSE is a suitable method to stratify cardiovascular risk and predict significant CAD on CA, however subsequent PCI does not conclusively show decreased event rates. Larger studies are required to establish the role of revascularisation.

FR-PO1007

Racial Differences in Survival of Incident Home Hemodialysis and Kidney Transplant Patients

Miklos Zsolt Molnar, Vanessa A. Ravel, Elani Streja, Csaba P. Kovesdy, Rajnish Mehrotra, Kamyar Kalantar-Zadeh, Univ of Tennessee Health Science Center, Memphis, TN; Univ of California, Irvine, CA; Univ of Washington, WA.

Background: Previous studies have indicated that patients on maintenance dialysis have worse survival compared to kidney transplant (KTx) recipients. However, none of these studies have compared mortality in United States(US) patients using alternative dialysis modalities such as home hemodialysis(HD) with KTx recipients.

Methods: Comparing patients who started home HD with those who received KTx in the US between 2007-2011, we created a 1:1 propensity-matched cohort of 4,000 patients and examined the association between treatment modality and mortality using Cox proportional hazard models.

Results: The mean±SD age of the matched home HD and KTx patients at baseline were 54±15 and 54±14 years, 65% were male (both groups), 70% and 72% of patients were white and 19% were African American (both groups), respectively. Over 5 years of follow-up, home HD patients had 4-times higher mortality risk compared to KTx recipients in the entire patient population (HR=4.06, 95%CI:3.27-5.04), and similar differences were found across each race stratum (Figure).
Survival of Elderly Incident Home Hemodialysis and Kidney Transplant Patients  
Miklos Zsolt Molnar,1 Vanessa A. Ravel,2 Elani Streja,2 Csaba P. Kovessy,1 Danh V. Nguyen,2 Rajnish Mehrotra,1 Kamyar Kalantar-Zadeh,2 1Univ of Tennessee Health Science Center, Memphis, TN; 2Univ of California, Irvine, CA; 3Univ of Washington, WA.

Background: The proportion of elderly (≥65 years) patients with kidney failure is increasing. Previous data suggest that the projected increases in the life spans of kidney transplant (KTx) patients compared to conventional dialysis were 2.8 and 1.1 years for patients aged 65-69 and 70-74 years, respectively. However, no studies have compared mortality of elderly patients using alternative dialysis modalities such as home hemodialysis (HD) with KTx recipients.

Methods: Comparing elderly patients, who started home HD with those who received KTx in the US between 2007-2011, we created a 1:1 propensity score (PS) matched cohort of 960 elderly patients (480 KTx and 480 HD) and examined the association between treatment modality and all-cause mortality using Cox proportional hazard models.

Results: The mean±SD age of the PS matched home HD and KTx patients at baseline were 71±6 years and 71±5 years, 69% were male (both groups), and 81% and 79% of patients were whites in home HD and KTx group, respectively. Median follow-up time was 205 days (IQR: 78-364 days) for home HD patients and 795 days (IQR: 366-1,221 days) for KTx recipients. There were 97 deaths (20%, mortality rate 253 [297-309]/1000 PY) in the home HD group, and 48 deaths (10%, 45 [34-60]/1000 PY) in the KTx group. Over 5 years of follow-up, home HD patients had almost 5-times higher mortality risk compared to KTx recipients in the entire patient population (HR: 4.74, 95%CI:3.25-6.91).

However, during the first year of therapy, while white home HD patients had higher mortality risk (HR:4.21, 95%CI:3.10-5.73) compared to their KTx counterparts, there was no significant difference in mortality risk between African American home HD and KTx patients (HR: 1.62, 95%CI:0.77-3.39). These results were consistent across different types of kidney donors.

Conclusions: Among all patients, home HD is associated with 4 times higher mortality compared to KTx recipients regardless of the type of kidney donor.

Beyond the Bones – The Association Between Vitamin D, Graft Outcomes and Vascular Disease

Aravind Chenkuru1, Santhanakrishnan Balasubramanian,2 Rebekah Molyneux,2 Richard J. Baker,2 1Univ of Pittsburgh; 2Univ of Leeds.

Background: Vitamin D deficiency in KTRs is an emerging theme. The purported associations between Vitamin D deficiency and various metabolic, cardiovascular and non-metabolic adverse events have not been thoroughly studied in kidney transplant recipients (KTRs).

Methods: Here, we examined the association between Vitamin D deficiency and graft loss, mortality, NODAT, cardiovascular events and development of cancers.

Results: 504 KTRs had their vitamin D checked in 2008 and were followed up for 6 years. Vitamin D deficiency was defined as a level<50nmol/L. In this population, the prevalence of vitamin D deficiency was high at 66.5% with a significantly higher prevalence in older (71.9% vs. 60.9%, P=0.006) and female recipients (male 62.1% vs. female 73.2%, P=0.006) and in relatively new transplants (recent transplants 72.3% vs. old transplants 66.6%, P=0.003). KTRs who were vitamin D deficient had significantly worse overall (77% vs. 62.9%, P=0.001), death censored graft survival (89% vs. 96%, P=0.009), development of NODAT (19.8% vs. 10%, P=0.005) and cardiovascular events (19.9% vs. 2.9%, P=0.002) when compared to those with normal levels. In a stratified analysis, this was noted to be worse in KTRs on maintenance steroids, with relatively worse baseline renal function and proteinuria, with secondary hyperparathyroidism, deceased donor transplants and earlier vs. late transplants. Although vitamin D deficiency is not associated with a higher incidence of malignancy, it is associated with higher mortality in those with cancer (33.3% vs. 12.9%, P=0.005). In a multivariate Cox model, vitamin D deficiency was associated with significantly worse overall graft (HR 2.7, P=0.001) and death censored graft survival (HR 2.4, P=0.04). NODAT (HR 2.3, P=0.03) and cardiovascular events (HR 4.0, P=0.004) independent of age, PTH levels, gender, graft number, type of transplant, time since transplantation, graft type and renal function measured by both proteinuria and eGFR.

These results were consistent across different types of kidney donors and recipients characteristics.

Conclusions: Elderly home HD patients appear to have almost 5 times higher mortality compared to KTx recipients regardless of the type of kidney donor.

Funding: Other NIH Support - R21AG047306 and R01DK95668

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only  
Underline represents presenting author.
Conclusions: In conclusion, vitamin D deficiency which is highly prevalent in KTRs is associated with adverse outcomes. Our study stresses the need for a prospective trial of vitamin D replacement in KTRs.

Funding: Private Foundation Support

FR-PO1010

Acute Tubular Necrosis Changes in Living Kidney Donor Implant Biopsy

Associates with Higher Rejection Rates Post-Transplant

Dept of Nephrology and Hypertension, Glickman Urological and Kidney Inst, Cleveland Clinic, Cleveland, OH.

Background: Ischemic injury may occur during organ retrieval. In deceased kidney donor transplants, delayed graft function, a form of acute tubular necrosis (ATN), associates with acute graft failure. Histological changes consistent with ATN can also be seen in implants procured with living donors (LD), however, the influence of LD-like changes at time on donation from LD on recipient graft outcomes is unclear, especially its impact on graft rejection.

Methods: We retrospectively studied all LD kidney transplants at our center from Jan 2005 to Dec 2014 who had an implant biopsy. We perform protocol biopsies at 3-6, 12 and 24 months post-transplant and for cause biopsies in all of our patients. Post-transplant biopsy results were reviewed, and patients with subclinical and clinical borderline and/or Banff scored graft rejection were captured.

Results: The study included 350 LD kidney transplant recipients, the mean age was 47.8±13.7 years (range 10-75) and 224/64% were male. The incidence of ATN in implant biopsies was 16% (n= 56). Patients with ATN had a trend toward higher risk of graft rejection in post-transplant biopsy compared with those without ATN (32.1% vs. 21.7%, p=0.09). When the study population was stratified by time from transplant to post-transplant biopsy, there was a statistically significant higher incidence of graft rejection in those biopsies performed between 1 and 24 months post-transplant (31.0% in the ATN group vs.17.8% in the non-ATN group, respectively, p=0.02). No statistical correlation was found between ATN and graft rejection after 24 months post-transplant. Importantly, implant ATN has no impact on GFR at 3, 6, 12, 24 months post-transplant.

Conclusions: Histological changes consistent with ATN in LD kidney implant biopsy are associated with higher rates of graft rejection between 1 and 24 months post-transplant. However, ATN does not affect graft function at 3, 6, 12, or 24 months.

FR-PO1011

Impact of Pre-Transplant Cardiovascular Risks on Renal Allograft Survival: A Multi-Center Prospective Study

Jung Nam An1, Song Vogue Ahn2, Chuin Soo Lim2, Yong Su Kim1, Jong-hoon Kim1, Jung-ho Lee, Jung Pyo Lee.

1Seoul National Univ Boramae Medical Center; 2Seoul National Univ College of Medicine; 3Yonsei Univ Wonju College of Medicine; 4Asan Medical Center and Univ of Ulsan College of Medicine, Republic of Korea.

Background: Cardiovascular (CV) disease is a leading cause of mortality in patients with end-stage renal disease. Even after successful renal transplantation, CV risks can induce CV morbidity and mortality in renal transplant recipients. However, the impact of pre-transplant CV risks on renal allograft outcomes has not been reported.

Methods: We analyzed the graft outcomes of 2902 renal transplant recipients who were enrolled in a multi-center cohort from 1997 to 2012. We calculated pre-transplant CV risk scores by the Framingham risk model using age, sex, total cholesterol levels, smoking and a history of hypertension. Cox proportional hazard models were used to assess hazard ratios (HRs) with and without competing risks of post-transplant CV deaths, adjusting for risk factors of allograft failure including recurrence of glomerulonephritis and acute rejection.

Results: Hypertension and vascular disease (a composite of ischemic heart disease, peripheral vascular disease, and cerebrovascular disease) were noted in 84.1% and 6.5% of the patients, respectively. During a median 6.4 years of follow-up, 122 (4.2%) patients died and 286 (9.9%) patients developed allograft failure. In multivariable-adjusted models, pre-transplant vascular disease was associated with increased risk of renal allograft failure (HR 2.43; 95% confidence interval [CI] 1.58-3.71). The HR for renal allograft failure comparing the highest with the lowest tertiles of pre-transplant CV risk scores was 1.49 (95% CI 1.11-2.00). In competing risk models, the HR for pre-transplant vascular disease was 2.01 (95% CI 1.20-3.36) and the HR for renal allograft failure comparing the highest tertiles of pre-transplant CV risk scores was 1.44 (95% CI 1.05-1.98).

Conclusions: Both pre-transplant CV risk and vascular disease are independently associated with renal allograft failure in this multi-center prospective study. Pre-transplant CV risk assessment could be useful to predict renal allograft failure.

FR-PO1012

Blood Pressure (BP) Control in Kidney Transplant Recipients: A Single Centre Experience

Kristin Vibeke Veijpeg, Jacqueline C. Nevol, Panagiotis Chondrogiannis, Amanda Jane Laird, Irene Synodinou, Doreen Zhu, Katherine A. Alington, Nichola Dawn Pugh, Chun ying Ung, Gopalakrishnan Venkat-Raman.

Wessex Kidney Unit, Portsmouth Hospitals NHS Trust, Portsmouth, United Kingdom.

Background: Cardiovascular disease is the leading cause of death among kidney transplant recipients (KTRs), however there remains uncertainty regarding optimal BP targets. Current UKRA, KDIGO and KDQI guidelines advocate BP control to 130/80 in KTRs; UKRA/KDIGO advocate tighter control (125/70) in proteinuric KTRs. We examined BP control and proteinuria in all KTRs under longterm follow up at one centre, and adherence to these recommendations.

Methods: As of 1 March 2015, 839 KTRs were attending for regular clinic review (excluding recent KTRs<1yr). We performed a retrospective database review of BP, proteinuria, renal function and antihypertensive use.

Results: The cohort was 60% male with mean allograft age 10±0.28 years. Mean decline in eGFR was 0.83ml/min/m² per year (p=0.0004). Mean SBP was 134±0.56, DBP 79±0.37. 48% had SBP<130, 62% DBP<80, 39% both. 78% received 1 antihypertensive, 42% 2-3, 4% 4-24 agents. Only 9% had PCR measured. In those with PCR>2.50, 19% had BP treated to 125/75. Dipstick proteinuria was recorded in 58% and showed a significant association with SBP (p=0.01). There were significant correlations between reducing eGFR and increasing PCR (R²=0.11, p=0.0001), and between PCR and ACE/ARB use (p=0.0002). There was no correlation between CNI level and BP (CyA p=0.88, FK506 p=0.69). There was a significant stepwise decrease in renal function (eGFR >p=0.005, eGFR p=0.01) and increase in dipstick proteinuria (p=0.03) when data were analysed in sbp groups <120, 120-140 and >140. In terms of DBP, the stepwise decrease in renal function remained (eGFR <p=0.01, eGFR p=0.0001) when data were analysed in groups<70, 70-90 and >90. DBP>90 had the most significant impact on eGFR, DBP was not associated with proteinuria.

Conclusions: The optimal BP target remains uncertain. Adherence to current guidelines is reasonable in our unit but could be improved. This study again demonstrates that SBP is the key risk factor for proteinuria, however increases in DBP >90 were most strongly associated with graft dysfunction.

FR-PO1013

Dobutamine Stress Echocardiography (DSE) Significantly Reduces the Need for Coronary Angiography in Renal Transplant Patients

Daniela Musta1,2, Isabella Jones3, Michael I. Stoker2, Roberto Maghelli, Maria Ventura, Sami Firoozi, Juan Carlos Kaski, Rajan Sharma, Deborah Banerjee.

Renal and Cardiology Unit, St. Georges Univ Hospitals NHS Trust, United Kingdom.

Background: There is significant controversy regarding optimal cardiac workup strategy for kidney transplantation. Some centres perform coronary angiograms (CA) in all patients whereas others have adopted a tailored approach using non-invasive techniques such as Exercise Tolerance Testing (ETT) and ischaemia assessment with cardiac imaging. This study examines the role risk stratification and DSE for cardiac workup in this patient group.

Methods: We analysed data on patients referred between 1/2012 and 31/12/2014 who were risk stratified and investigated according to the protocol (figure 1).

Results: Of 233 patients referred 92 were high risk and went on to have DSE. All other patients underwent echocardiography with/without ETT (33 ETT, 122 echocardiography and 33 CA). 16 patients had CV events, but none were peripereative. Overall event rate was 4% per year. 11 of 92 patients who had DSE had events. 11 of 33 patients who had CA had event. 28 of 92 patients had a positive DSE (i.e. suggestive of myocardial ischaemia) and of these 23 went on to CA. 6 of 28 patients with a positive DSE and 5 of 64 with a negative DSE had an event (figure 2, log rank p=0.1). 25 of 33 patients had evidence of coronary artery disease (CAD) at CA of which 13 received coronary artery stents. There was no significant difference between those with significant (>50% stenosis) CAD on CA who had events (8 of 21 patients) compared to those without significant (>50% stenosis) CAD who had events (3 of 12) (log rank p = 0.7). 6 patients with significant CAD who had PCI had events. 35 patients underwent ETT, 4 had CA following positive ETT. One patient with negative ETT had an event.

Conclusions: A careful risk stratification and using DSE decreases the need for CA and achieves very low event rates.

FR-PO1014

Levels of Indoxyl Sulfate in Kidney Transplant Patients, and the Relationship with Hard Outcomes

Sophie Lieu1,2, Lucie Desjardins,1 Ziad Massy,3 François Brazier,1 Dimitri Titeca Beaufort,1 Momar Diofa,4 Grier Lrl1,3,4, Raymond C. Doherty,1 Maite Jaureguy,1 Gabriel Choukroun,1 1Nephrology, Amiens; 2Nephrology, Ambroise Pare; 3Nephrology, Gent.

Background: Kidney transplant recipients are at greater risk of cardiovascular disease (CVD). Indoxyl sulfate (IS) is a protein-bound uremic toxin that is known to be associated with the risk of CVD and mortality in both pre-dialysis and dialysis patients. Data on levels of protein-bound uremic toxins in kidney transplant patients are scarce. The objective
of the present study was to evaluate the levels of IS in kidney transplant patients and their relationship with biochemical parameters and hard outcomes (including mortality, cardiovascular (CV) events and graft loss).

Methods: In 311 consecutive kidney transplant patients, total and free IS levels were measured immediately before transplantation (T0) and then 1 month (M1) and 12 months (M12) afterwards. In a case controlled substudy (n=90), IS levels in transplant patients were compared with those in non-transplant patients with chronic kidney disease matched for age, gender and estimated glomerular filtration rate (eGFR). Over a mean ± standard deviation follow-up period of 113 ± 29 months, 55 deaths, 70 CV events and 71 graft losses were recorded.

Results: We observed a rapid, consistent, significant decrease in IS levels after kidney transplantation. Majority of IS levels were below or near the normal value at M1 and M12. We did not observe a correlation between IS levels and eGFR at M1 and M12. Total and free IS levels at M12 were significantly higher in non-transplant patients (0.34±0.23 mg/dl and 0.04±0.007 mg/dl, respectively) than in transplant patients (0.21±0.17 mg/dl and 0.001±0.01 mg/dl; p=0.003 and <0.0001 respectively), despite having similar eGFRs. Lastly, IS levels were not associated with overall mortality, CV events or graft loss at T0, M1 or M12.

Conclusions: Free and total IS levels were significantly lower in transplant recipients than in non-recipient matched for, age, gender and renal function - suggesting that kidney transplantation protects against an increase in IS levels. Importantly, serum IS levels were not associated with hard outcomes at any of the three time points.

FR-PO1015

Background: In the general population, abdominal obesity is more closely associated with metabolic and cardiovascular (CV) risk than high BMI. The ideal measure of obesity to identify risk in pediatric kidney transplant (Tx) recipients, who have impaired growth and altered body composition, has not been established. In this prospective study we compared ability of BMI, Waist Circumference (WC), and Waist-to-Height ratio (WHtR) to identify metabolic and CV risk in pediatric kidney Tx recipients.

Methods: Kidney Tx recipients 3-20 years old and 0-30 months post-Tx had WC, BMI, WHtR, blood pressure (BP), fasting lipids, leptin, HbA1c%, standard and speckle echocardiogram and carotid intima-media thickness (CIMT) measured. Patients were classified as obese or lean by 3 methods: WC (ATP cut-point male=94th%ile,females=84 th%ile), WHtR(CDC cut-point>=0.539), and BMI(>95%iles). Logistic regression determined association of metabolic and CV risk factors.

Results: The study group comprised of 33 Tx recipients, age 13.6±0.3 years. Prevalence of obesity by BMI, WC, and WHtR was 21.2%, 33.3%, and 48.5%. Prevalence of hyperglycemia/diabetes(TG) was 24.2%, high LDL 15.2%, high leptin 39.3%, high HbA1c% 12.1%, left ventricular hypertrophy(LVH) 30.3%, hypertension(HTN) 69.6%, and high CIMT48.4%. In all groups (WHr, WC, and BMI), obese children were more likely than to have HTN(OR4.5.2,2.6,6,0 1)LVH(OR5.4.7,4.8,8,8,0 0), low HDL(OR5.0,4.3,8,0 01), and low leptin(OR13.1,1.7,3,0 00). Obese children in WHr and WC groups, but not BMI group, had greater chance of high TG(OR5.4,3,2,0 01), high CIMT(OR2.0,4,5,0 05), and impaired myocardial strain(OR1.2,1.1, p<0.01). Five patients with short stature (height z>2.50) and CV risk factors (3.0 0,5 factors/patient) were not identified as obese by WC criteria(height z>0.8,0 01). Obesity were defined as WHtR (height z>2.50) and CV risk factors. WC and WHtR are more effective than BMI for detecting metabolic and CV risk amongst pediatric Tx recipients. WC may underestimate prevalence of obesity in children of short stature, and therefore WHtR may be a more sensitive method for identification of children with increased metabolic and CV risk in the kidney Tx population.

FR-PO1016

Background: Kidney transplant (KT) is the treatment of choice for end stage renal disease (ESRD). Knowledge of dialysis patients about the benefits of KT is an important determinant of their active engagement in the decision making process. We studied factors associated with patients’ knowledge about benefits of KT.

Methods: We sent flyers to 1,283 dialysis units. Of 2536 interested participants fulfilling inclusion criteria, we randomly selected and invited 1400 to complete the questionnaire. Independent variables were demographic factors, distance to dialysis unit, and modes of education about options. In multivariable analysis, we calculated odds ratios (OR) and 95% confidence intervals (CI) for the probability of responding correctly to each of 4 questions about benefits of KT.

Results: 673 participants responded to questions about overall survival benefit of KT (correct: 32%), benefits of KT for diabetic patients (correct: 46%), for patients > 60 (correct: 29%) and for patients transplanted pre-emptively (correct: 17%). Receiving 3 or more modes of education about KT was associated with higher likelihood of correct response to questions about overall survival benefit of KT (OR:2.19;CI:1.50 to 3.20), survival benefit of KT for diabetics (OR:2.60;CI:1.39 to 3.90) and patients transplanted pre-emptively (OR:1.67;CI:1.06 to 2.64). White race was associated with higher likelihood of correct response to questions about overall survival benefit of KT (OR:1.59;CI:1.11 to 2.28) and the benefit of KT for patients > 60 (OR:1.54;CI:1.07 to 2.21). Age > 60 was associated with lower likelihood of correct response to the question about overall survival benefit of KT (OR:0.65;CI:0.45 to 0.94), benefits of KT for diabetics (OR:0.54;CI:0.38 to 0.77), and for patients > 60 (OR:0.64;CI:0.44 to 0.93). Patients on dialysis > 5 years were less likely to be aware of the benefit of KT for diabetics (OR:0.68;CI:0.48 to 0.98).

Conclusions: Dialysis patients’ knowledge about survival benefits of KT is rather limited. The most significant modifiable contributor to improvement in knowledge is diversity of modes of education about KT. Other factors include race, age and number of years on dialysis.

FR-PO1017
Pretransplant HbA1c Predicts New-Onset Diabetes After Transplantation Among Renal Transplant Recipients Jung-Im Shin, Mari Palta, Arjang Djamali, Brad C. Astor. Univ of Wisconsin School of Medicine and Public Health, Madison, WI.

Background: New-onset diabetes after transplantation (NODAT) is a common complication among renal transplant recipients and is associated with a higher risk of cardiovascular events and poorer graft and patient survival. The association of pretransplant HbA1c with NODAT remains unclear. Identifying recipients at greatest risk of NODAT may help guide monitoring and treatment strategies to prevent or delay the onset of NODAT.

Methods: We assessed the association between pretransplant HbA1c and NODAT in 1522 non-diabetic recipients using data from the United States Renal Data System (USRDS) from 2004-2011. Cox proportional hazards models adjusted for demographics, cause of ESRD, year of transplantation, number of prior transplants, duration of pretransplant dialysis, comorbidities, lipid levels, hemoglobin level, body mass index, HCV and CMV serostatus, donor type and age, HLA mismatch, and posttransplant steroid and tacrolimus use.

Results: Median HbA1c was 5.4% and 531 (34.9%) patients had HbA1c ≥ 5.7% (i.e., prediabetes)A total of 404 (26.5%) patients developed NODAT during a median follow-up of 1.7 years. Pretransplant HbA1c was associated with the risk of NODAT in a non-linear fashion. The adjusted hazard ratio (HR) associated with 1% higher pretransplant HbA1c was 0.94 (95% confidence interval (CI): 0.62, 1.42) for HbA1c lower than 5.4% and 1.87 (95% CI: 1.30, 2.68) for HbA1c higher than 5.4%.

Conclusions: Pretransplant HbA1c is independently associated with the risk of NODAT among renal transplant recipients. A continuous relationship between pretransplant HbA1c and the risk of NODAT suggests that greater risk starts at levels below the standard threshold for prediabetes.

FR-PO1018

Background: Because mortality on the kidney transplant waitlist is high (4-6% per year), being placed on the waitlist earlier versus later has important clinical consequences. Per U.S. Organ Procurement and Transplantation Network (OPTN) rules, patients begin accruing time on the waitlist when renal function declines beyond a threshold defined as “measured (actual urinary collection) creatinine clearance level or calculated glomerular filtration rate (Cockcroft-Gault or other reliable formula) less than or equal to 20 mL/min”.

Methods: We assessed the relative performance of three commonly used kidney-function equations (Cockcroft-Gault, MDRD, and CKD-EPI). We first compared the equations mathematically to determine under what age and serum creatinine combinations each pair of equations yields discordant waitlist qualification statuses (i.e., a patient would qualify for the waitlist with one equation were used but not the other). We then applied the equations to serial creatinine measurements from three patient cohorts: one of waitlisted patients at a major U.S. academic center and two national, multicenter cohorts of CKD patients (the NIH-sponsored AASK and MDRD studies).

Key: TH = Thursday; FR = Friday; SA = Saturday; OR = Oral; PO = Poster; PUB = Publication Only Underline represents presenting author.
Results: Mathematically (assuming average weights), the Cockcroft-Gault equation almost always yields higher numeric values compared with the MDRD and CKD-EPI equations. When applied to the three actual patient cohorts, Cockcroft-Gault consistently disadvantaged patients, delaying average time to waitlist qualification by 1 to 2 years.

Conclusions: This study identified a potential source of significant inequity (on the order of 1-2 years) in wait-time accrual for kidney transplantation that stems from imprecise rules for waitlist qualification. The OPTN may need to revise the language in their kidney transplantation policies so that consistent methods to assess renal function are adopted and patients are not inadvertently disadvantaged.

New Onset Diabetes Has Unfavorable Effect on Patient but Not on Allograft Survival

Thomas Diemennan,1,2 Naohiko Fujii,1,3 Roy D. Bloom,4 Harold I. Feldman,5 Yimei Li.2 1Dept of Medicine, Perelman School of Medicine- Univ of Pennsylvania, Philadelphia, PA; 2Dept of Epidemiology and Biostatistics, Perelman School of Medicine, Philadelphia, PA; 3Dept of Renal Medicine and Hypertension, Univ of Erlangen, Erlangen, Germany.

Background: New onset diabetes after transplantation (NODAT) has been linked to higher rates of graft loss and shorter patient survival. More recent awareness, improvements in care, and changes in immunosuppression may have modified this association.

Methods: Retrospective single center analysis of 1427 (age=18) first time renal transplant recipients (KTR) without pre-transplant(Txp) diabetes. Patients with <1 year of follow up and those with allograft failure in the first year post-Txp were excluded. NODAT was defined as prescription of a glucose lowering medication 1 year after Txp. Cox models adjusted for multi: potential confounders were used to examine the relationship of NODAT with allograft and patient survival.

Results: The incidence of NODAT was 16.1%. Median follow up was 5.9 years(IQR:3.5-9.2) for allograft and 6.3(IQR:3.8-9.8) for patient survival. Age, BMI, non-white race and HCV were independently associated with NODAT (all p<0.01). Compared with KTRs without DM NODAT was not associated with an increased risk of overall graft failure (aHR 1.15, CI 0.86-1.52) or death censored graft survival (DCGS) (aHR 1.12, CI 0.73-1.71) in multivar. analysis. NODAT remained borderline significant after adj. for multiple other factors for patient survival (aHR 1.39, CI 1.00-1.91 p=0.49), but not for death with functioning graft (aHR 1.34, CI 1.09-2.02). The associations between NODAT and outcomes were not detectably different over time (p=0.095 for patient survival and p=0.25 for DCGS).

Conclusions: In this cohort of KTRs NODAT had no impact on graft survival but was indep. associated with reduced overall survival.

FR-PO1020

Frequency of Hospital Readmission Post Kidney Transplantation

Eassy Mozaffari,1 Jay Lin,2 Melissa Lingohr-Smith. 2Chimerix Inc., Mendham, NJ; 3Novosys Health, Green Brook, NJ.

Background: Early hospital readmission following kidney transplantation has been identified to be a strong predictor of adverse sequelae that can have significant clinical and economic implications. Our goal was to quantify the frequency of hospital readmissions post kidney transplantation, as well as the reasons for the rehospitalizations.

Methods: Patients who received a kidney transplant between Jan 2009 and Sept 2013 were identified from the Premier Hospital database by ICD-9-CM code. The first transplant procedure was defined as the index event. The frequency and causes for hospital readmissions were evaluated during the first 12-month after index transplant hospitalization using hospital discharge records.

Results: Of patients who received kidney transplant (n=5,402; mean age: 50.8 years) 61% were male. Most patients received transplant in urban (98%), large (≥600 beds: 61%), teaching hospitals (84%). During index transplant hospitalizations 5 deaths occurred, resulting in 5,367 evaluable patients. Among this study population, 43% had a hospital readmission for any cause during the 12 months following kidney transplant, with 41% occurring within 1 month and 67% occurring within the first 3 months. Readmissions were most frequently related to opportunistic infections (25%) including viral infections (6%), followed by renal impairment (25%), and neutropenia (4%). Among the readmissions related to viral infections, the majority were related to CMV (79%). Readmission of patients with high severity APR-DRG levels of 3 (major) and 4 (extreme) at 30% and 9%, respectively (severity of illness level rated 1-4: minor, moderate, major, and extreme).

Conclusions: Over 4 in 10 of the kidney transplant recipients in this study were rehospitalized post transplantation. A significant number of the readmissions occurred in the first month post-transplant and the majority were within the first three months; almost 4 in 10 readmissions were classified as major or extreme severity level. Among hospital readmissions, more than half of them were related to an opportunistic or viral infection, underscoring unmet needs for the prevention of these infections.

**Associations of Serum Soluble α-Klotho, Fibroblast Growth Factor 23, and 25 (OH) Vitamin D with Kidney Function and Left Ventricular Hypertrophy in Japanese Kidney Transplant Recipients**

Makoto Tsujita,1 Shoichi Maruyama,1 Transplant Surgery, Nagoya Daini Red Cross Hospital, Japan; Nephrology, Nagoya Univ School of Medicine, Japan.

**Background:** Deterioration of kidney function and left ventricular hypertrophy (LVH) is crucial for kidney transplant recipients. Any marker for predicting kidney function and LVH is needed to prevent complications.

**Methods:** This was a retrospective cohort study. Forty-seven consecutive patients were enrolled in this study at Nagoya Daini Red Cross Hospital in 2011.

Serum intact fibroblast growth factor (FGF) 23, soluble α-Klotho (sαKlotho), 25(OH) vitamin D[25(OH)D], estimated glomerular filtration (eGFR), left ventricular mass index (LVMI) and other clinical parameters after 1 year and eGFR after 3 years since kidney transplantation were measured to investigate the usefulness of these markers for predicting kidney function and LVH.

**Results:** The median serum sαKlotho, intact FGF23, 25(OH)D were 516.3 pg/ml, 58.7 pg/ml, 7.8 ng/ml, and 5.7 ng/ml, respectively. Serum sαKlotho levels were associated with difference between eGFR after 1 year and after 3 years (DeGFR) (r = 0.37, p = 0.01), but not with difference between LVMI after 1 year and after 3 years (ΔLVMI). Patients were divided into two groups based on median serum FGF23 level. Higher serum intact FGF23 levels were associated with ΔLVMI. Serum 25(OH)D levels were associated with eGFR after 1 year (r = 0.34, p < 0.05), but not with DeGFR and ΔLVMI. Multivariate regression analysis revealed that serum sKlotho was the strongest predictor of kidney function and serum intact FGF23 was that of LVMI.

**Conclusions:** Serum sαKlotho may be a good marker for kidney function and intact FGF23 for LVH in Japanese kidney transplant recipients.

**Determinants of Hepcidin, the Key Regulator of Iron Homeostasis, in Renal Transplant Recipients**

Michele F. Eisengart,1 Stefan P. Berger,2 Robin P.F. Dullaart,1 Aiko P.J. De Vries,3 Stephan J.L. Bakker,1 Carlo A. Gaillard.1

**Background:** Hepcidin is synthesized in the liver and secreted into the circulation. Circulating concentrations may be influenced by body iron availability, inflammation, insulin sensitivity and tissue hypoxia reflected by erythropoietin, rather than in variation to renal clearance. The study aims at evaluating the association of donor/recipient MYH9 genotypes with circulating parameters of iron status in kidney transplant recipients.

**Methods:** Circulating concentrations of hepcidin were measured in 295 kidney recipients and their donors using a validated ELISA method. Genotyping was performed in 202 recipients and 193 donors. Mixed models were used to assess relations of SNPs and PI, RI values.

**Results:** Genotyping was performed in 295 kidney recipients and their donors, in 202 at least one US was done. In the longitudinal observation between first day and 2 years after engraftment, recipients carrying T alleles in rs5756168 showed significantly different PI indices in opposition to allele C carriers, p=0.04, for RI the differences did not reach statistical significance (p=0.14). In two-factor analyses the effects of rs5756168 different PI indexes in opposition to allele C carriers, p=0.04, for RI the differences did not reach statistical significance (p=0.14). In two-factor analyses the effects of rs5756168 different PI indexes in opposition to allele C carriers, p=0.04, for RI the differences did not reach statistical significance (p=0.14).

**Conclusions:** Identified association of transplanted kidney blood flow parameters and MYH9 polymorphism additionally confirms MYH9 effect on graft functioning shown in our previous study cited above. The study supported by grant from National Science Center NN40266840.
Circulating Inflammatory Cell Subsets Are Associated with Cardiac Function in Renal Transplant Recipients

Stephan J.L. Bakker, 1 Danielle Richler-Potters, 1 Maurice Dungey, 1 Patrick Highton, 2 N. Martin, 3 Nicollete C. Bishop, 2 Alice C. Smith, 2 Leicester Kidney Exercise Team, Univ of Leicester, United Kingdom; 3 School of Sport, Health and Exercise Sciences, Loughborough Univ, United Kingdom.

Background: Cardiovascular (CV) disease is a major cause of mortality and morbidity in renal transplant recipients (RTRs). Systemic and vascular inflammation is paradoxically common despite immunosuppression and is an important non-traditional CV risk factor. Monocytes are heterogeneous: the intermediate phenotype (CD14++CD16+) is particularly pro-atherogenic and pro-inflammatory compared to the classical phenotype (CD14++CD16-). Regulatory T-cells (TRegs) maintain peripheral tolerance and minimise tissue damage. This study aimed to explore the association of circulating inflammatory cell subsets with cardiac function in RTRs.

Methods: 18 stable RTRs (Mean age 55 years, 61% male) and 5 healthy controls participated. Blood monocytes and T cells were analysed by flow cytometry, and cardiac hemodynamic function measured by bioimpedance (NICOM).

Results: Circulating pro/anti-inflammatory cell subsets differed significantly in RTRs compared with whites. Closer alignment of frailty status with support for KT access may only be a marker for LGF, but also an interesting target for intervention to prevent decline with increased risk for LGF after kidney transplantation. Increased IDO activity may not only be a marker for LGF, but also an interesting target for intervention to prevent decline of renal transplant function leading to LGF.

Conclusions: ID is highly prevalent among RTR and is associated with an increased risk of mortality, independent of anemia. Since iron deficiency is a modifiable factor, correction of iron deficiency could be a target to improve survival.

Funding: NIDDK Support

Indoleamine 2,3-Dioxygenase Activity and Late Graft Failure After Kidney Transplantation

Lauren V. del Vries, 1 Claude P. Van der Ley, 2 Casper F.M. Franssen, 1 Gerjan Navis, 1 Stefan J.L. Bakker, 1 Ido Peter Kema, 1 Dept of Nephrology, UMCG, Netherlands; 1 Dept of Laboratory Medicine, UMCG, Netherlands.

Background: Long-term graft survival after kidney transplantation remains a major clinical problem. Therefore, markers that allow for early identification of patients at risk for late graft failure (LGF) are urgently needed. Indoleamine 2,3-dioxygenase (IDO) catalyzes tryptophan along the kynurenine pathway. Recent studies found IDO activity associated with occurrence of acute rejection and renal function decline shortly post-transplant. We hypothesized that IDO activity could also be a marker for LGF after kidney transplantation.

Methods: We prospectively included outpatient renal transplant recipients (RTR) with a functioning graft >1 yr, between 2001-2003. Follow-up was recorded until May 2009. Death-censored GF was defined as return to dialysis or re-transplantation. Serum kynurenine (KYN) and tryptophan (TRP) were measured with LC-MS/MS; KYN/TRP is a widely accepted measure of IDO activity.

Results: We studied 562 RTR (age 51±12 yrs, 56% men, 6.0 [2.6-11.6] yrs post-transplant). Baseline concentration of serum KYN was 1.8 [1.4-2.2] µmol/l, that of TRP was 40.0 [34.5-46.0] µmol/l, and KYN/TRP was 44.3 [35.0-57.9] µmol/mmol. In multivariable linear regression analyses, KYN/TRP was positively associated with proteinuria (β=0.17, P<0.001) and waist circumference (β=0.12, P<0.001), and inversely with eGFR (β=-0.54, P<0.001) and HDL-c (β=-0.14, P<0.001). During follow-up for 6.9 [6.1-7.4] years, 51 (9.2%) RTR developed GF. In multivariate Cox-regression analyses, KYN/TRP was positively associated with GF (age, sex, eGFR, and proteinuria adjusted HR 3.6 [95% CI 1.3-9.9], P<0.01). Further adjustment for waist circumference and HDL-c did not materially change this association (HR 3.1 [95% CI 1.3-8.9], P=0.02).

Conclusions: IDO activity, as measured by KYN/TRP, is cross-sectionally associated with eGFR, proteinuria, waist circumference, and HDL-c. Prospectively, it is associated with increased risk for LGF after kidney transplantation. Increased IDO activity may not only be a marker for LGF, but also an interesting target for intervention to prevent decline of renal transplant function leading to LGF.
Methods: A total of 2,779 adult recipients who underwent pretransplant echocardiography from 1997 to 2012 were evaluated. We divided the patients into two groups by two different categories: LVDD grade 0-1 vs. 2-3, and LA size<38 mm vs. >38 mm. Post-KT fatal/non-fatal acute coronary syndrome (ACS), graft failure (GF), and all-cause mortality was evaluated.

Results: During a mean follow-up of 4.5 years, fatal/non-fatal ACS was occurred in 49 (1.8%) patients. A total of 231 (12.4%) patients experienced GF and 116 (6.2%) died. The recipients with LVDD grade 2-3 (P=0.005) and LAE (P=0.001) showed higher occurrence of fatal/non-fatal ACS after KT. Graft failure and all-cause mortality was not different between the groups depending on both the LVVD grades and LAE. In a multivariate analysis, increased age (P<0.001), previous history of CV event (P=0.001) and LVDD of grade 2-3 (hazard ratio[HR]:2.98, 95% confidence interval[Ci]:1.535-5.787;P=0.001), and LAE (HR:1.052, 95% CI:1.006-1.101;P=0.025) were associated with ACS. However, none of LVVD grade and LAE was significantly associated with mortality and GF in a multivariate analysis.

Conclusions: In patients of KT candidate, pretransplant LVDD and LAE were independently associated with high occurrence of ACS after KT.

FR-PO1030
day-onset Risk Blood Pressure and Urinary Protein Excretion on Renal Transplant Recipients on RAAS-Blockade Laura V. de Vries,1 Linn Charlotte Dobrowolski,2 C.T.P. (Paul) Krediet,2 Frederik J. Beemelman,3 Stephan J.L. Bakker,1 Gerjan Navis,1 1Dept of Nephrology, UMCU, Netherlands; 2Renal Transplant Unit, AMC, Netherlands.

Background: In CKD patients on RAAS-blockade, it is well established that dietary sodium restriction exerts renoprotection by reduction of blood pressure (BP) and by reduction of urinary protein excretion (UPE), which is partly independent of BP. In renal transplant recipients (RTR), the effect of sodium restriction is not well-documented. We therefore studied the dietary effects of sodium restriction on BP and UPE in RTR.

Methods: We performed a randomized, cross-over trial in stable outpatient RTR with a median age of 60±9 yrs (range 41-80 yrs) and a median of 12±0.8 months post-transplantation (time from dialysis start to KTx evaluation). 30 RTR were randomized to a low-sodium diet (LS) with a sodium intake of 156±130 mmol/24h or to a regular-sodium diet (RS) (68±55 mmol/24h). We measured BP and UPE at the end of each diet period. Dietary sodium restriction was assessed by 24h urine sodium excretion.

Results: We randomized 23 RTR, of which 22 RTR (age 58±1 yrs, 50% men, eGFR 51±21 ml/min) completed the study. One patient dropped out, due to orthostatic complaints on the LS diet. Sodium intake was 156 [130-193] vs. 68 [55-86] mmol/24h on RS vs. LS diet resp. (P<0.0001). Sodium restriction significantly reduced systolic and diastolic BP. There was, however, no material change in UPE, UAE and eGFR.

Conclusions: Dietary sodium restriction effectively reduces BP in stable RTR on RAAS-blockade, but, at variance with findings in CKD, has no material effect on UPE or GF in a multivariate analysis.

FR-PO1031

Individual Blood Calcification Propensity in a Cohort of Renal Transplanted Patients Carlo M. Alfieri,1 Andreas Pasch,1 Anna Regalia,1 Maria Meneghini,1 Maria Teresa Gandolfo,1 Valentina Binda,1 Deborah Mattinzi,1 Masami Ikeda,1 Piergiorgio Messa,1 Nephrology, Dialysis and Renal Transplantation, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy; 1Nephrology, Hypertension and Clinical Pharmacology, Uni Hospital and Uni of Bern, Switzerland.

Background: Vascular calcifications and related cardiovascular disease have a strong impact in kidney transplanted patients (KTx). Calcification propensity (T50) is a new measure of individual blood calcification propensity. Our aim is to explore in a cohort of KTx patients1) the levels of T50 and their modifications during the 1st year of KTx and 2) the relationship between T50 and routine clinical and biochemical parameters;2) the relationship between T50 and home mineral density(BMD)and aortic calcification(ACI).

Methods: 70 KTx pts(M=38, Age:48±12 yrs).transplanted between 2005 and 2009 were recruited. Along with T50 evaluation, routine clinical and biochemical parameters and FGF-23,OPG, fetuin A and 25-(OH)-Vitamin D were tested at 1,6 and 12mth after KTx. At 1st mth, femoral Dual X-ray absorptionmetry and vertebral column X-ray for BMD(cm^2) and ACI(Kauppi) evalation were performed. T50(min.) was determined using a Nephelostar nephelometer(BMG Lacthe, Offenburg, Germany) in the laboratory of one of the authors.

Conclusions: Dietary sodium restriction effectively reduces BP in stable RTR on RAAS-blockade, but, at variance with findings in CKD, has no material effect on UPE or GF in a multivariate analysis.

FR-PO1032

Prediction of Acute Rejection in Kidney Transplant Recipients Using a Multicenter Cohort Kyoung Don Yoo,1 Junhyung Noh,2 Hajong Lee,1 Dong Ki Kim,1 Chun Soo Lim,1 Young hoon Kim,1 Yon Su Kim,1 Gunhee Kim,2 Jung Pyo Lee.1 Seoul National Univ College of Medicine; 2Seoul National Univ College of Engineering; 1Eulsan Univ College of Medicine.

Background: More than 20% of kidney transplant recipients (KTR) are likely to have rejection episode, which is associated with graft loss. However, the impact of risk factors on acute rejection had not been well clarified. Here, we aimed to build new prediction models through considering variables related to immunologic and non-immunologic factors using machine learning methods.

Methods: This multicenter cohort study included adult KTR admitted to 2 major experienced tertiary hospitals in Korea between 1997 and 2014. A total of 3,117 KTRs were enrolled. Biopsy-proven acute rejection (BARP) of these recipients was investigated by the individual learners such as decision tree, logistic regression, and ensemble learners such as random forest.

Results: We analyzed 2,045 recipients' records, with more than 50 attributes. Among them, we found that age, HLA-mismatch, CNI, and BARP incidence for building our models. In the decision tree model for the prediction of BPAR after three years of KTx, HLA DR mismatch was found to be the most important predictor. In the case of HLA DR mismatch, donor specific antibody (+) predicted in 66.6% of BPAR incidence at three year after transplantation, and also posttransplant infection episode showed significant association with BPAR. In the case of HLA full matched, old age with heavy weight recipient showed high probability of BPAR (71.4%). The final modeling represent AUC performance 0.670 (logistic regression) and 0.665 (random forest) in the BPAR prediction.

Conclusions: In this study, machine learning modeling could present an accurate and versatile tool for forecasting probability of having BPAR episode during the early years following the transplant.

FR-PO1033

Prediction of Long-Term Prognosis of the Kidney Transplantation Using Comorbidity Score Jae Yoon Park,1 Eunjin Bae,1 Sejoong Kim,1 Dong Ki Kim,1 Chun Soo Lim,1 Kwon Wook Joo,1 Yon Su Kim,1 Jung Pyo Lee.1 Seoul National Univ College of Medicine, Seoul, Korea.

Background: Comorbidity assessment is important to the informed interpretation of kidney allograft outcomes. Weights assigned to comorbidities to predict survival may vary based on the type of index disease and advances in the management of the comorbidities. We developed a modified Charlson comorbidity index (CCI) in renal allograft recipients (mCCI-KT), thereby improving risk stratification for mortality.

Methods: A total of 3,765 recipients in multicenter cohort were included to develop comorbidity score. The weights of comorbidities per the CCI were recalibrated using Cox proportional hazards model. The modified score was validated in an independent nationwide cohort (n=1,538).

Results: The Cox proportional hazards model revealed that peripheral vascular disease, mild liver disease, and diabetes with end-organ damage in the CCI significantly predicted mortality. Thus, the mCCI-KT included 3 comorbidities with recalibrated severity weights. In the validation cohort, both the CCI and the mCCI-KT were correlated with mortality. Thus, the mCCI-KT included 3 comorbidities with recalibrated severity weights. In the validation cohort, both the CCI and the mCCI-KT were correlated with mortality. The mCCI-KT stratified the risk better for mortality in renal allograft recipients compared with the CCI, suggesting that it could be a preferred index for use in clinical practice.

FR-PO1034

Patient Uncertainty Regarding Kidney Transplantation Associated with Length of Dialysis prior to Transplant Evaluation Laura J. McPherson,1 Mohua Basu,1 Stephen O. Pastan,1 Sumit Mohan,2 Rachel E. Patzer.1 Emory Univ, Atlanta, GA; 2Columbia Univ, New York, NY.

Background: End stage renal disease (ESRD) patients’ uncertainty about undergoing kidney transplantation (KTx) — i.e., decisional conflict — may be affected by cumulative time spent on dialysis prior to KTx evaluations. We aimed to investigate the association between time from dialysis start to KTx evaluations and decisional conflict.

Methods: In an ongoing clinical trial of study patients measuring the effectiveness of a shared decision tool at a single KTx center, ESRD patients were asked 10 questions assessing decisional conflict related to KTx, with possible scores ranging from 0 (none)

to 100 (high). Patients were dichotomized as having (score > 0) or not having (score of 0) decisional conflict. Time from dialysis start to KTx evaluation was abstracted from electronic medical records, and time on dialysis prior to evaluation was categorized as: <1 year, 1-5 year, >1 year. Logistic regression was used to assess odds ratios (ORs) for decisional conflict by time on dialysis prior to KTx evaluation.

**Results:** Of 70 surveyed patients, 64% were male, 62% were African American, and 66% had hypertension; the average age was 51 years. Patients with any decisional conflict (65%) were more likely to be male and African American in addition to having lower literacy and numeracy scores. Crude logistic regression showed that, compared to patients who had never been on dialysis prior to KTx evaluation, patients on dialysis for <1 year and >1 year evaluation were 1.4 (95% CI: 0.4, 4.9) and 2.5 (95% CI: 0.7, 9.2) times more likely to have decisional conflict, respectively.

**Conclusions:** Results suggest that longer time on dialysis prior to KTx evaluation may be associated with decisional conflict regarding KTxs. Identifying characteristics of patients with longer time on dialysis prior to KTx evaluation could help inform intervention efforts to improve patients' abilities to make decisions about treatment of their kidney disease.

Haptoglobin and Long-Term Outcomes in Renal Transplant Recipients

Isidor Minovic, Ineke J. Riphagen, Else van den Berg, Jenny E. Kootstra.

**Ido Peter Kema,** Haptoglobin and Long-Term Outcomes in Renal Transplant Recipients

Background: Haptoglobin (Hp) is a hepatocyte-derived protein that protects against oxidative damage by binding free hemoglobin (Hb). Being an acute-phase protein, Hp is upregulated by inflammation. We hypothesized that both low and high Hp are risk factors for all-cause mortality and graft failure in renal transplant recipients (RTR).

**Methods:** Hp was measured using a turbidimetric immunoassay in a well-characterized prospective RTR cohort. Cox regression analysis was used to assess the association of Hp with endpoints.

**Results:** We included 707 RTR (57% male, age 53±13 y, eGFR 49±18 ml/min/1.73m² and 58% used a calcineurin inhibitor). Median Hp was 4.1 (IQR 1.0-8.1) g/L. Hp phenotype 1-1, 1-2, and 2-2 distribution was 18%, 50%, and 33%, resp., with Hp levels of 1.7 [1.3-2.1], 1.4 [1.1-1.8] and 1.1 [0.9-1.7] g/L resp. (P<0.001). Median 38 [32-46] minths follow-up, 81 (12%) RTR died and 45 (6%) developed graft failure. Hp showed a U-shaped association with mortality (P=0.01, fig. 1), but not with graft failure (P=0.7). Accordingly, the lowest (<0.9 g/L) and highest (>1.6 g/L) quintiles of Hp levels were associated with mortality (HR 2.65 [95% CI 1.11-6.35] and 3.10 [3.0-1.7] resp., P=0.001). Adjustment for sex, age, hsCRP, serum albumin, eGFR, BMI, Hba1c, LDH and Hp polymorphism did not materially influence the association of low Hp with mortality (HR 3.55 [1.42-8.84]). However, adjustment for hsCRP and serum albumin markedly weakened the association of high Hp with mortality (HR 2.06 [0.84-5.08]).

**Conclusions:** Low Hp is independently associated with mortality, but not graft failure, in RTR. High Hp was also associated with mortality, but this association largely depended on hsCRP and serum albumin.

**FR-PO1036**

Pre-Transplantation Flow-Citometry Crossmatch Can Be a Predictor of Outcome when Donor-Specific Antibodies Are Present

Anna Rita Aguire, Patrícia Soares Souza, Gislene Oliveira Bezerra, Flavio Jota Paula, Elias David-Neto, Maria cristina R. Castro. Renal Transplant Service, Hospital das Clínicas - Univ of Sao Paulo School of Medicine, Sao Paulo, Brazil.

**Background:** Clinical relevance of pre-transplant (Tx) donor-specific-antibodies (DSA) detected by single antigen beads (SAB) when pre-Tx CDC-AHGG crossmatch (XM) is negative is still unclear. The aim of this study was to evaluate the importance of a positive flow-citometry-XM (FCXM) in patients with DSA over patient and graft survival.

**Methods:** Retrospective study, performed between Jan09 and Dec13 evaluating FCXM influence on antibody-mediated rejection (AMBR) incidence, and over graft and patient survival. Biopsies were classified according to Banfi’s09 criteria and DSA by Luminex SAB.

**Results:** From 2009-2013, 1002 kidney transplants (Tx) were performed in our center. 26125(%) were sensitized (PRA>0%) and 87.8% presented pre-Tx DSA. 60 (69%) of them had FCXM performed with serum collected before transplantation: 22 (33%) positive and 38 (64%) negative. There was no difference between the highest DSA-MFI between Tx with positive or negative FCXM [FCXM+ : 5080 (1046-15360) vs FCXM- : 3120 (397-14600)], or between the sums of all DSA-MFI of each patient between these groups [FCXM+ (247:97): (597-14600) vs FCXM- (957-15730)]. However, among patients with ABMR, FCXM+ had a significantly higher incidence of ABMR than DSA+FCXM- Tx [FCXM+ 25% vs FCXM- 90%] (p = 0.011). Patient survival did not differ between FCXM+ (82%) and FCXM- (95%) neither was affected by ABMR.

**Conclusions:** A positive pre-Tx FCXM is related to a higher incidence of ABMR in the first year after Tx and to worse graft survival, and did not influence patient survival.

**FR-PO1037**

Pre-Transplant Mental Health Disorders and Non-Adherence and Post-Transplant Outcomes in Kidney Transplant Recipients

Jeytn Mucia, Franz-Marie Gurnab, Marta Novak, Joseph Kim, Olusegun Famure. Multi-Organ Transplant Program, Univ Health Network and Univ of Toronto, Toronto, ON, Canada.

**Background:** Mental health disorders (MH) and non-adherence (NA) have been associated with lower access to kidney transplantation (KT) and poorer clinical outcomes. We examined the relationship between history of MH problems, NA, and post-transplant outcomes (i.e., biopsy proven acute rejection; BPAR, death censored graft failure; DCGF; or total graft failure; TGF).

**Methods:** This was a single-centre retrospective cohort study of adult patients transplanted at our KT program from July 1, 2004 and Dec 31, 2012, and followed up until June 30, 2014. Patients with complete information about pre-transplant MH problems or NA or post-transplant history of NA in their medical record (n=9555) were included and multivariable associations between MH, NA and time to event (for BPAR, TGF and DCGF) were explored using log rank analysis and Cox proportional hazards models.

**Results:** The mean (±SD) age was 50.5 (±13.4) years, 61% of patients were male and 27% had a history of diabetes. Twenty-two percent had a positive history of MH problems and 11% had a history of NA. Fifteen percent of the patients had BPAR, 5,6% had DCGF and 13% had TGF (death or DCGF). Participants with a history of pre-transplant NA but not with history of MH had higher risk for BPAR (log rank test p = 0.049 and p=0.46 for NA and MH, respectively). This difference, however, was not significant after adjusting for socio-demographic characteristics, donor type and HLA mismatch: adjusted HR (95% CI) 1.36 (0.84-2.23) and 1.16 (0.77-1.75) for Na and MH, respectively. Neither the history of pre-transplant MH nor pre-transplant NA was associated with DCGF or TGF. These results remained qualitatively unchanged after multivariable adjustment: adjusted HR (95% CI) 1.81(0.96-3.42) and 0.99 (0.58-1.70) for Na and MH, respectively.

**Conclusions:** A history of pre-transplant mental health disorders or non-adherence are not associated with poor post-transplant outcome in a select group of patients who are cleared for transplantation. Post-transplant patients with such problems should have equal access to kidney transplantation compared to patients with no MH problems.

**Funding:** Government Support - Non-U.S.

HLA Profile and Short and Long Term Outcomes in African American Donors and Recipients

Rabi Yacoub, Girish N. Nadkarni, John C. He, Paolo Cravedi, Rebecca L. Kent, Ioannis Konstantinidis, Karen Lok yee Keung, Sander Florman, Peter S. Heeger, Barbara T. Murphy, Madhav C. Menon. Mount Sinai, NY.

**Background:** We have previously reported the apparent greater impact of HLA-matching over both allograft and recipient ABO status, in African American (AA) recipients and AA-donor organs in deceased donor kidney transplantation (DDKT).

**Methods:** We utilized data from the UNOS database (1995 – 2012), and analyzed 10 year death censored graft survival (DCGS), 1 year clinical acute rejection (1y-AR), and delayed graft function (DGF) using Cox-regression and logistic regression in a combined multivariable model including HLA-matching and mismatching adjusted for key covariates. We performed sensitivity analysis using a subgroup of DDKT patients after 2003 with less betweentool HLA nomenclature and implementing bootstrap sampling.

**Results:** We had complete data (outcomes and predictors) for 96236 recipients (Age 49.23±15.13, 60.4% male). AA-recipients constituted 30.2% while AA-donor organs were utilized 13.1% of DDKT (n=29071&12575, respectively). Similar to the whole UNOS cohort, among AA-recipients both HLA-matching and mismatching individually had significant stepwise association with all outcomes (10-yr DCGS, 1y-AR & DGF). However, distinct from the whole cohort, we identified that when added in a combined model along with other covariates and adjusted for each other, HLA-matching and mismatching had equal effects on each of the three examined outcomes. Among AA-donors, neither HLA-A
Below-average physical QOL at 12-months was observed in 23% of patients and was associated with pre-transplant BMI (OR 1.12 per 1 kg/m² increase, CI 1.02-1.23, p<0.02) and a pre-transplant SPBB score < 12 (OR 3.05, CI 1.17-7.97, p=0.02). In contrast, pre-transplant diabetes, dialysis, maintenance steroids and 12-month eGFR were not associated with physical QOL.

Conclusions: Decreased pre-transplant physical function predicts impaired physical QOL one year after kidney transplant. Further studies are needed to determine whether physical rehabilitation interventions can improve post-transplant QOL.

FR-PO1041

Ist Report of Korean Organ Transplantation Registry (KOTRY) Tai Yeon Koo,1 Hye Jin Lim1, Kyungok Min,2 Hyunjin Ryu,2 Jong Cheol Jeong,3 Jae Seok Yang,2 Myoung Soo Kim,2 Jae-Joong Kim,2 Curie Ahn,1 Kotry Study Group.1 Transplantation Center, Seoul National Univ Hospital; 2Dept of Nephrology, Ajou Univ School of Medicine; 3Dept of Surgery, Yonsei Univ College of Medicine; 4Devision of Cardiology, Asan Medical Center; 5Korean Organ Transplantation Registry, Republic of Korea.

Background: The Korean Organ Transplantation Registry (KOTRY) were launched in 2014 to construct the nationwide transplant database system which encompasses outcomes of various transplanted organs by support of the Korea Centers for Disease Control and Prevention.

Methods: In 2014, kidney, liver and heart transplant cohorts were established with participation of 29/58 centers for kidney, 13/35 centers for liver, and 4/8 centers for heart, covering more than 80% of total cases. Lung and pancreas transplant cohorts are also in progress since 2015. A web-based database system and attached biobank system have been developed. Annual data report and related information of database development process are available at http://www.kotry.org. From July 2014 to December 2014, 419 transplants in kidney transplantation (KT), 430 in liver transplantation, and 77 in heart transplantation were registered.

Results: Among 419 KT, deceased donor (DD) was performed in 156 patients (37.2%). Mean age was 47.7±11.2 and 56.8% of transplants were males. Diabetic recipients were 23.2%, and 5.8% of transplants were older than 65 years. Their original kidney disease was most often chronic glomerulonephritis (39.6%), followed by diabetic nephropathy (18.6%). Among DD, deceased donor transplantation was performed in 21.7% of living donor KT. Mean age of donors was 45.3±13.2 and 59.9% were males. Among DD, expanded-criteria donor was 23.7%. Mean serum creatinine of living donor before and after KT were 0.81±0.18mg/dl and 1.16±0.27mg/dl, respectively.

Conclusions: The KOTRY is expected to provide infrastructures for research in the field of KT and invaluable data for the Asian organ transplantation field.

FR-PO1044

Comorbidity Burden of Kidney Transplant Recipients Predicts Emergency Usage Despite increased Family Physician Visits

Hatem A. Alnasser, Sita Gourishankar, Kevin C. Wen. ¹Univ of Alberta, Canada; ²King Fahad Specialist Hospital, Saudi Arabia.

Results: Of 354 maintenance RTRs (mean age: 54.3 ± 11 years), 60.5% were male and 39.5% were female. The mean number of comorbidities (mean ± SD: 3.4 ± 1.9) was significantly higher in female recipients (4.0 ± 2.0) compared to male recipients (3.0 ± 1.6). The most common comorbidities were hypertension (47%), diabetes mellitus (35%), and coronary artery disease (20%).

Methods: We performed a retrospective study of 354 maintenance RTRs attending a single center renal transplant clinic between 1 Jan 2007 and 31 Dec 2012. Comorbidities were defined using a modified Charlson Comorbidity Index and the number of medications prescribed to treat these conditions was recorded. The primary outcome was the number of emergency department visits (EDVs) per year, defined as an in-person encounter within 72 hours of a patient’s kidney transplant. The secondary outcomes were the number of inpatient hospitalizations and the number of emergency admissions per year.

Results: The mean number of EDVs per patient was 1.4 ± 1.5, 1.2 ± 1.3, and 1.0 ± 1.3 for patients with 0–2, 3–4, and 5 or more comorbidities, respectively. In multivariate analysis, a greater number of comorbidities was associated with a higher number of EDVs (OR = 1.35, p=0.001). Similarly, a greater number of medications was associated with a higher number of EDVs (OR = 1.001, p<0.001). The number of inpatient hospitalizations and emergency admissions per year also increased with an increasing number of comorbidities.

Conclusions: Comorbidity burden of kidney transplant recipients is a significant predictor of emergency usage. This study highlights the importance of comprehensive management of comorbidities in order to reduce emergency visits and improve health outcomes in kidney transplant recipients.

Stroke Predictors and Outcome in Renal Transplant Recipients

Mark Duncan Findlay. ¹,² Peter C. Thomson, ²Patrick B. Mark. ¹Glasgow Renal and Transplant Unit, Glasgow, United Kingdom; ²Glasgow Renal and Transplant Unit, Glasgow, United Kingdom.

Background: End-stage renal disease is associated with a high incidence of cerebrovascular disease. Conventional risk factors do not always apply and established preventative strategies may be ineffective. The incidence, predictors & outcomes following stroke in those with a functioning renal transplant is not well described.

Methods: All adult patients with a renal transplant attending Glasgow Renal and Transplant Unit between 1st Jan 2007 and 31st Dec 2012 were identified using the electronic patient record. Clinical, demographic & laboratory data were collected including presence of diabetes, cardio- or cerebrovascular disease (CeVD), atrial fibrillation, deprivation, serum renal and bone chemistry and use of immunosuppressants. Stroke was identified via discharge codes, cerebral imaging or death certification. Independent predictors of stroke were identified via multivariable regression analysis. Fatality & causes of death are presented.

Results: 636 patients were identified, mean age 58 years (SD 12.9). 60.5% were male and 9.1% had AF. During follow-up 7.1% received a transplant as first RRT modality. 23 patients experienced a stroke during 3455 patient years of follow-up. 83.3% were ischemic. Stroke incidence was 6.9/1000 patient years for all stroke and 3.76/1000 patient years for first stroke. A stepwise backward regression revealed predictors of stroke as older age (HR 1.05, p=0.025) and previous CeVD (HR 18.16, p=0.001). Significant independent predictors for first stroke were age, diabetes and AF (p=0.005). There were no cases of SAH in PCKD. AF associated with time to stroke (p=0.003), but there was no detectable benefit from use of warfarin. 134 died during follow-up. 62.5% deaths followed stroke with 7, 28 and 365 day fatality of 20.8, 25 and 45.8%. Cardiovascular (75%) or malignancy (13%) were the cause of death in most cases.

Conclusions: Renal transplant recipients have a high incidence of stroke and poor outcome following stroke. Risk factors include prior CeVD, age, diabetes and AF. Although AF associated with time to stroke, the role of warfarin in prevention is poorly defined, requiring further study.

Factors Influencing Racial Disparities in Renal Transplantation Outcomes
Sumit Mohan, Barry I. Freedman, William Mark Brown, Stephen O. Pastan, Ajay K. Israni, David P. Schlaff, Robert S. Gaston, R. Bray, Amber M. Reeves-Daniel, Bruce A. Julian, Jasmin Divers, Coffee Hill, Wake Forest School of Medicine, Emory Univ, Univ of Minnesota, Minneapolis Medical Research Foundation, Univ of Alabama at Birmingham.

**Background:** Kidney transplants from African American (AA) deceased donors have worse outcomes than kidneys procured from donors of other ethnic groups; deceased donor kidney transplants (DDKTs) engrafted into AAs fare worse than kidneys placed into recipients of other ethnic groups. The role of biological and environmental factors in these disparities remains unclear. We sought to identify factors contributing to these ethnic differences in AA and European American (EA) recipients of kidneys from AA and EA donors, in a study using donor-matched design to eliminate donor-specific confounding effects.

**Methods:** We compared allograft survival of DDKTs in 4 types of donorrecipient pairs (TDRP) (AA-AA, EA-AA, EA-AA, and EA-EA). Models were fitted using a mixed effect Cox model with particular focus on effect modifiers of the TDRP association with allograft survival.

**Results:** We identified 669 AA and 3,383 EA donors resulting in 669 AA-AA, 669 AA/EA, 3,383 EA-AA and 3,383 EA/EA DDKTs. In agreement with previously reported trends, AA donors were more likely to be younger, male, hypertensive, and with higher serum creatinine, while EA recipients were more likely to be employed (46% vs. 37% and 33%) and less likely to experience delayed allograft function (DGF) (19% vs. 28% and 23%). Adjusted analyses controlling for donor and recipient characteristics identified strong interaction effects between the TDRP and incidence of DGF (P<0.009) and between the TDRP and employment status (P=0.04). Observed hazard ratios varied from 0.9 for an employed (EA/EA) pair without DGF to 4.3 for an unemployed (AA/AA) pair with DGF.

**Conclusions:** Ethnic differences in employment status and incidence of DGF were the strongest effect modifiers of the association between the TDRP and allograft survival for DDKTs. These differences partially explained the observed racial disparity in outcomes for DDKTs.

**Funding:** Other NIH Support - NIH RO1 DK070941 (BF), NIH RO1 DK084149 (BF), NIH RO1 MD090655 (JD, BIF), NIH/NIAD Genomics of Transplantation S1U1-AI070119 (AKI)

FR-PO1047
Renal Transplantation in Bardet-Biedl Syndrome
Robert M. Haws, Aditya Joshi, Siddharth A. Shah, Omar M.A.A. Alkandari, Martin A. Turman.

1Dept of Pediatrics, Marshfield Clinic, Marshfield, WI; 2Dept of Pediatrics, Univ of Oklahoma Health Science Center, Oklahoma City, OK; 3Dept of Pediatric Nephrology, Univ of Louisville, Louisville, KY; 4Dept of Pediatrics, Mubarak Al-Kabir Hospital & Hamid Al-Essa Transplant Center, Safat, Kuwait.

**Background:** Bardet-Biedl syndrome (BBS) is a rare, multisystemic genetic disorder frequently associated with chronic kidney disease (CKD). Data regarding renal transplantation (RT) in BBS is lacking and reports tend to highlight complications. We report RT outcomes in the largest BBS cohort examined to date.

**Methods:** An international BBS registry was interrogated to identify individuals that had undergone RT and capture age, gender, body mass index (BMI), transplant and patient survival, donor source, and comorbidities.

**Results:** RT was performed in 19/171 (11%) registry subjects (mean age 9 y; range 2-25 y). RT patients were younger (9 vs. 17.9 y, p<0.05) and more likely to be female (82% vs. 50%). Deceased donors provided 12/21 kidneys; one patient received a combined liver/renal transplant. Two patients that underwent RT in the 1980s and died at <10 y of age were excluded from further analysis. Patient and kidney survival is shown.

**Conclusions:** Outcomes following RT in patients with BBS is favorable. Female predominance raises questions regarding gender as a potential modifying factor impacting CKD prevalence.

**Funding:** Private Foundation Support

FR-PO1048
Kidney Transplant Recipient Hospital Readmission: Examination of Discharge-Level Factors
Michelle L. Lubetzky, Maria Ajaimy, Layla Kamal, Graciela De Boccardo, Enver Akalin.

1Department of Medicine, Transplantation, Montefiore, Bronx, NY.

**Background:** Early rehospitalization after kidney transplantation (KTxs) is common and is considered a quality metric. Few studies have examined preventability or discharge factors associated with early rehospitalization.

**Methods:** We performed a single-center, retrospective cohort study between 2011-2015 of adult KTx recipients. The primary outcome was at least one readmission within 30 days after discharge. Secondary outcomes were reason for readmission, potential for process improvement to reduce readmission, and all-cause graft failure.

**Results:** Of 462 KTx, 31.4% were readmitted within 30 days of discharge. The reason for discharge was surgical in 20.1%. Of those with non-surgical reasons, 21.7% were from infection, 20.9% graft dysfunction, 21.7% gastrointestinal, 21.7% metabolic, and 13.9% other. Readmission was significantly associated with all-cause graft failure (p=0.006). The assessment of preventability showed that the reason for readmission was present at the time of discharge in 17.7%, additional hospital resources may have abrogated the readmission in 15.8%, and 12.4% could have been managed as outpatient. On univariate analysis, risk factors for rehospitalization were: presence of comorbidities (p=0.03), complication during hospitalization (p<0.001), discharge electrolyte abnormalities (p=0.001) and kidney function at discharge (p=0.003). Table 1. On multivariate analysis, the presence of 3 comorbidities pre-KTx (OR 2.01 95% CI 1.84-3.86), electrolyte abnormalities at discharge (OR 1.77 CI 1.17-2.69), delayed graft function (OR 1.65 95% CI 1.27-2.17), and post KTx complications (OR 1.79 CI 1.11-2.71) were associated with increased risk of readmission.

**Table 1:** Comparisons of Patients Requiring Rehospitalization versus No Readmission

**Conclusions:** Early readmission is associated with worse graft survival. Many readmissions may be preventable and review of process improvement may reduce early readmission after KTx.

Thrombosis and infection resulted in graft loss in the first year in 1 patient with 2 kidneys. One patient died awaiting a second RT. Acute reversible rejection in the first year was seen in 1/17 kidneys. Diabetes, hypertension, and obesity were present in 18%, 71%, and 88% of subjects, respectively. Malignancy was not observed (mean follow-up 9.8 y; range 1-21 y). BMI was increased compared to age-matched BBS patients without RT (42.2 v. 35.2, p<0.05).

Kidney Transplant Outcomes for Patients with Amyloidosis – A United Network for Organ Sharing Database Analysis

Ali Khalil, Tim E. Taber, Muhammad Ahmad Mujtaba, Muhammad S. Yaqub, Asif A. Sharfuddin. Medicine/Neph, Indiana Univ, Indianapolis, IN.

Background: Outcomes of patients with Amyloidosis who receive a kidney transplant have not been extensively studied. We examined UNOS database for outcomes of such recipients.

Methods: UNOS database was queried for recipients with code “3016” which corresponds to “Amyloidosis”. Duration of study period was Nov 1987 to Dec 2014.

Results: A total of 625 recipients were identified as in the table.

After excluding multi-organ transplants, the 1 year unadjusted graft survival was 88.6% and the 1 year patient survival was 92.1%. Kaplan Meier Survival Curves are in the Figure.

FR-PO1050

Early Experience with the New Kidney Allocation System

Background: On December 3, 2014, major changes to deceased donor kidney allocation were implemented under the new Kidney Allocation System (KAS).

Methods: Using national registry data, we compared changes in rate of DDKT among adult kidney-only waitlist registrants 1/2011-3/2015 pre vs post-KAS via Poisson regression, adjusting for age, sex, race, ABO blood type, calendar year, calculated panel reactive antibody (CPRA), and wait time. We compared donor service area-level geographic disparity pre vs post-KAS using multilevel Poisson regression and median incidence ratio (MIRR). We also compared CPRA of DDKT recipients pre vs post-KAS, and incidence of delayed graft function (DGf).

Results: Pre-KAS, access to DDKT was poorer for women (IRR=0.92, African-Americans (AAs) (IRR=0.88, Hispanics (IRR=0.79), all p<0.01). Access was best for patients of ABO type AB (IRR vs O=2.29, p=0.01) and worst for ABO type B (IRR vs O=2.29, p=0.01). KAS was associated with no change in overall DDKT access (p=0.7), but with improved access for AAs (IRR=1.16, interaction p<0.001) and patients of ABO type AB (IRR=1.29, interaction p<0.001). Geographic disparity declined post-KAS (MIRR=1.76 pre-KAS, 1.64 post-KAS). Median CPRA at transplant was 0 both pre and post-KAS; the proportion of recipients with CPRA 80-99 decreased from 13.6% to 10.1% (p<0.001), but the proportion with CPRA=99 rose from 1.6% to 14.0% (p<0.001, Figure 1).

Conclusions: After recent changes to kidney allocation, DDKT access improved for AA patients and geographic disparity declined. Women and Hispanic patients are still disadvantaged, and disparity by ABO type worsened. The proportion of recipients with CPRA=99 rose dramatically. Increase in DGF may suggest risk of poorer long-term outcomes.

Kidney Transplantation Tourism: High Risk and Bad Outcome for the Recipients

Amjad E. Elagroudy. Internal Medicine Dept, College of Medicine and Medical Sciences, Arabian Gulf Univ, Manama, Bahrain.

Background: While the ethical aspects of transplant tourism have received much attention recently, less has been written about the medical safety of this practice. We retrospectively evaluated the outcomes of patients who purchased organs internationally and presented to our center for follow-up care.

Methods: We report the outcome parameters of 270 local recipients of unrelated kidney (URT) vendor transplants presenting to our institute between 1986 and 2014. Their outcome was compared with 123 recipients of living-related donor transplants matched for age, gender and transplant duration done in our center as controls (RT).

Results: Age of unrelated recipients was 42.6±13.4 years with Male % of 68. The country of transplant was mainly in Philippines (n=35), Pakistan (n=36), India (n=57), Iran (n=40) and Egypt (n=25). Comparison of commercial recipients with controls showed high co morbidities (P=0.01) with hepatitis-C (n=2 vs. 0) and hepatitis-B (n=2 vs. 0) and cytomegalovirus (n=4 vs. 1). Donor age was 25.9±3.8 vs. 34.6±8.6 years (P=0.0001) and 90.4% were male. Biologic agents induction in 74 (27.4%) vs. 123 (100%) (P=0.0001), acute rejections in 65 (24.1%) vs. 26 (21.1%) (P=0.7), while recurrent rejection in 13 (4.8%) vs.1 (0.8%) (P=0.04), surgical complications including lymphocele 16 (5.9%) vs. 0 (0%) (P=0.0001), ureretal obstruction 7 (2.6%) vs. 0 (0%) (P=0.007), hematoma 4 (1.5%) vs.1 (1.1%) (P=0.06) and recurrent urinary tract infection 18 (9.9%) vs.6 (6.8%) (P=0.3). Overall 1- and 10-year for graft survival was 91% and 22% vs. 98% and 44% and for patient survival 96% vs. 70% vs. 98% and 78% in URT and RT, respectively (P=0.001).

Conclusions: Although 1 year graft and patient survival of kidney transplants in recipients with Amyloidosis is inferior to standard outcomes, long-term outcomes are not remarkably different. Careful selection of this population can lead to satisfactory outcomes. To our knowledge this is the first and largest report on the outcomes of these patients from the US national database.
Conclusions: Although recent developments increased success in renal transplantation, receiving a kidney from a paid living donor at a commercial transplant center still carries greater risks for the recipient.

Methods: We analyzed 93 patients who received a 2nd transplant at The Royal London Hospital between November 1994 and January 2015. 59 patients did not receive primary transplant nephrectomy (TNx) and had failed allograft in situ at the time of second graft (group A) whilst 34 patients underwent TNx prior to second graft (group B). 2nd transplant survival was the primary end point. Sensitization, waiting time for 2nd graft, graft function and rejections were second end points.

Results: Group A patients had significant longer graft survival than group B (100.6 months vs 40.2 months, p<0.001). Waiting time from primary graft loss to second graft in group A was shorter than group B (36.7 months vs 59.1 months, p=0.013). In total, 33 patients had pre-formed anti-HLA antibodies (low titre). Group B had significantly higher rate of pre-formed anti-HLA antibodies than group A (50.0% vs 29.3%, p=0.047). The rate of HLA class I in group B was also significantly higher than that in group A (47.1% vs 25.7%, p=0.038). Group B had numerically higher rate of acute rejection than group A (32.4% vs 15.3%, p=0.033). GFR between both groups did not differ until 3 years post-transplant. In group A, 2nd graft survival rates at 6month, 1.3 and 5 years were 94.9%, 93.0%, 87.0% and 82.3%, and were significantly better group B (73.3%, 70.0%, 60.6% and 46.8%, p<0.001). On multivariate analysis, waiting time for second transplant, TNx, second transplant donor age and delayed graft function were independently associated with second graft survival. TNxs had highest hazard ratio (2.83, 95% CI 1.22-6.67, p=0.015).

Conclusions: Prior TNx is associated with inferior 2nd renal graft survival in this observational study and calls for an urgent randomized control trial.

FR-PO1053

Induction Agent Use, Mortality and Acute Rejection in Older KT Recipients

Background: Induction agents are commonly used as an initial intensive immunosuppression after kidney transplantation (KT) to prevent acute organ rejection; this presentation is the first to label. Little is known about induction agent use in older KT recipients.

Methods: Data on 19,546 older KT recipients (2005-2013) was ascertained from the Scientific Registry of Transplant Recipients. Induction agents were classified as thymoglobulin/ATG, IL-2, or other induction agents. The risk of mortality was estimated using a proportional hazards Cox regression model (hazard ratio (HR)) adjusting for all confounding KT factors (age, sex, race, BMI, peak PRA, history of diabetes, years on dialysis) and KT factors (HCV, HLA mismatches, cold ischemia time, donor type, donor age, and donor sex). The relative risk (RR) of 1 year acute rejection was estimated using modified Poisson regression adjusting for all recipient and KT factors.

Results: The mean age was 69 (SD-3.8 years), 36% female, 19% black and 27% live donor recipients. There is an increasing utilization by year of induction agents, with 84% use in older recipients. Compared to those who did not receive induction, the risk of mortality for older recipients was decreased for those who received thymoglobulin/ATG (HR=0.86, 95%CI:0.79-0.94), IL-2 induction agents (HR=0.89, 95%CI:0.81-0.97), and other induction agents (HR=0.85, 95%CI:0.75-0.97). Additionally, compared to those who did not receive induction, the risk of 1 year rejection for older recipients was increased for those who received IL-2 induction agents (HR=1.36, 95%CI:1.15-1.61), as well as other induction agents (HR=1.27, 95%CI:1.03-1.57) but not thymoglobulin/ATG (HR=1.06, 95%CI:0.90-1.25).

Conclusions: For older KT recipients, there is an increasing trend in the use of induction agents and a decreased risk of mortality regardless of the type of induction agent used. However, there is little evidence for a protective effect of induction agent use for 1 year acute rejection.

Funding: Other NIH Support - NIA, Private Foundation Support

FR-PO1054

Background: The aging immune system has fewer naïve T cells, more memory T cells, and less T cell receptor variability. Older transplant patients tend to have more comorbidities and less functional reserve. This combination makes them more difficult to immunosuppress with higher risk of infection, and potentially increased mortality from rejection treatment.

Methods: In order to determine the impact of rejection treatment on outcomes in our transplant recipients >70 years of age, we reviewed the outcomes of recipients transplanted at our center from 1/2009-12/2013. Induction regimens varied; maintenance immunosuppression consisted of tacrolimus, mycophenolate, and rapid steroid withdrawal.

Results: During this time period, we transplanted 110 over 70 years of age. Of these, 27 patients had rejection – 24 ACR, 1 combined AMR/ACR, 1 AMR. Followed by ACR (see table). 11 of these patients received Tcell depleting agents, the rest received IV steroids +/- IVIg. There was no difference in age, race, donor type, prior transplant, or induction therapy between the two groups. Mean creatinine was higher in the rejection group. Treatment aimed to stabilize functions - the rate of decline in estimated GFR after rejection treatment was no different between groups. Within 6 months of rejection treatment, there were 12 infectious complications, only 3 of which required hospitalization (urosepsis-2, CMV-1). There were no differences in rates of BK viiremia, CMV viiremia, graft survival, or mortality. 7 of the 27 patients died at some point after rejection, only one was related to infection >1 year later and not related to treatment.

Conclusions: Among our >70 patients, rejection treatment appeared well tolerated with few complications requiring hospitalizations and no treatment related mortalities. In addition, it appeared that treatment stabilized function in the majority of patients.

FR-PO1055

Mortality After Kidney Allograft Failure and Return to Dialysis

Anupriya Brar, Edem Nguannon Timpo, Rahul M. Jindal, Nabil Sunrami, Faridah Moos, Ambera C. Hargraves, Andrew DeMarco, Edem Nguannon Timpo, Rahul M. Jindal, Nabil Sunrami, Faridah Moos, Ambera C. Hargraves, Andrew DeMarco.

Background: Our hypothesis was that kidney allograft failure (KAF) and return to dialysis (RTD) results in greater mortality versus patients with end-stage renal disease (ESRD). We also sought to identify variables associated with mortality after KAF.

Methods: We used an incident cohort of patients from the United States Renal Data System who initiated any form of dialysis between Jan 2003 and Dec 2008 after KAF. We followed patients until retransplantation, death or Sept 2009. Multivariable Cox analysis was used for statistical associations.

Results: 7,156 patients were followed for a mean of 30.8±22.6 months. 3,622 (50.6%) patients were lost to follow up. Main causes of death were cardiovascular (37.0%), infection, 1.54%, other 16.4% and metabolic/endocrine (7.9%) causes. Predictors of all-cause mortality included age at KAF (hazard ratio (HR)= 1.03, 95% confidence interval (CI) 1.03-1.04), diabetes (DM) as cause of kidney failure (HR=1.52, CI 1.36-1.68), congestive heart failure (CHF) (HR= 1.19, CI 1.04-1.36), peripheral arterial disease [PAD] (HR= 1.23, CI 1.04-1.55), stroke (HR= 1.27, CI 1.12-1.43), and female sex (HR=1.17, CI 1.09-1.25).

61A
The ideal intravenous (IV) fluid for kidney transplantation (KTx) has not been defined, despite the common use of normal saline (NS) in the perioperative period. The high chloride content of NS is associated with an increased risk of hyperchloraeic metabolic acidosis, which may increase the risk of hyperkalemia and delayed graft function (DGF). Balanced electrolyte solutions (BESS) have a lower chloride content, which may decrease this risk and avoid the need for dialysis due to hyperkalemia. Randomised controlled trials (RCTs) have used biochemical outcomes to compare fluids and have been underpowered to address patient-centred outcomes such as DGF. We systematically reviewed the effect of BES versus NS on DGF, hyperkalemia and acid-base status in KTx recipients.

Methods: We searched the Cochrane Renal Group’s Specialised Register to 24th March 2015. We included RCTs of KTx recipients that compared perioperative IV lower-chloride solutions to NS. Two independent investigators assessed studies for eligibility and risk of bias. Data were extracted using standardised forms and pooled according to a published protocol.

Results: Six studies (477 participants) were included in the review. All participants were adult KTx recipients and 70% received live-donor KTx. The overall risk of bias was low for selection bias and unclear for remaining domains. There was no difference in the risk of DGF (RR 1.03, 95%CI 0.62–1.70, P=0.91) or hyperkalemia (RR 0.48, 95%CI 0.04–6.10, P=0.57) for participants who received BES compared to NS. Compared to NS, BES were associated with a higher blood pH (mean difference pH 0.07, 95%CI 0.05–0.09, P<0.00001), higher serum bicarbonate (mean difference HCO₃⁻ 3.04mmEq/L, 95%CI 2.13–3.94mmEq/L, P<0.00001) and lower serum chloride (mean difference chloride -9.93mmol/L, 95%CI -19.96–0.11mmol/L, P<0.05).

Conclusions: Intraoperative balanced electrolyte solutions are associated with less hyperchloraeic metabolic acidosis compared to normal saline. However, these data do not support their use to reduce clinical events.
FR-PO1060

Outcomes of Kidney Transplant Recipients from Donation After Circulatory Death Donors without Pre-Agonal Heparin Administration

Layla Kamal, Joel Lindower, Maria Ajaimy, Michelle L. Lubetzky, Graciela De Boccardo, Enver Akalin, Liis K. Kayler.
Montefiore-Einstein Center for Transplantation.

Background: Protocols of organ donation after circulatory death (DCD) are considerably varied. Heparin administration during the pre-agonal phase has been recommended to improve organ perfusion and prevent blood clots; however some protocols avoid heparin before verification of death based on legal or professional concerns. We assessed outcomes of kidney transplant recipients who received DCD kidneys recovered with and without heparin.

Methods: We retrospectively evaluated recipients of kidney transplants between 2013 and 2014 from controlled DCD donors who received (n=23) or did not receive (n=29) pre-agonal heparin.

Results: All kidneys underwent machine perfusion. No DCD donors had a similar kidney donor profile index but were more likely to have mild histologic changes, elevated terminal creatinine perfusion resistant index, and to be imported from non-local donor service areas compared to the Heparin donors. Recipients of No Heparin kidneys were more likely to be female, sensitized, prior solid organ recipients, and to receive thymoglobulin induction but were less likely to have diabetes. None of these differences reached statistical significance. Post-transplantation, 1 patient died early due to a cardiac event (no Heparin group). Graft failure occurred in 2 patients in the no Heparin group (one each of sepsis/ intraparenchymal venous thrombosis and chronic histologic changes suggestive of donor disease) and 1 patient in the Heparin group (renal artery thrombosis). Between group differences were small in terms of delayed graft function, 6-month acute rejection, and estimated GFR at 3, 6, and 12 months.

Conclusions: Our findings suggest that DCD kidneys recovered without pre-agonal heparin are not at increased risk for primary non-function or thrombosis.

FR-PO1061

Effects of Dopamine Donor Pretreatment on Graft Function After Kidney Transplantation: Five-Year Follow-Up of a Randomized Controlled Trial

Urs Brech, Bernhard K. Krämer, Peter Schneulle. V. Medical Clinic, Univ Medical Center Mannheim, Mannheim, Germany; Nephrology, Center for Renal Diseases, Weinheim, Germany.

Background: For the study group: A previous multicenter randomized controlled trial reported reduced dialysis requirements after kidney transplant with dopamine donor pretreatment. Data on long-term outcomes are needed.

Methods: We calculated five-year graft survival from follow-ups at 60 European centers. We analyzed intention-to-treat and on-study medication and proteinuria prevalence estimates as tertiles of dopamine exposure because infusion times varied by treatment arm (range 0-1,929 min). Recipients with functioning grafts at three months were analyzed separately to differentiate early events from long-term consequences of the trial intervention. Statistical analyses were performed by multiple logistic regression and Cox regression using SAS. Results were considered significant if p < 0.05.

Results: 234 children (61% male) with an age of 2.5 ± 2.4 years (range 0.02-21.2 years) were included in the study, 128 (55%) from the dopamine and 106 (45%) from the saline group. At the end of the five-year follow-up, 223 recipients (95%) were alive. Graft survival rates at five years were 98.4% and no allograft was lost due to thrombotic complications. The causes of death were acute respiratory distress syndrome (1), cancer (1), and trauma (1). The overall death censored graft survival was 83.3 ± 8.0% (HR 0.84, 95%CI 0.54-1.29; p = 0.42) in the dopamine group compared to 92.7 ± 5.0% (HR 0.25, 95%CI 0.03-0.23; p < 0.001) in the saline group. The incidence of eGFR at 3, 6, and 12 months.

Conclusions: Dopamine administered for >270 min provided a long-term graft survival advantage independent of early events after Transplantation.

FR-PO1062

Does Calcineurin Inhibitor Timing Matter? Single Center Experience with En-Bloc Kidney Transplantation

Maya Campana, Oksana A. Kucher, Sanjeev Akkina, Ignatius Yun-Sang Tang. Pharmacy Practice, Univ of Illinois at Chicago; Medicine, Nephrology, Univ of Illinois at Chicago.

Background: En-bloc kidney transplantation (KTx) has excellent outcomes. To minimize vascular complications and nephrotoxicity, calcineurin inhibitor (CNI) therapy is often delayed. The purpose of our study is to investigate the impact of CNI initiation timing on 1-year graft outcomes.

Methods: This is a single-center, retrospective review of adult en-bloc KTx between 2001 and 2013. Timing of CNI initiation was decided by the operating surgeon. Patients were divided into two groups, those that received CNI therapy early (<48 hours) or delayed (>48 hours) posttransplant. The primary objective was to compare one year estimated glomerular filtration rate (eGFR) between the groups. Secondary outcomes included graft and patient survival, CNI levels, incidence of delayed graft function (DGF), rejection and graft failure rates.

Results: Twenty-one en-bloc KTx recipients were included in the analysis. Ten patients received CNI therapy within 48 postoperative hours (Early CNI Group). There was no difference in age, race, gender, PRA, cause of ESRD or BMI between the groups. Only 50% of Early CNI patients received lymphocyte depleting therapy vs. 100% in the Delayed CNI group (p = ns). In the Early CNI Group, 3 patients were on anticoagulants; all other patients received tacrolimus and mycophenolate maintenance. There was no difference in eGFR between groups at one year or at any other time points. Comparable therapeutic tacrolimus trough was observed at 5, 10 and 30 days posttransplant. There was no difference in DGF or graft failure incidence. In the delayed CNI group, one patient died of sepsis at 6 months.

Conclusions: Timing of CNI initiation had no impact on one year graft function and patient survival.

FR-PO1063

Reduction of Pediatric Renal Transplantation Vascular Thrombosis Rates Utilizing Low Dose Heparin Infusion

Background: Pediatric renal allograft thrombosis rates are 4-10% and often result in allograft loss. Thrombotic risk factors are smaller native vessel size, deceased donor source, and time between donor and recipient death. In our pediatric program from 1971 – 1992, 5 of 69 consecutive renal transplants (7.2%) were lost to vascular thrombosis. This study assesses if low dose continuous heparin infusion reduces the risk and outcome of thrombosis in pediatric renal transplants.

Methods: Over 22 years (1993-2015), 44 of 100 consecutive children post renal transplant received low dose continuous heparin (10 units/kg/hour) for 1 week for thrombotic risk: 1) age < 6yr (n=24); 2) laboratory profile of hypercoagulability (n=10); 3) oliguric/nadir creatinine (n=2); 4) high risk: 5) patient history of access thrombosis or vasculitis (n=1). Renal scans were obtained on days 1, 3, 5 and when clinical deterioration occurred.

Results: Only 2 thrombotic events were noted which did not cause graft loss: 1) 24RD transplant- venous thrombosis immediately post-op with successful thrombectomy at 2hr and allograft recovery; 2) 17yr DD double renal artery allograft arterial thrombosis of smaller inferior renal artery on day 10 (heparin stopped day 7). One patient on heparin infusion required laparotomy 3hrs after surgery for thrombosis external to the anastomosis. One patient not on heparin also required laparotomy in the first 24hrs post-op for hemoptysis evacuation. One patient in each group had primary non-function/surgical loss with removal of the kidney within the first 3 days post transplant. Graft survival at 1yr was 96% and no allograft was lost due to thrombotic complications.

The Influence of Induction Immunosuppressive Therapies and Diabetes on Graft Loss After Kidney Transplant

Hosam A. Faraj, 1 Nasrollah Ghahramani, 1 Tarek Alhamad. 1

1 Public Health Dept, Penn State College of Medicine, Hershey, PA; 2 Nephrology Dept, Penn State College of Medicine, Hershey, PA; 3 Public Health Dept, Penn State College of Medicine, Hershey, PA; 4 Nephrology Dept, Washington Univ, St. Louis, MO.

Background: Induction therapy plays a significant role to reduce the rate of acute rejection in kidney transplant (KT). Understanding differences in outcomes associated with various induction agents may lead to improvements in KT care. Our objectives were to examine the influence of various induction therapies and diabetes on graft and patient survival after KT.

Methods: We used the 2000-2013 United Network for Organ Sharing (UNOS) data to evaluate the effectiveness of induction therapies and diabetes on graft and patient survival after KT. The patients were divided into four groups based on induction therapy: Basiliximab (n=24,484), alemtuzumab (n=3,321), rabbit anti-thymocyte globulin (n=ATG) (n=54,974) and daclizumab (n=13,358). Also the patients were divided into four groups based on diabetic status: non-diabetic (n=192,333), type1 diabetes (n=11,863), type 2 diabetes (n=45,543) and new onset of diabetes (n=10,509). The main outcome were the risk of graft loss and death at 1.3, 5.10 years. Cox proportional hazards model was used to estimate the hazard ratios.

Results: Graft loss was significantly higher in alemtuzumab group (HR=1.171; P<0.002) and rabbit anti-thymocyte globulin group (HR=1.109; P<0.0001) versus basiliximab group. Daclizumab group showed significantly lower risk for graft loss (HR=0.902; P<0.001) than basiliximab group. Death was significantly higher in rabbit anti-thymocyte globulin group (HR=1.075; P<0.0001) versus basiliximab group. Daclizumab group showed significantly lower risk for death (HR=0.850; P<0.0001) than basiliximab group. Graft loss was significantly higher in type 2 diabetes (HR=1.451; P<0.0001).

Conclusions: Induction immunosuppressive therapies and diabetic status play significant role in long-term graft and patient survival. Basiliximab and daclizumab as IL-2 RA receptor antagonists have better long-term graft and patient survival outcomes.

FR-PO1065

Doc-Induction Type Influence Outcomes in Kidney Transplant Recipients at Different Phases of Hepatitis B Infection

Khalil K. Sureshkar, Richard I. Marcus, Bhuyna Chopra. Nephrology and Hypertension, Allegheny General Hospital, Pittsburgh, PA.

Background: Host response to hepatitis B virus (HBV) infection is variable with some patients progressing to chronic liver disease. Immunosuppression associated with kidney transplantation in such patients may increase the risk of disease progression. We aimed to analyze the impact of potent depleting vs. non-depleting antibody induction on the outcomes in kidney transplant recipients (KTRs) at different serological stages of HBV infection.

Methods: Using UNOS database, we identified adult KTRs from 2001 to 2011 who at the time of transplantation were in one of the 3 serological stages of HBV infection: HBsAg+/HBcAb- (early infection), HBsAg+/HBcAb+ (inactive carrier or immune tolerant), or HBsAg+/HBcAb+ (clearing infection) sero-status. These findings support a practice of choosing induction type based on the immunological risk in such recipients rather than the serological status following HBV infection.

Health Economic Analysis of Rabbit Antithymocyte Globulin (Thymoglobulin) versus Basiliximab (Simulect) in Renal Transplantation – A German perspective

Friedrich Thaiss, 1 Thomas Benzing, 2 John Reitan, 3 Thomas Paivanas, 4 Meghan E. Gallagher, 5 Michael Sean Wiesener, 6 Nikolai Zink, 6

1 Univ. Hospital, Nephrology, Hamburg, Germany; 2 Univ. Hospital, Nephrology, Cologne, Germany; 3 RfM Group, Crown Point; 4 TAP & A, Annandale; 5 Sanofi, Cambridge; 6 Univ. Hospital, Nephrology, Erlangen-Nuernberg, Germany.

Background: Kidney transplantation is now accepted as a proven therapeutic modality prompting a greater need to understand the cost-effectiveness of different treatment approaches.

Methods: The primary objective of this study was to quantify the economic consequences of acute rejection and adverse events in patients undergoing cadaveric kidney transplantation and receiving ATG (Thymoglobulin - Thymo) compared with those receiving basiliximab (Simulet - Sim). Health economic data were collected according to reimbursement calculations from 3 German sites in an existing database (Brennan et al NEJM, 2006).

Results: Based on the clinical data from the Brennai trial, the study quantified current cost and changes in treatment patterns. Results demonstrate that at 12 months the cost of the Thymo-regimen is €5,753 more than that of the Sim-regimen. However, costs of delayed graft function, nonfatal graft failure events and post-graft failure dialysis are lower among Thymo treated patients. Thymo treated patients incurred higher graft maintenance costs, consistent with their longer graft survival. In total the associated cost-offset from less rejection events with Thymo offset the added cost from drug treatment and therefore Thymo is a more cost-efficient resource vs Sim due to cost avoidance. To further evaluate differences between the two groups we considered quality-adjusted life year differences. The Thymo cohort is projected to enjoy 405,714 QALY after 1 year. After a decade, the Thymo cohort is projected to cost 332,232 Euros less than the Simulet cohort while enjoying 10.8 more QALYs.

Conclusions: This analysis was intended to provide information that should be considered when weighing the costs and benefits of two immunosuppressive regimens and to investigate if treatment changes might result in more cost-effective care.

Thymoglobulin Induction Therapy; Results for 5 Years – Improving the Survival of Renal Allograft and Patient
Virginia Barra Pedroza, Benjamin Gómez-Navarro. Nephrology and Transplantation, Centro Medico Nacional de Occidente, Guadalajara, Jalisco, Mexico.

Background: The factor that impacts the survival of renal allograft is the presence of acute rejection. In our city, using Thymoglobulin has offered to patients at high immunological risk, and through the years has sought to reduce adverse events use. The objective is to evaluate the frequency of acute rejection during the last 5 years in patients receiving Thymoglobulin induction.

Methods: An ambispective cohort, patients transplanted in UMAE HE-CMNO, Jalisco, Mexico is included in the period June 2010 to June 2014 who received induction therapy with Thymoglobulin. Was recorded the frequency of acute rejection, the frequency of infections, use of Filgrastim(G-CSF), graft loss and death at 12 months of transplantation.

Results: A 370 patients were included, which received initial doses of Thymoglobulin 0.6mg/kg-1.5mg/kg. In 2013, by multivariable analysis Thymoglobulin dose was that associated with a lower incidence of acute rejection was analyzed and found that 1mg/kg for 4 days (cumulative dose 4mg/kg) is a protective factor for the occurrence of acute rejection (IC 95‰ 0.11-0.60, OR 3,7, p<0.001), for this reason almost patients received this dose. In 2010, the rate of rejection was 10‰ and actually is 7.8‰ (p=0.05;).

Infections disease was reduced about 30‰. Currently few patients use of r-g-CSF because leukopenia-neutropenia, lost the renal graft or die during the first year.

Conclusions: Interestingly, in our hospital, we observed a lower rate of acute rejection and improved patient survival and allograft. Apparently finding the right dose in our patients has allowed thymoglobulin induction is safe and minor complications.

FR-PO1069
Randomized Trial of Tacrolimus/Everolimus versus Tacrolimus/Enteric-Coated Mycophenolate Sodium to Prevent Biopsy-Proven Acute Rejection and Chronic Allograft Injury in Adult, Primary Kidney Transplantation
Giselle Coated Mycophenolate Sodium to Prevent Biopsy-Proven Acute Rejection
Randomized Trial of Tacrolimus/Everolimus versus Tacrolimus/Enteric-Coated Mycophenolate Sodium and steroids. Primary endpoint was change in eGFR (MDM4) from RND to M12. Main secondary endpoint a composite efficacy of treated biopsy-proven acute rejection (IBPR, Banff ≥II), graft loss, or death and safety.

Results: At M12, the clinical benefit observed in eGFR did not achieve statistical significance (1.70, 95% CI -0.53, 3.95; p=0.134) whilst eGFR at M24 for EVR was significantly better (p<0.006). The composite efficacy endpoint was comparable at M12 & M24. Overall acute rejection rates were very low with more iBPVR in EVR, but mild in severity (Banff IIA & IB). In both the groups, number of patients with de novo DSA at M12 or M24 was low and unrelated to outcomes. At M24, rate of CAN (IF/TA) was significantly higher in the CNI versus EVR (35.1 vs 26.7%, p=0.029).

Conclusions: Early conversion to EVR at 3 months vs continued CNIs better preserved renal function with comparable overall efficacy and safety up to 2-years.

Early Conversion to Everolimus in De Novo Renal Transplant Recipients: 24-Month Results from the ELEVATE Study
Johan W. De Fijter, Hallvard Holdaas, Patricia M. Lopez, Cesar Escrig, Zailong Wang, Josep M. Cruzado, Markus van der Giet. For the ELEVATE Study.

Background: Long-term therapy with calcineurin inhibitors (CNIs) is associated with nephrotoxicity i.e., glomerulosclerosis and interstitial fibrosis (IF). We present the 24 month results from the ELEVATE study (NCT01114529), which compared an early conversion to everolimus (EVR) vs standard CNI in renal transplant recipients (RTxR).

Methods: ELEVATE, a 24M, multicenter, open-label, randomized, de novo RTxRs 10–14 weeks post-Tx to convert from CNI to EVR (n=360; C, 6–10 ng/mL) or standard CNI (n=357; C, TAC 5–10 ng/mL, CSA 100–250 ng/mL); all received enteric-coated mycophenolate sodium and steroids. Primary endpoint was change in eGFR (MDM4) from RND to M12. Main secondary endpoint a composite efficacy of treated biopsy-proven acute rejection (IBPR, Banff ≥II), graft loss, or death and safety.

Results: At M12, the clinical benefit observed in eGFR did not achieve statistical significance (1.70, 95% CI -0.53, 3.95; p=0.134) whilst eGFR at M24 for EVR was significantly better (p<0.006). The composite efficacy endpoint was comparable at M12 & M24. Overall acute rejection rates were very low with more iBPVR in EVR, but mild in severity (Banff IIA & IB). In both the groups, number of patients with de novo DSA at M12 or M24 was low and unrelated to outcomes. At M24, rate of CAN (IF/TA) was significantly higher in the CNI versus EVR (35.1 vs 26.7%, p=0.029).

Conclusions: Early conversion to EVR at 3 months vs continued CNIs better preserved renal function with comparable overall efficacy and safety up to 2-years.

FR-PO1071
Early Conversion from Cyclosporine to Everolimus Following Living-Donor Kidney Transplantation: Outcomes at Five Years Post-Transplant in the Randomized ZEUS Trial: A Post-Hoc Analysis
Ingeborg A. Hauser,1 Frank Lehner,1 Wolfgang Arns,1 Clemens Butke,1 Ute Eisenberger,2 Rudolf P. Wuthrich,2 Petra Reineck,1 Rolf A. Stahl,1 Anja Susanne Mühlfeld,1 Heiner H. Wolters,1 Barbara M. Suwelack,1 Katharina M. Heller,1 Martina Porstner,1 Oliver Witzke,1 Claudia Sommerer,1 2ZEUS Study Group, Germany; 2ZEUS Study Group, Switzerland; 3Novartis Pharma, Germany.

Background: To study renal function and patient outcome after 5 years in living-donation subgroup of kidney de novo transplant recipients after conversion to an everolimus (EVR) based regimen and withdrawal of calcineurin inhibitor therapy.

Methods: Post hoc subgroup analysis from the prospective, open-label, controlled, multi-center study ZEUS. 300 renal transplant (Tx) patients were randomized at month (mo) 4.5 post Tx to either receive EVR plus enteric coated-mycophenolate sodium (EC-MPS) or cyclosporine (CsA) plus EC-MPS regimen. Of these 80 living donation recipients (EVR group n=42; CsA group n=38). Patients could enter an observational follow-up (FU) period where outcome on patients’ safety and efficacy was recorded until mo 60 post Tx.

Results: Adjusted eGFR (Nankivil) in living-donation subgroup at mo 60 was 67.2 (95% CI [62.5, 71.9]) mL/min/1.73m2 in EVR vs 60.8 (95% CI [56.0, 65.6]) mL/min/1.73m2 in CsA patients, resulting in a difference of +6.4mL/min/1.73m2 in favor of EVR patients (p=0.031, ANCOVA). Unadjusted mean eGFR after 5 years was 69.5 mL/min for EVR vs 66.0 mL/min for CsA (p=0.006, Wilcoxon). BPVRs during FU since mo12 occurred in 4 patients of the EVR and 3 of the CsA group, all BANFF grade IA except one BANFF grade IIa among EVR patients. From randomization to mo 60 one death occurred in CsA living-donor recipients, two in the EVR living-donation subgroup; one graft loss occurred in the EVR, none in the CsA group. Overall safety profile was similar between both treatment groups.

Conclusions: The presented analysis shows that EVR-based regimen with early elimination of CNI therapy in living-donor kidney transplant recipients is associated with a significant benefit on renal function maintained over 5 years post Tx without compromising safety and efficacy.

FR-PO1072

Background: Tacrolimus (TAC) and Sirolimus (SRL) are commonly used immunosuppressive drugs in kidney transplantation. SRL has been shown to induce the expansion of regulatory T cells in post-transplant recipients converted from TAC to SRL.

Methods: This study included 84 renal transplant recipients from a randomized trial of SRL conversion (n=55) or TAC maintenance (n=29). The conversion started at 12 months post-transplant. PBMC were collected at 0(baseline), 6, 12, 24, 36 and 48 months post-randomization. T cell subpopulations were analyzed by flow cytometry.

Results: Absolute frequencies of CD4+Foxp3+ T cells were similar in both groups (0.63±0.06%; SRL) VS 0.66±0.12% (TAC) % of Lymphocytes, p=0.79). SRL conversion led to a significant increase in CD4+Foxp3+ T cells at 6, 12 and 24 months post conversion with highest frequencies observed at 12 months post conversion (2.23±0.23% (SRL) VS 0.08±0.12% (TAC) %, p<0.01). However, we observed a decline of CD4+Foxp3+ T cells started at 24 months and the differences were no longer significant compared to the TAC group at 36 and 48 months post-conversion (1.41±0.60% (SRL) VS 1.07±0.44% (TAC) %, p=0.23).

Conclusions:Switching from TAC to SRL results in an expansion of CD4+Foxp3+ T cells which peaked at 12 months post-conversion but no significant frequency differences were observed at 48 months follow-up and we observed more percentage of T cells that co-expressed IFN-γ and RORgt which are Th1 and Th17 markers respectively.

FR-PO1073

Pulmonary Complications in Kidney Transplant Recipients: Role of Everolimus Giannhi Cappelli, Andrea Solazzo, Fabio Nava, Decenzo M. Bonuichi. Nephrology Dialysis & Renal Transplant Unit, Univ Hospital of Modena, Modena, Italy.

Background: Kidney transplant recipients are at higher risk to develop pulmonary side-effects, which are frequently drug related and a relationship with cyclosporine (CyA). Everolimus (EVL) and Cyclosporine (CyA) are commonly used immunosuppressive agents in kidney transplantation. SRL has been shown to induce the expansion of regulatory T cells in post-transplant recipients converted from CyA to SRL.

Methods: We performed a translational study. First we analyzed the in vivo pulmonary pro-fibrotic potential of Everolimus (EVE) by computing a pulmonary fibrosis index score (PFIS), obtained by using several computerized tomography, hemogasanalysis and spirometric parameters, in 13 RT patients in EVE treatment and 13 patients treated with CyA (CyA group). Subsequently, we carried out an in vitro study in which we assessed whether EVE at low- (5, 10 nM) or high-dosage (50 nM, 500 nM e 5 μM) was able to induce EM in bronchial epithelial cells (Nuli-1) and human type II pneumocyte-derived A549 cells. Additionally, microarray analysis was performed to identify biomarkers in each cell line.

Results: In the in vivo part of the study, we found that the PFIS was higher in EVE-treated patients compared to those treated with ADV (mean±SD 2.58±1.83 versus 1.21±1.25). This effect was positively correlated to the trough levels (TL) in EVE-treated patients (R2=0.35). The higher PFIS score was measured in patient of the EVE group that reached a TL>5. Interestingly, in vitro, only very high doses of EVE were able to up-regulate alpha-SMA, Fibronectin and Vimentin in gene and protein levels and A549. No effects were seen in Nuli-1. Interestingly, microarray analysis confirmed the above-mentioned results.

Conclusions: All together, our data suggested that only very high doses of EVE may induce pulmonary fibrosis and that this effect could be mediated by EM in pneumocyte cells.

FR-PO1075

Efficacy and Safety of Three Different Treatment Regimen in De Novo Renal Transplant Patients: 48 Months Follow-Up Results of the HERAKLES Trial Wolfgang Arms, Volker Klicem, Claudia Sommerer, Johannes Jacobi, Bruno Vogt, Ingeborg A. Hauser, Petra Reinkic, RolflA. Stahl, Thomas Rath, Martina Porstner, Martin G. Zeier, Frank Lehner, Klemens Budde, Oliver Witzke. HERAKLES Study Group, Germany; HERAKLES Study Group, Switzerland; Novartis Pharma, Germany.

Background: To compare safety and efficacy of 3 different immunosuppressive regimen at month (mo) 48 after kidney transplantation (KTx).

Methods: 802 patients (pts) were included in this 1 year, prospective, open-label, randomized, controlled multi-center study with observational follow-up (FU) to mo 60 post Tx. After induction therapy all pts received cyclosporine A (CSA), enteric-coated mycophenolate sodium (EC-MPS) and steroids. 3 mo post Tx, 499 pts were randomized 1:1:1 to either a) Everolimus (EVR) 5-160mg (81pts) and CyA (100-180mg/ml) EC-MPS (n=166) (5 nM, 500 nM e 5 μM), b) to a calcineurin inhibitor (CNI)-free regimen with Everolimus (EVR) (5-10mg/ml) + EC-MPS (n=171) or c) to a CNI-reduced regimen with ERV (3-8mg/ml) + reduced CSA (50-75mg/ml; n=162). All pts continued on steroids. At time of mo 48 FU Interims-analysis of data were available from 110(73%) STD, 117(79%) CNI-free and 111(76%) CNI-low treated pts of the FU ITT population.

Results: From randomization to mo 48 BPAR was reported in 19/151(13%) STD, 24/149(16%) CNI-free and in 23/147 (16%) CNI-reduced pts (ITT; p=ns). 5 deaths (3%) occurred in STD, 3(2%) in CNI-free and 6(4%) in the CNI-reduced group. 96% graft losses were observed in the STD, 6(4%) in the CNI-free and 2(1%) in the CNI-reduced group. Composite failure (BPAR, death, graft loss, loss to FU) occurred in 32(21%) STD, 36(24%) CNI-free and in 39(27%) CNI-reduced treated pts. Premature discontinuation due to AEs was reported for 5(3%) of STD, 5(3%) of CNI-free and 11(15%) of CNI-reduced patients (safety-population) since mo 12 to 48. cGFR (Nankivell, LOCF) was significantly improved by +8.6ml/min in favor of the CNI-free regimen at mo 48 (ITT=p<0.02).

Conclusions: Mo48 results from HERAKLES show that immunosuppressive regimen using EVR with reduced-dose or without CNI-exposure reflect an efficacious and safe therapeutic approach offering the opportunity for an individualized immunosuppression to minimize CNI-exposure.

FR-PO1076

SparTacus: Multicentre, Prospective Randomised Study Comparing Tacrolimus Hexal® versus Prograf® Based Regimen in De Novo Renal Transplant Recipients Wolfgang Arms, Thomas Rath, Lars C. Rump, Klemens Budde, Daniel Baumer, Peter Schenker. 1Spartacus Study Group; 1Novartis Pharma Germany.

Background: In a transplant (Tx) setting, studies evaluating pharmacokinetic (PK) parameters and therapeutic equivalence of generic tacrolimus vs the reference drug are lacking. SparTacus (NCT01649427) study was designed to compare PK profile of tacrolimus hexal® with prograf® in renal Tx recipients (RTx).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Methods: In this prospective, two-phase open-label study, 76 de novo RTxR were randomized to receive tacrolimus hexal® (n = 35) or prograf® (n = 41), both in combination with entero-derived mycophenolate sodium + corticosteroids + basiliximab induction therapy. Starting dose of tacrolimus was 0.15 mg/kg/day, adjusted to target trough levels (C0) of 8–12 ng/ml from Tx to month (M) 1; 5–10 ng/ml up to M3; and 5–8 ng/ml up to M6. Primary objective of the study in phase 1 was to demonstrate comparability of Tacrolimus hexal® vs prograf®. Here we present the PK results of the first month.

Results: At M1, the dose-normalised tacrolimus 12-h-AUC (h/10^3XL) was comparable between tac. hexal® vs prograf® (2.02 ± 2.0 vs. 2.02 ± 2.0; difference, 0.0 ± 0.0; 90% CI: 0.0, 0.0; p = 0.998). C0 for tac. hexal® vs prograf® was 12.2 ± 1.7 vs. 12.2 ± 1.7 (90% CI: -0.134, 0.377; p = 0.581), C0 at day 11, respectively. Of 76 patients, 40 (PK-Set 40 pts.) to date completed 6-M treatment; tac. hexal®, n = 19; prograf®, n = 21. At M6, tacrolimus hexal® vs prograf® had a comparable incidence of composite events (ITT, n = 77; 5.7% vs 9.8%, p = 0.681) and its individual components (BFAR [5.7% vs 7.3%], graft loss [0.0% vs 2.4%], death [0.0% vs 2.4%]). Incidence adverse events (AES, SAE) were comparable (AES: 97.1% vs 100%; serious AES: 37.1% and 42.1%).

Conclusions: Tacrolimus hexal® has a PK profile similar to that of prograf®, with comparable efficacy and safety in de novo RTxR.

Intensified Dosing of Mycophenolate Mofetil Is Associated with Slower Progression of Chronic Renal Allograft Injury – Results from a Randomized Controlled Trial

Mladen Knotek,1 Miha Arni,2 Jadranka Buturovic,1 Danica Galesic Ljubanovic,1 Nika Jogić,2 1Dept of Medicine, Renal Div, Univ of Zagreb Medical School, Merkur Univ Hospital, Zagreb, Croatia; 2Dept of Nephrology, Univ Medical Centre Ljubljana, Ljubljana, Slovenia; 1Inst of Pathology, Univ of Ljubljana Medical Faculty, Ljubljana, Slovenia; 2Dept of Pathology, Dubrava Univ Hospital, Univ of Zagreb Medical School, Zagreb, Croatia; 3Univ of Zagreb School of Medicine, Dubrava Univ Hospital.

Background: Intestinal fibrosis (ci) is a major histological predictor of long-term graft outcome. This randomized controlled trial (NCT01860183) was designed to evaluate the effect of intensified mycophenolate mofetil (MMF) dosing on progression of ci during the first year post kidney transplantation (KT).

Methods: Immunologically low-risk KT recipients were randomized on MMF 3g/d or 2g/d during the first year post KT. Immunosuppression consisted of basiliximab induction, with tacrolimus, MMF ± steroids. Protocol biopsies were performed at implantation, and at 1 and 3 months post KT and at the 12th month post KT. Progression of ci (Di) was calculated as ci12-ci0. MMF dose was calculated as an average dose at 1, 3, 6 and 12 months. Difference in Di with respect to MMF dose was analyzed in an ITT population using one-way ANOVA.

Results: Here we report interim results from patients who completed 12 months follow-up by June 1st 2015. Patient and KT data are similar in MMF 3g and MMF 2g group, except for average MMF dose, which was higher in the 3g group (2697 ± 321.6 vs. 1745.5 ± 359.0 g, p < 0.001). In an overall study population ci progressed during first 12 months post KT from 0.45 ± 0.51 (ci0) to 1.41 ± 0.87 (ci12) (p < 0.001). Di was lower in the MMF 3 g group (0.60 ± 0.74) as compared with MMF 2g group (1.36 ± 0.93; p = 0.01). Serum creatinine at 1 year was similar in both MMF groups (116.5 ± 25.0 vs. 115.1 ± 33.7; p = 0.899). Incidence of acute rejection was similar and no significant differences were seen in common adverse events between both groups.

Conclusions: Intensified dosing of MMF (3g daily) during the first posttransplant year in a tacrolimus-based regimen may be associated with slower progression of chronic allograft injury.

FR-PO1080

Safe Conversion from Tacrolimus to Belatacept in Kidney Transplant Recipients with Allograft Dysfunction

Anil Reham, Dhiren Kumar, Hasan Fattah, Anne L. King, Pamela Kimball, Ankur Atal Gupta, Gaurav Gupta. Virginia Commonwealth Univ, Richmond, VA.

Background: Belatacept might be an alternative to Calcineurin Inhibitors (CNI) to avoid short and long-term nephrotoxicity. Prior data on low immunologic risk de-novo kidney transplant recipients (KTxP) with stable graft function switched from a CNI to belatacept demonstrated improved renal function. There is minimal data on the use of belatacept for sensitized patients and those with impaired graft function [estimated glomerular filtration rate (GFR) <50].

Methods: EBV seropositive patients were converted to belatacept from tacrolimus for biopsy proven presumed acute CNI toxicity and/or interstitial fibrosis/tubular atrophy. Belatacept was initiated based upon prior published protocol (Grinyo et al., Transpl Int. 2012 Oct). Mycophenolate dose was increased from baseline dose of 1-2g/d to a dose of 2-3g/d to minimize risk of rejection.

Results: Seventeen (mean age: 46±10 years) patients were switched from tac to belatacept at a median of 4 months post-KTxP. A majority were African-American (13/17; 76%) and received deceased donor KTxP (76%). Seven patients (41%) were sensitized (median PRA: 31%; range 5-99%). Renal function improved significantly from a peak mean GFR of 28.1±12 ml/min/1.73m^2 to an GFR of 42±11±12 ml/min/1.73m^2 (p<0.001) at a median follow-up of 15 (range-7-30) months post-conversion. Surveillance biopsies performed in 7/17 patients did not show rejection or worsening of chronicity. No evidence of delayed donor specific antibody (DSA) was noted in 1617 (94%) patients. One patient with pre-existing DSA and stable creatinine had rising DSA after a viral infection. A biopsy showed subclinical antibody-mediated rejection. There were no cases of BK viremia, CMV disease or malignancies.

Conclusions: In this study first on KTxP patients with significantly reduced GFR we report remarkable improvement in renal function in patients converted from tacrolimus to belatacept with acute CNI toxicity and chronic allograft fibrosis without a significant concurrent increase in risk of rejection, worsening chronicity and DSA. Further studies with protocol biopsies are needed to ensure safety and wider applicability of this approach.
FR-PO1081

Infusion of Belatacept in Kidney Transplant Recipients

Flavio Vincenti,1 M. Abouljoud,2 JH Helderman,2 R. Zhang,3 K. Calderon, S. Chen,4 SG Rizk,5 D. Gerber.* 1University of California, San Francisco; 2Henry Ford Hospital, Detroit; 3Vanderbilt Univ, Nashville; 4Tulane Univ Hospital and Clinic, New Orleans; 5BMS, Lawrenceville; 6Univ of North Carolina, Chapel Hill.

Background: Belatacept (bela) is an IV administered selective T-cell co-stimulation blocker approved for preventing organ rejection in EBV-positive adult kidney transplant recipients. The logistics of IV maintenance therapy are challenging for some pts/caregivers; the safety of home infusion has not been well described. Phase 2/3 study participants have received bela home infusion under certain circumstances. Here, we compare the safety of bela infused in the home vs a facility.

Methods: Pts in the 008 (BENEFIT/NCT002556570), 027 (BENEFIT-EXT/NCT00114777), 010 (NCT00402168), and 034 (NCT00455010) studies were eligible to receive bela home infusion if the site sought IRB approval and if the pt lived ≥2 hrs from the site and had been exposed to bela for ≥28 wks in 008 or 027, >16 wks in 010, or >6 wks in 034. 008 and 027 compared bela with CsA regimens with basiliximab induction. In 010, pts receiving a stable CNI regimen were switched to a bela regimen. 034 compared bela with tacrolimus steroid-sparing regimens under thymoglobulin induction. Rate and time to pre-specified peri-infusional AEs and peri-infusional serious AEs were recorded in pts who received bela in the home (N=66) or in a facility (N=672).

Results: Pts administered bela in the home received a median of 32.5 (range, 1–61) infusions. No pre-specified or serious peri-infusional AE was reported, including in the 034 study.

Conclusions: No pt (irrespective of steroid use) receiving home infusion of bela had a pre-specified or serious peri-infusional AE. These data suggest that bela was safely administered in the home.

FR-PO1082

Optimizing the Immunosuppression Regimen with Belatacept

David Wojciechowski,1 Sindhu Chandran,2 Flavio Vincenti.* 1MGH; 2UCSF.

Background: Belatacept with basiliximub induction plus maintenance MMF/corticosteroids is associated with a higher 3-year eGFR compared to cyclosporine but a higher 1-year incidence of acute rejection. In an attempt to optimize the belatacept immunosuppression regimen we investigated the safety and efficacy of a novel combination utilizing belatacept with rATG induction (3 mg/kg) and maintenance everolimus+corticosteroids.

Methods: Retrospective single center analysis of the first 33 patients to receive our belatacept regimen compared to a historical control group of 66 patients matched for donor type, KDPI, ESRD cause, CIT, and corticosteroid protocol who met our belatacept criteria (EBV seropositive and low immunologic risk [first transplant, no DSA ≥500 MFI, cPRA ≤30%]) but received basiliximub induction with maintenance tacrolimus/MMF+corticosteroids. We compared the 6-month eGFR and the rates of rejection and infection between the groups.

Results: Demographic and transplant characteristics were similar. Mean tacrolimus trough (SD) at months 3 and 6 were 8.7 (2.5) and 8.4 (2.8), respectively. Mean everolimus trough (SD) at months 3 and 6 were 5.5 (2.6) and 5.3 (2.6), respectively. Eleven patients didn’t tolerate everolimus and were placed on MME. Rejection occurred in 3 patients (1 of each: type 1a, type 1b and type 2b) and 1 belatacept patient (type 2a) (P=0.07). The belatacept rejections occurred in patients who didn’t tolerate everolimus and occurred after everolimus was discontinued. By month 6 two grafts were lost in the tacrolimus group with a 100% patient survival for both groups. eGFR at month 6 for belatacept and tacrolimus treated patients was 61.9 (15.3) and 60.1 (21.2), respectively (P=0.51). The incidence of CMV infection, BK viremia, and UTI was similar between the groups.

Conclusions: The findings suggest that a belatacept regimen with limited T cell depletion and an mTORi can maximize efficacy and maintain safety. These results of a synergistic effect of costimulation blockade and mTOR inhibition are consistent with experimental studies and phase 2 data. A larger prospective trial is warranted to fully evaluate this approach.

A Change in Insulin Sensitivity and Lipid Profile in Renal Transplant Recipients Converted from Cyclosporine or Standard Release Tacrolimus to Once-Daily Prolonged Release Tacrolimus

Soo young Kim,1 Young wook Yang,2 Hee So Shin,1 Ji Won Kim,1 Yeon soon Jung,3 Hark Rim,1 Bong geon Chun,1 Hyun yul Rhew.* 1Internal Medicine, Kosin Univ College of Medicine, Busan, Republic of Korea; 2Internal Medicine, Good GangAn Hospital, Busan, Republic of Korea; 3Pathology, Kosin Univ College of Medicine, Busan, Republic of Korea; 4Urology, Kosin Univ College of Medicine.

Background: New-onset diabetes after transplantation may be associated with the use of tacrolimus (Tac) causing impaired insulin release or reduced insulin sensitivity. And, dyslipidemia commonly occurred after transplantation. Such effects in insulin sensitivity and lipid profile have not been studied in renal transplant recipients receiving traditional twice-daily tacrolimus (TacBID) or cyclosporine and then compared to the new once-daily prolonged release formulation of tacrolimus (TacOD).

Methods: We performed an observational prospective study of 15 stable non-diabetic renal transplant recipients on change in insulin sensitivity and lipid profile in renal transplant recipients converted from cyclosporine or standard release tacrolimus to once-daily prolonged release tacrolimus. We evaluated the level of HbA1c,total cholesterol, HDL, LDL, TG, apolipoprotein A1, apolipoprotein B, serum creatinine, fasting plasma glucose, fasting insulin and HOMA-β at base line, two and four months. To analyze differences in parameter, we performed a t-test in both groups (cyclosporine to TacOD conversion group/ TacBID to TacOD conversion group), and GLM-repeated measures ANOVA. HOMA-β = (360 x Fasting insulin)/(Fasting glucose-63) HOMA-RI (insulin resistance) = (Fasting glucose x Fasting insulin)/405.

Results: At baseline, parameters were not different in both groups (cyclosporine to TacOD conversion group/TacBID to TacOD conversion group). In GLM-repeated measures ANOVA, the result did not showed and any change in insulin sensitivity and lipid profile and revision at baseline, two and four months.

Conclusions: Conversion from standard TacBID or cyclosporine to TacOD is safe. In spite of a reduced Tac exposure, there was no change in insulin sensitivity and lipid profile in renal transplant recipients.

FR-PO1084

Tacrolimus Dose Requirement Based on the CYP3A5 Genotype in Renal Transplant Patients

Zhoutao Xie, Hong Jiang, Jianghua Chen. The First Affiliated Hospital, College of Medicine, Zhejiang Univ, China.

Background: Tacrolimus and ciclosporin A (CsA)are widely used to protect graft function after renal transplantation. The aim of the present study is to determine whether CYP3A5*1 and CYP3A5*2 genotype is a predictive index of tacrolimus dose requirement, and evaluate the selection accordance of tacrolimus or CsA treatment.

Methods: We tested archival peripheral blood of 218 kidney recipients for CYP3A5 genotyping with PCR-SSP. The doses and blood concentrations of tacrolimus and CsA for recipients were measured at day7, 1st month , 3rd month,6th month and 12th month after renal transplantation, as well as hepatic and renal function. In addition, we also observed the incidence of acute rejection happening on these participants.

Results: 123 patients took tacrolimus treatment and 95 patients took CsA treatment after renal transplantation.In tacrolimus treatment group, genotype CYP3A5*5G was associated with low tacrolimus dose-adjusted concentration after transplantation, showing lower acute rejection rate compared to CYP3A5*AA/AG group but with no significant different (P=0.154).In CsA treatment group, there was no significant difference in acute rejection rates between CYP3A5*AA/AG and CYP3A5*GG(P=0.494) with no different in dose-adjusted concentration as well. For CYP3A5*GG patients, tacrolimus treatment cause lower acute rejection rate than CsA treatment (P=0.030), taking shorter time to get a stable immune situation than CsA treatment. For CYP3A5*AA/AG patients, tacrolimus treatment cause similar acute rejection rate with CsA treatment (P~0.982), but took longer time to get a stable immune situation than CsA treatment. What’s more, tacrolimus treatment costs much than CsA treatment.

Conclusions: These results indicate that CYP3A5*5A/AG carriers need higher tacrolimus dose than CYP3A5*GG homozygote to achieve the target blood concentration. And, CsA carriers preferred to tacrolimus treatment and CYP3A5*5A/AG carriers preferred to CsA treatment depended on the incomes. CYP3A5 genotyping is a new approach for detecting tacrolimus dose requirement and a predictive index for the tacrolimus or CsA treatment selection in the kidney recipients.
FR-PO1085
Intratpanel Tacrolimus Level Variability in Pediatric Kidney Recipients
Predicts Allograft Loss After Transfer to Adult Care
Hilda E. Fernandez,1 Sandra Amaral,2 Amanda A. Shaw,1 Roy D. Bloom,3 Alden Michael Doyle,1 Sumit Mohan,1 Susan L. Furth,2 Columbia Univ; CHOP; PENN; Hahnemann Univ.

Background: Allograft loss is especially common in 17-24 year olds and is associated with non-adherence around the time that transplant care is transferred from the pediatric to adult setting. We explored whether coefficient of variation of tacrolimus (CV TAC) levels post-transfer, as a marker of non-adherence, was associated with allograft loss in a cohort of pediatric kidney recipients transferring to adult transplant centers.

Methods: Retrospective cohort of transplant recipients at Children’s Hospital of Philadelphia transplanted 1999 to 2011 who transferred care to University of Pennsylvania or Hahnemann University Hospital, identified by chart review. CV TAC was calculated as SD divided by mean TAC over 12 mos. Date of transfer was defined as the last Pediatric visit. We compared pre-transfer TAC CV in those that subsequently lost their graft to those that did not.

Results: 24 of 65 subjects had sufficient data for analysis. Median age at transplant was 15.9y (8.5-18.9). The cohort was primarily male (66%), White (77%), had CUKAT (8%), and 46% had LRKT. Median age at transfer was 20y (17.4-22.1). Four patients had allograft loss within 365 days post-transfer. Pre-transfer CV TAC for subjects with allograft loss post-transfer (n=4) was significantly higher as compared to subjects without allograft loss (n=20) (49.4% vs 26.2%, p = 0.0275).

Conclusions: CV TAC may aid in identifying patients at risk for allograft loss post-transfer. Future analysis will investigate the effect of race, age at transfer, rejection, de novo DNA pre-transfer that may also help predict adolescent kidney transplant recipients at risk for allograft loss following transfer to adult transplant centers.

FR-PO1086
High Tacrolimus Level Variability in the Early Post-Transplant Period Is Associated with Reduced Patients and Graft Survival After Kidney Transplantation
Benanya Rozen-zy1, Avry Chagacna,1 Ruth Rahamimov,2 1Nephrology and Hypertension, Rabin Medical Center, Petach-Tikva, Israel; 2Organ Transplantation, Rabin Medical Center, Petach-Tikva, Israel.

Background: The effect of Tacrolimus levels variability in the early period after kidney transplantation is not properly understood. We sought to evaluate whether increased drug level variability is associated with reduced graft survival and evaluated the relative effect of exposure to high and low drug levels.

Methods: We screened the Rabin Medical Center registry database for adult patients from 2001 to 2013 that were treated with tacrolimus, mycophenolate mofetil and corticosteroids and had at least 6 values of drug level during the first six months after the transplantation. Variability was defined as the time average of the absolute value of the difference from the mean and this value was divided by the mean to get the variability index. Univariate and multivariate Cox proportional hazard model was used with the combination of death and graft failure as composite outcome.

Results: We identified 803 patients who met the inclusion criteria, ninety eight (12.2%) of them reached the end point during median follow up time of 3.7 years (range 0.5 to 12.9 years). The increased variability index was associated with increased hazard of death or graft failure by univariate (Hazard Ratio (HR) 1.029 per %, 95% Confidence Interval (CI) 1.006-1.052, p=0.013) and multivariate models (HR 1.036 per %, 95% CI 1.01-1.062, p=0.006). Variability was still significantly associated with reduced graft survival after introducing acute rejection into the model (HR 1.038 per %, 95% CI 1.008-1.056, p=0.006) by introducing exposure to levels above 15 ng/ml into the model didn’t change the association between variability index and the composite outcome while introducing exposure to levels below 5 ng/ml eliminated the association and made it non-significant (p=0.18).

Conclusions: High variability index in the first six month after kidney transplantation is associated with increased mortality and graft loss. This association is, probably, mediated by exposure to low drug levels.

FR-PO1087
Decision Tree Analysis of Renal Transplantation Recipients Outcomes: A Single Center Data Mining
Jingyi Zhou, Jianghua Chen. Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, China.

Background: Results from former literature on factors influencing renal transplant outcomes are quite confusion and few include factors influencing outcomes of rejection cases. This study was intended to get the factors in order and to provide reliable predictive models for clinical practice with decision tree analysis, and attempted to discuss about decision tree integrated with renal transplant database, predict the model development and to serve personal medical care in big data era.

Methods: Renal transplant recipients registering between May 1988 and April 2014 in Kidney Center of the First Affiliated Hospital of Zhejiang University were included. Living state, not registred by chart review. CART was evaluated by decision tree.

Results: Totally 3921 cases were included. The loss-to-follow rate is 9.7%. With survival rate as the object, we got the most important factor, steroids (P<0.01). Patients in the following factor combination showed the highest survival rate: steroids, mycophenolate mofetil (MMF), stenting, warm ischemic time (WIT) ≤6.5min, cold ischemic time (CIT) £300min, and aspartate aminotransferase (AST) 6 months post operation£34UL (survival rate 95%, no rejection cases). Patients had the lowest acute rejection rate when in the factor combination: steroids, antihuman thymocyte globulin or basiliximab induction, no blood transfusion history and female (0%, 83). Patients with acute rejection were regarded as a new database. The patients who took steroids and received stents shows similar outcomes with patients who had no rejection. Important factors that could be intervened for long-term outcomes included stenting, statins, steroids, etc.

Conclusions: Decision tree analysis is an outstanding choice for risk stratification, prognosis prediction and dynamic follow-up. Immunosuppression therapy was regarded as the most important factor for renal transplant recipients' survival, rejection and other outcomes. Factors should be considered in combination for each specific patient.

FR-PO1088
Comparison of Clinical Outcome Between ABO Incompatible and Compatible Spousal Donor Kidney Transplantations
E. Minha Lim,1 Byung ha Chung,1 Bum soon Choi,1 Curie Ahn,2 Sung-joo Kim,1 Chul Woo Yang,1 1Transplantation Research Center, Internal Medicine, Nephrology, Seoul St. Mary’s Hospital, Seoul, Republic of Korea; 2Transplantation Center, Seoul National Univ Hospital, Seoul, Republic of Korea.

Background: Spousal donor is an important source to overcome shortage of living donor in kidney transplantations (KTs). We aimed to compare the clinical outcomes in ABO incompatible KT (ABOi-KT) to those of ABO compatible KT (ABOc-KT) from spousal donors.

Methods: We analyzed 580 KT cases from spousal donors among 3043 living donors KT cases registered in the Korean Organ Transplantation Registry. Clinical outcome between ABOi-KT and ABOc-KT were compared by episodes of acute rejection (AR), graft function, grafts and patients survival rates.

Results: The proportion of spousal donors in ABOc-KT was higher than that of ABOi-KT (40.9% vs. 21.4%, P<0.001). The biopsy proven AR-free survival rate in ABOi-KT was comparable to ABOc-KT (79.7% vs. 82.3%, P=0.188). The renal allograft function showed no difference until 16 months after KT. The 3-year graft survival (92.5% vs. 95.7%), and patient survival (96.4% vs. 98.5%) were not significantly different between ABOc-KT and ABOi-KT groups (P=0.05, respectively). Multivariate analysis revealed that ABOc-KT from spousal donors did not affect the graft, patient survival and BPAR-free survival rate.

Conclusions: The results of our study show that the ABOc-KT donor is an important source of living donor, and can be a good alternative of overcoming donor organ shortage.

FR-PO1089
3-Year Outcomes After ABO Incompatible Kidney Transplantation without Steroids

Background: Early steroid withdrawal paired antibody induction therapy provides comparable outcomes to steroid maintenance patients. However, ABOc transplantation is considered higher immunologic risk, and it unclear if a steroid free regimen is appropriate for this population.

Methods: We performed 40 ABOc transplants with pre-transplant plasmapheresis (PP) with IVIG to an isohemagglutinin titer 1:16 and 2 post-tpx PP/IVIG treatments, immunosuppression with tacrolimus, mycophenolate, and intraoperative rituximab (375mg/ 125mg). Prior to 2008, patients received an IL-2 receptor blocker, and prednisone tapered to 5 mg by 6 months. After 2008, induction included Thymoglobulin® (6 mg/kg in 4 divided doses) and steroid withdrawal by postop day #3. Patients underwent protocol biopsies at predefined intervals. We compared outcomes at 3 years between those who had and had not received maintenance steroids.

Results: 24 patients received maintenance steroids and 16 underwent rapid steroid withdrawal. There were no differences in sex, starting isohemagglutinin titer, or blood group mismatch between the groups. Antibody mediated rejection was more common in the steroid maintenance group (41% vs 31%) as was cellular rejection (50% vs 47%), though not significantly different. At 3 years, renal function was similar between those with and without steroids- eGFR 46±25 cc/min vs 52±15 cc/min, respectively. Approximately 50% of patients underwent protocol biopsy at 3 years. There were no differences in the degrees of interstitial fibrosis, glomerulosclerosis, or transplant glomerulopathy between groups. Graft survival, patient survival, and infectious complications were also similar.

Conclusions: Even in higher immunologic risk ABOc transplant recipients, rapid steroid withdrawal appears to provide similar medium term results as steroid maintenance therapy without the longterm side effects.
FR-PO1090

Three Year Outcome of a Pioneer ABOi Renal Transplant Programme in Malaysia
Si-Yen Tan,1 Mohan Rao,2 Eng-Thye Koh.2 1Medicine, Prince Court Medical Centre, Kuala Lumpur, WP, Malaysia; 2Surgery, Prince Court Medical Centre, Kuala Lumpur, WP, Malaysia.

Background: ABO incompatible (ABOi) renal transplantation increases organ donor pool and is an option for patients with no blood group compatible donors. We report here results of a pioneer ABOi renal transplant programme in Malaysia which was first established in Prince Court Medical Centre in 2011.

Methods: Ten patients entered into our ABOi programme between July 2011 and December 2013. Data were analyzed to determine the number of therapeutic plasma exchange (TPE) and/or immunoadsorption (IA) with Glycosorb columns to achieve target pre transplant ABO antibody titres of < 1:16 and ABO titres post transplant. Graft function and rejection rates together with graft and patient survival at 3 years were also determined.

Results: Median baseline ABO titres was 1:128 and all patients achieved target pre transplant ABO titres of < 1:16 after a median of 4 TPE and/or IA. Median follow up was 32 months with all patients maintaining ABO titres of < 1:16 at follow up with no protocol post transplant TPE/IA. There was 1 case (10%) of acute cellular rejection at one year which was reversed with steroids but none had antibody mediated rejection. Patient and graft survival was 100% at 3 years with current median serum creatinine 108μmol/L.

Conclusions: The results of our pioneer ABOi renal transplant programme with graft and patient survival of 100% at 3 years is extremely encouraging and suggest that graft and patient outcome is similar to ABO compatible renal transplants. The use of ABO incompatible donors may effectively increase organ donor pools especially in countries where both cadaver and living related kidney transplant rates remain poor. Our results also suggest that national ABOi renal transplant programmes may be effectively introduced and led by a private medical centre to complement and support more established renal transplant programmes in government institutions which are now beginning to perform their own ABOi renal transplants in light of our success.

Improved Graft Outcome After Blood Transfusion: Still in Effect?
Gowrie Balasubramaniam,1 Arun Gupta,1 Neil Ashman,2 Raj Thuraisingham.2 1Dept of Medicine, Southend Univ Hospital, Southend, Essex, United Kingdom; 2Dept of Nephrology and Transplantation, Barts and The Royal London Hospital, London, United Kingdom.

Background: Blood transfusions can lead to sensitisation in potential transplant patients. We previously quantified the risk of sensitisation from transfusion per se by looking at a cohort of male patients on the transplant waiting list and ascertaining the transfusion history from electronic records and questionnaires. Prior to standard triple immunosuppression, transfusions were associated with overall better graft outcome possibly by a tolerogenic effect or by selecting non-sensitisers. The majority of patients who were transfused do not become sensitised, we wanted to characterise graft outcome in this group.

Methods: We obtained graft outcome information on the original cohort of patients. Data was collected prospectively as part of routine surveillance.

Results: 100 out of the initial 126 male patients were transplanted. 10 were excluded from further analysis due to death or graft loss in the immediate post-transplant period. 11 of remaining 90 patients were DSA prior to transplantation, 8 also had a history of previous blood transfusion. 4 of the 8 patients with a previous blood transfusion and DSA had a rejection episode (2 AMR and 2 ACR). Of the remaining 79 patients who were DSA negative prior to transplantation, 26 had a previous transfusion (TR+ DSA-) and 53 did not have a history of transfusion (TR- DSA-). Comparison between the two groups is shown in (table 1).

Conclusions: Lack of sensitisation with a history of leuco-depleted transfusion is associated with a lower risk of rejection post-transplantation. This suggest that previous mechanisms of transfusion tolerance or “non-sensitisers” are still relevant in the modern immunosuppression era.

FR-PO1092

Geriatric Renal Transplantation in Deceased Donor Showed Compatible Clinical Outcomes to Younger Recipients
Heungjin Cho,1 Eunhye Shin,2 Hyosang Kim, Su-Ki Park.1 1Dept of Internal Medicine, Div of Nephrology, Asan Medical Center, Seoul, Republic of Korea; 2Dept of Medicine, Southend Univ Hospital, Southend, Essex, United Kingdom.

Background: According to USRDS annual report, while 50.3% of patients who start hemodialysis were aged over 65 years, only 19.3% of patients who underwent renal transplantation was aged over 65 years. Elderly ESRD patients still are not underwent renal transplantation as much as younger recipients. There were many previous studies about geriatric renal transplantation outcome in white, however data in Asain were limited. The aim of this study is analysis of geriatric kidney transplantation outcome in Korea.

Methods: From May 1993 to December 2013, kidney transplantations performed in Asan medical center were retrospectively reviewed. Recipients younger than 20 years and who underwent other organ transplantation were excluded. Binary logistic regression was used for evaluating risk factors of graft failure before half-life. Half-life of kidney allograft was defined as 10 years according to previous study.

Results: Regardless of donor type, there is no statistically significant difference in death censored graft survival between geriatric population and younger recipients.

Conclusions: Geriatric renal transplantation can be encouraged in Asain ESRD patients.

Long-Term Survival and the Associated Risk Factors for Death in Patients (pts) with Kidney Transplantation (Tx) Tanja Abeling,1 Irina Scheffner,1 Verena Broecker,2 Michael Mengel,1 Hermann G. Hailer,3 Anke Schwarzer,2 Wilfried Gwinner,1 1Hanover Medical School, Germany; 2Cambridge Univ, United Kingdom; 3Univ of Alberta, Canada.

Background: Deaths over a period of up to 10 years (yrs) and the related risk factors were studied in Tx pts with protocol biopsies (Bx) (total observation: 4805 patient-yrs). 

Methods: 892 pts with kidney Tx in 2000-2007 were included. Protocol Bx were taken at 6 weeks, 3 and 6 months post-Tx (n=2251). 862 Bx for cause were taken in the 1st year and 262 thereafter. Lost-to-follow up was negligible (n=15). All acute rejections and clinical borderline cases in protocol Bx were treated.

Results: Patient and graft survival was 80% at 5yrs and 68% at 10yrs. Patient survival was 92% at 5 yrs and 82% at 10 yrs. 99 deaths occurred, related to infection (24%), cardiovascular disease (15%), malignancy (16%), other specified causes (8%). Deaths were less in living donor or kidney/pancreas Tx and more frequent for extended donor criteria-Tx. A three-level multivariate Cox regression model was created in a stepwise fashion, using significantly different variables from the pre-Tx, peri-operative, and long-term post-Tx period between survivors and deceased pts. Pre-Tx variables in the final model included recipient age, HLA-DR mismatches, diabetes, coronary heart disease, heart failure, and peripheral arterial disease. A significant peri-operative variable was cold ischemia time. In the long-term course, variables for death included increased loss of graft function, urinary tract infection, and higher PTH levels. Compared to the survivors, deceased pts received more therapies for rejection seen in protocol Bx (0.30 vs. 0.43 per patient) and in Bx for cause (0.29 vs. 0.34 per patient), however, this was not a significant factor in the final model. Also, the proportion of anti-rejection treatments was not higher in pts who died from infections, compared to pts dying from other causes. Concordance of the final model was 0.79; 200-fold bootstrapping confirmed its applicability.

Conclusions: Based on these results a tool is presented that readily allows risk calculation and stratification of individual pts, as a pre-requisite for individualized and optimal pre- and post-Tx care.

Causes of Death-Censored Kidney Allograft Failure: A Matched Case-Control Study of 340 Kidney Allograft Recipients Mohamad M. Alkald,1 Jim Kim,1 Choli Hartono,1 Thangamani Muthukumar,1 Meredith J. Aull.1 1Medicine, Well Cornell Medical College, New York, NY; Surgery, Well Cornell Medical College, New York, NY.

Background: Causes of kidney allograft failure in the current era of immunosuppression have not been clearly defined.

Methods: We did a matched case-control study of death-censored allograft failure among the 1672 adult kidney transplants at our center between 11/2001 and 12/2011. The cases and controls were matched 1:1 for age, donor type and year of transplant. We reviewed the charts and used the last available biopsy diagnosis for each case to determine the cause of death. Concordance of the final model was 92% at 5 yrs and 82% at 10 yrs. 99 deaths occurred, relating to infection (24%), cardiovascular disease (15%), malignancy (16%), other specified causes (8%). Deaths were less in living donor or kidney/pancreas Tx and more frequent for extended donor criteria-Tx. A three-level multivariate Cox regression model was created in a stepwise fashion, using significantly different variables from the pre-Tx, peri-operative, and long-term post-Tx period between survivors and deceased pts. Pre-Tx variables in the final model included recipient age, HLA-DR mismatches, diabetes, coronary heart disease, heart failure, and peripheral arterial disease. A significant peri-operative variable was cold ischemia time. In the long-term course, variables for death included increased loss of graft function, urinary tract infection, and higher PTH levels. Compared to the survivors, deceased pts received more therapies for rejection seen in protocol Bx (0.30 vs. 0.43 per patient) and in Bx for cause (0.29 vs. 0.34 per patient), however, this was not a significant factor in the final model. Also, the proportion of anti-rejection treatments was not higher in pts who died from infections, compared to pts dying from other causes. Concordance of the final model was 0.79; 200-fold bootstrapping confirmed its applicability.

Conclusions: Based on these results a tool is presented that readily allows risk calculation and stratification of individual pts, as a pre-requisite for individualized and optimal pre- and post-Tx care.

Effect of Simultaneous Native Nephrectomy on the Outcome of Kidney Transplant Recipients with Autosomal Dominant Polycystic Kidney Disease Jeong Ho Kim, Bum Soon Choi, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim, Byung ha Chung. Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea.

Background: End stage renal disease (ESRD) patients with autosomal dominant polycystic kidney disease (ADPKD) required native nephrectomy because of limited space for renal allograft. However, the appropriate timing for nephrectomy and also its effect on allograft patient survival has not been fully investigated.

Methods: We retrospectively analyzed 41 kidney transplant recipients with ADPKD in whom transplantation was done either simultaneously, after or without native nephrectomy at Seoul St. Mary’s hospital between January 1987 and February 2014. We divided patients into 2 groups; simultaneous nephrectomy group (group A, n=13), after or without nephrectomy group (group B, n=28) and compared the perioperative outcome, post-transplant complications, allograft survival rate.

Results: There was no significant difference in the proportion of anti-rejection treatments (0.29 vs. 0.34 per patient), however, this was not a significant factor in the final model. The mean operative time was significantly longer in group A than group B (6.48 ± 1.84 vs. 5.27±0.84 hours, P = 0.048). The mean intraoperative blood transfusions was also significantly more needed in group A than B (3.66±3.43 vs. 0.75±0.26 units; P = .018). However, there were no differences in the incidence of acute rejection and other complications such as post-operative bleeding, infectious complication between the two groups (P > .05). The graft survival rate also did not differ between the two groups (P > .05).

Conclusions: Our study suggests that the complication rates were acceptable and there was no significant impact on graft survival rate when native nephrectomy was done during kidney transplantation in ADPKD patients with ESRD. Therefore, if native nephrectomy is needed in ADPKD for kidney transplantation it can be done safely during transplantation.

FR-PO1096
Predictors of Renal Function Change After Kidney Transplantation Yoshifumi Hamasaki,1 Kent Doi,2 Akihiko Matsumoto,2 Daigoro Hirohama,1 Nobuhioko Sato,1 Daiculture Katagiri,1 Rei Ishikshi,1 Wako Kawarazaki,1 Eisei Noiri,1 Masaomi Nangaku.1 1Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; 2Emergency and Critical Care Medicine, The Univ of Tokyo, Tokyo, Japan; 3Urology, The Univ of Tokyo, Tokyo, Japan.

Background: Several perioperative factors including histological findings of allograft biopsy are known to be associated with graft function during the early post-transplantation (KT). Urinary L-type fatty acid binding protein (u-L-FABP) was reported to be correlated with serum creatinine, serum cystatin C, and estimated glomerular filtration rate (eGFR) in a cross sectional study evaluating post-KT patients. It is unclear what factors in post-KT period predict the longitudinal change of renal function.

Methods: The data from post-KT patients followed at The University of Tokyo Hospital were collected retrospectively. Patients followed-up less than 6 months after KT were excluded. To identify predictors of the longitudinal change of renal function, we analyzed data including clinical parameters measured at each outpatient visit. The primary outcome was determined as the change of eGFR during 6 months period.

Results: 32 post-KT recipients were analyzed in this study. Age and eGFR at baseline of these patients were 51.3 ± 12.7 years old and 41.2 ± 16.1 ml/min/1.73m² (mean ± SD), respectively. The duration from KT to collection of clinical parameters was 6.8 ± 7.3 years (mean ± SD). Changes of eGFR were evaluated 6 months after. When patients were divided into two groups with (N = 15) and without (N = 17) eGFR decline after 6 months, u-L-FABP and urinaly and protein were significantly higher in the eGFR decline group (u-L-FABP, 11.6 ± 5.1 vs 5.1 mg/ml, and urinary protein; 272.7 ± 97.2 vs 97.2 mg/gCr, respectively). On ROC analysis, u-L-FABP and urinary protein predicted eGFR decline after 6 months (AUC [95%CI] = 0.78 [0.60-0.96] and 0.70 [0.51-0.89], respectively). On multiple regression analysis, u-L-FABP and urinary protein were significantly correlated with the absolute and relative eGFR changes during 6 months observation period.

Conclusions: u-L-FABP and urinary protein measured at outpatient clinic can predict the change of renal function of post-KT patients.

FR-PO1097
Plasma Proenkephalin and Poor Long-Term Outcome in Renal Transplant Recipients Lyanne M. Kienek,1 Joachim Struck,1 Michel M. Joosten,1 Rudolf A. de Boer,1 Oliver Hartmann,2 Stephan J.L. Bakker,1 1Nephrology, UMC Groningen, Netherlands; 2Sphingotec GmbH, Germany; 3Cardiology, UMC Groningen, Netherlands.

Background: Enkephalins are well-known endogenous opioid peptides. Recent evidence indicates that they are not only involved in regulation of pain, but also in homeostasis of the immune system and the circulation. Proenkephalin (pro-ENK) is stable in plasma and has been established as reliable surrogate marker for unstable enkephalins. Recent studies found associations of pro-ENK with acute kidney injury and prognosis after myocardial infarction. We aimed to investigate whether pro-ENK could be linked to chronic kidney injury and poor long-term outcome in renal transplant recipients (RTR).

Methods: We included 664 RTR who were 8.1 ± 7.6 years after transplantation. Plasma levels of pro-ENK were measured with a double monoclonal sandwich immunoassay.

Results: Mean age was 53±13 years, 56% was male, estimated glomerular filtration rate (eGFR) 49 ml/min/1.73m² (interquartile range [IQR]: 37-64 ml/min/1.73m²) and
urinary albumin excretion (UAER) 40 mg/24h (IQR: 10-196 mg/24h). Median pro-ENK was 110 pmol/L. Pro-ENK was correlated with both eGFR (r = 0.73, P < 0.001) and UAER (r = 0.35, P < 0.001). During a median follow-up of 3.1 years (IQR: 2.7-3.9 years), 45 RTR developed graft failure and 76 died. Pro-ENK was both associated with increased risk of graft failure (hazard ratio per standard deviation increment of the log of pro-ENK: 2.25, 95% confidence interval, 1.69-4.5) and all-cause mortality (1.83; 1.24-2.69), independent of age, sex, eGFR, and UAER. These associations remained materially unchanged after additional adjustment for body mass index, alcohol consumption, smoking, systolic blood pressure, antihypertensive drug use, use of calcium channel inhibitors, and high-density lipoprotein.

Conclusions: High concentrations of pro-ENK are linked to chronic kidney injury as reflected by correlations with eGFR and UAER. In addition, pro-ENK was independently associated with increased risk of graft failure and mortality in RTR. Pro-ENK is an interesting new biomarker which may aid in early identification of RTR at risk for large graft failure and premature mortality.

Pre-Kidney Transplant Left Ventricle Ejection Fraction, Long-Term Allograft Function, and Survival

Adults with ESRD were recruited from the renal transplant waiting list. The studies concerned the association between post-transplant serum albumin concentration and post-transplant outcomes in kidney transplant recipients (KTRs) and allograft survival. Methods: To evaluate the impact of serum albumin level on graft and patient survival, we performed a retrospective multi-center cohort study in Seoul National University Hospital, Asan Medical Center, and Kangdong Sacred Heart Hospital. A total of 2815 KTRs who underwent renal transplantation from Jan 1997 to Jan 2012 were classified into two groups according to the level of serum albumin at 1 year after transplantation (higher albumin group, ≥4.0 g/dL, n=1978 vs. lower albumin group, <4.0 g/dL, n=837). The Cox proportional hazard model was adjusted with age and gender of recipient, donor type, age of donor, diabetes mellitus, and estimated glomerular filtration rate (eGFR) at 1 year after transplantation. Results: The mean age of the recipients was 41.7±11.3 (range, 18-73) years, and 59.1% were male. The rate of graft failure was higher in lower albumin group compared to higher albumin group (Hazard ratio [HR] 1.84, 95% confidence interval [CI] 1.367-2.477, P<0.001), even though eGFR at 1 year after transplantation was not different between the two groups (61.7±19.8 vs. 62.1±15.8 mL/min, P=0.615). Both all-cause mortality and non-cardiovascular mortality rates were higher in lower albumin group (HR 2.227, 95% CI 1.258-3.943, P=0.006, and HR 2.784, 95% CI 1.254-6.179, P=0.012, respectively). Every 1.0 g/dL higher serum albumin concentration was associated with 69.2% lower all-cause mortality (HR 0.308, 95% CI 0.196-0.483, P<0.001). Conclusions: Serum albumin level at 1 year after transplantation is a prognostic factor for graft failure and patients’ mortality in KTRs. Therefore, evaluation and management for hypoalbuminemia should be considered to improve outcomes in KTRs.

FR-PO1101
Progression of Coronary Artery Calcification in Renal Transplant Recipients – A Follow-Up Of 7 Years

Sibel Gulcicek, Nurhan Seyahi. Dept of Internal Medicine, Div of Nephrology, Istanbul Univ, Cerrahpasa Medical Faculty, Istanbul, Turkey.

Background: In the general population coronary artery calcification (CAC) and its progression is associated with cardiovascular and all cause mortality. We conducted a study to determine the progression of CAC in renal transplant recipients; we also examined the factors associated with progression and the impact of the analytic methods used to determine CAC progression. Methods: We used multi-detector computed tomography to examine CAC in 113 prevalent renal transplant recipients, who did not have a documented cardiovascular disease. After CAC scoring was performed and changes in CAC scores were evaluated in each patient individually, to calculate the incidence of CAC progression. Univariate and Multivariate logistic regression analysis was used to evaluate the determinants of CAC progression.

Results: Baseline CAC prevalence was 34.5% and the mean CAC score was 47.08 ± 135.25. At follow-up scan that was performed after an average of 6.9 ± 0.5 years, CAC prevalence increased to 47.6% and the mean CAC score to 140.18 ± 332.11. Progression of individual CAC score was found between 32.7 and 34.5 %, depending on the method used to define progression (Hokanson and Sevrukov). In patients with baseline CAC, median annualized rate of CAC progression was 13.8. Based on univariate analysis, age, presence of baseline CAC, high baseline CAC score, high body mass index were significantly associated with CAC progression defined according to both the Hokanson and Sevrukov methods. Moreover, HDL cholesterol level was significantly associated with CAC progression when progression was defined according to Hokanson’s method and donor type, high triglyceride levels and systolic blood pressure were significantly associated with CAC progression according to Sevrukov’s method.Based on multivariate analysis baseline CAC and high triglyceride were the independent determinants of CAC progression.
Conclusions: Progression of CAC is the usual evolution pattern of CAC in renal transplant recipients. Besides baseline CAC, high triglyceride level were also associated with progression of CAC.

FR-PO1102

Background: Although the risk for morbidity and mortality has been studied in subjects with renal transplantation (RTxs), a few study has investigated the role of adiponectin (ADPN) for cardiovascular disease (CVD) in RTxs recipients.

Methods: We studied 57 adult RTxs subjects (39 males, 18 females; 10 cadaveric donors) with at least three years of allograft survival (median 251 months). We examined clinical backgrounds such as treated drugs, blood pressure (BP, mmHg), body mass index (BMI), and blood chemistry including cholesterol (total, LDL-C, HDL-C), glucose, glycated hemoglobin (HbA1c), and serum high- and low-molecular-weight (HMW-LMW) ADPN fractions with regard to the associations of the visceral and subcutaneous fat areas on CT scan. We also analyzed the associations of CVD and post-transplant diabetes mellitus (PTDM) with ADPN fractions and the fat areas.

Results: The visceral fat area was inversely correlated with serum HMW- and LMW-ADPN levels (r=-0.400, p=0.002 and r=-0.296, p=0.025, respectively). Furthermore, the visceral fat area was inversely correlated with the HMW ratio and positively with the LMW-ADPN ratio (r=-0.444, p=0.001 and r=0.467, p=0.001, respectively), but no significant correlation was noted between the subcutaneous fat area and the ADPN ratio. On multiple regression analysis, eGFR and visceral area were significant reducing factors of ADPN HMW levels, and the alteration of eGFR was identified as an increasing factor of HMW-ADPN levels. Patients with CVD had higher visceral fat area (p=0.004), lower HMW-ADPN ratio (p=0.022) and higher LMW-ADPN ratio (p=0.049), but not in the subcutaneous fat area. On multiple logistic analysis, the higher HMW-ADPN ratio and statin treatment were identified as reducing factors of the development of CVD, but the LDL-C level was an aggravating factor. Moreover, the higher LMW-ADPN ratio and the visceral fat area were aggravating factors of PTDM.

Conclusions: Even in Japanese renal transplant recipients, visceral fat area and ADPN fractions were significant factors for the development of both CVD and PTDM.

FR-PO1103

Background: Post transplant outcomes, in obese chronic kidney disease (CKD) patients having bariatric surgery (BS) as a bridge to renal transplantation, have not been widely reported.

Methods: The database at our center of renal transplant recipients having BS prior to transplant from was reviewed. Control group: all obese renal transplant recipients not having BS with body mass index (BMI) greater than 37 at time of transplant. BMI, patient and graft survival, time on wait-list, acute rejections and infections requiring hospitalization were compared between both groups. Immunosuppressant drug levels were assessed in both groups.

Results: 11 patients had BS prior to transplant. There were 25 obese controls. Median follow up post transplant was 12 months (range 2 to 39 months) in BS group versus 63 months (range 48 to 75 months) in the controls. There were no deaths in the BS group but 5 deaths among controls, of which 4 had functioning grafts at time of death. No significant difference in patient survival was found (P = 0.18). There were 2 graft losses in the BS group versus 6 in the controls (P = 0.77). 4 of which were due to death with functioning grafts. Death-censored graft survival was borderline worse in the BS group (P = 0.05). Rejections were more frequent in the BS group. 4/11 patients had acute rejections in the BS group versus 3/25 in the control group (P = 0.01). Tacrolimus levels were at target in cases seen in Biopsy. Bespect in 1 patient who was non-adherent. Tacrolimus levels were lower in cases of rejection seen in the controls. There were no significant differences in time on waitlist, BMI prior to BS or mean eGFR at 6 months (60.6 in BS and 64.8 mL/ min/1.73 m2 in controls). However, the rate of infections was significantly higher in the BS group, 9/11 versus 10/25 in the control group (P = 0.02).

Conclusions: Despite possible increased transplant candidacy in obese CKD patients having BS, higher rejection rates and inferior death-censored graft survival compared to matched controls seen in this study suggest that vigilance is mandatory. Further investigation is required.

FR-PO1104

Association Between Serum Magnesium Level and the Risk of New-Onset Diabetes After Renal Transplantation in Korea Hoon Yu, Hyungjin Cho, Eunhye Shin, Su-Kil Park. Div of Nephrology, Asan Medical Center; Univ of Ulsan College of Medicine.

Background: New onset diabetes mellitus after transplantation (NODAT) is a serious complication following renal transplantation. Association between serum magnesium level and new-onset diabetes after renal transplantation is controversial. The aim of this study was to identify the association between serum magnesium level and the development of NODAT in Korea.

Methods: The recipients who underwent living donor kidney transplantation between January 2009 and April 2012 were reviewed. Diagnosis of NODAT is defined by American diabetes association criteria. Serum magnesium level were measured at pretransplant, 3 days, 7 days and 3 months posttransplant. Univariated and logistic regression analysis were performed to examine the association between serum magnesium level and NODAT at 1 year posttransplant.

Results: Total 419 patients were enrolled. NODAT was diagnosed in 85(20%) patients. Mean magnesium level at 3 and 7 days after transplantation was significantly lower in patients who diagnosed with NODAT. On logistic regression analysis, Age >40, Obesity, pretransplant glucose were associated with NODAT. However, there is no a association between serum magnesium and NODAT.

Conclusions: A lower magnesium level at posttransplant may be associated with NODAT after renal transplantation in Korea.

FR-PO1105

Is NODAT Really Associated with Acute Rejection in Kidney Only Transplantation? Rosa M. Montero, Florence R. Delaney, Manohursingh Ranglal, Paula Mobillo, Syed K. Hasan, Param Shivshahry, Maria P. Hernandez-Fuentes. 1-3 Nephrology & Transplantation, Guy’s & St Thomas’ NHS Foundation Trust, London, United Kingdom; 2NHR Comprehensive Biomedical Research Centre at Guy’s and St Thomas’ NHS Foundation Trust in partnership with King’s College London and King’s College Hospital, London, United Kingdom; 3MRC Centre for Transplantation, DTMB, King’s College, London, United Kingdom; 4King’s Clinical Trials Unit, Biostatistics Dept, King’s College, London, United Kingdom; 5Nephrology & Transplantation, King’s College Hospital NHS Foundation Trust, London, United Kingdom; 6Nephrology & Transplantation, East Kent Hospitals Univ NHS Foundation Trust, London, United Kingdom.

Background: Previous reports suggest an association with New Onset Diabetes After Transplantation (NODAT) and rejection however it is unclear whether this effect is secondary to hyperglycaemia or a result of previous episodes of treated rejection. This observational study aims to determine the association between acute rejection(AR) and NODAT.

Methods: 381 renal transplant recipients (RTRs) from the KALIBRE study were analyzed. Clinical details and laboratory results were collected in this cohort from 2010-2014. Episodes of AR were identified by renal transplant biopsies;Banff 2009 Categories 2&4 and 3 that were treatment responsive. NODAT was defined as HbA1C>6.5% 3months post renal transplantation. Cox’s regression proportional hazards was used for survival analysis. diabetes associated 381 RTRs (39female, 64%white, 39%non-white, Age at transplant range:17-75). 47 patients were diagnosed with NODAT (13.1%) and 93 (24.4%) with AR. 17/47 (36.2%) patients with NODAT had AR. Rejection free survival in NODAT group was significantly lower than patients without NODAT (p=0.036 HR 1.75). Mean tacrolimus

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

623A
levels between rejectors and non-rejectors were not significantly different (10.1 and 10.3 ng/mL, respectively). T1DM and T2DM combined did not increase the rates of rejection in the cohort.

Conclusions: An association between NODAT and AR has been observed that was independent of tacrolimus levels. RTRs with diabetes mellitus did not have the same effect on AR rates suggesting a different underlying mechanism specific to NODAT rather than just hyperglycaemia.

5. GSTT Kidney Patient Association

**Conclusions:** Secondary hyperparathyroidism associated with ESRD improves after kidney transplantation (KT) in most patients. However, in some patients, high PTH persists post-KT to cause a tertiary hyperparathyroidism (THPT) state, leading to hypercalcaemia and worsening post-transplant bone disease. New calcimimetic drugs are often delayed by insurance post-KT leaving few options for physicians.

Methods: In this retrospective study, we identified kidney transplant recipients between 2008 and 2013 who underwent parathyroidectomy (PTx) for THPT.

Results: We identified 26 (2.5%) patients who underwent PTx, 10 of 101 patients who underwent KT at our center. Pre-surgery mean calcium andPTH levels were 10.4±1.3 mg/dL and 508±404 pg/mL respectively. Post-KT, median time to PTx was 482 days (Q1,Q3: 275,999); 65% underwent PTx greater than one-year post-KT. PTx indications included persistent hypercalcaemia despite medical therapy (62%) and worsening osteoporosis (42%). Sestamibi scan showed hyperplasia and adenoma in 50% and 34% respectively. However, surgical pathology showed hypercellular parathyroid tissue in 25/26 (96%) patients. Predictive value of the Sestamibi scan was poor (Cohen’s kappa index 0.1). PTx complications included hypercalcaemia (19%), transient renal failure (12%), and temporary nerve paresis (4%). There was no deleterious effect on long-term allograft function after PTx compared with baseline values, serum creatinine was identical at 1 month (1.3±0.5 vs. 1.3±0.6, P=0.34), and PTx complications included hypercalcaemia (19%), transient renal failure (12%), and temporary nerve paresis (4%). There was no deleterious effect on long-term allograft function after PTx.

Conclusions: In one of the largest case series, we have shown that (a) Parathyroidectomy is required for tertiary hyperparathyroidism to treat hypercalcaemia refractory to medical therapy and worsening osteoporosis (b) Sestamibi scan is inaccurate in differentiating between hyperplasia and adenoma and (c) Parathyroidectomy is well tolerated with no long-term deleterious effect on allograft function.

FR-PO1108

**Parathyroidectomy for Tertiary Hyperparathyroidism in Kidney Transplant Recipients** Brian M. Zwecker, 1 Zahra Deen, 1 Sreedhar A. Mandalayam, 1 Luan D. Truong, 2 A. Osama Gaber, 2 Emad H. Asham, 2 Dana M. Hong, 2 Venkat Ramanathan. 1 Nephrology, Baylor College of Medicine; 2 Transplant, Houston Methodist Hospital.

**Background:** Hyperparathyroidism is a common complication following kidney transplantation (KT) and is associated with increased mortality. PTx is used when medical therapy fails.

**Methods:** We identified kidney transplant recipients who underwent PTx from 2008 to 2013 who underwent parathyroidectomy (PTx). PTx indications included persistent hypercalcaemia despite medical therapy (62%) and worsening osteoporosis (42%). Sestamibi scan showed hyperplasia and adenoma in 50% and 34% respectively. However, surgical pathology showed hypercellular parathyroid tissue in 25/26 (96%) patients. Predictive value of the Sestamibi scan was poor (Cohen’s kappa index 0.1). PTx complications included hypercalcaemia (19%), transient renal failure (12%), and temporary nerve paresis (4%). There was no deleterious effect on long-term allograft function after PTx compared with baseline values, serum creatinine was identical at 1 month (1.3±0.5 vs. 1.3±0.6, P=0.34), and PTx complications included hypercalcaemia (19%), transient renal failure (12%), and temporary nerve paresis (4%). There was no deleterious effect on long-term allograft function after PTx.

**Conclusions:** In one of the largest case series, we have shown that (a) Parathyroidectomy is required for tertiary hyperparathyroidism to treat hypercalcaemia refractory to medical therapy and worsening osteoporosis (b) Sestamibi scan is inaccurate in differentiating between hyperplasia and adenoma and (c) Parathyroidectomy is well tolerated with no long-term deleterious effect on allograft function.

FR-PO110

**Insulin Resistance: Is It a Risk Factor for Left Ventricular Hypertrophy in Pediatric Renal Transplant Recipients?** Jale Sezer, Nur Canpolat, Gulseren Pehlivan, Salim Caliskan. Pediatric Nephrology, Istanbul Univ Cerrahpasa Faculty of Medicine, Istanbul, Turkey.

**Background:** Renal transplantation reverses uremia-related risk factors for cardiovascular disease; however, immunosuppressive therapy causes metabolic abnormalities such as insulin resistance, hyperglycemia and dyslipidemia. The aim of the present study was to evaluate the effects of these metabolic abnormalities as a risk factor for left ventricular hypertrophy in pediatric renal transplant recipients.

**Methods:** This is a retrospective study involving 31 renal transplanted children and adolescents (19 male; age 4-20 years) and 19 healthy controls. Anthropometric indices, office blood pressure (BP) and laboratory measurements and also left ventricular mass index (LVMI) at the same time were recorded from the patients’ files. The homeostasis model assessment of insulin resistance (HOMA-IR) was calculated. Insulin resistance was defined as a HOMA-IR ≥ 2.5. Dyslipidemia was defined as HDL-C<40 mg/dL, and/or LDL-C>130 mg/dL, and/or TG>150 mg/dL.

**Results:** Age at transplantation was 12.4±4.4 years with a median follow-up of 27 months. One patient received pre-emptive transplantation, 25 were on PD and 5 on HD before transplantation; 25 patients received a kidney from a living donor. Triple immunosuppressive therapy was used in all patients, except two who were not using steroids at time of the enrolment. Patients had significantly higher BMI-SDS, fasting glucose, fasting insulin, HOMA-IR and TG as well as lower HDL-C levels than controls (p<0.05 for all). Nine patients (29%) had insulin resistance; 11 (42%) were dyslipidemic; and 15 (50%) were hypertensive. LVMI was significantly higher in the patients than the controls (40.0±9.1 vs. 25.8±5.71; p<0.001); left ventricular hypertrophy was noted in 11 patients (48%); LVMI was correlated only with indexed diastolic BP (r=0.433, p=0.039), however, not with any of the lipid parameters or HOMA-IR. HOMA-IR was correlated with only BMI (r=-0.381, p=0.035). There was no association between HOMA-IR and steroid doses.

**Conclusions:** Although insulin resistance and dyslipidemia are prevalent in pediatric renal transplant recipients, hypertension appears to be the main risk factor for left ventricular hypertrophy.

FR-PO107

**Mediterranean Type Diet Is Associated with Low Risk of New-Onset Diabetes and Mortality After Renal Transplantation** Marvse Ostik,1 Eva Corpeleijn,1 Gerjan Navis,1 Charlotte A. Keyzer,1 Sabita Soedamah-muthu,2 Else van den Berg,1 Daan Kromhout,1,2 Stephan J.L. Bakker.1 1Univ of Groningen; 2Univ of Wageningen, Netherlands.

**Background:** The incidence of new-onset diabetes after transplantation (NODAT) and cardiovascular events leading to premature mortality is high in renal transplant recipients (RTR). We hypothesized that a Mediterranean type diet protects against development of NODAT and premature mortality in RTR.

**Methods:** In a prospective cohort study consisting of 707 adult stable RTR with a median follow-up of 3.8 years (interquartile range [IQR], 3.0-4.6 years) from baseline, 28 (6%) developed NODAT and 52 (11%) patients died. RTR with ≥ 5 points were both significantly associated with a lower risk of developing NODAT (hazard ratio [HR], 0.43; 95% confidence interval [CI], 0.20-0.94; P=0.04) and mortality (HR, 0.54; 95% CI, 0.31-0.94, P=0.03), both adjusted for age and sex. The results of multivariable analyses, in which we adjusted for potential confounders including total energy intake, physical activity and smoking status, did not materially change the results of the analyses adjusted for age and sex.

**Conclusions:** Dietary habits that resemble the Mediterranean type diet may protect against NODAT and mortality after kidney transplantation. More attention should be directed to the nutritional habits of renal transplant recipients.
Intra-Abdominal Hypertension and Renal Dysfunction in Pregnancy

Wongmarn Kittanamongkolchai,1 Elliott G. Richards,2 Mari Charisse B. Trinidad,3 Wendy White,2 Vesna D. Garovic,1 Nephrology, Mayo Clinic, Rochester, MN; 4Maternal Fetal Medicine, Mayo Clinic, Rochester, MN.

Introduction: The effects of high intra-abdominal pressure (IAP) on renal function have been known for over a century. However, the diagnosis of peripartum intra-abdominal hypertension (IAH)/abdominal compartment syndrome (ACS) is challenging due to the lack of specific symptoms. Cases of IAP in pregnancy without ACS have been reported.

Case Description: A 32 year old obese primigravida with a twin pregnancy at 33 weeks gestation was admitted for intractable nausea and vomiting. She was oliguric and unresponsive to IV fluid. Her blood pressure was normal. Cr increased from a baseline of 0.8 mg/dL to 1.7 mg/dL. A FeNa obtained after fluid resuscitation was 0.02%. Renal ultrasound showed patent renal vessels and no hydronephrosis. A diuretic was given with slight improvement in urine output. IAP measured by an intravesical catheter was 35 mmHg, and abdominal perfusion pressure (APP) (difference between mean arterial pressure and IAP) was 46 mmHg (normal ≥ 50-60 mmHg). She was suspected to have IAH/ACS and was closely monitored. 2 days later, she developed hypertension, an increase in liver transaminases, and proteinuria. The decision was made to deliver with delivery due to severe preeclampsia. IAP measured immediately after C-section decreased to 18 mmHg, and it was 7 mmHg prior to delivery. Urine output increased to 2.5 L per day and Cr declined to 0.7 mg/dL after delivery.

Discussion: Animal and human studies indicate that oliguria and acute kidney injury are frequent consequences of IAH/ACS, and can be present at relatively low levels of IAP. In our case, the IAP of 35 mmHg was quite extreme compared to IAP of 4-28 mmHg observed in cohort studies of peripartum patients. We suspected that obesity and twin pregnancy contributed to the extreme IAH. Her APP was significantly low and restoration of renal function was readily observed after reduction of IAP. Our case may support the theory that IAH/ACS is underdiagnosed and underappreciated. Recent reports from IAH/ACS is probably underrecognized as IAH is not routinely measured. Further study is needed to elucidate the impact of IAH in pregnancy.

SA-PO002 Diabetes, Deafness and Renal Disease – A Case Report

Ioliada Godinho, Joana Gameiro, Noélia Lopez Santos, Sofia C.A. Jorge, Fernando Abreu, Estela Nogueira, Maria Alice Fortes, Jose António Lopes, Patricio Aguiar, Dolores López Præsa, António Gomes da costa. Hospital Santa Maria, Lisbon, Portugal.

Introduction: Deafness and kidney disease as well as diabetes and kidney disease are associations of which the Nephrologist is well aware. However, the concomitance of the three is not as usual, neither is a family history of these diseases.

Case Description: This is the case of a 78 year old woman with non-nephrotic proteinuria, no haematuria, normal renal function, slowly progressive bilateral sensorineural hearing loss and recently diagnosed diabetes and maculopathy and a maternal family history of deafness, diabetes and renal disease. The patient progressed with increasing proteinuria despite antiproteinuric measures and a renal biopsy was performed, revealing Focal and Segmental Glomerulosclerosis (FSGS). Alport syndrome and Fabry disease investigation was negative. Facing the personal and maternal family history, the mitochondrial mutation m3243A>G was pursued and identified in heteroplasmia and maternally inheritance. Mitochondrial Diabetic Diabetic Diabetic Diabetic Diabetic Diabetic Diabetic Diabetic Diabetic Diabetic Diabetic Diabetic Mitochondrial Diabetic Diabetic Diabetic Disease (MIDD) with renal involvement as FSGS. The renal biopsy ultrastructural study is ongoing. While waiting the etiologic investigation because of symptomatic nephropathy the patient was started on prednisolone 1mg/kg/d with no antiproteinuric response and with side effects causing her to interrupt this medication.

Discussion: Mitochondrial diseases constitute a group of rare diseases in which renal involvement is uncommon, although possible. This is the case with MIDD, in which patients present with non-insulin dependent diabetes and sensorineural hearing loss, which may be accompanied by other manifestations as cardiomyopathies or maculopathy. Renal involvement is possible, mostly as tubulointerstitial nephritis or less frequently presenting as glomerulopathy, namely FSGS. In this type of FSGS, the proteinuria is usually non-nephrotic, with scarce response to antiproteinuric measures, and slow progression to chronic kidney disease. The association of FSGS with mitochondrial diseases is not well known to the nephrologic community. Its timely diagnosis is particularly important to avoid exposure to ineffective and toxic immunosuppression.

SA-PO003 Chronic Inflammatory Demyelinating Polyneuropathy Associated with Advanced Focal Segmental Glomerular Sclerosis Albert Ndzonga,1 Rada Petrinjac-Nmeadic,2 Lelka K. George,3 Elvia Gospamanova.1 Nephrology, UTHSC, Memphis, TN; 2Neurology, Tri-State Neurology, PLLC, Memphis, TN.

Introduction: Chronic demyelinating polyneuropathy (CDP) is rarely reported in patients with nephrotic syndrome (NS). CDP tends to manifest concomitantly with NS. We report a case of CDP developing at a time of focal segmental glomerular sclerosis (FSGS) progression to ESRD and mimicking uremic neuropathy.

Case Description: A 23-year-old female with NS was admitted to our hospital for proven dry 1y collapsing FSGS and serum creatinine (SCr) 1mg/dL was initiated on oral prednisone and lisinopril. He was lost to follow up and returned 1.5 years later complaining on burning pain and numbness in both feet in 4 weeks. Physical exam was normal except for unsteady gait, inability to perform tandem gait, decreased sensation from feet to upper legs, depressed Achilles and ankle flexor reflexes. Laboratory tests showed Scr 44mg/dL, hyperkalemia, metabolic acidosis, normocytic anemia, and normal creatinine phosphokinase. A diagnosis of ESRD due to progression of untreated FSGS was made and dialysis was started. CT head and MRI spine were normal. Cerebrospinal fluid had protein of 74 mg/dL. Serum creatinine (SCr) was 1mg/dL. Electromyography (EMG) showed absent compound muscle action potential (CMAP) and F-waves in both peroneal and tibial nerves, active denervation in tibialis anterior, gastrocnemius and extensor digitorum brevis muscles, and prolonged distal latencies and reduced motor action velocity with normal amplitude of CMAP on both arms. Sensory nerves action potentials on sural and peroneal nerves were absent with prolongation of peak latencies on other nerves. The constellation of clinical, EMG and normal inflammatory, infectious and autoimmune laboratory markers was consistent with diagnosis of CIDP. Plasmapheresis was performed with partial improvement of neurological symptoms and was followed by intravenous immunoglobulin infusions as a maintenance therapy.

Discussion: CIDP should be considered in patients presenting with peripheral neuropathy and history of FSGS. Correct diagnosis of CIDP is critical as untreated CIDP leads to inability to walk. Autoimmune mechanisms may be responsible for CIDP and glomerular damage in FSGS but remain to be proven.

SA-PO004 Alloimmune Membranous Nephropathy in Fabry Disease Zuhair T. Lathara,1 Josephine E. Ambruits1 Department of Coe et al. Medicine, Medical College of Wisconsin, Milwaukee, WI; 2Pathology, Nephropath, Little Rock, AR.

Introduction: Use of enzyme replacement therapies may cause allo-reactivity that causes illness superimposed on the primary disease.

Case Description: A 20 year old male with Fabry disease developed proteinuria. He has the 3.1 kb alu-alu deletion including exon 2. His most recent agalsidase serum enzyme activity was low at 0.8 mg/hour/ml (normal 6.2 to 18.6). He has chronic arthralgia and progressive hearing loss. He has had a stroke secondary to right hemisphere infarction. His last agalsidase level was 7.32 mg. He has hypertension, with 2 blockers. His urine protein creatinine ratio was 2.0 mg/mmol. He had a 1 gram of protein per gram of urine creatinine. His proteinuria had ranged from 1.3 to 2.9 gram/gram over the preceding four months. Serological testing showed a negative RPR, negative tests for hepatitis B and C, and an antibody 1 of 1640 titer. A kidney biopsy showed Fabry disease and superimposed membranous nephropathy. Lisinopril 2.5 mg/day was started. Rheumatological evaluation showed no evidence of lupus erythematosus. The most recent protein to creatinine ratio was 0.71 gram/gram, with a serum creatinine of 0.8 mg/dL.

His kidney biopsy stained positive for anti-agsalsidase, but normal control kidney did not. He had anti-agalsidase antibodies in his serum that did not block agalsidase activity. Immunofluorescence for the phospholipase A2 receptor (PLA2r) was negative within the glomeruli and his serum did not have antibodies to PLA2r.

Discussion: Enzyme replacement therapies may lead to allo-reactivity. Membranous nephropathy has been described in three such patients but not in Fabry disease. Its occurrence may change the therapy of the primary disease and force specific treatment of the nephritis superimposed on the primary disease. Funding: Veterans Administration Support, Clinical Revenue Support

SA-PO005 Silicone Implant Associated Acute Kidney Injury in a Male Transgender Patient

Frank J. O Brien, Brian Y. Young. Div of Nephrology, Santa Clara Valley Medical Center, San Jose, CA.

Introduction: Obstructive kidney disease secondary to nephrolithiasis is a well-described cause of acute kidney injury. Stone formation is often due to dietary or metabolic factors, often no predisposing factors are found. We describe a rare case of obstructive acute kidney injury associated with hypercalcuria and hypercalciemia in a 32-year-old transgender patient. Patient was found to have granulomatous disease associated with silicone implants.

Case Description: 32-year-old male to female transgender patient presented to our institution with fatigue. Routine labs showed creatinine 11 mg/dL, BUN 140 mg/dL, K 7 mmol/L. She was emergently dialyzed, and imaging showed obstructing ureteric calculi, requiring bilateral stent insertion. Patient had a history of silicone implants in hips, buttocks and thigh 5 years previous. These were inserted by a non health care professional. There was no history of calcium stone production or hormonal therapy use. Diagnostic work up for nephrolithiasis revealed; 24 hour urinary calcium 866 mg/24 hours, serum calcium 12.5 mg/dL, phosphorus 4.2 mg/dL. Other 24-h calcium and 24-h CMAP on both limbs were normal. ACE level was 216 units/L. CXR was normal. PTH and malignancy work up was negative. CT abdomen revealed subcutaneous edema in lower back/gluteal area, around the sites of previous silicone implants, and inguinal lymphadenopathy. Subsequent galium scan showed tracer uptake around inguinal area, buttock and hips, consistent with granulomatous activity around silicone implants. Excisional lymph node biopsy revealed foreign body type giant cells consistent with granulomatous disease. Empty vacuoles were noted within the giant cell cytoplasm consistent with silicone induced granulomas. Hypercalcemia was managed with both calcitonin and total parenteral fluids and definitive therapy with prednisone was commenced when diagnosis was made.

Discussion: Hypercalcemia due to silicone implant associated granulomatous disease is a rare, but important presentation. Our patient developed symptoms years after initial implant insertion. With the growing prevalence of cosmetic surgery, particularly in the transgender community, physicians need to be increasingly aware of the associated long term complications.
**SA-PO006**

Isolated Diplopia Caused by Calcineurin Inhibitor Therapy in a Patient with Idiopathic Membranous Nephropathy  
Nader S. Bahri, Ashwani K. Gupta.  
Nephrology and Hypertension, Univ of Florida, Jacksonville, FL.

**Introduction:** Neurotoxicity is a common side effect of treatment with calcineurin inhibitors. Tremors are frequently reported as the most common manifestation. Variable presentations can include headaches, seizures, visual hallucinations or blindness. Six nerve palsy has been reported in previous cases of bone marrow and cardiac transplant patients receiving calcineurin inhibitors. In many of these previously reported cases, the drug was administered intravenously and very high drug levels were found.

**Case Description:** 42-year-old Caucasian female with biopsy proven idiopathic membranous nephropathy (IMGN) who was being treated with tacrolimus and prednisone for nephrotic syndrome. Her tacrolimus levels were maintained between 6.8-9.8 ng/mL. Her urine protein/creatinine ratio of 8 gm/gm was successfully reduced to less than 1 gm/gm. She continued to be in complete remission but after 3 months of therapy she presented with diplopia. The diplopia was binocular and vertical. The patient was seen for an ophthalmologic evaluation. Her visual acuity was 20/20. Pupils were equal and reactive to light and accommodation. No nystagmus was observed. Visual fields and color vision was also normal in both eyes. Assay for Acetyl-choline receptor antibody was negative.

The patient remained compliant with her medications despite the side effects. At this time she was switched to low dose Cyclosporin (CyA) in anticipation that similar side effects may not be observed. Though CyA levels were 44 ng/mL and 59 ng/mL on two occasions but her symptoms did not resolve. A consultation with neuro-ophtalmology was sought and the patient was instructed to discontinue CyA. The symptoms completely resolved 4 days after stopping CyA.

**Discussion:** This is the first reported case of isolated diplopia secondary to calcineurin inhibitors in low doses for treatment of IMGN. Monitoring of serum concentrations of these drugs has not been correlated with toxicity. The mean duration to onset of symptoms in these previous reports is 2-3 weeks and the symptoms completely resolved in all of these cases within a week of discontinuation of the drug.

**SA-PO008**

A Case of Minimal Change Disease After the Administration of Anti-RANKL Monoclonal Antibody  
Keisuke Horikoshi, Norihiko Sakai, Yasuyuki Shinozaki, Shinji Kitajima, Akinori Hara, Yasunori Iwata, Miho Shimizu, Kengo Fujiuchi, Takashi Wada.  
Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan.

**Introduction:** Receptor activator of nuclear factor kappa B (RANK)-RANK ligand (RANKL) has emerged as an important regulator of bone mineral density and microstructure. In addition to bone, recent studies have revealed that RANKL may contribute to the podocyte survival signal after its injury. Here we report a case that RANKL inhibition might contribute to the onset of nephrotic syndrome.

**Case Description:** A 59-year-old male without any episodes of proteinuria was given denosumab, a fully human monoclonal antibody to RANKL, to treat osteoporosis. Two weeks after its administration, he showed bilateral peritidal edema. Laboratory tests revealed that he had microscopic hematuria, severe proteinuria (15g/gCr), hypoproteinemia (4g/dL) and hypoalbuminemia (1g/dL). The proteinuria selectivity index was below 0.1, indicating that he had selective proteinuria. Based on the results, he was diagnosed to have nephrotic syndrome. Renal biopsy showed minor glomerular abnormality with less tubulointerstitial damage, indicating minimal change disease (MCD). Taken altogether, glucocorticoid therapy of prednisolone 50 mg/day had started. After four weeks of treatment, the level of urinary protein was still high (4.1g/gCr), but it decreased gradually to the range of partial remission (1.2g/gCr) with another 8 weeks treatment of prednisolone.

**Discussion:** This may be a rare case to report the association of RANKL inhibition with MCD. The responsiveness to glucocorticoid therapy was not good enough to promptly induce complete remission, suggesting that podocyte injury due to RANKL inhibition could be responsible at least in part in MCD in this case.

Eculizumab in Management of Thrombotic Lesions in Kidney Allograft of Patient with Anti-Phospholipid Syndrome  
Anju Yadav, Ravi Sunderkrishnan, Andres Rodrigo Caero.  
Nephrology, Thomas Jefferson Univ Hospital, Philadelphia, PA.

**Introduction:** Thrombotic microangiopathy (TMA) is one of the hallmarks of anti-phospholipid syndrome (APS). Eculizumab is a humanized anti-C5 monoclonal antibody which has been used in atypical hemolytic uremic syndrome. Recently, there have been reports of use of Eculizumab in transplant patients with APSL TMA.

**Case Description:** We present a case of a 58 year old Caucasian man with history of systemic lupus erythematosus, APSL on warfarin, hypertension, rheumatoid arthritis, transient ischemic attack, coronary artery disease with triple vessel bypass, chronic kidney disease stage 5 for which he received pre-emptive living unrelated kidney transplant. After an uneventful post-transplant course, he was discharged on warfarin. He presented to the hospital 4 days later, with acute renal failure, pain over the graft and sub-therapeutic INR. A perinichreatic collection was drained. Cytomegalovirus and BK polyoma viremia were ruled out. Transplant kidney biopsy, revealed TMA with segmental necrosis and small vessel fibrin thrombi and no acute rejection. High dose steroids along with aggressive anticoagulation was received two sessions of plasmapheresis. After meningococcal meningitis immunization, Eculizumab 900mg/week was started. After 4 doses, Eculizumab was changed to 1200mg/two weeks. Creatinine trended down from 7.3 to 3.0 mg/dl and dialysis was stopped after 7 sessions. He was positive for IgG anticardiolipin, beta-2 glycoprotein, and lupus anticoagulant and was started on daily aspirin and warfarin with INR goal of 2.5-3.5.

**Discussion:** Treatment with Eculizumab and plasmapheresis resulted in a relatively rapid and dramatic improvement of graft function in our patient and should be considered in difficult to manage TMA/APS in transplant patients. Its use permits a safer approach of controlling the complement final common pathway.

Transient Gestational Diabetes Insipidus in a Patient with Pre-Eclampsia  
Anju Yadav, Ravi Sunderkrishnan, Andres Rodrigo Caero.  
Dept of Nephrology, Thomas Jefferson Univ Hospital, Philadelphia, PA.

**Introduction:** Diabetes insipidus (DI) is manifestation of post pituitary insufficiency characterized by polyuria and polydipsia. DI can be neurohypophyseal, nephrogenic, polydipsia related or gestational (GDI). L-deamino-8-d-arginine vasopressin (DDAVP) is a vasopressin analogue which had higher and prolonged anti-diuretic activity with no effects on smooth muscle. An increase in urine osmolality by at least 50% following administration of DDAVP is diagnostic of disorder.

**Case Description:** We present a case of a 22-year-old African American primigravida woman with no past medical history, in 32nd week of pregnancy, admitted with pre-eclampsia with no liver injury. On admission, blood pressures were between 140-165/60-70 mmHg. After an uneventful delivery she had urine output ranging 6-9 liters along with polydipsia. Both of these were present all through out her third trimester. On exam there was no evidence of volume overload or dehydration. Labs were sodium 137mEq/L, Potassium 2.8mEq/L, Ab 3.0mg/dl, TSH 4.16, urea nitrogen <0.3, creatinine 0.4, serum osmolality 284, urine osmolality 141, spot urine protein/creatinine ratio of 0.8. With one dose of 5mcg subcutaneous DDAVP improved diuresis and urine osmolality to 358 within 24hrs. Oral DDAVP

SA-PO011

Introduction: The dangers of baclofen toxicity in patients with advanced kidney disease and in particular patients on dialysis remain underappreciated by many physicians.

Case Description: We present a case of a 64 year old male who developed an uncommon case of altered mental status during his hospitalization. His medical history included ESRD for which he was receiving in-center hemodialysis, diabetes and hypertension. He initially presented to the hospital with complaints of shortness of breath and hiccups. His shortness of breath was attributed to volume overload and resolved with two consecutive days of dialysis with fluid removal. For his intractable hiccups, he was started on baclofen. During his hospitalization, he became lethargic and was unable to move his lower extremities. Laboratory data including serum sodium, potassium, glucose, calcium, BUN, phosphorus, liver function tests, troponins, inr work up and ammonia levels were unremarkable. Neuroimaging, including CT head and brain MRI, were unchanged from previous studies and revealed moderate diffuse cerebral atrophy. An EEG was also performed and did not suggest signs of epileptic activity. Further investigation revealed that he had received a total of 20 mg of baclofen over 2 days. After other etiologies were ruled out, we determined that he may have suffered from baclofen induced encephalopathy. His baclofen was stopped and he was prescribed daily sessions of hemodialysis for three days with the intent of clearing baclofen. He was dialyzed for 4 hours during each dialysis session with a high flux dialyzer. After his first session of dialysis, the patient was more alert and would follow simple commands. At 3 days, the patient’s mental status returned to baseline and he was able to move his extremities.

Discussion: Although the kinetics of baclofen elimination during hemodialysis are not well understood, this case demonstrates the resolution of baclofen induced encephalopathy with frequent and consecutive dialysis. Furthermore, we hope this case raises awareness among physicians of the toxic effects that baclofen can cause in dialysis patients.

SA-PO012

Introduction: Urea cycle disorders (UCDs) are rare pediatric diseases but partial enzyme deficiency can persist throughout adulthood. Little has been published about the role of hemodialysis in addressing the acute complications of UCDs in adulthood. Catabolic states are well known trigger factors for the life-threatening acute hyperammonemia.

Case Description: We are reporting a 32 year old male patient with history of partial ornithine transcarbamylase deficiency diagnosed at age of 6 months. He presented with altered mental status due to acute hyperammonemia (100mg/dl). He was treated with a pre-specified protocol (infusion of Na Phenylacetate/benzoate and Arginine HCl, fasting for 36 hours along with intravenous administration of lipids and glucose followed by protein restricted diet of 35 grams per day and Na phenyl butyrate & L-citrulline). This was consistent with Pauci-Immune Glomerulonephritis or ANCA negative vasculitis.

Discussion: This was consistent with Pauci-Immune Glomerulonephritis or ANCA negative vasculitis. It can lead to TMA causing multi-organ failure and the potential for death if not managed in time. Pregnancy can cause aHUS in any trimester. One should maintain a low suspicion for aHUS in a pregnant patient with prompt initiation of eculizumab to prevent negative outcomes.

SA-PO013

Introduction: Atypical Hemolytic Uremic syndrome (aHUS) is known to cause acute thrombotic microangiopathy (TMA) in pregnancy with adverse maternal and fetal outcomes. A French study showed that aHUS usually occurs postpartum when activity of placentally derived factor E selectin is low and deposition of IgM is high. We present a case of a young lady early in pregnancy with severe thrombocytopenia and acute renal failure suspicious for TTP, but later diagnosed with aHUS, which improved with eculizumab.

A 30 year old G1P5A5LS 10 weeks pregnant with a past medical history of 5 first trimester miscarriages presented with vomiting, vomiitng and watery diarrhea whose labs show a hemoglobin (Hgb) 7.8 g/dl, platelet (PLT) count 15K/ul, BUN 65 mg/dl and serum creatinine 2.44 mg/dl along with a LDH of 1,847 U/L, haptoglobin <8 mg/ml, and albumin 3.2 g/dl. Liver function tests (LFTs) and coagulation studies were normal. She was suspected to have TTP and transferred to our tertiary medical center. Urinalysis revealed 3+ protein and 3+ blood. Blood smear showed schistocytes. A diagnosis of TMA was made and plasmapheresis was started. Serologies for lupus and anti-phospholipid antibody syndrome were negative and LFTs remained normal, ruling out HELLP. The ADAMS-13 activity level was not to be 129%. Renal function declined requiring the initiation of hemodialysis(HD). On the basis of ongoing hemolytic anemia with thrombocytopenia, renal failure and a negative ADAMS-13, she was started on Eculizumab. After 2 doses, her renal function and urine output improved and HD was stopped. At discharge, her Hgb was 8.5 g/dl, PLT 150 K/uL, and BUN/creatinine 23/1.84 with the plan to receive monthly eculizumab infusions.

Discussion: aHUS is caused by activation of the complement system due to a genetic deficiency of its regulatory proteins, specifically complement factor H, factor I, and membrane cofactor protein. It can lead to TMA causing multi-organ failure and the potential for death if not managed in time. Pregnancy can cause aHUS in any trimester. One should maintain a low suspicion for aHUS in a pregnant patient with prompt initiation of eculizumab to prevent negative outcomes.

I've Got a Fever and the Only Prescription Is More Colchicine: Familial Mediterranean Fever Related Pauci-IgM Glomerulonephritis Ashvin Bang, Anam Khan, Celia A. Peña, Rajeev Raghavan. Nephrology, Baylor College of Medicine, Houston, TX.

Introduction: Relatively few renal manifestations have been detected in Familial Mediterranean Fever (FMF). We present a case of biopsy proven pauci-immune glomerulonephritis (GN) in a patient with clinically diagnosed FMF and review past treatments of pauci-immune GN in FMF patients.

Case Description: We present an interesting case of a 22 year old man who had suffered for nearly seven years a constellation of symptoms including fever, nausae, vomiting, abdominal pain, arthralgias, chest pain, and an erythematous rash consistent with a clinical diagnosis of Familial Mediterranean Fever. He had a normal serum creatinine of 1.0 mg/dl which peaked at 2.0 mg/dl. Repeated urinalysis indicated 6-10 RBCs per high powered field (hpf) and 6-21 WBCs hpf. Laboratory testing revealed only an elevated C-reactive protein. A kidney biopsy was performed which revealed 41% of the total glomeruli globally sclerosed and 54 % of the viable glomeruli with active crescents and 25% interstitial fibrosis with tubular atrophy. Immunofluorescence revealed minimal C3 staining. This was consistent with Pauci-IgM Glomerulonephritis or ANCA negative vasculitis. It was suspected to have TTP and transferred to our tertiary medical center. Urinalysis revealed 3+ protein and 3+ blood. Blood smear showed schistocytes. A diagnosis for mutations in the MEFV gene in the diagnosis of FMF is ongoing. He has had no relapse of his FMF with initiation of colchicine and now has had resolution of his hematuria, proteinuria, and acute kidney injury.

Discussion: In the literature, there is minimal knowledge about the renal manifestations of Familial Mediterranean Fever and fewer documented reports on the treatments for ANCA negative vasculitis in FMF. We were able to treat ANCA negative vasculitis in a patient with FMF with only pulse steroids and maintenance immunosuppression with mycophenolate mofetil with great response.

SA-PO015
Stress of Surgery – Is It Just Mental or Can It Be Renal as Well? Mitali Nani Patel, Maria M. Picken, Kavitha Vellanki. Nephrology, Loyola Univ Medical Center, Maywood, IL.

Introduction: Waldenstrom’s macroglobulinemia (WM) is a rare clinicopathological disorder with a reported annual incidence of 3 per 100,000 people. It is characterized by Ig M monoclonal gammapathy in the blood and lymphoplasmacytic lymphoma in the bone marrow. Clinical manifestations are non-specific and generally related to Ig M infiltration of hematopoietic tissues. While deposits of Ig M in the glomerular basement membrane may be seen, renal failure per se is unusual. Here, we present a unique case of recurrent episodes of acute kidney injury (AKI) post-operatively in a patient with underlying WM with spontaneous recovery each time.

Case Description: 75 year old woman with WM, hypertension, obstructive sleep apnea and paroxysmal atrial fibrillation presented for an elective surgery for lumbar stenosis to relieve her post-operative shortness of breath and anuria. Under general anesthesia, her renal function and urine output improved and AKI was reversed. She was transferred to rehabilitation floor on day 3. She had gradual worsening of lower extremity swelling and shortness of breath and repeat labs showed a serum creatinine of 3.32 mg/dl (0.94 mg/dl normal).
mg/dl, 5 days prior) and renal service was consulted for AKI. She had a prior episode of AKI with knee replacement in 2008, dialysis-dependent for 33 days with subsequent spontaneous recovery. Further work up revealed fairly active urine sediment with new onset 24 hour urine protein of 3.3 grams. C3 was normal, C4 <5 mg/dl, cryoglobulin was positive, rheumatoid factor of <20 ug/dl, serum Ig M were elevated at 64g/mg/dl (normal 30-304 mg/dl) and serum immunofixation showed an abnormal restricted band between the beta and gamma regions. Kidney biopsy showed strongly PAS positive hyaline-like precipitates in the glomerular capillaries with immunofluorescence strongly positive (3+) for IgM and lambda light chains. There were abundant, confluent electron dense deposits in the mesangial and subendothelial space. Her symptoms improved with diuretics and she refused any other major intervention. Renal function eventually improved with serum creatinine of 1.2 mg/dl at the time of discharge.

Discussion: In conclusion, we believe the stress of surgery precipitated intraglomeruli deposition of Ig M leading to AKI with spontaneous resolution thereafter.

New Causes of Secondary Hyperparathyroidism: Unforeseen Effects of New Drugs on the PTH-Calcium Axis

Cortese, Xochiquetzal J. Geiger, Nabeel Aslam. Nephrology, Baylor Univ Medical Center, Dallas, TX.

Introduction: Calcium homeostasis is a function of the interplay between GI absorption, renal excretion and bone resorption. Although numerous effectors control these processes, PTH is primarily responsible. PTH affects the kidney and bone through PTH receptor 1. In the kidney PTH decreases phosphorus reabsorption, increases calcium reabsorption and stimulates 1-hydroxylisation of vitamin D. In the bone PTH up-regulates expression of RANKL and decreases expression of osteotoprotein. This process increases RANKL binding to RANK on osteoclast precursors stimulating them to become osteoclasts that increase bone resorption. New drugs that inhibit RANK are used to treat osteoporosis and bone metastases.

We describe two patients who developed chemotherapy agents who developed severe hypocalcemia, and secondary hyperparathyroidism with hypophosphatemia due to renal P400 wasting. We hypothesize that these drugs inhibit RANK.

Case Description: Case 1: A 72 y/o woman with metastatic leiomyosarcoma received Trabectatin, an experimental agent which interacts with DNA. She subsequently complained of weakness. Labs are shown. Case 2: A 73 y/o man with ALL positive for BCR-ABL was t...Downloaded from https://escholarship.org/uc/item/7981n2k7 by guest on 10 April 2023

Creatinine was 0.7 mg/dl in patient 1 and 0.8 mg/dl in patient 2.

Discussion: Both patients developed secondary hyperparathyroidism. The renal effects of PTH appeared to be intact with increased calcium resorption, phosphorous excretion and 1-hydroxylisation of vitamin D. The effects of PTH on bone resorption, however, appeared blunted. Because PTH acts on both kidney and bone through the same receptor, we believe that this represents a posterior receptor phenomena involving the RANKL-osteoprotein system. The tyrosine kinase inhibitor, Imatinib, has been shown to decrease the expression of RANKL and decreases expression of osteoprotegrin. This up-regulates expression of RANKL and decreases expression of osteoprotegrin system. The tyrosine kinase inhibitor, Imatinib, has been shown to decrease the expression of RANKL and decreases expression of osteoprotegrin. This up-regulates expression of RANKL and decreases expression of osteoprotegrin.

Connection or Coincidence: Behçet’s Disease and Focal Segmental Glomerulosclerosis with Nephrotic Syndrome

Deanne Leonard, Chermise M. Cortese, Xochiquetzal J. Geiger, Nabeel Aslam. Mayo Clinic, Jacksonville, FL.

Introduction: Behçet’s Disease (BD) often presents with aphthous and genital ulcers, uveitis, and erythema nodosum. Rarely, renal amyloidosis, IgA nephropathy and crescentic glomerulonephritis result. Here we present a case of nephrotic syndrome from focal segmental glomerulosclerosis (FSGS) in a patient with BD in evidence to suggest a direct connection.

Case Description: 49 y/o female with history of hypertension and BD on enalapril, colchicine and carvedilol. Following a recent prednisone taper, she developed oral ulcers, uveitis, pathergy reaction and proteinuria. Physical exam: Blood pressure: 170/90, aphthous ulcer, uveitis, and 3+ bilateral leg edema. Laboratory data: serum albumin 3.3 g/dl, total cholesterol 209 mg/dl, uric acid 5 mg/dl, creatinine 1.1 mg/dl. Urinalysis: 3+ proteinuria, 10 RBC/ hpf and a random protein/creatinine ratio of 8.5. Normal complement levels, DS-DNA, SS-A, SS-B, Sm Ab, RNP Ab, ScI 70 Ab, and Jo Ab. Renal biopsy: Light microscopy: focal segmental lesions. Immunofluorescence: IgM trace mesangial granular staining, consistent with immunoglobulin trapping. IgG, IGA, C3, C1q, kappa, and lambda: negative. Electron microscopy: near total visceral epithelial cell foot process effacement with villous formations.

Treatment included losartan and prednisone 1 mg/kg/day which resulted in resolution of edema and reduction of protein to creatinine ratio to 0.14 along with resolution of oral ulcers and uveitis.

Discussion: At present, there is no proven correlation between BD and FSGS with nephrotic syndrome. Our patient presented with BD flare coinciding with the development of nephrotic syndrome both of which improved simultaneously with steroids suggesting a direct connection. Therefore, the clinician should be aware of this possible link and screen accordingly for proteinuria both qualitatively and quantitatively to detect early renal involvement in patients with BD.

SA-PO018

Reversal of Dialysis-Dependent Renal Failure and Nephrotic Syndrome after Conservative Therapy in an Adult with Proliferative Glomerulonephritis with C3-Dominant Deposition

Eriko Takehara, Shinitaro Mandra, Shiichi Uchida. Dept of Nephrology, Shuinai General Hospital, Saitama, Japan; Dept of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental Univ, Tokyo, Japan.

Introduction: C3 glomerulonephritis (C3GN) is a recently described entity in a reclassification of membranoproliferative glomerulonephritis, characterized by isolated or predominant glomerular C3 deposits. Although abnormalities in the alternative pathway are known to be involved in the pathogenesis, efficient therapeutic approaches have yet to be established.

Case Description: In December 2012, a 55 year-old man was admitted with rapidly progressive glomerulonephritis and nephrotic syndrome. In May 2011, his serum creatinine (Scr) was 0.63 mg/dl. Seven weeks previously, he was admitted to another hospital with hemorrhagic gastric ulcer accompanied by renal failure (Scr 4.61 mg/dl, urinary protein 15 g/gCr, and moderate hematuria), in the absence of preceding infection. At admission to our hospital, Scr increased to 7.60 mg/dl, ANCA, anti-nuclear antibody, and decrease in complement factors were absent. A renal biopsy specimen showed crescentic and endocapillary proliferative GN with dominant C3 and trace IgG. Conservative therapy was started, given the repeated hemorrhagic ulcer, and decreased rate of renal function decline. Hemodialysis was initiated on hospital day 20 because of oliguria, but was ceased on day 60 with recovery of kidney function. Scr decreased to 1.2 mg/dl, and urinary protein decreased to <1 g/gCr. One year after discharge, he developed nephrotic-range proteinuria, and the second renal biopsy revealed the increased sclerotic glomeruli and fibrous crescents with isolated C3 deposits.

Discussion: To our knowledge, this report is the first to describe reversal of dialysis-dependent renal failure after conservative therapy in a C3GN patient. Similarly to the present case, the histological morphology and clinical presentation infrequently mimic the picture of postinfectious GN, although the transient recovery is usually partial. A novel classification of such cases among C3GN may be needed to avoid an unnecessary immunosuppression.
Discussion: MPGN II may cause drusen and choroidal neovascularization. Eye examination is useful to diagnose visually threatening complications. The newer high-speed spectral-domain optical coherence tomography instrument may define the precise location of the drusen-like deposits when using En face OCT.

SA-PO020
Severe Hyponatremia following the Treatment of Pulmonary Strongyloides Stercoralis Infection
Renu Regunathan-Shenk, Woonin Ahn, Sumit Mohan.
Nephrology, New York Presbyterian-Columbia Univ Medical Center, New York, NY.
Introduction: Strongyloides stercoralis is a soil transmitted nematode which can cause serious infection in immunocompromised patients through skin penetration. The helminth can cause abdominal and pulmonary symptoms and can continue to autoinfect patients if untreated. It has been infrequently reported to cause hyponatremia which resolves with treatment of the infection.
Case Description: A 59-year-old Dominican man with a history of single lung transplant and chronic abdominal pain was admitted for treatment of pulmonary strongyloides infection found on routine outpatient bronchoscopy. On admission he was found to have an E. Coli bacteremia which was attributed to gastrointestinal translocation. The patient was started on ivmectin (15 mg/day orally) and pipercillin tazobactam (4.5 grams every 8 hours intravenously in 5% dextrose solution). He developed a rapid decline in his serum sodium concentration from 135 mmol/L prior to admission to 109 mmol/L on hospital day 5. Physical exam at this time was notable for euvoletic appearance, lethargy, and inattention. Laboratory evaluation confirmed a hypo-osmolar hyponatremia with elevated urine osmolality (576mOsm/kg) consistent with Syndrome of Inappropriate ADH Secretion (SIADH). Thyroid studies and cerebral fluid studies were unremarkable. He was treated with hypertonic saline and desmopressin until he achieved normonatremia. He has experienced euvolemic hyponatremia, especially in patients who have traveled to endemic areas or who are immunocompromised. Prior case reports have shown resolution of hyponatremia with euvolemic hyponatremia, especially in patients who have traveled to endemic areas or who are immunocompromised. Prior case reports have shown resolution of hyponatremia with strongyloides treatment, however we present a patient who worsened after bronchoscopy and initiation of ivmectin. We propose that this may have occurred due to increased systemic parasite exposure after the bronchoscopy procedure.

SA-PO021
A Case of Disseminated HSV Infection in PD Patient with Bulbous Pemphigoid
Yuiro Machida, Kentaro Fujii, Ayumi Yoshifugi, Naoki Washida, Hirofumi Torukuma, Matushiko Hayashi, Shu Waking, Hiroshi Itoh. Dept of Internal Medicine, Keio Univ School of Medicine, Tokyo, Japan.
Apheresis and Dialysis Center, Keio Univ School of Medicine, Tokyo, Japan.
Introduction: Patients with end stage renal disease (ESRD) are affected by various infections with high mortality because of the immunodeficiency. We report a rare case of disseminated Herpes simplex virus (HSV) infection in peritoneal dialysis (PD) patient, who was treated with high-dose steroid for bulbous pemphigoid (BP).
Case Description: A 72-year-old man under the treatment with PD for 2 months for ESRD caused by nephroclerosis was admitted to our hospital because of blisters and ulceration on his whole body for two weeks. He had had BP and been treated with 60 mg of prednisolone. Twenty-nine days after the admission, peritoneal fluid became yellowish-brown and proteinuria was suspected from the elevation of inflammatory markers. Although the cell count of peritoneal fluid was within the normal range, multineuclear, frosted glass-formed cells were detected in PD fluid, which indicated HSV pritisons. Serum HSV-DNA elevated to 6x10^6 copies and he was diagnosed as disseminated HSV infection. After 200 mg of Ayclovir daily was administered, he had a severe disturbance of consciousness. Although differential diagnosis between acyclovir encephalopathy and HSV encephalitis was difficult, the results of spinal fluid tap and head MRI concluded acyclovir encephalopathy. Introduction of hemodialysis recovered his consciousness. HSV-DNA was decreased, although he developed multiple complications of hemophagocytic syndrome, bacterial infection and invasive pulmonary aspergillus, and died 56 days after hospitalization.

Discussion: We experienced a rare case of disseminated HSV infection and PD-related HSV peritonitis. The combination of ESRD, hypogammaglobulinemia, and BP contributed to the severe immune-compromised state and disseminated HSV infection. Since an early diagnosis determines the prognosis of disseminated HSV infection, cell pathology in peritoneal fluid would assist preemptive therapy.

SA-PO022
Use of Rituximab in Goodpasture’s Disease with Pulmonary Hemorrhage
Shenk, Wooin Ahn, Sumit Mohan.
Nephrology, New York Presbyterian-Columbia Univ Medical Center, New York, NY.
Introduction: Goodpasture’s syndrome (GPS) is a rare autoimmune disease, where pathogenic autoantibodies deposit in the basement membrane. It presents with rapidly progressive glomerulonephritis, with or without pulmonary hemorrhage. The current standard treatment of Anti-GBM disease is immunosuppressive therapy to reduce antibody production and plasmapheresis to remove existing antibodies in circulation. Rituximab, a monoclonal antibody directed against CD-20 antigen present on B-lymphocytes, approved for various B-cell lymphoproliferative diseases has been used in ANCA associated vasculitis with success; however it’s use in anti-GBM disease is scarce and data regarding safety and efficacy is lacking. We report use of Rituximab in the treatment of GPS with pulmonary hemorrhage.
Case Description: A 35-year-old man presented in 2012 with two week history of nausea, vomiting, intermittent fevers and dark urine. Laboratory findings were creatinine 18 mg/dL, potassium 6.1 mmol/L, Hgb 11.6 g/dL, and platelet count 288 x 10^9/L. Urinalysis showed nephrine urinary sediment. Serology test including ANCA was negative. Anti-GBM antibodies levels were greater than 8 with peak 27. CT chest with pulmonary angiogram was normal with no evidence of pulmonary hemorrhage. Renal biopsies were consistent with GPS (cresceni GN linear anti-GBM on IF). Plasmapheresis was initiated and patient received four doses of Rituximab. Anti-GBM level on discharge from hospital was 2.9. Since initial presentation, patient had two admissions to the hospital in 2014 and 2015 with undetectable Anti-GBM levels.
Discussion: Patients with anti-GBM renal disease have high mortality, especially when pulmonary involvement is present. The use of steroid, immunosuppresives and plasmapheresis alone or in combination has led to a significant improvement of both patient survival and clinical symptoms. Anti-GBM disease is a rare disease in which data regarding the safety and efficacy of alternative therapies are lacking. There are few reported cases of anti-GBM disease treated with rituximab. We present a case of anti-GBM disease with pulmonary hemorrhage successfully treated with Rituximab.

SA-PO023
A Rare Case of Aluminum Toxicity
Khurram Saleem, Khaleed Boobes, Yazen M. Alia, Muhammad H. Hasan, Jennifer A. Tuazon.
Nephrology, Northwestern Memorial Hospital, Chicago, IL.
Introduction: Aluminum toxicity was initially described in enchephalopathics patients with renal failure, overdosing of aluminum-based phosphate binders and attributed to contamination of water used for dialysis treatments. Use of alum for irrigation of the peritoneum for treatment of refractory hemorrhagic cystitis was first reported in 1982. It was described as a safer alternative to formalin bladder irrigation. We report a case of bladder perforation after alum irrigation, leading to intra-peritoneal aluminum exposure. Our patient expired despite chelation and renal replacement therapy. Her serum aluminum concentration is the highest reported level to date.
Case Description: 67 year old female with cervical cancer, admitted for uroscopy, was noted to have hematuria and urinary retention. Her catheter was changed due to clot obstruction and bladder irrigated with saline. Following day continuous bladder irrigation was instituted for persistent hemuria. She underwent cystoscopy with fulguration for persistent hematuria secondary to radiation cystitis. Her CRI resumed with alum irrigant. Overnight, alum irrigant was placed on a pump for infusion. Hours later, patient transferred to ICU for hypotension. CT abdomen revealed free intraperitoneal air, large volume of new fluid, air around bladder suspicious for bladder perforation, and absence of contrast outside of the bowel. Bilateral puncetaneous nephrostomy performed for urinary diversion and to evacuate free fluid. Aluminum levels were drawn. Patient was intubated, placed on vasopressors. Had non-gap metabolic acidosis and worsening renal function, concerning for high-dose aluminum toxicity due to intra-abdominal bladder perforation in the setting of alum irrigation. Deferoxamine was started and CVVH for acidosis. However patient developed refractory shock, and expired. Shortly before her death, aluminum level resulted 163.7mcg/L (normal 0 to 20mcg/L). Subsequent levels peaked at 1455.2mcg/L.
Discussion: We report systemic absorption of alum-containing irrigant following bladder perforation. Large aluminum load to the peritoneum resulted in systemic toxicity, multi-organ failure and death. Chelation therapy and CVVH were inadequate. We report the highest serum aluminum level to date.

SA-PO024
Primary Glioblastoma Multiforme in a Renal Transplant Patient
Hernes Garcia-Sanchez, Arshad Ali, Stephen O. Pastan.
Nephrology, Emory Univ, Atlanta, GA.
Introduction: Glioblastoma multiforme is the most common and most aggressive malignant primary Brain tumor in humans, involving glial cells and accounting for 52% of all functional tissue brain tumor cases and 20% of all intracranial tumors. Incidence of 2.3 per 100,000 population. The principal risk factor for primary brain glioblastoma multiforme is non-Hodgkin lymphoma while gliomas are rarely described.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only. Underline represents presenting author.

Erythematous Skin Rash and Gastrointestinal Bleeding as Presenting Features of ANCA Negative Pauic-Immune Glomerulonephritis

Introduction:

Pauic-immune glomerulonephritis (PGN) is one of the common causes of RPGN. In most patients with PGN, circulating antineutrophil cytoplasmic autoantibody (ANCA) is present, however 10% of the patients are ANCA-negative. Usually extra renal manifestations in ANCA-negative PGN are rare, but the case reported here is a rare manifestation having skin rash and gastrointestinal (GI) manifestations.

Case Description:

A 50-year-old female was admitted with low-grade intermittent fever, erythematous maculopapular rash all over the body and asymptmetrical arthralgia involving large and small joints for about 3 months. She had one week history of pain abdomen and melena followed by decreased urine output and generalized edema. On examination BP 156/94 mmHg, Birmingham Vasculitis Activity Score of 23/63. Investigations: Hb 9.9 g/dL, serum creatinine 4.0 mg/dL, urinalysis – protein ++, RBC 2-3/hpf, 24 hour urine protein 4.75gm/day. Serum uric acid and C3 were normal. Serum ANA, pANCA, cANCA, and RFA factor were negative. Skin biopsy for IgG, IgM, IgA, C3, C4c was negative. USG showed normal sized kidneys. Renal biopsy: Light microscopy showed segmental fibrinoid necrosis and early cellular crescents with mild increase in cellularity of mesangial matrix. Immunofluorescence: IgG, IgM, IgA, C3, C1q, kappa and lambda chains were negative. Diagnosis of ANCA negative pauic-immune GN with crescents was made and patient was started on systemic steroids and cyclophosphamide pulse therapy. Patient improved symptomatically and creatinine levels gradually declined.

Discussion:

Patients with ANCA negative PGN rarely present with skin and GI manifestations. In a study done in China comparing clinical features of ANCA negative patients only 7% were found to have GI manifestations and 17.9% had skin rash. These patients were treated similarly to ANCA-positive patients, although no study has focused on having skin rash and gastrointestinal (GI) manifestations.

SA-PO033

A Case of ANCA-Associated Nephritis Mainly Localized to the TubuloInterstitial Area, Successfully Treated by Steroid Therapy

Tomomi Nakajima, Yosuke Nakagawa, Takuya Isegawa, Masahiro Koizumi, Masafumi Fukagawa. Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.

Introduction:

The typical pathological findings of antineutrophil cytoplasmic antibody (ANCA)-associated nephritis consist of extracapillary proliferation and necrotizing crescent formation. Nevertheless, a few cases of ANCA-associated nephritis, in which the tubulo-interstitial area was mainly affected, are reported. Here, we present such a case of ANCA-associated tubulo-interstitial nephritis, and review its characteristics compared to ANCA-associated glomerulonephritis.

Case Description:

A 74 year-old generally healthy female developed bilateral hearing loss, and thereafter suffered from persistent fever. With a diagnosis of bacterial pneumonia, she was admitted to another hospital and treated with several broad-spectrum antibiotics without improvement. Four weeks later, she was referred to our hospital. On admission, weight loss and peripheral numbness and weakness was noted in addition to advanced hearing loss and fever. Serum creatinine level was elevated to 3.5 mg/dL, while urinalysis revealed mild proteinuria with few red blood cells and no cast in the sediment. Sinusitis and alveolar hemorrhage were observed by CT scan. Immunological tests demonstrated positive myeloperoxidase (MPO)-ANCA (104 U/ml). In view of multiple organ involvements, ANCA biopsy, thoracic vasculitis was suspected. Renal biopsy showed diffuse interstitial infiltrates and remarkable vasculitis in small arteries and capillaries with only a small number of crescentic glomeruli, which was consistent with ANCA-associated tubulointerstitial nephritis. Steroid therapyameliorated not only kidney dysfunction, but also hearing loss.

HCV-Related Cryoglobulinemic Glomerulonephritis and B Cell Lymphoma: Early Antiviral Therapy Crucial

Introduction:

Untreated chronic Hepatitis C Virus (HCV) infection often leads to a spectrum of severe extra hepatic manifestations related to B cell dysregulation, which include cryoglobulinemia, renal diseases, and lymphoproliferative disorders.

Case Description:

A 58 year-old Caucasian man with history of hypertension, recent ve chronic HCV infection was hospitalized for several weeks with severe extra hepatic manifestations related to B cell dysregulation, which include cryoglobulinemia, renal diseases, and lymphoproliferative disorders.

Type I membranoproliferative glomerulonephritis (MPGN) associated with type II mixed cryoglobulinemia is the most common HCV related kidney disease, with membranoproliferative glomerulonephritis being less frequent.

Case Description:

A 58 year-old Caucasian man with history of hypertension, recent ve chronic HCV infection was hospitalized for several weeks with severe extra hepatic manifestations related to B cell dysregulation, which include cryoglobulinemia, renal diseases, and lymphoproliferative disorders.

Type I membranoproliferative glomerulonephritis (MPGN) associated with type II mixed cryoglobulinemia is the most common HCV related kidney disease, with membranoproliferative glomerulonephritis being less frequent.

dose steroids, plasma exchanges, and a second dose of Rituximab, with clinical and renal improvement. One month after discharge, he was re-admitted with ARDS and diagnosed with B-cell lymphoma.

**Discussion:** There is a paucity of data on anti-HCV therapy in patients with renal failure often resulting in a delay of antiviral therapy. Immunomodulatory therapies may provide transient improvement of symptoms but bear the risk of significant adverse reactions. Early initiation of antiviral therapy is vital in order to prevent spectrum of HCV-related complications.

**SA-PO034**

**A Case of Membranous Nephropathy with an Adjacent Smooth Muscle Cell Tumor**  
Laith Al-Ababdi,1 Cathy J. Byrne-Dugan,2 Stanley D. Crittenden,1 Helmut G. Renkse,1 Laurence H. Beck,1 Boston Medical Center; 2Brigham and Women’s Hospital.

**Introduction:** Different stromal tumors can occur in the kidney and potentially skew the true extent of parenchymal injury induced by different glomerular diseases. Most of these stromal tumors are benign. The value of renal biopsy in assessing interstitial sequelae may be compromised by the mass effect of the infiltrating tumor cells.

**Case Description:** We describe a case of a 65 year old male patient, with a history of primary membranous nephropathy 20 years ago. He had initially been treated with the Pontocell protocol with favorable response. He continued to be in remission until a few months prior to presentation when he developed anasarca. His 24 hour urine collection revealed 8 grams of protein, and creatinine was 1.8 mg/dl. The decision was made for the patient to undergo a kidney biopsy which confirmed recurrence of primary membranous nephropathy with positive staining for PLAC2. It also revealed advanced chronic changes that included focal global glomerulosclerosis (87%) in addition to interstitial fibrosis 80%. However, adjacent to this atrophic area, there was a tumor of spindle-shaped cells with smooth muscle characteristics. There was no atypia or mitosis and no clear capillary but the tumor cells appeared to infiltrate and surround the tubules and vasculature. This was labeled by the pathologist as a fragment of a smooth muscle cell tumor of undetermined malignant potential. The possibility of leiomyosarcoma could not be ruled out. MRI abdomen and pelvis did not show any evidence of extra renal involvement. The possibility of the parenchymal tissue being significantly influenced by its close proximity to the tumor prompted us to pursue another renal biopsy from the other kidney. Surprisingly, repeat biopsy showed only 15% of tubular atrophy and interstitial fibrosis. The patient was initiated on Rituximab and tolerated two courses of treatment. He achieved partial remission with UPCR less than 3 gram with stable Cr at 1.8 mg/dl.

**Discussion:** Coexistence of smooth muscle tumors and membranous nephropathy is rare. The extent of parenchymal involvement should be confirmed, with repeat biopsy, when there are concerns about tissue distortion by neighboring tumor.

**SA-PO035**

**Freezing Point: Sjögren’s Disease Leads to Cryoglobulin Induced Membranoproliferative Glomerulonephritis**  
Manuel A. Fernandez Palmer, Roberto L. Collazo-Maldonado. Nephrology, Methodist Dallas Medical Center; Dallas, TX.

**Introduction:** Sjögren’s disease is chronic autoimmune inflammatory disorder mainly affecting salivary and lacrimal glands but rarely it can present with systemic manifestations including kidney involvement. The kidney manifestations may include hypokalemic RTA, interstitial disease and rarely MPGN.

**Case Description:** This is a 30 year old woman with no medical history who arrived to ER complaining of a three day history of SOB and increasing edema on lower extremities. She denied toxic habits. Review of systems positive for lower extremity rash. She had no prior medical history. She was afebrile, with normal blood pressure of 120/80 mmHg, heart rate of 90/min, temperature of 38.3°C and respiratory rate of 25/min. Patient had no urine output. There is minimal swelling on the dorsum of right hand of the patient. When we detailed history about this finding, she remembered that she saw mice in her working place in the night shift. Peripheral blood smear showed large numbers of fragmented red blood cells. Disseminated intravascular coagulation panel was normal. Viral hepatitis markers and serology for anti-nuclear antibodies, anti-double stranded DNA, Anti-Smith, Anti-La, Anti-Ro, Anti-La, Anti-H, Anti-Ro/SSA, Anti-La/SSB, ANA, Rheumatoid factor, ANCA, Cryoglobulins were all negative. MRI abdomen and pelvis did not show any evidence of extra renal involvement. The possibility of the parenchymal tissue being significantly influenced by its close proximity to the tumor prompted us to pursue another renal biopsy from the other kidney. Surprisingly, repeat biopsy showed only 15% of tubular atrophy and interstitial fibrosis. The patient was initiated on Rituximab and tolerated two courses of treatment. He achieved partial remission with UPCR less than 3 gram with stable Cr at 1.8 mg/dl.

**Discussion:** Coexistence of smooth muscle tumors and membranous nephropathy is rare. The extent of parenchymal involvement should be confirmed, with repeat biopsy, when there are concerns about tissue distortion by neighboring tumor.

**SA-PO036**

**Postinfectious Glomerulonephritis Associated with Escherichia coli Infection Caused by Transurethral Prostatectomy**  
Eleni Cheloti, Alexia Papadakou, Evdokia Efthimiou, Ionnis Xatzis, Maria Tsiilivivou. Dept of Nephrology; General Hospital of Piraeus, Athens, Greece.

**Introduction:** Postinfectious glomerulonephritis (PIGN) is an immune-mediated glomerulonephritis (GN) caused by non-renal bacterial infection. In adults, PIGN is more common in immunocompromised patients, particularly diabetics. The major site of infection is the urinary tract. In terms of causative agents, Staphylococcus is the most common cause in elderly people, followed by Streptococcus. Gram-negative bacteria, including Escherichia coli, E. coli), are responsible for up to 70% of cases of adult PIGN and 5% of cases in the elderly. We report a patient with PIGN associated with E. coli infection caused by transurethral prostatectomy.

**Case Description:** A 76-year-old Caucasian man with a history of coronary artery disease and recent transurethral prostatectomy was admitted with complaint of fever, and urematic symptomatology that necessitated dialysis therapy. Blood and urinary cultures were positive for E. coli and radiographic examination confirmed a renal abscess. We report a patient with PIGN associated with E. coli infection caused by transurethral prostatectomy.

**Discussion:** In post-infectious glomerulonephritis (MGN) it is considered to be an immune-complex disease and patients are treated with prednisone in order to reduce the inflammatory mediator. The present case report describes a man with a history of transurethral prostatectomy and PIGN associated with E. coli infection. In the present case, neither the patient’s regular preoperative medications nor the postoperative medications can be incriminated for the development of PIGN. However, in the present case, PIGN was associated with E. coli infection, which is a rare cause of PIGN. The patient was treated with five days of parenteral antibiotics (gentamicin and ceftriaxone) followed by three weeks of oral antibiotics (trimethoprim-sulfamethoxazole) and prednisone 40 mg once a day. After 3 weeks of therapy, the patient achieved complete remission of proteinuria, decreased renal size, and stabilization of serum creatinine level. The patient was discharged to home on prednisone 10 mg daily. At 6 months follow-up, the patient was in complete remission with normal renal function.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**  
Underline represents presenting author.  
632A
proteinuria, making it possible to decrease dosage of the other immunosuppressants and gradually stop them, even the GCS. Patient is now in complete remission after 2 years of treatment with no signs of relapse after stopping additional medication. 

Discussion: Belimumab is indicated in treatment of seropositive active SLE in addition to standard therapy, when lack of clinical improvement despite optimal standard therapy. Two large, phase 3, multicenter, prospective, randomized, controlled trials (BLISS-52 and BLISS-76) compared belimumab with placebo in patients with SLE who were receiving standard therapies. Both studies showed significant improvement in SRI (Systemic Lupus Erythematos Responder Index) with 10 mg/kg of belimumab as compared with placebo. A phase 3 study (BLISS-LN) is recruiting patients with lupus nephritis since these post-hoc analysis of the BLISS trials suggest that belimumab may offer renal benefit in patients with SLE. The treatment is so far not recommended in these cases. We can conclude that our case shows excellent results of belimumab in lupus nephritis with persistent nephrotic range proteinuria under conventional treatment. Alternatives are scarce and mostly limited due to toxic effects and by failure to control disease.

SA-PO039

Overlap Syndrome or Drug Reaction? Varun Gaur, Michael T. Eadon, Jesus H. Dominguez. Medicine, Indiana Univ, Indianapolis, IN.

Introduction: The overlap of ANCA-Associated Vasculitis (AAV) with other autoimmune diseases is well known. However, the association of AAV with the use of TNF-α antagonists in Rheumatoid Arthritis (RA) patients is less understood.

Case Description: A 44 y/o white female with RA had prior treatment with methotrexate (3 yr), adalimumab (2 yr) and etanercept (2 yr). She concluded all DMARD therapy 3 yr prior to presentation (PTP), and then her RA flared 5 months PTP. After initiation of leflunamide and steroids, she had partial resolution. Two weeks PTP, she received golimumab for onset of severe neurological manifestations including right foot drop, distal extremity numbness, and a right 4th digit ischemic lesion. Upon presentation, she was admitted with persistence of these symptoms. Her serum creatinine increased from 0.9 (mg/dl) to 1.4 with 2 gm proteinuria. Her urinalysis had hematuria and serology was positive for PR3-positive cANCA. Her renal function deteriorated with a peak creatinine of 6.7, necessitating intermittent dialysis. A biopsy revealed pauci-immune diffuse necrotizing and crescentic glomerulonephritis consistent with AAV. She received pulse solumedrol, cytoxan, and plasma exchange. Her neurological symptoms improved after a month of therapy. After 6 weeks, she did not require dialysis and her serum creatinine was 2.4.

Discussion: We present a case of a patient previously treated with TNF-α inhibitors who then developed PR3-positive AAV years later. An association between AAV and RA has been described and RA may precede AAV by up to 8 years. Different theories explain this association. One reason may be the common genetic predispositions to autoimmunity, involving HLA or PTPN22 genes, reported in a series of both RA and AAV. Second theory suggests TNF antagonists may predispose one to develop secondary autoimmunity. In our case, the patient discontinued DMARDs 3 yr PTP, although had recently received Leflunamide and Golimumab. There are no reports that associate leflunamide use with AAV and only one case report suggests an association of golimumab with AAV. Our case highlights the need to further understand the importance of AAV in RA patients, and the potential role of TNF inhibitors on the development of AAV.

SA-PO040

Introduction: Silver is a transition metal element with a range of industrial and ornamental uses and is known to be toxic when ingested in significant amounts. Silver exposure causing argyria (skin deposition) and argyrosis (eye deposition) is well-recognised but the renal consequences of silver toxicity are poorly understood.

Case Description: A 47 year old woman with a T-cell lymphoma who refused conventional chemotherapy for 18 months but self-medicated with a remedy containing colloidal silver was admitted with acute dialysis-dependent kidney injury. The serum silver concentration was strikingly elevated at 127.1 nmol/l (reference value <2.8 nmol/l). Kidney biopsy demonstrated a pauci-immune crescentic glomerulonephritis and glomerular tufts with fine, dark, granular material scattered within the mesangium and along the glomerular basement membrane (GBM). Electron microscopy confirmed the presence of electrondense granules in the mesangium and along within the GBM.
The patient was treated with pulse IV methylprednisolone and Rituximab 375mg/m2 weekly for four doses. Three months following induction therapy, his creatinine improved from a peak of 3.6mg/dL to 1.4 mg/dL. His CT findings and hematuria resolved. His PR3-ANCA slowly decreased and became negative 6 months after induction.

**Discussion:** This patient’s presentation with lung nodules on chest CT, necrotizing crescentic GN, and a high serum level of PR3-ANCA support a diagnosis of Granulomatosis with Polyangiitis with a strong temporal relationship to vaccination against influenza. This is the 9th case of ANCA associated vasculitis following influenza vaccination reported in the literature. Clinicians should be aware of the possible association between systemic vasculitis and influenza vaccination.

**SA-PO047**

**C3 Glomerulonephritis Associated with Monoclonal Gammapathy**

**Aumyot Prongdong,1 Weeraporn Srisung,1 Mustafa G. Aly,2 Irfan Warraich,1 Faisal Jamal.1 Nephrology, Texas Tech Univ Health Sciences Center, Lubbock, TX;2Pathology, Texas Tech Univ Health Sciences Center, Lubbock, TX.**

**Introduction:** A case of C3 glomerulonephritis associated with monoclonal gammapathy responding effectively with immunosuppressive therapy.

**Case Description:** The patient is a 65 year-old Hispanic female who presented with lower extremity edema and dyspnea. She had acute kidney injury with nephritic urinary sediments. C3 and C4 were low. Hepatitis B & C profile, ANA, ANCA, anti-GBM and SLEP were within normal limits. There was a faint monoclonal band on the gamma region of a serum protein electrophoresis. Kidney biopsy revealed mesangial immune complex deposits.

**Discussion:** C3 glomerulonephritis is related to dysregulation of alternative pathway of complement (AP) that can be associated with monoclonal gammapathy. Treatment of underlying monoclonal gammapathy may be of benefit in such a situation. Genetic studies for dysregulation of AP might be helpful.

**SA-PO043**

**Late-Onset Fabry Disease with a R112H GLA Mutation and Mild Increase in Plasma Globotriaosylsphingosine**

**Akifumi Onishi,1 Reika Takemoto,2 Tsutomu Hiramasa,2 Hidetoshi Kagawa,2 Hiroki Maruyama,1 Ichiei Naria,3 Hitoshi Sugiyama,4 Jun Wada.1 Okayama Univ Graduate School, Okayama, Japan;2Himeji Red Cross Hospital, Himeji, Japan;3Nigata Univ Graduate School, Niigata, Japan.**

**Introduction:** Fabry disease (FD), a lysosomal storage disorder caused by α-galactosidase A (GLA) gene variants, has a heterogeneous phenotype. GLA variants can lead to a late-onset and non-classical phenotype. We herein describe a 42-year-old Japanese male with FD diagnosed by a renal biopsy exhibiting a R112H GLA mutation and a mild increase in plasma globotriaosylsphingosine (Lyso-Gb3).

**Case Description:** A 42-year-old Japanese male was referred to our hospital due to proteinuria. He had never experienced neuropathic pain, cutaneous angiokeratomas, or hypohidrosis. He had no family history of FD. At 32 years of age, positivity for urinary proteinuria. He had never experienced neuropathic pain, cutaneous angiokeratomas, or hypohidrosis. He had no family history of FD. At 32 years of age, positivity for urinary protein. Kidney biopsy showed global proliferative changes along with splitting of glomerular basement membrane. C3 deposits were seen on immunofluorescence. No reactivity was seen for IgA, IgG, IgM, C1q, C4, fibrinogen and albumin. Electron microscopy showed subendothelial and mesangial immune complex deposits.

**Diagnosis** was determined as C3 glomerulonephritis associated with monoclonal gammapathy. Patient was successfully treated with pulse glucocorticoids followed by oral glucocorticoids and mycophenolate mofetil. C5b-9 was elevated whereas factor H, C3 nephrin factor, and factor B were within normal limits.

**Discussion:** C3 glomerulonephritis is related to dysregulation of alternative pathway of complement (AP) that can be associated with monoclonal gammapathy. Treatment of underlying monoclonal gammapathy may be of benefit in such a situation. Genetic studies for dysregulation of AP might be helpful.

**SA-PO045**

**A Unique Case of Granulomatous Acute Interstitial Nephritis from Ipilimumab**

**Kenneth Ralfo,1 Seymour Rosen,2 Melanie P. Hoenig,1 Nephrology, Beth Israel Deaconess Medical Center, Boston, MA;2Pathology, Beth Israel Deaconess Medical Center, Boston, MA.**

**Introduction:** Ipilimumab is a CTLA-4 inhibitor which is used for the treatment of melanoma. We report a case of granulomatous interstitial nephritis due to ipilimumab, which developed after the first dose and featured a prominent component of granulomatous vasculitis.

**Case Description:** A 70 year old man with stage IV melanoma presented with low grade fevers and malaise. He was found to have acute kidney injury with a creatinine of 6.0 mg/dL. Two months earlier, he had received a single dose of ipilimumab at which time his creatinine was 0.9 mg/dL. Laboratory data was notable for the absence of eosinophilia. Urinalysis showed 5-10 WBCs/hpf and many hyaline casts. A renal biopsy showed granulomatous interstitial nephritis with a component of granulomatous vasculitis (figure: H&E, Masson trichrome). He was treated with high-dose prednisone, which resulted in improvement of his renal function without the need for hemodialysis. After ten weeks of steroid therapy, his creatinine had decreased to 1.6 mg/dL.

**Discussion:** Ipilimumab is a potent activator of T cells and can interfere with the immune system’s tolerance of self-antigens. This drug is known to cause a variety of immune-related adverse events including hypophysitis, hepatitis, colitis and dermatitis. Interstitial nephritis is a rare diagnosis, but has been reported to occur after exposure to...
ipilimumab. Additionally, there have been reports of a sarcoïd-like type response involving the lung and skin. This injury pattern is typified by angiocentric non-necrotizing well formed granulomas. Steroid therapy is effective at treating these immune-related adverse events and does not appear to impair the antineoplastic effects of ipilimumab. With the increasing use of immune-modulating antibodies for treatment of malignancies, it is important to be aware of this potential complication.

SA-PO046
Severe Rhabdomyolysis Secondary to Adenovirus Infection Daniel Tevlin, Sharon E. Maynard.

Introduction: A 38-year-old male presented to the ER with a 4-day history of weakness, subjective fever, and diffuse myalgias as well as recent left eye viral conjunctivitis. He noted dark urine and poor urinary output. On arrival to the ER his vitals were stable. He had full muscle strength and no neuro deficits. He was oliguric. His Sctr 5.04, CPK 1,149,533 despite volume resuscitation including bicarb-containing fluid. He required HD. Workup was positive for adenovirus. Muscle biopsy was deferred in setting of known cause. He required 4 weeks of HD and was able to come off with impaired GFR of 67.

Case Description: A 38-year-old AA male presented to the ER with a 4-day history of weakness, subjective fever, and diffuse myalgias as well as recent left eye viral conjunctivitis. He noted dark urine and poor urinary output. On arrival to the ER his vitals were stable. He had full muscle strength and no neuro deficits. He was oliguric. His Sctr 5.04, CPK 1,149,533 despite volume resuscitation including bicarb-containing fluid. He required HD. Workup was positive for adenovirus. Muscle biopsy was deferred in setting of known cause. He required 4 weeks of HD and was able to come off with impaired GFR of 67.

Discussion: Two cases of rhabdomyolysis from adenovirus have been reported. Most commonly manifests as a febrile illness with pharyngitis. Management strategies have been adopted from studies on crush injury victims. Early volume resuscitation is recommended to mitigate renal failure. Despite the theoretical benefits of bicarbonate-containing resuscitation fluids, no consensus exists. Adenoviral infection can lead to rhabdomyolysis with severe acute kidney injury. Respiratory viral panel should be included in workup of rhabdomyolysis when no other cause is evident. Treatment relies on supportive care, intravenous fluid resuscitation, and hemodialysis in cases of severe renal failure.

SA-PO047

Introduction: The anti CD20 monoclonal antibody Rituximab is an increasingly used therapy in modern medicine. It is associated with rare but potentially serious adverse events, notably Posterior Reversible Encephalopathy Syndrome (PRES), and Acute Respiratory Distress Syndrome (ARDS).

Case Description: A 60 year-old female was admitted with symptoms of peripheral oedema, arthralgia and muscle swelling. She was noted to have a widespread vasculitic rash, nephrotic range proteinuria and new acute kidney injury. Renal biopsy demonstrated mesangio-occlusive glomerulonephritis with multifocal extraglomerular necrotising vasculitis, in keeping with cryoglobulinemia. She was commenced on plasma exchange, prednisolone and Rituximab. 2 days after the initial dose of Rituximab she developed acute respiratory distress and was found to be in florid pulmonary oedema. This was managed with ultrafiltration, furosemide and oxygen therapy. She received a second dose of Rituximab 1 week later, and rapidly developed tonic-clonic seizures,a further episode of flash pulmonary oedema, encephalopathy and hyperreflexia. MRI brain revealed subcortical white matter high T2 and FLAIR signal in the occipital and posterior parietal lobes consistent with PRES.

Rituximab was reintroduced in half of the cases. Mean recovery time was 4 days, and an additional risk factor was present in 5 cases. The occurrence of ARDS in association with rituximab is rare, only 3 confirmed cases exist . ARDS may occur as a delayed reaction.

SA-PO048
Atypical Hemolytic Uremic Syndrome Associated with Rituximab Kristina Angela Rathmell, Shilpa Gadde.

Introduction: Hemolytic uremic syndrome (HUS) is classified as a thrombotic microangiopathies (TMA). Atypical HUS (aHUS) occurs in 0.5 to 2 per million population per year, 50% progress to end-stage renal disease (ESRD), and 25% may die in the acute phase. Atypical HUS is linked to uncontrolled activation of the complement system. A variety of genetic abnormalities of the alternative pathway of complement have been described in aHUS, occurring in 60% of cases. aHUS is diagnosis when toxin producing bacterial infections, ADAMTS13 deficiency, and systemic-associated diseases are all excluded.

Case Description: A 57 year-old woman with a history of dermatomyositis and associated interstitial lung disease (ILD) was being treated for her ILD with Rituximab. She presented with altered mental status, shortness of breath, and fatigue after receiving an infusion of Rituximab. She was noted on physical exam to have peripheral oedema and cardiac rales on lung exam. On laboratory evaluation, her creatinine level was 4.0 (baseline 1), hemoglobin 7, and platelets 20 with schistocytes on peripheral smear and a low C3 and C4. ADAMTS13 showed normal activity. She was initially treated with high dose steroids and plasmapheresis. She was started on Eculizumab. She required hemodialysis. Renal biopsy showed thrombi consistent with thrombotic microangiopathy as well as mild acute tubular necrosis. She is still hemodialysis dependent.

SA-PO049
Acute Renal Failure Associated with Parenchymal Involvement of Lambda-Restricted Neoplastic Plasma Cells Mark C. Siegert, Amanda K. Hall, Mazdak A. Khalighi, Josephine Abrahm. Div of Nephrology, Univ of Utah, Salt Lake City, UT.

Introduction: The pathogenesis of renal disease in multiple myeloma (MM) is diverse, but biopsy shows that cast nephropathy, light chain amyloidosis and monoclonal Ig deposition are the most common. Renal function often correlates to the degree of cellular injury, not the degree of cast burden, amyloidosis or light chain deposition and direct involvement by plasma cells is rare. We present a case of diffuse interstitial involvement by neoplastic plasma cells, contributing to renal failure.

Case Description: A 70-year-old male with MM presented with acute renal failure. He was diagnosed with IgG lambda myeloma 8 years prior but refused therapy until 7 months ago. He failed CyBorD (M-protein remained at 9g/dl) prior to starting Carfilzomib-Revimlud.
On day 8 of therapy he was admitted with a Cr of 3.4, acutely elevated from 1.7. He denied hematuria, oliguria, fevers, edema or NSAID use. Renal ultrasound was without obstruction. He underwent renal biopsy. Pathology revealed diffuse interstitial involvement by lambda-restricted neoplastic plasma cells and minimal cast nephropathy, but no significant interstitial fibrosis, tubular atrophy or monoclonal deposition disease. Congo red studies were negative for amyloid. There were no features of TMA. Chemotherapy was resumed.

Discussion: Kidney disease with MM is common but it is rare to see involvement of plasma cells in the renal parenchyma. Several review articles list renal parenchymal involvement of plasma cells as a cause of renal failure and, to our knowledge, one case report suggests the same. It is unknown the extent to which parenchymal involvement by plasma cells contributes to the pathogenesis of renal failure. To our knowledge, this is one of only several cases of renal failure that can be attributed to neoplastic plasma cell involvement.

SA-PO050

AL Amyloidosis with Rapidly Progressive Renal Failure and Massive Liver Involvement: A Case Report

Introduction: AL amyloidosis is a plasma cell disorder clinically dominated by organ organization of light chains, mainly in renal and cardiac tissues. Although hepatic disease is described, clinical manifestations are usually mild and frequently undetected. We report a severe case of AL amyloidosis with a massive hepatic involvement and rapidly progressive renal failure (RPRF).

Case Description: One month before coming to our attention, a 67 year old male was admitted to another institution for acute and scrotal edema. Past medical history included hypertension, previous hepatitis B virus infection and estimated daily alcohol intake of 60g. Renal function was normal (serum creatinine of SCr 0.7 mg/dL), while hepatic lysis indexes were moderately positive. A serum monoclonal component IgA kappa (0.21 g/dL) was detected and the bone marrow aspirate showed 10% plasma cell infiltration. Hepatic ultrasound showed hepatosplenomegaly and portal hypertension. Final diagnosis was compensated alcoholic liver disease. After discharged, nephrotic syndrome (NS) (albumin 2.4 g/dL, proteinuria 12 g/24h), RPRF (SCr 1.6 mg/dL) and cholestasis appeared (ALP 1359 IUL, GGT 462 IUL, AST-ALT normal). The patient was admitted to our institution and renal biopsy was performed revealing AL amyloidosis, with prominent IgA (++) and Kappa (++) mesangial deposits, coherently with the serology. The hepatic disease was rediscussed, and the liver biopsy revealed coarse deposits of amyloid as for the kidney. Other organs, heart, liver, lungs and bones were normal. Serum protein electrophoresis showed hypogammaglobulinemia. Echocardiogram revealed type II diastolic dysfunction. Renal biopsy showed nodular glomerulosclerosis. Investigation of haematological disease revealed serum kappa light chain band and urine Bence Jones kappa. Free kappa light chains, serum kappa/lambda ratio and serum Beta-2-microglobulin were elevated. Bone marrow biopsy and aspirate showed 10% monoclonal plasmacytosis. No lytic lesions or masses were detected. Immunofluorescence of the renal biopsy revealed linear staining for kappa light chains along the tubular basement membrane and scarcer in the glomeruly. Electron microscopy is underway. Multiple myeloma was diagnosed and started chemotherapy with Bortezomib. Although there was maintained remission of pulmonary hemorrhage she remained on dialysis.

Discussion: Light chain deposits disease (LCDD) should be considered in the differential diagnosis of PRS. Renal involvement is typical in LCDD with nodular glomerulosclerosis as the common pathologic finding. Pulmonary haemorrhage is unusual and might suggest coexistence of fibrillary glomerulonephritis.

SA-PO052

Acute Cadiorenal Syndrome as a Presenting Symptoms for Scleroderma

Renal Crisis

Introduction: Systemic scleroderma is known to have renal manifestations including scleroderma renal crisis. Acute decompensated heart failure was not described in the literature as the presenting symptom.

Case Description: 50 year-old female with benign past history was diagnosed with new acute decompensated diastolic heart failure and hypertension 160/89 and acute kidney injury with elevated serum creatinin (SCr) 2.6 mg/dL from normal kidney function 2 months prior. Right heart catheterization showed elevated right heart pressures. Endomyocardial biopsy showed small vessel vasculitis. Urinalysis was bland. Renal ultrasound was unremarkable. Renal artery Duplex showed high resistant signals with low velocity. Suspensive immunology screen showed elevated antinuclear antibodies >1:1280, elevated RNA Polymerase III >80 and normal C3 and C4. Renal biopsy showed changes consistent with systemic sclerosis; the glomeruli were ischemic in general and one was sclerosed, the arteriols were with marked walls thickening and swelling of the intima, some undergone occlusive changes with onion skinning of their walls, while others undergone focal fibrinoid necrosis, the tubules were with mild to moderate atrophy, the interstitium was diffusely scarred, with mild to moderate focal and scattered cellular of lymphocytes (biopsy). Retrospectively, the patient reported skin tightening noticed 6 months prior to admission. Blood pressure was controlled with nicardipine drip, captopril, diuretics and bosentan. SCr peaked up to 6.72 mg/dL but renal replacement therapy was avoided. She was discharged on bosentan, amlopidine and lisinopril. SCr improved to 1.78 mg/dL after 8 months.

Discussion: Scleroderma renal crisis can present as acute cardiorenal syndrome.
SA-PO053

Dent’s Disease: An X-Linked Tubulopathy

Sambhavi Krishnamoorthy, Tingting Li. Renal Div, Washington Univ in St. Louis, St. Louis, MO.

Introduction: Dent’s disease is an X-linked recessive disorder of the proximal tubule characterized by low-molecular weight proteinuria, hypercalcuria, nephrocalcinosis/ nephrolithiasis, and progressive renal failure. This disorder is caused by mutations in either the CLCN5 gene, or less commonly the OCR1L gene, leading to disruption of tubular endocytosis and the characteristic clinical findings.

Case Description: We describe an interesting case of a 24 year old Caucasian male with a longstanding history of excessive thirst and polyuria. He had no known history of renal disease. He denied history of urinary tract infections, nephrolithiasis, or NSAID use. Physical examination was unremarkable. Laboratory data showed a serum creatinine of 3.6. Hemoglobin A1c was normal. Urinalysis showed 2+ blood and 2+ protein. Urine osmolality was 277 mosm/kg. A 24 hour urine collection showed proteinuria of 1.7 g/day. ANA, ANCA, and hepatitis panel were all negative. Renal ultrasound showed multiple bilateral renal calculi and nephrocalcinosis. Further testing showed a daily urinary calcium excretion of 735 mg, phosphate 2150 mg and sodium 257 mg. His urine beta microglobulin level was significantly elevated at 29817 mcg/L. The presence of significant low molecular weight proteinuria, hypercalcuria, hyperphosphaturia, nephrocalcinosis/nephrolithiasis, hematuria/ subnephrotic proteinuria, and chronic kidney disease fulfilled criteria for the diagnosis of Dent’s disease. No obvious X-linked pattern had been noted in his family history. Further genetic testing is pending at this time. On initiating hydrochlorothiazide, urinary calcium excretion reduced by 50%. Polyuria, which we attributed to nephrogenic diabetes insipidus in the setting of nephrocalcinosis, also improved significantly with the thiazide.

Discussion: This case report highlights the importance of recognizing this rare X-linked tubulopathy when presenting in adulthood. Commercially available genetic testing can be utilized for supporting the diagnosis and for appropriate genetic counseling for family members. The treatment focuses on reducing urinary calcium excretion and formation of nephrocalcinosis/nephrolithiasis with the ultimate goal of slowing progression to end stage renal disease.

SA-PO054

Phlegmasia Cerulean Dolens: Complication of Femoral Vein Catheterization

Introduction: There are three manifestations of acute massive venous thrombosis and obstruction of the venous drainage of an extremity. They are phlegmasia alba dolens, phlegmasia cerulea dolens (PCD) and venous gangrene.

Case Description: We present a 55-year-old hypertensive, presented with pedal oedema and breathlessness. About a month ago, she fell down and had dislocation of left patella. She was treated with a plaster cast and immobilization for 3 weeks. Her serum creatinine was 8.8 mg/dL. She was initiated on hemodialysis via two single lumen catheters in the left forearm. She was started on heparin treatment but blebs increased and limb became blue. Below knee amputation of left leg was started but blebs increased and limb became blue. Below knee amputation of left lower limb was performed.

Discussion: The causative factor in phlegmasia is massive thrombosis and occlusion of the major venous channels. Perkin et al reported that in 10 percent of patients no cause is found. It is common in women between fifth and sixth decades of age. Swelling, pain and cyanosis are the triad of PCD. Amputation rates are 12-20%. In our patient the effect of immobilization is compounded by femoral vein catheterization. PCD after femoral vein catheterization for haemodialysis has not been reported yet.

Figure: The patient presented with a black ulcer on the second finger of her right hand. The ulcer completely healed 4 weeks later after paclitaxel-coated angioplasty balloon.

Given the concerns for steal syndrome, she was referred for a banding procedure. On physical exam, the graft had good thrill and bruits. Right radial artery pulse was very weak. A black ulcer was noticed on the 2nd finger of the right hand. Decreased sensation in the 1st, 2nd and 3rd fingers of the right hand. Fistulogram was performed which demonstrated occluded lesion in the proximal right radial artery, which was recanalized and angioplastied with 2mm, 3mm and 4mm balloon. However, at one-month clinic follow up, her ulcer only had minimal improvement. Repeat arteriogram showed moderate radial artery stenosis, which was angioplastied with 4mm paclitaxel coated angioplasty balloon. The ulcer healed completely 1 month later.

Discussion: Paclitaxel coated balloon was recently approved by FDA to treat PAD in the lower extremities. This case report showed upper extremity PAD can also be treated successfully with paclitaxel coated angioplasty balloon.

SA-PO055

Successful Treatment of Ischemic Hand Ulcer by Paclitaxel Coated Balloon

Jie Cui,1 Yongfeng Liu,2 Zubin Irani.1 1Nephrology, Massachusetts General Hospital, Boston, MA; 2Interventional Radiology, Chinese People’s Liberation Army General Hospital, Beijing, China; 3Div of Vascular Imaging and Intervention, Massachusetts General Hospital, Boston, MA, China.

Introduction: Hand ischemia is a common complication in end stage renal disease (ESRD) patients. Steal syndrome from dialysis access is the most common cause of ischemic hand, and is usually treated with banding procedure. However, exclusion of peripheral arterial disease (PAD) prior to banding is crucial.

Case Description: A 74 year-old women with history of ESRD due to diabetes mellitus on hemodialysis presented to access clinic for right hand ulcer. She had a right side brachiobasilic graft placement 3 years ago and has been dialyzed through this graft without any issues. However, 3 months prior to the presentation, she started to notice severe right hand pain, especially during dialysis treatment. Four weeks ago, she developed an ulcer in the 2nd finger of her right hand.

Minimal Change Disease Associated with Invasive Ductal Carcinoma of the Breast: A Case Report and Literature Review

Siddhesh R. Lotlikar,1 Julian D. Rose,2 Soumya Patnaik,2 Supakanya Wongrakpanich,2 Mary Carolina Rodriguez Ziccardi,2 Mark S. Morginstin,7 Rasib Raja,2 Eric J. Bloom.2 1Sidney Kimmel Medical College; 2Albert Einstein Medical Center, Philadelphia.

Introduction: A tenth of malignancies have been associated with nephrotic syndrome, the diagnosis of which may precede the detection of cancer. In an adult with Minimal Change Disease (MCD), paraneoplastic etiology should be explored. Here, we describe a rare case of MCD associated with breast cancer.

Case Description: Our patient is a 72-year-old Caucasian female who presented with bilateral lower extremity edema for 1 week. Home medications were notable for occasional Diclofenac use. Urinalysis on admission showed nephrotic-range proteinuria. MCD was suspected and confirmed on renal biopsy. CT ruled out lymphoma and thymoma. MCD was presumed secondary to Diclofenac use and she was discharged on daily prednisone with instructions to avoid NSAIDs. Two months later, she presented with a pulmonary embolus and CT showed concerning breast changes. Biopsy confirmed a stage IIIc invasive ductal adenocarcinoma. She was tapered off steroids, continued on furosemide and started on Paclitaxel.

Discussion: Breast cancer mainly causes antibody-mediated paraneoplastic syndromes. Yet, studies have shown intratumoral IFN-a expression correlates with induction of autoreactive T-cells, presenting a route for breast cancer to cause a T-cell mediated process such as MCD. Our patient had no lymphoma or thymoma and the lack of evidence of AIN and failure of improvement on discontinuation of NSAIDs argue against NSAID-induced MCD. The relationship of MCD with breast carcinoma is reinforced by her improved proteinuria with chemotherapy.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

Introduction: Donor-derived infections are an unusual but recognized complication of solid organ transplantation. Between 2005-2011, there were 118 reported donor bacterial infections, of which 34 recipients had confirmed transmission of infection and 9 deaths due to donor derived bacterial infections. Herein, we describe a unique case of donor-derived enterococcal pyleonephritis in a kidney transplant recipient with HIV infection.

Case Description: 47 year old male with history of HIV infection (CD4 - 534 cells/mm³, VL<20 copies), ESRD on peritoneal dialysis, hypertension had deceased donor kidney transplantation. Post-op patient was given 1 dose of cefazolin as surgical prophylaxis. Basiliximab and intravenous immunoglobulin was used for induction therapy. Patient was started on tacrolimus, mycophenolate mofetil and prednisone for maintenance therapy. POD#3 we were notified by organ procurement organization (OPO) that donor urine had enterococcal pyelonephritis in a kidney transplant recipient with HIV infection.

Discussion: There is no clear consensus on treatment regimens for donor-derived infections. This case demonstrates transmission of donor-derived enterococcal infection despite timely initiation of appropriate antimicrobial therapy. Because of increased morbidity and mortality associated with post-transplant infection extended duration of antimicrobial therapy should be considered in these patients.

Introduction: Managning patients with end stage liver disease associated with portal hypertension, ascites and end-stage kidney disease using peritoneal dialysis therapy is challenging for a number of reasons including chronic hypotension, poor nutrition, coagulopathy, high infection rates, and encephalopathy. It is difficult to assess accurate dry weights because of the large variation patient weights depending on how much ascites they have at the time of dialysis, with weight fluctuations in excess of 10 kg. There is also a reluctance on the part of the transplant community to utilize PD because of the perception that these patients may not be able to go on to receive a successful liver transplant.

Case Description: Herein, we report our experience with 5 consecutive patients with decompensated cirrhosis who progressed to ESKD and required dialysis support. One patient did not tolerate HD and was switched to PD, the other 5 started with de novo PD. In each case, the patients were admitted to hospital for PD catheter placement with a surgeon experienced with patients who had advanced liver disease and stayed in the hospital for initial recovery period with IV albumin to support blood pressure. By our protocol, ascites fluid was drained in the OR and then drained each morning for the next 2 weeks before dialysis was initiated. Blood pressures ranged from 80/50-110/65 mmHg, patients remained asymptomatic. All patients received oral midodrine for BP support. Adequate ultrafiltration achieved and edema improved. Serum albumin was monitored at regular intervals, ranged from 2.5-3. One patient had peritonitis from time of surgery, which was treated successfully; no other cases of peritonitis were noted.

Focal Segmental Glomerulosclerosis Presenting Concurrently with Chromophobe Renal Cell Carcinoma Injun O. Owoyemi, Denise J. Thornton, Hiren J. Joshi, M.J. Barcheman. Nephrology, East Carolina Univ/Vidant Medical Center, Greenville, NC.

Introduction: Chromophobe renal cell carcinoma (CRCC) is a rare variant of RCC with distinct histochemical, ultrastructural and genetic characteristics. CRCC accounts for approximately 4% of all kidney neoplasms. Chromogloparaphyses are often diaged in patients with malignancies, particularly hematological cancers with membranous nephropathy being the most common variant. We present a case of resistant hypertension in a young adult male found to have focal glomerulosclerosis (FSGS) with concurrent CRCC. This case highlights the association and emphasis of screening for secondary hypertension in resistant patients, early referral and the pitfalls of percutaneous biopsy for solid renal masses.

Case Description: A 34 year old Nigerian male initially presented to the Internal Medicine clinic to establish care in 2011. His past medical history was significant for hypertension and gross hematuria. He was subsequently referred to Nephrology due to persistent microalbuminuria, hematuria and passage of blood clots in his urine. On presentation to Nephrology, he was found to have nephrotic range proteinuria. Renal ultrasound was significant for several lesions in the right kidney with the largest measuring 3 cm. Percutaneous renal biopsy performed for proteinuria revealed focal segmental glomerulosclerosis with moderate tubulointerstitial scarring. He was evaluated on steroids however he was lost to follow up for approximately 9 months. Upon return, his renal lesions were readdressed with an MRI of the abdomen which could not exclude multiple solid masses in the right kidney. A subsequent ultrasound-guided fine needle aspiration and core biopsy of the right kidney lesion diagnosed chromophobe renal cell carcinoma. He underwent a right nephrectomy with biopsy result negative for metastasis.

Discussion: We were able to unravel this unique finding of FSGS co-presenting with chromophobe renal cell carcinoma. The prevalence of FSGS in RCC has not been established with precision. This case highlights the importance of timely evaluation of secondary hypertension and biopsy of suspicious renal masses.

We performed biopsies of the structure. Surprisingly its histology looked like the normal peritenum. On the surface of the biopsy, a single layer of mesothelial cells was present. There are no apparent fibrosis (thickening) and sclerosis. This case suggests that his peritenum-like membrane might be the very early stage of sclerosing capsule of EPS. Since little has been known about transition from a normal state to EPS through pre-EPS state, this case is valuable to identify one part of the mechanisms of EPS. We report this rare case with some literature review.
**SA-PO061**

**Abdominal Compartment Syndrome: An Overlooked Culprit of Acute Kidney Injury in Immediate Post-Liver Transplantation**

Ekamol Tantisattamo, Praveen Ratansirmetha, Siwadon Pitukweerakul.
1. Nephrology, Northwestern University; 2. Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; 3. Presence St. Francis Hospital, Evaston.

**Introduction:** Acute kidney injury (AKI) is a common complication after liver transplantation and often times, dialysis is required. Abdominal compartment syndrome (ACS) is a treatable cause of prerenal AKI without dialysis needed.

**Case Description:** A 60-year-old man with HCV and alcoholic cirrhosis underwent an OLT. He had massive blood loss during the uncomplicated operation and required massive transfusion and fluid resuscitation. Postoperatively, renal function initially was stable at the baseline serum creatinine (Scr) of 0.8 mg/dL. However, hemoglobin dropped from 9.1 to 5.7 g/dL and tacrolimus level elevated up to 53 mg/L on postoperative day (POD) 4. Scr rose up to 1.3 mg/dL and urine output (UOP) decreased on POD 7. Renal function continued to decline with a peak BUN and Scr of 120 and 2.73 mg/dL on POD 14, respectively. Dialysis was initially planned. However, he had progressively increased ascites with markedly tense abdomen. Bladder pressure revealed intraabdominal hypertension (IAP) with the pressure of 20 mmHg. FE_K and FE_lum were 0.7% and 21%, respectively. Therefore, abdominal paracentesis was performed with an 8 L of yellowish clear ascitic fluid removed. UOP significantly increased shortly after paracentesis. Scr continued to rise and dialysis was not required.

**Discussion:** Our patient presented with prerenal AKI secondary to perioperative hypovolemia concomitant with supertherapeutic tacrolimus level. Massive blood transfusion and fluid resuscitation in the setting of major abdominal surgery caused IAH and subsequently ACS contributing to worsening prerenal AKI. Bladder pressure is a bedside diagnostic tool to detect IAH. AKI could be reversed and dialysis could be avoided by abdominal paracentesis.

**Figure 1: Clinical course during perioperative orthotopic liver transplantation.**

**Rasburicase: A Salvage Strategy to Prevent Renal Allograft Loss in Acute on Chronic Urate Nephropathy**

Ekamol Tantisattamo, Praveen Ratansirmetha, Siwadon Pitukweerakul.
1. Nephrology, Northwestern University; 2. Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand; 3. Presence St. Francis Hospital, Evaston.

**Introduction:** Chronic hyperuricemia can lead to chronic kidney disease (CKD) and acute on chronic hyperuricemia potentially causes renal failure. Rasburicase is an effective uric lowering agent indicated for the treatment of acute hyperuricemia especially in tumor lysis syndrome. We report a case of kidney transplant recipient with acute hyperuricemia-related acute kidney injury (AKI) which was resolved with rasburicase.

**Case Description:** A 51-year-old man with ESRD secondary to type 2 diabetes underwent a kidney transplantation and often times, dialysis is required. Abdominal compartment syndrome (ACS) is a treatable cause of prerenal AKI without dialysis needed.

**Case Description:** A 38-year-old female presented in 2013 with leg edema and two grams of proteinuria. Creatinine (Cr) was 1.3 mg/dL. Of note, her thyroid function tests were consistent with severe hypothyroidism, with a TSH of 129 IU/ml and thyroid peroxidase antibodies >900 IU/mL. Serologic workup for hepatitis B, C, and HIV and complements were negative. She had a history of Raynaud’s but did not fulfill clinical and immunological criteria for SLE. Kidney biopsy was consistent with immune complex MPGN with immunofluorescence positive for IgG and C3 only. Patient was non-compliant with thyroid replacement therapy and was lost to follow-up. She reappeared in 2015 with arthralgia, dyspnea, and leg edema. Her Cr was worsened to 1.7 mg/dL with 16 gram proteinuria. She was found to have a pericardial effusion. TSH was 174 IU/mL. Repeated testing for SLE was negative and a repeat renal biopsy demonstrated immune complex mediated MPGN with minimal staining for full house immunoglobulins. She was placed on thyroxine hormone and also initiated on mycophenolate mofetil, given that both her thyroid and renal disease appeared to be driven by an autoimmune antibody mediated process.

**Discussion:** HT, immune complex MPGN and clinical findings in our patient were initially thought to be due to SLE however patient failed to fulfill any immunologic criteria for SLE. HT is rarely associated with MPGN and specific mechanisms remain unclear. Proteinuria in glomerular disease associated with HT is not correlated with levels of thyroid hormone. Therefore, de-novo thyrotoxicosis and thyroid hormone mediated MPGN should be considered as a differential diagnosis.

**SA-PO064**

**Immune Complex MPGN Associated with Hashimoto’s Thyroiditis in a Young Female**

**Introduction:** Glomerular disease associated with Hashimoto’s Thyroiditis (HT) is a rare occurrence infrequently reported in the literature. We present a case of membranoproliferative glomerulonephritis (MPGN) that was thought initially to be due to systemic lupus erythematosus (SLE) in a young woman.

**Case Description:** A 38 year old female presented in 2013 with leg edema and two grams of proteinuria. Creatinine (Cr) was 1.3 mg/dL. Of note, her thyroid function tests were consistent with severe hypothyroidism, with a TSH of 129 IU/ml and thyroid peroxidase antibodies >900 IU/mL. Serologic workup for hepatitis B, C, and HIV and complements were negative. She had a history of Raynaud’s but did not fulfill clinical and immunological criteria for SLE. Kidney biopsy was consistent with immune complex MPGN with immunofluorescence positive for IgG and C3 only. Patient was non-compliant with thyroid replacement therapy and was lost to follow-up. She reappeared in 2015 with arthralgia, dyspnea, and leg edema. Her Cr was worsened to 1.7 mg/dL with 16 gram proteinuria. She was found to have a pericardial effusion. TSH was 174 IU/mL. Repeated testing for SLE was negative and a repeat renal biopsy demonstrated immune complex mediated MPGN with minimal staining for full house immunoglobulins. She was placed on thyroxine hormone and also initiated on mycophenolate mofetil, given that both her thyroid and renal disease appeared to be driven by an autoimmune antibody mediated process.

**Discussion:** HT, immune complex MPGN and clinical findings in our patient were initially thought to be due to SLE however patient failed to fulfill any immunologic criteria for SLE. HT is rarely associated with MPGN and specific mechanisms remain unclear. Proteinuria in glomerular disease associated with HT is not correlated with levels of thyroid hormone. Therefore, de-novo thyrotoxicosis and thyroid hormone mediated MPGN should be considered as a differential diagnosis.

**Hypervitaminosis D – A Rare Complication of PJP in a Transplant Patient**

Khaled Boobes, Khurram Saleem, Yazan M. Alia, Muhammad H. Hasan, Anescha A. Shetty, Mohammed Javed Ansari. Nephrology, Northwestern University/Northeastern Memorial Hospital, Chicago, IL.

**Introduction:** Pneumocystis jiroveci Pneumonia (PJP) is a known complication in immunocompromised hosts including transplant recipients, usually in the first six months of transplant. Hypercalcemia (HCa) is not a classic symptom of the disease. We present a case of a patient with simultaneous kidney and pancreas transplantation nineteen years ago who presented with PJP and developed HCa (highest value 14.8mg/dL [8.3-10.5] mg/dL. Parathyroid Hormone (PTH) was appropriately suppressed with a level of 6 [12-88] pg/ml. 1,25-(OH) vitamin D concentration was elevated (125 [18-72] pg/ml). After treatment with taurine and- sulfamethoxazole her Calcium concentration returned to normal along with PTH and 1,25-(OH) vitamin D. It is thought that, like other granulomatous disease-induced HCa, it is likely that endogenous extrarenal production of 1-alpha-hydroxylase by activated macrophages and by interferon-gamma involved in granuloma formation results in increased conversion from 25-(OH) vitamin D to 1,25-(OH) vitamin D and, consequently, in suppression of PTH secretion. Although only few cases of PJP-associated HCa have been reported to date, it is possible that this association is more frequent than previously thought. Hypercalcemia in transplant recipients with pulmonary symptoms must raise suspicion of PJP.
SA-PO066

A Rare Case of Tubulointerstitial Nephritis Associated with Primary Biliary Cirrhosis  Jatinder K. Holdi, 1 Jingyin Yan, 1 William F. Glass. 2 1Dept of Nephrology, Baylor College of Medicine, Houston, TX; 2Dept of Pathology, Univ of Texas Health Science Center, Houston, TX.

Introduction: Primary biliary cirrhosis (PBC) is a chronic autoimmune liver disease characterized by positive antimitochondrial antibodies (AMA), immune-mediated epithelial damage of small bile ducts, which leads to liver cirrhosis as the disease advances. In addition to liver injury, other autoimmune diseases, such as Sjögren’s syndrome and Raynaud’s syndrome, are reported in approximately 2-20% patients with PBC. However, the association of PBC and renal injury is rarely documented.

Case Description: Here we present a case of tubulointerstitial nephritis (TIN) in a patient with PBC. A 35-year-old female with past medical history of PBC developed sub-nephrotic range proteinuria and chronic kidney disease stage 3. A renal biopsy showed moderate to severe renal cortical and focal medullary tubulointerstitial inflammation with infiltration of lymphocytes, plasma cells and occasional eosinophils, as well as significant tubulitis.

The patient was treated with a short course of oral prednisone and her renal function improved.

Discussion: This case highlights a very rare cause of TIN and suggests that steroid therapy is effective in this setting.

SA-PO067

Plasma Exchange as Adjunctive Therapy for Crescentic IgA Nephropathy  Jicheng Li, Xinfang Xie, Fude Zhou, Minghui Zhao, Hong Zhang. Renal Div, Peking Univ Inst of Nephrology.

Introduction: Recent KDIGO guidelines recommend an aggressive immunosuppressive therapy in patients with crescentic IgA nephropathy (CreIgAN). While large cohort study from our center suggest that even with such a therapy, the 1- and 5-year renal survival rates remained low at 65% and 28%, respectively. Especially patients who present with serum creatinine (Scr)>580μmol/L hardly recovered from dialysis. In this study we aim to evaluate the efficacy of plasma exchange(PE) in severe CreIgAN.

Case Description: In this pilot study we give PE as adjunctive therapy to patients with severe CreIgAN on the back of high dose steroids and cyclophosphamide. Severe CreIgAN is defined as diffuse crescent forming with kidney failure that needs dialysis or presents with severe CreIgAN.

Overall ten patients with severe crescentic IgA nephropathy received PE from 2011 to 2015.

Y: yes, N: No

Among them 7 patients reached dialysis at presentation with serum creatinine (768±176mmol/L). Another 3 cases showed progressively kidney decline even after an aggressive immunosuppressive therapy. Patients received 5-10 PEs. After a mean 13 month follow-up, 4 of the 7 patients who had dialysis successfully recovered from dialysis. One of the 3 patients with persistent kidney progression showed serum creatinine decline.

Discussion: Plasma exchange as adjunctive therapy may achieve benefit for patients with severe crescentic IgAN.

SA-PO068

Introduction: Fibrillar glomerulonephritis (FGN) is characterized by nonbranching randomly arranged fibrils along the mesangium and glomerular capillary walls that do not stain for Congo red, have a diameter of 16-24 nm, and usually show polyclonal IgG, C3, and light chain deposition by immunofluorescence. Found in ≤ 1% of native renal biopsies, FGN is usually idiopathic, although some cases are associated with malignancy, monoclonal gammopathy, and autoimmune diseases. Association of FGN with demyelinating neuropathy has been rarely described.

Case Description: A 38-year-old Indian man with 3-year history of hypertension and 10-month history of end stage renal disease attributed to hypertension, presented to our institution with a 3-week history of progressive, bilateral lower extremity weakness. During his hospital stay, he was diagnosed with non-infectious pleural and pericardial effusions. Lab work revealed normal Anti nuclear antibody, anti double stranded DNA antibody, serum complements, anti nuclear cytoplasmic antibodies. Serologies for hepatitis and human immune deficiency virus were negative. Electromyography revealed demyelinating sensorimotor polyneuropathy. Chest, abdomen and pelvis imaging was unrevealing for malignancy. No monoclonal peaks on serum and urine electrophoresis or immunofluorescence. Fat pad biopsy negative for amyloid. Bone marrow biopsy showed 60% cellularity with tri lineage hematopoietic activity, no B cell clonality or T cell aberrance. He was started on high dose steroids with gradual improvements of weakness. Renal biopsy showed findings of chronic FGN with IgG4 dominant deposition. 44 of 48 glomeruli were globally sclerosed with 80% fibrosis and no activity. Sural nerve biopsy results are still pending.

Discussion: FGN is a rare and leads to ESRD in the majority of cases. There are very few cases describing FGN in association with demyelinating polyneuropathy without associated plasma cell dyscrasias. Although FGN renal prognosis remains poor, early identification is important as it may help identify an underlying malignancy or systemic autoimmune disorder with potential for treatment. FGN may be a precursor for future lymphoproliferative disorder.
SA-PO069
Acute Inflammatory Polyarthritis following Kidney Transplantation
Paul P. Maraj, Nephrology, Baylor College of Medicine, Houston, TX.

Introduction: An acute inflammatory polyarthritis develops one month after deceased donor kidney transplantation in a 54 year old male. He had no prior diagnosis of any form of arthritis, crystalline, inflammatory or otherwise. Following workup he was diagnosed with Rheumatoid arthritis and improved with an increased dose of steroids. To date there are no case reports which described this disorder precipitated by kidney transplantation. This case report describes this unique clinical scenario and the dilemmas with diagnosis.

Case Description: 54 year old man with a medical history of end stage renal disease secondary to hypertensive nephrosclerosis who underwent deceased donor kidney transplant one month prior and was admitted for joint pains. During kidney transplantation he had induction with thymoglobulin, plasmapheresis and rituximab as per institutional protocol for positive DSA. Maintenance immunotherapy consisted of tacrolimus, mycophenolate mofetil and prednisone taper dose. Following transplantation he was asymptomatic until one month after transplantation when he developed bilateral shoulder pains which then migrated to elbows and wrist; this was associated with significant morning stiffness and malaise. Xrays which were negative for bony abnormalities, MRI wrist revealed small to moderate joint effusion. Fluid analysis was negative for septic arthritis and crystals. Serum uric acid was within normal limits. Autoimmune workup negative including ANA, C3, C4. Rheumatoid factor was positive to titer 1:4, anti CCP was significantly positive at>250. He was treated with oral steroids which resulted in resolution of his symptoms.

Discussion: To date there have been no reports of rheumatoid arthritis in the immediate post-transplant period. There have been reports of an acute inflammatory syndrome related to mycophenolate use which improved on discontinuation, anti-CCP titers were unknown in these cases. Mycophenolate was continued in this patient and his symptoms did not recur after steroid taper making a reaction to mycophenolate less likely. Anti CCP is very specific for diagnosis of rheumatoid arthritis but its validity post transplant is unknown. The temporal relation with transplantation also raises the possibility of a drug induced reaction.

SA-PO070
IgM Nephropathy: A Neglected Pathology of Nephrotic Syndrome
Krysthla Z. Andujar, Carlos Antonio Cortes Sanchez, Hector R. Cordova, Medical Service, VA Caribbean Healthcare System, San Juan, PR.

Introduction: IgM nephropathy is defined by the presence of immunoglobulin M (IgM) as the dominant immunoglobulin in the mesangium of the glomeruli in a diffuse and global distribution. Clinically, a poor response to steroids distinguishes this disease from Minimal Change Disease.

Case Description: An 80-year-old man with past history of Hypertension, Alzheimer’s dementia, and benign prostatic hypertrophy complained of progressive shortness of breath associated with severe bilateral lower extremity edema and decreased urine output. Vital signs revealed blood pressure of 171/77mmHg. Lung auscultation was remarkable for bibasilar rales. The patient had anasarca. Laboratory tests showed serum creatinine at 2.2mg/dL (baseline of 1.2mg/dL), BUN of 36mg/dL and albumin of 2.2g/dL. Urinalysis showed microscopic hematuria and proteinuria (> 500mg/dL). Renal sonogram revealed normal kidney size without hydrenephrosis or nephrolithiasis. The 24-hour urinary protein excretion was 6.7gms/day. Serum creatinine rose to 7.7mg/dL a week later. Kidney biopsy was performed and steroid pulse therapy was started. Hemodialysis was initiated. Renal biopsy results showed mild increase in mesangial matrix and interstitial fibrosis. Sections stained for IgG, IgA, albumin C1q and kappa and lambda light chains were negative. Staining for IgM showed granular deposits in the mesangial areas compatible with a diagnosis of IgM Nephropathy. Hemodialysis was discontinued after two sessions since the patient had rapid recovery of kidney function after the 3 day steroid pulse therapy. Steroid therapy was tapered and eventually discontinued. Three months later, 24 hour urinary protein excretion was normal and the serum creatinine was 1.6mg/dL.

Discussion: Patients with IgM Nephropathy are less likely to respond to immunosuppressive agents. The presence of mesangial IgM deposits and interstitial fibrosis entails a worse prognosis. However, in our case, the patient had a prompt response to steroid therapy with resolution of the nephrotic syndrome and recovery of renal function.

SA-PO071
Renal Infarct from Traumatic Renal Artery Dissection
Eduardo J. Zouain, Ismael El Hachem, Germaine Z. Chan, Steven D. Smith, Nephrology Dept, Mt. Sinai St. Luke’s Hospital and Icahn School of Medicine at Mt. Sinai, New York, NY.

Introduction: Renal infarcts are characterized by acute onset of flank or generalized abdominal pain, nausea, vomiting, and occasionally fever and hypertension. Elevated WBC, CRP and LDH have also been associated. Renal artery dissection secondary to trauma is rare and has been associated with anatomical variations and acceleration/deceleration injury leading to intimal tearing. The two goals of treatment are organ preservation and improvement of renovascular hypertension. The treatment options include surgical reconstruction, endovascular repair, or conservative treatment. Our patient was initially placed on empiric anticoagulation with heparin. After hypercoagulable disorder, vasculitis, and embolic source was ruled out, anticoagulation was stopped. The patient was discharged on conservative treatment.

SA-PO072
Persistent Fever in a Patient with Wunderlich Syndrome
Marijeta Pezec, Kshitij Thakur, ’Dept of Medicine, Crozer Chester Medical Center, Upland, PA; ’Clinical Renal Associates, Crozer Chester Medical Center, Upland, PA.

Introduction: Wunderlich syndrome is spontaneous, nontraumatic renal hemorrhage confined to the subcapsular and periperal space. We present a case of a patient with a Wunderlich syndrome complicated by renal abscess.

Case Description: Patient was a 43 year old male who presented with nausea and generalized weakness, found to have sepsis secondary to urinary source. Ultrasound obtained during work up showed a old right perinephric hematoma. Patient continued to be febrile despite IV antibiotics. Repeat imaging with CT scan showed large abscess in place of the previously described subcapsular hematoma. Successful CT-guided drainage of the abscess led to marked improvement and resolution of fever.

Discussion: Wunderlich syndrome is secondary to neoplastic and non-neoplastic causes. It usually presents as mild flank pain, flank tenderness, or hematuria. Depending on blood loss, symptoms of hypovolemic shock may develop. Treatment varies according to severity, ranging from monitoring of the hematoma to nephrectomy. Our case is interesting since Wunderlich syndrome provided a nidus for infection and eventual abscess formation causing persistent fevers and flank pain with preserved hemodynamic stability. It demonstrated the need for CT imaging in order to fully appreciate the extent of the hemorrhage which in this case converted into an abscess. In the right clinical scenario, Wunderlich syndrome should be evaluated as a possible factor in infectious presentations.

SA-PO073
Gaucher’s Disease and Lupus, Two Diseases in the Same Scope?

Introduction: Gaucher’s disease is a rare inherited lysosome storage disease caused by genetic mutations that encodes for glucocerebrosidase enzyme. It’s deficiency leads to glucocerebroside (GC) accumulation in mononuclear macrophage system, including liver, spleen and bone marrow. Kidney involvement is usually rare. Systemic lupus erythematosus

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

641A
Underline represents presenting author.

Case Description: A 32-year-old woman with Gaucher’s disease diagnosed at 17 years old, having velaglucerase, presented several clinical clues suggesting SLE. Months later started presenting face and limbs edema and hypertension. She was admitted with microcytic and hypochromic anemia, 77000 platelets, creatinine serum levels of 1.38mg/dl and hypocalcemia. The urinalysis showed hematuria and proteinuria of 7628mg in the 24h urine collection. The patient had positive anti-nuclear antibodies, Anti-Sjogren’s syndrome related antigen, negative anti-double stranded DNA antibodies, anti-neutrophil cytoplasmic antibodies, viral serologies. Both complement levels were low. A kidney biopsy was performed.

It has been suggested that progressive accumulation of GC may trigger macrophage activation resulting in enhanced cytokine secretion and subsequent clonal B-cell expansion leading to chronic stimulation of the immune system. GC changes natural killer T cell function, a regulatory lymphocyte that has a role in infectious, neoplastic and inflammatory processes, therefore having a potential role in inducing other autoimmune disease. NKT lymphocytes are considered to be a link between innate and adaptive immune responses and were shown to have a role in a number of immune-mediated disorders. In an animal model of SLE, a selective reduction in NKT cells precedes the development of autoimmune phenomena.

Discussion: This case highlights a possible immunologic proximity between Gaucher’s disease and SLE, bringing up the already existing doubt that the defects in lipid metabolism, could contribute to the development of autoimmunity.

SA-PO074

Chronic Periaortitis, a Known Cause of Obstructive Uropathy
Margaret Daffy,1 Smita Mahendrakar,1 Mandeep Samra,1 Michael Yudd.2
1Nephrology, Rutgers-New Jersey Medical School, Newark, NJ; 2Nephrology, East Orange Veterans Administration Hospital, East Orange, NJ.

Case Description: A 59 year-old man with hypertension presented with one week of gradually decreasing urine output, nausea, generalized weakness, and vague dull left lower quadrant pain with radiation to the left flank. He was afibrile with blood pressure of 170/90 mmHg, pulse of 77 beats per minute, respiratory rate of 16 breaths per minute, and oxygen saturation of 98% on room air. His abdominal exam was unremarkable except for non-tender scrotal swelling bilaterally. Laboratory studies were notable for the following values: WBC 12.1 x 10^9/L, BUN 62mg/dL, SCr 13.8mg/dL (baseline SCr 1.1mg/dL), ESR 57mm/hr, CRP 67mg/dL, U/A clear, yellow, specific gravity 1.01, pH 6, moderate blood, negative protein, leukocyte esterase, or nitrites. A renal ultrasound showed moderate hydronephrosis with patent renal arteries and veins bilaterally. CT of the abdomen and pelvis revealed moderate bilateral hydronephrosis, an abdominal aortic aneurysm (3.6cm), and a retroperitoneal soft tissue mass measuring 2 cm in diameter with associated ureteral obstruction. There was no inguinal iliac lymphadenopathy or suggestion of discrete malignancy. Based on combined clinical and radiographic evidence the patient was diagnosed with chronic periaortitis and retroperitoneal fibrosis. He was started on mycophenolate mofetil and prednisone taper with complete resolution of symptoms within 6 months.

Discussion: Retroperitoneal fibrosis (RPF) is a relatively rare condition characterized by the presence of fibrosis and inflammation of the retroperitoneal tissues that often surrounds the ureters and other abdominal organs and can lead to renal failure in advanced cases. Our case demonstrates the importance of considering RPF as an etiology of flank pain and renal failure as medical treatment is effective in reversing obstructive uropathy.

SA-PO075

IgA Nephropathy in HIV Positive Patient with Acute Kidney Injury
Giovanna Y. Arteaga Müller,1 Lilía María Rizo Topete,1 Elisa María Guerrero González,1 Gabriela Alarcón-Galván,2 1Nephrology, Univ Hospital José E. González UANL, Monterrey, Mexico; 2Anatomic Pathology, Univ Hospital José E. González UANL, Monterrey, Mexico.

Introduction: Acute kidney injury is common in patients with HIV, being prerenal variant the predominant etiology. Among the intrinsic causes are thrombotic microangiopathy, the antiretroviral drugs associated and the immune complexes associated (3.5%-10%) being the collapsing focal segmental glomerulosclerosis the most frequently found.

Case Description: Male 41 year old, with use of cocaine, marijuana, benzodiazepines tattoos and high-risk sexual behavior, diagnosed with HIV nine years ago, treated with antiretrovirals which suspended two years ago. Begins 3 months before with malaria, a week prior to his admission presented progressive dyspnea on moderate to high stresses accompanied by productive cough and fever. Chest radiogram showed fine intestinal infiltrate, compatible with pneumocystis jiroveci, laboratories: HBv 4.9g/dl, creat 3.0 mg/dl, BUN 350 mg/dl, urine protein 4.7g/24 hrs, the urinalysis reported reddish urine, with granular casts, hematuria and pyuria. Hepatitis B, Hepatitis C, CMV and tuberculosis tests were all negative and the renal ultrasonography was normal. Renal biopsy revealed IgA nephropathy.

Direct immunofluorescence technique (400X).Mesangial granular staining (+) for IgA. Early treatment with anti-proteincuric general measures and prednisone improved renal function with a decreased in creatinine to 1.3mg/dl.

Discussion: The immune complexes associated nephropathy in patients with HIV is more common due to the start of antiretroviral therapy, however IgA nephropathy remains uncommon in this patients. In our patient the indication for renal biopsy was the erythrocyturia and the proteinuria in nephritic range. Early detection and treatment can prevent progression to ESRD.

SA-PO076

Ketorolac Induced Mesangiolysis: A Clinical Example of Anti-Thy 1.1

SA-PO077

IgA Nephropathy in HIV Positive Patient with Acute Kidney Injury
Gonzalez,1 Alarcón-Galván,1 Muller1,2
1Nephrology, Rutgers-New Jersey Medical School, Newark, NJ; 2Nephrology, Centro Hospitalar do Algarve, Faro, Portugal.

Introduction: NSAIDS are known cause of acute kidney injury, but do not usually cause glomerulonephritis. We share an unusual presentation of glomerulonephritis after only one dose of ketorolac. No renal biopsy findings in acute ketorolac-related acute kidney injury appear to have been published based on an Ovid literature search.

Case Description: This is a 42 year old male with past medical history of nephrolithiasis and urethral stricture, who presented to the hospital for a cystoscopy procedure. The patient had urinary obstruction after the procedure and developed oliguric acute kidney injury with serum creatinine of 3.1 mg/dl (baseline 0.8 mg/dl). Of note, the patient also received one dose of ketorolac during the procedure. Urinalysis showed 2+ blood with many red blood cells, and 9 grams of proteinuria as TP/creatinine ratio. Lab work demonstrated high LDH, low haptoglobin but stable hematocrit and platelet count. Peripheral smear did not reveal schistocytes. Urine microscopy showed RBC casts. Renal ultrasound showed normal sized kidneys with no hydronephrosis. Kidney biopsy revealed acute tubule-interstitial nephritis with tubular necrosis and mesangiolysis. Electron microscopy showed patent capillary loops with focal epithelial foot process effacement, visceral epithelial cells with cytoplasmic vacuolization, dilated capillaries with endothelial apoptosis and mesangial lysis. Glomerular basement membrane thickness was increased. There was evidence of acute tubular injury. No electron dense deposits, thrombosis or crescents were identified. Immunofluorescence of glomeruli was negative. The patient remained oliguric and required renal replacement for short term followed by full recovery of renal function.

Discussion: Renal toxicity of ketorolac has been described, and appears generally to be reversible, but could lead to glomerulonephritis in a rare setting. The pathological findings in the glomeruli resembled those described in experimental animals with Thy-1 induced glomerulonephritis treated with rofecoxib (COX-2 inhibitors). In this model, glomerular disease is initiated by immune-mediated mesangial cell damage, resulting in mesangiolysis.

SA-PO077

Disseminated Cytomegalovirus Disease in Induction Treatment with Mycophenolate Mofetil in a Lupus Nephritis Patient

Introduction: Mycophenolate mofetil (MMF) is an immunosuppressive agent that exerts relatively selective antiproliferative effects on T and B lymphocytes and is increasingly being associated with higher incidence of tissue-invasive cytomegalovirus (CMV) disease in transplant receivers and other immune-mediated diseases. The case presented is a patient who developed CMV enteritis while receiving MMF and corticosteroids for lupus nephritis (LN).

Case Description: 59 year-old man with LN class IV (Ga) + V under MMF (2.5g/day) and prednisolone (60mg/day) when started having weight loss, diarrhea, nausea, dysphagia and haematochezia. The blood count showed severe anemia and leucopenia. Comprehensive chemistry profile revealed Pcr 2.7mg/dl improving proteinuria from 11.7 to 2g/day and normal urinary sediment. CMV serology IgM came positive (PCR CMV: 834 copies/mL). Immunology tests were negative. Upper endoscopy and colonoscopy were performed. Biopsies showed CMV infection signs and esophageal candidiasis. MMF was tapered to 1g/day and prednisolone to 20mg/day. The patient was started on intravenous ganciclovir

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underlines represent presenting author.

462A
and fluconazole, with favorable clinical response. Proteinuria then worsened to 7.9g/day. Renal biopsy was repeated showing collapse of LN class V. Renal function improved PCR 1.6mg/dl having 2g MMF and prophylactic oral valganciclovir. CMV virus directly infects the bowel causing mucosal erosions or ulcerations. We can only find little evidence that CMV disease explains the gastrointestinal adverse event profile associated with MMF but we bring up again the hypothesis that high local concentrations of MMF have a direct toxic effect on cells of the small intestine, causing gastrointestinal upset. Associated with MMF but we bring up again the hypothesis that high local concentrations of MMF have a direct toxic effect on cells of the small intestine, causing gastrointestinal upset. Data on the incidence of CMV disease with the MMF induction protocol for LN are scarce.

Discussion: Similarly to transplant recipients receiving MMF, LN patients presenting gastrointestinal upset demand exclusion of CMV infection. This report highlights the importance of clinical follow-up of lupus patients with GI symptoms undergoing intense immunosuppression and accurate serological and histological diagnosis.

SA-PO078
Cryoglobulinemic Nephropathy with Successful Childbirth After Recurrent Episodes of Nephrotic Syndrome During Pregnancy Miho Karube, Shinya Kaname, Kazuhiro Fukuda, Hideki Shimizu, Yoshinori Komagata, Yoshihiro Arimura. The First Dept of Internal Medicine, Kyorin Univ School of Medicine, 6-20-2 Shinkawa Mitaka-city, Tokyo, Japan.

Introduction: It is unknown whether pregnancy affects clinical course of cryoglobulinemic nephropathy and how to treat pregnant patients complicated with it.

Case Description: A 35-year-old woman was admitted to our hospital because of massive proteinuria that developed during the third pregnancy. The previous two pregnancies had been terminated for similar episodes of nephrotic syndrome. No history of hypertension was observed, but during the course she presented cryoglobulinemia, a high titer of RF and low serum complement levels. The renal biopsy performed 10 days after the third termination revealed MGN-like lesions with lobulation in glomeruli, double contour of GBM, endotheliosis, and moderate mesangial cell proliferation. Immunofluorescence study showed IgG, IgA, IgM, C3, C4, and C1q all positive mainly along the glomerular capillaries, and subendothelial deposits were confirmed by EM, thus she was diagnosed as cryoglobulinemic nephropathy. Because the histological findings of repeated renal biopsies were not improved two months after the disappearance of proteinuria, treatment with 30 mg/day of PSL was started, followed by intravenous cyclophosphamide 6 times and plasma exchange, since she had a desire for baby. Finally at the fourth pregnancy, she bore a healthy baby weighing 2.342g on vaginal delivery at 36 weeks despite of recurrent appearance of nephrotic syndrome. After delivery, she was given 30 mg/day of PSL and proteinuria subsided.

Discussion: We experienced a rare case of type III cryoglobulinemic nephropathy that repeatedly developed nephrotic syndrome during pregnancy, but finally bore a baby after immunosuppressive therapy. Although the pathogenesis of pregnancy-induced exacerbation of cryoglobulinemic nephropathy was not clear in this patient, aggressive treatment may have been helpful for ameliorating it, leading to successful delivery.

Renal Recurrence of Acute Lymphatic Leukemia Anna Bertram, Jan H. Brasek, Ansgar Reising. 1Nephrology and Hypertensiology, Hannover Medical School, Hannover, Germany; 2Pathology, Hannover Medical School, Hannover, Germany.

Introduction: Renal complications of hematologic neoplasia can be therapy- or neoplasia-associated. We report a case of acute kidney injury (AKI) in the long term follow-up of a patient with acute lymphatic leukemia (ALL).

Case Description: The 42y old patient was diagnosed with ALL in 2009 and treated according to recommendations with chemotherapy and peripheral blood stem cell transplantation. In 2012, extramedullary ALL recurrence in his right knee was treated with irradiation. Starting from September 2014, molecular markers of minimal recurrence without evidence of lymphoblasts were found in bone marrow biopsies, and the patient received donor lymphocytes to induce graft vs. host reaction. In December 2014, ramipril was started for newly diagnosed hypertension, after which creatinine increased within several days to 290µmol/L. Because of this association, we suspected renal artery stenosis, toxic AKI, or acute interstitial nephritis. Ultrasound revealed diffusely swollen and dense kidneys (Fig.1A). Renal artery stenosis could be excluded, but - untypical for interstitial nephritis - segmental arteries seemed compressed. Kidney biopsy revealed ALL recurrence with extensive lymphoblast infiltration. DOTA-CXCR4-PET-CT confirmed diffuse infiltration of both kidneys (Fig.1B) without bone marrow affection. After starting chemotherapy, creatinine rapidly ameliorated. Ultrasound and PET-CT-controls 10 weeks after starting therapy confirmed good treatment response (Fig.1C-D).

SA-PO080
A Rare Cause of Acute Kidney Injury in Non-Renal Solid Organ Transplantation Sameer Gupta, Wasay Humayun, Ramapritya Sinnakruchanen, Liliana Osadchuk. Nephrology, Medical College of Wisconsin, Milwaukee, WI.

Introduction: Acute kidney injury (AKI) is a frequent complication of non-renal solid organ transplantation (SOT). Here we report a case of rapidly progressive renal failure leading to end stage renal disease (ESRD) due to acute oxalate nephropathy (AON) in a patient with non-renal SOT.

Case Description: A 63 year old female with past history of pulmonary fibrosis status post bilateral lung transplant, obesity status post Roux en Y gastric bypass (RYGB) surgery, and hypertension presented with worsening kidney function with BUN and creatinine of 55 mg/dl and 6.18 mg/dl respectively. She had normal kidney function with serum creatinine of 0.5mg/dl prior to transplant 8 months ago. Induction regimen included Basiliximab followed by tacrolimus, prednisone and mycophenolate (MMF) as maintenance therapy. Ensuing transplantation, she had multiple episodes of AKI attributed to calcineurin inhibitor (CNI) toxicity and hypovolemia from MMF and clostridium difficile associated diarrhea. Her average tacrolimus trough level was 12 ng/mL. Several urinalyses showed acute tubular necrosis casts. Renal ultrasound revealed bilateral echogenic small kidneys compared to normal kidney size prior to transplant. Her kidney biopsy unexpectedly revealed oxalate nephropathy. She is currently on hemodialysis.

Discussion: AON has been poorly described in patients with RYGB surgery and SOT. In our patient with prior RYGB, chronic diarrhea, and numerous antibiotics unulled AON. This superimposed with CNI toxicity resulted in rapid progression to ESRD. Antibiotic use depletes colonization of oxalate consuming bacteria (Oxalobacter formigenes). This combined with fatty acid malabsorption from prior RYGB increases colonic oxalate absorption resulting in hyperoxaluria. Diarrhea causes hypovolemia and metabolic acidosis leading to low urinary pH and hypocitraturia promoting calcium oxalate crystallization. Additional steps should be taken for SOT patients with RYGB, like diet modification, probiotic use, citrate supplementation, administration of fatty acid binding agents, and monitoring for hyperoxaluria. High suspicion for AON in patients with risk factors may lead to early diagnosis and treatment.

SA-PO081
Paraneoplastic Membranous Nephropathy and Myelodysplastic Syndrome – A Rare Combination Krishna K. R. Manoh, Madhuri Manne, Dagmar Klinger. Renal Medicine, Univ of Massachusetts Medical School, Worcester, MA.

Introduction: We report a case of Membranous Nephropathy (MN) seen in association with Myelodysplastic Syndrome (MDS). This occurrence is rare and only 3 cases have been reported in literature previously. Up to 5-20% of adults with MN have been reported to have most commonly a solid tumor and less frequently, a hematologic malignancy.

Case Description: Our patient is a 58 y/o man who has chronic kidney disease of unclear etiology with serum creatinine (SCr) of 1.3 and MDS. He was admitted with acute kidney injury in the setting of pneumonia and had nephritic range proteinuria along with dysmorphic red blood cells on the urinary sediment. Renal biopsy showed MN with relatively recent immune complex deposition. There was no colocalization of IgG4 membranous deposits with phospholipase A2 receptor. He was hospitalized again with pancytopenia, marked inflammatory markers and infectious complications. Although bone marrow biopsy was not diagnostic, this syndrome was diagnosed as hemophagocytic
lymphohistiocytosis by clinical criteria and therapy was initiated with high-dose steroids and etoposide. The patient's serum Cr peaked at 1.02 mg/dL and was gradually tapered to 5 mg over 1 month and he was discharged with sCr of 1.39 mg/dL. 5 days after the operation of fracture, he was referred to the nephrology clinic for evaluation of renal dysfunction.

**Case Description:** A 73-year-old male was admitted because of subtrochanteric fracture. On admission, he had normal kidney function with serum creatinine (Cr) level of 1.02 mg/dL. 5 days after the operation of fracture, he was referred to the nephrology department due to abruptly increased level of Cr. On postoperative day 10, despite adequate intravenous hydration, he became anuric and Cr rose to 4.40 mg/dL requiring hemodialysis. Serum C3 level was low (38mg/dL). Kidney biopsy revealed mesangiocapillary glomerulonephritis, duplication of the glomerular basement membranes, subendothelial deposits and predominant C3 immunofluorescent staining suggestive of MPGN type I. Secondary causes such as infection, autoimmune disease, monoclonal gammapathy, neoplasia, complement dysregulation were excluded. He was diagnosed as idiopathic MPGN type I and high dose steroid therapy (40mg/day of prednisolone) was started. After 17 days of therapy, urine output was increased and dialysis was discontinued accordingly. Prednisolone was gradually tapered to 5mg over 1 month and he was discharged with sCr of 1.39 mg/dL.

**Discussion:** The early trials of the treatment of idiopathic MPGN have given inconsistent results, and should be interpreted with great caution since many of the reports likely included cases of secondary MPGN. The clinical presentation of MPGN is variable, from benign and slowly progressive to rapidly progressive, and different therapeutic approaches should be applied in regard of the disease course. Studies are needed to identify the natural course and effective treatment of MPGN.

**SA-PO084**

**A Case of Advanced IgG4 Related Tubulointerstitial Nephritis Complicating Multiple Lymphadenopathy and Intrathoracic Nodule, Mimicking Malignant Lymphoma**

**Case Description:** A 56 year old Caucasian man with history of colon tubular adenoma, NHL - status post chemotherapy and radiation 30 years back, hypothyroidism presented with new-onset nephrotic-range proteinuria. He was not taking any medications and physical examination noted generalized edema. Laboratory exam noted elevated serum creatinine (1.5 mg/dL) and proteinuria (2.4 g/dL). Blood work up for autoimmune and neoplastic causes of membranous nephropathy was negative. Proteinuria worsened to 11 g/24h despite six months of conservative therapy with lisinopril and low protein diet. Additional labs obtained came back positive for PLA2R autoantibodies (IFA 1:1000, ELISA 976.6 RU/ml). Kidney stained positive for PLA2R glomerular deposits suggesting IMN. The patient was then treated with a modified Ponticelli protocol using alternating monthly prednisone and oral cyclophosphamide (2 mg/kg/d) for six months. After three months, proteinuria, albumin and edema improved.

**Discussion:** Relying on histopathologic differentiations to distinguish between idiopathic and secondary membranous nephropathy may lead to incorrect diagnosis and delay in treatment. The presence of circulating and tissue PLA2R autoantibodies may be more relevant to new-onset nephrotic-range proteinuria. It is unclear whether tissue anti-PLA2R antibodies are more specific in the diagnosis of IMN than serum antibodies. The clinical significance of the presence of circulating anti-PLA2R antibodies remains to be determined.

**SA-PO085**

**Presence of PLA-2R Autoantibodies in a Patient with Clinical and Histopathological Evidence Suggestive of Secondary Membranous Nephropathy**

**Case Description:** A 56 year old Caucasian man with history of colon tubular adenoma, NHL - status post chemotherapy and radiation 30 years back, hypothyroidism presented with new-onset nephrotic-range proteinuria. He was not taking any medications and physical examination noted generalized edema. Laboratory exam noted elevated serum creatinine (1.5 mg/dL) and proteinuria (2.4 g/dL). Blood work up for autoimmune and neoplastic causes of membranous nephropathy was negative. Proteinuria worsened to 11 g/24h despite six months of conservative therapy with lisinopril and low protein diet. Additional labs obtained came back positive for PLA2R autoantibodies (IFA 1:1000, ELISA 976.6 RU/ml). Kidney stained positive for PLA2R glomerular deposits suggesting IMN. The patient was then treated with a modified Ponticelli protocol using alternating monthly prednisone and oral cyclophosphamide (2 mg/kg/d) for six months. After three months, proteinuria, albumin and edema improved.

**Discussion:** Relying on histopathologic differentiations to distinguish between idiopathic and secondary membranous nephropathy may lead to incorrect diagnosis and delay in treatment. The presence of circulating and tissue PLA2R autoantibodies may be more relevant to new-onset nephrotic-range proteinuria. It is unclear whether tissue anti-PLA2R antibodies are more specific in the diagnosis of IMN than serum antibodies. The clinical significance of the presence of circulating anti-PLA2R antibodies remains to be determined.

Silent Malakoplakia in a Recipient of Kidney-Pancreas Transplant
Diagnosed on Surveillance Biopsy of Kidney Allograft: A Patient-Centered Approach to Treatment of Malakoplakia

Jin Shoji, Ravinder K. Walli; Dept of Kidney Disease and Hypertension, George Washington Univ, Washington, DC; Inova Transplant Center, Inova Fairfax Hospital, Falls Church, VA.

Introduction: Malakoplakia is an inflammatory disease leading to chronic morbidity and organ dysfunction. It was originally described in association with genitourinary tract infections with coliform bacteria and can manifest as acute pyelonephritis, acute or chronic renal failure, or renal mass. We present a case of a 40-year-old female recipient of simultaneous pancreas-kidney transplant who developed an acute rise in serum creatinine without apparent cause and found to have malakoplakia on kidney allograft biopsy. Patient was started on treatment to reverse of allograft dysfunction and resolution of histological features of malakoplakia.

Case Description: 40-year-old Caucasian female with type 1 diabetes mellitus and end-stage renal disease on peritoneal dialysis underwent SPK transplant. After induction with thymoglobulin, she was maintained on tacrolimus and mycophenolate mofetil. Two months later, she was treated for acute T-cell mediated rejection (Banff Grade IA) with thymoglobulin. Serum creatinine returned to baseline and maintenance prednisone was added to her regimen. Her posttransplant course was complicated by multiple infections including parvovirus B19 infection, primary CMV infection, two episodes of urinary tract infections, and influenza A pneumonia. Due to an increase in serum creatinine without apparent cause, a kidney allograft biopsy was performed which revealed lesions consistent with malakoplakia.

Discussion: Treatment of malakoplakia in kidney transplant recipients is not well established but include surgical resection and use of antimicrobial agents. In the era of cyclosporine and azathioprine, it was speculated that the use of azathioprine may be associated with the development of malakoplakia. Discontinuation of azathioprine was shown to improve more bactericidal activity of mononuclear cells. This case report illustrates that in the era of immunosuppression with tacrolimus and mycophenolate mofetil, the maintenance therapy with tacrolimus may be continued while treating for malakoplakia.

SA-PO087
Common Weight Loss Medication Pill—“Qsymia” Causing Hypokalemia and Renal Tubular Acidosis

Iyotova Thakkar, Mala Sachdeva. Div of Nephrology, North Shore -LI School of Medicine, Great Neck, NY.

Introduction: The obesity epidemic is growing. Aside from the traditional diet and exercise, weight loss pills are more commonly prescribed. Qsymia is one such weight loss pill consisting of topiramate and phentermine. We report potentially life threatening side effects of Qsymia causing severe hypokalemia, proximal renal tubular acidosis (pRTA), and cardiac dysrhythmia.

Case Description: A 68 year old female with history of hypertension presented with complaints of tingling of her left arm and jaw of one day duration. Her home medications included Aspirin and Hyzara (Losartan and Hydrochlorothiazide). She had self discontinued the Hyzara five days prior to presentation. Patient was recently started on the weight loss medication “Qsymia” three months prior. She denied any alcohol use. On initial presentation, she was noted to be in atrial fibrillation (HR 150s) and hypotensive (BP 84/43 mmHg). Urinalysis showed pH 8 with glucosuria. Urine Lytes showed potassium 38 mmol/L, chloride 43 mmol/dL, and sodium 141 mmol/L.

Discussion: It was suggested that patient’s clinical presentation and electrolyte disorders were due to the weight loss medication, and Qsymia was discontinued. Qsymia was approved by FDA in 2012 for weight loss. Most common side effects reported include paresthesia, dizziness, insomnia, constipation and dry mouth. In the U.S., drug label contains warnings for increased heart rate. Topiramate is known to cause pRTA. Our patient had mild acidoses, hypophosphatemia and glucosuria which we believe was a result of an early pRTA, induced by topiramate. Although hydrochlorothiazide is known to cause hypokalemia, our patient was not taking the medication for five days.

Weight loss medications are now being more commonly used to treat obesity. Prescribers should be aware of the potential nephrotoxic side effects of Qsymia. Monitoring serum potassium and bicarbonate levels regularly should be taken into consideration.

SA-PO088
Multiple Myeloma as the Underlying Cause of Thrombotic Microangiopathy

Venkata Buddharaaju, Liga Yusvirazi, Anastasios Papagou, Savneek S. Chugh, Rahul N. Pawar. Nephrology, Westchester Medical Center, Valhalla, NY.

Introduction: Thrombotic microangiopathy (TMA) describes a pathological process of microvascular thrombosis, consumptive thrombocytopenia and microangiopathic hemolytic anemia, leading to end-organ ischemia and infarction affecting particularly the kidney and brain. TMA is a pathological feature of a number of clinical disorders including Hemolytic uremic syndrome (HUS) and atypical HUS. Rare but important, TMA may also occur in malignancy, connective tissue disease, malign ant hypertension, and renal transplantation (rejection or drug toxicity). We present a rare case where patient developed AKI from TMA but found to have plasma cell dyscrasia as possible underlying etiology.

Case Description: A 42 y/o man with h/o myopathy, questionable mixed connective tissue disorder on prednisone and celiectomy, Pulmonary Hypertension on home oxygen, CHF with preserved EF and Anemia requiring multiple transfusions went to an outside hospital with SOB and pedal edema found to have AKI with serum creatinine of 4 and 2x proteinuria. Serologies were negative except for anti-RNP and ESR, with no improvement in renal function the patient had a renal biopsy which showed TMA, mild fibrosis and atherosclerosis. The patient was started on RRT and then transferred to Westchester medical center for treatment with Eculizumab for atypical HUS. After reviewing the labs we ordered Serum and urine protein electrophoresis which showed monoclonal IgM spike, the patient underwent bone marrow biopsy which showed Plasmacytoma with 18% Plasma cells. The patient’s renal function improved in the hospital stay and stabilized with creatinine of around 2.0 mg/dL, but unfortunately the patient had a severe sepsis and passed away before initiation of management for Multiple myeloma.

Discussion: Multiple Myeloma accounts for 10% of hematological malignancies. Atleast 50% of patients with MM have evidence renal insufficiency and more than 80% have proteinuria. Multiple myeloma can present as has wide range of renal manifestations including myeloma cast nephropathy, Immune deposition disease, CKD Fanconi syndrome. Though rare Multiple myeloma can cause TMA and the Pathogenesis still remains unclear.

SA-PO089
Drug-Induced Acute Interstitial Nephritis Managed with Early and Aggressive Steroid Therapy

Introduction: Pantoprazole (PPZ), a Proton Pump Inhibitor, is known to cause acute interstitial nephritis (AIN). We report a case of PPZ induced AIN in a young adult with just 3 doses of drug exposure.

Case Description: A 21 year old Asian American male with no past medical history was sent to the hospital by his Internist for elevated serum creatinine (Scr). He had nausea and abdominal pain 3 weeks earlier and was prescribed PPZ, which he took for 3 days. He denied use of any other medications including herbal supplements and NSAIDS. Laboratory data showed BUN of 82 mg/dL, Scr 15 mg/dL (baseline 6.6), bicarbonate of 15 mmol/L and normal electrolytes. Urine showed sterile pyuria with no cosinophils, glycosuria with normal blood glucose, mild proteinuria (900mg/24 hrs). Serum and urine toxicology, protein electrophoresis, auto-immune work up were unremarkable. A Renal biopsy revealed diffuse expansion of the interstitium due to accumulation of cellular infiltrates consisting of lymphocytes, plasma cells and eosinophils with accompanying tubulitis consistent with AIN.

He received pulse steroids for 3 days and was continued on prednisone 1mg/kg/day with a plan to taper over 8-12 weeks. He required a few sessions of renal replacement therapy before his renal function started to recover, 6 weeks later his Scr was 1.4 mg/dL.

Discussion: Any drug can cause AIN, although the categories of antibiotics, diuretics and NSAIDs are most commonly implicated. Drug-induced AIN is not dose dependent, and recurrence can occur with a second exposure to the same or a related drug. The data on time of initiation, dosage and duration of steroids in drug induced AIN is limited due to lack of randomized control trials. On review of literature and our experience, we conclude that stopping the culprit agent and early steroid use confers better prognosis in drug induced AIN.

SA-PO090
Metastatic Sarcomatoid Carcinoma of Urothelial Origin in Failed Renal Allograft

Venkata Buddharaaju, Rajat Lamba, Daniel G. Glicklich. Nephrology, Westchester Medical Center, Valhalla, NY.

Introduction: Renal cell carcinomas are more common in ESRD than the general population and renal transplant patients with enhanced longevity may be at particular risk. Sarcomatoid renal cell carcinomas represents 1-15% of all renal cell carcinomas but has been very rare among described cases in renal allograft. The median age at diagnosis is 16 years with 45-77% of patients with locally advanced or metastatic disease at the time of diagnosis. We describe a case sarcomatoid tumor of urothelial origin in a transplanted renal allograft.

Case Description: A 54 y/o man with ESRD from polycystic kidney disease, HTN, aortic dissection repair, mechanical AVR, paroxysmal AFB, who had 2 failed renal transplants in the past and was on dialysis for past 12 years, was admitted for left lower quadrant pain, fever and leukocytosis for which he was started on vancomycin and
astreamet. On imagine, he was found to have a mass around the left transplant kidney, ascites, omental caking, retroperitoneal lymphadenopathy and heterogeneous liver lesions. Retroperitoneal lymph node biopsy and ascitic fluid cytology was negative for malignant cells. Left kidney mass could not be biopsied because of technical difficulties and he had biopsy of the liver lesions which showed sarcomatoid tumor. He developed respiratory failure and septic shock requiring pressor support and expired. An autopsy was performed which showed Metastatic Sarcomatoid carcinoma of urethral origin.

Discussion: Malignancy in post transplant is related to direct effects of immune-suppressants as well as their effects to suppress immune surveillance and to stimulate the activation of oncogenic viruses. It is generally recommended that patients on the active transplant list and renal transplant recipients be screened every several years for renal tumors. However after allograft failure, it is unclear how often to do cancer screening tests. Although in this particular case it is unclear whether screening would have made a difference in outcome, we recommend routine screening for renal cell carcinoma even if the renal allograft has failed.

SA-PO091
Parathyroidectomy on a Patient with Sickle Cell Disease and End Stage Renal Disease
Farid Ilpakil, Mary C. Mallappally, David Kau, Moro O. Salifu. Sunny Downstate Medical Center, Brooklyn, NY.

Introduction: Patients with End Stage Renal Disease (ESRD) can develop elevated parathyroid hormone (PTH) levels with hypercalcemia. Some fail or cannot tolerate medical therapy. They eventually require parathyroidectomy. Tertiary hyperparathyroidism (3PTH) is the autonomous function of the parathyroid gland due to increased mass. Our case is unique as there are no reported cases of tertiary hyperparathyroidism in sickle cell patient, whereas 3PTH was found in renal osteodystrophy in sickle cell crisis which worsened with parathyroidectomy. 25 year old man with sickle cell disease, ESRD on hemodialysis since 2012, (3HTP), presents after many admissions for sickle cell pain crisis. Cause of ESRD was unknown but attributed to sickle cell nephropathy. Current admission for knee pain, imaging showed 36 x 27 x 26 mm mass, with enhancing right kidney mass with parathyroid adenomas. "Sustained scan: "equivocal slow washout focus in region of right lower pole of thyroid gland extending posteriorly. Suspicious for but not definitive for parathyroid adenoma". On the day prior to surgery, PTH (3PTH) was 4078 pg/ml with serum calcium (Ca)=10.3 mg/dL. Immediately after surgery, a 265 pg/ml sample showed Ca=8.9 mg/dL. The first day after surgery, PTH (3PTH)=36 pg/ml with Ca=7.6 mg/dL. Patient admitted for 3 days due to his requirement of intravenous calcium and daily hemodialysis. Since discharge, patient has had fewer admissions for pain. He has however, remained hypocalcemic and is on 5 grams of calcium carbonate, 4 mcg of doxercalciferol, and is dialyzed with a 3 mEq NaCl bath.

Discussion: 3PTH is common in ESRD patients that can leave them debilitated. Those who fail medical therapy may benefit from resection. In sickle cell disease symptoms of 3PTH was masked by vaso-occlusive crises and could be distinguished by marked reduction in symptoms after resection.

SA-PO092
Synthetic Cannabinoids (SC) in End Stage Renal Disease. Chyi Chyi Chong, Pallavi D. Shirsath,1 Ramesh Marahatta,1 Neville R. Dossabhoy.2 1LSU Health Science Center, Shreveport; 2VA Medical Center, Shreveport.

Introduction: Synthetic cannabinoids (SC) are drugs of abuse especially among young adults. They are affordable, widely available and mostly importantly undetectable by standard urine toxicity screen. The avoidance of detection in the urine contributes to their allure and abuse. Acute kidney injury (AKI) related to synthetic cannabinoids has been reported. However, effect of synthetic marijuana in end stage renal disease (ESRD) patients remains unknown.

Case Description: We present a case of severe high anion gap metabolic acidosis (HAGMA) with acute respiratory failure in an ESRD patient. A 37-year-old African American female with ESRD, hepatitis C and hypertension was found smoking synthetic marijuana under a tree, and in a confused state. Upon arrival to the emergency room, the patient was severely hypertensive with blood pressure of 230/140 mmHg, and subsequently developed acute respiratory failure requiring intubation. Chest x-ray showed bilateral pulmonary edema. Laboratory data revealed: WBC 18K/uL, Na 138 mEq/L, K 3.6 mEq/L, Cl 104 mEq/L, CO2 10 mEq/L, Anion Gap 24. On Blood Gas: pH 6.95, pCO2 42 mmHg, pO2 73 mmHg, HCO3 8.3 mmHg. Urine drug screen was positive for benzodiazepine and marijuana. On Admission: creatinine 2.1 mg/dL, Na 138 mEq/L, K 3.6 mEq/L, Cl 104 mEq/L, CO2 10 mEq/L, Anion Gap 24. On Blood Gas: pH 6.95, pCO2 42 mmHg, pO2 73 mmHg, HCO3 8.3 mmHg. Urine drug screen was positive for benzodiazepine. Ionized calcium was 7.6 mg/dL. 

Discussion: Synthetic cannabinoids are sold under different trade names and the exact effect of SC. SC effect on ESRD patients remain unknown. Our patient developed (HAGMA), which could very well be related to synthetic marijuana use. Physicians should be aware of designer drugs use in ESRD patients.
SA-PO095

Leukocyte Chemotactic Factor 2 (LECT2)-Associated Renal Amyloidosis: A Case Report
Alejandro Pepen Romero, 1 James Drakakis, 1 Joseph Mattana. 1
1Nephrology Dept, Winthrop Univ Hospital, Mineola, NY; 2Pathology Dept, Columbia Univ, New York, NY.

Introduction: ALECT2 amyloidosis is a frequent form of systemic amyloidosis, represents 2.7-10% of all cases of renal amyloidosis. Most patients are elderly who presents with chronic renal insufficiency and bland urinary sediment.

Case Description: We report a 76-year-old Egyptian male who presented after a recent hospitalization for self limited gastroenteritis and severe acute renal failure presumed secondary to acute tubular necrosis. Due to non-improving renal function and uremic symptoms, renal biopsy was done and showed patchy Interstitial amyloidosis deposits that did not stain for IgG, IgM, IgA, Kappa, Lambda chains or Amyloid A; sample was sent to Mayo Clinic where Liquid chromatography tandem mass spectrometry detected a peptide profile consistent with ALECT2 Amyloidosis.

Discussion: This case suggests that ALECT2 Amyloid can present with bland uroanalysis and non-nephrotic range proteinuria in elderly patients.

SA-PO096

Monitoring Disease Activity in ANCA Associated Vasculitis (AAV): A Case for Activated Circulating Monocytes? Florin Gunnar Scurti, 1 Leon Brian Schubert, 2 Noemi Rose Emma Doll, 2 Marius Früh, 2 Tobias Hilscher, 2 Andreas Jeros, 1 Dunja Bruder, 2 Peter R. Merz, 1 Christos D. Chatzikyriou, 1 Nephrology, Hypertension, Diabetes and Endocrinology, Otto-von-Guericke Univ Magdeburg; 1Inst of Microbiology, Otto von Guericke Univ Magdeburg.

Introduction: We are still in need for more reliable markers to monitor disease activity in AAV.

Case Description: The clinical course of a patient with therapy refractory AAV is presented.

Disease activity was assessed by means of the BVAS and VDI score and by serial measurements of the CD19/CD20 cell count and the MPO titer. The last renal flare was on 11/2014 and was corroborated by renal biopsy. Monocyte subsets were also identified by flow cytometry with the use of the surface markers CD14, CD16, CCR2 and CxCR3.

The expression of different proteins reflecting antigen presentation or activation status as well as scavenger receptor and toll like receptor functions was quantified in the monocyte subpopulations. Blood samples of a healthy individual were used as controls. Results of the antigen presentation marker HLA-DR and the monocyte activation marker CD11b are presented here.

Renal and pulmonary disease progressed despite the use of an impressive immunosuppressive therapy. The CD19/CD20 cell count and the MPO titer did not predict relapse. The intermediate CD14+CD16+CCR2lowCXCR1++ monocyte subpopulation was increased but expressed less of the HLA-DR protein. The CD11b antigen expression was increased in the classical monocyte subpopulation CD14+CD16-CCR2highCXCR1++, whereas no differences in the HLA-DR and CD11b expression were observed in the non-classical monocyte subpopulation CD14+CD16+CCR2lowCXCR1+high.

Discussion: There appear to be functional alterations in the different monocyte subpopulations during relapse of AAV. Their pathophysiologic significance remains to be elucidated.

SA-PO097

A Case of Rhabdomyolysis Induced AKI with Two Questions: Serum Myoglobin versus CPK and the Potential Role for Rasburicase Mehd Nouri kolouhi. Nephrology, Baylor College of Medicine, Houston, TX.

Introduction: Rhabdomyolysis induced AKI is a common scenario. The mechanisms include myoglobin and uric acid crystal induced tubular injury. The role of uric acid lowering agents in such conditions remains to be defined. Here we describe such a case, in which uric acid lowering agent successfully lowered uric acid level and possibly contributed to renal function recovery. In this case CPK level was not high enough to justify AKI and a very high serum myoglobin level established the diagnosis.

Case Description: A 37 years old man without known history was brought to ER with agitation and delusional-combative behavior. Vital signs included temp=100.4, BP=165/85, RR=12/min, HR=110/min. On examination, he was mildly volume depleted. On lab work, it was found to have AKI with BUN=76, Cr=4, K=6.7 and metabolic acidosis. Urine toxicology was positive for amphetamines. CPK level was 4200 U/L and uric acid level was 21 mg/dL. Supportive management including aggressive IV fluids was initiated for amphetamine toxicity with favorable outcome. Urine exam showed hematocrit casts. Serial CPK levels were not high enough to justify AKI. However serum myoglobin level was very high at >20000 ng/mL and confirmed severe rhabdomyolysis. one session of dialysis was done due to persistent metabolic acidosis and hyperkalemia. However uric acid level remained high at same range. We used a dose of Rasburicase at 3 mg which reduced uric acid level to 5.5 six hours later. After few days, renal function and clinical status started to improve and he was discharged in stable condition.

Discussion: There may be a therapeutic/ prophylactic role for uric acid lowering agents in rhabdomyolysis induced AKI. In our case, Rasburicase successfully lowered uric acid level after it had remained high post-dialysis. Similar results have been reported in the past, however further research is needed in the future. Besides, Although AKI in rhabdomyolysis is usually seen with CPK levels>20000, our patient had much lower levels and a very high serum myoglobin established the diagnosis of severe rhabdomyolysis. Serum myoglobin is more accurate to determine the severity of rhabdomyolysis and predict the risk of AKI.

Post Renal Transplant Follow Up in Focal Segmental Glomerulosclerosis with 24 Hour Urine Protein Collection – Traditional and True

*Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

**Introduction:** Random Urine Protein Creatinine Ratio (PCR) is commonly used to estimate proteinuria compared to 24 hour urine protein measurement (24-UP). However, there are concerns over the diagnostic accuracy and reliability of such an approach in post-transplant setting. We present a case of post-transplant focal segmental glomerulosclerosis (FSGS) illustrating this.

**Case Description:** A 39 year old male with primary FSGS, on peritoneal dialysis for 4 years received a cadaveric kidney transplant. His panel reactive antibody was 0% and HLA cross-match was negative. Peri-operative course was uneventful. Given the history of FSGS, PCR was monitored. By post-op day 5, serum creatinine had decreased from 7.3 mg/dl to 3.2 mg/dl and PCR from 4.3 to 2.8. However, his 24-UP came back 8 g, which was markedly different.

Early recurrence of FSGS was diagnosed. A biopsy was withheld to avoid delay in timely management and risk of bleeding with plasmapheresis which was immediately initiated. He was switched from tacrolimus to cyclosporine. He required plasmapheresis for 5 weeks and had satisfactory recovery in the ensuing months.

**Discussion:** Logistics have led to the widespread use of PCR in follow-up of kidney transplant recipients. However changing creatinine excretion with recovering renal function, lower precision with heavier proteinuria, and limited data on accuracy compared to 24-UP, potentially limit its utility at detecting early post-transplant recurrence of FSGS. Our case highlights marked discordance between the PCR and 24-UP, detection of which allowed a timely change in management. We conclude that it is prudent to monitor proteinuria by timed urine collection in preference to random PCR in the immediate post-transplant setting for recipients with primary FSGS.

**SA-PO101**

Donor Kidney Lithiasis: A Case of Throwing Out the Baby with the Bathwater?

Ravinder Pal S. Bhatti,1 Sameh R. Abul-Ezz,1 Lakshmi P. Nadimpalli,2 Gary Wickens Barone,2 1Nephrology, 2Transplant Surgery, Univ of Arkansas for Medical Sciences, Little Rock, AR.

**Introduction:** Cadaveric kidneys account for a majority of transplants in the United States. However, only 10% of waitlisted patients receive one annually, making optimal utilization critical. Donor nephrolithiasis represent a small yet significant proportion of kidneys discarded. We present a patient who received such a kidney which otherwise could have been discarded.

**Case Description:** The donor was a healthy 31 year old female who suffered anoxic brain injury in a motor vehicle accident. Her CT abdomen showed 2 stones in the right kidney as represented in the figure’s inset. The kidney became available to us on a regional list after it was declined locally due to concerns over kidney quality. Our recipient was a 50 year old female with hypertensive nephropathy, on hemodialysis for the past 2 years. Her panel reactive antibody was 90% and HLA cross match was negative. Intra-operatively, a large stone measuring 2 cm was identified in the hilum of the donor kidney and was extracted via pyelotomy. A smaller middle calyceal stone was localized by fluoroscopy and successfully removed by irrigation.

**Discussion:** Our case suggests IEP was a transient reaction to the catheter placement rather than a reaction to the PD set or solution.

**SA-PO102**

A Peritoneal Dialysis Catheter Leak Complicated by Burkholderia Gladioli Peritonitis

Ravinder Pal S. Bhatti, Dumitru Rotaru.

*Nephrology, Univ of Arkansas for Medical Sciences, Little Rock, AR.*

**Introduction:** Dialysate leaks can occur any time after peritoneal dialysis (PD) catheter placement. Early leaks usually manifest as an exit site leak, though may also present with air in the PD catheter. Leaks increase the risk for exit site infections (ESI) and peritonitis. We present such a patient developing peritonitis with an unusual pathogen.

**Case Description:** A 74 year old male who had been on Continuous Cycling Peritoneal Dialysis for 3 years, presented with exit site erythema a week after trying to push in an extruded cuff. Prophylactic antibiotics were started but he declined surgery. The ESI recurred soon after completing 3 weeks of antibiotics. He agreed to catheter replacement with an exit site change. He was started on low volume exchanges. Two weeks later, he noted air bubbles in the PD catheter upon draining.

There were no perioperative complications and the recipient had excellent immediate graft function. Her creatinine progressively improved by time of discharge, remaining normal in subsequent months.

**Discussion:** The new kidney allocation policy aims to address organ shortage by reducing donor and graft survival mismatch. Traditionally, donor hemodynamics, age, serum creatinine and histopathology have influenced decisions on accepting a kidney. The perceived quality and utilization techniques widely vary for deceased donor kidneys with lithiasis. Our case illustrates how this can lead to non-acceptance of an otherwise healthy kidney, which can be transplanted with a favorable outcome.

**SA-PO103**

A rare observation, air in a PD catheter is almost pathognomonic of a dialysate leak. Our case highlights several key points in such a scenario. Firstly, use of sharps is a major risk factor and should be discouraged. Secondly, an increased risk of peritonitis...
including by rare pathogens warrants appropriate antibiotic prophylaxis and lastly a more limited approach than catheter exchange may be used even for leaks close to exit sites based on the location and local experience.

SA-PO103
Nephrology, Baylor College of Medicine, Houston, TX.

Introduction: Acute kidney injury (AKI) after kidney transplantation can occur from myriad of causes. We present an interesting case of a young woman with history of Celiac disease who developed AKI and biopsy-proven oxalate nephropathy within 3 months post-transplantation, as a result of enteric hyperoxaluria associated with gluten noncompliance.

Case Description: A 35 year-old woman with type 1 diabetes mellitus, and celiac disease underwent living unrelated kidney transplantation for ESRD related to biopsy-proven diabetic nephropathy. Her original renal ultrasound did not show nephrocalcinosis. After transplantation, nadir serum creatinine was 1.0 mg/dL. Three months later, she presented with six-day history of diarrhea and AKI. Serum creatinine peaked at 2.6 mg/dL. Since volume replacement did not improve her allograft function and she had high panel reactive antibody levels pre-transplant, a kidney biopsy was performed that showed acute tubular injury with significant oxalate crystalline deposits. Initial serum oxalate level was undetectable, but 24-hour urine oxalate excretion was elevated at 98 mg/dL. Pending gene testing, she was treated with intravenous fluids, low oxalate diet, gluten free diet, vitamin B6, oral alkaI and calcium carbonate. Subsequent gene testing did not reveal an gene mutation in the oxalate pathway. Her urIne output was maintained between 3 to 4L per day. With strict gluten avoidance and low oxalate diet, urine alkalinization and oral calcium, her allograft function has improved to baseline.

Discussion: Celiac disease exacerbation and subsequent malabsorption can lead to significant gut oxalate absorption and hyperoxaluria. Resulting oxalate nephropathy is a rare cause of AKI after kidney transplantation.

SA-PO104
Unusual Presentation of Tumor Related Membranous Nephropathy Tahir Zaman,1 Frederic Clayton,2 Josephine Abraham,1 Nephrology, Univ of Utah, Salt Lake City, UT; 1Pathology, Univ of Utah, Salt Lake City, UT.

Introduction: The literature is laden with evidence of several solid tumors causing secondary membranous nephropathy. It is also described in the literature that solid tumors could also ANA positivity.

Case Description: A 62-year-old male with a history of hypertension presented with oliguric renal failure following an episode of gastroenteritis. History was unremarkable with patient denying smoking or other vices. Urine analysis revealed rare dysmorphic RBC’s and minimal proteinuria (spot protein/creatinine ratio 0.5 gms). Serologic workup revealed +PR3 (ANCA negative) and abnormal Kappa/Lamda Ratio thus renal biopsy was performed, which revealed membranous nephropathy and acute tubular necrosis (ATN). Immunofluorescence was positive for C3, IgG, though negative for PLA-2R, IgA and C1q. ANA was strongly positive (1:10240 speckled pattern), HIV serology was negative. Sublingual mass was found which revealed squamous cell carcinoma. Bone marrow biopsy revealed smoldering multiple myeloma. The patient’s ATN resolved and he subsequently underwent left partial glossectomy. His cancer was staged at T2N0 and he is undergoing chemotherapy and radiation therapy.

Discussion: Secondary membranous nephropathy has a known association with solid tumors. The positive ANA raised the concern of concomitant connective tissue disease. With strict gluten avoidance and low oxalate diet, urine alkalinization and oral calcium, her allograft function has improved to baseline.

SA-PO105
A Case of Severe Adrenal Insufficiency due to Long-Term Glucocorticoid Administration for Pediatric Nephrotic Syndrome Yuko Fujii,1 Akira Ashida,1 Hideki Matsumura,2 Akihiko Shirasu,1 Hyogo Nakakura,1 Motoshi Hattori,2 Hiroshi Tamai,1 1Pediatrics, Osaka Medical College, Takatsuki, Osaka, Japan; 2Pediatric Nephrology, Tokyo Women’s Medical Univ, Shinjuku, Tokyo, Japan.

Introduction: One of the adverse effects of long-term glucocorticoid therapy in supraphysiologic doses is suppression of the hypothalamic-pituitary-adrenal axis, although symptomatic adrenal insufficiency is considered to be an unusual complication of glucocorticoid therapy for nephrotic syndrome in pediatric patients. Here we describe a case of secondary adrenal insufficiency due to long-term glucocorticoid therapy for steroid-dependent nephrotic syndrome.

Case Description: A 12-year-old boy who had developed steroid-dependent nephrotic syndrome at the age of 2 years had been treated repeatedly with corticosteroid, cyclosporine and mizoribine. On relapse of the disease at 4 years of age, the nephrotic syndrome had been resistant to steroid therapy including 2 mg/kg prednisolone and 4 courses of methylprednisolone pulse therapy, but had responded to additional cyclophosphamide therapy at 7 months after relapse onset. During tapering of the glucocorticoid therapy, the patient had shown various symptoms, including general fatigue, facial edema, decreased urine volume, appetite loss, and dizziness from the age of 5 years. At that time, the basal value of cortisol was not detectable and a rapid ACTH loading test elicited a low response. In the CRH and insulin loading test, the basal value of ACTH was not detectable and an over-response of ACTH was demonstrated. Therefore the patient was diagnosed as having glucocorticoid-induced hypothalamic adrenal insufficiency and treated with cyclosporine, a decreased dose of prednisolone, and hydrocortisone supplementation. The supplement ACTH and cortisol values increased gradually. An insulin loading test at the age of 12 years demonstrated normal responses of the ACTH and cortisol levels.

Discussion: The very long-term nature of the therapy for this patient with idiopathic nephrotic syndrome resulted in glucocorticoid-induced adrenal insufficiency. Periodic evaluation of adrenal function and re-evaluation of the treatment is important for patients with nephrotic syndrome receiving steroid therapy.

SA-PO106
Henoch-Schönlein Purpura in Adult, from a Clinical Case Migdal Goucsel, Pedro Vieira, Jose Duras, Luis Resende, Nuno Rosa, Jose Alves Teixeira, Gil Silva. Nephrology, Hospital Dr. Nélio Mendonça, Funchal, Portugal.

Introduction: Henoch-Schönlein purpura is a small vessel vasculitis mediated by IgA-immune complex deposition with multisystemic involvement. Rare in adults, it is characterized by purpura, arthralgias, abdominal pain, and renal involvement. Viral infections have been reported as trigger.

Case Description: The authors present the case of a 25 years old male, without relevant medical history, admitted to the Nephrology Department in May 2014 by severe hypertension, renal failure (creatinine 6.7mg/dL), erythrocyturia and proteinuria. Renal ultrasound was normal. Renal biopsy revealed IgAnephropathy (M1E1S1T2). Our investigation revealed chronic hepatitis B virus (HBV) of vertical transmission origin (viral load 150 IU/mL). Corticosteroid therapy was started, with slight improvement in renal function. He was readmitted 2 months later by asthenia, epistaxis, weight loss, palpable purpura, altered mental status and oral and nasal ulcers. Laboratory tests revealed hemoglobin 9.2g/dL, creatinine 4.3mg/dL, normal transaminases, albumin 20g/L, urinary spot protein:creatinine ratio 1300mg/g, hypocomplementemia, negative p-ANCAs, e-ANCAs and cryoglobulins, HBV load 379.980IU/mL. During hospitalization the patient initiated progressive pancytopenia, diffuse abdominal pain, generalized skin purpura and fever (with no identifiable infectious origin and interpreted as immunologic). We made clinical diagnosis of Henoch-Schönlein purpura and started with cyclophosphamide and entecavir. A few days later appeared hypoxemia and oliguria, requiring urgent dialysis. Cneli CT scan showed microangiopathic leukoencephalopathy of unspecified etiology and alveolar hemorrhage in chest CT scan. Due to life threatening multisystemic involvement we started methylprednisolone pulses, intravenous immunoglobulin and plasmapheresis. Patient completely recovered, but remained dependent on dialysis. 6 monthly cycles of cyclophosphamide were maintained, with no signs of recurrence.

Discussion: We emphasize the rare severe multisystemic involvement of a Henoch-Schönlein purpura in an adult, the onset of the disease with exacerbation of viral infection, and the therapeutic challenge of an HBV patient with a vasculitis.

SA-PO107
Rare Etiology for Chronic Kidney Disease: Bronchiectasis Related Secondary Amyloidosis Alper Alp,1 Hakam Akdam,2 Aysegul Ormeci,1 Ibrahim Meteoglu,2 Alparslan Unsal,1 Yazuv Yenicieroglul,1 1Nephrology, Van Education and Research Hospital, Van, Turkey; 2Nephrology, Adnan Menderes Univ, School of Medicine, Aydin, Turkey; 1Pathology, Adnan Menderes Univ, School of Medicine, Aydin, Turkey.

Introduction: Here we present an elderly patient with a known posttuberculosis bronchiectasis, nephritic-range proteinuria and renal failure was detected. Renal biopsy revealed AA amyloidosis. Tuberculosis and tuberculosis related systemic disorders still have clinical impact in nephrology practice especially in developing countries.
Case Description: A 67 yo man was referred to our hospital with renal failure and proteinuria. PMH was remarkable for tuberculosis (41 years age) and posttuberculosis bronchiectasis for long years. On physical examination pretilial edema was evident. Chest X-ray, thorax CT revealed left sided total bronchiectasis and pulmonary nodules. Malignancy was excluded with PET/CT and bronchoscopy. On admission biochemical tests: urea: 220mg/dL, creatinine: 5.86mg/dL, potassium: 4.8mmol/L, GFR: 10.3mL/min/1.73m2, ANA 1/100 positivity (cytoplastic). Renal ultrasonography revealed bilateral echogenic kidneys with normal size and shape. 24 hour urinary proteinuria, albuminuria was 7924 mg/dL, 4789mg/dL respectively. Renal biopsy was compatible with AA amyloidosis (segmental homogeneous deposits of amyloid in the glomeruli and interstitium). Immunohistochemistry was positive for staining of AA amyloid. There was no immunofluorescence staining with IgG-A-M-C3 fibrinogen.

Tunneled catheter was placed and hemodialysis was started.

Discussion: FMF and rheumatological disorders are the leading causes of amyloid AA in Turkey. However other rarely seen etiologies should not be missed in clinical practice. Secondary amyloidosis as a multisystemic disease has a high mortality risk. Renal manifestations include nephrotic syndrome and renal failure.

SA-POI08

Sunitinib Induced Acute Renal Failure and Nephrotic Syndrome in a Patient with Metastatic Neuroendocrine Tumor: A Case Report and Review of the Literature

Srijita Mukherjee,1 Carla L. Ellis.2 1 Nephrology, Emory Univ Hospital and School of Medicine, Atlanta, GA; 2 Pathology, Emory Univ Hospital and School of Medicine, Atlanta, GA.

Introduction: Sunitinib is a chemotherapeutic agent used to treat advanced malignancies via inhibition of tyrosine kinase phosphorylation. We present a case of sunitinib induced acute renal failure with nephrotic syndrome, occurring within one week of initiation for persistent carcinoid syndrome secondary to hepatocellular carcinoma of a primary small intestinal neuroendocrine tumor.

Case Description: A 63 year old man with metastatic neuroendocrine tumor was initiated on sunitinib to treat persistent carcinoid syndrome despite initial therapy. Within one week of initiation, he developed new onset peripheral edema, 20 pound weight gain and acute renal failure with nephrotic syndrome, occurring within one week of initiation for persistent carcinoid syndrome secondary to hepatocellular carcinoma of a primary small intestinal neuroendocrine tumor.

Discussion: Literature review reveals reports that vary both in time to onset and degree of resolution of renal disease after initiation and discontinuation of sunitinib therapy, respectively. Renal pathology also varies, including acute tubular necrosis, acute interstitial nephritis, diffuse podocyte foot process effacement, and thrombotic microangiopathy. Our patient developed a greater severity of renal failure than most reported, including a higher peak serum creatinine, longer duration of renal replacement therapy and current lack of renal recovery. To our knowledge, this is also the first report of the onset of renal failure in the specific clinical scenario described. Given the near immediate adverse effect of sunitinib in our patient, we recommend monitoring of creatinine and urine protein at baseline and within the first three to five days of medication initiation.

SA-POI09

Cryoglobulinemic Glomerulonephritis After Successful Treatment of Hepatitis C

Nupur Gupta, Chad A. Zarse, Allon N. Friedman. Nephrology, IU School of Medicine, IN.

Introduction: The optimal treatment of cryoglobulinemic glomerulonephritis (GN) in the setting of Hepatitis C (Hep C) with sustained viral response (SVR) is unknown. Only expert opinion obtained from case reports provide guidance to the clinician. Some reports show no benefit with Rituximab may be beneficial.

Case Description: 58yo male with h/o treated Hep C currently with an undetectable viral load, gastric ulcer, anemia, and HTN presented to clinic for evaluation of CKD. Hep C was initially diagnosed when he was found to have leukocytoclastic vasculitis on a skin biopsy of skin rash. Labs were positive for serum cryoglobulins, rheumatoid factor, low C4, and Hep C viral load. Renal function was normal and he was successfully treated for cryoglobulinemic vasculitis due to Hep C with interferon alpha, telaprevir and ribavirin and achieved a SVR. He presented 1 year later with renal insufficiency (creatinine -2.2 mg/dL) and proteinuria. He had minimal proteinuria and no hematuria. He had no new evidence of vasculitis. SPEP revealed IgM kappa monoclonal with negative UPEP. C4 was low and cryoglobulins remained positive. Kidney biopsy showed immune complex GN with organized deposits. Bone marrow biopsy was negative for lymphoproliferative disease. He was diagnosed with cryoglobulinemic GN with SVR. Initially, he was treated with prednisone followed by Rituximab and plasmapheresis. He failed the treatment and was started on hemodialysis.

Discussion: Cryoglobulinemic GN is frequently due to Hep C but is rare in patients achieving a SVR. In our case an underlying B cell lymphoma was ruled out and it was felt that B cell immune dysregulation due to Hep C was the culprit, in part due to prior published cases. However, in our case treatment with rituximab and plasmapheresis was unsuccessful. It remains possible, as others have demonstrated, that the virus may persist within the liver, macrophages, lymphocytes, and even kidney. The pathological basis for persistent vasculitis in setting of a SVR requires further study so that targeted and more effective treatment strategies can be designed.

SA-POI10

Diagnostic Intrapartum Dilemma: Distinguishing Glomerulonephritis from Preeclampsia in Pregnancy

Harsharan Kaur Singh.

Introduction: Distinguishing glomerular disease from preeclampsia intrapartum can be challenging due to overlap of clinical findings. Unfortunately, this diagnostic dilemma can result in unwarranted early delivery. Here we present 5 cases of glomerulonephritis (GN) complicating pregnancy.

Case Description: 3 patients (ages 22, 31 and 33) presented during pregnancy with proteinuria, dysmorphic hematuria and persistent kidney dysfunction. In 2 cases, acute kidney injury. In all 3 cases, the concern for preeclampsia prompted induction of labor (IOL), and postpartum kidney biopsy showed IgA nephropathy. 2 patients were treated with steroids and ACE inhibitors (ACEI) with improvement in proteinuria. The one with the most severe kidney dysfunction was treated with cyclophosphamide (CYC). Unfortunately, she became dialysis-dependent 1 month postpartum. The fourth patient (age 20) presented with HELLP syndrome at 25 weeks and underwent IOL. 5 months post-partum, she developed clinical symptoms of lupus in the setting of proteinuria, dysmorphic hematuria and persistent kidney dysfunction. Kidney biopsy was performed. She showed diffuse proliferative glomerulonephritis, which was true proliferative lupus nephritis, which was positive for anti-PCNA on IF, and negative for ANA and CYC. Unfortunately, she continued to have renal dysfunction despite treatment. The fifth patient (age 37) had minimal change disease (MCD) and was in remission at the time of pregnancy. She did well on cyclosporine until 25 weeks gestation when she developed hypertension, edema, and nephrotic-range proteinuria. It was unclear whether this represented preeclampsia or a MCD flare since she underwent IOL. Subsequent placental pathology failed to show signs of preeclampsia. She was treated postpartum with steroids and ACEI and re-entered remission.

Discussion: Here we show that pregnancy can aggravate (as in the case of our patient with MCD) or unmask (as in the other 4 cases) underlying glomerular disease. Diagnosis can be delayed due to risks related to kidney biopsy during pregnancy, and treatment is complicated by safety concerns for the developing fetus. Further work is needed to identify meaningful mechanisms to accurately differentiate preeclampsia from GN during pregnancy.

SA-POI11

A Case of Rapidly Progressive Glomerulonephritis Associated with Metastatic Lung Cancer

S. Mendes,1 Eduarido J. D. de Sa Carneiro Filho,2 Victor Longo Silva,1 Lilian Cordeiro, Veronica T. Costa e Silva,3 Elerson Costalonga.

Introduction: Several solid malignancies have been associated with glomerulonephritis. Rapidly progressive glomerulonephritis (RPN) has been reported in association with renal cell carcinoma and lung cancers. We report a case of RPN associated with metastatic lung cancer treated with chemotherapy agents.

Case Description: A 57-year-old male with metastatic epidermoid lung cancer, treated previously with paclitaxel plus carboplatin, cisplatin plus gemcitabine and carboplatin plus docetaxel, was admitted with dysuria and hematuria for last 1 week. Upon physical examination: edema of the lower limbs. Laboratory results demonstrated normal liver function, positive anti-Hbc, negative HbsAg and anti-Hbs, hemoglobin 6.5 g/dL, serum creatinine of 3.78 mg/dL (baseline 1.5), C3 154 mg/dL, C4 24.8 mg/dL, negative ANA, negative MCV. Urinalysis showed proteinuria (>1 g/L), more than 100 leukocytes per field and more than 100 red cells even after antibiotic treatment for presumed urinary infection. Due to persistent

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
proteinuria (3.7 g/24h), evidence of dysmorphic hematuria and worsening of renal function
(Cr 4.1 mg/dL), he received methylprednisolone 1g for three days and renal biopsy was
proposed. It revealed pauci-immune crescentic glomerulonephritis. Immunofluorescence showed
mesangial deposition of C3 (++) and lambda chains (++). Treatment was followed by monthly
i.v. cyclophosphamide and proteinuria decreased to 0.87 g/24h. aCtANCA became positive
(1/160) 4 months after diagnosis.

Discussion: Membranoproliferative glomerulonephritis is the most commonly reported glomerulonephritis
especially with pulmonary cancer, but several reports suggest an association between rPgn and
malignancies. The increased risk for malignancy has been confirmed in a retrospective
review of 200 patients with ANCA-associated vasculitis, demonstrating a significantly
increased relative risk (6.02) compared with age-matched controls. Biaya et al reported
seven cases of rPgn associated with a coexisting nonrenal malignancy (6 carcinomas and
1 lymphoma). The pathogenetic mechanisms by which neoplasms lead to the development
of ANCA-associated vasculitides and rPgn are largely unknown.

SA-PO112
A Case of Encapsulating Sclerosing Peritonitis in a Type I Diabetic on Peritoneal Dialysis
Zachary Freestone, Josephine Abraham, Akram M. Shaaban.
Nephrology, Univ of Utah, Salt Lake City, UT.

Introduction: Encapsulating sclerosing peritonitis (ESP) is a rare disorder associated
with PD. It is characterized by peritoneal fibrosis and encapsement of the bowel. Symptoms
associated with ESP are non-specific and may be attributed to other etiologies. Abdominal
imaging is required to evaluate ESP and diagnostic confirmation is achieved by laparoscopy.
ESP should be considered in patients on peritoneal dialysis with symptoms involving the
gastrointestinal tract, weight loss, or inadequate solute clearance.

Case Description: A 34 year old Caucasian male on PD presented to the clinic with complaints of nausea and abdominal pain. He had a history of type I DM, ESRD,
neuropathy, and gastroparesis. He was started on PD 8 years ago and has had 3 prior episodes of peritonitis. The patient appeared ill and malnourished. His abdomen was soft
on examination and non-tender to palpation. An abdominal x-ray indicated that he had calcification in the abdomen and pelvis. CT imaging showed calcification of the parietal
peritoneum, abdominal cavity, omentum, and bowel. The patient underwent exploratory
laparotomy with simultaneous PD catheter removal. The visual examination revealed a
brown, inflamed rim encompassing the peritoneum, omentum, bowel, and colon. Peritoneal
dialysis was discontinued and the patient was transitioned to hemodialysis.

Discussion: Encapsulating sclerosing peritonitis (ESP) is a condition associated with
peritoneal dialysis. Its presenting symptoms are often non-specific and may be attributed to
other causes. Abdominal imaging is necessary to evaluate for suspected ESP, CT being the
preferred method. ESP is characterized by peritoneal thickening and fibrosis that encases
the bowel. Treatment includes cessation of PD with transfer to hemodialysis and bowel rest.
Other attempted treatments of this disease have included steroids and total enterolysis.

SA-PO113
Acute Kidney Injury from Enterovesical Fistula Secondary to Squamous Cell Carcinoma of Bladder
Eleni Chelioti, Evdokia Efthimiou, Alexia Papalexandrou, Maria Sotiraki, Ioannis Xatris, Maria Tsiviligou.
Dept of Nephrology, General Hospital of Piraeus, Athens, Greece.

Introduction: Squamous cell carcinoma (SCC) of the bladder is a relatively rare tumor.
Predisposing factor is chronic irritation of the bladder by urinary infection, calculi and
non-tender to palpation. An abdominal x-ray indicated that he had calcification
necrotizing enterocolitis. review of 200 patients with ANCA-associated vasculitis, demonstrating a significantly
increased relative risk (6.02) compared with age-matched controls. Biaya et al reported
seven cases of rPgn associated with a coexisting nonrenal malignancy (6 carcinomas and
1 lymphoma). The pathogenetic mechanisms by which neoplasms lead to the development
of ANCA-associated vasculitides and rPgn are largely unknown.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

651A
formation in tubular lumens with severe tubular atrophy. Cell accumulation and fibrotic lesion were also detected in interstitium. Mesangial matrix was mildly expanded in glomeruli. Amyloid deposition was not observed.

Discussion: Herein, we showed clinical course and renal pathology of the patient with IgG-lambda type MM. Although steroid pulse therapy decreased serum levels of IgD, renal function did not improve. Renal pathology showed cast nephropathy, interstitial fibrosis and cell infiltration. The renal manifestation of IgD type MM requires further investigation.

SA-PO116
Sunitinib-Induced Nephrotic Syndrome and Acute Kidney Injury in a Malignant Insulinoma Patient: A Case Report
Wakana Shoda, Naofumi Yui, Shokaro Naito, Soichiro Imori, Koichiro Susa, Takayasu Mori, Nahoiro Nomura, Eisei Sohara, Tomokazu Okado, Tatemitsu Shi, Shinichi Uchida. Dept of Nephrology, Tokyo Medical and Dental Univ, Bunkyo, Tokyo, Japan.

Introduction: Sunitinib, a tyrosine kinase inhibitor targeting vascular endothelial growth factor receptors (VEGFR), has been proven to be effective in the treatment of several types of cancer, including pancreatic neuroendocrine tumors. However, its risk of renal complications, such as proteinuria, renal dysfunction, and hypertension, are underestimated.

Case Description: A 71 year-old man with malignant insulinoma treated on sunitinib for six months, developed proteinuria, acute kidney injury and hypertension. Kidney biopsy showed thrombotic microangiopathy (TMA) like lesions such as double contour, edematous endothelial cells and microaneurysms, suggesting injuries induced by sunitinib. Decreased VEGF expression in podocytes was demonstrated by immunohistochemistry, supporting the diagnosis. Sunitinib was discontinued and partial remission of the renal complication was achieved in two weeks. However, the patient mandatorily needed to restart sunitinib because of poor control of blood glucose level due to pancreatic cancer exacerbation. By reducing the dose of sunitinib and administering losartan concurrently, the patient was able to maintain stable renal function with serum creatinine level of 1.4 mg/dl and urinary protein level under 1.0 g/day.

Discussion: VEGF blockade by sunitinib is featured by adverse effects including hypertension and renal injury. In the present case, renal injury partially improved after discontinuing sunitinib. Reducing the dosage of sunitinib and administering losartan made it possible to restart sunitinib treatment while controlling its renal side effects. VEGF, which is expressed and secreted by podocytes, is an important factor for development and maintenance of glomerular endothelium. Renal biopsy in this case showed down regulation of postoperative renal recovery.

SA-PO117
Liver-Kidney versus Liver Transplant Alone: Decision Making in the Operating Room
Ekamol Tantisattamo,1 Siwadon Pitukweerakul,2 Praveen Ratanasirirnetha.3 1Nephrology, Northwestern Univ; 2Presence St. Francis Hospital, Evaston; 3Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand.

Introduction: Acute kidney injury (AKI) is a common complication of decompensated chronic liver disease and hepatorenal syndrome (HRS) is one of the leading causes. Liver transplantation (LT) is a definitive treatment for HRS; however, simultaneous liver-kidney transplantation (SLK) is pursued due to the severity of preoperative AKI with uncertainty of postoperative renal recovery.

Case Description: A 60-year-old Caucasian woman with ESLD due to alcoholic cirrhosis had been readmitted twice over 2.5 months with AKI from HRS. Even though, she was treated with albumin, midozolam, and ocotroide, serum creatinine (SCR) had been elevated from the initial baseline of 1 mg/dL and had never returned to the baseline. Instead, it was worse every time she had AKI (Figure 1). After the last episodes of AKI, SCR had been stable at 2.5 mg/dL and she was listed for SLK. One week later, she was offered for SLK. After the LT, she started making a significant amount of urine immediately; therefore, the kidney was not transplanted and transferred to other potential kidney transplant recipient in another transplant center. Postoperatively, SCR had trended down to 1.1 mg/dL.

Discussion: Even though, our patient had recurrent episodes of AKI from HRS and persistently elevated SCR even >3 months period, it was thought that the chance of meaningful renal recovery was small and SLK was initially planned. Fortunately, her renal function was recovery immediately after the LT alone. Preoperative evaluation for SLK versus LT alone sometimes becomes uncertain. Intraoperative finding of signs of renal recovery after LT is crucial as it can avoid unnecessarily kidney transplantation and provide opportunity to utilize kidney organ to other potential kidney transplant recipients.

SA-PO118
Is Portopulmonary Hypertension Patient a Good Candidate for Liver Transplantation? Ekamol Tantisattamo,1 Praveen Ratanasirirnetha,2 Siwadon Pitukweerakul,3 1Nephrology, Northwestern Univ; 2Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand; 3Presence St. Francis Hospital, Evaston.

Introduction: Portopulmonary hypertension (PPH) is one of the most feared complications of end-stage liver disease (ESLD). Liver transplantation (LT) may reverse this complication with uncertain outcomes. We report a case of ESLD women complicated by severe pulmonary arterial hypertension (PAH) secondary to PPH and acute kidney injury (AKI) who had prolonged pre- and post-operative simultaneous liver-kidney transplantation (SLK) with partial liver improvement, un-meaningful renal recovery, and bed bound with reconditioning.

Case Description: A 48-year-old women had ESLD from cryptogenic cirrhosis complicated by portal hypertension, PAH-related to PPH and sarcoidosis presented with AKI requiring CRRT. She was treated with treprostinil, sildenafil, and ambrisentan until suitable for SLK. Postoperatively, liver and renal allografts worked well and PA pressure was decreased. However, she still required treprostinil and diuresis to control PAH and volume status. After 5 months of ICU stay, she developed severe deconditioning and malnutrition. She had AKI with SCR of 0.5 mg/dL up to 1 mg/dL over 3 weeks. Calculated average clearance from 24-hour urine collection was 15 ml/min. Transplant renal allograft biopsy revealed moderate ATN and borderline changes. Diuretic dose was decreased and SCR was improved to 0.7 mg/dL. She still required treprostinil as well as intensive rehabilitation and nutritional supplementation. She remains in ICU for the majority of the time posttransplantation.

Discussion: PPH is one of the challenging scenarios for ESLD requiring LT. Reversibility from PPH after LT is uncertainty. It is still a dilemma in managing this difficult situation between LT to prolong life with poor quality and conservative management. LT is a life-saving surgery but may not always reverse a severe complication of ESLD such PPH and thus prolongs no postoperative quality of life. Therefore, LT in such a complex underlying condition needs to be individualized.

SA-PO119
Flash Pulmonary Oedema in Renal Artery Stenosis: An Indication for Stenting? Elise Chiu, Martine David, Neil Chapman. Medicine, Imperial College, United Kingdom.

Introduction: Renal artery stenosis (RAS) is an unusual but potentially treatable cause of flash pulmonary oedema. Although national guidelines recommend percutaneous revascularization (level of evidence B), we present a case of recurrent flash pulmonary oedema which suggests a need for further evidence to support use of revascularization therapy in elderly patients with multiple comorbidities.

Case Description: A 78 year old woman presented with a fourth episode of sudden onset dyspnoea in 4 months. Her medical history included CAD, AF, hypertension (HTN) and severe pulmonary HTN due to heart failure with preserved ejection fraction (HFPEF). On admission, there were bilateral respiratory crackles and pulmonary congestion on chest XR. BP 164/95, creatinine 110umol/L, eGFR 42. Echocardiogram showed concentric LVH, preserved EF and raised PAP. Because of recurrent symptoms despite apparently adequate medical management of HFPEF, she underwent CT angiography which revealed bilateral ostial RAS (70% right, 40% left). Following multidisciplinary team discussion, bilateral balloon angioplasty with stent insertion was performed with radiologically successful results and she was discharged on ticauroxaban for stroke prevention. Since then, she has had no further episodes of pulmonary oedema. However, renal function deteriorated post-procedure (max creatinine 228umol/L, eGFR 18 at 6 weeks; no evidence of in-stent thrombosis) and she has diuretic-resistant pedal oedema severely impacting quality of life.

Complement Mediated Hemolytic Uremic Syndrome Secondary to SLE
Aala Complement Mediated Hemolytic Uremic Syndrome Secondary to SLE

Discussion: This case highlights the importance of recognizing RAS as a cause of flash pulmonary oedema, especially in bilateral disease due to lack of compensatory mechanisms. Observational studies and case series have demonstrated that angiotensin +/- stenting reduces the incidence of flash pulmonary oedema. However, there is limited literature to guide management (eg. on risks and benefits of unilateral vs. bilateral intervention, degree of stenosis) and limited experience in the elderly in whom comorbidities may increase the risks of procedural complications such as deterioration of renal function due to contrast nephropathy and/or cholesterol emboli.

SA-PO121
Idiopathic Nodular Glomerulosclerosis Presenting with Nephrotic Range Proteinuria and Normal Renal Function
Hassan E. Osman, Dany H. Issa.
Dept of Internal Medicine - Div of Nephrology, Saint Louis Univ, Saint Louis, MO.

Introduction: Idiopathic Nodular Glomerulosclerosis (ING) is a well-established but uncommon entity that has been described in 1985 by Chan JY et Al. It is common in older white men with history of long-standing hypertension, obesity, and smoking and typically presents with renal Insufficiency & Nephrotic Range Proteinuria. Multiple reports and meta-analyses of patients with ING demonstrate an average creatinine ~ 2.0 mg/dl and progressive kidney dysfunction leading to ESRD.

Case Description: We report a case of a 57 year old Caucasian obese female who presented with edema and heavy proteinuria (9 gms/day). She is a 40-pack year smoker with long-standing hypertension with variable control. Serum Creatinine on presentation was 0.7 mg/dl. Hba1c was 6.0% and fasting/random sugars never met criteria for overt Diabetes Mellitus. Urine showed 3-10 rbcs/hpf and none where dysmorphic with an otherwise bland urinalysis. The patient was treated with diuretics and ACE-Inhibitor lead to improvement in volume status and recovery of renal function. Nine-months into follow up renal function remain stable.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

SA-PO122
Hemofiltration Reinfusion Equilbrium Can Be An Answer to Malnutrition and Hypotension in Dialysis
Nicoletta Pertica, Dept of Nephrology, Verona Hospital (AOU VR), Verona, Italy.

Introduction: We analyze the impact of A-HFR on intradialytic tolerance, nutritional status and on the clinical condition of two malnourished patients of our dialysis center.

Case Description: We performed an observational study for 12 months on 2 patients shifted to A-HFR caused to dialysis intolerance towards other methods. We monitored Blood Gas (pre and post treatment), clinical, biochemical, and dialitic data. Patient 1: 62 years old man on dialysis since 2008, suffering from malnutrition and anorexia due to cerebellar stroke (BMI 15.8) with intra and interdialytic hypotension. On February 2014 he started IPDN (Intradialytic Parenteral Nutrition) + HDF online without any clinical improvement. On June 2014 he was shifted to A-HFR+IPDN with improved hemodynamics control, weight (10% compared to its initial), nutritional and inflammatory indexes. In addition, he improved his quality of life with disappearance of hypotensive episodes and reduced consumption of EPO. Patient 2: 44 years old woman: kidney-panceases transplanted, on dialysis since 2011. In 2012 she started an antibiotic therapy for curing a pulmonary TBC, burdened by malnutrition and severe peripheral neuropathy with persistent hypotension, also during dialysis. In 2015 she was shifted to A-HFR and improvements regarding bodyweight, blood pressure, inflammatory markers and peripheral neuropathy were observed.

Discussion: A-HFR has dynamic profiles of ultrafiltration and conductivity of the dialysate: this aspect creates an iso-osmolar dialysate, ensuring a better periferal refilling and improving compliance during the dialysis treatment. This is due to the use of biosensors. A-HFR also reduces the Amino acids loss. This report has numerical limitations but provides encouraging data on the use of AHFR in malnutrition and disequilibrium syndromes. This experience underlines the importance of further efforts towards customized dialysis procedures.

SA-PO123
Monoclonal Gammopathy of Renal Significance: The Significance Is Not Always Unknown
Umair S. Ahmed, Nephrology, West Virginia Univ, Morgantown, WV; Nephrology, West Virginia Univ, Morgantown, WV.

Introduction: Membranoproliferative glomerulonephritis (MPGN) is a pattern of glomerular injury noted on microscopy. It is less commonly associated with monoclonal gammapathies, including monoclonal gammapathy of unknown significance (MGUS). Case Description: Patient is a 67 years old female, with a history of rheumatoid arthritis, on Methotrexate, who presented to an outside facility with progressively worsening fatigue for four months. Investigations showed pancytopenia, following which she was transferred to our hospital for further management. On arrival at our hospital, patient was noted to have an acute kidney injury. A random urine protein/creatinine ratio showed 5.5 gm proteinuria. Serum protein electrophoresis showed a monoclonal spike, with an Ig M kappa clone. Immunglobulin (Ig) G was low at 161 mg/dl, while Ig M was increased at 378 mg/ dl. Bone marrow biopsy done showed 5 % plasma cells, with no morphological features of a plasma cell neoplasm, leukemia or lymphoma. Serum electrophoresis showed a monoclonal spike, with an Ig M kappa clone. Immunglobulin (Ig) G was low at 161 mg/dl, while Ig M was increased at 378 mg/ dl. Bone marrow biopsy done showed 5 % plasma cells, with no morphological features of a plasma cell neoplasm, leukemia or lymphoma. Kidney biopsy done showed MPGN, with positive immunofluorescence for IgM, C3, kappa, along with large subendothelial and mesangial deposits. Both C3 and C4 were low. Work up was negative for hepatitis B and C. Serum cryoglobulin levels were normal. No evidence of lupus was noted. Infectious work up was also unremarkable. Patient was diagnosed as having MGUS by the hematologic service. MPGN was assessed to be secondary to MGUS in the absence of other possible etiologies. Patient was started on high dose steroids for 3 days followed by a taper, along with intravenous Rituximab 375 mg/m² weekly for 4 weeks. Due to worsening renal functions patient was started on hemodialysis. Unfortunately due to lack of renal recovery, patient was declared as having end stage renal disease.

Discussion: MGUS is the most common plasma cell disorder and may be a precursor for myeloma. It is characterized by a lack of end organ damage. A small subset of patients, however, may rarely have renal involvement, with MPGN being noted on renal biopsy. MGUS can therefore be associated with morbidity and mortality, and therefore its significance may not always be unknown.
SA-PO124
A Case of Chronic Unilateral Hematuria Treated by Segmental Renal Artery Embolization
Hanse K. Kim,1 Joon Seok Oh,2 Yong Ki Park,2 Dongyeol Lee.1 1Nephrology, Bongseong Memorial Hospital, Busan, Korea; 2Nephrology, Dongrae Bongseong Memorial Hospital, Korea.

Introduction: Chronic unilateral hematuria is characterized by intermittent or continuous hematuria that cannot be diagnosed using standard radiographic and hematologic methods. Unilateral hematuria is probably a benign condition that seldom requires surgical treatment, but some cases were managed with partial or total nephrectomy. Recently, a variety of treatments, including the ureteroscopic interventions have been attempted if the bleeding focus is identified. However, if not identified on ureteroscopy, surgical treatment has been considered a priority. We report the case of treatment of chronic unilateral hematuria with segmental renal artery embolization.

Case Description: We experienced a case of chronic unilateral hematuria in a 42-year-old woman who was admitted to our hospital due to intermittent gross hematuria and anemia for 31 months. About 29 and 19 months ago she already underwent CT scan, renal angiography, and renal biopsy at other tertiary hospitals, but didn’t find any other specific abnormalities repeatedly except some blood clots in left renal pelvis on ureteroscopy. She underwent CT urography, renal arteriography, cystoscopy and ureteroscopy again. Ureteroscopic findings only showed bleeding in the upper third of left renal calyces but definite bleeding focus could not be identified. Thus we decided to manage with segmental renal artery embolization than partial nephrectomy to minimize the reduction in renal function and to reduce operational risk. The superior and superoanterior segmental renal arteries were successfully embolized with 3mm coils and gelatin sponge. Gross hematuria disappeared on the 4th day after the procedure, microscopic hematuria disappeared on the 5th day. In 11th day, infarction in the upper third portion of left kidney was confirmed on CT scan. In 13th day, the patient was discharged. Thereafter serial urinalysis showed no hematuria.

Discussion: Patients with chronic unilateral hematuria often require surgical or upper urinary tract endoscopic procedures. Segmental renal artery embolization will be a better treatment for patients unable to identify the bleeding focus on the upper urinary tract endoscopy.

SA-PO125
An Unusual Cause of Acute Kidney Injury in a Patient Several Months Post Renal Transplant
Sweta Carpenter, Karthik M. Rangan. Nephrology, Drexel Univ.

Introduction: Urinary anastomosis leaks after kidney transplants are no longer a common phenomenon. Due to advancements in reconstruction techniques, urologic complications after renal transplant are now reported to occur in only 2-2.5% of patients. If a urinary anastomosis leak develops, the patient needs to be managed with segmental renal artery embolization than partial nephrectomy to minimize the reduction in renal function and to reduce operational risk. The superior and superoanterior segmental renal arteries were successfully embolized with 3mm coils and gelatin sponge. Gross hematuria disappeared on the 4th day after the procedure, microscopic hematuria disappeared on the 5th day. In 11th day, infarction in the upper third portion of left kidney was confirmed on CT scan. In 13th day, the patient was discharged. Thereafter serial urinalysis showed no hematuria.

Case Description: We present a case of a 60 year male with a history of a living unrelated kidney transplant who developed acute kidney injury 5 months after transplant. He had a baseline creatinine of 1.5-1.7 mg/dL and initially presented to the hospital with fevers and a creatinine of 2.96 mg/dL. A fungal urinary tract infection with Candida Albicans was deemed the culprit of his symptoms and so he was promptly started on fluconazole with only a slight improvement in his creatinine. A renal ultrasound of the kidneys revealed a 12.4 cm R and 12.6cm L kidney with multiple cysts. Taking into account the history of candida infection, urine culture, and the absence of significant hematuria, initial workup for causes of renal failure was negative. She underwent CT urogram, CT angiogram and CT cystoscopy. She was admitted to hemodialysis and a kidney biopsy was performed which showed Candida Albicans.
SA-PO129
Clostridium Difficile Associated Peritonitis in a Patient on Peritoneal Dialysis

**Dimpu M. Patel,** Gaurav Jain. Nephropath, Univ of Alabama at Birmingham, Birmingham, AL.

**Introduction:** Culture negative infectious peritonitis (CNP) is a common and serious complication in peritoneal dialysis (PD) patients. It is usually a result of samples failing to reach the threshold of microbiological detection, recent antibiotic exposure, or simply unusual symptoms. Our patient tested positive for Clostridium difficile (C. diff) infections have become more frequent, and more refractory to treatment, and dialysis patients are often affected by C diff secondary to repeated exposure to antibiotics, as well as hospitalizations. C diff infection should be considered in the differential for CNP in dialysis patients.

**Description:** A 41 AA male on PD since 2012 presented to PD unit with complaints of abdominal pain and cloudy fluid. He started on intraperitoneal antibiotics (Vancomycin and Cefazidime) as an outpatient, though his symptoms of abdominal pain worsened requiring a hospital admission within 48 hrs of onset of symptoms. He complained of nausea and cloudy fluid for 12 hrs on his day of admission. On exam, he was diffusely tender in his abdomen, with no guarding/rigidity. Lab data was significant for peritoneal fluid WBC count of 7,130 with 85% polys and he was continued on broad-spectrum IV antibiotics. Stool C diff toxin resulted positive on day 2 of hospitalization and he was started on IV metronidazole. His abdominal pain persisted, and a recheck of PD fluid cell counts on Day 3 revealed a WBC count of 17,671 with 79% polys. The PD fluid cultures were negative for unusual organisms not routinely tested for. Clostridium difficile (C. diff) infections have become more frequent, and more refractory to treatment, and dialysis patients are often affected by C diff secondary to repeated exposure to antibiotics, as well as hospitalizations.

**Results:**
- Our case study describes culture negative peritonitis in a patient with C diff that did not respond to broad spectrum IV antibiotics. This prompted further investigation of C difficile peritonitis that was confirmed on lab testing. This case highlights the importance of suspecting C diff peritonitis in PD patients with CNP.

**SA-PO130**

Adequacy of Australian Nephrology Training

Nicholas A. Gray, 1 Thomas Joseph Beaton, 2 Rathika Krishnasamy, 1 Nigel David Toussaint, 1 Richard K S Phoon. 2
1 Renal Unit, Sunshine Coast Hospital and Health Service, Nambour, Queensland, Australia; 2 Renal Unit, Westmead Hospital, Westmead, New South Wales, Australia; 3 Renal Unit, Royal Melbourne Hospital, Parkville, Victoria, Australia.

**Background:** There has been an increase in the number of doctors training in nephrology in Australia. This study aimed to assess the adequacy of nephrology training by measuring self-determined competency and skill relevance among recently graduated nephrologists.

**Methods:** A survey was developed by the Nephrology Advanced Training Committee of the Royal Australasian College of Physicians. The survey was administered on-line in 2015 via the annual subscription to the Australian and New Zealand Society of Nephrology. Nephrologists who were awarded Fellowship after 2002 were invited to participate.

**Results:** 113 of a 306 eligible Fellows (37%) completed the survey. 8 respondents had moved overseas and were excluded. Median age was 41 years (interquartile range 37-44) and 63% were male. Medical school was completed in Australia (59%), India (15%), and New Zealand (7%). 35% received at least some training in a rural area and 25% were qualified in another specialty (mainly internal medicine). 56% had completed and 21% commenced a higher degree. Higher degrees were undertaken for career development (43%) and desire for a research career (30%). Respondents indicated good training and competency in most clinical skills that were relevant to their practice. In training home hemodialysis (37%), and living kidney donor assessment (51%) were considered less adequate, despite these areas being considered very relevant to practice. There was a greater mismatch identified between training and importance of skills for management and research. This included inadequate training in managing complaints (82%), managing a private practice (98%), health system knowledge (86%) and regulations (93%), medical directorship (94%), ethics approval (76%), research funding (88%), and quality assurance (73%).

**Conclusions:** Nephrology training in Australia meets the clinical needs of new nephrologists. Similar to findings in USA, training in management and research was considered insufficient for the practices of new nephrologists and should be addressed in updates of the curriculum.

**SA-PO131**

Pediatric Nephrology Workforce and Training: An International Perspective

Dorey A. Glenn, 1 Adam R. Weinstein, 2 Maria E. Ferris. 1
1 Univ of North Carolina at Chapel Hill; 2 Dartmouth Hitchcock Medical Center; 3Univ of North Carolina at Chapel Hill.

**Background:** There is a shortage of pediatric nephrology providers in a number of areas around the world. We sought to determine pediatric nephrologists’ perspectives on this issue.

**Methods:** A voluntary web-based survey was deployed via the Qualtrics™ survey engine. Members of the International Pediatric Nephrology Association responded anonymously to questions about their geographic location, time spent on training, practice setting, and impressions on local workforce challenges and opportunities.

**Results:** The number of responses to date was 38, representing 21 countries from all continents. Six percent of the respondents treat both children and adults. The number of years required to train in pediatric nephrology was reported as: 2 years (35%), 3 years (58%) and 4 years (8%). Nearly 80% of practices were associated with academic settings. Specialty training programs are reported in 63% of the respondents’ institutions and 50% of those with training programs stated that it was difficult or very difficult to recruit trainees. Forty two percent of the respondents stated that it was difficult or very difficult to find a job after training. The themes most frequently cited on qualitative analysis include low availability and interest in the field by trainees, poor compensation, demanding schedule and competing family demands.

**Conclusions:** In this preliminary study of an international cohort of pediatric nephrologists, our data suggests a perception of a decreased pediatric nephrology workforce. There is also a perceived shortage of available positions in the field. Further data collection on workforce issues as it pertains to country-related factors is needed.

**SA-PO132**

Taking Guessed Out of Milestone Ratings -- Simplify the Evaluation System to Easily Achieve the Next Accreditation System (NAS) Report

Samantha J. Thompson, Laura J. Maurerett. Div of Nephrology, Univ of Wisconsin School of Medicine and Public Health, Madison, WI.

**Background:** In an effort to translate into competency-based training, the ACGME has developed 24 milestones specific to fellowship. While the milestones are comprehensive, it is challenging to determine an individual’s rating through faculty evaluations; many of whom are untrained in this system. We aimed to create a simple scoring system that translates the milestones into observable nephrology activities that can be completed daily on a handheld device.

**Methods:** For each nephrology rotation, a list of 5-10 frequent activities was developed. For every activity, a description for the five levels of competency was written to standardize the score. The activities were completed in 1-4 NAS milestones. The evaluations were built in Google Forms and delivered daily to supervising faculty members. Using a four-click system, the observer can submit a fellow evaluation with most done on mobile devices. If faculty members wish to express a narrative, a free-text response box is provided for comments.

**Results:** Of the 914 possible evaluations over a nine-month period of time 727 evaluations were returned. This provided data points to distinguish scores among all fellows in all of the NAS milestones.

**Fellow Performance Per Milestone-Yearend 2014-15**

In Clinical Competency Committee meetings thus far, 1 of 276 scores have been adjusted from the scores provided by the evaluation system.

**Conclusions:** This is an easy to use scoring system that has resulted in immediate feedback that is activity-specific and feed into NAS milestones easily and effectively. By translating the evaluation system into specific activities that any nephrologist can observe, a robust amount of valuable data has been obtained. The 4-click system has yielded an excellent response rate with more narrative comments than were previously obtained with monthly evaluations.
Methods: ITE annual reports provided by the National Board of Medical Examiners were reviewed and summarized.

Results: Scale score for all was 480: 104 (mean ± SD); 1st-year fellows (n = 2,020) 445.96, 2nd-year (Y2, n = 2,005) 515±100, and 3rd-year and higher (n = 112) 509±113. Standard error of the mean ranged 41-45. The 2010 ITE had 150 core items only. 2011 and 2012 ITE had separate OS-TE, urinalysis and renal pathology modules administered to Y1 and Y2 respectively (not included in total test statistics). In 2013 and 2014, all completed 20-item modules on these topics (included in statistics). A mean of 6.6 core items (4.4%) were deleted per year after adjudicating items with high difficulty or negative discrimination. Content areas aligned with American Board of Internal Medicine Certification Exam: General Aspects of Chronic Kidney Disease (CKD), Glomerular/ Vascular (GV), Tubulointerstitial/Cystic (TUC), Acute Renal Failure/ICU Nephrology (ARF/ICU), Kidney Transplant, Hypertension, Sodium/Water (Na/H2O), Acid-Base/ Poisoning, Mineral Metabolism (M/M), and Clinical Pharmacology (CP). Ethics. Though examinee abilities typically vary yearly, overall total average test p-value was 0.67. ARF/ICU, Na/H2O, MM, and CP tended to be less difficult (average p value 0.7) and TUC more difficult (average p-value 0.58). Total test mean item discrimination bias correlation averaged 0.21, highest for A-B/K (0.28) and lowest for CKD (0.18). Total test reliability (α) averaged 0.81; highest for GV (0.46) and lowest for TIC (0.25).

Conclusions: As expected, scale scores were higher for Y2 than Y1 fellows. Over 95% of administered items were scored; among those, mean item difficulty, item discrimination, and reliability varied among content areas.

Funding: Private Foundation Support

SA-PO134
What Are We Doing? A Survey of U.S. Nephrology Fellowship Program Directors

Methods: We distributed a survey for nephrology program directors via the Training Directors’ website. The survey addressed fellows’ service load and the scope of educational activities offered by the fellowship.

Results: 57 out of 147 programs responded (39%). Most are 2 years long, with a mean of 7 fellows, and are “front loaded”- 64% require ≥ 7 months of inpatient service during year one. Inpatient services are usual (93%) covered by one fellow with significant resident involvement. NP’s and PA’s help cover about 15% of services. The busiest services have about 21-25 patients, although 13% of programs averaged ≥ 26 patients. At their busiest, these services have more than 30 patients, occasionally surpassing 50 patients. About one quarter of these programs are exclusive of patients in which a fellow is involved for which a fellow is involved. Night call is most often divided equally among all years. Weeknight call is typically one night at (74%) covering a single hospital (66%). Fellows in the call rotation typically cover ≥ 10 nights over a three month period and ≥ 1 week-end a month. Most fellows do one weekly half day clinic, averaging 4-6 patients per session with a faculty: fellow ratio typical ≥ 1:2. Clinic structure is not usually modified during fellows’ inpatient service. Longitudinal coverage of HD and PD patients is provided by 82% and 61% of program respectively. Educational conferences ranged from 2-6 hours per week. Faculty didactic teaching varies from < 1 hour a week to 5 hours per week; one hour is typical. Fellows usually give 2-6 formal presentations yearly, although in some programs this is significantly more.

Conclusions: Our survey underscores the large variety in workload, practice patterns and frequency of educational conferences at different institutions and provides a framework to help address the service/education balance during nephrology fellowship.

SA-PO135
Perceptions of Nephrology Among Internal Medicine Residents

Methods: This is a repeated cross-sectional survey of IM residents to assess perceptions of nephrology and the impact of these perceptions on career decisions. All categorical IM residents in the last two years of training were invited to participate in 2012, prior to the initiation of a nephrology fellowship program (Group 1); and in 2015, three years following initiation of a nephrology fellowship program (Group 2).

Results: 131 of 156 residents (84.0%) completed the survey. A total of 14.8% (19/131) of residents indicated interest in a nephrology career, with 6.25% (8/131) indicating Nephrology as their first choice. Cardiology (21.1%) and Hospitalist (12.5%) were the most popular career choices. The presence of a Nephrology Fellowship program did not increase resident interest in nephrology (14.5% in Group 1 vs. 15.1% in Group 2). In perceptions of nephrology were not significantly different in Group 1 vs Group 2. Negative perceptions of nephrology most commonly endorsed by residents were: renal pathophysiology is too complex (22%), poor preparation in medical school (22.14%), few opportunities for procedures (26.7%), long work hours (24.4%), and long hours/desire call for nephrology fellows (27.5%). The majority of residents (83.2%) reported exposure to positive role models in nephrology. Experiences cited as having a high impact on career choice included: mentors/role models in the field (71.65% of residents) and rotations during residency (57.14%).

Conclusions: The presence of a nephrology fellowship program had no effect on IM residents’ interest in nephrology careers. Residents endorsed several negative perceptions of nephrology which may affect career choice.

SA-PO136
Insight into the Declining Interest in Nephrology

Methods: A web-based survey was conducted using survey monkey. 10 questions designed to help understand the reasons behind the decline of interest in nephrology were utilized. The survey link along with recruitment letter and consent form were sent to all US IM residency programs. Email addresses were obtained from the Alliance for Academic Internal Medicine website.

Results: 531 residents responded to the survey. 81% of those who completed the survey answered “No” to the question asking if they had interest in nephrology. The most common reason cited was a disheartening patient population, followed by salary, work hours & lack of understanding. 50.9% found nephrology “difficult” with the most challenging topics being glomerulonephritis (GN), acute base & transplant. The respondents noted that exposure to interventional nephrology, transplant & GN might increase their nephrology interest. Of those interested, more exposure to GNS during residency was felt to likely increase their interest.

Conclusions: These survey results demonstrate that most IM residents aren’t interested in nephrology and that restructuring of nephrology electives in residency programs to include enhanced exposure to GNS, transplant, and nephrology procedures might increase interest. Nephrology rotations are primarily an inpatient experience with exposure to critically ill AKI patients or complicated ESRD patients with significant recidivism. This experience leads to the perception that the nephrology population is disheartening. Since this is the most common reason why residents lack interest, changing the structure of nephrology electives in IM residencies to allow for more outpatient exposure with emphasis on GNS and transplant might be crucial for enhancing interest in nephrology fellowship training and a career in this subspecialty.
SA-PO138
Creating and Enhancing Interest in Nephrology Careers: A Novel Nephrology Elective Experience for Medical Students
Hitesh H. Shah, Kenan D. Jhaveri. Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY.

Background: Interest in nephrology careers continues to decline in the United States (US). The type of nephrology elective that US medical students experience may play an important role in creating and enhancing interest in nephrology careers.

Methods: At our institution, we created a novel 4-week nephrology elective experience for medical students. Our redesigned elective included both 2-week inpatient (IP) and 2-week outpatient (OP) nephrology experiences. The OP rotation included 10 half-days of various nephrology clinic experiences, 2 half-days of immediate post-transplant clinic, 1 half-day of hemodialysis clinic, 2 half-days of peritoneal dialysis clinic, and 3 half-days of outpatient hemodialysis unit rounding. The redesigned elective also included education conferences. From 7/2012 to 2/2015, nine 4th year medical students (all from different US medical schools) completed our redesigned nephrology elective. To evaluate the novel elective experience, all medical students were asked to complete an anonymous online survey upon completion of their rotation.

Results: All students responded to our survey. All reported adequate OP nephrology exposure during their elective. 89% had worked with 1 or 2 faculty members during the IP setting. In comparison, 78% were exposed to at least 4 different faculty members during the OP experiences. All students had interacted with at least 3 fellows. All reported that the elective experience enhanced their exposure and knowledge in nephrology and that they would recommend this elective to other medical students. They also thought that this elective structure provided them with a better insight into what nephrologists do in practice. 78% reported that this elective experience created an interest in nephrology career. 56% responded that they would consider nephrology as one of their 3 top career choices as a result of this elective experience.

Conclusions: We believe that the restructured nephrology elective provides the medical student with a much needed and realistic exposure to nephrology careers. Based on our experience, we recommend all training programs to consider this elective structure for medical students.

SA-PO139
Journal Publication of Nephrology Fellows Case Report Presentations at ASN Kidney Week 2012-2013
Hitesh H. Shah, Nairi H. Shah, Rushang Parikh, Kenan D. Jhaveri. Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY; Colgate Univ, NY; SUNY Upstate Medical Univ, NY.

Background: The inception of the fellows case report (CR) category at the ASN Kidney Week (KW) occurred in the year 2012. However, the number and types of CR abstracts accepted for presentation at ASN KW is not known. Peer-reviewed journal publication (PR-JP) of these previously presented CR abstracts at ASN KW is also not known.

Methods: All previously accepted fellows CR abstracts from ASN KW 2012-2013 were reviewed and categorized as follows: glomerular diseases (GN), tubulointerstitial diseases (TIN), acute kidney injury (AKI), fluid-electrolyte and acid-base disorders (FE-AB), dialysis (D), kidney transplant (KT), genetic disorders (GD), mineral diseases (MD), and other (O) cases. To determine the PR-JP rate of these CR abstracts, a literature (PubMed) search was performed in November 2015.

Results: A total of 415 abstracts were presented in the fellows CR category at the ASN KW 2012-2013. Compared to KW 2012, there was a 7.5% increase in CR abstract presentations at KW 2013. Over these previous two KW meetings, nearly one-third (31.6%) were CR abstracts. The remaining abstracts were FE-AB (15.2%), AKI (14.4%), KT (11.8%), D (11.8%), TIN (5%), MD (4%), and O (4%), and GD (2.2%) related presentations. Compared to KW 2012, there was an increase in GN related presentations (from 55 to 76) at KW 2013. So far, only 72 (17.3%) out of the 415 abstracts have been published as papers in peer-reviewed journals. One abstract was published as a letter to the editor format. Of those that were published, 31.5% were GN related case reports. Interestingly, 22% of these journal publications did not list the lead author of the KW CR abstract as the primary author of the paper.

Conclusions: Based on our study, it seems that there is an increased interest among fellows to present CR abstracts at ASN KW. Nearly one-third were GN related case presentations. However, so far, less than one-fifth of the fellows CR abstracts presented at KW 2012-13 have been published in peer-reviewed journals. Reasons for this low publication rate is not known. Measures to enhance CR publications need to be considered.

Analysis of Published Medical Student Related Nephrology Medical Education Research
Sarah B. Baveyksly, Hitesh H. Shah, Kenan D. Jhaveri. Hofstra NSLIJ School of Medicine; Nephrology, Hofstra NSLIJ School of Medicine.

Background: Undergraduate (medical student) related medical education research in nephrology is not well studied. This analysis aims to assess the rigor of the studies describing teaching methods used in medical student education in nephrology.

Methods: A review of the English literature on nephrology education of medical students was conducted on two major online academic search engines (PubMed and ERIC). References from the papers discovered in this search were also reviewed. Conference abstracts were not investigated. The empirical studies were categorized by subject within nephrology. The research design of each study was then recorded.

Results: 26 original studies were found in which a method of teaching nephrology to medical students was described. The studies dates from 1977 to 2015. The focus of these teaching experiences was as follows: anatomy (3.3%), physiology (23.3%), pathophysiology (26.7%), pathology (10%), treatment (20%), and general nephrology (16.7%). 4 of the pathophysiology studies were also classified under other categories, so there were 30 studies. The papers were also categorized into types of assessment. One type of assessment containing two different types of studies for a total of 28 types of assessment. 14.2% had either no assessment of the educational experience or had a description too vague to categorize it; 3.6% involved a questionnaire about the existing educational approach prior to implementing the new teaching method; 14.2% rated the effectiveness of the new teaching method based on student performance; 14.2% rated student performance. 22% of these journal publications did not list the lead author of the KW CR abstract as the primary author of the paper.

Conclusions: Based on our study, it seems that there is an increased interest among fellows to present CR abstracts at ASN KW. Nearly one-third were GN related case presentations. However, so far, less than one-fifth of the fellows CR abstracts presented at KW 2012-13 have been published in peer-reviewed journals. Reasons for this low publication rate is not known. Measures to enhance CR publications need to be considered.
SA-PO143

Awareness of AKI in Low Resource Settings: A Global Survey
Joseph Lunyera,1 Kajri Kilonzio,2 Andrew J. P. Lewington,2 Karen E. Yeates,3 Fredric O. Finkelstein,3 Duke Univ; 4KCMC; 5Leeds Teaching Hospitals; 6Queen’s Univ; 7Izade Univ.

Background: The ISN has set a goal of eliminating preventable deaths from AKI by 2025—the “0x25” initiative. However, there is limited awareness of the challenges presented by AKI in terms of diagnosis, treatment and management in low resource settings (LRS).

Methods: We reached out to nephrologists working in LRS using a web-based instrument of 18 questions. Responders were asked what strategies should be considered to increase the awareness of AKI in LRS and recommend approaches to heighten this awareness. A total of 5 respondents from 5 WHO world regions, including 54% from Africa.

Results: The major barriers to raising awareness cited by all were inadequate training, shortage of adequately trained health workers and lack of awareness of the significance of AKI by healthcare workers, government officials and the general public. Additional factors cited were limited patient access to health facilities, limited diagnostic and treatment facilities, lack of support for AKI programs, lack of clinical practice guidelines for AKI, poor communication systems, limited research funding and lack of linkages of AKI programs to other health projects. Health centers (HCs) were broken down into rural, district and regional HCs. Supplies available for diagnosis (serum creatinine and BUN) and management (IV fluids, antibiotics, anti-venom) of AKI are limited in rural HCs. All noted that hemodialysis services were available but only in selected, large urban centers.

Conclusions: Increasing the awareness of AKI in local, district, and regional HCs requires a multi-faceted approach, reaching out to government officials, hospital administrators, physicians, nurses, local health care workers, community leaders, international organizations and the general public. The success of this initiative involves the development of meaningful and targeted educational programs, training materials, and treatment guidelines tailored to the local situations. Alliances will need to be formed with governmental agencies, non-profit organizations and global health programs. Support needs to be provided for additional research programs.

SA-PO144

Acute Kidney Injury Education to Nursing and Assistant Health Care Staff Mansoor N. Ali, Renal Medicine, Calderdale and Huddersfield Hospitals NHS Foundation Trust, United Kingdom.

Background: Acute kidney injury (AKI) is a global healthcare problem. It carries significant mortality and incurs heavy costs to the National Health Service. Extensive work has been done recently both at undergraduate and postgraduate level to ensure front line medical staff have better understanding in managing AKI. One such important area of focus involves the need for training nursing and assistant healthcare staffs who care for patients presenting with AKI.

Purpose of the study: To gauge the understanding of AKI amongst nursing and healthcare assistants working on busy acute medical admissions unit.

Methods: The anonymous questionnaire was aimed at the nursing and assistant health care staff working on the admissions unit at two large district hospitals. The length of time since qualification ranged from few weeks to 16 years. The questionnaire was followed by planned teaching, simulation training and workshop sessions. The process was carried out within a period of 2 months.

Results: The questionnaire was completed by 50 staff members. It included series of questions aimed at defining and managing AKI from a nursing perspective. 24 out of 50 were able to define AKI. Only 5 out of 50, have never cared for patients with AKI. Not many were aware of the symptoms of AKI; common answers given by 40 respondents were “reduction in urine output” and “dehydration.” All participants answered “yes” to monitoring urine output and understood the significance of fluid monitoring but all admitted more needed to be done to ensure accurate documentation in the patient’s notes. Other questions asked were if nurses check patient’s blood results on the system server to which most replied “no” and if medications were regularly reviewed during drug rounds. Surprisingly, not all were aware of nephrotoxic medications and only 20 respondents would regularly review drug charts in the context of renal failure.

Conclusions: The questionnaire and the training sessions identified lack of better understanding of AKI and its management. There needs to be a stronger emphasis on the introduction of AKI and its management during their training years and development of mandatory online e-learning modules.

SA-PO145

Background: AKI occurs in 1-in-3 hospitalized patients, and majority of those are managed by non-nephrology specialties, including trainees.

Methods: The renal fellowship program designed an online anonymous survey, distributed to trainees (students, residents, fellows), to understand their level of knowledge in recognition and management of AKI. 37 questions were classified into following categories: knowledge of guidelines; prognostic factors; and drug safety. Results are represented as % age and awareness.

Results: 104 trainees responded to the online survey; 50% were male, 84% US medical graduates and 70% were residents/fellows. 50% were affiliated to medical specialties; and 53% had spent at least one elective in nephrology. In terms of AKI definition: 51% use serum creatinine (SCR) as the most important factor to diagnose AKI, whereas 20% use urine output. Majority (76.1%) agreed that rise of 0.3 mg/dl or 1.5 times of baseline SCR was clinically relevant, in concordance with current guidelines. RIFLE criteria were most commonly used (42%), followed by KDIGO (13%); and 90% agreed that guidelines help in standardization, and management of patients. 85% concurred that AKI impacts short and long-term outcomes, however, majority (60%) felt dialysis requirement was the most important clinical predictor of outcome. Majority (67%) felt that early involvement of nephrology services is helpful in AKI management; 66% sought nephrology input to determine the cause of AKI/co-management, and 7% viewed nephrology role purely for procedural delivery of dialysis. As for drug safety, 89% reported to pay attention to renal function while drug dosing, but 70% felt that this was the responsibility of either pharmacy or ordering team. In terms of follow-up 61% of subjects felt that follow-up was only needed in moderate to severe AKI cases or in non-recovery; 86% preferred that in > 30 days, and 64% preferred that to be with primary care.

Conclusions: Most of the trainees displayed good knowledge of AKI guidelines (RIFLE), seek timely nephrology involvement and view it to be beneficial. More work needs to be done in terms of improving knowledge/practice about drug safety and follow-up care in AKI.

SA-PO146

Adherence to Care Bundles for AKI – Challenges in Supporting Education and Measuring Compliance Melanie Louise Sally, Christopher J. Mulgrew. Renal Medicine, Royal Devon & Exeter Hospital, Exeter, Devon, United Kingdom.

Background: AKI typically occurs as a consequence of intercurrent illness in patients with multiple comorbidities and risk factors. The use of clinical guidelines to assist medical and nursing staff in AKI management has been adopted by most secondary care institutions in the UK. We have previously presented our use of e-alerts for AKI as a prompt to improve AKI care (Mulgrew et al, ASN, 2013). Clinical guidelines were prompted by the e-alert and widely publicised to staff.

Methods: In a model similar to the NHS Safety Thermometer, snapshots of compliance with 6 key elements of the AKI guidelines on 4 medical wards was measured by identifying patients from AKI e-alerts. These included documentation of AKI, medication review, clinical judgment and ongoing investigation/monitoring. Awareness was supported by an AKI Education nursing team, working with medical and nursing staff. Monthly compliance was assessed over a period of one year.

Results: Mean compliance for all elements of the guidelines improved from 52% to 69% over the year. Significant variability was seen, often associated with notable workforce challenges such as new medical staff or periods of increased activity.

Conclusions: Supporting medical and nursing teams to manage AKI in secondary care in order to prevent progression and treat promptly remains challenging. A number of external factors frequently impact upon adherence to guidelines and support needs to be planned in order to continue to maintain high standards and optimise patient care. The use of a Safety Thermometer, allowing performance to be analysed and comparisons made between clinical areas, may continue to be useful in improving performance and patient outcomes in AKI.

SA-PO147

Internal Medicine Residents Knowledge of Vein Preservation in Chronic Kidney Disease Patients Sandesh Joshi, Jamie Alton Green, Maria C. Bermudez. Nephrology, Geisinger Medical Center, Danville, PA.

Background: Vein preservation is important among CKD patients for future arteriovenous fistula potential. House staff plays critical role in managing these patient population and preserving their vein for future arteriovenous fistula. Their knowledge and current practices directly affects the outcome for vein preservation among these patients.

Methods: We conducted a survey among 44 internal medicine residents to understand their baseline knowledge and current practices regarding vein preservation. The survey was conducted at Geisinger Medical center, Danville, PA.

Results: 44 residents were included in the survey. Only 6.8% (3) were able to correctly identify patient population, on whom we should avoid particular arm for IV draws, BP measurements, peripherally access or peripherally inserted central catheters. Two-third (27) answered non-domain arm to avoid for these procedure and 13.5% (6) responded side does not matter. 81.8% (36) answered that nephrology should be consulted prior to peripherally inserted central catheters placement for CKD 4 patient. 93.1 % (41) answered...
and transplant nephropathy (all p-values <0.01). Factors associated with improvement in adjustments were endurers after July 2014, ICU encounters and less than 10 years of academic experience (all p-values <0.01).

Conclusions: Standardized templates led to significant reductions in revenue/work RVU losses per encounter at a large academic nephrology center. Nephrologists with more than 10 years of academic experience and transplant nephropathists performed worse than their peers. Efforts to improve documentation and billing may have important implications for academic nephrologists.

SA-PO150
Nephrology Documentation and Billing Educational Needs at an Academic Medical Center Leslie P. Wong, Emilio D. Poggio, Nephrology and Hypertension, Cleveland Clinic, Cleveland, OH; Transplant Center, Cleveland Clinic, Cleveland, OH.

Background: Reimbursement in nephrology depends on accurate documentation and billing. Academic nephrologists are under increasing pressure to meet financial productivity targets. An analysis of nephrology reimbursement was performed at an academic medical center to find deficiencies and identify targets for education.

Methods: 75,097 inpatient nephrology encounters by 22 nephrologists from January 2012 and March 2015 were reviewed. Data included the current procedural terminology (CPT) code specifying the type of service and any charge adjustments made by the coding department. Adjusted charges were accompanied by the reason for adjustment, the corrected CPT code and a revenue change based upon Medicare reimbursement. RVUs were calculated using the Medicare National Physician Fee Schedule. Multivariate regression analysis was performed to identify factors associated with RVU adjustments.

Results: 5615 (7.5%) of encounters were adjusted by coders. 3832 (68%) were due to incorrect documentation or billing and 1683 (32%) were due to services performed but not billed by nephrologists. For submitted charges, revenue was reduced by $995,976 and 4227 work RVUs as a result of incorrect documentation or billing. The potential loss of revenue from unbilled services was $603,014 and 2823 work RVUs. Inadequate documentation of physical exam (p<0.01) and inadequate documentation of supervision of medical students/residents/fellows (p<0.01) were independently associated with RVU adjustments. Incorrect charge selection, duplicate charges, competing charges from another nephrologist and conflicting discharge/observation/post-operative care CPTs were also independently associated with RVU adjustments (p<0.01).

Conclusions: There was a substantial loss in gross revenue and work RVUs due to incorrect documentation and billing in an academic nephrology setting. These reductions in reimbursement and productivity might be avoided through better physician education and training. Specific targets include documentation of physical exam and supervision of trainees, correct CPT charge selection and ensuring all services performed are billed.

SA-PO151
Reaching Renal Goals – A Quality Improvement Project Mihran V. Nalivian, Oksana I. Ninkivech, Vecheslav Fedorchenco, Sara Jacob Coulon, Kimberly Cox Fremin, Zohayr M. Al Shaial. Medicine, LSUHSC School of Medicine, New Orleans, LA.

Background: The purpose of this study was to improve our patient care in a renal clinic at a large university hospital by using one of the core competencies- patient care, systems based practice, and practice based learning and improvement.

Methods: A check-out sheet was developed and given to all trainees in the nephrology clinic. Data was collected for 174 visits over 6 months. Data include age, gender, eGFR, and CKD stage. Each patient’s blood pressure, hemoglobin, phosphorus, Vitamin D, PTH, bicarbonate, and the extent of renal replacement therapy planning were acquired and further analyzed to determine whether nephrology goals were met based on KDOQI/KDIGO guidelines.

Results: Achievements in goals for CKD 3-5 as per KDOQI/KDIGO guidelines based on a percentage value of the patients seen each month. Data are from April to October. Hemoglobin of <10 g/dl were met in 64%, 64%, 76%, 98%, 96% and 83%, respectively. Blood pressure of <140/90 mmHg (or <130/80) were met in 52%, 64%, 45%, 67%, 68%, 54% and 71%, respectively. Vitamin D of >30 mg/ml were met in 36%, 36%, 78%, 30%, 41%, 48% and 47%, respectively. PTH of ≤ 150 were met in 52%, 27%, 67%, 45%, 63%, 45% and 71%, respectively. Proteinuria (<300 mg/day) were met in 12%, 9%, 22%, 26%, 53%, 80%, and 55%. Phosphorus ≤ <5.5 mg/dl were met in 76%, 73%, 89%, 85%, 81%, 88% and 96%, respectively. Attending renal education classes were met in 40%, 73%, 56%, 41%, 50%, 59% and 42% respectively.

Conclusions: Referral rates for kidney transplantation by Nephrology fellows improved by 32%. A chart review and educational intervention were performed. Vascular access referrals from this study remained stable. This work suggests that outpatient performance improvement projects conducted by Nephrology fellows confer peer review accountability for outpatient practice habits, heightens trainee awareness of key referral issues, and appears to help sustain or improve referral rates for vascular access and kidney transplantation.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Our project was helpful in educating trainees in the treatment goals and actions for patients in the renal clinic and standardized an approach to patient care. Overall, the results show a trend towards improvement in all goal areas except for renal education. This study did not account for patients who were new to our clinic and therefore had never received renal education previously.

SA-PO152
A Simulation Exercise to Assess Renal Replacement Therapy and Kidney Biopsy Communication Skills Lisa K. Prince,1 Maura A. Watson,1 Anna M. Howle,1 Christina M. Yuan,1 Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; 2Medical Simulation, Walter Reed National Military Medical Center, Bethesda, MD.

Background: We piloted a nephrology-specific “Breaking Bad News” simulation to assess Interpersonal Communication Skills and Professionalism during renal replacement therapy (RRT) and kidney biopsy (Bx) counseling. Assessment tools were a 9-point Likert Mini-Clinical Examination Exercise (Mini-CEX) adapted for RRT and Bx counseling, and the Essential Elements of Communication-Global Rating Scale 2005 (EEC-GRS).

Methods: There were three cases: 1) a middle-aged woman with polycystic kidney disease and CKD5, 2) a critically-ill elderly man with AKI whose wife was his surrogate decision maker, and 3) a previously healthy soldier with nephrotic syndrome. There were 5 nephrology fellow examiners. One patient actor performed for each case, assessing each examinee with the EEC-GRS. One faculty assessed all examinees for one case using the EEC-GRS and mini-CEX. Encounters lasted 15 minutes, followed by 5 minutes for examination counseling by the actor and faculty.

Results: Post-simulation, 3/3 faculty surveyed felt that the examice met objectives, and was an excellent assessment tool. 4/5 examinees felt the exercise was “good” and met objectives. 5/5 felt that simulation time was too short to assess communication skills. 2/5 felt that a mini-CEX assessing a real patient encounter was superior. Median examined EEC-GRS performance assessed by actors and faculty was 4 (range 3-5). Median mini-CEX performance was 6 (range 5-9).

Conclusions: Based on feedback, the original mini-CEX was too detailed for a 15-minute encounter, and was simplified. Instructions now stress that, because of encounter brevity, counseling is unlikely to be completed, and completion is not required for satisfactory grading. A second set of scenarios was developed to permit a yearly simulation in a two-year cycle. We plan to test the revised simulation in a larger group of nephrology fellows within the next year. The views expressed are those of the authors and do not reflect the official policy of the Department of the Army, the Department of the Navy, the Department of Defense or the United States Government.

SA-PO153
Implementation of KDIGO CKD Guidelines Leads to Decreased Diagnosis of CKD Heather M. Mascio,1 Deeti S. Moon,2 Ryan J. Altenburg, Lisa K. Prince, Dustin J. Little, Nephrology Service, Walter Reed National Military Medical Center, Bethesda, MD.

Background: Estimated glomerular filtration rate (eGFR) is used to diagnose and classify CKD. The accuracy of creatinine-based eGFR-Creat is inferior to eGFR calculated using multiple renal filtration markers. CKD guidelines suggest using serum creatinine and cystatin C to evaluate for CKD in select patients, but methods for, and results of guideline implementation have not been reported.

Methods: We reviewed new patient nephrology clinic encounters in a three month period to establish baseline guideline adherence. Combined creatinine/cystatin C (eGFR(Creat,CysC)) was considered indicated in patients eGFR-Creat 45-59 ml/min/1.73m2 and no albuminuria, urine sediment abnormalities, or other markers of kidney damage. Consultation review was modified such that a nephrologist reviewed every referral request, with the option of ordering labs to be obtained prior to a clinic visit. During a six-month implementation period, guideline awareness was targeted via didactics, signs posted in exam rooms, and “cystatin C—just check it” t-shirts. Seven months of charts were reviewed following the intervention period, and pre and post-intervention adherence was compared using Fisher’s exact test. Patients with eGFR-Creat,CysC<60 ml/min/1.73m2 were considered to have no evidence of CKD. Inpatients for whom eGFR-Creat,CysC was obtained, mean eGFR-Creat and eGFR-Creat,CysC were compared using paired t test. Results: Cystatin C was significantly higher in the post-intervention period compared to the pre-intervention period (testing obtained in 30 of 40 (75%) vs.12 of 32 (37.5%)) indicated cases; p =0.002). Mean eGFR-Creat,CysC was significantly higher than eGFR-Creat (77.1 ± 13.5 vs. 58.3 ±9.1ml/min/1.73m2; p=0.001). eGFR-Creat,CysC was ≥60ml/min/1.73m2 in 85.3% of cases.

Conclusions: By modifying our consult review process and raising awareness among nephrology providers, we significantly implemented eGFR-Creat,CysC guidelines and determined that the vast majority of tested patients had no evidence of CKD. Our results suggest testing as suggested in the guidelines has the potential to markedly decrease the number of inaccurate CKD diagnoses.

SA-PO154
Improving Pathology Curriculum for Nephrology Fellows Enrica Fung,1 Orlando Camacho,1 Michelle M. O’Shaughnessy,1 Adetokunbo A. Taiwo,1 Gabriela Velez,1 Neeraja Kambham,2 Timothy W. Meyer,1,2 Nephrology, Stanford; 1Pathology, Stanford; 2Nephrology, VA Palo Alto

Background: Stanford fellows were previously exposed to renal pathology through attendance at monthly hour-long “biopsy conferences” where faculty and fellows discussed difficult cases; and informal quarterly “fellows-only conferences” where fellows asked pathologists questions on core topics. Our project sought to improve fellows’ education in renal pathology.

Methods: Twelve first to third year fellows participated in this project. Two renal pathologists led five orderly review sessions, dedicated to fellows only: 1. Common renal pathologies: 2. Primary glomerulonephritis; 3. Secondary glomerulonephritis; 4. Plasma cell dyscrasia-related renal disease; 5. Renal transplant pathology. Second year fellows helped in preparation of teaching material. Fellows were encouraged to ask questions. Participants completed a survey to measure their satisfaction with renal pathology teaching and their confidence in interpreting renal biopsies before and after this project. Five 10-question pre-session quizzes and a comprehensive 40-question post-project final measured knowledge acquisition.

Results: Prior to our project, 55% of fellows felt somewhat satisfied to “satisfied” with the current pathology conferences, and 10% of fellows felt somewhat confident in their abilities to interpret biopsy findings. Most fellows (83%) viewed renal pathology to be an “important” or “very important” part of their overall nephrology training. After the project, 100% of fellows felt somewhat satisfied to “very satisfied” with the project, and 66% of fellows felt “somewhat confident” in their abilities to interpret biopsy findings. To date, fellows answered 63% of quiz questions correctly prior to the project and 60% of final questions correctly after the project.

Conclusions: Survey of nephrology fellows revealed poor confidence in interpreting renal pathology prior to our project despite perceived importance of the topic. To date, post project evaluation suggested improved confidence in renal pathology but lack of significant change in knowledge base. This may be due to issues with knowledge acquisition, inter-test comparability or instruction method.

SA-PO155
Improving the Communication Skills of Nephrology Fellows by Utilizing MBTI Training Anna Marie Burger,1 Julia Lewis,1 Vanderbilt Univ School of Medicine, Nashville, TN.

Background: Communication skills can both positively and negatively affect the patient-physician relationship. Although many things impact successful communications, individuals’ personality types affect the way they communicate and the way they interpret the communications of others. It has been suggested that a lack of understanding of the basic difference between personality types contributes to poor communication and unsuccessful interactions. Nephrologists work in a unique environment in the dialysis unit with a complex interdisciplinary team and a “captured” audience of anywhere from 10-40 patients in a single room. In the dialysis unit, communication between the multi-disciplinary team and the patients and between the multidisciplinary team’s individual members impacts the successful achievement of dialysis outcomes.

Methods: Eleven nephrology fellows underwent a curriculum designed to increase their awareness of their own Myers Briggs Type Indicator (MBTI) personality preferences, their knowledge of the different basic personality preferences, and how those differences impact communication. Knowledge of the MBTI preferences was tested pre-intervention, immediately post intervention, and 8 weeks post intervention. Communication skills were measured pre-intervention and through dialysis nurse observations of fellows during fellow-real patient interactions. Fellows were also asked to describe how they used their knowledge at 8 weeks post intervention.

Results: The intervention led to a sustained increase in the nephrology fellows’ MBTI personality preference knowledge. At 8 weeks post intervention, fellows reported utilizing their personality preference knowledge to improve their communication with their patients as well as with members of their team. However, nephrology fellows’ communication skills, as measured by the Kalamazoo Essential Elements Communication Checklist Adapted (KEECC-A), did not change.

Conclusions: Although training in MBTI personality preferences led to a significant, sustained increase in MBTI knowledge and fellows continued to report utilizing their knowledge at 8 weeks post intervention, there was no change in their measurable communication skills utilizing nurse observations.

SA-PO156
Lung Ultrasound: A New Skill for Nephrologists for Volume Overload Quantification in End Stage Renal Disease Patients on Hemodialysis Marc M. Saad,1 Wissam Mansour, Elias Moussaly, Jeanne Karam, Boutros Karam, Cara Brown, Monica Kapoor, Elic El-Charabaty, Suzanne E. El Sayegh.1 Internal Medicine/Nephrology, Staten Island Univ Hospital, Staten Island, NY.

Background: Many methods have been tried to assess the volume status in patients on hemodialysis (HD). While the estimated dry weight is still the only method widely used, it is often inaccurate and poses a clinical challenge. Pulmonary congestion detected as B lines on ultrasound (BLUS) is rising as a novel parameter for assessing volume status; we evaluated the accuracy and reliability of measuring BLUS performed by residents following training in the technique.

Conclusions: Overall, the results show a trend towards improvement in all goal areas except for renal education. This study did not account for patients who were new to our clinic and therefore had never received renal education previously.
Methods: Residents underwent a 3 hour course under the supervision of ultrasonound-fellowship trained Emergency Physicians (EP). The course included a didactic section, a simulation hands-on training, and an Objective Structured Clinical Examination prior to enrolling the trainees as investigators; Residents performed lung ultrasound (LU) on ESRD patients post HD sessions in a supine position over 28 intercostal windows. They obtained at each window a 6s clip that were reviewed by 2 blinded EP. BLUS was summed up categorizing patients into different classes of pulmonary congestion mild (0-14), moderate (15-30) and severe (>30).

Results: A total of 81 ESRD patients on HD were scanned. 71.6% were males; mean age 59.74 years, mean BMI 28.59±5.62 kg/m²; mean test duration was 15 min. The B-lines score found by the study investigators and EPs was 15.8±21.3 and 12.06±21 respectively. The difference was 3.77±16.8 (0.0475). When categorized into the 3 classes, there was no significant difference between both classification (0.085), and were in moderate agreement-kappa 0.56 [0.42-0.71].

Conclusions: B-lines visualized on bedside LU can provide a reliable and quantifiable assessment for lung congestion. Our study shows that a short training course can render novice users of ultrasound capable of performing this quick evaluation. This can aid in objectively assessing volume overload in a timely manner in HD patients who present a unique clinical challenge. LU has emerged as a new tool, readily available at bedside, providing immediate results, yet is an easily learned skill.

SA-PO157

Background: Percutaneous kidney biopsy is the gold standard for diagnosis of kidney disease but is underutilized due to wariness of complications. Based on clinical and laboratory data, Nephrologists try to predict the renal pathology (clinical gestalt). However, to our knowledge, no study has compared the diagnostic accuracy of the clinical gestalt with the kidney biopsy result.

Methods: Division of Nephrology at Stroger Hospital of Cook County conducts a monthly biopsy conference. Three case summaries are presented followed by discussion and presentation of the biopsy findings. Between September 2014 and April 2015, using a structured form Fellows and Nephrologists were asked to provide their top diagnosis for each case and this was compared with the actual histologic diagnosis. All physicians apart from the primary Nephrologist were blinded to the diagnosis. The study was deemed exempt by IRB.

Results: 23 cases were discussed in the biopsy conference involving 13 unique diagnoses and 286 unique responses were obtained. Overall diagnostic accuracy was 53.49% (153/286); Fellows (52.5%) and Nephrologists (54.36%). Diagnostic accuracy for nephrologists was 100% for ANCA vasculitis and Minimal Change Disease (MCD) and 86% for Diabetes but < 50% for stages of Lupus and other seronegative GNs.

Nephrologists with > 10 years’ experience tended to more accurately predict the diagnosis than those with < 10 years’ experience (64.4 vs. 48.3%, p=0.07).

Conclusions: Nephrologists more accurately diagnosed ANCA vasculitis, MCD & Diabetics by clinical gestalt, but were less accurate for stages of lupus and other seronegative GNs. Regardless of training and experience kidney biopsy is still the diagnostic tool of choice in patients with kidney disease.
for lupus, polycystic kidney disease, and genetics. Regarding patient compliance within specialty clinics, 40% indicated no change, 40% improved, and 20% much improved. On patient satisfaction, 32% indicated no change, 49% improved, and 19% much improved. No respondents perceived decreased patient compliance or satisfaction. Trainees participated in 98% of specialty clinics with a 91% satisfaction rate; 29% were very satisfied. 45% of specialty clinics had ongoing research projects, with an average of 5.5 research projects in those clinics.

Conclusions: Subspecialty clinics can be an irreplaceable tool for both trainees and patients; both groups reported high satisfaction levels. These clinics also enable research by providing a well-established database of patients with specific disease processes. Access to such information is essential to quality research and may streamline the development of key clinical trials.

SA-PO161

Background: The distribution of renal replacement therapy (RRT) modalities among patients varies from country to country, and is often influenced by non-medical factors. In our department, patients progressing towards end-stage renal disease (ESRD) go through a structured Pre-Dialysis Education Program (PDEP). This PDEP is conceived with patients association and nursing educator.

Methods: Forty nine patients with CKD who were receiving care in a multidisciplinary predialysis clinic (mean age 73.5, 63% men). The patients are accompanied by family members. They have received educational education, followed by two workshops in groups and a final educational evaluation. The workshops are carried out in groups of 6 to 10 patients. The PDEP consisted of: (1) psychosocial assessment, (2) education about dialysis and choice of modalities, (3) counseling sessions with patient, family members, (4) education about dietetic and dialysis.

Results: - Choice of the substitution method at the end of the workshops: 61% peritoneal dialysis, 18% haemodialysis and 21% absence of choice - 94% of the patients began the substitution treatment with a chosen modality. - 100% Satisfaction of the patients, 26% decrease of the anxiety. (p=0.0005), 25% (p= 0.0001) increase in the consent for the treatment, 61% increase in the engagement in the treatment (patient ready to receive treatment) (p=0.00001), 47% increase knowledge of RRT (p=0.00001).

Conclusions: Most studies dealing with the pre-dialysis information show a balanced choice of the RRT, but only 50% of the patients actually begin DF. Our workshops of help and assistance to the choice enable to significantly reduce the anxiety linked to the dialysis and thus increase the adherence and engagement for the chosen method RRT. A two-phase educational intervention can increase the proportion of patients who intend to initiate dialysis with self-care dialysis. In our centre offering all treatment RRT modalities, a high percentage of patients exposed to a structured PDEP start with a self-care RRT modality.

SA-PO162
Frequency of Use of Social Media in CKD Patients on Hemodialysis: Pilot Study in Ecuador Fabian A. Ortiz-Herbert, Juan Carlos Calderon, Walter Mejías, David J. Jurado, Byron Jose Haz, Ivan Manuel Cherrez. 1Inst Ecuatoriano de Diálisis y Transplantes, Guayaquil, Guayas, Ecuador; 2Respiral, Guayaquil, Guayas, Ecuador; 3School of Medicine, Univ de Especialidades Espiritu Santo, Samborondon, Guayas, Ecuador.

Background: CKD on dialysis is defined as <15% of kidney function. In Latin America, 461 per million are on dialysis. Region is the third largest Internet user. Social media includes communications spread electronically, shared by individuals and discussed by a committed population. Hispanic Americans with CKD used it, to inform and be informed, includes communications spread electronically, shared by individuals and discussed by a committed population.

Methods: Observational, cross sectional, pilot study. Patients were recruited in dialysis center in Guayaquil. Survey included demographical and clinical items, Charlson score and 4 questions about frequency of use of social media were included. Also, questions about obtaining information; and interest in receiving or asking physician questions related to illness in social media. Frequencies and mean (SD) were employed. Chi-square, ANOVA and M-W U was used for comparisons. Also, Cronbach were calculated.

Results: 34 patients participated, with mean age of 56.5 (SD 16.3), mean years on dialysis of 3.9 (SD 4), 52.0% were women. Comorbidity’s rate was very high (82.4%). 70.6% of patients believed that dialysis control symptoms of disease. 11.8% hadn’t got cellular-phone neither Internet. 61.8% hadn’t got SMS. Almost half of patients had smartphones. Women had a high comorbidity (41.2%), p<0.05. Around 30.0% reported using SMS, Facebook, YouTube, Internet an email at least once a week. 46.7% use Internet as principal source of information, YouTube (20.0%) and email (16.7%). 40.0% of patients reported high interest in receiving information by SMS, Facebook (33.3%) and email (26.6%). 33.3% reported high interest in asking by SMS, email (26.7%) and Facebook (20.0%). 25.5% reported interest in receiving information and asking by whatsapp. Conrach was 0.884.

Conclusions: Internet use is very common for searching information related to disease. WhatsApp, SMS, Facebook and email were reported as new tools for providing illness related information to the patient. The survey had a good reliability and consistency.

SA-PO163
The Impact of Predialysis Education on Patient Understanding, Preparedness, and Decisional Conflict Regarding Renal Replacement Therapy Options Syed Amir Hamid Ali Shah,1 Ion D. Bucaloiu,1 Amanda Young,2 Jamie Alton Green.1 1Nephrology, Geisinger Medical Center, Danville, PA; 2Center for Health Research, Geisinger Medical Center, Danville, PA.

Background: Predialysis education is recommended to prepare patients with advanced chronic kidney disease (CKD) for initiation of renal replacement therapy; however, the impact of various approaches to medical decision-making is not well understood.

Methods: We surveyed 91 advanced CKD patients before and after a 2-hour nurse led group education class to assess patient understanding of renal replacement therapy options (1=poor to 5=excellent), preparedness to make a decision (1=not at all to 5=very prepared), and decisional conflict using a validated scale (0=no decisional conflict to 100=extremely high). The class included a combination of direct verbal instruction and video presentation, tailored to patients with a variety of health literacy and sociodemographic backgrounds. Content included the advantages/disadvantages of hemodialysis (HD), peritoneal dialysis (PD), transplant, and conserving renal function.

Results: Mean age was 66.58, 58% male, 94% white, 44% had a high school or lower level of education, and 46% had low health literacy. Mean level of understanding increased significantly for all modalities pre-post (2.02 vs. 4.10 for HD, 1.95 vs. 4.14 for PD, 2.35 vs. 4.15 for transplant, and 2.10 vs. 4.12 for conservative management; all p<0.001). Decision preparedness also increased significantly from 2.44 to 3.50 (p<0.001). Improvements were similar regardless of age, gender, educational level, or health literacy. At the end of the class, overall decisional conflict was low (median score 10; IQR 0, 20). Equal proportions of patients preferred HD (24%) or PD (22%), compared with transplant (12%) and conservative management (4%), yet nearly (30%) of patients remained unsure of their decision.

Conclusions: Despite significant improvements in patient understanding and preparedness about renal replacement therapy options, a substantial number of patients remain uncertain of their decision after routine predialysis education. Additional decision supporting interventions may be needed to improve decision-making in advanced CKD patients.

SA-PO164
Chronic Kidney Disease Knowledge Among English and Non-English Speakers Anushya Jeyabalan, Pranaav S. Garimella, Lesley Inker. Nephrology, Tufts Medical Center, Boston, MA.

Background: Patient education regarding CKD is an important part of pre-dialysis care. While educational interventions have also shown to improve clinical outcomes among dialysis patients, there is little information however, on health literacy in CKD populations.

Methods: We performed a cross-sectional survey of patients identifying themselves as proficient English or Chinese (Mandarin or Cantonese) who were visiting an outpatient nephrology clinic at a single tertiary hospital. A validated Kidney Knowledge Survey (KiKS) that has been used to assess CKD knowledge in previous studies was translated into Chinese and then self-administered in English or Chinese. All patients had at least 1 prior visit with a nephrologist.

Results: 102 participants completed the survey of which 70 were English speakers and 32 were Chinese speakers. Chinese speakers were older, more likely to have less than high school education and had a greater prevalence of diabetes (Table). Estimated glomerular filtration rate (eGFR) and urine protein to creatinine ratio were not different between groups. Mean KiKS score was lower in Chinese speakers compared to English speakers (11.9 vs. 17.2; p<0.001). Chinese speakers scored lower in all domains of the KiKS; general kidney knowledge (6.2 vs. 4.5), knowledge of kidney function (5.5 vs. 4.0) and knowledge of medications (0.4 vs. 3.7).

Conclusions: While our results for CKD knowledge among English and Chinese speakers are comparable to previously published data (mean score 18.0), scores among non-English speaking CKD patients is lower than English speakers. Whether this finding is associated with differences in care management and clinical outcome needs to be evaluated. Furthermore, educational material and programs may need to be tailored to specific populations to improve health literacy.

SA-PO165
Follow-Up with Doppler Ultrasound of Asymptomatic Arteriovenous Fistula (AVF) After Renal Biopsy (RB) Maite Rivera,1 Saul Enrique Pampa,1 Ingrid Viviana Raoch Michaels,1 Emanuel Lope de la Manzanara P,1 Saul Enrique Pampa,1 Cristina Gareano,1 Ingrid Viviana Raoch Michaels,1 Rodolfo Hernandez Loyola,1 Amanda Liano.1 1Nephrology, Hospital Unam Ramon y Cajal UAH, Madrid, Spain; 2Nephrology, Hospital Unib San Carlos, Madrid.

Background: RB is an essential percutaneous technique in Nephrology that entails major and minor complications, one being the AVF which is usually asymptomatic and underdiagnosed because of the absence of routine Doppler examination post RB. We analyzed the natural history of asymptomatic AVF post RB of native kidney (NK) and transplanted (RT) detected by Doppler examination following RB. We evaluated the natural history of asymptomatic AVF post RB of native kidney (NK) and transplanted (RT) detected by Doppler examination following RB.

Methods: We analyzed the presence of AVF on 327 RB between January 2011 and December 2013, included in our database. 47 (14%) RB developed AVF detected by Doppler ultrasound performed at 24th post RB. We studied the following data: AVF size and its relation to the needle caliber and time to spontaneous closure and its relationship to the AVF size. All RB were real-time ultrasound-guided RB performed with a biopsy gun (Acuson, Tok., Japan), the RT caliber 16G and 14G in the NK.
SA-PO166
The Role of Post Biopsy Ultrasound in Predicting Complications After Percutaneous Renal Biopsy of Native Kidneys
Dept of Nephrology, Allama Iqbal Medical College/Jinnah Hospital Lahore, Lahore, Pakistan.

Background: The percutaneous renal biopsy (PRB) of native kidneys has been an essential tool in the diagnosis and management of renal diseases. Despite all advances, clinically evident bleeding complications do occur in up to 30% of patients after PRB of native kidneys. Traditionally patients are kept under observation for 24 hours after the procedure. An earlier investigation to anticipate the likelihood of complications will help to reduce the overall length of stay for these patients and thus the resource burden. Post PRB ultrasound is a non-invasive, accurate diagnostic tool in predicting procedure related major complications. Our purpose was to conduct a study to evaluate the role of early post PRB ultrasound to predict procedure related complications in our patient population.

Methods: 46 patients undergoing renal biopsy at department of Nephrology, Jinnah Hospital were considered for this study. Renal biopsy was performed using a 16-gauge automated core biopsy needle. After the biopsy, patients were closely monitored in the recovery room and after 1 hour, the biopsied kidney was examined by ultrasound. These patients were admitted and were kept under observation to assess any complications for next 24 hours. Results: Of these 46 patients, 24 (52%) were males with mean age 39 (16 to 60 years). More than 3 cm hematoma was seen in 2 (4.3%) patients at 1 hour post biopsy ultrasound scan. Of those 2 patients, only 1(2%) patient had major complications including hypotension, decrease in hemoglobin etc. Thus 45 (97.8%) patients had uneventful recovery. Sensitivity of more than 3 cm hematoma formation at 1 hour post biopsy in predicting major complications was 100% with specificity of 97.7%.

Conclusions: Our study showed that the frequency of major complications was minimal in patients without >3 cm hematoma formation at one hour post-PRB. Post-PRB ultrasound is a non-invasive, accurate diagnostic tool in predicting procedure related major complications.

SA-PO167
1Pediatric Nephrology, Children’s Hospital at Montefiore, Albert Einstein College of Medicine, Bronx, NY; 2Pediatric Rheumatology, Children’s Hospital at Montefiore, Albert Einstein College of Medicine, Bronx, NY.

Background: Most children with SLE develop LN, which significantly worsens morbidity and mortality. Progression to ESRD occurs in 5-10%. Early diagnosis and treatment improve long-term outcomes, thus prompt evaluation is essential. Therefore, a combined pediatric nephrology/rheumatology clinic (LN Clinic) was started in 2013. The primary aim was to evaluate the number of days between onset of proteinuria (first-ami urine pc ≤0.2) and performance of a renal biopsy (bx) for SLE patients (pts), pre- and post-establishment of the LN Clinic. We aimed for a 20% reduction in time to renal bx within 2yr of establishment of this clinic. The secondary aim was a reduction of steps in the referral process.

Methods: SLE pts with an outpt renal bx were identified by an EMR query. Pts were selected if a bx was performed within 5yr pre or 16mo post establishment of the LN Clinic. Our sample selection was cross-referenced with an established lupus registry. A chart review provided the date of proteinuria onset, disease activity markers, and LN class. Pts diagnosed in the inpt setting were excluded. A process map determined the number of steps occurring between new-onset proteinuria and first evaluation by a nephrologist.

Results: We show that pre LN clinic, the median number of days between onset of proteinuria and renal bx was 51 (IQR=25–83.5d), compared to 34 (IQR=14–48d) post (p=0.057). This is a 33% decrease in time. There was a negative association between amount of proteinuria and days to bx (r=–0.5826, p=0.001). There was no association between hematuria or markers of disease activity and days to bx. There was also no association between LN class and days to bx. Pre LN clinic, a referral required 10 steps, which was reduced to 6.

Conclusions: The LN clinic has resulted in earlier renal bx and fewer steps in the referral process. For pts with proliferative LN, this translates to earlier initiation of treatment and a chance at improved outcome.

SA-PO168
Antidepressant Efficacy and Safety Observations: USRDS ACTIVE-ADIPOSE Study
Nancy G. Kutner, Rebecca H. Zhang, Yiyan Huang, C. Barrett Bowling,2 1Emory Univ, Atlanta, GA; 2Atlanta VA Medical Ctr.

Background: Although depression is a prominent issue, depression management in advanced CKD and ESRD patients is not well understood. Antidepressant medications are the most frequent therapy, but efficacy and safety data are limited (Hedaya et al. 2012). A new treatment paradigm for depression management in MHD patients, the focus of a current PCORI trial, is important.

Methods: The primary exposure of interest was use of antidepressant medications among 771 maintenance hemodialysis (MHD) patients ages 20-92 in 14 outpatient clinics who were enrolled 2009-2011 in the ACTIVE-ADIPOSE special study (median ESRD treatment 3.2 years). Gender distribution and ESRD etiology were similar to the overall MHD population, but the proportion non-white and younger than age 65 was higher in the study cohort. Medication efficacy was defined by participants’ scores (<18 vs. 18+) on the Center for Epidemiologic Studies-Depression (CES-D) scale (Hedaya et al. 2006). Adjusted odds for recent falls observed in association with antidepressant use and CES-D score provided an indicator of safety.

Results: Antidepressants were prescribed for 15% of study participants. 40% of those with prescribed antidepressants had an elevated CES-D score, suggesting lack of drug efficacy. Efficacy did not appear to vary by patients’ age or vintage, but more whites had elevated CES-D scores. Recent falls were more frequent among patients on antidepressants with elevated CES-D score (adjusted odds ratio 2.27 [1.05, 4.90], p = 0.04, compared with patients not on antidepressants and CES-D score <18). Fall risk was similar across type of prescribed antidepressant (SSRI, atypical, and tricyclic drugs).

Conclusions: Efficacy of antidepressant medications was unclear for 40% of those with these drugs prescribed, and safety hazard was suggested by increased fall risk. Continued evaluation of nonpharmacologic as well as pharmacologic options for depression management in MHD patients, the focus of a current PCORI trial, is important.

SA-PO169
Sofosbuvir Use in Patients with Hepatitis C Virus Infection and Severe Chronic Kidney Disease
Alberto J. Sabucedo, Marie Essen Antoine, Delvis Jorge, Aileen Andreu, Fernando E. Pedraza, Maria Del Pilar Hernandez, Lennox Jeffers, Marco A. Ladino/Avelaneda. Dept of Medicine. Divs of Nephrology and Hepatology, Miami VA Medical Center/Univ of Miami, Miami, FL.

Background: Chronic hepatitis C virus (HCV) infection is a major health problem. The use of new direct acting antiviral (DAA) based regimens has been shown to provide a high sustained virologic response with less adverse reactions compared to interferon–ribavarin regimens. The American Association for Study of Liver Diseases recommends expert consultation on patients with eGFR less than 30 mL/min because safety and efficacy data are not available on these patient populations. We propose that these DAAs are safe to use in patients with advanced kidney disease.

Methods: A total of 23 HCV positive patients had the following descriptive statistics, 20 males (87%) and 3 females (13%). 15 patients had Genotype 1a (65%), 7 patients had Genotype 1b (31%) and 1 patient had Genotype 2b (4%). 3 patients (13%) had End Stage Renal Disease (ESRD) and were on hemodialysis, 9 patients (39%) had Chronic Kidney Disease stage IV (CKD IV - eGFR<30 mL/min) and 11 patients (48%) had Chronic Kidney Disease stage IIIb (CKD IIIb - eGFR<45 mL/min). The HCV viral load of the 23 patients (100%) had a statistically significant decrease as the therapy progressed through completion with a statistically significant T-test with a p < 0.05. No side effects were present on the patients during DAA therapy. Patients with CKD grades IIIb and IV on DAA treatment had a preserved kidney function by the end of therapy.

Conclusions: Efficacy of sofosbuvir in patients with a preserved kidney function by the end of therapy.
Conclusions: Sofosbuvir is safe and effective in patients with Hepatitis C Virus infection, particularly in severe Chronic Kidney Disease, controlling infection and close monitoring by Hepatology and nephrology is necessary due to the lack of data in safety and efficacy.

SA-PO170

Enoxaparin as Bridging Therapy in Veterans with Advanced Kidney Disease Chui L, Low Renae A. Minnema. Pharmacy, VA San Diego Healthcare system, San Diego, CA.

Background: Patients with CrCl < 30 mL/min on anticoagulation require temporary bridging therapy. Low-molecular weight heparins (LMWH) have longer half-lives and predictable anticoagulant effect but require anti-Xa monitoring in CKD. This study aims to evaluate the safety and efficacy of lovenox as a bridge therapy in patients with CrCl < 30mL/min.

Methods: A retrospective study was conducted from Jan 1, 2012 to Dec 1, 2014. Patients with CrCl < 30 mL/min, received enoxaparin 1 mg/kg as a bridge therapy to warfarin, and had at least one anti-Xa level checked were included in the study. Patients were excluded if they had major bleeding or thromboembolism in previous 3 months before enoxaparin, history of bleeding disorders, or used enoxaparin for other indications. A dosing nomogram was used to guide dosage adjustment to keep anti-Xa levels within the target range (0.5-1.0 mcg/mL). The primary outcomes are 0 of minor/major bleeds and thromboembolic events. The proportion of anti-Xa levels within goal range was assessed.

Results: 12 patients met inclusion and exclusion criteria. The mean age was 62.4 ± 11.9 years, 91.7% were male, 58% were diabetic and 46% had congestive heart failure. 50% were on both warfarin and aspirin. The mean treatment duration of enoxaparin was 11.4 ± 4.6 days, the average CrCl was 17.6 ± 4.5 mL/min. A total of 19 anti-Xa levels were included for analysis. There were 2 (16.7%) bleeding events, 1 (8.3%) major and 1 (8.3%) minor bleed. None of the patients developed thromboembolic complications. The most common adverse event was bruising at the injection site that did not lead to any early discontinuation of therapy. Seventeen (89.4%) were within target range.

Conclusions: Majority (83.3%) of patients had minimal or no adverse events and none with thromboembolic outcomes. In patients with bleed, no correlation was seen with the anti-Xa levels. The dosing protocol is effective, with 89.4% of anti-Xa levels within goal range. The results of this study support the safety and efficacy of the enoxaparin dosing protocol as a bridge therapy peroperatively in patients with CKD. Funding: Veterans Administration Support

SA-PO171

Thiopurine Methyltransferase (TPMT) Genotyping to Predict Myelosuppression Risk in Chinese Patients with Nephropathy Xuehui Li, Jie Ma. Nephrology, Peking Union Medical College Hospital, Beijing, China.

Background: Pharmacogenetic study in nephritis is mainly focused onrogens involved in the metabolism of Azathioprine (AZA). Use of AZA is limited by its toxicity. Variants in the Thiopurine S-methyltransferase (TPMT) have been associated with AZA toxicity. The aim of this study was to determine the contribution of TPMT variants in the development of AZA-related myelosuppression in Chinese patients with nephropathy.

Methods: Variants associated with the decrease of enzymactivity in TPMT genes were genotyped in 42 nephritis patients treated with AZA, and correlated with the clinical response and development of adverse drug reactions in a retrospective case-control study. Three common mutation alleles of TPMT [TPMT* 3A (G460A/A719G), TPMT* 3B (G460A/A719G), TPMT* 3C (A719G)] were detected by polymerase chain reaction-high resolution melting and sequencing in 12 patients, included 4 patients with myelotoxicity and 8 patients without myelotoxicity.

Results: Genotypic analysis showed only one of the 4 patients with myelotoxicity was detected TPMT*3C polymorphisms, no TPMT*2, *3A, *3B or *3C polymorphisms were detected in any of the 11 patients.

Conclusions: Single-nucleotide polymorphisms of TPMT could not explain the azathioprine-related adverse events.

SA-PO172

Lanthanum Carbonate-Induced Granulomatous Gastritis Francesco Iannuzzella,1, Loredana De Marco,2 Sonia Pasquali.1 1Dept of Internal Medicine, Nephrology and Dialysis Unit, Aretespital Santa Maria Nuova, IRCCS, Reggio Emilia, Italy; 2Dept of Human Pathology, Aretespital Santa Maria Nuova, IRCCS, Reggio Emilia.

Background: Long-standing non-calcium based phosphate binders administration has been recently associated with a number of different gastroduodenal lesions. We describe a rare case of lanthanum carbonate-induced granulomatous gastritis. A 58-year-old woman was admitted to our hospital because of nausea, vomiting and weight loss. Because of a well-known stage 5 chronic kidney disease, she was started on peritoneal dialysis. About one month later, CAPD was well-tolerated with an adequate dialysis dose. Nevertheless, she continued to complain of nausea, vomiting and dyspepsia. A gastroscope revealed chronic granulitis with superficial erosions and a histopathology consisting of non-necrotising, sarcoid-like granulomas with aggregates of multinucleated giant cells. Orange crystalloid material was seen within granulomas. Special stains for fungi and mycobacteria were negative. Her previous medical history was only significant for hypertension and type 2 diabetes mellitus. Physical examination was unremarkable. A chest X-ray was normal. A tuberculin skin test was negative. ANCA titres was negative and serum angiotensin converting enzyme (ACE) level was in the laboratory reference range. At the time of our evaluation, she had been receiving lanthanum carbonate 1 g bid for about 6 months.

Conclusions: At the best of our knowledge, so far, only 7 cases have been described in the literature.

The histopathologic picture in our patient was compatible with a lanthanum carbonate-induced gastritis with some peculiar characteristics: a granulomatous reaction and the appearance of lanthanum carbonate crystals not only within histiocytes/multinucleated giant cells but also inside the cytoplasm of the epithelial glandular cells.

SA-PO173

Relative Incidence of Adverse Events with Ferumoxytol versus Other Intravenous Iron Products in Non-Dialysis-Dependent Chronic Kidney Disease Disease Research Group, Minneapolis Medical Research Foundation, Minneapolis, MN.

Background: All intravenous (IV) iron products confer risk of hypersensitivity reaction (HSR). The relative safety of ferumoxytol versus other IV iron products is not established. We used Medicare claims to assess relative safety of ferumoxytol versus other IV iron products in non-dialysis-dependent chronic kidney disease (NDD-CKD) patients.

Methods: We analyzed a 20% sample of Medicare Parts A and B claims in 2009-2012. Patients received a first dose of IV iron between Jan 1, 2010, and Nov 30, 2012, and had diagnosed NDD-CKD without IV iron treatment during the 1 year before first dose. For each ferumoxytol user, we identified 1 propensity score-matched control who used another IV iron product; the score included demographics, comorbidity, and concomitant IV medication. Patients were followed until change in IV iron product, end stage renal disease, death, or Dec 15, 2012. With Cox regression stratified by matched pair and cumulative number of prior IV iron doses, we assessed relative incidence of anaphylaxis, HSR symptoms, hospitalizations, emergency room visits, hospitalization, and death within 1 day of first dose and within 1 day of each subsequent dose.

Results: We identified 7358 ferumoxytol users and 7358 matched controls. Baseline characteristics were balanced across groups. There were too few cases of anaphylaxis and death to permit comparisons. However, after first dose, hazard ratios (ferumoxytol users vs. matched controls) were 0.90 (95% confidence interval, 0.80-1.01) for HSR symptoms, 1.06 (0.66-1.72) for hypotension, 0.72 (0.55-0.94) for ER visit, and 0.78 (0.60-1.02) for hospitalization. After subsequent doses, corresponding hazard ratios were 1.07 (0.90-1.27) for HSR symptoms, 0.91 (0.80-1.01) for hospitalization, and 0.87 (0.63-1.18) for ER visit, and 0.90 (0.70-1.35) for hospitalization.

Conclusions: Relative to other IV iron products, ferumoxytol was not associated with excess risk of adverse events in NDD-CKD patients, following both first dose and subsequent doses. The incidence of anaphylaxis and death was very low in ferumoxytol users and matched controls.

SA-PO174

Efficacy, Safety, and Pill Burden of Sucroferric Oxyhydroxide, an Iron-Based Phosphate Binder, Over 52 Weeks in African American Dialysis Patients Jie Ma, Anjay Rastogi, Mark Ketteler, Adrian C. Covic, Jürgen Floege, Viacheslav Rakov, Liera Armando Salums, M. Coburg Clinic and KFH-Dialysis Center, Germany; *Go. T. Popa University of Medicine and Pharmacy, Romania; ‡RWHU University Hospital Aachen, Germany; †Vifor Pharma; ‡Temple Univ, Philadelphia.

Background: A post hoc analysis of data from a randomized, open-label, Phase 3 study and its extension investigated the efficacy and safety of the iron-based phosphate binder sucroferric oxyhydroxide (SFOH; VELPHORO®) vs sevelamer carbonate (SEV, Renvela®) in African American dialysis patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Methods: Overall, 1059 patients were randomized to SFOH (1.0–3.0 g/day; n=710) or SEV (2.4–14.4 g/day; n=349) for 12 weeks’ dose titration then 12 weeks’ maintenance. Eligible patients enrolled in a 28-week extension study.

Results: Of the 549 patients who completed the extension study, 100 were African American patients, equally distributed between the treatment groups despite the 2:1 randomization (n=48, SFOH; n=52, SEV). Serum phosphorus decreased rapidly and to a similar extent with SFOH and SEV, and remained relatively constant thereafter (Table). Mean ± standard deviation number of tablets/day was lower for SFOH (3.4±1.35) vs SEV (7.6±2.92) over 52 weeks. The incidence of serious or severe treatment emergent adverse events and deaths were similar in both treatment groups. Gastrointestinal-related disorders were the most frequently observed adverse events for SFOH and SEV.

Conclusions: SFOH efficacy was maintained long-term, with a lower pill burden than SEV and similar safety profile, in African American dialysis patients. Post hoc results reflect those from the overall study population.

Table: Treatment efficacy and safety in African American patients.

Safety and Adherence in End Stage Renal Disease Patients on Chronic Hemodialysis

Background: Missed hemodialysis and abbreviated hemodialysis sessions are common in end stage renal disease patients on maintenance hemodialysis. Dialysis non-adherence has been associated with increased mortality and morbidity in chronic hemodialysis patients. Our quality assessment performance improvement data revealed that on an average 15% of patients missed and abbreviated hemodialysis (HD) sessions over a period of 6 months.

Methods: We evaluated patients’ perception about missed and abbreviated sessions, and safety during HD sessions at our dialysis center. A questionnaire regarding patients’ views about missed, abbreviated and safe hemodialysis sessions using a visual analog scale (0–100 mm, where 0 means ‘No’ and 100 means ‘Yes’) was conducted in-person by a nephrology fellow or a social worker on all HD patients. Data are presented as mean ± SD.

Results: Ninety patients participated in the survey. Sixty eight (75.6%) patients with a mean score of 78±29.6 felt like coming for their HD sessions during the last one month. Fifteen of 89 (16.9%) did not know why they came for HD sessions. Twenty seven percent came because they wanted to live while 18% came because they did not want to die. Eighty nine (98.9%) patients with a mean score of 94.5±17.3 felt safe during the HD sessions. Seventeen (18.8%) patients indicated missing the HD sessions. Thirty six of 83 (43.4%) patients with a mean score of 71±37.6 wanted to miss HD sessions during the last one month. Fifteen of 89 (16.9%) signed against medical advice for the abbreviated HD sessions during the last one month.

Conclusions: Data suggest that safety of HD sessions does not appear to be a factor for missing HD sessions. Lack of patients’ understanding of importance of HD treatments as well as lack of adherence likely leads to non-adherence and abbreviation to HD sessions. The safety of HD treatment was not the core issue behind increasing patients’ absenteeism. Active patients’ participation and individualization of HD sessions may improve adherence to HD sessions.

SA-PO177

Validation of a Tool to Assess Nursing Workload in Hemodialysis

Clara Bohm,1 Brett M. Hiebert,1 Joe A. Buetti,1 Jan Schneider,2 1Univ of Manitoba; 2Winnipeg Regional Health Authority.

Background: Patient classification scales (PCS) to assess nursing workload predict staffing needs and facilitate transparency in assignments resulting in improved work environment, patient safety and quality of care. Few validated PCS tools exist for hemodialysis (HD). This study validates a point-of-care PCS developed for in-centre HD at a Canadian tertiary care centre.

Methods: Using LEAN framework, from Sept 1, 2013 to Mar 1, 2014 at the Health Sciences Centre in Winnipeg, Canada, iterative consultations with stakeholders resulted in creation of a PCS consisting of 9 domains and 67 subdomains. At each HD session between April 7-21, 2014, bedside HD nurses completed both a visual analogue scale (VAS), which assessed general level of nursing care required, and the PCS tool. Karnofsky scale and time-series studies were completed in 50 and 28 randomly selected HD patients, respectively. Analysis: Internal consistency and reliability were assessed using Cronbach’s alpha and Intraclass Correlation Coefficient (ICC), respectively. Multi-trait multi-method analysis (MTMM) determined item homogeneity. Spearman’s correlation of PCS with VAS, Karnofsky Score and time-series studies assessed criterion and predictive validity. Linear regression was performed to determine the association of each subdomain with PCS score.

Results: A PCS and VAS data for 1640 HD sessions (380 patients) was obtained.

<table>

PCS correlated well with VAS (0.769). Correlation of PCS with Karnofsky scale and time-series studies was -0.56 and 0.39, respectively. ICC was 65%. MTMM identified 4 subdomains never used and 2 which were redundant. Linear regression identified 16 subdomains with minimal contribution to overall PCS score. Reconsultation with stakeholders resulted in a revised 41-item PCS tool. Correlation between the revised tool and VAS, Karnofsky score and time-series was similar to the original model (0.77, -0.51 and 0.316, respectively).

Conclusions: Preliminary results suggest excellent reliability and validity of this PCS tool. Validation studies at other HD centres with expanded time-series and reliability studies continue.
Feasibility of a Hemodialysis Safety Checklist for Nurses and Patients

Methods: Patients received the checklist for the first 3 months. The checklist was completed for 556 of 757 (73%) treatments. The most common reasons for non-completion were the availability of nursing staff trained in Hemo intervention. The checklist was completed for 556 of 757 (73%) treatments. The primary outcome was Hemo Pause completion, which was determined weekly using the percentage of checklists in the patient chart with all 17 items assessed. We also measured Hemo Pause acceptability using local patient safety surveys.

Results: There were 799 hemodialysis treatments pre-intervention and 757 post-intervention. The checklist was completed for 556 of 757 (73%) treatments. The most common reasons for non-completion were the availability of nursing staff trained in Hemo Pause and patient admission to hospital. Among hemodialysis nurses, 93% (15/14) agreed that Hemo Pause was easy to use and 79% (11/14) agreed it should be expanded to other patients. Among hemodialysis patients, 73% (16/22) agreed that Hemo Pause made them feel safer and should be expanded to other patients. Negative comments by nurses or patients occurred on 4% (7/200) of survey responses.

Conclusions: A hemodialysis safety checklist (Hemo Pause) was acceptable to both nurses and patients over a 3 month period. Our next step is to spread Hemo Pause locally and conduct a mixed methods study to determine mechanisms by which Hemo Pause may improve safety culture, patient engagement, and reduce adverse events.

Community-Based Parenteral Anti-Infective Therapy (COPAT) for ESRD Patients

Background: Infections are the leading cause of hospital admissions for patients with ESRD. The majority will need to continue antimicrobial therapy when discharged. Community-based parenteral anti-infective therapy (COPAT) refers to the practice of administering antimicrobial therapy in the outpatient setting. It requires a multidisciplinary and the goals are to improve outcomes, reduce toxicity, drug resistance, and decrease hospital stay. ESRD patients have the advantage that IV antibiotics can be given at their dialysis unit. The downfall is that every outpatient dialysis provider has their own policies for therapy. The majority will need to continue antimicrobial therapy when discharged.

Methods: We conducted a single center, prospective time series study. A convenience sample of 14 nurses and 22 prevalent in-center hemodialysis patients participated. All patients were trained in the administration of Hemo Pause, completed the checklist at every hemodialysis session for 3 months and were free to suggest checklist modifications consistent with quality improvement methodology. The primary outcome was Hemo Pause completion, which was determined weekly using the percentage of checklists in the patient chart with all 17 items assessed. We also measured Hemo Pause acceptability using local patient safety surveys.

Results: There were 799 hemodialysis treatments pre-intervention and 757 post-intervention. The checklist was completed for 556 of 757 (73%) treatments. The most common reasons for non-completion were the availability of nursing staff trained in Hemo Pause and patient admission to hospital. Among hemodialysis nurses, 93% (15/14) agreed that Hemo Pause was easy to use and 79% (11/14) agreed it should be expanded to other patients. Among hemodialysis patients, 73% (16/22) agreed that Hemo Pause made them feel safer and should be expanded to other patients. Negative comments by nurses or patients occurred on 4% (7/200) of survey responses.

Conclusions: A hemodialysis safety checklist (Hemo Pause) was acceptable to both nurses and patients over a 3 month period. Our next step is to spread Hemo Pause locally and conduct a mixed methods study to determine mechanisms by which Hemo Pause may improve safety culture, patient engagement, and reduce adverse events.

Improving Emergency Room (ER) to Dialysis Flow in a Busy Inner City ER

Methods: Delays in access to hemodialysis during hospitalization are not uncommon and negatively impact on quality of patient care and lead to avoidable complications and unnecessary hospitalizations. Triple Aim is a sought after goal for health organizations to optimize health system performance. We hoped to target one of the three components which is to improve the experience of care.

Methods: The objective was to ensure initiation of dialysis for all non-emergent patients within four hours of ER triage. We analyzed retrospectively in a 8 week observation period, Electronic Medical Record (EMR) data on all hemodialysis patients >18 years of age presenting to the ER, with emphasis on time from triage to initiation of dialysis (TID). We also analyzed factors contributing to delays in dialysis initiation. Data were collected daily on each patient and tabulated weekly. We instituted two measures to address the obstacles.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
These were i)-educating the ER staff about timeliness of informing the renal team and ii) the second was to institute a track and trigger system to systematically gather detailed data on patient transport metrics such a time to patient pick up from initial contact with the transport office.

**Results:** Baseline data revealed average TID from triage was 8 hours. Two major contributory factors identified were late notification by ER to renal team and delays in transport. By instituting measures targeting these, we were able to achieve being able to provide dialysis within 4 hours of triage in over 80% of our non-urgent hemodialysis patients.

**Conclusions:** We were able to improve the patient experience and care with simple measures. This has a positive impact on patient safety by minimizing late treatments and staff fatigue. Though Triple Aim is a goal at the population and health care delivery level, we believe processes can be implemented at a local level that align with the CMS goals of triple aim. In today’s environment it is incumbent upon us to make efforts to innovate for better patient care and to minimize health care costs.

**SA-PO183**

**Quality Improvement Project in Dialysis: Improving Access to Dialysis for Patients Presenting to the Emergency Room (ER)**

**Nikulkumar Chaudhari,** 1 Bonnie Carnes,2 Cherryll Moore,3 Roshni Uppatallia,1 Parikshith Thakur,1 Naheed Ansari,1 Anjali Acharya.1 1Nephrology, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY; 2Nephrology, Atlantic Dialysis, Queens, NY.

**Background:** Hemodialysis patients presenting to the emergency room are a vulnerable patient population. Majority of them have significant comorbid conditions. Delays in evaluation and institution of dialysis are common in busy emergency rooms. We undertook a project to improve quality of patient care as well as the patient experience with a goal to provide timely dialysis.

**Methods:** We analyzed baseline data from electronic medical record (EMR) pertaining to all hemodialysis patients presenting to the ER in a specified 8 week period. After period of data collection we identified a factor that was seen as obstacles in providing timely dialysis. One of them was the time from patient triage to notification of the renal team. We instituted an educational program with the ER staff with focus on the timeliness of informing the renal team, establishing “tria to renal team notification time” of less than 30 minutes as a meaningful metric. Data was collected at pre and post intervention. The objective was to meet this goal >80% of the time over the 2 month intervention period.

**Results:** There was a positive impact on the triage to renal notification time. The percentage of timely notifications as defined, rose to >85% from a baseline of <25% and this effect was sustained over the 8 weeks. Most patient notifications happened within 10 minutes of triage.

**Conclusions:** A simple intervention on educating the ER staff made a significant impact on timely evaluation of dialysis patients presenting to the ER. There was an observable positive impact on patient experience. We view this as a simple first step in optimizing patient care and experience towards a seamless journey through the hospitalization. Simple innovative steps such as this could contribute to cost control by avoiding/minimizing dialysis treatments during off hours. In addition it could help mitigate staff fatigue and treatment errors thus improving patient safety.

**SA-PO184**

**Diagnostic Reference Values for Cerebrospinal Fluid May Not Be Useful in Haemodialysis Patients Suspected of Having Central Nervous System Infection**

**Thomas Oates,** Damien Ashby. Imperial NHS Trust, London, United Kingdom.

**Background:** Invasive investigations in haemodialysis (HD) patients can be associated with complications due to bleeding, and standard diagnostic tests, such as pleural fluid biochemistry, have been shown to be of limited value in this patient group. As a result, we examined the utility of cerebrospinal fluid (CSF) analysis in HD patients suspected of central nervous system (CNS) infection.

**Methods:** We used electronic records to retrospectively examine laboratory data from HD patients who had CSF analysis in a 3 year period. All patients were initially suspected of having a CNS infection due to relevant culture and polymerase chain reaction tests ultimately proved negative for bacterial, mycobacterial, fungal or viral infections in all cases.

**Results:** 30 CSF samples from 29 patients were identified in the study period.

CSF protein concentration was available for 16 samples (median 0.40g/L, range 0.19-1.06g/L, corrected for number of red cells in sample) and paired CSF and plasma glucose concentration was available for 16 samples (median 0.40g/L, range 0.19-1.06g/L, corrected for number of red cells in sample). Additionally, 13 out of 25 samples had a CSF:serum glucose ratio of less than the normal value of 0.6 (see Figure horizontal line) which is also suggestive of CNS infection.

**Conclusions:** CSF biochemistry is frequently used in the diagnosis of CNS infection. Our preliminary results suggest CSF protein and glucose concentrations should be interpreted with caution in HD patients and may not add diagnostic information in suspected CNS infection. We are currently investigating the hypothesis that CSF biochemistry may be influenced by duration of chronic kidney disease and HD vintage.

Cystatin C in Predicting Cardiorenal Syndrome Type 1 and Mortality in Patients with Acutely Decompensated Heart Failure with Preserved Renal Function

Carlos Federico Varela,1 Ivan Constantin,2 Gustavo Cristian Greloni,1 Griselda Bratti,1 German Barrera Hugalde,1 Cesar Belziti,2 Rodolfo Pizarro,2 Guillermo Javier Rosa diez.1 *Nephrology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; 2Cardiology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.

Background: Cardiorenal Syndrome type 1 (CRS 1) is defined as a worsening renal function that complicates acutely decompensated heart failure (ADHF). These patients experience higher mortality and morbidity. Serum creatinine (SC) is slow to reflect changes in kidney function. Cystatin C (CysC) has emerged as a novel biomarker with a stronger correlation with cardiovascular disease than SC. The aim of our study was to evaluate CysC in predicting CRS 1 and outcomes in patients admitted with ADHF and preserved renal function.

Methods: We conducted an observational and prospectively study. We included patients above 18-years old with ADHF with preserved renal function defined as a SC below 1.3 mg/dL. We excluded patients with heart valvular disease and acute coronary syndrome. CysC blood samples were collected on admission. We defined CRS 1 as a rise in creatinine by 0.3 mg/dL or more during five days.

Results: 166 patients aging 85 median (IQR 77-89) years old were enrolled. The incidence of CRS 1 was 29.7%, with an in-hospital mortality of 3.1%, and a total mortality (TM) of 24.4%. The median follow-up was 193 days. CysC was significantly higher in patients with CRS 1 compared to those without (1.72±0.58 vs 1.51±0.41; p=0.03) and predict TM but did not predict in-hospital mortality (1.69± vs 1.57±0.48; p=0.58) or readmission (1.47±0.4 vs 1.6±0.5; p=0.58). In the multivariable analysis CysC was an independent predictor of mortality (OR 3.31; IC 1.38-7.93) while SC at admission was not (OR 0.48; IC 0.05-3.48). The area under the receiver-operating characteristic curve of Cys for CRS 1 was 0.60 and for TM was 0.65. The best cutoff value was 1.6 mg/dL for both end points. It had a sensitivity and specificity of 61.2 % and 60.3 % for CRS 1, and 61.5 % and 62 % for TM, respectively.

Conclusions: Above a cut-off value of 1.6 mg/dL, CysC predicts CRS 1 and mortality in patients admitted with ADHF with preserved renal function.

Is Cystatin C a Better Biomarker of AKI in ICU compared to NGAL?

Itir Yegenoglu, Fatih Kamis. Internal Medicine, Kocaeli Univ Medical School, Kocaeli, Izmit, Turkey.

Background: Serum creatinine levels can be affected with many variable factors. We concluded that better bio-marker is needed to recognize AKI as early as possible. We studied Cystatin C (CysC) and Neutrophil Gelatinase Associated Lipocalin (NGAL) in ICU patients to determine which is more predictable.

Methods: Hundred and eighty three (85 male; mean age: 65) critically ill patients with no previous chronic renal failure history were included to this study. Clinical, laboratory evaluations were noted and blood was taken in 48 hours for CysC and NGAL and followed for 7 days, if they meet the RIFLE criteria.

Results: CysC and NGAL values for every stages RIFLE and serum CysC value were significant only for RIFLE-L stages (p<0.05) but not urinary CysC. NGAL in serum and also in urine were significantly different in RIFLE-L,F. Biomarkers were compared when evaluated in urine were significantly different in RIFLE-I,F. Biomarkers were compared when

While sNGAL and u NGAL were significantly different between these two groups. Serum CysC level was related to mortality (figure 1)(AUC-ROC 0.68 CI; 0.575-0.733).

Conclusions: In our cohort NGAL obtained in 48 hours is more predictable biomarker than CysC for early AKI diagnosis following 7 days. But CysC levels were fairly predictive for mortality.

The Effect of Point of Care (POC) Creatinine/eGFR Measurement on the Incidence of Contrast-Induced Acute Kidney Injury (CI-AKI) following Primary Percutaneous Coronary Intervention (PPCI) for the Treatment of ST Elevation Myocardial Infarction (STEMI)

Background: Contrast-induced acute kidney injury (CI-AKI) is a predictor of mortality, morbidity and length of hospital stay. During STEMI treatment with primary percutaneous coronary intervention (PPCI) there are a number of predictors of AKI including existing renal dysfunction (eGFR < 60) and contrast volume used.

Methods: A retrospective audit over 6 months at the Essex Cardiothoracic Centre identified 348 patients who had presented with STEMI and had PPCI. These patients formed the standard care control group. Prospectively 131 consecutive patients presenting with STEMI and under-going PPCI had a point of care creatinine measurement (STATSENSOR, Nova Biomedical). A comparison in rates of AKI was made between the two groups.

Results: In the standard care group, 9.7% of patients with normal renal function and 26.6% of patients with impaired renal function developed AKI. When creatinine was measured pre-PPCI, 8% of patients with normal renal function and 16.1% of patients with renal impairment developed AKI; a 39.5% reduction in AKI in those with renal dysfunction in the POC creatinine group. The average contrast volume in the standard care group was 159 ml compared to 117.5ml when renal function was found to be impaired (eGFR < 60) pre-PPCI. 186ml was used on average in the POC group when creatinine was found to be normal.
SA-PO190
Serum Creatinine Variability Predicts Progression to CKD4

Carlos E. Palant,1,2 Lakhmir S. Chawla,1,2 Ping Li,1,2 Paul L. Kimmel,1,2,3 Charles Faselis,1,2 Richard Amundr.1,2 1Medicine, Washington DC VA Medical Center; Washington, DC; 2Medicine, George Washington Univ Medical School, Washington, DC; 3NIDDK, National Insts of Health, Bethesda, MD.

Background: Pre-dialysis patients have high serum creatinine (SC) variability. SC variability is associated with high death rates. We examined the association between SC variability and CKD progression in a large cohort of US veterans with a wide range of baseline eGFR.

Methods: VA patients admitted 10/1999 - 12/2005 with at least 4 months with SC and initial eGFR>30 ml/min/1.73 m² (using CKD-EPI) were selected. Autoregression-based slope was computed for each patient using monthly peak SC. SC variability was root mean-square residual of peak SC readings from the regression line. CKD4-date was the first date when eGFR permanently fell below 30 ml/min/1.73 m². Logistic regression was used to predict CKD4 using: initial eGFR, SC variability, SC slope, age, race, months with SC readings, and comorbidities (DM, CAD, PNE, MI, angina, AKI, COPD, CHF). Kaplan-Meier (KM) analysis was used to examine time from first admission to entry into CKD4, stratified by SC variability quartile and baseline eGFR, and Cox regression was used to adjust survival estimates for the covariates above.

Results: Of 342,066 patients, 36,108 (10.6%) reached CKD4. The logistic model had strong prediction accuracy (c=94) with specificity and sensitivity both 86. SC variability was strongly associated with entry into CKD4 (adjusted OR 3.79 [3.67-3.91], p<0.001). Time to CKD4 differed by level of SC variability in KM (p<0.001; Figure) and Cox (HR 1.34 [1.31-1.36], p<0.001).

Conclusions: SC variability is strongly independently associated with rate of decline in renal function, at all baseline eGFR levels, after accounting for covariates, and is an important risk factor for entry into CKD4.

Assessment of Methods Used to Substitute for Missing Preadmission Creatinine Values in the Diagnosis and Staging of Acute Kidney Injury

Amelie Bernier-Jeant,1 Anatolie Duca,2 Francois Madore,2 Remi Goupil,2 Stephan Troyanov,3 Joscé Bouchard.1 1Nephrology, Hopital du Sacre-Coeur de Montreal, Canada; 2Univ of Calgary, Canada; 3IIBISMED, Univ Mayor de San Simon, School of Medicine, Bolivia; 1Hospital du Sacre-Coeur de Montreal, Canada; 2Univ of California San Diego Medical Center.

Background: Missing preadmission serum creatinine values (SCr) are a common obstacle to the diagnosis and staging of acute kidney injury (AKI). As a workaround, the KDIGO guidelines suggest using a baseline SCr computed from the MDRD formula assuming a baseline estimated glomerular filtration rate (eGFR) of 75 ml/min per 1.73m². We hypothesized that surrogates for preadmission SCr will misclassify AKI incidence and severity when compared to a known preadmission SCr.

Methods: Over a 12-month period, we performed a retrospective single-center study of critically ill patients with known preadmission SCr to identify the most accurate method to estimate baseline SCr for AKI diagnosis and staging (KDIGO criteria). We assessed three surrogate methods: 1) the first hospital admission SCr, 2) the minimal SCr after ICU admission and 3) SCr computed for a eGFR of 75 ml/min per 1.73 m² using MDRD. We hypothesized that surrogates for preadmission SCr will misclassify AKI incidence and severity when compared to a known preadmission SCr.

Results: Of 1001 randomly selected patients, a preadmission SCr was available for 498 and 14 were excluded for requiring acute renal replacement therapy. Median age was 67 (IQR 58-76), 60% were male and 98% were Caucasian or Asian. The median time between SCr measurement and admission was 116 (IQR 78-179) days. AKI incidence according to preadmission SCr was 24.8%. We reported in table 1 the AKI incidence, sensitivity, specificity and kappa values for each surrogate method.

Conclusions: Measuring the POC creatinine of 131 patients presenting with STEMI and undergoing PCI reduces the rates of AKI by 39.5% in those with renal dysfunction. This appears to be mediated in part by a reduction in contrast volume in those patients identified with renal dysfunction (117.5ml) compared to normal renal function (186 ml).

SA-PO192
Fluid Balance and Oliguria in Early AKI Diagnosis After Liver Transplant

Camila L.1,2 Luciana Haddad,2 Luiz M. Malbouisson,2 Luiz Augusto Carneiro D’Albuquerque,2 Etienne Macedo.1 1Nephrology, Univ of Sao Paulo, Brazil; 2Gastrointestinal Surgery, Univ of Sao Paulo, Brazil; 2Anesthesiology, Univ of Sao Paulo, Brazil.

Background: AKI is a frequent complication of liver transplant (LT), associated with increased morbidity and mortality. Early diagnosis can translate into secondary preventive measures and improve outcomes. We hypothesized that adjusting Scr for positive fluid balance (FB) and applying urine output(UO) criterion would improve timing of AKI diagnosis. In addition, we investigate whether sequential assessment of urinary biochemistry after LT can improve prediction of early-onset post-operative AKI development.

Methods: In a prospective cohort study, we recorded UO, FB and labs of patients undergoing LT. We assessed urine and blood biochemistry perioperatively (before induction of anesthesia, after portal reperfusion, 6, 18, 24 hours after surgery). AKI diagnosis was based on UO and the scCr KDIGO criterion before and after correcting scr for FB (Scr adjusted), using the formula: ((weight*0.6)/(FB))/weight*0.6).

Results: Fifty-five patients >18 years undergoing LT from Jun13 to Oct14 were included in the analysis. Twenty-seven percent (15) of patients developed AKI based on Scr criterion within 7 days of follow-up (early AKI). By adjusting Scr for fluid balance 38%(21) patients were classified as early AKI. Applying the UO criterion, 43patients were classified exclusively by this criterion as early AKI. All patient showed a decline in FeNa and the FeU after portal reperfusion. Patients developing early AKI had a higher decline and maintained lower levels for 24h. FeNa/FeU values were significantly different 6 hours after surgery in early AKI patients. Patients with early AKI based on both criteria or exclusively by UO had a higher mortality and longer ICU and hospital stay than non-AKI patients.

Conclusions: Applying UO criteria and adjusting Scr for FB can help in the early identification of patients developing AKI after liver transplant. Tubular function assessment could be utilized along with biomarkers of kidney injury to identify patients with increased risk of developing AKI. Standardized approach for early AKI diagnosis in high-risk patients could improve outcomes.

SA-PO193
Renal Angina Index: A Practical Tool to Identify Patients at Increased Risk of Acute Kidney Injury

Rolando Clurio-Del Granado,1 Andrea Pero,1 Josec Bouchard,2 Ravindra L. Mehta,2 1Physician - Hospital de la Princesa, Madrid; 2IIBISMED, Univ Mayor de San Simon, School of Medicine, Bolivia; 2Hospital du Sacre-Coeur de Montreal, Canada; 2Univ of California San Diego Medical Center.

Background: Reliable prediction of acute kidney injury (AKI) has the potential to optimize treatment. Recently Goldstein SL et al. proposed an empiric clinical model of renal angina using patient demographic factors and early signs of injury to identify critically-ill children who would be at higher risk of AKI. We test the hypotheses that in a cohort of adult critically-ill patients, a modified renal angina index (RAI) will identify patients at high risk of developing AKI, and could be related to in-hospital mortality.

Methods: We included 124 consecutive patients admitted to our medical ICU. We measured serum creatinine (sCr) every 24 h for 7 consecutive days after ICU admission. AKI was defined as follows: 1) elevation of sCr >25% at 48h after day 0 (RAI ≥2), 2) sustained sCr ≤50% increase within 48h of surgery (early AKI). By adjusting Scr for fluid balance 38%(21) patients were classified as early AKI. Applying the UO criterion, 43 patients were classified exclusively by this criterion as early AKI. All patient showed a decline in FeNa and the FeU after portal reperfusion. Patients developing early AKI had a higher decline and maintained lower levels for 24h. FeNa/FeU values were significantly different 6 hours after surgery in early AKI patients. Patients with early AKI based on both criteria or exclusively by UO had a higher mortality and longer ICU and hospital stay than non-AKI patients.

Conclusions: Applying UO criteria and adjusting Scr for FB can help in the early identification of patients developing AKI after liver transplant. Tubular function assessment could be utilized along with biomarkers of kidney injury to identify patients with increased risk of developing AKI. Standardized approach for early AKI diagnosis in high-risk patients could improve outcomes.

Funding: Other U.S. Government Support

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusions: The RAI provides a clinically feasible methodology to identify critically-ill patients at high risk of developing AKI before a rise in sCr occurs. This tool would permit the early identification of AKI to initiate preventive and treatment strategies minimizing extension of kidney injury.

SA-PO194

The Renal Angina Index Identifies Patients at High-Risk of Acute Kidney Injury – Analysis from AWARE: A Prospective Multinational Study of AKI in Critically Ill Children Rajat K. Bassi,1,2 Ahmad Kaddourah,3,1 Stuart Goldstein,1,3 1Pediatrics, Center for acute Care Nephrology, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; 2On behalf of the AWARE Study Investigators, Multinational Pediatric ICU.

Background: We conducted a global, prospective observational study of critically ill children to study the epidemiology of pediatric acute kidney injury (AKI). We analyzed the accumulation of the renal angina index for prediction of AKI and patient outcomes.

Methods: Data from 32 centers (5 continents, data collection for 3 consecutive months in 2014) from children (aged 3 months to 25 years) admitted to a pediatric intensive care unit were analyzed. The renal angina index (RAI) was calculated on the day of admission (Day 0) as previously described. A cut-off of ≥ 8 on Day 0 was used to determine fulfillment of absence of renal angina (RA- vs. RA+). The primary outcome was the prevalence of severe AKI on Day 3, defined by change in serum creatinine from baseline using KDIGO stage 2-3 criteria (Day 3 AKI). Other patient outcomes were assessed at 28 days.

Results: 9.6% (501/5231) of children were RA+ on Day 0. The area-under-curve receiver operating characteristic of the Day 0 RAI for Day 3-AKI was 0.797 (95% confidence interval 0.759-0.836). RA+ was associated with a higher net fluid balance on Day 3 than RA- (p<0.001). Compared to RA-, Day 0 RA+ was associated with prolonged duration of mechanical ventilation, longer length of stay, increased use of extracorporeal therapies, and higher incidence of mortality.

Conclusions: In AWARE, the largest prospective multi-center epidemiologic assessment of AKI in critically ill children, we demonstrate the ability of the renal angina index to identify patients at high risk of AKI, three days in advance. Fulfillment of renal angina early in the ICU course is associated with poor patient outcome.

SA-PO195

Background: The bioelectrical impedance analysis (BIA) is a noninvasive and painless technique to perform and compares body composition. We offer information about membrane cell integrity, volemia and clinical status. We evaluate use of this body composition technique and easy to perform, which is used for determining body composition. Can offer a tool to identify patients at high risk of AKI, three days in advance.

Methods: We conducted a global, prospective observational study of critically ill children to study the epidemiology of pediatric acute kidney injury (AKI). We analyzed the accumulation of the renal angina index for prediction of AKI and patient outcomes.

Results: 9.6% (501/5231) of children were RA+ on Day 0. The area-under-curve receiver operating characteristic of the Day 0 RAI for Day 3-AKI was 0.797 (95% confidence interval 0.759-0.836). RA+ was associated with a higher net fluid balance on Day 3 than RA- (p<0.001). Compared to RA-, Day 0 RA+ was associated with prolonged duration of mechanical ventilation, longer length of stay, increased use of extracorporeal therapies, and higher incidence of mortality.

Conclusions: In AWARE, the largest prospective multi-center epidemiologic assessment of AKI in critically ill children, we demonstrate the ability of the renal angina index to identify patients at high risk of AKI, three days in advance. Fulfillment of renal angina early in the ICU course is associated with poor patient outcome.

Preoperative Renal Resistive Index Predicts the Risk of Acute Kidney Injury in Patients Undergoing Cardiac Surgery Daniel P. Olsson Hertzberg,1 Ulrik Sartipy,2 Martin Holmznan.1 1Dept of Medicine, Karolinska Inst, Stockholm, Sweden; 2Dept of Anesthesiology, Surgical Services and Intensive Care Medicine, Karolinska Univ Hospital, Stockholm, Sweden; 3Dept of Molecular Medicine and Surgery, Karolinska Inst, Stockholm, Sweden.

Background: Previous studies have indicated that Renal Resistive Index (RRI), an ultrasound-based measurement, can predict AKI in a variety of settings. To our knowledge, there are no studies investigating the predictive value of preoperative RRI and the risk of AKI in cardiac surgery patients. The aim of this study was to investigate whether an elevated preoperative RRI predicts AKI in a general cardiac surgery population.

Methods: Patients undergoing elective cardiac surgery were included prospectively between September 21, 2014 and April 22, 2015 at the Karolinska University Hospital. RRI was measured before surgery. An elevated RRI was defined as >0.7. The outcome AKI was defined as an absolute increase in post-compared to preoperative serum creatinine by 0.3 mg/dL (≥26.2µmol/L) or a relative increase by >50%. The odds ratio for AKI was calculated by logistic regression in patients with a RRI >0.7 versus those with a RRI <0.7.

Results: 98 patients were included. In patients with a RRI 0.7, 6 (15%) patients developed AKI, compared to 19 (33%) in patients with a RRI >0.7. The mean increase in postoperative serum increase in patients with RRI ≤0.7 was 0.12 mg/dL (11 µmol/L) compared to 0.34 mg/dL (30 µmol/L) in those with RRI >0.7 (P=0.03). The odds ratio for developing AKI in patients with a RRI >0.7 compared to those with a RRI ≤0.7 was 2.76 (95% 1.71-7.71).

Conclusions: We found that patients with an elevated RRI before cardiac surgery had an increased risk of developing AKI postoperatively. RRI might be a valuable tool for identifying patients with an increased risk of developing AKI connected to cardiac surgery.

SA-PO197

Development of a Postoperative Risk Stratification Tool via Bayesian Model Averaging for Acute Kidney Injury After Cardiac Surgery Allison Meisner,1 Kathleen F. Kerr,1 Heather Thiessen Philbrook,2 Francis Perry Wilson,3 Amit X. Garg,2 Michael Shlipak,1 Peter Kavsak,1 Richard P. Whitlock,1 Steven G. Coca,1 Chirag R. Parikh,1 Univ of Washington, Seattle, WA; 2Western Univ, ON, Canada; 3Icahn School of Medicine, New Haven, CT; 1UCSF; 2McMaster Univ, ON, Canada; 3Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Acute kidney injury (AKI) is a frequent complication of cardiac surgery. We sought predictive combinations of biomarkers measured 0-6 hours after surgery, potentially in combination with cardio pulmonary bypass (CPB) time (to account for the degree of insult).

Methods: The primary endpoint was sustained mild AKI, defined as an increase of 50% or more in serum creatinine over preoperative levels lasting at least two days during the hospital stay. Severe AKI were AKI (secondary endpoint) was defined as a serum creatinine increase of 100% or more or dialysis during hospitalization. Data were from a cohort of 1219 adults undergoing cardiac surgery at 6 medical centers; among these, 117 developed sustained mild AKI and 60 developed severe AKI. We considered CPB time and 2 biomarkers as candidate predictors. We used Bayesian Model Averaging (BMA) methods to develop center-adjusted combinations for sustained mild AKI by (1) maximizing the posterior model probability and (2) retaining predictors with posterior variable probabilities above 0.5.

Results: The maximum posterior model probability combination included plasma NT-proBNP, plasma h-FABP and change in serum creatinine; the median probability combination additionally included plasma IL-6. The center-adjusted, optimism-corrected AUCs for these combinations were 0.80 (95% CI: 0.78, 0.88) and 0.81 (0.77, 0.88), respectively, for predicting sustained mild AKI, and were 0.81 (0.77, 0.90) and 0.83 (0.76, 0.90), respectively, for predicting severe AKI. For these data, the BMA methods yielded combinations with predictive capacity comparable to that achieved by standard frequentist methods but with smaller models.

Conclusions: Pending external validation, the identified combinations could be used to identify individuals at high risk of AKI immediately after cardiac surgery and could facilitate clinical trials of renoprotective agents.

SA-PO198

Low Pre-Operative Serum Bicarbonate Levels Predict Acute Kidney Injury After Cardiac Surgery 2 Yonsei Univ College of Medicine, Seoul, Korea.

Background: Low serum bicarbonate levels are known to be risk factors for renal function deterioration in chronic kidney injury patients. However, it is not well known whether preoperative low serum bicarbonate levels are associated with the development of acute kidney injury (AKI) in patients who undergo cardiac surgery. Therefore, clinical implications of preoperative serum bicarbonate levels on AKI occurrence after cardiac surgery were evaluated.

Methods: The patients who underwent coronary artery bypass or valve surgery at Yonsei University Health System from January 2013 to December 2014 were enrolled. The patients were categorized into three groups according to pre-operative serum bicarbonate levels (group 1 <23 mEq/L, group 2 23-24 mEq/L, group 3 >24 mEq/L). Multivariate logistic regression analysis was performed to determine the effect of pre-operative serum bicarbonate levels on development of AKI at 48 hours after cardiac surgery.

Results: Among 452 patients, 228 patients (26.1%) developed AKI at 48 hours after cardiac surgery. Incidence of AKI was higher in group 1 (34.6%) than group 2 (26.3%) and group 3 (39.0%) (P < 0.001). The duration of post-operative intensive care unit (ICU) stay was longer in AKI patients (AKI vs. non-AKI, 6.2 vs. 2.7 days, P < 0.001). In addition, post-operative ICU stay was longer in the low pre-operative serum bicarbonate level groups (group 1 4.4 days, group 2 3.6 days, group 3 3.3 days, P < 0.001). In multivariate logistic regression analysis, low pre-operative serum bicarbonate levels were significantly associated with post-operative AKI development even after adjusting for age, sex, hypertension, diabetes mellitus, operation type, hemoglobin, and glomerular filtration rate (group 3 as reference, odds ratio=2.36, 95% confidence interval=1.57-3.54, P < 0.001).

Conclusions: Low serum bicarbonate levels were associated with higher incidence of AKI and prolonged ICU stay. Correction of low serum bicarbonate levels before cardiac surgery may reduce the risk of AKI development.

Admission Hyperuricemia Increases the Risk of Acute Kidney Injury in Hospitalized Patients 1 Charat Thongprayoon, 2 Stephen B. Erickson. 1 Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 1 Internal Medicine, Bassett Medical Center, Cooperstown, NY.

Background: The association between elevated admission serum uric acid and risk of in-hospital acute kidney injury (AKI) is limited. The aim of this study was to assess the risk of developing AKI in all hospitalized patients with various admission serum uric acid (SUA) levels.

Methods: This is a single-center retrospective study conducted at a tertiary referral hospital. All hospitalized adult patients who had admission SUA available from January 2011 through December 2013 were analyzed in this study. Admission SUA was categorized based on its distribution into six groups (less than 3.4, 3.4 to 4.5, 4.5 to 5.8, 5.8 to 7.6, 7.6 to 9.4, and greater than 9.4 mg/dL). The primary outcome was in-hospital AKI occurring after hospital admission. Logistic regression analysis was performed to obtain the odds ratio of AKI of various admission SUA levels using the most common SUA level reference range (5.8 to 7.6 mg/dL) as the reference group.

Results: Of 4,135 patients enrolled, AKI occurred in 263 patients (18%). The incidence of AKI and need for dialysis was increased in patients with higher admission SUA levels. After adjusting for potential confounders, SUA greater than 9.4 mg/dL was associated with an increased risk of developing AKI with odds ratios of 1.79 (95% CI 1.13-2.82). Conversely, admission SUA of less than 3.4 mg/dL and 3.4 to 4.5 mg/dL was associated with decreased risk of developing AKI with odds ratios of 0.38 (95% CI 0.17-0.75) and of 0.50 (95% CI 0.28-0.87) respectively.

Conclusions: Elevated admission SUA was associated with an increased risk for in-hospital AKI.

SA-PO200

Hypoalbuminemia Is a Strong Risk Factor for Acute Kidney Injury Progression in Elderly Patients in Intensive Care Unit 1 Yu Kurata, 2 Keita Hirano, 2 Fumio Omata, 1 Yasuhito Komatsu. 1 2 Div of Nephrology, Mitsui Memorial Hospital, Chiyoda-ku, Tokyo, Japan; 1 2 Div of Nephrology, St. Luke’s International Hospital, Chuo-ku, Tokyo, Japan; 1 Center for Clinical Epidemiology, St. Luke’s International Hospital, Chuo-ku, Tokyo, Japan.

Background: Population aging is a global issue; especially, Japan is experiencing rapid aging, at a faster speed than any other developed country, and those aged 65 or older comprised 25.9% of Japan’s population as of September 2014. Previous studies showed elderly patients are at high risk for developing acute kidney injury (AKI). AKI is also a common clinical syndrome in the ICU setting, but its clinical presentation varies from mild to severe. Predicting whether AKI progress or not is difficult but can guide clinical decision making. The aim of the present study is to elucidate different factors of AKI progression among elderly patients in ICU.

Methods: A retrospective study of patients age 65 and older who developed AKI during ICU stay between January 2004 and September 2013. AKI was defined as increase in serum creatinine (sCr) of ≥1.5 times baseline. The primary outcome was the progression to AKI stage 3 (increase in sCr of 3 times over baseline or need for renal replacement therapy (RRT)) within 14 days after AKI development. Prerenal AKI, postrenal AKI, and AKI Stage 3 at diagnosis of AKI are excluded; prerenal AKI is diagnosed when serum BUN-to-creatinine ratio ≥ 20 and postrenal AKI is diagnosed based on clinical situation.

Results: 418 patients were included. The mean age of 80.6 ± 8.2 years, baseline sCr ≤0.89 ± 0.40 mg/dL, and baseline eGFR 66.1 ± 32.3 ml/min/1.73m2. Among 418 patients, 77 (18.4%) experienced AKI progression and 83 (19.9%) died. Of the 77 patients with AKI progression, 25 (6.0%) patients received RRT. AKI stage 2 at diagnosis (OR=2.33, 95%CI=1.23-4.36), RAS inhibitor use (OR=2.84, 95%CI=1.33-5.93), bacteremia (OR=1.69, 95%CI=0.89-3.14), hypoaalbuminemia (OR=5.10, 95%CI=2.94-9.06) were risk factors for AKI progression.

Conclusions: Hypoalbuminemia is a strong risk factor for AKI progression in older patients in ICU. Further study is needed to evaluate whether correction of hypoaalbuminemia could prevent AKI progression or not.

SA-PO201

Impact of Preexisting Serum Prolaumin in All-Cause Mortality in Community-Acquired and Post-Operative Acute Kidney Injury Patients Yanfang Zhou, 1 Dan Wen, 1 Jingyuan Xie, 1 Xiaonong Chen, 2 Wen Zhang, 3 Nan Chen. 1 Nephrology, Ruijin Hospital, Shanghai, China; 2 Nephrology, Ruijin Hospital; 3 Nephrology, Ruijin Hospital.

Background: To explore the impact of pre-existing prolaumin concentration on all-cause mortality in AKI (acute kidney disease, AKI) patients.

Methods: From 2000 to 2010, 477 patients diagnosed with community-acquired AKI (CA-AKI) and treated in the Department of Nephrology, Ruijin Hospital, Shanghai Jiaotong University were enrolled in the CA-AKI group. 138 patients diagnosed with AKI after cardiac operations were enrolled in the post-operative AKI (PO-AKI) group. Data were collected at the time of AKI onset and one year after the discharge.

Results: Patients with CA-AKI were younger than PO-AKI patients. Compared with PO-AKI patients, more patients in CA-AKI group suffered from chronic kidney disease, obesity and hyperlipidemia and less patients with cerebrovascular disease (CVD), anemia, diabetes mellitus, hypertension and so on. Levels of SUA were higher for CA-AKI patients compared with PO-AKI patients. CA-AKI patients had higher frequency of RAS inhibitor use (9.5% vs 4.8%, P=0.048). AKI in CA-AKI group was significantly associated with increased cumulative survival rate of patients in normal PA group (PA>20mg/dL) was higher than that in low PA group (P=0.031). Similarly, in PO-AKI group, normal PA level was associated with a higher survival rate (74.1% vs 47.8%, P=0.019).

Conclusions: A significant difference was detected between CA-AKI group and PO-AKI in general characteristics, comorbidities, laboratory examinations, outcome, and risks. Patients with PA<20mg/dL showed better survival rate.

Usefulness of Serum Ischemia-Modified Albumin Levels to Predict Dialysis Requirement in Patients with Acute Renal Injury Mehmet Uzun, Harun Akar. Internal Medicine, Izmir Tepecik Education and Research Hospital, Turkey.

Background: Ischemia-modified albumin is a promising biomarker for early diagnosis of diseases related with ischemia. Ischemia leads to modification in albumin molecule by reducing its binding to cobalt. The aim of this study was to evaluate the levels of ischemia-modified albumin in patients with acute kidney injury (AKI).

Methods: Levels of serum ischemia-modified albumin were estimated in 51 patients with AKI.

Results: The mean age of 28 female and 23 male patients were 65.39±15.28 and 76.48±12.71, respectively. Levels of IMA were found to be high in 75.5 % of the patients (>400) and were found to be normal in 25.5 % of the patients (<400). Kaplan-Meier survival analysis showed that the survival was not different between IMA groups. Urine amounts were significantly different between IMA groups. The urine volume was lower in patients with higher IMA levels (>400).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author. 671A
Conclusions: In the present study, the levels of IMA were found to be significantly higher in those who needed hemodialysis treatment. IMA levels do not predict mortality. Taking these results together, serum IMA levels might give an idea about dialysis requirement in patients with AKI. More studies with larger sample groups may help to establish the role of IMA on decisions regarding dialysis initiation.

**Urinary TIMP-2 and IGFBP7 Elevate Early After Vancomycin Administration in Critically Ill Patients Who Develop AKI**

*Maria Ostermann,*¹ Lui G. Forni,² Lakhmir S. Chawla,² Jing Shi,² Kianoush Banaei-Kashani,² John A. Kellum,⁶ ‘King’s College London, London; ‘Royal Surrey County Hospital, Guildford; ‘George Washington Univ, Washington; ‘Walter Biocience, Carlshbad; ‘Mayo Clinic, Rochester; ‘Univ of Pittsburgh, Pittsburgh.

**Background:** We previously validated a biomarker combination of tissue inhibitor of metalloproteinase-2 (TIMP-2) and insulin-like growth factor binding protein 7 (IGFBP7) for risk stratification of acute kidney injury (AKI).¹ A cutoff of 0.3 (ng/ml)/1000 for [TIMP-2][IGFBP7] indicated AKI stage 2-3 at least 24h prior to serum creatinine.¹ We also showed that nephrotoxic drug use was common in patients developing AKI and that [TIMP-2][IGFBP7] test could have identified patients earlier. In this sub-analysis of the Sapphire study,¹ we examined the temporal changes in [TIMP-2][IGFBP7] following vancomycin.

**Methods:** We identified patients who received vancomycin and grouped them according to their maximum KDIGO AKI stage within 3 days of 1st dose of vancomycin. We calculated the median daily [TIMP-2][IGFBP7] value from day prior to 1st dose of vancomycin until 5 days after. A bootstrap analysis was used to calculate 1-sided p-values for comparison to their maximum KDIGO AKI stage within 3 days of 1st dose of vancomycin. We calculated the [TIMP-2][IGFBP7] test could have identified patients earlier.

**Conclusions:** In patients with AKI 2-3, median [TIMP-2][IGFBP7] values were significantly elevated on the day of the 1st vancomycin dose and remained elevated for the following 2 days. These 5 days after. A bootstrap analysis was used to calculate 1-sided p-values for comparison to their maximum KDIGO AKI stage within 3 days of 1st dose of vancomycin. We calculated the [TIMP-2][IGFBP7] test could have identified patients earlier. In this sub-analysis of the Sapphire study¹, we examined the temporal changes in [TIMP-2][IGFBP7] following vancomycin.

**Figure 1.** Kinetics of urinary [TIMP-2][IGFBP7] in critically ill patients who received vancomycin.

In patients with AKI 2-3, median [TIMP-2][IGFBP7] values were significantly elevated on the day of the 1st vancomycin dose and remained elevated for the following 2 days. These 5 days after.

Conclusions: In patients with AKI 2-3 after vancomycin administration, urinary [TIMP-2][IGFBP7] was significantly elevated on the first 2 days after the 1st dose. These biomarkers have the potential to improve management in patients receiving vancomycin.

SA-PO204

**Peri-Operative Serum IL-33 Concentrations in Matched AKI and Non-AKI Patients Undergoing Cardiac Surgery**

*Charles L. Edelman,*¹ Heather Thiessen Philbrook,² Jay L. Koyner,² Michael Shlipak,² Steven G. Coca,³ Chirag R. Parikh.² ¹Univ Colorado Denver; ²Yale Univ; ³Univ Chicago; ⁴UCSF.

**Background:** Endothelial cell damage and death in the nephron is an early feature of AKI. Damage-associated molecular patterns (DAMPs) are endogenous molecules released by damaged cells including endothelial cells. IL-33, a DAMP, has been shown to be present in blood vessels in the kidney and released into the blood, but not the urine, in cisplatin-induced AKI in mice before the increase in serum creatinine. We sought to determine whether serum IL-33 levels are a biomarker of AKI in humans in a nested case-control study.

**Methods:** Perioperative plasma samples were obtained from patients enrolled in the TRIBE-AKI cohort. 35 cases of AKIN Stage 2 AKI or higher within the first 4 post-op days were matched to 70 controls with no AKI by pre-op GFR, age, sex, site and cohort. Blood samples were available pre-op, day 1 (0-6.6 hours), days 2 and 3. Serum IL-33 was measured by ELISA.

**Results:** The pre and post-operative levels of IL-33 are shown in Table 1. Using a mixed model accounting for the matching in the data, the first post-operative value of IL-33 was significantly different (p=0.005) between cases and controls after adjusting for pre-op values. There was a non-significant trend towards higher IL-33 levels on day 2.

**Conclusions:** While most patients in the TRIBE-AKI Cohort experienced stage 1 AKI when classified by peak serum creatinine increase, one-third of those have duration of AKI of ≥3 days. Elevated urinary kidney injury biomarker within 6 hours of surgery may help in identifying of patients at risk for longer AKI duration, which may serve as a reliable metric for drug development trials.

Urinary Biomarker Evaluation in Cancer Patients Receiving Cisplatin
Blessy George, 1 Amanda Roque-Atiáno, 2 Cara A. Chang, 3 Nickie L. Johnston, 4 Madeleine Gomez, 5 Lucas Ellison, 6 Xia Wen, 5 Lauren Aleksunes, 1 Daniel Bowles, 1 Cindy L. O’Bryant, 6 Melanie S. Joy. 7 1School of Pharmacy, Rutgers Univ, NJ; 2Schools of Pharmacy and Medicine, Univ of Colorado, CO.

Background: The study explored the time dependency of urinary biomarker changes and correlations between the biomarkers and traditional markers of kidney injury in a cohort of patients receiving cisplatin.

Methods: Urine was obtained at baseline, 2Day and 3Day 10 from patients (n=42) receiving cisplatin (25 mg/m²). Urinary kidney injury molecule-1 (Kim-1), calbindin, beta-2 microglobulin (B2M), clusterin, monocytic chemotactant protein-1 (MCP-1), cystatin C, trefoil factor 3 (TFF3), tissue inhibitor of metalloproteinase 2 (TIMP2), and insulin growth factor binding protein 7 (IGFBP7) were measured by multiplex or ELISA.

A: baseline vs. Day 3: p<0.05, B: baseline vs. Day 10: p<0.05, C: Day 3 vs. Day 10: p<0.05

The biomarker-GFR correlations were: TFF3 (r: -0.259), B2M (r: -0.2017), Kim-1 (r: -0.1758), MCP-1 (r: -0.1390), cystatin C (r: -0.0935), IGFBP7 (r: -0.0764), clusterin (r: -0.067), calbindin (r: -0.0647), and TIMP2 (r: -0.0619). The biomarker-albumin correlations were: calbindin (r: 0.7813), TFF3 (r: 0.5949), clusterin (r: 0.5869), Kim-1 (r: 0.3166), TIMP2 (r: 0.3016), MCP-1 (r: 0.2340), IGFBP7 (r: 0.2217), cystatin C (r: 0.1375), and B2M (r: 0.1149).

Conclusions: Urinary biomarkers display time dependent increases post cisplatin and exhibit variable degrees of correlation with GFR and urinary albumin. TFF3 had high concordance with both GFR and urinary albumin, which may be a favorable characteristic.

Prediction of Long-Term Renal Outcomes in AKI Survivors by Urinary Biomarkers
Rei Isshiki, 1 Kent Doi, 1 Maki Sumida, 2 Yoshifumi Hamasaki, 2 Naoki Yahagi, 2 Masaoi Nangaku, 1 Eisei Noiri. 1 1Nephrology and Endocrinology, Univ Hospital, Univ of Tokyo, Tokyo, Japan; 2Emergency and Critical Care Medicine, Univ Hospital, Univ of Tokyo, Tokyo, Japan.

Background: Although several epidemiological studies suggested that acute kidney injury (AKI) in tropics with lot of morbidity and mortality. The aim of this study was to (I) evaluate the carbonyl and oxidative stress in these group and their pathogenesis link and (II)identify the risk factors and possible interventions.

Methods: We conducted an observational study examining the association of three urinary biomarkers measured at ICU admission [L-type fatty acid-binding protein (L-FABP), neutrophil gelatinase-associated lipocalin (NGAL), and N-acetyl- β-D-glucosaminidase (NAG)] with CKD progression after discharge without major adverse kidney events. The study explored the time dependency of urinary biomarker changes in two groups of critically ill patients who frequently suffer from multiple and transient/peristent renal insults. This study was aimed to evaluate whether serial measurement enables to predict AKI progression and recovery in these patients.

Results: Among the enrolled 272 patients, 33 were determined as newly developed AKI after ICU admission, 64 showed worsening of kidney function and 63 recovered from AKI. ROC analysis showed that biomarkers at day 2 showed no significantly additional benefit in predicting these three AKI outcomes compared with those measured at day 1. However, net reclassification improvement (NRI) analysis demonstrated adding AKI biomarkers at day 2 to the clinical model consisted of clinical variables and biomarker at day 1 significantly improved prediction of these AKI outcomes.

Conclusions: Serial measurement of AKI biomarkers involved in clinical models could contribute to prediction of AKI outcomes in a heterogeneous cohort of adult mixed ICU.

SA-PO208

Significance of Serial Measurement of Acute Kidney Biomarker in Intensive Care Unit
Rei Isshiki, 1 Kent Doi, 2 Maki Sumida, 1 Naoki Yahagi, 2 Masaoi Nangaku, 1 Eisei Noiri. 1 Nephrology and Endocrinology, Univ Hospital, Univ of Tokyo, Tokyo, Japan; 2Emergency and Critical Care Medicine, Univ Hospital, Univ of Tokyo, Tokyo, Japan.

Background: AKI biomarkers have been developed with the concept of earlier detection of kidney damage than serum creatinine. However, single time point measurement appears not to provide sufficient information for detecting and predicting AKI in ICU patients who frequently suffer from multiple and transient/peristent renal insults. This study was equipped to evaluate whether serial measurement enables to predict AKI progression and recovery in these patients.

Methods: Serial measurements of AKI biomarkers including plasma and urinary NGAL, urinary L-FABP, and urinary NAG at ICU admission (day 1) and 24 hr after (day 2) were conducted in adult critically ill patients who were treated in a mixed ICU.

Results: Among the enrolled 272 patients, 33 were determined as newly developed AKI after ICU admission, 64 showed worsening of kidney function and 63 recovered from AKI. ROC analysis showed that biomarkers at day 2 showed no significantly additional benefit in predicting these three AKI outcomes compared with those measured at day 1. However, net reclassification improvement (NRI) analysis demonstrated adding AKI biomarkers at day 2 to the clinical model consisted of clinical variables and biomarker at day 1 significantly improved prediction of these AKI outcomes.

Conclusions: Serial measurement of AKI biomarkers involved in clinical models could contribute to prediction of AKI outcomes in a heterogeneous cohort of adult mixed ICU.

SA-PO209

Role of Carbonyl Stress Revisited in Pathogenesis of Tropical Acute Kidney Injury
Pinaki Mukhopadhyay. 1 Nephrology, NRS Medical College, Kolkata, West Bengal, India.

Background: Malaria and snake bite are two common causes of Acute Kidney Injury (AKI) in tropics with lot of morbidity and mortality. The aim of this study was to (I) evaluate the carbonyl and oxidative stress in these group and their pathogenesis link and (II)propose the oxidative stress marker in this AKI.

Methods: All cases of falciparum malaria mediated AKI (FMAKI) (n=50), confirmed by antigen and/or in peripheral blood smear and snake bite mediated AKI(SAKI) (n=58) were included. AKI was calculated as per RIFLE criteria. Demographical, clinical and biochemical data were analysed and were followed from hospitalization to discharge/ death. Oxidative and carbonyl stress markers [advanced oxidation product protein (AOPP), advanced glycation end product (AGE), pentosidine, dityrosine, thiobarbituric acid reactive substance (TBARS) and methyl glyoxal (MG)] were measured consecutively according to standard protocol. Predictive importance was assessed from trend analysis, receiver operated characteristic(ROC) curve analyses and multiple logistic regression with AKI as positive response.

Results: The Oxidative stress index(OSI) of FMAKI patients were 1.89 higher than controls. The TBARS, MG level were 6.49 and 5.56 times higher indicating a significant carbonyl stress in these patients. AOPP level was 2.33 times higher indicating proteins being highly insulted in FMAKI. Similarly in SAKI significantly elevated total oxidant stress with decreased total antioxidant stress leads to net oxidative stress in SAKI patients depicted by increased OSI values (p<0.001). MG was increased by 3.48 times (p<0.001).Only AOPP (p<0.001) and MG (p=0.004) were found to be significantly elevated in expired patients than the survived indicating their predictive power for adverse outcome. At univariate level,
all parameters can differentiate between AKI and the non-AKI group. At multivariate level, methylglyoxal, AOPP and dityrosine appeared to be independent predictor of AKI in snake bite and malaria infected patients (p<0.05).

Conclusions: 1. MG, the carbonyl stress marker along with oxidative stress are significantly raised and possibly linked to the pathogenesis of AKI. 2. MG and AOPP can be used as a surrogate marker in these tropical AKI.

SA-PO210

Prediction of Short-term and Long-term Outcomes of AKI-Based on Plasma NGAL Karina Soto,1,2 Fernando Pereira,1 Liliana Maria Goncalves Cunha,1 Iola Pinto,1 Ana Luisa Papoila,1 Prasad Devarajan,1 Nephrology, Hospital Fernando Fonseca; 1Inst Superior de Engenharia de Lisboa; 2Nova Medical School/FCM, Univ Nova de Lisboa, Portugal; 2Nephrology, Cincinnati Children’s Hospital Medical Center, OH.

Background: We have previously shown a good performance of Plasma NGAL (pNGAL) as an AKI biomarker in emergency settings. Now we investigated a new AKI classification based on pNGAL for prediction of kidney dysfunction at discharge and at the end of follow-up.

Methods: Patients from a previous study at ED were followed for >5y. During the index hospitalization, 21% were AKI (based on Scr), 26% transient azotemia, 51% normal function and 2.4% stable CKD. All patients had Scr and pNGAL measured at 0, 6, 12, 24 and 48H of admission. A new AKI classification based on pNGAL levels (AKI:pNGAL+) defined AKI as pNGAL≥110 ng/mL (cut-off by GAMS). A multivariable logistic and Cox regression models were applied.

Results: Of 599 patients admitted, 97.8% were available at discharge and 54.4% at last follow-up. At admission 42.6% were reclassified as AKI:pNGAL+ whereas only 21.7% were based on Scr. All significant clinical variables were included in multivariable analysis at discharge.

Variables
OR 95% CI
AKI:pNGAL+ 4.2 2.3-7.6
Age 1.1 1.0-1.1
CVD 1.2 1.2-3.2
DM 1.5 1.5-4.0

p<0.001 all unless CVD=0.007

Having pNGAL≥110 at ED corresponded to 4-fold increased odds for eGFR<60 mL/min (p<0.001 ROC-AUC 0.82). The cumulative incidence of CKD showed that most of AKI:pNGAL+ developed CKD at 60 mo (the highest proportion 77%) (figure 1) HR for CKD: 2.4 for patients AKI:pNGAL+ in long-term (p=0.001 ROC AUC 0.74) NRI 56.3 and IDI 0.03.

Conclusions: Patients who were AKI:pNGAL+ had significant lost kidney function at discharge and more than 2-fold risk of developing CKD in long-term evolution. Plasma NGAL is a useful tool for CKD prediction, independent of serum creatinine.

SA-PO211

The Use of Novel Serum and Urinary Biomarkers to Predict the Development of Hepatorenal Syndrome in Patients with Advanced Cirrhosis

Desmond Y.H. Yap,1 Wai Kay Seto,1 James Yf Fung,1 See-Ching Chan,1 Siu-Ho Chok,2 Man-Fung Yuen,1 Daniel Tak Mao Chan.1 Medicine, The Univ of Hong Kong, Hong Kong, Hong Kong; 1Surgery, The Univ of Hong Kong, Hong Kong, Hong Kong.

Background: Hepatorenal syndrome (HRS) is associated with high mortality rates in advanced cirrhotic patients without liver transplantation. Prediction of the development of HRS remains difficult.

Methods: We prospectively recruited patients with Child’s B or C cirrhosis and followed them at 2-week intervals 12 weeks or until HRS developed. Serum cystatin C (CysC), serum Neutrophil Gelatinase-Associated Lipocalin (NGAL), serum IL-18, urine kidney injury molecule-1 (KIM-1) and urine liver-type fatty acid binding protein (LFABP) were measured at recruitment (Baseline).

Results: 43 patients were included. 12 developed HRS at 7.3±5.1 weeks from Baseline. pNGAL at recruitment had a higher Baseline level of serum CysC (4.42±0.51 mg/L vs. 1.07±0.50 mg/L, p=0.021), serum NGAL (129.0±68.66 ng/mL vs. 72.84±48.91 ng/mL, p=0.025), serum IL-18 (759.91±477.05 mL/mL vs. 358.13±153.00 mL/mL, p<0.001), urine KIM-1 and LFABP (3.64±3.34 ng/mL vs. 1.18±1.68 ng/mL and 10.17±8.37 ng/mL vs. 3.28±4.20 ng/mL, p=0.023 and 0.035 respectively) when compared to patients who did not develop HRS. The cut-off and positive and negative predictive values for HRS were shown in Table 1.

Serum NGAL and IL-18 and urinary KIM-1 at Baseline were significantly associated with the development of HRS (OR 1.017, 95% CI 1.001-1.033, p=0.035; OR 1.007, 95% CI 1.002-1.013, p=0.012; OR 0.963, 95% CI 0.937, p=0.045, respectively)

Conclusions: Serum IL-18 and urinary KIM-1 could serve as biomarkers to predict HRS in patients with advanced cirrhosis.

Robust Risk Assessment of Acute Kidney Injury After Acute Myocardial Infarction Using the Novel Biomarker C-Terminal Fragment of Agrin (cAF)

Spyridon Arampatzis, 1 George Chatliakis, 1 Vasileios Devetzis, 1 Stefan Hettwer,2 Dimitros Tziakas,1 Uyen Huynh-do,1 Nephrology, Hypertension and Clinical Pharmacology, Uni. Hospital Bern, Inselspital, Switzerland; 2Cardiology, Democritus Univ of Thrace, Greece; 3Neurotune AG, Switzerland.

Background: Acute kidney injury (AKI) complicating acute myocardial infarction (AMI) increases subsequent morbidity and mortality. The objective of this study was to validate c-terminal fragment of agrin (cAF) as a novel AKI biomarker in patients with AMI.

Methods: 403 consecutive patients with AMI were enrolled, samples were collected and presentation for serum (sCAF), urine (uCAF) CAF, neutrophil gelatinase-associated lipocalin (NGAL), interleukin-18 (IL-18) and cystatin-C analysis. The presence of AKI was evaluated at 48 hours post admission and at discharge.

Results: The incidence of AKI was 6.7%±14.6% depending on time-point and criteria used and increased across quartiles of uCAF (x<0.001). Both uCAF and sCAF significantly correlated with serum creatinine on admission (r=0.233, p<0.001 & r=0.175, p<0.001), at 48 hours (r=0.263, p<0.001 & r=0.226, p<0.001) and with peak creatinine as well (r=0.317, p<0.001 & r=0.225, p<0.001). The predictive accuracy for AKI of uCAF was good (AUC=0.630, 95%CI 0.552-0.708) and slightly better as that of urine NGAL (AUC=0.616, 95%CI 0.540-0.692), uCAF vs. sCAF (p=0.733), whereas that of sCAF was moderate (AUC=0.587, 95%CI 0.509-0.666). A uCAF value of 1033 pg/mL is suggested to have the best discriminating ability. The sensitivity of uCAF was 37% and the specificity 85% (NPV; 89%; PPV; 30%). Univariate analysis showed a strong association of uCAF with AKI incidence (OR 1.45, 95%CI 1.15-1.82, p=0.002) which remained significant even after adjustment for several confounders (OR 1.35, 95%CI 1.05-1.74).

Conclusions: Urine CAF analysis allows a robust risk stratification of AKI after AMI and thus optimized management in such patients.

At Myeloma Diagnosis, Age and Free Light Chain Level Predict Renal Function and These Factors with Free Light Chain Response Predict Renal Outcome

Punit Yadav,1,2 Mark Trehan Drayson,1,2 Mark Cook,1,2 Jennifer H. Pinney,1 Hannah V. Giles,1 Yu san dar Aung,1,2 Paul Cockwell.1,2

1Univ Hospital Birmingham, UK; 2Univ of Birmingham, UK.

Background: Elevated involved immunoglobulin light free chain (FLC) is a major cause of renal impairment (RI) in myeloma. Relationships between presentation and post-induction (PI) renal function and serum FLC levels are not established.

Methods: We used central laboratory data from the MRC Myeloma IX trial which compared biphosphonate and thalidomide-based therapies. Patients were divided into 3 eGFR categories: eGFR ≥60 mL/min, normal renal function; eGFR 30-59 mL/min, mild-moderate RI; eGFR <30 mL/min, severe RI. Linear regression and Logistic regression modelling were used to explore independent determinants of renal function. Results:

- 52.8% had an eGFR ≥60 mL/min; 37.3% had an eGFR 30-59 mL/min and 9.8% had an eGFR <30 mL/min. Median eGFR in patients with involved FLC was significantly lower than those with κFLC (58 [IQR 42-77] vs 63 [IQR 46-80]; P=0.01). Median eGFR for light chain only myeloma (LCO) was also significantly lower than those with IgG and IgA myeloma (49 [IQR 28-78] vs 62 [IQR 47-79] vs 63.5 [IQR 42.2-82.0]; P=0.0001).
- Patients with a difference between involved and uninvolved FLC (dFLC) ≥500 mg/L had a lower eGFR compared to those with dFLC 100-499 mg/L and dFLC <100 mg/L (52 [IQR 35-72] vs 66 [IQR 52.0- 82.6] vs 67 [IQR 54.2-82.0]; P=0.0001). A dFLC level of 700 mg/L was the optimal cut-off value for prediction of severe RI, with an AUC of 0.8.

Conclusions: Age and serum FLC level predict eGFR at presentation and age, presentation eGFR, and serum FLC response predict PI renal outcome.

SA-PO214

Urinary Biomarkers Improve the Prediction and Prognostic Assessment of Acute Kidney Injury in Critically Ill Patients

Patrick T. Murray, Teresa Martin, Eoin J. Cotter.

UCD Clinical Research Centre, School of Medicine, Univ College Dublin, Dublin, Ireland.

Background: Acute kidney injury (AKI) is common in intensive care unit (ICU) patients, and is diagnosed late by serum creatinine. New biomarkers may permit earlier detection and better management.

Methods: All patients admitted to the ICUs of two university hospitals were screened for this prospective cohort study. Clinical information and urine were collected on admission and daily for 7 days. Urine biomarkers analysed were neutrophil gelatinase-associated lipocalin (NGAL), α- and ʌ- glutathione-S-transferases (GSTs), kidney injury molecule-1 (KIM-1), liver fatty acid binding protein (L-FABP), creatinine, and albumin. AKI was defined by modified KDIGO criteria, using ICU admission creatinine as reference. Values were compared between those who did or did not develop AKI or 30d adverse outcomes by a clinical score (including age, gender, serum creatinine & urea, urine output) and urine biomarker values on admission. In patients developing AKI, ROC curves were similarly generated for the prediction of clinical outcomes with values obtained at time of AKI diagnosis.

Results:

- 659 patients were enrolled; 181 patients (27%) developed AKI within 7d of ICU admission. AKI stages at diagnosis were: Stg1(n=81,45%), Stg2(n=17,9%), Stg3(n=83,46%).
- Best predictors were KIM-1 and NGAL, and the combination improved the prediction of AKI in the first 48h in ICU (AUC(95% CI): 0.79 (0.72-0.82)).
- A dFLC level of 700 mg/L was the optimal cut-off value for prediction of severe RI, with an AUC 0.8.
- New biomarkers may permit earlier detection and better management.

Conclusion: Age and serum FLC level predict eGFR at presentation and age, presentation eGFR, and serum FLC response predict PI renal outcome.

SA-PO215

Association of Growth Factor Biomarkers with Acute Kidney Injury and Long-Term Mortality in Adults following Cardiac Surgery

TRIBE-AKI Consortium.

Background: Following the structural damage and functional impairment from acute kidney injury (AKI), the kidney undergoes a coordinated process of repair involving regenerative growth factors. We conducted an ancillary analysis of a large, prospective study of adults undergoing cardiac surgery to investigate the utility of epidemical growth factor (EGF) and vascular endothelial growth factor (VEGF) in predicting kidney injury and mortality.

Methods: Patients undergoing cardiac surgery at high risk for AKI were enrolled at six academic centers. AKI was defined as a doubling in serum creatinine from baseline or receiving acute dialysis during the hospital stay. Postoperative plasma levels of EGF, VEGF, and a combination model of the two growth factors were evaluated for association with outcomes of AKI or long-term, all-cause mortality at a mean follow-up of 3 years.

Results:

- First postoperative and peak plasma EGF were not associated with AKI.
- Peak plasma VEGF was independently associated with increased risk of AKI (adjusted odds ratio [OR] 7.4, 95% confidence interval [CI] 1.1-47.9).
- First postoperative EGF was inversely associated with a lower risk of mortality (adjusted HR=0.67; 95% CI: 0.47-0.97).
- First postoperative VEGF was likewise associated with a lower risk of mortality (unadjusted HR=0.36; 95% CI: 0.16-0.82), though the association was attenuated following adjustment (adjusted HR=0.36; 95% CI: 0.15-1.04).

Conclusions: Postoperatively, EGF and VEGF are released in response to AKI, and their concentrations were inversely associated with long-term mortality. These growth factors may serve as biomarkers of long-term outcomes in adults undergoing cardiac surgery.

Procalcitonin as a Predictor of AKI in Patients with Sepsis

Jonathan Chavez,1 Maria de la luz Alcantar Vallin,1 Guillermo Garcia-Garcia,1 Luis Arnoldo Muñoz.2

1Nephrology Service, Hospital Civil de Guadalajara, Guadalajara, Mexico; 2Internal Medicine, Hospital Civil de Guadalajara, Guadalajara, Mexico.

Background: Sepsis is a common cause of AKI. Identifying patients at risk for AKI could improve clinical outcomes. Procalcitonin (PCT) reflects accurately the presence of sepsis and its severity. We evaluated the role of PCT as predictor of AKI in septic patients.

Methods: Cross-sectional study of 72 septic patients between January to December 2014. Patients with Scr >1.5 mg/dl before admission, ESRD patients and those with autoimmune comorbidity were excluded. PCT, Scr, urea, and WBC were measured on admission, and at 24 h and 48 h of hospitalization. X2 and t-test were used when appropriate. A ROC curve for PCT value on admission as well as the area under the curve (AUC), the standard AUC error, and sensitivity and specificity of PCT values were determined.

Results:

- Patients' mean age was 50.8 y (18-79); 37 (51.4%) were women. 18 (25%) patients had PCT value at <0.5 ng/mL (negative) and 54 (75%) 0.5 ng/mL (positive) on admission. Forty-two (58.3%) patients developed AKI, 19 (45.2%) KDIGO 1, 12 (28.6%) KDIGO 2, and 11 (26.2%) KDIGO 3. Of the 42 patients who developed AKI, 37 (88.1%) had a positive value of PCT at admission (p<0.01, OR 5.659, 95% CI 1.738 to 18.425).
- The ROC curve for PCT value on admission as well as the area under the curve (AUC), the standard AUC error, and sensitivity and specificity of PCT values were determined.

Conclusions:

- We found a significant association between levels of PCT and AKI and development of AKI in patients with sepsis. A cutoff PCT value of 2.565 ng/mL on admission had the highest validity for predicting AKI with an SE of 61.9%, one SP of 80%, a PPV of 44.52%, and NPV of 56.18%.
Elevated Erythropoietin Concentration in AKI Is Associated with IGFBP-1 Rather Than Hemoglobin
Tetsushi Yamashita, Eisie Noiri, Yoshifumi Hamasaki, Naoki Yahagi, Masaoi Nangaku, Kent Doi. The Univ of Tokyo, Tokyo, Japan.

Background: EPO expression will be increased by hypoxia in the kidney and hypoxic injury plays a crucial role in pathogenesis of AKI. However, little is known about blood EPO levels in critically ill patients complicated with AKI.

Methods: This study prospectively enrolled 98 adult critically ill patients who admitted to the adult ICU. We measured plasma EPO and also measured plasma IGFBP-1 as a hypoxic marker, which is produced mainly by liver, and plasma NGAL and urinary NAG as renal damage biomarkers on ICU admission. This study was conducted to evaluate whether plasma EPO levels in AKI patients was regulated by other factors than anemia.

Results: AKI occurred in 42 (42.9%) patients. Significantly higher plasma EPO in the AKI group was detected compared with the non-AKI group (16.13 [9.87–28.47] mIU/mL, p<0.05). Plasma EPO concentration was strongly and negatively correlated with hemoglobin in the non-AKI group but not in the AKI group.

Conclusions: Plasma EPO had a predictive value for diagnosing AKI but it itself had a limited value for distinguishing prerenal AKI from other causes of AKI.

Predictive Value of Plasma Neutrophil Gelatinase-Associated Lipocalin (NGAL) to Distinguish Prerenal AKI to Other Causes of AKI
Chae Ho Lim, Young-II Jo. Div of Nephrology, Dept of Internal Medicine, Konkuk Univ Medical Center; Gwangjin-gu, Seoul, Republic of Korea; Div of Nephrology, Dept of Internal Medicine, Konkuk Univ Medical Center, Gwangjin-gu, Seoul, Republic of Korea.

Background: Plasma Neutrophil gelatinase-associated lipocalin (NGAL) is a promising biomarker for acute kidney injury, but it’s role for distinguishing prerenal AKI from other causes are not well known. The aim of this study was to evaluate the predictive value of plasma NGAL to distinguish prerenal AKI to other causes of AKI.

Methods: We reviewed all NGAL test from December 26, 2011 to February 28, 2015 in Konkuk University Medical center (Seoul, Republic of Korea) and subtract patients who taken factional excretion of sodium (FENa) test at the same time. Patients were first grouped with Acute Kidney Injury Network (AKIN) stages and evaluated it’s diagnostic role for AKI and second divided with prerenal AKI and other causes of AKI.

Results: Total 5814 NGAL test were done from December 26, 2011 to February 28, 2015 in Konkuk University Medical center, and 495 patients taken FENa test at the same time. In AKI group, plasma IGFBP-1 was strongly and positively correlated with plasma EPO. Multiple logistic regression analysis revealed plasma EPO in the AKI group was significantly associated only with plasma IGFBP-1 and complication of diabetes mellitus.

Conclusions: EPO production in AKI was enhanced by not anemia but systemic hypoxic stimuli evaluated by IGFBP-1, indicating unknown independent pathway of renal EPO production in AKI.

Neutrophil/Lymphocyte Ratio for Early Detection of Acute Kidney Injury (AKI) in Patients Admitted to the Emergency Room
Mehsen Abo Alfeili, Ruh N. Sotkla, Linda Shavit. Adult Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel.

Background: Neutrophil to lymphocyte ratio (NLR) is a readily available biomarker of systemic inflammation. Several studies have provided evidence of an association between elevated NLR and adverse outcomes in a variety of medical and surgical conditions, including CKD. In this study, we evaluated the predictive capacity of single Emergency Room (ER) measurement of NLR for early diagnosis of acute kidney injury (AKI).

Methods: We prospectively studied 294 patients aged 71.6±17. NLWR was measured at presentation to the ER. AKI was defined as a new-onset 1.5-fold or more increase in serum creatinine or a 25% decrease in estimated GFR sustained for at least 3 days despite volume resuscitation. The primary outcome was AKI. Secondary outcome was in-hospital mortality.

Results: 36 patients (12.2%) developed AKI and 26 (9%) died. Mean NLR was significantly higher in AKI compare to non-AKI patients (11.7±15.2 vs 6.45±15.2; p=0.048). A multivariate model adjusted for age, gender, blood pressure, and plasma albumin levels confirmed that NLR is higher in AKI patients (p=0.048). Receiver operating characteristics curve revealed AUC 0.715 (95% CI 0.63-0.8) sensitivity 0.78, specificity 0.65, OR 6.423 (CI, 2.659 to 16.026) for a cutoff value of NLR 5.5. The association between NLR and in hospital mortality was not statistically significant (p = 0.92).

Conclusions: Single ER measurement of NLR can be a useful tool for early diagnosis of AKI. This finding is particularly important in light of the widespread availability and low cost of NLR, especially compared with other biomarkers currently under study in the context of AKI.
in AKI cases, and within 24h of ICU admission in frequency-matched controls. AKI was defined by KDIGO criteria. Longitudinal data from AKI cases were obtained throughout hospital stay. Renal recovery was defined as the ratio of follow-up SCr/baseline SCr £1.5. Urine Klotho was measured by immunoprecipitation-immunoblot. Mixed-effects linear models were constructed to assess longitudinal trends of Klotho in AKI survivors.

Results: Mean (SD) age was 58 (17) years, 62% were men and 75% white. Patients with AKI had higher critical illness scores than controls without AKI. Five (17.2%) patients died and 8 (27.6%) required RRT in the AKI group. Only 3.5% patients died in the control group. Urine Klotho adjusted by urine creatinine (uKlotho/Cr) was significantly lower in AKI cases than in controls, median 10 [IQR 4–20] vs 28 [14–52] fmol/mg, p = 0.003. Furthermore, uKlotho/Cr significantly increased with time in patients that exhibited renal recovery (n=7, ∆+216%, p = 0.05) but not in those that did not (n=7, ∆+8%, p = 0.91), median follow-up 24 days.

Conclusions: uKlotho/Cr is significantly lower in patients with AKI when compared to ICU controls without AKI. uKlotho/Cr recovered only in patients that recovered kidney function. Klotho may serve as a prognostic marker for AKI recovery.

SA-PO221

Biomarkers of Acute Kidney Injury in Children Treated with Cisplatin

Kelly McMahan,1 Shahrad Rod Rashek,2 Kirk Raymond Schultz,2 Maury N. Pinsky,1 Tom D. Blydt-Hansen,3 Cherry Mammen,2 Ross T. Tsuyuki,2 Prasad Devarajan,1 Michael Zappitelli.1 1McGill U, Montreal; 2U British Columbia, Vancouver; 3U Alberta, Edmonton, Canada; 4Cincinnati Children’s Hosp, Cincinnati.

Background: Cisplatin(CisP) causes acute kidney injury(AKI) and may cause chronic kidney disease(CKD). Biomarker(BioM) may allow early AKI diagnosis and treatment. Applying BioM to Long-Term Effects in Child/Adolescent Cancer Treatment(ABLE) is a Canadian study of cancer treatment toxicities, including nephrotoxicity. We study BioM of child CisP treatment for early and late renal outcome prediction. This analysis evaluates neutrophil gelatinase-associated lipocalin(NGAL), kidney injury molecule-1(KIM-1) and serum Cystatin C(CysC) with CisP therapy in the first 1/3 of subjects.

Methods: Ongoing, 8-site, prospective cohort of 150 children receiving CisP. Excluded: severe CKD. Protocol includes 2 “acute” visits[AV] around CisP infusion(pre, post, discharge urine/blood) for serum creatinine(SCr), CysC, urine NGAL, KIM-1. Outcomes: AKI(Kidney Disease Improving Global Outcomes[KDIGO] SCr criteria; AKI by National Cancer Institute(NCI) criteria(based on serum electrolytes).

Results: Data available in 44/60 (mean/SD age 7.4yrs; AV1/AV2 hospital stay 16±27/12±26 days; 55% male). AV1: 11% KDIGO AKI, 46% NCI AKI, 50% with either. AV2: 14% KDIGO AKI, 72% NCI AKI, 75% with either. BioM drop immediately post-CisP (n=25), followed by a rise at discharge.

A similar pattern is seen in AKI and non-AKI groups and when expressing BioM/urine creatinine(not shown).

Conclusions: This is a novel study of AKI BioM excretion in CisP-AKI. NCI-AKI is more common than SCr-AKI. The immediate BioM drop post-CisP may be related to injury protection from high fluid rate and/or urinary alkalization peri-CisP. Our larger sample size will allow to further characterize BioM excretion and evaluate BioM associations with AKI definition and outcomes.

Elevated Renal Injury Biomarkers Fall Transiently After Stenting in Human Atherosclerotic Renal Artery Stenosis (ARAS)

Wei Wang,1 Ahmed Saad,1 Sandra Herrmann,1 Alfonso Erín,1 Hui Tang,1 Lilach O. Lerman,1 Stephen C. Te此刻,1 Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 2Nephrology, Dalian Municipal Central Hospital, Dalian, Liaoning, China.

Background: ARAS reduces blood flow and perfusion pressures to the post-stenotic kidney (STK), ultimately producing inflammatory injury. The aim of our study was to identify and track renal injury biomarkers for 24 hours and 3 months after combined CT imaging and stent revascularization.

Methods: 12 patients with severe ARAS scheduled for revascularization for clinical indications were enrolled in a 3 day inpatient and restudied 3 months later. All subjects maintained ACE/ARB Rx and fixed Na+ intake, and were compared with Essential Hypertensives(EH) (n=12) undergoing the same biomarkers and imaging studies. Glomerular filtration rate (GFR) was measured by iothalamate clearance, blood flow and perfusion by Multidetector Computerized Tomography (MDCT) and NGAL, MCP-1, IL-10, TNF-α, KIM-1, IGFBP7 and TIMP-2 in renal vein and peripheral blood/IVC samples every 6 hours for 24 hours and after 3 months.

Results: Kidney perfusion, whole kidney blood flow, single kidney isohalometric GFR were reduced in the STKs compared to kidneys from EH and increased after stent revascularization.
date, it is unclear which intrinsic factors trigger the onset of SIRS and associated AKI. We investigated the role of mtDNA during systemic inflammation and AKI and the role of platelets herein.

**Methods:** Human platelets were stimulated with mitochondrial DNA, genomic DNA or unmethylated CpG-enriched oligonucleotides (CpG ODN). Platelet activation was monitored using FACSTM. In a single centre prospective observational study we included 37 patients diagnosed and classified for the onset of SIRS with or without the development of AKI that were admitted to the ICU. As a control we included (n=25) patients after elective major surgery without a diagnosis of either SIRS or AKI. Blood and urine samples were isolated and processed. Free circulating plasma and urinary mtDNA was determined by RT-PCR. Inflammatory mediators and PUF in urine were measured using specific ELISA.

**Results:** Mitochondrial DNA, but not genomic DNA triggered platelet activation. Unmethylated CpG ODN, dose dependently stimulated platelet activation. Compared to ICU-controls, critically ill patients had elevated plasma and urinary mtDNA and proinflammatory cytokines. Compared to SIRS patients without AKI, the patients with AKI displayed elevated levels of urinary PUF indicative of platelet activation.

**Conclusions:** The development of AKI in critically ill patients is associated with platelet activation, possibly triggered by mitochondrial DNA.

**Invaders in the Night: Sleep Apnea and Sub-Clinical Renal Injury**

**Aaron A. Rampersad,** Shahab Bozorgmehr, 1 Areef Jishani, 1, 2, 4 F. David Weiner, 1, 4 Satish P Ramachandran, 1 Rebecca Bethy, 1, 4 Muna T. Canales, 1, 4 1Univ of Florida, Gainesville, FL; 2Minneapolis VAMC; 3Univ of Minnesota, Minneapolis, MN; 4Malcom-Randall VAMC, Gainesville, FL; 5Univ of California, San Diego, CA.

**Background:** Sleep apnea is common in patients with CKD. We postulated that sleep apnea may cause renal injury through repeated ischemia-reperfusion. The current study correlated overnight changes in urinary excretion of renal injury biomarkers with severity of sleep apnea.

**Methods:** 39 consecutive participants in the SNORE Study, a longitudinal study of sleep apnea and kidney function decline, underwent overnight sleep study and provided spot urine samples before and after sleep. We measured urinary NGAL, L-FABP, KIM-1, and urinary cys-c levels, and correlated differences between AM and PM levels (AM-PM) with severity of sleep apnea or hypoaxia. Sleep apnea was defined by the apnea-hypopnea index (AHI, events/hour); hypoaxia was ≥ 90% time sleep < 90% SaO2 (%TST90). Data were log-transformed to normalize distribution.

**Results:** Patient characteristics: Mean age, 73.6±6.4 years; 90% male; 87% Caucasian, 13% black; BMI 29.4±4.2 kg/m2; MDRD eGFR, 34.3±18.1 ml/min/1.73m2; Median urinary albumin/creatinine ratio, 46 mg/g Cr [IQR 9.3–357 mg/g Cr]. 69% had sleep apnea (AHI≥5); median AHI, 10 [IQR 2–23]; median %TST90, 15 [IQR 3–22] with 34% %TST90≥10%. Higher %TST90 was correlated with higher AM KIM-1 values (r=0.40, p=0.01) and greater increase in urinary KIM-1 (AM-PM) (r=0.32, p=0.04). None of the remaining urinary biomarkers correlated with %TST90. Also, none of the overnight urinary biomarker changes correlated with AHI.

**Conclusions:** The correlation of KIM-1 with hypoaxia suggests that SA may contribute to CKD through ischemic renal injury. Future studies with larger sample size and in non-CKD populations are needed to further test this hypothesis.

**Body Mass Index and Acute Kidney Injury in Hospitalized Patients**

**Yan Lun Allen Liu,** Milind Nikam, Lee Ying Yeo. Dept of Medicine, Khoo Teck Puat Hospital, Singapore.

**Background:** Acute kidney injury (AKI) is common in hospital settings. The association between AKI and Body Mass Index (BMI) in general hospitalized patients is not well known. This study is to explore the incidence of AKI and the impact of BMI on AKI in hospitalized patients.

**Methods:** This was a single centre, retrospective, case-control study. All patients aged 21 or above under in-hospital care from January to December 2013 were recruited for analysis. Mean age was 62.5 ± 8.4 years; 90% male; 87% Caucasian, 13% black; BMI 29.4±4.2 kg/m2; Median urinary albumin/creatinine ratio, 46 mg/g Cr [IQR 9.3–357 mg/g Cr]. 69% had sleep apnea (AHI≥5); median AHI, 10 [IQR 2–23]; median %TST90, 15 [IQR 3–22] with 34% %TST90≥10%. Higher %TST90 was correlated with higher AM KIM-1 values (r=0.40, p=0.01) and greater increase in urinary KIM-1 (AM-PM) (r=0.32, p=0.04). None of the remaining urinary biomarkers correlated with %TST90. Also, none of the overnight urinary biomarker changes correlated with AHI.

**Conclusions:** The correlation of KIM-1 with hypoaxia suggests that SA may contribute to CKD through ischemic renal injury. Future studies with larger sample size and in non-CKD populations are needed to further test this hypothesis.

**Funding:** Other NIH Support - DK079337 UAB-UCSD O’Brien Center, Veterans Administration Support

**SA-PO224**

**AKI Development Upon SIRS Is Associated with Platelet Activation, Possibly Triggered by Mitochondrial DNA Derived from Damaged Cells**

**Marcel Jansen,** Wilco P. Pulsksens, 2 Diba Emaa, 1 Sandrine Florquin, 1 Joris J. Roelofs, 1 Jaklleen Leeman, 1 Nephrology, Academic Medical Center, Amsterdam, Netherlands; 2Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.

**Background:** Multiple inflammatory pathways are activated by non-infectious agents during Systemic inflammatory response syndrome (SIRS) leading to collateral damage, including the development of acute kidney injury (AKI). Pattern recognition receptors (PRRs) of the innate immune system sense Damage-Associated Molecular Patterns (DAMPs) leading to an immune response. Components of mitochondrion e.g. unmethylated CpG-enriched mitochondrial DNA (mtDNA) that leak upon cell injury, are a source of DAMP. Platelets express several PRRs and play an important role in innate immunity. To
Conclusions: Preliminary results revealed underweight hospitalized patients had increased risks of developing stage 1 AKI. Stage 2 AKI was more commonly seen in patients with BMI <25. BMI status was not associated with the development of severe AKI (stage 3).

SA-PO227

Hypermagnessemia as a Risk Factor for the Mortality in Intensive Care Unit Patients with Acute Kidney Injury. Shumichi Shibazaki, 1 Makoto Araki, 1 Kohel Muira, 1 Daio Inaguma. 2 Dept of Nephrology, Sawa Central Hospital, Chino, Nagano, Japan; 2 Dept of Nephrology, Nagoya Daini Red Cross Hospital, Nagoya, Aichi, Japan.

Background: We need an easily measured biomarkers predicting for the mortality in acute kidney injury (AKI) because of high mortality rate. Therefore, we paid attention for serum magnesium (sMg) levels which reflects the renal tubular damage, and study the relationship sMg and prognosis in intensive care unit (ICU) patients with AKI.

Methods: A cohort study was conducted by collecting data from January to December 2014 in Nagoya Daini Red Cross Hospital. According to sMg at ICU 1st day, three groups were divided; low Mg group (sMg < 1.8mg/dL), normal Mg group (1.8mg/dL ≤ sMg < 2.6mg/dL), and high Mg group (sMg ≥ 2.6mg/dL). AKI was defined as serum creatinine (sCr) abrupt increase to ≥1.5 times baseline or sCr increase by ≥ 0.3mg/dL.) The primary endpoint was 28 days mortality after ICU admission. The secondary endpoint was the renal replacement therapy (RRT) induction rate, and the transition rate to endpoint was 28 days mortality after ICU admission. The secondary endpoint was the renal replacement therapy (RRT) induction rate, and the transition rate to endpoint was 28 days mortality after ICU admission.

Results: Out of 1614 ICU patients, 200 patients were included. The number of each groups are following; low Mg group was 55, normal Mg group was 115, and high Mg group was 30. The mortality was higher in high Mg group than in other Mg group (p = 0.011). A multivariate analysis identified high Mg group as an independent risk factor for the mortality (p = 0.041). High Mg group had 2.39-fold increased odds of mortality against recovery rate, the renal replacement therapy (RRT) induction rate, and the transition rate to endpoint was 28 days mortality after ICU admission. The secondary endpoint was the renal replacement therapy (RRT) induction rate, and the transition rate to endpoint was 28 days mortality after ICU admission.

Conclusions: Hypermagnessemia is an independent risk factor for the mortality in ICU patients with AKI.

SA-PO228

Gemcitabine-Induced Thrombotic Microangiopathy (TMA): A Report from the French Pharmacovigilance Network. Noemie Jourde-chiche, 1 Florence Daviet, 1 Frank Rouby, 1 Bertrand Gondouin, 1 Marion Sallée, 1 Julie Moussi-Frances, 1 Stéphane Burtry, 1 Pascale Poullin, 1 Bertrand Dussol, 1 Joelle Micallet. 1 Nephrology, Aix-Marseille Univ, Marseille, France; 2 Pharmacology and Pharmacovigilance, Aix-Marseille Univ, Marseille, France; 3 Hemapheresis, Aix-Marseille Univ, Marseille, France.

Background: Gemcitabine is a chemotherapy which use can be limited by renal adverse events, in particular thrombotic microangiopathy (TMA). This study evaluated the occurrence of gemcitabine-induced TMA, and described therapeutic strategies and outcomes.

Methods: All spontaneous reports of TMA attributed to gemcitabine in the French Pharmacovigilance Network database, between January 2000 and May 2015, were reviewed using a standardized questionnaire.

Results: 81 cases of TMA were reported in 48 male (59%) and 33 female (41%), with a median age of 63.5 yrs (range 39-87). Gemcitabine was prescribed for pancreatic (59%), pulmonary (15%), breast (8%), biliary tract (6%), urinary tract (5%), uterine (5%), testicular (1%) or liver (1%) cancers, or T lymphoma (3%). TMA occurred after a median of 7 months (range 0.2-60), and a median cumulative dose of 21.8g (range 1.1-48.6). Main symptoms were hypertension (51%), diffuse edema and/or congestive heart failure (42%), acute renal failure (86%), thrombocytopenia (67%), hemolytic anemia (86%). Median creatinine level was 1.8 mg/dL (range 0.8-17). In 6 patients, renal TMA was biopsy-proven. Renal replacement therapy was required in 10 (12%) patients, plasma exchanges (PEX) were performed in 17 (21%), 8 (10%) received fresh frozen plasma infusions, 9 (11%) corticosteroids, and 3 (4%) eculizumab (after PEX failure). Evolution data were available for 59 (73%) patients, among which the 17 treated with PEX. Hematological and renal remission was achieved in 35% with PEX versus 50% without, hematological remission without renal improvement in 18% with versus 26%, and no improvement was observed in 47% with versus 24% without PEX. Only one patient improved with eculizumab.

Conclusions: Gemcitabine treatment can be associated with TMA and severe renal adverse effects. The benefit of plasma exchange or eculizumab in this setting remains uncertain.

SA-PO229

Contribution of Drugs versus Risk Factors in Drug-Induced Renal Injury. Celina D. Cededa, 1 Linda Awulidi, 1 Etienne Macedo, 1 Dinna Cruz, 2 Stuart Goldstein, 1 Jorge Cerda, 2 David T. Seleowski, 1 Michael Zappitelli, 1 Andrew J.P. Lewington, 1 Ravindra L. Mehta. 1 Nephrology, Univ of California San Diego, San Diego, CA; 2 Nephrology, Univ of Cincinnati, Cincinnati, OH; 3 Nephrology, Albany Medical College, Albany, NY; 4 Nephrology, Univ of Michigan, Ann Arbor, MI; 5 Nephrology, Univ of Montreal, Montreal, QC, Canada; 6 Nephrology, Care Hospital India, Hyderbad, India; 7 Nephrology, St. James’s Univ Hospital, Leeds, London, United Kingdom.

Background: Drug-induced renal injury (DRI) is an increasing cause of acute kidney injury (AKI). Contribution of DRI requires consideration of the drug exposure, the number of drugs involved and underlying or concomitant risk factors (RF). We hypothesized that underlying RF would influence attribution of DRI.

Methods: The drug induced renal injury (DIRECT) study is an ongoing prospective multicenter study evaluating genetic determinants of the drug exposure, the number of drugs involved and underlying or concomitant risk factors (RF). Each enrolled case was adjudicated for causality by two independent nephrologists. We analyzed the first consecutive 86 adult and pediatric AKI cases. We evaluated the percent agreement, kappa statistic, and contribution of each drug (in setting of multidrug injury) and AKI RF.

Results: Adjudicators agreed 87.2% (n = 75) had DRI. For non-DRI cases, causality could not be established because of competing AKI RF. RF contributed to AKI in 86% of adults and 70% of children. Adjudicators disagreed on the percent attribution for each drug in 52%. For DRI cases, inter-rater agreement on percentage attributed to drug 1 was 48% with kappa=0.239 (p=0.001). For non-DRI cases, inter-rater agreement for drug 1 was 81.8% and RF attribution was 90%.

Conclusions: Underlying RF are common in DRI associated AKI. Causality assessment in DRI is complex due to difficulty in determining the attribution of drug and RF. CAT for DRI should incorporate AKI RF and their interaction with drugs. Funding: Private Foundation Support

Acute Kidney Injury in Patients with Chronic Kidney Disease: Aetiology and Survival Comparisons to Non-Acute Kidney Injury Chronic Kidney Disease Population Akib Khan.1 James Ritchie;2 Sneeta Sinha.3 Senior House Officer, Imperial NHS Foundation Trust, London, United Kingdom; ‘Renal Medicine, Univ of Manchester, Manchester, United Kingdom; ‘Nephrology, Salford Royal Foundation Trust, Salford, United Kingdom.

Background: AKI, described by an acute (hours to days) fall in kidney function, is associated with significant morbidity and mortality. Poor outcomes exist when AKI is superimposed on CKD, a disease involving structural or functional renal abnormalities in a chronic setting (>3 months). We present a single-centre prospective observational study; retrospectively analysed. We determined the factors surrounding AKI on CKD. Aetiology, length of stay, specialist review and medication data were examined. We compare AKI on CKD patients’ survival to matched non-AKI CKD patients.

Methods: CRISIS database CKD patients matching inclusion criteria treated at Salford Royal Foundation Trust were studied (n=542). A 2.0-3.0 and >3.0 times serum creatinine increase from last measurement was used to define Acute Kidney Injury Network stages 2 (n=17) and 3 (n=10) events respectively. Controls were matched by age, eGFR and blood pressure. Logistic Regression, Cox-Hazard Ratio and Kaplan-Meier Survival Plots were used.

Results: Aetiological factors associated with AKI included sepsis (48.1%), drug-induced (29.6%) and dehydration (25.9%). Septic-AKI had a 1.405 odds ratio (95%CI:0.999-19.936,p=0.801) of death compared to non-septic events. Hazard ratio for death due to AKI on CKD compared to non-AKI CKD was 1.77 (95%CI:0.72-4.33,p=0.207). Kaplan-Meier survival function clearly demonstrates this.

Conclusions: Aetiology of AKI in our patient group was similar to that seen in non-CKD studies. There was a clear trend towards increased all-cause mortality in patients with AKI on CKD in comparison to non-AKI CKD patients. Renal function decline rate following AKI on CKD should be explored in the future.

SA-PO232

Prospective Study of Incidence and Early Detection of Acute Renal Failure in Preterm Babies in a Tertiary Center in South India Indira Agarwal, Nithya Ponmudi, Anil K. Kuruvilla, Vijayakumar Theophilus-Sunder. Pediatric Nephrology, Christian Medical College, Vellore, Tamil Nadu, India; Neonatology, Christian Medical College, Vellore, Tamil Nadu, India; Nephrology, Christian Medical College, Vellore, Tamil Nadu, India.

Background: Preterm babies are at risk for ischemia, hypovolemia and hypotension and thus vulnerable to acute kidney injury (AKI). We aimed to study the incidence and predisposing factors for AKI in preterm babies and to assess the usefulness of urinary NGAL as a predictor of kidney injury.

Methods: Babies born < 32 weeks or 6 weeks were recruited; those with abnormal antenatal renal scans and major congenital anomalies were excluded. Weekly monitoring of urine output, clinical progress, interventions, ventilation, unexpected events and use of nephrotoxic drugs was done. Serum creatinine and urine NGAL was collected at 72 hours of age and weekly thereafter. Descriptive statistics using mean±SD for continuous variables, ANOVA and chi-square test for AKI detection test for categorical variables and Risk factor analysis using log binomial was performed.

Results: Of the 4823 live births, 80 fulfilled inclusion criteria (10.14%). The incidence of AKI was 12.6%. The risk factors included oligosomnia, PDA, nephrotoxic drugs, low Apgar, mechanical ventilation, CPAP and abnormal antenatal scans. Urine NGAL was estimated in 31 babies. It rose earlier and was significantly elevated in those on mechanical ventilation by week 2 while Creatinine rose only by week 3.

SA-PO233

Acute Kidney Injury Electronic Alerts in Primary Care Conor Patrick Moran.1 Ying C. Kuan,2 Patrick Lm Lynch,2 Francis Mccarroll.1 1Dept of Nephrology, Altnagelvin Hospital, Londonderry, United Kingdom; 2Dept of Clinical Chemistry, Altnagelvin Hospital, Londonderry, United Kingdom.

Background: Acute Kidney Injury, (AKI), is common with a variably reported mortality, (15-60%). A UK national audit reported that up to 30% of cases were avoidable and that as much as 43-61% of post-admission AKI experienced an unacceptable delay in recognition. AKI is regarded as the remit of Secondary Care and there have been few studies examining Community Acquired AKI, (CA-AKI). Guidelines have recommended the utilisation of electronic alerts (e-alerts) for AKI in both Primary and Secondary care. We examined the incidence and mortality of CA-AKI.

Methods: We introduced AKI e-alerts with accompanying e-guidance in late October 2014 and prospectively collected data on the patients identified with severe AKI in Primary, Community and Secondary Care. Data collection was carried out for 3 months. The demographics of both cohorts were compared.

Results: Median age, (74.5 years vs. 75 years), gender distribution, (M:F: 48% / 52% vs. 44.5% / 55.5%), and median time to death, (8 days vs. 11 days), were comparable. 44 Alerts were from Primary Care and 77 from Emergency Department. Of the Primary Care Alerts, 20 patients were subsequently admitted. Of those who were not, 3 died within 30 days, (1. Died at 5 days, 2. Died at 8 days, 3. Died at 21 days). Despite this, Community-acquired AKI was associated with a 30-day mortality of 10.7%. Hospital-acquired AKI, (HA-AKI), was associated with a 28.2% 30-day mortality, (p=<0.001). Sub-group analysis showed Primary care alert associated with 13.64% mortality and Primary Care alerts with 9.76%, (p=<0.001). Median Age at Death; CA-AKI 80 years. Median time to death; CA-AKI 5 days, HA-AKI 11 days.

Conclusions: AKI is common and associated with a significant morbidity and mortality. CA-AKI is common opportunities at diagnosis and intervention are often missed with grave
consequences. Appropriate management of CA-AKI could help reduce the economic and physical burden associated with AKI and reduce the long-term burden of CKD. Further work is required to expand the role of AKI e-Alerts in Primary Care.

SA-PO234

Acute Kidney Injury Causes and Outcome: A Single Center Experience from Sudan

Was 13%. AKI causes.

29 patients (42%) experienced recovery of normal renal function; the recorded mortality blood urea levels on admission were 14.7.

SOBA Univ Hospital, Khartoum, Sudan; 2Renal Research Inst, New York, NY; 3Fresenius Medical Care, Bad Homburg, Germany.

Background: Acute kidney injury (AKI) is a challenging problem in Africa—a diverse continent with regards to population and financial and medical resources. There are no reliable statistics about the incidence of AKI in Africa. Based on sporadic regional publications the incidence has been estimated at 150 per million population. In addition to infectious diseases; toxins play a major etiologic role in AKI.

Methods: In this study we analyzed data from Omer Belail Renal Center in Soba University Hospital, Sudan, a tertiary referral center with a catchment area of 3 million citizens. All hemodialysis (HD) patients treated for AKI in the period between 1/1/2013 and 12/31/2014 were included in the study.

Results: Out of 520 hemodialysis patients we identified 69 patients with AKI; 39 (56.5%) were males. The mean/SD age was 40.5±17.4 years. Serum creatinine and blood urea levels on admission were 14.7±6.7 and 245±125 mg/dL, respectively. Serum creatinine and blood urea levels at discharge were 2.5±2.1 and 53±32 mg/dL, respectively. 29 patients (42%) experienced recovery of normal renal function; the recorded mortality was 13%. AKI causes.

Acute tubular necrosis 15 (22.7%)
Obstructive urethropy 10 (14.5%)
Glomerulonephritis 7 (10.5%)
Acute interstitial nephritis 6 (8.7%)
Sepsis 6 (8.7%)
Snake bite 5 (7.2%)
Hair dye poisoning 4 (5.8%)
Hemolytic uremic nephritis 3 (4.3%)
Fluid depletion 1 (1.4%)
Others 12 (17.4%)

Conclusions: AKI has become increasingly prevalent in developing countries, and is associated with severe morbidity and mortality. Many causes of AKI can be prevented by interventions at the individual, community, and regional levels. Efforts should be directed to eradicate causes of AKI, expedite diagnosis, and aggressively manage pre-renal conditions and specific infections.

SA-PO235

Usefulness of Pressepil, Procalcitonin and IL6 as a Biomarkers of Adverse Renal Outcome and Mortality After Cardiac Surgery

Alessandra Brocca, Grazia Maria Virzi, Maria Jimena Mucino-Bermejo, Davide Giavarina, Massimo de Cal, Claudio Ronco. S Bortolo Hospital, Vicenza.

Background: Cardiac surgery (CS) is now possible in increasingly high-risk patients (pts): accurate evaluation of surgical risk is crucial. Mortality and negative impact on distant organs must be evaluated. In a large number of clinical scenarios, biomarkers have been proven to be reliable tools in clinical settings either for single a single biomarker or a biomarker panels. Presepsin has been reported to be useful for stratifying mortality as "add-value" rather than a "unique-predicting" data. Presepsin and IL6 by ELISA assay. A p-value of <0.05 was considered statistically significant.

Methods: Observational single center study includes 122 adult CS pts. Blood samples were collected at the second day after surgery. Pressepil was tested by the PATHFAST Immunanalyzer system, Procalcitonin by BRAHMS PCT sensitive KRYPTOR and IL6 by ELISA assay. A p-value of <0.05 was considered statistically significant.

Results: We observed that Pressepil and IL6 are better predictors of inhospital (AUC=0.831 and 0.819), 30day (AUC=0.723 and 0.785) and global mortality (AUC=0.759 and 0.793) than Procalcitonin (p=0.05). Pts with worse renal outcome (defined as AKI, change on CKD stage or need for CRRT) have significantly higher Presepsin and Procalcitonin levels (p=0.05). IL6 is not significantly different in pts with adverse renal outcome compare whith those without.

Conclusions: Presepsin and IL6 levels correlate with the risk of death better than Procalcitonin. Higher Presepsin and Procalcitonin levels are associated with adverse renal outcomes in this population. It is possible that a combination of these three biomarker in an inflammatory multi-biomarker panel as opposed to a single biomarker should betaken as "add-value" rather than a "unique-predicting" data.

Allopurinol Attenuates Rhabdomyolysis-Induced Acute Kidney Injury: Renal and Muscular Protection

Background: Myoglobinuric acute kidney injury(AKI) is the most severe complication of rhabdomyolysis. Aim: To evaluate the efficacy of allopurinol(Allo) on rhabdomyolysis-induced AKI.

Methods: Male Wistar rats were injected intramuscularly with 5ml/kg body weight(BW) of either 50% glyceral(Gly) or 0.9% saline(S). Five groups were studied: S(n=5), S+Allo(n=6), Gly(n=7), Gly+Allo(n=7), Gly+ivAllo(n=7). S and Gly+Allo rats received Allo(300mg/L) in drinking water 7 days prior to and for 24h after Gly injection.Gly+ivAllo: intravenous Allo(50mg/kg BW) 30’ after Gly injection and 300mg/L in drinking water thereafter.

Results: Gly rats showed markedly reduced glomerular filtration rate(GFR,umilin clearance) associated with renal vasoconstriction,renal tubular damage,increased oxidative stress,apoptosis and inflammation. Allo treatment ameliorated all these alterations. Allo reduced muscular oxidative stress and accelerated its recovery.

Funding: Government Support - Non-U.S.

Cell Cycle Progression in the Early Phase of Septic Kidney

Daisuke Nakano, Akira Nishiyama. Dept of Pharmacology, Kagawa Univ, Kagawa, Japan.

Background: The recovery of renal function after acute kidney injury (AKI) is likely controlled by proliferation of survived tubular cells in damaged nephrons containing cell death or sloughing. However, recent studies revealed that AKI concomitant with sepsis had significantly less tubular cell death than other forms of AKI, such as ischemic- and drug-induced AKI. It has not been examined whether septic AKI accelerates tubular cell proliferation in the condition with less cell death. In the present study, we examined the time-course changes in tubular cell proliferation after sepsis.

Methods: Lipopolysaccharide (LPS) and cecum ligation and puncture (CLP) model were used to induce sepsis in mice. Cell cycle progression was assessed by intravital imaging of Tg(FucciG1)#596Bsi (Fucci) mice, which express monomeric Kusabira-Orange2 in G1/0 phase. LPS or CLP was used to induce sepsis in mice. Cell cycle progression was assessed by intravital imaging of Tg(FucciG1)#596Bsi (Fucci) mice, which express monomeric Kusabira-Orange2 in G1/0 phase.

Results: Fucci mice (8 weeks of age) showed an increase in Ki67 and bromodeoxyuridine staining were increased only in young mice (Ki67 cell number: 1.5±0.1 fold in LPS mice and 1.0±0.1 fold in CLP mice compared to normal control), not in old mice (Ki67 cell number: 0.8±0.1 fold in LPS mice and 1.0±0.1 fold in CLP mice compared to normal control) at a similar time course observed in Fucci mice. Etoposide, an anti-cancer drug, abolished the cell proliferation after LPS injection in young mice. Importantly, old mice or etoposide-treated young mice showed much worse AKI as compared to young mice.

Conclusions: Prophylactic and therapeutic Allo attenuates Gly-induced AKI by reducing oxidative stress (systemic, muscular and renal),inflammation and apoptosis. It may represent a new therapeutic approach for rhabdomyolysis and myoglobinuric AKI.

Hepcidin Mitigates Endotoxin-Induced AKI
Yogesh M. Scindia, Paromita Dey, Sundararaman Swaminathan. Medicine, Univ of Virginia, Charlottesville, VA.

Background: Sepsis is a common cause of acute kidney injury (AKI). Sepsis-associated inflammation induces hypoferremia and thereby limits iron availability to pathogens. It has been shown that hepcidin-induced degradation of ferroporin and consequent iron restriction are key for this hypoferric state. Since, iron has been implicated in the pathogenesis of both sepsis and AKI, we hypothesized that hepcidin pretreatment would mitigate bacterial endotoxin-induced AKI.

Methods: C57BL/6 were treated with saline or 50 mg of hepcidin, 24 hours prior to LPS (Escherichia coli O111:B4) injection (6.5 mg/kg). Renal function, injury and inflammation markers were examined up to 24 hours post LPS injection. Mouse glomerular endothelial cells were cultured with 100 ng/mL of hepcidin for 6 hours after treating them with and without 1 mg/mL hepcidin for 12 hours.

Results: Kidney function (as measured by serum BUN) significantly declined 2 hours post LPS injection and progressively deteriorated for 24 hours. This was prevented by hepcidin treatment (BUN: 83.55 Vs Hepcidin = 32.33, p < 0.001). Renal injury markers expressed similarly in BUN (NGAL: LPS = 6.74 Vs Hepcidin + LPS = 0.78, p < 0.001). Hepcidin treatment also reduced early systemic TNF alpha production following LPS injection (TNF alpha: 2266 Vs Hepcidin + LPS = 1248, p < 0.01). The ultra-structural morphology of the glomeruli revealed extensive loss of endothelial fenestrae and epithelial mitochondria in LPS treated mice, which was prevented by hepcidin treatment. However, MGEc cultures treated with or without hepcidin up-regulated endothelin gene to similar levels after stimulation with LPS.

Conclusions: Our results demonstrate a novel protective role of hepcidin in endotoxin-mediated AKI, which is largely exerted through down regulation of systemic cytokine production.

SA-PO239
ELK-B Peptide Prevents Renal Histological Damage and Mortality in Septic Mice
Aria C. Souza, 1,2 Irina Baranova, 1 Jonathan Street, 1 Xuzhen Hu, 3 Peter S.T. Yuting 1, Robert A. Star. 1,2 ‘Kidney Disease Branch, NIDDK, NIH, Bethesda, MD, 3, Clinical Center, NIH, Bethesda, MD.

Background: Targeting SR-BI/II and CD36 receptors with L-37pA, an antagonist peptide, reduced multi-organ failure, peritoneal bacterial counts, and increased survival from 6 to 27% in antibiotic-treated mice subjected to cecal ligation and puncture (CLP)-induced sepsis (J Immunol. 2012). We tested ELK-B, a peptide more specific to the CD36 receptor.

Methods: Because the free peptide was toxic, ELK-B was formulated with micellar 1-conjugated oligo-glycrrhop-3-phospholipid. For survival study, animals were randomized into two groups: CLP (N=16) and CLP+ELK-B (15 mg/kg, N=15). A blinded observer administered treatments every 12h until death or until euthanized per protocol. For acute studies, 10 mice/group were subjected to CLP+saline (CLP) or CLP+ELK-B; saline or ELK-B was administered IV 0 and 6h after CLP. 18h post-CLP mice were euthanized for peritoneal lavage, and blood/organs collection. Serum creatinine (Cr) was measured by HPLC, BUN by colorimetry, and AST, ALT by an autoanalyzer. PAS-stained kidney sections were scored for renal tubular damage. Peritoneal bacterial cell counts were expressed per mouse. Caspase-3 IHC was performed on spleens. Data were analyzed by ANOVA and log-rank test.

Results: ELK-B significantly increased survival: all CLP+vehicle mice died by 78h, whereas 31% of ELK-B treated mice were still alive at 7 days. The survival curves did not diverge until 36h. At 18h (before survival curves diverged), ELK-B did not alter Cr (sham, CLP, CLP+ELK-B = 0.017, 0.30, 0.06, and 0.21±0.06 mg/dl; BUN, ALT, AST, ALT by an autoanalyzer. PAS-stained kidney sections were scored for renal tubular damage. Peritoneal bacterial cell counts were expressed per mouse. Caspase-3 IHC was performed on spleens. Data were analyzed by ANOVA and log-rank test.

Conclusions: ELK-B reduced 7 day mortality and 18h renal histological damage after sepsis. However, it did not alter other biochemical outcomes at 18h. This suggests that it may act late in sepsis, perhaps by increasing bacterial killing.

Renal Ischemic Preconditioning Protects against Septic Acute Kidney Injury via miR-21
Ping Jia,1 Yi Fang,1 Mingyu Liang,1 Xiaoqiang Ding,1 Department of Nephrology, Zhongyou Hospital, Fudan University, Shanghai, China; 1, 2 Department of Physiology, Medical College of Wisconsin, Milwaukee, WI.

Background: Septic acute kidney injury(AKI) is one of the most common and life-threatening complications in critically ill patients, and there is approved effective treatment. We have shown ischemic preconditioning upregulates miR-21, provides renoprotection against subsequent ischemia reperfusion injury. Here we studied the effects of renal ischemic preconditioning on septic AKI and its mechanisms.

Methods: Bilateral renal pedicles were clamped for 15 min in mice before the induction of septic AKI, and septic AKI was induced by intraperitoneal injection of lipopolysaccharide. The effects of renal ischemic preconditioning on LPS-induced AKI were investigated, including changes of renal function, histology, inflammation and apoptosis in kidneys. The role of miR-21, in renal protection conferred by the ischemic preconditioning was examined using in vivo knockdown of miR-21 and miR-21 signaling pathways were analyzed.

Results: We observed that renal ischemic preconditioning provided morphological and functional renoprotection, characterized by attenuation of renal tubular damage, cell apoptosis, and a reduction in inflammation in circulation. Furthermore, we found that renal ischemic preconditioning significantly upregulated the expression of miR-21 in kidneys, suppressed proinflammatory factor PDD4D expression and NFκB activity, improved renal tubular production. Meanwhile, renal ischemic preconditioning also suppressed the expression of PTEN which is a proapoptotic protein, activating Akt signaling pathway, subsequently increasing the expression of Bcl-2 and inhibiting Caspase-3. A locked nucleic acid-modified anti-miR-21, given before renal ischemic preconditioning, knocked down miR-21 effectively, and upregulated its target effector PTEN expression, resulting in increase of apoptosis, exacerbated LPS-induced AKI.

Conclusions: Our findings demonstrate that renal ischemic preconditioning protects against LPS-induced AKI, and miR-21 coordinates its downstream signaling to reducing cell apoptosis and circulatory inflammation, contributing torenal protection.

SA-PO241
Remote Ischemic Preconditioning Protects against Contrast-Induced Nephropathy via Renalase Induced by TNFα/FnbB Pathway
Feng Wang, Zeyuan Lu, Jiangyong Yin, Guangyuan Zhang, Niansong Wang. Nephrology, Shanghai Jiao Tong Univ Affiliated Sixth People’s Hospital, Shanghai, China.

Background: Renalase is a flavin adenine dinucleotide-dependent amine oxidase which has recently been suggested to be a renoprotective molecule. Herein we suggested that renalase expression induced by circulatory TNF-α which was evoked by remote ischemic preconditioning (rIPC) play a key role in contrast-induced nephropathy(CIN) protection.

Methods: CIN model was setup by ioversol intravenous injection to SD rats. Limbs ischemic preconditioning was carried out 24 hours before CIN induction. TNF-α blocking, NF-Kβ blocking, HIF blocking and renalase blocking were performed respectively. TNF-α administration was also performed as rIPC mimic. Renal injury, kidney oxidative stress, renal function, renal expression, and circulating TNF-α after IPC were assessed. HK2 exposure to TNF-α and its blocker were studied and renalase expression was assessed.

Results: Reduced tubular injury, decreased oxidative stress and improved renal function were observed in CIN rats following rIPC. The therapeutic effects could be neutralized by renalase blocking. Renalase expression was significantly up-regulated after rIPC. rIPC induced renalase expression could be abolished by TNF-α blocking or NF-Kβ blocking but not HIF blocking. Up-regulated renalase triggered by TNF-α could also be blocked by NF-Kβ both in vivo and in vitro.

Conclusions: Renalase expression which mediated by TNFα/FnbB pathway played an essential role in renoprotection of rIPC for CIN.

DNA Methylation in Cisplatin-Induced Acute Kidney Injury
Chunyan Gao,1 Xiao Xiao,2 Qingqing Wei,1,2 Zheng Dong.1,2 Cellular Biology and Anatomy, Georgia Regents Univ, Augusta, GA; 1,2-Charlie Norwood VA Medical Center, Augusta, GA.

Background: DNA methylation is a major epigenetic modification, which plays an important role in regulating gene transcription without changing primary nucleotide sequence. DNA methylation has been implicated in major diseases, such as cancer. However, the changes of DNA methylation in kidney diseases, such as cisplatin-induced nephrotoxicity, remain unclear.

Methods: We determined the global DNA methylation changes in cisplatin-induced AKI by reduced representation bisulfitie sequencing (RRBS) using kidney cortex from mice treated with cisplatin. We also established proximal tubule-specific Dnm1t1 (PT-DNMT1) knockout mice to determine the role of DNA methylation in cisplatin-induced AKI. Results: Totally 1.5 and 1.9 millions of CpG sites were analyzed in the control and cisplatin treated kidney samples, respectively. Compared with control, cisplatin-treated samples showed aberrant DNA methylation changes, resulting in the identification of 236 differentially methylated regions (DMRs). Further analysis identified 15 genes that contained DMRs at 5‘ end regulatory promoter region or 5‘ UTR. To determine the pathological role of DNA methylation, we established the PT-DNMT1 model, in which the DNA methyltransferase 1 gene was specifically deleted from kidney proximal tubules. Compared with wide type mice, PT-DNMT1 knockout mice showed higher necritic tubular damage at 4 day after cisplatin injection. However, mice did not show the difference between wide type and knockout mice, serum creatinine was increased in knockout mice treated with cisplatin.

Conclusions: Cisplatin induced significant changes in DNA methylation in kidney tissues, which may contribute to gene regulation and related kidney injury.

Blockade of KCa3.1 Potassium Channels Protects against Cisplatin-Induced Acute Kidney Injury

Cheng-Lung Chen, Li-Heng Pao, 1,2,3,4 Graduate Inst of Life Sciences; 5School of Pharmacy, National Defense Medical Center, Taipei, Taiwan; 6Graduate Inst of Health-Industry Technology; 7Research Center for Industry of Human Ecology, Chang Gung Univ of Science and Technology, Taoyuan, Taiwan.

Background: Anti-tumor efficacy of cisplatin chemotherapy is mainly limited by its toxicity to normal tissues, particularly the kidney toxicity. Tubular apoptotic cell death significantly contributes to the pathogenesis of cisplatin-induced acute kidney injury (AKI). KCa3.1, a calcium-activated potassium channel, has been reported to participate in cell apoptosis. However, the involvement of KCa3.1 in cisplatin-induced AKI is unknown.

Methods: We examined KCa3.1 mediates cisplatin-induced tubular apoptotic cell death in vitro, as well as the development of cisplatin-induced AKI in KCa3.1- and pharmacological blockade mouse models in vivo.

Results: Cisplatin treatment triggered an early induction in KCa3.1 expression, which is associated with apoptotic cell death in HK-2 cells, as well as with the development of renal tubular damage and cell apoptosis in mice. By treating with highly selective blocker TRAM-34, we found KCa3.1 inhibition suppressed cisplatin-induced apoptotic cell death in HK-2 cells. In the in vivo study, KCa3.1 deficiency reduced renal function loss, renal tubular damage and apoptotic marker caspase-3 induction in kidneys after cisplatin administration in KCa3.1-/- mice. Pharmacological blockade of KCa3.1 by TRAM-34 similarly attenuated cisplatin-induced AKI in mice. Furthermore, we dissected the underlying mechanisms in which KCa3.1 blocking reduces cisplatin-induced apoptosis. We found KCa3.1 inhibition attenuated the cytochrome c release and the increase of intrinsic apoptotic mediator Bax. Bax mimotope exposure was delayed for 4 or more hours after cisplatin treatment. We also found KCa3.1 blocking inhibited cisplatin-induced the increase of ER stress mediator caspase-12, which is independent of calcium-dependent protease m-calpain activation.

Conclusions: Blockade of KCa3.1 protects against cisplatin-induced AKI through the attenuation of tubular apoptosis by interfering with intrinsic apoptotic and ER stress-related mediators, and that provides a potential target for the prevention of cisplatin-induced AKI.

Bax Mimotope Therapy: Effective Treatment for Ischemic Acute Kidney Injury (AKI)

Zhiyong Wang, Ryan M. Mulhern, Andrea Havasi, Ramon G. Bonegio, Steven C. Borkan. Renal Section, Boston Univ Medical Center; Boston, MA.

Background: Ischemic AKI causes renal cell death partly by Bax-mediated apoptosis. Recent studies show that Bax requires the chaperone nucleosomophilin (NPM) for mitochondrial targeting and apoptosis. We propose that a mimotope that interferes with Bax-NPM interaction is an effective treatment for ischemic AKI.

Methods: To assess mimotope efficacy, 2 mg control or therapeutic Bax mimotope was administered by a single tail vein injection in 6-week old B6 mice either before or after renal ischemia caused by 2 min of bilateral renal pedicle clamping, an insult that produces severe AKI. BUN/Cr, histologic injury score, caspase 3 activity, Bax activation and Bax-NPM interaction were compared in each experimental group at the above time points (n = 8 each group).

Results: Compared to control, Bax mimotope administration 15 min before or 15 min, 1.2 or 3 hr after ischemia significantly improved renal function. No protection was observed if Bax mimotope exposure was delayed for 4 or more hours after ischemia. Although 12% of controls died of AKI, only 2% of animals died in the Bax mimotope groups. Despite equivalent Bax activation in both groups, the Bax mimotope improved histologic injury score, reduced caspase 3 activation and decreased Bax-NPM interaction as assessed by co-immunoprecipitation.

Conclusions: Selective interference of Bax-NPM interaction with a Bax mimotope within several hours of acute ischemia improves survival, significantly reduces the severity of AKI (lower BUN and Cr), decreases histologic injury score and inhibits Bax-mediated apoptosis downstream of Bax activation.

Role of AMPK in Aristolochic Acid-Induced Acute Kidney Injury

Anne-Emilie Deleveles, 1 Inês Jadot, 2 Vanessa Colombaro, 3 Eric De prez, 1 Isabelle Habsc, 1 Kumar Sharma, 1 Nathalie Caron, 2 Joelle L. Nortier. 3 Free Univ of Brussels; 4 Univ of Namarit; 5 Univ of California, San Diego.

Background: Experimental aristolochic acid nephropathy (AAN) is a pertinent model of tubulo-interstitial nephritis characterized by an early phase of acute kidney injury (AKI) followed by chronic inflammation and fibrosis (CKD). AMPK has been previously reported to be involved in the regulation of renal fibrosis. This study was conducted to determine the role of AMPK in renal outcomes and its involvement in the AKI-to-CKD transition.

Methods: C57BL/6J male mice were randomly subjected to i.p. injection of either sterile saline solution, AA, AA+AICAR (the specific AMPK activator) for 4 days. Mice were then euthanized either at day 5 or day 20.

Results: AA-treated mice displayed loss of renal function, as reflected by significant increases in plasma creatinine level and proteinuria at days 5 and 20. In addition, impairment of tubular function was associated by the expression of markers of renal oxidative stress, inflammation and fibrosis.

Conclusion: Mixed results were obtained in terms of AMPK activation in AA-induced AKI.

Funding: Government Support - Non-U.S.

Nrf2 Activation in Tubular Cells Prevents Progression of AKI to CKD

Masahiro Nitsu, 1,2,3,4 Tomokazu Souma, 1,2,3 Sadayoshi Ito, 2 Norio Suzuki, 2 Masayuki Yamamoto, 1 Dept of Medical Biochemistry, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan; 2Div of Nephrology, Endocrinology, and Vascular Medicine, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan; 3Div of Interdisciplinary Medical Science, Tohoku Univ Graduate School of Medicine, Sendai, Miyagi, Japan.

Background: Acute kidney injury (AKI) is one of the major risk factors for chronic kidney disease (CKD). Reactive oxygen species are generated by ischemia-reperfusion injury (IRI) during transition of AKI to CKD, and oxidative stress contributes to defects of renal tubular cells. Nrf2 is a master transcription factor for cellular defense against oxidative stress. In an E3 ubiquitin ligase Keap1 knockdown mutant (KD) and tubular-specific Keap1-null mutant (TKO) mice were used for genetic activation of Nrf2. A Keap1 inhibitor CDDO-Im was used for pharmacological activation of Nrf2.

Results: Remaining tubular areas at 14 days after IRI were 64%, 51% and 34% in KD, TKO and wild-type mice, respectively compared with their contralateral kidneys. Genetic Nrf2 activation treatment after IRI to wild type mice also protected against tubular defects (CDDO-Im, 63%). Nrf2-irrelevant antioxidant defenses (Nqo1, Hmox1, Gclc, Gclm, and Srxn1) were transiently up-regulated in 3-6 hours after IRI in wild-type mice, while both genetic and pharmacological activation of Nrf2 maintained expression of these genes at high levels throughout the observation period.

Conclusions: Activation of Nrf2 alleviates IRI-induced tubular loss through enhancing the antioxidant response system. Nrf2 inducers are one of prospective therapeutic candidates for preventing AKI-to-CKD transition.

Acute Kidney Injury in the Rat Is Prevented by Pirfenidone

Izabel Quezalzilli Lima Posada, 1,2,3,4 Francisco Fontana, 1,2,3,4 Nathan Berman, 1,3,4 Giorgio Coppelli, 1,3,4 Norma Marques, 1,2,3,4 Francesca Pompei, 1,3,4 Maxime Veysseyre, 1,2,3,4 Franck Ricard, 1,2,3,4 Laboratorios Posada (1) and Universidad Nacional de los Andes LC-1, Bogota, Colombia; (2) Laboratorios Posada (1) and Universidad Nacional de los Andes LC-1, Bogota, Colombia; (3) Laboratorios Posada (1) and Universidad Nacional de los Andes LC-1, Bogota, Colombia.

Background: Pirfenidone (PFN) is an orally active small molecule which acts mainly through an anti-fibrotic effect, but also possesses antioxidant and anti-inflammatory properties.

This study was designed to evaluate the effect of the prophylactic treatment with PFN on acute kidney injury (AKI) due to bilateral renal ischemia (IR) in the rat. We studied this group of rats: 1) sham operated, (S) 21 rats undergone 20 min of ischemia and 24-h of reperfusion and, 3) rats treated with PFN (700 mg/kg), 24-h before ischemia (IR/PFN). Serum creatinine, creatinine clearance (CrCl) protein excretion, urinary levels of Hsp72 (UHsp72V) and nitrates and nitrites (UNO2/NO3V) were assessed. Mean arterial pressure (MAP) and renal blood flow (RBF) were recorded 24-h after surgery. Tubular injury (TI) was evaluated in fixed kidneys by counting the cast number and the number of injured tubules per field.

Results: As expected, the IR group showed a reduction in CrCl (IR 0.2 ± 0.4 vs. S 0.7 ± 0.6, p<0.05), urinary output (IR 20.9 ± 5 vs. S 32.7 ±19.3 ml/day; p<0.05), RBF (IR 1.08 ± 0.37 vs. S 1.53±0.17 ml/min/100 g BW; p<0.05), and a significant increase in UHsp72V assessed by Western blot. Extensive TI was evidenced by histological analysis. These alterations were associated with a decrease in UNO2/NO3V (IR 3.1±1.3 vs. S 5.4±2.5 mmol/24h; p<0.05). In contrast, IR+PFN group showed restoration of CrCl (1.33±0.4 mmol/100g BW; p<0.05), urinary output (47.5 ± 5.7 ml/day; p<0.05), RBF (1.51±0.15 ml/min/100g weight; p<0.05). The levels of urinary Hsp72 were undetectable or very low and the histological signs of TI were significantly reduced. Interestingly, UNO2/NO3V was completely recovered (7.05±0.78 mmol/24h; p<0.05).

Conclusions: Our results revealed that pre-treatment with PFN prevents AKI in the rat.

Part of its renoprotective effects seems to be related with the restoration of NO production. These findings suggest that PFN could be a promising tool in the prevention of AKI.

HDAC8 Plays a Critical Role in the Epigenetic Activation of Fibroblasts and the Pathogenesis of Renal Fibrosis

Scott R. Manoson, Qiusha Guo, Katelynn H. Moore, Paul F. Austin.

Dept of Surgery, Div of Urology, Washington Univ, St. Louis, MO.

Background: The development of renal fibrosis is associated with changes in the expression of approximately 10% of the genome, suggesting widespread transcriptional dysregulation. Nonetheless, the roles of critical epigenetic pathways in disease progression remain poorly understood. Here, we examine the biological and therapeutic importance of histone deacetylases (HDACs) in the function of fibroblasts and the pathogenesis of renal fibrosis.

Methods: Renal fibrosis was modeled in vitro by treatment of NRK-49F fibroblasts with the pro-fibrotic cytokine TGF-β and in vivo in mice by unilateral ureteral obstruction (UUO). The role of HDAC proteins was assessed by treatment with the broad spectrum HDAC inhibitor Trichostatin A (TSA) and the HDAC-specific inhibitor PCI-34051. The translational relevance of these findings was assessed in patients who underwent a nephrectomy following UPJ obstruction.

Results: UUO leads to a 6.1-fold increase in HDAC8 expression that localizes specifically to myofibroblasts. In NRK-49F cells, treatment with PCI-34051 promotes myofibroblast differentiation and apoptosis, but suppresses proliferation and matrix synthesis. These findings extend to the injured kidney in vivo, where HDAC inhibition results in a 41.6% decrease in COL1A1 and a 61.6% decrease in α-SMA. Furthermore, there is a 77.9% decrease in the interstitial proliferative response, a 43.0% decrease in myofibroblast number, and a 31.1% decrease in renal fibrosis. Finally, the development of renal fibrosis in patient with obstructive urologic disease is associated with a 32.1% increase in the number of HDAC8-positive cells.

Conclusions: Together, these findings demonstrate that HDAC8 plays a critical role in regulating fibroblast activation. Treatment with HDAC inhibitors is also an effective therapeutic approach to reverse the epigenetic changes associated with the pathogenesis of renal fibrosis. Finally, since an increase in HDAC8 expression occurs in patients during disease progression, HDAC8-targeted therapies have therapeutic potential for the treatment of chronic kidney disease.

Reciprocal Effects of HDAC1 and HDAC2 Deletion on Renal Ischemia-Reperfusion Injury

David Dean Authahuser,1 Zhonglin Wang,1 Guanghui Ge,1 Tricia Bhatti,1 Wayne W. Hancock,1 Matthew H. Levine,1 Surgery, Hospital of the Univ of Pennsylvania and the Children’s Hospital of Philadelphia, Philadelphia, PA; 1Pathology and Laboratory Medicine, The Children’s Hospital of Philadelphia, Philadelphia, PA; 1Pathology and Laboratory Medicine, Hosp of the Univ of Pennsylvania, Philadelphia, PA.

Background: Histone/protein deacetylase proteins (HDACs) have been implicated in renal ischemia-reperfusion injury (IRI). HDACs 1 and 2 are highly homologous Class I HDACs thought to have similar function.

Methods: This study included wild type C57BL/6 (B6) and inducible HDAC1- or HDAC2 gene deleted mice (HDAC1KO and HDAC2KO). Renal-specific or extra-renal gene deletion of the HDACs thought to have similar function.

Results: HDAC1KO mice had impaired renal IRI tolerance compared to controls with higher BUN levels (p<0.01; Figure 1A) and increased fibrosis post-injury. HDAC2KO mice had improved early renal function (p=0.01; Figure 1B) and decreased fibrosis (p<0.01) compared to controls and tolerated extended periods of ischemia. In transplant models, renal-specific HDAC2KO mice had superior IRI tolerance with less renal impairment (p<0.01) and decreased fibrosis (p=0.01) compared to extra-renal HDAC2KO and controls. After transplantation with 18 hours of cold ischemia, HDAC2KO donor kidneys had improved BUN (p=0.02) and survival compared to controls.

Conclusions: HDAC1 and 2 have reciprocal effects on murine renal IRI tolerance, with HDAC1 deletion increasing vulnerability and HDAC2 deletion providing protection. The effect of HDAC2 deletion is profound, is intrinsic to the kidney, and extends to cold ischemia and renal transplantation.

Renoprotective Effect of Long Acting Thiorodoxin by Modulating Oxidative Stress and Macrophage Migration Inhibitory Factor against Rhabdomyolysis-Associated Acute Kidney Injury

Hiroshi Watanabe,1 Kento Nishida,1 Masafumi Fukagawa,2 Toru Maruyama.1 1Dept of Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kamamoto Univ, Kamamoto, Japan; 1Dept of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Kanagawa, Japan.

Background: Rhabdomyolysis-associated acute kidney injury (AKI) is a serious life-threatening condition. As such, more effective strategies are needed for its prevention and treatment. Although thiorodoxin-1 (Trx) possesses superior biological activities, such as anti-oxidative and anti-inflammatory effect via the modulating macrophage migration inhibitory factor (MIF), its short blood retention limits the therapeutic application. To overcome this, we engineered a long acting Trx by genetically fused with human serum albumin (HSA-Trx), and examined its renoprotective effect against glycerol-induced AKI.

Methods: HSA-Trx was prepared by using Pichia expression system. The mouse model of rhabdomyolysis-associated AKI was induced by the administration of a 50% glycerol solution.

Results: An intravenous HSA-Trx pre-treatment attenuated the glycerol-induced decline in renal function, compared to a PBS, HSA or Trx alone. HSA-Trx caused a reduction in the tubular injuries and in the number of apoptosis-positive tubular cells. Renal superoxide, 8-hydroxy deoxyguanosine, nitrotyrosine and the plasma Cys34-cysteinylated albumin were clearly suppressed by the HSA-Trx treatment. Prior to decreasing TNF-α and IL-6, HSA-Trx suppressed an increase of plasma MIF level. In LLC-PK1 cells, HSA-Trx decreased the level of reactive oxygen species and lactate dehydrogenase release induced by myoglobin. HSA-Trx treatment resulted in a threefold increase in the survival of lethal glycerol-treated mice. The post-administration of HSA-Trx at 1 and 3 hr after glycerol injection exerted a significant renoprotective effect.

Conclusions: HSA-Trx, a long acting Trx, has potential for use in the prevention and treatment of rhabdomyolysis-associated AKI via its extended effects of modulating oxidative stress and MIF.

Selective Endothelin-A Receptor Antagonism Prevents the Progression of Acute Kidney Injury to Chronic Kidney Disease

Neera Dhuam, Queen’s Medical Research Inst, Univ of Edinburgh, Edinburgh, United Kingdom.

Background: AKI is common and associated with significant morbidity and mortality. AKI often progresses to CKD and endothelin-1 (ET-1) contributes to this. We hypothesized that therapeutic administration of selective ET-A receptor antagonist would protect from the transition of AKI to CKD.

Methods: 28 FVB mice underwent prolonged (50min) unilateral ischemia-reperfusion injury (IRI) with 28d recovery. 14 mice received daily selective ET-A receptor antagonism (fractional excretion of ET-1: IRI vs. control and for IRI 28d). We assessed blood pressure (BP) via telemetry, vascular function, renal injury and measures of the ET system.

Results: Systolic BP increased by ~5mmHg after IRI and was associated with vascular dysfunction in both resistance and conduit vessels. Sitaarten partially prevented both of these. At 28d after IRI kidney weight was reduced (~55%) and associated with significant macrophage infiltration and fibrosis compared to the contralateral control kidney. Mice treated with sitaxentan had normal kidney weight, reduced macrophage infiltration and less renal injury. IRI vs. IRI kidney vs. IRI kidney with sitaxentan: F30/stain/high power field: 2.5±0.2 vs.0.8±0.0%; picrosirius red stain/high power field: 8.6±0.48 vs.3.1%. For both macrophage infiltration and fibrosis, p<0.05 for IRI vs. control and for IRI vs. IRI with sitaxentan, p=3.0; control vs. IRI with sitaxentan. Furthermore, an up-regulation of both the ET-A (28-fold) and ET-B (2-fold) receptors as well as pre-pro-ET-1 (10-fold) mRNA was seen in both the cortex and medulla of the IRI kidney relative to control. With sitaxentan treatment ET-A receptor and pre-pro-ET-1 mRNA remained similar to baseline levels. Finally, renal ET-1 production increased following IRI and this was prevented by ET-A receptor antagonism (fractional excretion of ET-1: IRI vs. IRI with sitaxentan: 47%±16%, p<0.05).

Conclusions: In an in vivo model of AKI progressing to CKD, ET-A receptor antagonism reduced BP and vascular dysfunction and prevented progression of renal injury and ET system activation after AKI. Therefore, selective ET-A receptor antagonism offers a potentially novel therapy for AKI. Translational studies are now warranted.

Inhibition of Vascular Adhesion Protein-1 Suppresses Neutrophil Infiltration and Preserves Renal Function in the Rat Model of Renal Ischemia–Reperfusion Injury

Shinji Toru Maruyama,1 Tetsuhito Tanaka, Reiko Inagi, Masaomi Nangaku. Div of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan.

Background: Vascular adhesion protein-1 (VAP-1) is an adhesion expressed in endothelial cells. With its unique properties as an ectoenzyme which catalyzes oxidative deamination of primary amines, VAP-1 plays a critical role in leukocyte trafficking. In light of a growing body of evidence that VAP-1 controls inflammation in various organs, such as the liver and the lung, we examined the effect of VAP-1 inhibition in the rat model of renal ischemia–reperfusion injury.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

**Methods:** Rats were subjected to left renal ischemia for 45 min after right nephrectomy, followed by 24 h of reperfusion. A specific VAP-1 inhibitor, RTU-1096 (R-Tech Ueno, Tokyo, Japan), or vehicle was administered to rats since 7 days before the surgery (mixed with feed, 40 mg/kg/day).

**Results:** Immunofluorescence studies suggested that VAP-1 is expressed not only in endothelial cells of capillaries but also in interstitial cells of non-endothelial lineage. In vitro, higher mRNA expression of VAP-1 was confirmed in cultured pericytes. In vivo, VAP-1 enzyme activity in the whole kidney was unaffected by the surgery, but following VAP-1 inhibition by RTU-1096 (0.9:0.1 vs. 7.0:1.3 pmol/mg protein/min), renal function was significantly improved as compared to the vehicle group (0.5±0.1 vs. 69.1±13.95 mg/dl, Cr: 1.4±0.1 vs. 2.5±0.02 mg/dl; P<0.01), which was accompanied by amelioration in histological tubular injury and decreased KIM-1 mRNA levels. Immunohistochemical analysis revealed a significantly decreased number of neutrophils in the cortical interstitium in IRI mice (3.1±1.3 vs. 9.2±2.2 mmHg) than in Sham operated mice (7.5 mmHg) when compared to Sham operated mice (9.5±4.2 mmHg).

**Conclusions:** We found that mean Pf was higher in PU mice (48.9±1.2 mmHg) than in Sham group mice (220 pg/ml in RP and 734 ± 16 pg/ml in RA group, respectively). Histology by PAS staining showed that all AKI mice had a significant increase in renal tubular necrosis (2.3± ± 0.1%, 2.2± ± 0.1% and 8.9± ± 1.3% for normal, Sham-operated and PU mice, respectively). Thus, IL233 cytokine attenuates kidney inflammation to protect from IRI.

**Vagus Nerve Stimulation (VNS) Protects Kidneys from Ischemia-Reperfusion Injury Through Alpha 7 Nicotinic Acetylcholine Receptor (α7nAChR) Expressing Splenocytes**

**Background:** The nervous and immune systems interact in complex ways to maintain homeostasis and respond to stress or injury. The inflammatory reflex referred to as the cholinergic anti-inflammatory pathway (CAP) modulates innate and adaptive immunity, and modulation of the reflex by VNS is effective in inflammatory disease models. The effect of VNS on AKI has never been examined. Experimental activation of vagal efferent fibers suppresses inflammation in a manner that depends on α7nAChR in the CAP. However, the site of the essential α7nAChR was not established.

**Methods:** We applied electrical VNS (5 Hz, 50μA for 10 min) 24 hr prior to kidney IRI and assessed kidney injury by evaluating plasma creatinine (PCr, mg/dl), kidney-1 mRNA expression and histology (H&E). The effect of VNS on IRI was assessed by: a) prior splenectomy and b) adoptive transfer of splenocytes from VNS-stimulated mice to recipient mice subjected to IRI.

**Results:** VNS applied 24 hr prior to IRI markedly attenuated IRI. VNS reduced the IRI-induced increase in PCR by 65% (P<0.01) and Kim-1 mRNA expression in whole kidney by >70% (P<0.01). H&E- and stained sections confirmed the functional data. When splenectomy was performed 7 d before VNS and IRI, the protection by VNS was abolished. Adoptive transfer of splenocytes from VNS-treated mice to recipient mice subjected to IRI provided greater protection than splenocytes from mice who received sham VNS stimulation (PCr: 0.41 and 1.54 (P<0.001) for VNS- and sham-VNS-treated splenocytes, respectively). To evaluate the role of α7nAChR, VNS was initiated 24 hr prior to IRI in α7nAChR knock out (α7KO) and WT mice. Compared to the protective effect of VNS on IRI in WT mice, no protection was observed in α7KO mice. In addition, recipient mice were protected (PCR) if IRI if they received splenocytes from VNS-treated WT mice (0.41) but not from VNS-treated α7KO mice (1.57; P<0.01).

**Conclusions:** VNS-induced protection from IRI is consistent with activation of the CAP.

**Elevations of Intraglomerular Pressure Exacerbate Ischemia Reperfusion Injury-Induced Acute Kidney Injury**

**Background:** The physiological and pathophysiological mechanisms of renal ischemia reperfusion (IR)-induced acute renal injury (AKI) are complex and have not been elucidated. We sought to determine whether intraglomerular hydrostatic pressure (Pg) during the ischemic phase plays a critical role in IR-induced AKI.

**Methods:** We created two transgenic zebrafish models of Kim-1 overexpression in nephrons employing the cd17 promoter. One model utilized a constitutive active promoter while the other utilized a tamoxifen-induced Cre-ERT2 recombinase to express Kim-1 in nephrons in a temporally-controlled manner. The role of mTOR signaling was evaluated using a specific mTOR inhibitor, Rapamycin. Zebrafish GFP was determined using the elimination rate of fluorescein-labeled dextran.

**Results:** Kim-1 was markedly upregulated after gentamicin-induced kidney injury and had conserved phagocytic activity in zebrafish. Both constitutive and tamoxifen-induced expression of Kim-1 in zebrafish kidney tubules resulted in shedding of the tubule brush border, reduced GFR, pericardial edema and increased mortality rate. Kim-1-induced kidney injury was associated with inhibition of growth of adult fish. Kim-1 expression led to mTOR pathway activation, and inhibition of this pathway with rapamycin increased survival. mTOR pathway inhibition in Kim-1 overexpressing transgenic mice also significantly reduced serum creatinine, proteinuria, tubular injury and kidney inflammation.

**Conclusions:** Persistent Kim-1 expression resulted in chronic kidney damage and growth impairment in zebrafish. Kim-1-mediated kidneys tubular injury was mediated by mTOR pathway activation. This observation in zebrafish prediction the role of the mTOR pathway and therapeutic efficacy of rapamycin to protect the mouse kidneys against Kim-1-mediated kidney injury and fibrosis.

**Treg and ILC2 Contribute to IL233 (a Novel Fusion Cytokine)-Mediated Protection in AKI**

**Background:** Inflammation is an early event in AKI and studies have shown regulatory T cell (Treg)-mediated protection in inflammation driven injuries. Since we found that intraglomerular pressure (Pg) may be a novel therapeutic target for AKI, we explored the zebrafish model for investigating the role of Pg. Pg was measured with servo-nulling method during ischemia. Pf was used as an index of Pg. Elevations of Pg in ischemia and 24 hours of reperfusion (IRI)-induced acute renal injury (AKI) are complex and have not been elucidated.

**Methods:** A specific VAP-1 inhibitor, RTU-1096 (R-Tech Ueno, Tokyo, Japan), or vehicle was administered to rats since 7 days before the surgery (mixed with feed, 40 mg/kg/day).

**Results:** Immunofluorescence studies suggested that VAP-1 is expressed not only in endothelial capillaries but also in interstitial cells of non-endothelial lineage. In vitro, higher mRNA expression of VAP-1 was confirmed in cultured pericytes. In vivo, VAP-1 enzyme activity in the whole kidney was unaffected by the surgery, but following VAP-1 inhibition by RTU-1096 (0.9:0.1 vs. 7.0:1.3 pmol/mg protein/min), renal function was significantly improved as compared to the vehicle group (0.5±0.1 vs. 69.1±13.95 mg/dl, Cr: 1.4±0.1 vs. 2.5±0.02 mg/dl; P<0.01), which was accompanied by amelioration in histological tubular injury and decreased KIM-1 mRNA levels. Immunohistochemical analysis revealed a significantly decreased number of neutrophils in the cortical interstitium in IRI mice (3.1±1.3 vs. 9.2±2.2 mmHg) than in Sham operated mice (7.5 mmHg) when compared to Sham operated mice (9.5±4.2 mmHg).

**Conclusions:** We found that mean Pf was higher in PU mice (48.9±1.2 mmHg) than in Sham group mice (220 pg/ml in RP and 734 ± 16 pg/ml in RA group, respectively). Histology by PAS staining showed that all AKI mice had a significant increase in renal tubular necrosis (2.3± ± 0.1%, 2.2± ± 0.1% and 8.9± ± 1.3% for normal, Sham-operated and PU mice, respectively). Thus, IL233 cytokine attenuates kidney inflammation to protect from IRI.

GFR in Conscious Mice After Sepsis: Role of Tubuloglomerular Feedback

Jonathan Street, Yuning George Huang, Peter S.T. Yuen, Robert A. Star. NIDDK, Bethesda, MD.

Background: Reabsorption of glomerular filtrate by the tubules is an energy-intensive process. During sepsis the ability of the tubules to meet this energy demand may be impaired. To prevent renal salt wasting during sepsis it is hypothesized that activation of tubuloglomerular feedback reduces GFR and subsequently the metabolic demand on the tubules. "acute renal success". Mice without tubuloglomerular feedback should maintain higher levels of GFR. In conscious mice we detected early changes in GFR using a novel transcutaneous measurement of a fluorescent filtration marker. Because adenosine 1a receptor (A1AR) signaling is required for tubuloglomerular feedback we directly measured GFR following sepsis in A1AR knockout mice.

Methods: Sepsis was induced in male A1Ar knockout mice and littermate controls by cecal ligation and puncture. GFR was monitored in awake mice for five hours by transcutaneous measurement of a fluorescent filtration marker. Because adenosine 1a receptor (A1AR) signaling is required for tubuloglomerular feedback, unexpectedly, GFR begins to decrease earlier after sepsis suggesting impaired autoregulation. The sudden decrease in GFR in WT mice at two hours after induction of sepsis does not occur in A1AR KO mice. Tubuloglomerular feedback modestly supports, not suppresses, GFR in the first hour following sepsis, and only later acts to suppress GFR.

Results: The baseline GFR was similar in A1AR WT and KO mice. In WT mice, GFR was stable during the first hour following induction of sepsis. GFR slowly declined over hour two, and then fell rapidly to <10% of normal and remained low for five hours. In contrast, the GFR was lower in KO mice than in WT mice in the first hour following sepsis (p=0.0226), then fell gradually to 27% of normal, with a smaller decrease observed after two hours compared to WT mice (p=0.0286).

Conclusions: In mice lacking tubuloglomerular feedback, unexpectedly, GFR begins to decrease earlier after sepsis suggesting impaired autoregulation. The sudden decrease in GFR in WT mice at two hours after induction of sepsis does not occur in A1AR KO mice. Tubuloglomerular feedback modestly supports, not suppresses, GFR in the first hour following sepsis, and only later acts to suppress GFR.

Renal Functional Reserve May Be Inferred from Variation of Renal Resistive Index: Preliminary Evidence

Sara Samoni,1 Federico Nalesso,2 Gianluca Villa,2 Silvia De Rosa,1 Ilaria Petrucci,1 Massimo di Cal2; Fiorenza Ferrari,2 Alessandra Brendolan,2 Mario Meola,1 Claudio Ronco3.1 Sant’Anna School of Advanced Studies, Pisa; 2IRRI, Vicenza.

Background: The increase of glomerular filtration rate(GFR)after a protein load represents the renal functional reserve(RFR).Mechanical abdominal stress(MAS),through the compression of renal arteries and the consequent reduction of renal blood flow,can activate the autoregulation mechanism to maintain glomerular perfusion.Both phenomena are related to the afferent vasodilation,which can be displayed by the drop of renal resistive index(RI)measured by color Doppler. We hypothesized that the variation of RI during MAS may predict the RFR.

Methods: In 15 healthy volunteers,MAS was performed through the application of a saline bag on abdominal wall. According to the performed dose-response curve,we used bags which weigh 10% of subject’s BW.We recorded RI in mesorenal interlobar arteries each min for the 10 min of MAS.The RI reduction was defined by the difference between baseline RI and the lowest RI reached during MAS and expressed as percentage reduction(pDRI).

RFR was measured through a standardized protein loading test.Spearman’s correlation was applied to evaluate if pDRI correlates with RFR.

Results: We enrolled 9 M and 6 F with a median of 30(24-75) yrs old,The median baseline CrCl was 99.2(70.3-132.8)ml/min/1.73m2. The RFR ranged between 11.55% and 134.66% with a median value of 38.55%. The median baseline RI was 0.600(0.50-0.67) while pDRI ranged between 13.35% and 29.23% with a median value of 20%. The correlation between pDRI and RFR was r=0.16 (p=0.01). According to physiology, RFR and pDRI may not be directly proportional; indeed, while ranges of RFR may widely broaden,pDRI should reach a plateau value. For this reason, we analyzed the linear regression model between pDRI and logarithm[ln] of RFR. According to this model, we found that an increase in pDRI was associated to an increase in the ln of RFR(coef0.10,p=0.001,95%CI:0.06,0.15,R2=0.66).

Conclusions: Our results suggest that the variation of RI during MAS is an indirect measure of RFR,putting the bases for the development of a stress test that could be used for a rapid screen of RFR before potentially nephrotoxic procedures.

5-Aminolevulinic Acid Attenuates Rhabdomyolysis-Induced Acute Kidney Injury in Mice

Atsushi Uchida, Minoru Satoh, Tamaki Sasaki, Naoki Kashihiro, Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Okayama, Japan.

Background: Rhabdomyolysis often occurs after severe skeletal muscle injury, and high mortality have been reported with the acute kidney injury (AKI) that develops subsequently. Thus, the establishment of effective prevention and treatment is a pressing problem. 5-Aminolevulinic acid (ALA) is the naturally occurring metabolic precursor of heme, and serves as protein material related to energy production. Previous study demonstrated that ALA has the potential to prevent cisplatin-induced AKI via the induction of heme oxygenase (HO-1), and prevention of tubular apoptosis. We hypothesize that ALA plays a protective role by induction of the induction of HO-1 and anti-apoptotic pathway in rhabdomyolysis-induced AKI.

Methods: Male C57BL/6 mice were used. Rhabdomyolysis-induced AKI was induced by intramuscular injection of glycercol (50%) 5 ml/kg bw. ALA (30 mg/kg) was administered at 24 hr before or 24 hr after glycercol administration. These mice were sacrificed at 72 h after glycercol injection, and the blood and renal tissues were harvested. In vitro experiment, human proximal tubule cells were stimulated by 100 μM hemin to induce apoptosis. Cells were incubated for 24 h with or without 1 μM ALA. Apoptotic cells were examined by TUNEL staining and caspase-3 expression.

Results: In vivo experiments, serum creatinine, blood urea nitrogen and urine NGAL excretion were increased in glycercol-injected group compared with saline-injected control group. ALA significantly reduced these changes in both pre and post treatment. ALA also ameliorated glycercol-induced morphological tubular damages. HO-1 level was increased in glycercol-injected group and further up-regulated by ALA treatment. ALA significantly attenuated macrophage infiltration and pro-inflammatory cytokine (IL-1β and TNFα) expression. In vitro experiments, TUNEL-positive cells and caspase-3 expression were increased by hemin and were significantly reduced by ALA co-treatment.

Conclusions: ALA has renoprotective effects in glycercol-injected AKI. ALA is already used for tumor diagnosis in human. So the safety of the drug is proved in clinical use. ALA treatment may be a new therapeutic target in rhabdomyolysis-induced AKI.

Ferroptosis as a Cause of Proximal Tubule Injury

Joel M. Weinberg,1,2 Andreas Linkermann,1 Nephrology, VA Healthcare System Ann Arbor, Ann Arbor, MI; 1Nephrology, Univ of Michigan, Ann Arbor, MI; 2Nephrology, Christian Albrechts Univ, Kiel, Germany.

Background: ‘Ferroptosis’ has recently been described as a form of iron-dependent, lipid peroxidation-mediated cell death with a distinct injury pattern relative to other forms of necrosis and there is evidence that it contributes to AKI in vivo.(PNAS 111:16835,2014, Nat. Cell Biol. 16:1180,2014). Here, we have refined approaches to study ferroptosis in freshly isolated proximal tubules (PT) and assessed new agents being developed to ameliorate it.

Methods: Freshly isolated rabbit (R) and mouse (M) PT were treated with either tert-butylhydroperoxide (tBHP, 5 mM) or hydroxquinoline + ferrous ammonium sulphate (HQ+Fe,10 μM each) followed by incubation for 120 min, then measurement of LDH release, malondialdehyde (MDA) production, mitochondrial membrane potential, and GSH.

Results: tBHP and HQ+Fe induced progressive LDH release that was more severe in M PTs (R0: R60'-35.5 ± 6.8%, R120'-51.4 ± 9.6%; M60'-72.1 ± 2.6%, M120'- 87.4 ± 3.25%). These changes were accompanied by 5 fold increases of MDA levels and GSH depletion. LDH release and MDA production were iron and NAPHA oxidase (Nox)-dependent since they were blocked by deferoxamine or the Nox1/4 inhibitor GKT 137831. Feri, the prototypical ferroptotic inducer, did not target that phase of injury. Ferrostatins were not effective against acute cell killing and energetic deficits induced by hypoxia/reoxygenation, indicating that the benefit seen during in vivo ischemia/reperfusion does not target that phase of injury.

Conclusions: Ferroptosis is strongly expressed in fully differentiated PTs, is suppressed by both newly developed ferrostatins and the classical lipophilic antioxidant, DPPD, and is an injury process that can be targeted to alleviate AKI.

Identification and Characterization of IGFBP7 and TIMP2 Expression in Human Proximal and Distal Tubule Cells

David R. Emlet,1 Nuria M. Pastor-Soler,2 Allison L. Marciszyn,1 Xiaoyan Wen,1 Jacob K. Volpe,1 John A. Kellum,2 1Center for Critical Care Nephrology, Dept of Critical Care Medicine, Univ of Pittsburgh, Pittsburgh, PA; 2Renal Electrolyte Div, Dept of Medicine, Univ of Pittsburgh, Pittsburgh, PA.

Background: IGFBP7 and TIMP2 have been identified as biomarkers for Acute Kidney Injury (AKI), but little is known regarding any role in the pathogenesis of the disease. To study this question we established primary cell culture models of human proximal and distal tubule epithelial cells.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Methods: The cortex of human kidneys were dissociated and viable cells cultured. Proximal and distal tubule epithelial cells (PTECs and DTECs) were isolated with antibodies against CD163 and CD227 using the Dynabead pan-mouse IgG system. Isolated cells were cultured on transwell supports and characterized by immunoblot and immunofluorescence.

Results: CD163 isolated cells were positive for the PTEC markers Gamma Glutamyl Transpeptidase and Aquaporin-1. CD227 isolated cells were negative for GGT and AQP1 but positive for the distal tubule markers CD227 and E-cadherin. Microscopy demonstrated that both PTECs and DTECs formed tight junction monolayers with a low percentage of cells in cycle as identified by Ki-67. Analysis of conditioned media demonstrated that both cell types secreted high GGBP7 and TIMP2. Importantly, we identified a preferential expression of IGFBP7 in PTECs and of TIMP2 in DTECs. Furthermore, we discovered evidence suggesting that TIMP2 is primarily secreted across the apical surface, while the majority of GGBP7 is secreted across the basolateral surface. Despite this, we also found that some PTECs and some GGBP7 can be secreted apically, primarily in PTECs.

Conclusions: We have developed human cell culture model systems of PTECs and DTECs for the cellular/molecular analysis of AKI. We confirmed that IGBP7 and TIMP2 can be expressed and secreted by these cells, and we have identified differential expression and secretion of these proteins across cell types and spatially within cells. These systems and knowledge will now allow for investigation of the potential role of these biomarkers in the molecular etiology of AKI.

Klotho and S100A8/A9 as Discriminative Markers Between Pre-Renal and Intrinsic AKI

Yong Joon Kim,1 Eun Sik Jung,2 Byoungcho Choi,1 Yun Jung Oh,2 Chung Sik Lee,2 Han Ro,1 Jae Hyun Chang,1 Hyeon Hee Lee,2 Wookyung Chung.1

1Dept of Nephrology, Dept of Internal Medicine, Gachon Univ Gil Medical Center, Incheon, Republic of Korea; 2Dept of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea.

Background: Early detection and accurate differentiation of the cause of acute kidney injury (AKI) is of prognostic significance for patients. However, to date, there are few reliable biomarkers for the discrimination of pre-renal and intrinsic AKI. The purpose of this study was to determine whether AKI is associated with an altered level of klotho and the expression of S100A8/A9 in serum; 3361.11 ± 101.96 ng/ml; P = 0.003 in urine). Serum and urinary NGAL showed no difference between pre-renal and intrinsic AKI group. The model of renal IRI was induced by the release of bilateral renal pedicle clamping for 60 min. Mice were subjected to renal LR and treated with DNAse1 or saline (5 mg/kg). All animals were euthanized 72 hr after first IF injection. We also performed a proof of concept cross-sectional study to measure serum and urinary biomarkers in 77 hospitalized patients with established AKI.

Results: Compared with intrinsic AKI group, pre-renal AKI group caused a marked depression of urinary klotho level (13.21 ± 17.32 vs. 72.97 ± 17.96 pg/ml; P = 0.002). In addition, intrinsic AKI group caused a marked elevation of S100A8/A9 level than those of pre-renal AKI group (2629.97 ± 598.05 ng/ml vs. 685.09 ± 111.85 ng/ml; P = 0.002 in serum; 1361.11 ± 230.86 ng/ml vs. 741.72 ± 101.96 ng/ml; P = 0.003 in urine). Serum and urinary NGAL showed no difference between pre-renal and intrinsic AKI group. The proof of concept study with hospitalized AKI patients also demonstrated decreased urinary klotho in pre-renal AKI patients and increased urinary S100A8/A9 concentrations in their urine samples.

Conclusions: The attenuation of urinary klotho and increment of urinary S100A8/A9 may contribute to discriminate the pre-renal AKI and intrinsic AKI.

Release of Extra Cellular DNA Contributes to Renal Ischemia Reperfusion Injury Through Platelet Activation and Formation of Neutrophil Extracellular Traps

Marcel Janssen, Diba Emal, Xin Liu, Xiaofang Yu, Myung Soh, Jieru Cai.

Dept of Internal Medicine, Gachon Univ Anam Hospital, Seoul, Republic of Korea; Dept of Internal Medicine, Eulji University Hospital, Seoul, Republic of Korea.

Background: There have been considerable growth in older population and age-related kidney disease in the world. It was demonstrated that the impairment in the potentiality to repair and regenerate of renal resident cells is a hallmark of biological processes associated with aging. However, the impact of senescence of bone marrow derived cells (BMDC) on kidney injury is not known. Here, we investigated the role of senescence of BMDC in the development and progression of ischemic acute kidney injury (AKI).

Methods: Seven wk-old female mice were sublethally irradiated and reconstituted with bone marrow from 12-mo-old (old-to-young, old BMT) or 7-wk-old (young to young, young BMT) mice. Then we performed renal ischemia reperfusion injury (IRI) in old or young BMT mice, and functional, histological kidney damage and inflammation were compared.

Results: The Y chromosome was detected in peripheral blood of BMT mice indicating successful reconstitution of female mice with male bone marrow. Although the population of intracellular DNA in splenocytes from old and old BMT mice was significantly different, old BMT mice showed less renal functional deterioration and histological damage after IRI. This was associated with less infiltration of F4/80 macrophages and lower level of tissue cytokine (IL-12). In vitro study with BMDCs also revealed that LPS-induced cytokine productions (IFN-γ, MCP-1 and IL-10) were significantly suppressed in old BM cells than young BM cells.

Conclusions: Our data shows that senescence of BMDC could affect susceptibility and response to renal ischemic injury possibly via immune modulatory effect. A better understanding of these processes could help to develop new strategies that are specifically tailored for treatment of the elderly population.

Optimal Transplantation Timing of Mesenchymal Stem Cell in Rat Model of Renal Ischemia Reperfusion Injury

Xiaoxue Liu, Xiaofang Yu, Yong Joon Kim,1 Eun Sik Jung,1 Yoon Soo Na,2 Soon Young Lee,2 Sang Kyung Jo,1 Won Yang Cho.1

1Dept of Internal Medicine, Korea Univ Anam Hospital, Seoul, Republic of Korea; 2Dept of Internal Medicine, Eulji University Hospital, Seoul, Republic of Korea.

Background: It is optimal timing to transplant MSCs in IRI before kidney injury is not known. Here, we investigated the role of senescence of BMDC in the development and progression of ischemic acute kidney injury (AKI).

Methods: The serum creatinine level peaked at 24h of reflow (470.6 ±1066 pg/ml, P<0.05) and NGAL peaked at 12h(767.1±106 pg/ml, P<0.05). The highest expression of inflammatory factor was in 1h and 4h groups, and the lowest was in 1h and 4h groups. In vitro, there was lower cell apoptosis and higher proliferation in 1h and 0h groups compared with other groups. Significant kidney function and histological damage improvement was observed after the treatment of MSCs in 1h and 4h groups. Meanwhile, the expression of proinflammatory factor significantly decreased in 1h and 0h groups compared with other point time groups and control group. In addition, we also observed more obvious inhibition of renal tubular cell apoptosis and promotion of proliferation in 1h and 0h groups compared with other groups. Consistent with the improvement above, the viability of implanted MSCs also increased in 1h and 0h groups.

Conclusions: MSCs transplantation 1h before reperfusion or immediately after reperfusion protects from I/R injury. It is the optimal timing to transplant MSCs in IRI before the inflammatory response is established.

Renal Protective Role of Par1 in Acute Kidney Injury

Abhijeet Pal,1 Natalie S. Uy,1 James M. Pullman,2 Zhongfang Du,1 Kimberly J. Reidy.1 1Pediatric Nephrology, Children’s Hospital at Montefiore, Montefiore Medical Center/Albert Einstein Medical College, Bronx, NY; 2Pathology, Montefiore Medical Center/Albert Einstein Medical College, Bronx, NY.

Background: Par1 has been shown to be involved in the development of renal injury. However, the role of Par1 in acute kidney injury has not been well elucidated.

Methods: We stimulated platelets with necrotic renal cells in presence of absence of deoxyribozonuclease 1 (DNase1). Platelet activation and platelet-leukocyte formation were measured by FACS. We stimulated granulocytes with activated platelets and measured DNA release – indicative of NET formation. Vicious versa we stimulated platelets with NETs and measured platelet activation, resulting in tissue damage. It has been shown that platelet inhibition protects from I/R. How platelets are activated upon renal I/R is not entirely clear. In this study we investigate renal cell death, extracellular DNA release and neutrophil extracellular traps (NETs) as potential triggers for platelet activation and renal I/R injury.

Results: We stimulated platelets with necrotic renal cells in presence or absence of DNAse1 reduced platelet activation. Activated platelets generated NETs in vitro and, vice versa, NETs stimulated platelet activation ex vivo. Mice subjected to renal I/R showed a significant increase of extracellular DNA and PF4 levels in the circulation. Treatment with DNase1 improved renal functional outcomes. Pretreatment with DNase1 reduced renal swelling and inflammation. Treatment with DNase1 resulted in a trend towards fewer NETs and granulocytes in tissue.

Conclusions: Both DNA from necrotic kidney cells and NETs activate platelets, which in turn cause further NET formation, leading to a vicious triad in the pathogenesis of I/R injury. Treatment with DNase1 may have therapeutic benefits in the context of renal I/R injury.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
are functionally redundant on kinase assays. We have identified a role for Par1α/b in glomerular and proximal tubular development in mice associated with downregulation of Notch signaling. We hypothesized that Par1α/b would contribute to renal epithelial repair in the setting of acute kidney injury.

Methods: Expression of Par1α/b and Notch signaling was examined using western blotting and immunofluorescence in models of tubular injury and human kidney tissue (leftover from clinically indicated renal biopsy). Proximal tubular injury was induced by in wild-type(WT) and Par1α knockout mice by injecting cisplatin (30mg/kg, ip) or folic acid (250 mg/kg, ip). The degree of histological damage was assessed by light microscopy. Par1α/b migration was studied using developing mouse kidney and comparison with normal adult human kidney.

Background: Heat shock protein beta-1 (HSPB1, also known as HSP27) is a small heat shock protein involved in various cellular processes and reported to protect cells against oxidative and chemical stress. Autophagy protects cells from many types of stress and is thought to play a key role in preventing stress in acute kidney injury (AKI). However, little is known about the role of HSPB1 in autophagy and apoptosis in the pathogenesis of AKI.

Methods: We used a rat ischemia/reperfusion AKI model and cultured renal tubular cells as an in vitro model. To elucidate the regulation of HSPB1, we evaluated the promoter activity and expression of HSPB1 in normal rat kidney (NRK)-52E cells in the presence of H2O2. To examine the regulation of autophagy by HSPB1, we established NRK-light chain 3 (NRK-LC3) cells that were stably transfected with a fusion protein of green fluorescent protein and LC3.

Results: The results of immunohistological examination showed that HSPB1 was expressed in proximal tubule cells after AKI. Real-time quantitative reverse transcription-polymerase chain reaction and western blot analysis showed that HSPB1 mRNA and protein expression were upregulated 6–72 h and 12–72 h, respectively, after ischemia/reperfusion injury. HSPB1 promoter activity as well as mRNA and protein expression indicated dose-dependent induction by H2O2. HSPB1 overexpression-induced autophagy in NRK-3LC3 cells under normoxic conditions was confirmed with confocal microscopy, which revealed the presence of LC3-positive granules. Furthermore, H2O2-induced autophagy was inhibited by the transfection of small interfering RNAs for HSPB1. Overexpression of HSPB1 reduced BAX activation and H2O2-induced apoptosis, as measured by caspase 3 activity and terminal deoxynucleotidyl transferase deoxyuridine triphosphate nick end labeling assay.

Conclusions: These results indicate that HSPB1 upregulation plays a role in the pathophysiology of AKI.

SA-PO268

Background: Cisplatin, a commonly used chemotherapeutic for the treatment of many solid cancers is known to induce acute kidney injury (AKI) in 30% of patients. Patients that develop cisplatin-induced kidney toxicity must either have the dose severely reduced or be switched to an alternative therapy to prevent long-term renal damage. In many cases the alternative therapy may be less effective at treating the tumor. Due to cisplatin’s complex nephrotoxicity, development of new agents remains a challenge. Currently there are no FDA approved drugs for the protection of cisplatin-induced AKI. The standard mouse model of cisplatin-induced AKI is a single high dose of cisplatin (10-30 mg/kg), and animals are sacrificed 72h after injection. This model does not accurately represent the clinical dosing regimen, which involves repeated dosing of cisplatin.

Methods: In this study we compared the standard single dose model to a new multiple dose model where mice received lower doses of cisplatin once a week for 4 weeks. We measured and compared indicators of kidney function (KIM-1, NGAL, BUN, and Serum Creatinine). We also measured markers of inflammation (IL-6, IL-1β, TNFα, MCP-1). Indicators of apoptosis and cell death were measured as well as indicators of fibrosis (i.e. TGF-β, CTGF, BMP-7, and Sirtus Red staining).

Results: In comparing the results of the single and multiple dose models, BUN values were similar, suggesting a comparable loss of kidney function. However, KIM-1 and NGAL were reduced by roughly 10-fold and 100-fold, respectively. Inflammation was also decreased in this model with TNFα, IL6 and IL1-β reduced by 4, 10 and 5-fold, respectively. Fibrosis was nearly non-existent in the single dose model; however, the multiple dosing model showed a significant increase in fibrosis. Also, expression of PAI-1, a marker of fibrosis was significantly increased in the multiple dosing model compared to the single dose model.

SA-PO269

Background: Heat shock protein beta-1 (HSPB1, also known as HSP27) is a small heat shock protein involved in various cellular processes and reported to protect cells against oxidative and chemical stress. Autophagy protects cells from many types of stress and is thought to play a key role in preventing stress in acute kidney injury (AKI). However, little is known about the role of HSPB1 in autophagy and apoptosis in the pathogenesis of AKI.

Methods: We used a rat ischemia/reperfusion AKI model and cultured renal tubular cells as an in vitro model. To elucidate the regulation of HSPB1, we established NRK-light chain 3 (NRK-LC3) cells that were stably transfected with a fusion protein of green fluorescent protein and LC3.

Results: The results of immunohistological examination showed that HSPB1 was expressed in proximal tubule cells after AKI. Real-time quantitative reverse transcription-polymerase chain reaction and western blot analysis showed that HSPB1 mRNA and protein expression were upregulated 6–72 h and 12–72 h, respectively, after ischemia/reperfusion injury. HSPB1 promoter activity as well as mRNA and protein expression indicated dose-dependent induction by H2O2. HSPB1 overexpression-induced autophagy in NRK-3LC3 cells under normoxic conditions was confirmed with confocal microscopy, which revealed the presence of LC3-positive granules. Furthermore, H2O2-induced autophagy was inhibited by the transfection of small interfering RNAs for HSPB1. Overexpression of HSPB1 reduced BAX activation and H2O2-induced apoptosis, as measured by caspase 3 activity and terminal deoxynucleotidyl transferase deoxyuridine triphosphate nick end labeling assay.

Conclusions: These results indicate that HSPB1 upregulation plays a role in the pathophysiology of AKI.

SA-PO270

The Protective Role of Doxycycline for Cisplatin-Induced AKI by Its Anti-Inflammatory and Anti-Oxidative Effects Tetsuya Nakagawa,1 Yutaka Kakizoe,1 Yoshikazu Miyasato,1 Teruhiko Mizamato,1 Manabu Hayata,1 Yuichiro Izumi,1 Takashige Kawaiura,2 Taku Miyoshi,1 Masataki Adachi,1 Kenichiro Kitamura,2 Masashi Mukoyama.1 Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan;1 Internal Medicine III, Univ of Yamanashi Faculty of Medicine, Yamanashi, Japan.

Background: Cisplatin (CDDP) is a chemotherapeutic drug widely used for the treatment of solid tumors. However, its nephrotoxicity is the major dose-limiting factor. Doxycycline (Dox) is a tetracycline antibiotic commonly used in a variety of infections, but several other properties have been suggested such as an anticancer effect or the inhibition of matrix metalloproteinase (MMP). In this study, we investigated whether Dox exerts the protective effects on CDDP-induced acute kidney injury(AKI).

Methods: Ten-week-old male C57BL/6J mice were divided into following four groups: 1) Control, 2) Dox (2mg/ml in drinking water), 3) CDDP (25 mg/kg, intraperitoneally) and 4) CDDP+DOX. After 7 days pretreatment with Dox, CDDP was administrated, and animals are sacrificed 72h after injection. Protective effects on CDDP-induced acute kidney injury(AKI).

Results: No apparent adverse effects were observed in Dox group. Dox did not affect mRNA expression of transporters for CDDP (OCT-1, OCT-2 and MATE1) in the renal tubules. CDDP caused severe tubular damages along with elevated BUN and Cr levels. It also increased mRNA expression of inflammatory and profibrotic molecules, together with enhanced oxidative stress in the kidney. Dox alleviated significantly those detrimental changes (Cr: Control, 0.13±0.01; Dox, 0.13±0.03; CDDP, 1.04±0.20 and CDDP+Dox, 0.30±0.12 mg/dL). Moreover, Dox suppressed the activities of MMP-2 and 9 as well as serine proteases, which were enhanced by CDDP in the kidney tissue.

Conclusions: Dox mitigated CDDP-induced AKI through its pleiotropic effects, i.e., anti-inflammatory, anti-oxidative, and anti-fibrotic factors. Our results suggest that Dox could become a new strategy for the prevention of CDDP-induced nephrotoxicity in humans.

Funding: Government Support - Non-U.S.
Methods: For in vivo study, male C57BL/6 mice were given a single intraperitoneal injection of cisplatin. In vitro, the cisplatin-resistant proximal tubular cells (RPTC) were incubated with cisplatin. To determine the role of heat shock factor 1 (HSF1), HSF1 was knocked down by stable transfection of specific siRNAs.

Results: In RPTC, cisplatin induced a rapid expression of HSF1 and specific heat shock proteins, including Hsp70, Hsp27, and Crystallin-αB. The expression of these proteins was transient and decreased at late time points of cisplatin treatment. Similar changes were verified in kidney tissues following cisplatin injection, whereas Hsp90 did not change significantly. Knockdown of HSF1 decreased Crystallin-αB expression and pro-RPTC apoptosis. Interestingly, p38 activation was enhanced in these cells. Moreover, inhibition of p38 with SB203580 markedly inhibited cisplatin-induced apoptosis in HSF1-knockdown cells.

Conclusions: Induction of HSF1 is a cytoprotective response during cisplatin nephrotoxicity. Crystallin-αB appears to be a key heat shock protein induced by HSF1 for its protective effect. Heat shock response may regulate or co-operate with other signaling pathways, such as p38, to regulate tubular cell apoptosis.

The Effect of the Cytoplasmic Domain of Tissue Factor in Contributing to Renal Ischemic Reperfusion Injury Is Both Protease Activated Receptor-1 (PAR-1) and Strain Dependent

Jonathan H. Erlich,1,2 Sean E. Kennedy,1,2 Joseph J. Murphy,1 Calum Wai Kit Chong.1 1Dept of Medicine, Univ of New South Wales, Randwick, Australia; 2Dept of Nephrology, Sydney Childrens Hospital, Randwick, NSW, Australia; 3Dept of Nephrology, Prince of Wales Hospital, Randwick, NSW, Australia.

Background: The cytoplasmic domain of tissue factor plays a role in cell signaling and regulation of apoptosis and inflammation. It may do so by regulating protein tyrosine phosphorylation and via modulating protease activated receptor signaling. Previously we have shown that mice on a mixed genetic background deficient (MGB) in the cytoplasmic domain of tissue factor (TFcyt) mice developed severe renal injury. They have increased cytokine and PAR-1 expression, which contributed to the importance of increased PAR-1 signaling and the strain background of the mice.

Methods: Mice WT or TFcyt/deltact on MGB or mice backcrossed onto C57BL/6 mice background underwent 2.5 min bilateral warm ischemia and 24 reperfusion. Renal function was assessed by serum creatinine and renal injury was further assessed by histology and expression of inflammatory mediators form renal tissue. The role of PAR-1 was assessed using the inhibitor SCH79797.

Results: TFcyt/deltact mice on the MGB developed more severe injury at 24 than WT on a similar genetic background. These mice developed greater PAR-1 mRNA expression and treatment of these mice with the PAR-1 inhibitor reduced injury similar to PAR-1 deficient mice. In contrast the effect of TF cytoplasmic depletion was not seen in mice on C57BL/6 background. These mice had similar PAR-1 induction to that observed in WT C57BL/6. WT mice with a MGB had lesser renal injury and lower basal PAR-1 expression than WT C57BL/6 mice. TFcyt/deltact mice on MGB having similar basal PAR-1 expression and much greater inducible PAR-1 expression (5 fold compared to 2.8 fold for WT). TFcyt/deltact on a C57BL6 background had similar renal injury and PAR-1 induction to WT mice.

Conclusions: The cytoplasmic domain of TF may contribute to renal IR injury by regulating PAR-1 expression. The role of the TF cytoplasmic domain in regulating renal injury is genetic background dependent.

Protective Effects of Endonuclease Inhibitors on Cisplatin-Induced Acute Kidney Injury

Dae Song Jang,1 Tariq Fahmi,1 Todd Fite,1 Narsimha Reddy Penthalah,1 Dolapo Taiwo Odeniyi,1 Alena Savenka,1 Peter A. Crooks,2 Sudhir V. Shah,1,2 Alexei G. Basnakian.1,2 1Univ of Arkansas for Medical Sciences, Dept of Pharmacology and Toxicology, Little Rock, AR; 2Central Arkansas Veterans Healthcare System, Div of Nephrology, Little Rock, AR, 3Univ of Arkansas for Medical Sciences, COP Pharmaceutical Science, Little Rock, AR.

Background: Cisplatin is one of the most commonly used and the most nephrotoxic anticancer drugs. Acute kidney injury induced by cisplatin cannot be overcome and may lead to chronic kidney failure. Our previous studies showed that genetic inactivation of two kidney apoptotic endonucleases, DNase I and EndoG, was partially protective against tubular epithelial cell death induced by cisplatin. Until very recently, pharmacologically meaningful inhibitors of the endonucleases, which would be non-toxic and effective in vivo, were not available.

Methods: This study was aimed to determine if the two new endonuclease inhibitors recently identified by us, IG-17 (1,3-polyethylen-bis-aminoguanidine hydrochloride) for DNase I and PNR-382 (5,8-(1H-2-naphthyl)-5-methoxy-1H-indol-3-yl(ethylen)-2-thioxoimidazoline-4(1H,5H)-dione) for EndoG, could ameliorate cisplatin toxicity to kidney tubular epithelial cells in vitro and in vivo.

Results: In vitro experiments using NRK-52E cells showed that the compounds are able to suppress endonuclease activity inside the cells provide partial protection against cisplatin toxicity measured using LDH release assay and TUNEL, and are non-toxic at the used concentrations. The inhibitors were found to markedly suppress the total-body endonuclease activity in mice at the dose of 5 mg/kg administered subcutaneously; and were non-toxic up to 25 mg/kg as measured using 14 blood plasma markers of organ toxicities.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

689A
Conclusions: Importantly, cisplatin-induced kidney injury was functionally (creatinine) and structurally (acute tubular necrosis, TUNEL) reduced by the administration of the inhibitors (5 mg/kg) in mice suggesting their potential therapeutic value.

Involvement of CYLD as a Regulatory Factor in Fibrotic Response of Ischemic AKI Kidney and Hypoxic HK-2 Cells

Background: The effect of oxygen and hypothermic therapy on the prevention of acute kidney injury (AKI) is an important risk factor of chronic kidney disease (CKD). We investigated the role of microRNA-17 (miR-17) regulation in kidney against damage in ischemia-reperfusion injury.

Methods: Renal ischemia-reperfusion was induced in C57 mice by bilateral clamping for 36° C body temperature. Prior treatment was given to six groups in different ways. The left kidneys were used for control. After a catheter was placed in a bladder, oxygen was cooled for hypothermic therapy before the induction of acute kidney injury. The kidneys were extracted after the induction of acute kidney injury with clamping. Gross examination of both kidneys during the clamping and after the extraction was performed. Results: Gross examination of kidneys demonstrated less ischemic changes of kidneys treated with oxygen or hypothermic oxygen during and after the induction of acute kidney injury. As shown in Figure 1, right kidneys that received oxygen therapy or hypothermic oxygen showed less ischemic changes on gross examination during the clamping and after extraction.

Oxygen therapy

Control

Hypothermic oxygen

Figure 1

Conclusions: This pilot study shows novel methods for the prevention and treatment of acute kidney injury. Further study is necessary to investigate the effects of catheter oxygen and hypothermic therapy in the prevention and treatment of acute kidney injury.

MicroRNA-17 Is Induced via P53 to Protect against Renal Ischemia-Reperfusion Injury by Targeting Death Receptor 6

Background: MicroRNA-17 (miR-17) regulates cell survival and proliferation pathways by acting as a deubiquitinating enzyme. Recent studies have revealed that CYLD could play a pathological role in regulating pathways by acting as a deubiquitinating enzyme. Recent studies have revealed that CYLD could play a pathological role in regulating fibrosis. It is well-documented that tissue fibrosis is common hallmark of chronic kidney disease (CKD), and CKD progresses toward end-stage renal disease through renal fibrosis. However, the molecular pathogenesis of renal fibrosis is not fully understood yet. In this study, we elucidated the roles of CYLD in renal fibrosis by using in vivo and in vitro models.

Methods: We generated model mice of ischemia/reperfusion (I/R)-induced acute kidney injury (AKI) and hypoxic human kidney (HK)-2 cells. CYLD protein expression was markedly decreased (0.4-fold) in a time-dependent manner. Interestingly, fibrosis gene expression (PAI-1: 12-fold, CTGF: 2.5-fold, COL1A1: 4-fold) was significantly increased in response to the treatment on the development of fibrosis, neither treatment (at doses demonstrated to be effective in more mild injury models) showed effect in the vitro model. Broad anti-inflammatory suppression by dexamethasone attenuated fibrotic gene expression. We speculate that the natural course of renal demise after UIRI is very robust and highly likely to require a multi-target approach. Whether some combination of the therapies tested here could have efficacy in this model remains to be determined.

Effect of Oxygen and Hypothermic Therapy on the Prevention of Acute Kidney Injury

Background: There is no effective therapy for acute kidney injury. The effect of oxygen, hypothermic therapy delivered through urinary tract on the treatment of acute kidney injury has not been known. This pilot study was performed as a proof of concept of a catheter-based oxygen and hypothermic oxygen therapy in preventing and treating acute kidney injury.

Methods: Rats (n=6) were used for the experiment. Three rats were used to compare oxygen therapy and control. The other three rats were used to compare hypothermic oxygen therapy and control. Oxygen was cooled for hypothermic oxygen therapy before it was delivered to the kidney. Right kidneys treated receive oxygen or hypothermic oxygen therapy and left kidneys were used for control. After a catheter was placed in a bladder, oxygen (or cooled oxygen) was delivered to the right kidney from the bladder through the catheter for five minutes for pretreatment before clamping. Both right and left renal arteries were clamped for 30-45 mins to induce acute kidney injury. Only right kidneys continued to receive oxygen or hypothermic oxygen during the clamping of renal arteries. The kidneys were extracted after the induction of acute kidney injury with clamping. Gross examination of both kidneys during the clamping and after the extraction was performed. Results: Gross examination of kidneys demonstrated less ischemic changes of kidneys treated with oxygen or hypothermic oxygen during and after the induction of acute kidney injury. As shown in Figure 1, right kidneys that received oxygen therapy or hypothermic oxygen showed less ischemic changes on gross examination during the clamping and after extraction.

SA-PO279

The Effect of Oxygen and Hypothermic Therapy on the Prevention of Acute Kidney Injury

Background: Ischemic acute kidney injury (AKI) is an important risk factor of chronic kidney disease (CKD). We optimized a mouse model of AKI to CKD by unilateral ischemia-reperfusion (UIRI) with development of renal fibrosis. To validate this model for use in therapeutic intervention studies, 3 experimental treatments were tested: administration of 1) recombinant human CCN3 (CCN2/CTGF antagonist), 2) TGFβ1 neutralizing antibody (ID11) or 3) dexamethasone (corticosteroid).

Methods: Male C57Bl/6 mice underwent 21 min of unilateral ischemia-reperfusion (UIRI) at 36° C body temperature. 8 treatment groups (n=4/group, ip) were included: dexamethasone (10 mg/kg, daily), vehicle (PBS, daily), rCCN3 (5 μg/kg, daily), vehicle (PBS, daily), antibody to TGFβ1 (0.5 mg/kg, every other day), vehicle (PBS, every other day), an untreated UIRI group and a sham group. Three weeks after UIRI renal fibrotic outcome was determined by gene expression analysis (qPCR) of collagen I, TGFβ, CTGF, CCN3, PAI-1 and TNF-α.

Results: UIRI induced a ~40% reduction in renal mass. Treatment with rCCN3, anti-TGFβ or dexamethasone did not attenuate this reduction. UIRI induces significant upregulation of the fibrosis-related genes. rCCN3 treatment had no effect on gene expression. Anti-TGFβ antibody treatment induced significantly less upregulation of TGFβ1 and CCN3 gene expression, however, vehicle also reduced TGFβ expression. Dexamethasome treatment induced significantly less upregulation of collagen I and CCN2/ CTGF gene expression and a trend towards higher CCN3 upregulation.

Conclusions: Despite the earlier proven benefits of TGFβ1 antagonism and CCN3 treatment in the development of fibrosis, neither treatment (at doses demonstrated to be effective in more mild injury models) showed effect in the vitro model. Broad anti-inflammatory suppression by dexamethasone attenuated fibrotic gene expression. We speculate that the natural course of renal demise after UIRI is very robust and highly likely to require a multi-target approach. Whether some combination of the therapies tested here could have efficacy in this model remains to be determined.

Proximal Tubule-Derived CSF-1 Mediates Expansion and Polarization of Renal Macrophages/Dendritic Cells and Recovery in Acute Kidney Injury

Yinpeng Wang, Bing Yao, Raymond C. Harris, Ming-Zhi Zhang. Medicine, Vanderbilt Univ, Nashville, TN.

Background: Colony-stimulating factor-1 (CSF-1)-mediated renal macrophage expansion and polarization play an essential role in recovery from acute kidney injury in ischemia/reperfusion (IR)-injury and selective apoptotic proximal tubule injury in transgenic mice expressing the human diphtheria toxin receptor (DTR) and exposed to DT (DTR-AKI). In the kidney, a major site of CSF-1 production is in proximal tubular epithelial cells.

Methods: Male DTR mice with CSF-1-/- (wild-type) or with γ-GT-Cre-CSF-1+/- (CSF-1 KO in renal proximal tubule) were used for DTR-AKI and for IR injury (30 min of ischemia and contralateral nephrectomy).

Results: CSF-1 expression in the proximal tubule and its deletion in CSF-1 KO mice were confirmed with immunostaining. Six days after DTR-AKI, activation of the CSF-1 receptor (p-c-fms) was markedly attenuated in both renal tubules and interstitial cells, including macrophages (F4/80 and p-c-fms dual positive cells). Flow cytometry and qPCR indicated fewer renal macrophages/dendritic cells and reduced mRNA levels of M2 phenotype markers (CD206, IL-4Rα, TGF-β and 15-LOX) in CSF-1 KO mice 6 days after DT injection. Although selective proximal tubule CSF-1 deletion did not affect the severity of kidney injury, it delayed renal functional recovery, in association with increased oxidative stress, increased secondary necrosis (HMGB1 expression) and severe tubulointerstitial fibrosis, with increased Picro-sirus red staining of fibillary collagen and increased profibrotic and fibrotic components (α-SMA, CTGF, Fbronectin, collagen I and IV). Selective proximal tubule CSF-1 depletion also led to delayed functional recovery after IR injury, with decreased mRNA levels of M2 phenotype markers in isolated renal macrophages/dendritic cells and more severe renal fibrosis. In both IR injury and DTR-AKI, selective proximal CSF-1 deletion had minimal effects on the expression of M1 phenotype markers.

Conclusions: These studies demonstrate that proximal tubule is a major source of CSF-1 that mediates the expansion and polarization of renal macrophages/dendritic cells that play an essential role in recovery following AKI.

Ablation of Myo-Inositol Oxidase Protects against Cisplatin-Induced Acute Kidney Injury by Inhibiting p53 Activation

Rajesh K. Dutta, Yashpal S. Kanwar. Dept of Pathology, Northwestern Univ, Chicago, IL.

Background: MIOX is a renal tubular enzyme. Its role in the pathogenesis of diabetic nephropathy is currently being investigated. Conceivably, it modulates redox imbalance and apoptosis in tubular cells in diabetes via modulation of glucuronate-xylulose (G-X) pathway. However, its role in acute kidney injury (AKI) is unknown.

Methods: In this study we used both MIOX-over-expressing transgenic and MIOX null mice to elucidate its role in a model of cisplatin induced AKI.

Results: We observed severe cisplatin-induced proximal tubular injury in MIOX transgenic and protection in null mice compared to wild type mice. In transgenic mice an increased serum creatinine and urea levels, caspases-3 activity and tubular apoptosis along with marked deterioration of tubular morphology was observed. Renal injury was remarkably less in null mice compared to wild type mice. Cisplatin treatment led to p53 activation in wild type and MIOX transgenic mice, whereas minimal p53 activation was observed in MIOX null mice. Likewise, we noted that cisplatin induces mTOR pathway in both wild type and MIOX transgenic mice while such an effect was not observed in MIOX null mice. Treatment with mTOR inhibitor, rapamycin, prevented cisplatin-induced MIOX expression, p53 activation and deterioration of tubular morphology in control mice. In vitro studies revealed significantly high levels of ROS generation, caspases-3 activity and apoptosis in MIOX over-expressing cells compared to control cells transfected with empty vector following cisplatin treatment.

Conceivably, this was attributed to the accentuated induction of G-X-pathway and its associated myriad enzyme system.

Allopurinol Protects against Rhabdomyolysis and Acute Kidney Injury Induced by a Membrane Protein (Lp25) from Pathogenic Leptospires
Antonio C. Seguro,1 Daniele Canale,1 Patricia A. Abru,2 Denize Monariz,2 Tatiana B. Gotti,2 Larissa R. Matos,2 Thales de Brito,2 Pedro H F Gois,1 Antonio J. Magalhã,1 1Nephrology, Hospital das Clínicas FMUSP, São Paulo, Brazil; 2Lab. de Bacteriologia, Inst Butantan, São Paulo, Brazil.

Background: Acute kidney injury (AKI) in leptospirosis is frequently nonoliguric, hypo or normokalemia. Higher serum potassium levels, elevated creatinine phosphokinase (CPK) associated with maximum serum creatinine level were observed in non-survivor patients suggesting that rhabdomyolysis contributes to more severe AKI in leptospirosis. Previous study from our group demonstrated that Lp25, a protein membrane from pathogenic Leptospires, was responsible for hyperkalemia AKI induced by rhabdomyolysis in guinea pigs. Recent studies suggest that Allopurinol (Allo) protects individuals from exercise-induced rhabdomyolysis. The aim of this study was to evaluate the effect of Allo on guinea pigs injected with Lp25.

Methods: Three groups of guinea pigs were studied: 1. Sham (phosphate-buffered solution); 2. Lp25-3-L: Lp25+Allo. One mL of PBS and Lp25 (400μg of Lp25/mL) were intraperitoneally injected for 4 days. Lp25+Allo received Allo (300mg/Kg) in drinking water during this time. On the 5th day, animals were placed in metabolic cages for 12 hours urine collection. We measured urinary volume (Ur V/12h), creatinine clearance (ml/min/100gBW), serum potassium (mEq/L), CPK (U/L), uric acid (mg/dL), phosphate (mg/dL). Data are mean±SEM.

Results: Lp25 induced hyperkalemia, rhabdomyolysis (elevated CPK, uric acid, phosphate) and oliguric AKI. Allo ameliorated CPK, serum potassium, CPK and uric acid.

Conventional Autophagy Regulates the Degradation of AQP2 in Hypokalemia
Wan-Young Kim,1 Sun-ah Nam,1 Yumi Kim,1 Arum Choi,1 Yong kyun Kim,2 Jin Kim.1 1Anatomy and Cell Death Disease Research Center, The Catholic Univ of Korea, Seoul, Korea; 2Internal Medicine and Cell Death Disease Research Center, The Catholic Univ of Korea, Bucheon, Korea.

Background: Autophagy is a catabolic pathway utilized to maintain a balance among the synthesis, degradation, and recycling of cellular components, thereby playing a role in homeostasis. Abundance of AQP2 is regulated through balance between production by tration and removal by degradation. Although AQP2 degradation is supposed to be occurred via lysosomal or proteasomal degradation, the precise mechanisms still remain unknown. It has been known that prolonged hypokalemia causes vasopressin-resistant polyuria and induces autophagy especially in principal cells (PC) of collecting duct.

Methods: To investigate the role of autophagy in the degradation of AQP2, we generated AQP2-cre;Atg7-/- mice, in which Aqp7, an essential gene for mammalian autophagy, was selectively inactivated in PCs. Hypokalemia was induced by K-depleted diet for 2 weeks.

Results: In control AQP2-cre;Aqp7+/- mice, the distribution pattern of AQP2 was not different from AQP2+/- mice. Immunolabeling of pS261-AQP2 was localized mostly subapical and cytoplasmic in appearance in the PCs. In contrast to pS261-AQP2, immunolabeling of pS256-AQP2 was localized mainly at the apical plasma membrane and subapical domains. In hypokalemia Aqp7+/- mice, the abundance of pS261-AQP2 was significantly reduced and redistributed to intracellular vesicles, and co-localized with LC3-positive vacuoles. In hypokalemia Aqp7+/- mice, there was a decrease of conversion of LC3-I to LC3-II and a marked accumulation of p62 selectively in PCs. Rab9 protein, an essential molecule for alternative autophagy pathway, and Rab9-positive vacuoles were markedly increased. Interestingly, pS261-AQP2 was distributed throughout the cytoplasm and not co-localized with Rab9 or LC3-positive vacuoles in the PCs of AQP2-cre;Aqp7+/- mice. There was no difference in localization of pS256-AQP2 at the plasma membrane from each genotype.

Conclusions: These results suggest that down regulation of AQP2 in hypokalemia could in part be caused by degradation of pS261-AQP2 in PCs through a LC3/Atg7-dependent conventional autophagy pathway.

SA-PO286
Early Autophagy Precedes Angiotensin II-Induced Podocyte Apoptosis
Tae-Sun Ha. Pediatrics, Chungbuk National Univ, Cheongiu, Chungbuk, Korea.

Background: Autophagy is a highly regulated catabolic process that is involved in the turnover of unwanted cellular materials, on the other hand, apoptosis removes damaged or unwanted cells. Therefore, autophagy and apoptosis constitute the two processes through which injured/aged cells or organelles are eliminated. Angiotensin II (Ang II) induces apoptosis in the podocytes in vitro and in vivo. However, the relationship between autophagy and apoptosis in Ang II-induced podocytes is not elucidated and the role of Ang II-induced autophagy in podocyte survival remains unclear. We investigated the sequential relationship between autophagy and apoptosis in Ang II-induced podocytes.

Methods: Podocytes were cultured in media in various concentrations of Ang II and at different incubation times. The changes of podocyte autophagy and apoptosis were observed by electron microscopy, confocal imaging, Western blotting, and FACS assay according to the presence of Ang II. Results: Ang II-treated podocytes showed an increase in autophagosomes compared with control cells at early phase in a dose-dependent manner. This pro-autophagic effect of Ang II was inhibited by pretreatment with 3-methyladenine, an inhibitor of PI3-kinase class III. Ang II enhanced podocyte expression of autophagic proteins such as LC3-II and beclin-1. Ang5 siRNA further reduced the expression of LC3-II and cleaved caspase-3 suppressed by Ang II at 12 hrs. However, Ang5 siRNA did not affect the expression of Ang5, LC3-II, and cleaved caspase-3 in the presence of Ang II at 24 hrs. Thereafter, Ang II induced podocyte apoptosis significantly in concentration- and time-dependent manners in FACS assays. LC294002 and Ang5 siRNA further increased podocyte apoptosis induced by Ang II. Therefore, high concentrations of Ang II induced apoptosis, while autophagy response decreased, which implicated that autophagy preceded apoptosis for cytoprotection in angiotensin II-induced podocyte injury.

Conclusions: We suggest that Ang II induced autophagy in mouse podocytes prior to apoptosis as an early adaptive cytoprotective mechanism for podocyte survival after Ang II treatment and the imbalance between autophagy and apoptosis causes podocyte injury.

Funding: Government Support - Non-U.S.

SA-PO287
Emodin Amediates Cisplatin-Induced Renal Tubular Cell Apoptosis Through Activation of Autophagy
Hong Liu,1 Wei Sun,2 Yi Ogamoto,1 Liubao Gu,1 1Dept of Nephrology, Affiliated Hospital of Nanjing Univ of Chinese Medicine, Nanjing, China; 2Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing Univ Medical School, Nanjing, China; 3Center for Diabetes Care, Education and Research, Jiangsu Province Inst of Geriatrics, Nanjing, China.

Background: Autophagy plays a key role in regulating cell survival. Emodin can activate the cisplatin-related protective autophagy pathway, thus explored the effects and mechanisms of emodin on cisplatin-induced apoptosis in NRK-52E cells by activation of autophagy.

Methods: NRK-52E cells were treated with cisplatin with or without emodin, cell morphology and expressions of cleaved Caspase-3 and autophagy makers LC3-II, and LC3-I were detected by fluorescence microscopy. The level of LC3 was tested after treated with Bafilomycin A1 and mTOR inhibitor rapamycin. Besides, morphological changes of apoptotic cells were observed and cell death was evaluated by FACS analysis. Finally, AMPK/mTOR signaling pathway related proteins were detected. Further, changes of cell morphology and the level of cleaved Caspase-3 were detected after the addition of compound C, which is an AMPK inhibitor.

Results: Emodin improved cisplatin-induced cell shape change, cell viability and caspase 3 cleavage. This protective effect of emodin was associated with increased LC3 conversion and occurrence of RFP-LC3 punctate structures. Further studies revealed that the suppressive effect of emodin on cisplatin-induced apoptosis could be abolished by suppression of autophagosome bafilomycin A1 and mimicked by activation of autophagy with rapamycin. Additionally, AMPK/mTOR signaling pathway was important for the induction of autophagy and inhibition of apoptosis.

Conclusions: Induction of autophagy could be an important mechanism by which emodin protected renal tubular cells against cisplatin-induced cell injury, and the potentially protective effect of emodin-induced autophagy may be attributed to the activation of AMPK and inhibiting mTOR signaling pathway. Emodin may have a therapeutic potential in the prevention of cisplatin-induced nephrotoxicity.

Autophagy in Renal Tubular Epithelial Cells Plays a Protective Role in Renal Fibrosis
Yong Kwon Kim,1 Sun-Ah Nam,2 Wan-Young Kim,2 Arum Choi,2 Yumi Kim,2 Ho Cheol Song,1 Jin Kim.2 1Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Seoul, Korea; 2Dept of Anatomy and Cell Death Disease Research Center, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.

Background: Renal tubulointerstitial fibrosis (TIF) is the final common pathway of various renal injuries. Autophagy is a cellular process of degradation of damaged cytoplasmic components and regulates cell death or proliferation. Recent studies reported that autophagy has protective role in renal TIF. However, the mechanism of autophagy...
regulating fibrosis is not fully understood. In this study, we investigated the proposed mechanisms of autophagy in renal TIF induced by UUO by using conditional knockout mice in which Atg7 is genetically ablated specifically in tubular epithelial cell (TEC).

**Methods:** Atg7-flanked mice were crossed with Ksp-Cre mice to generate TEC-specific Atg7 knockout mice (Atg7$^{−/−}$Ksp-Cre’). Unilateral ureteral obstruction (UUO) was performed. We examined the expression of epithelial-mesenchymal transition (EMT) markers. The expression of TGF-β, plasminogen activator inhibitor 1 (PAI-1) and p62 as markers of autophagy were examined. We determined apoptosis and proliferation of TECs with the expression of TGF-β, PAI-1 and p62 during renal TIF. Autophagy also regulates apoptosis and proliferation of TECs in mice with TEC-specific Atg7 deletion after UUO. TEC-specific Atg7 deletion enhanced renal TIF after UUO. TEC-specific Atg7 deletion increase expression of TGF-β, PAI-1 and p62 during renal TIF. Autophagy also regulates apoptosis and proliferation of TECs through the expression of c-Myc as a regulator of cell apoptosis and proliferation.

**Results:** In vitro, TGF-β treatment induced autophagy. In vivo, TEC-specific Atg7 deletion enhanced renal TIF after UUO. TEC-specific Atg7 deletion increase expression of TGF-β and enhance tubular EMT (decrease E-cadherin and increase α-smooth muscle antibody and vimentin) after UUO. In electron microscopy, TEC-specific Atg7 deletion results in ultrastructural alterations of TEC after UUO. TEC-specific Atg7 deletion increase expression of PAI-1, P62 after UUO. TEC-specific Atg7 deletion enhanced apoptosis and proliferation of TECs after UUO. The expression of c-Myc was significantly increased mice with TEC-specific Atg7 deletion after UUO.

**Conclusions:** Our data suggest that autophagy regulate expression through TGF-β, PAI-1 and P62 during renal TIF. Autophagy also regulates apoptosis and proliferation of TECs in mice with TEC-specific Atg7 deletion after UUO.

SA-PO289
Partial De-Differentiation of Parietal Epithelial Cells Caused by Reduced Expression of Sirt1 and Concomitant Increased Expression of p21 and CD133 in Diabetic Nephropathy Kazuhiro Hasegawa, Shu Wakino, Hiroshi Itoh. Keio Univ.

**Background:** We have previously reported the role of proximal tubular Sirt1 in diabetic nephropathy (DN). Parietal epithelial cells (PECs) and their cellular metabolism reportedly play a pivotal role in kidney. Sirt1 is a key energy sensor, whereas DN disrupts energy metabolism.

**Methods:** Thus, we examined the effect of Sirt1 expression in PECs on DN.

**Results:** In two DN murine models including streptozotocin-treated and db/db mice, expression of Sirt1 in proximal tubules and PECs was decreased at 8 weeks after the onset of DN, corresponding to the early stage of DN. Sirt1 expression was also downregulated in podocytes at 24 weeks. We further investigated the changes in PECs at 8 weeks. No change was found in the number of PECs. The morphology of all PECs showed hypertrophy, and some PECs contained autophagic vesicles, especially in the periphery or the border of the plasma membrane at basal lateral sides.

**Conclusions:** Partial de-differentiation of PECs could be related to loss/decay of variants APOL1 mRNA or to some extent defects in protein translation/decay. Since HIV AN occurs in APOL1 variants only, presence of APOL1 variants seems to be critical to sustain HIV-induced podocyte injury.

SA-PO290
APOL1 Variants are Critical to Induce Vitamin D Receptor (VDR) Down Regulation in Dedifferentiated Podocytes Shabirul Haque, Xqian Lan, Amrita Kaur Chawla, Riva Lederman, Rabani Bharara, Ramachandra prasanna Bongu, Ashwani Malhotra, Pravin C. Singhal, Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; 2Medicine, Ramhanh Health Care Campus, Haifa, Israel.

**Background:** APOL1 variants have been reported to contribute to higher prevalence of kidney diseases in African Americans. APOL1 gene is known to contribute to kidney cell injury but the mechanisms involved are not clear. Interestingly, renal biopsy specimens in kidney disease patients with APOL1 variants displayed lower podocyte expression of VDR compared with APOL1 homozygotes. However, the involved mechanism for lower APOL1 expression in these patients is not clear. Gene sequence alterations/mutations hamper either mRNA transcription defect or defects in protein translation. We hypothesized that mutation in APOL1 would lead to modulation of protein expression in podocytes.

**Methods:** Protein blots of human podocytes (HPs) stably expressing vector, APOL1G0, APOL1G1 and APOL1G2 were probed for APOL1 and reprogrammed for acina. RNAs were extracted with HPs expressing VDR, G0, G1 and G2 and CDNA were amplified with APOL1 specific primer. 293 T cells were transfected with equal amount of plasmids (vector, G0, G1 and G2) for 48 hours. Protein blots were probed for APOL1 and reprogrammed for acina. To evaluate stability/decay rate of APOL1 mRNA, APOL1/APOL1 variants expressing HPs were pulsed with actinomycinD and RNAs were harvested at different time points (0, 0.5, 1.0, 3.0, 8.0, and 24 hours) by Trizol method.

**Results:** APOL1 variants (G1/G2) expressing HPs displayed lower expression of APOL1 when compared APOLIG0. 293 T cells also displayed lower expression of G1 and G2. However, there was no difference in mRNA expression in APOL1G0 and APOL1G1/G2 expressing cells. Stability/decay kinetic assay revealed that variants (G1 and G2) of APOL1 mRNA decayed in an accelerated mode (more than 35%) during ½ to 24 hours after actinomycin D exposure.

**Conclusions:** These results suggest that APOL1 variants protein instability may be related to loss/decay of variant APOL1 mRNA or to some extent defects in protein translation/decay.

**Funding:** NIDDK Support

SA-PO291
Post-Transcriptional and Post-Translation Status of APOL1 (G0) and Its Variants (G1and G2) in Podocytes and 293T Cells Post-Transcriptional and Post-Translation Status of APOL1 (G0) and Its Variants (G1and G2) in Podocytes, 293T Cells, and Human and rabbit Podocytes Xinlian Yan, Gauri P. SA-PO292

**Background:** Dysregulated growth and loss of podocytes are important features of HIV-associated nephropathy (HIVAN). In a recent report, HIV induced programmed cell death in T cells has been implicated to pyroptosis as a consequence to inflammation formation. We hypothesized HIV would also be promoting podocyte loss through the induction of pyroptosis. We evaluated the role of HIV in podocyte NOD-like receptor family, pyrin domain containing (NLRP) 3 protein complexes (inflammasomes) formation both in vitro and in vivo.

**Methods:** Renal cortical sections of control and TG6 (HIVAN) mice (n=4) were labeled with inflammasome molecular markers (IMMs; NLRLP3, ASC, cleaved caspase-1 and IL-1β). Protein blots of renal tissues of control and TG6 mice were also probed for IMMs and actin (n=11). Protein blots of empty vector (EV) - and NL-3 (HIV)-transduced human podocytes (HPs) were probed for IMMs and actin (n=4). EV/HPs and HIV/HPs were evaluated for pyroptosis by PI staining under a fluorescence microscope as well as by FACS analysis. Effect of Tempol (SOD mimetic), caspase-1 inhibitors, and glyburide (an inhibitor of K-eflux inhibitor was evaluated on HIV induced podocyte pyroptosis by morphologic assay and FACS analysis.

**Results:** Renal cortical sections of HIV-transgenic mice (TG6) displayed increased podocyte expression IMMs. Renal tissues of TG6 mice also displayed enhanced mRNA

Underline represents presenting author.
expressions as well as protein expressions of IMM. Serum from Tg26 mice showed higher levels of IL-1β. HIV promoted pyroptosis in podocytes in a dose as well as time dependent manner. Since caspase-1 inhibitor not only attenuated podocyte expressions of caspase-1 and IL-1β in addition to protection against pyroptosis; this would confirm that HIV induced podocyte injury was mediated by caspase-1 activated complexes. Interestingly, HIV-induced podocyte pyroptosis could be partially inhibited by tempol as well as by glyburide.

Conclusions: These findings indicate that generation of reactive oxygen species and potassium efflux contributed to HIV-induced pyroptosis in podocytes.

Urinary Cytochrome C (Cyto C) Detects Subliminal Injury and Correlates with Apoptosis in Acute (AKI) and Acute on Chronic Kidney Disease (A-CKD)

Methods: In male Sprague Dawley rats (i) adeno-CKD was induced by diet supplementation with 0.025% adenine, days (d) 0 to 28 and monitored until d56 (n=8). On d56, AKI was induced in rats by a sub nephrotoxic (2mg/kg; n=8) or nephrototoxic (4mg/kg; n=8) cisplatin (Cis) dose and monitored until d91 (n=8 in matched controls). (ii) Aristolochic-acid nephropathy (AAN) was induced by AA-1 (0.2%km/g) ip for five days and monitored for d21 (n=6) or d42 (n=6) then driven 2mg/kg (n=6) or 4mg/kg (n=6) Cis and monitored to d28 and d49 respectively. Cyto C was measured by ELISA. Tubulointerstitial damage (TID) and TUNEL were quantified on d63.

Results: Cyto C levels increased in subliminal AAN (d1 to d7) and adeno-CKD (d3 to 21) without change in sCr, but increased in both CKD groups after 2mg/kg and 4mg/kg Cis dose in controls. In AAN, Cyto C levels increased progressively (d22 to d28) after inducing controls given 4mg/kg whereas Cyto C was lower after Cis on d42 to d49. Regardless of Cis dose, Cyto C increased in controls and adeno-CKD. A-CKD rats displayed diffuse medullary and cortical TID with positive TUNEL staining while injury in CKD alone was largely in outer medulla. In ANN peak Cyto C, 72 hours post Cis, correlated significantly with outer medullary TID and cortical apoptosis (R=0.85 and 0.86 respectively; p<0.01). In adeno fed rats, Cyto Correlated only with medullary apoptosis (R=0.79**). sCr correlated only with severe diffuse cortical TID (R=0.94*) (P<0.05).

Conclusions: Cyto C detected subliminal injury and correlated strongly with outer medullary apoptosis in A-CKD, which alone did not increase sCr. Cyto C is a useful biomarker for early detection of apoptotic kidney injury.

Assessment of Graphene Toxicity to Kidney Tubular Epithelial Cells and Cell Spheroids Using DNase Activity Probe

Methods: Non-modified graphene (50 μg/ml) exposed with cultured rat kidney tubular epithelial NRK-52E cells induced TUNEL-type DNA fragmentation usually associated with cytoxicity. Ramon spectroscopy showed the TUNEL-positive cells have significantly higher graphene content than TUNEL-negative cells. DNase activity was quantified in live cells using the oligonucleotide-based NIFR probe. Quantitative immunocytochemistry (qICC) was then used to measure apoptotic DNases such as caspase-activated DNase (CAD), endonuclease G (EndoG), and DNase I, and the marker of oxidative stress, heme oxygenase-1 (HO-1).

Results: The NIFR fluorescence and all of the above qICC markers were induced in NRK-52E cells by graphene exposure. In addition, a 50% colocalization of HO-1 with DNase activity was observed suggesting a possible link between oxidative stress and the DNases. Furthermore, we developed kidney spheroids (mini-kidneys) model by culturing NRK-52E cells using 3D hanging drop method, and tested the graphene toxicity in this model by measuring the DNase activity using the NIFR probe. The result showed a strong dose-dependent increase of DNase activity induced by graphene.

Conclusions: Measuring of DNase activity by using NIFR probe in combination with TUNEL assay and qICC are appropriate tools for assessment of graphene toxicity. Funding: NIDDK Support, Other U.S. Government Support, Veterans Administration Support

Identification of a Novel Bidirectional Regulatory Mechanism Involving AKT/B-Catenin and Anillin That Drives Podocyte Proliferation

Methods: Mutations of the F-actin binding protein Anillin (ANLN) have been shown to cause familial Fanconi anemia (FA). ANLN is a suspected modulation of phosphoinositol-3 kinase (PI-3K) signaling, specific interactions with PI-3K pathway intermediates and the role of these interactions in the pathogenesis of FS is remains unknown.

Results: siRNA-mediated gene knockdown studies, immunoblot and proliferation assays were performed by in vitro methods in conditionally immortalized human podocytes (CHP) to examine the effects of ANLN depletion on PI-3K pathway signaling in podocytes. CHP lines stably expressing GiFP-vector control or GiFP-ANLNKD were established via lentiviral transduction to characterize the effects of ANLN overexpression on PI-3K signaling in podocytes.

Conclusions: We evaluated the effect of ANLN overexpression and targeted ANLN knockdown (KD) on AKT activation in podocytes. Additionally, we explored the effects of pharmacologic inhibition of AKT on ANLN expression in podocytes. Finally, we examined the role of AKT-mediated activation of β-Catenin via the direct phosphorylation of serine 552 in podocyte ANLN expression. We determined that ANLN overexpression significantly attenuated AKT activation. Conversely, ANLN KD significantly enhanced AKT activation and upregulated AKT-mediated phosphorylation/activation of β-Catenin at serine 552. Pharmacologic inhibition of AKT also inhibited basal podocyte proliferation. Finally, we demonstrated that pharmacologic inhibition and targeted gene knock down of β-Catenin significantly attenuated podocyte ANLN expression.

Conclusions: These findings elucidate a novel mechanism of reciprocal regulation involving AKT/β-Catenin signaling and ANLN which may provide valuable insights into the role of ANLN in the pathogenesis of FS and other proliferative podopathies.
response to stress and survival, and is a target of mTORC2 and an upstream activator of mTORC1. mTORC1 is the master regulator of autophagy and metabolism. mTORC1 and 2 are also implicated in the regulation of cytoketosis and cell motility.

**Methods:** Using conditionally immortalized proximal tubular epithelial cells (PTECs) and podocytes originating from cystinosis patients and healthy donors, we performed biochemical and microscopic analysis of phosphorylation and activation of protein kinases in response to various stimuli.

**Results:** Phosphorylation of Akt1 and 2 was increased in cystinosis podocytes and PTEC in response to nutrient/growth factor replenishment and wounding of cellular monolayer. In podocytes, such increased phosphorylation, was associated with altered cytoketosis, disturbed focal adhesion sites and increased motility. Treatment with specific Akt inhibitor demonstrated a prominent decrease of motility and Akt phosphorylation. mTORC1 activation in response to nutrient replenishment was delayed in cystinosis PTECs accompanied with abnormal subcellular distribution of the kinase complex, as revealed by antibody staining of mTOR.

**Conclusions:** We demonstrate that cystinosis dysfunction is associated with disturbed signalling of protein kinases mTORC1 and Akt1 and 2.

**Intestinal Pericytes Decrease in Aged Mouse Kidneys**

Anna Maria Stefanska,1 Diana G. Eng,2 Natalya V. Kaverina,1 Jeremy Stuart Duffield,3 Jeffrey W. Pippin,3 Stuart J. Shankland.1

1 Division of Nephrology, Dept of Medicine, Univ of Washington, Seattle, WA; 2 Biogen Idec, Cambridge, MA

**Background:** With increasing age, the kidney undergoes characteristic changes in the glomerular and tubulo-interstitial compartments, which are ultimately accompanied by a reduced kidney function. Studies have shown age-related loss of perivascular cells. Normal perivascular cell tone, function and survival depend on neighboring pericytes. Pericyte detachment leads to vascular damage, which can be accompanied by their differentiation to fibroblasts and myofibroblasts, a state that favors matrix production. Here we aim to determine the impact of age on pericyte populations.

**Methods:** To better understand the fate of pericytes in the aged kidney, 27-month-old mice were studied. Picrosirius red staining was performed to evaluate kidney fibrosis. Histological sections were stained against endothelial antigen CD31 together with pericyte markers PDGFRα and NG2. Additionally, immunoreactivity of myofibroblast marker αSMA was assessed together with pericytes.

**Results:** Compared to 3 month-old young adult mice, aged kidneys showed a substantial decrease in capillaries, identified by CD31 staining, in both cortex and medulla. This was accompanied by a marked decrease in surrounding NG2+/PDGFRα+ pericytes. This decrease was more pronounced in the medulla. Capillaries devoid of pericytes were typically dilated and podocytes originating from cystinosis patients and healthy donors, we performed biochemical and microscopic analysis of phosphorylation and activation of protein kinases in response to various stimuli. In podocytes, such increased phosphorylation, was associated with altered cytoketosis, disturbed focal adhesion sites and increased motility. Treatment with specific Akt inhibitor demonstrated a prominent decrease of motility and Akt phosphorylation. mTORC1 activation in response to nutrient replenishment was delayed in cystinosis PTECs accompanied with abnormal subcellular distribution of the kinase complex, as revealed by antibody staining of mTOR.

**Conclusions:** We demonstrate that cystinosis dysfunction is associated with disturbed signalling of protein kinases mTORC1 and Akt1 and 2.

**Interactions of Urotensin II and Mitophagy in Diabetic Nephropathy and Its Implications on Drug Design**

Guang-Jong Chen, Fei Wu, Ai-hua Zhang, Dept of Nephrology, Peking Univ Third Hospital, Beijing, China

**Background:** Urotensin II (UII), an important vasoactive neuropeptide, and the processes of mitophagy have been considered as possible therapeutic targets for treating diabetic nephropathy (DN). The present study is to determine the interaction between UII and the process of mitophagy under the setting of DN.

**Methods:** Immunohistochemistry and western blot analysis were conducted on the protein extracts harvested from the kidney tissues of DN mice that were induced eighteen weeks after the injection of streptozotocin. For in-vitro cell experiment, HK-2 cells were cultured and treated with different concentrations of UII (10⁻³-10⁻⁷ mol/L) for 12 h and 3-MA treatment was used as a negative control. The cell protein extracts were then analyzed by western blot. For immunohistochemistry and western blot analysis, BNIP3 was used as a marker for mitophagy.

**Results:** Immunohistochemistry and western blot analysis showed that the expressions of UII and BNIP3, marker of mitophagy, are upregulated for DN kidney compared to that of controls. In-vitro cell experiment results also demonstrate UII can upregulate BNIP3. Further data indicates that UII expression is positively associated with the expression of BNIP3.

**Conclusions:** Our results indicate that UII expression can upregulate mitophagy in DN. Past studies already demonstrate that mitophagy can have a therapeutic role in DN. Our results carry the implications that UII and its effect on the process of mitophagy presents potential therapeutic implications for DN.

**Reduction in CTGF Leads to Increased Proliferation Through Influences on Claudin-1 and Extracellular Matrix Protein Spondin 2**

Leighton R. James, Yongxin Gao. Medicine, Univ of Florida, Jacksonville FL.

**Background:** Accumulation of extracellular matrix is a characteristic feature of diabetic kidney disease. We have recently demonstrated that connective tissue growth factor (CTGF) mediate influences in extracellular matrix production, proteinuria and scarring in mice. In addition, CTGF may have anti-proliferative properties. In specific human neoplasm (breast, colon), increased CTGF have been linked to reduced proliferation, improved response to therapy and prognosis but data is not consistent. On the other hand, metastatic melanoma progression correlates with CTGF levels and inhibition of CTGF reduces invasion and metastasis.

**Methods:** To define a possible role for CTGF in proliferation, embryonic fibroblasts (MEF) generated from wild-type and a previously reported CTGF knock mouse line were studied. Expression array (Illumina) was used to identify changes in gene expression in MEF with CTGF expression was validated by Immunoblotting. Inhibition of MAPK (SP600126, SB203580 and U0126) were used to assess role of MAPK in glucose-mediated CTGF expression by cultured MEF.

**Results:** CTGF gene disruption lead to enhanced proliferation (3-fold) in CTGF knockout cells compared with wildtype cells. Reduced CTGF led to 50% decreased expression of the gene for the extracellular protein, procollagen 4, alpha 2 (Col4a2; confirmed at protein level)) in association with 2.8-fold increased expression of claudin-1, a member of the tight junction proteins. In addition, there was a 3.2-fold increased expression of spondin-2 and a 1.6-fold increased expression of Secreted protein, acidic and rich in cysteine-like 1 (SPARC1). Immunoblotting confirmed the observation for claudin-1. Glucose induced CTGF expression (2-3 fold) was attenuated by inhibitors of p38MAPK and JNK, but unaffected by inhibition of ERK (p42/44 MAPK).

**Conclusions:** In MEF, targeted gene disruption of CTGF led to increased proliferation and altered matrix protein linked to increased expression of claudin 1 and other extracellular protein. Secondly, glucose-induced CTGF level is mediated by MAPK (p38 and JNK). Targeted alteration in CTGF along with one or more of these extracellular protein may offer new approaches to manage glomerulosclerosis.

**miR21 Upregulates YY1 to Increase Renal Cell Apoptosis in Diabetes**

Adam Kost,1 Sitai Liang,2 Samy L. Habib,2 Geriatric Research, Education and Clinical Affairs (GRECAH), CTR, South Texas Veterans Health System, San Antonio, TX; 2 Cellular and Structural Biology, The Univ of Texas Health Science Center, San Antonio, TX.

**Background:** The regulation of miRNAs in response to hyperglycemia that contributes to the pathogenesis of kidney disease has been underscored.

**Methods:** In the current study, we investigated the role of miR21 in regulation of cells apoptosis in human renal proximal tubular cells (HK2) cells exposed to high glucose and in type II diabetes mouse model.

**Results:** Cells pretreated with either miR21 inhibitor or antisense before exposed to HG resulted in decrease YY1 expression and decrease cleavage of caspase 3. Nuclear extracts from HK2 cells exposed to high glucose for 48hrs showed increase in binding of YY1 to the YY1 promoter element in nuclear extracts of cells EMSA. On the other hand, pretreatment with miR21 inhibitor or antisense significantly decrease the binding of miR21 to YY1 in nuclear extracts of cells grown in NG or treated with HG. The DNA-protein complexes were significantly decreased in the presence of the YY1 antibody, indicating that YY1 is indeed a component of these complexes. Transfected the cells with promoter/reporter construct of miR21 showed significant increase in miR21 promoter activity in cells exposed to HG while cells pretreated with miR21 inhibitor reverse the effect of HG. In addition, significant increase in the percentage of TUNEL-positive tubular cells stained in the kidney sections of db/db mice compared to kidney sections of the wild type mice. Quantitation of miR21 by real-time PCR showed significant increase miR21 levels in kidney of diabetic mice (db/db) compared to kidneys from wild type mice. Immunostaining analysis of miR21 showed that majority of miR21 staining within the tubular cells and glomerular compartments.

**Conclusions:** In summary, expose renal cells to HG and increase hyperglycemia in kidney of diabetic mice resulted in significant increase in miR21. Increase binding of YY1 to miR21 under HG condition suggesting the important role of miR21 in regulating YY1 to increase cell apoptosis. The data provide a novel role of miR21 as a target for controlling renal cell death that induced by hyperglycemia during diabetic nephropathy.

**The Role of miR-302 and Let7 in Macrophage Polarization**

Thomas K. Dodd, John Crean, Letizia De Chiara, Orina Belton. Diabetic Complications and Renal Disease, Univ College Dublin, Dublin, Ireland.

**Background:** Recent advances in the pathogenicity of renal injury highlighted the critical role of the immune system in the onset and resolution of disease. Monocytes canto differentiate along two pathways: pro-inflammatory (M1) due to the secretion of cytokines such as IL-6 and a pro-resolution attributable to the secretion of cytokines such as IL-10. Bane/Fet et al. have suggested that the ratio of M1 and M2 macrophages is controlled
interplay between two micro RNAs, miR302 and Let7. We have recently shown that the silencing targets of miR302 and Let7 are the TGFβ type II and type I receptors respectively and hypothesize that this circuitry plays a critical role in macrophage differentiation.

Methods: The pro-resolving lipid mediator, conjugated linoleic acid (CLA), inhibits the acquisition of a pro-inflammatory macrophage phenotype by priming monocytes towards an anti-inflammatory phenotype. To identify pathways associated with this phenotype we performed proteomic analysis of THP-1 cells treated with CLA. Exosomes were isolated from urine samples taken from patients with renal injury and analyzed for miRNA expression. Renal cells were transduced with miR302 and let7 virus. TGFβ receptor expression and signaling was analyzed by western blot. Additionally, THP-1 cells were co-transduced with miR302 and let7 and their effects on macrophage differentiation as assessed for expression of CD68 and CD206.

Results: Bioinformatic and Western blot analysis revealed enrichment of the TGFβ signaling pathway in THP-1 cells treated with CLA. miR302 expression was increased in the urine of patients compared to controls. Cells transduced with miR302 and Let7 displayed low levels of expression of the TGFβ type II and type 1 receptors respectively and dampened Smad3 phosphorylation. miR302 and let7 prevented renal epithelial cell dedifferentiation. THP-1 cells transduced with both miRs demonstrated similarly enhanced plasticity. Manipulation of this circuitry results in enhanced cell plasticity. In vitro studies suggest that this results in the generation of pro-resolution cellular phenotypes in both resident cells and macrophages.

Dopamine D2 Receptor Regulates Wnt3/-β-Catenin Signaling and Apoptosis in Human Renal Proximal Tubule Cells
Fei Han, Prasad Konkalattam, Jianghua Chen, Pedro A. Josè, Ines Armando. 1 Kidney Disease Center, First Affiliated Hospital of China Medical University, Hunheer, Shenyang, China; 2 Dept of Medicine, School of Medicine, University of Maryland, Baltimore, MD.

Background: Dopamine D2 receptor (D2R) in the kidney has a direct role in regulating renal tubulointerstitial injury and, blood pressure. Some common single nucleotide polymorphisms (D2R SNPs) with a frequency of 5% have been identified in the human D2R gene and are associated with decreased D2R expression and function.

Methods: We measured apoptosis and activation of Wnt3/-β-catenin signaling pathway in human renal proximal tubule cells (RPTC) carrying these D2R SNPs (RPTC-D2R SNPs), and in RPTC carrying wild type (RPTC-D2R WT).

Results: RPTC-D2R SNPs showed increased apoptosis compared with RPTC-D2R WT (1.0% vs 0.8%; P<0.05; protein: 133±4% vs 100±0.3%; P<0.05). RPTC-D2R SNPs showed activated Wnt3/-β-catenin signaling pathway demonstrated by decreased β-catenin phosphorylation (64±4% vs 100±0%; P<0.05) and increased expression of downstream pro-apoptotic factors Bax (136±4% vs 100±0%; P<0.05) and FasL (12±5% vs 11±0%; P<0.05). Silencing D2R in RPTC-D2R WT increased Wnt3/-β-catenin phosphorylation and increased expression of Bax and FasL. In contrast treatment of RPTC-D2R WT with a D2R agonist (quinpirole, 1µM, 24h) or transfection of RPTC-D2R SNPs with a D2R inhibitor (Rho327; which restored D2R expression decreased Wnt3/-β-catenin phosphorylation and decreased β-catenin phosphorylation and increased Bax and FasL expression. Moreover Wnt3/-β-catenin silencing in RPTC-D2R SNPs increased β-catenin phosphorylation (132±5% vs 100±0%; P<0.05), decreased Bax (68±2.5% vs 100±0%; P<0.05) and FasL (70±5% vs 100±0%; P<0.05) expression and reduced the number of apoptotic cells (6±1.0% vs 12±0.9%; TUNEL positive cells, P<0.01).

Conclusions: D2R protect cells from apoptosis by regulating the Wnt3/-β-catenin pathway. These results may have clinical relevance for subjects bearing D2R SNPs.

SA-PO304
Effect of Omega-3 Fatty Acids on Nrf-2 Expression and Its Regulation in Cyclosporine Induced Rat Model
Wen Suk An,1 Eu Gene Jeong,1 Hansae Kim, 2 Dongyeol Lee,1 Yun Jung Oh,1 Joon Hyuk Kim,1 Jung Hoon Yoon,2 Young Ki Son,1 Seong Eun Kim.1 1 Dept of Internal Medicine, Dong-A University Hospital, Busan, Republic of Korea; 2 Dept of Internal Medicine, Bong Seng Memorial Hospital, Busan, Republic of Korea.

Background: Cyclosporine (CsA)-induced kidney injury is characterized by kidney dysfunction with inflammatory cell infiltrations, apoptosis, and fibrosis. Although Nrfa2 regulates antioxidant and anti-inflammatory process in kidney injury model, it is not clear omega-3 fatty acid (FA) role on Nrf-2 expression. The aim of this study is to investigate whether omega-3 FA (300 mg/kg/day) treatment attenuates the renal injury and improve Nrf-2 expression and release of HMGB1 from the cells. Both pharmacologic inhibition and siRNA-mediated knock-down of HMBG1 led to reduced cell viability as determined by MTT assay.

Results: Following exposure to a high salt diet, pharmacologic inhibition of HMBG1 resulted in more severe kidney damage as assessed by the percentage outer medullary area with tubular dilatation and protein casts, when compared with vehicle-treated rats. Inhibition of HMBG1 was associated with a significant increase in tubular cell apoptosis in comparison to vehicle treatment on TUNEL staining. Also, inhibition of HMBG1 led to significantly higher urinary albumin excretion and blood pressure at day 21 compared with vehicle treatment. Exposure of NRK52E cells to hyperosmotic medium resulted in increased expression of Nrf-2 and related inflammation and fibrosis. The expression of Nrf-2 was decreased in CsA-treated rats but Nrf-2 activation related with urinary albumin excretion and blood pressure at day 21 compared with vehicle treatment.

Conclusions: HMBG1 plays an important role in renal tubulointerstitial cell survival during hypertensive stress.

KIM-1-Mediated Phagocytosis Defines a New Mechanistic Paradigm for Kidney Epithelial Cells, which Involves Autophagy and Anti-Inflammatory Antigen Presentation
Craig R. Brooks, Melissa Y. Yeung, Takaharu Ichimura, Joseph V. Bonventre. 1 Renal Div; Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background: The expression of kidney injury molecule-1 (KIM-1), the protein most upregulated during proximal tubular epithelial cell apoptosis (PTC) and transition of PTCs into senescent phenotypes. The processing of phagocytosed cells to the lysosome can determine the immunogenicity of antigens derived from the phagosomal cargo. Here we compare the phagocytic processing of KIM-1-expressing PTCs to that of professional phagocytes and establish distinct mechanisms.

Methods: LLC-PK1 cells expressing KIM-1 were exposed to apoptotic cells. LC3 localization to the phagosome, phagosome acidification and degradation were measured by live cell imaging, phagosome isolation and western blotting. NADPH oxidase (NOX) activity was blocked with diphenyleneiodonium and reactive oxygen species (ROS) were measured with fluorescent probes. MHC presentation was measured in primary PTCs directly using specific antibodies by flow cytometry. Functional implications were determined by activation of CD4+ and CD8+ T cells.

Results: KIM-1 binds to and induces phagocytosis of apoptotic cells within ~5-30 min, similar to professional phagocytes. Following uptake, however, PTCs process phagosomes more slowly than professional phagocytes, with delayed phagosome acidification and degradation (4-12 hrs v 1-2 hrs). Mechanistically, PTCs do not upregulate NOX-induced production of ROS, a process necessary for efficient acidification and degradation of the phagosome. LC3 associated phagocytosis (LAP), an important NOX-dependent feature of professional phagocytic function, is not observed in PTCs. PTCs instead induce canonical autophagy to clear phagocytosed debris. Delayed phagosomal processing and increased autophagy result in increased PTC antigen presentation and decreased T cell activation.

Conclusions: Autophagy plays a critical role in KIM-1-mediated phagocytosis in PTCs, distinguishing the epithelial cell process from the mechanism used by professional phagocytes. The PTC has evolved a distinct process which leads to anti-inflammatory antigen presentation which is beneficial in acute kidney injury.

A apoptotic cells activate AMPK and inhibit proximal tubular cell (PTC) growth without change in intracellular energy stores

Nephrology, University of Illinois at Chicago, Chicago, IL; Nephrology, Stony Brook University Medical Center, Stony Brook, NY.

Background: Apoptosis plays an indispensable role in the maintenance and development of tissues. We have shown that receptor-mediated recognition of apoptotic target cells by viable kidney PTCs inhibits the proliferation and survival of these viable PTCs. Here, we examined the effect of apoptotic target cells on PTC cell growth (cell size during G1 phase of cell cycle).

Methods: We used BUMPT cells, a conditionally immortalized PTC line, as responder cells. BUMPT cells, induced to undergo apoptosis in several ways, were used as apoptotic targets. Autophagy is the process by which cells remove and recycle unwanted structures, contributing to intracellular homeostasis and energy production. Cardiac autophagy activation led to decreased activity of its downstream target, ribosomal protein S7 kinase (p70S6K) and concomitant inhibition of cell growth. Importantly, these events occurred without detectable change in intracellular levels of AMP, ADP, or ATP. Inhibition of AMPK, either pharmacologically by compound C or molecularly by shRNA, diminished the effects of apoptotic targets, and largely restored p70S6K activity and cell size to normal levels. Autophagic targets also inhibited Akt, a second signaling pathway regulating cell growth. Expression of a constitutively active Akt construct partially relieved cell growth inhibition, but was less effective than inhibition of AMPK. Inhibition of cell growth by apoptotic targets was dependent on physical interaction between apoptotic targets and PTCs, but independent of phagocytosis.

Conclusions: We conclude that receptor-mediated recognition of apoptotic targets mimics the effects of intracellular energy depletion, activating AMPK and inhibiting PTC cell growth. By acting as sentinels of environmental change, apoptotic death may enable nearby viable cells, especially non-migratory epithelial cells, to monitor and adapt to local stresses.

The Effect of Uremia on Cardiac Autophagy

William White, Steven Michael Harwood, Petros Andrikopoulos, Muhammad M. Yaqoob.

Background: Autophagy is the process by which cells remove and recycle unwanted structures, contributing to intracellular homeostasis and energy production. Cardiac autophagy has a role in maintaining heart protection and ventricular remodeling, and decreasing autophagy is central to aging. Evidence suggests these processes are disorderd in CKD. We have previously demonstrated that autophagy may be down-regulated at a transcriptional level in uremic hearts, and now present data concerning cardiac autophagic-protein expression (LC3, p62) and senescence marker p53 in models of uremia.

Methods: In Vitro Rat cardiac myoblast cells (H9C2) were cultured in the presence of indoxyl sulphate (IS) to simulate a uremic milieu, for 24 or 48 hrs. In Vitro, to mimic nephrogenic glucocorticoid, PTCs were exposed to albumin. Autophagy was assessed in tissue samples from mice and primary PTCs. Steady state LC3-II, an autophagy marker was quantified by immunoblot. Autophagosomes (APs) were visualized in cell culture using fluorescent markers and in renal cortical tissue using immunohistochemistry. Mitochondrial morphology and colocalization with autophagosomes were imaged using confocal microscopy. Reactive oxygen species production was measured using a 2',7'-dichlorofluorescin diacetate assay.

Results: Exposure to excess albumin induced defective autophagy and mitophagy in vitro. In renal cortices, proteinuria decreased both the number of LC3-II positive APs and the amount of LC3-II detected in cell lysates. Albumin-exposed cells accumulated damaged mitochondria with altered mitochondrial function and morphology. Albumin exposure caused mitochondrial dysfunction as evidenced by decreased oxygen consumption rate from coupled ATP production. Increasing albumin exposure time caused an increase in ROS production.

Conclusions: Dysfunctional autophagy caused by proteinuria likely contributes to tubular cell toxicity leading to renal progression.

Decorin Potentially Alleviates TGF-β1 Induced Podocyte Injury by Inactivating mTORC1 and Increasing Autophagy

Xing Mao, Zhigang Zhang, Huijuan Wu. Dept of Pathology, Shanghai Medical College, Fudan Univ, Shanghai, China.

Background: TGF-β1 is the major factor mediating podocyte injury during mesangial proliferative glomerulonephritis (MsPGN), manifested by decreased autophagy, cytoskeleton relaxation and increased apoptosis. Decorin (DCN), mainly secreted by mesangial cells (MCs) in glomeruli, is a natural antagonist of TGF-β1 and has been shown to protect against cell death induced by TGF-β1 (DCN2A). This study aims to investigate the possibility of any possible differences between DCN2A expression, VC and CVD in a CKD population.

Methods: DCN2A expression was determined in epigastic arteries (n=43) from patients with end-stage renal disease (ESRD) undergoing living donor renal transplantation (RTX). All arteries were scored for degree of calcification in percent. Coronary artery calcification (CAC) score was also obtained.

Results: The arterial expression of DCN2A was significantly associated with VC (p=0.01, p=0.04), CVD (p=0.0002), CAC score (p=0.008, p=0.5) and diabetes mellitus (p=0.05). In addition, arterial DCN2A expression was associated with MGP (p=0.007, p=0.4) and RUX2 (p=0.046, p=0.3) expression in artery, both of which are involved in osteogenic transformation of vascular smooth muscle cells.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Albumin Endocytosis in the Proximal Tubule Causes Accumulation of Dysfunctional Mitochondria

Renal, Boston Univ Medical Center, Boston, MA.

Background: Proteinuria is a major risk factor for chronic kidney disease progression. Furthermore, exposure of proximal tubular epithelial cells (PTEC) to excess albumin promotes tubular atrophy and fibrosis, key predictors of progressive organ dysfunction. The mechanism by which protein exposure causes tubular cell injury is unclear. We hypothesize that albumin endocytosis causes tubular cell injury by inhibiting autophagy, including mitophagy, resulting in an accumulation of dysfunctional mitochondrial leading to enhanced ROS production, mitochondrial and cellular injury.

Methods: The effect of proteinuria was examined both in vivo and in vitro experiments. Proteinuria was induced in mice by injection of a sheep nephrotic serum that causes acute immune-complex glomerulonephritis with massive proteinuria by 24-48 hrs. In Vitro, to mimic nephrogenic glucocorticoid, PTECs were exposed to albumin. Autophagy was assessed in tissue samples from mice and primary PTECs. Steady state LC3-II, an autophagy marker was quantified by immunoblot. Autophagosomes (APs) were visualized in cell culture using fluorescent markers and in renal cortical tissue using immunohistochemistry. Mitochondrial respiration was measured in primary cells. Mitochondrial morphology and colocalization with autophagosomes were imaged using confocal microscopy. Reactive oxygen species production was measured using a 2',7'-dichlorofluorescin diacetate assay.

Results: Exposure to excess albumin induced defective autophagy and mitophagy in vitro. In renal cortices, proteinuria decreased both the number of LC3-II positive APs and the amount of LC3-II detected in cell lysates. Albumin-exposed cells accumulated damaged mitochondria with altered mitochondrial function and morphology. Albumin exposure caused mitochondrial dysfunction as evidenced by decreased oxygen consumption rate from coupled ATP production. Increasing albumin exposure time caused an increase in ROS production.

Conclusions: Dysfunctional autophagy caused by proteinuria likely contributes to tubular cell toxicity leading to renal progression.

Funding: Government Support - Non-U.S.
Background: The inflammasome may be superior to targeting apoptosis. Caspase-1, but not of caspase-3, ameliorates diabetic podocyte injury. Markers of inflammasome activation (Nlrp3, caspase-1 cleavage) are reduced by 80%. Then, we inject BSA intraperitoneally in these RTN1-A knockdown tubular cell-specific RTN1-A shRNA knockdown mice, in which RTN1-A expression was reduced by 80%. These data suggest that RTN1-A mediated HSA-induced ER stress and apoptosis in tubular cells of RTN1-A knockdown mice and their control littermates to generate albumin overload mouse model. Mice with BSA injection developed significantly increased proteinuria in both knockdown and wild-type mice. However, RTN1-A knockdown mice developed less tubulointerstitial injury than wild-type mice. Also, there was less apoptosis and lower expression of ER-stress markers in tubular cells of RTN1-A knockdown mice than wild-type mice.

Conclusions: These data suggest that RTN1-A likely mediates proteinuria-induced tubular cell injury and progression of kidney disease through ER stress and apoptosis.

Endothelial Autophagy Is Essential for Vascular Lipid Homeostasis
Kumiko Torisu,1 Subodh Verma,2 Takehiro Torisu,2 Krishna K. Singh,2 Toren Finkel.1 1Center for Molecular Medicine, National Heart, Lung, and Blood Inst, NIH, Bethesda, MD; 2Div of Cardiac Surgery, St. Michael's Hospital, Univ of Toronto, Toronto, ON, Canada; 3Graduate School of Medical Sciences, Kyushu Univ; Fukuoka, Japan.

Background: Cardiovascular disease is one of the common complications in chronic kidney diseases. It is known that autophagy plays a critical role in the course of kidney diseases. The resulting cardiovascular diseases are presumably regulated by autophagy. However the physiological role of autophagy in the vascular endothelial cells remains poorly understood.

Methods: Using human umbilical vein endothelial cells (HUVECs), induction of autophagy by ox-LDL, and uptake and transcytosis of LDL are analyzed. To inhibit autophagy pharmacologically, chloroquine is used. The essential autophagy gene, Atg7 shRNA-mediated knockdown are performed to inhibit autophagy genetically. To assess an acute and chronic in vivo model of lipid exposure, we generated endothelial specific Atg7 knockout in ApoE deficient mice (Atg7/−/Apoe KO).

Results: Ox-LDL induced autophagosome formation in HUVECs. Moreover, native or ox-LDL appeared to be engulfed within autophagosomes by live cell imaging and electron microscopy. Atg7 knockout or pharmacological inhibition of autophagy resulted in higher accumulation of intracellular LDL, suggesting that in vascular endothelial cells, autophagy is one of the degradation machinery of excess lipids. As an acute model of lipid exposure in vivo, Atg7/−/Apoe mice showed longer retention of ox-LDL within the retina after infusion of Dil-ox-LDL. In a chronic model of lipid excess, we analyzed atherosclerosis in Atg7/−/Apoe KO mice. Atg7/−/Apoe KO mice demonstrated markedly increased atherosclerosis.

Conclusions: In endothelial cells, autophagy appears to play a critical role in regulating excess intracellular lipids. Moreover, in both acute and chronic in vivo model, endothelial autophagy is essential to attenuate LDL accumulation within endothelial layer. Prevention of the decline in autophagy flux accompanied by kidney diseases pharmacologically might be beneficial to treat atherosclerotic diseases.

Targeted Mutations at the p66 Locus Antagonize Stem Cell Aging and Delay Expression of Senescent Phenotypes in Diabetic Kidneys
Himanshu Vashista,1 Antonio G. Jimenez,2 Sixto G. Giusti,3 Allyson E. Bradley,1 Ashwani Malhotra,1 Pravin C. Singhal,1 Leonardo G. Meggs.1 1Nephrology, ITR, Ochsner Health System, New Orleans, LA; 2Nephrology, Feinstein Inst for Medical Research,North Shore Long Island Jewish Health System, New York, NY.

Background: Senescence has important implications for the biologic function of tissue stem cells, which maintain tissue homeostasis by replacement of old or dying cells and via the repair of tissue injury. The p66 longevity gene plays a key role in the activation of gene programs that induce senescent and apoptotic phenotypes. We hypothesize gene base strategies targeting p66 will delay or prevent stem cell senescence and premature aging phenotypes in diabetic kidneys.

Methods: Mesenchymal stem cells (MSCs) were isolated from kidneys of p66 KO mouse (p66 KO-MSCs) using established methods and plated in high glucose (H3) containing media. Microarray was used to profile secreted factors expressed by MSCs. p66 KO diabetic mice were generated and evaluated survival of MSCs in diabetic kidneys, glucose metabolism, resistance to oxidative stress and autophagy. Confocal imaging and immunofluorescence staining was used to identify MSCs, podocytes, renal tubular cells and to detect senescent protein p16(Ink4a) and proliferation marker Ki-67.

Results: Cultured p66 KO-MSCs at HG escape entry to senescence and apoptotic programs and display enhanced secretion of IGF-1, VEGF and HGF. Microarray detected unexpected crosstalk talk between p66 and Wnt regulatory genes that antagonize senescence. Kidney sections from p66 KO diabetic mice show increased numbers of MSCs in glomeruli and tubules, with barely detectable histologic markers of aging and near normal urine albumin excretion. Kidney nuclei staining (+) for p16(Ink4a) was upregulated, whereas p16(Ink4a) was downregulated.

Conclusions: These findings suggest a genetic link between p66 longevity gene, stem cell aging and senescence phenotype(s) in diabetic kidneys.

The Full Time Course and Localization of mTOR Activation in Compensatory Renal Hypertrophy
Jinxian Xu,1 Meichu Cheng,1 Jianchun Yuan,1 Kang-Chun Che.1 1Cellular-Biology & Anatomy and Medicine, Georgia Regents Univ, Augusta, GA; 2Medicine, Vanderbilt Univ, Nashville, TN.

Background: Previous studies documented an essential role for mTOR activation in mediating compensatory renal hypertrophy induced by unilateral nephrectomy (UNX) but the time course and localization of the mTOR activation are unclear.

Methods: 8-week-old male FVB/NJ mice were subjected to right UNX or sham surgery, followed by sacrifice at different time points to collect left kidney and determine the time course and localization of mTOR activation by immunoblotting and immunofluorescence staining for phospho-S6K1 and phospho-p56, along with nephron segment-specific markers.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: In this inbred mouse strain, UNX induced 8.27 ± 0.93% renal hypertrophy within 1 week. The hypertrophy continued to rise up to 12.74 ± 3.32%, 39.78 ± 7.06%, 45.56 ± 7.72%, 45.92 ± 2.80%, 49.13 ± 2.09%, and 50.26 ± 9.87% by 48 hours, 1 week, 2 weeks, 1 month, 3 months, and 4-7 months, respectively. Thus, the hypertrophy is complete within 3-4 months, with ~50% hypertrophy on average. Immunoblotting indicated that UNX increased the expression of CCN3 within 3 min, indicative MTOR activation, but had no effect on Akt, TSC2, AMPK, or ERK1 and ERK2 phosphorylation in the remaining kidney at any time points examined. The mTOR activity peaked at 24 h, remained at the plateau level even after 48 h, declined but still activated by 1 month, and returned to the basal level by 3 months in UNX. Immunofluorescence staining visualized the most prominent mTOR activation in the cytoplasm of LTL-positive tubules in response to UNX, although the basal mTOR activity in the kidney of sham-operated control mice was largely confined in THP-, calbindin-, and DBA-positive tubules, with very little in LTL-positive tubules. Therefore, mTOR activation represents a very modest reduction of VEGF-A secretion indicating that mTOR and p42/44 MAPK may act via parallel pathways in VEGF-A regulation. Finally, we demonstrate that the hypertrophy continued to rise up to 23.66 ± 3.32%, 69.53 ± 10.54%, 84.81 ± 13.73%, and 91.75 ± 15.92% by 48 hours, 1 week, 2 weeks, and 3 months, respectively, post UNX.

EGF Dependent Regulation of VEGF-A Secretion by Proximal Tubule Cells
Diana Zepeda-Orozco,1 Hsiang M. Wen,1 Nandita S. Raikwar,1 2 Bruce P. Thomas.2
1Pediatrics, Univ of Iowa, Iowa City, IA; 2Internal Medicine, Univ of Iowa, Iowa City, IA.

Background: Vascular endothelial growth factor A (VEGF-A) plays a critical role in periarticular capillary development by promoting vasculogenesis and angiogenesis. It is now recognized that there is increased expression of VEGF-A by proximal tubular epithelial cells in ischemia reperfusion injury and in chronic tubulointerstitial injury. Although hypoxia is known to induce expression of VEGF-A at the protein level in this cell type, it remains unclear how hypoxia affects the regulation of VEGF-A at the transcriptional level and in vivo, the mechanisms regulating VEGF-A secretion by proximal tubule epithelial cells in normoxia has not been established.

Methods: We utilized HK2 cells, an immortalized human proximal tubule cell line, to characterize the epithelial growth factor (EGF)-dependent regulation of VEGF-A secretion by proximal tubular epithelial cells.

Results: The intracellular expression of VEGF-A, EGF receptor and upregulation of mTOR and p42/44 MAPK pathways. P42/44 MAPK dependent even in normoxia. EGF stimulates HIF1-a and VEGF-A via activation of the EGF receptor, and stimulation of HIF1-a. EGF stimulates proliferation of HK2 cells via the secretion of HGF. EGF-induced VEGF-A expression is mediated by a canonical pathway that is partially dependent on MAPK.

Conclusions: The present study indicates that there is increased expression of VEGF-A by proximal tubular epithelial cells in ischemia reperfusion injury and in chronic tubulointerstitial injury. It is now recognized that there is increased expression of VEGF-A by proximal tubular epithelial cells in ischemia reperfusion injury and in chronic tubulointerstitial injury. Although hypoxia is known to induce expression of VEGF-A at the protein level in this cell type, it remains unclear how hypoxia affects the regulation of VEGF-A at the transcriptional level and in vivo, the mechanisms regulating VEGF-A secretion by proximal tubule epithelial cells in normoxia has not been established.

Selective Regulation of a Novel Truncated CCN3 Protein by TGFβ1 in Human Tubule Epithelial Cells
Matthew Potting,1 Bruce L. Riser,2 Mark E. Dockrell.1
1SWT Inst for Renal Research, London, United Kingdom; 2BLR Bio, WI.

Background: CCN3 is a member of the matricellular CCN family of proteins along with the structurally similar CCN2/CTGF, a powerful fibrotic agent, but recent work supports hypothesis that CCN2 and CCN3 are in opposition to each other regulating fibrosis. In renal cells, CCN3 is induced by TGFβ. The truncated form of CCN3 in HT-1080 cells in vitro has been shown to counter regulate the expression of CCN2 and CCN3 in the vertebral nucleus pulposus and in mesangial cells. We have previously characterised TGFβ1 induction of CCN2 in proximal tubule epithelial cells (PTEC) here we investigate the expression of CCN3 in human PTEC and its potential regulation by TGFβ1.

Methods: Primary human PTEC were cultured on collagen IV in supplemented medium. At 80% confluence cells were treated with TGFβ1 (1-25-2.5 ng/ml) for 24 & 48h, medium was collected and cells lysed. Equal amounts of lysate were subjected to PAGE and Western blotting then probed with antibodies (Ab) to the C-terminal Ab (anti-CCN3 hinge) and the N-terminal Ab (anti-CCN3). Immunoblotting indicated that TGFβ1-stimulated excess of full length CCN3, but not the truncated form apparently lacking the CT domain. The characteristics of this smaller protein are not consistent with any known splice variants and may represent an alternative splice variant of CCN3. The lack of the CT domain would change the 3 dimensional conformation of the protein, inhibit its binding to various interactions and potentially remove the ability of the molecule to inhibit cell proliferation.

Deletion of TGF-β Receptor in Renal Proximal Tubule Cells Impairs HGF Signaling
Stelller Nlandu Khodou,2 Leslie S. Gewin.1, 2
1Research, Tennessee Valley Veterans Affairs, Nashville, TN; 2Medicine, Div of Nephrology, Vanderbilt Univ, Nashville, TN.

Background: The growth factors TGF-beta and HGF have antagonistic and synergistic interactions that govern renal development and response to injury. We previously showed that TGF-beta worsens the epithelial response to acute renal injury, so we postulated that impairing TGF-beta signaling may inhibit responsiveness to HGF, a growth factor that mediates beneficial effects following epithelial injury. Methods: To address how TGF-beta signaling alters epithelial responsiveness to HGF, we generated proximal tubule (PT) cDNA with the TGF-beta type 2 receptor, necessary for cell signaling, either intact (TbRII) or deleted in vitro with adenov-Cre (TbRII). Responses to HGF was assessed by receptor (cMet) phosphorylation, and the biological relevance of altered HGF signaling was determined by branching morphogenesis studies in 3D gels and migration assays.

Results: TbRII PT cells had increased tubular branching and impaired migration compared to cells with the receptor intact. Unexpectedly, PT cells lacking TbRII had impaired response to HGF in both branching morphogenesis and migration assays compared to TbRII cells. Consistent with this, TbRII PT cells had impaired cMet phosphorylation associated with reduced membrane expression of cMet and transcriptional downregulation of the HGF receptor. Notch signaling, a known inducer of cMet transcription, was increased in cells with TbRII intact, and Notch inhibition by gamma-secretase equalized the responses to HGF by PT cells with and without the receptor.

Conclusions: PT cells lacking TbRII have impaired responsiveness to HGF signaling, and this result is due to reduced Notch-mediated cMet transcription. Thus, efforts to block TGF-beta signaling may inadvertently inhibit signaling pathways of other growth factors such as HGF.

Enhancement of HGF-Induced Tubulogenesis by Endothelial Cell-Derived GDNF
Masano Nakatani, Akito Maeshima, Shunsuke Takashiki, Hidetaku Itochi, Toru Sakai, Yoraki Kaneko, Keiju Hiromura, Yoshihisa Nojima. Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Gunma, Japan.

Background: Renal proximal tubular epithelium can regenerate itself after a variety of insults. However, the microenvironment that regulates regeneration process of renal tubules after injury remains unclear. We previously established an in vitro 3D tubulogenesis assay which at least partly mimics in vivo regeneration processes of renal tubules after injury (Am J Physiol Renal Physiol: 301: F387-95, 2011). Utilizing this system, the endothelial cell-derived factors that regulate tubulogenesis were examined.

Methods: Human renal proximal tubular epithelial cells (RPTC) were cultured in gels (type I collagen/matrigel mixture) in the presence of HGF with or without human umbilical vein endothelial cells (HUVEC) using Transwell filter system. The signaling pathway activated by co-culture with HUVEC in tubular structures were examined using phospho-receptor tyrosine kinase (RTK) array.

Results: HGF, a potent renotrophic factor, induced aquaporin-1-positive tubular structures with microvilli, suggesting that these structures are morphologically equivalent to tubulogenic structures in vivo. When co-cultured with HUVEC, HGF-induced tubular formation was significantly enhanced. Tubulogenic effect of HGF was also enhanced in the presence of HUVEC-conditioned media (HUVEC-CM), but not in the presence of VEGF, basic FGF or PDGF. Co-culture with HUVEC did not induce tubular structures in the absence of HGF. RTK array revealed that phosphorylation of RET (GDNF receptor) was markedly enhanced in tubular structures cultured with HUVEC-CM compared to those without HUVEC-CM. HUVEC produces GDNF and RPTC expresses both RET and GFR alpha1 (co-receptor). HGF-induced tubulogenic formation was significantly enhanced by addition of GDNF.

Conclusions: RET is the receptor for GDNF acting in a paracrine manner. GDNF-RET signaling may play a role in the crosstalk between renal tubular cells and surrounding endothelial cells during tubular regeneration after injury.

Massive Formation of Ang(1-7) from AngII(1-8) Is Largely ACE2 Independent
Peter Daniel Serfozo, Jan A. Wysocki, Minghao Ye, Daniel Batlle. Div of Nephropathy, Northwestern Univ - Feinberg School of Medicine, Chicago, IL.

Background: Ang(1-8) degradation mechanisms are complex including clevage by aminopeptidases that form AngIII and carboxypeptidases like ACE2 and PDGF. Co-culture with HUVEC did not induce tubular structures in the absence of HGF. RTK array revealed that phosphorylation of RET (GDNF receptor) was markedly enhanced in tubular structures cultured with HUVEC-CM compared to those without HUVEC-CM. HUVEC produces GDNF and RPTC expresses both RET and GFR alpha1 (co-receptor). HGF-induced tubulogenic formation was significantly enhanced by addition of GDNF.

Conclusions: RET is the receptor for GDNF acting in a paracrine manner. GDNF-RET signaling may play a role in the crosstalk between renal tubular cells and surrounding endothelial cells during tubular regeneration after injury.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author. 699A
Methods: After acute AngII(1-8) infusion to WT mice plasma concentrations of AngII(1-8), Ang(1-7) and Ang(1-5) were measured by LC-MS/MS. Additional measurements of Ang(1-7) by RIA and ELISA were performed for confirmatory purposes. Plasma ACE2 and PRPC activity in WT mice was measured using a fluorogenic substrate.

Results: Following AngII(1-8) infusion to WT mice plasma Ang(1-7) levels measured by MS were extremely high. Similarly high levels were also found when this peptide was measured by RIA and ELISA (Table).

<table>
<thead>
<tr>
<th></th>
<th>AngII(1-8)</th>

</tbody>
</table>

In an ACE2 KO line there was no significant difference in Ang(1-7) levels as compared to WT mice and the levels of ACE2 activity in plasma of WT mice were low. Moreover, activity of PRPC, another Ang(1-7) forming enzyme is very low at the plasma normal pH. We therefore hypothesize that Ang(1-7) formation after AngII(1-8) infusion must be largely ACE2 and PRPC independent. To give further support for this hypothesis, we infused a different set of mice with AngII(1-8) in the presence of recombinant murine ACE2 or ACE2 + MLN, a specific inhibitor. Under all these conditions the levels of Ang(1-7) were massively increased and therefore unaccountable only by the conversion of AngII(1-8) to Ang(1-7) by ACE2 cleavage.

Conclusions: Formation of Ang(1-7) during AngII(1-8) infusion is massive and largely ACE2 independent. The increase in Ang(1-7) after AngII(1-8) infusion suggests the presence of unknown Ang(1-7) forming enzymes that are very active in plasma.

HIF1α and HIF2-Induced Erythropoietin Production Along the Nephron

Yuihiro Izumi, Yukiko Yasuoka, Yushi Nakayama, Hideki Inoue, Masashi Mukoyama, Katsumasa Kawahara, Hiroshi Nonouchi,

Nephrology, Kidney Research Institute, Jichi Medical University, Japan.

Background: Kidney peritubular interstitial cells produce erythropoietin (Epo) in response to hypoxia and/or anemia. By using in situ hybridization method, we have shown that Epo is also produced by the cortical nephrin segments (mainly in PCT, DCT and CCD) in control and/or hypoxic conditions (Nagai, et al, 2014). The role of renin-angiotensin-aldosterone system has been suggested to exacerbate anemia in chronic kidney disease, suggesting aldosterone-regulated erythropoietin production.

Methods: To characterize the molecular machineries for Epo production in renal tubules, we examined the mRNA expressions of HIF1α, HIF2α, PHD2, mineralocorticoid receptor (MR) and EGF-receptor (EGFR) along the nephron in basal condition. Each nephrin segment from SD rats was microdissected in the presence of ribonucleoside vanadyl complexes. After the extraction of RNA, mRNA expression was measured using RT-PCR and real time PCR.

Results: Epo mRNA expression was confirmed in whole nephron segments by RT-PCR in basal condition. The expressions of HIF1α, HIF 2α and PHD2 mRNAs were detected in whole nephrin segments both in RT-PCR and real time PCR. The largest expression of HIF2α mRNA was observed in PCT. HIF2α mRNA expression was larger than HIF1α in whole nephron segments both in RT-PCR and real time PCR. The largest expression in basal condition. The expressions of HIF1α, HIF 2α and PHD2 mRNAs were detected in whole nephrin segments both in RT-PCR and real time PCR.

Conclusions: The results suggest the presence of HIF2α induced-Epo reduction in renal tubules. The presence of MR in whole nephrin segments suggest that aldosterone may have physiological effects for Epo production not only in distal but also in proximal tubules.

Cytokine Response of Primary Human Mesangial Cells In LS Strain Dependent

Margaret M. O'Neill, Carine Boustanly, Steven S. Pullen.

CardioMetabolic Diseases Research, Boehringer Ingelheim Pharma. Inc., Ridgefield, CT.

Background: LPS stimulation of Toll-like receptor 4 (TLR4) induces the release of proinflammatory cytokines which activate potent immune responses. LPS is an important structural component of the outer membrane of Gram-negative bacteria and consists of three parts: lipid A, a core oligosaccharide, and an O side chain. It has been studied extensively in models of inflammation with E.coli 011:B4 most often referenced in the literature. The antigenicity of LPS varies from strain to strain depending on the composition of its O side chain. A comparative study was designed to identify the optimal strain to be used for LPS-stimulated release of proinflammatory mediators from primary human mesangial cells (HMC).

Methods: HMC were stimulated with 7 strains of LPS and 24 hour supernatants were analyzed for production of inflammatory mediators ([IL-1β, IL-6, IL-8, TNF-α and MCP-1]). Cell viability of HMC was assessed with MTS kits Proliferase and Annexin V/PI assays for 4-plex II and MCP-1. TLR4 antagonists EXX0076824 a small molecule and FHAN_2014062 an antibody were tested to evaluate inhibition of LPS activity in HMC using 3 LPS strains with most pronounced inflammatory effects.

Results: LPS induced strain-dependent increases in IL-6, IL-8, and MCP-1 in HMC, while there was no effect on IL-1β and TNF-α. When compared to controls, IL-6 production was significantly (p<0.05) increased. E.coli 0111:B4 (25X), LPS-EB (10X), E.coli K12 (44X), E.coli 055:BS (8X), S.Minnesota (99X), S.pyogenes (18X) and P.gingivitis (6X). All strains induced IL-8 and MCP-1 except for E.coli 055:BS (IL-8) and E.coli K12 (MCP-1). Both TLR4 antagonists blocked LPS induced production of IL-6, IL-8, and MCP-1 in a dose dependent manner. IC50 values for both inhibitors (EXX0076824: 30-60mM; FHAN_2014062: 800-2700ng/ml) were consistent across LPS strains and analyte detected.

Conclusions: In this study we demonstrate that LPS-stimulated release of inflammatory mediators in HMC is strain dependent, and can be blocked using TLR4 antagonists. These data highlight the importance of identifying the most effective LPS strain in a cell type of interest, prior to initiating pharmacology studies.

Effect of Angiotensin II Type 1 Receptor Blocker on 12-Lipoxygenase Activity and Slit Diaphragm Protein Nephrin and P-Cadherin Expression in Type 2 Diabetic Rat Glomeruli

Pravin C. Singhal, Margaret R. Lewis, Eunice Hurst, Shengfang Wang, Xiqian Xu, Yuanyuan Zhang, Hongzhao Xu, Fu-zhe Ma, Tao Sun, Hang Yuan, Mindan Sun, Zhong-gao xu. Nephrology, The First Hospital of Jilin Univ, Changchun, Jilin, China.

Background: 12-lipoxygenase (12-LO) and angiotensin II/AngII interaction plays an important role in the development of diabetic nephropathy (DN), in which proteinuria was thought to be associated with decreased expression of glomerular slit diaphragm protein nephrin and P-cadherin. However, it is unclear whether Ang II type 1 receptor blocker (ARB) regulates 12-LO activity and slit diaphragm protein expression in type 2 diabetic rat glomeruli and hence was investigated in this study.

Methods: Podocytes and glomeruli isolated from rats were used in this study. The 12-LO products 12(S)-HETE and Ang II were infused to rats by osmotic mini-pump. Rats fed high fat diet received low dose streptozotocin to make type 2 diabetes. Glomeruli were isolated with sieving method and classified into small glomeruli (SG, on the 75mm sieve) and large glomeruli (LG, on the 125mm sieve). ELISA, RT-PCR and Western blot for related targets were performed respectively.

Results: Ang II increased 12(S)-HETE levels in podocytes and glomeruli. Direct infusion of rats with 12(S)-HETE and Ang II significantly decreased LG nephrin, but increased SG nephrin expression compared to control. The glomerular P-cadherin expression was reduced after Ang II and 12(S)-HETE treatment and there was no difference between LG and SG. ARB did not affect blood glucose levels but completely attenuated increases in 12(S)-HETE content, AT1 expression and proteinuria induced by diabetes. Nephrin protein expression was significantly reduced in diabetic LG but increased in diabetic SG compared to control. P-cadherin expression was decreased in both diabetic LG and SG. These abnormalities were partially but significantly prevented by ARB treatment.

Conclusions: ARB could ameliorate the progression of DN via upregulation of glomerular nephrin and P-cadherin expression through inhibition of 12-LO activation in type 2 DN.

APOL1 Risk Variants and HIV Stimulate Induction of PDGF-β Receptor in Podocytes

Xiaoian Lan, Hongxue Wen, Ashwani Malhotra, Karl Leon Schiffer, Pravin C. Singhal, Karl Leon Schiffer, Shengfang Wang, John H. Park, Shari A. Mavor, Stephen Alpers, Marcia J. Greene, Shengfang Wang, NYU Medical School, Great Neck, NY; Medicine, Rambam Health Care Campus, Haifa, Israel.

Background: Clinical reports demonstrated that two coding sequence variants (G1 and G2) in the APOL1 gene are responsible for the higher percentage of kidney disease in African Americans. This disparity between patients with APOL1 variants versus wild type APOL1 increases by 10 fold for the development of HIVAN in patients of HIV infection who are not on antiretroviral therapy. Podocytes do not express platelet-derived growth factor (PDGF) receptors constitutively but, nonetheless, in experimental animal models, podocyte

unregulated expression of PDGFs manifested as progressive glomerulonephritis. We hypothesized that APOL1 risk variants and HIV carry potential for the induction of the activation of the PDGF pathway in podocytes.

**Methods:** To determine the effect of APOL1 and APOL1 variants expression, stably expressing Vector, APOL1, APOL1G1, or APOL1G2 human podocyte (HP) cell lines were developed. Expression of HIV (NL4-3 or empty vector) (control) virus was transduced into APOL1G0/HPs, APOL1G1/HPs and APOL1G2/HPs. After 48 h, RNAs were extracted. cDNAs were amplified with specific primers for PDGF-A, PDGF-B, PDGF-C, PDGF-D, and PDGFRβ. Hairpin transcript significantly induced expression of PDGF-A, PDGF-B, PDGF-C, PDGF-D, and PDGFRβ in podocytes.G0/HPs, G1/HPs, and G2/HPs with or without HIV transduction did not display any change in the expression of PDGF-B, PDGF-C, or PDGF-D, when compared with vector; whereas, G2/HPs in HIV milieu displayed enhanced expression of PDGF-A. Interestingly, both G1/HPs and G2/HPs displayed 10 fold increase in PDGFRβ expression when compared to vector or G0/HPs.

**Conclusions:** These findings indicate that PDGFs and their receptor PDGFRβ can be induced by HIV and APOL1 risk variants. The present study could lead to new therapeutic targets for HIVAN.

**Assessment of Urinary Liver Type Fatty Acid Binding Protein in Patients of Type 2 Diabetes Mellitus with Early Chronic Kidney Disease**

**Om Prakash Kalra, 1 Mohit Garg, 1 Ashok Kumar Tripathi, 1 Sanil Agrawal, 1 Medicine, UCMS & GTB Hospital, Delhi, India; 2 Biochemistry, UCMS & GTB Hospital, Delhi, India.

**Background:** Diabetes mellitus is the most common cause of chronic kidney disease (CKD) worldwide. Various markers are being indentified which can detect nephropathy at an earlier stage. Both glomerular and tubular injury play an important role in etiopathogenesis of diabetic nephropathy (DN) and tubular damage precedes glomerular damage. Tubular markers are considered as tubular injury markers. Liver type fatty acid binding protein (L-FABP), a 14 kDa cytosolic protein expressed in a wide variety of tissues including peritubular myofibroblasts, is increased in kidney injury. In the present study, we assessed the role of urinary L-FABP as a tubular injury marker.

**Methods:** This was a case control, cross sectional study. Eighty four subjects in the age group 30–60 years of either sex were taken and were divided into three groups: Group I: Healthy controls (n=28) Group II: Type 2 diabetes patients with normoalbuminuria (n=28) Group III: Type 2 diabetes patients with microalbuminuria (n=28). Detailed history, physical examination, investigations were done and creatinine to albumin ratio (ACR) was done. Urinary L-FABP was measured by ELISA (CMIC, Tokyo).

**Results:** The urinary ACR levels were comparable in group I and II. Subjects in Group III had significantly elevated ACR values. Levels of urinary L-FABP were higher in subjects of group II and III when compared with group I. Values of L-FABP were also higher in group III compared to group II. There was a significant positive correlation found between urinary ACR and urinary L-FABP levels. A significant negative correlation was found between urinary L-FABP and eGFR.

**Conclusions:** Urinary L-FABP are markedly increased in patients of diabetic nephropathy as compared to healthy controls. Levels were also increased in diabetes patients with normoalbuminuria suggesting early tubular injury in these patients. This suggests that urinary L-FABP may be a promising early marker for detection of diabetic nephropathy.

**Neuropilin1 Regulates Pericyte Behavior in Postnatal Kidney**

**Monika Neuropilin1 (Nrp1) is a transmembrane co-receptor implicated in the regulation of endothelial cell migration during angiogenesis. In the adult kidney, Nrp1 is however not only expressed in pericytes but also by pericytes including peritubular pericytes and mesangial cells.

**Methods:** To determine the effect of Nrp1 and Nrp1 variants expression, stably expressing Vector, APOL1, APOL1G1, or APOL1G2 human podocyte (HP) cell lines were developed. Expression of HIV (NL4-3 or empty vector) (control) virus was transduced into APOL1G0/HPs, APOL1G1/HPs and APOL1G2/HPs. After 48 h, RNAs were extracted. cDNAs were amplified with specific primers for PDGF-A, PDGF-B, PDGF-C, PDGF-D, and PDGFRβ. Hairpin transcript significantly induced expression of PDGF-A, PDGF-B, PDGF-C, PDGF-D, and PDGFRβ in podocytes.G0/HPs, G1/HPs, and G2/HPs with or without HIV transduction did not display any change in the expression of PDGF-B, PDGF-C, or PDGF-D, when compared with vector; whereas, G2/HPs in HIV milieu displayed enhanced expression of PDGF-A. Interestingly, both G1/HPs and G2/HPs displayed 10 fold increase in PDGFRβ expression when compared to vector or G0/HPs.

**Conclusions:** These findings indicate that PDGFs and their receptor PDGFRβ can be induced by HIV and APOL1 risk variants. The present study could lead to new therapeutic targets for HIVAN.

**Development of a Spontaneous, Reproducible and Treatable Kidney Fibrosis Model**

**Jessica Marie Overstreet, Ming-Zhi Zhang, Raymond C. Harris, Medicine, Vanderbilt Univ, Nashville, TN.

**Background:** Kidney fibrosis in chronic kidney diseases causes gradual loss of kidney functionality. Currently, only a few kidney fibrosis models are available. New kidney fibrotic models are needed. Since our previous studies indicated that activation of epidermal growth factor receptor (EGFR) contributes to the development of renal fibrosis, we have developed a model with selective overexpression of an EGFR ligand, human heparin-binding EGF (hHB-EGF) in renal proximal tubule, were generated. Male C57BL/6 homozygous HBB-EGF mice received vehicle (water) or erlotinib (80 mg/kg/ day) by daily gastric gavage & females to control.

**Results:** Kidney cortical hHB-EGF mRNA and protein levels were dramatically higher in homozygous hHB-EGF mice than in heterozygous mice. Profound renal interstitial fibrosis was found in both B6D2 and C57BL/6 homozygous hHB-EGF mice, but not in heterozygous mice, as indicated by histology and increased levels of the pro-fibrotic and fibrotic components (CTGF, a-SMA, collagen I and IV). Homozygous hHB-EGF mouse kidneys also exhibited increased oxidative stress and infiltration of both macrophages and T lymphocytes. Interstitial fibrosis appeared as early as 4 weeks old. Homozygous hHB-EGF mice exhibited increased kidney fibroblast activation (increased phosphorylation of EGFR) and activation of downstream signaling, p-ERK and p-AKT. In addition, there was markedly increased p-Smad 2/3. p-EGFR, p-ERK, and p-Smad 2/3 were all primarily localized to proximal epithelial cells, indicating that hHB-EGF-mediated EGFR activation in proximal epithelial cells is the primary event in the development of interstitial fibrosis. Treatment with erlotinib, an inhibitor of EGFR tyrosine kinase activity, inhibited EGFR signaling pathways and attenuated the development of renal interstitial fibrosis.

**Conclusions:** These studies suggest that ligand-mediated EGFR activation in renal proximal tubular epithelial cells leads to spontaneous, reproducible, and treatable renal interstitial fibrosis. Therefore, homozygous hHB-EGF mice may be a useful renal fibrosis model to test the effectiveness of anti-fibrotic agents.

**LPA-LPA, Signaling Regulates Fibroblast Proliferation and Myofibroblast Differentiation Dependent on Epithelial Cell-Fibroblast Interaction**

**Norihiko Sakai, Yasutaka Kamikawa, Akihiro Sagara, Yasuyuki Shinozo, Shinji Kitajima, Akinori Hara, Yasunori Iwata, Miho Shimizu, Kengo Furuchi, Takashi Wada. Div of Nephrology, Kanazawa Univ, Kanazawa, Japan.

**Background:** Renal fibrosis is a common pathway of progressive renal diseases, resulting in renal failure regardless of its cause. The accumulation of fibroblasts and myofibroblasts is a hallmark of renal fibrosis. The activation of downstream signaling, p-ERK and p-AKT. In addition, there was markedly increased p-Smad 2/3. p-EGFR, p-ERK, and p-Smad 2/3 were all primarily localized to proximal epithelial cells, indicating that hHB-EGF-mediated EGFR activation in proximal epithelial cells is the primary event in the development of interstitial fibrosis. Treatment with erlotinib, an inhibitor of EGFR tyrosine kinase activity, inhibited EGFR signaling pathways and attenuated the development of renal interstitial fibrosis.

**Methods:** In this study, we focused on the effects of LPA-LPA, signaling on the interaction between renal tubular epithelial cells (RTEC) and renal fibroblasts (RFB). The stimulation of RTBC with LPA-induced CTGF expression in both RTEC and RFB in a time- and dose-dependent manner. The induction of CTGF in both cells was suppressed by the treatment with LPA, antagonist (AM095). In addition to that, LPA-induced CTGF expression in both cells was diminished by the treatment with Rho inhibitor (C3 toxin) and Rho kinase inhibitor (Y27632). In both cells, LPA enhanced the nuclear translocation of myocardin-related transcription factor (MRTF)-A/B and the transcriptional activity of MRTF-serum response factor (SRF), whereas Y27632 treatment inhibited those. The inhibition of MRTF-A/B-SRF pathway by the treatment with siRNA or a chemical inhibitor suppressed the expression of CTGF in both RTBC and RFBC. Finally, the treatment of LPA-LPA enhanced the proliferation of RFBC and the expression of alpha smooth muscle actin in RFBC.

**Conclusions:** In conclusion, LPA-LPA, signaling regulates epithelial cell-fibroblast interaction to induce fibroblast proliferation and differentiation into myofibroblasts through CTGF production dependent on Rho/Rho kinase/MRTF-SRF pathway.

**TWEAK/Fn41 Signaling Promotes Kidney Disease by Driving Myofibroblast Activation, Inflammation and Vascular Instability**

**Ivan G. Gomez, 1 Allie M. Roach, 1 Gamze Karaca, 1 Linda Burkly, 1 Jeremy Stuart Duffield. 1 Medicine, Univ of Washington, Seattle, WA.

**Background:** We identified Fibroblast growth factor-inducible 14 (Fn41) as a receptor on pericytes, which is strongly upregulated as they differentiate into myofibroblasts in vivo in kidney disease. TNF-related weak inducer of apoptosis (TWEAK), a TNF-family
cytokine produced predominantly by myeloid leukocytes has been reported to activate NFκB and TAZ. We have previously reported that NFκB signaling was activated in myofibroblasts in vivo and hypothesized that TWEAK/Fn14 signaling might be an important driver of pathological myofibroblast in kidney disease.

Results: Fn14 deficiency ameliorates myofibroblast appearance, fibrosis and microvascular pathology in vivo. TWEAK activates primary human cultures of kidney fibroblasts and epithelial cells, which suggests that TWEAK activation could be involved in the progression of kidney fibrosis. TWEAK activation was observed in kidney fibroblasts and epithelial cells in vivo and in vitro.

Conclusions: These findings suggest that targeting the TNF superfamily TWEAK/Fn14 pathway is an approach to modulate myofibroblast activation and a novel way to block both inflammatory and fibrotic aspects of chronic kidney disease.

SA-PO331
Deregulation of Hippo-TAZ Pathway During Renal Injury Promotes Fibrotic Phenotype Rohan Samarawick, Lucas Falke, Roel Goldschmeding, Paul J. Higgins. 1Center for Cell Biology and Cancer Research, Albany Medical Center, Albany, NY; 2Dept of Pathology, Univ Medical Center Utrecht, Utrecht, Netherlands.

Background: Hippo pathway is the principal regulator of organ size. Transcriptional co-activator with PDZ-binding motif (TAZ), a nuclear transducer of Hippo pathway, is activated during renal injury, tensional forces and soluble factors. TAZ has been implicated in the progression of lung fibrosis and cancer. However, role of Hippo-TAZ pathway in chronic kidney disease (CKD) is unknown.

Methods: We utilized three mouse models of renal injury [ureteral ligation (UOL), aristoclastic acid nephropathy (AAN), streptozotocin (STZ)-driven diabetic nephropathy] and TAZ genetic manipulation in HK-2 tubular epithelial cells and NRK-49F renal fibroblasts to investigate role of TAZ in renal fibrosis.

Results: TAZ is activated [as evident by increased nuclear accumulation (4-fold) and expression (2.5-fold) at both in the tubular and interstitial cells and decreased TAZ-dependent phosphorylation] in the UO kidney compared to contralateral controls. TAZ expression is also upregulated in AAN and STZ-induced renal injury models. TAZ activation correlated with increased pSmAD3 in the fibrotic kidney. TGF-beta1 and Angiostatin II stimulation, moreover, promoted TAZ and pSmAD3 nuclear entry in HK-2 cells suggesting that these cytokines likely disable core Hippo signaling. TAZ stable gene silencing in HK-2 cells, indeed, suppressed TGF-beta1 and Angiostatin II induced CTGF, PAI-1 and fibronectin expression. Stable TAZ overexpression in HK-2 cells promoted epithelial dedifferentiation and proliferative arrest.

Conclusions: Activated during renal injury, TAZ is a novel profibrotic effector of TGF-beta1 and Angiostatin II induced phenotypic responses. TAZ nuclear accumulation in response to TGF-beta1 and Angiostatin II is suggestive of cross-talk among Hippo pathway and these cytokines.

SA-PO332
Design and Characterisation of Novel BMP Agonists and Antagonists Daniel Craig, Satnam Surace, Finian Martin, Catherine Godson. UCD; UCD; UCD.

Background: We have previously reported a role for the Bone Morphogenic Protein [BMP] antagonist Gremlin in a driver of diabetic nephropathy and fibrosis in both kidney and lung. Bone Morphogenetic Proteins are integral regulators of bone and organ development. BMPs are secreted proteins and signal by associating with membrane bound receptors. The activity of BMP agonists is modulated by a family of secreted protein antagonists, including Noggin, Chordin and Gremlin that limit BMP receptor association by binding to the ligand and thereby inhibiting receptor binding.

Methods: We have analysed BMP-receptor and BMP-antagonist interactions using a newly designed automated pipeline, Protein Complex Tool (PCT). Co-crystal structures of the BMP-BMP receptor and the BMP-antagonist complexes were submitted to PCT and in silico alanine substitution scans were performed to calculate the free energy contribution of each BMP-2, or BMP-7, residue to the stability of the complexes with receptors, BMPRIA (BMP-2 only) and AciriRla, and antagonists, Crossveinless-2 (BMP-2 only) and Noggin (BMP-7 only).

Results: The free energy calculations identified the key contributions of BMP residues to both binding events and suggested mutations that might generate super-agonist and dominant negative molecules. Further in silico analysis was performed by mutating each residue to each of the other 19 amino acids. From this we identified potential super-agonist and dominant negative mutants for both BMP-2: L51V and N102T (super-agonists) and S88G and L92D (dominant negatives), and BMP-7: E60T, D191H, I124A and K127E (super-agonists) and F117E and V122D (dominant negatives). The super-agonists will bind and activate the receptor but will be resistant to binding by antagonist, in contrast, the dominant negatives, bind antagonist but not receptor.

Conclusions: Data will be presented from our investigations of these molecular tools, which may be involved in upregulating genes associated with the unfolded protein response and potential therapeutic leads for treating fibrotic disease and renal DN.

SA-PO333
Engaged Growth Factors to Treat Acute Kidney Injury Shalwdeh Fahhabi, Karin Kuchenbecker, Tim Stowe, Matt Onsum. Silver Creek Pharmaceuticals, San Francisco, CA.

Background: Acute kidney injury remains a major unmet medical need and economic burden. There are no therapies that act directly on damaged kidney cells to promote survival. At Silver Creek Pharmaceuticals, we are engineering a new class of therapeutics called Smart Growth Factors that act selectively on damaged kidney cells to safely deliver pro-survival signals and restore kidney function.

Methods: We harness the ability of growth factors to act on survival and mitogenic signaling of growth factors and engineer more desirable drug-like properties, including extended half-life and cell type-specific targeting. Our first SGF, designed to reduce cardiomyocyte death following acute myocardial infarction, has shown positive pre-clinical efficacy and is being prepared for an Investigational New Drug Application. We are now designing an SGF to treat acute kidney injury, where apoptosis of proximal tubule cells is a leading mechanism of pathology. We developed an in vitro model of tubule cell apoptosis using hypoxia to screen wild type growth factors for the ability to restore cell viability and promote proliferation. We then used computational models to design SGFs that could maximize pro-survival signaling and targeting in damaged kidney tubule cells.

Results: SGF variants were built, expressed and purified in-house, and screened for their ability to act on pro-survival and proliferative signals selectively in damaged cells using the in vitro hypoxia model. SGFs with favorable rescue ability, selectivity and pharmacokinetics will be tested in a rodent AKI model using bilateral ischemia.

Conclusions: Smart growth factors have the potential to transform the treatment of acute kidney injury, but safely delivering potent pro-survival and mitogenic signals specifically to damaged cells, hopefully leading to better outcomes for this patient population.

SA-PO334
Loss of the Podocyte Glucocorticoid Receptor Exacerbates Proteinuria Julie Goodwin, Xia Fei Tian, Shuta Iwahashi, Pediatrics, Yale Univ School of Medicine, New Haven, CT; Internal Medicine, Yale Univ School of Medicine, New Haven, CT.

Background: Nephrotic syndrome is one of the most common renal diseases in children and podocyte foot process effacement is the histologic hallmark. Glucocorticoids (GC) are the mainstay of treatment. Podocytes express the glucocorticoid receptor (GR) and new evidence suggests that podocyte-specific GC effects may be central to controlling proteinuria.

Methods: Mice with knockout of GR in podocytes were generated by crossing GR null mice with podrec Cre mice. Proteinuria was induced using both a systemic stimulus (LPS) and a renal-specific insult (nephrotic serum (NTS)). Urine protein/creatinine ratios, serum albumin and GIM morphology were assessed in both controls and knockout animals. In vitro, wound healing assays and analysis of stress fiber formation after stimulation with LPS in the presence or absence of dexamethasone (DEX) were performed in primary podocytes isolated from animals of both genotypes.

Results: Podocyte GR knockout mice did not have a phenotype at baseline. Their weight, serum creatinine, serum albumin, urine protein/creatinine ratios and foot process diameter were similar to controls. When challenged with low-dose LPS (12.5 mg/kg, IP), knockout mice developed significantly more proteinuria (2.11 ± 0.77 vs. 0.60 ± 0.21; p<0.05, n=5/group) than did controls. Knockout mice also showed greater foot process effacement by EM after LPS (855 ± 157 nm vs. 466 ± 8 nm, p<0.05, n=5/group) compared to controls. When treated with NTS, similar results were noted. In vitro, GR knockout podocytes showed fewer and more disorganized stress fiber formation and impaired wound healing after LPS treatment compared to control podocytes. Administration of DEX could rescue the in vitro phenotype in control, but not GR knockout, podocytes.

Conclusions: These results demonstrate that (1) loss of podocyte GR exacerbates proteinuria in two different models in vivo, (2) podocytes lacking GR are more intolerant to injury, and (3) DEX administration ameliorates cellular injury in control, but not GR- deficient podocytes. We conclude that the podocyte GR plays a key role in maintaining the integrity of the slit diaphragm after injury.

SA-PO335
Deletion of Inositol-Requiring Enzyme-1a in Podocytes Disrupts Glomerular Capillary Integrity and Autophagy Daniel Robert Kaufman,1 Joan Papillon,2 Takao Iwawaki,3 Andrey V. Cybulsky.

1Physiology, McGill Univ, Montreal, QC, Canada; 2Medicine, McGill Univ, Montreal, QC, Canada; 3Medicine, Gamma Univ, Maebashi, Japan.

Background: Inositol-requiring enzyme-1a (IRE1a) is an endoplasmic reticulum (ER)-transmembrane endoribonuclease-kinase, which plays an essential function in normal development, and is activated during ER stress. IRE1a is involved in upregulating genes associated with the unfolded protein response and...
ER-associated degradation, as well as in the activation of c-Jun N-terminal kinase (JNK)-1, and induction of apoptosis and autophagy. In this study, we address the functional role of miR-192 in podocytes.

Methods: Podocyte-specific miR-192 knockdown (KO) mice were generated by breeding mice with loxP sites surrounding exons 20-21 with podocin (NPHS2)-Cre mice. LoxP-mediated excision in glomeruli was confirmed by PCR.

Results: In male mice, deletion of miR-192 in podocytes resulted in albuminuria beginning at 5 months of age, and worsening with time. Electron microscopy revealed focal podocyte foot process effacement in 9 month old male KO mice, as well as microvillous transformation of podocyte membranes and cytosolic vacuolation. By light microscopy, glomerular cross-sectional area (an indicator of hypertrophy) was greater in KO mice, compared with control, and capillary lumens occupied a higher fractional area of KO glomeruli, suggesting formation of anurysms. By immunofluorescence microscopy, WT-positive cells per glomerulus were comparable in KO and control males. Immunoblotting showed reduced LC3B-II expression and JNK-1 phosphorylation in KO glomeruli, in keeping with reduced autophagy. There was also a reduction in nephrin maturation in KO glomeruli, suggesting impaired ER function. Finally, expression of IRE1α or IRE1α K599A (dominant inhibitor) in cultured COS-1 kidney cells did not affect ERAD, as monitored by the efficient detection of the CD3A ERAD reporter.

Conclusions: Podocyte-specific deletion of IRE1α leads to albuminuria and morphological evidence of podocyte injury. Thus, IRE1α is essential to the maintenance of podocyte integrity as mice age. The mechanism may, at least in part, relate to disruption of autophagy in podocytes.

Funding: Government Support - Non-U.S.

Consistent Downregulation of Autophagy Gene Atg12 Through MicroRNA-192 in Diabetic Nephropathy

Supriya Deshpande, Mitsuo Kato, Mei Wang, Rama Natarajan.

Background: Autophagy (Atg) plays a key role in the pathogenesis of kidney diseases, however its role in Diabetic Nephropathy (DN), and particularly in mesangial cells (MC) is not clear. TGF-β1, a key player in the pathogenesis of DN, regulates expression of various microRNAs (miRs) including miR-192. Also, several miRs regulate expression of various Atg genes. We hypothesized that miR-192 plays an important role in Atg regulation in DN.

Methods: Atg gene expression was analyzed in type-2 diabetic (db/db) and in STZ-injected type-1 diabetic mice. To analyze the role of miR-192 in Atg regulation, STZ-injected type-1 diabetic mice were treated with control locked-nucleic acid (LNA) oligonucleotides (oligo) or LNA oligos targeting miR-192 (anti-miR-192-LNA), and Atg gene expression was analyzed in kidneys. Atg gene expression was also analyzed in kidneys of WT and STZ-injected miR-192 knockout (KO) mice. The effect of TGF-β1 on Atg gene expression and GFP-RFP-LC3 puncta formation was analyzed using mouse MC (MMC).

Results: Expression of several Atg genes was decreased in kidneys of type-1 and type-2 diabetic mice compared to controls. Treatment with LNA-anti-miR-192 reversed the effect of diabetes on some of the Atg genes. Further, Atg gene expression was not affected in kidneys of diabetic miR-192-KO mice compared to controls. In vitro studies using MMC treated with TGF-β1 also showed a decrease in Atg gene expression compared to control. Transfection of MMC with miR-192 mimic oligos decreased expression of certain Atg genes. In addition, transfection of MMC with a GFP-RFP-LC3 plasmid decreased the average number of RFP-LC3 puncta/cell following TGF-β1 treatment, and this effect was reversed in MMC from miR-192-KO mice. Of all Atg genes analyzed, Atg12 expression was consistently decreased in these mouse models, and its decrease was reversed by anti-miR-192 LNA oligos as well as in miR-192-KO mice.

Conclusions: These results demonstrate that consistent downregulation of Atg12 through miR-192 contributes to an overall decrease in autophagy and subsequent increase in cellular hypertrophy in response to TGF-β1 in MC and in glomeruli of diabetic mice leading to DN.

SA-PO337

mTOR Dependent Regulation of the Podocyte Metabolic Profile

Tillmann Bork, Wei Liang, Tobias B. Huber.

Background: Podocytes play a critical role in the formation and maintenance of the kidney filtration barrier. Previously we have highlighted the role of mTOR signaling as regulator of podocyte adaption, differentiation and size-control. However, the eventual link between podocyte size control and the regulation of podocyte metabolism by mTOR remains elusive.

Methods: Mice models of mTOR hyperactivation (Tsc1 PcKO) and mTOR loss of function (Raptor PcKO) were crossed to a Tomato/eGFP reporter line to efficiently isolate podocytes for primary cell culture studies. Mitochondrial respiration and ATP synthesis were assessed using Seahorse bioanalyzer with specific inhibitors of glycolysis and ATP synthase.

Results: Lipids are the main source for ATP synthesis due to oxidative phosphorylation in podocytes. Anerobic glycolysis is the dominating pathway to use glucose. Active mTOR signaling pathway massively enhances basal metabolic activity and the capacity for oxidative phosphorylation in podocytes.

Conclusions: Podocyte metabolism relies on β-oxidation of lipids and anerobic glycolysis. mTOR signaling regulates metabolic activity without affecting the preferences for the used metabolic pathways. Targeting the predominant metabolic pathways of podocytes might help to ameliorate diabetic nephropathy or podocyte ageing.

Derlin-2 Knockout Mice Unravel an Essential Role for Protein Dislocation in Podocytes

Guohui Ren, Kwi Hye Koh, Jing Li, Changli Wei, Mehmet M. Altintas, Jochen Reiser.

Background: Protein quality control represents a balance between chaperone-assisted removal and folding of misfolded proteins from the endoplasmic reticulum (ER). Disturbed balance results in ER stress in podocytes that is associated with cellular injury. Derlin-2, a component that mediates cellular dislocation machinery, has been identified as an important element in skeletal and matrix producing cells.

Methods: Western blot and immunofluorescence staining were used for detection of protein expression. Derlin-2 knockdown or overexpression in podocytes was achieved with transfection of lipirivus containing shRNA or CDN. Podocyte-specific Derlin-2 knockout mice were generated by crossing Derlin-2-flox mice with podocin-Cre mice. Autophagy was detected with the conversion of LC3-I to LC3-II. Activation of caspase-12 was measured by cleavage of procaspase-12.

Results: Derlin-2 was expressed in both mouse and human podocytes. Derlin-2 deficiency in podocytes could be compensated for by inositol-requiring enzyme 1 (IRE1) induced autophagy at baseline conditions. However, in situations with induced ER stress owed to adriamycin (ADR) or other compounds, the compensatory response of autophagy was overwhelmed. Meanwhile, caspase-12 mediated apoptosis pathway was activated, and severe cellular injury ensued, leading to heavy proteinuria in podocyte-specific Derlin-2 knockout mice, as compared with wild type C57BL/6j control mice. In contrast, Derlin-2 overexpression in vitro attenuated podocyte injury. Derlin-2 expression was induced during in situ glomerulosclerosis (FSGS) and diabetic nephropathy (DN) as well as in ADR nephropathy in BALB/cj mice, streptozotocin (STZ)-induced diabetic mice and BBTR oh/oh DN mice.

Conclusions: Podocytes like osteocytes and chondrocytes emerge from mesenchyme and belong to a group of cells that employ Derlin-2 to guarantee protein quality and minimize ER stress for cellular homeostasis. Overexpression of Derlin-2 may be a mechanism to rescue damaged podocytes. Induction of Derlin-2 expression in vivo may have applications for prevention and therapy of glomerular diseases.

Protein O-GlcNAcylation Is Essential for Normal Podocyte Structure and Function

Shinya Ono, Masako Yasuda, Shiniji Kume, Osamu Sekine, Jun Nakazawa, Hisuzumi Araki, Masami Kanasaki, Shin-ichi Araki, Daisuke Koya, Masakazu Haneda, Takashi Uzo, Hiroshi Maegawa.

Background: Podocytes like osteocytes and chondrocytes emerge from mesenchyme and belong to a group of cells that employ Derlin-2 to guarantee protein quality and minimize ER stress for cellular homeostasis. Overexpression of Derlin-2 may be a mechanism to rescue damaged podocytes. Induction of Derlin-2 expression in vivo may have applications for prevention and therapy of glomerular diseases.

Results: O-GlcNAcylation was immunohistochemically observed in the nuclei of podocytes in wild-type mice, but was completely absent in Podo-OGTKO mice. Podo-OGTKO mice showed normal birth rate and growth up to 32 weeks of age. Proteinuria was first apparent at 8 weeks of age and increased with age up to 32 weeks. Scanning transmission electron microscopy showed disruption of podocyte foot processes in Podo-OGTKO mice after 8 weeks of age. Immunofluorescence showed podocin to have a punctate distribution in Podo-OGTKO podocytes and to be at a reduced level compared with wild-type mice. Furthermore, the numbers of podocytes in 16-week-old Podo-OGTKO mice were significantly decreased compared with wild-type mice. Finally, severe glomerular sclerosis with tubulointerstitial damage was observed in Podo-OGTKO mice at 32 weeks of age.

Conclusions: O-GlcNAcylation of intracellular proteins by OGT is necessary to maintain podocyte numbers and normal foot process structure. Our results provide new insight into podocyte biology.

SA-PO340

Identification of Novel Gene Products That Regulate Podocyte Function

Davide Pietro Cina, Chengjin Li, Jason Moffatt, Susan E. Quaggin.

Background: Podocytes are a major component that nucleates cellular dislocation machinery, has been identified as an important element in skeletal and matrix producing cells. To identify novel gene products that regulate podocyte function, we designed an mTOR dependent regulation of the podocyte metabolic profile.
SA-PO341

Targeted Deletion of Drp1 in Podocytes Mitigates Mitochondrial Remodeling and Progression of Diabetic Nephropathy

Methods: A pool of knockdown podocytes was generated using this library and plated on both 24-well plates followed by separation of the adherent and floating fractions and deconvolution by illumina sequencing. We developed a stringent method for statistical analysis and 'hit' determination and performed a small-scale validation of this method by interrogating top candidate genes individually. We also performed a larger scale validation using a secondary, focused pooled Cas9 mediated knockdown screen.

Results: We identified 121 genes that increased adhesion to fibronectin and 145 genes that increased adhesion to sFLLT1/Fc. We also identified 66 genes that decreased adhesion to fibronectin and 106 genes that decreased adhesion to sFLLT1/Fc. DPH1, DPH2, DPH3 and DPH4 were among the top ten hits for increased adhesion to both fibronectin and sFLLT1/Fc. Stable podocyte knockdown lines for these genes displayed increased adhesion to both substrates. We also generated Cas9 mediated podocyte knockout lines for DPH1, DPH2 and DPH3, which displayed increased adhesion and a spreading defect.

Conclusions: We have developed a novel method for identifying genes that regulate podocyte function. Future work will investigate how DPH1, DPH2 and DPH3 regulate podocyte adhesion, and select novel candidate genes that decrease podocyte adhesion. This unbiased approach will yield a list of genes that broaden our understanding of podocyte physiology and the disease states that perturb this system resulting in kidney disease.

Podocyte Oxidative Stress Coupled with Ubiquitin C-Terminal Hydroxylase Deletion Exacerbates Renal Damage

Kidney Disease Branch, NIDDK, NIH, Bethesda, MD.

Background: Ubiquitin C-terminal hydroxylase L1 (UCHL1) may promote antioxidation by hydrolyzing ubiquitin-thioester bonds on glutathione (GSH) thereby protecting GSH from degradation. Podocyte UCHL1 is upregulated in diseased glomeruli where it may maintain redox balance. UCHL1 deleted mice overexpress podocyte-specific NOX5 should exhibit exacerbated glomerular damage due to unregulated oxidative stress.

Methods: COST cells were infected with AdGFP or AdNOX5 and UCHL1 levels determined by immunoblotting, mRNA levels determined by qPCR. UCHL1+/+ and NOX5−/− mice were crossed to generate NOX5−/−/UCHL1−/− mice. Albuminuria (ACR) was measured by ELISA. Renal mass was normalized to tibia length. Glomerular filtration rate (GFR) was assessed by FITC-Inulin. Immunofluorescence with anti-PNA and anti-renin was performed on renal sections. Blood pressure was determined by tail cuff plethysmography.

Results: UCHL1 protein increased 1.9-fold in COST cells infected with AdNOX5 vs. AdGFP-infected controls. Similarly, glomeruli from 12-week-old NOX5−/− mice showed limited UCHL1 mRNA induction (1.5-fold). ACR increased in NOX5−/−/UCHL1+/+ mice at 12 weeks (40 μg/mg) but not in nonTG, UCHL1−/− and NOX5−/−/UCHL1−/− mice (24, 28 and 25 μg/mg). Renal mass was reduced by 10% in both UCHL1+/+ and NOX5−/−/UCHL1+/+ mice as compared to nonTG mice. Interestingly, GFR was elevated in NOX5−/−, UCHL1+/+ and NOX5−/−/UCHL1+/+ mice (283, 362 and 352 μl/min) vs. nonTG (196 μl/min). In UCHL1−/− mice regardless of NOX5 expression, hypercellularity was evident in the juxtaglomerular region. However, no differences were found in renin or PCNA expression, suggesting that the increased GFR is independent of the renin-angiotensin system. Blood pressure in NOX5−/−/UCHL1−/− mice (121 mmHg) was the same as NOX5−/−/UCHL1+/+ mice, but was different from NOX5−/− mice (127 mmHg) at 12 weeks.

Conclusions: UCHL1-null mice have altered renal function and mass. When intercrossed with NOX5−/− mice, UCHL1 deletion combined with unchecked oxidative stress promotes filtration barrier damage.

Inulin Receptor Isoform A Is Implicated in Podocyte Injury in Diabetic Kidney Disease

Kidney Disease Branch, NIDDK, NIH, Bethesda, MD.

Background: Genetic variants apolipoprotein L1 (APOL1), present in individuals of recent African descent, are strongly associated with glomerular disease, but the molecular mechanisms through which APOL1 nephropathies may be driven by podocyte inflammation and the TLR and IL-1 pathways have not been established. We hypothesized that APOL1 nephropathies may be driven by podocyte inflammation and the TLR and IL-1 pathways.

Methods: Differentiated human podocytes were cultured in the presence of TNFa (100 ng/ml) and Caspase 3 activator was determined in human podocytes. Cyclodexrin (CD) was used to deplete cholesterol.

Results: FSGS sera treated podocytes demonstrated increased TNFα expression. Increased TNFα expression correlate with decreased ABCA1 expression in glomerular basement membrane (GBM) of FSGS patients and treatment of podocytes with TNFa + CD for 12 weeks (40ug/mg) but not in nonTG, UCHL1−/− and NOX5−/−/UCHL1−/− mice. Albuminuria (ACR) was measured by ELISA. Renal mass was normalized to tibia length. Glomerular filtration rate (GFR) was assessed by FITC-Inulin. Immunofluorescence with anti-PNA and anti-renin was performed on renal sections. Blood pressure was determined by tail cuff plethysmography.

Results: UCHL1 protein increased 1.9-fold in COST cells infected with AdNOX5 vs. AdGFP-infected controls. Similarly, glomeruli from 12-week-old NOX5−/− mice showed limited UCHL1 mRNA induction (1.5-fold). ACR increased in NOX5−/−/UCHL1+/+ mice at 12 weeks (40 μg/mg) but not in nonTG, UCHL1−/− and NOX5−/−/UCHL1−/− mice (24, 28 and 25 μg/mg). Renal mass was reduced by 10% in both UCHL1+/+ and NOX5−/−/UCHL1+/+ mice as compared to nonTG mice. Interestingly, GFR was elevated in NOX5−/−, UCHL1+/+ and NOX5−/−/UCHL1+/+ mice (283, 362 and 352 μl/min) vs. nonTG (196 μl/min). In UCHL1−/− mice regardless of NOX5 expression, hypercellularity was evident in the juxtaglomerular region. However, no differences were found in renin or PCNA expression, suggesting that the increased GFR is independent of the renin-angiotensin system. Blood pressure in NOX5−/−/UCHL1−/− mice (121 mmHg) was the same as NOX5−/−/UCHL1+/+ mice, but was different from NOX5−/− mice (127 mmHg) at 12 weeks.

Conclusions: UCHL1-null mice have altered renal function and mass. When intercrossed with NOX5−/− mice, UCHL1 deletion combined with unchecked oxidative stress promotes filtration barrier damage.

Cyclodexrin Improves Renal Function in Experimental Alport Syndrome

Kidney Disease Branch, NIDDK, NIH, Bethesda, MD.

Background: Alport syndrome (AS) is an inherited disease caused by gene mutations involved in collagen type IV biosynthesis. No treatments are currently available for AS. 2-hydroxypropyl-β-cyclodextrin (CD) is a cholesterol depleting agent that is now in clinical trials for treating Niemann-Pick disease type C. We have recently reported that CD protects in experimental DKD by reducing cholesterol dependent podocyte damage. We hypothesized that CDs improves renal function in an experimental model of AS.

Methods: Collagen Co4a3 knockout (KO) mice were used as a model for AS. Four-week-old Co4a3 (KO) and wild type (WT) female mice were injected subcutaneously with CD (4000 mg/kg) or vehicle (0.9% Saline solution). 3 times per week for 3 weeks. Four weeks post CD treatment or vehicle treatment, renal function was tested by measuring serum creatinine and blood urea nitrogen (BUN) which were measured by mass spectroscopy and ELISA respectively. Additionally,_fence perfused kidneys from Co4a3 KO and WT mice. Kidneys were harvested for histological analysis (H&E, PAS) and for Oil Red O (Staining).

Results: H&E staining showed no toxicity at the site of CD injections. No body weight changes were observed during treatment. CD administration reduced glomerular

Santos, Gloria Michelle Ducasa, Sandra M. Merscher, Christopher E. Pedigo, Judith T. Molina David, Mayrin Correa-Medina, Catherine A. Pedigo, Paula Zelaya, Allia Mitrofanova, Sandra M. Merscher, Alessia Fornoni, Div of Nephrology & Hypertension, Univ of Miami, FL, Dep of Surgery, Univ of Miami, FL.

Results: Podocytes overexpressing SMPDL3b (OE) showed significant increase of IRB/IRA mRNA expression ratio compared to control podocytes (CT) (1.0±0.00 vs. 0.74±0.05, p<0.05). Co-IP demonstrated that both IRA and IRB interact with Cav1. SMPDL3b overexpression augmented IRA/Cav1 interaction and suppressed IRB/Cav1 interaction. OE podocytes showed bigger cell surface area compared to CT (2778±0.00 vs. 2467 and 2117±0.54, p<0.05). Insulin stimulation had no effect on the caspase-3 activity in CT podocytes while it induced apoptosis in OE cells (1.19±0.08 and 2.14±0.32, p<0.05).

Conclusions: Our data suggest SMPDL3b overexpression in human podocytes impairs IRB signaling leading to increased apoptosis and augments IRA signaling resulting in cell death and apoptosis.

TGF Mediated NFAT Activation Causes Podocyte Cholesterol Accumulation in FSGS

Christopher E. Pedigo, Peggy and Harold Katz Family Drug Discovery Center, Univ of Miami, Miami, FL, Dep of Surgery, Univ of Miami, FL.

Methods: Cyclodexrin improves renal functional in experimental Alport Syndrome. Cyclosporine A (CsA) which directly influences podocyte Nuclear Factor of Activated T-Cells (NFAT) activation. However, a potential link between TNFα-NFAT-APOL1 nephropathies has not been established. We hypothesized that TNFα causes NFAT mediated lipopid dependent podocyte apoptosis in FSGS.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

The Glomerular Matrisome in Alport Syndrome Is Altered prior to the Onset of Albuminuria

*Michael J. Randles,* 1, 2 *Sophie C. Collinson,* 1  *Jeffrey H. Miner,* 1  *Rachael Lennon.* 1

**1**Welcome Trust Centre for Cell Matrix Research, Faculty of Life Sciences, Univ of Manchester, Manchester, United Kingdom, 2Inst of Human Development, Faculty of Medical & Human Sciences, Univ of Manchester, Manchester, United Kingdom; 3Renal Div, Washungton Univ School of Medicine, St. Louis, MO.

**Background:** Alport Syndrome is caused by genetic defects in COL4A3, COL4A4 or COL4A5, but despite this knowledge there are currently no targeted therapies. We aimed to build our basic understanding about the glomerular extracellular matrix (ECM) in Alport syndrome and performed global analysis of composition and ultrastructural imaging in the Col4a3/-/- mouse.

**Methods:** Cellular and extracellular matrix (ECM) fractions from wild type and Col4a3/-/- mice at 6 and 16 weeks of age were analysed by mass spectrometry (MS) and imaged using serial block face-scanning electron microscopy (SBF-SEM).

**Results:** MS analysis revealed moderate changes in the composition of glomerular ECM at 6 weeks, even prior to the onset of barrier dysfunction. These included complete absence of type IV collagen α3, α4, α5 and upregulation of type VI collagen in α2, α6 and type V1 collagen. At 16 weeks more dramatic changes were detected including elevated type IV collagen α1, α2, fibronectin, type 1 collagen, laminin α2 and fibrinogen chains. Global and pathway analysis of cellular fractions indicated changes in actin regulating proteins at 6 weeks and mitochondrial dysfunction at 16 weeks. SBFSEM demonstrated thickened and irregular glomerular basement membranes with evidence of podocyte protrusions into this ECM.

**Conclusions:** Our data demonstrate that Alport syndromes progress with distinct early changes in ECM followed by more profound ECM accumulation, disruption and mitochondrial dysfunction. Enhanced understanding about the pathways that control podocyte matrix adhesion may ultimately inform therapeutic strategies to correct or repair glomerular barrier function in Alport syndrome.

Creation and Analysis of Mouse Models of Human Nephrotic Syndrome Caused by the Laminin b2 (LAMB2) S80R Mutation

*Steven Daniel Funk, Jeffrey H. Miner. Renal Div, Washungton Univ School of Medicine, St. Louis, MO.*

**Background:** Most cases of congenital nephrotic syndrome in the first year of life are caused by mutations in 4 genes expressed in podocytes: NPHS1, NPHS2, LAMB2, LAMB2 encodes laminin b2, a glomerular basement membrane component critical for glomerular filtration. We previously created transgenic mice using the laminin promoter to study missense mutations discovered in patients with congenital nephrotic syndrome, including R246Q and C321R, which inhibit laminin-521 secretion and/or LAMB2 polymerization domain that was discovered in a delayed nephrotic syndrome patient; this delay suggests that chronic dysfunction in glomerular filtration may be the pathogenic mechanism.

**Methods:** In our first approach the S80R mutation was engineered into the rat laminin b2 cDNA and placed under the control of the nephrin promoter; this construct was used to create transgenic mice expressing S80R in podocytes on the LAMB2-/- background. In a second approach, we utilized CRISPR/Cas9 and homologous recombination to "knock-in" the S80R point mutation into the endogenous LAMB2 gene.

**Results:** Several transgenic mouse lines were characterized as very high, high, and moderate expression in podocytes in the LAMB2-/- background. In a second approach, we utilized CRISPR/Cas9 and homologous recombination to "knock-in" the S80R point mutation into the endogenous Lamb2 gene.

**Conclusions:** The LAMB2-S80R mutation seems to be mild vs. other LAMB2 mutations. S80R is in the laminin N-terminal (LN) domain important for laminin polymer formation. High transgenic expression may compensate for S80R-induced polymorphism defects, which will be avoided with CRISPR/Cas9-induced, S80R knock-in mutants.

Differential Roles of Cell Surface Proteoglycans in Podocyte-Glomerular Basement Membrane Adhesion

*Angela C. DiPoto-Brahmhatt, Deborah J. McCarthy, Kevin J. McCarthy. Pathology and Translational Pathobiology, LSU Health Sciences Center-Shreveport, Shreveport, LA.*

**Background:** Cell surface proteoglycans (PG), via their heparan sulfate (HS) chains, work in a cooperative fashion alongside integrins to mediate podocyte (PG)-glomerular basement membrane (GBM) interactions. Results of our previous studies have shown that the expression of HS at the podocyte cell surface leads to the establishment of foot process effacement. Since podocyte HS have been shown to be capable of mediating such interactions, the purpose of this study was to determine the effects of selective deletion of the cell surface PG, syndecan-1 (Sdc1) or syndecan-4 (Sdc4) on podocyte function in vivo.

**Methods:** Frozen tissue sections of kidneys from *Col4a3* knockout (KO) mice were immunostained with antibodies against the core proteins of Sdc1 and Sdc4, HS (antibody HS4C3), syndaptoedin (SYN), nephrin, and α-actinin-4. To determine the potential for loss of anionic charge associated with HS, 500nm sections of unfixed kidneys were treated with polyethyleneimine (PEI) followed by fixation and processing for transmission electron microscopy.

**Results:** TEM studies showed that the GBMs of both Sdc1 and 4 KO mice had GBM irregularities, the POD in Sdc4KO mice showing moderate foot process effacement. Immunostaining for HS did not show differences in staining intensity for HS between Sdc1 and Sdc4KO mice. However, PEI labeling showed that the GBMs in Sdc4 KO mice had larger aggregates of PEI than those found in the GBM of Sdc1 KO mice. Immunostaining showed that a compensatory increase in Sdc4 expression in Sdc4KO glomeruli or Sdc1 expression in Sdc4KO glomeruli did not occur. The glomeruli of Sdc1 KO mice showed disruption of nephrin organization compared to Sdc4 and WT mice. Immunostaining for α-actinin-4 in both Sdc1 KO and Sdc4KO glomeruli was also disrupted compared to control.

**Conclusions:** The data show that disruption of either Sdc1 or Sdc4 interactions with the GBM affects the manner by which POD interact with the GBM. Although loss of Sdc4 was associated with the development of foot process effacement, the loss of either Sdc1 or Sdc4 have effects on POD cytoskeletal organization.

ERMT Protein Activation by CLIC4 in Glomerular Endothelial Cells

*Abass Almomany, 1 Mahat Tavasoli, 1 Laiji Li, 1 John C. Edwards, 2 Barbara J. Ballermann, 3 Medicine, Univ of Alberta, Edmonton, AB, Canada; 2Internal Medicine, St. Louis Univ; 3St. Louis, MO.*

**Background:** We reported (J. Cell Sci. 2014, 127:1564) that the podocyte-predominant CLIC5A stimulates PI[4,5]P2 production and consequent ERM ( ezrin, radixin, moesin) protein activation (pERMs) and a decrease in the endothelial glycocalyx as a contributor to development of albuminuria (albumin in the urine) and eventually DN. TNFα which is important in the development of microvascular diseases in diabetes caused a disruption of the glomerular endothelial cells (GEnC) and a key regulator of vascular permeability. Increasing evidence points to disruption of such interactions, the purpose of this study was to determine the effects of selective deletion of the cell surface PG, syndecan-1 (Sdc1) or syndecan-4 (Sdc4) on podocyte function in vivo.

**Methods:** Frozen tissue sections of kidneys from *Col4a3* knockout (KO) mice were immunostained with antibodies against the core proteins of Sdc1 and Sdc4, HS (antibody HS4C3), syndaptoedin (SYN), nephrin, and α-actinin-4. To determine the potential for loss of anionic charge associated with HS, 500nm sections of unfixed kidneys were treated with polyethyleneimine (PEI) followed by fixation and processing for transmission electron microscopy.

**Results:** TEM studies showed that the GBMs of both Sdc1 and 4 KO mice had GBM irregularities, the POD in Sdc4KO mice showing moderate foot process effacement. Immunostaining for HS did not show differences in staining intensity for HS between Sdc1 and Sdc4KO mice. However, PEI labeling showed that the GBMs in Sdc4 KO mice had larger aggregates of PEI than those found in the GBM of Sdc1 KO mice. Immunostaining showed that a compensatory increase in Sdc4 expression in Sdc4KO glomeruli or Sdc1 expression in Sdc4KO glomeruli did not occur. The glomeruli of Sdc1 KO mice showed disruption of nephrin organization compared to Sdc4 and WT mice. Immunostaining for α-actinin-4 in both Sdc1 KO and Sdc4KO glomeruli was also disrupted compared to control.

**Conclusions:** The data show that disruption of either Sdc1 or Sdc4 interactions with the GBM affects the manner by which POD interact with the GBM. Although loss of Sdc4 was associated with the development of foot process effacement, the loss of either Sdc1 or Sdc4 have effects on POD cytoskeletal organization.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Online; Underline represents presenting author. 706A
glycosalys through shedding of SDC4 and heparan sulphate (HS). We seek to investigate the role of vascular endothelial glycosalys in DN and determine the mechanisms involved in its disruption in DN.

**Methods:** DN was induced in DBA2 mice by giving daily intraperitoneal injection of streptozotocin (STZ) at 50mg/kg for 5 days. The mice became hyperglycemic at 2 weeks and significantly albuminuria in glomeruli in DN, suggesting shedding of vascular SDC4. An increase in SDC4 shedding was recorded in a mock mechanism resulting in an increase in SDC4 mRNA synthesis in isolated glomeruli and Gfrc. The glycosalys SDC4 synthesis coincides with albuminuria, strongly suggesting that vascular glycosalys SDC4 damage is likely to contribute to albuminuria in DN. There was a significant elevation in gelatinase matrix metalloproteinase-9 (MMP9) in glomeruli in DN, suggesting that MMP9 could mediate SDC4 shedding. My in vitro data in human Gfrc showed that gelatinase MMP9 was upregulated and resulted in the shedding of SDC4 and HS. This resulted in an increase in BSA permeability across the monolayer.

**Conclusions:** MMP9-mediated shedding of SDC4 is likely to contribute to vascular endothelial glycosalys damage and albuminuria observed in DN. Potential therapies targeted at glycosalys protection will be of benefit not only in DN but also in ameliorating systemic vascular disease in diabetes.

**Blood Cell Velocities in Glomerular Capillaries Measured by 2-Photon In Vivo Microscopy:** Revealing Heterogeneous Blood-Flow

**Debora Pedotti,** 1, 2 Eugenio Gutierrez, 1 Luca Bordoni, 1 Sara Damiano, 1 Francesco Trecipiccione, 1 Giovanni Batista Capanna, 1, 2, 3 Sebastian Frische. 1, 2 Dept of Biomedicine, Aarhus Univ, Aarhus, Denmark; 3 Dept of Cardio-Thoracic and Respiratory Science, Second Univ of Naples, Napoli, Italy; 1 Center for Functionally Integrative Neuroscience, Aarhus Univ, Aarhus, Denmark; 2 Biogem, Ariano Irpino, Italy.

**Background:** Theoretical models have shown that the blood-flow within a glomerulus may be heterogeneous and that flow heterogeneity may affect the ultrafiltration coefficient and thus GFR. The aim of this study is to provide experimental data to test these model predictions by measuring glomerular capillary flow velocities by in vivo 2-photon microscopy.

**Methods:** Male Munich-Wistar rats were intubated, anesthetized with isoflurane, and mechanically ventilated. Blood pressure and heart-rate were monitored. The left kidney was externalized and the rat placed in the 2-photon microscope. Blood plasma was labeled by i.v. injection of 0.2 mg oxytetracycline/kg. Longitudinal lines in the lumen of capillaries in superficial glomeruli were scanned at a frequency of >700 Hz. The axial movement of single blood cells was measured. 308 different capillaries were analyzed in 17 glomeruli from 5 different rats.

**Results:** Blood cell velocity was 2.99 mm/s ± 0.54. A Gaussian distribution and a Gamma-distribution were fitted to data from 13 glomeruli in which >12 capillaries were studied. C-tests (p = 0.05) showed 5 of 13 datasets not to follow a Gaussian distribution and 1 of 13 not to follow a Gamma-distribution. The data from all 308 capillaries normalized to the mean of the respective glomerulus did not follow a Gaussian distribution (p < 0.05). The Gamma-distribution allows an asymmetrical distribution around the mean and provided the best description.

**Conclusions:** This study provides experimental evidence of heterogeneity and an asymmetrical distribution of blood cell velocity in glomerular capillaries. This new experimental evidence calls for refinement of current models of glomerular blood flow heterogeneity and invokes the possibility to investigate the potential regulatory control of the ultrafiltration coefficient by regulation of capillary flow heterogeneity, e.g. by the activity of mesangial cells.

**Assessment of Exosomes Derived from Mesangial Cells Stimulated with High Glucose**

Antonio S. Novoa, 1 Fernanda Teixeira Borges, 1 Marcus Dias, 1, 2 Mirian A. Boim. 1, 2 Medicine, Federal Univ of Sao Paulo, Sao Paulo, SP, Brazil; 1 CIPE - Centro Internacional de Pesquisa, A.C. Camargo Cancer Center, Sao Paulo, SP, Brazil.

**Background:** Exosomes and microvesicles (MV) are extracellular vesicles (EV) that are released by cells and contain substances such as proteins and nucleic acids such as microRNAs (miRNA). This study aimed to ascertain the role of exosomes and MV secreted by human mesangial cells (MC), a cell type involved in glomerular diseases, including IgA nephropathy (IgAN). Platelet-derived growth factor (PDGF) is a potent stimulator of MC, activating multiple signaling pathways associated with proliferation of MC. Our global kincrome profiling revealed that activity of multiple kinases in MC increased after PDGF stimulation, including tyrosine kinase Axl. As there is limited information on the association of PDGF signaling and activation of Axl in human MC, we studied details of Axl involvement in human MC stimulated by PDGF.

**Methods:** MC were obtained from a commercial source or isolated from biopsy samples of patients with IgAN or other glomerular diseases. Quiescent primary human MC were stimulated by PDGF AB in the presence or absence of different inhibitors. MC lysates were analyzed by global tyrosine-kinome profiling using PamStation®12 platform and Western blotting. MC proliferation was measured by BrdU incorporation. The expression and distribution of Axl in MC were assessed by immunofluorescence.

**Results:** Tyrosine-kinome profiling indicated that PDGF AB increased Tyro3, Abl, and Ltk kinase activities. Further data analyses predicted Axl as one of the key upstream kinases activated in PDGF-AB-stimulated MC. We found that Axl was activated in all tested primary human MC. PDGF AB stimulated proliferation of MCs; this effect was inhibited by Axl-specific inhibitor R428. Signaling studies revealed that PDGF AB increased phosphorylation of multiple signaling proteins, including Axl, PDGFR-β, Akt1, and ERK1/2. R428 significantly inhibited phosphorylation of Axl and Axl1, and, to a lesser extent, also of ERK1/2 and PDGFR-β. MEK1/2 inhibitor U0126 and PI3K inhibitor LY294002 did not affect phosphorylation of Axl.

**Conclusions:** Axl is involved in PDGF-induced proliferation of cultured MC through multiple signaling pathways. Targeting Axl may provide a new therapeutic strategy for IgAN.

**Funding:** Government Support - Non-U.S.

**Different Effects and Mechanisms of Prostaglandin E2 Receptor Subtypes EP1, EP4 in TGF-β1-Induced Mesangial Cell Injury**

Chen Xiao Lan, 1, 2 Yuan Li, 1 2 Affiliated Hospital of Nantong Univ; 2 Affiliated Hospital of Nantong Univ.

**Background:** To study effects of prostaglandin E2 receptor subtypes 1 and 4 (EP1 and EP4) in mesangial cell injury by transforming growth factor -β1 (TGF-β1) and relevant signaling pathways.

**Results:** 1. After TGF-β1 stimulation, expression of FN and CTGF increased; the expression of FN and CTGF in Group EP2KO increased; the expression of FN and CTGF in EP4KO decreased; 2. after TGF-β1 stimulation, the Smad3 phosphorylation level in EP2KO increased; while the Smad3 phosphorylation level markedly decreased in EP4KO; 3. the PGE2 level of WT mesangial cell increased at 12h after TGF-β1 treatment; 5. the AML-1 phosphorylation in EP2KO was less than that of the control; PKA activity obviously declined; the PGE2 content in EP4KO after stimulation with TGF-β1, the PGE2 content obviously declined; PKC activity increased; 6. ERK inhibitor blocks the function caused by agonist EP4; while PKA inhibitor blocks the inhibition function of agonist EP2.

**Conclusions:** EP2 and EP4 have different regulating effects on injury and renal fibrosis of mesangial cells: EP2 receptor mediated PGE2 induced up-regulation of the level of cAMP and PKA activity, so as to inhibit transduction effects of TGF-β1/IgA3 pathway and reduced the occurrence of injury and fibrosis of mesangial cell; while EP4 may mediate the promoting effect of mesangial cell injury induced by TGF-β1 by activating phosphorylation ERK pathway, resulting in regulating effects different from that of EP2.

Characterization of Circulating APOL1 Complexes and Their Kidney Distribution in African Americans

**Background:** The apolipoprotein L1 gene (APOL1) G1 and G2 renal-risk variants associate with non-diabetic nephropathy and cardiovascular disease in African Americans (AAs). Although substantial APOL1 protein is present in the circulation, with enrichment in podocytes compared to other renal cells, little is known about circulating APOL1 protein.

**Methods:** Total serum APOL1 levels were examined by Western blot in a cohort of healthy AAs who had a 1-year relative degree with kidney disease. APOL1 protein complexes were isolated from fast protein liquid chromatography (FPLC) peak fractions and characterized by proteomic analyses. Results were subsequently verified by co-immunoprecipitation and Western blot.

**Results:** No significant differences were detected in serum APOL1 protein concentration based on APOL1 genotypes. However, serum APOL1 protein is bound to other protein complexes. Non-denaturing gel electrophoresis and FPLC demonstrated that serum APOL1 protein existed in two non-overlapping peaks (12.2nm and 20.0nm in diameter, respectively). The smaller complex was labeled complex A and the larger complex B. Density gradient ultracentrifugation and agarose gel electrophoresis confirmed that neither APOL1 protein complex was associated with HDL or LDL cholesterol. The exposure of APOL1 complex A surface epitopes appeared to be altered by G1/G2 renal-risk variants based on avicabeadic specificity to a monoclonal antibody from a non-G1/G2 associated immunogen (p=0.01). APOL1, haptoglobin-related protein (HPR), and complement C3 were present in APOL1 complex A. APOL1, HPR, IgM, and fibronectin were present in APOL1 complex B. In APOL1 complex A, HPR-α was more abundant in those with G1 and G2 renal-risk variants, relative to G0 (GENMOD p=0.04, total N=12). Serum HPR-α was only present in APOL1 complexes. Small amounts of HPR protein were detected in renal tubule cells but not glomeruli, whereas HPR mRNA was absent in the kidney.

**Conclusions:** Results provide unique insights on the composition of circulating APOL1 complexes. The role of circulating APOL1 in kidney and cardiovascular disease in AAs requires further investigation.

Deep Mapping of the Native Mouse Podocyte Proteome

**Background:** The entirety of proteins expressed within a podocyte is still not known.

**Methods:** We performed mass spectrometry based absolute and relative quantification of the proteome of FACS-sorted native mouse podocytes.

**Results:** We resolved the podocyte proteome at a near-comprehensive resolution (more than 8000 identified proteins). Absolute copy numbers of proteins correlated with copy numbers obtained from deep-sequencing transcriptomic analysis. The dataset indicates agreement between transcriptome and proteome regarding expression of proteins which are mutated in hereditary forms of proteinuria and FSGS in humans. 541 proteins were enriched within podocytes at very high ratios and significance. This study suggests that the podocyte is not only target to inflammatory stimuli such as TNFalpha and IFN gamma, but also unanticipated other stimuli. In addition, this study delineates podocyte enriched tyrosine kinases, a few of these are drugable. Protein domains significantly enriched in podocyte proteins comprise not only PDZ and Fn3 domains, but also i-set domain, an adhesion domain. The majority of podocyte specific proteins also stain positive for filaments in human samples, with a weak correlation between staining intensity and absolute protein abundance measured by MS/MS.

**Conclusions:** This initial, near comprehensive draft of the podocyte proteome reveals untapped molecules and mechanisms. This dataset will be of benefit to understand podocyte physiology, pathobiology and develop potential therapeutic strategies.

Maternal Obesity Is a Significant Risk Factor for the Development of Diabetic Nephropathy

**Background:** Our previous studies have shown that maternal obesity is associated with increased proteinuria in the offspring. We hypothesised that a second-hit such as diabetes may further exacerbate diabetic nephropathy in offspring exposed to maternal obesity.

**Methods:** Female C57Bl6 mice were fed either normal or high-fat diet (HFD) for 6 weeks prior to pregnancy, during pregnancy and weaning and their offspring were weaned to chow diet or HFD. At Week 8, the male offspring were randomized to streptozotocin (STZ) 55mg/kg/day for five consecutive days. 100 mg/kg once or placebo. Weight and glucose levels were measured fortnightly. 24 h urine collection was performed at Week 20 and 30. The kidneys were harvested at Week 32. The renal structure was observed. Serum levels of proinflammatory, prooxidative and oxidative stress markers were measured by real time PCR and confirmed with protein quantification with Western blot and/or immunohistochemistry.

**Results:** Offspring of obese mothers had increased fat deposition. Diabetic offspring had reduced weight gain, hyperglycaemia, glycosuria and microalbuminuria. Urinary albumin levels in offspring were highest in offspring of obese mothers exposed to 5 days of STZ. The kidneys of the offspring exposed to maternal obesity and induced with diabetes had increased structural damage, renal fibrosis and increased inflammatory changes and markers of oxidative stress when compared to the kidneys of diabetic offspring of normal weight mothers. There was significant intrarenal lipid deposition in obese offspring, exacerbated by maternal obesity and diabetes.

**Conclusions:** Offspring exposure to maternal obesity accelerates the severity of damage to the kidney caused by diabetes. Fetal programming of renal inflammation and oxidative stress may be a key component to the accelerated risk. Offspring diet has a powerful effect on renal outcome.

Leucine-Rich Glycoprotein 1 : A Candidate Biomarker for Early Renal Function Decline in Type 2 Diabetes

**Background:** Patients with type 2 diabetes were recruited into training (n=56) and independent, non-overlapping test (n=37) groups (median baseline eGFR = 80.3 ± 29.5 ml/min/1.73m²). LRG1 was measured in spot urine collections by ELISA, and performance was assessed as area under the receiver operating characteristic curve (AUC) with adjustment for clinical covariates of DKD.

**Methods:** Patients with type 2 diabetes were recruited into training (n=56) and independent, non-overlapping test (n=37) groups (median baseline eGFR = 80.3 ± 29.5 ml/min/1.73m²). LRG1 was measured in spot urine collections by ELISA, and performance was assessed as area under the receiver operating characteristic curve (AUC) with adjustment for clinical covariates of DKD.

**Results:** Urine LRG1 was associated inversely with eGFR (r = −0.546, P=0.001) and positively with ACR (r = 0.283, P = 0.034). The AUC of LRG1 for identifying participants with baseline eGFR 90 – 60 was 0.815 ± 0.103, in contrast, the AUC of the albumin/creatinine ratio was 0.465 ± 0.093 (P < 0.01 versus LRG1). Adjustment for age, sex, race, duration of diabetes, and HbA1c, did not alter the AUC for LRG1, and these results were replicated in the test group. In participants with eGFR > 60/ml/min/1.73m² at baseline, LRG1 predicted a 5-year outcome of eGFR < 60 or ESRD better than ACR (0.782 ± 0.085, P = 0.01 versus ACR, 0.520 ± 0.119).

**Conclusions:** Taken together, these results suggest LRG1 may identify patients with early renal function decline more accurately than ACR. Evaluation of LRG1 in prospective cohorts of type 2 diabetes may lead to a better biomarker for identifying and monitoring DKD.

A Longitudinal Study on Kidney Function, Pathology, and Multiple Urinary Biomarkers in ZSF1 Rat Model of Type II Diabetic Nephropathy  
Kidney Research, Abivie, North Chicago, IL.

Background: Obese ZSF1 rats display many clinical features of human type II diabetic nephropathy (DN). To further understand this model and to identify relevant biomarkers of disease progression, we followed the development of DN by measuring glomerular filtration rate (mgFR), histopathology, and a variety of urine and tissue biomarkers over 24 weeks after uninephrectomy (Unx). Correlations between mgFR and individual urinary biomarkers were assessed.

Methods: Male rats (9-week old) underwent either a sham or Unx (right kidney) surgery and were fed a high carbohydrate diet. GFR was measured by transdermal clearance of FITC-sinistrin. Urine samples were collected every 2-4 weeks for biomarker analysis, and renal tissue was examined for collagen deposition as well as for the levels of key inflammatory and fibrogenic genes.

Results: Kidney hypertrophy was observed (2-3 fold increase in mgFR) in obese rats 2-week after surgery lasting until week 4. The mgFR subsequently declined over time in these rats and was 2-fold lower than control rats by end of study. Compared to lean rats, obese rats also demonstrated time-dependent increases in urinary excretion of protein, KIM-1, L-FABP, NGAL, Cystatin C, Clustatin, Beta2-microglobulin, alpha1-acid glycoprotein, VEGF, MCP-1, TIMP-1, Collagen IV, TGF-b1, and TGF-b2. A significant correlation was found between mgFR and a number of urinary biomarkers (L-FABP, KIM-1, TIMP-1, Clustatin, Cystatin C, and TGF-b2). Kidney fibrosis was significantly elevated by week 12 post surgery and continued to expand in the following weeks. Unx increased the weight and glomerulosclerosis of the remaining kidney and accelerated the decline of mgFR in obese rats during late weeks of observation.

Conclusions: ZSF1 rats showed a progressive increase of fibrosis and loss of mgFR over the 24-week study. A number of urinary biomarkers demonstrated a strong inverse correlation with the time-dependent changes in mgFR. Additionally, Unx significantly increased glomerulosclerosis and loss of GFR in obese rats.

Haptoglobin 2-2 Genotype Is Associated with Decreased Levels of Vitamin D Receptor (VDR), Klotho and Accelerated Renal Apoptosis in Mice and Humans with Diabetic Nephropathy  
Farid N. Makhouil,1 Farber Evgeny,2 Nadia Thawho,3 Andy Levy,4 Inbal Dahan.5  
Diabetic Nephropathy Lab, Baruch-Paduch Porvus M. Center, Lower Galilee, Israel; 5Nephrology, Faculty of Medicine In Galilee Bar Ilan Univ, Israel; 6Vascular Medicine, Technion, Haifa.

Background: Haptoglobin (Hp) is an antioxidant protein by its ability to bind free hemoglobin (Hb) and prevents heme-iron mediated oxidation. Diabetic mice & humans with different Hp genotype (1-1, 2-2) have a different susceptibility to develop Diabetic Nephropathy (DN) due to impaired Hb clearance and increased iron deposits in the lysosomes of the kidney proximal tubules (PCT). This leading to increased renal oxidative stress and cell damage. Our study proposed a molecular mechanism explaining the influence of Hp genotype, klotho expression on 1-α hydroxylase and active vitamin D/VDR in DN patients.

Methods: Slides from kidney biopsies of DN patients and mice with different Hp genotype (1-1, 2-2) were subjected to Immunohistochemistry staining of iron modified with DAB method, klotho, active caspase 3, vitamin D receptor (VDR) and 1-α hydroxylase, using specific antibodies. Blood samples to Haptoglobin test and ELISA DAB method, klotho, active caspase 3, vitamin D receptor (VDR) and 1-α hydroxylase, were used to measure Vitamin D levels.

Results: There were significant increased iron deposits in the renal PCT of Hp-2/2 mice and patients there was a significant increase expression of active caspase-3 staining that was accompanied with decreased renal expression of VDR, 1α hydroxylase and klotho levels.

Conclusions: Hp 2-2 genotype associated with increased iron deposits and high levels of PCT apoptosis Decreased levels of the anti oxidant klotho and VDR in the renal PCT. We propose a molecular mechanism explaining the influence of Hp genotype and klotho expression on renal PCT apoptosis in DN patients. These results provide new insights into the role of Klotho and VDR expression on the pathogenesis of DN in patients with Hp-2-2 genotype.

Resistance Exercise Training Prevents Kidney Hypertrophy and Increases the Biogenesis Mitochondrial in Diabetic Rats  
Luciana Jorge,1 Kleiton Augusto Santos Silva,2 Rafael Luiz,2 Rodolfo Rosseto Rampaso,1 Janaina Paulini Aguair,2 Nestor Schor.1  
Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil; 2Molecular Biology, Univ of Utah, Salt Lake City, UT.

Background: Diabetic nephropathy(DN) is a progressive complication arising from diabetes. kidney cell response to injury includes cell division, cell hypertrophy and apoptosis. Increasing evidence indicates that the disruption of mitochondrial bioenergetics and structural change in the kidney may be important in the development and progression of DN. Therefore, is fundamental the understand of a non pharmacological intervention as exercise training to prevent those complications. We investigated the effect of resistance training(RT) on the DN pathogenesis.

Methods: Male Wistar rats were divided into control(C), control trained(CT),diabetic(D) and diabetic trained (DT). DM was induced by STZ. Trained groups were submitted to a resistance exercise training on Ladder climb (8wk). Urinary volume and proteinuria were evaluated.Tissue weight/tibial length ratio was used as kidney hypertrophic index. Expression of P-Akt,P-Mtor,P-AMPK and Mfn2 protein was evaluated by western blotting.

Results: RT improved renal parameters in DT group show a decreased urinary volume(160±160;120±120;13±13;14±14;proteinuria(45±32;32;17;7 mg/24h) (p<0.05).Diabetes resulted in increased hypertrophic index (50%) and RT prevented it. Renal expression of PAMPK and Mfn2 was reduced in D group and RT normalize this expression(p<0.05). Moreover, the renal expression of PAKT and PmTOR were increased in the DM and the RT influence on it(p<0.05). Histological analysis showed glomerular hypertrophy in D and RT prevent this complication.

Conclusions: RT attenuated progression of diabetic nephropathy; Those improvements could be a result of increased AMPK/Mfn2 pathway, an important pathway to biogenesis mitochondrial; and inhibition of AKT/mTOR pathway, responsible for hypertrophic response, demonstrating that those complications were prevented by exercise training. Our findings demonstrated that RT is an important approach to avoid, both molecular and functional complications in diabetic kidney.Funds from FAPESP,CNPq and CAPES.

Aerobic Exercise Training Improves Proteinuria and Renal Inflammatory Factors in Rats with Diabetic Nephropathy  
Rodolfo Rosseto Rampasso, Rafael Luiz, Kleiton Augusto Santos Silva, Luciana Jorge, Edison Andrade Pessoa, Mario Luis Ribeiro Cesaretti, Nestor Schor. Nephrology, UNIFESP, SP, Brazil.

Background: The objective of this study was to evaluate the effects of aerobic exercise training in controlling the progression of diabetic nephropathy, inflammatory factors, and its possible renoprotective effects.

Methods: Adult male Wistar rats/4 groups, n=8/group: Sedentary controls (C-SED), Diabetics+Sedentary (DM-SED), Diabetes+Exercise (DM-EXE) and control exercise (C-EXE). Diabetes was induced with STZ,50 mg/kg. The exercise training were conducted on a treadmill 60min/day, 5 days/week/8 weeks. Weekly certain, maximal exercise test(set at 65-70% of MEtest). Glycemia after post 24 education(24 glycemiapt), MEtest, creatinine clearance(BW)(CCRWB), arterial pressure(AP), proteinuria(protein), renal inflammatory factors IL-6, IL-10 and TNF-a were measured. Data as mean ± SD.

Conclusions: Reductions in blood glucose and AP ~11% comparing DM-EXE vs DM-SED. The DM-EXE controlled weight loss ~40% compared to DM-SED, but did not prevent change in CCRWB with this protocol. However, the effect was surprisingly observed EXE reduction in both excretion through uPro ~60% and ~25% in MD-inflammatory factors comparing SED vs DM-EXE. Preliminary data suggests that aerobic exercise can reduce proteinuria and inflammatory factors in diabetic animals and hence reduce the potential effects caused by diabetic nephropathy and could reduce the progression of renal failure.
Inhibition of miR-25 Processing Mediated by MeCP2 Phosphorylated by HIPK2 Can Uregulate NOX4 in Early Diabetic Nephropathy

**Background:** Altered microRNA (miR) levels play key roles in the pathogenesis of diabetic nephropathy (DN), but it is unclear if miR processing is involved. Phosphorylated methyl-CpG binding protein 2 (p-MeCP2), known to act as a transcriptional repressor, was recently reported to suppress the processing of several miRs. Homeo-domain interacting protein kinase2 (HIPK2) can bind to and phosphorylate MeCP2. However, it is not known if MeCP2 and HIPK2 are involved in processing and expression of candidate miRs in DN.

**Methods:** p-MeCP2 and HIPK2 staining in kidney sections from 4-week streptozotocin (STZ) injected diabetic and control mice, was studied by immunohistochemistry. Protein, miRNA and miR levels were examined by Western blotting (WB) or RT-qPCRs in TGf-b1- or high glucose (HG)-treated mouse mesangial cells (MMCs).

**Results:** p-MeCP2 and HIPK2 immunostaining, and their protein levels were significantly higher in renal glomeruli (but not cortex) of STZ mice than control. Moreover, Seven in Absentia Homolog 1 (SIAH1), which mediates proteasomal degradation of HIPK2, was decreased in STZ mice compared with control. Among several regulated miRs, miR-25 and -93 levels were significantly decreased in STZ mice relative to control. The precursors of miR-25 and -93 were also significantly decreased in STZ mice, while conversely, NADPH oxidase4 (NOX4), a target of miR-25 that is associated with renal fibrosis and DN, was significantly increased in STZ mice. Protein levels of p-MeCP2 and HIPK2 were also increased in vitro in TGf-b1-or HG-treated MMCs compared to control. Moreover, miRNA levels of the genes mentioned above in vivo were similarly regulated in MMCs in vitro, although only miR-25 and its precursor were significantly decreased in the treated MMCs.

**Conclusions:** These data suggested that podocyte injury is associated with defective autophagy level under high glucose condition. Ursolic acid could reduce podocyte injury with 3-MA treatment at 8 weeks and with DA1229 at 12 weeks in diabetic mice. However, activity of serum DPPIV was not different from each other. Activity of serum DPPIV combined treatment with DA1229 or LC158809 significantly decreased accumulation of ECM protein, TLR4 and oxidative stress markers were not different from each other. Activity of serum DPPIV was significantly reduced with DA1229. 24h albuminuria significantly decreased with LC158809 treatment at 8 weeks and with DA1229 at 12 weeks in diabetic mice. However, no additive effect on albuminuria was observed with combined treatment. Administration of DA1229 or LC158809 significantly decreased accumulation of ECM protein, TLR4 and NOX4 expressions in glomeruli. Nephropathy was observed in the group with untreated albuminuria. Urinary excretion of nephrin was increased in diabetic mice and was decreased in combined treatment with DA1229 and LC158809. In vitro, DPPIV was expressed on the surface of podocytes. The expression of podocyte associated protein and endogenous accumulation of LC3. autophasogosomes were observed using electron microscopy.

**710A**
podocyte membrane and its expression was activated by angiotensin-II. Nephrin expression in cultured podocyte was attenuated by high glucose and angiotensin-II. This attenuation was recovered with DA1229 treatment, but not with other DPPIV inhibitors.

**Conclusions:** Our data suggest that renoprotective effects of DA1229 in experimental diabetic mice might be associated with protective effect of podocyte injury. DA1229 might be a potential therapeutic agent to slow the progression of diabetic nephropathy.

**SA-PO373**

**PBI-4425, A Novel Anti-Inflammatory/Fibrotic Compound, Improves Kidney Function and Structure in the Diabetic db/db Mouse Model**

**Background:** Kidney disease associated with diabetes mellitus is a major health problem worldwide. Glomerular injury plays a pivotal role in the development of diabetic nephropathy. PBI-4425 possesses a pleiotropic mechanism of action with anti-inflammatory, antioxidant and anti-fibrotic properties. The aim of this study was to investigate the protective effect of PBI-4425 on kidney function and structure in uninephrectomized (NX) diabetic (db/db) mice.

**Methods:** Total nephrectomy of the right kidney was performed on day 0 and animals were treated with vehicle or PBI-4425 (100 mg/kg, oral once a day) from day 1 through 105. Kidney function (GFR), kidney mesangial lesions, modulation of gene expression, and serum cytokines were investigated.

**Results:** GFR assessed by inulin clearance was significantly reduced in NX-db/db mice compared to NX-C57BL/6j negative control mice, and PBI-4425 treatment significantly improved GFR. As shown by PAS staining, NX-db/db mice had larger glomeruli with increased mesangial lesions scores which were significantly reduced by PBI-4425 treatment. Gene expression of inflammation, fibrosis, oxidative stress, and extracellular matrix remodeling markers were assessed. Kidney MCP-1, IL-6, Collagen I, NOS, MMP2, and Timp1 mRNA expression were markedly increased in NX-db/db mice, and PBI-4425 treatment induced a significant decrease of these markers. Glomerular response to injury was accompanied by activation of kidney development-related genes, such as glomerular epithelial protein 1 (GLEPP1); expression of GLEPP1 was significantly increased in NX-db/db mice, and restored to the negative control level following treatment with PBI-4425. Moreover, PBI-4425 significantly reduced serum pro-inflammatory cytokines IL-6, IL-1β, IL-12(p70), as well as THP-1-type pro-inflammatory cytokine IL-9.

**Conclusions:** These results suggest that PBI-4425 offers the potential as a novel therapy for diabetic nephropathy by improving kidney function and structure, and reducing pro-inflammatory and pro-fibrotic markers.

**SA-PO374**

**The Effect of Nox Inhibitor APX-15 on Diabetic Kidney Disease**

**Jim Jun Chia,** Hye Sook Min, Kitea Kim, Jung Eun Kim, Jungyeon Ghee, Hyunwook Kim, Ji Eun Lee, Ji Young Han, Young Sun Kang, Dae R. Ch. 1 Internal Medicine, Korea Univ Medical College, Ansan Hospital, Ansan, Republic of Korea; 2 Internal Medicine, Wonkwang Univ Medical College Sanbon Hospital, Gunsan, Republic of Korea; 3 Pathology, Inha Univ College of Medicine, Incheon, Republic of Korea.

**Background:** Excess reactive oxygen species generated by NADPH oxidases (Nox) have been implicated in the inflammatory and fibrotic processes of chronic kidney disease. Recent studies have suggested the importance of renal Nox in the progression of diabetic nephropathy. Therefore, we investigated the effect of a novel NOX-inhibitor APX-15 on diabetic nephropathy in an experimental model of type 2 diabetic mice.

**Methods:** 8 to 10 week old db/m and db/db mice were treated with APX-15 for 12 weeks. APX-15 was administered by oral gavage at a dose of 60mg/kg/day. To compare the effects of APX-15 with a selective Nox inhibitor, db/db mice were treated with GKT136901 according to same protocol.

**Results:** APX-15 significantly improved insulin resistance in diabetic mice similar to GKT136901. Oxidative stress measured by plasma 8-isoprostane level was decreased in APX-15 group compared to diabetic control. All lipid profiles, both in plasma and tissues (kidney, fat, liver) improved with Nox inhibition. Nox mRNA expressions in adipose tissue (Nox1, Nox2) and in kidney tissue (Nox4) were downregulated and Nox protein expressions were decreased with APX-15. 24 hour urinary albumin excretion was reduced and creatinine clearance was preserved with APX-15. In diabetic kidney, structural changes were notably attenuated with APX-15. Importantly, mesangial expansion was significantly improved with APX-15, but not with GSK 136901. Kidney PAI-1 and TGF-β expressions were decreased and nephrin expression increased in both APX-15 and GKT136901 groups compared to diabetic control. Additionally, F4/80 infiltrations in the adipose tissue and the kidney were decreased with APX-15.

**Conclusions:** Our findings suggest that APX-15 may have a better renoprotective effect compared to selective inhibitor GKT136901 in experimental animal model of diabetic nephropathy. Broad Nox inhibition with APX-15 might be a promising therapy for diabetic nephropathy.
Methods: Male db/db mice at 8 weeks of age were fed resveratrol (20 mg/kg/day) via gavage for 12 weeks. Serum and renal tissue were obtained to analyze for changes in metabolic parameters, molecular levels and renal structure.

Results: Resveratrol treatment showed favorable effects on albuminuria, glomerular matrix expansion and inflammatory cell infiltration. Increased expressions of AdipoR1 and AdipoR2 were observed with increased phosphorylated AMPK and PPAR-α level. It also ameliorated free fatty acid and triacylglycerol accumulation in the kidney which was related to increases in the phosphorylation of AMPK and the activation of SIRT1-PGC-1α signaling and of the key downstream effectors, the PPARs. Resveratrol increased the expression of the anti-inflammatory/anti-fibrotic activator and converted the circadian rhythm of blood pressure from a non-dipper to dipper pattern. It improved glucose metabolism. Luseogliflozin also significantly decreased blood pressure (−1.6 and −132.0 mmHg, P=0.04 and P<0.01, respectively) and urine protein (−0.7 and −148.0 mg/dL), or (iv) luseogliflozin + diuretics for 5 weeks (n = 6 for each group). Blood pressure and glucose metabolism were evaluated by a telemetry system and oral glucose tolerance test, respectively.

Results: Vehicle-treated SHRcp developed non-dipper type hypertension (dark-light period mean arterial pressure (MAP) 148.0±7.0 and 148.0±7.0 mmHg, respectively, P<0.01), which were associated with a significant increase in urininary excretion of sodium. Addition of diuretics did not influence luseogliflozin-induced improvement of glucose metabolism and circadian rhythm of blood pressure in SHRcp.

Conclusions: These data suggest that a SGLT2 inhibitor elicits its beneficial effects on glucose metabolism and hypertension in subjects with metabolic syndrome undergoing treatment with ACE inhibitors.

SGLT2 Inhibition Slows the Progression of Diabetic Nephropathy in the db/db Mouse
Li Tang, Yuanyuan Wu, Yufeng Huang. Fibrosis Research Laboratory, Div of Nephropathy, Univ of Utah, Salt Lake City, UT.

Background: It has been shown that SGLT2 inhibitor not only enhanced renal glucose excretion and lowered blood glucose (BG) but also reduced albuminuria in patients with Type 2 diabetes (T2DM). However, the renoprotective effect of SGLT2 inhibition in diabetes has not fully established.

Methods: This study sought to determine whether dapagliflozin, a selective SGLT2 inhibitor, could slow the progression of glomerulosclerosis in the uninephrectomized db/db mouse, a model of T2DM.

Results: Untreated uninephrectomized db/db mice developed progressive albuminuria and glomerulosclerosis between wks 18 and 22, associated with increased renal expression of TGFβ1, PAI-1, type IV collagen and fibronectin. Treatment with dapagliflozin (1mg/kg/d) via gel diet from wks 18 to 22 did not affect body weight but reduced BG from 573.3±21.7 to 373.1±45.52 mg/dL, P<0.05) and HbA1c levels. Of note, treatment with dapagliflozin reduced the increase in albuminuria and markers of glomerulosclerosis seen in db/db mice between wks 18 to 22. Renal expressions of NF-kBp67, MCP-1, Nox4, Nox2, and p47phox and urinary TBARS levels, the markers of renal inflammation and oxidative stress, were increased during disease progression in db/db mice. Treatment with dapagliflozin reduced these markers. In addition, db/db mice had markedly increased daily water intake, urinary output, urinary sodium and potassium excretion but decreased urinary osmolality. Dapagliflozin had no effects on these measurements. Interestingly, dapagliflozin

ameliorated diabetes-induced glomerular hyperfiltration determined by elevated creatinine clearance rates (2.44±0.55 ml/min in treated db/db vs. 1.72±0.63 ml/min in db/db) and caused a significant reduction in renal RAS activity determined by urinary aldosterone levels (45.5±4.93 vs. 60.9±4.01, p<0.05).

Conclusions: These results suggest that SGLT2 inhibitor not only reduces albuminuria but also leads to regression in the glomerulosclerosis resulting from T2DM by improving hyperglycemia and renal inflammation and oxidative stress. Decreasing glomerular hyperfiltration and negatively regulating renal RAS activity by SGLT2 inhibitor may be also renoprotective.

SA-PO384

Background: SGLT2 inhibitors have recently been approved in type 2 diabetes and long-term clinical trials are ongoing to further establish efficacy and safety. Humans with familial renal glycosuria due to mutations in SGLT2 do not show signs of general renal tubule dysfunction or other pathological changes, and they seem to have normal life expectancies. Here we compared the phenotype of non-diabetic aged male mice (at 24 months) that lack SGLT2 (Sgl2−/−) with their wild-type littermates (WT).

Methods: In awake mice, blood pressure (BP) and heart rate (HR) was measured by an ultrasonic tail-cuff system and GFR by FITC-inulin plasma eliminations kinetics.

Results: Out of initially 11 Sgl2−/− and 14 WT, 2 mice per genotype died for unknown reasons before reaching an age of 24 months; thus 9 Sgl2−/− and 12 WT mice were analyzed. Consistent with results previously reported in young adult mice (3-5 months): aged Sgl2−/− and WT showed similar blood pressure (133±6.0 vs. 132±10.9 mm Hg), glucose blood (105±6 vs. 116±10 mg/dl), and GFR (329±36 vs. 370±20 ml/min); Sgl2−/− had higher urinary glucose excretion (381±71 vs. 5±1 µmol/ml creatinine) associated with higher intake of food (3.8±0.1 vs. 3.2±0.1 g/day) and fluid (9.8±0.2 vs. 5.1±0.1 ml/day) and smaller adipocytes in subcutaneous and epididymal fat tissue (4790±446 vs 6348±130 and 809±390 vs 11811±778 µm² in each P<0.01); urine pH was similar (6.0±1 vs. 6.5±0.2) and no bacterial growth detected in bladder urine. Different from previous findings in young adult mice: aged Sgl2−/− had modestly higher kidney weight (15.4±0.9 vs 12.6±0.4 g/body weight), BP (105±2 vs 93±1 mm Hg) and HR (660±7 vs 625±9 1/min) than WT and lower hematocrit (38±1±0 vs 41.3±0.4%) each P<0.01.

Conclusions: Aged Sgl2−/− mice show many of the expected phenotypes previously observed in young adult mice, and have preserved GFR and no evidence for ascending blood vessels. An increased kidney weight has been previously reported in 7.5 months old Sgl2−/− mice. Further analyses aim to better understand the latter findings and the observed modest changes in BP and hematocrit.

Renal Secretion of the SGLT2 Inhibitor Empagliflozin and Rightward Shift in Its Glucosuric Response Curve in Mice Lacking OAT3 Yiling Fu,1 Akira Onishi,1 Panai Song,2 Falk Bernhard Batz,3 Eric W. Mayoux,Volker Vallon.1 1Div of Nephrology, UC San Diego & VA San Diego Healthcare System, La Jolla, CA; 2Boehringer Ingelheim, Biberach, Germany.

Background: SGLT2 inhibitors, like empagliflozin (EMPA), may reach their target in the brush border of the early proximal tubule through nephrone filtration and tubular secretion. The organic anion transporter OAT3 in the basolateral membrane of the proximal tubule contributes to secretion.

Methods: Renal H+-inulin clearance studies were performed in wild-type (WT) mice to characterize the renal handling of EMPA. EMPA was given in diet for 3 weeks (~30mg/kg body wt x day) i.p. bolus (10 mg/kg 1 hr before study)). EMPA was determined by LC/MS/MS. Mean fractional protein binding of empagliflozin in mouse plasma is constant over a wide range (up to ~50µM) at 88.1±1.0±0.5%. B) Metabolic cage studies were performed in mice lacking OAT3 and WT littermates (EMPA 0.3-30 mg/kg) or vehicle was applied i.p. bolus (10 mg/kg 1 hr before study)). EMPA was determined by LC/MS/MS. Mean fractional protein binding of empagliflozin in mouse plasma is constant over a wide range (up to ~50µM) at 88.1±1.0±0.5%. B) Metabolic cage studies were performed in mice lacking OAT3 and WT littermates (EMPA 0.3-30 mg/kg) or vehicle was applied i.p. bolus (10 mg/kg 1 hr before study)). EMPA was determined by LC/MS/MS. Mean fractional protein binding of empagliflozin in mouse plasma is constant over a wide range (up to ~50µM) at 88.1±1.0±0.5%. B) Metabolic cage studies were performed in mice lacking OAT3 and WT littermates (EMPA 0.3-30 mg/kg) or vehicle was applied i.p. bolus (10 mg/kg 1 hr before study)). EMPA was determined by LC/MS/MS. Mean fractional protein binding of empagliflozin in mouse plasma is constant over a wide range (up to ~50µM) at 88.1±1.0±0.5%. B) Metabolic cage studies were performed in mice lacking OAT3 and WT littermates (EMPA 0.3-30 mg/kg) or vehicle was applied i.p. bolus (10 mg/kg 1 hr before study)). EMPA was determined by LC/MS/MS.

Results: Comparing freely filtered and excreted amounts of EMPA revealed a fractional renal excretion of ~350-500% for free plasma concentrations in the range of 1-2 nM (with chromatographic delay in diet, which is close to the IC50 for mouse SGLT2) to 20-22 nM (with additional bolus application), indicating that 2/3 or more of the renal excretion of EMPA derived from renal secretion. B) OAT3−/− showed a small but significant rightward shift in the glucosuric response curve to EMPA (ED50 ~6.5 vs. 3 mg/kg in WT; with significantly lower glucosuria at 1.3, and 10 mg/kg (P<0.05), whereas vehicle (0.3 mg/kg and 30 mg/kg induced similar minimal and maximal glucosuria, respectively) (n=19-20/dose).

Conclusions: The SGLT2 inhibitor empagliflozin is secreted by the kidney; this may involve OAT3 in the early proximal tubule whose activity is a determinant of the acute glucosuric effect of EMPA.

SGLT Inhibition Significantly Increases Oxygen Consumption of the Medullary Thick Ascending: A Modeling Study Anna T. Layton, Volker Vallon, Aurelie Edwards.1 1Mathematics, Duke Univ; Durham, NC; 2Medicine and Pharmacology, Univ of California San Diego, La Jolla, CA; 3Centre National de la Recherche Scientifique, Paris, France.

Background: The objective of this study was to investigate how changes in sodium reabsorption in the proximal tubule affect oxygen (O2) consumption and the metabolic efficiency of the nephron.

Methods: To do so, we developed a detailed mathematical model of solute transport in a nephron of the rat kidney. Glucose is reabsorbed via sodium-glucose cotransporters (SGLTs) in the proximal tubule, which expresses the isoform SGLT2 in S1-S2 and the isoform SGLT1 in S3. We used the model to investigate the effect of inhibiting SGLT2, a novel treatment for reducing proximal tubule glucose uptake in diabetes, on renal Na+ transport and renal oxygen consumption (QO2).

Key - TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: Inhibiting SGLT2 shifts Na\(^+\)-transport to downstream nephron segments, possibly increasing their Q\(_{\text{m}}\). In particular concerns are the S3 segment and medullary thick ascending limb (mTAL), which are at risk for hypoxic injury. Dual SGLT1-SGLT2 inhibition protects the S3 segment, but could further reduce mTAL oxidation. Model simulations suggest that SGLT2 inhibition substantially increases S3 Q\(_{\text{m}}\). Together with elevated renal perfusion (mTALi) increase mTAL Q\(_{\text{m}}\). Additionally, we used the model to determine the optimal combination of SGLT1 and SGLT2 inhibition, in terms of suppressing tubular glucose uptake and maintaining sufficiently low S3 and mTAL Q\(_{\text{m}}\).

Conclusions: SGLT inhibition significantly increases oxygen consumption of the mTAL. This research was supported in part by NIH grant DK-89066.

Background: The renal sodium gradient dependent glucose transport protein SGLT2 expression is increased in renal biopsies from human subjects with diabetic nephropathy.

Methods: To determine the potential mechanisms of beneficial effects of SGLT2 inhibition in progression of diabetic renal disease we treated db/db mice with a selective SGLT2 inhibitor.

Results: We found that SGLT2 inhibition caused marked decreases in systolic blood pressure, kidney weight:body weight ratio, urinary albumin (745±3.8 mg/kg in db/db vs. 207±5 mg/kg in treated db/db, p<0.001) and urinary thromboxin A2-reacting substances (TBARS). SGLT2 inhibition also a) prevented renal lipid accumulation via inhibition of LPL, SCAD-1 and DGAT1, key enzymes that mediate fatty acid and triglyceride synthesis, b) decreased inflammation via inhibition of CD68 macrophage accumulation, and expression of p65, TLR4, MCP-1 and 1OPN, and c) increased CD73 and decreased adenosine A receptors. Among the factors associated with mesangial expansion, accumulation of extracellular matrix proteins fibronectin and type IV collagen, as well as loss of podocyte markers WT1 and synaptopodin, as determined by quantitative immunofluorescence microscopy.

Conclusions: In summary, our study showed that SGLT2 inhibition modulates renal lipid metabolism and inflammation and prevents the development of nephropathy in db/db mice.

Loss of Angiotensin-Converting Enzyme 2 Alters Glomerular Structure in Non Obese Diabetic Mice

Heleia Roca-1
Maria Jose Soler,1
Vanderbilt Univ.

Background: ACE2 has been shown to play an important role in diabetic nephropathy (DN). We studied renal morphology and kidney function in non-obese diabetic (NOD) female mice (with spontaneous autoimmune diabetes) carrying a deletion on ace2 gene (NOD.-/-.). We studied in WT and ACE2KO mice (C57BL6/J and FVB/N genetic backgrounds) that were rendered diabetic using STZ (2x150 mg/kg).

Methods: Treated female NOD.ACE2-/- mice (with spontaneous autoimmune diabetes) carrying a deletion of ace2 gene (NOD.-/-.). We studied renal morphology and kidney function in non-obese diabetic (NOD) female mice. Treated female NOD.ACE2-/- mice (with spontaneous autoimmune diabetes) carrying a deletion on ace2 gene (NOD.-/-.).

Results: Glomerular hypertrophy, mesangial matrix expansion and podocyte loss were found in female NOD.ACE2-/- mice. In diabetic NOD.ACE2-/- and NOD.ACE2+/- mice, there was a modest but significant reduction in podocyte number in diabetic NOD.ACE2-/- mice. These results suggested that ACE2 deletion worsens kidney injury in diabetic NOD mice.

Ace2 Deficiency Accenutated AngII-Induced Hypertension and Albuminuria in Diabetic Mice

Sergi Clotet-Freixas, Maria Jose Soler, Marta Rebull, Julio Pascual, Marta Riera. Nephrology, Hospital del Mar-Inst Hospital del Mar d’Investigacions Mèdiques, Barcelona, Spain.

Background: Angiotensin-II (AngII) promote renal vasoconstriction, albuminuria, fibrosis, apoptosis and inflammation. ACE2 deficiency exacerbates hypertension in AngII-infused male mice. However, the effect of ACE2 deletion on diabetic and AngII-infused female mice has not been previously studied.

Methods: We evaluated the effect of AngII infusion in age matched C57BL/6 wild-type (WT) and ACE2KO streptozotocin (STZ)-induced female mice and their respective non-diabetic controls. At week 8 of follow-up, mice were anesthetized and micromops for AngII infusion and AngII were surgically implanted. Sham-operated (SHAM) mice were used as control groups. Study groups: WT-Control (CONT) + SHAM, WT-CONT + ANGII, WT-Diabetic (DB) + SHAM, WT-DB + ANGII, ACE2KO-CONT + SHAM, ACE2KO-CONT + ANGII, ACE2KO-DB + SHAM, ACE2KO-DB + ANGII. Blood glucose, body weight, kidney weight:body weight (KW/BW), heart weight:body weight (HW/BW), systolic blood pressure (SBP) and urinary albumin excretion (UAE) were studied.

Results: Hyperglycemia and reduced BW were observed in all groups given STZ. ACE2 deletion and AngII infusion suppressed a modest decrease in body weight in control and diabetic mice. Both, SHAM and AngII-infused ACE2KO diabetic mice showed higher HW/BW as compared to WT. AngII infusion significantly augmented HW/BW and SBP in control and diabetic ACE2KO mice as compared to non-infused mice. Diabetes and AngII infusion were accompanied by increased UAE in all groups. This increase was more pronounced in ACE2KO mice. Within AngII-infused groups, ACE2KO-CONT + ANGII and ACE2KO-DB + ANGII showed significantly higher HW/KW, SBP and UAE than WT-CONT + ANGII and WT-DB + ANGII.

Conclusions: Loss of ACE2 accentuated renal hypertrophy and AngII-induced hypertension, albuminuria and cardiac hypertrophy in diabetic female mice.

Results: In ACE2 deficient db/db mice, there was a modest but significant reduction in podocyte count (3.0±0.9 vs. 2.4±0.7, p<0.001) and an increase in glomerular cellularity which was identified by PAS-positive material in the glomerulus and factored by the glomerular tuft area. Area calculations were performed using ImageJ software. To assess podocyte number in glomerular tuft, WT-1 staining was performed.

Conclusions: Glomerular hypertrophy, mesangial matrix expansion and podocyte loss were found in female NOD.ACE2-/- mice. In diabetic NOD.ACE2-/- and NOD.ACE2+/- mice, there was a modest but significant reduction in podocyte number as compared to NOD.ACE2+/-

Blood Pressure-Independent Amelioration of Glomerulosclerosis in Diabetic Rats Treated with Dual AT1,Receptor-Neprilysin Inhibition versus AT1-Receptor Blockade Alone

Lodzi C.W. Roksnog,1 Richard Van Veldh,1 Marian Claesen - van Groningen,2 René De Vries,1 Ingrid M. Garrelsd,1 Usha M. Bhaggoe,1 Jeanette M. Van Gool,1 Edith C.H. Friesema,1 Frank P.J. Leijten,1 Ewout J. Hoorn,3 Alexander H. Danser,1 Wendy W. Batenburg.1 Div. Pharmacology and Vascular Medicine; Dept Internal Medicine, Erasmus MC, Rotterdam, Netherlands; 2Dept Nephrology, Dept Internal Medicine, Erasmus MC, Rotterdam, Netherlands; 3Dept Pathology, Erasmus MC, Rotterdam, Netherlands.

Background: Dual AT1 receptor-neprilysin inhibition (ARNI) has recently been shown to exert beneficial effects on blood pressure (BP), NT-proBNP, and estimated GFR in heart failure patients, compared with AT1 receptor blockade (ARB) alone. Neprilysin is upregulated in epineural arterioles of diabetic rats. We hypothesized that ARNI improves cardiac and kidney parameters in diabetic TGR(mREN2)27 rats, a model displaying angiotensin II-mediated hypertension.

Methods: Rats were made diabetic with streptozotocin, for 5 or 12 weeks. In the final 3 weeks rats were treated with vehicle, the ARB irbesartan (15mg/kg/day) or irbesartan (15mg/kg/day) + the neprilysin inhibitor thiorphan (0.1mg/kg/day; ARNI). BP was measured by telemetry in the 5-week group only.

Results: Baseline mean arterial BP (MAP) was 157±5mmHg. ARNI and ARNI lowered MAP identically over the 3-week period, reaching a maximum reduction of –50mmHg around day 7. Heart weight/body weight ratio in 12-week diabetic rats was 17% lower after ARNI treatment vs. ARB treatment (P<0.05). Proteinuria and albuminuria were observed in 8% of diabetic mice towards. ARNI reduced proteinuria more strongly than ARB (78% vs. -48%, P<0.05), and a similar trend was seen for albuminuria. Kidneys of ARNI-treated rats showed less focal segmental glomerulosclerosis than those of ARB-treated rats. At the end of the study, no differences between ARNI- and ARB-treated rats were found regarding diuresis, natriuresis, plasma endothelin-1, vascular reactivity (acetylcholine and endothelin-1 responses), or kidney sodium transporters.

Conclusions: ARNI reduces proteinuria, focal segmental glomerulosclerosis, and cardiac hypertrophy in diabetic TGR(mREN2)27 rats more strongly than ARB, and this occurs in a blood-pressure-independent manner.

SA-PO392
Collateral Effects of Atrasentan on Renin-Angiotensin System Lidia Aquipano, Marta Riera, Marta Rebull, Julio Pascual, Maria Jose Soler.
Nephrology, Hospital del Mar-Inst Hospital del Mar d’Investigacions Mèdiques, Barcelona, Spain.

Background: Endothelin-1 is a vasoconstrictor peptide that has been shown to be increased in diabetic kidney disease. In kidney cortex from obese diabetic mice ACE2 activity is increased whereas ACE activity is decreased. Objective: study the effect of atrasentan, an antagonist of type II endothelin receptor, on renin-angiotensin system (RAS) in obese diabetic mice (db/db) and its respective controls (db). Methods: Diabetic groups: vehicle (VehDB), 10mg/kg/day atrasentan (10DB), 25mg/kg/day atrasentan (25DB), 50mg/kg/day atrasentan (50DB). Non-diabetic groups: vehicle (VehCONT), 10mg/kg/day atrasentan (10CONT). Animals were included in the study at 12-weeks of life and treated for 16weeks. Systolic (SBP) and diastolic (DBP) blood pressure and ACE and ACE2 enzymatic activities in serum and kidney were analyzed.

Results: See table. Atrasentan therapy significantly decreased SBP and DBP in diabetic mice. Circulating and renal ACE2 activities were significantly increased in VehDB mice as compared to VehCONT. Atrasentan treatment at 25 and 50mg/kg/day reduced circulating and renal ACE2 activities. Circulating and renal ACE2 activities were decreased in VehDB as compared to VehCONT, with no modulation by atrasentan treatment.

Conclusions: Atrasentan prevented the increase of circulating and renal ACE2 in diabetes, indicating a collateral effect by RAS modulation. These results suggest that the beneficial effect of atrasentan in diabetic nephropathy may be related with endothelin blockade and its effect in the non-classic RAS pathway.

SA-PO393
P16\textsuperscript{ink4a} Expression Is Increased via 12-Lipoxigenase in High-Glucose-Stimulated Glomerular Mesangial Cells and Type 2 Diabetic Glomeruli Yuanjuan Zhang, Fu-zhe Ma, Tao Sun, Wan-ning Wang, Hang Yuan, Zong-gao Xu.
Nephrology, The First Hospital of Jilin Univ; Changchun, Jilin, China.

Background: Arachidonic acid-metabolizing enzyme 12-lipoxigenase (12-LO) is involved in glomerular hypertrophy of diabetic nephropathy (DN), in which cyclin-dependent kinase inhibitors (CDKs) play important roles. However, it is unclear whether 12-LO regulates the expression of the CKI p16\textsuperscript{ink4a} in DN.

Methods: Primary glomerular mesangial cells (MCs) and glomeruli isolated from rats were used in this study. The rats were fed a high-fat diet and given low-dose streptozotocin to induce type 2 diabetes. The 12-LO product 12(S)-hydroxy-6,9,11-eicosatrienoic acid [12(S)-HETE] was infused through an osmotic minipump. Enzyme-linked immunosorbent assay, Western blot, and morphometric analyses were performed.

Results: High glucose (HG) increased p16\textsuperscript{ink4a} protein expression in MCs, but this increase was prevented by the 12-LO inhibitor cinammyl-3,4-dihydroxy-o-cynanoacetamine (CDA). The levels of p-p38MAPK and p16\textsuperscript{ink4a} in MCs were significantly elevated after 12(S)-HETE treatment, whereas the p38MAPK inhibitor SB203580 prevented these increments. Compared with levels in control MCs, marked increases in p38MAPK activation and p16\textsuperscript{ink4a} expression were observed in MCs plated on collagen IV, while CDA treatment prevented these changes. Subcutaneous injection of CDA did not affect glucose levels but completely attenuated the diabetes-related increases in 12(S)-HETE content, p16\textsuperscript{ink4a} expression, p-p38MAPK levels, glomerular volume, and kidney/body weight ratio. Compared with levels in controls, p16\textsuperscript{ink4a} and p-p38MAPK in the glomeruli derived from 12(S)-HETE-treated rats were significantly increased.

Conclusions: 12-LO-p38MAPK mediates the upregulation of p16\textsuperscript{ink4a} in HG-stimulated MCs and type 2 diabetic glomeruli, and new therapies aimed at 12-LO inhibition might be beneficial in ameliorating diabetes-induced glomerular hypertrophy.

SA-PO394
The Effect and Mechanism of Probufol on Diabetic Nephropathy Tubulointerstitial Injury via Down-Regulating P66Shc Shi-kun Yang,1 Xiaoxuan Xu,1 Chun Hu,1 Li Xiao,1 Fuyou Liu,1 Lin Sun.1 Dept of Nephrology, Kidney Inst of Central South Univ, Changsha, Hunan Province, China; 2Dept of Nephrology, Kidney Inst of Central South Univ, Changsha, Hunan Province, China.

Background: P66Shc induce mitochondrial ROS overproduction and lead to renal oxidative stress. Probufol has the renal protective effect on the progression of DN. However, the mechanism remains poorly understood.

Methods: ICR mice were divided into control (n=10), DN (n=10), probufol (10mg/kg/d) group (n=10), DMSO group (n=10). The DN model was induced by injection of STZ (40mg/kg body weight). Probufol was intraperitoneally injected to the mice every other day for 12 weeks after the model was built. Renal lesions and the expression of SIRT1, P300, AcH3, P66Shc, FN were detected by HE staining, TUNEL, DHE, immunohistochemistry and western-blot respectively. In addition, HK-2 cells were incubated with different concentrations of D-glucose (5, 30mM) with or without probufol, 1mM AICAR or 20mM Dormorphin or 1mM EX-527. The expression of P66Shc, SIRT1, P300, AcH3, AMPK, p-AMPK in HK-2 cells were detected by realtime-PCR,Western-blot and immunofluorescence assays. In addition, chromatin immunoprecipitation (ChIP) assay was used to determine the effect of probufol on acetylation of histone of P66Shc gene. Results: Compared to control, the reduced ECM protein and renal tubular damage were observed in DN mice after treated by probufol. It also decreased the expressions of P300, P66Shc, FN in the kidney of DN mice. In addition, Probufol can reduce the levels of renal ROS levels and apoptosis, while boost the expressions of p-AMPK and SIRT1. Furthermore, pretreatment with the selective AMPK inhibitor Dormorphin or SIRT1 inhibitor EX-527 could block the inhibitory efficiencies of probufol. The ChIP analysis showed that probufol treatment could decrease the acetylation of histone h3 in p66shc gene promoter regions (-535 bp to -276 bp) in HK-2 cells induced by high glucose.

Conclusions: Probufol could epigenetically suppress the expression of P66Shc through p-AMPK-SIRT1-AcH3 pathway, then ameliorate the apoptosis and oxidative injury in HK-2 cells induced by high glucose.

Macrophages in Type 2 Diabetic Nephropathy Celine Klessens, Malu Zandbergen, Ron Wolterbeek, Jan A. Bruijn, Ton J. Rabelink, Ingeborg M. Bajema, Daphne Thomas-ijpelaar. Leiden Univ Medical Center.

Background: Inflammation seems to play a role in type 2 diabetic nephropathy (DN). Therefore, novel therapies focus on inhibition of inflammation to inhibit renal failure in DN. Intestinal macrophages are present in progressive interstitial lesions, however, the role of glomerular macrophages in the development of diabetic glomerular damage remains incompletely understood. In this study we investigated the accumulation of macrophages in glomeruli and interstitium of humans with various stages of DN.

Methods: Kidney samples obtained at autopsy of type 2 diabetes patients (N=88) with histologically proven DN were stained with CD68 and CD163, as global and M2 macrophage markers. As controls, renal autopsy samples of 5 non-diabetic and 18 diabetic
patients without DN were used. Macrophages in 50 glomeruli per sample were counted. Intestinal and interstitial macrophages were counted semi-quantitatively. Glomerular and interstitial macrophages were correlated to histological and clinical parameters.

Results: Glomerular CD68+ and CD163+ cells were present in all stages of DN according to the histopathological class and did not differ between classes, but the accumulation was varied widely. The mean influx of glomerular CD68+ cells over the classes was 4.2 (range 0-19) and the mean influx of glomerular CD163+ cells was 2.1 (range 0-14.74). The mean ratio of CD163/CD68+ cells amounted 0.5. Glomerular macrophages were also present in the control groups. Renal function was associated with the number of CD163+ cells. CD163+ cells were significantly associated with histological lesions. Intestinal macrophages significantly correlated with clinical parameters like GFR stage and albuminuria.

Conclusions: We showed that macrophages (including anti inflammatory CD163 + macrophages) are present in all stages of DN both in the glomerulus and interstitium. Correlation between clinical data and interstitial macrophages indicates that interstitial inflammation probably influences the progression of DN. In addition, presence of glomerular macrophages in early diabetic nephropathy suggests that they influence the glomerular diabetic damage as well. Therefore, therapies targeting macrophages might be a useful novel therapy in DN.

SA-PO396
Activation of CXCL16/CXCR6 Pathway by Inflammation Accelerates the Progression of Diabetic Nephropathy Zhe Hu, Kun Ling Ma, Yang Zhang, Wn Yu, Bi-Cheng Liu.

Instit of Nephrology, Southeast Univ, Nanjing City, Jiang Su Province, China.

Background: Diabetic nephropathy(DN)was considered as a chronic inflammatory disease. Inflammation plays critical roles in the progression of DN. This study investigated the role of CXC chemokine ligand 16 (CXCL16)/CXCL6 pathway in DN under inflammatory stress and explored its potential mechanisms mediated by purinergic receptor P2X ligand-gated ion channel 7 (P2X7RT).

Methods: Diabetes were randomly divided into two groups: db/db, and db/db+casein for eight weeks. Casein was subcutaneously injected to induce chronic inflammation. The morphological change of renal pathology and ultra-microstructure were checked by pathological staining and electron microscopy. Lipid accumulation in kidneys was observed by Filtrin staining and quantitative assay of intracellular free cholesterol. The expression of CXCL16/CXCL6/CXCR6 pathway, inflammatory cytokine, and fibrin index related molecules were detected by immunohistochemistry, immunofluorescence staining, and Western Blas.

Results: The 24-hour urinary protein, tubulointerstitial injury, inflammatory cell infiltration, and the expression of monocyte chemotactic protein 1 (MCP-1), tumor necrosis factor α (TNFα), CD68, A-smooth muscle actin (a-SMA), and fibronecin (FN) in kidneys of db/db+casein mice were significantly increased compared with the db/db mice. Furthermore, there was significant lipid accumulation, increased protein expression of CXCL16 and CXCR6 and decreased disintegrin and metalloproteinase-10 (ADAM10) expression in kidneys of db/db+casein mice compared with db/db mice, with increased P2X7R expression. Further analysis demonstrated that there was a positive correlation between P2X7R and CXCL6/CXCR6 expression.

Conclusions: Inflammation accelerates tubulointerstitial injury in DN partly through the activation of CXCL16/CXCR6 pathway, which may facilitate inflammation induction and lipid accumulation in cells. The P2X7R pathway may be involved in the activation of CXCL16/CXCR6 pathway.

Albumin Glycation Induces Structural Changes That Reduce Proximal Tubule FcRn Binding and Reclamation Mark C. Wagner, J.ered Myśliński, Shiv Pratap Singh Yadav, George Rhodes, Raben M. Sandoval, Sudhanshu Kumar, Sarah E. Wean, Fnu Ashish, Bruce A. Moltisort 1,2 Nephrology, Dept of Medicine, Indiana Univ School of Medicine, Indianapolis, IN; 1 Cellular & Integrative Physiology, Indiana Univ School of Medicine, Indianapolis, IN; 1 CSIR-Inst of Microbial Technology, Chandigarh, India.

Background: Diabetic nephropathy remains the leading cause of chronic kidney disease (CKD) and ESRD. It results in increased albumin glycation and this is believed to be involved in proximal tubule cell injury and the pathophysiology of interstitial fibrosis and CKD progression.

Methods: To understand the mechanisms we have addressed specific in vitro albumin modifications and their impact on albumin-FcRn binding since proximal tubule FcRn is necessary for transcytosis and reclamation of filtered albumin.

Results: These studies showed markedly reduced binding to FcRn when albumin was glycated proportional to the level of glycation. To address the mechanism for reduced PT pH dependent FcRn binding, which alters lysosomal catabolism resulting in reduced PT pH dependent FcRn binding, which alters lysosomal catabolism leading to transcytosis and reclamation resulting in a shorter serum half life and may mediate the enhanced interstitial inflammation and fibrosis in diabetic nephropathy.

The Effects of Glucagon-Like-Peptide-1 and Vitamin D on Inflammatory and Histological Changes of Diabetic Nephropathy in db/db Mice Yael Einbinder,1,2 Sydney Benachriti,2, Tali Zitman-Gal.1 Renal Pathology Laboratory, Dept of Nephrology and Hypertension, Meir Medical Center, Kfar Saba, Israel; 2 Sackler Faculty of Medicine, Tel Aviv Univ, Tel Aviv, Israel.

Background: Glucagon-like- peptide-1 is a gut incretin hormone that stimulates insulin secretion and may affect the inflammatory pathways involved in type 2 diabetes mellitus (T2DM). Calcitriol plays an important role in renal, endothelial, and cardiovascular protection. We evaluated the anti-inflammatory and histological effects of GLP-1 and calcitrol in a db/db mice diabetic model.

Methods: C57BL/6 (WT) and BKS.Cg-Dock7m+ /Leprdb/db (db/db) mice were randomized to: a) WT mice; b) db/db mice (diabetic control group); c) db/db mice+GLP-1 analog (100 nmol/kg); and d) db/db mice+GLP-1 analog + calcitrol (250 ng/kg). Blood glucose levels and weight were measured weekly. At the end of the 4-week treatment, kidneys were perfused and removed for protein analysis and histology.

Results: Blood glucose levels and weight were significantly higher in db/db mice compared to control WT mice. Blood glucose level was non-significantly lower in the db/ db GLP-1 group compared to untreated db/db mice (460±83.2 mg/dL vs. 526±3.33 mg/dL). GLP-1 treatment significantly up-regulated eNOS protein expression and significantly down-regulated p65 protein expression compared to the db/db control group. Vitamin D did not further improve the beneficial effect observed on protein expression. Kidney VDR protein expression increased only in the vitamin D group compared to the db/db control group. Kidney histology demonstrated beneficial effect of GLP-1 treatment on glomerular hyperfiltration in db/db mice at 26 weeks of age but had no significant effect on the severity of mesangial expansion.

Conclusions: In the experimental model of diabetic nephropathy (db/db mice), GLP-1 analog treatment improved the protein expression involved in the inflammatory response and significantly ameliorated the glomerular hypertrophy seen in the diabetic control group.

Mineral Metabolism and Interleukin-6: Predictive Risk Factors for Left Ventricular Hypertrophy in Patients with Diabetic Nephropathy Teresa M. Jeronimo,1 André Fragoso,1 Filipa Brito Mendes,1 Ana Paula Silva,1,2 Ana Pocinho Pimentel,1 Nelson Tavares,2 Pedro L. Neves,1,2 Nephrology, Centro Hospitalar do Algarve, Faro, Portugal; 1 Dept of Biomedical Sciences and Medicine, Univ of Algarve, Faro, Portugal; 2 Cardiology, Centro Hospitalar do Algarve, Faro, Portugal.

Background: Left ventricular hypertrophy (LVH) is an important risk factor for cardiovascular disease in patients with diabetic nephropathy (DN) and is an independent predictor of mortality in patients with chronic kidney disease (CKD). The aim of this study was to evaluate the predictive risk factors of LVH in a population of patients with DN.

Methods: The authors analysed the relationship of LVH with gender, body mass index (BMI), systolic blood pressure (SBP), estimated glomerular filtration rate (eGFR), albumin, cholesterol, hemoglobin A1C, calcium, phosphorus, parathyroid hormone (PTH), urine albumin-to-creatinine ratio (UACR), interleukin-6 (IL-6), hemoglobin A1c (HbA1c) and insulin resistance (HOMA-IR). Descriptive statistics, Student’s t-test and logistic regression model were used.

Results: In a cross-sectional study were included 119 type 2 diabetic patients with CKD stages 3 and 4. Patients with LVH had significant lower values of eGFR and albumin, higher levels of UACR, HOMA-IR and IL-6. Phosphorus (odd ratio (OR) = 0.602 (1.075-4.414), p = 0.038), PTH (OR = 1.009 (1.990-3.000), p = 0.004) and IL-6 (OR = 1.264 (1.836-7.619), p = 0.0001) were independently related with LVH.

Conclusions: PTH, Phosphorus and IL-6 were independent risk factors of LVH in our diabetic population with CKD stages 3 and 4.

Variable | Adjusted OR (95% CI) | p-Value
--- | --- | ---
Gender | -1.012 (0.064-2.076) | 0.255
Age | 0.032 (0.890-1.053) | 0.455
BMI | 0.810 (0.969-1.448) | 0.498
SBP | -0.008 (0.944-0.043) | 0.757

Far-Infrared Retrieves Pancreatic Beta Cell Function and Survival in a Streptozotocin-Nicotinamide-Induced Type 2 Diabetic Mouse Model
Yung-Ho Hsu,1 Tso Hsiao Chen,2 Cheng-Hsien Chen.1,2 1Div of Nephrology, Dept of Internal Medicine, Shuang Ho Hospital, Taipei Medical Univ, Taipei, Taiwan; 2Div of Nephrology, Dept of Internal Medicine, Wan Fang Hospital, Taipei Medical Univ, Taipei, Taiwan.

Background: In diabetes, the apoptotic cell death of insulin-producing beta cells leads to insulin deficiency. Recently, we found low-temperature far-infrared (FIR) irradiation increased proliferation and survival of human umbilical vein endothelial cells via prolymicotic leukaemia zinc finger protein (PLZF)-mediated PI3K/Akt activation.

Methods: In this study, we investigate the protective effects of FIR on pancreatic beta cell function and survival in the nicotinamide (NA) and streptozotocin (STZ)-induced type II diabetic mouse model. eLS via prolymicotic leukaemia zinc finger protein (PLZF)-mediated PI3K/Akt activation.

Results: The present study showed that FIR therapy decreased non-fasting blood glucose levels and increase blood insulin levels in diabetic mice in a dose-dependent manner. Immunohistochintchemistry staining revealed that FIR therapy retrieved insulin production of pancreatic beta cells in diabetic mice. But the influence of FIR on blood glucose and insulin levels was not found in NA-STZ-treated FIR-KO-knockout mice. We also used the insulin-secreting beta cell line INS-1 to investigate the protective effects of FIR in vitro. FIR irradiation promoted cell proliferation and inhibited STZ-induced apoptosis in INS-1 cells. FIR also induced PLZF nuclear translocation and increased PI3K expression and Akt phosphorylation in INS-1 cells. PI3F siRNA transfection inhibited the influence of FIR on INS-1 cells.

Conclusions: Our data suggest that FIR therapy retrieves pancreatic beta cell function and survival in diabetic mice via a PLZF-mediated pathway.

Transgenic Mice Overexpressing Human CD39 (ENTPD1) Are Protected from High-Fat Diet-Induced Obesity and Insulin Resistance
Anna U. Brandes,1 Yue Zhang,1 Krisztina M. Heiney,1 Simon C. Robson,2 Bellamkonda K. Kishore.1 1Internal Medicine, Univ of Utah & VAMed Ctr, Salt Lake City, UT; 2Internal Medicine, BIDMC, Harvard Univ, Boston, MA.

Background: CD39 is a vascular ecto-nucleotidase that sequentially hydrolyses extracellular ATP to ADP and AMP, thus terminating P2 receptor signaling. Previously we reported that deletion of Cd39 in hepatic insulin resistance (IR). We also found that deletion of Atp1a1/Utp1a1 activated P2Y12 confers significant protection against high-fat diet (HFD)-induced obesity and IR. Hence, we hypothesized that global overexpression of human CD39 (hCD39), which decreases the availability of extracellular nucleotides should attenuate development of HFD-induced obesity and IR.

Methods: Groups of age-matched adult wild type C57/B16 (WT) and syngeneic transgenic (TG) mice globally overexpressing hCD39 (HCD39), which decreases the availability of extracellular nucleotides should attenuate development of HFD-induced obesity and IR. We hypothesized that global overexpression of human CD39 (hCD39), which decreases the availability of extracellular nucleotides should attenuate development of HFD-induced obesity and IR. Hence, we hypothesized that global overexpression of human CD39 (hCD39), which decreases the availability of extracellular nucleotides should attenuate development of HFD-induced obesity and IR.

Results: In response to HFD feeding, both genotypes showed significant increases in BW over the experimental period as compared to their counterpart pairs fed regular diet. However, the gain in BW in HCD39 mice was significantly less in TG vs. WT mice (mean 21.5 ± 0.3 vs. 15.3 ± 0.3 g, n = 7, p = 0.0001). There were no significant differences between the genotypes in the amount of food consumed, nor was there evidence of steatorrhea indicating malabsorption. Fasting blood glucose levels in HFD fed mice were 2-fold higher vs. WT mice (179 ± 12 vs. 88 ± 5 mg/dL, n = 7, p = 0.0001). When fed HFD, both genotypes exhibited glucose intolerance, but this was less severe in TG mice. In parallel, insulin sensitivity was significantly better in HFD-fed TG vs. WT mice.

Conclusions: Our results demonstrate that overexpression of hCD39 confers significant protection against the development of HFD-induced obesity and IR, and thus validating the proposition that dominantly deleterious roles are played by extracellular nucleotides in metabolic homeostasis.

Mass Spectrometry Imaging Reveals a Role for Glomerular Sphingomyelin in Suppressing AMPK Activity by Stimulating ATP Production in Mesangial Cells
Satoshi Miyamoto,1,2 Cheng-Chih Hsu,1 Gregory Hamm,2 Manjula Darshi,3,4 Jonathan Stauber,2 Peter Dorrestein,4 Kumar Sharma.1,2,3 1Instit of Metabolicolmics, Univ of California San Diego, La Jolla, CA; 2Center for Mass Spectrometry, Univ of California San Diego, La Jolla, CA; 3Inst of Translational Medicine, Univ of California San Diego, La Jolla, CA; 4Vetens Affairs San Diego Healthcare System, La Jolla, CA; 5Therapeutic Discovery Mass Spectrometry Center, Univ of California San Diego, La Jolla, CA; 6ImaBiotech, MS Imaging Dept, Lille, France.

Background: We have recently shown that the ATP/AMP ratio is increased in the glomeruli in a mouse model of type I diabetes by matrix-assisted laser desorption/ionization mass spectrometry imaging (MALDI-MSI) and may be the basis for reduced AMP-activated protein kinase (AMPK) in diabetic glomeruli. Here, we applied MALDI-MSI to identify a key metabolic event regulating levels of global ATP/AMP.

Methods: For MALDI-MSI, 23 weeks-aged male diabetic Akita (C57BL/6J-Inj-2mouse), NOD-SCID (N), and age-matched (W) and gender-matched (H) were used. For cell culture study, murine mesangial cells (MMCs) were treated with sphingomyelin(δ18:1/16:0) (SM)-containing liposomes (SL), control liposomes (CL) and vehicle. For ATP measurements, MMCs were transfected with sphingomyelin synthase (SNSM), 2 or control siRNA before treatment with liposomes.

Results: By MALDI-MSI, we found that SM(d18:1/16:0) was preferentially distributed in the glomeruli in W and H. Importantly, we found that SM is more abundant in glomeruli of A compared with W, and associated with increased SNSM and 2 in the glomeruli of A. In SM(d18:1/16:0) stimulated AK5 expression in MMCs compared with CL (p<0.01), and was inhibited by siRNA based inhibition of SNSM. AMPKα activity and PGC1α protein expression were significantly reduced by SL (p<0.05). In addition, SL increased glucose consumption and lactate production in high glucose conditions (p<0.05) suggesting a role for increased glycrosylation.

Conclusions: We demonstrate using MALDI-MSI that the accumulation of glomerular SM in type I diabetic mice is associated with increased ATP in glomeruli and may contribute to reduced AMPK activity in diabetic cells. These findings suggest that reducing of SM may lead to novel therapeutic targets for the treatment of diabetic kidney disease.

Chronic Hyperglycemia Activates Autophagy Through an Increased Lysine-63 Linked Ubiquitination: A Candidate Mechanism in the Progression of Tubular Damage in Diabetic Nephropathy
Paola Pontrelli,1 Annarita Oranger,1 Mariagrazia Barozzino,1 Francesca Conserva,1 Massimo Papale, Matteo Accetturo,1 Maria Teresa Rocchetti, Loreto Gesualdo,1 Dept of Emergency and Organ Transplant, Nephrology Unit, Univ of Bari, Italy.

Background: Chronic hyperglycemia, a key pathogenic factor of diabetic nephropathy (DN), can alters autophagy whose role in tubular cells under hyperglycemic conditions (HG) remains unclear. We reported that lysine63-ubiquitination (K63-Ub) plays a key role in the progression of tubular damage in DN; moreover K63-Ub promotes protein autophagic clearance. Aim of our study was to: evaluate the HG effect in modulating autophagy in tubular cells (HK2), evaluate in vivo the autophagy state in patients with diabetes without renal damage and in different DN classes, investigate the K63-Ub role in the modulation of tubular cells autophagy.

Methods: K63-Ub was inhibited in HK2 under HG (30mM) by UBE2v1 silencing. E2 enzyme involved in K63-Ub, or by NSC697923 inhibitor. The expression of the autophagic factor LC3 was monitored by western blotting and confocal microscopy, (ICHC) and immunofluorescence (IF) were performed on kidney biopsies of 3 control patients, 3 diabetic, 9 DN (classes IIb, III and IV).

Results: HK2 showed a significant increase in LC3 protein after 24h of HG. UBE2v1 silencing completely abolished LC3 induced protein expression after 24h of HG. Confocal microscopy showed the reduction of autophagic vesicles induced by HG in the presence of the K63-Ub inhibitor (NSC697923). IHC on kidney biopsies revealed an increased tubular expression of LC3 in diabetic patients vs controls, that persists in all DN classes and class IV patients showed cytoplasmatic accumulation of fused-vesicles. The same tubules with activated autophagy, expressed K63-Ub proteins both in diabetic and in DN patients (IF).

Conclusions: In conclusion, our data demonstrate that chronic hyperglycemia induces an increase in autophagy, linked to the accumulation of K63 ubiquitinated proteins. However, uncontrolled autophagic levels could lead to tubular damage through the generation of intracellular vesicles, bringing to the progression of renal damage in DN patients.

Complexome Profiling of Mitochondrial Respiratory Chain Proteins from Podocytes of Diabetic Mice
Zenchun Yu,2,3 Shawn S. Badal,1 Daniel L. Galvan,1 Jianyin Long, Farhad R. Danesh.1 1Department of Internal Medicine, Univ of Utah & VA Med Ctr, Salt Lake City, UT; 2Veterans Administration Support

Background: Mitochondria play essential roles in many aspects of biology, and their dysfunction has been linked to diverse diseases, including diabetic nephropathy (DN). Central to proper mitochondrial function is oxidative phosphorylation (OXPHOS), coordinated by respiratory chain complexes encoded by both nuclear and mitochondrial genomes. Whether alterations in specific OXPHOS complex protein expression/activity contribute to mitochondrial dysfunction in DN remain largely unknown.

Methods: To assess complexome profiles, mice were isolated from podocytes of db/db mice and non-diabetic (db/dm) mice. Blue Native Gel Electrophoresis (BNE) was carried out using mass spectrometry (nano-HPLC/ESI/MS/MS) to identify known and unknown macromolecular protein complexes.

Results: We identified a total of 1216 mitochondrial proteins. Complexome profiling revealed mitochondrial complexes 1 and III were markedly reduced in podocytes compared to controls. Consistent with MS results, Complex 1 activity was significantly reduced in podocytes of db/db mice compared to controls. Importantly, we found that the protein expression levels of Ndufa2, Ndufb3 and Ndufb8, all components of complex I, were significantly reduced in podocytes of db/db mice. We further validated...
our initial results and found that the podocyte-derived mitochondria from diabetic db/db mice are decreased in mass and protein expression and reduced mRNA levels of Ndufb8. These changes are coincident with significantly decreased Complex I activity from analogously isolated and processed mitochondria derived from db/db mice.

Conclusions: Our study uncovers a previously unrecognized role of complex I in the progression of DN. We propose that deficiencies in components of complex I may disrupt complex I assembly, eventually reducing mitochondrial oxidative metabolism of podocytes in diabetic kidney disease. Further genetic studies are currently underway in our laboratory to establish the value and limitations of using Ndufb8 transgenic mice in experimental models of diabetes as a model for targeting mitochondrial dysfunction in DN.

Hyperglycemia and Hyperinsulinemia Increased Cell Proliferation and Regulated DNA Damage/Repair Pathways in Type II Diabetic (db/db) Mouse

Samy L. Habib,1 Sitali Liang,1,2 Geriatric Research, Education and Clinical CTR, South Texas Veterans Health System, San Antonio, TX; 1Cellular and Structural Biology, The Univ of Texas Health Science Center, San Antonio, TX.

Background: The mechanisms by which hyperglycemia and/or hyperinsulinemia activate cell proliferation to regulate the DNA damage/repair pathways and increase renal cell damage in diabetes remain unclear.

Methods: In the current study, we investigated the role of hyperglycemia and hyperinsulinemia in regulating cell survival and cell proliferation to regulate the DNA damage/repair pathways in the type II diabetic (db/db) mouse.

Results: Significant increase in proteinuria, albuminuria, creatinine in 24h urine as well as albuminuria/creatinine ratio was detected in db/db mice compared to wild type mice. Cell proliferation was measured by Ki67 staining and PCNA expression in kidney sections of the in type II diabetic (db/db) mouse. DNA damage/repair pathways were also investigated and we found that the Akt/PKB and AMPK pathways were activated in the type II diabetic (db/db) mouse. We further found that the expression of p53, Bax and cytochrome c was significantly increased in the diabetic db/db mice as compared to wild type mice. The level of PCNA was increased in the diabetic db/db mice compared to wild type mice. The level of phospho-p53 and phospho-Bax were significantly increased in the diabetic db/db mice compared to wild type mice. The level of phospho-PCNA was increased in the diabetic db/db mice compared to wild type mice.

Conclusions: In summary, our data provide a novel mechanism of increased renal cell damage through decreased binding of Nfr2 to the OGG1 promoter and consequence deficiency in DNA repair that lead to accumulate DNA damage and lead to renal complications under hyperglycemia and hyperinsulinemia condition in diabetic mice.

SA-PO407

Spleen Tyrosine Kinase Activation Promotes the Progression of Diabetic Nephropathy in the Early Stage

Fei Liu, Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.

Background: Inflammation triggered by metabolic disorder has played an important role in the pathogenesis of diabetic nephropathy (DN) in the early stage. The inflammatory cytokines binding to immunoglobulin G Fc receptors (FcγRs) in the surface of cell contribute to the progression of inflammation. It was found in our previous study that there was an increased expression of FcγRs with an immunoreceptor tyrosine-based activation motif (ITAM-FcγRs) in the kidney of diabetic CRP-Tg mouse induced by streptozotocin (STZ). It was also observed that ITAM-FcγRs were increased and spleen tyrosine kinase (SYK) were activated in rat glomerular mesangial cells (GMC) cultured with high glucose. SYK is a cytoplasmic nonreceptor tyrosine kinase and plays critical role in intracellular signal transduction of ITAM-FcγRs. It has been established that activated SYK signal cascade leads to the pro-inflammatory cytokines production in antibody-dependent kidney disease. However, the role of SYK in the progression of DN remains unclear. The present study investigates the potential of SYK activation in the early stage of DN.

Methods: Diabetes was induced by STZ in Sprague Dawley (SD) rats for assessment of kidney injury at 2, 4, 8weeks by real-time PCR, immunohistochemistry and western blot analysis. In vitro, the pathogenic effect of SYK was observed. Renal and urinary albumin excretion significantly increased in diabetic SD rats at 2, 4 and 8 weeks after STZ injection. Renal inflammation has been developed with enhanced infiltration of macrophages and T cells, and upregulation of pro-inflammatory cytokines (IL-1β, TNFα) in diabetic rats. Enhanced renal inflammation in diabetic kidneys caused the increase of SYK, phosphorylation and the over-activation of nuclear factor kB (NF-kB) signaling pathway. In vitro, high glucose significantly upregulated pro-inflammatory cytokines (IL-1β, TNFα) via SYK cascade, which further promoted high glucose-mediated renal inflammation.

Conclusions: These findings suggested that SYK may be as “signal switch” to activate NF-kB signaling pathway and promote the progression of renal injury in the early stage of DN.

Smooth Muscle Specific Heavy Chain Ferritin Knockout Mice as a Model of Obesity

Vivcca Walker, Bo Chen, Rony Joseph, Anupam Agarwal. Nephrology Research and Training Center, Div of Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.

Background: Ferritin, consisting of heavy (H) and light (L) chain subunits, is a highly conserved ubiquitous protein that safely sequesters iron in a non-toxic form. During the course of our studies to evaluate the role of heavy chain ferritin (FH) in a model of vascular calcification in TGD, we generated a transgenic mouse using the cre-lox system with smooth muscle cell-specific deletion of FH (FHΔ547). Serendipitously, we discovered the FHΔ547−/− mice gained more weight compared to control “floxed” FH mice and exhibited features resembling metabolic syndrome.

Methods: To characterize FHΔ547−/− mice as a model of obesity, male FHΔ547−/− mice and FHΔ547+/− control mice were individually housed from 6-28 weeks of age to monitor weight, food intake, and body composition utilizing quantitative magnetic resonance (QMR) imaging. Protein analysis was performed on skeletal muscle and fat to determine expression levels of F sustained signaling and iron regulators. RNA analysis of inflammatory markers expressed in white fat was also performed.

Results: At 28 weeks old, FHΔ547−/− mice gained more weight (30.58g ± 2.02 vs. 27.72g ± 1.06 controls) during the observation period and consumed significantly more food starting at 20 weeks of age than the controls. QMR studies revealed that FHΔ547−/− mice had slightly more fat, lean and water mass compared to controls. Protein analyses of skeletal muscle and white fat revealed a loss of GLUT4 expression and iron trafficking proteins, respectively, in transgenic mice. Moreover, there was an increase in tissue iron concentration and gene expression of TFNα in the fat tissue of FHΔ547−/− mice compared to controls. Interestingly, review of publicly available microarray data sets (NCBI, GEO data set GDS3876) derived from human samples suggest a significant (~1.5 fold) increase in FH gene expression in obese individuals compared to lean controls.

Conclusions: Over a third of the adults in the United States are obese. Obesity predisposes individuals to other health risks, including CKD, diabetes, stroke, and cardiovascular disease. Our studies provide a novel mouse model for obesity.

The Induction and Role of p53 in Tubular Cell Apoptosis During High Glucose Treatment and Diabetes

Lin Li,1 Zhengwei Ma,1 Changlin Mei,2 Zheng Dong,1 1Dept of Cellular Biology and Anatomy, Georgia Regents Univ, Augusta, GA; 2Dept of Nephrology, Shanghai Changcheng Hospital, 2nd Military Medical University of PLA, Shanghai, China.

Background: p53, known as a tumor suppressor, plays a crucial role in the cellular response to various stresses. P53 has been implicated in diabetic kidney disease but its role remains unclear and controversial.

Methods: Kidneys from Akita mice and STZ-treated diabetic mice were collected for in vivo studies. In vitro, renal proximal tubular cells (RPTC) with or without p53 dominant negative (p53-DN) were cultured in medium containing 5.5 mM or 30 mM glucose. Apoptosis was detected in renin tubules within a few weeks of diabetes, which was accompanied by p53-p/p53 expression. In cultured RPTC cells, high glucose induced apoptosis and p53. In these cells, there were Bax translocation to the mitochondria and cytochrome c release. Interestingly, these changes and apoptosis were attenuate in p53-DN cells. Consistently, they were also suppressed by pifithrin-α, a pharmacological inhibitor of p53.

Conclusions: These results suggest that p53 may be an upstream mediator of tubular cell apoptosis during high glucose treatment and in diabetic kidneys. P53 is induced under these conditions and may activate the mitochondrial pathway of apoptosis.

Mechano-Growth Factor Regulates mTOR and Other Growth Factor Expression in Mouse Mesangial Cells. Enhancing Cell Proliferation and Extracellular Matrix Production: Implications for Diabetic Glomerulosclerosis

Yongxin Gao,1,2,3 Walker, Thanhna Lam,1,2,4 Stamatios I. Kostopoulos, Charles W. Heilig. Medicine, Univ of Florida College of Medicine-Jacksonville, Jacksonville, FL.

Background: MGF-S mesangial cells (MC) overexpress Mechano-Growth Factor (MGF) protein expression, while SM22−/− mice display markedly reduced mRNA and protein expression levels of Ndufb8. These changes are coincident with significantly decreased Complex I activity from analogously isolated and processed mitochondria derived from db/db mice.

Conclusions: Our study uncovers a previously unrecognized role of complex I in the progression of DN. We propose that deficiencies in components of complex I may disrupt complex I assembly, eventually reducing mitochondrial oxidative metabolism of podocytes in diabetic kidney disease. Further genetic studies are currently underway in our laboratory to establish the value and limitations of using Ndufb8 transgenic mice in experimental models of diabetes as a model for targeting mitochondrial dysfunction in DN.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
of S6 kinase (phospho-S6 kinase) protein 8.7-fold. This increase in mTOR and active S6 kinase was dependent on cellular proliferation rate. mTORC1 had suppressed mTOR by 69%, but suppressed active S6 kinase by an insignificant amount. VEGF expression was suppressed 60% in MGF-AS vs MGF-EV. TGF beta 1 protein was increased 1.8-fold in MGF-S, and reduced 46% in MGF-AS. GLUT1 protein in MGF-S was increased 7.2-fold compared to GLUT1 expression. In contrast, H2-Dog uptake was suppressed 85% in MGF-AS vs. MGF-EV. In MGF-S, Type IV collagen (Col-Iv) was increased 4.2-fold.

Conclusions: MGF-S MC demonstrated increased mTOR with S6 kinase activation, consistent with their enhanced proliferation rate, while the increased VEGF and TGF beta 1 promote Col-Iv protein expression. Overexpression of MGF in MC to mimic events in diabetic glomeruli recreates many features of high glucose-exposed MC. MGF-AS MC demonstrate a role for MGF in basal VEGF and TGF beta 1 expression.

High Fat and High Sucrose Diet Induce Steatohepatitis That Is Dependent on Fructokinase
Takui Ishimoto,1 Miguel A. Lanasa,1 Shoshi Maruyama,1 Richard J. Johnson.2 1Nephrology, Nagoya Univ of Graduate School of Medicine, Nagoya, Aichi, Japan; 2Renal Diseases and Hypertension, Univ of Colorado, Denver, Aurora, CO.

Background: High fructose intake from added sugars, which are high in Western diet, correlates with the epidemic rise in obesity, metabolic syndrome, nonalcoholic fatty liver disease, and chronic kidney disease. However, the interaction of fructose with high fat intake, which is also rich in Western diet, remains unclear. Here we tested the interaction between fructose and fat, and determined whether this was dependent on a primary enzyme in fructose metabolism, fructokinase.

Methods: Wild type mice and fructokinase knockout mice (C57BL6/J background, male) were assigned to one of three groups (n = 8-9) respectively, matching mean body weight among the groups. Mice had free access to tap water, and a low fat (11%, LFD), high fat (36%, HFD) or high fat (36%) and high sucrose (30%) diet (HFSD) for 15 weeks. Urine samples were collected at 13 weeks using metabolic cages. At 15 weeks, blood was withdrawn, and tissues including kidney and liver were taken after 6 h fasting.

Results: Both wild type mice fed HFD and fructokinase knockout mice fed HFD developed high hepatic steatosis without hepatic inflammation compared to mice fed LFD. In contrast, wild type mice fed HFSD developed more severe hepatic steatosis and low grade inflammation and fibrosis in pathological analysis, but not in fructokinase knockout mice. Increased CD68, TNF-alpha, MCP-1, alpha-smooth muscle actin, and collagen I and TIMP1 expression were found in wild type mice fed HFSD. These changes were prevented in the fructokinase knockout mice. Meanwhile, there was no significant change of urinary protein and urinary NGAL, and no apparent renal pathological change among groups.

Conclusions: This study demonstrated an additive effect of high fat and high sucrose diet on the development of hepatic fat accumulation. Furthermore, the combination of sucrose with high fat diet may induce steatohepatitis. These results indicate the important role of fructose in the development of fatty liver and nonalcoholic steatohepatitis.

The Succinate Receptor 1 Contributes to Obesity-Induced Type II Diabetes and Chronic Kidney Disease
Peter M.T. Deen,1 Claudia Carmone,1 Janna A. Van diepen,1 Joris Hubertus Robben,1 Ana Carolina Ariza,1 Olivier Devuyst,1 Richard J. Johnson.2 1Division of Nephrology, Ningbo Urology and Diabetes Research Center, School of Medicine, Ningbo Univ, Ningbo, China; 2Div of Nephrology, Ningbo Urology and Diabetes Research Center, School of Medicine, Ningbo, China.

Background: Cell stress-induced release of mitochondrial succinylate and activation of its SUCNR1 receptor in the macula densa is essential for type 1 diabetes mellitus (T1DM)-related renin release and hypertension. Obesity-induced T2DM and Chronic Kidney Disease (CKD) are aggravated by hypertension and go with cell stress in adipose/kidney tissue and macrophages, which express SUCNR1. Here we tested the role of SUCNR1 in obesity-induced T2DM and CKD.

Methods: Wild-type (wt) and SUCNR1-/- mice were fed a low fat diet (LFD; 10%) or high (H) FD (60%). At different weeks, mice were weighed, and subjected to metabolic cages (electrolyte measurements), glucose tolerance tests (GTT). Mice were sacrificed and blood and tissues collected.

Results: Blood succinate was increased in diabetic patients versus healthy controls. Isolated adipose tissue of wt and SUCNR1-/- mice revealed increased succinate release with hypoxia or high glucose. 16 weeks LFD/HFD showed similar body weight and kidney weight gain for both HFD groups, but liver and heart weight gain was reduced in HFD SUCNR1-/- versus wt mice. Starving glucose levels were similarly increased in both HFD groups, but SUCNR1-/- mice had a better GTT response. Inflammatory signals and macropage infiltration was higher in adipose tissue of wt than SUCNR1-/- mice. Bone marrow derived cells of SUCNR1-/- mice migrated less efficiently towards chemotactic signals from diabetic/hypoxic 3T3 cells. Blood sodium and urine volumes were similarly decreased and eGFR increased in both HFD groups versus LFD controls. However, only HFD SUCNR1-/- mice showed albuminuria, elevated collagen IV expression, and some increase in inflammatory gene expression in the kidney.

Conclusions: SUCNR1-mediated chemotaxis of macrophages to affected adipose tissue, locally increased SUCNR1-mediated hypertension, contributes to obesity-induced T2DM and CKD development. If similar in humans, SUCNR1 may form a novel therapeutic target for T2DM and CKD.

Fluoxetine Disrupts E-Cadherin-Mediated Cell Adhesion and Calcium Homeostasis in Pancreatic β Cells
Yun-wen Chen,1 Huang-Yu Chang.1 1Pharmacology, National Cheng Kung Univ, Tainan, Taiwan; 2Pharmacology, National Cheng Kung Univ, Tainan, Taiwan.

Background: Major depressive disorder (MDD) is a common psychiatric illness and it affects as many as 840 million people.MDD and Type 2 diabetes (T2D) are disorders with various risk factors identified in prevalence study reports. Antidepressant treatment could be another critical factor affecting the bidirectional associations between MDD and T2D. Long-term use of selective serotonin reuptake inhibitors (SSRIs), the most commonly prescribed class of antidepressants, is associated with an increased risk of developing T2D. E-cadherin mediated cell-cell adhesion has been linked to diseases such as cancer and diabetes. Loss of cell-cell adhesion in beta cells decreases insulin secretion.

Methods: Here we examine the effects of the SSRI fluoxetine (Prozac®) on beta cell function employing MIN6 cells, a mouse beta cell line, to elucidate the underlying molecular mechanisms.

Results: We showed that fluoxetine treatment significantly reduced glucose stimulated insulin secretion (GSIS). We found that fluoxetine has no effect on the total expression of E-cadherin, but decreased the surface of E-cadherin. Moreover, fluoxetine triggered E-cadherin reorganizing in cell border, mainly localized in Golgi, not in endoplasmic reticulum (ER). Our immunohistochemistry showed that reduction cell surface E-cadherin is due to increased endocytosis. Moreover, ER calcium release and the activation of store-operated calcium entry (SOCE) were suppressed by fluoxetine.

Conclusions: Taken together, the results suggested that the impairment of E-cadherin and calcium homeostasis may be underlying mechanisms by which fluoxetine caused the reduction of GSIS in pancreatic beta cells.

Involvement of Ischemic Condition in the Pathophysiology of Renal Damages in Obesity-Induced Kidney Injury
Koji Futatsugi,1 Hirobumi Tokuyama,1 Makiko Naitoh,1 Shu Wakino,1 Hiroshi Itoh.1 Internal Medicine, Keio Univ School of Medicine, Tokyo, Japan.

Background: We have reported hypertrophic proximal tubules in obese mice which implies an inefficient oxygen supply in this area (Obesity Int, 2012). We examined whether hypoxic condition in proximal tubules is involved the pathogenesis of obesity-induced renal injury. We also test the hypothesis that this injury can be ameliorated by molecular intervention of prolyl hydroxylase domains (PHDs), sensors for tissue oxygen levels that is a crucial molecule for tissue response to hypoxia.

Methods: Tissue hypoxic conditions were assessed by pimonidazole immunostaining. Peritubular capillaries (PTCs) were evaluated by counting CD34 stained vessels. Tamoxifen (Tam)-inducible proximal tubules-specific PHD2 deficient mice were created by crossing PHD2floxtm/mice and Tam-inducible N-myc downstream-regulated gene-I-Cre mice on C57BL6/J background. These inducible conditional knock out (KO) mice mised their wild-type littersmates (WT) were fed a high fat diet (HFD) or a low fat diet (LFD) for 12 weeks. The expressions of PHD2 and VEGF were measured by real-time PCR and immunohistochemistry.

Results: The WT mice on HFD manifested renal histological changes, including cellular enlargement of proximal tubules and a rarefaction of PTCs, which were consistent with more hypoxic area in proximal tubules than in WT mice on LFD. Urinary albumin and NGAL excretion were higher in HFD-fed mice, indicating ischemic tissue damage in proximal tubular area. However, expression of either PHD2 or VEGF was unchanged in HFD-fed WT mice, suggesting the lack of hypoxic tissue response in HFD-fed WT-Injecting Tam to HFD-fed KO mice downregulated PHD2 in proximal tubules, increased VEGF expression, increased the number of PTCs, decreased hypoxic area, and attenuated proximal tubular damages and albuminuria.

Conclusions: Hypoxic condition due to enlarged cell with vascular rarefaction is evident in the proximal tubular area of obese mice whereas tissue reaction to hypoxic damages failed to properly compensate. The early reduction of PHD2 specifically in the proximal area may constitute a novel strategy against the progression process from an early stage of obesity-induced kidney injury.

Herbal Mixture of Radix Puerae and Fructus Crataegi Prevents Renal Injury in Type 2 Diabetes via Inhibition of AKT/P38
Zhenyue Chen,1 2Pharmacology, National Cheng Kung University, School of Medicine, Ningbo Univ, Ningbo, China; 2Div of Nephrology, Ningbo Urology and Nephrology Hospital, School of Medicine, Ningbo Univ, Ningbo, China.

Background: It has been reported recently that radix puerae (RP) is one of the best herbal medicines for metabolic diseases, as it has pronounced anti-oxidative effects and helps improving insulin resistance and lowering blood sugar and lipid levels. Fructus crataegi

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

719A
(FC) also possesses strong antioxidant activity in vitro. The present study was designed to investigate whether RF and FC together (RF/FC) can prevent renal injury through a diabetic rat model generated by a high-fat diet and a low-dose streptozotocin (STZ).

**Methods:** A Type 2 diabetic model was generated by feeding rats with high-fat diet followed by injecting a low dose of STZ. Rats were randomly divided into five groups: normal diet, high-fat diet plus RF/FC prevention, diabetes mellitus plus RF/FC prevention. RF/FC was given to rats daily by intragastric gavage for 3 weeks. The rats were monitored for body weight, blood glucose, oral glucose tolerance, blood insulin and lipids, serum creatinine and urea nitrogen, urine protein. Renal pathological changes were examined with hematoxylin and eosin staining, periodic acid schiff staining, and Masson trichrome staining. The mRNA and protein levels of α-smooth muscle actin (α-SMA) and collagen IV in the kidney were detected by RT-PCR, Western blot and immunohistochemical staining. The levels of PI3K and AKT were determined by Western blot.

**Results:** Rats treated with RF/FC showed reduced 24 h urinary protein excretion and decreased blood glucose level compared with corresponding vehicle treated rats, but RF/FC prevention did not affect blood lipids. Glomerular mesangial matrix expansion, renal capsule constriction, and renal tubular epithelial cell edema were less severe following RF/FC prevention. Moreover, RF/FC prevention markedly reduced protein levels of PI3K, AKT, α-SMA and collagen IV in the kidney of diabetic rats.

**Conclusions:** Combined prevention with RF/FC may inhibit the PI3K/AKT pathway in the kidney, thereby preventing renal injury in diabetic rats.

High Protein Diet Markedly Accelerates Diabetic Nephropathy Whilst Nephrectomy Inhibits Its Development Effects In Obese Diabetic Mice

**Background:** Progression of diabetic nephropathy (DN) is accompanied by an increase in urinary albumin excretion rate (AER) and severity of lesions. obese diabetic BTBR ob/ob mice exhibit hyperinsulinemia and hyperglycemia with marked albuminuria and glomerular morphological alterations. Disease progression was increased in the presence of high protein content diet. Using high protein content diet appears to be a straightforward approach to investigate the effects of high protein diet on obesity and type 2 diabetes.

**Methods:** Obese BTBR ob/ob mice at 8 weeks of age were fed a normal diet or high protein diet (18 weeks) with or without unilateral nephrectomy (performed at 7 weeks of age). Glomerular filtration rate (GFR) was measured by 125I-iothalamate clearance, blood pressure was measured by tail cuff, blood glucose level was measured by tail prick. The urinary albumin excretion rate (AER) was measured by an enzyme-linked immunosorbent assay (ELISA) kit. The mRNA and protein levels of α-smooth muscle actin (α-SMA) and collagen IV in the kidney were examined with real-time quantitative PCR and Western blot.

**Results:** High protein diet increased AER 332-fold in BTBR ob/ob at 18 weeks age compared with lean controls. Nephrectomy significantly decreased the number of podocyte slits per mm GBM. Although the high protein diet increased GBM thickness and decreased the number of podocyte slits per mm GBM, the urinary albumin excretion rate (AER) remained unchanged. Moreover, nephrectomy increased the number of podocyte slits per mm GBM, indicating a partial preservation of podocyte ultrastrutures.

**Conclusions:** High protein diet markedly accelerates diabetic nephropathy, whereas nephrectomy inhibits its development.

Insulin Stimulates Renal Proximal Tubule Sodium Transport in Overt Type 2 Diabetic Nephropathy

**Background:** Type 2 diabetic nephropathy is a major cause of end-stage renal disease. Although insulin is secreted in response to hyperglycemia, the role of insulin in the pathogenesis of diabetic nephropathy remains unclear. We determined the role of insulin in regulating renal sodium transport and glomerular filtration rate (GFR) in a model of type 2 diabetic nephropathy.

**Methods:** Male wild-type and db/db mice were fed either a normal or high-fat diet for 8 weeks. After 8 weeks of diet intervention, the mice were injected with streptozotocin (STZ) to induce diabetes. Blood glucose levels were monitored weekly. Kidney function was assessed by determining serum creatinine and urine albumin concentrations. Kidney morphology was evaluated by light microscopy.

**Results:** In db/db mice, insulin administration significantly increased GFR and renal sodium reabsorption. In contrast, in wild-type mice, insulin had no effect on GFR or renal sodium reabsorption.

**Conclusions:** These results suggest that insulin plays a role in the pathogenesis of diabetic nephropathy by regulating renal sodium transport.

SA-PO418

Modulation of Akt/AS160 Phosphorylation Mediates Insulin Resistance in a Rat Model of Metabolic Syndrome

**Background:** Insulin resistance is the underlying pathophysiological hallmark of metabolic syndrome (MS) which is most often associated with obesity. While adipokines and inflammatory cytokines have been implicated in the insulin resistance of MS, the exact underlying mechanisms and signaling processes have not been defined. The current study assessed the molecular mechanisms of insulin signaling in the skeletal muscle in ZSF1 rats which have leptin receptor mutation and phenotypically manifest MS.

**Methods:** Obese ZSF1 rats were maintained from the 8th week and sacrificed at 24 or 32 weeks and fed on high calorie high fat diet (Purina 5008) while control rats (lean ZSF1) were fed normal chow. Blood weights and water intake were monitored weekly and blood and urine samples were obtained at 8 weeks and at the time of sacrifice for determination of serum glucose, insulin and lipids by standard laboratory procedures. The mRNA and protein levels of insulin signaling related proteins, insulin receptor substrate-1 (IRS-1), Akt, AS160, and Glut4 were examined by Western blot.

**Results:** The obese ZSF1 rats showed full blown MS with obesity, hyperlipidemia, hypertension and hyperglycemia while the lean ZSF1 and SD rats were normoglycemic. The expression of GLUT4 was decreased in both skeletal muscle and fat tissue of obese rats. Studies done previously in our lab demonstrated that compared to non-diabetic rats, plasma adiponectin levels were lower in obese ZSF1 rats and adiponectin expression was decreased in fat tissue but not in skeletal muscle. The expression of adiponectin receptor 1 and insulin receptor substrate 1 (IRS1) were similar in all rats. Furthermore, the expression of phosphorylated Akt and AS160 were reduced by 74% and 38% in diabetic obese ZSF1 rats compared to non-diabetic controls.

**Conclusions:** Our results demonstrate that while GLUT4 expression in insulin sensitive tissues is decreased in obesity mediated diabetes, several intermediary steps in insulin signaling are unaltered. However the most consistent finding was reduced phospho Akt/ AS160, which could be a major determinant of insulin resistance in obesity.

Blockade of CDK9 and Smad3/4 Signaling Reduces Renal Fibrosis in Mice with Unilateral Ureteral Obstruction

Departments of Medicine, Monash University, Clayton, Victoria, Australia; Department of Pediatrics, The First Affiliated Hospital of Sun Yat-Sen Univ, Guangzhou, Guangdong, China; Department of Medicine, Monash Medical Centre, Monash University, Clayton, Vic., Australia.

Background: TGFβ1/Smad signaling plays a central role in the pathogenesis of renal fibrosis. Smad3 and Smad4 are pro-fibrotic, while Smad2 is anti-fibrotic. However, these Smads form heterogeneous complexes the functions of which are poorly understood.

This study investigated Smad complexes in renal fibrosis in mouse unilateral ureteric obstruction (UUO).

Methods: UUO was established in wild type mice, mice heterozygous or homozygous for Smad3 and/or Smad4 (reduction of 50 mmol/L) but most importantly in an increase in survival (55% non-treated versus 80% with late treatment) at day 128. Results: Early treatment with PBI-4050 resulted in significant improvement (up to three months) relative to control in GFR. There were significantly reduced proteinuria, histological lesion scores of kidney were also significantly (p<0.05) decreased in PBI-4050-treated rats (2.7 ± 1.5) compared to control (3.9 ± 1.4), as determined by HPE, PAS and Masson's trichrome staining. Early treatment with PBI-4050 induced a significant reduction of urine protein level. Furthermore, early treatment with PBI-4050 reduced the overexpression of fibrogenic (TGFβ1, collagen I and α-SMA), pro-fibrotic cytokines (IL-23p19 and IL-6), remodeling (MMP2, SPARC and fibronectin), and oxidative stress (iNOS) markers. Late treatment with PBI-4050 resulted in mild improvement of GFR and serum creatine level (decrease of 50 mmol/L) but most importantly in an increase in survival (55% non-treated versus 80% with late treatment) at day 128.

Conclusions: These results suggest that PBI-4050 offers the potential as a novel therapy for chronic kidney disease by reduction of fibrosis and may potentially improve residual kidney function in patients with end-stage renal failure.

SA-PO424

Fibroblast Growth Factor 23 Is Synthesised Locally by Renal Proximal Tubular Cells and May Be Pro-Fibrotic

Edward Robert Smith, Sven-Jean Tan, Stephen G. Holt, Tim Hewitson, The Royal Melbourne Hospital, Melbourne, Victoria, Australia; Dept of Medicine (RMH), The Univ of Melbourne, Melbourne, Victoria, Australia.

Background: Physiologically, FGF23 synthesis occurs predominantly in bone and regulates mineral handling in the kidney. In Chronic Kidney Disease, circulating levels have been found elevated and are thought to be strongly predictive of disease progression. However, the mechanisms by which FGF23 acts are not fully understood. Recent studies suggest that FGF23 may act to exacerbate chronic kidney disease and fibrosis.

Methods: We aimed to determine whether FGF23 production is increased in vivo in chronic kidney disease in a model of chronic kidney disease.

Results: In a 5/6 nephrectomised rat model of chronic kidney disease, serum FGF23 levels were increased compared to non-kidney disease controls. FGF23 was expressed by renal proximal tubular cells in vivo, as assessed by immunohistochemistry and in situ hybridisation.

Conclusions: These findings suggest that FGF23 synthesis is increased in vivo in chronic kidney disease, and that FGF23 may contribute to the progression of chronic kidney disease by an autocrine mechanism.

SA-PO423

Targeting Cardiorenal Connectors Reduces Renal and Cardiac Fibrosis in Experimental Chronic Renocardiac Failure

Nynke R. Oosterhuis,1 Lennart G. Borgartz,2 Branko Braam,3 Marienette C. Verhaar,1 Roel Goldschmeding,2 Carlo A. Guillard,2 Jaap A. Joles,1 UMC Utrecht, Nethelands;1,2 UMC Groningen, Netherlands;1,2 Univ of Alberta, Edmonton, Canada.

Background: Cardiorenal connectors (CRC) play a major role in progression of organ dysfunction in chronic kidney disease (CKD). Our studies suggest that PBI-4050 offers the potential as a novel therapy for chronic kidney disease by reduction of fibrosis and may potentially improve residual kidney function in patients with end-stage renal failure.

Methods: In rats subtotal nephrectomy was followed by coronary ligation (wk 8) [Borgartz, AJP, 2012]. In wk 11 we administered losartan (RAS), or PDTC, tempol and meldonium (Inflammation-NO/Ros) or all of these plus metoprolol (all-CRC) until wk 16.

Results: Tubulo-interstitial (TI) fibrosis decreased in all treated groups (fig 1A). However, renal function was not significantly affected by any treatment. Systolic dysfunction stabilized in all treated groups, but declined further in vehicle-treated rats (fig 1B). Cardiac fibrosis improved in all treated groups without significant additive effect of targeting all CRC (fig 1C). TI and cardiac fibrosis correlated (fig 1D). Only all-CRC reduced MAP. Diastolic hemodynamics and ventricular and cardiomyocyte size were not affected by any treatment. Reducing TI injury and renal and cardiac CTGF mRNA expression was most effective by targeting all CRC.

Conclusions: Pharmacological targeting of cardiorenal connectors in this model of chronic renocardiac syndrome ameliorated the severity of cardiac and renal fibrosis and prevented further decline in systolic dysfunction.
production is observed in diseased heart and vascular tissue, and is associated with the activation of pro-fibrotic cascades, the involvement of renal FGF23 synthesis and potential fibrogenic effects warranted investigation.

**Methods**: Kidneys were harvested from FVB mice at day 0 or after 3 or 9 days post-unilateral ureteric obstruction (UO) (n=6). Paraffin-embedded sections were stained for FGF23 and with lectins to identify specific nephron segments. Total RNA was extracted from whole kidney tissue and laser-capture microdissected glomerular and tubular regions, and analysed by qPCR. Rat renal fibroblasts were cultured with exogenous recombiant human FGF23 and stained for α-smooth muscle actin (aSMA) to assess myofibroblast differentiation.

**Results**: Generalised-low level FGF23 protein staining was observed in proximal tubules at day 0, with more intense focal staining at days 3 and 9 post-UO. Local FGF23 synthesis was confirmed by qPCR of whole kidney extracts, and specifically, in proximal tubular cells, but not glomeruli. Normalised FGF23 expression increased 11-fold in day 3 UO relative to day 0 (both p<0.01). Treatment of rat UO fibroblasts with 10ng/ml FGF23 resulted in 4-fold increase in aSMA staining over 72h, equivalent to the effect of 1ng/ml transforming growth factor-β (both p<0.01).

**Conclusions**: Local renal FGF23 synthesis in proximal tubular cells is enhanced by tubulointerstitial injury and may augment myofibroblast differentiation.

Quantitating Intracellular Oxygen Tension in Kidney by Phosphorescence Lifetime Measurement

**Yosuke Hirakawa,1 Imari Mimura,1 Toshitada Yoshitara,2 Makiko Kamiya,3 Tatsurupe Uruno,1,4 Seiji Tobita2,5 Masaoi Nangaku,1 1Graduate School of Medicine, The Univ of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo, Japan; 2Dept of Chemistry and Chemical Biology, Gunna Univ, 1-5-1 Tenjincho, Kur, Gunna, Japan; 3PRESTO, Japan Science and Technology Agency, 4-1-8 Honcho, Kawaguchi, Saitama, Japan; 4Graduate School of Pharmaceutical Sciences, The Univ of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo, Japan; 5CREST Japan Science and Technology Agency, 4-1-8 Honcho, Kawaguchi, Saitama, Japan.

**Background**: Hypoxia plays critical roles in the progression of chronic kidney disease, since intracellular reactions to hypoxia depend on intracellular oxygen (O2) tension. However, existing techniques to detect intracellular hypoxia cannot quantify O2 tension.**

**Methods**: Phosphorescence lifetime (PL) measurement is reported to be useful to quantify O2 tension in vivo, however, most phosphorescent probes distribute extracellularly. Here we used BTPDM1, a lipophilic phosphore probe, to quantify intracellular hypoxia in the kidney. We measured PL in Human Kidney 2 (HK-2) cells and murine kidney after BTPDM1 administration.

**Results**: We first made a calibration curve between PL and partial pressure of O2 (pO2) in HK-2 cells. Then we confirmed that BTPDM1 distributed in tubular cells in vivo. Next we measured PL of the murine kidney in normal condition, renal ischemia, hypoxemia and anemia. PL were calculated to be 1.8±0.2µs, 4.0±0.3µs, 2.8±0.2µs, 2.2±0.2µs, respectively. We also investigated chronic kidney damaged model mice of 7 days after 30 minutes unilateral ischemia-reperfusion (I/R) injury of kidney. PL of I/R injured kidney was lower than contralateral kidney (2.2±0.2µs vs 1.8±0.1µs). We also found an increase in pimonidazole adduct protein and a decrease in peritubular capillary density in I/R injured kidneys. We quantitated in vivo intracellular pO2 by extrapolating the calibration curve in HK-2 cells. The intracellular pO2 of normal kidney tubule was estimated to be 50mHg, which was compatible with published value obtained by needle O2 electrode.

**Conclusions**: Our novel technique allowed accurate estimation of intracellular O2 tension of the normal and diseased kidney in vivo for the first time.

SA-PO426

Resveratrol Increases Expression of Heme Oxygenase-1 via Nrf2 Signaling to Ameliorate Renal Damage by Anti-Complement, Anti-Oxidative, and Anti-Apoptotic Effects in a Murine Model of Membranous Nephropathy

**Chia-shao Wu,1,2 Kuo-cheng Lu,1,3 Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; 1Dept and Graduate Inst of Microbiology and Immunology, National Defense Medical Center, Taipei, Taiwan; 2Dept of Medicine, Cardinal Tien Hospital, School of Medicine, Fu Jen Catholic Univ, New Taipei City, Taiwan.

**Background**: Idiopathic membranous nephropathy (MN) is an autoimmune-mediated glomerulonephritis and a common cause of nephrotic syndrome in adults. There are limited available treatments for MN. We assessed the efficacy of resveratrol (RSV) therapy for treating MN in a model of this disease.

**Methods**: Murine MN was experimentally induced by cationic bovine serum albumin, with phosphate-buffered saline used in control mice. MN mice were untreated or given RSV. Disease severity and pathogenesis was assessed by determination of metabolic and histopathological parameters, profile of reactive oxygen species, apoptosis, production of heme oxygenase-1 (HO1) and signalings.

**Results**: MN mice given RSV had significantly reduced proteinuria and a marked amelioration of glomerular lesions. RSV also significantly attenuated immunofluorescent staining of glomeruli in vivo and MC in vitro. MGF is a stimulus to VEGF and TGFbeta1 expression in vivo in these mice. MGF expression is increased both in glomeruli in vivo and MC in vitro. MGF is a stimulus to VEGF and TGFbeta1 as observed here. These growth factors are associated with excess ECM production, and these results are consis tent with the reduction of ECM production and 3H2-deoxyglucose uptake rates in the kidneys of MN mice. We also found an increase in pimonidazole adduct protein and a decrease in peritubular capillary density in I/R injured kidneys. We quantitated in vivo intracellular pO2 by extrapolating the calibration curve in HK-2 cells. The intracellular pO2 of normal kidney tubule was estimated to be 50mHg, which was compatible with published value obtained by needle O2 electrode.

**Conclusions**: Our novel technique allowed accurate estimation of intracellular O2 tension of the normal and diseased kidney in vivo for the first time.

SA-PO427

FVB Os/+ Mesangial Cells Exhibit Enhanced mTOR and Growth Factor Expression, Modeling the FVB Os/+ Glomerulosclerosis Mouse

**Yongxin Gao,2 Charles W. Heilig, Medicine, Univ of Florida College of Medicine-Jacksonville, Jacksonville, FL.

**Background**: We previously reported FVB Os/+ mice which exhibit rapidy progressive glomerulosclerosis beginning within the first 2 weeks after birth. Here we examine primary culture mesangial cells (MC) from FVB Os/+ mice and FVB Os/+ control mice to examine the potential of FVB Os/+ MC and identify cellular mechanisms which may contribute to glomerulosclerosis (GS) in vivo. FVB Os/+ MC have excess ECM production.

**Methods**: Primary culture MC were studied between passages 5 -12. Western analyses were performed with specific antibodies against selected proteins to examine mTOR, phospho-S6 Kinase, and growth factor expression important to excess extracellular matrix (ECM) production. GLUT1 glucose transporter expression and SH2-deoxyglucose uptake rates were also determined. Plotted for comparison in a graph. FVB Os/+ MC also had increased VEGF (1.6-fold) and TGF beta (2.7-fold), which likely contribute to the excess ECM production of these cells. The increased VEGF in vitro stimulates increased VEGF in FVB Os/+ glomerulus in vivo. MGF was increased in FVB Os/+ MC (2.7 fold), mimicking increased glomerular MGF in vivo. We previously found MGF stimulates VEGF and TGFβ1 in MC. FVB Os/+ MC carry the Os mutation which impairs cell division, explaining their slow proliferation. Consistent with this, phospho-ERK1/2 was reduced 66%. In spite of increased mTOR (3.8-fold) and downstream phospho-S6 kinase (5.2-fold), the cells could not proliferate normally.

**Conclusions**: FVB Os/+ MC exhibit growth factor expression simulating glomerular growth factor expression in vivo in these mice. MGF expression is increased both in glomeruli in vivo and MC in vitro. MGF is a stimulus to VEGF and TGFbeta1 expression as observed here. These growth factors are associated with excess ECM production in FVB Os/+ MC, despite suppressed Erk1/2, indicating another pathway is important to excess ECM production.

SA-PO428

Role of Sodium-Glucose Linked Cotransporter-2 Inhibitor in the Kidneys of Salt Sensitive Hypertension

**Mikio Hisamichi,1 Atsuko Ikemori,1,2 Takeshi Sugaya,3 Kenjiro Kimura,4 Yugo Shibagaki,5 1Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Japan; 2Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Japan; 3Dept of Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.

**Background**: Sodium-glucose linked cotransporter-2 (SGLT2) is expressed in the apical side of the proximal tubules and can transport not only glucose but also sodium. Because salt is an aggravated factor for the salt sensitive hypertensive renal injury model, SGLT2 expression may be related to the progression of renal injury due to salt sensitive hypertension. The aim of this study is to reveal the role of SGLT2 inhibitor in angiotensin II (AII) induced renal injury.

**Methods**: Male C57BL6/wild-type mice were divided into three groups: The Ang II group was systemically infused with Ang II for 16 days. The SGLT2 inhibitor (SGLT2-I) group was given an oral dose of the dapagliflozin SGLT2 inhibitor of 1mg/kg/daily in addition to an injection of Ang II. The control group was injected with a vehicle.

**Results**: In both the Ang II and the SGLT2-I groups, the degree of hypertension, the glycemic levels in blood and the body weight were similar. Renal gene expressions of angiotensinogen in the SGLT2-I group were significantly increased both in the AII and the SGLT2-I groups than the control group. Renal gene expression of the angiotensinogen in the SGLT2 inhibitor group tended to be lower than that in the AII group. The degree of macrophage infiltration and urinary albumin levels tended to be lower in the SGLT2-I group than in the AII group. These results suggested that SGLT2 inhibitor may attenuate the renal damage due to salt sensitive hypertension via inhibiting the activation of renal renin angiotensin system.

**Conclusions**: In conclusion, SGLT2 inhibitor may be a useful treatment of hypertensive renal disease.
The Renoprotective Effect of Nuclear 1 Factor Related Factor 2 (Nrf2) Activator, Bardoxolone Methyl, in Aldosterone and High Salt-Induced Renal Injury

Mikako Hisamichi,1 Atsuko Ikemori,2,1 Takashi Sugaya,1 Kenjiro Kimura,2 Yugo Shibaegaki.1 1Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; 2Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; 3Dept of Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.

Background: Activation of nuclear 1 factor related factor 2 (Nrf2) is reported to have anti-oxidant and anti-inflammatory effects. In the aldosterone (Ald) and high salt-induced renal injury model using mice, we previously reported that severe tubulointerstitial damage was provoked by oxidative stress. The aim of this study is to reveal the renoprotective effect of the Nrf2 activator in this model.

Methods: To evaluate the degree of tubulointerstitial damage using the urinary liver type fatty acid binding protein (L-FABP), known as a biomarker of the tubulointerstitial damage, we used human L-FABP chromosomal transgenic (L-FABP⁺) mice. Male L-FABP⁺ mice were divided into three groups: The Ald group received systemic aldosterone infusions via an osmotic minipump and were given 1% NaCl water for 14 days. The Ald-Nrf2 group was given Bardoxolone Methyl of the Nrf2 activator intraperitoneally at a dose of 10mg/kg/day in addition to an injection of aldosterone and salt. The control group was given only a vehicle.

Results: The gene expression of MCP-1, the gene expression of RANTES, the gene expression of collagen type I and type III and the degree of macrophage infiltration were significantly greater in the aldosterone group compared to those in the control and renal inflammatory reaction and renal fibrosis were significantly attenuated in the Ald-Nrf2 group. The degree of renal L-FABP gene expression and urinary L-FABP levels increased in the Ald group compared to the control and decreased in the Ald-Nrf2 group.

Conclusions: The Nrf2 activator, Bardoxolone Methyl, could attenuate renal oxidative stress induced by aldosterone and high salt, and consequently, renal inflammatory reaction and the production of renal collagen were prevented. Bardoxolone Methyl may be a useful treatment for renal disease.

Detection of Mesangial Tissue Transglutaminase Activity in Human Kidney Biopsy Specimens

Kazuo Takahashi,1,2 Tomohiro Mizuno,2 Takanoi Onouchi,1 Shin-ichi Akiyama,1,3 Hideki Tatsuawa,1 Mamoru Kasaka,1 Tadashi Nagamatsu,1 Yutaka Tsutsui,1 Shoichi Maruyama,1 Hiroshi Kitamura,1 Jan Novak,2 Kiyotaka Hitomi,1 Yuki Yuzawa.1 1Fujita Health Univ School of Medicine, Toyoake, Aichi, Japan; 2Meijo Univ, Nagoya, Aichi, Japan; 3Graduate School of Pharmaceutical Sciences, Nagoya University, Nagoa, Aichi, Japan; 4NHO Chiba-East Hospital, Chiba, Japan; 5Univ of Alabama at Birmingham, Birmingham, AL.

Background: Tissue transglutaminase (TG2) is a protein-cross-linking enzyme that plays an important role in tubulointerstitial fibrosis in animal models of chronic kidney disease and diabetic nephropathy. However, its pathological significance in human glomerular diseases remains unclear. TG2 transforms into catalytically active TG2 through an unknown mechanism, and this accumulation aggravates kidney injury.

Methods: A total of 241 renal biopsy specimens obtained between January 2010 and December 2013 were assessed for TG2 activity by immunofluorescence microscopy with FITC-labeled highly reactive TG2 substrate peptides. The presence of the active form of TG2 was assessed by immunohistochemistry.

Results: Fifty-five of 65 (56%) patients with IgAN, 23 of 40 (58%) patients with lupus nephritis (LN), and 7 of 11 (64%) patients with secondary IgAN, including 8 IgA nephropathy (IgA), showed mesangial TG2 activity. Male Tgm2e (n=24) were fed a 0.2% w/w adenosine-containing diet. Two weeks later from the start of the diet, renal dysfunction of these mice were confirmed and were divided into the four groups: the adenine group was given only the diet containing adenine. The Fexubostat (Fe) group and the Topiroxostat high (Top-H) or low (Top-L) groups were given the diet containing each Fe (3mg/kg), Top-H (3mg/kg), Top-L (1mg/kg) in addition to adenine for another 2 weeks. Thereafter, adenosine-containing diet was stopped, only each medication was continued for additional 2 weeks and the kidneys in each group were removed.

Results: Renal dysfunction, the degree of macrophage infiltration, tubulointerstitial damage and renal fibrosis were significantly attenuated in the kidneys of the Feb, the Top-L and the Top-H groups compared to those in the adenine group. Serum uric acid levels and renal xanthine oxidoreductase activity in the Feb, the Top-H and the Top-L groups were significantly lower than those in the adenine group. Those levels in the Top-H group were significantly lower than those in the Feb group. Urinary excretion levels of L-FABP in both the Top-H and Top-L groups were significantly lower than those in both the adenine and Feb groups.

Conclusions: In conclusion, Topiroxostat attenuated the renal damage induced by hyperuricemia and may be a useful treatment for hyperuricemic renal damage. Funding: Private Foundation Support

Accumulation of Indoxyl Sulfate in Renal Tubular Cells Aggravates Kidney Injury in Rats with 5/6 Nephrectomy

Aynao Konagai,1,2,3,1 Kari Kikuchi,1 Ayako Fujieda,1 Sumie Goto,1 Hiroko Iijima,1 Yoshinao Itoh.1 1Pharmaceuticals Division, Kureha Corporation, Tokyo, Japan.

Background: Indoxyl sulfate (IS), a representative uromic toxin, is detected in renal tubular cells of CKD patients and 5/6 nephrectomized rats administrated with IS. It has been suggested that the retention of IS is induced through organic anion transporters in the basolateral membrane of renal tubular epithelial cells and this retention leads to nephrotoxicity. However, the mechanism for IS accumulation in renal tubules remains unclear. To reveal the correlation between IS accumulation and renal dysfunction in 5/6 nephrectomized rats, we investigated the expression of transporters in the apical or basolateral membrane and of markers for renal injury, and a content of IS in renal tubular epithelial cells using a novel antibody against IS.

Methods: To study the serum concentration of IS, we used high performance liquid chromatography (HPLC) and our newly developed enzyme-linked immunosorbent assay (ELISA). The renal sections were stained with the antibody for IS. The expression of transporters in renal tubular cells and the markers for renal injury such as Kidney Injury Molecule-1 (KIM-1) were detected by immunohistochemistry.

Results: Serum level of IS was identified to be increased in the 5/6 nephrectomized rats compared to the normal rats by the newly ELISA. The new system could sensitively detect the low concentration of IS. The value determined by ELISA is in a good correlation with HPLC. Immunohistochemistry showed a significant IS staining in renal sections of the model rats. We found the presence of IS in hyper tubular cells, where the expression of a transporter in the apical membrane mediating IS secretion was decreased, while the expression of a transporter in the basolateral membrane was retained. KIM-1, the marker for early kidney injury, was highly expressed in some tubules, but not in the IS positive cells.

Conclusions: Our findings suggest that IS is accumulated in renal tubular cells at the later stage of renal injury due to unbalance expression of transporters between in the apical membrane and in the basolateral membrane, and this accumulation aggravates kidney injury. IL-15 as a Potential New Therapeutic Treatment for Renal Fibrosis

L. Lecreul,1 A. Devocelle,1 V. Le coz,1 C. Gallerne,1 S. Ferlicot,1 A. Durbach,1 P. Eid,1 B. Azzarone,1 H. Francois,1 J. Girou-michel.1 1UMRS Inserm 1197, Villejuif, France; 2Bicetre Hospital, Kremlin-Bicetre, France.

Background: The human epithelial cells of various tissues produce interleukin-15 (IL-15), which acts not only on immune cells, but also on epithelial cells, mainly via its anti-apoptotic action. Thus, human and mouse renal tubular epithelial cells (RPTEC) constitutively secrete IL-15. Our group recently reported that IL-15 preserves epithelial phenotype in human kidney tubular cells since IL-15 is sufficient to induce MCT commitment of RPTEC. Therefore, the goal of our study is to explore the renoprotective potential of IL-15 in vitro and in vivo in renal fibrosis.

Loss of the Vascular Class 3 Semaphorin, Semaphorin 3G, Leads to Attenuated Fibrosis and Reduced Tubular Injury by Unilateral Ureteral Obstruction in Mice

**Methods:** Our study sought to examine if IL-15 could inhibit EMT in tubular epithelial cells by reducing secreted cytokines that contribute to tubulointerstitial fibrosis. We used the unilateral ureteral obstruction model (UO) in mice. We also analyzed IL-15 expression in various human nephropathies.

**Results:** IL-15 expression decreased in human renal disease and in mice during UO (p=0.05, n=19). IL-15 treatment coupled with its soluble receptor (IL-15Rα), prevents interstitial fibrosis during UO (10.7 ± 1.1% in control group, vs 8.2 ± 0.7% in IL-15 treated mice and 6.4 ± 0.6% in IL-15/IL-15Rα treated mice, p<0.01, n=7 mice/group). Quantified by Sirius Red and Western Blot, through two different mechanisms. We found a direct inhibition of IL-15 on collagen synthesis, in both HCC (collagen IV) and myofibroblasts (collagen I and III).

**Conclusions:** In conclusion, IL-15 can attenuate TGFβ-induced EMT by acting directly through a reduction of collagen synthesis, both on myofibroblasts, the main effector of fibrosis, and tubular cell. IL-15 also modulates macrophages infiltration in vivo in UO. Therefore IL-15 could be a novel therapeutic player in renal diseases.

Leukemia Inhibitory Factor Attenuates Tubulointerstitial Fibrosis in Unilateral Ureteral Obstruction

**Background:** Tubulointerstitial fibrosis is a common chronic kidney disease which is often sustained by chronic inflammation. CD4+ T-cells play an important role in the formation of renal fibrosis, its precise mechanisms are still unclear. Semaphorin 3G (Sema3G) belongs to a class 3 family of secreted semaphorin. Various cytokines are known to be involved in the formation of renal fibrosis, its precise mechanism is still unclear.

**Methods:** To understand the role of Sema3G in renal fibrosis, Sema3G knockout mice and control mice are subjected to unilateral ureteral obstruction (UUO).

**Results:** Histologically, UUO kidneys does not show obvious difference between control and Sema3G KO mice. However, although mRNA expression of Tgfα and Sna1, a key regulator of Tgfb-induced fibrosis, increases by UUO in controls, these increases are attenuated in Sema3G KO UUO kidneys (for Tgfα, 55% suppression compared to controls, p<0.05; and for Sna1, 39% suppression, p<0.01 at day 7), suggesting that Sema3G KO mice are protected from tubular injury.

**Conclusions:** Together, these data demonstrate that endothelial Sema3G acts on adjacent tubular/interstitial cells and promotes fibrosis by UUO. Identification of the mechanism of this interaction would provide new therapeutic targets for CKD and renal fibrosis.

**SA-PO436**

**Methods:** We observed that dendritic cell (DC) (CD11c) and myeloid cells (CD11b) infiltrated the renal interstitium in the early phase of acute tubular damage and a later phase of IF. To evaluate the role of TLR4 in renal inflammation-fibrosis, we analyzed the degree of inflammation that is dependent on TLR4 in WT and TLR4 mutant mice subjected to LPS. We further compared IF by Masson trichrome stain. Changes in IF (after adjusting for day 2 log BUN) were analyzed by regression analysis.

**Results:** Compared to control mice, CKO mice showed significantly higher serum creatinine at 40 and 60 days. Anti-dsDNA antibody was detected at low levels at 8 weeks and markedly elevated at 20 and 40 weeks. At 40 weeks, CKO mice showed severe proliferative glomerulonephritis and tubulointerstitial nephritis by light microscopy with mesangial IgG and C3 depositions by IF staining. Electron microscopy revealed electron dense depositions in mesangial area, but few in subendothelial or subepithelial area. Immunohistochemical staining showed marked accumulation of DCs (CD11c+), macrophages (F4/80+) and helper T cells (CD4+) at periglomerular and tubulointerstitial area. Infiltration of numerous DCs was also observed within glomeruli. Flow cytometric analysis of the CKO kidney showed the inflammatory cells increased with increasing age. Despite the prominent morphological changes, there was no significant increase of albuminuria, even at 40 weeks.

**Conclusions:** The DC-specific ablation of Shp-1 in mice resulted in development of unique autoimmune glomerulo- and tubulointerstitial nephritis, which is distinct from typical lupus nephritis characterized by wire-loop lesions and heavy proteinuria.

A New Mouse Model of Glomerular Foam Cell Accumulation in Disease
Minseob Eom,1 Kelly L. Hudkins, Anna Batorsky, Charles E. Alpers. Department of Pathology, Univer of Washington School of Medicine, Seattle, WA.

Background: Foam cells are lipid-laden cells of monocyte/macrophage origin which have a key role in the development of atherosclerosis. Similar foam cells are found in human kidney biopsies in various diseases (e.g. type 2 diabetes and focal segmental glomerulosclerosis (FSGS), diabetic nephropathy, and the interstitium in nephrotic states). The pathophysiologic significance of foam cells in the kidney is poorly understood, in part due to lack of good animal models. We sought to develop a robust animal model for foam cell accumulation in the kidney to test their pathogenic significance.

Methods: Adult Wistar rats were injected with anti-Thy-1.1 antibody to induce Nephrotic nephritis (NTN) in the HPMC-Tween treated group. Untreated age-matched controls. Each organ including kidney was harvested for histologic evaluation. Immunohistochemical staining (IHC) for Mac2 was performed to quantify the state of monocyte/macrophage infiltration and urinalysis was conducted to calculate the urine albumin-creatinine ratio (ACR) and total albumin excretion.

Conclusions: These experiments show that DAC treatment had a protective effect on NTN phenotypes in WKY rats with a reduction in DNA cytosine methylation in both nephritic glomeruli and macrophages. These results suggest that DNA methylation may be involved in the pathogenesis of CRGN and may represent a target for intervention.

Macrophages Present an Essential Source of Anti-Inflammatory Annexin A1 Signals During the Course of Acute Anti-Thy-1.1 Nephritis
Robert Labes,1 Philipp Dittert,2 Sebastian Bachmann,1 Alexander Palijecz.1 1Dept of Anatomy, Charité · Universitätsmedizin Berlin, Berlin, Germany; 2Dept of Nephrology, Charité · Universitätsmedizin Berlin, Berlin, Germany.

Background: Macrophage subpopulations exert distinctive effects during inflammatory kidney disease and may either aggravate kidney damage or foster renal repair. The anti-inflammatory protein annexin A1 (AnxA1) has been shown to shift macrophage polarization towards the anti-inflammatory M2 phenotype. Cellular sources and regulation of intrinsic AnxA1 signals during renal inflammation remain to be elucidated.

Methods: Adult Wistar rats were injected with anti-Thy-1.1 antibody to induce mesangiocapillary glomerulonephritis and examined after 24h (initiation phase), 5d (proliferation phase), and 15d (resolution phase). Regulation of AnxA1 was studied by real-time PCR and Western blot. AnxA1 levels were also determined in vitro in co-cultures of THP-1 macrophages, mesangial cells, and T cells. Quantification of AnxA1 in cells was performed by flow cytometry.

Results: AnxA1 expression was significantly increased in mesangial cells and macrophages in the proliferative phase of nephritis. In vitro co-culture experiments demonstrated that AnxA1 expression was induced by T cell stimulation, suggesting an important role for T cells in the regulation of AnxA1 during renal inflammation.

Conclusions: These data provide evidence for a role of T cells and macrophages in the regulation of AnxA1 expression during acute anti-Thy-1.1 nephritis. Further studies are needed to elucidate the mechanisms underlying AnxA1 expression in vivo.

5-Aza-2-Deoxycytidine Reduces Nephrotic Nephritis and DNA Cytosine Methylation in Nephritic Glomeruli and Macrophages In Vitro
Thomas Oates,1 Stephen Paul McCaod,2 Charles D. Pusey,2 H. Terence Cook,3 Enrico Pettetto.1 1Imperial NHS Trust, London, United Kingdom; 2Imperial College London, London, United Kingdom; 3MRC Clinical Sciences Centre, London, United Kingdom.

Background: Nephrotic nephritis (NTN) is a macrophage dependent rat model of crescentic glomerulonephritis (CRGN). We investigated whether DNA cytosine methylation could determine dysregulation of macrophage activity and contribute to CRGN susceptibility, by examining the effect of 5-aza-2-deoxycytidine (DAC), an inhibitor of DNA methylation, on NTN phenotypes and DNA methylation in both nephritic glomeruli and bone marrow derived macrophages.

Methods: NTN was induced in male WKY rats. 6 rats were treated with intraperitoneal DAC and 6 controls with vehicle only. Treatment was given every three days prior to sacrifice at 10 days and then NTN phenotypes assayed. The effect of DAC on DNA methylation was examined by multiplexed PCR sequencing of bisulfite converted DNA in both nephritic glomeruli from NTN animals, and in WKY bone marrow derived macrophages treated in vitro with DAC.

Results: DAC treated animals had fewer glomerular crescents, less proteinuria and less glomerular macrophage infiltration (ED1 staining).

DNA methylation in nephritic glomeruli was decreased across 200 cytosine bases in DAC treated samples compared to controls (P = 0.049, Wilcoxon rank sum test). This decrease was driven by 39 cytosines that showed demethylation in DAC treated animals. In vitro sequencing in macrophages showed diverse methylation changes after DAC treatment depending on length of exposure and dose.

Conclusions: These experiments show that DAC treatment had a protective effect on NTN phenotypes in WKY rats with a reduction in DNA cytosine methylation in both nephritic glomeruli and macrophages. These results suggest that DNA methylation may be involved in the pathogenesis of CRGN and may represent a target for intervention.

Reduced Mitochondrial Energy Production in the Kidney Induces Focal Segmental Glomerulosclerosis in Low-Birth-Weight Rats at Adulthood
Toshiyuki Imasawa, Kidney Center, National Hospital Organization Chiba-East Hospital, Chiba-City, Chiba, Japan.

Background: Intraglomerular hypertension has been linked with the pathogenesis of focal segmental glomerulosclerosis (FSGS) lesions in low-birth-weight (LBW)-related nephropathy, which is associated with a decreased number of nephrons. However, other mechanisms may participate in the pathogenesis of LBW-related nephropathy. Here, we investigated innate factors that could induce LBW-related nephropathy at adulthood.

Methods: LBW rats (N = 7) were obtained by intraperitoneally injecting pregnant rats with dexamethasone. Normal-birth-weight (NBW) rats (N = 7) were obtained by saline injection. At 4 weeks of age, the left kidney was removed and used for histological analysis (immuno-)histological analyses for crystal density, tissue cellularity, tubular dilation, inflammatory infiltration, and fibrosis, and vascularization.

Results: At 4 weeks of age, glomerular numbers in LBW rats were significantly lower than NBW rats (p < 0.01). However, there were no scrotal lesions, and neither group showed any other pathological changes at this age. At 9 weeks of age, FSGS lesions were observed in 7.4% of glomeruli in LBW rats, but only 0.5% of glomeruli had lesions in NBW rats. The pathological changes in LBW rats at 9 weeks of age resembled that of human LBW-related nephropathy. Quantitative proteomics using the renal cortex from 4-week-old rats revealed that 685 proteins decreased in LBW rats compared with NBW rats, and among them, 97 proteins (14.2%) were mitochondrial proteins. In such reduced kidney disease (CKD), but direct evidence that prolonged exposure to tissue Hyp initiates renal IL-1β or TLR-4 in S. Unexpectedly, Hyp attenuated IL-1β, TLR-4, and urothelial cancer complications in countries using traditional herbal medicine. Early detection of renal tubular injury could be useful in individuals at risk of exposure to AA.

Mean ± SE, *p < 0.05 vs. respective S, #p < 0.05 vs. respective Nor.

Methylation Decreases Expression of Erythropoietin in Fibrosing Kidney Disease
Ching-chin Yang, Yu-ting Chang, Szu Yu Pan, Yu-hsiang Chou, Yung-ming Chen, Shuei-Liong Lin.1,2 "Physiology, National Taiwan Univ College of Medicine, Taipei, Taiwan; 1Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan.

Background: Renal erythropoietin-producing cells remain in atrophic kidneys and are capable of producing erythropoietin in dialysis patients who take the stabilizer of hypoxia-inducible factors. The mechanism of decreased response of renal erythropoietin-producing cells to anemic stimulation in chronic kidney disease remains unclear.

Methods: We use genetically modified mice who report pericytes/myofibroblasts and express pericyte-specific Cre recombinase to perform in vivo study. We also isolate pericytes/myofibroblasts from these mice for in vitro analysis of epigenetic modification and erythropoietin expression.

Results: Here we show that Foxd1+ progenitor-depleted;Col1a1-GFP+;PDGFRbeta+ kidney pericytes are erythropoietin-producing cells regulated by hypoxia-inducible factor 2α (HIF-2α) and decrease such a function upon their transition to myofibroblasts in fibrosing kidney disease. Hypermethylation of erythropoietin 5′- untranslated region is demonstrated and associated with decreased expression of erythropoietin in kidney myofibroblasts. Demethylation with 5-azacytidine or knockdown of upregulated DNA methyltransferase 1 in kidney myofibroblasts is found to increase expression of erythropoietin in fibrosing kidney disease.

Conclusions: These studies demonstrate that epigenetic modifications may provide a molecular basis for decreased response of renal erythropoietin-producing cells to anemic stimulation in fibrosing kidney disease.

Multiparametric Magnetic Resonance Imaging for Assessing Renal Histopathology in a Mouse Model of CKD
Günter Schlegl,1 Jutta Janko,2 Kai-Uwe Eckardt,1 Tobias Bäuerle,1 Carsten Willam.1 "Nephrology and Histology, Univ of Erlangen-Nuremberg, Erlangen, Germany; 2Radiology, Univ of Erlangen-Nuremberg, Erlangen, Germany.

Background: Multiparametric magnetic resonance imaging (MRI) allows non-invasive assessment of renal pathologies, especially in patients with chronic kidney disease (CKD) as is does not require contrast agent administration. We aimed to establish an imaging protocol for multiparametric MRI in an experimental CKD mouse model and correlate radiological and histopathological parameters.

Methods: CKD was induced in male C57BL/6 mice (n=8) by feeding an adinidine-supplemented diet for 3 weeks resulting in deposition of dicyruxiadecrine crystals, tubular dilation, capillary loss, tubulointerstitial inflammation and fibrosis. Untreated animals (n=8) served as controls. Kidneys were fixed in paraformaldehyde and subjected to MRI in a 7-Tesla scanner ex vivo. Volumetry of renal cortex and medulla was performed on T2 weighted sequences. MRI parameters (apparent diffusion coefficient (ADC), fractional anisotropy (FA), T1, T2, T2* relaxation times) were determined for 3 regions of interest in both cortex and medulla, whereas ADC was increased only in the cortex of diseased kidneys and correlated with (immuno-)histological analyses for crystal density, tissue cellularity, tubular dilation, inflammatory infiltration, fibrosis, and vascularization.

Results: CKD resulted in significant volumetric augmentation of the medulla. T1 times decreased in control and diseased kidneys, T2 and T2* times were significantly increased in both cortex and medulla, whereas ADC was only increased in the cortex of diseased kidneys in comparison to controls. In contrast, FA was significantly reduced in diseased cortex and medulla. T2 time correlated with the relative area of fibrosis (Francois’ rho 0.71 or 0.79 for cortex or medulla), infiltrated macrophages (0.69, 0.81), and tubular lumen (0.74).

Conclusions: Multiparametric MRI enabled characterization and diagnosis of chronic changes in the presented CKD model and showed correlation of T2 times with fibrosis, inflammatory infiltration, and tubular dilation. These results may help to broaden our understanding of MRI findings in CKD patients.

Nuclear Magnetic Resonance Based Metabonomic Profiles Produced by Aristolochic Acids: Comparison with Well-Known Tubulotoxic Agents
Marie Colet,1 Jean-Noël de Roziers,1 Françoise,3 Eric De prez,2 Jean-Marie Colet,1 Joelle L. Nortier,2 "1Lab Human Biology & Toxicology, UMONS; 2Lab Experimental Nephrology, ULB; 3Lab Histology, UMONS.

Background: Aristolochic acids (AA) are powerful nephrotoxic and carcinogenic products derived from Aristolochiaceae responsible for acute to chronic renal failure and urothelial cancer complications in countries using traditional herbal medicine. Early detection of renal tubular injury could be useful in individuals at risk of exposure to AA.

Methods: The Consortium of Metabonomic in Toxicology (COMET) has developed predictive models of renal toxicity based on the NMR-based metabonomic evaluation of urine and serum samples collected from rats acutely exposed to various well-characterized nephrotoxins. Using this COMET protocol, we studied the metabonomic urine profile of rats injected with aristolochic acid or AA and other compounds (72, 100mg/kg). We then compared it to those obtained with 3 molecules known for their toxicity on the proximal tubule, i.e l(isoflavone (I: 7, 70mg/kg), genticamin (Gent: 40, 400mg/kg) and cisplatin (Cis: 0.5, 5mg/kg), respectively.

Funding: Government Support - Non-U.S.
Results: Metabolic results obtained in AA rats demonstrated a urinary increase in medullary rCBF (turbine, brain, glycine) in osmotic (lactate) and in reabsorptive capacity of the tubular epithelium (glucose), and a significant reduction of Krebs’ cycle components (alpha-ketoglutarate, succinate, citrate), suggesting a mitochondrial injury. The comparison of these AA profiles with those obtained with Ido, Gentamicin, and Cis revealed significant similarities in 2D plots. However, the 3D modelization approach showed very close score plots shared by AA, Ido and Cis and a different behaviour exhibited by Genta samples. Conclusions: This metabonomic study confirms the mode of action of AA toward the proximal tubule and provides an original signature of induced mitochondrial insult. This approach could bring new insight in understanding the toxicity pathways of AA within the kidney. Moreover, it could be a useful tool of noninvasive screening in populations at risk of AA intoxication.

SA-PO447
Establishment of a 3-Step Method to Obtain the Absolute Number of Nephrons in Mice Xiaogang Chg., Jian-Kang Chen. Depts of Cellular Biology & Anatomy and Medicine, Georgia Regents Univ, Augusta, GA.

Background: Low nephron number is implicated in hypertension and kidney disease. Existing methods to determine nephron number have various limitations. While using the Cre reporter mice expressing membrane-Tomato/membrane-Green fluorescent protein (mT/mG) for other studies, we fortunately noted that the Tomato fluorescence remarkably visualized all glomeruli in the kidneys, which prompted us to establish a 3-step (Separate-Press-Count) method to obtain the exact nephron number in mice.

Methods: One homozygous mT/mG mouse (S232, available from the Jackson Laboratory, Stock Number: 007576) was bred with FVB/NJ mice. This produced ~11 heterozygous pups per litter. After the pups reached 6 weeks of age, they were weighed and euthanized. Each kidney was decapsulated, weighed, and blantly separated into 35-45 pieces (~2-3 mm3) each using forceps with non-serrated but blunted tips. Each piece was pressed between a microscope slide with grids and a coverslip, followed by counting of every single glomerulus under a fluorescence microscopy.

Results: The nephron number in male mice ranged from 10421 to 15577 (mean = 12977 ± 2136) for left kidney and 10374 to 15691 (mean = 13271 ± 2414) for right kidney (n=6) while that of female mice ranged from 13890 to 16277 (mean = 15184 ± 993) for left kidney and 14547 to 16165 (mean = 15555 ± 741) for right kidney (n=5). Thus, the mean total nephron number in male mice (25562 ± 4330) is lower than that of female mice (30739 ± 1443). This is still true when expressed as mean nephron number per gram of body weight (mG): that of male 1025 ± 179 vs. female 1362 ± 90 (n=5, p<0.001), 5.6 nephrons (Nn) in male mice decreased N/Gbw down to 156 ± 17, increased blood pressure (BP) up to 142 ± 7 mmHg, elevated BUN level up to 292 ± 99 (n=5), and caused 37.5% mice to die within 2 weeks while the remaining 5.6 N/Gn mice with >241 N/Gbw had 130 ± 8 mmHg BP and 73 ± 25 mmHg BUN and were still alive even 4 weeks after 5/6 Nx.

Conclusions: We have established a new simple method to count the absolute nephron number and are using it to define the minimum number of nephrons per gram of body weight that can maintain the normal blood pressure and kidney function in mice.

Funding: NIDDK Support

SA-PO448

Background: One of the many unresolved questions regarding the permeability of the glomerular filtration barrier is the reason for the difference in permeability between albumin and polysaccharide probe molecules such as Ficoll. The difference in sieving coefficients between albumin and a Ficoll molecule of the same molecular size (~36 A) is ~2-3 orders of magnitude. Although this large difference in permeability has been attributed mainly to charge effects, we have previously shown that this would require a supraphysiological amount of charge on the filtration barrier, being about ~10 times more (~36 Å) for other studies, we fortunately noted that the Tomato fluorescence remarkably visualized all glomeruli in the kidneys, which prompted us to establish a 3-step (Separate-Press-Count) method to obtain the exact nephron number in mice.

Methods: The classic heteroporous model by Deen, Bridges, Brenner and Myers (Deen et al, AJP Renal Physiology, 1985) was extended by introducing size distributions on the selective elements of the barrier. This is well in line with experimental data, which has been established; however etv4 is also expressed in the metanephric mesenchyme. We asked what role Etv4 plays during nephrogenesis.

Methods: To inhibit etv4 function in the metanephric mesenchyme, we crossed mice with a loxP-flanked dominant-negative etv4 (R26/+;Flp;DNT-etv4) with a metanephric mesenchyme-specific sx2-cre mice (sx2-TGC m/+); cre-negative littermates served as control.

Results: Six2cre-DN-Etv4 mice express DN-etv4 in the nephron progenitor population starting dpc10.5. Cre-positive mice have lower body weight and fail to thrive. At four weeks, they have a reduced nephron number (~42 ± 2 vs. ~80 ± 6 glomeruli per g tissue, p<0.001). They develop kidney failure (at 4 weeks: BUN 103.8±17.8 mg/dl, p< 0.001) and proteinuria (21.29±7.23 g Albumin/g Creatinine vs. 0.14±0.03 g Albumin/g Creatinine in urine, p<0.05). Their kidneys show all features of chronic kidney failure proteinosis, glomerulosclerosis, fibrosis) and they die at 3-5 weeks of kidney failure.

Conclusions: Expression of etv4 in the metanephric mesenchyme is required for normal kidney development, and expression of DN-etv4 in the sx2+ population leads to defective kidney development with reduced nephron number and progressive chronic kidney failure at 3-5 weeks of age. Titration of DN-etv4 expression in metanephric mesenchyme may provide a novel genetic model for low nephron endowment and progressive CKD.

Funding: NIDDK Support

SA-PO451
NO Depletion by L-NAMe Causes Increases in Rat Glomerular Permeability In Vivo – Reversal with Temporal and L-Arginine, but Not with the Potent NO-Donor DEA-NONOate Bengt Rippe, Julia Dolinina, Kristinn Sverrisson, Anna Rippe. Dept of Nephrology, Lund Univ, Lund, Sweden.

Background: There is increasing evidence that the permeability of the glomerular filtration barrier (GFB) is regulated by a balance between the bioavailability of nitric oxide (NO) and the presence of reactive oxygen species (ROS). It has been postulated that normal or moderately elevated NO levels protect the GFB from permeability increases, while ROS, through reducing the bioavailability of NO, have the opposite effect.

Methods: In anesthetized Wistar rats, the left ureter was cannulated for urine collection, while simultaneously blood access was achieved. To test the tentative antagonism between NO and ROS, rats were systemically infused with either L-NAME (6 mg/kg/min) or L-NAMe together with the superoxide scavenger tempol (1 mg/kg/min), or L-NAMe together with L-arginine (290 mg/kg/min). Furthermore, we tested whether the potent NO donor, DEA-NONOate, could reverse the permeability effects of L-NAMe. To measure glomerular sieving coefficients (S) to Ficollic, rats were infused with fluorescein
isochoicancat (FTC)-Ficol 7/400 (mol.ruclus 10-80A). Plasma and urine samples were analyzed by high performance liquid chromatography (HPLC) for determination of 0 for Ficolll repeatedly during up to 2 hours. 

**Results:** L-NAME increased 0 for Ficoll in 0.27 to 1.0 x 10^-6 to 5.9 x 10^-6 x 27 (n=6; p<0.05) in 15 min. Tempol (n=6) completely abrogated these increases in glomerular permeability. Furthermore, the 0 for Ficoll, being 7.0 (2.1) x 10^-15 at 15 min, which was also seen with L-arginine. However, DEA-NAMEOate did not reverse the permeability effects following L-NAME. 

**Conclusions:** NO depletion in vivo by L-NAME caused increases in glomerular permeability, which could be reversed by either the ROS antagonist, tempol, or by L-arginine. By contrast, the potent NO-donor, DEA-NAMEOate, did not ameliorate the permeability effects of L-NAME. It is concluded that moderate levels of elevated NO production act to protect the permeability of the GFB, whereas very high levels of NO, as produced following systemic DEA-NAMEOate infusion, may actually be detrimental to the GFB.

**Funding:** Government Support - Non-U.S.

SA-PO452 Down-Regulation Of Renal Tubular Wnt/β-Catenin Signaling Induces Tubular Cell Death in Proteinuric Nephropathy

**Methods:** Wnt/β-catenin expression was measured in control/ human serum albumin (HSA)-treated human kidney 2 (HK-2) cells and kidney cortical lysates of protein-overloaded mice given 4- or 8- week BSA injection by Western blotting and IHC staining. Genetic knockdown of β-catenin in HK-2 cells was achieved using siRNA transfection. Apoptotic phenotypes were evaluated by qPCR, Western blotting, IHC staining/ activity assay and TUNEL assay. 

**Results:** Upon 4-day/BSA stimulation, protein levels of active nuclear β-catenin in HK-2 cells declined by 67±0.04 (p=0.05) versus control. Similarly, Bax/Bcl-2 gene expression ratio increased significantly. HSA treatment with or without β-catenin siRNA transfection in HK-2 cells up-regulated Bax/Bcl-2 gene expression ratio by 116±0.02 (p<0.05) and 52.0±0.05 (p=0.05), respectively. Similarly, TUNEL and caspase-3 activity was also increased by silencing β-catenin. In protein-overloaded mice, dynamic expression of β-catenin was observed at the early stage and associated with up-regulation of NGL and KIM-1 gene expressions. 

**Conclusions:** Protein-overload promotes renal tubular apoptosis via abrogation of Wnt/β-catenin signaling in vitro and in vivo. Funding supports: Hong Kong Society of Nephrology Research Grant (2013), and the National Basic Research Program of China 973 program no. 2012CB176000 (no. 2012CB517606).

**SA-PO453 Endothelin-1 Induces Proteinuria by Heperanase-Mediated Disruption of the Endothelial Glyocalyx**

**Methods:** Endothelin-1-stimulated podocytes increased transendothelial albumin passage, which is HPSE-dependent. Experimental type 1 diabetes in wild type (WT) mice revealed proteinuria and renal damage, accompanied with an increased glomerular HPSE expression and a reduced glomerular HS expression. Proteinuria and renal damage were reduced in the diabetic podocyte-specific endothelin receptor knockout (podETRKO) mice, which showed a normal HPSE and HS expression. Importantly, glyocalyx thickness was reduced after induction of diabetes in the WT mice, but preserved in the diabetic podETRKO mice. 

**Conclusions:** Our data show that endothelin-1 induces HPSE expression in the podocyte in experimental DN. Furthermore, these results suggest that HPSE cleaves HS in the endothelial glyocalyx, which results in a reduced glyocalyx thickness and the development of proteinuria.

**SA-PO454 Endothelin-1 Increases Glomerular Permeability in Sickle Cell Mice Malgorzata Kasztan, 1 Chiao-Wang Sun, 2 David M. Pollock. 1 Cardia-Renal Physiology&Medicine, Univ of Alabama at Birmingham, Birmingham, AL; 2Biochemistry&Molecular Biology, Univ of Alabama at Birmingham, Birmingham, AL.** 

**Background:** Sickle cell disease (SCD) leads to nephropathy manifested by increased glomerular permeability (P_{alb}) and albuminuria/proteinuria. The endothelium-derived peptide endothelin-1 (ET-1), with its powerful vasoconstrictor and pro-inflammatory effects mediated primarily through ET, receptors, is elevated in SCD patients and may contribute to the development of sickle cell glomerulopathy. Therefore, the aim of the study was to determine whether ET-1 contributes to increased glomerular permeability to albumin in SCD and if ET-1 receptors blockage alters albuminuria in the SCD. Furthermore, because our preliminary studies showed sex differences in the vasconstrictor response to ET-1 in sickle cell mice the study was designed to determine if sex differences exist in this response. 

**Methods:** Experiments utilized 12 week old humanized sickle cell mice (HSSS) and generated controls (HAA) recently developed by the Towery’s lab. Ambrisentan (ETa antagonist), A-18206 (ETa antagonist) or vehicle was administered during drinking water (10mg/kg/day) for 2 weeks. Glomeruli were isolated for direct permeability measurements as a volume response of glomerular capillaries to an oncopressive medium generated by defined concentrations of albumin. 

**Results:** P_{alb} was significantly higher in glomeruli from sickle mice (both in males and females) than control mice (0.5±0.07 and 0.47±0.06 vs. 0.13±0.02 and 0.10±0.02, respectively). Ambrisentan treatment significantly reduced the elevated P_{alb} in glomeruli from male (0.24±0.05 vs. 0.50±0.07) and female (0.20±0.03 vs. 0.47±0.06) HSBS mice. ET_{a} receptors antagonism with A-18206 also significantly decreased the P_{alb} in glomeruli from male (0.28±0.06 vs. 0.50±0.07) and female (0.24±0.03 vs. 0.47±0.06) HSBS mice. Treatment with both antagonists did not alter P_{alb} in HAA mice. 

**Conclusions:** These data suggest that ET1 treatment may play an important role in the development of sickle cell nephropathy and support the use of chronic ETa antagonism as a prospective treatment for sickle cell nephropathy. 

**Funding:** Other NIH Support - NHI/HLB01 (U11 HL11764-01)
choline in their drinking water. Mice with total CHOP knockdown were used to test the role of CHOP in the development of CKD to assess changes in blood pressure and 24h total urinary protein and albumin measurements. On day 21 post-implantation, mice were sacrificed and PASM staining was used to evaluate renal interstitial cast formation and glomerular damage.

**Results:** In response to the CKD model, both CHOP−/− and wild type (WT) mice experienced significant increases in systolic and diastolic blood pressure. However, CHOP−/− mice showed significantly lower proteinuria and albuminuria. In addition, CHOP deficiency significantly decreased interstitial cast formation and glomerular damage in response to the model compared to WT.

**Conclusions:** CHOP deficiency resulted in a decrease in proteinuria and renal tissue damage. Along with inducing apoptosis, CHOP has been shown to interact with inflammatory pathways resulting in NFκB activation. Further tests will evaluate the effect of CHOP deficiency in inflammatory, fibrotic and apoptotic response in our model. Our findings could lead to the development novel therapeutics to halt the progression of CKD.

**Caveolin-1 Is Crucial in the Pathogenesis and Progression of Light Chain Deposition Disease but Not in Al-Alamyloidosis**

**Jiaxin Peng, Paola Guo, John P. Hwang, and Shuling Zhou**

**Background:** In vitro models of glomerulopathic light chains (GLCs), including light chain deposition disease (LCDD) and light chain amyloidosis (AL-Am) have provided solid platforms to study the pathogenesis of these diseases and how initiation and progression takes place. C-fos and NF-κB have been found to be important signaling mechanisms in the initiation phase of these two disorders. The role of caveolin-1 in the initiation / progression phases was explored in this study using human and mouse caveolin-1 knock-out (KO) and wild type (WT) mouse MCs.

**Methods:** Human and Caveolin-1 KO and WT mouse MCs were grown on dishes (2D) and Matrigel (3D), and incubated with GLCs 10 μg/ml purified from the urine of renal biopsy-poorly treated patients with LCDD and AL-Am. Downstream effects were tested by determining whether c-fos and NF-κB transcriptional activity occurred and whether the promotion of expression and amounts of α-hemoglobin (αHb) fibril formation were observed in WT caveolin-1 MCs.

**Results:** When LCDD GLCs were incubated with caveolin-1 KO cells, no c-fos or NF-κB transcriptional activity was observed and similar amounts of amyloid fibril formation occurred when WT and caveolin-1 KO MCs were incubated with AL-Am GLCs.

**Conclusions:** Caveolin-1 (through activation of c-fos and NF-κB) plays a crucial role in signaling in LCDD and subsequent downstream effects. The absence of caveolin-1 at the surface of MCs abolishes downstream effects in LCDD but not in AL-Am. While amyloid production still occurs when MCs are incubated with Am-AL GLCs, the production of excess extracellular matrix is abolished when LCDD GLCs are incubated with caveolin-1 KO MCs.

**Histone Methyltransferase EZH2: A Novel Therapeutic Target for Renal Fibrosis**

**Xiaozhu Zhou, Muruguayu Ponnusamy, Evelyn Tolbert, George P. Bayliss, Shougang Zhuang.**

**Dept of Medicine, Rhode Island Hospital and Alpert Medical School, Brown University, Providence, RI.**

**Background:** EZH2 (Enhancer of Zeste Homolog 2) is a methyltransferase that induces histone H3 lysine 27 trimethylation (H3K27me3) and functions as an oncogenic factor in many cancer types. However, its role in renal fibrogenesis remains to be explored. In the course of this study, the potential role EZH2 plays in renal interstitial fibroblasts and development of renal fibrosis in a murine model of unilateral ureteral obstruction as well as mechanisms involved.

**Results:** Our results showed that EZH2 and H3K27me3 were highly expressed in the cultured renal fibroblasts and kidney from mice with unilateral ureteral obstruction. Pharmacological inhibition of EZH2 with 3-deazaneplanocin A (D3/3Nz) and GSK126, or silencing of EZH2 with its specific siRNA inhibited serum- and TGFβ1-induced activation of renal interstitial fibroblasts in vitro. Administration of 3-D3Nz ameliorated expression of extracellular matrix deposition and preserved kidney structure and function in the obstructed kidney. Mechanistically, 3-D3Nz inhibited expression of type I TGFβ receptor and phosphorylation of Smad3, along with preservation of Smad7 expression. 3-D3Nz was also effective in blocking phosphorylation of the EGFR and PDGFR receptors, and suppressing activation of STAT3 and ERK1/2 signaling pathways in the injured kidney. Moreover, 3-D3Nz treatment abolished injury-induced renal expression of αvβ6 integrin, Notch1 and Notch3. Finally, EZH2 inhibition increased expression of Pten, a protein tyrosine phosphatase associated with dephosphorylation of multiple tyrosine kinase receptors, in the kidney after ureteral ligation.

**Conclusions:** This study has identified EZH2 as an important epigenetic regulator of renal fibrosis and suggested that it could be a novel target for therapeutic interference in chronic kidney disease.

**Targeting PHD2 for the Treatment of Anemia and Interstitial Fibrosis in Chronic Kidney Disease**

**Rachael Peralta, Xiaokun Xiao, Melanie Katz, Shuling Guo, Gene Hung, Sue Murray.**

**Anti-Cancer Drug Discovery, Iris Pharmaceuticals, Inc., Carlsbad, CA.**

**Background:** Anemia is a common manifestation of chronic kidney disease (CKD) and is associated with cardiovascular disease. The predominant cause of anemia in CKD is erythropoietin (EPO) deficiency. EPO is a hormone produced primarily by adult kidneys and is essential for the production of red blood cells. It has been shown in many animal models that EPO protects the kidney against interstitial fibrosis. Proxil hydroxylation of domain 2 (PHD2) is a primary regulator of hypoxia-inducible factors (HIFs) that regulate genes involved in cellular adaptation to reduced oxygen availability. When PHD2 is reduced, HIFa is stabilized and upregulates several genes to promote survival in low-oxygen conditions. Systemic PHD2 inactivation has been found to increase renal EPO production and stimulate red blood cell synthesis, which can improve anemia in CKD patients (Minamishima et al, Science 2010).

**Results:** Using antisense oligonucleotides (ASOs) designed against the PHD2 mRNA, we have demonstrated a 60% reduction of kidney PHD2 expression after 4 weeks of treatment in adenine (7 mg/70 g bw/week) compared to the saline group. In addition, we observed increases in EPO mRNA expression in the kidney interstitial fibroblasts by RT-PCR (~550-fold) and in-situ analysis. We sought to demonstrate an improvement in anemia and renal fibrosis using our PHD2 ASO. We developed an adenine-induced mouse model of CKD that developed severe anemia and interstitial fibrosis. After simultaneous administration of the 0.2% adenine diet and the PHD2 ASO (12 mg/12 weeks) for 12 weeks, we observed significant increases in kidney EPO mRNA (~35-fold) and plasma EPO levels (~12-fold) compared to the control ASO group. Histological analysis showed improved fibrosis based on reduced Sirius Red staining. There were also improvements in anemia based on whole blood analysis of hemoglobin and hematocrit levels.

**Conclusions:** These data indicate that reducing PHD2 with ASOs may be a viable option for treating CKD patients with severe anemia and renal fibrosis.

**Fibronectin Assembly Mediates KIM-1 Induced TGFβ-Dependent Kidney Fibrosis**

**Venkata Sambisetty, Cuiyan Xin, Sandhya Padmanabhan, Bhargavi Chandrasekhar, Akinwande A. Akinfolarin, Joseph V. Bonventre.**

**Dept of Cellular, Molecular & Nutritional Div, Brigham and Women’s Hospital, Harvard Medical School, Boston, MA.**

**Background:** Cell-extracellular matrix interactions play a crucial role in kidney fibrosis. Localized activation of TGFβ is critical for excretion of its cellular effects. Kidney injury molecule-1 (KIM-1) is upregulated in dedifferentiated proximal tubular cells (PTECs) following kidney injury and has been shown to induce kidney fibrosis in vivo. Here, we report that KIM-1 mediates fibrosis by up-regulating the critical components of the TGFβ activation machinery including fibronectin and corresponding integrins uniquely in vivo. In blocking fibronectin assembly reduces kidney fibrosis.

**Methods:** Full-length KIM-1 or the KIM-1 mutant was overexpressed in LLC-PK1 and HEK cell lines and fibronectin and integrin levels were evaluated. Active TGFβ was measured using a bioassay. Mice were subjected to ischemia/reperfusion injury (IRI) or

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

**Underlines represent presenting author.**

729A
unilateral ureteral obstruction (UUO). In the UUO model, mice were treated with fibronectin blocking peptide or control peptide to evaluate the effects of inhibition of fibronectin assembly on fibrosis.

**Results:** KIM-1 expressing PTECs produced significantly increased levels of fibronectin and fibronectin receptors. These increases were abrogated when phosphorytrosine-350 of KIM-1 was mutated or KIM-1 was deleted. KIM-1 expressing cells displayed higher levels of total and activated TGFβ as compared to control cells. In vivo, KIM-1 expressing tubular epithelial cells were characterized by high fibronectin staining after ischemia/reperfusion injury or UUO. Blocking fibronectin assembly with a blocking peptide decreased fibrosis in the UUO model.

**Conclusions:** KIM-1 induced localized activation of TGFβthrough up-regulation of TGFβ, fibronectin and integrin receptors. Blocking fibronectin assembly reduced fibrosis in response to UUO in vivo. This mechanism can contribute to the fibrosis associated with chronic expression of KIM-1 and may be a common feature of chronic kidney disease. Blocking fibronectin assembly may be therapeutically beneficial to prevent or reduce kidney fibrosis.

**Complement Modulation by C1-Inhibitor Hampered Pericyte (PC) to Myofibroblast Trans-Differentiation (TDF) and Vascular Rarefaction in Ischemia/Reperfusion (I/R) Injury** Giuseppe Castellano,1 Rossana Franzin,1 Chiara Divella,1 Alessandra Stasi,1 Angelica Intini,1 Margherita Gigante,1 Marco Fiorentino,1 G. Lucarelli,1 M. Battaglia,1 Giuseppe Grandaliano,1 Loretto Gesualdo1 1Nephrology and Urology Unit, Univ of Bari;2Dept Medical and Surgical Science, Univ of Foggia, Italy.

**Background:** Preservation of endothelium-Pericyte (PC) interaction is critical to counteract renal fibrosis during chronic kidney disease; no data are available on PC involvement in AKI. We investigated whether Complement might modulate PC activation in I/R.

**Methods:** Ten pigs underwent to 30 min of renal warm I, followed by 24h of R. Five pigs were treated with C1-Inhibitor (C1-Inh, 500U/Kg). Biopsies were analyzed by IHC and IF for PDGFRβ, Caspase3 and aSMA. FACS, Ann-V-IP and IF were performed on human PC (PDGFRβ cells) stimulated with CsA (1x10⁻⁴ M) for 24h in vitro.

**Results:** I/R induced PC to myofibroblasts TDF by reducing PDGFRβ without PC apoptosis (PDGFRβ/Caspase3) in vivo. TDF was accompanied by a significant decrease in capillary lumen area (Fig1A: %T0:11.3±2.1; T24:3.9±2.3; p<0.05) and aSMA up regulation (Fig1B): C1-Inh preserved PDGFRβ expression in PC and restored peritubular capillary area (T24C1-Inh:12.06±3.5 vs T24). In accordance, C5a induced PC proliferation and Collagen I production without apoptosis (Ann V) in vitro. CsA induced PC to myofibroblasts TDF, with PDGFRβ down-regulation (Fig1C: %Bas: 15.2i±3.6; CsA:3.6±2.3; TGFβ:2.08±1.04 p<0.05) and remodeling of aSMA stress fibers, with contractile phenotype. Finally, CsA significantly up-regulated iId2 factor in PC, which is pivotal for cellular de-differentiation.

**Conclusions:** Complement might contribute to PC to Myofibroblasts TDF in I/R injury, leading to vascular rarefaction and renal fibrosis. C1-Inh may be an effective strategy to prevent renal development in transplanted kidney.

Establishment of a Novel Mouse Strain to Trace Erythropoietin Producing Cells at Desired Time Points Keiichi Kaneko, Motoko Yanagita. Nephrology, Kyoto Univ, Kyoto, Japan.

**Background:** We previously reported that resident fibroblasts including Erythropoietin (Epo) producing cells were labeled with myelin proteolipid protein and transdifferentiated into myofibroblasts during fibrosis with concomitant loss of Epo production. However, the previous method could not distinguish between Epo-producing cells and other resident fibroblasts and the behavior of Epo-producing cells remains unclear. Recently, Epo-Cre mice were generated which enabled the lineage tracing of Epo-Cre labeled cells during fibrosis development and the history of Epo production. Using the mouse strain, the transdifferentiation of Epo-Cre labeled cells into myofibroblasts during fibrosis has been demonstrated. Because Epo-Cre mice labeled the cells with the history of Epo production from fetal period to adult life, we tried to narrow down the period of labeling and to trace the certain cell population with the current Epo-producing ability at desired time points.

**Methods:** We generated a novel mouse strain in which inducible form of Cre is knocked-in at the locus of Epo gene (Epo-CreERT2 mice). Epo-CreERT2 mice were crossed with B26f1Tomato mice. Tamoxifen was administered to induce inducible form of Cre, EpoERT2.

**Results:** Epo-CreERT2 labeled cells were located in the interstitium of the cortical and corticomedullary region of the kidney, and the numbers increased with the induction of anemia. Epo-CreERT2 labeled cells expressed PDGFRβ and CD73, suggesting that Epo-CreERT2 labeled cells are resident fibroblasts and are likely to be Epo-producing cells. After unilateral ureteral obstruction (UUO), Epo-CreERT2 labeled cells transdifferentiated into myofibroblasts. The ratio of Epo-CreERT2 labeled cells transdifferentiated into myofibroblasts was 68 % at day 3 and 86 % at day 5 of UUO. The numbers of Epo-CreERT2 labeled cells were increased 1.9-fold at day 3 and 2.1-fold at day 5 of UUO.

**Conclusions:** We generated a novel mouse strain and succeeded in labeling Epo-producing cells at desired time points. We demonstrated that Epo-producing cells transdifferentiated into myofibroblasts and were increased in fibrotic kidney. We aim to elucidate the mechanism of injury and repair of Epo-producing cells with this strain, Epo-CreERT2 mice.

**Role of P13 Kinase γ in Recruitment of Bone Marrow-Derived Fibroblasts and Development of Renal Fibrosis** Yumaho Wu, Hua Liang, William E. Mitch, Yanlin Wang. Medicine, Baylor College of Medicine, Houston, TX.

**Background:** Renal fibrosis is a prominent pathological feature of chronic kidney disease leading to progressive loss of renal function. Although activated fibroblasts are responsible for the production and deposition of the extracellular matrix, the origin of activated fibroblasts mediating renal fibrosis remains debatable. Recent studies have shown bone marrow-derived fibroblasts contributed significantly to the pathogenesis of renal fibrosis. We previously showed that CNXCL16 plays a critical role in recruiting bone marrow-derived fibroblasts into kidney. However, the signaling mechanisms are not known. In the present study, we examined the role of P13 kinase γ (PI3Kγ) in the recruitment of bone marrow-derived fibroblasts and development of renal fibrosis. We have previously shown that CXCL16 plays a critical role in recruiting bone marrow-derived fibroblasts and the development of fibrosis using a mouse model of follic acid-induced nephropathy in wild-type (WT) and PI3Kγ-knockout (KO) mice in vivo and migration of cultured mouse monocyte treated with CXCL16 in vitro.

**Results:** Compared with WT mice, PI3Kγ-KO mice exhibited significant preservation of kidney function as measured by serum urea nitrogen and displayed significantly fewer bone marrow-derived fibroblasts dual positive for CD45 and PDGFRβ in the kidney 2 weeks after follic acid treatment. Furthermore, PI3Kγ-KO mice exhibited fewer α-smooth muscle actin (α-SMA) positive myofibroblasts and expressed less α-SMA protein in the kidney following follic acid treatment. Consistent with these findings, PI3Kγ-deficiency significantly reduced total collagen deposition and suppressed expression of extracellular matrix proteins (collagen 1 and fibronectin). In cultured mouse monocytes, CXCL16 activated PI3Kγ and induced bone marrow migration, which was abolished in the absence of PI3Kγ.

**Conclusions:** These data indicate that PI3Kγ plays a pivotal role in recruiting bone marrow-derived fibroblasts into the kidney and developing renal fibrosis. Inhibition of PI3Kγ signaling may represent a novel therapeutic strategy for chronic kidney disease.

**Inhibition of K-Ras prior to Induction of Acute Kidney Reduces Long-Term Progression to Chronic Kidney Disease in a Murine Model of Aristolochic Acid Nephropathy** Sujit Kumar Saha, Bruce M. Hendry, Claire C. Sharpe. Dept of Renal Sciences, King's College London, London, United Kingdom.

**Background:** Acute kidney injury (AKI) is recognised to be an early harbinger of chronic kidney disease (CKD). We have previously shown that K-Ras expression and activation are up-regulated in renal fibrosis and reducing K-Ras expression can prevent scarring. In this study our aim was to test whether transiently reducing K-Ras expression in the peri-AKI period can reduce progression to CKD.

**Methods:** CD1 mice received i.p. injections of either 3.5mg/kg Aristolochic Acid (AA) or normal saline on Day 1 and on Day 5. A treatment group were also given a single...
subcutaneous injection of 100mg/kg of mouse K-Ras antisense oligonucleotide (ASO) 2 days prior to the first AA injection. A vehicle group was given a subcutaneous injection of saline 2 days prior to the first AA injection. Renal function at multiple time points was assessed through a blood urea nitrogen (BUN) assay. The degree of fibrosis was ascertained through Picrosirius Red (PSR) and Masson Trichrome (MT) staining to quantify collagen deposition. The expression of K-Ras was determined by Q-PCR.

Results: CD1 mice given AA suffered an AKI with a 4.6 fold rise in BUN at Day 12 that returned to baseline by Day 30. However by Day 80, the AA mice had a 57% higher BUN than control mice, demonstrating later onset CKD. AA mice treated with mouse K-Ras ASO pre-AKI suffered a similar AKI but BUN at Day 80 was 48% lower than untreated AA mice and was comparable with healthy controls. PSR and MT staining demonstrated a 5 fold increase in collagen deposition by Day 80 in AA mice which was reduced by 30% in ASO-treated animals. K-Ras expression was consistently unregulated in the untreated AA mice throughout the chronic phase but the transient treatment with ASO prior to the acute injury resulted in normalisation of K-Ras mRNA by Day 80.

Conclusions: Transiently reducing K-Ras expression in the peri-AKI period in a murine model of aristolochic acid nephropathy reduces downstream fibrosis and prevents the decline in renal excretory function. Targeting K-Ras may provide a future therapeutic option for preventing renal fibrosis and CKD following AKI.

Non-Osmotic Sodium Storage Affects Glomerular Endothelial Cell Permeability
Rik H.J. Oude Eggeling,1 Peter Ochodnicky,2 Simon C. Satchell,3 Ed van Bavel,4 Liffert Vogt5 Nephrology, AMC, Amsterdam, Netherlands; 1Pathology, AMC, Amsterdam, Netherlands; 2Renal Unit, Univ of Bristol, Bristol, United Kingdom; 3Biomedical Engineering and Physics, AMC, Amsterdam, Netherlands.

Background: High dietary NaCl intake may affect glomerular permeability via pressure effects or via direct effects. In this respect, the Na+ buffering capacity of heparan sulfate glycosaminoglycans (HS-GAGs) in the endothelial surface layer (ESL) is of interest. The objective of this study is to investigate the interplay between Na+ and HS-GAGs and their effects on glomerular permeability.

Methods: Human glomerular endothelial cell (GEnCi) permeability to macromolecules was tested by measuring FITC-labeled albumin passage. Electrical resistance of a GEnCi monolayer, reflecting ESL Na+ content, was assessed with the ECIS® system at 4000 Hz. We studied the expression of gene coding enzymes involved in heparan sulfate (EXT-1, EXT-2) and chondroitin sulfate (CHSY) synthesis using real-time qPCR. Measurements were performed at different NaCl concentrations (125/150/175 mM NaCl ± HS degradation enzyme heparinase, 0.7 U/mL). We added mannitol to keep osmolality constant.

Results: Relative to 125 mM, EXT-1 and EXT-2 expression was higher after stimulation with 150 mM NaCl while CHSY expression remained unchanged (Fig A). Albumin permeability decreased after 2 and 5 days stimulation with 150 and 175 mM NaCl (Fig B). ECIS experiments showed that NaCl addition led to a concentration-dependent decrease in resistance (Fig C). NaCl did not alter resistance in the absence of cells. Heparinase increased resistance when added to 125 and 150 mM NaCl (Fig D). Mannitol did not alter permeability or resistance.

Conclusions: High NaCl stimulates HS-GAG synthesis of the glomerular endothelium, which may facilitate more Na+ binding. Subsequent higher ESL Na+ content may seal the glomerular barrier as suggested by both lower permeability and lower resistance.

Precision-Cut Human Kidney Slices as a Model to Elucidate the Pathogenesis of Renal Fibrosis
Elisabeth G.D. Stribos,1,2 Thereth Luangmongkon,2 Annemarie Lellivel,1 Igle J. de Jong,1 Willem Van Son,3 Jan-luik Hillebrands,2 Marc Maj Seelen,1 Harry Van Goor,2 Peter Olinga,2 Henricus A.M. Muttersa.1
1Dept of Internal Medicine, Div of Nephrology, Univ of Groningen, Univ Medical Center Groningen, 2Dept of Pathology and Medical Biology, Div of Pathology, Univ of Groningen, Univ Medical Center Groningen, Netherlands; 3Dept of Urology, Univ Medical Center Groningen, Groningen, Netherlands.

Background: Renal fibrosis is a major problem in chronic kidney disease and chronic renal transplanted failure. Unraveling the mechanisms underlying the initiation and progression of renal fibrosis is of key importance to identify new therapeutic targets. However, suitable human in vivo models for renal fibrosis are lacking. Here, we explored precision-cut human kidney slices (PCKS) as a model for human renal disease.

Methods: PCKS were prepared from human cortical kidney tissue obtained from tumor-nephrectomies and cultured up to 96th. Morphology, cell viability (ATP levels, LDH leakage) and metabolic functionality (UDP-glucuronosyltransferase and transporter activity) were determined to assess PCKS integrity. Furthermore, inflammation- and fibrosis-related gene expression was characterized. To validate the model, renal fibrogenesis was induced using transforming-growth factor b1 (TGF-b1).

Results: Preparation of PCKS induced an inflammatory tissue response, while long-term incubation (96h) induced fibrogenesis as seen by increased expression of collagen type 1a1 (COL1A1) and fibropectin (FN1). Importantly, PCKS remained functional for more than 48h as evidenced by active glucuronidase and phospholipasef epoxide uptake. Moreover, treatment with TGF-b1 augmented fibrosis, as illustrated by at least 1.8-fold increase of multiple fibrosis markers including COL1A1, FN1, plasminogen activator inhibitor-1 and a-smooth muscle actin.

Conclusions: With extensive characterization, PCKS appear to be an excellent model to investigate renal pathology e.g. renal fibrosis. Moreover, the human origin of PCKS makes this ex vivo model very suitable for translational research.

Centrality of Bone Marrow-Derived Fibroblasts in Magnetic Resonance Imaging Contrast-Induced Systemic Fibrosis
Viktor Dröl,1 Catherine Do,1 Chunyan Tan,1 Brent Wagner,2 South Texas Veterans Health Care System, San Antonio, TX; 3Dept of Medicine, Univ of Texas Health Science Center at San Antonio, San Antonio, TX.

Background: So-called “nephrogenic” systemic fibrosis is a ghastly sclerotic condition that occurs only in conditions of low renal function (acute kidney injury or severe chronic kidney disease) and gadolinium-based contrast exposure. Nothing is known about the pathology.

Methods: Experiments were designed to test if bone marrow from magnetic resonance imaging contrast–treated donors is stimulated to induce fibrosis, and to what degree these cells can be primed to home to affected organs. Male Fisher 344 rats that express human placental alkaline phosphatase (hPLAP) were divided into two groups, one served as control, the other treated with the glycosaminoglycan-type grade gadodiamide (Osmianc, General Electric) 2.5 mol/kg IP daily, aiming for dosing over 4 weeks or evidence of systemic fibrosis. Rats with 5/6 nephrectomies were lethally–irradiated (900 Rad) followed by salvage bone marrow transplant from the control or contrast–treated donors. After an engraftment period, these recipients were divided into control and contrast–treated groups.

Results: Regardless of bone marrow source, contrast–treated recipients demonstrated severe skin fibrosis. Fibronectin was similarly increased by immunofluorescence and immunoblot, but a synergistic effect evident in recipients of contrast–treated animals. The fibroblast precursor (“fibrocyte”) markers, CD45RO and procollagen I, were increased in the contrast–treated recipients. Recipients of marrow from contrast–treated donors demonstrated greater dermal CD34 without histologic evidence of fibrosis.

Conclusions: Bone marrow from contrast–treated animals did not induce systemic fibrosis, therefore target organs (such as the skin) appear central to the process. However, given the synergistic effect, “primed” fibroblast precursors do have an increased affinity for diseased lesions. Clinically, this may explain why repeat administrations of gadolinium–based contrast correlate with chronicity.

SOCS2 Plays No Major Role in the Mouse Remnant Kidney Model of Fibrosis
Yael Segal,1 Muhamed Assadi,2 Ralph Rabkin,2 Daniel Landau,2 Pediatrics B, Schneider Children’ s Medical Center, Petach Tikva, Israel.

Background: SOCS2, a key negative regulator of GH stimulated JAK/STA T5 signaling, is overexpressed in muscle, bone and liver of uremic rats and is presumably a cause of uremic GH resistance and growth retardation. SOCS2 deficient mice are GH sensitive, exhibit gigantism and accumulate collagen in skin, trachea and lungs (Reiser K et al, AJP 2004). Since GH overexpression is one of the key causes renal fibrosis, we tested whether SOCS2 deletion, by decreasing GH sensitivity, accelerates renal kidney fibrosis.

Methods: SOCS2 Plays No Major Role in the Mouse Remnant Kidney Model of Fibrosis
β-arrestin2, Downstream of Angiotensin II Type I Receptor Biased Signaling Pathway, Plays an Important Role in Renal Fibrosis

**Methods:** We used a combination of molecular and cellular approaches to investigate the role of β-arrestin2 in renal fibrosis. We generated a mouse model where β-arrestin2 is selectively expressed in the renal proximal tubule (β-arrestin2-RRTPC). We then subjected these mice to unilateral ureteral obstruction (UUO) and renal ischemia/reperfusion injury (IRI) to induce renal fibrosis. In addition, we performed in vitro experiments using NRK-49F cells treated with SII, which activates the β-arrestin pathway.

**Results:**

1. **SII-induced β-arrestin2 phosphorylation**: We found that SII induced the binding of β-arrestin2 to the AT1R, but not β-arrestin1.

2. **SII-induced collagen synthesis**: SII increased the synthesis of collagen I and fibronectin in NRK-49F cells.

3. **Transfection of β-arrestin2 enhanced SII-induced fibronectin expression**: Transfection of β-arrestin2 enhanced SII-induced fibronectin expression in NRK-49F cells.

4. **Role of β-arrestin2 in renal fibrosis**: Deletion of β-arrestin2 in the renal proximal tubule (β-arrestin2-RRTPC) resulted in decreased renal fibrosis compared to wild-type mice.

**Conclusions:** Our results suggest that β-arrestin2 plays a critical role in renal fibrosis by promoting collagen synthesis and fibronectin expression. This target is a potential therapeutic intervention for renal fibrosis.

**Deletion of ATR, a Master Molecule of DNA Damage Response, in the Proximal Tubule Exacerbates Kidney Injury and Increases Fibrosis**

**Methods:** To investigate the role of ATR (ATM: ataxia telangiectasia and Rad3-related) in renal fibrosis, we generated RPTC-/- mice and subjected them to models of kidney injury, such as unilateral ureteral obstruction (UUO) and renal ischemia/reperfusion injury (IRI).

**Results:**

1. **Lowered renal function in ATR-/- mice**: RPTC-/- mice exhibited decreased renal function compared to wild-type controls.

2. **Increased histological damage in ATR-/- mice**: RPTC-/- mice had more severe histological damage compared to wild-type controls.

3. **Increased kidney fibrosis in ATR-/- mice**: RPTC-/- mice showed increased kidney fibrosis compared to wild-type controls.

**Conclusions:** The deletion of ATR in the renal proximal tubule exacerbates kidney injury and increases renal fibrosis.

**Funding:** This work was supported by the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) grant DK106704.

**Role of Heparanase in Renal Epithelial-Mesenchymal Transition Induced by Ischemia/Reperfusion**

**Methods:** To study the role of heparanase in EMT, we used a mouse model of ischemia/reperfusion injury (IRI) and measured the expression of EMT markers.

**Results:**

1. **Increased heparanase expression**: Heparanase expression was increased in the kidneys of mice subjected to IRI.

2. **Impaired EMT induction**: Inhibition of heparanase reduced the induction of EMT markers.

**Conclusions:** Heparanase plays a role in promoting EMT during renal ischemia/reperfusion injury.

**Funding:** This work was supported by the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) grant DK106704.

**SA-PO473**

**Hydrogen Sulfide Deficiency in the Kidney and Brain in Aging Mice**

**Methods:** To study the role of H2S in aging, we used a mouse model of aging and measured the expression of H2S-related genes.

**Results:**

1. **Reduced H2S expression**: H2S expression was decreased in the kidneys and brains of old mice.

2. **Increased mTORC1 activation**: mTORC1 activation was increased in the kidneys and brains of old mice.

**Conclusions:** H2S deficiency in aging mice contributes to the increased mTORC1 activation.

**Funding:** This work was supported by the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) grant DK106704.

The Role of Ergothioneine/OCTN1 in CKD 

Yusukeki Shimozaki,1 Kengo Furushi,1 Shinji Kitajima,1 Akinori Haru,1 Yusunori Iwata,2 Norihiko Sakai,1 Miho Shimizu,1 Takashi Wada.1,2 'Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan; 2Dept of Laboratory Medicine, Kanazawa Univ, Kanazawa, Ishikawa, Japan.

**Background:** Chronic kidney disease (CKD) is a strong risk factor for end stage kidney disease, and closely complicates with other organ damages. Organic cation transporter 1 (OCTN1) is known as a specific transporter for ergothioneine (ERGO). ERGO is reported to have a strong antioxidant effect. We hypothesized that OCTN1 function and the reduction of ERGO were closely related to the progression of CKD.

**Methods:** To evaluate the effects of OCTN1 function in CKD, everted sac method was used in CKD model or control mice. Furthermore, the pathological changes and oxidative stress in the kidney of OCTN1-/- or OCTN1+/- were evaluated in the CKD model mice. Moreover, the amount of ERGO in red blood cells of was measured in CKD patients.

**Results:** The uptake of ERGO in everted sac significantly decreased in CKD mice than control mice. Interstitial fibrosis, that evaluated by azan stain, sirius red stain, and the accumulation in the aging kidney. 

**Conclusions:** The uptake of ERGO through OCTN1 decreased in CKD. The reduction of ERGO in CKD may participate in oxidative stress and progression of kidney injury.

SIRT2-MDM2 Signaling Attributes to Fibroblasts Activation but Not Tubular Epithelial-Mesenchymal Transition During Tubulointerstitial Fibrosis 

Chun Zhang, Renuy You, Hua Su. Nephrology, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.

**Background:** Renal resident fibroblasts and tubular epithelial cells are the main sources for extracellular matrix producing myofibroblasts during tubulointerstitial fibrosis (TIF). Histone deacetylases (HDAC) inhibitors are shown to have an anti-fibrotic effect in skin, liver and lung. Sirtuin 2 (SIRT2), belonging to class III HDAC, mediates p53 deacetylation and subsequently sensitizes the sequestration of p53 by MDM2, thereby resulting in a p53 reduction and cell cycle progression. Up to now it is unclear the role of SIRT2 and its association with MDM2 during renal fibrosis.

**Methods:** Unilateral Ureteral Obstruction (UUO) animal model was constructed on B57CL/6 mice. In vitro study cultured tubular epithelial cell line NRK-52E (TEC) and renal fibroblast cell line NRK-49F were employed. The expression of MDM2 and SIRT2 was regulated by its pharmacologic inhibitors or transfection of Lentiviral shRNA.

**Results:** It showed the protein level of SIRT2 was elevated markedly in UUO mice as well as the fibroblasts treated with TGF-b1. Nevertheless, in TECs the abundance of SIRT2 was not altered under TGF-b1 exposure. Additionally, AGK2, a specific SIRT2 inhibitor, attenuated the severity of TIF in UUO mice and the fibroblast activation triggered by TGF-b1. Next in fibroblast we found MDM2, a p53 inhibitor, was upregulated simultaneously under TGF-b1 stimulation. Interestingly, the increased MDM2 level can be minimized by pharmacologic or genetic blocking of SIRT2 which was not interfered by the specific inhibitor of the interaction between MDM2 and p53. Thus, it indicated SIRT2 regulating MDM2 was p53 independent. Moreover, genetic deletion of MDM2 by shRNA transfection didn’t affect the expression of SIRT2, although which could alleviate fibroblast activation.

**Conclusions:** Our current study suggests that besides p53, SIRT2 also could modulate MDM2 during fibroblasts activation, and targeting SIRT2-MDM2 signaling may be a potential strategy for the treatment of renal fibrosis.

**Funding:** Government Support - Non-U.S.

SA-PO476

The Role of ePLA2, in Experimental Renal Fibrosis 

John Ross Montford, Allison M.B. Lehman, Raphael A. Nemenoff, Seth B. Furgeson. Div of Renal Disease and Hypertension, UC School of Medicine, Aurora, CO.

**Background:** Chronic kidney disease (CKD) is characterized by progressive renal fibrosis involving poorly defined signaling events between renal epithelial cells, fibroblasts, and inflammatory cells. Cystosolic phospholipase A2 (cPLA2) is abundant in renal epithelium and inflammatory cells and serves as the rate-limiting enzyme in eicosanoid production. Since eicosanoids regulate many biological processes important in renal injury, we aimed to investigate the role of cPLA2 in the progression of renal fibrosis in a mouse model.

**Methods:** Wild-type (WT) and cPLA2 globally deficient (KO) C57BL/6 mice were subjected to unilateral ureteral obstruction (UUO). In separate experiments WT mice were lethally irradiated and transplanted with either WT bone marrow or cPLA2-deficient bone marrow. We then performed UUO 5-6 weeks after bone marrow transplantation. After UUO, we collected unfractioned and injured kidneys for RNA, protein, flow cytometry, and histologic analysis, and preparation of single cell suspensions for flow cytometry.

**Results:** Compared with WT, cPLA2 KO animals had a 1.5-2.0 fold increase in histologic fibrosis at 14 days after UUO. In addition, the KO animals had elevated levels of renal injury proteins such as collagen and fibrinectin, pro-fibrotic chemokines such as fractalkine, and inflammatory markers such as MCP-1 after UUO as compared with WT animals at 7 days. By flow cytometry, cPLA2 KO animals had significantly more infiltration of CD45+; CD11b positive-Ly6C negative cells than WT animals after UUO. Additionally, adoptive bone marrow transplant from cPLA2 KO mice into WT mice yielded worsening of histologic fibrosis after UUO as compared with transplants derived from WT animals.

**Conclusions:** Depletion of cPLA2 and/or its products, predominantly from circulating myeloid cells, contribute to the development of experimental fibrosis using a UUO model in mice.

**Funding:** Other NIH Support - 1 F32 DK104475-0

SA-PO477

Delayed Administration of Suramin Attenuates Peritubular Fibrosis in Rats 

Chen Xu,3 Xiong Shuya1,2,4,5; 1Dept of Medicine, Rhode Island Hospital and Alpert Medical School, Providence, RI; 2Dept of Nephrology, Shanghai East Hospital, Tongji Univ School of Medicine, Shanghai, China.

**Background:** Peritubular fibrosis is one of the most serious complications in patients with peritoneal dialysis (PD) and lacks effective treatments. Our recent study showed that treatment with suramin, a compound that inhibits the interaction of multiple cytokines with their receptors, attenuated the development of peritoneal fibrosis in rats exposed to peritoneal fibrosis induced by chlorhexidine gluconate (CG). In the current study, we further assessed the therapeutic effect of suramin on the progression of peritoneal fibrosis in this model.

**Methods:** Rats were given a daily intraperitoneal injection of chlorhexidine gluconate (CG) for 3 weeks to induce peritoneal fibrosis followed by weekly administration of suramin at 20 mg/kg for an additional one or two weeks before kidneys were harvested.

**Results:** Delayed administration of suramin attenuated peritubular membrane thickening and collagen fibril deposition occurred after CG exposure. Suramin was also effective in reducing CG-induced expression of a-smooth muscle actin, fibronectin and collagen I. However, peritubular membrane thickening in CG exposed mice was not reversed by suramin. Moreover, delayed application of suramin suppressed CG-induced expression of several inflammatory cytokines in fibrotic peritoneum.

**Conclusions:** Our results indicate that suramin treatment inhibits the progression of peritoneal fibrosis via a mechanism involved in suppression of TGF-b1 and EGFR signaling pathways, and suggest that suramin holds a therapeutic potential for treatment of peritoneal fibrosis.

SA-PO478

MDM2 Mediates Tubulointerstitial Fibrosis and Fibroblasts Activation via p53-Independent Pathway 

Hua Su, Chen Ye, Chun Zhang. Nephrology, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.

**Background:** MDM2 is an E3 ubiquitin ligase which plays essential roles in podocytes and tubular epithelial cells injury or repair by regulating cell cycle and mediating inflammatory process. MDM2 exerts its pathophysiological effects via p53 dependent or independent pathway. However whether MDM2 is implicated in tubulointerstitial fibrosis (TIF) and fibroblasts activation is still unknown.

**Methods:** Patients with TIF (secondary glomerulonephritis and interstitial nephritis were excluded) were enrolled in this study and Unilateral Ureteral Obstruction (UOO) animal model was constructed on B57CL/6 mice. In vitro study cultured renal fibroblast cell line NRK-49F was employed. The expression of MDM2 and Notch1 was regulated by its pharmacologic inhibitors or transfection of Lentiviral shRNA. PYR-41 was used as an inhibitor of ubiquitin E1 activating enzyme.

**Results:** Here, we found that unilateral UUO interstitial MDM2 was increased in patients with TIF as well as UUO mice. And interstitial MDM2 mainly originated from (myo) fibroblast. In vitro the expression of MDM2 was upregulated with fibroblasts activation under TGF-b1 stimulation, whereas was not amplified by MDM2 knocking down but by MDM2-p53 pathway inhibitor—Nutlin-3. Consistently, in UUO mice Nutlin-3 treatment cannot alleviate the interstitial fibrosis. Interestingly, we found Notch1, a molecule positively or negatively affecting the processes of proliferation, differentiation and apoptosis in a context-dependent manner, was reduced in cultured fibroblast treated with TGF-b1 which could be reversed by either genetic or pharmacologic blocking Notch1 signaling. Moreover, although pharmacologic or genetic blocking Notch1 signaling could trigger fibroblast activation it did not affect MDM2’s abundance.

**Conclusions:** Our current study suggests that MDM2-Notch1 signaling pathway, not the classic MDM2-p53 pathway, is involved in fibroblast activation in a ubiquitin dependent manner during tubulointerstitial fibrosis.

The cAMP-epac Pathway Regulates Renal Fibrosis by Promoting Mitochondrial Biogenesis of Tubular Epithelial Cell
Lei Jiang, Junwei Yang, Heli Yang, Agnes B. Fogo.
1Dept of Pathology, Microbiology and Immunology, Vanderbilt Univ; 2Div of Pediatric Nephrology, Vanderbilt Univ, Nashville, TN.
Background: Thymosin β4 (Tβ4) is a G-actin sequestering protein with effects on angiogenesis, cell migration and matrix. Our previous data showed that exogenous Tβ4 treatment ameliorated ameloblastoma accumulation at day 14 after unilateral ureteral obstruction (UUO). In this study, we investigated whether knockdown of Tβ4 only on endothelial cells has effects on renal fibrosis.
Methods: We generated inducible endothelial cell Tβ4 knockdown mouse (Tβ4 KD) by mating Tβ4 sRNAlox mosaic mice with SCL Cre mice. SCL Cre negative mice were used as control (Cont). Tamoxifen was administrated to induce Tβ4 knockdown (+, qod, from 8d).
Results: Peritubular capillary density, assessed by CD31 staining, was significantly decreased in Tβ4 KD mice (Tβ4 KD 2.39±0.11 vs. Cont 3.20±0.08 %, P<0.001). Peritubular capillary permeability, measured by injecting Evans blue dye in vivo and assessing extravasated dye in the kidney, also was reduced in Tβ4 KD mice (Tβ4 KD 107.01±5.49 vs. Cont 161.85±16.32 mg/KW, P<0.05). Tβ4 KD had significantly decreased collagen I, assayed by IHC, vs. Cont (Tβ4 KD 15.24±0.57 vs. Cont 17.68±0.71 %, P<0.05), but no significant change in Sirius red positive area (Tβ4 KD 0.91±0.03 vs. Cont 1.14±0.15 %). Total collagen (Tβ4 KD 48.06±5.01 vs. Cont 53.50±2.34 mg/mg). Tβ4 KD had less EndoMT (α-SMA- and CD31- double positive cells/high power, Tβ4 KD 1.20±0.11 vs. Cont 1.74±0.17, P<0.05).
Conclusions: We conclude that endothelial cell thymosin β4 knockdown results in increased peritubular capillary density and function, with reduced collagen and EndoMT in UUO. We speculate that Tβ4 KD in endothelial cells may change endothelial function and modulate EndoMT.

Endostatin and Transglutaminase 2 Are Geroncic Proteins Involved in Fibrosis of Aging Kidney
Chunlin Jiang, Xiaowei Sun, Tianjin Ma, Junwei Yang, Yi Liu, Junwei Yang, Jonathan Shein, Zhengtao Zhang, Jonathan Feola, Michael S. Goligorsky.
1New York Medical College; 2Univ of Rochester; 3Univ of Oulu, Finland.
Background: Endostatin (EST), the C-terminal fragment of collagen XVIII and a potent anti-angiogenic factor, is highly enriched in aging kidneys. It has also been recently observed that a protective patterning protein, transglutaminase 2 (TG2), is described as an interactive partner of another profibrogenic factor, transglutaminase 2 (TG2), underlining its role in aging kidney. Moreover, a month-long delivery of EST peptide via implanted minipumps to aging kidney. Moreover, a month-long delivery of EST peptide via implanted minipumps has effects on renal fibrosis.
Methods: Studies were conducted in young and aging wild type mice, overexpressing EST and mice kidney of subcapsular injection of Tg2 or EST.
Results: In wild type mice, aging kidneys exhibited 2-4-fold increase in TG2 paralleled by the increased cross-linking of extracellular matrix proteins and striped fibrosis. Ex vivo aortic rings embedded in matrigel supplemented with TG2 showed suppressed angiogenesis and proteolytic degradation. Injection of TG2 in the intact kidney produces increased cross-linking within 48h. Transgenic microveurexpressing EST showed renal interstitial fibrosis already at the young age, suggesting that EST may contributes to interstitial fibrosis in the aging kidney. Moreover, a month-long delivery of EST peptide via implanted minipumps to mice kidney also showed increased renal fibrosis, which became more robust when superimposed on the early "wound healing" phase of folic acid (FA)-induced nephropathy, an "accelerated" response in the kidney, also was reduced in Tβ4 KD mice (Tβ4 KD 0.91±0.03 vs. Cont 1.14±0.15 %). Total collagen (Tβ4 KD 48.06±5.01 vs. Cont 53.50±2.34 mg/mg). Tβ4 KD had less EndoMT (α-SMA- and CD31- double positive cells/high power, Tβ4 KD 1.20±0.11 vs. Cont 1.74±0.17, P<0.05).
Conclusions: We conclude that endothelial cell thymosin β4 knockdown results in increased peritubular capillary density and function, with reduced collagen and EndoMT in UUO. We speculate that Tβ4 KD in endothelial cells may change endothelial function and modulate EndoMT.
Funding: NIDDK Support

Biomarkers of Collagen Type III and VI Turnover Can Predict Poor Recovery of Kidney Function in Kidney Transplant Recipients
Daniel Guldager Kring Rasmussen,1,2 Signe Holm Nielsen,1 Federica Genovese,1 Morten Asser Karsdal,1 Shengqiang Xia,2 Martin Tepel.1 1Nordic Bioscience, Denmark; 2Univ of Southern Denmark, Denmark.
Background: Allograft dysfunction is a common complication after renal transplantation (Tx). The turnover of extracellular matrix proteins, collagen type III and type VI, contributes to renal repair mechanisms which accompany allograft dysfunction. Distorted turnover may lead to progressive fibrosis and to loss of renal function. The objective of our study was to evaluate the role of specific collagen type III and type VI cleavage fragments for early allograft dysfunction after kidney Tx.
Methods: 171 incident patients, receiving a kidney allograft were enrolled at Odense University Hospital. Plasma and urine samples were collected at the first postoperative days. C3M and Pro-C6 were measured in samples using novel ELISAs. Early allograft dysfunction was defined as eGFR less than 30 ml per minute per 1.73m2 29 days after Tx. The correlation of change of plasma creatinine (RCP) is the difference between plasma creatinine (pCrea) on the preoperative and first postoperative day divided by preoperative pCrea. Follow-up data on pCrea from a subset of patients was available at 6- and 12-months.
Results: Plasma Pro-C6 (pPro-C6) levels were significantly different in patients who received a deceased donor (DD), living donor (LD) and AB0 incompatible (AB0) donor kidney (p<0.001). pPro-C6 had a negative correlation with eGFR 29 days post Tx (p<0.001, r=-0.35) and a positive correlation with pCrea at 6- (p=0.0001, r=0.31) and 12 months (p<0.0001, r=0.32). With a cut-off of 0.3 for the RCPC, ROC curves showed that pPro-C6 predicted allograft dysfunction (p<0.0001, AUC=0.898). pCrea levels were significantly different in patients receiving a DD, LD and AB0 donor kidney, uC3M plasma Pro-C6 predicted allograft dysfunction (p<0.0001, AUC=0.898). uC3M levels were significantly different in patients receiving a DD, LD and AB0 donor kidney (p<0.0001, r=-0.35). Plasma C3M was associated with plasma CRP (p<0.0001, r=0.62).
Conclusions: The study indicates that specific collagen type III and type VI cleavage fragments, i.e. C3M and Pro-C6, are both markers for early and late allograft dysfunction after kidney Tx, and reflect the underlying pathophysiology.

Inhibitory Effect of Proximal Tubular Cells-Derived Neuropilin-1 in TGF Beta Signaling Pathway
Rui Chen, Xuejin He, Symon Ma, Jianxing Ma, Physiology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.
Background: Neuropilin-1 (NRP-1) is a co-receptor for multiple growth factors including class 3 semaphorins, VEGF, PDGF and TGF-β, and promotes signaling pathway involved in tumor growth, axonal chemorepellents, angiogenesis and liver fibrosis. In contrast, its function in the renal fibrosis has not been defined.
Methods: Primary renal proximal tubular cells (MRPTCs) were cultured from Nrp-1−/− mice. After infection of Nrp-1−/− cells with adenovirus expressing Cre resulted in Nrp-1 Knock-out (Nrp-1−/−) in the primary cells. Human proximal tubular cell line HKC-8, MEF cells and 3T3-L1 cells were used in this study. TGF-β-driven promoter transcriptional activity was measured by luciferase assay.
Results: NRP-1 was down-regulated by TGF-β in HKC8 and up-regulated in MEF cells and 3T3-1L cells, suggesting the different regulation mechanisms and functions of NRP-1 in proximal tubular cells and fibroblasts. Over-expression of NRP-1 suppressed TGF-β-induced phosphorylation of Smad2/3 and expression levels of fibronectin. HKC-8 cells over-expressing NRP-1 showed significantly decreased levels of both TGF-β receptor I and receptor II. The Nrp-1−/− cells showed higher TGF-β-induced Smad2/3 transcriptional activities and expression of fibronectin in Nrp-1−/− MRPTCs, compared with control adenovirus-infected Nrp-1−/− MRPtcs.
Conclusions: Proximal tubular cells-derived NRP1 inhibits the TGF beta signaling pathway. NRP1 functions are cell-type-specific in the kidney.

Angiopoietin-1 Deficiency Increases Tubulointerstitial Fibrosis Krishnapriya Loganathan,1 Susan E. Quaggin,2 Marie Jeansson. 1Department of Immunology, Genetics and Pathology, Uppsala Univ, Uppsala, Sweden; 2Feinberg School of Medicine, Northwestern Univ, Chicago, IL.

Background: Renal tubulointerstitial fibrosis is predictive of progressive decline in kidney function, independent of underlying disease. It is characterized by an increase in αSMA+ fibroblasts, myofibroblasts that produce collagen. Identification of factors that regulate the profibrotic response are excellent candidate targets for treatment of kidney diseases. We previously showed that loss of Angiopoietin-1 (Angpt1) in adult mice predisposes to fibrosis in wound healing and diabetic nephropathy. Angpt1 acts through the Tie2 tyrosine-kinase receptor expressed on endothelial cells and a subset of myeloid cells. Here, we test the hypothesis that loss of Angpt1-Tie2 signaling destabilizes endothelial cells and results in an increased fibrotic response.

Methods: To investigate the role of Angpt1 in renal fibrosis we utilized Angpt1 conditional knockout mice in experimental models of renal fibrosis, including unilateral ureter obstruction (UUO) and ischemia/reperfusion injury. Gene and protein regulation of fibrotic markers were investigated at different time points. We also performed lineage tagging experiments using Tie2-Cre and LysM-Cre to better understand the contribution of Tie2+ cells and macrophages to the myofibroblast population in UUO.

Results: Angpt1 deficient mice showed a significant (p<0.01) increase in fibrotic area 3days after UUO, 9.7±0.45%, compared to controls, 7.9±0.24%. At the same time point, there was a trend (n.s) towards an increased number of myofibroblasts per field from 15.4±1.8 in controls to 20.1±1.4 in Angpt1 deficient mice. Ischemia/reperfusion experiments are ongoing. In our lineage tagging experiment we found that 18.5±0.03% of myofibroblasts came from the Tie2-lineage whereas the LysM lineage contributed minimally, 2.4±1.00%.

Conclusions: Our results suggest that loss of Angpt1-Tie2 signaling increases tubulointerstitial fibrosis as seen by the increased expression of fibrosis markers in Angpt1 deficient mice. Ongoing work is designed to use other models of fibrosis and to elucidate the mechanisms(s).

SA-PO485
Inter-Alpha-Inhibitor Heavy Chain5 Interactions Control Fibroblast: Myofibroblast Differentiation John Martin, Timothy Bowen, Soma Meran, Aled O. Phillips, Robert Steadman. Nephrology, Cardiff Univ, Cardiff, Wales, United Kingdom.

Background: Fibroblasts are central to CKD through their Transforming Growth Factor-β1 (TGF-β1)-triggered profibrotic transition into contractile, α-smooth muscle actin (α-sma)-positive myofibroblasts. Transition is dependent on an increase in the synthesis and accumulation of a pericellular matrix of hyaluronan (HA) and the HA-dependent α-sma-positive myofibroblasts. TSG-6, however, contributes to the mechanism(s).

Methods: Fibroblasts were incubated for 72 h with 10ng/ml TGF-β1 to become myofibroblasts. RT-PCR was used to assess mRNA, sIRNA was used to knockdown mRNA expression of TSG-6, HA, α-SMA and SDNPA4. Western Blotting assessed protein levels.

Results: Following TGF-β1 treatment, TSG-6 and α-sma, had different kinetics of induction. Using siCD44 or EGFR inhibitor AG1478 to interfere with the CD44/EGFR-dependent signal initiation prevented differentiation but had no effect on TGF-β1 expression. TSG-6, however, was essential for differentiation and using monoclonal antibody A3K, HA-oligosaccharides, Cobalt, or siBknkin to interfere with the activity of TSG6, all prevented phenotypic change. These results suggested that it was the TSG6/siAld heavy chain (HC) interaction that was necessary for the effect. HC5 was shown to be the principal HC expressed in these cells. HC5 was released by hyalurondase treatment of the fibroblast cell surface and siCD44, siTSG6 and siBknkin all inhibited the expression of HC5 protein. Finally, HC5 could be deleted on the cell by specific siRNA and this resulted in antagonism of phenotypic change, confirming its role in myofibroblast differentiation.

Conclusions: The mechanisms regulating TGF-6 and HA synthesis, during TGF-β1-dependent induction of myofibroblasts are distinct. TSG-6, however, contributes to the pro-fibrotic response through its catalytic transfer of IntⅤ HC5 to HA leading to the subsequent induction of phenotypic change.

SA-PO486
Role of IL-4 Receptor α in Bone Marrow-Derived Fibroblast Activation and Renal Fibrosis Hua Liang, Yuanbo Wu, Yanlin Wang. Medicine, Baylor College of Medicine, Houston, TX.

Background: Renal fibrosis is a common pathway leading to progression of chronic kidney diseases. We and others have shown that bone marrow-derived fibroblasts contribute significantly to the pathogenesis of renal fibrosis. However, the signaling pathways underlying the activation of bone marrow-derived fibroblasts in the kidney are incompletely understood. We have found that IL-4 and its receptor α (IL4Rα) are induced in the kidney during the development of renal fibrosis. However, little is known about the role of IL-4Rα in the activation of bone marrow-derived fibroblasts and the development of renal fibrosis.

Methods: We examined the role of IL-4Rα in the activation of bone marrow-derived fibroblasts and the development of renal fibrosis using renal fibroblasts from IL-4Rα-deficient mice with a pericellular matrix of hyaluronan (α-sma)-positive myofibroblasts. Transition is dependent on an increase in the synthesis and accumulation of a pericellular matrix of hyaluronan (HA) and the HA-dependent α-sma-positive myofibroblasts. TSG-6, however, contributes to the mechanism(s).

Results: Compared with wild-type (WT) mice, IL-4Rα-deficient (KO) mice exhibited significant preservation of kidney function as measured by serum urea nitrogen and accumulated significantly fewer bone marrow-derived fibroblasts dual positive for CD45 and PDGFR-β in the kidney 2 weeks after fibrotic treatment. Furthermore, IL-4Rα-KO mice exhibited fewer α-smooth muscle actin (α-sma) positive myofibroblasts and expressed less α-sma protein in the kidney following fibrotic acid treatment. Consistent with these findings, we also observed significantly decreased collagen deposition and suppression of extracellular matrix proteins (collagen 1 and fibrocin). In cultured bone marrow monocytes, IL-4 activated STAT6 and induced expression of α-SMA and extracellular matrix proteins, which was abolished in the absence of IL-4Rα.

Conclusions: Our results strongly suggest that IL-4Rα plays an important role in the activation of bone marrow-derived fibroblasts and the development of renal fibrosis. These results indicate that IL4R signaling may represent a novel therapeutic target for chronic kidney disease.

Role of Scaffolding Protein JLP in Preventing Renal Fibrosis in Obstructive Nephropathy Qiang Fu, Qi Yan, Qin Zhang, Guohua Ding, Huiming Wang. Renmin Hospital of Wuhan Univ.

Background: Renal fibrosis is a common pathological lesion in the end stage of various progressive kidney diseases, and is characterized by interstitial inflammation, proliferation of fibroblasts, and accumulation of extracellular matrix (ECM). The ECM-associated leucine zipper protein (JLP) is a crucial scaffolding protein in signals transduction and molecular trafficking. JLP has been found expressed in mouse tissues of brain, lung, spleen, testis, and kidney. We reported here, for the first time, the effects of JLP deficiency on the progression of renal fibrosis in mice model of unilateral ureteral obstruction (UUO).

Methods: JLP Wild type (jlp+/+) and jlp deficient (jlp−/−) mice were divided into four groups: jlp−/− and jlp−/+ sham-operated groups, jlp−/− and jlp−/+ unilaterally ureteral obstruction (UUO)-operated groups (jlp−/− UUO group and jlp−/− UUO group). Mice were sacrificed at the days of 7 and 14 to evaluate the fibrosis by Masson and H&E staining. The expression of transforming growth factor-β1 (TGF-β1), α-smooth muscle actin (α-sma), collagen I (COL-I), and collagen III (COL-III) were assayed by immunohistochemistry staining.

Results: One week after the surgery, more collagen deposition was observed in the renal interstitial area in jlp−/− UUO group than in jlp−/+ UUO group. Similar to that, the expression of COL-I and COL-III were significantly increased in the kidney cortices in jlp−/− UUO-operated group than in jlp−/+ UUO-operated group. The expression of TGF-β1 and α-SMA was also significantly higher in jlp−/+ UUO-operated group than in jlp−/− UUO group.

Conclusions: Scaffolding protein JLP is critical in preventing renal fibrosis through the mechanism of inhibition TGF-β1 expression and myofibroblast induction.

SA-PO488
HGF-Producing Cell Sheet Suppress Renal Fibrosis Induced by Unilateral Ureteric Obstruction in a Rat Masatoshi Oka,1 Sachiko Sekiya,2 Ryoichi Sakiyama,2 Kosaku Nitta,1 Tatsuya Shimizu.2 ‘Nephrology, Tokyo Women’s Medical Univ, Shinjuku, Tokyo, Japan; ‘Tokyo Women’s Medical Univ Inst of Advanced Biomedical Engineering and Sciences, Shinjuku, Tokyo, Japan.

Background: Tubulointerstitial fibrosis is a typical pathological finding in chronic kidney disease (CKD) and is associated with the progression of renal dysfunction. Recently several studies reported to suppress renal fibrosis by transplantation of cells expressing several growth factors, for example hepatocyte growth factor (HGF) with HGF-producing cell sheet (HGF sheet) transplantation. The expression of transforming growth factor-β1 (TGF-β1), α-smooth muscle actin (α-sma), collagen I (COL-I), and collagen III (COL-III) were assayed by immunohistochemistry staining.

Methods: Human mesothelial cells transplanted human HGF gene by lipofection were cultured on temperature-responsive dish for 4 days. When temperature reduced, these HGF-producing cells were detached from dishes as cell sheet without enzyme-treated. We performed unilateral ureteric obstruction (UUO) in nude rat and transplanted the HGF sheet immediately. To compare HGF sheet transplantation with intermittent administration of HGF protein, we also injected HGF protein from tail vein every 24 hours for UUO rat (HGF iv). The kidney volume after operation measured with CT every 7 days for 4 weeks. After the 1st week, the one week after operation, the biopsies were collected. The expression of α-sma and smooth muscle actin in kidney transplanted HGF sheet was significantly less compared to that in HGF iv kidney. Moreover, the kidney volume treated HGF sheet with UUO was significantly less compared to control 4 weeks after operation. And it maintained thick cortex features with a lot of glomeruli, tubule and microvessels in the kidney treated HGF sheet.

Conclusions: Local and sustained HGF administration with HGF sheet strongly suppressed renal fibrosis induced by UUO in a rat. Our results suggested that cell sheet therapy may be a promising strategy for renal disease.

Extracellular Matrix Modulates Macrophage Phenotype Profile

Asgik Petrovyan, 1 Stefano Da Sacco, 2 Sargis Sedrakyan, 3 Giuseppe Orlando, 3 Matthew Edward Thornton, 1 Brendan Grubbs, 3 Roger E. De Filippo, 1 Laura Perin. 1 1University of Southern California; 2Children’s Hospital Los Angeles; 3Wake Forest School of Medicine.

Background: It is known that macrophages play an important role in kidney damage and resolution. An increase in macrophages phenotype type 1 (M1) is known to promote scarring while an increase in macrophage phenotype type 2 (M2) leads to prophylactic kidney healing processes. However little is known on how the extracellular matrix (ECM) can direct macrophages toward a specific phenotype acquisition during development, tissue homeostasis and disease.

Methods: Using established protocols we decellularized human adult, healthy, diseased, and fetal kidneys; monocytes were seeded on the different ECMS and macrophage phenotype switch after 24hrs and 5 days was assessed. Macrophage maturation was tested by releasing culture of IL-10, IFN-γ, TNF-α and IL-4 in the culture media along with qRTPCR and immunochemistry to evaluate expression of M1 (CD80 and CD86) and M2 (CD16, CD163, CD14 and CD200R) phenotypes.

Results: We observed that monocytes cultured on ECMS were able to mature into macrophages and present an increase in M1 marker (CD80) on diseased ECM, an increase in M2 markers (CD163, CD200R) on healthy ECM, and an increase in anti-inflammatory M2 marker (CD16) on fetal ECM, after 24hrs. After 5 days of co-culture there was an overall decrease in gene expression for all markers followed by an increase in media secretion of IL-10 on diseased ECM vs healthy and fetal ECM. Additionally after 5 days higher number of seeded monocytes appear to adhere onto the adult ECM vs the fetal ECM. IFN-γ, IL-4, IL-10 or CD64 expression was not detected during 24hrs and 5 days. Monocytes capacity to mature into macrophages was confirmed in vitro by administration of phorbol myristate acetate (PMA) and 1,25-dihydroxy vitamin D3 with LPS.

Conclusions: Our work suggests that the ECM has the capacity to modulate macrophage phenotype and might contribute to disease progression. Additionally, this model may be used to investigate mechanisms of ECM-dependent macrophage activation during renal disease and regeneration.

High Salt Diet Induces Blood Pressure Independent Tubulointerstitial Remodeling and Lymphangiogenesis in Rat Kidney Ryanne S. Hijmans, Saleh Yazdani, Gerjan Navis, Jacob van den Born. Nephrology, Univ Medical Center Groningen, Groningen, Netherlands.

Background: In chronic kidney disease (CKD), proteinuria is an important cause of tubular activation and progressive tubulointerstitial damage. It has been shown that high salt (HS) intake can aggravate this renal damage. Although earlier studies mainly focused on the blood pressure dependent (BP) effects of sodium on the kidney, recent studies suggest there is a BP independent route as well. A HS diet has been shown to store Na+ in the skin and as a result of binding of Na+ to proteoglycans, the influx of macrophages stimulates the secretion of vascular endothelial growth factor C (VEGF-C). Macrophage-derived VEGF-C has been shown to induce lymphangiogenesis (LA) in the skin. As LA has a role in inflammatory remodeling, we hypothesize that HS diet exerts its BP independent effects on the kidney by inducing LA and renal tubulointerstitial (TI) remodeling. We tested this hypothesis in normal rats, to avoid interference with TI remodeling due to the primary renal disorder.

Methods: Male Wistar rats (n=15) were randomly assigned to one of three study groups. Two groups (both n=5) received a high salt diet of 8% salt, while the control group (n=5) had a normal salt diet. After 2 weeks, one of the two groups on a high salt diet was sacrificed, and the other group was sacrificed at 4 weeks. The kidneys were stained and quantified for lymphangiogenic, fibrotic and inflammatory markers.

Results: Rats with HS intake showed an increased number of lymph vessels compared to their controls at weeks 4 (p=0.06). ED1+ macrophages also increased in the HS group at week 4 (p=0.06). There was a significant increase of myofibroblasts (α-SMA) after 4 weeks in the HS group (p<0.02). Except for week 1 (p<0.05), the HS groups showed no significant BP differences with their controls at 2, 3 and 4 weeks.

Conclusions: We showed that high salt intake induces tubulointerstitial remodeling, inflammation and profibrotic changes in rat kidneys, even when the BP is not significantly different between the groups. This finding supports our hypothesis that the HS intake has BP independent effects next to it’s well known BP dependent effects in CKD.

Genetic and Epigenetic Analysis of the MicroRNA-200 Family for Association with End Stage Renal Disease Laura Jane Smyth, 1 Gareth J. McKay, 1 Alexander P. Maxwell, 1 A. J. McKnight. 1Centre for Public Health, Queen’s Univ of Belfast, Belfast, Northern Ireland, United Kingdom; 2Regional Nephrology Unit, Belfast City Hospital, Belfast, Northern Ireland, United Kingdom.

Background: DNA methylation and miRNA profiles are associated with complex diseases including kidney diseases. We evaluated CpG sites, gene expression and SNPs of the miRNA-200 family and their target genes, including exploration of relevant methylation quantitative trait loci (meQTLs).

Methods: Quantitative DNA methylation was extracted from existing epigenome-wide association data (Illinima’s 450K Methylation array) for individuals with and without kidney disease (n=407). Following stringent quality control, a total of 14 significant CpG sites were identified within the miRNA-200 family, the p-value significance of which was cg23655182 (MI924, P=4.1x10^-16). The top 20 predicted target genes were determined using mirDB for each miRNA (MIR141, MIR200A, MIR200B, MIR200C and MIR429). Target genes had 308 CpG sites with methylation data; the most significant for MI924 were cg16682004 in EL2 and cg19038462 in ZFBI (P=4.2x10^-10). RNA-Se analysis was performed on renal transplant recipients and healthy controls using the Ion Proton™ RNA was selectively depleted for ribosomal RNA and up to 40 million reads were gained per sample. Differential methylation status was associated with expression of miRNA and their target genes. Additionally, using mirQTL data (rs9568773 and rs10200550) for miRNA-200, miRNA-200 family and their target genes for MI924. Genome-wide significant results (n=476 SNP) were obtained for 67 target genes (maximum P=9.98x10^-11). These genes may influence miRNA regulation.

Conclusions: CD36, the top-ranked gene, has previously been linked to kidney disease where it is suggested that it has a prominent role in the development of renal fibrosis. We have provided a genomic map of the miRNA-200 family using novel data in order to assist in determining its association with ESRD.

A MicroRNA Signature of Epithelial–Mesenchymal Transition in Progression of Chronic Renal Disease Ali Ramezani, 1 Joseph M. Devaney, 2 Akshay Roy-Chaudhury, 3 Richard Scott, 2 Sara Karandish, 2 Susan Knoblauch, 2 Jeffrey B. Kopp, 1 Dominick S. Raj. 1 ‘Div of Renal Diseases and Hypertension, George Washington Univ, Washington, DC; 2 Center for Genetic Medicine Research, CNMC, Washington, DC; 3 NIDDK, NIH, Bethesda, MD.

Background: Irrespective of the diverse initial causes, progression of CKD is characterized by increasing tubulointerstitial fibrosis. There is a great need for accurate, noninvasive biomarkers for early detection of fibrosis in the kidney and the progression of kidney disease. Recent evidence suggests that miRNAs participate in the fibrotic process in the kidney. The aim of this study was to examine the urinary and circulatory miRNA expression profiles regulating the EMT and whether they are reflected by parallel changes in the pro-fibrotic factors and the progression of kidney disease.

Methods: Blood and urine samples were obtained from 28 patients with CKD. Patients were divided into two groups according to their GFR: GFR<30 and GFR>30. Plasma and urinary levels of two biomarkers of fibrosis, collagens III (PIIINP) and IV, were measured. To determine involvement of miRNAs in kidney fibrosis, the plasma and urinary miRNA expression profiles of the patients were analyzed.

Results: Plasma and urine PIIINP and CIV levels were significantly increased in patients with GFR<30 compared with patients with GFR>30. Furthermore, miRNA expression profile of the patients showed 58 downregulated and 60 upregulated miRNAs in urine, and 51 downregulated and 61 upregulated miRNAs in the plasma of the patients with GFR<30 compared with GFR>30. A panel of 4 urine and 6 plasma miRNAs was identified which not only distinguished patients with GFR<30 from GFR>30, but their altered expression were also implicated in the phenotypic changes that occur during EMT and fibrosis. The altered expression levels of these miRNAs were validated in a tubular epithelial cell line, and studies are underway to validate their expression in vivo, in the Alt-TGFβ mouse model.

Conclusions: Plasma and urinary miRNAs are reliable, noninvasive, and inexpensive nephrofibrotic miRNAs. These studies may provide a basis for the development of large cohorts plasma- and urine-based assays could provide a more feasible and safer screening compared to biopsy.

The PR3 Receptor CD177 Is Controlled by Epigenetic Mechanisms Claudia Eulenberg, 1 Sylvia Bähring, 2 Friedrich C. Luft, 1 Ralph Kettertz, 1 Charité-Buch, Experimental and Clinical Research Center, Berlin, Germany; 2Nephrology and Intensive Care Medicine, ECRC, Berlin, Germany.

Background: Proteinase 3 (PR3) is a major ANCA antigen in granulomatosis with polyangiitis (GPA). PR3-ANCA binding to membrane-PR3 (mPR3) is a key event for neutrophil activation and vascular damage. The neutrophil-specific CD177 gene expression pattern. We hypothesized that epigenetic mechanisms control CD177 gene expression.

Methods: Haplotype analysis, genome-wide methylation analysis, chromatin immunoprecipitation (ChIP) analysis and CD177 expression studies were performed in neutrophils and HeLa cells.

Results: Methylation analysis on CD177 in PR3 and mPR3 neutrophils revealed three CpGs in the potential CD177 promoter that were methylated in CD177 in GPA patients, but not in CD177 in controls. ChIP analysis revealed enrichment of the H3K4me3 mark (enhocromatin) in the predicted CD177 promoter region in CD177 in neutrophils (p<0.05; n=4). This putative promoter region contains a TATA box and binding sites for several transcription factors, including the AP1 family. We established a HeLa cell model that recapitulates the neutrophil specific expression of the observed CD177 in GPA and HeLa cells. HeLa cells also had euchromatic in the promoter region and CD177 mRNA followed a monomethlic expression pattern.
Application of Human Kidney RNA-seq Expression Quantitative Trait Loci in Chronic Kidney Disease Yi-An Ko, Frank S. Chinga, Nora Ledo, Katalin Susztak. Renal Electrolyte and Hypertension Div; Perelman School of Medicine, Univ of Pennsylvania, Philadelphia, PA.

Background: There are more than 5 million sequence variants in humans. Somogeneous variations influence transcript levels and therefore have the ability to interfere with cell and organ function. Such genetic variants are called expression quantitative trait loci (eQTL). The goal of our study was identify such functionally important genetic variants at the genome-wide level.

Methods: This analysis requires the collection of large number of human tissue samples with genotype and transcript level data. Here we used 99 human kidney samples of Central European descents RNAseq and genotype data was normalized and genotype data was imputed using 1,000 Genome reference data. The association between genotype and transcript levels was performed using Matrix eQTL software and was limited to cis-eQTL where the genetic variant and transcript levels were within 2 megabases distance.

Results: We identified 164 significant target genes (we call these eGenes) and 7590 significant SNPs (eSNPs) that passed the threshold for statistical significance after multiple testing correction using adjusted p-values<10^-6. Next we compared variants that influence gene expression in the kidney to those that have been published for other organs using the publicly available Genotype-Tissue Expression project (GTEx). Of the 164 eGenes,103 were common between the kidney and other organs, indicating that there are cell type specific and cell type independent eGenes. Using kidney specific epigenome maps, we found that eSNPs were enriched on kidney specific regulatory elements, including promoters and enhancers. We also found a significantly greater overlap between kidney eGenes and polymorphisms that are associated with CKD development, compared to other tissues (digestive, nervous, immune system diseases, hematological measurement, cardiovascular, and metabolic disease).

Conclusions: We identified transcript level changes associated with genotypic variations. These results can highlight kidney specific regulatory elements and may also help to identify target genes for polymorphisms associated with kidney function related traits.

Gene Expression Based Dissection of Chronic Kidney Disease Traits Pazit Beckerman, Katalin Susztak. Renal, Electrolyte and Hypertension Dept, Univ of Pennsylvania, Philadelphia, PA.

Background: Chronic kidney disease (CKD) is a progressive decline in kidney function. There are several manifestations of CKD including glomerular function change, albuminuria, glomerulosclerosis, tubulointerstitial fibrosis and metabolic changes. These traits are strongly correlated but the question remains whether they are driven by identical mechanisms.

Methods: We conducted genome wide transcript level analysis of 95 microdissected human kidney tubule samples. We used transcript level changes as quantitative traits to dissect underlying mechanisms. These samples included subjects with normal eGFR with or without diabetes (DM) or hypertension (HTM) and diseased kidney samples with low eGFR, fibrosis and sclerosis, with or without DM or HTM.

Results: We identified 1430 transcripts with significant linear correlation with eGFR. Pathway analysis indicated significant enrichment for TGFβ and Wnt signaling and ECM receptor interactions only in earlier CKD stages. Our analysis identified 1606 transcripts that correlated with fibrosis and 1803 transcripts correlated with glomerulosclerosis. Similar to the clinical overlap between eGFR and fibrosis, we found that 78% of transcripts with identical. Transcripts that showed correlation with fibrosis but not with eGFR were enriched for inflammation related pathways. On the other hand, metabolism related genes correlated with eGFR but not with fibrosis. There were significant differences between male and female samples as well.

Conclusions: Our transcriptome-based dissection method highlights the relatedness of eGFR and kidney fibrosis, but also indicates potential differences in the underlying mechanisms of the two processes.

SA-PO497

Background: Apolipoprotein L1 (APOL1) susceptibility alleles have been associated with kidney disease progression and ESRD in hypertensive African Ancestry (AA) populations. We explored whether these APOL1 alleles are associated with blood pressure-related traits in AA enrolled in the electronic medical records and genomics (eMERGE) Network.

Methods: Study populations included the Mount Sinai BioMe biobank discovery (dis) cohort (<5,213) and three EMR-linked biobank replication (rep) cohorts, including Vanderbilt BioVU (<2,889), Northwestern NUgene (<6,163), and Mount Sinai BioMe (<5,165). APOL1 single nucleotide polymorphisms (SNPs) rs73885319, rs71785313 and rs60910145 were genotyped in BioMe samples and imputed in BioVU and NUgene samples to determine APOL1 G1 and G2 risk alleles. Longitudinal phenotypic data were extracted from EMRs. Linear regression models & meta-analyses (META) were performed with age, sex, mean BMI, and eGFR as covariates.

Results: Compared with carriers of [0/0] APOL1 G1/G2 risk alleles, carriers of [2] risk alleles were diagnosed with hypertension a mean of 2.5 years (95%CI 1.9-2.9 yrs) earlier in life (P<0.04, P<3x10^-6; Cox hazard); manifested 2.3 mmHg higher systolic BP (SBP) in younger AA (age 20-39) (P<0.007, P<0.04); and were exposed to more antihypertensive medication classes (P<0.01, P<3x10^-6). Carriers of [2] risk alleles were more likely to manifest concentric left ventricular hypertrophy by echocardiogram (OR(95%CI)=1.521[1.14-2.02], P<0.01) and hemorrhagic cerebrovascular accidents (OR in 16C=2.42[1.01-5.79], P<0.05).

Conclusions: APOL1 G1/G2 susceptibility alleles are associated with early-onset, more severe form(s) of hypertension & with hypertensive complications hemorrhagic stroke
and concentric LVH independent of kidney function & BMI. These results may warrant a shift from kidney-intrinsic to systemic vascular pathomechanisms attributable to APOL1 G1/G2 susceptibility alleles.

**Apolipoprotein L1 (APOL1) Gene Variants and Incident Proteinuria: Results from the African American Study of Kidney Disease and Hypertension (AASK)**

**Teresa K. Chen,** Carmen A. Peralta, Lawrence J. Appel, Michael J. Choi, Michelle M. Estrella, *Nephrology, Johns Hopkins Univ; Nephrology, Univ of California San Francisco; Medicine, Johns Hopkins Univ.*

**Background:** APOL1 gene variants are associated with kidney function decline. Whether these same gene variants are associated with incident proteinuria in the context of pre-existing chronic kidney disease (CKD) is unknown.

**Methods:** Using the trial and cohort phases of AASK (median follow-up of 6.8 years, maximum follow-up of 12.2 years), we evaluated participants who had hypertension-attributed CKD and who did not have proteinuria at baseline. Cox proportional hazards models were used to estimate the relative hazard of incident proteinuria (defined as a doubling of urine protein-to-creatinine ratio and UP/Cr >0.22) comparing APOL1 high-risk genotype (2 risk alleles) vs. low-risk genotypes (0-1 risk alleles). We adjusted for age, gender, baseline GFR, percentage of European ancestry, randomized blood pressure goal (usual vs. low), and randomized blood pressure drug (ramipril vs. metoloprol vs. amlodipine). Effect modification by randomized trial interventions and dietary sodium intake (as estimated by 24-hour urine sodium) was assessed.

**Results:** Of the 480 participants included in our study, 17% (n=82) had the APOL1 high-risk genotype. Individuals with the APOL1 high-risk genotype were 83% more likely to develop incident proteinuria compared to those with the low-risk genotypes (adjusted HR: 1.83; 95% CI: 1.36 to 2.47; p=0.001). The association between APOL1 and incident proteinuria was not modified by randomized blood pressure goal, randomized blood pressure drug, or dietary sodium intake (p-interaction>0.05 for each).

Conclusions: Among African-Americans with CKD attributed to hypertension but without baseline proteinuria, high-risk variants of APOL1 are associated with a greater risk of incident proteinuria.

**Funding:** NIDDK Support, Pharmaceutical Company Support - The AASK trial and cohort were also supported by the following pharmaceutical companies: King and Upjohn.

**Role of Klotho Genetic Polymorphisms in Salt-Sensitivity: A Link Between Salt and Aging?**

**Chiara Lanzoni, Lorena Citterio, Elena Brioni, Simona Delli Carpini, Marco Simonini, Guido Gatti, Elisabetta Messaggio, Paolo Manunta, Nephrology and Hypertension, San Raffaele Hospital, Milan, Italy.**

**Background:** Previous data in transgenic mice showed that one-half klotho deficiency resulted in extensive premature aging, increased salt sensitivity and caused salt-sensitive hypertension. Recent gene expression study confirmed the expression of klotho in renal distal tubular cells. The aim of this study is to evaluate the role of Klotho polymorphisms in salt sensitivity hypertension.

**Methods:** Design: study of pressure-natriuresis relationship in essential hypertensive patients, never treated before, naive (NHP) by Acute salt load (Na load: 310 mmol in 2 h iv) and low salt diet (Low SD: <100 mg/die for 15 days).

**Results:** GWA analysis identified 32 SNPs in Klotho gene (restricted to 15 with tagging r²>0.80). Six of these resulted significantly associated to BP variation after Na load and Low SD. The effect of intron 2 and 3 SNPs genotype on SBP variation after Na load and Low SD are reported in the (figure 1) confirming the similar effect in the two manoeuvres.

Conclusions: These results are the first demonstration of the role of Klotho gene in salt homeostasis and hypertension development and suggest that Klotho polymorphisms affect sodium renal tubular excretion. If confirmed these results propose Klotho as key gene in salt sensitivity and aging.

**Funding:** Government Support - Non-U.S.

**SA-POS51**

**Associations Between the Reticulon 1 Gene (RTN1) and End-Stage Kidney Disease**

**Jason A. Bonomo, Nicholette D. Palmer, Ying Fan, John C. He, Donald W. Bowden, Barry I. Freedman, *Center for Genomics & Personalized Medicine Research, Wake Forest School of Medicine; Dept of Internal Medicine, Section on Nephrology, Mount Sinai School of Medicine; Dept of Internal Medicine, Section on Nephrology, Wake Forest School of Medicine.**

**Background:** RTN1 encodes endoplasmic reticulum stress proteins that have recently been associated with chronic kidney disease. We sought to determine if genetic variants within RTN1 were associated with end-stage renal disease (ESRD) in African Americans (AAs) and European Americans (EAs) with diabetic (T2D-ESRD) and non-diabetic forms of ESRD.

**Methods:** We examined the RTN1 gene region using a published AA T2D-ESRD genome-wide association study (Discovery study; n=922 cases, n=861 controls). Seven single nucleotide polymorphisms (SNPs) with p<0.015 were identified and genotyped in replication samples of AAs with T2D-ESRD (n=1,312) and controls (n=774), as well as increased UACR. Analyses used generalized linear mixed models that accounted for the sampling strategy and family relatedness, age, sex, diabetes, systolic blood pressure and anti-hypertensive medications, and stratified by Hispanic background.

**Results:** There were 41% men, and mean age was 46 (SD =14). The prevalence of increased UACR was 14%, reduced eGFR was 4%, and combined CKD outcomes was 16%. Caribbean Hispanics (Cuban, Dominican, Puerto Rican, N=5380) had higher prevalence of 2 APOL1 risk alleles (1% vs 0.1%) and rs334 allele (2% vs. 0.7%) compared to Mainland Hispanics (Central American, Mexican, South American, N=6,539). APOL1 alleles were associated with increased UACR (p<0.01) and the composite CKD outcome (p<0.01), and rs334 was associated with same outcomes (UACR, p<0.01; CKD composite outcome, p<0.01) among Caribbeans only.

Conclusions: African-specific alleles are associated with CKD in Hispanics, but associations vary by Hispanic background. Medical care providers should be aware of the impact of these genetic variants for CKD risk in Hispanics.

EAs with T2D-ESRD (n=602) and controls (n=1030). SNPs were also investigated in AAs considering pseudogenes, compared to two independent NGS exome sequencing strategies (1) Panel for glomerular disease (26 genes, 89 patients) and (4) Panel for tubule/interstitial disease (36 genes, 120 patients). Our results suggest that the significant SNPs identified in our study may be useful in the development of diabetic nephropathy.

Conclusions: The results of this study may provide new insights into the genetic basis of nephropathy.

SA-P050

An Efficient and Comprehensive Strategy for Genetic Diagnostics of All Hereditary Kidney Diseases

Lisbeth Silva, M. Lara Besada-Cerecedo, Xiaoxu Ge, Langen Zhuang, Ming Li, Yong Zhang, Fang Wang, Niansong Wang.

Dept of Nephrology, Sixth People’s Hospital, Shanghai Jiao Tong Univ Affiliated Sixth People’s Hospital, Shanghai, China.

Background: Sanger is a traditional and reliable method for sequencing, but next generation sequencing (NGS) has improved genetic diagnosis in a time and cost effective manner. We established and validated a NGS strategy for all hereditary kidney diseases, and compared it with traditional and NGS exome sequencing technologies.

Methods: Based in clinical classification and population prevalence, we generated four panels and test them in 318 patients with renal disease during 2 years of routine clinical practice: (1) Panel for common, rare and ultra-rare cysitic diseases (72 genes, 48 patients); (2) Panel for glomerular disease (26 genes, 89 patients) and (4) Panel for tubule/interstitial disease (36 genes, 52 patients).

Results: This strategy has shown greater gene coverage, sensitivity and specificity considering pseudogenes, compared to two independent NGS exome sequencing strategies (ampliseq n=2 and sureselect n=115). Moreover, we also used an in-house database containing a total of 6945 genomic variants (248 frameshift and 66 nonframeshift insertion/deletion/substitutions, 44 stopgain, 102 splicing, 807 nonsynonymous SNV, 592 synonymous SNV and 39326 non coding variants) that we have used to classify and re-classify considering every single genetic variant described into the literature. We have identified genetic interaction as the most common functional genetic diagnosis and the major mechanism of phenotypic inter- and intra-familial variability.

Conclusions: Here we describe a novel strategy to anticipate disease and provide complete genetic information for clinical decision-making, in a time- and cost-efficient manner.

SA-P050

The First Genome-Wide Association Study of Diabetic Nephropathy in Korean Type II Diabetes Patients

Byeongwoo Kim, Yeong Hoon Kim, Sang Ho Lee, Sunwoo Kang.

Dept of Nephrology, Inje Univ, Busan Paik Hospital, Busan, Korea; Dept of Nephropathy, College of Medicine, Kyung Hee Univ, Seoul, Korea.

Background: It has been suggested that genetic susceptibility plays an important role in the pathogenesis of diabetic nephropathy. Recently, several genome wide association studies (GWASs) suggested that specific polymorphisms of candidate genes were associated with susceptibility to diabetic nephropathy. However, there was weak point in contents of GWAS DNA chip for GWAS. In fact, previous contents of GWAS DNA chip were fixed and did not cover SNPs in exon region and promoter region. In present study, we used the Axiom® Genome-Wide Human Assay. The contents of assay are selected by researcher and useful to investigate association between several candidate SNPs in specific diseases.

Methods: To investigate whether specific polymorphisms are involved in the development of the diabetic nephropathy, 87 diabetic nephropathy patients and 104 diabetic controls in Korean with type II diabetes were studied. We firstly selected 47,777 genes of homo sapiens in NCBI gene database and searched the SNPs in dbSNP database. And the criteria for selection exonic SNPs, promoter SNPs, and intron SNPs in each gene were following: (1) SNPs with >10% minor allele frequency (MAF), (2)<0.1 heterozygosity, (3) known genotype frequencies of SNPs in Asian population, (4) SNP studies in previous study, (5) unknown SNPs. Finally we selected 378,707 SNPs. Logistic regression models were performed to determine odds ratio (OR), 95% confidence interval (CI), and P value. The analysis was using Helixtree program.

Results: Among 378,707 SNPs, three SNPs (rs3214159 in ABC8 gene, rs3747636 in PIK3C2G gene, and rs3765156 in PIK3C2B gene) showed strongly significant association with diabetic nephropathy (p<0.00001).

Conclusions: These results suggest that these significant SNPs may be useful to investigate the development of diabetic nephropathy.

Exome Sequencing as Diagnostic Tool in Daily Clinical Nephrology Practice
Ilse M. Rood,1,2 Dorien Lutgenburg,1,2 Elisabeth AM. Cornelissen,1 Jeroen Schoots,1 Nicole Van De Kar,1 Michiel F. Schreuder,1 Linda Koster-Kamphuis,1 Jeroen Deegens,1 Julia M. Hofstra,1 Tom Nijenhuis,1 Jack F. Wetzels,1 Ronald Roepman,1 Ernie M.H.F. Bongers,1 Radboud Center Renal Disorders, RadboudUMC, Nijmegen, Netherlands; Shared first author.

Background: Next generation sequencing, e.g. exome sequencing (ES), is currently the state of the art technique to identify mutations in genetic diseases. We developed a workflow for implication of ES in daily clinical practice for patients with a suspected hereditary kidney disease. The aim of this study was to analyze the diagnostic yield of this approach in clinical practice.

Methods: We developed a two-tier analysis, in which the first step is a kidney disease gene panel to screen for pathogenic variants in 187 genes, minimizing the chance of coincident findings. If causative mutations are not identified (first step), the complete exome data set was analyzed after additional written informed consent. We analyzed the diagnostic yield of this approach.

Results: From Jan. 2013 till Jan. 2015 we included 74 unrelated patients with kidney disease, defined as glomerular disease (n=34), cystic renal disease (n=16), electrolyte disorders (n=11), renal insufficiency of unknown cause (n=4) and other (n=9). The kidney disease gene panel revealed pathogenic mutations in 11 (15%), and likely pathogenic variants in 12 other cases (16%), necessitating follow-up studies. Further analysis of the complete exome data set in 19 patients, revealed candidate genes in 6 patients that are under investigation. In addition, copy number variation analysis revealed a pathogenic deletion in 2 patients (in one patient another pathogenic mutation was also identified in step one). There was 1 coincidental finding necessitating follow up for colon carcinoma. In 23 patients open exome analysis is currently ongoing. Nine patients refused further analysis.

Conclusions: Currently, in 30 out of 74 patients (41%) (likely) causative mutations or new candidate genes were identified. We conclude that diagnostic exome sequencing is a powerful tool for detecting causative mutations in daily clinical practice without having the limitations of other gene testing approaches (single gene testing/targeted sequencing).

Atypical Hemolytic Uremic Syndrome Targeted Re-Sequencing Study in a South Italian Cohort of Patients
Matteo Accetturo,1 Anna Zito,1 E.D. Stein,1 Maddalena Gigante,2 Paola Pontrelli,3 S. Diella,1 Giuseppe Castellano,1 M. Giordano,1 L. Sanganella,3 Loreto Gesualdo,1 Emergency and Organ Transplants, Nephrology Unit, Univ of Bari, Italy; 1Medical and Surgical Sciences, Nephrology Unit, Univ of Foggia, Italy; 1Giovanni XXIII Hospital, Italy.

Background: Atypical hemolytic uremic syndrome (aHUS) is a multifactorial disease due to autoimmune or genetic factors leading to deregulated alternative complement pathway activation. At present 12 genes are associated to aHUS, however 30-50% of patients lack mutations in these genes resulting in still partially obscure genotype-phenotype correlations.

Methods: We enrolled 20 aHUS patients and 2 relatives from Apulia Region, Italy. We performed targeted parallel re-sequencing of the 12 known genes plus ADAMTS13, in a split design for generic diagnostic routine screening. We analyzed the genotype investigating the overlapping with other alternative complement pathway disorders, such as C3 glomerulopathy, Age-related Macular Degeneration (AMD) and drusen. We selected patients for their history of sporadic aHUS. Target enrichment was performed using an Illumina TrueSeq Custom Amplicon panel. Sequencing was performed on Illumina MiSeq Desktop Sequencer. All variants were evaluated for their pathogenicity according to CADD, Sift and Polyphen algorithms.

Results: We identified 30 missense and one nonsense variants in known aHUS genes, plus seven missense variants in ADAMTS13. Several combined variants were identified which might explain the different phenotypic nuances of our patients, as well as, in some cases, their signs of other Complement-related diseases. We evidenced that different combination of variants together with different triggering factors result in a phenotypic spectrum encompassing all the Complement-related disease range. Additionally, in presence of some combinations, also other underlying pathologies can act as a triggering background for aHUS.

Conclusions: Our data suggest that (i) ADAMTS13 gene should be routinely sequenced for aHUS (ii) the overlapping with other complement-related diseases is considerable. Mutations should therefore be analyzed in combination, and the high-throughput strategy is the only feasible in this scenario.
Discovery of New Risk Gene Loci in IgA Nephropathy: Genome-Wide Human Assay

**Background:** IgA nephropathy (IgAN) is the most common form of glomerulonephritis in Korea. The etiology of IgAN is complex with high genetic heterogeneity. Several genome-wide association studies (GWAS) have suggested that specific polymorphisms of candidate genes are associated with susceptibility to IgAN. However, previous contents of GWAS image chip were fixed and did not cover SNPs in exonic region and promoter region.

**Methods:** We used the Affymetrix Genome-Wide Human Assay by Affymetrix. The contents of assay are useful to investigate association between several candidate SNPs and end-stage renal disease. We selected 47,777 genes of homo sapiens in NCBI gene database and searched the SNPs in dbSNP database. And the criteria for selection exon, promoter, and intron SNPs in each gene were following: SNPs with >10% minor allele frequency, >0.1 heterozygosity, known genotype frequencies of SNPs in Asians. SNPs were studied in previous study, and unknown SNPs. Logistic regression models were performed to determine odds ratio (OR), 95% confidence interval (CI), and P value. The analysis was using Helix tree program.

**Results:** To investigate whether specific polymorphisms are involved in the development of IgAN, 182 biopsy confirmed IgAN patients and 455 healthy controls were studied. We selected 378,707 SNPs. We carried out genome wide genotyping on customized Affymetrix Genome-Wide Human Assay Among 378,707 SNPs, 19SNPs showed strongly significant association with IgAN (p<0.00001). We identified at rs201580039, rs12219125 and rs57351989 that implicated the genes encoding KLIF14, Kruppel-like factor 14, ITGB3, OR 8.04, 1.7x10^{-3}, and 5.1x10^{-3} as susceptibility genes. To validate the previous reported susceptibility SNPs of IgAN, we selected and genotyped 19 SNPs, rs660895 of HLA-DRB1 and rs2856717 of HLA-DQB1 were significantly different between two groups.

**Conclusions:** These results suggest that these significant SNPs may be useful to investigate the development of IgAN.

**SA-PO511**

Mannan-Binding Lectin 2 Polymorphisms Were Associated with Progression of IgA Nephropathy

**Background:** Our aim is to evaluate whether MBL2 polymorphism associates with progression of IgA nephropathy (IgAN). Patients with Primary IgAN were retrospectively recruited from 2009 to 2013. Renal specimen was semi-quantitative scored according to the Oxford scoring system. Whole coding and promoter regions of MBL2 were sequenced in 101 patients. Then 3 SNPs (rs11003125, rs7096206 and rs7095991) in promoter and 1 SNP (rs1800845) in exom of MBL2 were genotyped in other 185 patients by Sanger sequencing. The associations of the 4 SNPs with patients' clinical, pathological and prognostic parameters were analyzed. Serum MBL level was measured by ELISA.

**Results:** A total Of 286 patients were enrolled, mean age at time of biopsy was 36.2 years, and 192 patients were male (67.1%). Previous study showed mean follow-up time was 34.80 months. Among the 4 SNPs, only rs1800845, coding the 54 amino acid of MBL, significantly increased the risk of ESRD. More patients with rs1800845-A allele (27.3%) progressed to ESRD compared to patients with GA genotype (15.5%) (P=0.326) or GG genotype (9.9%) (P=0.011). Then all patients were divided into GG group (n=91), GA group (n = 84) and AA group (n=11) based upon genotypes of rs1800450. There were no differences of demographic, clinical and pathological parameters at time of biopsy, except for proteinuria (P=0.028). Interestingly, serum MBL levels in patients with AA genotype (median 0.9ng/ml) were significant lower than GA genotype (median 243.29ng/ml) [P=0.001] and GG genotype (median 1033.03ng/ml) [P=0.001]. Kaplan-Meier survival analysis showed that survival time of AA group (38.90 months) [P<0.001] and GG genotype (median 1033.03ng/ml) [P<0.001] was significantly shorter than GA group (66.01±1.9 months) [P=0.173] and GA group (56.37±2.6 months) [P=0.001]. Finally, AA independently increased the risk of ESRD (AA vs GG-GA, HR=26.73, 95%CI 14.92-145.30, P<0.001) after adjusted by sex, age and clinical indicators by COX regression analysis.

**Conclusions:** IgAN patients with rs1800450-A allele have a higher risk of disease progression probably as a result of lower MBL levels in these patients, which may increase the risk of infection.

**SA-PO512**

ARHGAP32 as a Candidate Gene for Primary Focal Segmental Glomerulosclerosis

**Background:** Focal and segmental glomerulosclerosis (FSGS) is one of common causes of end-stage renal disease worldwide. Previous studies showed that genetic factors played an important role in the pathogenesis of FSGS. The purpose of this study was to identify the candidate genes of FSGS in Chinese familial FSGS.

**Methods:** Total 21 individuals of a FSGS pedigree were involved in this study. First, we detected the mutations of ACTN4, TRPC6, and NPHS2 in this pedigree. Then we conducted a genome wide scan for linkage study. And DNA of four members were assayed by whole exome sequencing. The data were filtered according to the 1000 Genomes Project, ESP5500 and dbSNP information, and database with 69 exome sequence (Exome Sequencing Project) (without kidney diseases). By PIR sequencing methods, we detected candidate causal mutation. And then, we tested the mutation in other 97 sporadic FSGS patients and 96 normal controls.

**Results:** No mutation was detected from these exons of INP2, ACTN4 and TRPC6 in the FSGS pedigrees. 8 loci suggested for linkage were identified, and the multipoint parametric LOD score of 1.69 was marked by DS21215. A mutation (c.1213G, p.L405V) of ARHGAP32 gene was identified by combination with exome sequencing, genome-wide scan, function prediction of coding proteins. A new mutation (c.A5539G, p.R1870H) of ARHGAP32 gene was detected in one sporadic FSGS patient from 97 cases and 96 controls. The ARHGAP32 expression was detected in the glomerul and tubule. Conclusions: We found a candidate mutation of ARHGAP32 gene for primary FSGS by combination with whole genome linkage analysis and whole exome sequencing.

Premature Death in First Degree Relatives of End Stage Renal Disease Patients

Ranveig Skruenes,1,2 Einar Svarstad,1,2 Anna Reisaeter,1,2 Hans-Peter Marti,1,2 Bjorn Egil Vikse,1,2

1 Dept of Medicine, Haukeland Univ Hospital, Bergen, Norway; 2 Dept of Clinical Medicine, Univ of Bergen, Bergen, Norway.

Background: Increased risk of end stage renal disease (ESRD) and death in Norwegian living kidney donors has been reported. The majority of donors were related to the recipients.

Methods: The present study investigates risk of death in first degree relatives of ESRD patients. A cohort-design was used, ESRD in a first degree relative was the main exposure variable. All citizens born in Norway with at least one registered first degree relative were included.

Results: Five thousand two hundred and sixty eight (5180) articles were identified. Fifty-three articles investigating 55 genetic variants were included, 31 of which remained associated with EAV in a meta-analysis. These genetic variants were in or near the following genes: SERPINA1, CD226, CTLA4, HLA-B, HLA-DR, HLA-DQ, HLA-DQ, HLA-DRD1, RF35, RF11, RENG1, RYX2, RFX, and TRAF2. Moreover, we identified genetic distinctions between granulomatosis with polyangiitis and Wegener granulomatosis and between proteinase 3 ANCA vasculitis and myeloperoxidase ANCA vasculitis. In 79% of the genetic variants, subdivision based on ANCA serotype resulted in higher odds ratios than subdivision based on clinical diagnosis.

Conclusions: This meta-analysis identified 31 genetic variants associated with AAV, supporting a role for alpha-1-antitrypsin, the major histocompatibility complex system, and several distinct inflammatory processes in AAV pathogenesis. Our results indicate that subdivision of AAV based on ANCA serotype has a stronger genetic basis than subdivision based on clinical diagnosis.

Meta-Analyses of Genetic Associations in New Onset Diabetes After Kidney Transplantation

Katherine A. Benson,1 A. J. McKnight,1 Alexander P. Maxwell,1 1 Centre for Public Health, Queen’s Univ Belfast, Belfast, Northern Ireland, United Kingdom; 2 Regional Nephrology Unit, Belfast City Hospital, Belfast, Northern Ireland, United Kingdom.

Background: New-onset diabetes after transplantation (NODAT) is a serious complication following solid organ transplantation. Although a genetic contribution to this disease and we have previously identified genetic risk factors associated with NODAT following kidney transplantation. These meta-analyses examine the pooled effect of genetic variants associated with NODAT in kidney transplant populations.

Methods: Relevant articles investigating the association between genetic markers and NODAT were identified by means of a database search of PubMed, Web of Science and Google Scholar from 1945 to 2015. Variants replicated in a minimum of three studies were included for analysis. Data was analysed using a random effects model in Review Manager 5.3. The association between identified variants and NODAT was calculated at the per-study allele level, where original studies were concordant with Hardy-Weinberg Equilibrium, to generate overall significance values and effect sizes.

Results: Our literature search returned 4,147 citations. Of the 36 eligible articles identified, 21 genetic variants from 13 genes were included for analysis. Of these, three were significantly associated with NODAT by meta-analysis at the 5% level of significance: TCF7L2 rs7903146 p<0.01 OR=1.41, 95%CI=1.07-1.85 (n=2967 individuals), CDKL1 rs1046398 p<0.006 OR=1.43, 95% CI=1.11-1.85, (n=696 individuals), and KCNJ12 rs2237892 p<0.007 OR=0.70, 95% CI=0.54-0.91, (n=1270 individuals).

Conclusions: These meta-analyses identified three genetic variants statistically associated with NODAT. Ideally, these variants should be assessed in less heterogeneous studies with larger numbers of kidney transplant recipients with a carefully defined NODAT phenotype.

New Prioritization and Burden Analyses of Rare Variants in 208 Candidate Genes Are Questioning the Pathogenicity of Previously CAKUT-Associated Genetic Variants

Navin Nicolai,1,2 Sara L. Pult,1 Isaac J. Nijman,1 Albertien M. van Eerde,1 Ernie M.H.F. Bongers,2 Rachel H. Giles,2 Nine V. Knoers,1 Kirsten Y. Renkema,1 1 Medical Genetics, UMC Utrecht, Utrecht, Netherlands; 2 Human Genetics, Radboudumc, Nijmegen, Netherlands; 3 Nephrology and Hypertension, UMC Utrecht, Utrecht, Netherlands.

Background: The leading cause of end-stage renal disease in children is attributed to congenital anomalies of the kidney and urinary tract (CAKUT). Familial clustering and mouse models support the presence of monogenic causes. Genetic testing is insufficient as it mainly focuses on HNF1B and PAX2 mutations that are thought to explain CAKUT in 5–15% of patients.

Methods: To identify novel, potentially pathogenic variants in additional genes, we designed a panel of genes identified from studies on familial forms of isolated or syndromic CAKUT and genes suggested by in vitro and in vivo CAKUT models. The coding exons of 208 genes were analyzed in 453 patients with CAKUT using next-generation sequencing. Rare truncating, splice-site variants and non-synonymous variants, predicted to be deleterious and conserved, were prioritized as the most promising variants to have an effect on CAKUT.

Results: Previously reported disease-causing mutations were detected. Five variants were fully penetrant causal mutations that improved diagnosis. We prioritized 148 candidate genes. We found no significant excess of rare variants in any of the genes in our cohort compared to controls.

Conclusions: Thus, in a study that represents the largest set of genes analyzed in CAKUT patients to date, the contribution of previously implicated genes to CAKUT risk is significantly smaller than expected and the disease may be more complex than previously assumed.

Genetic Variants in ANCA-Associated Vasculitis: A Meta-Analysis

Chinar Rahmatullah1, Antien Mooyaart,2 Daphne Van Hoovem,1 Jan W. Schoonjes,1 Jan A. Bruijn,1 Olaf Dekkers,1 European Vasculitis Genetics Consortium,1 Ingeborg M. Bajema,1 1 Leiden Univ Medical Center; 2 Aarhus Univ Hospital.

Background: Genetic factors may influence the pathogenic pathways leading to anti-neutrophil cytoplasmatic antibody (ANCA)-associated vasculitis (AAV). We performed a meta-analysis to determine the genetic variants most likely associated with AAV and investigated whether diagnostic and serological subtypes within AAV have distinct genetic backgrounds.

Methods: Studies investigating the association between genetic variants and AAV in humans were searched in PubMed, Embase, and Web of Science. All variants significantly associated with AAV in at least one study and investigated in at least two studies were included. Additionally, data on these genetic variants from the largest GWAS in AAV were included to increase the validity of this meta-analysis.

Results: One thousand one hundred and eighty articles were identified. Fifty-three articles investigating 55 genetic variants were included, 31 of which remained associated with AAV in a meta-analysis. These genetic variants were in or near the following genes: SERPINA1, CD226, CTLA4, HLA-B, HLA-DR, HLA-DQ, HLA-DQ, HLA-DRD1, RF35, RF11, RENG1, RYX2, RFX, and TRAF2. Moreover, we identified genetic distinctions between granulomatosis with polyangiitis and Wegener granulomatosis and between proteinase 3 ANCA vasculitis and myeloperoxidase ANCA vasculitis. In 79% of the genetic variants, subdivision based on ANCA serotype resulted in higher odds ratios than subdivision based on clinical diagnosis.

Conclusions: This meta-analysis identified 31 genetic variants associated with AAV, supporting a role for alpha-1-antitrypsin, the major histocompatibility complex system, and several distinct inflammatory processes in AAV pathogenesis. Our results indicate that subdivision of AAV based on ANCA serotype has a stronger genetic basis than subdivision based on clinical diagnosis.
Background: The PediGFR Consortium aims to identify genetic factors associated with pediatric chronic kidney disease (CKD) progression. The optimal model for CKD progression for testing is unclear. To address this question, we performed genome-wide association studies (GWAS) of two different definitions of CKD progression, slope of the annual change in estimated GFR (eGFR) versus time-to-event (TTE).

Methods: There were >8 million genotyped and imputed markers from 1,122 patients. The calculation of slope was based on 2-41 eGFR values per patient. TTE was a combined endpoint of dialysis, transplant, 50% GFR loss or GFR <5 ml/min/1.73m2. Respectively, cox proportional hazards and linear regressions were used for the GWAS of TTE and slope. Baseline variables were adjusted for age, sex, principal components, and baseline eGFR. For each definition, data were meta-analyzed from five study-ancestry specific groups in PediGFR.

Results: For TTE, follow-up time was 1.66-5.0 years (IQR) and an event rate of 34%. For slope, mean slope was -4.2 ml/min/1.73m2. For comparison, we focused on SNPs present in all five groups with a minor allele frequency >0.05, and I2<50%. For TTE, 6 genomic regions contained one or more of such SNPs with p<1E-6, one of which reached genome-wide significance (p=3E-8). Hazard ratios per allele range from 1.58-1.97. For slope, there were 3 regions with p<1E-6, one of which reached genome-wide significance. All GWAS variants were nominally associated with TTE, of which 2 of the 3 slope variants were nominally associated with TTE. None of the loci with p<1E-6 overlapped between the two definitions.

Conclusions: Genetic variants associated with CKD progression differed based on the definition of the phenotype. GWAS of TTE identified more loci at p<1E-6 than slope, and these were biologically more plausible based on current knowledge of kidney disease. However, the number of genome-wide significant loci was the same.

SA-PO521
New Candidate Genetic Loci Associated with Pediatric Proteinuria in the CKiD Cohort
Sophie Limou,1 Dennis Ng,1 Kimberly J. Reidy,1 Robert Wortoniecki,1 Susan L. Furth,2 Bradley Warady,2 Craig S. Wong,1 Jeffrey B. Kopp,1 Cheryl Ann Winkler,1 Frederick J. Kaskel,1 Leidos Biomedical Research Inc; NCI-Frederick National Laboratory; Johns Hopkins Bloomberg School of Public Health; Children’s Hospital at Montefiore/ Albert Einstein College of Medicine; Stony Brook Univ Hospital; Children’s Hospital of Pennsylvania; Children’s Mercy Hospital; Univ of New Mexico; NIDDK, NIH.

Background: Proteinuria is an early marker for chronic kidney disease in adults and children. Here, we sought to identify genetic variants associated with baseline proteinuria in African American children diagnosed with chronic kidney disease from the CKiD cohort.

Methods: We genotyped 149 CKD participants using the Illumina HumanMethylation450 BeadChip v2.1 comprising over 250,000 markers, including putative functional exonic variants that were implicated in common metabolic disorders. 81,460 SNPs passed quality control and were tested for association with baseline proteinuria in 129 children with chronic kidney disease. T-tests were adjusted for age, gender, and the first five eigenvectors from the population stratification analysis.

Results: We identified several genetic loci that were significantly associated with proteinuria (PE100), as well as new candidate loci (10-90-10). Among the top hits, we notably revealed gene-expressed genes that were previously associated with the TGFbeta pathway, renal homeostasis, IgA nephropathy, congenital kidney disease, and vascular integrity (e.g. V4P3, STRA4, and HDAC7).

Conclusions: Our study emphasizes the power of unbiased large genetic screenings to discover new factors associated with pediatric kidney conditions. These new results warrant independent replication and functional validation.

SA-PO522
Genotype-Phenotype Analysis in Pediatric Patients with WT1 Glomerulopathy Eunjin Park,1 Yo Han Ahn,1 Hee Gyung Kang,1 Hye Won Park,1 IL-Soo Ha,1 Hae Il Cheong,1,2 Dept of Pediatrics, Seoul National University Children’s Hospital, Seoul, Korea; Research Coordination Center for Rare Diseases, Seoul National University Hospital, Seoul, Korea; Dept of Pediatrics, Seoul National Univ Bundang Hospital, Seongnam, Korea.

Background: The WT1 gene plays an essential role in urogenital and kidney development and its mutations manifest two different types of glomerulopathies, Denys-Drash syndrome (DDS) and Frasier syndrome (FS). In this multicenter retrospective cohort study, genotype-phenotype correlations in Korean pediatric patients with WT1 mutations were analyzed.

Methods: During the period from 2001 to 2015, WT1 mutations were detected in a total of 28 patients by gene screening.

Results: The patients were grouped into FS (n=10, having a mutation in intron 9) and DDS (n=13, having an exon mutation). Nine (69%) DDS patients presented as congenital nephrotic syndrome (CNS) or infantile nephritic syndrome (INS), while 7 (70%) FS patients presented as segmental focal segmental glomerulosclerosis. Interestingly, monoxynogotic twin patients with DDS presented as end-stage renal disease (ESRD) without any previous history of glomerulopathy. Progression to ESRD was noted in 11 (85%) DDS patients at the median age of 0.22 (interquartile range [IQR], 0.07-1.65) years and in 5 (50%) FS patients with a median age of 16.50 (IQR, 10.16-16.50) years. 10 (77%) DDS patients died at the median age of 0.22 (IQR, 0.07-1.65) years, whereas 2 (26%) FS patients presented as congenital nephrotic syndrome at the median age of 0.22 (IQR, 0.07-1.65) years. Disorder of sexual development (DSD) was accompanied in 8 (62%) DDS and 7 (70%) FS patients. Three (13%) patients (2 with DDS and 1 with FS) had diaphragmatic defect/ hernia. Five (22%) and six (26%) patients underwent prophylactic nephrectomy and gonadectomy, respectively. Among the rest of the patients, Wilms tumor and gonadal/blastoma developed in 3 DDS patients and 1 FS patient, respectively.

Conclusions: The clinical manifestations and disease course of the Korean patients with WT1 glomerulopathy were mostly same as those of previous reports. Of note, patients with DDS presented as congenital nephrotic syndrome manifested two different types of glomerulopathies, Denys-Drash disease by linear regressions adjusted for age, gender, and the first five eigenvectors of recombination in each generation for n generations from 6 to 48.

Methods: Inheritance of the V260E mutation from two parents with a common ancestor will result in a region of homozygosity surrounding the locus, indicating the overlap of extended haplotypes preserved around the locus. To test for this we genotyped 10 individuals homozygous for the mutation, and 74 individuals homozygous for the wild type variant, with the Illumina exome chip. After QC, this chip provided 1674 markers within 20 megabases (Mb) of V260E. To predict the distribution of lengths of homozygous regions around the locus as a function of the number of generations between parents and their common ancestor carrying the mutation, we performed 10,000 coalescence simulations of recombination in each generation for n generations from 6 to 48.

Results: Plotting heterozygous and homozygous loci in the region surrounding V260E clearly showed regions of homozygosity around the locus. 8 of the 10 individuals had segments of homozygosity from 1.9 to 3.6 Mb. This distribution of lengths is inconsistent with a common ancestor within the last 20 generations.

Conclusions: Cryptic consanguinity does not explain the presence of homozygosity for NPHS2 V260E among Durban children with SR-FSGS. The indicated age of the mutation is consistent with introduction by the Omanii Empire, which spread in East Africa beginning in the 1600s.

Cell-Free Hemoglobin and HMox1 in Sickle Cell Nephropathy

Santosh Saraf,1 Xia Zhang,1 Binal N. Shah,1 Krishnamurthy P. Guidehi,2 Jose A.L. Arruda,1 Ashok K. Singh,2 Victor R. Gordeuk.1 1Medicine, Univ of Illinois at Chicago, Chicago, IL; 2Nephrology, John H. Stroger, Jr Hospital of Cook County, Chicago, IL.

Background: Chronic kidney disease (CKD) is observed in over 50% of adults with sickle cell disease (SCD) and hemoglobinuria, a consequence of intravascular hemolysis, is independently associated with CKD stage and its progression. In this study we investigate the mechanistic role of hemoglobinuria and HMox1, the rate limiting enzyme for heme metabolism, in SCD nephropathy.

Methods: Urinary tubular (kidney injury molecule-1, KIM-1) and glomerular (neprhin) biomarkers of injury were measured in 32 SCD patients by ELISA from the University of Illinois at Chicago (UIC). We then cultured human-kidney (2HK) tubular cells with lyophilized hemoglobin (L-Hb) to determine biological responses and expression of candidate genes. We examined the association of KIM with 11 tag SNPs and the GT-repeat polymorphism in HMox1 in 247 UIC SCD patients and in a separate replication cohort (Walk-PhaSt) of 482 SCD patients.

Results: Urine KIM-1 correlated with increasing urine cell-free hemoglobin concentration (P=0.005), while urine nephrin levels did not. HK2 culture studies showed increasing KIM-1 concentrations in the culture medium (P=0.01), decreasing HK2 cell viability (P=0.01), increased HMox1 expression (P=0.0001) and protein concentration (P<0.0001) with incremental concentrations of L-Hb. We identified a SNP in HMox1 (rs7438111, MAF=0.14) that was significantly associated with KCD stage (OR 2.8, P=0.0093) and CKD stage 3 (OR 3.0, P=0.02) in the UIC cohort and with ESRD (OR 9.8, P=0.0004) and CKD stage 3 (OR 2.3, P=0.04) in our replication cohort. UIC SCD patients with E25 GT-repeat in the promoter region of HMox1, known to be associated with increased HMox1 inductability and activity, had higher estimated glomerular filtration rate (eGFR)(P=0.2, P=0.01).

Conclusions: Cell-free hemoglobin contributes to sickle cell nephropathy through renal tubular injury. A tag-SNP in HMox1, rs743811, was associated with kidney disease and the presence of shorter (GT)n repeats correlated with increasing eGFR, raising the possibility that altered HMox1 activity has a critical role in SCD-nephropathy.

Differences in Susceptibility to Cisplatin Nephrotoxicity Among 8 Mouse Strains

Gabor Bodonyi-Kovacs, Rosa Chan, Thu H. Le. Renal Div, Univ of Virginia, Charlottesville, VA.

Background: Cisplatin is a widely used chemotherapeutic agent with remarkable efficacy, but its use is limited by significant nephrotoxicity. Significant differences in susceptibility to nephrotoxicity among individual mouse strains have been noted, but predicting those at risk remains a challenge. To begin to identify genes that play a role in susceptibility to cisplatin nephrotoxicity (CPN), we set out to determine differences in CPN among 8 genetically distinct founder mouse strains of the Collaborative Cross: A/J, C57BL/6J, 129S1/SvJ, NOD/ShiLtJ, NZO/HIL1CAST/EJ, PWK/Phl, and WSB/EJ.

Methods: 10-14 week old male mice received ip. injection of 25 mg/kg cisplatin and serum was collected 72 hours later to sacrifice. Serum urea nitrogen (BUN) was measured for the 8 strains using a nonenzymatic, colorimetric kit (Arbor Assays) and analyzed by one way ANOVA and two sided t-test. Serum creatinine was measured using an enzymatic, colorimetric kit (Crystal Chem) and analyzed by a two sided t-test for the 2 strains that showed the largest difference in BUN.

Results: The 8 strains differed significantly in their serum BUN values (p=0.042). The number of animals in each group, and the mean and SD of BUN (mg/dl) were as follows: C57BL/6J (n=14) 188.6±9.2, CAST/Eij (n=3) 207.9±32.7, NOD/ShiLtJ (n=5) 256.7±93.0, PWK/Phl (n=4) 240.9±57.2, WSB/EJ (n=5) 254±15.6, A/J (n=5) 267.6±62.3, NZO/HIL1 (n=5) 290.0±50.7, 129S1/SvJ (n=4) 319.5±28.3. The biggest differences were seen between the C57BL/6J and 129S1/SvJ strains, (p=0.0001). In direct comparison the serum creatinine was significantly different between C57BL/6J (n=10) and 129S1/SvJ (n=9) strains, (p=0.0084) (Figure 1).

subjects. Among healthy Montreal newborns, this same PAX2 SNP (rs11190739) was associated with a 10.2% decrease in newborn combined kidney volume in 14.6% of babies who were heterozygous for this common variant (p=0.036).

**Conclusions:** Our study provides the first evidence that a common PAX2 variant associated with newborn renal hypoplasia is also associated with decreased eGFR among Caucasians with diabetes mellitus for 15-25 years.

Cefepime Dosing in Modeled Critically Ill Patients Receiving SHIFT Hemofiltration or Hemodialysis Renal Replacement Therapies

Katherine N. Gharibian, Susan J. Lewis, Bruce A. Mueller. College of Pharmacy, Univ of Michigan, Ann Arbor, MI.

**Background:** Cefepime is an antibiotic commonly used in the ICU where acute kidney injury (AKI) is prevalent. SHIFT therapy, a 6-12 hour renal replacement therapy (RRT), also referred to as Prolonged Intermittent Renal Replacement Therapy (PIRRT) or Slow Low Efficiency Daily Dialysis (SLEDD), is increasingly utilized to help treat AKI. However, dosing information for cefepime in critically ill patients receiving SHIFT therapy is currently lacking.

**Methods:** Using previously-published pharmacokinetic (PK) data and a PK model developed for critically ill patients receiving SHIFT RRT, a series of 5000-subject Monte Carlo simulations were performed for 18 cefepime regimens in 8 scenarios with varying duration (8 & 10 hr), effluent rate (4 & 5 L/hr), modality (HF/HD), and time of SHIFT relative to cefepime doses. Cefepime regimens were evaluated on the probability of attaining a free drug concentration equal to at least the minimum inhibitory concentration (MIC) for ≥60% of the dosing interval during the first 48 hours of therapy. Optimal regimens yielded a probability of target attainment (PTA) ≥90% for MIC values ≤8 mg/L using the smallest total daily dose.

**Results:** Cefepime 1 g q6h hours with a 2 g loading dose was the only regimen to yield a PTA ≥90% in all 8 SHIFT settings while limiting the total daily maintenance dose to 4 g. This dosing regimen resulted in 48-hour mean trough concentrations >32 mg/L in most subjects.

**Conclusions:** In PK models of critically-ill subjects receiving 8 or 10 hours of SHIFT RRT, a cefepime dose of 1 g q6h hours with a 2 g loading dose yielded pharmacodynamic target attainment for >90% of the population.

Identification of Optimal Ceftazidime Dosing Regimens in Modeled Critically Ill Patients Receiving SHIFT Renal Replacement Therapy

Katherine N. Gharibian, Susan J. Lewis, Bruce A. Mueller. College of Pharmacy, Univ of Michigan, Ann Arbor, MI.

**Background:** Ceftazidime is an antibiotic commonly used in critically ill patients. Ceftazidime doses of 2 g every 12 hours have been recommended for continuous renal replacement therapies (CRRT), however, no studies have evaluated the optimal dose in patients receiving SHIFT Therapy (NxStage Medical), a 6-12 hr RRT commonly referred to as Prolonged Intermittent Renal Replacement Therapy (PIRRT) or SLEDD, according to the shifts in settings including duration (8 & 10 hr), effluent rate (4 & 5 L/hr), modality (HF/HD), and time of SHIFT relative to cefazidime dose. Using a series of 5000-subject Monte Carlo simulations, 12 cefazidime regimens were applied to each model and evaluated for the probability of attaining free drug concentrations equal to or greater than the minimum inhibitory concentration (MIC) of Ceftazidime administered in 4 g total daily doses (2 g q12h; 1 g q6h) yielded a PTA ≥90% in all 8 RRT models. Continuous infusion of the drug (3 g continuous infusion with a 2 g loading dose) achieved similar PTA values.

**Conclusions:** Published ceftazidime CRRT doses (2 g every 12 hours) yielded 90% PTA in modeled critically ill patients receiving 8 or 10 hours of SHIFT RRT. Future studies should validate these findings in the clinical setting.

**Funding:** Pharmaceutical Company Support - NxStage Medical, Inc.

Use of Monte Carlo Simulation to Determine Optimal Meropenem Regimens in Patients Receiving SHIFT Renal Replacement Therapy

Susan J. Lewis, Katherine N. Gharibian, Bruce A. Mueller. College of Pharmacy, Univ of Michigan, MI.

**Background:** Current antibiotic dosing regimens often result in subtherapeutic concentrations in critically ill patients, but scant pharmacokinetic (PK) data exist to support antibiotic dosing. This study applied Monte Carlo simulations (MCS) to determine the initial meropenem regimen to treat critically ill patients receiving SHIFT Renal Replacement Therapy (RRT), a daily prolonged intermittent RRT.

**Methods:** Body weight & PK parameter [non-renal clearance, free fraction, volume of distribution & extraction coefficients] estimates with variability were obtained from relevant published studies. Values were randomly selected from the log-Gaussian distribution within the assigned limits to vary individual free meropenem concentration profiles. MCS were performed for 13 meropenem regimens including weight-based and pre- & post-SHIFT dosing, in 4 different SHIFT settings (4L/hour x 10 hours or 5L/hour x 8 hours in hemodiagnosis or hemofiltration) occurring either at the beginning of or 14-16 hours after meropenem infusion. Probability of target attainment (PTA) was evaluated using a pharmacodynamic target of ≥40% free meropenem concentrations above 4 times the minimum inhibitor concentration (TI<4xMIC) for Pseudomonas aeruginosa (2 µg/mL) for the first 48 hours of therapy. A ≥90% of PTA with the smallest daily dose was defined as optimal.

**Results:** Meropenem regimens using 2g/day attained ≥90% PTA. Meropenem 1g q12h and 1g given pre- & post-SHIFT were optimal regimens for all SHIFT settings. Weight-based dosing did not yield better target attainment than fixed-dose regimens.

**Conclusions:** This simulation indicates that meropenem regimens using 2g/day should be used initially to treat critically ill patients receiving 8 or 10 hour SHIFT RRT. These results warrant clinical validation.

Evaluation of Piperacillin/Tazobactam Regimens in Patients with SHIFT Renal Replacement Therapy: Susan J. Lewis,1 Katherine N. Gharibian,1 Ashita J. Tolwani,2 William Henry Fissell,3 Bruce A. Mueller.1 1College of Pharmacy, Univ of Michigan, MI; 2Univ of Alabama, AL; 3Vanderbilt Univ, TN.

Background: SHIFT Renal Replacement Therapy (RRT) is a prolonged intermittent RRT to treat critically ill patients with acute kidney injury, but lack of antibiotic pharmacokinetic (PK) data in this RRT limits its utility. This study evaluated probability of target attainable (PTA) of piperacillin/tazobactam regimens recommended in critically ill patients receiving SHIFT RRT, using Monte Carlo Simulations (MCS).

Methods: Mathematical PK models were constructed using literature-derived demographic/PK data with known variability. Four daily-SHIFT settings (hemofiltration or hemodialysis with effluent rates of 5L/hour x 8 hours or 4L/hour x 10 hours) occurring at 2 different times relative to drug dose were modeled. PTA of 13 piperacillin regimens (2-4g q6h-8h and 3 tazobactam regimens (0.5g q6h) with intermittent or prolonged infusion (4-hour or continuous) were evaluated. MCS generated free drug concentration profiles for each regimen in the 5,000 virtual patients. Pharmacodynamic targets were >90% of time free piperacillin concentrations above 4x the minimum inhibitory concentration (MIC) of Pseudomonas aeruginosa (16 µg/mL) and ≥50% of time free tazobactam concentrations above corresponding threshold (4 µg/mL) for the initial 48-hour-therapy. The optimal regimen required ≥90% of PTA for both agents.

Results: The attainment of ≥90% of PTA required piperacillin 16g/day and tazobactam 2g/day in all SHIFT settings. Prolonged infusion was not superior to intermittent infusion to yield better PTA in patients receiving SHIFT RRT.

Conclusions: Piperacillin/tazobactam 4.5g q6h is recommended for critically ill patients receiving 8 or 10 hour SHIFT RRT. These PK simulation results need to be clinically validated.

Beta-Blocker Dialyzability in Chronic Hemodialysis Patients: Alvin Tieu,1 Thomas Velenosi,1 Andrew S. Kucey,1 Laura Elisabeth Mccuaig,1 Matthew A. Weir,1 Brad Urquhart.2 1Dept of Physiology and Pharmacology, Schulich School of Medicine and Dentistry, London, ON, Canada; 2Dept of Medicine, Div of Nephrology, Western Univ, London, ON, Canada.

Background: There is a paucity of data available to describe beta-blocker dialyzability. Of the available information, most were obtained prior to implementation of high-flux dialysis membranes. This study aims to characterize the dialyzability of four of the most commonly prescribed beta-blockers in patients undergoing conventional high-flux hemodialysis (HD). Based on physicochemical properties, we hypothesize atenolol and metoprolol to be extensively removed by HD, while bisoprolol and carvedilol to be poorly dialyzed.

Methods: HD patients from the London Health Sciences Centre were recruited for a Dialyzer and Recovery Clearance study investigating the removal of piperacillin (1 g) and tazobactam (0.5 g) from plasma. A total of 10 patients were included and dialysis was performed until a minimum of 90% removal was obtained. The plasma samples were collected prior to and at various times during dialysis.

Results: Following dialysis, 6.78 mg of atenolol, 0.66 mg of bisoprolol, 0.02 mg of carvedilol, and 1.53 mg of metoprolol were recovered in spent dialysate. The amounts of diazylized beta-blockers were applied in the recovery clearance method to produce dialytic clearance values of 124.0, 91.5, 1.3, and 150.2 mL/min for atenolol, bisoprolol, carvedilol, and metoprolol, respectively.

Conclusions: Beta-blocker efficacy can be hindered if substantial dialytic clearance occurs. Accordingly, atenolol and metoprolol were extensively cleared by HD, while carvedilol displayed low dialyzability. Contrary to previous literature, our data suggests moderate dialyzability for bisoprolol. With recent studies indicating heightened recurrence risk in HD patients prescribed highly-dialyzable beta-blockers, drug dialyzability data is critically important to optimize pharmacotherapy in HD patients. Definitive characterization of beta-blocker dialyzability can allow for determination of post-dialysis supplemental drug dosing strategies. Patients.

Rituximab Exhibits Altered Pharmacokinetics in Patients with Membranous Nephropathy: Uma R. Foegi,1 Visit Cheungpasitporn,2 David Bourne,1 Fernando C. Fervenza,2 Melanie S. Joy.1 1Schools of Pharmacy and Medicine, Univ of Colorado, Aurora, CO; 2Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.

Background: Rituximab (RTX) is an anti-CD20 antibody used in the treatment of glomerular diseases including membranous nephropathy (MN). There is little information about the pharmacokinetics of therapeutic proteins, including RTX in patients with glomerular diseases. The study evaluated rituximab pharmacokinetics in patients with MN from a pilot investigation(Fervenza et al, 2010).

Methods: Patients with MN (n=20) received 4 RTX weekly IV infusions (375mg/m²), with a repeat of the identical treatment at 6 months. Patient baseline characteristics were: gender (17M/3F), age (49±13.3 y), BSA (2.22±0.24 m²), urinary protein excretion (11.3±4.1 g/d), creatinine clearance (72.3±33 mL/min). Pharmacokinetic analysis was performed using rituximab-plasma concentrations. Comparisons of pharmacokinetic parameters were made between the MN patients and published data from other populations.

Results: The MN population had a favorable reduction in urinary protein excretion 3 months after each RTX treatment course (7393±4114 mg/day and 4131±3441 mg/day, respectively), while creatinine clearance values were similar to baseline (72±31 mL/min and 82±37 mL/min, respectively). Patients with MN exhibited a shortened half-life (T1/2), greater volume of distribution (Vd), and enhanced clearance of RTX vs. previous reports in other patient populations. These characteristics resulted in an exposure (AUC) that was significantly reduced in patients with MN.

Conclusions: The pharmacokinetics of RTX in patients with MN are significantly altered compared to published data from cancer and autoimmune populations. These results suggest shorter T1/2 and lower exposures to RTX in MN may necessitate higher doses and/or changes to dosing frequency in order to elicit an optimal therapeutic effect.

Eculizumab Treatment Efficiently Prevents C5 Cleavage without C5a Generation in Atypical Hemolytic Uremic Syndrome: Gretthe Bergseth,1 Nicole Van De Heuvel,2 Lambertus P.W.J. Van den Heuvel,1 Tom Eirk Mollnes.2 1Dept of Physiology and Pharmacology, Schulich School of Medicine and Dentistry, London, ON, Canada; 2Radboud Univ Medical Center, Nijmegen, Netherlands; Nordland Hospital, Bodø, Norway.

Background: The C5 inhibitor eculizumab has been successfully used to treat atypical hemolytic uremic syndrome (aHUS), however, available data on pharmacodynamics of this medication are limited. Recently, increased generation of C5a in a single patient with HELLP syndrome treated with eculizumab has been reported. Since this observation was unexpected, we aimed to reproduce these data and search for possible explanations for the findings.

Methods: Levels of C5a were analyzed in EDTA plasma samples of aHUS (n=3) patients using three commercial ELISA kits, one of the kits was also used in the HELLP study and other two kits were included as controls. The samples were collected before the first eculizumab dose and then at various time points during treatment.

Results: In line with the report on HELLP patient, the C5a values, measured by one of the commercial ELISA kits, increased significantly in all aHUS patients after the first eculizumab dose as compared to the values obtained before treatment (p<0.016). C5a remained elevated throughout the treatment period. Such increase could not be reproduced by using another two commonly available commercial kits. When eculizumab was added in vitro to normal human serum prior to activation, no generation of C5a was measured by all used kits.

Conclusions: Our data indicate that existing commercial assays require validation for specificity before being used to monitor effect of eculizumab, especially in clinical laboratory practice. This example illustrates how false conclusions can be drawn when based on results from one single commercial assay not satisfactorily validated for the purpose it is used.

Sensitive, Reliable and Easy-Performed Laboratory Monitoring of Eculizumab Therapy in Atypical Hemolytic Uremic Syndrome: Elena Volokhina,1 Nicole Van De Kar,1 Gretthe Bergseth,2 Theo J. Van der Velden,3 Jack F. Wetzels,1 Lambertus P.W.J. Van den Heuvel,1 Tom Eirk Mollnes.2 1Radboud Univ Medical Center, Nijmegen, Netherlands; 2Radboud University, Nijmegen, Netherlands; 3Nordland Hospital, Bodø, Norway.

Background: Atypical hemolytic uremic syndrome is a severe renal illness caused by complement dysregulation. Treatment with the complement C5 inhibitor eculizumab is effective, but associated with high costs. Laboratory monitoring of these patients with eculizumab therapy is therefore of great importance, but laboratory assays are still not widely available.

Methods: We evaluated the performance of three commercially available C5a ELISA kits (Bender, MyBioSource, and Empower) on EDTA plasma samples from patients with atypical hemolytic uremic syndrome treated with eculizumab. The kits were compared to a recently published calibration curve. The performance characteristics of these kits were determined in a blinded, quality controlled study.

Results: The performances of all kits were within the limits of recommendation. The kits were used to monitor the therapy of 10 patients with atypical hemolytic uremic syndrome. The time to reach the initial C5a nadir, and the number of days until the C5a concentration reached the treatment threshold was significantly lower compared to historical controls. The results of this study are consistent with published data from other institutions.

Conclusions: Eculizumab treatment is well tolerated by patients with atypical hemolytic uremic syndrome. The monitoring of C5a levels using commercially available kits is feasible and reproducible. Further studies are needed to establish the optimal monitoring strategy.

Funding: Government Support - Non-U.S.
respect to complement function has not been standardized. The aim of this study was to evaluate level complement functional assays for their application in routine follow-up of eculizumab-treated patients.

Methods: Complement activity in serum samples was analyzed using Wieslab® complement screen assay. The presence of eculizumab-C5 complexes in serum, EDTA plasma samples and in urine was measured using ELISA. Levels of scf5b-9 in urine were measured using electroluminescent epitope assay.

Results: First, we documented that the Wieslab® complement screen assay showed a sensitivity of 1-2% of C5 activity by adding purified C5 or normal human serum to a C5 deficient serum. Second, we documented that all the patient samples obtained during the standard treatment course, were completely blocked for terminal complement pathway activity. Moreover, complement remained fully blocked when intervals between the eculizumab infusions were extended to four weeks. Levels of complexes between eculizumab and C5 were inversely correlated to the complement activity (p=0.01). Third, titrating serum from eculizumab-treated patients into normal serum, revealed that eculizumab was present in excess up to four weeks after infusion. Finally, we showed that increased urine scf5b-9 disappeared after eculizumab treatment.

Conclusions: We demonstrate sensitive, reliable and easy-performed assays to monitor eculizumab-treated patients, which can be used to design individual dosage regimens.

Funding: Government Support - Non-U.S.

SA-PO537

Background: AKB-6548 is a novel, once-daily, oral hypoxia-inducible factor prolyl-hydroxylase inhibitor (HIF-PHI) in development for the treatment of anemia in non-dialysis dependent (NDD) and dialysis dependent (DD) chronic kidney disease (CKD). Studies in NDD-CKD patients have shown AKB-6548 produces physiologic increases in erythropoietin, enhances iron mobilization, and produces a dose dependent increase in hemoglobin levels.

Methods: The pharmacokinetics (PK) of AKB-6548 have been evaluated in single and multiple dose studies in healthy volunteers and CKD patients (NDD-CKD and DD-CKD) over a broad range of dose levels. An analysis of results across studies was conducted to assess the potential impact of renal function on selecting the dose levels and dosing regimen in CKD patients. The analyses evaluated dose-linearity in drug exposure, clearance routes of AKB-6548 and its metabolites, as well as the impact of CKD severity and the hemodialysis procedure on drug disposition.

Results: In healthy volunteers, AKB-6548 demonstrated dose linearity and proportionality over single doses of 80-1200 mg and multiple doses of 500-900 mg/day. The PK parameters of AKB-6548 in healthy volunteers, NDD-CKD and DD-CKD patient populations except for a slightly longer half-life with declining renal function (4.7 hr., 7.9 hr. and 9.1 hr., respectively). A mass balance study (using 13C-labeled drug) in healthy volunteers demonstrated both renal and fecal routes of parent drug and metabolite clearance, supporting use of AKB-6548 in CKD patients without significant differences in drug exposure. Moreover, AKB-6548 was minimally cleared by the hemodialysis procedure and the PK parameters were similar whether AKB-6548 was administered prior to or following dialysis.

Conclusions: The results demonstrate a linear dose-exposure relationship for AKB-6548 over a wide range of dose levels and support the utility of once-daily dosing and similar dose levels across the spectrum of CKD severity.

Nonclinical Pharmacokinetics and Toxicokinetics of RG-012, an Inhibitor of MicroRNA-21 Being Investigated for Treatment of Alport Syndrome John Stewart Grundy,1 Kai Liu,2 Steven Neben,3 Cindy L. Berman,2 Deidre Mackenna,1 Neil W. Gibson,1 2Regulus Therapeutics, San Diego, CA;2Berman Consulting, Wayland, MA.

Background: RG-012 is a single-stranded chemically modified oligonucleotide being developed to treat patients with Alport syndrome, which is characterized by loss of renal function associated with defects in specific collagen genes expressed in the kidney glomerular basement membrane. RG-012 inhibits miR-21, a microRNA target known to have increased expression in context of kidney stress and associated with renal dysfunction.

Methods: In vitro pharmacokinetic (PK) evaluations of RG-012 conducted during preclinical development included: tissue protein binding, metabolic stability in whole blood and liver lysates, and CYP3A5 inhibition/induction potential in cryopreserved human hepatocytes. In vivo PK and toxicokinetic (TK) properties of RG-012, and its major active metabolite (G0005), were determined upon subcutaneous dosing of RG-012 in a set of nonclinical PK, pharmacology, and safety studies in CD-1, SV129, and COL4A3 mice (62.5 mg/kg weekly) and folicacid-dependent mice (3x225 mg/kg/wk).

Results: Both RG-012 and RG0005 were highly bound (≥98%) to proteins in plasma from mice, monkeys, and humans. RG0005 was the only major degradation product seen from mice, monkeys, and humans. RG0005 was the only major degradation product seen from mice, monkeys, and humans. RG-012 demonstrated dose dependent displacement of miR-21 from polysomes in both liver and kidney with a maximum effect reached at dose levels that are efficacious in the Col4A3 mouse models. Loss of miR-21 from the polysomes was specific as levels of Let-7a, a control microRNA to which RG-012 has no complementarity, were unaffected. In the liver, target engagement was also assessed using mRNA derepression of a set of confirmed miR-21 target genes. Here, target gene derepression strongly correlated with polysome displacement. This comparison was not possible in kidney, however, because target genes are not regulated in kidneys in the absence of stress.

Conclusions: RG-012 directly and specifically inhibits miR-21 resulting in its displacement from actively translating polysome complexes and subsequent derepression of messenger RNA targets.

SA-PO540
Tacrolimus Pharmacokinetics in Nephrotic Stage Maria Medeiros,1 Saul Valverde,1 Luis Velasquez-Jones,1 Ana M. Hernandez,2 Gilberto Castaheda-Hernandez,2 Guido Filler.1 Hospital Infantil de México Federico Gomez, Mexico;2CINVESTAV, IPN, Mexico;1Children’s Hospital, Univ of Western Ontario, Canada.

Background: While tacrolimus (Tac) therapy is not first-line therapy for childhood nephrotic syndrome, it is often used instead of cyclosporine to ameliorate the side effects. The pharmacokinetics of Tac can be influenced by many conditions, and it has a high plasma protein binding. The Tac pharmacokinetics during relapse and remission of childhood nephrotic syndrome have not been well described.

Methods: We performed 14 pharmacokinetic (PK) profiles (with measurements before and 0.5, 1, 2, 4 and 12 hours post intake) in 7 children with steroid-resistant nephrotic syndrome (SRNS) during relapse and in remission. These data were compared with historical PK data of 161 PK profiles in 87 pediatric renal transplant recipients with measurements before, 0.5, 1, 2, 4, 6, 8 and 12 hours post intake. Tac levels were measured using the Abbott Tacro II assay. We used descriptive statistics to generate percentiles and compared these with the SRNS patients. We also compared the PK profiles during relapse and remission.

Results: Median age of SRNS patients was 3.2 years. Tacrolimus dose, biochemical values and pharmacokinetics parameters are shown in Table 1. Values as median and interquartile range.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

747A
The PK profiles were well within the percentiles of the transplant children. **Conclusions:** Tac profiles are not different in children with nephrotic syndrome during relapse and remission. **Funding:** Government Support - Non-U.S.

*Clinical and Genetic Determinants of Longitudinal Dose-Corrected CNI Exposure in Chilren Under Renal Transplantation*  
_Norrel Knox,1 Elena N. Lofts,2 Dirk R. Kuppers,2 Pediatric Nephrology, Univ Hospitals Leuven, Belgium; 2Nephrology, Univ Hospitals Leuven, Leuven, Belgium.*

**Background:** Calcineurin-inhibitors (CNI) have a narrow therapeutic index and dosing is difficult due to inter- and intra-individual variation in pharmacokinetics (PK). Polymorphisms in genes involved in drug metabolism can play a critical role in individual exposure. Data concerning long-term CNI exposure in relation to dose in children are scarce and in general based upon trough levels. We present the longitudinal follow up of 124 children in the period from the time of transplantation to 1-year post transplant in relation to dose, clinical and genetic factors in a cohort pediatric renal allograft recipients.

**Methods:** Retrospective single center study in subjects after renal transplantation (age 0-20 years) with annual PK assessments (6-point AUC0-12hr) for tacrolimus (Tac) or cyclosporine (CsA). Clinical and laboratory data were retrieved. Analysis of polymorphisms in CYPIA4, CYPIA5, CYPIA7, POR, CYP3A4, CYP3A5, CYP3A7, CYP2C9 was performed.

**Results:** We collected 180 “full” AUCs for Tac, 56 for CsA in 51 kids. Mean age at Tx: 9.9 yrs (1-19). FU after Tx: 4.6 yrs (0-16). Dose-corr exposure according to BS, in contrast to bodyweight, CL/LBW were noted with sex sub-analysis and summarized as Phenotypic Mean with Underline represents presenting author.

**Conclusions:** Sex-race differences in Tac PK contribute to differential dosing requirements in AA vs C. A more individualized approach to chronic Tac immunosuppression integrating sex-race with TDM and a standardized adverse effect assessment may benefit RTR. **Funding:** NIDDK Support, Pharmaceutical Company Support - Astellas Scientific and Medical Affairs, Inc.

**SA-PO543**

*Sex and ABCB1 Haploype Associations with Tacrolimus Pharmacokinetics in Renal Transplant Recipients*  
_Kathleen M. Tomatore,1 Daniel Brzezka,2 Calvin J. Meaney,3 Louise M. Cooper,1 Rocco C. Venuto.3 NTS Center of Excellence in Bioinformatics & Life Science; Pharmacy, School of Pharmacology & Pharmaceutical Sciences; 3GAP-Core Faculty; Schools of Pharmacy & Medicine, Univ of New England, Portland, ME; 3Medicine, ECMC, School of Medicine; 1Univ at Buffalo, Buffalo, NY.*

**Background:** Tacrolimus (TAC) is the mainstay calcineurin inhibitor for immunosuppression in renal transplant recipients (RTR). Tac exhibits interpatient variability in pharmacokinetics (PK) attributed primarily to CYP 3A5 isoenzymes and P-glycoprotein (Pgp). Pgp is encoded by the ABCB1 gene. The common single nucleotide polymorphisms (SNP): rs12367726 (T>C) and rs77752582 (C>T) have conflicting associations to TAC PK. This study objective evaluated these common SNPs as haplotypes in relation to TAC PK.

**Methods:** During a 12-hr PK study, trough (C0), apparent clearance (CL) and lean body weight (LBW) normalized CL were determined in 29 female and 36 male African American (AA) and Caucasian (C) stable RTR greater than 6 months post-transplant receiving Tac and mycophenolic acid. TAC dosage was adjusted to C0 range of 4-9 ng/ml. The ABCB1 SNPs: rs12367726 (T>C) and rs77752582 (C>T) were assessed. **Results:** TAC C0 range of 5-10 ng/ml with no difference between groups in spite of higher doses in AA (P<0.0001). Significant associations of TTT to TAC dose, CL and CL/LBW were noted with sex sub-analysis and summarized as Phenotypic Mean with Confidence Interval (CI) of WT compared to variant in table. These data suggest RTR with TTT variant received lower doses and had slower TAC CL relative to sex.

**Conclusions:** Sex-race differences in Tac PK contribute to differential dosing requirements in AA vs C. A more individualized approach to chronic Tac immunosuppression integrating sex-race with TDM and a standardized adverse effect assessment may benefit RTR. **Funding:** NIDDK Support, Pharmaceutical Company Support - Astellas Scientific and Medical Affairs, Inc.

**Conclusions:** The ABCB1 haplotypes provide important insight into interpatient variability in TAC PK post renal transplant and the role of P-gp that is also influenced by sex. **Funding:** NIDDK Support, Pharmaceutical Company Support - Astellas Scientific and Medical Affairs, Inc.
Methods: This study was undertaken in the University Hospitals of Ulm (Frieder Keller) and Heidelberg (Claudia Sommerer, Thomas Giese, Martin Zeier). Tacrolimus trough concentrations (Trough) and 1.5 – 2 hours later the peak concentrations (Peak) were measured by LCMS. Simultaneously, the Nfat trough effect (Trough) and the nadir effect (Nadir) were determined. The pharmacokinetic half-life (T1/2) was estimated from peak (Peak) and trough concentrations (Trough) considering the time distance between steady-state peak and troughs (10.5 – 10 hours). The pharmacodynamic concentration producing the half-maximum effect (CE50) and the Hill coefficient (H) were estimated from trough effect (Trough) at trough concentrations and from nadir effect (Nadir) at peak concentrations. The two equations were solved by numerical iteration for an estimate of the two unknown parameters (CE50, H).

Results: A total of 10 stable kidney transplant patients were included. The median age was 58 years and the median serum creatinine was 306 μmol/L. The pharmacokinetics of tacrolimus were estimated with T1/2 = 11 hours, CL/F = 64 L/h and Vd/F = 480 L. The median value for Nfat was 89% (Trough) of normal gene expression, and the nadir effect was 43% (Nadir) representing the strongest immunosuppression of basal gene expression. The pharmacodynamics of tacrolimus were estimated with CE50 = 7.7 ng/ml and the Hill coefficient with H = 4.6, respectively.

Pharmacodynamic Hill equation

![Figure 1: Tacrolimus pharmacokinetics (blue) and pharmacodynamics (red).](image)

Conclusions: While on triple immunosuppression, the Nfat pharmacodynamics indicate a low concentration producing the half-maximum effect and a high Hill coefficient. These findings suggest a narrow trough-to-peak target concentration range of 4.0-to-9.5 ng/ml for tacrolimus.

**SA-POS456**

Renal Nitrates in Chronic Kidney Disease

**Background:** Endogenously synthesised nitric oxide (NO) is rapidly oxidised to nitrite and nitrate. These oxidation products can be recycled back into nitric oxide via a complex entero-salivary pathway, thus preserving NO activity. It has previously been shown that 66% of circulating nitrite is excreted in the urine in 48 hours with the fate of the remainder unknown. 24-hour urinary nitrate excretion is often used to estimate total body nitrite oxide synthesis rates. It is not known what effect declining GFR has on renal nitrate clearance.

**Methods:** 27 subjects, 14M,13F, median age 70 (range 27-74 years) with CKD-EPI eGFR between 9 and 89 were recruited. Following 24hrs low nitrate diet plasma nitrate concentration and 24 hour urinary nitrate excretion were measured to determine renal nitrate clearance using a microplate spectrophotometric method. 24-hour urinary nitrate excretion is often used to estimate total body nitrite oxide synthesis rates.

**Results:** There was a statistically significant correlation between renal nitrate clearance and eGFR. Pearson r = 0.748, p<0.0001. There was no relationship between plasma nitrate concentration and eGFR, p=0.239, or between plasma nitrate concentration and renal nitrate clearance, p=0.547.

**Conclusions:** As plasma nitrate concentration is unchanged despite diminished renal nitrate clearance at lower eGFRs, we suggest that non-renal clearance is responsible for a greater proportion of nitrate elimination as GFR falls. We conclude that 24 hour urinary nitrate excretion cannot be considered a reliable measure of total body nitric oxide synthesis in CKD. Elucidating the non-renal pathways of loss of the NO storage molecule, nitrate, may lead to novel therapeutic strategies in CKD and cardiovascular disease.

The Pharmacodynamic Effect of Tenapanor Is Most Pronounced when Administered After Food in Healthy Volunteers

**Methods:** In this open-label, 3-way crossover study (NCT02226783), 18 healthy adults (mean age=SD, 35±11 years; 14 men) completed a randomized sequence of 4-day treatments with tenapanor hydrochloride 15 mg bid: before food (5–10 min before breakfast and dinner); after food (30 min after the start of breakfast and dinner); and at fasting (1 h before breakfast, and 3 h after dinner). As plasma nitrate concentration is unchanged despite diminished renal nitrate clearance at lower eGFRs, we suggest that non-renal clearance is responsible for a greater proportion of nitrate elimination as GFR falls. We conclude that 24 hour urinary nitrate excretion cannot be considered a reliable measure of total body nitric oxide synthesis in CKD. Elucidating the non-renal pathways of loss of the NO storage molecule, nitrate, may lead to novel therapeutic strategies in CKD and cardiovascular disease.

**Results:** Stool Na content was higher for tenapanor taken before food than for after food or at fasting, with least-squares mean differences significant in both cases (Table). Differences in urinary Na were not significant. The difference in stool phosphorus (P) content was significant for tenapanor taken before food versus at fasting. The difference in urinary P was significant for administration before food or after food versus at fasting. Stool frequency and consistency were similar across treatments, and there were slightly higher stool weights for administration before or after food, compared with at fasting. There were no serious AEs or discontinuations due to AEs.

1 Martin Kaufmann, 1Glenville Jones, 1Rachel M. Holden, 2Michael A. Adams, 1Biomedical and Molecular Sciences, Queen’s Univ, Kingston, ON, Canada; 1School of Medicine, Queen’s Univ, Kingston, ON, Canada.

**Background:** The lack of simple and sensitive tools for longitudinal kidney function assessment in rodent models has impeded analysis of CKD onset and progression and the impact of interventions. This study evaluates 2-sample plasma clearance (pCl) of iohexol, a radio-contrast agent, compared to previously validated inulin pCl in rats to estimate GFR.

**Methods:** Progressive CKD was induced with a 0.25% adriamycin diet in male Sprague-Dawley rats (N=8). Following serial tail vein injections of iohexol (51.92 mg/kg) and FITC-inulin (2.5 μL/kg of 5% solution), 12 saphenous blood samples were taken from conscious rats over 5 hours, weekly (control, 5 weeks of adenine). Plasma creatinine was measured via the Jaffrey method, FITC-inulin via fluorometry, and iohexol via UPLC-MS.

Two reference methods for pCl calculation were used: a 2-compartment model (2 COM) and trapezoidal approximation (TRA) of area under the curve.

**Results:** Reference methods of inulin pCl agreed well with iohexol pCl.

pCl of iohexol and inulin was significantly decreased, compared to baseline, after one week (p<0.005), whereas plasma creatinine concentration was not significantly elevated until the third week (p=0.02). Characterisation of a 1-compartment model using 2-samples was employed: samples at 30 and 90 min post injection yielded high agreement (R²=0.98) and no significant bias.

**Conclusions:** Iohexol pCl sensitively and accurately measures an early decline in kidney function, especially compared to creatinine. The 2-sample method for assessing kidney function is straightforward and is therefore suitable for large rat cohorts. This approach will both enable detection of early kidney disease and facilitate concise interpretation of results derived from pre-clinical studies.

**SA-POS547**

Renal Nitrates in Chronic Kidney Disease

**Background:** Endogenously synthesised nitric oxide (NO) is rapidly oxidised to nitrite and nitrate. These oxidation products can be recycled back into nitric oxide via a complex entero-salivary pathway, thus preserving NO activity. It has previously been shown that 66% of circulating nitrite is excreted in the urine in 48 hours with the fate of the remainder unknown. 24-hour urinary nitrate excretion is often used to estimate total body nitric oxide synthesis rates. It is not known what effect declining GFR has on renal nitrate clearance.

**Methods:** 27 subjects, 14M,13F, median age 70 (range 27-74 years) with CKD-EPI eGFR between 9 and 89 were recruited. Following 24hrs low nitrate diet plasma nitrate concentration and 24 hour urinary nitrate excretion were measured to determine renal nitrate clearance using a microplate spectrophotometric method.

**Results:** There was a statistically significant correlation between renal nitrate clearance and eGFR. Pearson r = 0.748, p<0.0001. There was no relationship between plasma nitrate concentration and eGFR, p=0.239, or between plasma nitrate concentration and renal nitrate clearance, p=0.547.

**Conclusions:** As plasma nitrate concentration is unchanged despite diminished renal nitrate clearance at lower eGFRs, we suggest that non-renal clearance is responsible for a greater proportion of nitrate elimination as GFR falls. We conclude that 24 hour urinary nitrate excretion cannot be considered a reliable measure of total body nitric oxide synthesis in CKD. Elucidating the non-renal pathways of loss of the NO storage molecule, nitrate, may lead to novel therapeutic strategies in CKD and cardiovascular disease.
Conclusions: The pharmacodynamic effect of tenapen, as judged by stool Na content, was greatest when tenapen was taken before food. This supports taking tenapen before meals in future trials.

Triferic Does Not Induce Non-Transferrin Bound Iron or Labile Plasma Iron: In-Vivo/In-Vitro Correlation Raymond D. Pratt,1 Dorine W. Swinkels,2 Carrie D. Guss,1 Ajjay Gupta.1 1R&D, Rockwell Medical Inc., Wixom, MI; 2Radioud Univ Medical Center, Nijmegen, Netherlands.

Background: Triferic is a complex iron salt approved for administration via hemodialysis to maintain hemoglobin in patients with CKD SHD. Triferic crosses the dialyzer membrane and binds to transferrin during hemodialysis replacing the obligate iron losses in HD patients. Serum iron and transferrin saturation (TSAT) values rise after HD and return to the baseline by the end of the next dialysis session.

Methods: A pharmacokinetic (PK) study in healthy volunteers administered up to 10 mg of Triferic iron over 4 hours and up to 20 mg Triferic iron over 12 hours assessed the PK of serum total iron (sFe-total) and transferrin bound iron (TBI). An in-vitro study assessed labile plasma iron (LPl). Triferic iron was added to plasma like medium (40 mg/ml human serum albumin) at a concentration range of 0 to 112 mg/dL. In addition, Triferic was added to 5 different human plasma’s (TSAT, range 10 - 46%; total iron binding capacity (TIBC), mean 374 mg/dL, range: 342-446 mg/dL) across a concentration span up to and exceeding 100% TSAT. LPl was measured in the presence of 40 mM ascorbate used dihydorodihamine (DHR)-123 in the presence of 50 mM deferiprone (DFO) to detect iron-catalyzed radical generation.

Results: In the human PK study, sFe-total and TBI showed an identical PK profile. Non-transferrin bound iron (NTBI), calculated as the difference between sFe-total and TBI, showed no dose dependent increase up to a TSAT of 100%. In plasma like medium, LPl increased with increasing concentrations of Triferic iron. When Triferic was added to human plasma, there was a small increase in LPl observed when iron concentrations were less than 100% TSAT. The mean magnitude of LPl (expressed in concentration units) at approximately 100% TSAT was 5.35 mg/dL (mean 1.4% of the total iron concentration). Once 100% TSAT was exceeded, the LPl increased rapidly.

Conclusions: Triferic rapidly donates iron to transferrin in vivo and in vitro. In vivo, at TSAT less than 100%, NTBI was minimal. In vitro, the LPl results confirm the lack of redox active iron in plasma until the plasma TIBC is exceeded.

Impact of Tubular Luminal H+/Organic Cation Antipporter, MATE, on Imatinib-Induced Fluid Retention Moto Kaiwara,1 Satohito Masuda.1 1Dept of Pharmacy, Kyushu Univ Hospital, Fukuoka, Japan; 2Dept of Research and Development of Next Generation Medicine, Kyushu Univ, Fukuoka, Japan.

Background: A tyrosine kinase inhibitor, imatinib (IMA) is the first class agent against chronic myeloid leukemia. Although little is known about mechanism involved, more than 50% of imatinib-treated patients suffering from edema. In vitro study reported that clinical blood level of IMA inhibits multidrug and toxin extrusion (MATE, SLC47A)-mediated transport of metformin, a hypoglycemic drug. MATE is highly expressed in the brush border membrane of proximal tubular cells mediating the efflux of organic cations, such as metformin, monoamines. The renal dopaminergic system is likely responsible for regulating >50% of net renal salt and water excretion when salt intake increases. In this study, we test a hypothesized that IMA prevents natriuresis by inhibiting MATE-mediated dopamine (DA) secretion into tubule lumen and consequently causes edema.

Methods: C57BL/6 wild type mice (WT) and Mate1 knockout mice (KO) were used. By RT-qPCR. CYP3A4 and CYP3A5 protein expression was examined by Western blotting. Serums were collected from critically ill adults with varying AKI severity. Hepatic drug metabolism by cytochrome P450 3A (CYP) is reduced in end stage kidney disease (ESKD) and acute kidney injury (AKI). The underlying mechanisms are uncertain. Previously we reported suppression of CYP3A4 mRNA transcription when human hepatocytes ( HepG2) were exposed to serum from ESKD patients compared to healthy adults. CYP3A4 and 5 protein concentrations were unchanged. We now investigate whether serum from patients with AKI elicits similar results.

Methods: Serum was collected from critically ill adults with varying AKI severity. Sera from KDIGO 0 (n=15) and KDIGO 3 (n=16) AKI patients were applied individually to HepG2s for 24 h, when cells were lysed. CYP3A4 and 5 gene expression was examined by RT-qPCR. CYP3A4 and CYP3A5 protein expression was examined by Western blotting. The sera were also applied to HepG2 in a pooled fashion, alongside pooled sera from adults with ESKD prior to hemodialysis (n=10) and healthy adults (n=6), to allow comparison with previous data.

Results: AKI serum exposure doubled CYP3A4 gene expression compared to No AKI serum (p=0.0055 individual and p=0.003 pooled). AKI serum CYP3A5 mRNA increased approx. 25% compared to No AKI serum (p=0.11 individual and p=0.0098 pooled).

Conclusion: The correlations observed in this study indicate that patients poorly responding to one dose or mode of albuminuria lowering intervention also respond poorly to other doses or modes of intervention in the RAS. Whether other drugs targeting pathways beyond the RAS improve individual response variability requires further study.

SA-PO550

Optimizing Between-Patient Variability in Response to Renoprotective Drugs: Meta-Analysis of Rotation Trials Sergei Petrykiv,1 Dick de Zeeuw,2 Frederik I. Persson,2 Peter Rossing,2,3 Hans-Henrik Parving,2 Gozewijn Dirk Laverman,2 Hiddo Jan Lambers Heerspink,1 1Univ Medical Center; Groningen, Netherlands; 2Steno Diabetes Center; Gentofte, Denmark; 3Univ Copenhagen, Denmark.

Background: Individual response to albuminuria lowering intervention is highly variable among patients. To investigate whether up-titrating the dose of drug, changing the mode of intervention (with similar or different drug classes), or lowering dietary sodium intake improves individual response variability, we meta-analyzed individual responses to different modes of anti-albuminuric intervention in non-diabetic and diabetic patients.

Methods: Randomized rotation trials were analyzed to assess correlation of patient-specific responses (n=216 patients) to anti-albuminuric interventions. Included studies (N=20) compared the anti-albuminuric effect of up titrating the dose of intervention in the RAS (RAS) (N=10 comparisons) and NSAIDs (N=1), rotation within the same class of RAS (e.g. ACE1 to ARB; N=5) or NSAIDs (N=3), rotation between RAS and NSAIDs (N=2), and rotation from high to low sodium intake during RAS (N=1). A two stage meta-analysis was performed. First, deeming regression was conducted in each study to assess correlation in response. Individual study results were then meta-analyzed. Albuminuria was measured in 24-hr urine samples.

Results: The albuminuria response to one dose of RAS or NSAID positively correlated with the response to a higher dose of RAS or NSAID, rotation within the same class of RAS or NSAIDs, rotation between RAS and NSAIDs, and rotation from high to low salt intake. Correlations were consistent in diabetic and non-diabetic patients.

Conclusions: The correlations observed in this study indicate that patients poorly responding to one dose or mode of albuminuria lowering intervention also respond poorly to other doses or modes of intervention in the RAS. Whether other drugs targeting pathways beyond the RAS improve individual response variability requires further study.

Acute Kidney Injury Serum Upregulates Hepatic Transcription of Cytochrome P450 3A4 and 3A5 Katie Lane,1 John Dixon,1 Ekram Nabi,2 Barbara J. Philips,1 Iain Macphee,1 Mark E. Dockrell,2 1Critical Care, St. George’s Univ of London, United Kingdom; 2South West Thames Inst for Renal Research, United Kingdom.

Background: Hepatic drug metabolism by cytochrome P450 3A (CYP) is reduced in end stage kidney disease (ESKD) and acute kidney injury (AKI). The underlying mechanisms are uncertain. Previously we reported suppression of CYP3A4 mRNA transcription when human hepatocytes ( HepG2) were exposed to serum from ESKD patients compared to healthy adults. CYP3A4 and 5 protein concentrations were unchanged. We now investigate whether serum from patients with AKI elicits similar results.

Methods: Serum was collected from critically ill adults with varying AKI severity. Sera from KDIGO 0 (n=15) and KDIGO 3 (n=16) AKI patients were applied individually to HepG2s for 24 h, when cells were lysed. CYP3A4 and 5 gene expression was examined by RT-qPCR. CYP3A4 and CYP3A5 protein expression was examined by Western blotting. The sera were also applied to HepG2 in a pooled fashion, alongside pooled sera from adults with ESKD prior to hemodialysis (n=10) and healthy adults (n=6), to allow comparison with previous data.

Results: AKI serum exposure doubled CYP3A4 gene expression compared to No AKI serum (p=0.0055 individual and p=0.003 pooled). AKI serum CYP3A5 mRNA increased approx. 25% compared to No AKI serum (p=0.11 individual and p=0.0098 pooled).

Comparison of Pooled Serum (10%) Effects on HepG2 CYP3A4 and CYP3A5
gene expression

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
CYP3A4 and 3AS protein concentrations did not differ after exposure to AKI or No AKI sera (p=0.35, p=0.43).

Conclusions: In contrast to ESKD, hepatoocyte exposure to AKI serum upregulates CYP3A4 and CYP3A5 transcription compared to No AKI serum. CYP3A4 and 3AS protein concentrations were unchanged. Further serum analysis will determine whether differences in inflammatory profiles may be responsible. The results underscores the need to view drug metabolism in AKI as distinct from that in ESKD.

The Effect of Gut-Derived Uremic Toxins on the Expression of Hepatic Drug Metabolizing Enzymes in Chronic Kidney Disease  
Thomaz Velosenoi, Alvin Tieu, Andrew S. Kucey, David A. Feere, Brad Urquhart.  
Pharmacology, Univ of Western Ontario, London, ON, Canada.

Background: Hepatic drug metabolism is altered in patients with chronic kidney disease (CKD). Previous studies suggest that uremic toxins affect drug metabolizing enzymes in CKD. We hypothesize that gut-derived uremic toxins are involved in the downregulation of hepatic drug metabolizing enzymes and that removal of gut-derived uremic toxins by AST-120 will recover hepatic CYP3A4 and CYP2C enzyme function and expression in rats with CKD.

Methods: Huh7 human hepatoma cells were treated with various uremic toxins as well as a cocktail of all uremic toxins. Chronic kidney disease was induced in male Wistar rats using 0.5% adenine supplemented into rat chow. Control rats were pair-fed to CKD animals. After 5 weeks, control and CKD animals were further divided and received 8% AST-120 or a control diet. Rats were sacrificed 8 weeks after initiation of the study and plasma and liver tissue were obtained.

Results: Indoxyl sulfate caused a concentration-dependent decrease in Huh7 CYP3A4 expression with an IC50 value of 179.8 nM. AST-120 had indoxyl sulfate, p-cresyl sulfate and hippuric acid levels significantly lower than CKD animals and similar to control animals. Hepatic CYP3A2 mRNA expression was significantly decreased by 90% in rats with CKD (P<0.05); however, rats with CKD given AST-120 had a 25% recovery in CYP3A2 mRNA expression. Rats with CKD had decreased hepatic CYP2C11 mRNA expression that was not recovered by AST-120.

Conclusions: Uremic concentrations of indoxyl sulfate decreased CYP3A4 mRNA expression in Huh7 cells. AST-120 given to rats with CKD reduced indoxyl sulfate, p-cresyl sulfate and hippuric acid levels significantly lower than CKD animals and similar to control animals. Hepatic CYP3A2 mRNA expression was significantly decreased by 90% in rats with CKD (P<0.05); however, rats with CKD given AST-120 had a 25% recovery in CYP3A2 mRNA expression. Rats with CKD had decreased hepatic CYP2C11 mRNA expression that was not recovered by AST-120.

SA-PO553

The Effect of AST-120 on Hepatic and Intestinal Drug Transporter Expression in Chronic Kidney Disease  
Andrew S. Kucey, 1 Thomas Velosenoi, 1 Alvin Tieu, 1 Stephanie E. Nevison, 1 Brad Urquhart.  
Dept of Physiology and Pharmacology, Schulich School of Medicine and Dentistry, London, ON, Canada;  
Lawson Health Research Inst, London, ON, Canada.

Background: Chronic kidney disease (CKD) is the progressive decline in renal function over time. There is a marked reduction in both renal and non-renal drug clearance in CKD. AST-120 is an oral adsorbent that promotes the elimination of gut-derived toxins that accumulate in CKD due to impaired clearance. It is hypothesized that there will be a reduction in the expression of drug transporters in CKD conditions. AST-120 will help recover drug transporter expression in CKD by decreasing uremic toxins that accumulate in CKD.

Methods: In vivo: CKD was induced in Wistar rats by treatment with adenine (0.7%) in standard rodent chow for 7 weeks. Treatment groups received AST-120 in the final 3 weeks to decrease the concentration of uremic toxins. Expression of hepatic and intestinal transporters were determined by real-time PCR. In vitro: Using the human hepatic hepatoma cell line Huh7, specific uremic toxins (e.g. indoxyl sulfate, p-cresyl sulfate, CMP3) will be tested to see if they directly impair rosuvastatin transport. Rosuvastatin uptake will be measured with ultra-performance liquid chromatography coupled to mass spectrometry.

Results: Preliminary results have shown that OATP2 expression is decreased by 25% in CKD rat livers compared to control. Treatment with AST-120 causes a significant reduction in the plasma concentration of the uremic toxins indoxyl sulfate and p-cresyl sulfate. AST-120 treatment restores OATP2 expression to control levels.

Conclusions: Decreased hepatic OATP2 expression in CKD will result in reduced clearance of substrate drugs. This could lead to toxicity if a lowered dose is not administered. On average a CKD patient will be co-prescribed 10 different drugs. Clarifying the impact of CKD on drug transporter expression and activity will help guide dosing in this patient population.

Patient Characteristics and Genes Contribute to Kidney Function After Cisplatin Therapy  
Cara A. Chang, 1 Nickie L. Johnston, 1 Madeleine Gomez, 1 Lucas Ellison, 1 Lauren Alekssunes, 2 Steven R. Kleeberger, 1 Cindy L. O’Bryant, 1 Melanie S. Joy. 1  
Skaggs Schools of Pharmacy and Medicine, Univ of Colorado, Aurora, CO;  
Ernest Mario School of Pharmacy, Rutgers Univ, NJ;  
NIEHS.

Background: It is known that kidney function can decline after a single dose of cisplatin necessitating alternate chemotherapy regimens. The current study explored the contribution of patient characteristics and polymorphisms in drug metabolism and transport genes relevant to cisplatin kidney disposition on changes to renal function.

Methods: Blood (5mL) was obtained from patients (n=206) who received cisplatin. Genetic assessments included candidate SNPs in kidney uptake and efflux transporters (SLC22A2, ABCB2, SLC22A4) and metabolism pathways (GSTA1, GSTP1, GGT1). Genotyping was performed using QuantStudio multiplex assays and coded [0(0 wt/ wt), 1(0 wt/ var), 2(0 var/ var)]. Glomerular filtration rate (GFR, mL/min/1.73m2) and changes from baseline to cisplatin at the time just prior to the second dose were calculated. Univariate and multivariate analyses were performed using patient characteristics and genotyping results.

Results: Patient demographics (mean±sd) included: age 53±14 y, weight 80±20 kg, BSA 1.9±0.3, Caucasian 90%, gender (50%/50%), and cisplatin dose (65±23 mg/m2).

Specific patient characteristics that significantly (p<0.05) contributed to a beneficial effect on GFR were non-Caucasian race, baseline GFR, and non-fractionated cisplatin dosing. Genetic variant in GSTP1/GST pi-1 variant (rs1695) and wildtypes in SLC22A2/OCT2 (rs2279463 and rs1327573) significantly (p<0.05) contributed to a beneficial effect on GFR. Variables retained in the final model (R2: 25.2%, P<0.0001) were: Change in GFR, T OF: 38.0±6.8, CO: 0.17±4.0 (weight) −0.3685 (baseline GFR) + 5.953 (GFR; rs1695).

Conclusions: The results from this study demonstrate the combined role of patient characteristics and genetic variants in drug disposition genes on changes to GFR secondary to cisplatin. Appropriate risk stratification based on patient characteristics and genetics may be used to select precision medicine to reduce the risk of kidney injury from cisplatin and potentially other nephrotoxins.

Hospital for Special Surgery;  
Duke Univ Medical Center;  
Massachusetts General Hospital.

Background: The Rituximab in AA V (RA VE) trial compared rituximab (RTX) to CYC for treatment of AAV. Using the RAVE cohort we investigated whether known single nucleotide polymorphisms (SNPs) in FcgR or CYP450 enzyme genes were associated with the response to RTX and CYC treatment, respectively. Methods: SNPs for FcgR (FcgRIIA 491G>A, FcgRIIB 695T>C, FcgRIIA 559T>G) and CYP450 (CYP2B6 1459 C>T, CYP2C19 681 G>A) were analyzed by direct sequencing of PCR-amplified genomic DNA. Each SNP was tested as a predictor of the primary outcome, complete remission at 6 months, using logistic regression including the covariates baseline BV AS/WG, ANCA type, and new versus relapsing disease. The association of these SNPs with the trial’s secondary outcomes, including time to complete remission, time to relapse, and time to B-cell reconstitution, were analyzed by Kaplan-Meier and Cox proportional hazard ratios.

Results: No significant associations were identified between FcgRIIA, FcgRIIB, CYP2B6 or CYP2C19 SNPs and the primary outcome. However, the 491AA genotype of FcgRIIA was associated with a shorter time (183: 47 versus 241: 114 days) to complete remission (p=0.001) in the entire cohort.

Conclusions: None of the SNPs tested influenced response to treatment with RTX or CYC in AAV. The finding that FcgRIIA 491G>A was associated with a shorter time to complete with both RTX and CYC implies FcgRIIA may be involved in disease pathogenesis and response to therapy.

The GSTA1 Polymorphism and Cyclophosphamide Therapy Outcomes in Lupus Nephritis Patients  
Na Hong Wang, Jin Xue.  
Nephrology, Nephrology, Shanghai, China.

Background: Pulsed low-dose cyclophosphamide (CTX) therapy has become the most effective approach in improving the clinical outcomes of lupus nephritis (LN) patients. However, variations in CTX therapeutic outcomes in LN patients are incompletely understood.

Methods: We investigated the contributions of known allelic variants in CYP2B6, CYP2C19, CYP3A5, GSTA1, GSTP1, ABC17 and ABC4 genes to CTX therapy outcomes.
in LN patients. Pharmacokinetics of CTX and 4-hydroxycyclophosphamide (4OHCTX) were obtained from 22 patients randomly enrolled from 77 LN patients and applied to explore the mechanism.

**Results:** GSTA1, one of detoxification enzymes to CTX, gene polymorphism could greatly influence the therapeutic outcome to CTX treatment in these 77 LN patients. LN patients with a GSTA1*4 mutation (CT heterozygous) had a risk of non-response (P = 0.005).

Pharmacokinetics data indicated that patients with a GSTA1*4 heterozygous variant had a lower exposure to 4OHCTX compared to wild-type patients (12.8 (9.8, 19.5) h*mg/L vs. 27.5 (18.1, 32.8) h*mg/L, P = 0.023), but not CTX. And clinical efficacy was significantly related to higher exposure to 4OHCTX (P = 0.038).

Conclusions: LN patients with GSTA1*4 heterozygous genotypes had poor CTX treatment response due to less exposure to activated 4OHCTX. A pharmacogenomic approach using the GSTA1 SNP may be useful for predicting clinical efficacy to CTX therapy in LN patients, and facilitating individualized therapy.

**CKD Induces Intrinsic Alterations in Osteoblast Response to 1,25D**

Renata C. Pereira,1 Nadine Khouzam,1 Richard E. Bowen,1 Isidro B. Salusky,1 Katherine Wesseling-Perry,1 Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; Orthopedics, David Geffen School of Medicine at UCLA, Los Angeles, CA.

**Background:** Skeletal mineralization defects are common in pediatric CKD patients. In vivo 1,25(OH)2D3 (1,25D), the only currently approved therapy for the treatment of 2HPT in children, fails to normalize skeletal mineralization in these patients. We have recently demonstrated that primary osteoblasts obtained from patients with CKD have altered proliferation, differentiation and mineralization characteristics, suggesting that CKD results in intrinsic changes to osteoblast biology, independent of circulating mineral ion and hormone concentrations.

**Methods:** To evaluate the interaction between CKD and 1,25D therapy on osteoblast maturation and mineralization, primary human osteoblasts from 3 healthy controls, 3 pediatric dialysis patients with low bone turnover (adynamic bone) and 3 pediatric patients with high bone turnover (2HPT) were cultured under pro-mineralizing conditions consisting of 10μM β-glycerolphosphate and 100 μg/ml ascorbic acid in the presence of 1,25D at 1, 10, and 100 nM. After 2, 3, and 4 weeks of growth under mineralizing conditions, cells were washed with PBS, fixed with 10% formalin, and stained with 2% Alizarin Red S. The amount of mineral was assessed by measuring absorption of acetic acid-extracted Alizarin Red S dye (at 405 nm) normalized by live cell concentration (as assessed by absorption at 570 nm) of methanol-extracted Crystal Violet staining obtained from parallel cultures.

Results: 1,25D treatment decreased proliferation and increased mineralization; however, high concentrations were required in cells from CKD patients (Figure).

Conclusions: Diminished mineralization is present in CKD; as previously demonstrated in pediatric patients. Further studies are required to assess whether PTH, IGF1 and FGF23 have an effect on mineralization of human osteoblasts.

**SA-PO557**

**Effect of Growth Factors on Bone Mineralization in Health and CKD**

Nadine Khouzam,1 Renata C. Pereira,1 Isidro B. Salusky,1 Richard E. Bowen,2 Katherine Wesseling-Perry,1 1Pediatrics, David Geffen School of Medicine at UCLA, Los Angeles, CA; 2Orthopedics, David Geffen School of Medicine at UCLA, Los Angeles, CA, United Kingdom.

**Background:** Children with chronic kidney disease (CKD) develop unexplained resistance to PTH and GH. Moreover, bone expression of FGF23 is very high in CKD. Data suggest that FGF23 may directly suppress osteoblast maturation and mineralization in mice (Weng JBM 2009); however, it is not known whether excess expression of this hormone has direct effects on bone cells in CKD. We have previously demonstrated that primary osteoblasts isolated from patients with CKD have defects in maturation and mineralization, even when removed from the uremic milieu. We thus hypothesized that CKD-mediated alterations in osteoblast maturation may contribute to a blunted response to growth factors in pediatric CKD.

**Methods:** Human osteoblasts isolated from 3 patients with CKD and 3 normal controls were grown to confluence and induced to mineralize. Cells were treated twice weekly with fresh media and 100 nm of PTH, 200ng/ml of IGFl or 10ng/ml of FGF23 for 0, 2, 3, and 4 weeks. Cell density and mineralization were assessed by staining parallel wells with crystal violet and alizarin red respectively and quantified using spectrophotometry.

Results were expressed as the mean (+ SE) in optic density. A mixed model was used to test differences in proliferation between CKD cells and healthy controls and between hormone dosages over time.

Conclusions: Cells from CKD patients mineralized at a slower rate than cells from normal controls (p<0.05). The addition of growth factors did not have a significant effect on the rate of mineralization for the same size used.

Fourier Transform Infrared Spectroscopy Crystallinity Indices in Bone from Patients with ADPKD Renata C. Pereira,1  Berenice Y. Gitomer,1 Iisidro B. Salusky,1 Diana George,2 Jason W. Stoneback,2 Karen B. King,3 Myles S. Wolf,2 Michel Chonchol,2 1Pediatrics, UCLA, Los Angeles, CA; 2Medicine, Univ of Colorado, Aurora, CO; 3Orthopaedics, Univ of Colorado, Aurora, CO; 4Nephrology, Northwestern Univ, Chicago, IL.

Background: We have previously shown that patients with autosomal dominant polycystic kidney disease (ADPKD) and normal kidney function have a low bone turnover state. This is coupled with increased expression of fibroblast growth factor 23, dentin matrix protein 1 and osteopontin in bone compared to healthy controls. To further characterize the bone defect in ADPKD we have increased ADPKD and normal bone samples. The differences were more pronounced in the cortices (1.22 vs. 1.19; p = 0.03) than in the trabeculae (1.19 vs. 1.17; p = 0.08). There were no significant differences in heterogeneity of crystallinity, mineral matrix, carbonate/matrix, collagen maturity (cross links) or acid phosphatase substitution between ADPKD and historical control samples.

Conclusions: We describe for the first time a significant difference in the chemical composition of cortical bone measured by FTIR in patients with ADPKD when compared to historical control bone samples. Bone crystallinity has been associated with bone strength and stiffness, it is thus intriguing to hypothesize that the observed changes may impact bone quality and expression of bone proteins in ADPKD. Future studies that also assess bone strength and stiffness should be required to more fully investigate bone quality in ADPKD.

Late Onset Avascular Osteonecrosis in Renal Transplant Recipients Spyridon Arampatzis, Anita Maurer, Vasileios Devetzis, Uyen Huynh-do, Nephrology, Hypertension and Clinical Pharmacology, Uni. Hospital Bern, Inselpital, Bern, Switzerland.

Background: Avascular osteonecrosis (AO) after renal transplantation (RT) is a debilitating skeletal complication. In most studies patients with AO presented with the first 24 months after RT. In order to determine the prevalence and therapeutic outcome of late onset of AO (24 months after RT) we conducted a single-center retrospective study based on radiological/historical confirmed cases.

Methods: We conducted a single-center retrospective study about our RTR with a clinical diagnosis of AO over the past two decades. We evaluated 70 cases with a AO. In 46 patients AO was radiological/historical confirmed and all relevant clinical, radiological and laboratory data were extracted and analyzed.

Results: The average follow-up time was 14 (8-18) years after the first RT. The prevalence of AO was 5.4%. Overall, 41 patients showed AO of the femoral head, 23 bilateral AO of the femoral head, 5 of the knee and 5 of other locations, while 43 patients were symptomatic at diagnosis. At the first presentation, 72% presented AO osteonecrosis (2/3 months) AO after RT. On average, AO was diagnosed 90 months after RT (SD=78). Furthermore, RTR with late onset were younger at the first RT (39±15 years; p<0.01) than the ones with early on (53±14). A considerably higher cumulative dose of prednisone was administered to patients with late onset of AO prior to their first RT (21±11 g; early onset 8±1 g; p-value <0.001) and a higher percentage of late onset RTR received corticosteroids even prior to their first RT (48%) compared to the group of early onset (15%; p=0.038). Overall, 34% of the patients presented with an advanced stage of AO Ficat III or IV at first diagnosis of AO and 57% needed total hip arthroplasty.

Conclusions: Late onset avascular necrosis represent a corticosteroid related complication, with a particularly high prevalence among young RTR and is associated with a significantly higher percentage of late onset RTR received corticosteroids even prior to their first RT (48%) compared to the group of early onset (15%). AO of the femoral head is one of the most relevant complications in patients with CKD or on dialysis who receive corticosteroids.

Indoxyl Sulfate Exacerbates Low Bone Turnover Induced by Parathyroidectomy in Rats Junya Hirata,1 Kazuya Hirai,2 Naoko Jisumura,1 Yosuke Tsukui,1 Hironobu Asai,1 Hidetomi Nishiya,2 Shuichi Kato,1 Hironobu Yokoyama,1 Shota Kato,1 Takehiro Inamoto,2 Takeshi Takagi,1 1Kureha Corporation, Tokyo, Japan; 2Tokyo Univ of Agriculture and Technology, Tokyo, Japan.

Background: Low-turnover bone disease is one of the bone abnormalities observed in chronic kidney disease (CKD) patients and recognized to be associated with low serum parathyroid hormone (PTH) level and skeletal resistance to PTH. Indoxyl sulfate (IS) is a representative uremic toxin that accumulates in the blood as renal dysfunction progresses in CKD patients. In order to examine whether IS exacerbates low bone turnover, we produced IS by feeding rats with low-protein diet and then added IS to the low-protein diet, we fed these rats a diet containing indole, a precursor of IS, to elevate bone IS level from indole metabolism.

Methods: Male SD rats were maintained on the low-protein diet for 2 weeks. Then, the rats were fed a diet containing 0.5% indole (w/w) for 4 weeks. Serum IS levels and bone metabolism related markers were examined periodically. After the end of indole treatment, histomorphometric analyses in the secondary spongosia of the femur and measurement of bone mineral density of the tibia were performed.

Results: Histomorphometric analyses revealed significant decreases in both bone formation-related parameters (mineralized surface/bone surface, bone formation rate/bone surface) and bone resorption-related parameters (eroded surface/bone surface, bone resorption surface/bone surface) in PTH rats. In indole-treated PTX rats, further decreases in bone formation-related parameters were observed. On the other hand, there were no decreases in bone resorption-related parameters in indole-treated PTH rats compared to the PTH rats. Serum IS levels in indole-treated PTX rats were elevated during the indole treatment period and the levels were similar to those in CKD and dialysis patients.

Conclusions: IS exacerbates low bone turnover through inhibition of bone formation by mechanisms unrelated to skeletal resistance to PTH in rats. Our data suggest that IS might directly act as one of the uremic toxins that contribute to progression of low-turnover bone disease in patients with CKD or on dialysis whose serum IS levels are elevated because of renal dysfunction.

Changes of Marrow Adipocyte Away from Bone Surface After Parathyroidectomy in Patients with Secondary Hyperparathyroidism Aiji Yajima, Ken Tsujiuchi, Kosaku Nitta. Medicine, Tokyo Women’s Medical Univ, Tokyo, Japan.

Background: We’ve already reported that marrow adipocytes proliferated around bone surface after parathyroidectomy for secondary hyperparathyroidism. However, fibrous volume was reduced near bone surface where adipocytes proliferated after the surgery. It is suggested that adipocytes may be added with bone formation, because osteoblasts suppress the function of osteoblasts. Therefore, the parameters of marrow adipocyte, which are away from bone surface were histomorphometrically measured before and after parathyroidectomy for secondary hyperparathyroidism.

Methods: Sixteen hemodialysis (HD) patients suffering from secondary hyperparathyroidism (Age; 67 ± 14 years; HD duration; 14.3 ± 6.8 years) were treated by total parathyroidectomy with immediate autotransplantation (parathyroidectomy) and received iliac bone biopsies before and at 1 week (n=4) and at 4 weeks (n=10) after parathyroidectomy. Adipocyte volume per marrow volume (Fa/Vm/V), adipocyte number per marrow volume (N.Fa/Ma.V/mm²), and mean adipocyte volume (Fa/V:N.Fa/V=10^3 mm²/N) were obtained in the area away from bone surface. If there are so many artifacts in bone marrow, the bone samples were excluded from this research.

Results: Serum intact parathyroid hormone (i-PTH) level was decreased from 1268.8 ± 485.9 to 7.9 pg/mL. Fa/Vm/V was significantly increased from 22.4 ± 6.3 to 30.9 ± 8.1 % (P<0.001). N.Fa/Vm/V was also increased from 183.3 ± 48.1 to 217.7 ± 4.7 %/mm² (P<0.001), and Fa/V:N.Fa/V was not changed (146.9 ± 48.5 to 166.8 ± 54.8 %/10^-3 mm²/N) after parathyroidectomy.

Conclusions: The facts substantiate that an acute reduction of PTH induced an increase of adipogenesis. As reported previously, osteoblast surface transiently increased at 1 week after parathyroidectomy, but it acutely decreased at 4 weeks after the surgery. These findings mean that undifferentiated stem cells went to the adipogenesis after the acute reduction of PTH in patients receiving HD.

Evaluation of Marrow Adiposity in Patients Pre and Post-Kidney Transplantation: Comparison Between Bone Histomorphometry Mariel Jose Hernandez,1 Luciende dos Reis,1 Igor Marques,2 Feltypes C. Barreto,2 Elias David-Neto,3 Rosa M.A. Moyses,2 Ezequiel R. Bellorin-Font,1 Vanda Jorgetti,2 1Nephrology Div, Univ Central de Venezuela, Caracas, Venezuela; 2Nephrology Div, Univ de Sao Paulo, Sao Paulo, Brazil; 3Medical School, Pontificia Univ Católica, Curitiba, Brazil; 4Urology Div, Univ de Sao Paulo, Sao Paulo, Brazil; 5UNINOVE.

Background: The osteoblasts (Ob) and adipocytes (Ad) derive from the mesenchymal stem cells (MSCs). An imbalance in the differentiation of Obs and Ad could be decisive to preserve the integrity of bone. We analyzed bone histomorphometry and marrow adiposity in bone biopsies from patients before and after kidney transplantation (KT).

Methods: We compared biochemical parameters and bone histomorphometry data from KT patients before and after KT, under standard immunosuppressive therapy including glucocorticoids. Adipocytes area (Ad.Ar/T.Ar,%), number (N.Ad/B.Ma.V/mm²), and the ratio adipocytes/active osteoblasts (N.Ad/N.AcOb), and adipocytes/total osteoblasts (N.Ad/N.TOb) indexes were measured.

Results: Our patients were young (42.3 ± 11.6 vs. 30.6 ± 11.5), N.Ad/N.TOb (240.4 ± 65.7 vs. 674.6 ± 1192.4) and N.Ad/N.TOb (128.2 ± 362.3 vs. 230.5 ± 642.4) and a decreased osteoblast number/ tissue surface (22.8 ± 21.9 to 5.3 ± 2.8) was observed. In the post-transplant biopsies significant correlation was found between N.Ad/N.TOb and PTH (r=-0.48), trabecular number - Tb.N (r=0.29) and mineral apposition rate (r=-0.23), as well as between Ad.Ar/T.Ar and bone volume (r=0.36) and between N.Ad/B.Ma.V and mineral apposition rate (r=72).

Conclusions: KT improved biochemical findings related to bone mineral disease, however, this condition is also clearly associated with an inverse relationship of the bone
mass and osteogenic cellularity with marrow adiposity, compromising dynamic parameters. MSCs differentiation is competitively balanced; mechanisms that promote one cell fate actively suppress mechanisms that incline the alternative.

SA-PO564

High Marrow Adiposity Is Associated with Low Turnover Bone Disease in Peritoneal Dialysis Patients

Feliype C. Barreto,1 Rodrigo Axezedo de Oliveira,1 Mariel Jose Hernandez,2 Ana Clara Simões Flórido Almeida,1 Luciene dos Reis,1 Aluizio B. Carvalho,1 Vanda Jorgetti,2 Rosa M.A. Moyses,2,4 Pontificia Univ Católica do Paraná; 1Univ de São Paulo; 2Univ Federal de São Paulo; 3Univ Novo de Julho, UNINOVE; 4Univ Federal do Rio Grande do Norte; 5Univ de Caracas.

Background: Marrow adiposity has been implicated in the pathogenesis of bone disorders, such as osteoporosis and bone fragility. We sought to investigate the relationship between marrow adiposity and renal osteodystrophy in peritoneal dialysis patients.

Methods: We analyzed transiliac bone biopsy specimens from 41 peritoneal dialysis patients (age:50±10.2 yrs) by quantitative histomorphometry to assess bone and marrow adipocyte parameters. Selected biochemical parameters, such as serum markers of bone turnover and sclerostin, were measured.

Results: Adipocyte area (Ad.Ar), perimeter (Ad.Pm) and percentage of adipocyte volume per marrow volume (Ad.V/Ma.V) correlated positively with age. Diabetic patients had higher marrow adiposity than non diabetic patients (Ad.V/Ma.V= 50±14 vs 39±12%; P=0.009; Ad.Ar=619±0.06 vs 610±0.05 mm²; P=0.02). Ad.V/Ma.V demonstrated inverse association with bone specific alkaline phosphatase (r=−0.32;P=0.04) and direct relationship with sclerostin (r=0.38;P=0.01). No association was found between marrow adiposity and dynamic bone hystomorphometric parameters. Interestingly, patients with Ad.V/Ma.V > 41% (median) presented higher percentage of low turnover bone disease (P=0.04) as well as significantly lower bone specific alkaline phosphate (39.5±27.3 vs 65.3±28.9 U/L; P=0.006) and higher sclerostin (2.3±0.97 vs 1.6±0.97 ng/ml; P=0.02) levels than patients below the median.

Conclusions: Increased marrow adiposity seems to be associated to lower osteoblast activity and to low turnover bone disease in peritoneal dialysis patients. The higher marrow fat in diabetic and aged patients might expose them to an increased risk for fracture. Further studies are required to understand the possible contribution of marrow adiposity to the pathogenesis of renal osteodystrophy.

Role of Wnt10b Signaling in Cinacalcet-Induced Bone Anabolic Effects Cai-Mei Zheng,1 Yung-Ho Hsu,1 Yuh-feng Lin,2 Jia-Pwu Shyu,1 Kuo-cheng Lu,1,4 1Graduate Inst of Clinical Medicine, Taipei Medical Univ, Taipei City, Taiwan; 2Dept of Nephrology, Shuang Ho Hospital, New Taipei City, Taiwan; 3Biologue and Anatomy, National Defense Medical Center, Taipei City, Taiwan; 4Dept of Medicine, Cardinal-Tien Hospital, New Taipei City, Taiwan.

Background: Chronic kidney disease-mineral bone disorders (CKD-MBD) is important for osteoporosis and bone fractures in CKD patients. Since calcium receptor plays an important role in osteoblast differentiation, we assume that calcimetric agents (cinacalcet) might have a role in bone remodeling.

Methods: Bone marrow mononuclear cells isolated from rat femur and tibia were induced into osteocytes by M-CSF and RANKL treatments. Osteocytes were treated with different doses of cinacalcet. Untreated osteocytes used as control. The release of Tracing C LASTONE Wnt10b was measured by ELISA and Western blot. Alizarin red staining was used to evaluate mineralization of osteoblasts co-cultured with osteocytes. Flow-AFM staining was used to determine intracellular calcium changes. Cinacalcet treated and untreated CKD animal models (5/6 nephrectomy) were used to analyse the changes in calcitones and bone mineral density.

Results: In osteoclasts, cinacalcet decrease the TRAP stain reaction. However, ELISA analysis showed increases of Wnt10b expression in supernatant collected from the cinacalcet-treated osteoclasts. Pretreatment of Wnt10b secretion inhibitor, C-59, blocked the increase of Wnt10b induced by cinacalcet. Western blot analysis showed an increase intracellular Wnt10b in the cinacalcet-treated osteoclasts. Culture of osteoblasts with the cinacalcet-treated osteoclasts supernatant showed an increase of mineralization as induced by alizarin red staining. Intracellular calcium staining is increased in cinacalcet-treated osteoclasts, which demonstrated its effect on osteoclast Wnt10b release is through intracellular calcium oscillation. Calcitones and bone mineral density (BMD) changes are also noted in CKD rats before and after cinacalcet treatment.

Conclusions: Cinacalcet decrease osteoclastic activity, but increase the secretion of Wnt10b through intracellular calcium oscillation. Cinacalcet also related with certain calcitones and BMD changes in CKD animals.

SA-PO566

Changes of Osteocyte Number in Micropetrosis Area After Treatment of Secondary Hyperparathyroidism Aiji Yajima, Ken Tsuchiya, Kosaku Nitta. Medicine, Tokyo Women’s Medical Univ, Tokyo, Japan.

Background: Osteocyte number decreased after total parathyroidectomy with immediate autotransplantation (parathyroidectomy) for secondary hyperparathyroidism in hemodialysis (HD) patients (JBMR 2010). Osteocyte number in micropetrosis area around the middle area was measured before and after parathyroidectomy and treatment with cinacalcet hydrochloride (HCL).

Methods: Thirteen HD patients received parathyroidectomy and transiliac bone biopsies before and at 3-9 weeks after parathyroidectomy (Group I). And eight HD patients with secondary hyperparathyroidism were treated by cinacalcet HCL and received bone biopsies before and at 1 year after the treatment (Group II). Osteocyte number in micropetrosis area (N.Ot/Mp.V;N/mm²) and in the other area (N.Ot/(BV-Mp.V);N/mm²) were measured before and after the treatment.

Results: Serum intact Parathyroid Hormone (i-PTH) levels decrease from 1186.5 ± 768.3 to 24.8 ± 8.1 pg/ml after parathyroidectomy. No/OTi/Mp.V was decreased from 58.9 ± 7.1 to 110.1 ± 87.3 N/mm² (P<0.001) and No/OTi/(BV-Mp.V) was not changed (from 236.1 ± 69.3 to 262.2 ± 79.3 N/mm²) after parathyroidectomy (Group I). Serum i-PTH levels decrease from 903.6 ± 503.0 to 212.7 ± 98.1 pg/ml after the treatment with cinacalcet HCL. NO/OTi/Mp.V was not changed in both micropetrosia area (100.1 ± 68.2 to 99.6 ± 76.1 N/mm²) and in the other area (from 240.1 ± 56.3 to 279.6 ± 88.6 N/mm²) after treatment (Group II).

Conclusions: Cinacalcet HCL did not reduce osteocyte number in both micropetrosia area and in the other area, suggesting that this agent improves bone quality by maintaining osteocytic perilacunar/canalicular system. Parathyroidectomy reduces osteocyte number in only the micropetrosia area.

Funding: Private Foundation Support

SA-PO567

Trabecular Bone Score in Kidney Transplant Recipients Ylva Lynn Naylor,1 Lisa M. Liu,1 Didier Hans,2 Amir X. Garg,3,4 David N. Rush,2 William Leslie,31 Western Univ; 1Univ of Manitoba; 2Lassanne Univ Hospital; 3London Health Sciences Centre; 4Inst for Clinical Evaluative Sciences.

Background: Kidney transplant recipients have altered bone mineral metabolism and are at a higher risk of fracture compared to the general population. There is conflicting evidence regarding the ability of bone mineral density (BMD) to accurately predict fracture. Trabecular bone score (TBS) is a texture measure derived from dual energy x-ray absorptiometry (DXA) lumbar spine images which provides information independent of BMD. We assessed TBS in kidney transplant recipients.

Methods: We included 327 kidney transplant recipients from Manitoba, Canada, who received a post-transplant DXA (median 106 days post-transplant). We matched each kidney transplant recipient (mean age 45 years, 39% men) to three controls from the general population (matched on age, sex, and date of DXA). Lumbar spine (L1-L4) DXA images were used to derive TBS. Non-traumatic incident fracture (excluding hand, foot, and craniofacial) (n=31) were assessed during a mean follow-up of 6.6 years. We used logistic regression to determine predictors of TBS and hazard ratios per standard deviation decrease in TBS to express the gradient of risk for fracture prediction using Cox proportional hazards regression.

Results: Compared to the general population, kidney transplant recipients had a significantly lower lumbar spine TBS (1.41 ± 0.13 versus 1.37 ± 0.13, p<0.001). Multiple logistic regression revealed reduced TBS (lowest versus highest tertile) in kidney transplant recipients compared to the general population (adjusted odds ratio, 2.13 [95% confidence interval [1.47-3.07]). TBS predicted fractures in kidney transplant recipients independent of the Fracture Risk Assessment (FRAX) score and spine BMD (adjusted hazard ratio per standard deviation decrease in TBS 1.57, 95% CI 1.67-2.29).

Conclusions: Kidney transplant recipients had abnormal bone texture as assessed by TBS. Lumbar spine TBS was able to predict incident fractures in kidney transplant recipients and may provide novel insights into skeletal fragility in this unique population.

SA-PO568

Low Bone Turnover Disease Is Prevalent 1 Year After Successful Renal Transplantation: A Cross-Sectional Bone Biopsy Study Pieter Evenepoel,1 Patrick C. D’Haese,2 Liesbeth Vlaene,1 Geert J. Behets.1 1Nephrology, Univ Hospitals Leuven, Leuven, Belgium; 2Pathophysiology, Univ of Antwerp, Antwerp, Belgium.

Background: Studies evaluating bone histomorphometry in renal transplant recipients are scanty and so far hampered by small sample size and heterogeneity. Methods: We evaluated bone histomorphometry (according to TMV classification), laboratory parameters of mineral metabolism (including iPTH, FGF23, sclerostin, OPG, sRANKL), biomarkers of bone formation (bsAP) and bone resorption (TRAP5b, NTX), and inflammation (IL6) in an unselected cohort of 60 renal transplant recipients (64 males, age 56±12 yrs) 1 year after transplantation. Standard immunosuppressive regimen consisted of steroids, a calcineurin inhibitor and mycophenolate mofetil. Mean cumulative mycophenolate dose at 1 year was 1.7 g/d.

Results: Sixty-five % of the patients presented with disturbances in at least one of the bone turnover parameters.ハイリスクlow bone turnover disease were identified in 1.7, 45.0, and 53.3 % of renal transplant recipients, respectively. Mineralization was delayed in 17.0 % and bone volume was low in 15.0 %. Patients with persistent

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
hypercalcermic hyperparathyroidism (n=4, 7%) showed either low or normal bone turnover. Hypophosphatemia was present in 11%. Vitamin D stores were sufficient in 52% (median HydroxyvitaminD3 32 ng/ml). Spearman correlation revealed significant correlations between bone formation rate and biomarkers of bone formation & resorption (direct: b-AP: r=0.36, p=0.01; TRAP5b: r=0.40, p=0.01; NTX/r0.38, p=0.01) and inflammation (inverse: IL6: r=0.51, p=0.001), but not with mineral metabolism hormones (PTH, FGF23, sclerostin).

Conclusions: Low bone turnover disease is the most prevalent bone disease in renal transplant recipients 1 year after successful renal transplantation. Additional studies are required to clarify underlying pathophysiological mechanisms. PTH, FGF23 and sclerostin do not correlate with histomorphometric parameters and circulating biomarkers of bone turnover.

SA-PO569
Sclerostin Bone Expression and Blood Levels in Patients with Chronic Kidney Disease Stages 2-5
Florence Lima, Marie-claude M. Fugere, Hanna W. Mawad, Hartmut H. Malluche. Div of Nephrology, Bone & Mineral Metabolism, Univ of Lexington, KY, USA.

Background: Sclerostin (Scl) produced by osteocytes (ocy) was found to be increased in bone in early stages of CKD patients (pts) with renal osteodystrophy (ROD). The aim of this study was to establish when blood scl levels and bone expression are increased and how they progress with worsening CKD.

Methods: Fifty pts underwent anterior iliac crest biopsies and blood was drawn at time of biopsy. Kidney function was determined by creatinine clearance using MDRD calculation. There were: 11 CKD-2, 16 CKD-3, 9 CKD-4.5 pts, and 14 healthy age-matched controls. Scl concentrations in blood were determined by ELISA and scl expression in bone was determined in undecalcified bone sections by measuring number of ocy exhibiting positive Scl immunostaining. Measurements were done separately in cortical and cancellous bone. Bone sections were also evaluated by histomorphometry for turnover, mineralization and volume.

Results: Blood scl levels were significantly greater in CKD compared to controls with no differences between stages (P=0.01).

Bone scl expression was significantly higher in cortical CKD 2-5 pts compared to controls (P<0.01). Scl expression was significantly greater in cortical than in cancellous bone in CKD. In cancellous bone scl expression was higher in CKD; this reached significance in CKD-3 (Figure 1).

Scl expression in cortical and cancellous bone correlated with serum scl (rho=0.30, 0.40, r=0.05; P<0.05). Serum scl correlated negatively with bone formation, activation frequency and osteoblast number (rho=-0.33, -0.38, -0.43, P<0.05). Scl in bone correlated negatively with trabecular thickness (rho=-0.51; P<0.05), osteoblast and osteoclast surface, and erosion depth (rho=-0.50, -0.52, -0.05, P=0.01).

Conclusions: These findings ascribe a potential role to scl in the pathogenesis and management of ROD.

Single Timepoint and Longitudinal Serum Sclerostin Levels as Mortality Predictors in Prevalent Dialysis Patients
Lotte Lips,1 Camiel L.M. de Roij van Zuidewijn,1 Marc G. Vervoelt,2 Peter J. Blankestein,2 Denis Fouque,4 Solenne Pelletier, Peter M. Ter Wee,4 Menso Jan NBue,4 Muriel P. Grooteman.1,2,3

1Nephrology, 2PU Medical Center, Amsterdam, Netherlands; 3Nephrology, Univ Medical Center Utrecht, Utrecht, Netherlands; 4Internal Medicine, Maastricht Hospital, Rotterdam, Netherlands; 5Nephrology, Centre Hospitalier Univ de Lyon, Pierre Benite, France.

Background: Currently, data are conflicting whether high serum Sclerostin (sScl) levels, a 22kDa-sized glycoprotein inhibiting bone formation, are positively or negatively associated with mortality. Its concentration may change over time. Therefore, we investigated whether longitudinal sScl levels predict mortality better than a single measurement.

Methods: A post-hoc analysis on data from the CONTRAST study was performed, a RCT comparing online postdilution hemodiafiltration to hemodialysis in prevalent dialysis patients. sScl was measured in a subset of patients. Patients were eligible for analysis if a baseline (T0) and a 6 months (T6) sScl value were available. Hazard ratios (HRs) were calculated within quartiles for sScl level at T0, T6 and ΔsScl. All-cause mortality was used as end point. As the interaction between dialysis modality and ΔsScl was non-significant (p>0.1), pooled estimates are reported. To correct for multiple testing, a two-sided p-value <0.01 was considered statistically significant.

Results: Out of 714 patients, 341 were available for analysis. Baseline characteristics between the subgroups did not differ. Median sScl at T0, T6 and ΔsScl was 136.3 pmol/L (interquartile range [IQR] 98.7-186.1), 134.0 pmol/L (IQR 100.4-183.0) and 0 pmol/L (IQR -25 to 15), respectively. sScl values at baseline and T6 were negatively associated with mortality (adjusted HRs highest versus lowest quartile 0.49 [95% CI 0.30-0.81] and 0.48 [95% CI 0.29-0.82], respectively). However, we found no association between ΔsScl and mortality.

Conclusions: A single timepoint sScl is inversely associated with mortality in our cohort of dialysis patients. sScl change over a six month period does not predict mortality.

SA-PO571
Intereukin-1 Inhibition, Chronic Kidney Disease-Mineral and Bone Disorder (CKD-MBD), and Physical Function
Kristen L. Nowak,1,2 Adriana Hunj,3,4 Talat Alp Ikizler,3 Heather Farmer,1 Natjalie Salas,3 Rafa I. Chaudhry,2 Andrew N. Hoofnagle,4 Gerald John Smits,3 Michel Chonchol,1,4 Univ of Colorado Denver; 2Vanderbilt Univ; 3VA Tennessee Valley Healthcare System; 4Univ of Washington.

Background: Epidemiologic studies have suggested a possible link of chronic systemic inflammation with vitamin D deficiency, intact parathyroid hormone (iPTH), and fibroblast growth factor 23 (FGF23) excess, which are a central features of CKD-MBD. Declining renal function is also associated with worsening physical function, which may be explained by systemic inflammation, CKD-MBD, or both. We hypothesized that inhibiting inflammation with an interleukin-1 (IL-1) trap would improve vitamin D deficiency, iPTH and FGF23 excess, as well as physical function in patients with moderate-to-severe CKD.

Methods: In a two-site, double-blind trial, 42 patients with stage 3-4 CKD were randomized to receive either the IL-1 trap rilonacept (160 mg/week) or placebo for 12 weeks. The following CKD-MBD markers were assessed in serum before and after the intervention: calcium, phosphorus, 25-hydroxyvitamin D (25(OH)D), iPTH, FGF23, and parathormone (b-ALP). Also underlined by the KDIGO, clinical decision should be based on variations (or slopes) (∆, in%) of these biomarkers, more than on isolated concentrations. In this work, we studied the correlation between DPTH and ∆ of different bone biomarkers: PINP, CTX, TRAP-5b, osteocalcin and sclerostin. ∆ were studied at different timings, namely 6 weeks (T6W), 6 months (T6M) and 1 year (T1Y).

Results: We have prospectively followed the variations of these biomarkers over one year in patients from 3 independent dialysis centers at T6W (n=123), T6M (n=108) and T1Y (n=93). We analyzed DPTH with ∆ of bone biomarkers by univariate linear regression. We also categorized patients according to variations reaching the critical difference of the biomarkers at one year. Their results were analyzed by Mantel-Haenszel c² test.

Results: At T6W, a significant correlation was only found between DPTH and ∆CTX (r=0.38, p=0.0001). At 6M, a significant correlation was found between DPTH and ∆CTX (r=0.38, p=0.0001) and Dosteocalcin (r=0.27, p=0.0049). At T1Y, a significant correlation was found between DPTH and ∆CTX (r=0.47, p=0.0001), ∆PINP (r=0.4, p=0.0001), ∆b-ALP (r=0.29, p=0.0054) and Dosteocalcin (r=0.36, p=0.0004). No correlation was found at T1Y neither between DPTH and DTRAP-5b nor Dsclerostin. The same conclusions were reached when variations reaching the critical differences were considered. Correlations between DPTH and Dbone biomarkers were particularly poor in patients with low PTH levels (as defined by the KDIGO) at baseline. Conclusions remained the same if analysis was restricted to the 93 patients who completed the study.

Conclusions: A concordance between variations of PTH on one hand and variations of CTX, b-ALP, osteocalcin and PINP on the other hand can be observed in dialysis patients, but only after a long follow-up (at least one year). Variation of bone biomarkers need repeated measures and must not be analyzed on a too short period.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: 12 weeks of IL-1 inhibition did not improve circulating markers of CKD-MBD or physical function (although it tended to improve endurance). These results support that inflammation does not directly mediate CKD-MBD or select domains of physical function.

Serum Metabolomic Profiling and CKD-MBD: A New Tool for Bone Turnover Evaluation Aline Lourenco Baptista,1 Kallyんだ Padilha,2 Pamela Arauo Malagrino,3 Gabriela Venturini,4 Ana Carolina de Mattos Zeri,5 Janaina Silva Martins,6 Rodrigo Azevedo de Oliveira,7 Geusa Dutra,8 Luciene dos Reis,9 Vanda Jorgetti,10 Alexandre Costa Pereira,11 Rosa M.A. Moyaes,1,9b,19b Nephrology, USP; 12 Molecular Cardiology, INCOR, USP; 13 Cardiology, INIC, USP; 14 UFMG; 15 Master Degree Program, UNIOINIZE, Brazil.

Background: Bone biopsy still is the gold standard to assess bone turnover in CKD patients and serum biomarkers are not able to replace histomorphometry. Recently, metabolomics has emerged as a new technique that could potentially improve disease diagnosis and the understanding of pathophysiology. However, as this approach has never been tested in the CKD-MBD scenario we investigated whether a serum metabolomic profile could help us to better predict bone turnover in CKD patients.

Methods: Serum and bone histomorphometry data from hemodialysis (HD, n=51) and peritoneal dialysis patients (PD, n=40) were analyzed. They were classified as high (HT, 49.4%) or low turnover (LT). Metabolomic analysis was done through MRI spectroscopy, followed by identification and quantification of metabolites and PLS-DA. As HD had a completely different metabolome of PD group, we analyzed them separately. In addition, we selected the main metabolites found in each group and searched for the metabolic pathways involved.

Results: The difference between LT and HT was explained by 12 metabolites in HD and 8 in PD (p = 0.03 and 0.01, respectively). ROC curve analysis showed that parathormone (PTH) could help us to better predict bone turnover in CKD patients.

Conclusions: In this preliminary analysis, we identified new metabolites that might be used as biomarkers of bone turnover. Moreover, the differences in metabolome between the two dialysis modalities and the different metabolic pathways suggest that the pathophysiological mechanisms involved in the modulation of bone turnover in these patients might be different.

Role of the Sodium/Calcium Exchanger NCX1 in Osteoclasts Giuseppe Alibano,1,2,3 Candice Stoudmann,2,4 Willy Hofstetter,5 Olivier Bonny,5 Daniel G. Fuster,1,5a,6,7 Div of Nephrology, Hypertension and Clinical Pharmacology, Univ of Bern, Bern, Switzerland; 2Inst of Pharmacology and Toxicology, Univ of Lausanne, Lausanne, Switzerland; 3Dept of Clinical Research, Univ of Bern, Bern, Switzerland; 4NCCR Kidney.CH, Univ of Zürich, Zürich, Switzerland.

Background: Previous studies demonstrated that inhibition or siRNA-mediated knock-down of sodium/calcium exchanger 1 (NCX1) in osteoclasts decreases bone resorption in vitro, indicating a critical role of NCX1 in osteoclast-mediated bone resorption.

Methods: To test the role of NCX1 in osteoclasts in vivo, we generated mice with osteoclast-specific deletion of NCX1 (NCX1\textsuperscript{Cre/loxP}). For this purpose, mice with a floxed exon 11 of NCX1 were crossed with mice expressing Cre-recombinase under the influence of the osteoclast specific calspHEN K promoter.

Results: Osteoclasts differentiated from NCX1\textsuperscript{Cre/loxP} mice displayed an 80-90 % reduction of NCX1 protein compared to wild-type mice. NCX1 expression was unaltered in extraosseous tissues in NCX1\textsuperscript{Cre/loxP} mice. NCX2 and NCX3 were present at low levels in wild-type osteoclasts and not upregulated in NCX1\textsuperscript{Cre/loxP} osteoclasts. In vitro RANKL stimulation of bone marrow cells isolated from wild-type and NCX1\textsuperscript{Cre/loxP} mice yielded no differences in osteoclast development and resorptive activity. In addition, at 3 months of age, structural parameters of bone, quantified by high-resolution microcomputed tomography, were not different in NCX1\textsuperscript{Cre/loxP} mice compared to wild-type littermates. To stimulate osteoclast-mediated bone resorption, we performed surgical ovarectomy (OVX) in 12 week old female mice, but OVX-induced bone loss over 12 weeks was similar in WT and NCX1\textsuperscript{Cre/loxP} mice.

Interestingly, however, at 6 months of age, female NCX1\textsuperscript{Cre/loxP} mice had significantly higher bone volume whereas male NCX1\textsuperscript{Cre/loxP} mice displayed reduced bone volume compared to wild-type mice.

Conclusions: Our data indicate that genetically induced deficiency of NCX1 in osteoclast-precursors and mature osteoclasts does not affect osteoclast differentiation and bone resorption in vivo. However, NCX1\textsuperscript{Cre/loxP} mice display an age- and sex-specific phenotype. Additional studies are needed to unveil the underlying mechanisms.

The Impact of a Previously Created AV-Fistula on Radial Bone Mineral Density Measurements in Renal Transplant Recipients Spyridon Arampatzis,1 Vasileios Devetzis,1 Uyen Huynh-do,2 Nephrology, Hypertension and Clinical Pharmacology, Uni, Hospital of Bern, Inselspital, Bern, Switzerland.

Background: The arteriovenous-fistula (AVF) of the distal radius often remain patent after transplantation. Distal radius is the typical site for peripheral DXA measurements in renal transplant recipients (RTR). Since no data exist concerning the impact of a previously created AVF on peripheral bone characteristics in RTR we evaluated the effect of AVF on bone mineral density (BMD) as mirrored by collateral differences between forearms and explored the densitometric correlation of distal radius with the tibia as an alternative peripheral measurement site.

Methods: This cross sectional study included 40 renal transplant recipients (RTR) and 40 chronic kidney disease (CKD) patients matched for age, gender and BMI. In addition to relevant demographic, biochemical and clinical aspects we assessed bone characteristics of both forearms, femoral neck and tibia by DXA.

Results: The CKD patients without any AVF, displayed no significant discrepancies concerning BMD in both forearms. In RTR BMD was significantly lower in the AVF fistulated forearm in comparison to the contralateral non AVF forearm. This observation was evident at all measured subregions of the AVF radius sides, i.e. at the 1/3 radius (0.710±0.103 vs. 0.727±0.104, p=0.003), ultradistal radius (0.424±0.085 vs. 0.444±0.080, p=0.007) and total radius (0.571±0.090 vs. 0.589±0.090, p=0.001) as well. This significant side-to-side difference was 7.5% at the 1/3 radius, 7.2% at the total radius, and 7.0% at the ultradistal radius, respectively. The BMDT interclass analysis between radius and distal tibia showed a strong and highly significant correlation (r= 0.736±0.857) between corresponding peripheral sites.

Conclusions: In conclusion, a previously placed AVF in RTR exerts a negative impact on the ipsilateral radius resulting in side-to-side BMD differences. A strong densitometric association exist between peripheral sites and thus DXA measurements at corresponding peripheral measurement site.

Dialysis pts compared to the pre-dialysis population showed more denuded cortical bone, with decreased cortical thickness, increased osteobone formation rate and adjusted apposition rate. In this pre-dialysis population, external cortical porosity positively correlated with both trabecular bone volume and osteoid volume (respectively, r=0.70 and 0.76, p=0.016 and p=0.006). External cortical osteobone BFR correlated negatively with S-calcium (r=0.88, p=0.021) and positively with trabecular thickness (r=0.88, p=0.021). These findings were not observed in internal cortical suggesting that this is more stable to PTH effects.

**Conclusions:** In pre-dialysis pts, our findings support that PTH has a modulating effect on both trabecular and cortical bone. As renal disease progresses cortical thining is more pronounced, eventually contributing to the higher fracture rate. Understanding cortical abnormalities may have implications in the treatment of CKD-MBD.

SA-PO579

**Chronic Hyponatremia Is a Novel Risk Factor for Hip Fracture in Chronic Kidney Disease-Mineral Bone Disease**

**Sagar U. Nipwekar, 1 Andrew S. Allegretti, 1 Julia Beth Wenger, 1 Juan Carlos Ayus, 1 Ravi I. Thadhani, 1 Ishir Bhan, 1 Massachusetts General Hospital; 1 Renal Consultants of Houston.**

**Background:** Risk factors that make skeleton more fragile in chronic kidney disease (CKD) are uncertain. Considering recently reported direct effects of sodium depletion on bone health, we investigated chronic persistent hyponatremia (CPH) as a novel risk factor for hip fractures caused by CKD-mineral bone disease (CKD-MBD).

**Methods:** Cases for this multi-center case-control study were elderly (≥65 years) patients with CKD (eGFR <60 mL/min) with a new hip fracture. Controls (CKD patients with no hip fracture) were matched to cases on age, sex, race and comparative health. Primary exposure was serum sodium <135 mEq/L on at least 2 occasions ≥ 90 days apart within one year preceding hip fracture for cases and within the first year of study entry for controls (CH190). Secondary exposure definitions were hyponatremia on at least 1 occasion (H1) and hyponatremia on at least 2 occasions ≥ 180 days apart (CH180). Variables for multivariable logistic regression analyses were identified using stepwise selection.

**Results:** We analyzed 1,236 cases and 4,515 controls. Mean age of all patients was 84±9 years, 87% were whites, and 39% were females. Serum calcium, phosphate, parathyroid hormone and 25-hydroxy vitamin D levels were similar between cases and controls. Prevalence of CH180 (21.2 vs. 9.9%, P<0.001), CH180 (15.5 vs. 6.5%, P<0.001) and H1 (52.7 vs. 41.1%, P<0.001) were higher in cases compared to controls. In analyses adjusted for falls, tobacco-use, osteoporosis, eGFR, body mass index, heart failure and medications, CH190 and CH180 were associated with increased risk of hip fracture but H1 was not.

**Conclusions:** CPH is a risk factor for hip fractures caused by CKD-MBD. Mechanistic studies are needed to investigate the effects of CPH on bone turnover, mineralization and volume in CKD.

**Funding:** Private Foundation Support

SA-PO580

**Follicle Stimulating Hormone Is Associated with Low Bone Mineral Density in Women in Hemodialysis**

**Priscilla Ponce, 1 Enrique Rojas-Campos, Alfonso M. Cueto-Manzano, Benjamin Gonzalez-Navarro. 1 Unidad Investigación Médica en Enfermedades Renales, IMSS, Guadalajara, Jalisco, Mexico.**

**Background:** Prevalence of bone mineral density (BMD) in women during hemodialysis (HD) has been little explored. In the literature, FSH and estradiol were divided between female (FSH and estradiol) and estradiol (BMD) in women in hemodialysis (HD).

**Methods:** We performed a cross-sectional study of 46 women (20-60 years), at least 3 months in HD in a tertiary care setting between Jan-Jul 2014. Pregnant patients or those with steroid medication were excluded. Physical examination and blood markers of sexual hormonal and mineral-bone status were done. A bone densitometry of lumbar spine and non-dominant femur of the hip was performed; the results were classified as normal, osteopenia and osteoporosis.

**Results:** 5 had osteoporosis and 5 had osteopenia in the lumbar spine. In the femur, 2 had osteoporosis and 18 had osteopenia. Comparisons are shown in Table. BMI in lumbar spine was associated to FSH (R² 0.27, P<0.001), FSH (OR 0.52 [-0.02 - 0.008], P=0.001), on the other hand BMI in femur (R² 0.30, p<0.001), FSH (OR 0.34 [-0.01 -0.001], p=0.02), and CRP were significantly associated (OR 0.32 [-0.02 -0.001], P=0.03).
SA-PO581

Time Averaged Intact Parathyroid Hormone Concentration as a Risk Factor for Hip Fractures in Patients on Dialysis
Steven Fishbane, Azzour Hazzan, Kenar D. Jhaveri, Lin Ma, Eduardo K. Lacson. "Div of Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY; Fresenius Medical Care, North America, Waltham, MA.

Background: Recent studies found the incidence of hip fractures has increased greatly in patients on dialysis. Most of the increase occurred in patients with characteristics typical of bone frailty, where over suppression of intact parathyroid hormone (iPTH) could be harmful. Since recent studies have not addressed clinical risk factors, we studied time-averaged iPTH as a risk factor for hip fractures.

Methods: 142,407 prevalent patients of Fresenius Medical Care had hip fractures identified by ICD-9 codes. Four cohorts were constructed: observation periods 2001-2003, 2004-2006, 2007-2009, 2010-2012. For each, the prior year was used to measure exposure. Risks for fractures were analyzed for each cohort and for the combined cohorts. Three models for risk adjustment were created: Case Mix CM-adjusted: age, gender, race, dialysis vintage, and diabetic status, CM+Lab adjusted and CM+Lab+Med adjusted.

Results: For the combined cohorts, unadjusted analyses indicated higher hip fracture risk with lower iPTH (p<0.0001), lower calcium (p=0.003), lower phosphate (p=0.0001) and lower IV vitamin D (p=0.0001). In the fully adjusted model the two lowest iPTH quartiles were significantly associated with greater risk of fractures (HR 1.2, 95% CI 1.01-1.44, p=0.03 for lowest quartile, iPTH < 181 pg/ml). Similarly the lowest quartile iPTH quartiles were significantly associated with greater risk of fractures (HR 1.2, 95% CI 1.01-1.37, p=0.04). Serum phosphate and IV vitamin D were no longer associated with risk in the fully adjusted model.

Conclusions: In women, in the higher levels of FSH predicts lower BMD in the lumbar spine, while in the femoral region higher FSH and CRP predicts lower BMD.

SA-PO582

The Discriminative Ability of Three Fracture Risk Assessment Tools in Hemodialysis Patients
Ying Qian, An Jin Chang, Xiaonong Chen, Nan Chen. "Dept of Nephrology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ School of Medicine, Shanghai, China.

Background: The present study aimed to explore factors associated with fractures among hemodialysis patients, and assess the ability of the World Health Organization’s fracture risk assessment tool (FRAX) compared with bone mineral density (BMD) and OSTA to discriminate fracture status.

Methods: We enrolled 118 hemodialysis patients in this cross-sectional study. Parameters including serum calcium, phosphate, intact parathyroid hormone, 25 hydroxy vitamin D, alkaline phosphatase were analyzed. Clinical characteristics were also collected. BMD values were at the lumbar spine and hip region. OSTA and FRAX scores were calculated using formula or through the FRAX website. Factors associated with fractures were examined. Discriminative ability of BMD, OSTA and FRAX (non-BMD model and BMD model) in fracture status was assessed with receiver operator characteristic (ROC) analysis.

Results: There were 16 (13.5%) fractures in 118 hemodialysis patients. Patients with fractures were significantly older and more osteoporosis. All BMD parameters at hip region (including femoral neck, femoral shaft, and total hip) were notably lower in fracture group than in non-fracture group (p<0.05). But FRAX2 performed no better than FRAX1 (P>0.05). The best cutoff values were 0.91, -3, 7.2%, 3.4%.

Conclusions: Among hemodialysis patients, age and BMD at hip are associated with fracture. FRAX performs better than BMD and OSTA in discriminating fracture status, suggesting its usefulness of fracture risk prediction in hemodialysis patients.

Teriparatide for Low Bone Mass in Hemodialysis Patients
Rikako Hiratama, Yoshihumi Ubara, Junichi Hoshino, Kenmei Takaichi. "Nephrology Center, Toranomon Hospital, Tokyo, Japan.

Background: Fracture rates in dialysis patients are extremely higher than general population. Recently the prevalence of low turnover has greatly increased in dialysis population. Teriparatide would be also beneficial for low turnover dialysis patients with low bone mass. However, there have been only a few reports describing the use of teriparatide in dialysis patients.

Methods: Design This was a prospective, single-center, observational study. Hemodialysis patients with low iPTH (iPTH<60 µg/ml) coexisting low bone mass determined by lumbar spine (LS) or/and femoral neck (FN) T-score<-2.5 with DXA were eligible and subcutaneous recombinant human PTH(1-34) (Forteo) was injected 3 times per week at the end of each hemodialysis sessions. We analyzed the following parameters, including serum Ca, P, albumin, ALP, iPTH and bone metabolism makers including iPTH, BAP, and TRACP-5b at baseline and following teriparatide. BMD at LS and FN were measured at baseline, 6, 18 months after treatment.

Pharmacokinetics After the 24th administration of teriparatide, we measured the serum teriparatide acetate concentrations.

Results: Five patients (median age: 72 years old,median hemodialysis periods; 24 months) were included. After teriparatide injection, BMD of LS as well as FN at 6 months significantly increased from 0.67±0.18 to 0.86±0.19 g/cm² and from 0.44±0.08 to 0.48±0.07 g/cm², respectively. Corrected Ca levels significantly decreased at 3 and 6 months with increases in endogenous iPTH in response to lowering of serum Ca. As for bone metabolic markers, percent changes of serum BAP and serum iPTH significantly increased at 3 and 6 months. Conversely, serum TRACP-5b decreased after injection. Throughout this study, there were no fractures. Pharmacokinetics result is shown in Figure 1. There was a peak at 30 minutes at 157.2 µg/ml, and then it rapidly decreased to undetectable level at 240 minutes.

Conclusions: In conclusion, treatment with teriparatide, the dose was 20 µg 3 times/week, which is smaller than the suggested dose for non-dialysis patients, led to increase of BMD at LS and FN. Our data on pharmacokinetic of teriparatide suggested that we can use this agent in normal dose in dialysis patients.

Restless Leg Syndrome in Hemodialysis Patients: Possible Relationship with Mineral and Bone Metabolism
Precil D. Miranda de Menezes Neves,1 Ramaiane Aparecida Bridi,¹ Rosa M.A. Moyes,¹ Rosilene M. Elias,¹ "Nephrology Div, Univ of São Paulo, São Paulo, Brazil; ¹Nephrology Div, Univ. of São Paulo - UNINOVE, São Paulo, Brazil.

Background: Restless legs syndrome (RLS) is a movement sleep disorder that is common among patients on hemodialysis (HD) and is associated with cardiovascular morbidity and mortality. The pathophysiology of this syndrome is not completely understood, and CKD-MBD may be implicated. We aimed to evaluate the prevalence of RLS in patients on hemodialysis, testing the relationship with CKD-MBD markers.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

758A
Methods: Prevalence and severity of RLS were assessed using the International RLS Study (ILRS) case definition.

Results: Of the 101 patients (53.5% women) included, RLS was observed in 29 patients (28.7%), with mild, moderate, severe and very severe presentation in 1, 12, 3 and 3 patients, respectively. RLS was more frequent among women (62% vs 38%, p=0.04), and was more severe in younger age group (P=0.047). Moreover, the expression of Runx2 and HO-1 was induced in calcium medium. At 5 weeks: The expression of Nrf2, HO-1, Runx2 could be induced by H2O2, but the expression of Runx2-induced calcification medium decreased gradually within incubation time after H2O2, or SFN + H2O2, pretreated.

Conclusions: The calcification in RASMCs is associated with the overexpression of endogenous ROS. Overexpression of Runx2 induced by endogenous ROS, but not exogenous ROS, may be inhibited or attenuated by the activated Nrf2/HO-1 pathway.

Matrix Vesicles from Calcifying Vascular Smooth Muscle Cells (VSMC) Have Different MicroRNA (miRNA) Expression from Non-Calcifying VSMC

Neal X. Chen,1,2 Satandra Chandra Janga,3 Kalishita O’Neill,1 Manjunath Shashidhar,1 S. Siddappa,1 Neal Chen,1 Chad Zarse,1 Michael Sturek,4 Mariko Yamasaki,1 Kazukiyo Tsuruya,1 Shunsuke Yamada,2 Masanori Tokumoto,1 Shu An Hui,1 Shuichi Nakamura,1,2 Shun Suzuki,1 Kazukiho Tsuruya,2 Toshihiko Takei,1 Junichi Itoh,1,3

1,2,3,4Dept of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; 1,4Dept of Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’ s Hospital, Chengdu, Sichuan, China.

Background: Matrix vesicles (MVs) are the matrix vesicles from calcifying VSMC that initiate mineralization within the extracellular matrix of VSMC. MV are similar to exosomes which are known to contain miRNA important in cell-cell communication. We hypothesized that the miRNA expression profile in calcifying MV (CaMV) would differ from non-calcifying MV (CTLMV) isolated from CKD rats.

Methods: CaMV were suspended in the culture media (DMEM) of hVSMC with normal fasting or high glucose (HG) (100 or 450 mg/dl), although hVSMC are usually cultured with normal fasting glucose at Day 7 and 14. At Day 7, the mRNA expression of Sox9, a chondro-osteogenic differentiation marker, was upregulated in hVSMC cultured with HG. The degree of calcification, the content of calcium P nanoparticle (CPP) at Day 1 and the correlation was −0.37, also consistent with higher observed basal iCa levels. There was no difference in SOCE at 10 weeks but by 35 weeks was 22.8% of patients were already admitted to parathyroidectomy, we further categorized PTH as ≥ or <500pg/ml. We analyzed the miRNA on array that changed at least 2 fold in the comparison groups with a p value of < 0.01 and false discovery rate of < 20%. Bioinformatic target gene prediction was performed using Targetscan and Miranda. CTLMV or calcifying MV were also co-cultured with VSMC to assess the change in calcification.

Results: At Day 14, CaMV increase calcification when added to VSMC compared to CTLMV. The arrays demonstrated 33 increased miRNAs and 17 decreased miRNAs in CaMV vs CTLMV. Real time PCR confirmed the mir-30c expression, known to regulate vascular calcification, is increased in CaMV vs CTLMV. Additional regulatory miRNA identified via target prediction analysis followed by functional enrichment yielded multiple mRNA-miRNA networks. Narrowing the analyses to only those RNA controlled by at least 3 miRNAs identified important miRNAs, including cell signaling pathways known to be involved in vascular calcification: Decreased expression of miRNAs (Ca vs. CTL) that would upregulate the target genes involved in P21 kinase signaling. In contrast, increased miRNA expression in CaMV vs. CTLMV would lead to downregulation of several signaling pathways including MAPK, RAS, mTOR and FOXO.

Conclusions: Calcifying MV contain different miRNAs compared to CTLMV. MiRNAs contained in calcifying MV may be transferred to other VSMC and regulate signaling pathways involved in vascular calcification.

The Precedence of the Reduced Osteopontin Expression and the Increased Calcium Phosphate Calcification by the Calcification by Phosphate Load with Normal Fasting Glucose in Human Vascular Smooth Muscle Cells

Masanori Tokumoto,1 Shunsuke Yamada,1,2 Kazukiho Tsuruya,3 Takanari Kitazono,1 Hiroaki Oboishi,1 ,2,7 Div of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; 3Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 7Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.

Background: It is well-known that vascular calcification (VC) develops in diabetes mellitus patients. On the other hand, malnutrition is also reported to induce VC. Thus, we examined how glucose load affects phosphate (P)-induced calcification in human vascular smooth muscle cells (hVSMC).

Methods: We added P of 1, 1.5, or 2.0 mM in the culture media (DMEM) of hVSMC with normal fasting or high glucose (HG) (100 or 450 mg/dl), although hVSMC are usually cultured with HG. The degree of calcification, the content of calcium P nanoparticle (CPP) in the media, and the expression of both the intrinsic calcification inhibitors and the chondro-osteogenic differentiation markers were examined at Day 1, 7, and 14. Moreover, it negatively correlated with the content of CPP at Day 1 and the correlation was −0.37, also consistent with higher observed basal iCa levels. There was no difference in SOCE at 10 weeks but by 35 weeks was increased in the CKD+Ca cohort (p=0.05) with a trend toward significance in the CKD cohort (p=0.08), also consistent with higher observed basal iCa levels.

Results: Basal iCa levels were lower in 10 week CKD VSMC compared to NL (0.76±0.02 vs. 0.66±0.02, p=0.05) however increased 1.5-fold by 35 weeks to be greater than NL (0.98±0.01 CKD, 0.81±0.02 NL, 0.90±0.04 CKD+Ca, p=0.05). SR store release was greater in CaMV at both 10 weeks (0.45±0.02 vs. 0.37±0.02, p=0.05) and 35 weeks (0.62±0.02 CKD, 0.44±0.03 NL, 0.50±0.03 CKD+Ca, p=0.05). At 10 weeks: SERCA2a expression was greater in CaMV in part explaining the lower basal iCa levels, however, at 35 weeks SERCA2a and NCX1 were both decreased in CaMV, consistent with higher iCa levels. There was no difference in SOCE at 10 weeks but by 35 weeks was increased in the CKD+Ca cohort (p=0.05) with a trend toward significance in the CKD cohort (p=0.08), also consistent with higher observed basal iCa levels.

Conclusions: Basal iCa, SR store release, and SOCE increases with progressive CKD at least in part due to changes in the expression of the common calcium regulatory proteins SERCA2a, NCX1, and NCX2. The increase in iCa is likely a key mechanism in our previous observations that CKD VSMC display an osteogenic phenotype, which is known to worsen cardiovascular outcomes.

The Role and Mechanism of Nrf2/HO-1 Pathway in Oxidative Stress-Induced Vascular Calcification in End-Stage Renal Disease In Vitro

Li Wang,1,2 Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chengdu, Sichuan, China.

Background: To investigate the mechanism of Nrf2/HO-1 pathway in oxidative stress-induced vascular calcification in ESRD (in vitro), and to explore a new target for the intervention of vascular calcification in ESRD.

Methods: 1. Rat aortic vascular smooth muscle cells(RASMCs) were cultured and divided into 4 groups: the complete medium cultured group, the calcification medium cultured group, the group of complete medium cultured for 42h and then sulforaphane (SFN) cultured for 6h, the group of complete cultured medium for 46h and then H2O2 cultured for 2h. Detect nuclear Nrf2 expression in each group by western blot. 2. 4 groups of RASMCs were cultured: the calcification medium cultured group, the group of H2O2 pretreated for 2h and then calcification medium cultured, the group of SFN pretreated for 6h and then calcification medium cultured, the group of SFN pretreated for 6h and H2O2 pretreated for another 2h, and then calcification medium cultured. Detect the expression of intracellular reactive oxygen species (ROS) by using DCFH-DA probe, and the expression of Nrf2, Heme Oxygenase (HO-1), Protein-related trypsin inhibitor (PI), Runx2 were measured.

Results: 1. Nrf2 expression in nucleus was enhanced after SFN and H2O2 stimulation. 2. The expression of Nrf2,Runx2 and ROS, but not HO-1, were induced by calcification medium in a time-dependent manner. 3. ROS was significantly reduced after H2O2, SFN, SFN + H2O2 pretreated, and decreased gradually with incubation time (P<0.05). 4. The expression of Nrf2 and HO-1 were induced by SFN, and the expression of Runx2 was inhibited in calcification medium. 5. The expression of Nrf2, HO-1, Runx2 could be induced by H2O2, but the expression of Runx2-induced calcification medium decreased gradually within incubation time after H2O2, or SFN + H2O2, pretreated.

Conclusions: The calcification in RASMCs is associated with the overexpression of endogenous ROS. Overexpression of Runx2 induced by endogenous ROS, but not exogenous ROS, may be inhibited or attenuated by the activated Nrf2/HO-1 pathway.
VCAM - 1 and TNF Alpha Induce Vascular Calcification In Vitro
Kevin Willy, Ralf Schindler, Daniel Zickler. Dept of Nephrology and Internal Intensive Care Medicine, Charité Univ Medicine, Berlin.

Background: VCAM, TNF alpha and soluble TNF alpha receptor 1 (sTNFR1) are elevated in patients with chronic kidney disease (CKD). In previous clinical trials with high cut-off dialysis plasma levels of these molecules and in vitro vascular calcification were lowered. Here we assessed the role of sTNFR 1 and VCAM on in vitro calcification.

Methods: In human vascular smooth muscle cells (VSMCs) vascular calcification was induced by osteogenic medium (OM). VCAM, TNF-α and sTNFR1 were added. Calcification was quantified by alkaline phosphatase staining and alizarin red staining. Calcification was then normalized to WST – 8.

Results: VCAM enhances vascular calcification in vitro in a dose-dependent manner (p<0,0001). TNF-α -induced calcification was effectively inhibited by sTNFR1 (50% reduction of the initial level; p=0,0001). sTNFR1 alone does not promote vascular calcification.

Conclusions: VCAM and TNF alpha promote vascular calcification in vitro. Their elimination with high cut-off dialysis or their pharmacological blockade may be advantageous in regard to vascular calcification in CKD.

SA-PO590
The Tripehelical Collagen Analog (GPO)α Acts Cofactors of Vascular Smooth Muscle Cells in a Concentration Dependent Manner
Uwe Querfeld, Nadja Kretzschmar, Christian Freise. Pediatric Nephrology, Charité, Berlin, Germany; Center for Cardiovascular Research, Charité, Berlin, Germany.

Background: Extensive remodeling of the extracellular matrix and the transdifferentiation of vascular smooth muscle cells (VSMC) contribute to the pathogenesis of vascular calcifications in patients with chronic kidney disease (CKD). Matrix metalloproteinasises (MMPs) are proteolytic enzymes that impact on both of these processes and, thus, represent potential therapeutic targets. We have previously shown that the synthetic collagen analog (Gly-Pro-Hyp)3-α(GPO)α, a small peptide, could inhibit the enzymatic activity/stability of the gelatinases MMP-2 and -9 in a concentration dependent manner [1]. Aim of this study was therefore to investigate potential regulatory functions of GPO in an in vitro model of arteriolesclerotic VSMC calcification.

Methods: Cultures of murine VSMC were induced by a calcification medium (CM) containing elevated concentrations of calcium and phosphorus with or without the presence of different GPOα-concentrations (0.01; 0.1; 1 µM). VSMC calcifications were quantified by measuring calcium depositions and ALP-release.

Results: CM-induced VSMC calcification was enhanced in a concentration dependent manner (0.01; 0.1; 1 µM) while GPOα concentrations (0.01; 0.1; 1 µM) inhibited calcification in a concentration dependent manner. GPOα significantly reduced ALP release in VSMC cultures. These results suggest that GPOα inhibits the development of calcification in vitro.

Conclusions: GPOα acts as a cofactor of VSMC calcification. These results suggest that GPOα could be used as a potential therapeutic agent for the prevention of vascular calcification.

Protective Effects of Epigallocatechin Gallate (EGCG) on Vascular Calcification In Vitro and In Vivo
Uwe Querfeld, Karoline Websky, Christian Freise, Kerstin Sommer, Ursula Schulz, Veronika Bobb. Pediatric Nephrology, Charité, Berlin, Germany; Center for Cardiovascular Research, Charité, Berlin, Germany.

Background: Vascular calcifications are common in patients with chronic kidney disease (CKD). Our preliminary studies indicate that inhibition of matrix metalloproteinases (MMP)-2 and -9 suppresses the development of arterial calcification in uremic rats. Epigallocatechin gallate (EGCG), a polyphenol ingredient of green tea, has strong anti-inflammatory properties and inhibitory effects on MMPs. We therefore investigated potential protective effects of EGCG on vascular calcifications of smooth muscle cells (VSMC) in vitro and in an animal model of uremia-associated arteriosclerosis in vivo.

Methods: In vitro, calcifications of murine VSMCs were induced by a high phosphate (HP)-medium and cells were treated with different EGCG-concentrations (20–100µg/ml). VSMC calcifications were quantified using the orthro-cresolphthalein-method and proteolytic activities of MMP-2 and -9 in VSMC supernatants were determined by gelatin zymographies. In vivo, animals were treated with EGCG in drinking water. Animals were sacrificed after 2 weeks of treatment and aortic calcifications were quantified after von Kossa-staining.

Results: In vitro, EGCG provoked a dose-dependent increase of HP-induced calcification (up to 50%) of VSMCs and of proteolytic MMP-2 and -9 activities. In vivo, all EGCG-treated mice had severe arterial calcifications, involving 50% of the arterial wall wall after only 2 weeks of treatment. EGCG had no significant inhibitory effect on the development of vascular calcifications.

Conclusions: In this “negative experimental trial”, EGCG had no beneficial effect in the chosen animal model, which (considering the rapid development of calcifications) may have been too aggressive, thus overlooking potential protective effects of EGCG. Encouraged by the positive in vitro results, the effects of EGCG and other polyphenols should nonetheless be further investigated in other animal models of uremia-associated arteriosclerosis.

Mechanism of Calcification by Iron Stimulation in Vascular Smooth Muscle Cells
Savuri Kawada, Yasuyuki Nagasawa, Mutsumi Kawaibe, Aritoshi Kida, Mana Yahiru, Tomoko Kimura, Kiyoko Yamamoto, Masayoshi Nanami, Yukiko Hasuike, Takahiro Kuragano, Keiji Nakasho, Hidemi Ohyama, Takeshi Nakamichi. Dept of Internal Medicine, Div of Nephrology and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; Dept of Pathology, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.

Background: In CKD patients, atherosclerosis is one of important key factors which determine their prognosis. It was reported the calcification induced by TNF-α was related with iron in HUVeCs by our group. To reveal the relationship between calcification in vascular media and iron stimulation using vascular smooth muscle cells.

Methods: The aorta smooth muscle cells were cultured for three weeks. At day 0, we changed the usual culture medium to calcification medium, and TNF-α and iron were added to the calcification medium. Calcification in each condition was confirmed by Alizarin Staining. And to reveal early mechanism to enhance the calcification by iron and TNF-α-stimulation, we compared the gene expression profile between each condition in day 1 and day 3 using microarray analysis. We confirmed gene expression of cytokine which had increased in microarray analysis by real-time PCR.

Results: We confirmed both iron and TNF-α-stimulation enhanced calcium deposition in Alizarin Staining. Moreover, both iron and TNF-α-stimulation at the same time enhanced calcification more strongly than single stimulation. We picked up a cytokine which had increased with both iron and TNF-α-stimulation in the microarray analysis as similar as the Alizarin Staining result had shown. We confirmed gene expression of this cytokine by real-time PCR. Gene expression was increased at day 1 by stimulation of iron 5.8±3.0 fold change vs control), TNF-α (7.8±1.9 fold change vs control), and both stimulation (53.1±27.16 fold change vs control), synergistically.

Conclusions: Iron stimulation enhanced calcification in vascular smooth muscle cells along with TNF-α-stimulation. The possibility was suggested that this gene change from the early stage participated in the mechanism that iron promoted blood vessel media calcification.

Kidney Injury/Repair Stimulates Vascular Disease Through Activin and Systemic Wnt Inhibition
Matthew James Williams, Olga A. Agapova, Yifu Fang, Toshifumi Sugatani, Carmen M. Halabi, Keith A. Hruska. Pediatrics, Nephrology, Washington Univ School of Medicine, Saint Louis, MO.

Background: We show that the vascular effects of CKD are an interplay of Wnt inhibition and activin induction mediated modulation of Activin receptor (ActRIIA) function resulting in a stimulation of atherasclerosis and vascular calcification.

Methods: CKD with elevated activin and Wnt inhibitors, especially Dkk1, was induced in the mouse models for vascular calcification, lineage tracing, and Alport’s. Activin, Dkk1, ActRIIA, psmad 2/3, aklotho and collagen levels were measured by Elisa, RT-PCR and westerns. Vascular smooth muscle cell (VSMC) function was measured by pressure

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only; Underline represents presenting author.
induced arterial dilatation in situ. Cell lineage tracing was performed in Rosa-tdT mice bred to CAG-CreERT mice. Mice harboring Rosa-tdT express tomato red cells in rearing Cre recombinein.

**Results:** Circulating activin and Dkk1 levels were increased while aklotho levels were decreased by CKD. In diseased kidneys, activin was expressed in myofibroblasts, and activin signaling was increased. Activin signaling correlated with Dkk1 expression, indicating a decrease in VSMC differentiation and inhibited osteoblastic transition and atherosclerotic calcification. In the circulation, the ActRIIA ligand trap decreased Dkk1 levels. CKD induced expression of tomato red cells in the adventitia after two weeks of femoral artery injury in Tek-Cre/ Rosalcre TKO mice compared to Tek-Cre/Rosa-tdT mice with normal kidney function.

**Conclusions:** CKD increased circulating free activin levels, decreased VSMC function, stimulated aortic osteoblastic transition and atherosclerotic calcification. Decreasing effects of elevated activin in CKD with an activin receptor type IIa (ActRIIA) ligand trap increased VSMC differentiation and decreased vascular calcification.

*Translant Azotemia Episode Exacerbates Vascular Calcification in Adenine-Induced Uremic Rats* Daisuke Mori,1 Issai Matsui,2 Akihiro Shimomura,2 Yasuo Kusunoki,1 Sayoko Yonemoto,3 Masamitsu Senda,4 Yusuke Sakaguchi,5 Takayuki Hamano,5 Tetsuo Nakahara,5 Yoshikata Iiaka,3 Hiromi Kakuji,5 1Geriatric Medicine and Nephrology, Osaka Univ Graduate School of Medicine, Suita, Japan; 2Comprehensive Kidney Disease Research, Osaka Univ Graduate School of Medicine, Suita, Japan.

**Background:** Urea, the final metabolite of amino acids in the body, can carbanilate proteins at lysine residues, and thereby modifies characteristics of proteins reversibly. Several studies have revealed that functions of proteins are impaired by carbanylation. Acute kidney injury (AKI) is a representative pathological condition that elevates urea temporarily. Although AKI is not a perpetual condition, it is well-known that AKI increases subsequent risk of cardiovascular diseases through yet-unknown mechanisms. We evaluated the effects of transiently elevated serum urea on vascular calcification (VC).

**Methods:** Male Sprague-Dawley rats at age 9 weeks were divided randomly into two groups: cellulose-preload + adenine diet (group C+A) and urea-preload + adenine diet (group U+A). Urea-preload group received 10% urea diet from 9 to 13 weeks of age. Cellulose served as a control for urea. After one week of urea-washout period, all rats were euthanized for blood and tissue samples.

**Results:** Serum urea levels were 15.87 ± 2.96 mg/dL in cellulose-preload group and 39.20 ± 3.74 mg/dL in urea-preload group at the end of the preload period. Serum urea levels in urea-preload group were normalized to 14.73 ± 1.28 mg/dL during the washout period. At age 9 weeks, rats in group U+A developed severe VC in comparison with the rats in group C+A. Serum creatinine, urea nitrogen, calcium, phosphate, magnesium, albumin, and body weight were not different between the two groups at age 19 weeks. Western blot analysis of the aorta revealed that dietary preload of urea increased carbanilated proteins.

**Conclusions:** Preload of urea exacerbated VC in adenine-induced uremic rats. Protein carbanylation might link urea-preload to VC.

**SA-PO595**

*SNF472 Inhibits Cardiovascular Calcification in Uremic Rats* Joan Perello1,2 Carolina Salcedo,1 Ellen Neven,1 Geert J. Behets,1 Pieter H. Joubert,1 Patrick C. D’Haese,1,2 Miquel Ferrer,1 1R&D Dept, Laboratory Sanifit, Palma, Illes Balears, Spain; 2Laboratory of Renal Lithiasis Research, Univ of Balearic Islands, Palma, Illes Balears, Spain; 3Laboratory of Pathophysiology, Univ of Antwerp, Antwerp, Belgium.

**Background:** SNF472, an intravenous (i.v.) formulation of phytate, has been shown to inhibit cardiovascular calcification (CVC) in non-uremic conditions. We investigated the pharmacodynamics (PK) and efficacy (inhibition of CVC) of i.v. SNF472 in control and uremic rats.

**Methods:** The exposure to SNF472 in uremic animals was distinctly lower (5-fold for Cmax). SNF472 treatment resulted in a significant reduction in CVC of 80 and 88% in aorta and heart, respectively.

**Conclusions:** Daily SNF472 4 hour infusions of 50 mg/kg inhibit the development of CVC up to 88% in a rat, adenine model of uremia. These results support further investigation of SNF472 in the treatment of CVC in patients with calcification-related disorders such as calciphylaxis and ESRD patients.

**Funding:** Pharmaceutical Company Support - Laboratoris Sanifit S.L.

**SA-PO596**

*Enzyme Therapy for Vascular Calcification* W. Charles O’Neill,1 Kelly E. Manning,1 Koba A. Lomashvili,2 Nelson Haia,3 Peychi Lee,4 Francis T. Daney,5 Kim L. Askew,6 Anthony G. Quinn,7 1Renal Div; Emory Univ School of Medicine, Atlanta, GA; 2Synageva Biopharma, Lexington, MA.

**Background:** Pyrophosphate (PiPi) is a key endogenous inhibitor of hydroxyapatite formation that circulates at levels sufficient to prevent vascular calcification. PiPi is produced from extracellular ATP by the ectoenzyme, nucleotide pyrophosphatase pyrophosphorylase (NPP1) and deficiency of this enzyme produces severe fatal arterial medial arterial calcification in humans. Mice lacking NPP1 have undetectable plasma PiPi and also develop arterial calcification. We examined whether exogenous NPP1 can increase plasma PiPi and prevent vascular calcification in these mice.

**Methods:** Recombinant proteins containing the extracellular portion of human NPP1 fused to human IgG1 Fe (ENPP1-Fc) were created and injected into two mouse models of NPP1 deficiency (ENPP1−/− and ENPP1−/−/−). NPP1 activity was measured by conversion of [32P]ATP to [32P]Pi with separation by thin-layer chromatography. Plasma PiPi was measured by a radiometric enzyme assay using UDP-[14C]glucose and UDP-glucose pyrophosphorylase.

**Results:** Intravenous injection of NPP1-Fc (6 mg/kg) into ENPP1−/− mice increased plasma PiPi activity to a peak of +/− 18% of normal at 4 hours with a decline to 70 +/− 5% of normal by 72 hours. There was no increase in aortic NPP1. Plasma PiPi followed a similar pattern, with a peak of 2.2 +/− 0.6 µM at 4 hours declining to 0.21 +/− 0.04 µM at 72 hours (normal: 2.18 +/− 0.33 µM). With subcutaneous injection, plasma NPP1 was 110 +/− 13% of normal and plasma [PiPi] was 0.38 +/− 0.14 µM after 48 hours. Subcutaneous administration of NPP1-Fc 48 h reduced aortic calcium content 86 +/− 5% (p=0.001) after 18 days in ENPP1−/− mice fed a high phosphorus diet, and improved survival at 10 weeks from 15% to 50% (p=0.001) in ENPP1−/− mice fed a high phosphorus, low magnesium diet.

**Conclusions:** Administration of NPP1 in NPP1-deficient mice produces an increase in circulating PiPi that is sufficient to prevent vascular calcification and increase survival. The ability of ENPP1 fusion proteins to raise PiPi levels and inhibit tissue calcification supports the potential to reduce vascular calcification in other calcification-prone states.

*The Risk of Medial Arterial Calcification in Early Chronic Kidney Disease* W. Charles O’Neill,1 Kum Hyan Hun,2 Arshad Ali,1 Ansley O’Neill,1 Kelly E. Manning,1 1Renal Div; Emory Univ, Atlanta, GA; 2Internal Medicine, Dept of Internal Medicine, Inje Univ College of Medicine, Ilsan Paik Hospital, Goyang, Korea.

**Background:** Medial arterial calcification is common in advanced chronic kidney disease (CKD) but whether this risk begins in early CKD is unknown. There is also concern that possible benefits of vitamin D and calcium in this group may be offset by potential induction of vascular calcification. We have previously shown that breast arterial calcification is a readily available and specific marker of medial arterial calcification and that its prevalence is increased in advanced CKD.

**Methods:** From a computerized search of medical records, 446 women with CKD and mammograms were randomly selected. After exclusion of women with renal transplants or other stages of CKD, history of warfarin use, or non-screening mammograms, 333 women with CKD (MDRD formula) were identified and individually matched by age and diabetes status to women with an estimated GFR >90 ml/min/1.73 m². Digital mammograms were visually inspected for arterial calcification.

**Results:** Mean age was 69.5 +/− 0.6 (range: 44-91), mean eGFR was 49.5 +/− 0.4 ml/min/1.73 m², 20.1% had diabetes, 31.5% were receiving calcium supplements, 31.3% were receiving vitamin D (> 1000 units/d), and 1.8% were receiving an active form of vitamin D. Controls had a mean eGFR of 104.1 +/− 0.7 ml/min/1.73 m². The prevalence of arterial calcification was the same in CKD 3 patients (33.1%) and controls (33.3%). Dividing the CKD 3 patient group by different thresholds of serum creatinine yielded similar results. There was no difference in calcification between patients taking or not taking calcium supplements (36.2% vs. 34.1%), vitamin D (36.2% vs. 34.6%), or both (30% vs. 32.5% with neither). In a logistic regression, only age was a significant determinant of arterial calcification (p=0.0001).

**Conclusions:** The prevalence of medial arterial calcification is not increased in women with stage 3 CKD, indicating that the risk begins at stage 4 CKD. Supplementation of calcium or vitamin D does not increase the risk of medial arterial calcification in these patients.

**Funding:** Clinical Research Support.

Vascular Calcification: From Bench to Bedside

SA-PO598
Deoxycholic Acid (DCA), a Metabolite of Circulating Bile Acids, and
Coronary Vascular Calcifications in Chronic Kidney Disease (CKD)
Makoto Miyazaki,1 Shinobu Miyazaki-anzai,1 Audrey L. Keenan,1 Kristen L.
Nowak,1 Jessica B. Kendrick,1 Geoffrey A. Block,2 Michel Chonchol.1 1Univ
of Colorado Denver; 2Denver Nephrology.
Background: Our group has previously shown that DCA, a metabolite of circulating
cholic acid, induces vascular mineralization and osteogenic differentiation in animal models
and that circulating levels of DCA are elevated in patients with CKD. We investigated
whether increased DCA serum levels are associated with an increase risk for higher
coronary artery calcification (CAC) volumes and lower lumbar bone mineral density
(BMD) in CKD patients.
Methods: We used stored baseline serum samples in 112 patients with moderate to
advanced CKD (eGFR= 20-45 mL/min/1.73m2) who participated in a randomized-controlled
study to examine the effects of phosphate binders on vascular calcification. Circulating
DCA levels were assayed using liquid-chromatography-tandem mass spectrometry (LCMS/MS). CAC volume was obtained using GE-Imatron C150 scanner and lumbar BMD
was determined using abdominal computed tomography scans with a calibrated phantom
of known density. Linear regression models were used to examine the cross-sectional
association between DCA with CAC volume and lumbar BMD.
Results: Participant characteristics were as follows: mean age, 68±11 years; 50%
women; 10% black; mean eGFR, 32±8 mL/min/1.73m2; and median DCA 58.4 (IQR 29112) ng/mL. After adjusting for demographics, co-existing illness, body mass index, eGFR
and circulating markers of CKD-MBD including serum calcium, phosphorus, vitamin D,
parathyroid hormone and fibroblast growth factor 23, an increase serum DCA level > 58
ng/mL positively associate with CAC volume (ß: 494.84 ± 238.82; p=0.03) and negatively
associated with BMD (ß: - 20.35± 9.56; p=0.03).
Conclusions: Higher serum levels of DCA in patients with stage III and IV CKD is
independently associated with higher CAC volume and lower lumbar BMD. Larger cohort
studies are needed to confirm these findings.

SA-PO599
Fibroblast Growth Factor 23 and Fetuin A Levels in Pre-Dialysis Stage 4-5
Chronic Kidney Disease Patients with Aortic Calcification: A Case Control
Study Vijayakumar Theophilus-Sunder, Anna T. Valson, Vinoi George David,
Santosh Varughese, Tamilarasi Veerasamy. Dept of Nephrology, Christian
Medical College, Vellore, Tamil Nadu, India.
Background: Vascular calcification (VC) contributes to the increased cardiovascular
mortality seen in CKD. However, not everyone with advanced CKD develops VC, indicating
that circulating levels of factors that modulate VC may play a role in determining individual
susceptibility towards VC. We aimed to examine this hypothesis by measuring the levels
of FGF-23 and Fetuin-A in a group of pre-dialysis CKD Stage 4-5 patients who had
documented abdominal aortic calcification (AAC) and an age, gender and eGFR matched
group of patients who did not have AAC.
Methods: Out of a pre-existing cohort of 710 patients with CKD Stage 4-5, 28 patients
with AAC (Group 1, cases) were compared with an equal number of age, gender and eGFR
matched patients without AAC (Group 2, controls) with respect to their demographic and
biochemical parameters, including FGF-23 and Fetuin-A. AAC was assessed by lateral
abdominal X ray, while Fetuin-A and intact FGF-23 were estimated by ELISA in serum.
Results: Groups 1 and 2 were matched for age (mean age 57.7 and 57.8 years
respectively, p = 0.938), gender (84.6% males in both groups) and eGFR (median eGFR
14.5 and 13.1 respectively, p = 0.826), and were not significantly different with respect
to risk factors for AAC such as presence and duration of diabetes, hypertension, smoking
and obesity. Levels of calcium, phosphorus, PTH, 25 (OH) vitamin D, serum cholesterol,
triglycerides, HDL and LDL were also comparable between the two groups. However,
median FGF23 levels were significantly higher in Group 1 [25.2, (Q1= 14, Q3=34.2)]
compared to Group 2 [12.1 (Q1 = 6.6, Q3 = 14.1), n = < 0.001]. Median Fetuin-A levels
were also significantly higher in Group 1 [5.5 (Q1=4.4, Q3=6.5)] compared to Group 2
[4.1 (Q1 = 3.6, Q3 = 5.7, n = 0.034).
Conclusions: Pre-dialysis patients with Stage 4-5 CKD with AAC, had higher FGF23 and Fetuin-A levels compared to age, gender and eGFR matched patients who did not
have AAC. The nature and mechanism of this association between elevated FGF23 and
Fetuin-A levels and AAC requires further exploration.

SA-PO600
Lack of Association Between Serum Osteoprotegerin, Osteopontin and
Fetuin-A Levels and the Longitudinal Changes in Arterial Stiffness in CKD
Patients Undergoing Renin-Angiotensin System Blockade Cecilie Lyngsø,1
Marie Frimodt-Moller,2 Marianne Rix,2 Anne-Lise Kamper,2 Svend Strandgaard,1
Arne Høj Nielsen,1 Allan Flyvbjerg,3 Mette Bjerre.3 1Dept of Nephrology, Herlev
Hospital, Herlev, Copenhagen, Denmark; 2Dept of Nephrology, Rigshospitalet,
Copenhagen, Denmark; 3The Medical Research Laboratory, Dept of Clinical
Medicine, Aarhus Univ, Aarhus, Denmark.
Background: Osteoprotegerin (OPG), osteopontin (OPN) and fetuin-A, have been
suggested to participate in the accelerated development of arteriosclerosis seen in patients
with chronic kidney disease (CKD). We have previously shown that measures of vascular
stiffness were significantly reduced after 24 weeks of treatment with renin-angiotensin

Poster/Saturday

system (RAS) blocking agents. The aim of this longitudinal post hoc study was to investigate
whether serum levels of OPG, OPN and fetuin-A were associated with these same changes
in markers of arterial stiffness found in CKD patients treated with RAS blocking agents.
Methods: Serum OPG, OPN and fetuin-A levels were measured in 57 patients with
CKD stage 3-5, mean eGFR 29 ml/min, as a post hoc analysis of data acquired during a
24-week controlled trial in which patients were randomized to treatment with 16 weeks of
monotherapy with either enalapril or candesartan followed by 8 weeks of dual blockade.
Serum levels were obtained upon study entry and after 16 and 24 weeks of RAS blocking
therapy and compared to aortic pulse-wave velocity and augmentation index.
Results: Except for a significant correlation between OPG and central pulse pressure
(p < 0.05), serum levels of OPG, OPN and fetuin-A did not correlate to markers of vascular
stiffness. There were no significant changes in serum levels of OPG, OPN and fetuin-A
when monotherapy with enalapril or candesartan was compared to dual blockade.
Conclusions: The present results do not corroborate the use of OPG, OPN and fetuin-A
as surrogate markers for vascular stiffness in patients with CKD.

SA-PO601
Hyperuricemia Is Significantly Associated with Coronary Artery
Calcification and Vascular Stiffness in Asymptomatic Subjects Undergoing
General Health Examination Ah Ran Choi, Hae Yeul Park, Seok-Hyung Kim,
Hoon Young Choi, Sung-Kyu Ha, Hyeong Cheon Park. Nephrology, Gangnam
Severance Hospital, Yonsei Univ College of Medicine, Seoul, Korea.
Background: Recent studies suggest that hyperuricemia may be associated with
increased adverse cardiovascular events even in healthy subjects. Quantity of coronary artery
calcium (CAC) correlates with atherosclerotic plaque burden and increased cardiovascular
events. This study aimed to determine the relationship between serum uric acid level(sUA)
and brachial-ankle pulse wave velocity (ba-PWV), coronary artery calcium score (CACS)
as well as other traditional cardiovascular risk factors in asymptomatic subjects.
Methods: We consecutively enrolled 4,703 asymptomatic subjects who underwent
ba-PWV and coronary CT angiography as part of a general health examination. A high baPWV group, those having increased vascular stiffness, was defined as ba-PWV greater than
1497.5 cm/s (75th percentile). The subjects were stratified into four groups according to sUA.
Results: Mean age of enrolled subject was 52.8 ± 9.4 years, 61 % of the study
participants were male. Eight point four percent of the study participants showed CACS
greater than 100. The adjusted odds ratio (OR, 95% confidence interval) for the presence
of high ba-PWV in the second to fourth sUA quartile vs. first sUA quartile was 1.45 (1.1371.840, P<0.003), 1.42 (1.081-1.866 P<0.012), 1.66 (1.246-2.218, P<0.001), respectively
after adjusting for age, gender, diabetes, hypertension, smoking, body mass index (BMI),
estimated glomerular filtration (eGFR), fasting blood sugar (FBS) and calculated LDL.
Moreover, subjects with CACS greater than 100 also showed that fourth quartile of sUA
was associated with high ba-PWV compared with the first quartile of sUA [OR 2.4, (1.653.47, P<0.001)]. Multivariate linear regression analysis demonstrated that old age, male,
hypertension, diabetes, BMI, FBS, eGFR and sUA were significantly associated with mean
ba-PWV and log transformed CACS.
Conclusions: Our results show that sUA is an independent risk factor for increased
vascular stiffness and coronary atherosclerosis in asymptomatic adults undergoing health
examination.

SA-PO602
Abdominal Aortic Calcification Score on Plain Radiograph as a Predictor
of Coronary Artery Calcification Score on Computed Tomography and
T-Score on BMD in Dialysis Patients Eu Gene Jeong,1 Su Mi Lee,1 Young
Ki Son,1 Dongyeol Lee,2 Hansae Kim,2 Sung Hyun Son.3 1Dept of Internal
Medicine, Dong A Univ Hospital, Busan, Republic of Korea; 2Dept of Internal
Medicine, Bong Seng Memorial Hospital, Busan, Republic of Korea; 3Dept of
Internal Medicine, BHS Han Seo Hospital, Busan, Republic of Korea.
Background: Not only coronary artery calcification scores (CACS) on computed
tomography (CT) but also several VC scores on plain radiographs can predict cardiovascular
events. However, there is no study about the correlation between CACS on CT and VC
scores of several sites on plain radiographs. Therefore, we evaluated which VC scores among
several VC scores on plain radiographs are a predictor of CACS on CT in dialysis patients.
We also investigated the association between VC scores and bone mineral density (BMD).
Methods: We conducted this single center cross-sectional study from March 2013 to
September 2014. We checked the plain radiographs of the feet, hands, pelvis, and lateral
lumbar spine and estimated the VC scores. CACS on CT and BMD were evaluated. We
defined severe CACS as CACS > 1000. FGF-23, fetuin-A, osteoprotegerin (OPG) and
receptor activator of NF-κB ligand (RANKL) were analyzed with ELISA.
Results: The mean ages of 61 patients including 38 hemodialysis(HD) and 23 peritoneal
dialysis(PD) patients were 58.6±10.2 years. The prevalence rate of significant VC was 75.4%
and prevalence rate of severe CACS was 26.2%. The OPG levels were higher in patients
with severe CACS(p=0.019) and significant VC(p=0.009). Patients with AAC score≥5 had
lower T score of wrist and hip than patients with AAC score<5. CACS is positively correlated
with AAC score(r=0.639, p< 0.001), VC score of the hands and pelvis (r=0.494, p< 0.001).
AAC score is negatively correlated with T score of wrist(right: r=-0.286, p=0.027) and
hip(right: r=-0.259, p=0.045)on BMD. AAC score(B=59.4, C.I.=18.3-100.6, p=0.006) and
VC score of the hands and pelvis(B=225.8, C.I.=69.7-381.8, p= 0.006)on plain radiographs
were independently associated with CACS on CT.
Conclusions: AAC score among several VC scores on plain radiographs is the most
reliable predictor of CACS on CT and T score on BMD in dialysis patients.

of and after 12 months Kaupilla and Adragao study was to evaluate the influence of bone mineral disorders in VC and its progression patients; vascular calcification (VC) is common among them. The main objective of this study was to evaluate the influence of bone mineral disorders in VC and its progression in a prospective cohort of patients. Secondarily, we intend to identify clinical, laboratory, and imaging predictors of the presence and progression of VC.

Methods: Adult patients undergoing HD for ≥90 days were included. At the beginning of and after 12 months Kaupilla and Adragao methods were used to determine the VC score (VCS); and clinical, hormonal, inflammatory, biochemical, and nutritional markers were measured. Bone biopsy and histomorphometric analysis were performed at the beginning of follow up.

Results: Sixty patients completed the study; of them 41.7% were male, 43.4% diabetic, and the mean age was 56. 73±1.8 years. At the beginning of the follow-up, 75% of the participants had VC. Age >60 years (Odds ratio=5.2, 95%CI= 4.1-6.184, p<0.002), FG232 levels >3000 Ru/ml (Odds ratio=5.7, 95%CI= 1.00-3.29, p=0.05), and serum fetuin A >673 g/l (Odds ratio=7.3, 95%CI=1.26-43.7, p=0.03) were independent predictors of VC. Regarding VC progression age >60 years (Odds ratio=4.3, 95%CI=1.003-8.15, p=0.049), higher serum 1,25-dihydroxyvitamin D3 (Odds ratio=4.7, 95%CI= 1.47-27.9, p<0.01) no use of statins (Odds ratio=5.6, 95%CI= 1.13-28.1, p=0.03) were the only independent predictors. Bone turnover and histomorphometric findings were not associated with VC and its progression, which deserves new and more specific investigations.

SA-PO609

Increased Peripheral Arterial Calcification in Patients Receiving Warfarin

Kum Hwan Hah,1 W. Charles O’Neill,1 Renal Div, Emory Univ, Atlanta, GA;1 Internal Medicine, Inje Univ College of Medicine, Ilsan Paik Hospital, Goyang, Korea.

Background: Matrix gla-protein is a vitamin K-dependent inhibitor of vascular calcification. Factors including genetic deficiency or inhibition with warfarin produces medial vascular calcification in animals, raising concerns that warfarin may promote vascular calcification in humans. We recently showed that warfarin use is associated with increased breast arterial calcification but whether this is reflective of other arteries or occurs in men as well is unclear. Therefore, we compared the prevalence of calcification in peripheral arteries in patients with and without warfarin therapy.

Methods: A random sample from a computerized search of medical records yielded 430 patients with x-rays performed during or after warfarin therapy. Each was matched to a patient without warfarin exposure based on age and diabetes. Patients with warfarin exposure <1 month, history of ESRD, or serum creatinine > 2.0 were excluded. X-rays were reviewed visually for arterial calcification.

Results: Mean age was 66.9 ± 0.8, 41% were males, and 34% had diabetes. The indication for warfarin was atrial fibrillation in 45% and venous thrombosis or embolism in 44%, and mean duration of warfarin was 4.8 yrs (range: 1 month to 38 yrs). 68% were on warfarin at the time of the x-ray and the remainder had been off warfarin for a mean of 2.4 yrs (range: 1 day to 25 yrs). Serum calcium was slightly lower (9.04 +/- 0.3 vs. 9.17 +/- 0.2, p=0.003) in the warfarin patient but serum creatinine and phosphorus did not differ. Prevalence of arterial calcification was 44% greater in warfarin patients (30.2% vs. 20.9%, p=0.0023) but not on x-rays performed prior to warfarin (26.4% vs. 22.4%, p=0.156), indicating that the increase was due specifically to the warfarin and not to underlying disease or other patient characteristics. The increase in calcification was seen only after >3 yrs of warfarin and only in the ankle and foot. It was similar in men and women and greatest (2.4-fold) in patients under age 60 (15% vs. 6.3%, p=0.04).

Conclusions: Warfarin use is associated with lower extremity arterial calcification in both men and women independent of age, diabetes, and other patient characteristics.

Matrix Gla Protein and Vascular Calcification in Patients with End Stage Renal Disease

Hannes Olason,1 Christian L. Meuwese,1 Karin Luttropp,1 Annika Wernernson,1 Peter F. Barry,1 Cees Vermeer,2 Peter Stenvinkel,1 CLINTEC, Karolinska Inst, Sweden;1 VitaK, Maastricht Univ, Netherlands.

Background: Vascular calcification (VC) is a common and severe consequence of end-stage renal disease (ESRD). Matrix Gla protein (MGP) is a calcification inhibitor expressed by the vasculature that counters the development of VC.

Methods: In 84 ESRD patients undergoing LD-Tx at Karolinska University Hospital, biopsies from the inferior epigastric artery were obtained during surgery. Vascular calcification was assessed by von Kossa staining both by manual scoring (0-3) and by semi-automated analysis (%). Total uncarboxylated MGP (t-ucMGP) and dephospho-uncarboxylated MGP (dp-ucMGP) were measured in plasma. Tissue MGP expression was quantified in arterial biopsies by TaqMan RT-PCR. DNA methylation of the MGP gene was assessed in peripheral blood from 12 ESRD patients and 12 healthy controls.

Results: 50 patients (59.5%) had low VC scores (0 and 1) and 34 (40.5%) patients high VC scores (2 and 3). Plasma levels of dp-ucMGP were higher in patients with high VC scores compared to patients with low VC scores (2214 [1413-2995] vs. 1701 [1275-2233] pmoI/mL, p=0.005) and also associated with calcification (%) (Fig 1A: β [95%CI]: 26 [7 to 43] p<0.01). Additionally, calcification (%) associated with arterial expression of MGP (Fig 1B: β [95%CI]: 0.04 [0.02 to 0.06] p<0.0001). t-ucMGP levels were not associated with measures of VC. DNA methylation of the MGP gene was significantly lower in patients with ESRD compared to healthy controls (adjusted p<0.01).

A Nationally Representative Case Control Study of Calciphylaxis Risk Factors

Sagar U. Nigwekar,1 Sophia Zhao,1,2 Julia Beth Wenger,1 Franklin W. Maddux,2 Jeffrey L. Hymes,2 Ravi I. Thadhani,1 Kevin Chan,1,2 1MGH; 2Fresenius Medical Care North America.

Background: Prior studies evaluating calciphylaxis risk factors suffer from sample size limitations and none examine whether characteristics at dialysis initiation predict calciphylaxis risk.

Methods: Data for this matched case control study were derived from hemodialysis (HD) population at the Fresenius Medical Care North America (FMCNA). Cases were identified from FMCNA calciphylaxis prospective database. Controls (HD patients without calciphylaxis) were matched to cases on age, sex, and race. Data on variables at HD initiation were abstracted. Variables for multivariable logistic regression analyses were identified using stepwise selection.

Results: We analyzed 1,025 calciphylaxis cases (52% biopsy-confirmed) and 2,050 controls. Body mass index, diabetes mellitus (DM), serum parathyroid hormone (PTH) level, use of warfarin and phosphate binders were higher whereas serum calcium and active vitamin D use were lower at HD initiation in cases compared to controls.

Figure 1: The association between calcification % (as assessed by semi-automated analysis) and A) plasma dp-ucMGP levels, and B) tissue MGP expression.

Conclusions: Tissue and plasma levels of dp-ucMGP were higher in patients with VC versus those without, possibly indicating a compensatory up-regulation of MGP to prevent further progress. The observation that the methylation of the MGP gene was lower in ESRD than in controls suggests that the altered expression could be due to epigenetic regulation.

Funding: Government Support - Non-U.S.
No significant differences were noted for serum phosphorous, diatelyse calcium, use of statins and calcitriol. In DM subgroup, insulin injection use was more common in cases. In multivariable analyses, obesity (OR: 2.55, 95% CI: 1.82-3.50), DM (OR: 2.63, 95% CI: 1.88-3.69), use of warfarin (OR: 3.60, 95% CI: 2.40-5.41) and insulin injections (OR: 1.29, 95% CI: 1.07-1.89) were associated with higher risk. Similar results were noted in analyses restricted to biopsy-confirmed cases.

Conclusions: Obese, diabetic HD patients treated with insulin injections or warfarin are at high risk for calciphylaxis.

SA-PO612
Calciphylaxis Quality Improvement Project and Case Series Rohan V. Mehta, Jean Luc Franck, Jason Cobb. Renal Div, Emory Univ, Atlanta, GA.

Background: Calciphylaxis (Calcific Uremic Arteriopathy) is a serious condition characterized by extended length of stays and multiple hospital admissions. The treatment of calciphylaxis can become a burden on the healthcare system especially with the demands on hospital systems to become more efficient. The lengths of stay & 30 day readmission rates are becoming a measure of hospital quality. We developed a multidisciplinary team including nephrologists, hospitalists, dermatologists, hospital administration, nurses, wound care staff, social workers, dieticians, and palliative care. The purpose of the team is to improve the quality of care of our calciphylaxis patients. In development of this quality improvement project we began by examining our baseline patient population. We are reporting our baseline data as a case-series.

Methods: Retrospective chart review of calciphylaxis patients from 2001-2014 in our single center hospital which includes academic and community physicians. Baseline data reported included age, calcium, phosphorus, PTH, albumin, hemoglobin, creatinine, BUN, and the use of warfarin. Treatment options, the length of stay, and number of admissions were reported.

Results: In 20 reported patients, 19 were African-American. Average age was 61 years old. Average calcium levels of 8.8 mg/dl and phosphorus of 5.5 mg/dl. The average PTH was 573, albumin 2.75 g/dl, hemoglobin of 10.4 g/dl, BUN of 42, and creatinine 6.5 mg/dl. 13 patients received hyperbaric oxygen treatment, 9 patients received sodium thiosulfate infusions, and 6 patients received calcitriol. 11 patients were using warfarin for medical conditions including atrial fibrillation and deep venous thrombosis. The average length of stay was 45 days and 3 admissions per patient.

Conclusions: We reported one of the largest single center and predominant African-American calciphylaxis case series. In comparison to other reported calciphylaxis series our average PTH was lower and a high percentage of our patients were using warfarin at time of diagnosis. Future tasks include testing if the multidisciplinary quality improvement team interventions can improve our patient quality of care and hospital goals such as reductions in length of stay and 30-day readmission rates.

SA-PO614
Calciphylaxis – A Multi-Interventional Treatment Regimen Including Vitamin K Supplementation Might Reduce Mortality in Chronic Kidney Disease Patients Daniel A. Hochfellner, Barbara Binder, Werner Ribitsch, Alexander R. Rosenkranz, Gernot Schilcher. 'Clinical Div of Nephrology, Dept of Internal Medicine, Medical Univ of Graz, Graz, Austria; 'Dept of Dermatology, Medical Univ of Graz, Graz, Austria.

Background: Calciphylaxis is a rare disease predominantly affecting patients with chronic kidney disease (CKD) with a high mortality mainly due to wound infection. Recently, multimodal therapy schemes including sodium thiosulfate (STS) have been established. The role of a standardized Vitamin K supplementation remains unclear.

Methods: In a retrospective study we evaluated the impact of a standardized, multi-interventional treatment regimen on the mortality of calciphylaxis patients treated at the Clinical Department of Nephrology, Medical University of Graz, Austria between January 2009 and February 2014. Patients were treated with STS, dermatological wound management and high dose supplementation of vitamin K1 (Phytonadione 30mg/week). The primary endpoint was mortality compared to the present literature. Second endpoints included gender distribution, number of biopsy proven cases, analysis of triggering events and time from event to diagnosis. Data were collected from medical records.

Results: 20 patients with newly diagnosed Calciphylaxis at different CKD stages (CKD 5, n=15; CKD 4, n=3; CKD 3, n=1; no CKD, n=1) were included. The mortality was 25% versus 52% compared to recent literature. Gender distribution and amount of biopsy proven cases were comparable to other retrospective studies. 12 patients (60%) had a known preceding event such as trauma possibly having triggered development of calciphylaxis. The period from event to diagnosis was 103±94 days. 19 patients (95%) received STS. In contrast to other multimodal therapeutic concepts 95% (19) of our patients additionally received high dose vitamin K1 supplementation.

Conclusions: In our cohort calciphylaxis was associated with a markedly reduced mortality as compared to published outcome data. We hypothesize that supraphysiological support therapy and our multi-interventional treatment regimen play an important role in the treatment of calciphylaxis.

SA-PO615
The German Calciphylaxis Registry Vincent Brandenburg, Jürgen Floeg, Joanna Korbiel, Markus Ketteler. 'Cardiology, RWTH Aachen Univ Hospital, Aachen, Germany; 'Nephrology, RWTH Aachen Univ Hospital, Aachen, Germany; 'Nephrology, Klinikum Coburg, Coburg, Germany.

Background: Calciphylaxis (CUA) is a rare disease and for patients a devastating condition associated with high morbidity and mortality. CUA is characterised by painful, ischemic, partly necrotic skin ulcerations. Pathomorphologically, media calcification of cutaneous arteries and extracellular matrix remodelling are the hallmarks of CUA. Epidemiology and risk factors are incompletely understood. Referring patients to specialized units is limited due to high disease burden.

Methods: Therefore, we established an internet-based observational registry in 2006 (www.calciphylaxie.de) to allow online notification for pts with CUA. The registry includes a comprehensive data base with 71 parameters concerning patient and laboratory data, clinical background and presentation as well as therapeutic strategies. The diagnosis of CUA is made on clinical and/or histological grounds by the referring physician.

Results: Until Feb 2015 n=233 patients with CUA have been recorded (~ 30 pts/ year at constant rate) with a median delay of 28 days after onset: 99% Caucasians, 60% females; 76% HD and 10% PD patients; median age 66 (IQR 61-76) years. Co-medication at the time of diagnosis: 75% ESA, 51% vitamin K antagonists (VKA). Skin biopsy was done in 45%, prior PEX in 12%; major skin lesion in 80% at the legs. Median lab data upon diagnosis of CUA: AK Phos 113 u/L (IQR 86 - 167); PTX 173 g/mL (IQR 73-390), total calcium 2.20 mmol/L (IQR 2.04-2.36); phosphorus 1.62 mmol/L (IQR 1.28-2.00).

Conclusions: CUA is a rare disease among ESRD pts with high mortality. Therapeutic strategies vary significantly among centers; EBMs guidelines are absent. VKA usage appears to be a risk factor for CUA in ESRD pts. The German CUA registry is a valuable tool to collect data and may become a basis for a European registry (EuCalNet).

SA-PO616
Evaluation of the Effects of Sodium Thiosulfate Treatment on Calciphylaxis Pain Guillermo Ortiz, Joshua Wibecan, Julia Beth Wenger, Ravi I. Thadhani, Barbara Baer, Gernot Schilcher, Barbara Binder. 'Clinical Div of Nephrology, Medical University of Graz, Graz, Austria; 'Vascular Calcification: From Bench to Bedside, Emory Univ, Atlanta, GA.

Background: Intravenous sodium thiosulfate (STS) is commonly prescribed to treat calciphylaxis, a highly fatal disease that presents with excruciating painful skin lesions. Anecdotal reports suggest that STS may improve calciphylaxis associated pain (CAP) within 2 weeks of initiation; however, systematic evaluation of effects of STS on CAP is lacking.

Methods: This observational study included 22 patients with biopsy-confirmed calciphylaxis who were hospitalized at our center for ≥ 2 weeks during 2012-2014 for newly diagnosed calciphylaxis and were treated with STS. Medical records were reviewed to abstract clinical data including CAP severity (0-10 scale) and analgesic use. CAP scores restricted to biopsy-confirmed cases.

Results: Two patients with newly diagnosed calciphylaxis at different CKD stages (CKD 5, n=15; CKD 4, n=3; CKD 3, n=1; no CKD, n=1) were included. The mortality was 25% versus 52% compared to recent literature. Gender distribution and amount of biopsy proven cases were comparable to other retrospective studies. 12 patients (60%) had a known preceding event such as trauma possibly having triggered development of calciphylaxis. The period from event to diagnosis was 103±94 days. 19 patients (95%) received STS. In contrast to other multimodal therapeutic concepts 95% (19) of our patients additionally received high dose vitamin K1 supplementation.

Conclusions: In our cohort calciphylaxis was associated with a markedly reduced mortality as compared to published outcome data. We hypothesize that supraphysiological support therapy and our multi-interventional treatment regimen play an important role in the treatment of calciphylaxis.
predict 6-month outcomes. Baseline to 2-weeks (figure 1) despite steady doses of opiate medications. No significant predictors of CAP response were observed and CAP improvement at 2-weeks did not predict 6-month outcomes.

Conclusions: A large prospective trial is needed to ascertain the effects of STS on CAP.

SA-PO616

Long-Term Impact of Strict Blood Pressure Control During CKD on Mortality Risk After ESRD

Elaine Ku,1 Lawrence J. Appel,2 Jennifer J. Gassman,3 Miroslaw Smorodzinski,2 Mark J. Sarna,2 David V. Glidden,4 Chi-yuan Hsu,1 1UCSF; 2AASK; 3Tufts.

Background: In extended follow-up of the Modification of Diet in Renal Disease (MDRD) study, we reported that strict BP control did not lower risk of ESRD but associated with lower mortality risk after ESRD (HR 0.72 [95% CI 0.58-0.89]) (Ku Ki 2015). To further address this issue, we conducted parallel analyses in the African American Study of Kidney Disease (AASK) and post-hoc pooled analyses of AASK and MDRD.

Methods: AASK randomized 1094 persons with CKD attributed to hypertension to either intensive (70/100mmHg) or conventional (90/120mmHg) antihypertensive therapy. In extended follow-up, we evaluated the effect of time-updated exposure to RAS blockade versus all other antihypertensive medications in obese, hypertensive, non-diabetic patients with normal or mildly reduced kidney function using a Cox proportional hazards model as estimated by pooled logistic regression to assess the hazards of developing a 50% reduction in estimated glomerular filtration rate (eGFR) or end stage renal disease. In addition to adjusting for baseline comorbidities including age, gender, socioeconomic status, cardiovascular disease, and body mass index (BMI), we adjusted for time-varying covariates including systolic blood pressure (SBP), number of antihypertensive medications, use of mineralocorticoid antagonists, and eGFR.

Results: There were 219,701 patients that met inclusion criteria, with a median 4.9 years of follow-up. Median baseline eGFR was 72.6 mL/min/1.73m², median SBP was 146 mmHg, and median BMI was 32.8 kg/m². 59% of patients were on RAS blockade at baseline, and 69% of patients were on it for at least half the duration of follow-up. Taking into account time-updated exposure, there was a significantly reduced hazard of adverse renal outcomes in patients treated with RAS blockade compared to those treated with other antihypertensive medications (HR 0.93, p<0.01).

Conclusions: This study, conducted in a large real-world cohort of patients with detailed and time-updated data about blood pressure treatment, provides important evidence that RAS blockade may protect against deterioration in renal function among obese, hypertensive, non-diabetic patients.

SA-PO617

Obesity, Renin-Angiotensin System Blockade, and Chronic Kidney Disease: A Population-Based Cohort Study

Background: Obesity substantially increases the risk of the development and progression of chronic kidney disease. Adipose tissue expresses all of the components of the renin-angiotensin system (RAS), which is an important contributing factor to the high prevalence of hypertension in obese patients, and drives renal hyperfiltration and subsequent glomerular injury.

Methods: We performed a retrospective cohort study using the Health Improvement Network, a primary care database with comprehensive demographic, laboratory, and pharmacy data on 300,000 patients. We evaluated the effect of time-updated exposure to RAS blockade versus all other antihypertensive medications in obese, hypertensive, non-diabetic patients with normal or mildly reduced kidney function using a Cox proportional hazards model with time-varying covariates including systolic blood pressure (SBP), antihypertensive medications, use of mineralocorticoid antagonists, and eGFR.

Results: There were 397 cases of ESRD and 475 deaths (208 after ESRD). The risk for ESRD was 0.94 (95% confidence interval [CI] 0.77-1.14), risk for death after ESRD onset was 0.78 (95% CI 0.63-0.98), overall mortality risk was 0.92 (95% CI 0.77-1.10), and risk for death after ESRD was 0.82 (95% CI 0.66-1.02). Taking into account time-updated exposure to RAS blockade versus all other antihypertensive medications in obese, hypertensive, non-diabetic patients using a Cox proportional hazards model with time-varying covariates including systolic blood pressure (SBP), antihypertensive medications, use of mineralocorticoid antagonists, and eGFR, there was a significantly reduced hazard of adverse renal outcomes in patients treated with RAS blockade compared to those treated with other antihypertensive medications (HR 0.93, p<0.01).

Conclusions: In this population-based cohort study, obesity was a significant risk factor for ESRD and death after ESRD. These data provide the most persuasive evidence to date that aggressive management of BP prior to ESRD may have a persistent benefit after ESRD onset.

Distribution and Prognostic Value of Central Blood Pressure in Chronic Kidney Disease

Yun Jung Oh,1 Su Mi Lee,2 Ji Yong Jung,3 So Mi Kim,4 Chungsik Lee.1 1Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea; 2Dept of Internal Medicine, Dong-A Univ Hospital, Busan, Republic of Korea; 3Dept of Internal Medicine, Gachon Univ Gil Hospital, Incheon, Republic of Korea; 4Dept of Internal Medicine, Jeju National Univ Hospital, Jeju, Republic of Korea.

Background: Central blood pressure (CBP) has been shown to be a better predictor for cardiovascular events and target organ damages than brachial blood pressure. However, little is known about comparative values of CBP and brachial BP in chronic kidney disease (CKD) population. We investigated the distribution of CBP and evaluated the comparative value between CBP and brachial BP for the prediction of renal progression in both CKD and non-CKD population.

Methods: We conduct this study using data from 868 subjects who underwent CBP measurement by the radial artery tonometric method between 2009 and 2013. Demographic and clinical characteristics were obtained from a review of the medical records at the time of CBP measurement. The outcome was renal progression defined as decline of estimated glomerular filtration rate at least 30% from baseline follow-up.

Results: In overall, estimated central systolic BP (cSBP) was higher than brachial systolic BP (bSBP). The cSBP was significantly increased with age in non-CKD group, but such a correlation was not observed in CKD group. In CKD population, high cSBP group with greater than mean cSBP value (+150mmHg) had significantly increased probability of renal progression (P=0.016), while high bSBP (+140mmHg) did not predict the outcome (P=0.370). In contrast, the predictor of renal progression was high bSBP not cSBP in non-CKD population. In Cox analysis adjusted for covariates, high cSBP remained a predictor of renal progression in CKD population (HR 5.408; 95% CI 1.008-29.030; P=0.049), whereas high bSBP was not a significant predictor in non-CKD population (HR 2.891; 95% CI 0.786-10.650; P=0.110).

Conclusions: The CBP had different correlation with age and clinical significance according to presence or absence of CKD, and the high cSBP was strong independent predictor of kidney disease progression in CKD patients.

Clinical Characteristics and Outcomes Associated with Resistant Hypertension in a Large Cohort of U.S. Veterans Caoba P. Kovesdy,1,2 Miklos Zsolt Molnar,3 Adriana Hung,4 Jan Ling Lu,5 John J. Sim,6 Robert B. Canada,2 Elvira Gosmanova,3 Fredjth Thomas,7 Kamary Kalantar-Zadeh.1,2 1VA Medical Center, Memphis, TN; 2Univ of Tennessee Health Science Center, Memphis, TN; 3VA Medical Center, Nashville, TN; 4Kaiser Permanente, CA; 5Univ of California, Irvine, CA.

Background: The prevalence of true resistant hypertension (RH), the characteristics of patients with RH and its association with clinical outcomes is unclear.

Methods: From 2,398,778 patients with essential HTN, we identified 95,334 (4%) with RH, defined as: Failure to achieve BP>140/90 mmHg with >=3 antihypertensives (one being a thiazide diuretic) or success with >=4 drugs; excluding measurements when patient score was <5; when interfering medications were prescribed and excluding those with confounding conditions (CKD, secondary HTN, sleep apnea, urinary obstruction, arterial, thyroid and parathyroid over-activity). We examined with mortality, incident CKD, ESRD, steeper slopes of eGFR, incident coronary heart disease (CHD) and stroke in Cox models and logistic regression models adjusted for demographic and socioeconomic factors, comorbidities, BP, and antihypertensives.

Results: The mean SBP/DBP in RH and non-RH patients were 148±22/81±14 vs. 137±19/78±12 mmHg. Compared to non-RH, patients with RH were older (64±11 vs. 62±13), more likely to be black (25 vs. 17%) and had a higher prevalence of DM and CVD. Crude mortality was similar and the incidence of the renal and cardiovascular end points was higher in RH. After full adjustment the risk of CHD and stroke associated with RH remained significant, but the risk of renal outcomes was reversed (Figure).

Conclusions: RH is relatively infrequent (4%) among patients with essential HTN, and is associated with older age and a higher comorbidity burden. Patients with RH have a higher risk of incident CHD and stroke.

SA-PO620
Association of Components of Body Mass Index with Treatment-Resistant Hypertension in Men and Women with Chronic Kidney Disease Toshiyuki Aoki,1 Yasushi Ohashi,2 Reibin Tai,3 Kiyoto Koibuchi,4 Atsushi Aikawa,5 Ken Sakai,6,7 1Nephrology, Toho Univ School of Medicine, Ohta-ku, Tokyo, Japan; 2Nephrology, Saiseikai Eastern Hospital, Yokohama, Kanagawa, Japan.

Background: Treatment-resistant hypertension is a risk for cardiovascular disease and end-stage renal disease. However, the appropriate clinical management strategies remain unclear in patients with CKD. Our objective is to investigate the association of components of body mass index (BMI) with treatment-resistant hypertension in patients with CKD.

Methods: Body fluid composition was measured in 310 patients with CKD from 2005 to 2014, and BMI was separated into 3 components – (a) free water mass consisting of muscle, fat, and minerals, (b) intracellular water (ICW), and (c) extracellular water (ECW). Treatment-resistant hypertension was defined as an office BP of ≥130/80 mmHg, despite receiving ≥3 antihypertensives including diuretics, or ≥4 drugs usage. Patients with resistant hypertension were more adverse renal outcomes, as defined by a decline of 50% or more from baseline GFR (one being a thiazide diuretic) or success with ≥4 drugs; excluding measurements when patient score was <5; when interfering medications were prescribed and excluding those with confounding conditions (CKD, secondary HTN, sleep apnea, urinary obstruction, arterial, thyroid and parathyroid over-activity). We examined with mortality, incident CKD, ESRD, steeper slopes of eGFR, incident coronary heart disease (CHD) and stroke in Cox models and logistic regression models adjusted for demographic and socioeconomic factors, comorbidities, BP, and antihypertensives.

Results: 19 patients (10 men; median age 56 (48; 57) years; BMI 30.9±2.8 kg/m²) with resistant hypertension were enrolled in the study. In all patient plasma renalase concentration was measured before and after 4 months. The average number of antihypertensive agents prescribed was 4.8 ± 0.8 classes per patient. 3 (17%) and 2 (11%) patients were considered adherent by direct method and pill count, respectively. However, the agreement between methods was poor (Kappa correlation coefficient -0.15).

Conclusions: Adherence to therapy in patients with resistant hypertension was very low in both methods. There was no agreement between pill count and direct method. The best method to assess adherence in resistant hypertension is yet to be determined.

Funding: Government Support - Non-U.S.

SA-PO621
Adherence Assessment in Resistant Hypertension: A Comparison Between Pill Count and Direct Method of High Performance Liquid Chromatography Analysis in Urine Patricio Cardoso Alarcon Horí, Silvana de Barros, Indira Fernandes Braga Azam, Andrea Pio de Abreu, Andrea Cassia Perreira Sforsin, Vanusa Barbosa Pinto, Décio Mion Junior, Giovanio Vieira da Silva. Nephrology and Pharmacy, General Hospital of Sao Paulo Univ, Sao Paulo, Brazil.

Background: Poor adherence to antihypertensive therapy is one of possible causes of resistant hypertension. Pill count is currently considered the standard for assessing drug adherence, but as an indirect method, it is inaccurate. The aim of this study was to compare the pill count with the direct method of toxicological urine screening in patients with resistant hypertension.

Methods: Patients with resistant hypertension criteria were included: office blood pressure (BP) above goal (systolic BP> 140mmHg and/or diastolic BP> 90mmHg) taking 3 or more antihypertensive agents of different classes, one of them diuretic, or office BP below goal taking 4 or more classes. Adherence was assessed by direct method of high performance liquid chromatography analysis for antihypertensive drugs or their metabolites in 4 different urine samples, with 30-day interval between them. Simultaneously, pill count was also performed. Patient was considered adherent by direct method if it was found every prescribed agents in at least 3 urine samples. Regarding pill count, patient was considered adherent if he consumed at least 90% of prescribed agents.

Results: 18 patients were selected: 78% women, age 57.5 ± 5.7 years, body mass index 29.3 ± 3.6 kg/m², office mean BP 151/88 ± 20/15 mmHg and 24 hours mean BP by ambulatory blood pressure monitoring 132/85 ± 21/12 mmHg. The average number of antihypertensive agents prescribed was 4.8 ± 0.8 classes per patient. 3 (17%) and 2 (11%) patients were considered adherent by direct method and pill count, respectively. However, the agreement between methods was poor (Kappa correlation coefficient -0.15).

Conclusions: Adherence to therapy in patients with resistant hypertension was very low in both methods. There was no agreement between pill count and direct method. The best method to assess adherence in resistant hypertension is yet to be determined.

SA-PO622
Plasma Renalase Concentration Before and After Radiofrequency Renal Denervation in Patients with Resistant Hypertension: Preliminary Results Marcin Adamieczak,1 Beata Czerwińska,1 Maciej T. Wybraniec,1 Michal Lelek,1 Katarzyna T. Mizia-Stec,2 Andrzej Wieciec,1 1Dept of Nephrology, Transplantation and Internal Medicine, Medical Univ of Silesia, Katowice, Poland; 21st Dept of Cardiology, Medical Univ of Silesia, Katowice, Poland.

Background: Renalase is a catecholamine-metabolizing enzyme produced by proximal tubular cells in kidney which is supposed to be involved in blood pressure regulation. The aim of the study was to evaluate plasma renalase concentration after radiofrequency renal denervation (RDN) in patients with resistant arterial hypertension (HTN).

Methods: 19 patients (10 men; median age 56 (48; 57) years; BMI 30.9±4.4 kg/m² and eGFR 89±17.7 ml/min/1.73 m²) with resistant HTN were enrolled in the study. In all patient plasma renalase concentration was measured before and after RDN by ELISA method (Cloud-Clone Corp, Houston, USA).

Results: A significant decrease of both office systolic and diastolic blood pressure 6 months after RDN was found (192±31 vs. 177±28 mmHg, p=0.03; 113±23 vs. 99±21 mmHg, P=0.002, respectively). One and 3 months after RDN plasma renalase concentration decreased significantly, with a subsequent return to values comparable with baseline at 6- and 12-month follow-up (median of 22100 vs. 18550 vs. 17600 vs. 20750 vs. 20500 ng/mI respectively; Friedman analysis of variance p=0.054).

Conclusions: Plasma renalase concentration decreased significantly, with a subsequent return to values comparable with baseline at 6- and 12-month follow-up. These findings emphasize the importance of adequate weight and volume status.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

767A
Conclusions: RDN leads to the temporary decrease of plasma reninase concentration in patients with HTN. Lower plasma reninase concentrations seems to be a counteracted reaction to the antihypertensive effects of RDN.

A Non-Vascular Treatment for Resistant Hypertension  Richard R. Heuser,1 Adam Gold,2 1Cardiology, St. Luke’s Medical Center, Phoenix, AZ; 2Verve Medical, Scottsdale, AZ.

Background: Systematic arterial hypertension remains the most common and important risk factor for cardiovascular and renal disease. A safe and effective medical device effecting a significant and immediate fall in arterial BP addresses an unmet clinical need. Early clinical experience with the Verve non-vascular device causes an immediate BP drop in patients with resistant hypertension.

Methods: In humans, there is a greater abundance of efferent compared with afferent nerve fibers and the afferent nerves are much less abundant in general and are much less abundant as one goes away from the aorta. In contrast to the widespread distribution of EFFERENT Sympathetic nerve fibers in the kidney, the majority of the AFFERENT Renal Sensory nerves are located in the renal pelvic area. With our first generation device, we treated patients with resistant hypertension. Four patients with resistant hypertension were treated. They had immediate blood pressure drop (Systolic Mean 44mmHg, Diastolic Mean 13mmHg), which was maintained for 3 months. Because of the possibility of calyceal damage noted in follow-up in our animal model, we have redesigned the probe and shortened the duration of therapy.

Results: In over two dozen animals, it appears that we get a similar histopathologic results with our first generation probe without late pelvic or calyceal damage. In our first clinical application of this helical probe, there also is an immediate blood pressure drop.

Conclusions: Unlike other renal denervation treatments, the Verve natural orifice approach appears to treat the afferent nerves and results in an immediate blood pressure drop. More patients will need to undergo treatment to confirm these encouraging results. We will present our first series of resistant hypertensive patients treated with the helical device.

SA-PO624

Background: Preeclampsia is a hypertensive disorder of pregnancy associated high morbidity and mortality. Hallmarks of preeclampsia are endothelial damage and functional (e.g. proteinuria) and morphological renal aberrations. The only known remedy against this is the delivery of the placenta. Cell derived microparticles (MP) of different origins are elevated in preeclampsia but their mechanistic relevance is unknown. Preeclampsia is also associated with a pro-inflammatory condition but there are meager mechanistic insights into this as well.

Methods: To address these questions MP (endothelial or platelet derived) were injected into C57BI/6 pregnant mice and the pregnancy outcome (embryonic survival and growth, placenta morphology) was studied. Morphology of the kidney was studied using PAS staining and electron microscopy. Proteinuria was studied as a measure of renal dysfunction. To address mechanistic questions, inflammasome activation by MP in placenta and trophoblast cells was studied using western blotting and immunohistochemistry. Human trophoblast derived cells and placentas from pregnancies complicated with pre-eclampsia were also studied for activation of inflammasome. NLRP3 and Casp-1 KO mice were used to rescue the mice from disease conditions and establish causality of the mechanism.

Results: MP caused preeclampsia associated with fetal loss and embryonic growth restriction in mice. This was associated with renal damage indicated by proteinuria, glomerular enlargement, thickness of glomerular basement membrane, and podocyte effacement in the kidney. Human and mouse placenta analysis indicated inflammasome activation seen by elevated expression of NLRP3, cleaved casp-1 and IL-1β. The pregnancy outcome and renal function was rescued in NLRP3 and Casp-1 KO mice.

Conclusions: Our results establish that MP are causative of preeclampsia, fetal death, embryonic growth restriction, and renal injury. These pathogenic effects of MP are mechanistically linked with inflammasome activation in the placenta.

Funding: Government Support - Non-U.S.

Short Term Sequela of Preeclampsia  Michael Yannik Girsberger,1 Irene Mathilde Hoelsi,2 Michael Dickenmann. 1Clinic for Transplantation Immunology and Nephrology, Univ Hospital Basel, Basel, Baselstadt, Switzerland; 2Dept of Gynaecology and Obstetrics, Univ Hospital Basel, Basel, Baselstadt, Switzerland.

Background: Data on sequela in the first year after preeclampsia are scarce. We investigated kidney function, blood pressure, proteinuria and urine sediment in women with preeclampsia six month after delivery.

Methods: From January 2007 to July 2014 all women with preeclampsia and 6-months follow up at the university hospital Basel were prospectively analysed. Preeclampsia was defined as new onset of hypertension (³140/90 mmHg) or worsening hypertension and either proteinuria or signs of end-organ dysfunction. Hypertension was defined as a blood pressure (BP) ³140/90 or the use of antihypertensive medication. Proteinuria was defined as a protein-to-creatinine ratio in a spot urine > 11 mg/ml. Urine sediment was evaluated by a nephrologist.

Results: 202 women were included. Baseline characteristics are shown in Table 1 and follow up data are shown in Figure 1. The mean time of the follow up visit was 172 days (+/- 39.6) after delivery. The mean blood pressure at follow up was 124/76 mmHg (+/- 14/11, range 116-182/63-110) and the mean serum-creatinine was 61.8 umol/l (+/- 11.6). Mean estimated glomerular filtration rate (CKD-EPI) was 110.7 ml/min/1.73m2 (range 59.7-142.4 ml/min/1.73m2). No active urine sediment (e.g. signs of glomerulonephritis) was observed.

Conclusions: The findings stress the importance of a close follow up to identify those women who need further care.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

Preeclampsia: Long-Term Effects on Pediatric Neurologic Disability  
Alberto Tejedor Jorge, Clara Nicolas, Patrocínio Rodrigues Benitez, Olga Arroyo, María Silva, Laura Matesanz, Carmela Mercurio, Manuel Sánchez Luna.  
*Hospital General Univ Gregorio Marañón.*

**Background:** Preeclampsia affects up to 10% of pregnancies worldwide and is one of the main causes of fetal morbidity and mortality. Although it has been linked to developmental delay, its long-term effects on neurologic development in children have yet to be sufficiently quantified. Our aim is to evaluate whether the preeclampsia’s severity and the therapeutic options used to manage it correlate to the degree of developmental delay in these infants.

**Methods:** This is an observational and descriptive study performed on a population of 96 women who were diagnosed with preeclampsia at Hospital General Universitario Gregorio Marañón between 2007 and 2014, and their 111 children. To evaluate the mother, we gathered data pertaining to her medical history, renal function markers, and medical management of the preeclampsia. To assess the children, we collected fetal growth measurements, acute fetal distress markers and main diagnoses at birth. We used the Pediatric Disability Inventory in its computerized adaptive test version (PEDI-CAT) to study neurologic development, and the TNO-AZL Preschool children Quality of Life (TAQPOL) to estimate health-related quality of life.

**Results:** Early-onset and more severe preeclampsias were associated with higher preterm birth and perinatal mortality rates. Preeclampsias with a greater impact on maternal organ function showed a clear correlation to higher periventricular-intraventricular hemorrhage rates in the newborn. In terms of neurologic development, PEDI-CAT percentiles were consistently lower in the Social/Cognitive domain than in other areas. Lower Social/Cognitive percentiles were associated to both lower maternal IgG levels and presence of necrotizing enterocolitis during the neonatal period.

**Conclusions:** Early-onset preeclampsias have a greater negative impact on both maternal renal function and fetal morbimortality. A connection between preeclampsia and poor social/cognitive outcomes exists that warrants further research, as does the possible link between between preeclampsia, immaturity, and autistic features.

SA-PO627  
Do Hypertension Providers Inquire About Hypertension in Pregnancy?  
Andrew G. Kattah, Vesna D. Garovic. *Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

**Background:** Hypertensive pregnancy disorders are increasingly recognized as a risk factor for future hypertension and cardiovascular disease. However, knowledge of this risk may be inadequate among internal medicine providers.

**Methods:** We reviewed all new consults in a 2-month period in a hypertension subspecialty clinic. We determined the frequency with which providers documented a reproductive history, a history of hypertension in pregnancy and known cardiovascular risk factors. We also studied whether there were differences according to gender and level of training of the provider (consultants vs. residents/fellows) using the chi-square test.

**Results:** There were 102 consults for hypertension in the study period. The majority of consults were by consultants, 55/102 (53.9%), and 23/102 (22.6%) were by female providers. A reproductive history, including number of pregnancies, infertility and/or intent of pregnancy, were documented in 37/102 (36.3%) of notes. Chart review revealed that 85/96 (89%) of women had live births, but it was documented in only 31 (36.3%) of notes. Female providers were more likely to document pregnancies (36.3% vs. 30.3%, p=0.03). Of the women who had live births, 15/85 (17.7%) of providers inquired about hypertension of pregnancy, were documented in 37/102 (36.3%) of notes. Chart review revealed that knowledge of this risk factor for future hypertension and cardiovascular disease. However, knowledge of this risk may be inadequate among internal medicine providers.

**Conclusions:** Even in a minority, inner city population we found significant correlation between the 24 hour protein excretion and the SP/Cr ratio, especially in the 2nd and 3rd trimesters of preeclampsias. Our findings are in line with the literature despite a minority patient population.

SA-PO628  
Thiazide Diuretics for Hypertension in Kidney Transplant Recipients Using Tacrolimus  
Arthur David Moes, Dennis Alexander Hesselink, Anton H. van den Meiracker, Robert Zietse, Ewout J. Hoorn. *Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands.*

**Background:** Hypertension after kidney transplantation is common and associated with poorer graft and recipient outcomes. Recently, we and others showed that tacrolimus activates the thiazide-sensitive sodium chloride cotransporter to cause hypertension. This suggests that thiazide diuretics may be especially effective drugs in this context, but prospective data are lacking.

**Methods:** We conducted a non-inferiority crossover trial to compare chlorthalidone (CT, 12.5-25 mg) with amlopidine (AML, 5-10 mg). Patients were invited for ambulatory blood pressure measurement (ABPM) if office BP >140/90 mmHg. Other criteria included eGFR >30 ml/min, proteinuria > 1 g, and no use of glucocorticoids. The treatment periods were randomized, lasted 8 weeks (allowing dose titration after 2 weeks), and were separated by a 2-week wash-out. Background anti-hypertensive drugs were allowed except for other diuretics.

**Results:** 71 patients underwent initial ABPM of whom 45 patients (63%) with average wake SBP >140 mmHg were enrolled (median 2.6 years after transplantation). 38 patients completed the study (5 patients stopped during CT mainly due to electrolyte disorders vs. 2 during AML, p=0.4). CT and AML both markedly reduced ABPM after 8 weeks (151/85 ± 119/81 ± 12/9 mmHg vs. 151/84 ± 13/9/79 ± 14/7 mmHg). There was no statistically significant in blood pressure response between the two drugs (p=0.3 by 2-way ANOVA). Dose titration rates were similar (42% for CT vs. 37% for AML, p=0.8). CT decreased eGFR (53 ± 17 to 46 ± 15 ml/min), whereas amlopidine increased it (50 ± 16 to 53 ± 17 ml/min, P=0.001). The first post-CT eGFR returned to baseline (51 ± 17 ml/min). Treatment with CT resulted in less proteinuria (median 14 vs. 19 mg/mmol, p=0.03) and less edema (8 vs. 31%, p=0.02). Regression analysis showed that a higher aldosterone to renin ratio, lower baseline serum potassium, and higher baseline serum bicarbonate predicted a better anti-hypertensive response to CT.

**Conclusions:** Thiazide diuretics effectively lower blood pressure in kidney transplant recipients using tacrolimus. Thiazides are especially effective in patients with more aldosterone effect.

The Detrimental Effects of Beta-Blockers on Central Hemodynamic Parameters: A Propensity Score Analysis

Reemi Gouni,1 Dominique Dupuis,1 Stephan Troyanov,1 Francois Madore,1 Mohsen Agharazi,2 1Hôpital du Sacré-Cœur de Montréal, Montréal, QC, Canada; 2CHU de Québec, Hôtel-Dieu de Québec, Québec City, QC, Canada.

Background: Central blood pressure (BP) and arterial stiffness are better predictors of the cardiovascular burden than peripheral BP. Beta-blockers (BB) are known to reduce central BP to a lesser extent than peripheral BP, a hypothesized consequence of heart rate (HR) reduction. Therefore, the association between BB use, HR and central hemodynamics indices were studied in the treated hypertensive participants of the CARTAGENE study.

Methods: Using propensity score analyses, BB users (n=605) were matched to controls having similar clinical characteristics with (Model 1) and without (Model 2) adjustment for HR. This resulted in 457 and 510 pairs with adequate balance, except for a different HR in Model 2 (62.5 ± 10.5 vs. 70.4 ± 11.5 bpm, p<0.001).

Results: In Model 1, the difference between peripheral and central systolic BP (DSBP) was 8.3 mmHg (IQR 5.8, 11.6) with BB compared to 9.7 mmHg (7.1, 13.5) without (p<0.001), indicating that for any given peripheral BP, BB use resulted in higher central systolic BP. Pulse pressure amplification, augmentation index and augmented pressure were also less favorable with the use of BB. The different HR in Model 2 further increased the detrimental DSBP observed with BB to 7.9 (5.6, 11.0) vs. 10.6 (8.1, 14.3) without (p<0.001) and was associated with a higher central pulse pressure (46.5 ± 13.0 vs. 43.3 ± 11.3, p<0.001).

Conclusions: This study shows that the unfavorable central hemodynamic profile of BB has both a HR-dependent and a HR-independent component.

Risk of Development of Dementia During Treatment of Hypertension with Different Calcium Channel Blockers

Leonid Feldman,1 Shai Efrati,2 Ilia Beberashvili,1,2 Shlomo Vinker,2,3 Michail Shami,3 1Assaf Harofeh Medical Center, Israel; 2Tel Aviv Univ, Israel; 3Clalit Health Services, Israel.

Background: Arterial hypertension (HTN) is a risk factor for development of dementia. Medical treatment of HTN may decrease the risk of dementia. Experimental study pointed to the possibility of difference between different calcium channel blockers (CCB) in their neuro-protective effect. The aim of our study was to evaluate the risk of dementia during treatment of HTN with one of three different CCBs.

Methods: This is a retrospective cohort study based on electronic database of Clalit Health Services, Central District. Study period was 11 years (2002-2012). Inclusion criteria: age 40-75, diagnosis of HTN without diagnosis of “Dementia” at the starting point, minimal duration of treatment >30 months with single specific CCB. New diagnosis of dementia was established according to appearance of its diagnostic code in the chronic diseases register or prescription of medication for its treatment – whatever occurred first.

Results: 15,664 patients were included in the study: 3,884 were treated with amlodipine, 2,062 - with nifedipine, 699 – with lercanidipine and 9,109 never received CCBs. The mean age was 60.7 years, 52.9% were females and the mean baseline creatinine was 1.0 mg/dL. 2,062 - with nifedipine, 609 – with lercanidipine and 9,109 never received CCBs. The mean age was 60.7 years, 52.9% were females and the mean baseline creatinine was 1.0 mg/dL.

Conclusions: The unfavorable central hemodynamic profile of BB has both a HR-dependent and a HR-independent component.

The Association Between Antihypertensive Agents and Postural Blood Pressure Response Using Beat-to-Beat Data: Results from the Irish Longitudinal Study on Ageing

Mark N. Conneely,1 Matthew DI O’Connell,1 Catriona M. Murphy,2 Mark Alan Little,2 Conall M. O’Seaghdha,2 Rose Anne M. Kenny,1 1The Irish Longitudinal Study on Ageing, Trinity College Dublin; 2Trinity Health Kidney Centre, Tallaght Hospital Dublin, 3Dept of Nephrology, Beaumont Hospital Dublin.

Background: Beat-to-beat blood pressure (BP) measurements provide a dynamic picture of BP behavior during postural change. Impaired BP stabilization after standing is associated with substantial morbidity and mortality. We aimed to define the relationship between class of antihypertensive drug and BP stabilization during an active stand.

Methods: Cross-sectional analysis from The Irish Longitudinal Study on Ageing, a nationally representative cohort study of 8175 adults ≥50 years. Beat-to-beat BP was recorded in participants undergoing an active stand test. We defined grade 1 hypertension according to European Society of Cardiology criteria (systolic BP [SBP] ≥140-159mmHg or diastolic BP [DBP] ≥90-99mmHg). Orthostatic hypotension (OH) was defined as a drop in SBP ≥20mmHg or DBP ≥10mmHg. Outcomes were sustained OH (OH throughout the test) and impaired BP stabilization (OH at each 10-second (s) interval during the test [total 110s]). Outcomes were assessed using logistic regression models adjusted for potential confounding variables.

Results: A total of 536 participants with self-report hypertension were receiving monotherapy with a renin-angiotensin-aldosterone-system inhibitor (317), beta-blocker (89), calcium channel blocker (89) or diuretic (41). Betablockers were associated with increased odds of sustained OH vs untreated grade 1 hypertension (OR 3.4, 95% CI 1.9-6.0). This was evident from 20s after starting the study. Multivariable adjustment did not attenuate the association. No significant association was detected among the other drug classes.

Conclusions: In older hypertensive adults beta-blocker monotherapy was associated with a 3-fold increased odds of OH compared to subjects with untreated grade 1 hypertension. The effect was evident from 20s after standing and was sustained. This should inform decision-making regarding appropriate choice of antihypertensive agent in older adults.

Effect of Vitamin D on 24 Hour Ambulatory Blood Pressure: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial

Ciaran Joseph McMullan,1 Lea Borgi,2 Gary C. Curhan,2 Naomi D.L. Fisher,3 John P. Forman.2 1Renal Div, Brigham and Women’s Hospital, Boston, MA; 2Endocrine Div, Brigham and Women’s Hospital, Boston, MA.

Background: Lower levels of 25-hydroxyvitamin D (25(OH)D) have been associated with an increased risk of hypertension in prospective cohort studies, suggesting that vitamin D might be a modifiable target for the prevention of hypertension. Vitamin D supplementation has also been shown to decrease clinic blood pressure (BP) in some studies.

Methods: We performed a randomized, double-blind, placebo-controlled trial of nonhypertensive participants with body mass index ≥25, and 25(OH)D<20ng/ml; subjects were randomized to receive either ergocalciferol 50,000 units or placebo, once a week for 8 weeks. Mean 24 hour BP was measured using 24 hour ABPM at baseline and 8 weeks after starting the study.

Results: By the end of the trial, 29 and 27 participants randomized to receive vitamin D and placebo, respectively, had adequate 24 hour ABPM at both baseline and at 8 weeks. Mean vitamin D levels increased from 14.9 to 30.3 ng/ml in the intervention group and from 14.4 to 17.4 ng/ml in the placebo group. Vitamin D supplementation did not lower BP at 8 weeks; 24 hour systolic BP changed from 120±10 to 122±18 mmHg in the intervention group (p-value=0.29), and from 124±8 to 125±10 mmHg in the placebo group (p-value=0.38), with a treatment effect p-value of 0.92.

Conclusions: In this randomized, double-blind, placebo-controlled trial of overweight/ obese normotensive individuals, there was no improvement in mean 24 hour blood pressure after repletion of vitamin D. These findings are not consistent with vitamin D being a modifiable target for prevention of hypertension.

Effect of Uric Acid Lowering on Intrinsic Renal and Systemic Renin Angiotensin System Activity: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial

Ciaran Joseph McMullan,1 Lea Borgi,2 Gary C. Curhan,2 Naomi D.L. Fisher,2 John P. Forman.2 1Renal Div, Brigham and Women’s Hospital, Boston, MA; 2Endocrine Div, Brigham and Women’s Hospital, Boston, MA.

Background: Higher levels of uric acid have been associated with an increased activity of the renin-angiotensin system (RAS) in animal models of hypertension and kidney disease. Similarly, individuals with high levels of circulating uric acid have increased renal specific RAS activity measured using renal plasma flow (RPF). However, the effect of lowering serum uric acid on RAS activity in humans is unknown.

Methods: We performed a randomized, double-blind, placebo-controlled trial analyzing the Modifiable Effectors of Renin System Activation Treatment Evaluation (MODERATE). Normotensive individuals with body mass index (BMI) ≥25 and uric acid level ≥ 5.0 mg/
Effect of Vitamin D Supplementation on Intrinsic Renal and Systemic Renin Angiotensin System Activity: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial  

Background: Disruption of vitamin D signaling in rodents causes activation of the renin-angiotensin system (RAS). In humans low circulating 25[OH]D is associated with increased renal specific RAS activity (measured using renal plasma flow [RPF]; in addition, a small, open label, uncontrolled study found that vitamin D supplementation decreased renal specific RAS activity. However, the effect of vitamin D supplementation on the RAS in humans with vitamin D deficiency has never been examined in a rigorous manner.

Methods: We performed a randomized, double-blind, placebo-controlled trial of normotensive individuals with body mass index <25 and vitamin D deficiency (25[OH]D ≤20ng/ml). Subjects were assigned to receive either ergocalciferol 50,000 units or placebo, once a week for 8 weeks. Renal specific (assessed by RPF response to captopril in high sodium balance) and systemic RAS activity (plasma renin activity [PRA] and angiotensin II levels [AngII]) were measured at baseline and 8 weeks after starting the study.

Results: By the end of the trial, 43 and 41 participants allocated to receive vitamin D and placebo, completed the study with measurement of renal and systemic RAS activity. Mean vitamin D levels increased from 14.9 to 30.3 ng/ml in the ergocalciferol group and from 14.4 to 17.4 ng/ml in the placebo group. Renal specific RAS did not significantly change after vitamin D repletion: the RPF response to captopril was 33.9±56.1 ml/min at baseline and 35.7±47.7 ml/min at 8 weeks in the ergocalciferol group (p-value=0.26); and was 37.3±46.9 ml/min at baseline and 35.9±26.2 ml/min at 8 weeks in the placebo group (p-value=0.70), with a treatment effect p-value of 0.27. Similarly, vitamin D supplementation had no effect on PRA or AngII levels.

Conclusions: In contrast to animal experiments, observational studies, and open-label uncontrolled interventions, this randomized, double-blind, placebo-controlled trial found no effect of vitamin D supplementation on RAS activity in vitamin D deficient individuals.

Funding: NIDDK Support

Comparison of Office Orthostatic Blood Pressure and 24-Hour Ambulatory Blood Pressure Measurements in the Prediction of Autonomic Dysfunction  

Background: Evaluation of orthostatic hypotension (OH) may involve office orthostatic blood pressure (BP) measurements, 24-hour ambulatory BP (ABP) and autonomic reflex screen (ARS). We investigated the predictive performance of BP and the variables of ABP, i.e., reversal of circadian pattern (RCP), postprandial hypotension (PPH) and noncompensatory heart rate variability (HRV), to predict autonomic dysfunction as measured by the AUC of the ROC curves.

Methods: Data from previously published study were analyzed. Ninety-four patients were included for analysis. BP\textsubscript{OP}, RCP, PPH, HRV were investigated for the presence or absence of autonomic dysfunction. Autonomic dysfunction was defined as a CASS (composite autonomic scoring system) score of 1. Comparisons of the AUCs of the ROC curves of the candidate parameters were performed.

Results: ROCs of candidate parameters are shown in Fig. 1.

Funding: Government Support - Non-U.S.

Comparison of Office Orthostatic Blood Pressure and 24-Hour Ambulatory Blood Pressure Measurements in the Prediction of Autonomic Dysfunction  

Background: Blood pressure measurement (BPM) is a common procedure in clinical practice but in children (C) obtaining reliable values can be challenging. Casual office BPM, the standard of care, is all but accurate and ABPM may be difficult to perform or even misleading.

Methods: Office Blood Pressure Monitoring (OBPM) was developed at our Center in 2010 for evaluating BP in C with serial and automated ABPM (10 in at least 30 min)

The diagnostic performance to predict autonomic dysfunction for HRV was superior to PPH. Both were superior to RCP. RCP was a better predictor of autonomic dysfunction than office BP.

Conclusions: Our data suggests that ABP is a reliable, simple and inexpensive predictor of autonomic dysfunction in routine clinical practice.
with a standard oscillometric device. BP values are uploaded in a software to calculate the coefficient of variation (CV) after having excluded outlier values (< 5% and > 95% centiles of the recorded values).

Results: Since 2010 a total of 402 OBPMs have been performed but only the 282 in 110 C (59% Males) aged <18 yrs old (IQR 4.8-12.1) with a CV <10% for both syst and diast BP were considered for the analysis. The table compares BP as measured by OBPM with a single BPM (1st and 3rd) and with the mean of the 3 initial measurements (*: p<0.01 vs. others BPMs with student’s t test for paired data and c²).

Conclusions: OBPM provides significantly lower BP values, leading to a diagnosis of poor BP control in a smaller number of patients (~10%). Given the lack of a gold standard, the present analysis doesn’t demonstrate that OBPM is more reliable than standard procedures however serial BPM have the potential of reducing measurement biases and white coat effect. We recommend the routine use of OBPM for measuring BP in C at risk of hypertension rather then relying upon few measurements.

SA-PO639
A Simple Prediction Score for Incident Hypertension in a Korean Population
Jong-Hwan Jung, Sung Kwang Park, Won Kim, Kyung Pyo Kang, Sik Lee.
Dept of Internal Medicine, Chonbuk National Univ Medical School, Jeonju, Republic of Korea.

Background: We aimed to develop a simple prediction model for incident hypertension that could help to prevent or delay the onset of hypertension for some patients who did not experience hypertension yet.

Methods: The Korean Genome and Epidemiology Study was used for the model development (n=3533) and internal validation (n=1069). Hypertension was defined when experience hypertension yet.

Results: OBPM, age and DBP, parental hypertension, obesity, high density lipoprotein (HDL), current smoking and fasting glucose were significantly associated with incident hypertension. Integer scores were assigned to variables based on the magnitude of the coefficient of variation (CV) after having excluded outlier values (< 5% and > 95% centiles of the recorded values).

Conclusions: OBPM provides significantly lower BP values, leading to a diagnosis of poor BP control in a smaller number of patients (~10%). Given the lack of a gold standard, the present analysis doesn’t demonstrate that OBPM is more reliable than standard procedures however serial BPM have the potential of reducing measurement biases and white coat effect. We recommend the routine use of OBPM for measuring BP in C at risk of hypertension rather then relying upon few measurements.

SA-PO640
Hemodynamics and Cardiovascular Autonomic Efficiency During Blood Pressure Variations in Hemodialysis
Dan Sapoznikov, Rebecca Backenworth, Dvora Rubinger. Nephrology and Hypertension Services, Hadassah Univ Medical Center, Jerusalem, Israel.

Background: Chronic hemodialysis (HD) is associated with hematologic instability and with reduced cardiovascular autonomic efficiency (CaE).

Methods: To define hemodynamic changes associated with intradialytic blood pressure variations, beat-to-beat systolic blood pressure (SBP) and interbeat interval (IBI) monitoring using Finometer device and Beatscope software was performed during HD sessions in 69 non-diabetic patients (Pts), age 56±15 yrs. Cardiac output (CO) and total peripheral resistance (TPR) were calculated using the Modelflow simulation method. Differences in variability indices during SBP periods, 10% above (high) or below (low ) the mean SBP were considered representative of CaE.

Results: During low to high SBP periods, two patterns of changes were noted: increased CO and decreased TPR (18 Pts,TPR↓), and relatively stable CO with increased TPR (51 Pts, TPR↑). Low frequency (LF) range variability of SBP and IBI, CO and TPR (median and interquartile ranges) were:

Conclusions: OBPM provides significantly lower BP values, leading to a diagnosis of poor BP control in a smaller number of patients (~10%). Given the lack of a gold standard, the present analysis doesn’t demonstrate that OBPM is more reliable than standard procedures however serial BPM have the potential of reducing measurement biases and white coat effect. We recommend the routine use of OBPM for measuring BP in C at risk of hypertension rather then relying upon few measurements.

Antihypertensive Medications and Blood Pressure Control in Chronic Kidney Disease: A Cross-Sectional Analysis from the German Chronic Kidney Disease (GCKD) Study
Karl F. Hilleger,1 Matthias Schmid,2 Silvia Huebner,1 Martin Busch,1 Seema Baid-Aigrawal,1 Anna Kottgen,3 Georg Schlieper,1 Claudia Sommerer,1 Gunter B. Wolf, MHBA,1 Uwe Eckardt,3 Univ Hospital Erlangen;3 Univ of Bonn;1 Univ Hospital Jena;1 Charite Medical School;1 Univ of Freiburg; 2RWTH Univ Hospital, 3Univ Hospital Heidelberg, Germany.

Background: We reported low rates of blood pressure (BP) control in a large German cohort of patients with chronic kidney disease (CKD). Here, we analyzed the antihypertensive drug therapy to assess the prevalence of resistant hypertension, and to determine associations with control of BP.

Methods: The German Chronic Kidney Disease (GCKD) study is a prospective observational cohort study which enrolled 5217 patients with CKD in Germany. Inclusion criteria were an estimated glomerular filtration rate (eGFR) of 30-60 mL/min/1.73 m2 or overt proteinuria. At enrollment, office BP was measured by trained study nurses, and information on medications was collected from patients.

Results: Office BP was obtained from 5181 participants, 4958 (95% ) were classified as hypertensive (>= 140/90 mmHg or use of antihypertensive medication). In 2410 (49%) hypertensive patients, BP was controlled (defined as < 140/90 mmHg). Inhibitors of the renin-angiotensin system (RAS; ACE inhibitors, sartans and aliskiren) were the most prescribed class of antihypertensive drugs (56%), followed by beta-blockers (29%), diuretics (16%), calcium channel blockers (12%) and CCB (8%). In addition, 23% of patients received 2 or more different antihypertensive substances. Of the patients with uncontrolled hypertension, 49.9% met the definition of resistant hypertension (uncontrolled diastolic BP ≥ 90 or use of antihypertensive substances, including a diuretic). In multivariate analysis, RAS inhibitors were associated with better control of BP (odds ratio 1.48, p<0.001), as were diuretics (odds ratio 1.16, p=0.036).

Conclusions: Resistance hypertension was present in 49.9% of CKD patients whose BP was not controlled. RAS inhibitors were widely used and associated with better odds for controlled BP whereas the use of diuretics was less frequent than expected.

Associations Between Cystatin C Based eGFR, Ambulatory Blood Pressure Parameters, and In-Clinic versus Ambulatory Blood Pressure Agreement in Older Community-Living Adults

Tyler Woodell, Jan M. Hughes-Austin, Tiffany Tran, Atul Malhotra, Joseph A. Abdelmalek, Dena E. Rifkin.
UC San Diego.

Background: Although CKD IV-V has been associated with abnormal ambulatory blood pressure (ABP) patterns, the associations with milder CKD have not been determined. We examined the relationship between mild chronic kidney disease (measured by cystatin C-based eGFR) and abnormal ABPM (including nocturnal dipping) in healthy older adults. Further, we assessed agreement between clinic and ambulatory blood pressure monitoring.

Methods: 334 older community-living adults had clinic BP and 24-hour ABPM measured. Serum cystatin C levels were used to calculate eGFRs using the CKD-EPI equation. Multiple linear regression was performed to examine associations between eGFR < 60 ml/min/1.73m2 (CKD-eGFR) and ABPM parameters. Bland-Altman analysis was performed to evaluate agreement between clinic and ambulatory measurements.

Results: Average age was 72. Average eGFRs were 78 ± 20, and 60 individuals with CKD-eGFRs. Compared to those without CKD-eGFRs, individuals with CKD-eGFRs were older, more likely to have clinic-based hypertension and less likely to be dipper. After multivariable analysis, the presence of CKD-eGFRs was significantly associated with lower mean ambulatory diastolic blood pressure (DBP) (-2 mm Hg, p = 0.048), but not with nocturnal dipping or other ABPM parameters. Analyses using creatinine-based eGFR yielded similar results. Clinic systolic blood pressure (SBP) significantly overestimated mean wake time ambulatory SBP; mean difference was 11 mmHg for those without CKD-eGFRs (95% limits of agreement -5 to 35 mmHg) and 14 mmHg for those with CKD-eGFRs (95% limits of agreement -13 to 41 mmHg); there was no statistically significant effect modification by CKD status.

Conclusions: In older community-living adults, mild CKD as detected by cystatin C was associated with lower ambulatory DBP but not with dipping status. This result is in contrast to findings with more advanced CKD in other studies and suggests that abnormal ABPM may only emerge at more advanced stages of CKD. The presence of CKD did not affect interpretation of clinic vs. ABPM pressures, although accuracy of clinic SBP was poor in this older cohort.

Serum MicroRNA Biomarkers for Obese Children with Hypertension
Scott Saint-Amour, Santosh Kumar Patnaik, Sudha Garamella. Pediatric Nephrology, Univ at Buffalo, Buffalo, NY; Cardiothoracic Lab, RPCI, Buffalo, NY.

Background: Childhood obesity is a major health problem and 30% of obese children may develop hypertension. There is no clinical method to identify high risk obese children before they develop hypertension. MicroRNAs are non-coding RNAs that are implicated in pathways of inflammation and vascular injury. There has been no characterization of miRNA profiles of obese children with hypertension. This study aims to characterize miRNA profiles as a first step toward evaluating miRNAs as biomarkers for obesity-related hypertension.

Methods: 39 patients ages 3-21 were placed in four cohorts based on presence or absence of obesity and hypertension. Total serum RNA was isolated using miRcURYBiofluids kit Exiqon®, and examined for miRNAs by RT-PCR. Cβ values were normalized by the global mean method. Rates of false discovery (FDR) arising from multiple testing were assessed from P values with the Benjamini-Hochberg method.

Results: 69 of 179 examined miRNAs were detected in all samples. MiRNA measurements were globally reduced in sera of obese normotensive Vs. controls. Four miRNAs were identified as differentially expressed between these two groups at FDR <10%, whereas no miRNA was identified as differentially expressed between controls and hypertensive obese. Tukey plots of miRNAs in the cohorts are shown.

Conclusions: Serum levels of four miRNAs appear to be reduced in patients with obesity alone, but not in those with obesity and hypertension. While it is possible that these serum miRNA differences were because of variables such as serum lipid content and medications, our study suggests that serum miRNAs have utility in detecting hypertension risk in obese children. This should be validated in a larger study, and the biomarker value of the serum miRNAs correlated with ambulatory blood pressure monitoring data as well as left ventricular hypertrophy.

Funding: Pharmaceutical Company Support - Roswell Park Cancer Institute Support to Dr. Sai Yendamuri in the Cardiothoracic Lab at RPCI was used for this study.

SA-PO644

Effect of Prenatal and Childhood Lead Exposure on Blood Pressure at 4 Years of Age

Background: Prenatal lead (Pb) exposure occurs during a susceptible period of renal development and may program later life cardiovascular and renal disease.

Methods: Systolic and diastolic blood pressure (SBP and DBP) was obtained using an automated oscillometer from 397 children at 4 years of age in the PROGRESS cohort located in Mexico City. Maternal blood samples were previously collected at the 2nd trimester (2T), 3rd trimester (3T), and at delivery and children’s blood samples were collected at birth (cord blood), 1 year, and 2 years of age. Blood lead levels (BLLs) were analyzed via inductively coupled plasma-mass spectrometry. We performed linear regression to examine the associations between longitudinal BLLs and children’s SBP, DBP, and pulse pressure (mSBP + mDBP) adjusting for child’s age, sex, body mass index, maternal education and environmental tobacco smoke.

Results: Maternal 2T BLLs ranged between 0.7 and 18.8 mg/dL, and 89 (22%) prenatal BLLs were above the CDC guideline level of 5 mg/dL. Increased 2T and 3T BLLs were associated with decreased pulse pressure (p<0.05) and modestly associated with increased DBP (p=0.1).

No significant associations were observed for childhood BLLs and BP. Stratification by sex showed that the effect of prenatal Pb (2T and 3T) on decreased pulse pressure was significant only among females.

Conclusions: Prenatal Pb exposure may contribute to subclinical changes in the developing kidney or cardiovascular system leading to elevated BP in childhood. Future studies will assess if the contributions of early life Pb exposure to BP outcomes persist at later life stages.

Funding: Other NIH Support - Supported by grants from the NIHES R42ES016454; R01ES013744; R01ES021357; R01ES020268; P50ES023515.

Smoking, Microalbuminuria and Renal Function in Essential Never Treated Hypertensive Patients
Dimitrios Petras,1 Vanessa Tzamou,2 Athanasios Bramos,1 Panagiota E. Giannou,2 Stella-Maria Kyvelou,1 Eva Karpanou,1 Gregory Vysoulis.1 Nephrology Dept, Hippokration Hospital, Athens, Greece; 21st Cardiology Clinic, Onassis Cardiac Surgery Center, Athens, Greece; Hypertensive Unit, 1st Cardiology Clinic, Univ of Athens, Hippokration Hospital, Athens, Greece; Microbiology Dept, Hippokration Hospital, Athens, Greece.

Background: The aim of the present study was to identify possible differences depending on patient’s individual smoking history with renal function and microalbuminuria in essential never treated hypertensive patients.

Methods: The study included 6100 consecutive patients with essential hypertension. In each patient the smoking status has been assessed by means of a standard questionnaire. Each patient had renal profile work up including microalbumin levels, albumin creatinine ratio in 24h urine collection (ACR) and 24h creatinine clearance.

Results: The study population was divided according to the smoking status in three groups: Smokers (n=2350), Ex-smokers (n=663) and Non-smokers (n=3121). Microalbumin at ACR was significantly higher in smokers compared to ex-smokers and non-smokers ([26.3±24.3 vs 23.6±21.7 vs 22.0±20.0, p<0.0001], [31.5±30.2 vs 28.8±29.3 vs 27.4±27.2, p<0.0001], respectively). There was no significant difference in creatinine clearance among the three groups of smokers (p=NS)

Micronutrients (mg/dL) were also higher in Myanmarese than Koreans. Blood pressure was significantly higher in Myanmar adults than Koreans. This study is comparing salt taste thresholds and salt usage behavior scores between Myanmar and Korean adults. Background: Excessive oral salt intake can induce hypertension. According to previous studies, prevalence of hypertension is higher in Myanmar than Korea. We postulated that baseline salt taste thresholds and salt usage behavior scores between Myanmar and Korean adults are different. Methods: This cross-sectional study enrolled the patients who visited volunteer medical service clinic at Assung in Myanmar and Hfeug and Bago in Myanmar in August 2014. We measured salivary sodium, height and weight of each patient and evaluate detection threshold, recognition threshold, salt preference, all patients were urinalysis and checked spot urine Na. They also filled up the salt usage behavior questionnaires. Results: Total 1,371 patients were enrolled and 64 of them were Myanmarese and 67 were Koreans. Blood pressure was significantly higher in Myanmar adults than Koreans. Detection threshold, recognition threshold, salt preference, spot urine sodium and salt usage behavior score was also higher in Myanmar than Koreans.

We calculated correlation coefficient between spot urine Na and other parameters that related to salt intake. The salt usage behavior score detection threshold was significantly correlated with the spot Urine Na.

Conclusions: All parameters related to salt intake, such as detection thresholds, the recognition thresholds, salt preference, salt usage behavior score and spot urine sodium concentration, of Myanmarese were significantly higher than those of Korean.

Comparison of Salt Taste Thresholds and Salty Usage Behaviors Between Myanmar and Korean Adults

Huyen Ho 1,2, Hideki Fujii, Kentaro Nakai, Shunsuke Goto, Jun Ling Lu, Fridtjof Thomas, Kyamal Kalantar-Zadeh, Csaba P. Kovesdy,1
1Univ of Tennessee Health Science Center, Memphis, TN; 2Univ of California, Irvine, CA; 3VA Medical Center, Memphis, TN.

Background: Hypertension is associated with worse outcomes, and its treatment improves mortality and cardiovascular disease. Hospitalized patients undergo frequent BP measurements, and hence hospitalization is an opportunity to diagnose and treat hypertension. However, it is unclear if BP measured as inpatient is associated with outcomes.

Results: From 3,499,271 US veterans with normal eGFR, we identified 1,113,515 patients with inpatient and outpatient SBP recordings. We examined the association of baseline outpatient SBP, and baseline inpatient SBP (defined as the SBP obtained on the first day of the first hospitalization following cohort entry) with all-cause mortality in Cox proportional hazards analyses. Models included both in- and outpatient SBP and their interactions, and were adjusted for age, gender, race, eGFR, comorbidities, socioeconomic factors, and antihypertensives.

Conclusions: SBP shows markedly different associations in the outpatient vs inpatient setting, with higher blood pressures in the inpatient setting conferring less mortality risk compared to the outpatient setting. Until randomized controlled clinical trials are done, caution is warranted when treating hypertension in hospitalized patients.

Fibroblast Growth Factor 23 and Sodium-Volume Regulation: FGF23 Response to Sodium Restriction in Essential Hypertensive Subjects and to Long Term Extracranial Volume Reduction in Hemodialysis Patients

Francesca Mallamaci, Patrizia Pizzini, Daniela Leonardi, Sebastiano Cutrupi, Rocco Tripepi, Giovanni Tripepi, Carmine Zoccali, Clin. Epid. and Physiopath. of Renal Dis. and Hypert. & Nephrology, Dialysis, and Transplantation Unit, CNR-IFC & Azienda Ospedaliera, Reggio Calabria, Italy.

Background: Dietary sodium load causes volume expansion and hypertension in mouse models of FGF23 and αKlotho deficiency. FGF23 also associates with ultrafiltration volume in cross-sectional analyses in hemodialysis (HD) patients (pts) further implicating this bone hormone in extracellular volume regulation.

Methods: 32 uncomplicated essential hypertensive pts were randomized to a 2-weeks high-sodium diet (200mmol/day) or to a 2-weeks low sodium diet (10-20 mmol/day). After 1 week wash out, these treatments were crossed-over. At the end of each diet-period, pts underwent 24h urine sodium, 24h ABPM and serum intact FGF23 measurements. The FGF23 response to UF intensification was assessed in 52 hypertensive HD pts. FGF23 also associates with ultrafiltration volume in cross-sectional analyses in hemodialysis (HD) patients (pts) further implicating this bone hormone in extracellular volume regulation.

Results: In essential hypertensives, PRA and aldosterone (P<0.01) rose during low sodium. However, FGF23 remained unmodified [low sodium: median 36.2 pg/mL, inter-quartile range (IQR):32.4-44.0; high sodium: 33.9 pg/mL, IQR:29.5-41.0; P=0.18]. Changes in FGF23 were unrelated to systolic and diastolic ABPM, heart rate, PRA and aldosterone changes. In hypertensive HD pts, baseline FGF23 was 4062 pg/ml (IQR: 1381-12571). BP during the longitudinal study fell from 144 to 139 mmHg (P=0.02) along with a parallel decline in dry body weight (BW) from 63.7 to 62.8 Kg but FGF23 remained unchanged (3688 pg/mL, IQR: 1372-14117, P=0.30). Changes in FGF23 were unrelated (P=0.90) with ongoing changes in dry BW.

Conclusions: Changes in sodium intake that potentially activate the renin-aldosterone system do not alter FGF23 in essential hypertensives. Similarly, extracellular volume

Association of Urinary Albumin Excretion and Salt-Sensitivity of Blood Pressure: Genetic Epidemiology Network of Salt Sensitivity (GenSalt) Study
Jing Chen, 1, 2 L. Lee Hammi, 1 Chung-shiuian Chen, 2 Kevin K. Wu, 2 L. Gabriel Navar, 2, 7 Medicine, Tulane School of Medicine, New Orleans, LA; 7 Epidemiology, Tulane School of Public Health and Tropical Medicine, New Orleans, LA.

Background: Albuminuria is a marker of early kidney injury and associated with risk of hypertension, cardiovascular disease, end-stage renal disease, and premature death. However, it is unknown whether urinary albumin excretion is associated with salt- and potassium-sensitivity.

Methods: We investigated the association between urinary albumin excretion and salt- and potassium-sensitivity of blood pressure (BP) among GenSalt study participants. The GenSalt dietary intervention consisted of a 7-day low sodium diet (51.3 mmol sodium/day), 7-day high-sodium diet (307.8 mmol sodium/day), and 7-day high-sodium diet with potassium supplementation (307.8 mmol sodium/day and 60 mmol potassium/day).

Results: Urinary albumin-to-creatinine ratio (A/CR, mg/g) was significantly reduced during low-sodium and potassium-supplementation interventions to 2.26 (1.1.1.4.61) and 2.10 (1.46.2.46), respectively, from a baseline ratio of 2.97 (1.20.4.40) and increased during the high-sodium intervention to 3.23 (2.15, 5.73) with P for group difference = 0.005. One standard deviation higher of baseline log-transformed ACR (2.23 mg/g) was significantly associated with 1.5% (95% CI 0.3, 2.7) mm Hg higher in mean arterial BP (P = 0.01) from low-sodium to high-sodium intervention (salt-sensitivity) but not statistically significantly associated with potassium-sensitivity after adjusting for confounding factors.

Conclusions: These data indicate that urinary albumin excretion may be associated with BP salt-sensitivity.

Effects of Nephrectomy on Blood Pressure and Its Circadian Rhythm
Naro Ohushi, 1 Sayaka Ishigaki, 1 Shinshu Isobe, 1 Takayuki Tsujii, 2 Akihiko Kato, 2 Hideo Yasuda, 1 Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Japan; 2 Blood Purification Unit, Hamamatsu Univ School of Medicine, Hamamatsu, Japan.

Background: Intradural renin-angiotensin system (RAS) activation causes disturbance of sodium excretion from the kidney by increasing sodium reabsorption in the tubulus, with resultant blood pressure (BP) elevation and nocturnal hypertension. However, the effects of nephrectomy on BP and its circadian rhythm have not been clarified in the patients who have various renal functions.

Methods: We investigated 25 nephrectomized patients [17 men and 8 women, age: 61.3±14.7 years, chronic kidney disease stage 1 in 3 patients, stage 2 in 7, stage 3 in 5, stage 4 in 2 patients, stage 5 in 3 patients] on hemodialysis in 3 and peritoneal dialysis in 1]. Body weight (BW), circulating RAS [plasma renin activity (PRA) and plasma angiotensin II (AngII)] and 24-h ambulatory BP monitoring (ABPM) were examined before and after nephrectomy. We divided the daytime and nighttime for 24-h ABPM using sleep and waking times. Renal function [estimated glomerular filtration rate (eGFR)] was evaluated in non-dialysis patients.

Results: In non-dialysis patients, GFPR after nephrectomy was significantly decreased compared with that before nephrectomy [67.8±23.1 ml/min/1.73m²] and after nephrectomy, 47.9±16.5 ml/min/1.73m²; p<0.01]. There were no significant differences in the levels of BW, BP’s during daytime, nighttime and 24-h periods, and circulating RAS before and after nephrectomy.

Conclusions: Nocturnal hypertension may play a role in BP salt- and potassium-sensitivity.

Uric Acid Levels Are Associated with Peripheral but Not Central Blood Pressure Parameters in Normotensive Individuals
Pierre-Luc Lavoie, Stephanie Troyanov, Francois Madore, Remi Goupil. Nephrology, Hospital du Sacre-Coeur de Montreal, Montreal, QC, Canada.

Background: Uric acid is increasingly recognised as a risk factor for cardiovascular disease. Whether this could be explained by changes in peripheral or central blood pressure (BP) profiles remains controversial. The aim of this study was to assess the association of uric acid levels with peripheral and central hemodynamic parameters in untreated normotensive individuals.

Methods: Of 20,004 CADIENGENe participants, 8,420 were normotensive individuals not treated for hyperuricemia or hypertension with valid pulse wave analysis (46.9% male, 52.6% yo). The associations between uric acid levels and peripheral systolic BP (SBP), pulse pressure (PP) central systolic BP (cSBP), central PP (cPP), pulse pressure amplification (PPA), augmentation index (AIx) and augmented pressure (AP) were tested with linear regressions.

Results: In univariate analyses, uric acid levels were significantly associated with all parameters. In contrast, in multivariate analyses, only SBP and cSBP remained independently associated with uric acid levels. As cSBP is usually highly dependent of SBP, it was further adjusted for peripheral BP, where it was not independently associated with uric acid levels (β coefficient -0.003, p=0.51).

Differences of Carotid Intima-Media Thickness in Hypertensive Patients with Diabetes or Without
Hideo Okonogi, Tetsuya Kawamura, Akira Fukui, Shinnya Yokote, Nobuo Tsuboi, Yoichi Miyazaki, Makoto Ugar, Takashi Yokoo. Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan.

Background: Several studies reported that pulse pressure (PP) is the predictor of heart and kidney risks. On the other hand, arterial stiffness negatively correlates with renal function, and is the predictor of all causes mortality and mainly cardiovascular events in chronic kidney disease (CKD). Carotid-ankle vascular index (CA VI) is a non-invasive indicator of arterial stiffness, and is not influenced by the blood pressure (BP) at the time of examination. Therefore, we examined the relationship between various BP indexes and CA VI in patients with non-diabetic CKD.

Methods: Fifty-nine patients with non-diabetic CKD, who were diagnosed by first time biopsy, were included. Relationships between various BP indexes and CA VI were analyzed. Then receiver-operating characteristic (ROC) analysis for diagnosis of the presence of high arterial stiffness (CA VI<9, suggesting the presence of arterial sclerosis) were analyzed.

Results: As a result, systolic BP (SBP) and PP significantly correlated with CA VI (r=0.433, p<0.01 and r=0.624, p<0.01, respectively), while diastolic BP (DBP) and mean BP (MBP) did not correlate with CA VI. The ROC curves for diagnosis of the presence of high arterial stiffness by each index showed that SBP, DBP, MBP and PP had an area under the ROC curve (AUC) value of 0.786 (p<0.01), 0.425, 0.614 and 0.906 (p<0.01), respectively. Then, by two-graph ROC analysis, the threshold values of SBP and PP were obtained as 132.4mmHg (sensitivity 71%, specificity 71%) and 55.5mmHg (sensitivity 82%, specificity 82%), respectively.

Conclusions: These results indicated that PP has the most strong impact on arterial stiffness among various BP indexes. PP may affect renal function and cardiovascular risk via increase in arterial stiffness.

**Blood Pressure Trajectory and Events in the Cardiovascular Health Study**

Christopher C. Smoller,1 Rebecca Scherzer,1 Michael Shlipak,1 Mark J. Sarnak,1 Michelle Odden,2 Carmen A. Peralta,1 1UCSF; 2Tufts, OU.

**Background:** The association of blood pressure (BP) trajectories with clinical events in elders is not well established. The importance of integrating trajectories of systolic (SBP) and diastolic (DBP) is not known.

**Methods:** Among 4,067 participants in the Cardiovascular Health Study, we used repeated measures from the first 7 years to identify discrete trajectories of SBP, DBP and joint SBP/DBP: (1) concordant increasing, (2) discordant (stable SBP and decreasing DBP) and (3) concordant decreasing. Compared with a concordant increasing, a concordant decreasing and discordant trajectory had increased risk of death. Concordant decreasing was also associated with increased risk for incident CVD and HF, compared with concordant increasing and discordant trajectory had increased risk of death. Concordant decreasing was compared with concordant increasing. Findings did not differ when we stratified by use of antihypertensives.

**Results:** Of the 3828 individuals with treated self-declared hypertension, 155 had hypertension. The mean age was 48.7±8.7 years and majority of the participants were women (71%).

**Conclusions:** In normotensive individuals, uric acid levels were independently associated with SBP, but not with other hemodynamic parameters. Whether the increased risks associated with uric acid levels are explained by these parameters remains uncertain and needs further study.

**Funding:** Government Support - Non-U.S.

**Serum Uric Acid and Vascular Stiffness in African Americans with Hypertension**

Rajesh Mohandas,2 Xuerong Wen,3 Jorgiraj V. Tantravahi,2 Titte Srinivas,3 Richard J. Johnson,3 Mark S. Segal,2 1Nephrology and Hypertension Section, North Florida/South Georgia Veterans Health System, Gainesville, FL; 2Div of Nephrology, Hypertension & Transplantation, Univ of Florida, Gainesville, FL; 3Div of Nephrology, Medical Univ of South Carolina, Charleston, SC; 1Div of Renal Diseases and Hypertension, Univ of Colorado, Denver, CO.

**Background:** Elevation serum uric acid levels as well as vascular stiffness is associated with hypertension and cardiovascular (CV) disease. However, how uric acid affects vascular stiffness is not known. We examined the relationship between uric acid and vascular stiffness in a cohort of African American men and women with well-controlled hypertension.

**Methods:** 120 African-Americans with controlled hypertension were randomized in a double-blind, placebo controlled study to allopurinol (300mg/dl) or placebo for 4 weeks. Vascular stiffness was assessed by augmentation index at baseline and at 4 weeks after allopurinol therapy. Uric acid was characterized as low or high (>7 mg/dl in men and >6 mg/dl in women).

**Results:** The mean age was 48.7±8.7 years and majority of the participants were women (71%). Augmentation index was negatively correlated with uric acid at baseline (R=-0.24 p=0.009). The high uric group as compared to the low uric acid group, had a lower augmentation index (9.07 ± 5.52 vs. 11.22 ± 5.23 p=0.03) while the mean BP (119/75 vs 118/75), age (48.7 vs 48.6), and endothelial function as measured by endoPAT (2.2 ±2.2) were similar. With allopurinol therapy there was a drop in uric acid by 2.23±1.4 mg/dl as compared to placebo -0.15 ± 0.9 mg/dl but there were no significant changes in vascular stiffness or endothelial function.

**Conclusions:** In African Americans with hypertension uric acid is negatively associated with vascular stiffness and short-term therapy with allopurinol does not alter vascular stiffness. These changes are not explained by endothelial function. The mechanistic basis of how uric acid may be protective against vascular stiffness may explain the many conflicting studies on the contribution of uric acid to cardiovascular risk and merits further investigation.

**SA-PO657**

**The Impact of Renin-Angiotensin System Blockers on Renal Sodium Handling: An Analysis of CARTaGENE**

**Background:** Renin-angiotensin system blockers (RASB) reduce the effects of angiotensin II, and subsequently aldosterone, leading to vasodilation and natriuresis. The magnitude of the RASB-induced natriuresis compared to diuretics and other anti-hypertensive agents remains uncertain.

**Methods:** We identified patients treated for hypertension from the prospective CARTaGENE cohort, a random sample of the Quebec population aged 40 to 69, who had available urinary sodium levels. We compared the fractional excretion of sodium (FeNa) between patients on beta-blockers or calcium channel blockers without diuretics (Group 1), on RASB without diuretics (Group 2) and on diuretics (Group 3) with ANOVA and a general linear model adjusting for age, gender, estimated glomerular filtration rate (eGFR), diabetes and peripheral mean arterial pressure (pMAP).

**Results:** Of the 3828 individuals with treated self-declared hypertension, 155 had hypertension. Of these 61% were males, their mean age was 59±8 years, 23% had diabetes and the eGFR was 85±14 ml/min/1.73m² and 93±11 ml/min. Group 1, 2 and 3 included 42, 72 and 41 patients, respectively. In unadjusted analyses, patients in Group 1 (0.67±0.33) had lower FeNa than Group 2 (1.02±0.51, p=0.001) and Group 3 (1.25±0.70, p=0.001), while Group 2 had lower FeNa compared to Group 3 (p=0.029). In the adjusted analysis, Group 2 still had higher FeNa than Group 1, but the results were similar to Group 3.

**Conclusions:** After adjustment for important covariables, RASB therapy is associated with a natriuresis similar to diuretics and greater than other antihypertensive drugs in hypertensive patients. Whether the degree of natriuresis parallels the blood pressure response to these agents remains to be determined.

**Funding:** Government Support - Non-U.S.
Background: We previously demonstrated that mitochondrial injury contributes to renal dysfunction in swine renovascular disease (RVD), but its implications in human RVD remain unknown. Fragments of the mitochondrial genome released from dying cells are considered surrogate markers of mitochondrial injury. We hypothesized that RVD would be associated with increased urine mitochondrial DNA (mtDNA) copy numbers.

Methods: We prospectively measured urinary copy numbers of the mtDNA genes COX3 and ND1 by quantitative real-time PCR in essential hypertensive (EH), moderate RVD, and severe RVD patients (based on ultrasound criteria and evident loss of functional reserve). In RVD patients, urinary COX3 and ND1 directly correlated with RVD (R²=0.18, p<0.02 and R²=0.37, p<0.001), proteinuria (R²=0.33, p<0.001 and R²=0.53, p<0.001), and serum creatinine (R²=0.27, p<0.002 and R²=0.16, p<0.02, respectively), and inversely with eGFR (R²=0.10., p<0.05, respectively).

Conclusions: We found progressive increments in urine mitochondrial injury markers with increased severity of RVD, implicating mitochondrial injury in kidney damage in human RVD. Mitochondria might represent a novel therapeutic target in RVD.

Independent Association of Vitamin D on Endothelial Function: A Randomized, Double-Blind, Placebo-Controlled Clinical Trial Lea Borgi,1 Ciaran Joseph McMullan,2 Gary C. Curhan,1 Naomi D.L. Fisher,1 John P. Forman,1 Nephrology, Brigham and Women’s Hospital, Boston, MA; Endocrinology, Brigham and Women’s Hospital, Boston, MA.

Background: In nonhypertensive individuals, lower levels of 25-hydroxyvitamin D (25(OH)D) have been associated with increased risk of hypertension (HBP). Vitamin D deficiency has been associated with endothelial dysfunction in such individuals. However, the effect of vitamin D supplementation on endothelial dysfunction in nonhypertensive individuals has not been examined in a rigorous fashion.

Methods: In this randomized, double-blind, placebo-controlled trial of nonhypertensive, nondiabetic overweight or obese individuals with vitamin D deficiency (body mass index [BMI] 25 and 25(OH)D<20ng/mL), we assigned subjects to receive either ergocalciferol (1500 IU) or placebo, once a week for 8 weeks. Our primary outcome was endothelial-dependent vasodilation (EDV) measured by brachial ultrasound at baseline and 8 weeks post-randomization.

Results: By the end of the trial, 46 and 47 participants were allocated to receive ergocalciferol and placebo, respectively. Mean 25(OH)D levels increased from 14.9 to 30.3 in the vitamin D group and from 24.9 to 29.3 in the placebo group (p=0.006). EDV did not change significantly with either vitamin D repletion (from 6.3±3.6% at baseline to 6.1±4.6% at 8 weeks; p-value=0.78) or placebo (7.9±4.7% to 6.8±4.7%; p=0.17). The treatment effect p-value (comparing the 8-week change with ergocalciferol to the change with placebo) was 0.35.

Conclusions: In this randomized, double-blind, placebo-controlled trial, there was no improvement in endothelial function (measured as EDV) after repletion of vitamin D in overweight/obese non-hypertensive individuals.

Secondary Hypertension, Primary Hyperaldosteronism, and Renal Cell Carcinoma Nicole Pietro,1 Krishnanath Gaitonde,1 Charuhas V. Thakar,1 Cincinnati VA Medical Center; 2Univ of Cincinnati.

Background: Primary hyperaldosteronism (PH) is the most common cause of secondary hypertension. Renal cell carcinoma (RCC) can cause secondary hypertension, but as a renin-mediated process. We describe 5 cases referred for evaluation of PH (uncontrolled hypertension and hypokalemia), incidentally diagnosed with RCC, and the potential role of RCC as a renin-independent mechanism for hypertension.

Methods: At the initial renal visit, average blood pressure (BP) was 167/87 mmHg, with an average of 4 BP meds (nondiuretic blockers). Average serum levels of potassium, sodium, and bicarbonate were 3.1, 143, and 30 mEq/L respectively. Average plasma renin activity (PRA) was 0.12 ng/ml/hr, average serum aldosterone (sAldo) was 16.6 ng/dL, with a mean sAldo:PRA of 146. 24-hour urine analysis, aldosterone ranged from 11.8 to 30.2 ng/dL and sodium ranged 82-226 mEq/24 hours. All patients required 1 or 2 aldosterone blocking agents to achieve an average BP of 134/75 mmHg. Upon imaging, 4/5 had adrenal adenomas and all 5 patients had incidental solid renal masses with radiological characteristics of RCC. To date, 3/5 have had renal masses treated with partial/total nephrectomy or cryotherapy; all have confirmed pathology of RCC. All those undergoing TF treatment were on improved BP with 2/3 having reduced therapy. At presentation these 3 patients had an average BP of 159/87 mmHg and were on an average of 4.7% to 6.8% of 4.7%; p=0.17). The treatment effect p-value (comparing the 8-week change with ergocalciferol to the change with placebo) was 0.35.

Conclusions: In this randomized, double-blind, placebo-controlled trial, there was no improvement in endothelial function (measured as EDV) after repletion of vitamin D in overweight/obese non-hypertensive individuals.

SA-PO659

Association Between Urinary Big Angiotsin-25 and Microalbuminuria in Hypertensive Patients Yasuhiko Yamashita,1 Sayaka Nagata,1 Yui Sato,2 Kazuo Kitamura,1 Shouichi Fujimoto.1 1Dept of Circulatory and Body Fluid Regulation, Dept of Internal Medicine, Faculty of Medicine, Univ of Miyazaki, Miyazaki, Japan; 2Div of Nephrology, Brigham and Women’s Hospital, Boston, MA.

Background: In hypertensive patients, albuminuria is a predictive factor for cardiovascular events. Recently, a newly glycolated angiotensin-related peptide, Big angiotensin-25 (Bang-25), was isolated from human urine (Nagata et al. Biochem Biophys Res Comm 2013), and it was localized to podocytes in kidney tissue. Bang-25 may be involved in the renin-independent pathway for localized angiotension II generation, and can contribute to diagnosis in organ disorders. Using cross-sectional data, we investigated the relationship between urinary Bang-25 and albuminuria in hypertensive patients.

Methods: We examined the data of 408 hypertensive patients (male 50.5%; mean age ±10 years, BMI 25±7 kg/m², diabetes mellitus 36.8%, and eGFR 72±17 ml/min/1.73m²). We evaluated urinary albumin-creatinine ratio (ACR) and we measured urinary Bang-25 by specific AlphaLISA immunoassay. The association between urinary Bang-25/creatinine ratio and microalbuminuria was analyzed by a multivariate logistic ratio.

Results: Thirty patients were excluded because of microalbuminuria (ACR>300 mg/gCr). Of 378 patients, 96 had microalbuminuria (30<ACR<300 mg/gCr). Patients were then divided by quartiles of Bang-25/creatinine ratio. Older patients, females, lower hemoglobin, lower uric acid, and higher HDL were more prominent in higher Bang-25/creatinine quartiles. After adjusting for age, sex, eGFR, and presence of diabetes, the odds ratios (95% confidence intervals) for microalbuminuria per quartile, calculated using multiple logistic regression, were as follows: Q1, reference; Q2, 0.72 (0.33-1.54); Q3, 0.99 (0.49-2.01); and Q4, 2.05 (1.01-4.14).

Conclusions: Higher urinary Bang-25/creatinine quartile was significantly associated with microalbuminuria in hypertensive patients. As Bang-25 is localized to podocytes, it may play some role in the development of albuminuria.

Methods: In this randomized, double-blind, placebo-controlled trial of nonhypertensive, nondiabetic, overweight or obese individuals with elevated serum uric acid (body mass index [BMI] ≥25 and serum uric acid ≥5 mg/dL), we assigned subjects to receive one of the following: allopurinol 300 mg daily for 4 weeks followed by 600 mg daily for 4 weeks; probenecid 500 mg daily for 4 weeks then 1000 mg daily for 4 weeks; or matching placebo. Our primary outcome was endothelial-dependent vasodilation (EDV) measured by brachial artery ultrasound at baseline and 8 weeks post-randomization.

Results: By the end of the trial, 43, 44 and 47 participants were allocated to receive probenecid, allopurinol and placebo, respectively. Mean serum uric acid levels decreased from 7.9 ± 3.7 to 5.2 ± 2.4 mg/dL in the allopurinol group, and were unchanged in the placebo group (5.6 ± 5.7 mg/dL). EDV did not change significantly with either probenecid (from 7.6 ± 5.1% at baseline to 8.4 ± 5.2% at 8 weeks; p-value = 0.39), allopurinol (from 7.4 ± 6.0% at baseline to 5.9 ± 4.6% at 8 weeks; p-value = 0.09) or placebo (6.8 ± 3.8% to 7.1 ± 4.9%; p = 0.66).

Conclusions: In this randomized, double-blind, placebo-controlled trial, there was no improvement in endothelial function (measured as EDV) after lowering serum uric acid in overweight/obese non-hypertensive individuals.

Azelnidipine Can Restore the Deceleration Capacity of Heart Rate Variability (DC) in CKD Patients with Preceding Treatment with ARB

Michio Fukuda, Yoshitaka Miura, Yoshiaki Ogiyama, Ryosato Sato, Daisuke Fuwa, Hiroyuki Ito, Tetsuhei Matsuoka, Yukako Isole-Sasakai, Ken Kiyono, Yoshiharu Yamamoto, Junichiro Hayano, Nobuyuki Otte. Nagoya City Univ. ; Osaka Univ.; Tokyo Univ.

Background: Recently, we have hypothesized that DC, novel measure of cardiac vagal modulations, is also attributable to sympathetic nerve activities. Azelnidipine was reported to decrease non-Gaussianity index of HRV (I kh), which can serve as a marker of sympathetic cardiac overdrive.

Methods: In 43 hypertensive patients with CKD under treatment with an angiotensin receptor blocker (ARB), we tested whether 8-week add-on administration of azelnidipine can increase DC. DC was calculated by Bauer’s signal processing technique of phase-rectified signal averaging. For reference, the power of high frequency (HF, 0.15–0.40 Hz) obtained from frequency measure of HRV was examined as a conventional indicator of vagal activity.

Results: DC increased (6.17 ± 4.85 to 6.92 ± 4.18, p = 0.002) and I kh decreased (0.56 ± 0.15 to 0.17 ± 0.02, p = 0.001), while no significant changes were observed in other HR variability measures including HF (p = 0.9). Change in DC correlated inversely with the change in I kh (r = -0.38, p = 0.01), but not with the change in HF (p = 0.8).

Conclusions: Our findings are consistent with the thesis that DC is not a simple measure of vagal activity but a product of complex interplay between sympathetic and vagal nerve activities.

SA-PO664
Elevated Levels of Podocyte Derived Urinary Microparticles in Angiotensin II Induced Hypertension

Uta Erdbruegger, Christine Rudy, Sylvia Cechova, Rosa Chan, Joseph C. Gigliotti, Thu H. Le. Div of Nephrology and HTN, Univ of Virginia Health System, Charlottesville.

Background: Early and non-invasive biomarkers of kidney damage are needed to identify hypertensive patients at risk for kidney damage. Urinary microparticles (uMPs) have gained significant attention as potential novel biomarkers for kidney damage, and have already been identified in pre-albuminuric diabetic glomerular injury. These vesicles are less than 1 micron in size and carry markers of the parent cell. We hypothesized that podocyte derived uMPs are elevated in angiotensin II-induced hypertension (HTN).

Methods: Wild-type mice were treated with AII (400 ng/kg/min) via mini-osmotic pumps. Untreated WT mice served as controls. Blood pressure was measured with tail-cuff manometry. 24 hour urines were collected after 5 days of all treatment. Enumeration and phenotyping of MPs was done of podocyte culture supernatant and urine. UMP levels were normalized to urinary creatinine concentration. Podocalyxin (Pcal), podoplanin (Ppla) and annexin 5 (AV) were used as surface markers.

Results: Pcal and Ppla positive MPs as well as AV positive and negative MPs were detectable in supernatant from primary podocyte cultures. Compared to untreated controls (n = 3), AII treated mice (n = 2) had an increase in systolic blood pressure (SBP) by 33 ± 6 mmHg in the sulodexide and placebo arm, respectively (p = 0.037). The SBP reduction was most pronounced in the highest UACR tertile (-1.6 ± 1.5 vs 2.9 ± 1.6 mmHg; p = 0.042). Treatment (p = 0.015), baseline SBP (p = 0.001), heart rate (p = 0.007) and UACR (p = 0.007) were associated with SBP change. We found an interaction between treatment and UACR (p = 0.047), indicating that sulodexide and placebo differently affected SBP at various UACR levels. Age, eGFR, BMI, HbA1c and lipid profile (i.e., factors influencing ESL thickness) did not modify the treatment effect. The BP differences persisted during the first year of follow-up (p = 0.047).

Conclusions: Diabetic patients have a thinner endothelial surface layer (ESL), especially when macroalbuminuria is present. Sulodexide, a mixture of glycosaminoglycans (GAGs), increases ESL thickness. Previous data indicate that the ESL is pivotal for BP regulation. In this study, we assessed whether the BP reducing effect of sulodexide is modified by albuminuria severity (a surrogate for the ESL) in type 2 diabetic patients.

Methods: In a post-hoc analysis of the randomized, double-blind, placebo-controlled Sun-MACRO trial, including type 2 diabetic patients with macroalbuminuria and maximal angiotensin II receptor blocker therapy, we studied the BP effects of sulodexide 200 mg/d. We stratified patients in baseline urinary albumin-creatinine ratio (UACR) tertiles. We used ANCOVA to study whether baseline UACR modified the 3-month SBP changes of sulodexide.

Results: Data of 843 patients were available for analysis. Baseline BP was 138 ± 73 mmHg. At 3 months, mean (SEM) SBP change was -0.9 ± 0.9 and 1.7 ± 0.9 mmHg in the sulodexide and placebo arm, respectively (p = 0.037). The SBP reduction was most pronounced in the highest UACR tertile (-1.6 ± 1.5 vs 2.9 ± 1.6 mmHg; p = 0.042). Treatment (p = 0.015), baseline SBP (p = 0.001), heart rate (p = 0.007) and UACR (p = 0.007) were associated with SBP change. We found an interaction between treatment and UACR (p = 0.047), indicating that sulodexide and placebo differently affected SBP at various UACR levels. Age, eGFR, BMI, HbA1c and lipid profile (i.e., factors influencing ESL thickness) did not modify the treatment effect. The BP differences persisted during the first year of follow-up (p = 0.047).

Conclusions: In conclusion, podocyte derived urinary MPs are detectable in all HTN. These findings need to be confirmed in a larger group of animals. Urinary MPs can be potential marker for kidney end-organ damage in HTN.

Funding: Clinical Revenue Support

Blood Pressure Lowering Effects of Sulodexide Depend on Albuminuria Severity

Hikko Jan Lamberts Heerspink, Dick de Zeeuw, Liffert Vogt, Nephrology, AMC, Amsterdam, Netherlands; ’Clinical Pharmacy and Pharmacology, UMCG, Groningen, Netherlands.

Background: Diabetic patients have a thinner endothelial surface layer (ESL), especially when macroalbuminuria is present. Sulodexide, a mixture of glycosaminoglycans (GAGs), increases ESL thickness. Previous data indicate that the ESL is pivotal for BP regulation. In this study, we assessed whether the BP reducing effect of sulodexide is modified by albuminuria severity (a surrogate for the ESL) in type 2 diabetic patients.

Methods: In a post-hoc analysis of the randomized, double-blind, placebo-controlled Sun-MACRO trial, including type 2 diabetic patients with macroalbuminuria and maximal angiotensin II receptor blocker therapy, we studied the BP effects of sulodexide 200 mg/d. We stratified patients in baseline urinary albumin-creatinine ratio (UACR) tertiles. We used ANCOVA to study whether baseline UACR modified the 3-month SBP changes of sulodexide.

Results: Data of 843 patients were available for analysis. Baseline BP was 138 ± 73 mmHg. At 3 months, mean (SEM) SBP change was -0.9 ± 0.9 and 1.7 ± 0.9 mmHg in the sulodexide and placebo arm, respectively (p = 0.037). The SBP reduction was most pronounced in the highest UACR tertile (-1.6 ± 1.5 vs 2.9 ± 1.6 mmHg; p = 0.042). Treatment (p = 0.015), baseline SBP (p = 0.001), heart rate (p = 0.007) and UACR (p = 0.007) were associated with SBP change. We found an interaction between treatment and UACR (p = 0.047), indicating that sulodexide and placebo differently affected SBP at various UACR levels. Age, eGFR, BMI, HbA1c and lipid profile (i.e., factors influencing ESL thickness) did not modify the treatment effect. The BP differences persisted during the first year of follow-up (p = 0.047).

Conclusions: In conclusion, podocyte derived urinary MPs are detectable in all HTN. These findings need to be confirmed in a larger group of animals. Urinary MPs can be potential marker for kidney end-organ damage in HTN.

Under-Diagnosis of Hypertension in a Large Cohort of Overweight/Obese Adolescents

Brian William Sykes, Divya G. Moodalbail, Christopher J. LaRosa, Joshua Zaritsky. Nephrology, Nemours/A.I. duPont Hospital, Wilmington, DE.

Background: The obesity epidemic in children is strongly associated with increasing prevalence of childhood hypertension (HTN) along with heightened risk for cardiovascular morbidity and mortality in adulthood. Therefore we assessed the identification of HTN in overweight/obese adolescents cared for by a large healthcare system utilizing an EMR system.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: We performed a retrospective study of patients (pts) in the Nenmours Health Care System aged 12-17 years, with a BMI > 85%, and 3 documented BP > 120/80 in the outpatient setting, between 1/2010 and 12/2014. Pts with established diagnosis of hypertension (HTN) diagnosed 1992-2004, were excluded. Results: Of the 6604 distinct pts identified, only 253 (3.8%) received a diagnosis of HTN during the study period, while 6,349 (96.2%) were undiagnosed. Pts who were undiagnosed had lower BMIs and BPs and were less likely to be African American or have Medicaid and were seen less by Nephrology, Cardiology or Weight management subspecialties compared with those diagnosed with hypertension (table). Additionally undiagnosed pts had fewer abnormal BPs and had a longer interval between their 1st and 3rd abnormal BP compared with those diagnosed with hypertension.

Conclusions: In this large cohort of overweight/obese adolescents with HTN, the vast majority of pts were undiagnosed and not referred to subspecialists who manage BP monitoring and treatment. Thus it is crucial that future efforts focus on improving detection and early recognition of HTN in order to reduce cardiovascular morbidity and mortality in this at-risk population.

Multidisciplinary Selection of Angioplasty Indications in Atheromatous Renal Artery Stenosis Leads to an Improvement in Blood Pressure, Drug Sensitivity and Renal Function

Thomas Fournier,1 Florence Sens,2 Olivier Roussetie,2 Antoine Milton,1 Laurent Julliard,1 Nephrology, hôpital E. Herriot, Hospices Civils de Lyon, Lyon, France;1 Radiology, hôpital E. Herriot, Hospices Civils de Lyon, Lyon, France;1 Vascular Surgery, hôpital E. Herriot, Hospices Civils de Lyon, Lyon, France.

Background: Angioplasty as treatment of atheromatous renal artery stenosis (ARAS) is controversial since 3 large randomised trials (CORAL, ASTRAL, STAR) failed to prove the superiority of percutaneous renal artery angioplasty and stenting (PTRAS) over medical treatment alone (MT). However, since population selection was questionable among other biases, the extrapolation of these results in clinical practice is uncertain.

Methods: ARAS cases were discussed during bi-monthly multidisciplinary meetings gathering nephrologists, radiologists and vascular surgeons from April 2013 to February 2015. For every patient, we compiled clinical, biological and radiological data. We then recorded blood pressure (BP), renal function and treatment evolution after a one-year follow-up.

Results: During 23 months, 52 cases were discussed. Mean age was 69 years. Two-thirds of patients had at least 3 cardiovascular risk factors. Mean BP was 161±77 mmHg, despite the use of 2.5±1.1 anti-hypertensive drugs. CDK-EPI was 53mL/min/1.73m², 31% of patients had a history of pulmonary edema. Collective decisions were PTRAS for 21 patients (40%), MT for 28 patients (54%) and surgery for 3 patients (6%). PTRAS group showed a significant improvement at 1 year for clinic BP: 147±25 vs 130±15 mmHg (P<0.001), SCR: 1.1±1 vs 0.9±0.7 mg/dL (P<0.001), and were seen less by Nephrology, Cardiology or Weight management subspecialties. In the MT group, clinic BP: 148±27 vs 149±25 mmHg (P=0.76), SCR: 1.1±1 vs 1.1±1 mg/dL (P=0.12), and 3/4 patients were seen more by nephrologist.

Conclusions: Since the ARAS staging is controversial, the multidisciplinary approach proposed in this study is easy to implement and can result in significant reductions in blood pressure and improvement in renal function over one year.

Thus it is crucial that future efforts focus on improving detection and early recognition of HTN in order to reduce cardiovascular morbidity and mortality in this at-risk population.
kidney failure. HIV stage A (HR=0.3, p<10^-4) had a protective effect. Multivariate analysis revealed that age (HR=1.05, p=0.002) and CDC stage A (HR=0.35, p=0.01) were risk and protecting factors, respectively.

**Conclusions:** The prevalence of CKD in this very large cohort of people living with HIV-2 seems to be comparable to what is known in literature for people living with HIV-1. HIV-2 infection parameters determine most of the kidney risk. The role of ARV exposition remains to be taken into account.

**Effect of Nephropathy on the Frequency of Cardiac Dysautonomia in HIV Patients**

1 Dept of Nephrology, Allama Iqbal Medical College/Jinnah Hospital, Lahore, Pakistan; 2 HIV Clinic, Jinnah Hospital, Lahore, Pakistan.

**Background:** Dysfunction of autonomic nervous system including Cardiac Dysautonomia (CD) is seen in a variety of conditions like diabetes mellitus, adrenal insufficiency and renal failure. CD is well documented in patients with renal dysfunction. Prevalence of renal dysfunction (HIV Nephropathy) is high in our population of HIV positive patients, but the effect of HIV nephropathy on the frequency of CD has not been previously studied. We conducted this study to determine the effect of HIV nephropathy on the frequency of CD.

**Methods:** This cross sectional study was conducted at HIV clinic in collaboration with the Department of Nephrology Jinnah Hospital Lahore. A total of 47 HIV positive patients were enrolled; 13 (28%) with nephropathy and 34 (72%) without nephropathy. Patients underwent 5 tests for cardiac autonomic dysfunction including resting tachycardia, abnormal heart rate response to deep breathing, abnormal Valsalva ratio, abnormal 30:15 ratio and postural hypotension. Patients with 2 or more abnormal tests were considered positive for CD.

**Results:** Of 47 patients, 39(83%) were male, 5(11%) female and 3(6%) were transgender with median age of 31 years (range 19-56 years). The median CD4 count was 339 (range 39-797) and 96% (n=45) patients were on highly active anti-retroviral therapy (HAART). The median duration of HIV was 12 months (range 1-56) and median duration of HAART was 11 months (range 0-49). CD was seen in 42 (89%) patients. Seventeen (36.2%) patients had 2, 18(38.3%) had 3, 6 (12.8%) had 4 and 1 (2%) had 5 abnormal tests. The frequency of CD was comparable among patients with and without nephropathy [92% (12 out of 13) vs 88% (30 out of 34), respectively; p=0.01]. The presence of CD had no correlation with CD4 count, degree of renal impairment, treatment regimen and duration on HAART.

**Conclusions:** There was high frequency of CD in our population of HIV patients and it was independent of presence or absence of nephropathy, CD4 count and duration of anti-retroviral therapy.

**Gloermerul Filtration Rate Estimating Equations Using Beta-Trace Protein and Beta-2 Microglobulin in Chronic Kidney Disease**

**Background:** Beta-trace protein (BTP) and beta-2 microglobulin (B2M), like cystatin C (Cys), are novel serum filtration markers that have stronger associations with adverse outcomes than serum creatinine (Cr). However, comparisons of BTP and B2M to Cr have been replaced by relatively accurate equations derived from large epidemiological studies. Nonetheless, equations including Modification Diet in Renal disease-4 and 6 variables (MDRD-4, -6) and Chronic Kidney Disease-Epidemiology Consortium (CKD-EPI) are known to have wide variations in predicting GFR among patients with relatively good kidney function. As renal clearance of any solute is dependent on its presence in the plasma and not whole blood, we suspect that varying hemoglobin/hematocrit (Hct) may play an important role in the actual clearance of solutes. We aim to determine if adding the plasma factor PF (1 - Hct/100) to MDRD-4, -6, or CKD-EPI equations can improve the accuracy of determining actual GFR.

**Methods:** This is a retrospective pilot study where the most recent 200 existing 24-hour urine collections have been replaced by relatively accurate equations derived from large epidemiological studies. Nonetheless, equations including Modification Diet in Renal disease-4 and 6 variables (MDRD-4, -6) and Chronic Kidney Disease-Epidemiology Consortium (CKD-EPI) are known to have wide variations in predicting GFR among patients with relatively good kidney function. As renal clearance of any solute is dependent on its presence in the plasma and not whole blood, we suspect that varying hemoglobin/hematocrit (Hct) may play an important role in the actual clearance of solutes. We aim to determine if adding the plasma factor PF (1 - Hct/100) to MDRD-4, -6, or CKD-EPI equations can improve the accuracy of determining actual GFR.

**Results:** Of 162 samples of the total dataset. *p<0.001 for difference of 1-P from CKD-EPI Cr-Cys equation

</table>

The table shows the coefficients included in each equation and the performance of the equations in the validation dataset compared to the CKD-EPI Cr-Cys equation.
Results: 90 out 200 samples met inclusion criteria. Albeit small, when each of the aforementioned equation was adjusted for PF, R² variation improved. MDRD-4: unadjusted R² = 0.836 to adjusted R² = 0.853, MDRD-6, R² = 0.811 to 0.813, CKD-epi, R² = 0.746 to 0.747. Conclusions: Adding PF to MDRD-4, MDRD-6, and CKD-EPI equations reduced variations when correlated to 24-hour urine collections. Of interest, PF appears to improve MDRD (derived for CKD patients where anemia is prevalent) variations better than CKD-EPI. Large-scale reevaluation of eGFR estimates with consideration for PF is warranted.

SA-PO674
Interest of Cystatin C in the Evaluation of Glomerular Filtration Rate in Type 2 Cardio-Renal Syndrome
Delphine Kervella,1,2 Sundrine Lemoine,2 Florence Sensi,1,3 Eric Pouliquen,1,3 Laurence Dubourg,2,3 Fisum Guerbe-egziabher,1,3 Laurens Juillard,1,3 Nephrology, Hôpital Edouard Herriot, Hospices Civils de Lyon, Lyon, France; Renal Function, Hôpital Edouard Herriot, Hospices Civils de Lyon, Lyon, France; Univ Claude Bernard Lyon 1, Lyon, France.

Background: In patients suffering from type 2 cardio-renal syndrome (CRS2), glomerular filtration rate (GFR) is overestimated with creatinine based formulae, leading to the misclassification of these patients in chronic kidney disease stages. As cystatin C is less dependent from muscle mass than creatinine, the aim of this study was to determine if estimation of GFR based on cystatin C offers a better evaluation of renal function than creatinine-based estimations in patients with CRS2.

Methods: GFR measured by Inulin clearance (measured GFR, mGFR) in 50 patients with CRS2 was compared to estimations of GFR (eGFR) with CKD EPI ( Chronic Kidney Disease Epidemiology Collaboration) formulae based on creatinine (CKD EPI, cystatin (CKD EPI(cyst)), and cystatin and creatinine (CKD EPI(cyst,cr)). We calculated absolute bias (eGFR-mGFR) and accuracy 30% for each formula.

Results: Mean mGFR is 26.5±11.5 mL/min/1.73 m². eGFR are 35±1.5 and 35±14.5 mL/min/1.73 m² with CKD EPI, CKD EPI(cyst) and CKD EPI(cyst,cr) respectively. These values of GFR are significantly different from mGFR. Mean absolute bias are 15.4, 5.7 and 8.8 mL/min/1.73 m² and accuracies 30% are 30%, 68% and 48% respectively. The accuracy of CKD EPI(cyst) is significantly higher than the accuracy of CKD EPI.

Conclusions: Glomerular filtration rate is strongly overestimated with creatinine-based formulae, leading to the misclassification of these patients in chronic kidney disease stages. As cystatin C is less dependent from muscle mass than creatinine, the aim of this study was to determine if estimation of GFR based on cystatin C offers a better evaluation of renal function than creatinine-based estimations in patients with CRS2. CKD EPI formula based on cystatin C offers a better evaluation of GFR in this population. This high prevalence of malnutrition in this population can explain these results.

SA-PO675
Cystatin C in Capillary Blood: A New Tool for Instant Estimation of Glomerular Filtration Rate
Maurice Laville,1 Solene Pelletier,2 Denis Fouque,1 Nephrologie, Univ de Lyon, Pierre Benite, France; Nephrologie, Hospices Civils de Lyon, Pierre Benite, France.

Background: Serum creatinine is the most used endogenous marker to estimate glomerular filtration rate (eGFR) in clinical practice. A handheld device (SatSensor®, Nova Biomedicals) allows to measure creatinine level in capillary blood. The aim of the study was to assess the accuracy of GFR values (eGFR) estimated from capillary blood creatinine level (CBG), as compared to GFR values simultaneously measured by a gold standard method (mGFR) in patients with CKD.

Methods: The study included 79 adult patients (36 men, 43 women) who underwent renal function tests. The consent form contained information on the procedure and on the later use of the information for research. Inulin clearance was performed using a continuous infusion of inulin, and urine collections by periods of 30 min. Blood tests were done in the middle of each period of urine collection. Measurements of polycarboxylan concentration were performed using an enzymatic method. Inulin clearance was calculated in each period to obtain the average, and normalized to 1.73 m² body surface area. A drop of capillary blood was collected from a finger simultaneous to the first and the last blood sampling for inulin measurement. The drops were deposited on a test strip including enzyme reagents and inserted into the SatSensor® device. Reading was done at 30 sec. eGFR was calculated from CBCr with the CKD-EPI equation and the average of the 2 values was taken as eGFR. To assess the performance of CBCr-derived eGFR, the mean absolute bias (eGFR - mGFR) and the correlation coefficient (R2) were calculated.

Results: Mean age was 54±17 years, and mean BMI was 25.± 5 kg/m². Mean value of mGFR was 61±27 ml/min/1.73 m². Mean bias was -5.2 ml/min/1.73 m². On correlation analysis, there was no significant difference between the 2 methods (correlation coefficient 0.7, 0.7).

Conclusions: Estimation of GFR using instant measurement of capillary blood creatinine level and CKD-EPI formula provides consistent results as compared with a gold standard method for GFR measurement, and could be used for screening and self-assessment purposes.

SA-PO676
Renal Function Estimated with Different Formulae and Mortality in the CKD-EPI Cohort: Results After 8 Years Follow-up
Pietro Manuel Ferrara,1 Antonio Lupo,2 Giovanni Gambaro.1 Div of Nephrology, Catholic Univ of the Sacred Heart, Rome, Italy; Div of Nephrology, Univ of Verona, Verona, Italy.

Background: Chronic kidney disease is a known risk factor for adverse outcomes. Its presence and severity is usually ascertained with formulae to estimate renal function based on serum creatinine and/or cystatin C. We analyzed whether renal function estimated with different formulae has a different association with mortality.

Methods: The CKD-EPI cohort is a sample of the Italian population enrolled in 2006-07, with follow-up data available up to 2014. CKD stages were defined as GFR < 90, 60-90, 45-60, < 45 mL/min based on the following formulae: Cockcroft-Gault (CG), Cockcroft-Gault normalized to body surface area (nCG), abbreviated MDRD (MDRD, 6-variables MDRD (MDRD-6), CKD-EPI calculated with serum creatinine (EPI-Cr), with serum cystatin C (EPI-Cys), and with both serum creatinine and cystatin C (EPI-CrCys). CKD stage was then included in a Cox proportional hazards model together with age, body mass index, sex, high blood pressure, diabetes, dyslipidemia, previous cardiovascular disease, smoking status and albuminuria. Harrell's c statistics with 95% confidence intervals (CI) were then calculated and compared for each formula.

Results: The final sample included 2,916 participants, all Caucasians, 47.4% males, with an average age at enrollment of 59.9±11.4 years. Participants contributed a total of 22,514 person-years of follow-up (median follow-up 7.9 years) during which 198 death events occurred. Overall, the models were highly predictive of mortality.

The GFR-Cys model performed significantly better than MDRD-6 (difference in c-statistics of 0.008, 95% CI 0.001, 0.015; p=0.034), whereas all the other models performed similarly.

Conclusions: Our study suggests that CKD defined with the CKD-EPI cystatin C formula shows a better prediction of mortality after accounting for a large number of potential risk factors.

SA-PO677
Do the BIS Equations Better Predict Death in Older Women?
Muna T. Canales,1,2 Terri L. Blackwell,1 Areef Ishani,1,3 Brent C. Taylor,1 Allison Hart,2 Rebecca Beryl,2 Kristine E. Ensrud,4,5 Malcom-Randall VFCM, Univ of Florida, California Pacific Medical Center, Minneapolis VA Health Care System; Univ of Minnesota, Hennepin County Medical Center, Minneapolis, MN.

Background: KDIGO 2012 guidelines recommend use of the CKD-EPI equations to estimate GFR except when there are alternate equations that may perform better for certain populations such as older adults. The BIS equations were specifically developed in an aged population, but their performance when compared to the CKD-EPI equations to predict mortality in older adults is unclear.

Methods: We conducted a prospective study of 1289 community-dwelling elderly women (≥72 years old) enrolled in the Study of Osteoporotic Fractures (SOF) who had both serum cystatin-C(cysc) and creatinine(SCr) measured at Year 10(1992-1994). We defined CKD stages as GFR ≥90, 89-60, 59-45 and <45 mL/min based on the following formulae: Cockcroft-Gault (CG), Cockcroft-Gault normalized to body surface area (nCG), abbreviated MDRD (MDRD), 6-variables MDRD (MDRD-6), CKD-EPI calculated with serum creatinine (EPI-Cr), with serum cystatin C (EPI-Cys), and with both serum creatinine and cystatin C (EPI-CrCys). CKD stage was then included in a Cox proportional hazards model together with age, body mass index, sex, high blood pressure, diabetes, dyslipidemia, previous cardiovascular disease, smoking status and albuminuria. Harrell’s c statistics with 95% confidence intervals (CI) were then calculated and compared for each formula.

Results: The final sample included 2,916 participants, all Caucasians, 47.4% males, with an average age at enrollment of 59.9±11.4 years. Participants contributed a total of 22,514 person-years of follow-up (median follow-up 7.9 years) during which 198 death events occurred. Overall, the models were highly predictive of mortality.

The GFR-Cys model performed significantly better than MDRD-6 (difference in c-statistics of 0.008, 95% CI 0.001, 0.015; p=0.034), whereas all the other models performed similarly.

Conclusions: Our study suggests that CKD defined with the CKD-EPI cystatin C formula shows a better prediction of mortality after accounting for a large number of potential risk factors.

Canine Chronic Kidney Disease: New Protein Biomarkers and Treatment with Human Umbilical Cord Mesenchymal Stem Cells

**Background:** There are few strategies to prevent the progression of renal disease in humans or animals. In canine chronic kidney disease (cCKD), as in human CKD, proteinuria correlates with CKD progression, although there are no established urinary protein biomarkers. cCKD has become more common, dogs routinely being euthanized upon diagnosis. Treatment of cCKD is suboptimal because of lack of validated biomarkers for discrimination of mortality risk when compared to CKD-EPI equations.

**Methods:** We evaluated huMSC phenotypes with flow cytometry and immunocytochemistry. We compared human umbilical cord MSC (huMSC) administration to dogs with cCKD stages 1-4 (n=10/stage) and control dogs (n=10).

**Results:** huMSC administration slowed the progression of cCKD.

**Conclusions:** Human umbilical cord MSC (huMSC) administration slows its progression.

SA-PO680

Beta-Trace Protein as Renal Marker in Older Adults – Results from the Berlin Initiative Study

Johanna Schuchardt, Olga Jakob, Jan Bartel, Markus van der Giet, Mirjam Schuchardt, Christine A. White, Elke Schaefer.

**Background:** It has been shown that GFR estimation based on b-Trace Protein (BTP), a relatively novel biomarker, is reliable and might serve as an alternative in kidney transplant recipients. Whether BTP-based GFR equations can be applied in older adults is not known.

**Methods:** BTP has been measured by immunonephelometry with N-Latex BTP Assay on a BN ProSpec system. The Berlin Initiative Study (mean age: 78.5 years) who underwent iohexol clearance measurement (mean mGFR: 60.3 mL/min/1.73m2) for the 3 GFR-estimating equations, Incidence, Prevalence, Special Populations

Poster/Saturday

**Results:** The mean age was 79.5±4.6 years; 89% were white. Mean BMI was 27.5 kg/m2. Mean follow-up time was 9.4 years. %eGFR<60 was: CKD-EPI 33%, BIS2 48%, and CKD-EPI, 24% and BIS1 49%. When compared to eGFR<75 and after adjustment for age, race, BMI, HTN & DM, eGFR<45 by BIS2 was associated with a 2.1-fold greater risk of death (95% CI 1.5-3.0) vs 1.9-fold for eGFR<45 by CKD-EPI, (95%(CI 1.5-2.5); BSI eGFR<45 was associated with a 1.6-fold greater risk of death (95% CI 1.1-2.1) vs 1.8-fold for eGFR <45 by CKD-EPI, (95% CI 1.4; p trend <0.001 across categories for each equation). In category-based NRI analyses neither of the BIS definitions materially changed discrimination of mortality risk when compared to CKD-EPI equations.

**Conclusions:** In this cohort of older community-dwelling women, the BIS equations identified a greater proportion of participants as having CKD. With respect to mortality risk prediction, the BIS equations did not perform better than current CKD-EPI equations recommended by KDIGO 2012.

Chronic Kidney Disease: Long Term Prevalence Trends and Influence of Modifiable Risk Factors

Stein L. Hallan,1 Marius Altern Øvrehus,2 Solfird Romundstad,1 Dena E. Ritik,1 Arnulf Langhammer,1 Joachim H. Ix.1 UCSD, La Jolla, CA; *Faculty of Medicine, NTNU, Trondheim, Norway.

Background: Prevalence of chronic kidney disease (CKD) is high worldwide, and it has been increasing in the US. However, less strict treatment goals for hypertension have recently been suggested despite increasing prevalence of obesity and diabetes. We aimed to determine whether CKD prevalence is increasing in Norway, evaluating the influence of changing prevalence of CKD risk factors on CKD prevalence, and compared findings to corresponding US data.

Methods: We included general population based participants from the Nord-Trøndelag Health Studies (HUNT), Norway: 65237 from HUNT2 (1994-96) and and 50586 from HUNT3 (2006-08). eGFR and u-ACR based on fresh blood and 3 urine samples were used to diagnose CKD. Thorough quality-control and comparisons of methods over time excluded analytical drift. We used attendance weights used to avoid responder bias.

Results: Total CKD prevalence remained stable in Norway 1996-2007 (11.3%-11.1%, p=0.42) but increased in subjects >75 years (36.6%-39.3%, p=0.014). eGFR <60 ml/min/1.73m2 increased (4.5%-4.8%, p=0.033) while albuminuria >30mg/g decreased (7.9%-7.4%, p=0.034). The most important contributors were a strong blood pressure decline during this 10 years period, more physical activity and lower cholesterol; without these improvements 2.8, 0.7 and 0.6 percentage-point higher CKD prevalence would have been expected, respectively. In contrast, the prevalence of diabetes and obesity increased moderately, but diabetics received more intensive preventive therapy, and the proportion of diabetic patients with CKD decreased substantially (33.4%-28.6%, p=0.002). In contrast, published US data indicate a stronger increase in obesity and diabetes, and physical activity was low and not improving. Access to effective care was also suboptimal for a substantial group of the population.

Conclusions: In contrast to the US where CKD prevalence has been increasing, it remained stable over a 10 year period in Norway, likely due to substantial improvements in blood pressure, lipids and physical activity despite modestly increasing diabetes and obesity.

Natural Progression of Chronic Kidney Disease in Optimally Managed Patients on the Maximum Conservative Management Pathway

Background: The natural progression of advanced chronic kidney disease (CKD)/end-stage renal disease (ESRD) managed in a specialist palliative care nephrology clinic setting is unknown.

Methods: We conducted an observational study of all patients with advanced CKD undergoing predialysis counselling between 2009-2014 in a single UK center. All patients who opted for conservative management were followed up prospectively in a specialist conservative care clinic and their clinical phenotype and renal outcomes recorded. Change underlined represents presenting author.

Conclusions: Currently available eGFR equations that were developed for adult kidney transplant recipients are not applicable in non-transplanted elderly patients. Further research is necessary to evaluate whether BTP is a useful renal marker for older adults.

Funding: Private Foundation Support
Fall in eGFR in ml/min/year was 3.9 (1.8-8). Neither baseline eGFR (p=0.13) nor presence of diabetes (p=0.72) affected this rate of decline. Time to death from eGFR 10ml/min was 276 days.

Conclusions: In this first longitudinal study of conservatively treated patients with advanced CKD, variable rate of decline of eGFR ranging between 1.8-8ml/year led to death of 55% of the cohort within the median follow up period of 15 months. Reassuringly the majority of patients died at their preferred place of terminal care (home/hospice) and were registered as deaths due to ESRD. Over 50% of patient’s eGFR decline was less than 4 ml/min per year which could translate into a life expectancy of >1 year without dialysis in these exceedingly frail individuals. Prospective study is ongoing to determine the quality of life of these patients treated conservatively.

Estimating County-Level Prevalence of Chronic Kidney Disease (CKD) in the United States

Jain Excell Hussain, Jennifer L. Bragg-Gresham, Hal Morgenstern, Yi Li, Neil R. Powe, Delphine S. Tuot, Deborah Rolka, Sharon Saydah, Rajiv Saran, Univers of Michigan, Ann Arbor, MI; 2 Unv of California, San Francisco, CA; 3 Centers for Disease Control and Prevention, Atlanta, GA.

Background: The prevalence of adult CKD in the US, estimated from 2005-2012 national survey data, is about 13%; however, those surveys are not designed to provide estimates for small regions. Applying a Bayesian multi-level model (BMLM), we estimated adult CKD prevalence in US counties using national and state surveys.

Methods: Data on self-reported CKD and risk-factors were obtained from (i) the National Health and Nutrition Examination Survey (NHANES 2005-2012; n=20,831), and (ii) the Behavior Risk Factor Surveillance System (BRFSS 2011; n=506,467); NHANES also provided CKD laboratory data. CKD was defined as estimated glomerular filtration rate 15-60 ml/min/1.73m2 or urinary albumin-to-creatinine ratio >30mg/g. As BRFSS does not include laboratory data, CKD for each person in the BRFSS was multiply imputed using a logistic regression model trained on NHANES data. A BMLM that effectively borrows information from neighboring counties was then fit to each imputed dataset to produce 10 sets of county-level estimates of CKD prevalence. These estimates were combined to obtain a final prevalence estimate for each county.

Results: Estimated county-level prevalence of CKD ranged from 12.3 to 27.8% (median: 18.8%) in 2011 (see map).

The standard deviation of these estimates ranged from 0.8 to 7%, and the coefficient of variation ranged from 5 to 32% of the estimate, suggesting good statistical precision.

Conclusions: We believe this is the first attempt to estimate CKD prevalence in U.S. counties. Our approach yields estimates with improved statistical precision for small counties, and is being used to study geographic variation in CKD burden across the U.S.

Overall CKD Prevalence in the U.S. Has Stabilized in Recent Years

Daniel P. Murphy, Charles E. McCulloch, Feng Lin, Tanushree Banerjee, Jennifer L. Bragg-Gresham, Mark Eberhardt, Meda E. Pavkov, Rajiv Saran, Neil R. Powe, Chi-yuan Hsu, UCSF [Drs. CY Hsu and NR Powe are Co-Senior Authors]; 2 Univ of Michigan; 3 CDC.

Background: ESRD incidence rates in the U.S. have stabilized recently. We sought to better understand trends in CKD prevalence since 2003-2004.

Methods: We examined data on adults from the National Health and Nutrition Examination Surveys from 1988 through 2012. We determined prevalence of stage 3-4 CKD (CKD-EPI equation eGFR 15-59 ml/min/1.73m2) overall and by age, sex, race, and diabetes strata. We examined crude prevalence and adjusted prevalence for age, sex, race, and diabetes mellitus (diagnosed and undiagnosed). Restricted cubic splines were used to model trends. The years 2003-4 (last years with published literature) were compared to 2011-12 (most recent years of available data).

Results: Consistent with the published literature, we saw a rise in CKD prevalence from the late 1990s to the early 2000s. But since around 2003-4, adjusted and unadjusted prevalence of CKD have stabilized (Figure). This temporal trend was observed across age (p for interaction=0.11), sex (p=0.61) and racial-ethnic subgroups (p=0.07; although the trend in non-Hispanic blacks appeared to differ); and did not differ by diabetes status (p=0.17). There was no difference in overall stage 3-4 CKD prevalence comparing 2003-4 and 2011-12 (p=0.25). Similar trends were seen with an expanded definition of CKD to include persons with higher eGFRe but albuminuria or used the MDRD equation.

Conclusion: Over the last decade in the U.S., there has been stabilization in the overall prevalence of stage 3-4 CKD, with a possible exception in blacks. This is contrast to what has been reported by prior studies analyzing older data but consistent with the observed stabilization of overall ESRD incidence. Efforts should be continued to implement reno-protective measures, especially in blacks.

Global Prevalence of Chronic Kidney Disease Categories 3-5 – A Systematic Review

Background: Chronic kidney disease (CKD) has become a leading contributor to the global burden of disease. We performed a systematic review of published studies to estimate the global prevalence of CKD categories 3-5 defined by estimated glomerular filtration rate (eGFR) less than 60 ml/min/m2.

Methods: PubMed, EMBASE and Scopus were searched for studies published in English from 2003 to 2013 reporting prevalence of CKD categories 3-5 in the general population. Studies were included if they (1) sampled from the general adult population, (2) assessed CKD using CKD-EPI or MDRD Study equations, (3) not on renal replacement therapy.

Results: A total of 13,081 studies were considered, of which 566 studies from 54 countries assessed prevalence of CKD, and 284 studies were in unsellected general population. The global prevalence of CKD accounting for clustering among all adults aged 20 years or older are shown in table below

Prevalence of Chronic Kidney Disease in Diabetes and Glomerulonephritis in China

Luxia Zhang, Jinwei Wang, Ming Hui Zhao. Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China.

Background: Diabetes is the leading cause of end stage kidney disease worldwide, while glomerulonephritis is thought to be the predominant cause in developing countries. However, the surging prevalence of diabetes in developing countries such as China may have substantial impact on the spectrum of chronic kidney disease.

Methods: A national in-patient database involving 19.5 million patient-records was used. Diagnoses of chronic kidney disease with diabetes (DM-CKD) as well as with glomerulonephritis (GN-CKD) were extracted from International Classification of Diseases-10 codes of the discharge diagnoses. Furthermore, a general population-based, national representative sample of 47,204 participants was used. Identification of DM-CKD and GN-CKD was based on laboratory tests and the questionnaire inquiring about medical history. Then the prevalence of DM-CKD and GN-CKD was compared among both hospitalized population and general population.

Results: Among 19.5 million hospitalized patients, 1.19% and 0.79% were identified as with DM-CKD and with GN-CKD, respectively. Compared with GN-CKD, DM-CKD was associated with 7.2% (95% confidence interval [CI] 6.4-8.0%) 5.4% (95%CI 4.7-6.0%) and 59% (95%CI 46-73%) increase of costs, length-of-stay and in-hospital mortality, respectively. For general population, the prevalence of GN-CKD is also exceeded by that of DM-CKD at 0.84% (95%CI 0.68-1.00%) and 1.23% (95% CI 1.06-1.41%), respectively. The estimated number of DM-CKD patients in China was 20.1 million.

Conclusions: Our study indicates that DM-CKD surpassed GN-CKD in both hospitalized population and general population, which marked a transition of kidney disease spectrum in China. Furthermore, DM-CKD is associated with substantial increased healthcare resources utilization and increased risk of in-hospital mortality.

Prevalence of Chronic Kidney Disease on the U.S.-Mexico Border: Role of Acculturation

Jonathan Michael Starkey, Kristina Vatcheva, Susan P. Fisher-Hoch, Joseph B. McCormick. Inst for Translational Sciences, Univ of Texas Medical Branch, Galveston, TX; Univ of Texas School of Public Health, Houston, TX.

Background: Mexican-Americans are the dominant Hispanic group in the US and face significant health disparities, including end-stage renal disease, diabetes and obesity. We characterize the quantity and associations of chronic kidney disease (CKD) in Cameron County, TX where almost 90% of the population is Hispanic and is predominantly zero or first generation Mexican-American.

Methods: The Cameron County Hispanic Cohort (CCHC) is a random sample of the Hispanic population on the southernmost point along the US-Mexico border. 1,777 participants with baseline serum creatinine measurements from 2003-2014 are included in this cross-sectional study. The glomerular filtration rate (eGFR) is estimated from serum creatinine and CKD is defined as eGFR < 60 ml/min/1.73 m^2. The weighted prevalence of CKD is estimated. A multivariate model of factors associated with CKD outcome.

Results: The prevalence of CKD is 6.0% in the CCHC and estimates the prevalence in Cameron County, TX. Stratified by gender, the prevalence in men and women is 6.9% and 4.2% respectively. Multivariate analysis reveals significant associations of country of birth (OR 2.14, 95% CI [1.02, 4.46]) for those born in the US), hyperglycemia (OR 2.72, 95% CI [1.41, 5.239]) and granulocyte count (OR 1.345, 95% CI [1.038, 1.708]) with CKD status after adjusting for age, gender, diabetes status, cardiovascular disease history, hypertension, smoking history, obesity, LDL and statin use.

Conclusions: The prevalence of CKD in the CCHC is higher than previous national estimates in Hispanics or Mexican-Americans. The data suggest that acculturation, triglycerides and inflammation are associated with CKD in Hispanics living on the US-Mexico border. More research is needed in Mexican-Americans to investigate CKD in this growing minority population.

Validation of the Kidney Failure Risk Equation in Manitoba

Reid Whitlock,1,2 Paul Komenda,1,2 Claudio Rigatto,1,2 Allison Dart,1,2* Joe A. Bueti,1,2 Randy Wald,1 Navdeep Tangri,1,2,3 Community Health Sciences, Univ of Manitoba, Winnipeg, MB, Canada; 2Nephrology, Seven Oaks Hospital, Winnipeg, MB, Canada; 3Medicine, Univ of Manitoba, Winnipeg, MB, Canada; Nephrology, Health Science Centre, Winnipeg, MB, Canada.

Background: Patients with chronic kidney disease (CKD) are at risk for progression to kidney failure. We previously developed the Kidney Failure Risk Equation (KFRE) to predict the progression of CKD to kidney failure in patients referred to nephrologists. This study aims to validate the KFRE in an unreferred population in Manitoba, and to determine risk thresholds for clinical decision-making.

Methods: We included patients from the Diagnostic Services of Manitoba database with an eGFR < 60 ml/min/1.73 m^2 and a urinary albumin creatinine ratio measured between October 1, 2006 – March 31, 2007. Five year kidney failure risk was predicted using the 4-variable KFRE and compared with treated kidney failure events from the Manitoba Renal Program database. Sensitivity and specificity for KFRE thresholds (3% and 10% over 5 years) were then compared to eGFR thresholds (30 and 45 ml/min/1.73 m^2).
