Methods: The records of all adult patients with biopsy-proven proliferative lupus nephritis followed for at least 1 year were reviewed. All patients were pathologically classified according to the 2003 ISN/RPS classification of lupus nephritis and each pathological lesion was semiquantitatively scored.

Results: Patients with class III+V (class IV+V) presented with more severe proteinuria and chronic pathological lesions and milder acute pathological lesions than patients with class III (class IV); patients with subclass IV-G presented with more severe hypertension, proteinuria and hypocomplementemia, lower ANCA positivity rate, more severe glomerular cell proliferation and hyaline deposit, and milder fibrinoid necrosis and crescent than patients with subclass IV-S. The renal outcomes between patients with class III and class III+V, between class IV and class IV+V, and between subclass IV-S and subclass IV-G were not different respectively. Global glomerulosclerosis, cellular crescent, fibrous crescent, glomerular cell proliferation, tubular acute injury, interstitial inflammation and TMA were predictors for ESRD.

Conclusions: We found 25% of MLN patients with only one deposited immunoglobulin. The poor IF group compared to rich IF showed lower MDRD at baseline and even after one year. Studies are needed to elucidate the role of different patterns of deposits in the pathogenesis of MLN.

TH-PO764 Ability of Spot Urine Protein/Creatinine Ratio (Spot PCR) to Correctly Identify the Proteinuria Endpoints of Complete Remission (CR), Partial Remission (PR), and Treatment Failure (TF) as Determined by 24 Hour Urine PCR (24 PCR): Experience of the Abatacept and Cyclophosphamide Combination Efficacy and Safety Study (ACCESS) Brad H. Rovin,1 Lee A. Hebert,4 Div of Nephrology, OSUWMC, Columbus, OH; 1Div of Nephrology, OSUWMC, Columbus, OH; 4Div of Nephrology, OSUWMC, Columbus, OH. The present work is the first to rigorously test this hypothesis. ACCESS is a prospective randomized phase 2 trial of Abatacept or placebo added to the Euro-Lupus regimen of cyclophosphamide and prednisone. The error rate of spot PCR in identifying ACCESS proteinuria endpoints is high (defined by 24 PCR) was 23%. Proteinuria endpoints in LN trials are broad targets and Concordant 120, Discordant 35. P < 0.001 (null hypothesis that concordance is 95% is rejected). A unique feature of ACCESS was concurrent testing for spot PCR (monthly) and 24 PCR (each three months). ACCESS proteinuria endpoints were CR, PR, and TF assessed at 6 months and 12 months of follow-up (Arth Rheum Dis, 69, 2006, 3906, 2014). So, it is likely that using spot PCR rather than 24 PCR to guide management increases the risk of management error. So, it is likely that using spot PCR rather than 24 PCR to guide management increases the risk of management error. So, it is likely that using spot PCR rather than 24 PCR to guide management increases the risk of management error.

Results: At 6 month follow up, spot and 24 PCR were concordant in 36 CR, 25 PR, 10 TF, and discordant in 10 CR, 11PR, and 8 TF. At 12 month follow up, spot and 24 PCR were concordant in 36 CR, 11 PR, and 2 TF, and discordant in 4 CR, 2 PR, 0 TF. Tats: Concordant 120, Discordant 35. P < 0.001 (null hypothesis that concordance is 95% is rejected).

Conclusions: The error rate of spot PCR in identifying ACCESS proteinuria endpoints (defined by 24 PCR) was 23%. Proteinuria endpoints in LN trials are broad targets and mainly involve low level proteinuria. This minimizes the impact of spot PCR variability.

TH-PO765 Induction Treatments for Proliferative Lupus Nephritis: A Network Meta-Analysis Suetsenia Palmer,1 David J. Tunnillifice,2 Allisong Tong,2 Dimitris Mavridis,1 Jonathan C. Craig,3 Marcello Tonelli,4 David W. Johnson,5 Giovanni F.M. Strippoli,6,8 ’Univ of Otago Christchurch; 2 Univ of Sydney; ‘Univ of Ioannina; ‘Univ of Calgary; ‘Univ of Queensland; ‘Univ of Bari.

Background: Intra-venous cyclophosphamide has been standard care for inducing remission among patients with proliferative lupus nephritis (class III and IV). More recently, several agents have been tried, however, given the numerous treatment options and head-to-head trials, there is uncertainty about the comparative effectiveness of all available treatment options.

Conclusions: In global compared to focal proliferative lupus nephritis patients: male sex prevailed and renal function decreased on 3.6 years follow-up in spite of similar MDRD on baseline. Prospective studies are necessary to determine if histological pattern is relevant to guide the clinician’s therapy choice.
Methods: Immunosuppressive treatments to induce remission of kidney disease among patients with proliferative lupus nephritis (LN) have been evaluated using network meta-analysis of parallel-group randomized controlled trials. Outcomes were complete disease remission, treatment failure, all-cause mortality, end-stage kidney disease, major infection, alopecia, ovarian failure and malignancy. Effect sizes for treatments were calculated using random-effect meta-analysis and compared to intravenous cyclophosphamide (referent). Trials were critically appraised using Cochrane risk of bias.

Results: 47 studies involving 3510 patients were eligible. Mycophenolate mofetil was superior to intravenous cyclophosphamide for inducing disease remission (network odds ratio [NOR]: 7.7, 95% CI: 3.2-18, p<0.001), and resulted in CI of treated arms at follow-up of 0.26-0.87, and allopurinol (0.22, 0.13-0.39). Mycophenolate mofetil had uncertain risks of death (OR 1.14, 0.49-2.63), major infection (1.30, 0.88-1.92) and ovarian failure (0.48, 0.11-2.08) versus intravenous cyclophosphamide. Comparative effects of other treatments including rituximab and calcium inhibitors in combination were uncertain. Information for end-stage kidney disease and malignancy endpoints for all treatments was sparse. Treatment effects were generally consistent within networks. Methodological reporting in trials was frequently unclear.

Conclusions: Mycophenolate mofetil is more effective than intravenous cyclophosphamide for induction treatment of proliferative lupus nephritis.

TH-PO766
A Systematic Review on Tacrolimus Treatment in Lupus Nephritis
Timoke Krasia,1 Edwin Brendewold, Tom Huizinga, Tom J. Rabelink, Yoe Kie Onno Teng.1 Nephrology, LUMC, Leiden, Netherlands;2 Rheumatology, LUMC, Leiden, Netherlands.

Background: Recently, 2 large randomized controlled trials (RCTs) have been published on the efficacy of tacrolimus (TAC) in Asian LN patients. Both trials used different treatment regimens and efficacy was not consistent between the trials. Therefore, the role of TAC in the treatment of LN remains unclear. Thus, we performed a systematic review on TAC treatment for LN.

Methods: We searched multiple databases for all human studies investigating TAC treatment in LN. Then studies were selected on clinical relevance and results were analysed on renal response and adverse events.

Results: We found 26 clinical studies from which data were extracted from all controlled studies: 6 RCTs and 3 case-control studies involving a total of 888 patients. As induction treatment, TAC with steroids resulted in 82% responders of which 56% complete responders (CR). Induction with steroids, mycophenolate MMF (TAC) resulted in 85% responders, of which 46% CR. Data from 1 RCT performed with TAC in combination with steroids as maintenance treatment, resulted in 100% responders of which 56% CR. Generally, control patients receiving induction treatment with cyclophosphamide achieved 66% response of which 29% CR. Those receiving induction treatment with MMF achieved 76% response of which 53% CR. Overall infections were observed in 20% of TAC-treated patients compared to 26% of control patients treated with cyclophosphamide and 29% in MMF treated control patients. A rise in serum creatinine was observed in 5% of all TAC-treated patients compared to 2% in the cyclophosphamide control group and 0% in the MMF control group.

Conclusions: This systematic review suggests that TAC-based treatments can achieve comparable renal responses in LN as conventional regimens. Currently, limitations of the available studies are the heterogeneity of TAC-based regimens, lack of studies in non-Asian LN patients and lack of long-term safety data. Altogether, these data warrant further RCTs on TAC treatment in LN. At this time, TAC can only be advised as second-line treatment in difficult LN patients, such as therapy-refractory patients (especially if severe proteinuria is present) and in preparation or during pregnancy.

TH-PO767
Predicting Chronic Kidney Disease (CKD) in Lupus Nephritis (LN) Ana Malvar,1 Valeria Gabriela Alberton,1 Bruno Jorge Lococo,1 Haikady Nagaraja,2 Brad H. Rovin.3 Hospital Fernandez, Buenos Aires, Argentina;3 Ohio State Univ Wexner Medical Center, Columbus, OH.

Background: Early identification of LN patients likely to develop CKD may permit therapy to be adjusted and CKD to be avoided. Clinical and histologic parameters measured after induction treatment in LN patients were associated with long-term CKD in a cohort of LN patients to define predictors of new CKD.

Methods: Patients (n=69) with biopsy-proven class III/IV LN were induced with steroids and MMF (53%) or cyclophosphamide (46%) for 6 months, and had repeat kidney biopsy (biopsy 2, 6.6±0.7 months), and were put on maintenance therapy. Long-term (median 73 months) follow-up was available on 87% of the cohort. Multivariate linear regression was used to develop a predictive model for future serum creatinine (SCr) based on clinical and histologic variables obtained after induction.

Results: The impact of maintenance therapy in CKD at last follow-up among patients who did or did not achieve a complete clinical renal response after induction (19% vs 18.4%, respectively). Among patients with complete histologic renal remission after induction, 36% had a final SCr of 1.3-2.9 mg/dl. There was no relationship between the NIH activity index at biopsy 2 and long-term kidney function. However, the median number (range of 4-8) of patients who did not develop CKD (p<0.02). Regression analysis showed a significant linear correlation between CI ≥ 4 at biopsy 2 and log(SCr) at long-term follow-up (R=0.36, p<0.0001). In multivariate analysis CI and SCr at biopsy 2 were independent predictors of long-term SCr (R=0.48, p<0.0001). For a given level of SCr at biopsy 2, a 1 unit increase of CI in the range of 4-8 corresponded to a 20% increase in last SCr.

Conclusions: Neither clinical nor histologic remission after induction predicts long-term SCr, but complete histologic remission in LN at biopsy suggests a higher risk of CKD. The combination of SCr and chronicity index (CI) at biopsy accounts for 48% of the long-term variability of renal function in those patients who reach a threshold level (CI=4) of chronic kidney damage.

Funding: NIDDK Support

TH-PO768
Clinical and Histologic Remission in Class IVG and IVS Lupus Nephritis (LN) After Induction Therapy Ana Malvar,1 Bruno Jorge Lococo,2 Valeria Gabriela Alberton,1 Diego Morales,3 Brad H. Rovin.2 Hospital Fernandez, Buenos Aires, Argentina;3 Ohio State Univ Wexner Medical Center, Columbus, OH.

Background: The ISN/RPS classification of LN distinguishes class IV with predominantly segmental lesions (IVS) from class IV with global (IVG) lesions. It has been suggested that IVG may have a lower remission rate than IVS, possibly because it more like a vasculitis than IVG. However several studies found no significant difference in long-term kidney survival between these subclasses. We examined differences in histologic and clinical remissions between IVG and IVS in our LN cohort with serial kidney biopsies.

Methods: SLLE patients (n=43) were biopsied at first presentation of kidney involvement (Bx1) and again at 6 months after completing induction therapy (Bx2). Class IVG and IS patients were treated identically with steroids plus MMF or cyclophosphamide. NIH activity (AI) and chronicity (CI) indices, proteinuria and serum creatinine (SCr) were compared. Complete clinical response (CCR) was defined as normal SCr and proteinuria < 500 mg/dl.

Complete histologic remission was defined as an AI<0 at Bx2.

Conclusions: Clinical outcomes and histologic data are shown in the Table. All patients were ANCA negative. Final SCr and proteinuria were determined after a mean follow-up of 54±7 months. Only 4 patients were lost to long-term follow-up.

TH-PO769

Background: A complete remission (CR) in severe lupus nephritis (SLN) is associated with a favorable long-term outcome. Numerous factors including level of serum creatinine (SCr) at baseline have been shown to impact on CR rate and outcome. We assess the impact of SCr on CR rate and outcome in SLN.

Methods: We evaluated the 86 adult patients in the prospective, controlled trial of plasmapheresis in SLN and compared them based on SCr level at baseline (≤1.0, 1.01-1.5, 1.51-2.0, 2.01-3.0 and >3.0 mg/dl; n= 22, 23, 16, 12, 13 respectively). The CR rate (defined by a serum creatinine (SCr) of ≤1.4 mg/dl and UPro of 0.33 g/d) and long-term outcomes (stable renal function, dialysis and death) were compared. Patients were followed for 121±64 mo.

Results: Baseline clinical features (age, gender, race and UPro) were similar among the groups. All pts had ISN/RPS class IV lesions and while the activity index was similar (73±16 vs 71±15, respectively, the chronicity index (CI) 2.3±3 vs 3±5 vs 5±5, respectively). P (0.007) was significantly higher with increasing levels of SCr. At follow-up, CR rates (80% vs 52% vs 19% vs 25% vs 0%, respectively, P <0.0001) were significantly higher and occurred in a shorter period of time (6 vs 12 vs 23 vs 18 mo, respectively, P <0.0003) in pts with lower levels of SCr. Patients with a baseline SCr of 1.0 mg/dl were >16 times as likely (odds ratio, 16.2; 95% confidence interval, 4.2-61.5) to attain a CR and >6 times as likely (odds ratio, 6.1; 95% confidence interval, 1.9-18.6) to have stable renal function at last follow-up compared to pts with a SCr >1.0 mg/dl. The 15-yr renal survival (76% vs 57% vs 48% vs 25% vs 8%, respectively, P <0.0001) and patient survival without ESRD (76% vs 40% vs 24% vs 25% vs 8%, respectively, P <0.0001) was greatest in the patients with a SCr of 1.0 mg/dl at baseline.

Conclusions: The CR rate and outcome in SLN are significantly affected by baseline serum creatinine. The CR rate is highest and long-term prognosis most favorable in pts with a baseline SCr ≤1.0 mg/dl; the group with the least amount of chronic disease on biopsy. This emphasizes the importance of early diagnosis and treatment in pts with SLN.
TH-PO770

Urine Adiponectin Isoforms and Kidney Lesions in Lupus Nephritis (LN)

Biomarker Consortium, Huimeng Qi, Lining Wang

Background: Human adiponectin isoforms exert different effects on inflammation. Urine adiponectin is increased at LN flare, but the relationship between adiponectin isoforms and kidney lesions in LN has not been studied.

Methods: Urine and plasma total and high molecular weight (HMW) adiponectin isoforms were measured by specific ELISAs in samples from 39 normal controls and 97 biopsy-diagnosed LN patients. Urine adiponectin levels were normalized and log-transformed, and then examined for associations with histologic lesions on kidney biopsy by ANOVA, nonparametric Wilcoxon ranked-sum testing and multiple linear regression analysis.

Results: The HMW to total adiponectin ratio was increased in plasma (r=0.022) and urine (p=0.0004) of LN patients compared to controls. Total and HMW adiponectin levels were highly correlated within the plasma (R=0.91, p < 0.0001) and urine (R=0.64, p < 0.0001) in LN, but between plasma and urine only HMW adiponectin showed a correlation, and this was milder (R=0.21, p=0.037). Urine adiponectin levels increased with the severity of S NP/PS class. The highest total and HMW urine adiponectin levels were found in patients who had combined class III or IV + V LN. Using urine HMW adiponectin levels to differentiate between control and LN patients, and between single and combined LN classes, receiver-operating characteristic analysis showed areas under the curve of 0.96 and 0.85, respectively. Urine HMW adiponectin was significantly increased when glomerular proliferation, cellular crescents or interstitial inflammation were present on the biopsy, and the HMW adiponectin correlated with the biopsy activity index (R=0.31, p < 0.0001), but not chronicity index. Using HMW adiponectin plus urine hemopexin plus serum creatinine, an equation to predict biopsy chronicity index was constructed with R²=0.46.

Conclusions: Urine adiponectin isoforms increase with the severity of active kidney lesions in LN. The increase in urine adiponectin is not simply a reflection of changes in systemic adiponectin, and may be due to intra-renal processing.

Funding: NIDDK Support

TH-PO771

Significance of Serum Cystatin C as a Biomarker for Clinical Practice in Patients with Lupus Nephritis

Hua Zhou, Di Lu, Hairong Tang, Lizi Li, Huimeng Qi, Linig Wang

Nephrology Dept, 1st Hospital of China Medical Univ, Shenyang, China

Background: Serum Cystatin C (sCysC) as a novel biomarker of renal function has been studied in many primary glomerular diseases. However, sCysC was barely reported in lupus nephritis (LN). We aim to compare the changes of sCysC and traditional biomarkers in LN patients who had combined class III or IV + V LN. Using urine HMW adiponectin levels to differentiate between control and LN patients, and between single and combined LN classes, receiver-operating characteristic analysis showed areas under the curve of 0.96 and 0.85, respectively. Urine HMW adiponectin was significantly increased when glomerular proliferation, cellular crescents or interstitial inflammation were present on the biopsy, and the HMW adiponectin correlated with the biopsy activity index (R=0.31, p < 0.0001), but not chronicity index. Using HMW adiponectin plus urine hemopexin plus serum creatinine, an equation to predict biopsy chronicity index was constructed with R²=0.46.

Conclusions: Urine adiponectin isoforms increase with the severity of active kidney lesions in LN. The increase in urine adiponectin is not simply a reflection of changes in systemic adiponectin, and may be due to intra-renal processing.

Funding: NIDDK Support

TH-PO772

Neutrophil Modular Blood Transcriptional Signature Is Associated with Lupus Nephritis and Its Severity in SLE

Noemie Jourde-chiche, Bertrand Gondouin, Stephane Burty, Laurent Daniel, Bertrand Dussol, Laurent Chiche

Background: Lupus nephritis (LN) is a severe complication of SLE. The aim of this study was to assess the link between blood transcriptional signatures and LN, comparatively with other pathological conditions associated with renal injury.

Methods: 102 patients were included: 62 SLE patients, 40 controls with various conditions (10 with crescentic GN due to ANCA-associated vasculitis (AAV), 15 with severe bacterial sepsis, 15 with non-proliferative glomerular diseases), and their matched healthy controls. SLE samples were split in those at the time of: a biopsy-proven active LN (group 1, n=24); an extra-renal flare (group 2, n=11); a clinically quiescent visit (group 3, n=34). Microarray data were generated using Illumina beadchips and analyzed using modular repertoire analyses.

Results: Modular repertoire analysis in SLE patients revealed, in addition to the activation of IFN-related modules, a strong upregulation of M5.15, a module of 24 transcripts annotated “neutrophil”. There was no correlation between M5.15 and SLEDAI, anti-dsDNA level or IFN modules activity. M5.15 was strongly associated with active LN (p=0.009), but not with non-renal manifestations. The neutrophil modular signature was present in 67%, 18% and 47% of patients from group 1, 2 and 3 respectively. In group 2 and 3, its presence was associated with a past history of LN or the occurrence of LN during the follow-up. M5.15 was correlated with acute renal failure (p=0.03) and serum albumin (r=-0.14). AAV and sepsis patients shared the neutrophil signature observed in SLE, but displayed no IFN signature, while those with non-proliferative GN had none of these signatures.

Conclusions: Modular repertoire analysis demonstrates that neutrophil signature is correlated with occurrence and severity of LN in SLE. This result could allow the design of new biomarkers in LN.

TH-PO773

Anticoagulation and Longterm Outcomes in Patients with Renal Artery Stenosis and Antiphospholipid Syndrome

Alina L. Casian, Shirish Sangle, Sotiria Manoustitopoulos, David N. Cruze, Lupus Unit, Guy’s Hospital, London, United Kingdom

Background: Our previous data showed renal artery stenosis (RAS) is more prevalent in antiphospholipid syndrome (APS)(26%) compared to the general hypertensive population(8%), and anticoagulation with INR=3 was associated with initial reduction of chronic kidney disease (CKD) and hypertension.

Methods: We identified 37 patients with RAS and APS fulfilling Sapporo criteria: anticardiolipin IgG/IgM titer>40 units or >99 th percentile (or >1 lupus anticoagulant) on >2 occasions >=6 weeks apart AND vascular thrombosis (or pregnancy morbidity). RAS was diagnosed by magnetic resonance angiography(MRA).

Results: 15 patients had APS alone and 22 APS associated with autoimmune conditions (13 lupus, 5 ANCA vasculitis, 4 mixed). Median age at RAS diagnosis was 48 years, 31/37(83.8%) were female and median follow-up was 10.4 years. 25/37(67.6%) had ESRD or death, suggesting a non-thrombotic pathogenic process underlying RAS.

Conclusions: Modular repertoire analysis demonstrates that neutrophil signature is correlated with occurrence and severity of LN in SLE. This result could allow the design of new biomarkers in LN.

267A
RAS, e.g. minimal hyperplasia. Treatment of associated vascular risk factors and autoimmune disease is paramount. Anticardiolipin antibodies and renal MRA are useful for screening hyperplastic lupus patients.

TH-PO774

A Prospective Study to Investigate Mycophenolic Acid Pharmacokinetics and Its Clinical Correlations in Lupus Nephritis Patients

Desmond Y.H. Yang, Chun-Hay Tam, Sunny Sze Ho Wong, Maggie Kam Man Ma, Susan Yang, Dan Tai Mac Chan.

1 Medicine, The Univ of Hong Kong, Hong Kong, Hong Kong; 2 Medicine and Geriatrics, United Christian Hospital, Hong Kong, Hong Kong.

Background: The dosing regimen of mycophenolate mofetil (MMF) in the treatment of lupus nephritis (LN) is adopted from the kidney transplant experience. The role of therapeutic drug monitoring of mycophenolic acid (MPA) level in managing LN remains undefined.

Methods: We prospectively studied LN patients on maintenance treatment with prednisolone and MMF. Blood MPA level at 1, 2, 4, 8, 10 and 12 hours (i.e. C1, C2, C4, C8, C10 and C12) after MMF administration was measured with an enzymatic assay upon enrollment and repeated at 6-month intervals for 24 months, and at occurrence of clinically significant events, to investigate their clinical correlations.

Results: 51 patients were included, with prednisolone and MMF dose of 6.2±1.8mg/d and 1284±493mg/d respectively at baseline. C1, C2 and C12 MPA levels were 9.8±8.7mg/L, 8.6±6.2mg/L, 1.9±1.4mg/L during disease remission. C1, C2 and C12 MPA levels correlated with AUC(12)[r = 0.52, 0.85 and 0.77; p<0.004, <0.001 and <0.001 respectively]. C12 correlated inversely with hemoglobin, white cell and platelet counts [r = -0.359, -0.226, -0.20; p<0.001, 0.010 and 0.024 respectively]. There was no association between C12 and anti-dsDNA, serum creatinine or 24-hr urine protein excretion (r=0.53, 0.37 and 0.37 respectively). C1 and C2 showed no association with clinical or serological parameters.

Clinically significant events included infection in 2 patients, gastrointestinal upset in 3 patients, and renal flare in 5 patients. C12 MPA level at the time of these events were 1.7±1.9mg/L, 2.6±1.7mg/L and 1.5±0.9mg/L respectively.

Conclusions: C12 MPA level showed good correlation with drug exposure, and may be associated with renal flare and haematological side-effects but not infection.

Long-Term Prospective Study of Tacrolimus-Based Treatment in Lupus Nephritis Patients

Kazanori Karasawa, Keiko Uchida, Yukari Asamiya, Takahito Moriyama, Mitsuyo Itabashi, Takashi Takei, Kosaku Nitta, Dept Medicine, Kidney Center, Tokyo Women’s Medical Univ, 8-1 Kawada-cho, Shinjuku-ku, Tokyo, Japan.

Background: This study aimed to examine whether long-term maintenance treatment with tacrolimus for patients with lupus nephritis (LN) is effective and safe.

Methods: A total of 27 adult patients with LN after induction therapy were enrolled. Tacrolimus was initiated at a dose of 3 mg/day. Patients treated with other immunosuppressive agents were also switched to tacrolimus. Prednisolone doses were tapered during the period and their data were analyzed. The mean urinary protein/creatinine ratio significantly decreased from a baseline of 1.54 at 5 years (p = 0.016), while mean eGFR levels were unchanged throughout the 5 years of follow-up (4.7±4.1 ml/min/1.73m²).

Complications including acute myeloblastic leukemia, or their personal intention to become pregnant or discontinue medication. A total of 23 patients (mean age 52.6±11.8 years and mean duration of LN 15.6±8.7 years) were treated with tacrolimus throughout a 5-year period and their data were analyzed. The mean urinary protein/creatinine ratio significantly decreased from a baseline of 1.12±1.47 to 0.33±0.78 at 1 year (p = 0.005) and 0.40±1.54 at 5 years (p = 0.016), while mean eGFR levels were unchanged throughout the 5 years of tacrolimus treatment. The mean LNDAI was significantly decreased from a baseline of 3.54±2.53 to 1.96±1.40 at 1 year (p = 0.021) and 2.08±1.44 at 5 years (p = 0.022). Similarly, the mean prednisolone dose significantly decreased from a baseline of 0.35±0.21 mg/kg/day to 0.22±0.15 mg/kg/day at 1 year (p = 0.022) and 0.17±0.09 mg/kg/day at 5 years (p = 0.001). The mean blood concentration of tacrolimus was 4.0±2.3 ng/ml. Only one patient experienced a disease flare, and there were no deaths during the study period.

Conclusions: Our results suggest that tacrolimus can be potentially effective for the treatment of LN; moreover, the current dosage appeared to be generally well-tolerated for long-term maintenance treatment in patients with LN.

TH-PO776

Comparison of Kidney Function and Mortality of Mexican Children versus Adults with Lupus Nephritis

Background: Childhood-onset lupus nephritis (CLN; onset before 16 years of age) has been associated with a more aggressive disease course compared to adulthood-onset lupus nephritis (ALN). Kidney factors such as LN Class and Activity and Chronicity Indexes are related to renal prognosis. No information is available in our setting. Aim: To compare kidney function and mortality of CLN vs ALN.

Methods: Retrospective cohort study. Medical records of patients with LN biopsy proven performed Jan/2005 – Dec/2012 were reviewed. Clinical, kidney function and sociodemographical variables were recorded. Kidney biopsy findings, LN class, Activity and Chronicity Indexes, and patient status (alive/deceased) were also analyzed.

Results: There were 53 patients with CLN and 188 with ALN, with a follow-up of 24±23 vs 43±22 months, and age 12±2 vs 32±11 years, respectively. Main results are shown in the table.

Conclusions: Patients with CLN had higher mortality and those with ALN had lower CrCl at the end of follow-up. Children died mainly due to infectious causes which might be related to the immunosuppression used because of the high prevalence of class IV LN.

Determining Long-Term Outcomes in Lupus Nephritis Through Molecular Analysis of Serial Kidney Biopsies

Samar Parikh, Ana Malva, Huijuan Song, Jianying Zhang, Lianbo Yu, Brad H. Rovin, Div of Nephrology, The Ohio State Univ Wexner Medical Center, Columbus, OH; 2 Nephrology, Hospital Fernandez, Buenos Aires, Argentina.

Background: Most patients with proliferative lupus nephritis (LN) achieve a partial remission (PR) after induction therapy. With time some patients will attain complete remission (CR) while others will not improve. We tested whether gene expression in serial kidney biopsies could identify markers of long-term kidney outcome in patients who achieved a PR after induction.

Methods: The expression of 511 immune response genes was evaluated for 9 pairs of proliferative LN biopsies. A kidney biopsy was done at flare (bx1) and after induction therapy was completed (bx2). All patients achieved a clinical PR prior to bx2. At 3 year follow-up 4 patients were in CR and 5 patients did not improve or worsened (NR). Gene expression was analyzed by real-time PCR. The genes were selected based on their expression differences between bx1 and bx2.

Conclusions: Future studies will focus on validation of these markers and further characterization of the biology of these patients to more accurately predict long-term outcomes after induction therapy.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
expression profiles were compared at bx1 and bx2 between these CR and NR patients. Transcripts were considered differentially expressed only if they met both criteria of at least a 1.5-fold change (FC) and p-value < 0.01.

**Results:** At flare, 2 transcripts were differentially expressed between CR and NR. IL-28a, a type 3 interferon gene was decreased 2.6-fold (p = 0.006) and mannose-binding lectin serum peptide 1 (MASP1), a member of the complement lectin-pathway, was decreased 1.8-fold (p = 0.009) in CR versus NR. From bx1 to bx2, 8 genes were differentially expressed in the CR group. Expression of adhesion molecule VCAM1 and macrophage regulator CEBPB was decreased while expression of TGF-β activator SMAD3, inhibitor of TLR signaling, TOLLIP, and inhibitor of NFκB signaling, TRAF4 was increased. In NR, from bx1 to bx2, 9 genes were differentially expressed. Expression of the type 3 interferon, IL28b and the TNF-receptor TNRFSF13b (TACI) was decreased while expression of complement C2 and CFNB and the TNF cytokine TNFSF8 was increased.

**Conclusions:** This gene characterization of kidney biopsies at LN flare along with the change in expression after treatment identifies differentially-expressed genes among patients who eventually have or do not have a CR. Some of these genes may be candidate biomarkers of long-term renal outcomes in LN.

**Evaluation of Healthcare Resource Utilization and Costs by Immunosuppressant Pattern of Use in Lupus Nephritis**

**Shih-Yin Chen, Ning Wu, Ji-Ting, Fei Shih. Biogen.**

**Background:** US-based treatment guidelines recommend 6 months of immunosuppressant (IS) therapy before continuing or switching regimens for class IV/V lupus nephritis (LN) patients. Literature suggested that management of LN is costly, but published data on how costs and healthcare resource utilization (HRU) may vary by IS pattern of use are limited.

**Methods:** We identified LN patients initiating cyclophosphamide (CYC) or mycophenolate mofetil (MMF) in 2010-2013 from a US commercial/Medicaid claims database. All-cause costs and HRU during the year post-IS initiation were examined. Comparison was made between the following four groups based on their IS utilization:
1. Patients who remained on the same IS throughout IS continuously for at least 7 or up to 12 months (reference group),
2. Patients who switched/ discontinued IS at 6 months (305 patients),
3. Patients who switched/discontinued IS after 6 months (N=223),
4. Patients who switched/discontinued IS after 6 months, but then stayed on the same IS through 7-12 months. Identifying safe and efficacious therapies early for LN patients may have economic implications. Future study supplemented with clinical markers may help understand the economic impact of achieving early renal response is warranted.

**Retrospective Analysis of 65 Pregnancies in Patients with Lupus Nephritis in France**

**Jean-charles Puthet,1 Noemie Jourdier-chiche,2 Dominique Chauveau,3 Eric Daugas,4 Laurent Juillard.1 1Hôpital Edward Herriot - Hospices Civils de Lyon, France; 2Hôpital La Conception - CHU Marseille, France; 3Hôpital Rangueil - CHU Toulouse, France; 4Hôpital Bichat - APHP, on behalf of the French Cooperative Group on Lupus Nephritis, France.**

**Background:** Lupus nephritis (LN) mostly affects women of childbearing age. Despite the improvement in care over the last decades, pregnant women with LN are still at high-risk of maternal and foetal complications.

**Objective:** To understand the economic impact of achieving early renal response is warranted.

**Methods:** The aim of this study is to outline retrospectively the care and pregnancy progress of 65 pregnancies carried out after 2004, at the postpartum between 2004 and 2014, in patients with LN diagnosed before or during pregnancy.

**Results:** Data was collected from 65 pregnancies in 44 patients across nine French hospitals centres. LN was revealed by pregnancy in five cases. A preparation phase preceded the pregnancy in 90% of the cases, and complete remission from the disease was obtained for more than 24 months in 74% of them. Corticosteroids and hydroxycorticoamine were generally continued (68% and 73% respectively). Azathioprine and aspirin were administered in 37% and 65% of pregnancies. Maternal complications occurred in 40% of cases, with a 38% rate of premature birth. 68% of pregnant women with LN flares during these pregnancies were: the presence of positive anti-native DNA antibodies (p < 0.0001), low C4 (p = 0.004), the absence of complete remission of LN at conception (p < 0.001), or inactivity of LN inferior to 12 months (p = 0.003). Preeclampsia occurred more frequently with the deterioration of kidney function or an increase in proteinuria at conception (p = 0.011 and p = 0.001). The perinatal death rate was calculated at 6.8%. We observed 25% premature births and 15% intrauterine growth retardation (IUGR).

**Conclusions:** We found encouraging results. The incidence of maternal and foetal complications during pregnancy was reduced compared to previous European studies including lupus patients. Risk factors of major maternal complications are best characterized.

**Nephrotic Syndrome and Pregnancy**

**C. De Castro,1 J. Ashley Jefferson,2 Thomas R. Easterling,3 Div. of Nephrology, Dept. of Medicine, Univ of Washington School of Medicine; 2Dept of Obstetrics and Gynecology, Univ of Washington School of Medicine, Seattle, WA.**

**Background:** In the absence of hypertension or renal insufficiency, some consider the perinatal outcomes in pregnant women with nephrotic syndrome to be good. However, the diagnosis and management of both maternal and fetal well-being is challenging.

**Methods:** We describe the presentation, management, and maternal and fetal outcomes of 31 pregnancies in 24 women with biopsy proven nephrotic syndrome during pregnancy. We included demographical data, laboratory findings, antenatal and postnatal management, the relationship between the numbers of organ involvement and several fibrotic markers in Japanese patients with IgG4-Related Disease.

**Results:** There were 24 subjects (9 primiparas) with 31 pregnancies and 32 offming. Mean age was 27.6 years (range 16-39 years) and mean gestational age at presentation was 18.7 weeks (range 5-40 weeks). Labs revealed a mean creatinine 0.85mg/dl (range 0.4-1.4mg/dl), mean serum albumin 1.97g/dl (range <1.3-2.2g/dl), and mean proteinuria 0.86g/day (range 3.6-32g). UltraCOM cardiac output measurements were available for 18 pregnancies. Mean cardiac output at presentation was markedly elevated at 8.38L/min. 14 of 31 pregnancies were known to have kidney disease before pregnancy. Nephrotic syndrome was newly diagnosed in 16 patients. Biopsy was performed during pregnancy in 10 subjects (median age of gestation 20-5 weeks (range 2-27 weeks) changing management in 70%. 6 were biopsied postpartum. Biopsy diagnoses were FSGS(11), IgAN(3), lupus nephritis(3), membranous nephropathy(3), and 1 case each of Fibrillary GN, MPGN, C3GN, and minimal change disease. Maternal complications included preeclampsia(10/31), acute kidney injury(3/31) and cellulitis(3/31). Mean age of gestation at delivery was 35.4 weeks (range 25-40 weeks). 17 delivered via cesarean section. Fetal complications included birth weight <2500g(18), IUGR(3), and 10 were admitted to NICU.

**Conclusions:** Pregnant women with nephrotic syndrome are at high-risk for developing maternal and foetal complications despite the absence of significant hypertension or renal insufficiency.

**The Relationship Between Serum Cholinesterase, Number of Organ Involvement and Fibrotic Markers in Japanese Patients with IgG4-Related Disease**

**Hirofumi Nishikawa, Yoshinori Taniguchi, Tatsuki Matsumoto, Kazu Hamada-Ode, Yosiko Shinamura, Koji Ogata, Kosuke Inoue, Taro Horino, Shimpei Fujimoto, Yoshio Terada. Kochi Univ, Japan.**

**Background:** To evaluate the relationship between cholinesterase, number of organ involvement and serum fibrotic markers in Japanese patients with IgG4-related disease (IgG4-RD) including kidney involvement.

**Methods:** The clinical setting, laboratory, pathological and FDG-PET/CT findings of Japanese patients with IgG4-RD (n=20) were assessed. Several laboratory data of IgG4-RD with multiple organs’ involvement (IRDMO) (n=10), IgG4-RD with limited organ’s involvement (IRDL0) (n=10), ANCA-associated vasculitis (AAV) (n=10) and the pregnancy in 90% of cases were comparatively examined. Furthermore, we studied the relationship between the numbers of organ involvement (NOI) and several fibrotic markers (ELF score and serum Dkk-1) in IgG4-RD group.

**Results:** Serum cholinesterase (CHE) levels were significantly lower in IRDMO group than in AAV and SJS group, were considered significant of NE-RD and LN group. Serum albumin and IgG levels were significantly lower and CRP levels were significantly higher in AAV group, compared with IgG4-RD and SJS group. There were no significant differences in these levels between IRDMO and SJS. In total IgG4-Related Disease (IRDMO, IRDL0, SJS, SJS group), serum CHE levels inversely correlated with NOI, CRP levels positively correlated with NOI, Dkk-1 and without inhibitors, levels in IRDMO were significantly lower than IRDL0 and healthy subjects (p < 0.05).

**Conclusions:** The ELF score and serum Dkk-1 level might be a clinically useful indicators of active fibrosis and the extent of disease in Japanese patients with IgG4-RD. Notably, serum CHE levels could predict these phenomena.

Crescentic IgA Nephropathy – A Prospective Study Krishan L. Gupta, Prabhakar Doddi, 1 Rittambha Nanda, 2 Raja Ramachandran, 1 1 Nephrology, PGIMER, Chandigarh, India; 2 Pathology, PGIMER, Chandigarh, India.

Background: Crescentic IgA nephropathy (cIgAN) carries a very poor prognosis and the initial creatinine at presentation predicts long-term outcome. The present prospective study was carried out to evaluate the clinicopathological correlation and outcome of cIgAN.

Methods: We enrolled 21 IgAN patients, 14 recurrent tonsillitis (RT) patients without urinary abnormalities and 20 children with tonsillar hyperplasia (TH) who had been performed tonsillectomy. Genomic DNA from tonsillar crypts of each patient was extracted, and V4 regions of the 16S ribosomal RNA (rRNA) gene were amplified and analyzed using a high-throughput multiplexed sequencing approach. Differences of the genus composition among three groups were statistically analyzed by PERMANOVA, and visualized by principal component analysis (PCA).

Results: Our data suggested that bacterial diversity of cIgAN was different from that of TH. However, there was no bacterial genus that differs significantly in the frequency of between IgAN and RT. The PCA did not separate IgAN from RT, although it was discriminated from TH. In addition, we compared the bacterial composition between IgAN patients with higher and lower serum IgA levels; however, no difference in composition of microbiome between the two groups was observed.

Conclusions: Similar pattern of bacteria are present in tonsillar crypts of both IgAN and RT, suggesting that the host responsiveness to these bacteria is important in the development of IgAN.

TH-PO783
Comprehensive Microbiome Analysis of Tonsillar Crypts in IgA Nephropathy Hirofumi Watanabe, Shin Goto, Masafumi Tsuchida, Ichichi Narita. Div of Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.

Background: IgA nephropathy (IgAN) is the most prevalent primary chronic glomerular disease, in which the mucosal immune response, especially elicited in the tonsil or intestine, has been estimated to be involved with the development of the disease. To explore the relationship between IgAN and bacterial flora in the tonsils, we conducted a comprehensive microbiome analysis.

Methods: We enrolled 21 IgAN patients, 14 recurrent tonsillitis (RT) patients without urinary abnormalities and 20 children with tonsillar hyperplasia (TH) who had been performed tonsillectomy. Genomic DNA from tonsillar crypts of each patient was extracted, and V4 regions of the 16S ribosomal RNA (rRNA) gene were amplified and analyzed using a high-throughput multiplexed sequencing approach. Differences of the genus composition among three groups were statistically analyzed by PERMANOVA, and visualized by principal component analysis (PCA).

Results: Our data suggested that bacterial diversity of cIgAN was different from that of TH. However, there was no bacterial genus that differs significantly in the frequency of between IgAN and RT. The PCA did not separate IgAN from RT, although it was discriminated from TH. In addition, we compared the bacterial composition between IgAN patients with higher and lower serum IgA levels; however, no difference in composition of microbiome between the two groups was observed.

Conclusions: Similar pattern of bacteria are present in tonsillar crypts of both IgAN and RT, suggesting that the host responsiveness to these bacteria is important in the development of IgAN.

TH-PO784
Urinary N-Acetyl-d-Glucosaminidase Level Is Associated with Tubulointerstitial Fibrosis and Therapeutic Response in Immunoglobulin A Nephropathy Yousuke Yamada, Makoto Harada, Akinori Yamaguchi, Koji Hashimoto, Makoto Higuchi, Yuji Kamijo. Dept of Nephrology, Shinshu Univ School of Medicine, Matsumoto, Nagano, Japan.

Background: Therapeutic response in Immunoglobulin A nephropathy (IgAN) patients has been shown to be affected by the severity of chronic renal failure, such as tubulointerstitial fibrosis. Urinary N-acetyl-d-glucosaminidase (U-NAG) is a known biomarker of tubulointerstitial injury. The present study aimed to clarify if U-NAG level was associated with the severity of tubulointerstitial fibrosis and whether it could predict the therapeutic response to ST.

Methods: Among the 81 IgAN patients who were diagnosed by kidney biopsy and treated with ST between March 2005 and April 2015 at Shinshu University Hospital, the U-NAG data of 77 patients were investigated for relationships between clinical and histological data. To search for associations between U-NAG level and clinical remission (CR) rate, we examined 39 of the above 77 patients who were observed for 3 years following ST.

Results: Measurement may also aid in the prediction of therapeutic response to ST in IgAN.

TH-PO785
Beneficial Effect of Immunosuppressive Therapy for IgA Nephropathy with Moderately Impaired Renal Function Kyung sun Park, 1 Jongha Park, 2 Jong Soo Lee, 1 Hyun Chul Chung, 2 1 Div of Nephrology, Dept of Internal Medicine, Dongguk Medical Center, Ulsan, Korea; 2 Div of Nephrology, Dept of Internal Medicine, Ulsan Univ Hospital, Ulsan, Korea.

Background: A variety of treatment has been attempted to slow progression of IgA nephropathy (IgAN) such as renin-angiotensin system inhibitors and adding corticosteroid for patients with impaired renal function. We compared clinical outcomes of IgAN patients who were treated with vs. without immunosuppressive therapy (IST), and explored identified risk factors associated with progression of renal dysfunction.

Methods: Patients who were diagnosed as IgAN between 2001 and 2014 were screened. Among the 81 patients who had initial estimated glomerular filtration rate (eGFR) of 30-60 mL/min/1.73 m² and had followed up for at least 12 months were included in this analysis.

Results: A total of 92 patients were analyzed. 39 patients received IST (Group 1) and 53 did not (Group 2). Median follow-up (59 vs. 77 months) and mean age (46.6 vs. 47.4 years) were not significantly different. In Group 1, serum creatinine was increased (93 vs. 136 mg/dL, P<0.01), serum creatinine (1.66 vs. 1.45 mg/dL, P<0.003), and median amount of proteinuria (2033 vs. 1115 mg/day, P<0.001) were significantly higher, but mean cGFR (43.7 vs. 50.1 mL/min/1.73 m², P<0.001) and serum albumin (3.5 vs. 4.0 g/dL, P<0.009) were lower than Group 2. Three patient of Group 1 and 7 of Group 2 progressed to end-stage renal disease (ESRD). ESRD-free survival was comparable between two groups (P=0.639).

Conclusions: IST may have a beneficial effect for slowing progression of IgAN with moderately impaired renal function.

TH-PO786
Longitudinal Study of a Kindred with Familial IgA Nephropathy Reveals Stable Serum Levels of Galactose-Deficient IgA1 in a Kindred with Familial IgA Nephropathy Reveals Stable Serum Levels of Galactose-Deficient IgA1 Hiroyuki Park, 1,2 Yoshimi Ueda, 1,2 Zina Moldoveanu, 3 Stacy D. Hall, 1 Karen Hart, 1 Krzysztof Kiryluk, 1 Ali G. Gharavi, 3 Dana Rizk, 3 Bruce A. Julian, 3 Jan Novak, 1 1 Univ of Alabama at Birmingham, Birmingham, AL; 2 The Jikei Univ School of Medicine, Tokyo, Japan; 3 Columbia Univ College of Physicians and Surgeons, New York, NY.

Background: Patients with IgA nephropathy (IgAN) have elevated levels of circulating galactose-deficient IgA1 (Gd-IgA1). Familial form of IgAN has been reported among people of all ancestries. Serum Gd-IgA1 levels are heritable in patients with familial and sporadic IgAN. Moreover, 50% of first-degree relatives of patients with familial IgAN have high serum Gd-IgA1 levels (>50th percentile of healthy controls) without clinical signs of IgAN. This kindred had a longitudinal study of a large kindred with familial IgAN.

Methods: Pedigree includes 4 men with biopsy-proven IgAN. Members recruited in 2005 and 2014 included 2 IgAN patients, 13 relatives, and 7 genetically unrelated marry-ins. Serum Gd-IgA1 was measured using lectin ELISA and expressed relative to a standard serum Gd-IgA1 in U/100 ng of serum IgA. Spot urine sample was obtained for urinalysis and Gd-IgA1 in serum samples was determined.

Results: Change in serum Gd-IgA1 level was stable within families and in marry-ins (P=0.179 compared to baseline).

Conclusions: Serum Gd-IgA1 levels are stable within families and in marry-ins. Gd-IgA1 measurement may also aid in the prediction of therapeutic response to ST in IgAN.
Conclusions: Serum IgG-IgA levels in 22 individuals in this multiplex IgAN pedigree were stable over a 9-year period. No blood relative developed IgAN or exhibited a urinary abnormality during the 9-year follow-up period.

Childhood IgA Nephropathy with Nephrotic Syndrome (NS-IgAN) at Onset

Yuko Koike,1 Akihiro Shimizu,1 Nobuo Tsutobi,1 Keita Hiranuma,1 Makoto Ogura,2 Sayuri Shirai,1 Yoshinori Yasuda,1 Takashi Yasuda,1 Shoihi Maruyama,1 Tetsuya Kawamura,1 Seiichi Matsuo,2 Takashi Yoko,1 Ashikaga Red Cross Hospital,1 Hoshino Ashikaga,1,2

Background: Recently, in Japan, IgA nephropathy (IgAN) has been often treated by tonsillectomy. In this report, we investigated the clinical outcomes and factors affecting renal outcome of childhood NS-IgAN.

Methods: We retrospectively analyzed 1267 patients with IgAN biopsied between 1979 and 2010. Propensity scores were calculated using logistic regression. Associations between RASB and ESRD were examined using a Cox regression model adjusted by inverse probability of treatment weighted.

Results: During follow-up (median 5.1 years), 130 patients developed ESRD. With Cox regression adjusted by inverse probability of treatment weighted, RASB use was significantly associated with a lower risk of ESRD (hazard ratio, 0.57; 95% confidence interval [CI] 0.30-0.50, p<0.001). Among the 357 cases of NS- and other IgAN, the association was weaker (hazard ratio, 0.65; 95% CI 0.40-0.50, p<0.001). Among patients with IgAN using propensity score approaches.

Conclusions: In keeping with KDIGO recommendations, our results did not suggest improvement in renal prognosis by steroid therapy alone for IgAN with eGFR<50mL/min. However, IgAN patients referred to nephrologists often have reduced eGFR at the time of referral. Therefore, we evaluated the KDIGO guidelines to assess, and further develop their clinical significance for treatment of IgAN with reduced eGFR by a large multicenter cohort study in Japan.

TH-PO791
The Effect of Renin-Angiotensin System Blockade on the Incidence of End-Stage Renal Disease in IgA Nephropathy

Exhibition

Ritsuko Katafuchi,1 Kentaro Kitani,1 Yoshinari Nishiyama,1 Tetsuya Tsuruya,1 Takahito Uehata,1 Kenjiro Endo,1,2

Background: The impact of renin-angiotensin system blockade (RASB) on the incidence of end-stage renal disease (ESRD) remains unclear in IgA nephropathy (IgAN). This study assessed associations between RASB and ESRD in IgAN using propensity score-based methods.

Methods: We retrospectively analyzed 1267 patients with IgAN biopsied between 1979 and 2010. Propensity scores were calculated using logistic regression. Associations between RASB and ESRD were examined using a Cox regression model adjusted by inverse probability of treatment weighted, regression, stratification and matching.

Results: During follow-up (median 5.1 years), 130 patients developed ESRD. With Cox regression adjusted by inverse probability of treatment weighted, RASB use was significantly associated with a lower risk of ESRD (hazard ratio, 0.57; 95% confidence interval 0.41–0.79). Significant associations were observed for other propensity score-based methods.

Conclusions: In keeping with KDIGO recommendations, our results did not suggest improvement in renal prognosis by steroid therapy alone for IgAN with eGFR<50mL/min. However, IgAN patients referred to nephrologists often have reduced eGFR at the time of referral. Therefore, we evaluated the KDIGO guidelines to assess, and further develop their clinical significance for treatment of IgAN with reduced eGFR by a large multicenter cohort study in Japan.

TH-PO788
Predictive Factors of Spontaneous Remission in Patients with Immunoglobulin A Nephropathy

Hironobu Mukaiyama,1,2 Taketsugu Hama,1,2 Wook Kang,1,2

Background: Immunoglobulin A nephropathy (IgAN) is commonly considered as a lifelong disease, incidences of spontaneous remission (SR) have been occasionally reported. We investigate the incidence as well as the clinical predictors of SR in IgAN.

Methods: Medical records of biopsy-proven IgAN in Severance hospital from 2006 to 2014 were reviewed. SR was defined as complete remission reached without any corticosteroid therapy or combination therapy with tonsillectomy demonstrated significantly improved renal survival compared with no steroid therapy (hazard ratio [HR] 0.69, 95% confidence interval [CI] 0.50-0.93, p=0.015). Like KDIGO recommendations, multivariate analysis adjusted for other confounders showed that median level of proteinuria was a strong predictor of SR (HR 0.76, 95% CI 0.63-0.92, p=0.005). During a median follow up of 4 years, 70 patients (34.8%) reached primary outcome.

Conclusions: We conclude that treating the contributive factors to CR in multivariate analysis will tend to significant improvement in renal survival compared to no steroid therapy (HR 0.25; 95% CI 0.06-0.70, p<0.05).

TH-PO790
Evaluation of KDIGO Clinical Practice Guidelines for IgA Nephropathy by Japanese Multicenter Large Cohort Study

Kouko Watanabe,1 Kentaro Koike,1 Akihiro Shimizu,1 Nobuo Tsutobi,1 Keita Hiranuma,1 Makoto Ogura,2 Sayuri Shirai,1 Yoshinori Yasuda,1 Takashi Yasuda,1 Shoihi Maruyama,1 Tetsuya Kawamura,1 Seiichi Matsuo,2 Takashi Yoko,1 Ashikaga Red Cross Hospital,1 Hoshino Ashikaga,1,2

Results: Among the 84 patients with NS- and other IgAN, the association was weaker (hazard ratio, 0.65; 95% CI 0.40-0.50, p<0.001). Among patients with IgAN using propensity score approaches.

Conclusions: In keeping with KDIGO recommendations, our results did not suggest improvement in renal prognosis by steroid therapy alone for IgAN with eGFR<50mL/min. However, IgAN patients referred to nephrologists often have reduced eGFR at the time of referral. Therefore, we evaluated the KDIGO guidelines to assess, and further develop their clinical significance for treatment of IgAN with reduced eGFR by a large multicenter cohort study in Japan.

TH-PO789
Comparison of the Effect of Oral Steroid and Tonsillectomy Combined with Steroid Pulse Therapy for IgA Nephropathy

Yoshie Hoshino, Takahito Moriyama, Mitsuhiro Inabashia, Takashi Takei, Ken Tsuchiya, Kosaku Nitta, Dept of Medicine, Kidney Center, Tokyo Women’s Medical Univ, Tokyo, Japan.

Results: Recently, in Japan, IgA nephropathy (IgAN) has been often treated by tonsillectomy combined with steroid pulse therapy (TSP) instead of traditional oral steroid therapy (oPSL). However, there are few reports described about the comparison of them.
approaches. In stratified analysis, a beneficial association between RASB and ESRD was observed in patients with history of hypertension, reduced estimated glomerular filtration rate (<60 mL/min/1.73 m²), mesangial proliferation and segmental glomerulosclerosis (P for interaction <0.05), and tended to be greater in patients with proteinuria (>1.0 g/24 h), extracapillary proliferation, and receiving methyldopa/isoniazide pulse therapy (P for interaction <0.10).

Conclusions: Treatment with RASB was associated with a lower incidence of ESRD in the real-world practice of IgAN.

TH-PO794
Remission of Urinary Protein at 2 Years After Diagnosis with Normal Renal Function and Remission of Urinary Protein at 1 Year After Diagnosis with Decreased Renal Function as an Accurate Prognostic Marker in IgA Nephropathy Takayuki Fujii,1 Junichi Hoshino,2 Joichi Usui,1 Satoshi Suzuki,1 Yoshifumi Ubara,1 Kunihito Yamagata.1 1Seirei Sakura Citizens Hospital, Sakura, Japan; 2Tosanoumun Hospital, Tokyo, Japan; 3Unit of Toksuka, Toksuka, Japan.

Background: Level of proteinuria (UP) has a strong association with poor renal prognosis in IgA nephropathy. Recent studies reported that the level of UP, especially, remission of UP(CR) defined as less than 0.3 g/d, during the follow-up was a more accurate prognostic factor than at diagnosis. In this multicenter study, we evaluated which post-diagnosis measurement point achieving CR strongly associated with the renal prognosis.

Methods: 1,077 patients diagnosed with IgA nephropathy between March 1991 and December 2013, and could be followed-up for at least 3 years or reached end-stage kidney disease (ESKD) were enrolled. We performed a retrospective cohort study among 2 divided groups: 638 with eGFR<60 mL/min/1.73 m² (A) and 439 with eGFR<60 mL/min/1.73 m² (B). The endpoint of this study was a 50% decrease in eGFR or ESKD. The annual daily UP level until 3 years after diagnosis was categorized into 2 grades: <0.3 g/d and >0.3 g/d and its association with the renal prognosis was investigated. The hazard ratio of the endpoint adjusted with clinical and pathological findings and treatment was examined.

Results: Regarding CR as a reference, UP<0.3 g/d was not a significant poor prognostic factor at diagnosis, but at 1 year, especially at 2 years, it became a significant factor in group A. On the other hand, in group B, UP<0.3 g/d was already shown to be a significant factor at diagnosis and the strongest factor at 1 year.

Conclusions: CR within 2 years after diagnosis with normal renal function and CR within 1 year after diagnosis with decreased renal were the most accurate predictors for a favorable outcome in IgA nephropathy.

TH-PO795
Copetin, a Surrogate Marker for AVP, Is Associated with Disease Severity and Progression in IgA Nephropathy Patients Debbie Zittema,1 Jan A.J.G. van den Brand,2 Jack F. Wetzel,3 Ron T. Gansvoort,1 1Nephrology, Univ Medical Center Groningen, Groningen, Netherlands; 2Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.

Background: The disease course of IgA Nephropathy (IgAN) is difficult to predict. Copetin, a surrogate marker for AVP, has been described to cause kidney damage in various renal diseases. We investigated therefore the associations of copetin with disease severity and progression in IgAN.

Methods: Included were 60 biopsy proven IgAN patients from the Radboud UMC Nijmegen, of whom urine and blood samples were available. Urinary excretion of α1M, KIM-1, NGAL and plasma copeptin was measured at baseline. Survival analyses were performed for the composite outcome death, end stage renal disease (ESRD), doubling of serum creatinine, start of immunosuppressive therapy and the individual components.

Results: In IgAN patients (male: 72%, age: 42±13 year, eGFR: 48±21 mL/min/1.73m², copetin: 9.4±5.18 pmol/L) copetin was associated at baseline with proteinuria (St. β=0.34, p=0.01) and with start of immunosuppressive therapy (p=0.04) using a log rank test. When patients who started immunosuppressive therapy during follow up (n=14) were excluded, copetin (as continuous variable) was furthermore associated with the incidence of ESRD (p=0.01, HR=1.09; i.e. a 9% increase in risk of ESRD per 1 pmol/L increase in copetin), doubling of serum creatinine (p=0.004, HR=1.07) and the composite outcome (p=0.003, HR=1.07) in Cox regression models, adjusting for proteinuria and sex. After additional adjustment for eGFR, which is debatable as eGFR decline could be part of the causal pathway between copetin and outcomes, the survival analyses lost significance.

Conclusions: Copetin is a promising disease severity marker in IgAN with additive predictive value for future kidney function loss over proteinuria, but not over eGFR, the strongest predictor of disease progression in this study.

A Specific Transcriptomic Profile Characterizes Peripheral Blood Mononuclear Cells (PBMCs) from Uremic Patients (pts) Treated With On Line Hemodiafiltration (OL-HDF) Compared to Those Treated With Bicarbonate Dialysis (BHD)

Simona Simoncini,1 AnnaRita Chiari,1 Matteo Accurturo,1 Roberto Coricualo,1 F. Rascio,1 Paola Pontrelli,1 Giovanni Stellone,1 Lorenzo Gensini,2 Giuseppe Granito,1,2 Giovanni B. Pertossa,1 1Dept of Emergency and Organ Transplantation, Univ of Bari, Italy; 2Dept of Medical and Surgical Sciences, Univ of Foggia, Italy.

Background: Recent studies suggest that OL-HDF can reduce the progression of dialysis-related cardiovascular diseases, but the molecular mechanisms underlying this improvement are not yet known. The aim of our study was to identify, through a high-throughput approach, differences in gene expression profiles of PBMCs from pts undergoing OL-HDF compared to BHD.

Methods: The transcriptomic profile was evaluated in PBMCs isolated from 10 pts regularly dialyzed with OL-HDF (convective volume 22 L) and 10 pts treated with BHD using microarray analysis (Agilent Technologies). The results were evaluated by statistical (ANOVA) tests and functional pathway analysis (Ingenuity Pathway Analysis).

Results: We observed that 868 genes were differentially expressed in the comparison between OL-HDF and BHD (fold change>1.5). Thirty-seven functional gene networks were identified and atherosclerosis signaling was the top canonical pathway associated with BHD (p=2.45x10^-10). Among the downregulated genes in OL-HDF there were PDGF (FC=-2.13) and Clusterin (FC=-2.14), involved in vascular injury and Mononucone Oxidase A (MAO-A, FC=-2.43), an important source of oxidative stress and a major contributing factor to the development of ventricular hypertrophy and heart failure. Interestingly, Apolipoprotein E (APOE) gene, an anti-oxidant/ inflammatory protein, was upregulated (FC=+1.7) by OL-HDF. qPCR, performed in an independent testing-group [15 BHD, 15 OL-HDF] confirmed that PDGF, Clusterin and MAO-A were down-expressed in OL-HDF (p =0.01), whereas APOE resulted higher expressed (p<0.01).

Conclusions: The OL-HDF can contribute to cardiovascular risk reduction through the modulation of pathways involved in the progression of atherosclerotic disease. This observation could open new perspectives in the prevention of cardiovascular risk in dialysis pts.

Twice-Weekly versus Thrice-Weekly Hemodialysis in Patients with or without Residual Kidney Function

Hyeon Seok Hwang,1 Suk young Kim,1 Su Hyun Kim,1 Yong-Lim Kim,1 Yon Su Kim,1 Shin-Wook Kang,2 Chul Woo Yang,1 1College of Medicine, The Catholic Univ of Korea, Korea; 2Chang-Ang Univ College of Medicine, Korea; 3Kyanggook National Univ School of Medicine, Korea; 4Dept of Internal Medicine, Seoul National Univ College of Medicine, Korea; 5Yonsei Univ College of Medicine, Korea.

Background: Residual kidney function (RFK) accounts for large solute removal and significantly contributes to survival benefits in hemodialysis (HD) patients. However, there are no reliable outcome data suggesting that the frequency of HD might be safely reduced in patients with substantial RFK.

Methods: A total of 685 patients receiving more than 3 months HD therapy were included from the CRC registry for ESRD. The presence of RFK was defined as more than 100 ml/day of urine volume, and patients were classified into twice-weekly HD with RFK (n=113), thrice-weekly HD with RFK (n=137) and thrice-weekly HD without RFK (n=435).

Results: The baseline RFK was significantly higher in twice-weekly HD patients with RFK than in thrice-weekly HD patients with RFK (P<0.002). In multivariable analyses, compared with thrice-weekly HD patients without RFK, thrice-weekly HD patients with RFK were associated with lower risk for all-cause mortality (HR 0.65; 95% CI 0.39-1.04; P=0.04). For hospitalization of cardiovascular events, thrice-weekly HD treatment with RFK did not reduce the risk of mortality (HR 0.65; 95% CI 0.22-1.87). For hospitalization of cardiovascular events, thrice-weekly HD treatment with RFK was independently associated with lower risk, (HR 0.40; 95% CI 0.16-0.98), but twice-weekly HD patients with RFK were not associated (HR 0.89; 95% CI 0.38-1.71).

Conclusions: Twice-weekly HD patients with RFK have similar outcome compared to thrice-weekly HD patients without RFK. However, thrice-weekly HD patients with RFK were more advantageous for mortality and CVE than those without RFK.

Conclusions: Among a large racially/ethnically diverse United States population, FSGS was the most prevalent GN and was associated with the highest rate of progression to ESRD among all race/ethnic groups (36% overall) followed by membranous GN (12%), minimal change disease (10%) and MCD (7%).

Methods: Retrospective longitudinal cohort study in the period 1/1/2000 through 12/31/2013 among patients within Kaiser Permanente Southern California. Patients who had biopsy proven primary GN were characterized and followed until they reached the outcomes of ESRD or mortality. ESRD was defined as receiving dialysis or renal transplant.

Results: 2,849 patients were identified with biopsy proven GN. The mean age of the cohort was 47 yrs with 48% females, 37% Hispanics, 30% whites, 17% blacks, and 12% Asians. Focal segmental glomerulosclerosis (FSGS) was the most common GN among all race/ethnic groups (36% overall) followed by membranous GN (12%), minimal change disease (MCD) (12%), IgA nephropathy (IgAN) (10%), and others (31%). The mean follow up was 3.8 yrs. ESRD occurred in 26% (704 required dialysis and 38 had a renal transplant). Mortality occurred in 18%. ESRD occurred among 35% of FSGS, 19% among IgAN, 12% among MGN, 10% among MCD, and 29% among other GN's.

Comparison of Outcomes Between Incremental and Abrupt Initiation of Hemodialysis: A Propensity-Matched Analysis of a Prospective Cohort Study in Korea

Ji In Park,1,2 Yong-Lim Kim,2,3 Shin-Wook Kang,2,4 Chul Woo Yang,2,5 Yoon Su Kim,6,7 Jung Pyo Lee,7,8 Kangwon National Univ;9 ‘Clinical Research Center of End Stage Renal Disease in Korea;10 Kyungpook National Univ;11 Yonsei Univ;12 ‘The Catholic Univ of Korea;13 Seoul National Univ;14 Seoul National Univ Boramae Medical Center.

Background: When patients are diagnosed as end-stage renal disease (ESRD) and initiate hemodialysis (HD), thrice-weekly HD is a very common format. Recent report suggested possible benefit from beginning HD therapy less than three times weekly and incremental increase of dialysis dose, but there are not sufficient data. We compared outcomes of thrice-weekly and incremental HD.

Methods: A cohort of 1273 patients who were diagnosed as having ESRD and initiated hemodialysis from 2008 to 2014 were prospectively enrolled. The patients were classified into the abrupt initiation group (3 sessions/week) or the incremental initiation group (1-2 sessions/week). We compared HRQOL evaluated by KDQOL-SF and Beck’s depression inventory (BDI) score at 3 months and 12 months after HD, and residual renal function by daily urine volume at 12 months after HD and all-cause mortality between the groups.

Results: Before propensity score matching, the abrupt group tends to be younger and showed smaller daily urine volume, higher modified Charlson comorbidity index (mCCI), and higher serum blood urea nitrogen and creatinine level compared to incremental group. A total of 432 patients (288 for abrupt and 144 for incremental group) were selected by propensity score matching. HRQOL tends to be better in incremental group for every domain of KDQOL-SF and BDI, but none of them showed significant difference at 3 months. At 12 months after HD, only cognitive functioning domain was better in incremental group. Daily urine volume at 12 months after HD was similar in two groups. All-cause mortality was comparable between two groups before and after propensity score matching.

Conclusions: Incremental initiation of HD showed comparable results with abrupt group regarding HRQOL, residual renal function and all-cause mortality. Incremental HD might be considered as another format of initiating HD for selected ESRD patients.

TH-PO801
Predictors of Substantial Residual Kidney Function in the First Year of Hemodialysis Treatment
Yoshisuke Obu,1 Elani Streja,2 Connie Rhee,1 Anna Mathew,2 Joline L.T. Chen,3 Wei Ling Lau,4 Steven M. Brunelli,5 Csaba P. Kovesdy,6 Rajnish Mehrotra,7 Kamyar Kalantar-Zadeh,8 1UC Irvine; 2Hofstra North Shore-LI Health System; 3DaVita Clin Research; 4UTHSC; 5UW.

Background: Residual kidney function (RFK) plays a critical role in dialysis adequacy, quality of life, and survival in hemodialysis (HD) patients. Therefore, identifying predictors related to preservation of RFK may contribute to improving patient management and developing novel strategy for preserving RFK.

Methods: In a longitudinal cohort of 18,091 patients who initiated conventional HD over four years (1/2007-12/2010), we examined the association of baseline characteristics during the first 3 months of their dialysis treatment with RKF [renal urea clearance (KRU) or ≥600 mL/day of UV as outcomes with 2-level adjustments for case-mix variables and laboratory measurements in addition to baseline RFK values.

Results: Patients were 62-14 years old, 37% female, 29% non-Hispanic Black, and 67% diabetic. Median KRU and UV were 2.95 (IQR, 1.63-4.64) mL/min/1.73m2 and 800 (IQR, 500-1,300) mL/day, respectively. High γδ lymphocyte, higher serum concentrations of albumin and calcium, and lower serum concentrations of creatinine and phosphorus were consistently associated with better preserved RFK indices irrespective of models. A history of congestive heart failure was an independent predictor for loss of RFK.

Conclusions: Better nutritional and CKD-MBD indices were associated with preserved RFK while a history of congestive heart failure were associated with loss of RFK at 1 year of hemodialysis initiation in this large national cohort. Additional studies to preserve RFK in dialysis patients are needed.

TH-PO802
Clinical Determinants of Ultrafiltration Rates in Hemodialysis
Adam K. Horeish, Jeffrey M. Rimmer. Univ of VT Med Ctr, Bulington, VT.

Background: High rates of ultrafiltration (UFR) are associated with adverse events. Approaches to reduce UFR other than fluid restriction alone are needed.

Methods: We examined characteristics associated with ultrafiltration rates (UFR) in patients dialyzed at UVMMC. Ultrafiltration rates (volume removed/pre-dialysis weight/treatment time) were followed electronically. Charts of 213 patients treated in October 2015 were examined with IRB approval. Patient characteristics and laboratory values were determined for 177 patients receiving three treatments during each of 4 consecutive weeks. These include average weight (PWI), treatment duration (RT), and inter-dialytic weight gain (WtG); age, gender, dialysis vintage, sequence (TTTS vs MW), treating unit, diabetes, heart failure, prescribed diuretics, difference between serum and dialysate sodium (DifNa), percent urea reduction (PRU), absolute urea reduction, serum potassium, albumin, hemoglobin and pre and post dialysis blood pressure. The relation of weight, weight gain and treatment length were examined with descriptive statistics. Other potential explanatory variables were explored with multivariable regression models using both average UFR and average UFR for first weekly treatment as dependent variables.

Results: The range and median for PWT, RXT, and WtG respectively are 41.6 to 226, 81 Kg, 3 to 5.5, 4 hrs; and 0.63 to 8.38, 2.69 kg. When the values of PW, RXT and WtG are below the median, 48.4%, 44.8% and 19.1% of patients respectively have a UFR > 10 mL/kg/hr and 15.6%, 23.9% and 48.9% if above the median. Variables significantly associated with UFR by regression are enumerated in table 1.

Variables not listed did not reach significance.

Conclusions: The large effect of low PWt requires long RXT to avoid high UFR with moderate WtG. Other prescribed variables that could be used to modify UFR include TTTS vs MFV schedule, DifNa and possibly diuretic use.

Study on Hemodialysis (HD) Time and Prognosis in Maintenance HD Patients: The Q-Cohort Study
Kazuhiko Tsuruya,1 Shigeru Tanaka,2 Masatomo Taniguchi,3 Kazuhiro Tsunya,4 Hideki N. Hirakata,5 Takanari Kitazono. 1Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; 2Div of Nephrology, Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan.

Background: HD time has been recognized as an important factor of dialysis adequacy. However, there have been few reports on studying the associations between HD time and prognosis in maintenance HD patients. We present some findings from a prospective cohort study, the Q-cohort Study, which was set up to explore the risk factors for mortality in Japanese HD patients. In this present study, we examined the associations between HD time and mortality in Japanese HD patients.

Methods: A prospective multicenter cohort study (Q-Cohort Study) was conducted between December 2006 and December 2010. A total of 3,459 Japanese HD patients were prospectively followed for 4 years. We examined the association of HD time and prognosis using a Cox proportional hazards model. Propensity scores were calculated using logistic regression.

Results: During follow-up period, 566 patients died from any causes. Patients with HD of 5 hours or more (n = 2,144) showed significantly lower mortality risk for all cause death at hazard ratio = 0.82 (95% confidence interval: 0.68 to 0.99) compared with those with HD of less than 5 hours (n = 1,315) after adjusting for confounding risk factors. This association remained significant using a propensity score-based approach. We stratified the study, the Q-cohort Study, which was set up to explore the risk factors for mortality in Japanese HD patients.

Methods: In a longitudinal cohort of 18,091 patients who initiated conventional HD over four years (1/2007-12/2010), we examined the association of baseline characteristics during the first 3 months of their dialysis treatment with RKF [renal urea clearance (KRU) or ≥600 mL/day of UV as outcomes with 2-level adjustments for case-mix variables and laboratory measurements in addition to baseline RFK values.

Results: Patients were 62-14 years old, 37% female, 29% non-Hispanic Black, and 67% diabetic. Median KRU and UV were 2.95 (IQR, 1.63-4.64) mL/min/1.73m2 and 800 (IQR, 500-1,300) mL/day, respectively. Salt Taste Sensitivity, Sodium Intake, and Fluid Status in Hemodialysis

1 Univ of MI; 2 Renal Research Inst.

Background: Dietary Sodium intake (SI) contributes to volume status and blood pressure (BP) control in hemodialysis (HD) patients. Salt taste sensitivity (STS) may drive sodium intake, and has not been systematically studied in HD. We sought to assess the relationship between STS, SI, fluid status (as determined by bioelectrical impedance spectroscopy (BIS)) and pre-dialysis BP in HD patients.

Methods: As part of an ongoing randomized trial involving a low sodium diet, adults receiving outpatient HD were assessed for STS using commercial taste strips impregnated with 0.1-6% sodium chloride (NaCl); mean SI was estimated from 3-day food diaries. Total Body Water (TBW) and Extracellular Volume (ECV) were estimated using whole-body and segmental (calf-resistance) BIS, respectively.

Results: Baseline data on 33 enrolled patients (16 male, 17 black, 13 white, mean age 52±15yr) were analyzed. Mean monthly pre-HD systolic BP was 151±16 mmHg. Mean SI was 2.5±g/day (range: 1.1-5.2). Mean estimated SI was 0.8±g/day higher in patients without STS compared to those with STS (1.6±% NaCl (p=0.06). Higher SI correlated with higher calf ECV (r=0.38, p=0.04), whole-body-BIS TBW (r=0.65, p=0.0005) and ECV (r=0.34, p=0.09). Mean Calf ECV was significantly lower in those with STS vs those without STS at 1.6% (0.19 ± 0.23 L; p=0.04). There was no correlation between SI and pre-dialysis BP (in-center routine or standardized).

Conclusion: Salt taste sensitivity and measures of hydration status by bioelectrical impedance spectroscopy are correlated with sodium intake in hemodialysis. The findings suggest that patients with low salt taste sensitivity may be particularly at risk for fluid excess. Future research should examine mechanisms of Salt taste sensitivity and its role in management of hemodialysis patients.

Arrhythmic Risk in Patients with Type II Diabetes on Hemodialysis: Preliminary Results from the Monitoring in Dialysis (MiD) Clinical Study

Prabir Chaudhury, Don E. Williamson, James A. Tumlin, David M. Charytan, Kowdile chandrasekar Prakash, Vijay K. Khre; 1 Univ of Cincinnati; 2 Nephrology Associates; 3 Univ of Tennessee; 4 Brigham and Womens Hospital, Boston; 5 Apollo Hospitals-Chennai; 6 Medanta-Medicity.

Background: 40% of the overall ESRD population has diabetes and these patients are considered to be at increased risk of cardiac events. The goal of this analysis was to describe the pattern of both clinically significant events and documented arrhythmias in a subset of patients with Type II diabetes from the Monitoring in Dialysis (MiD) study.

Methods: The MiD study is a prospective, multi-center, observational study designed to characterize the type and frequency of documented and adjudicated arrhythmias in hemodialysis patients during a 6-month period, using an implanted continuous cardiac monitoring device (Medtronic Remote XT or Revel LINQ). All documented arrhythmias and clinically significant co-morbidities (CSA) defined as bradycardia ≥40 bpm for ≥2 sec, asystole ≥3 sec, sustained ventricular tachycardia ≥130 bpm for ≥30 sec and symptomatic arrhythmias during this period were then correlated temporally to the dialysis cycle (first, second or third dialysis session of the week; during or after hemodialysis; how long after hemodialysis).

Results: Type II Diabetes was present in 39/66 (59%) of the MiD patients. The mean age was 62 (36-76) years, 72% male, mean years on HD 2.8 (1-15), 36% with a history of cardiac arrhythmias with a mean follow-up of 8.6 months (range 0.6-13.9). Arrhythmic risk in the Type II diabetic patients was similar to the previously reported data on the entire study population, with the highest incidence of documented arrhythmias occurring in the 12 hour period starting with each dialysis session (particularly in the 8 hours after the end of the session). The incidence then decreased, followed by a gradual rise during the rest of the interdialytic period. Interestingly, the incidence of CSA in the 12 hour period starting with each dialysis session of the week was much greater than in the overall study population.

Conclusions: The increase in the incidence of CSA in diabetic ESRD patients suggests that these patients could be a target population for the use of the Reveal implant.

TH-PO806

Individualising Fluid Restriction Based on Target Weight Can Prevent a High Ultrafiltration Rate

Emily Sec, John W. MacD. Agar. Nephrology, Univ Hospital, Geelong, VIC, Australia.

Background: Fluid restriction (FR) in haemodialysis patients has traditionally been advised by residual urine output and an arbitrarily defined oral intake, commonly 750ml/day. Surprisingly, little attention has been paid to individualising FR according to target post-dialysis weight (TW), despite the logical argument that smaller patients require less fluid. Excessive inter-dialytic weight gain (IDWG), when calculated as a percentage of TW (IDWG%), results in a high ultrafiltration rate (UFR) if session length (t) is constant ([UFR(ml/kg/hr) = IDWG(ml) + TW(kg) ÷ (thr)]). Since a high UFR has been linked to a poor clinical outcome, these patients must be identified and targeted. We aim to determine if a high IDWG% can be predicted from TW and then be used to individualise FR.

Methods: Data were prospectively collected from 14,112 sessions in 139 patients undergoing in-centre thrice-weekly haemodialysis between Jan-Dec 2014. Mean age was 68.9yr, 56% were male. Mean TW and IDWG% were calculated every 6 weeks. Results were divided into IDWG% cohorts, within each of which an average TW was calculated.

Results: Mean IDWG% was 2.30% (range 0.1-6.4). IDWG% was inversely proportional to TW (r=−0.78).

From this data, we devised a formula that calculates an individualised FR based on the desired UFR (dUFR), the session duration (t), TW, and interval days between sessions (n). As [IDWG% = FR x n] and [IDWG% = dUFR x t x TW]; therefore [FR(ml) = dUFR x t x TW ÷ n x residual urine output]

Conclusions: Patients with low TW are most at risk of high IDWG% and, consequently, a high UFR. A high UFR leads to rapid intravascular volume contraction which triggers post-dialytic thirst and reinforces the inevitable cycle of further high IDWG%. As TW provides a readily accessible clinical end-point that predicts at-risk patients, we propose that FR be individualised according to TW to enable patients to remain below the desired UFR.

TH-PO807

Ultrafiltration Rate Should Be Independently Targeted as a Marker of Haemodialysis Adequacy

Emily Sec, John W. MacD. Agar. Dept of Nephrology, Univ Hospital, Geelong, VIC, Australia.

Background: For 30 years, solute clearance has been the key determinant of dialysis adequacy. This emphasis has marginalised the critical contribution of safe rates of fluid removal to “adequate” dialysis. Ultrafiltration rate (UFR) has been proposed as an easily measurable marker of volume management (Agar 2015 HDI) and several studies have demonstrated a correlation between high UFR and poor clinical outcomes. Despite this association, UFR is not routinely targeted and the proportion of patients who meet percentage reduction in urea (PRU) but not UFR targets is unclear. While a “safe” UFR may be yet to be conclusively defined, current literature supports an escalating clinical risk beyond a UFR of 10ml/hr/kg and an absolute risk above 1.5ml/hr/kg.

Results: Data were prospectively collected from patients undergoing in-centre thrice-weekly conventional haemodialysis over a 12-month study period (Jan-Dec 2014). PRU and mean UFR were calculated every 6 weeks. UFR <10ml/hr/kg was defined as “volume-adequate” and PRU >65% was considered “solute-adequate”.

Results: 720 episodes were collected from 115 patients. The mean age was 68.9yr and 56% were male. 73% of episodes met both adequacy targets (PRU+UFR+), 10% met the UFR but not the PRU target (PRU-UFR+), 16% met the PRU but not the UFR target (PRU+UFR-). 1% met neither (PRU-UFR-). In patients who met the PRU target 18% did not meet the UFR target.
Conclusions: Adequacy of solute removal does not equate to adequacy of volume removal. When a solute marker is used as the sole determinant of dialysis adequacy, a significant number of patients undergo “volume-inequivalent” dialysis. These patients were more likely to be female and have a lower post-dialysis weight. Given the potentially substantial clinical implications, we propose that UFR be independently targeted allowing composite solute and volume markers to together define truly “adequate” dialysis.

Fluid Management with Technology-Assisted Probing Peter B. De Oreo,1 Mary kay Deck,2 Anne M. Brunfield.3 1Medical Affairs, Centers for Dialysis Care 1, Shaker Heights, OH; 2Systems, Intelomed 2, Wexford, PA; 3Clinical Services, Intelomed 1, Wexford, PA.

Background: Intradialytic hypotension (IDH) is associated with mortality. Rapid fluid removal is associated with cardiovascular (CV) morbidity and mortality. Decreased pulse pressure during HD is associated with improved outcomes. A focused intervention approach assisted by monitoring technology was used to assess fluid management as defined by 1) achievement of post weight within 1 kg around dry weight, 2) avoidance of IDH (SBP<90), 3) decrease in pulse pressure (PP) from pre-post dialysis.

Methods: 24 patients (16 controls, 8 intervention) were included. Control data: 18 treatments (txs) prior to protocol along with 18 txs during active monitoring and guided probing. The protocol required setting goal to <2 KG < dry weight OR < .2 KG last post weight with small goal changes early in treatment, set of defined actions based on CV physiologic monitoring via CV Insight™ (CVI) [Intelomed, Wexford, PA] and relative plasma volume (RPV) via Crit-Line III® [Fresenius, Kayville, UT]. Interventions were employed based on monitoring data, with a goal to increase UF tolerance without increasing IDH events.

Results: Intervention patients demonstrated significant improvement in all three fluid management parameters during the protocol compared to preceding txs.

Conclusions: Although reducing DNa to < 140 mEq/L may have only a modest impact on IDW and predialysis SBP it has the potential to significantly decrease mortality.

TH-PO810
Comparison of Ordered versus Measured Dialysate Sodium Concentrations Ambreen Gul,1 Dana Miskulin,2 Leonard A. Armit,1 Siriram Narsipur,3 Susan Paine,1 Ronald Schrader,1 Philip Zager.1,2 1DCI, Albuquerque, NM; 2UNM, Albuquerque, NM 3Tufts, Boston, MA; 4SUNY, Stony Brook, NY; 5SUNY, Syracuse, NY.

Background: There is controversy regarding the optimal dialysate sodium concentration (DNa). Many investigators have urged the use of DNa of 134 to 138 mEq/L, while others have cautioned that low DNa may be associated with increased hospitalization and mortality. Unfortunately, throughout this debate, little attention has been paid to how closely delivered DNa matches ordered DNa.

Methods: We studied 333 hemodialysis (HD) patients at 4 DCI facilities. We sampled dialysate from the arterial dialyzer port prior to the start of HD for measurement of DNa. Units 1 and 2 used Fresenius 2008 K machines and Fresenius Granuflo® Dry Acid and Naturalyte®, mixed onsite from dry concentrates. Units 3 and 4 used Gambro Phoenix machines and pre-mixed acid concentrates obtained from Rockwell and bicarbonate cartridges from Baxter or Gambro. The online clearance feature was off.

Results: Measured DNa was usually higher than ordered DNa. The magnitude of difference varied by clinic (p <0.0001).

Conclusions: Intradialytic hypotension (IDH) is associated with mortality. Rapid fluid removal is associated with cardiovascular (CV) morbidity and mortality. Decreased pulse pressure during HD is associated with improved outcomes. A focused intervention approach assisted by monitoring technology was used to assess fluid management as defined by 1) achievement of post weight within 1 kg around dry weight, 2) avoidance of IDH (SBP<90), 3) decrease in pulse pressure (PP) from pre-post dialysis.

Results: Intervention patients also demonstrated significant improvement in IDH compared to Control patients that dialyzed without guided probing.

Conclusions: A focused effort to improve fluid management through technology guided probing supported by CVI measures of cardiovascular stress and RPV, was successfully executed by chair-side staff. Optimizing fluid removal goals while simultaneously avoiding IDH events illustrates the benefit of patient monitoring.

TH-PO809
Increased Mortality Associated with Higher Dialysate Sodium Concentrations Is Not Due Solely to Higher Interdialytic Weight Gains and Blood Pressure Ambreen Gul,1 Ronald Schrader,1 Susan Paine,1 Philip Zager.1,2 1DCI, Albuquerque, NM 2UNM, Albuquerque, NM.

Background: There is ongoing controversy regarding the optimal DNa. Many investigators have urged the use of DNa of 134 to 138 mEq/L, to limit interdialytic weight gain (IDWG) and improve control of hypertension. In contrast, others have cautioned that low DNa may be associated with increased hospitalization and mortality.

Methods: We conducted a retrospective observational study of 26,000 chronic hemodialysis (HD) patients treated in facilities operated by Dialysis Clinic Inc. from 2009-2013 to assess the relationships of DNa to IDWG and predialysis systolic BP (SBP) and their effect on mortality. We fit a time-varying Cox proportional hazards regression model for mortality, which included all incident and prevalent patients. There were over 630,000 patient-months of follow-up. Multiple data values for each patient were aggregated by month. Predictor variables in addition to DNa included demographics, monthly lab values, and session-level data including IDWG and pred- and post-dialysis BP. Individual clinic effects were fit as random effects. Time-varying predictors were lagged by 2 months.

Results: Higher DNa concentrations were associated with modest increases in IDWG and predialysis SBP [figure]. Moreover, neither predialysis SBP ≥ 150 mm Hg or IDWG < 4.2% of estimated dry weight were associated with increased mortality.

Least squares mean differences (95% CI) were larger at Clinics 1 [-3.27 (-4.02, -2.53) mEq/L] and 2 [-3.77 (-4.49, -3.05) mEq/L] vs. with Clinics 3 [-1.44 (-2.16, -0.78) mEq/L] and 4 [-1.78 (-2.47, -1.10) mEq/L]. The percentages of measured DNA concentrations within ±2 mEq/L of the ordered DNAs at Clinics 1, 2, 3 and 4 were 47, 25, 71 and 77%, respectively.

**Conclusions:** Measured DNA concentrations were often significantly higher than ordered DNA in facilities using Fresenius machines and dialysate concentrates mixed onsite. Routine measurement of DNA should be incorporated into facilities’ QAPI programs. Future studies looking at clinical outcomes associated with differences in prescribed DNA should include measurements of delivered DNA concentrations.

**Successful Use of Bivalirudin Protocol to Prevent Extracorporeal Thrombosis in Hemodialysis Patients with Heparin Induced Thrombocytopenia**

Abdullah Hamad, Fadwa S. Al-Ali, Hoda Tollia, Rania Abdelzahim Ibrahim, Mohamed Elsayed. *Nephrology, Fahad Bin Jassim Kidney Center, Hamad General Hospital, Doha, Qatar.*

**Background:** Heparin Induced Thrombocytopenia (HIT) has been reported in hemodialysis (HD) patients with a variable prevalence of 1-13%. There have been few reports using Lepirudin, Argatroban and Danaparoid in the management of extracorporeal thrombosis (ECT) during dialysis in these patients as heparin is contraindicated. We are reporting use of Bivalirudin to prevent ECT.

**Methods:** Our Study was done in Fahad Bin Jassim Kidney Center in Doha, Qatar (a large outpatient HD clinic of 300 patients). All patients diagnosed with HIT were included.

HIT was diagnosed by ELISA method.

**Results:** 8 patients had confirmed positive HIT AB, 2 were receiving warfarin for atrial fibrillation with no ECT events and were excluded. One patient had a negative repeat test for HIT AB with no ECT events so he was excluded too. 5 patients with HIT AB and recurrent ECT events during dialysis were included. 3 patients had fistula and 2 had permanent catheter. A protocol was developed to start and adjust Bivalirudin based on activated partial thromboplastin time (APTT) value. Table 1 summarizes patients dosing and adjustment on protocol.

**Bivalirudin Infusion Protocol for HIT in Hemodialysis Patients**

1. Initial Infusion Rate 0.625mg/kg/hr
2. Baseline aPTT should be checked and then 2 hours after infusion initiated
3. aPTT should be checked 2 hours after infusion every session until a PTT in therapeutic range with no further change then every once per week
4. APTT for bleeding versus thrombosis must be evaluated to determine safe and effective dose in high risk of bleeding
5. aPTT adjust at 1.5–2.5 X normal range
6. aPTT adjust to 2.0–2.5 X normal range

**Bivalirudin Infusion Protocol for HIT in Hemodialysis Patients**

**The Correlation of BNP and hANP in Hemodialysis Patients and Their Prediction Ability of Life Prognosis**

Koji Takemura, Fumitaka Fujino, Yoshihiro Miyauchi, Takashi Watanabe. *Nephrology, Asahi General Hospital, Asahi, Chiba, Japan.*

**Background:** B-type natriuretic peptide (BNP) and human atrial natriuretic peptide (hANP) have been reported to be useful for assessment of the volume status, cardiovascular risk, or life prognosis in hemodialysis patients. However, correlation or superiority of the two parameters are not clear. The aims of this study were to assess whether BNP and hANP have correlation, and whether they are predictive.

**Methods:** Two hundred and twenty-eight hemodialysis patients at one hospital were assessed in March 2012. BNP and hANP were measured at the end of hemodialysis. And we observed the patients’ survival until May 2015.

**Results:** This study analyzed 228 patients. Results showed that BNP and hANP had strong correlation in patients without chronic heart failure (EF>40%): R²=0.70 to those with atrial fibrillation (AI), R²=0.57 without AF. 69 deaths occurred in about 3 years; in univariate analysis, BNP and hANP were significant predicting factors (p=0.004 and p=0.013 for each) and in multivariate analysis, age and hANP were significant predicting factors in multivariate analysis (p=0.019 and 0.011).

**Conclusions:** BNP and hANP had strong correlation in hemodialysis patients without chronic heart failure. They also predicted life prognosis, and especially hANP had independent prediction ability. In hemodialysis patients, BNP and hANP are useful for assessment of life prognosis in spite of various known or unknown confounding factors.

**Intracranial Fluid Shifts During Hemodialysis Measured Using VIPS (Volumetric Integral Phase-Shift Spectroscopy) Is Influenced by Osmolarity, Sodium and Less So by Urea Nitrogen**

Chetham P. Venkatasubba rao,1 Sreedhar A. Mandayam,2 Eric Bershad,3 Euseba Calvillo,1 Jose Ignacio Suarez.1

1Neurology, Baylor College of Medicine, Houston, TX; 2Nephrology, Baylor College of Medicine, Houston, TX.

**Background:** End Stage Renal Disease (ESRD) patients undergoing hemodialysis(HD) experience a drop in serum osmolarity. This may result in cerebral edema. Cerebral edema has been measured by invasive monitors or imaging studies. We used Volumetric Integral Phase-Shift Spectroscopy(VIPS), a non-invasive technology that detects fluid-induced phase shifts in low-energy radio waves transmitted through the brain.

**Methods:** The protocol was approved by the IRB of Baylor College of Medicine. ESRD on HD subjects without Intracranial disorders were enrolled. VIPS monitoring was performed pre, intra and post HD. Measured and calculated serum osmolarity(osm) and mini state examination was performed pre and post HD.

**Results:** 19 patients (12 males) were enrolled. Median age was 50 years. 1 patient withdrew. Of the 31 HD runs, 21 complete data sets were analyzed. There was a mean increase of 10.6% in the total Intracranial fluid(ICF) value from baseline corresponding to an average of 7 mOsm reduction. The ICF change measured by VIPS correlated with osm changes (r=0.31), best with change in Sodium change [Post HD – pre HD] (r=0.51), less so with the BUN change (r=0.14) and least with glucose (r=0.01). Subjects with sodium < 135 at baseline had a tendency to develop lower ICF change (3% (n=5) as compared to euonaticern subjects (12%, n=16, p=0.22).

**Conclusions:** VIPS provides real-time non-invasive monitoring of intracranial fluid shifts. Subjects develop serum osmolar data sets were analyzed, which potentially be a model for studying cerebral edema. Sodium shifts had a higher correlation to ICF change in our study. Further research to confirm our findings are warranted.

Online Hemodiafiltration Using Citrata® Dialysis Solution – An Alternative to Systemic Anticoagulation? Pavlina Richtrova, Lukas Kielberger, Jan Mares, Tomas Reischig. 1st Medical Dept, Charles Univ Medical School and Teaching Hospital, Plzen, Czech Republic.

Background: Citrata® is a dialysis solution using citrate (contrary to more common acetate) as the acidifying buffer compound. According to recently published data, its application could decrease or even obviate the need for systemic anticoagulation in hemodialysis (HD) patients. Particularly so during online hemodiafiltration (HDF) as in this setting predialysis should provide yet higher in-dialyzer citrate concentrations resembling regional citrate anticoagulation (RCA).

Methods: In a prospective, randomized, cross-over study, 10 long-term HD patients were enrolled during 4h HDF procedure using Citrata® (0.8 mmol/l citrate) in a predialysis setting without additional systemic anticoagulation. Standard HDF procedure using acetate-buffered solution together with fractionated heparin was applied as a control. Along the session, blood and dialysate were sampled to enable analysis of thrombogenicity, acid base balance, calcium metabolism, and dialysis efficacy. Data are given as means±SD; statistical significance was calculated by ANOVA.

Results: No HDF session was terminated prematurely though the semiquantitative dialyzer clotting score showed increased clotting under citrate solution (p=0.001). At the same time, procedure efficacy assessed by spKt/V, as well as serum calcium, bicarbonate and pH did not differ significantly. While in controls the thrombin-antithrombin (TAT) levels remained unchanged, during citrate-buffered HDF a steady increase of TAT was observed: from 3.6±2.36 and 5.6±3.85 μg/l at 0h to 7.8±6.57 and 25.3±5.45 μg/l at 6h post HD and 15h post HD, respectively (p<0.001).

Conclusions: From a clinical standpoint, HDF using Citrata® excluding heparin may serve as a viable alternative to RCA where systemic anticoagulation is to be avoided. No issues were detected in terms of safety, tolerance, and dialyzer performance. Even then, increased laboratory markers of thrombogenicity suggest inferiority of such approach precluding its use for regular HD.

TH-PO816

Hypertension in Hemodialysis Patients: Dialysis Techniques and Hormonal Regulation Guido Gatti, Chiara Lananzi, Marco Simonini, Simona Pozzoli, Stefano Tentori, Elena Brioni, Lorena Citterio, Elisabetta Messaggio, Simona Delli carpi, Nunzia Nascaismima, Teresa Aricadinio, Maria Teresa Sciarrone Alibrandi, Rita Quatragno, Marco Melandri, Giorgio Slaviero, Donatella Spotti, Paolo Munanta. Nephrology, Dialysis and Hypertension, IRCSS San Raffaele Scientific Inst, Milano, Italy.

Background: Hypertension in hemodialysis patients has a prevalence of 50-80% and is associated to increased cardiovascular mortality. Endogenous ouabain (EO), a digitalis-like cardiotonic steroid produced by adrenal glands, in hemodialysis patients is associated to left ventricular mass, volume and eccentric hypertrophy remodeling. N-terminal pro B-type natriuretic peptide (NT-proBNP) is associated with heart failure and fluid overload. Hemodiafiltration (HDF) improves cardiovascular survival than bicarbonate hemodialysis (HD). The aim is to explore the relationship between BP values, hormonal regulation (EO and NT-proBNP) and hemodialysis techniques.

Methods: We enrolled 93 chronic hemodialysis patients; we performed ABPM of 24 hours, blood and effluent dialysis fluid analysis. 42 patients were treated with HDF, 51 with HD.

Results: NT-proBNP is directly associated with SBP of 24h and indirectly with EF of left ventricle; it is removed by HD by convective clearance (decrease of 57%), as medium molecular weight compounds, and not by HDF (increase of 21%). EO is directly associated with interdialytic weight gain and interdialytic sepium; it decreases with dialysis session independently of dialysis technique (decrease of 20%). Patients with cardiopathy have higher EO plasma levels than patients without cardiopathy. Beta-2 microglobulin is directly associated with NT-proBNP and SBP of 24h.

Conclusions: These data show that NT-proBNP is an index of hypertension and heart failure, while EO is linked to fluid overload and left ventricular hypertrophy. NT-proBNP is removed by convection, while EO decreases independently of dialysis technique (ultrafiltration determine the decrease?). Convective clearance, expressed indirectly by beta-2 microglobulin, may influence BP control through the modulation of NT-proBNP.

TH-PO817

NT-proBNP Is a Useful Biomarker to Identify Cardiac Dysfunction in Japanese Hemodialysis Patients Minako Shimizu,1 Ayumu Nakashima,2 Shigehiro Doi,2 Takao Masaki. 1Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan; 2Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.

Background: Serum N-terminal pro-brain natriuretic peptide (NT-proBNP) is a well-established diagnostic biomarker of heart failure in populations without kidney dysfunction. However, the clinical significance of NT-proBNP in hemodialysis (HD) patients remains unclear.

Methods: We enrolled 1428 HD patients from 14 dialysis centers in Hiroshima, Japan and performed cross-sectional analysis. Blood samples for measurement of serum NT-proBNP were collected at pre- and post-HD sessions. Among all participants, ultrasonic evaluations of carotid intima-media thickness (CIG) was performed in 395 patients (27.7%). We evaluated whether serum NT-proBNP levels were associated with left ventricular hypertrophy (LVH) on the electrocardiogram (ECG), and LVH and ejection fraction (EF) on UCG. We also used multiple regression analysis to investigate the clinical factors that correlated with the reduction ratio of NT-proBNP.

Results: The mean pre- and post-HD NT-proBNP levels were 8789 ± 15311 and 5257 ± 8939 pg/ml, respectively. Multivariate regression analysis revealed that the post-HD NT-proBNP was significantly correlated with LVH on ECG as well as EF and LVH on UCG (p < 0.001). When both the mean of post-HD NT-proBNP were analyzed, patients with the same odds ratios (ORs) for LVH on ECG, and LVH and EF on UCG were lower at pre- than post-HD (ORs: 1.36, 2.16, 3.47 versus 1.19, 2.37, respectively). However, the sensitivity and specificity of pre- and post-HD NT-proBNP to predict LVH and EF were similar. In multiple linear regression analysis, the reduction ratio (%) of NT-proBNP due to HD was correlated with Kt/V (p < 0.001), membrane area (p < 0.001), membrane type (p < 0.001), % body weight gain (p < 0.001), treatment time (p < 0.001) and ultrafiltration rate (p = 0.003).

Conclusions: NT-proBNP is a useful biomarker to identify LVH and LV dysfunction in HD patients. Blood samples should be taken post-HD despite the NT-proBNP reduction due to HD.

Similar Complement Activation by Heparin-Coated Dialyzer Compared with Heparin-Free Dialysis Using Predilution Susan J. Logtenberg,1,2 Casper F.M. Franssen,1 Marc Maj Seelen.1 1Nephrology, Univ Medical Center, Groningen, Netherlands; 2Internal Medicine, Diakonessenhuizen, Utrecht, Netherlands.

Background: Heparin-coated dialyzers have been shown to be an effective method for heparin-free hemodialysis and are increasingly used. Conflicting reports on complement activation by heparin have been published, however. Complement activation could therefore be potential harmful for patients that are scheduled for transplantation shortly after hemodialysis (HD). We investigated the difference in complement activation between heparin-coated dialyzers and heparin-free HD using conventional filters with predilution.

Methods: We measured C3 and C3d levels in 16 (5 F) consecutive patients that were treated with either a heparin coated filter (n=8 (Evodial®)) or a conventional filter (n=8 cellulose triclate, n=3 polyamide) with predilution 1-2h. C3 and C3d were measured before and at the end of a single HD treatment session. C3 to C3d ratios were calculated.

Results: Mean age was 58±16 years. The figure shows C3d/C3 ratios before and after HD for individual cases in the different filter groups. Mean C3/C3d ratios increased during HD with all types of dialyzers. Mean C3/C3d ratio in the heparin-coated dialyzer group increased from 9.7±7.6 before HD to 12.4±7.8 after HD (p<0.001). Mean C3/C3d ratio in the conventional filter group increased from 8.0±2.3 to 11.8±5.4 (p=0.03). C3d/C3 ratio increased during HD with both the polyamide (from 7.5±1.8 to 10.0±1.2; p<0.09) and the cellulose triclate dialyzer (from 8.3±2.4 to 12.9±6.9; p=0.02). There was no significant difference in the change of C3d/C3 ratio between the heparin coated filter group and the conventional filter group (2.7±1.4 v. 3.7±3.7, respectively (p=0.5).

Conclusions: Heparin-coated dialyzers induce similar complement activation during HD when compared to conventional dialyzers.

TH-PO819

A Heparin-Grafted Membrane plus Citrate Containing Dialysate versus Regional Citrate Anticoagulation: Results of the CITED Study Christoph Metalidis, Ruben Poesen, Annelore De winter, Dirk R. Kyupers, Pieter Evenepoel, Bjorn Meijers. Nephrology, Univ Hospitals Leuven, Belgium.

Background: Heparin is the mainstay anticoagulant during dialysis. Alternative anticoagulant strategies include regional citrate anticoagulation (RCA), heparin-grafted cardyzers or saline flushes. In the last case, RCA is the most efficacious, although technical complexity and labor intensiveness preclude widespread use. Heparin-grafted membranes are easy to use, but dialyzer patency is inferior to RCA. Whether combination of citrate-containing dialysate plus heparin-grafted membranes is non-inferior to RCA is unknown.

Methods: The CITrana plus EV odial in Dialysis (CiTED) study was an open, randomised crossover study comparing citrate-containing dialysate plus heparin-grafted membranes versus RCA. In the study arm, we scheduled 750 dialysis sessions using combination of a heparin-grafted AN69ST dialyzer (Evodial 180®, BAXTER) and 1 mmol/L citrate-containing dialysate (Selectroc Citrate®, BAXTER). In the control arm, the sessions of RCA were scheduled using Polysulfone 130 (BAXTER) dialyzers and calcium-containing dialysate. In all sessions, scheduled treatment duration was 4 hours.
No systemic heparin was used. Primary endpoint was non-inferiority for clotting events of the combination of a heparin-grafted membrane plus citrate-containing dialysate vs. RCA, with a prespecified non-inferiority margin of 10%.

Results: We included 25 patients, receiving 1285 study dialysis sessions in total, 636 in the study arm and 649 in the control arm. Both anticoagulation strategies were safe. Overall, clotting rates were low: 37/636 (5.82%) in the study arm and 42/649 (6.47%) in the control arm. The primary endpoint of non-inferiority was met (P < 0.0001). In secondary analysis, using Cox proportional hazard analysis, time to clotting did not differ between study arms (P 0.62).

Conclusions: Combination of a heparin-grafted dialyzer with citrate-containing dialysate is non-inferior to conventional RCA. The procedure is easy to perform without additional pumps or calcium measurements. Combination of a heparin-grafted dialyzer and citrate-containing dialysate is a valid alternative to RCA in patients requiring heparin-free dialysis.

TH-P0820
Effect of L-Carnitine on Markers of Mineral Bone Disease in the CARNIDAL trial. Lucile Meyread,1 Michel Chonchol,2 Messaad Ouzirila,3 Christine Fumerton,1 Aude Servais,3 Sophie Tezenas du montcel.2

Background: Previous studies suggested that L-carnitine in hemodialysis patients decreases intact parathyroid hormone levels (iPTH). We studied the effects of L-carnitine on markers of mineral bone disease (MBD), including fibroblast growth factor (FGF23) in a randomized, double-blind trial.

Methods: We evaluated the effects of 1 g of intravenous L-carnitine after each dialysis session for 1 year when compared to placebo in a randomized, double-blind trial. C-terminal FGF23 (cFGF23) were measured at baseline, every 3 months and end of study in 23 patients. Serum calcium, phosphate and iPTH were available at similar time points. The effect of L-carnitine on serum calcium, phosphate, iPTH and plasma cFGF23 was studied by mixed linear models for repeated measurements in intent-to-treat. We also examined the relation of cFGF23 with intravenous (IV) iron and EPO dose.

Results: Serum calcium increased more in the L-carnitine than in the placebo group (calcium: β of L-carnitine x time 0.005 ± 0.002 mmol/L/month, p=0.03; phosphate: β of L-carnitine x time 0.02 ± 0.006 mmol/L/month, p=0.001). In both groups, serum iPTH was stable over time and plasma cFGF23 increased (β log FGF23 0.05 ± 0.01 Hu/mL/month, p=0.0001). In multivariable analyses on 166 measurements, cFGF23 was positively correlated with serum calcium (β 1.5 ± 0.6, p<0.01), serum phosphate (β 1.2 ± 0.2, p=0.0001) and negatively correlated with EPO dose (β 0.41 ± 0.17, p=0.02). No association was observed between cFGF23 and IV iron administration (p=0.13), serum ferritin (p=0.7).

Conclusions: L-carnitine treatment slightly increased serum calcium and phosphate without an effect on iPTH or cFGF23. FGF23 was inversely correlated with ESA dose but not with IV iron dose.

Clinicopathological Characteristics of Lanthanum Deposition in the Gastrointestinal Tract of Dialysis Patients Shigevi Han,1 Akira Fujimori,1 Shinichi Nishi,2 Dept of Diagnostic Pathology, Kobe Univ Graduate School of Medicine, Kobe, Hyogo, Japan; 2Div of Pathology, Ako City Hospital, Ako, Hyogo, Japan; 3Div of Nephrology, Konan Hospital, Kobe, Hyogo, Japan; 4Dept of Nephrology, Kobe Univ Graduate School of Medicine, Kobe, Hyogo, Japan.

Background: Lanthanum carbonate (LC) is a phosphate binder for dialysis patients with hyperphosphatemia. Recent studies have reported gastric lanthanum deposition in patients treated with LC (Haratake J et al. Am J Surg Pathol 2015; Makino M et al. Pathol Int 2015; Tokumoto H i d e k i  N .  H i r a k a t a , 2,5 Comparative Effectiveness of Oral and Injectable Vitamin D Receptor Activator on Infectious Mortality in Hemodialysis Patients: The Q Cohort Study Shigeru Tanaka,1 Toshisharu Ninomiya,2 Masatomo Taniguchi,2 Masanori Tokumoto,2 Hideki N, Hirakata,2 Hiroko Ooboshi,2 Kazuhiko Tsuryu,2,3 Takanaori Kitazono,2,3 1Div of Internal Medicine, Fukuoka Dental College, Fukuoka, Japan; 2Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 3Div of Nephrology and Dialysis Center, Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan; 4Div of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 5Div of Research Management, Center for Cohort Studies, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.

Conclusions: A total of 3,278 subjects were divided into 3 groups by the administration type of VDRA: oral group (n=1,835), injectable group (n=459) and non-user (n=984). Impacts of VDRA on infectious mortality were examined using a Cox regression model adjusted with propensity score-based approaches.

Results: Among 3,324 patients during follow-up (median 3.9 years), 534 patients died and 115 patients developed infection death. The use of injectable VDRA was associated with a significant lower infectious mortality compared to non-user, while oral VDRA did not significantly reduce the risk of infection mortality compared to non-user (hazard ratio [HR] for injectable VDRA, 0.40; 95% confidence interval [CI], 0.13–0.91, and HR for oral VDRA, 0.78; 95% CI, 0.53–1.15, respectively). Direct comparison between oral and injectable VDRA revealed that the injectable group was also significantly associated with better survival than oral group (HR, 0.33; 95% CI, 0.13–0.83).

Conclusions: Treatment with injectable VDRA has a more favorable impact on the infectious mortality compared to oral VDRA in the real-world practice of hemodialysis patients.

TH-P0823
Alcoholism Levels in Patients on Hemodialysis/Relationship with the Metabolic Syndrome María Jose Fernandez Reyes,1 Manuel M. Heras,1 María Gonzalez,2 Olaia Rodriguez fraga,3 Ramiro Callejas,1 Álvaro Molina,1 Vanessa Lopes-martin,1 María astrid Rodriguez gomez,1 Leonardo Calle.1 1Nephrology, Hospital General Segovia, Segovia, Spain; 2Biochemistry, Hospital Univ La Paz, Madrid, Spain.

Background: Recently it has been shown that serum aldosterone (SA) levels are correlated with several components of the metabolic syndrome (MSy). OBJECTIVE: to establish SA levels on hemodialysis patients and its possible association with insulin resistance (homeostasis model assessment of insulin resistance HOMA-IR), excess body fat and/or serum adipokine levels.

Methods: 44 stable patients on HD, not taking ACE inhibitors/angiotensin receptor blockers. Mean age: 72.5±12.5years; 52.3% men; 34.1% diabetics. Mean time on HD:43±24.9 months. 28 patients were anuric. All measurements were done prior to the midweek HD session.

Results: SA levels were above the normal range (1.17-23.6 ng/dl) in 63% of patients. Plasma Renin Activity (PRA) was above the normal range (0,23-3.32 ng/mL/hour) in 27.3% of patients. Median: 31.15 (p25: 5.56; p75: 411 ng/mL); PRA median: 1.14 (p25: 0.45; p75: 20.9 ng/mL/hora). There were not statistically significant difference (Student’s t) in SA levels between anuric and non-anuric; male and female; presence and absence of myocardialopathy or diabetes. There were no statistically significant correlations (Spearman) of SA levels or PRA with urine volume; residual renal function; dose or length of time on HD; age; or Charlson Comorbidity Index. SA levels were positively correlated (Spearman) with AP (r= 0.72; p < 0.0001); body fat mass in kg/m² (r=0.32; p<0.045); serum leptin levels (r=0.30; p= 0.05); HOMA-IR (r= 0.36; p=0.017) and negatively with serum adiponectin levels (r= -0.31; p<0.041). Multivariate logistic regression analysis showed that SA levels above its median level were independently associated to PRA and HOMA-IR.

Conclusions: SA levels are elevated in a high percentage of HD patients and such elevation is associated with PRA and several components of MSy (insulin resistance; body fat mass; and serum levels of adipokines).

Higher iCa was also associated with higher HRV. The association of iCa with QTc interval and HRV remained significant in the repeated measures analysis. Associations with serum K, Mg, dCa, and dK were not significant at baseline or over follow-up. Serum-to-dialysate Ca gradient, but not K gradient was associated with higher HRV at baseline and over follow-up (β=0.3(0.0, 0.6) and 0.3(0.0, 0.6) respectively).

Conclusions: Serum iCa, but not K and Mg, is consistently inversely associated with QTc prolongation and the serum to dialysate gradient is also associated with HRV. This suggests that the absolute serum level as well as the lower dCa concentration increases arrhythmic risk.

TH-PO826
Phosphorus Kinetics During Hemodialysis: Further Validation of a Pseudo-One Compartment Model
J. Ken Luyckx1, 2, Baris U. Agar, 3 Alfred K. Cheung, 2 Angiello A. Bernardino, 2, 3 Medical Products (Renal), Baxter Healthcare Corporation, Deerfield, IL; 3 Medical Products (R&D), Baxter Healthcare Corporation, Round Lake, IL; 1 Nephrology, Univ of Utah, Salt Lake City, UT.

Background: A pseudo-one compartment model has been proposed to describe phosphorus kinetics during hemodialysis (HD) and postdialysis rebound. This model suggests that phosphorus mobilization from tissues is proportional to the difference between the predialysis serum (Cpre) and instantaneous serum concentration. The current study evaluated the ability of a pseudo-one compartment model to describe the kinetics of phosphorus during two short HD treatments on the same day separated by a 1-hr inter-treatment period without dialysis. The latter is the postdialysis rebound period for the first treatment.

Methods: Serum was collected frequently during both HD treatments and the inter-treatment period to assess phosphorus kinetics in 21 chronic HD patients. Phosphorus mobilization clearance (CMob) and predialysis central distribution volume (Vp) were estimated for each patient during the first HD treatment and the inter-treatment period. Assuming those kinetic parameters remained constant for each patient, phosphorus concentrations during the second HD treatment were used to estimate the driving force concentration (Cp) for phosphorus mobilization during that treatment.

Results: Treatment times (117±14 vs. 117±14 min), dialyzer phosphorus clearance (151±25 vs. 140±32 mL/min) and net fluid removal (1.44±0.74 vs. 1.47±0.76 L) were similar during both HD treatments. Phosphorus concentration at the start of the second HD treatment (3.3±0.9 mg/dL) was lower (P<0.001) than at the start of the first or Cpre (5.4±1.9 mg/dL). Kp and Vp were 98±44 mL/min and 11.0±4.2 L, respectively. Calculated Cm, was 4.9±2.0 mg/dL, not significantly different from Cpre (P=0.12). Cm and Cpre were correlated (R=0.72, P<0.001).

Conclusions: The results from this study demonstrate that the driving force concentration for phosphorus mobilization during HD is constant and equal to that predialysis, consistent with a fundamental assumption of the pseudo-one compartment model.

Association of Sleep Apnea and Sleep Quality with Left Ventricular Mass in Hypertensive Hemodialysis Patients in the Blood Pressure in Dialysis–SLEEP study
Manisha Jambh, 1 Cynthia A. Kendrick, 2 Dana Miskulin, 3 Lavinia A. Negrea, 4 David W. Ploth, 5 Jennifer J. Gassman, 6 Mark L. Unruh, 4 Philip Zaget, 7, 3, 6, 7 Univ of Pittsburgh; 8Cleveland Clinic; 7Tafts; 3Case Western; 4MUSC; 7UNM; DCD.

Background: Sleep apnea (SA), short and fragmented sleep may contribute to cardiovascular disease in hemodialysis (HD) patients. However, the relationship of sleep quality with left ventricular mass (LVM) is not well described.

Methods: Chronic HD patients joined an ancillary study during the baseline period of the Blood Pressure in Dialysis (BID) trial. SA was monitored for 1 night with a portable home monitor (ApneaLink with oximetry) and measured as Apnea Hypopnea Index (AHI). Sleep wake behavior was assessed by actigraphy over a 5-day period. LVM was measured by MRI.

Results: We studied 42 patients. SA was present in 84% and was moderately severe (AHI>15) in 48%. 61% of patients slept <6 hrs/night and 89% had poor sleep efficiency. Patients with AHI>15 had longer dialysis vintage, lower hemoglobin, and lower Kt/V than those with AHI<15. BMI, systolic BP, diastolic BP, heart rate, number of antihypertensive medications, inter-dialytic weight gain, history of myocardial ischaemia, and MRI characteristics did not differ between the two groups. LVM index was inversely correlated with sleep duration and efficiency (Pearson’s r = -0.35, p ≤ 0.04 for both, AHI (r = -0.01) and hypoxic index (r = -0.04).

Funding: The National Institutes of Health (NIH) National Heart, Lung, and Blood Institute (NHLBI) and the National Institute on Aging (NIA) (R01-AI068108 to J.C.)

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: SA and poor sleep quality were common among hypertensive HD patients. Short sleep duration and poor sleep efficiency, but not the severity of SA, were associated with higher LVM indices.

Role of Nicotinic Acid as Phosphate Lowering Agent in End Stage Renal Disease Patients on Maintenance Hemodialysis
Khalid Tahir,1 Hafiz I. Ahmad,1 Syed Rizwan Bokhari,1 Syed A. Khalid,1 Arif Asif.2 1Dept of Nephrology, Allama Iqbal Medical College/Jinnah Hospital, Lahore, Pakistan; 2Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.

Background: Hyperphosphatemia is associated with higher risk of mortality and morbidity in End Stage Renal Disease (ESRD) patients. Use of Nicotinic Acid as phosphorus lowering agent has been studied in many countries but available data is sparse and limited. We conducted a small longitudinal pilot study to investigate the effects of HD initiation on brain MRI and cognitive function in 4 HD patients by obtaining pre- and post-HD body temperatures were measured with thermometers. The dialysate temperature was measured by the HD machine. The dialysate-to-patient temperature gradient was computed as dialysate temperature minus patient temperature. A two-tailed paired t-test was used to compare pre- and post- initiation results. Patients provided written informed consent to participate in the IRB-approved protocol.

Methods: We conducted a small longitudinal pilot study to investigate the effects of HD initiation on brain MRI and cognitive function in 4 HD patients by obtaining pre- and post- initiation brain MRIs and cognitive testing. The MRIs were obtained at 3-6 months before HD initiation, and at 6-12 months after HD initiation. The Modified Mini-Mental State Examination (3MSE) was performed within one month of the baseline and 12 month MRI examinations. MR diffusion tensor imaging (DTI) measured white matter (WM) fractional anisotropy (FA) (connectivity), and pseudo-continuos arterial spin labeling (PCASL) imaging was used to evaluate GM cerebral blood flow (CBF).

Results: Progressive and significant declines in frontal and temporal WM FA (Fig. 1), prefrontal CBF (Fig. 2), and cognitive function (Fig. 3, left) were found following HD initiation (Table 1 for p values). The decline in frontal WM FA on MRI was correlated with the 3MSE decline (R=0.42)(Fig. 3, right).

Patient and Dialysate Temperature Characteristics in Incident Hemodialysis Patients: Results from a Large U.S. Population
Xiaoling Ye,1,2 Len A. Usvyat,2 Yue Jiao,1 Peter Kotanko,1 Franklin W. Maddux.1 1Renal Research Inst, New York, NY; 2Fresenius Medical Care North America, Waltham, MA;1Icahn School of Medicine at Mount Sinai, New York, NY.

Background: In chronic hemodialysis (HD) patients the use of dialysate at a temperature below the patient’s core temperature (“cool” dialysate) has been associated with improved outcomes in observational and prospective randomized studies [Odudu et al., CJASN 2015; Eldehni et al., JASN 2015; Selby, Sem. Dial 2008]. Little is known about temperature profiles in large US populations.

Methods: We include a subset of incident HD patients who were treated in Fresenius Medical Care North America facilities from 1/2010 to 12/2014 and who survived the first year of HD. Pre- and post-HD body temperatures were measured with thermometers. The dialysate temperature was measured by the HD machine. The dialysate-to-patient temperature gradient was computed as dialysate temperature minus patient temperature.

Results: We studied 20,360 incident HD patients (age 62.5 (SD 14.5) years; 57.6 % males; 68.1% White, 29.2 Black, 2.7% others). The vast majority (83.8 %) had a dialysate temperature above body temperature at the start; and at the end (80.6%) of HD.

Conclusions: We studied 20,360 incident HD patients who were treated in Fresenius Medical Care North America facilities from 1/2010 to 12/2014 and who survived the first year of HD. Pre- and post-HD body temperatures were measured with thermometers. The dialysate-to-patient temperature gradient was computed as dialysate temperature minus patient temperature.

Effect of a Single Hemodialysis Session on Visual Evoked Potentials

Savas Sipahi, Ahmed Bilal Genc, Yalcin Solak, Nephrology, Sakarya Univ Research and Training Hospital, Sakarya, Turkey; Neurology, Sakarya Univ Research and Training Hospital, Sakarya, Turkey.

Background: Some studies have shown that visual evoked potentials (VEPs) may be a marker of dysfunction in visual pathways in uremic subjects. However, data are scarce regarding the effect of hemodialysis procedure on VEPs. We aimed to compare VEPs of hemodialysis patients with healthy volunteers and in particular to assess the impact of a single hemodialysis session on VEPs.

Methods: Thirty hemodialysis patients were included in the study. We also recruited 30 age and gender matched control subjects. Patients with diabetes mellitus, cataracts, glaucoma, and stroke were excluded.

Demographic characteristics, midweek predialysis and postdialysis laboratory values, amount of ultrafiltration at that dialysis session were recorded. Patients underwent VEP measurement through which P100 latency values were determined just before hemodialysis session and 24 hours after hemodialysis. We assessed the changes in P100 values with single hemodialysis session and 24 after hemodialysis session. We assessed the changes in P100 values with single hemodialysis session and 24 hours after hemodialysis. We assessed the changes in P100 values with single hemodialysis session and 24 hours after hemodialysis.

Results: There was no difference between the groups in terms of age and gender (mean age 49 ± 12 and 48 ± 11 years, respectively). Median duration of hemodialysis was 78 months (range 12-192). At baseline there was no difference with respect to P100 values between the groups (100.6 ± 8.8 vs 99 ± 5.8, p=0.4, for hemodialysis and controls respectively). Both right and left eye VEPs showed a significant decrease measured 24 hours after dialysis session compared with baseline values (right VEP, 100.6 ± 8.8 predialysis and 97 ± 8.7 postdialysis, p<0.001; left VEP, 101 ± 9.2 predialysis and 97.3 ± 8.1, p<0.001). There was no correlation between baseline predialysis P100 values and age, serum urea, hemoglobin, and dialysis vintage. Amount of ultrafiltration was not significantly correlated with postdialysis P100 latency values.

Conclusions: Our results did not show a significant difference in P100 latency values between hemodialysis patients and healthy controls. A single hemodialysis session significantly shortened P100 latency values compared with baseline values.

Blood Pressure in Hemodialysis Patients: Which Measurement Is More Reliable?

Jose Mora-Macia, Francesc J. Moreso, Jose Ignacio Merello, Rosa Ramos. Hemodialysis, Fresenius Medical Care, Spain.

Background: The reliability of blood pressure (BP) measurements during the hemodialysis (HD) is controversial. The aim of this study was to evaluate which interval of intradialytic BP has less Bias in comparison with home BP monitoring (HBPM).

Methods: A cross-sectional study was done with interdialytic HBPM as reference standard and interdialytic BP measurement as test. Index BP recordings tested were predialysis (pre-HD), postdialysis (post-HD) and intradialysis (intra-HD). Dialysis unit BP recordings were averaged over 1 week: 2 pre-HD, 2 post-HD and 7 intra-HD (every 30 min); and HBPM over 1 week (the same days): 3 morning and 3 evening readings. BP measurements during dialysis were measured by dialysis nurses using the validated oscillometric BP monitor OMRON M3 (HEM 7051 E, Omron Healthcare), and the same HBPM recordings were used for the patient at home. Patients were instructed to bring the device to the dialysis. Patients with symptomatic hypotension during dialysis were excluded. To measure Bias, average HBPM was subtracted from each of these three index BP/intradialytic recordings. Bias was defined as the mean difference in BP (pre-HD, intra-HD, post-HD) compared with HBPM.

Results: 192 patients, mean age 63.8±14.8 y.o. (70% male), of 11 HD clinics of Fresenius Medical Care of Spain were included, 33% diabetic. All patients were on thr three times weekly HD. The mean time on HD was 46±57 months.

</table>

Data are expressed as mean/SD (range). * p<0.001 vs HBPM. ** p=0.062 vs HBPM. *** p<0.001 ANOVA between HD

Conclusions: BP at the end of the HD, in not hypotensive symptomatic patients, not differ from HBPM and have less Bias that predialysis or intradialysis BP measurements. So, the post-dialysis BP measurements are the most reliable BP readings.
TH-PO834
End-Dialysis Overweight and Chronic Inflammation: A Dangerous Association – A 36-Month Prospective Observational Study Ezio Movilli, U.O. of Nephrology, Spedali Civili and Section of Nephrology Univ of Brescia, Brescia, Italy.

Background: Attaining dry body weight is paramount in dialysis practice, but this goal is not always reached. We hypothesized that the amount of end-dialysis overweight (edOW), could be associated to increased chronic inflammation and mortality. Aim of the study: to evaluate the effect of edOW on serum C-reactive protein (hsCRP) concentrations and on survival in a cohort of 182 prevalent HD patients (pts) followed for 36 months.

Methods: In 182 pts (117 men, age 65±12 years, vintage 48 months; range 6-336), edOW was present in 98/182 (54%) pts. Mean value was 0.4±0.2 Kg (range: 0.1-1.4). In the 98 pts with edOW (Group 1) and in the other 84 (Group 2) we evaluated: Ultrafiltration rate (UFR), hsCRP dry body weight (dBW), Kt/V, protein catabolic rate (PCRn), interdialytic weight gain (IDWG), mean arterial pressure (MAP). Unpaired Student’s t test was employed to compare groups, linear regression analysis to test correlations, log-rank test and Kaplan-Meier curves to evaluate survival.

Results: Mean UFR was 11.7±2.8 ml/Kg/hour, dBW 64±12 Kg, hsCRP 6.6 (0.2-36) mg/L, Kt/V 1.27±0.09, PCRn 1.06±0.10 g/Kg/day, IDWG 2.8±0.4 Kg, MAP 97±6.5 mmHg. edOW and hsCRP were directly and significantly correlated (r= 0.67; p<0.0001). Comparison between pts with (Group 1) and without (Group 2) edOW showed significant differences in: UFR (12.7±2.6 vs 10.9±2.6 ml/Kg/hour; p<0.001), hsCRP (13.0±5.3 vs 2.6±0.2 mg/L; p<0.001), and PCRn (1.03±0.09 vs 1.08±0.10 g/Kg/day; p<0.004). 98 pts (54%) died during follow-up for cardiovascular complications in 69% of cases. Survival curves showed significantly greater mortality in Group 1 vs Group 2 in relation to the amount of edOW, and hsCRP (p<0.0001).

Conclusions: edOW and chronic inflammation are directly correlated in HD pts, and both are associated to a greater long-term risk of mortality.

TH-PO835
Suicidal Erythrocyte Death in Hemodialysis Patients Anna Clementi, Grazia Maria Virzì, Alessandra Brocca, Massimo de Cal, Antonio Granata, Claudio Ronco. “Nephrology, Agrigento,” “Nephrology-IRRI, Vicenza.”

Background: Even though anaemia in ESRD results mainly from the lack of erythropoietin, compelling evidence points to the contribution of accelerated erythrocyte death/eryptosis, which is characterized by phosphatidylserine (PS) exposure at surface, cell shrinkage and cell membrane scrambling. Eryptosis may be stimulated both by uremic toxins and the mechanical stress induced by hemodialysis (HD). We investigated the possible difference in terms of eryptosis levels between healthy subjects and HD patients before and after HD session.

Methods: We enrolled 15 patients (4F, mean age 65±16yrs, 33% with diabetes) undergoing chronic HD and 15 healthy subjects (CTR). Blood samples were collected prior to and after 4h standard HD session. Measurements were made in isolated erythrocytes (RBCs). PS exposure was estimated from AnnexinV binding in flow cytometer.

Results: The percentage of AnnexinV reflecting the percentage of RBCs exposing PS to RBC surface was significantly higher (more than twice) in HD patients than CTR (2.2%; IQR 1.2-4.1 versus 0.8%; IQR 0.7-1.3; p<0.05). The average forward scatter reflecting cell volume was significantly higher in RBCs from HD patients than in CTR. There was no statistically significant relationship between area levels and eryptosis in HD patients. The percentage of AnnexinV and cell volume were measured prior to and after 4h of HD: no significant differences were observed between pre and postdialytic eryptosis.

Conclusions: Our data suggest that HD may lead to a significant increase in eryptosis, but no differences were observed before and after HD session. Although this procedure is known to be responsible for cytokines and inflammatory mediators release, because of the interaction between blood and circuit lines and filters, it does not seem to induce eryptosis. Further studies are needed to compare different types of HD treatments.

TH-PO836

Background: The aim of this study was to investigate the potential effect of a Dialysis Hospitalization Reduction Program (DHRP) on hospital admissions.

Methods: We deployed DHRP to 69 patients between 1/1/2014 and 5/5/2015 in a network of Fresenius Medical Care North America (FMCNA) dialysis clinics. These clinics were identified as being at high risk for hospitalization based on FMCNA’s data driven predictive modeling efforts and clinical assessments. The DHRP encompasses multiple interventions, targeting malnutrition, non-compliance, mental status issues, fluid overload, and others. Each patient is identified to have one or more “clinical tags”; 88 tags were identified for 69 patients. Interdisciplinary teams were deployed to design and implement interventions. Hospitalization rates were measured 90 days before and after the program.

Results: DHRP was associated with a reduction of all-cause hospitalization from 7.5 to 4.4 per patient year (ppy) (-42%) (Figure 1A). Interventions targeting patients with “malnutrition” tag were associated with a reduction of hospitalizations from 9.3 to 4.1 ppy (-56%) (Figure 1B).

TH-PO837

Background: 3-day-a-week hemodialysis (HD) involves one long (72hr) and two short (48hr) inter-dialytic periods (IDP) with higher death risk after the long IDP. We investigated BP and CV biomarker patterns in clinically stable HD patients to determine whether BP control during the final 24 hrs of the long IDP is inferior to that of the short IDPs.

Methods: In an initial retrospective study, in-center BP readings over 1 month were analyzed for 81 adult HD patients with stable regimen and medical status for ≥ 3 mths. Next, 23 patients completed a prospective study in which ambulatory BP monitoring was performed for the final 24hrs of the long and one short IDP in the same week. Blood was collected for CRP, Tropomin T, BNP following each ABPM.

Results: In the retrospective study, mean pre-dialysis systolic and diastolic BP (SBP/ DBP) did not differ for the long and short IDPs despite greater weight gain during the long IDP. This observation was confirmed in the ABPM study and applied to both day- and night-time readings. Pre-dialysis CV biomarkers were not significantly higher following the long IDP. Inter-dialytic weight gain showed no correlation with BP indices.

Conclusions: Our data suggest that HD may lead to a significant increase in eryptosis,
Conclusions: In stable HD patients, BP control and CV biomarkers were similar during long compared to short IDP despite greater fluid gain. The adverse influence of excessive inter-dialytic fluid gain is unlikely to be mediated directly through a hypertensive effect.

Notch Signaling in Bone Marrow-Derived FSP-1+ Cells Mediates a Phenotypic Change in Smooth Muscle Cells Leading to AVF Failure Ming Liang,1,2 Ten Li,1 Jie Zhang,1,2 William E. Mitch,1 Yichong Cheng,1 Medicine, Baylor College of Medicine, Houston, TX; 2Nephrology, Guangzhou Medical Univ, Guangzhou, Guangdong, China.

Background: Societal and economic costs of failed arteriovenous fistulas (AVF) are well known but mechanisms of AVF losses are controversial. We have shown that smooth muscle cells (SMCs) from anastomosed artery compose of ~50% of neointima in AVF. Arterial SMCs are also infiltrated by bone marrow (BM)-derived FSP-1+ cells, potentially linking FSP-1+ cells to SMC activation. However, whether Notch/RBP-JK signaling involves in BM-derived FSP-1+ cell activation has not been studied. We propose that Notch/RBP-JK activation in BM-derived FSP-1+ cells causes a phenotype-switch of SMCs, resulting in SMC translocation from the artery to the venous anastomosis, forming neointima.

Methods: We created CKD and AVFs in wild type and Notch knock out mice. The role of Notch signaling in activation and function of BM-derived FSP-1+ cells was explored. Activated SMCs were characterized by a loss of differentiation markers plus in gain in proliferation (PCNA+). Using BM transplantation, we examined if FSP-1+ cells lacking RBP-JK in CKD mice would suppress SMC phenotype switch and neointima formation in AVFs.

Results: BM-derived FSP-1+ inflammatory cells in AVFs from CKD mice were 45% greater vs. results in pair-fed, control mice. In the artery anastomosis, increased infiltration of FSP-1+ cells led to loss of SMC differentiation markers, SMMHC, SM-22 and SMA-a. Activation of Notch signaling (NICD+ and RBP-JK+) raised expression of cytokines (IL-1β, MCP-1) and growth factors (PIGF-BB, bFGF and TGF-β) in FSP-1+ cells. The cytokines and growth factors caused a SMC phenotype switch (characterized by loss of SMC markers), resulting in SMC migration and proliferation. RBP-JK KO in BM-derived FSP-1+ cells significantly decreased the production of cytokines and growth factors, suppressed SMC activation of and neointima formation in AVFs.

Conclusions: Thus, Notch signaling in BM-derived FSP-1+ cells can induce a phenotype switch in SMCs stimulating neointima growth. Targeting Notch signaling in FSP-1+ cells could improve AVF function.

TH-PO839

Background: Placement of an arteriovenous fistula (AVF) provides vascular access for lifesaving hemodialysis to patients with severe and chronic kidney disease. A significant percentage of AVF’s initially mature; serve as successful hemodialysis access points; but fail at some later time due to neointimal hyperplasia that occludes the vein. The causative underlying molecular, biochemical, and cellular factors that contribute to AVF failure are incompletely understood. CaMKII is a positive regulator of VSM cell proliferation and migration that results in occlusion of carotid arteries in both mice and rats. Currently, there is little known regarding the role of CaMKII in either physiological or pathophysiological venous function.

Methods: Cephalic veins from patients prior to AVF placement and after AVF failure were obtained. Immunohistochemical studies were performed on OCT embedded frozen sections. Molecular analyses were performed on RNA extracts from these venous segments and protein analyses were performed on protein extracts.

Results: Our results indicate that there is an increase in CaMKII and CaMKII expression in failed AVFs as compared to cephalic vein prior to AVF placement. CaMKII activity is regulated by both phosphorylation and oxidation. NADPH oxidases (Nosx) generate reactive oxygen species (ROS) that increases CaMKII activity. Analysis of failed AVFs shows an upregulation of Nosx and Nosx. Further studies show an increase in CaMKII activity. Interestingly, our data indicates that only a subset CaMKII isoforms are oxidized under these conditions.

Conclusions: These findings lead us to conclude that increases in [Ca2+] and [ROS] after AVF placement may result in increases of CaMKII and CaMKII expression and sustained activity that contribute to AVF failure. They also identify CaMKII as a rational target for therapeutic manipulation to prevent AVF failure.

TH-PO840

Identification of Ca2+/CaM-Dependent Protein Kinase (CaMKII) Isoforms and Their Selective Regulation by NADPH Oxidases in Failed Arteriovenous Fistula from Hemodialysis Patients Yongfeng Liu, Julia Steppich, Roman G. Ginnan, David J. Conti, Harold A. Singer,1 ‘Center for Cardiovascular Sciences, Albany Medical College, Albany, NY; 2Div of Nephrology and Hypertension, Albany Medical College, Albany, NY; 3UCM Surgery Group-Transplantation, Albany Medical College, Albany, NY.

Background: Early arteriovenous fistula (AVF) failure remains an important cause of hemodialysis vascular access dysfunction. In order to understand the cellular and molecular mechanisms involved in early AVF failure we evaluated the gene methylation profile (epigenetics) in conjunction with the gene expression profile (RNA Seq) from venous segment tissue samples obtained at the time of AVF creation. This approach allows us to identify genes that have altered expression (RNA Seq analysis) as a result of epigenetic changes (DNA methylation). The latter can be induced by different factors, including stress, inflammation, nutrition, metabolism, drugs and infection (all of which are prominent in the biological milieu of patients with CKD and ESRD).

Methods: Genomic DNA (gDNA) and RNA were isolated from venous segments collected at the time of AVFcreation. We divided the samples into 2 groups, THICK (n=5) and THIN (n = 5), based on a histological evaluation of the amount of neointimal hyperplasia. Deep sequencing technologies were then used to identify differentially regulated levels of gene expression between the THICK and THIN groups, that also had significant differences in RNA Seq analysis. Standard bioinformatic techniques were used to identify/interrogate these changes.

Results: We were able to identify a number of genes that were differentially regulated, either at the level of the transcriptome or at the level of DNA methylation (epigenetics) between the THICK and THIN groups. However, we were not able to identify individual genes that had changes in both the RNA Seq and DNA methylation analyses, at a high level of statistical significance.

Conclusions: While we were unable to identify differences in both gene expression and methylation of DNA methylation for individual genes, between our two groups (perhaps because of a small sample size), we do believe that these techniques and technologies could be used in larger studies, to dive deep into the mechanisms of AVF failure at a molecular and genetic level.

Deep sequencing technologies were then used to identify differentially regulated levels of gene expression between the THICK and THIN groups, that also had significant differences in RNA Seq analysis. Standard bioinformatic techniques were used to identify/interrogate these changes.

Results: We were able to identify a number of genes that were differentially regulated, either at the level of the transcriptome or at the level of DNA methylation (epigenetics) between the THICK and THIN groups. However, we were not able to identify individual genes that had changes in both the RNA Seq and DNA methylation analyses, at a high level of statistical significance.

Conclusions: While we were unable to identify differences in both gene expression and methylation of DNA methylation for individual genes, between our two groups (perhaps because of a small sample size), we do believe that these techniques and technologies could be used in larger studies, to dive deep into the mechanisms of AVF failure at a molecular and genetic level.

Computational Fluid Dynamic Analyses in a Uremic Mouse Model of AV Stenosis: Of Surgery, Techniques and Computation
Begoña Campos,1 Yang Wang,2 Yong He,2 John M. Pearce,1 Richard Scott Dunn,1 Keith Louis Saum,3 Janaka Wansapura,2 Charles L. Dumoulin,1 Scott A. Berceli,2 Prabir Roy-Chaudhury,1 Univ of Cincinnati,2 Univ of Florida,3 CCHMC.

Background: Although arteriovenous fistulae (AVF) are the preferred form of vascular access for hemodialysis patients, over 50% of AVFs fail to mature (inability to increase blood flow and diameter adequately to support dialysis). Work performed in our laboratory suggests that AVF maturation failure is due to an interaction between “upstream hemodynamics” and “downstream vascular biology”. In order to better elucidate the mechanisms involved in both these processes, we herein describe the techniques needed to develop a shear stress profile within a uremic mouse model.

Methods: In order to create a uremic mouse model, C57Bl/6 mice underwent an initial cauter of the left kidney followed 2 weeks later by a contralateral nephrectomy. Four weeks later AVFs were created in the neck. In order to generate different shear stress profiles, we created AVFs between the carotid artery and jugular vein in the following surgical configurations (a) end of carotid artery to end of jugular vein (b) end of jugular vein to end of carotid artery and (c) end of carotid artery to side of jugular vein. Mice were then perfused with a silicone rubber casting agent (Microfil). Fistulae were harvested, stored in 4% paraformaldehyde, and treated with Lugol solution as a micro-CT contrast agent. Each AVF was then scanned using micro-CT imaging to create a 3D reconstruction of AVF geometry. In order to obtain blood flow parameters we have developed an MRI technique to develop a shear stress profile within a uremic mouse model.

Results: We have described for the first time a hybrid surgery-fluid dynamics approach, which could allow us to identify the differential impacts of different surgical configurations, with or without the impact of uremia on AVF fistula functionality (with the promise of also being able to use genetically manipulated animals in the future).

Conclusions: We firmly believe that teasing out the relative roles of upstream hemodynamics and downstream uremic vascular biology will allow us to identify target(s) for future therapeutic interventions.

TH-PO843
Biodegradable Stents Improve Arteriovenous Fistula (AVF) Maturation
Begoña Campos, Yang Wang, Zhangzhang Yin, Keith Louis Saum, Diego Celdran-Bonafonte, Mark J. Schulz, Vesselin Shanov, Prabir Roy-Chaudhury, Univ of Cincinnati.

Background: Arteriovenous fistula (AVF) maturation failure is currently a huge clinical problem with no effective therapies. At a pathogenetic level the three main causes of AVF maturation failure are (a) small veins (b) abnormal non-laminar flow profiles and (c) abnormal local endothelial function. We therefore, hypothesize, that the placement of a malleable, biodegradable magnesium based maturation enhancing stent (bMES) within the venous segment, at the time of surgical AVF creation would displace small veins, optimize the anatomical configuration, and serve as a conduit for the future delivery of therapies to improve local vascular biology during the critical initial 4-8 week period with an absence of long term side effects (no stent after 4-8 weeks).

Methods: bMES were fabricated using pure Mg foil (125 mm) and Mg-Zn alloy wire. Bilateral AVFs were created between the femoral artery and vein of Yorkshire pigs. A bMES was inserted on one side and dilated to 8mm. A control AVF was created on the contralateral side. CT angiograms and ultrasounds were performed to document blood flow and diameter for the control and stented AVF.

Results: Preliminary data documents almost complete degradation of the bMES at 4-8 weeks with an increase in diameter of the stented AVFs on CT angiograms at 2 weeks (Figure). Histological examination performed on both the stented and control AVFs did not reveal any evidence of necrosis or inflammation.

Conclusions: These initial results clearly demonstrate technical feasibility and safety for the bMES, and also provide us with an efficacy signal based on our CT angiogram data (Figure). We believe that this technology could significantly reduce the huge morbidity and mortality associated with AVF maturation failure and also expand the patient population considered to be suitable for AVF placement in the future.
Conclusions: There is large international variability in site of AVF placement and AVF maturation. Differences in blood flow used (much higher in the US vs. Europe and Japan) may lead to different interpretation of the term “maturation” internationally, and may influence maturation rates.

Vascular Access in Acute Kidney Injury: Results from the ATN Study Kavitha Ganta, Yue-Harn Ng, Herbert T. Davis, Mark L. Unruh. Department of Internal Medicine, Univ of New Mexico, Albuquerque, NM.

Background: Acute kidney injury requiring renal replacement therapy (RRT) portends a poor prognosis. Currently, the decision regarding catheter placement is based solely on physician discretion. Limited data exist to guide catheter placement. The Acute Renal Failure Trial Network (ATN) study was a multicenter, prospective, randomized trial on the effects of dialysis dose on mortality in critically ill patients. Using data from this study, we assessed the complications rates and the adequacy of dialysis based on different catheter locations.

Methods: Baseline characteristics were gathered. The outcomes of interest include catheter related infections, cardiac arrhythmias, excessive bleeding, local thrombosis and dialysis adequacy. Categorical variables were analyzed using Chi-square test while continuous variables were analyzed using the Student T test. The SAS software was used for all analyses.

Results: There were 242 (11.7%) subclavian (SC), 951 (46.1%) internal jugular (IJ) and 861 (41.7%) femoral (FC) catheters inserted. The baseline characteristics based on catheter location is shown in Table 1.

<table>

</table>

The rate of bacteremia was comparable between the 3 groups. (5.4% (SC) vs. 3.5% (IJ) vs. 3.5% (FC); p = 0.34). The IJ group experienced more cardiac arrhythmias (2%) compared to BM (0.8%) and FC (0.5%) group (p = 0.01) while the FC group had more venous thrombosis (0.7%) compared to none in the SC and IJ group (p = 0.02). Overall, complication rates were low. There was no clinically significant difference in the adequacy of dialysis between the 3 groups.

Conclusions: There was no significant differences in complication rates amongst the 3 catheter locations hence decision on catheter location should be based on operator experience and comfort level.

TH-PO848

Vascular Access at Dialysis Initiation in the United States Renal Data System (USRDS): Strong Agreement Between CMS 2728 Medical Evidence Form and CROWNWeb Purna Mukhopadhyay, Jeffrey Pearson, Kenneth J. Woodside, Sarah Bell, Ronald L. Pisoni, Douglas E. Schaubel, Kaitlyn Ratkowiak, Rajiv Saran. 1 Arbor Research Collaborative for Health, Ann Arbor, MI; 2 Univ of Michigan, Ann Arbor, MI.

Background: The USRDS has long reported vascular access (VA) at the start of hemodialysis (HD) initiation. This study compared VA used at the first HD session reported on the CMS-2728 and CROWNWeb. For pts incident during 2006-2013, data on VA at hemodialysis (HD) initiation (n=2,851) was categorized as catheter only (CVC), AV Fistula (AVF), AV Graft (AVG), CVC with maturing fistula, and CVC with maturing graft. Pts initiating HD between 6/1/2012-12/31/2012 (N=197), were tracked over 12 months. For prevalent pts, AVF & AVG groups include CVC/maturing fistula and CVC/maturing graft, respectively.

Results: From ’06-’12, incident pts began ESRD care using HD 39%, PD 36%, and transplant 25%. In 2013, in pts starting HD, 90% had a CVC, an increase from 84% in 2006. CVC was lower for the older pts (<4yrs: 99% vs. 14-17yrs: 83%, p<.05). VA trends over a year in a 7-month incident cohort showed the proportion of CVC decreased from 84% at 1 month to 31% at 1 year, while 16% were using or maturing an AVF. 1% were using or maturing an AVG. 13% of pts transitioned to PD and 35% received a TX by 1 year.

Conclusions: Our analysis confirms the large CVC burden among pediatric HD pts. Conversion to AVF were observed over the first year in an incident cohort where nearly 50% of pts transitioned to PD or TX. Further study will assess the impact of CVC dependence among pediatric ESRD pts with respect to future VA options and patient outcomes.

TH-PO850

In Search of an Optimal Screening Program for Containing Graft Thrombosis Nicola Tesseritore, Giuseppina Pessolato, Valeria Bedognà, Albino Poli, Antonio Lupò, Ennodialisi Borgo Roma, Verona, Italy; 2 Dept Public Health, Verona, Italy.

Background: KDOQI guidelines recommend regular screening for >50% stenosis (ST) in graft by surveillance (access blood flow (Qa) & venous static pressure ratio (vPVR) or Duplex Ultrasound to reduce the risk of thrombosis. Analysis of the literature suggests that the best predictor of thrombosis is sVPR>0.5, with an area under curve (AUC) of 0.81[95%CI:0.75-0.85] significantly higher than that of Qa:0.600 mmHg (0.72[95%CI:0.68-0.77]) & ST (0.49[95%CI:0.45-0.53]), but no study has compared vis-a-vis all of the tools.

Methods: To identify an optimal screening program, in 2013 we compared the diagnostic performance of the available tools for incipient thrombosis (within 3 mo) in the same population of 42 grafts (5 forearm loop & 37 straight upperarms), that underwent18 thrombotic episodes.

Results: Qa by Ultrasound Diffusion proved to be the best screening tool (AUC:0.81[0.69-0.93]) optimal thresholds between Qa:1000 mmH/min (63% sensitivity [SE], 18% false positives[FPR]) & Qa:1200 mmH/min (83% SE, 27% FPR). Its AUC was higher than that of ST (0.69[95%CI:0.54-0.84]) 78% SE, 39% FPR), monitoring (0.62[95%CI 0.45-0.79]) 33% SE, 9% FPR), & VAPR (0.58[95%CI:0.42-0.74]VAPR)0.87% SE, 58% FPR). At GLM analysis Qa was the only significant predictor of thrombosis, with 18%[95%CI 7-29] lower risk for each 100 mmH/min above a Qa 400 mmH/min. From January
The Impact of eGFR at Pre-HD Access Surgery on the Likelihood of Starting Hemodialysis with a Mature Vascular Access

**Background:** The optimal timing of pre-dialysis vascular access surgery is uncertain. Complications of CVCs may have economic consequences for dialysis providers and patients. The timing of surgery may influence the likelihood of starting HD within 2 years, and whether the permanent access was used on the first HD session.

**Methods:** We retrospectively queried a prospective computerized access database to identify patients with pre-HD access surgery (301 AVF and 64 AVG placed between 2006-12) with an eGFR recorded on the surgery date. Patients were stratified into 4 eGFR groups (<10, 10-14, 15-19, >20 ml/min).

**Results:** Overall, 208 (or 69%) of pts with pre-HD AVF surgery initiated HD within 2 years, but the proportion varied by eGFR at surgery (90, 81, 64, and 47% for eGFR <10, 10-14, 15-19, and >20 ml/min).

**Conclusions:** Our comparative study suggests that eGFR is the best predictor of graft patency & Qa surveillance using a Qa<1000 ml/min threshold allows for appropriate and timely stenosis repair & may contain the risk of thrombosis.

**TH-PO853**

**Obesity Related Decrease In Intraoperative Blood Flow Is Associated with Maturation Failure of Radiocephalic Arteriovenous Fistula**

**Background:** Successful arteriovenous fistula (AVF) maturation is often challenging in obese patients. Optimal intraoperative blood flow (IOBF) is essential for adequate AVF maturation. This study was conducted to elucidate the effect of obesity on IOBF and radiocephalic AVF maturation.

**Methods:** Patients who newly created radiocephalic AVF were included (n=252). Obesity was defined as a baseline BMI ≥25 kg/m², and primary maturation failure was defined as the failure to use AVF successfully by 3 months after its creation. IOBF was measured immediately after construction of AVF using a VeriQTM system.

**Results:** The mean BMI was 24.1±3.9 kg/m², and the prevalence of obesity was 31.3%. Particularly, 8.3% (21 patients) were BMI ≥30 kg/m². Primary maturation failure occurred in 100 (39.7%) patients and an IOBF <190 mL/min was closely associated with the risk of maturation failure (relative risk, 3.05; 95% CI, 1.52–6.11). Compared to non-obese patients, obese subjects had a significantly higher prevalence of diabetes and elevated hs-CRP levels, whereas diameters of vessels were similar. When the patients were further divided into 3 groups at the BMI <25, 25-29.9, and ≥30 kg/m², patients in higher BMI groups had significantly lower IOBF and higher maturation failure rate. According to multivariate analysis, the statistically significant variables that determined maturation failure were obesity, previous vascular disease, increased hs-CRP levels, and IOBF <190 mL/min.

**Conclusions:** Obese patients had a significantly lower IOBF, and both obesity and low IOBF contributed to the primary maturation failure of AVF. Obesity-associated inflammation and atherosclerosis may play roles in this association.

---

**TH-PO854**

**The Impact of Vascular Access on Hemodialysis Patient Survival and Risk Analysis**

**Background:** Maturation failure is the most common dialysis modality worldwide. However, the impact of different types of vascular access on hemodialysis patient survival has not been investigated in a large scale study. Therefore, we retrospectively reviewed the survival of hemodialysis patients in our center and analyzed the impact of vascular access on their survival. Other potential risk factors were also studied.

**Methods:** From 2001 to 2010, patients, who aged more than 40 years old and received regular hemodialysis in our center for at least 3 months, were included into this study. A total 916 patients were enrolled. The mean followed up interval was 4.4±2.5 years. Among these patients, 51.1% were male, while 48.9% were female. These patients were divided into three groups according to their vascular access. Group A: patients used either native arteriovenous fistula or arteriovenous graft at the all time and dialysis catheter had never been used during the whole study period. Group B: patients used either native arteriovenous fistula or arteriovenous graft before they used dialysis catheter at least once during study period. Group C: patients used dialysis catheter as their vascular access and arteriovenous shunt had never been established during the study period. Other survival associated factors were analyzed by using univariate and multivariate factor analysis.

**Results:** The results showed that group C patients had significantly worst survival rate (P<0.0001). The group B patients also had significantly worse survival rate when compared with group A patients.
with group A patients (P=0.0001). The hazard ratio was 1.71 (1.31-2.24) for group B and 3.56 (2.08-6.08) for group C when compared to group A patients. Multivariate analysis showed that the associated risk factors for patient survival were male sex, diabetes mellitus, low albumin, high hsCRP, and abnormal AST level.

Conclusions: The use of dialysis catheter imposed high risk for patient mortality on top of other associated risk factors. Early establishment of vascular access can eliminate this risk factor and improve patient outcome.

TH-PO855

Early Experience with a Novel Device for Ultrasound-Guided Management and Cannulation of Hemodialysis Vascular Access

William D. Paulson, 1 Deborah J. Brouwer-Maier, 2 Lillian A. Pryor, 3 John Jason White, 1 Laura L. Mullloy, 1 Lu Y. Huber, 1 Matthew J. Diamond. 1 1 Charlie Norwood VAMC & Georgia Regents Univ, Augusta, GA; 2 Fresenius Medical Care, Waltham, MA.

Background: The vascular access continues to be the Achilles heel of dialysis. Methods that facilitate easier management and cannulation of accesses are needed. We describe early experience with a novel ultrasound device.

Methods: The Sonic Window (Analogic Corp, Peabody, MA, USA) is designed to assist management of vessels in a variety of contexts. It differs from conventional ultrasound in that it provides a coronal view of vessels that yields determination of characteristics such as depth and luminal diameter, and assists in cannulation for dialysis. We have initiated a program in 4 FMC dialysis units which is designed to identify its role and limitations.

Results: Two experts in the use of the Sonic Window have trained dialysis staff in the 4 FMC units. Staff have successfully cannulated 33 AV fistulas and synthetic grafts. Set up and use of the device generally adds an extra 1-3 minutes to cannulation time. Staff are able to easily visualize advancement of dialysis needles into the vessel lumen (figure).

We plan to evaluate the following potential uses of the device: 1. Assessing fistula maturation by measuring increase in luminal diameter over time; 2. Evaluating accesses that are difficult to cannulate; 3. Evaluating accesses with low blood flow, or high negative arterial or positive venous dialysis pressure; 4. Identifying alternative access sites for cannulation. Possible disadvantages to be addressed: potential staff & patient reluctance to accept new technology and additional cannulation time, to be assessed in surveys.

Conclusions: Our early experience supports the concept that Sonic Window is a significant advance in managing and cannulating accesses in both routine and difficult situations.

Modifiable Risk Factors Affecting the Outcome Hemodialysis Graft

Jee eun Park, Jin Hae Kim, Subin Hwang, Do Hee Kim, Hye Ryoun Jang, Jung eun Lee, Wooseong Huh, Yoon-Goo Kim, Ha Young Oh, Dae Joong Kim. Nephrology Div, Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Korea.

Background: Arterio-venous graft (AVG) for hemodialysis has poorer outcome than arterio-venous fistula (AVF) with its frequent stenosis and thrombosis. We investigated modifiable risk factors affecting the outcome of AVG.

Methods: A single-center cohort of 254 patients (pts) receiving AVG for hemodialysis access from Sep 2010 to Oct 2014 were included. Demographics, laboratory data, comorbidities, and medications were collected from the medical records. Surgical factors related to AVG operation including the type and diameter of connected vessels, graft site, and type of operation (elective or emergent) were also recorded. End points was the interval from initial access formation to any intervention intended to restore patency (primary patency, days) and the total access survival duration (secondary patency, days).

Results: Data of 225 pts were analyzed. During the follow-up period, 139 (62%) pts received intervention and 45 (20%) pts underwent permanent failure. Survival analyses using Kaplan-Meier method was shown in the figure. In multivariate analysis, primary patency duration was associated with RAS inhibitor (hazard ratio [HR] 1.67, 95% confidence interval [CI] 1.13-2.46), and upper arm graft (HR 0.62, 95% CI 0.40-0.94). Secondary patency duration was associated with serum albumin level (HR 0.28, 95% CI 0.13-0.61), diastolic blood pressure (BP) (HR 0.93, 95% CI 0.89-0.98) and warfarin (HR 5.80, 95% CI 2.04-16.46).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Conclusions: A DBP ≥ 77 mmHg prior to surgery may be considered as a key prognostic indicator of the Bresciano-Cimiru procedure.

Vascular Access Outcomes following Peritoneal Dialysis to Hemodialysis Transition

Timmy C. Lee,1 Mae Thamer,1 Qian Zhang,2 Yi Zhang,2 Michael Allon.1 1 Univ of Alabama at Birmingham; 2 Medical Technology and Practice Patterns Inst.

Background: Few studies have evaluated vascular access (VA) use following transition from PD to HD. Our goal was to examine short-term VA utilization following PD to HD transition.

Methods: Using USRDS and Medicare claims data from July 2010-December 2012, we identified 3,565 incident Medicare-insured PD patients who were ≥85yrs and initiated dialysis between July 2010-June 2011. Patients had at least one dialysis claim within 90 days of dialysis initiation and were followed for 1 year until one of the following events: switched to HD, kidney transplant, death, or end of follow-up. We used Cox-regression models to examine the association of risk factors and switching to HD, with death and transplantation used as competing events.

Results: 991 (27.8%) patients switched from PD to HD during the 1 year follow-up. Of these, 46% switched to HD within 90 days of dialysis initiation and 66% by 6 months. The median switch time was 114 days (IQR: 32-226). Patients with cardiovascular disease (Adjusted Hazard Ratio (HR) 1.25, 95% CI 1.10-1.43), COPD (HR 1.29, 95% CI 1.01-1.66), and without pre-dialysis nephropathy care (HR 1.46; 95% CI 1.21-1.76 versus those with >12 months nephropathologist care) were more likely to switch from PD to HD. After switching from PD to HD, 89% used a catheter, 6.6% AVF, and 1.9% AVG. 90 and 180 days after switching to HD, 71% and 50% of patients, respectively, who remained on HD still used a catheter as their VA.

Conclusions: The majority of patients transitioning from PD to HD initiate HD with a catheter. 50% dialyze with a catheter at 6 months. This highlights the need for VA planning in patients with failed PD to ensure timely transition to permanent VA.

Temporal Trends in Pre-Hemodialysis Vascular Access Creation in Elderly Patients with CKD

Timmy C. Lee,1 Mae Thamer,1 Qian Zhang,2 Yi Zhang,2 Michael Allon.1 1 Univ of Alabama at Birmingham; 2 Medical Technology and Practice Patterns Inst.

Background: Optimal timing of pre-dialysis vascular access (VA) creation remains unclear. Elderly CKD patients with high comorbidity are more likely to die before starting HD, so deferring VA creation may be reasonable. We assessed whether nephrologists have started selecting healthier elderly patients for pre-HD VA surgery.

Methods: Using Medicare claims data we identified 3418 elderly patients (aged ≥70 years) with CKD undergoing pre-HD VA creation in 2004 to 2009, and divided them into 3 time cohorts (2004-05, 2006-07 and 2008-09). For each temporal cohort, we assessed the likelihood of initiating dialysis during 2 years of follow-up after VA surgery. We collected data on cardiovascular co-morbidities and cardiovascular events prior to VA surgery and after dialysis initiation to determine if there were significant changes in these variables during the 3 time cohorts.

Results: Of these, 46% switched to HD within 90 days of dialysis initiation and 66% by 6 months. The median switch time was 114 days (IQR: 32-226). Patients with cardiovascular disease (Adjusted Hazard Ratio (HR) 1.25, 95% CI 1.10-1.43), COPD (HR 1.29, 95% CI 1.01-1.66), and without pre-dialysis nephropathy care (HR 1.46; 95% CI 1.21-1.76 versus those with >12 months nephropathologist care) were more likely to switch from PD to HD. After switching from PD to HD, 89% used a catheter, 6.6% AVF, and 1.9% AVG. 90 and 180 days after switching to HD, 71% and 50% of patients, respectively, who remained on HD still used a catheter as their VA.

Conclusions: The majority of patients transitioning from PD to HD initiate HD with a catheter. 50% dialyze with a catheter at 6 months. This highlights the need for VA planning in patients with failed PD to ensure timely transition to permanent VA.

Hemodynamic Changes in Arteriovenous Fistula During Dialysis

Mary S. Hammes,1 Vikash Kumar Sinha,1 Tom Bilcharski,1 Michael Boghosian,2 Jane E. Hines,1 Sydeeka Watson,2 Kevin Cassel,3 S. M. Jadid Mahmoudzadeh A,2 1 Medicine/Nephrology, Univ of Chicago; 2 Dept of Mechanical, Materials and Aerospace Engineering, Illinois Institute of Technology; 3 Dept of Public Health Sciences, Univ of Chicago.

Background: Optimal blood flow velocity (BFV) in arteriovenous fistulas (AVF) to prevent neointimal hyperplasia is yet to be determined. We have hypothesized that changes in BFV and diameter in a brachiocephalic fistula (BCF) are affected by fistula maturation and blood flow induced during hemodialysis.

Methods: Eight subjects with primary BCF participated. Doppler BFV was measured pre-dialysis and during dialysis at 250, 350 and 450 mL/min blood flow for up to 14 months. BFV was measured in the straight portion of the cephalic vein 10 cm proximal to the cephalic arch. The relationship between BFV and diameter was examined using a linear mixed effects model. Computational modeling using venography was performed at 3 and 12 months.

Results: The change in measured diameter and BFV showed an inverse relationship with a significant association at baseline (p=0.0074) and 350 mL/min dialysis blood flow (p=0.0092). The computational model of the cephalic arch in one subject showed a 4 fold increase in Reynolds number with a dramatic recirculation region shown by a swirling eddy at the upper elbow of the arch.

Conclusions: From 2004-2009, there has been a progressive decrease in cardiovascular co-morbidities in elderly CKD patients undergoing pre-HD VA surgery, and this has been associated with a decrease in patients dying before HD and in patients with cardiovascular events after starting HD. Clinicians are becoming more selective in pre-HD placement of VA in this patient population.

TH-PO861

Arteriovenous Fistula (AVF) Maturation Among Hemodialysis (HD) Patients: Results from the USRDS

Rajiv Saran,1 Sarah Bell,1 Brett W. Platter,1 Douglas E. Schaubel,1 Sudipta Dasmunshi,1 Purna Mukhopadhyay,2 Jeffrey Pearson,1 Ronald L. Pisoni,1 Kenneth J. Woodside.1 1 Univ of Michigan; 2 Arbor Research Collaborative for Health.

Background: AVF are considered the gold standard for HD vascular access, but require time to mature and may not adequately develop, resulting in prolonged central venous catheter (CVC) use. We describe AVF survival from placement until time to first use for prevalent HD patients in the US.

Methods: We examined HD patients with new AVF placements during 2013 using Medicare claims. Failure of maturation was identified by non-use following placement using CROWNWeb (CW) where patient access use is reported monthly by the facility. Patients were followed until end 2014. We assessed the relationship between patient characteristics and time-to-first-use of AVF with a Cox model.

Results: In 2013, 51,561 AVF were placed among 42,160 HD patients followed through 2014. No subsequent evidence of use occurred in 44.3% of the placements. Of successfully used AVF, median time to first use was 113 days. Older age groups were incrementally associated with lower probability of using AVF. Pts in the 0-21 and 22-44yr groups (HR=1.23 [95% CI=1.06-1.44], and 1.06 [1.03-1.11], respectively), were more likely to use AVF’s compared to the 45-64yr group (ref). Sex (Female; Fig. 1a), race (e.g., Black; Fig. 1b), comorbidity (cardiovascular disease, peripheral artery disease, diabetes, needing assistance or institutionalized status), vintage ≤1year, CVC and/or AV graft use at incidence, were also associated with lower probability of AVF use.

This region, present at baseline and 3 months is much deeper at 12 months and with increased dialysis blood flow rate of 450 mL/min.

Conclusions: In patients with BCF, as the AVF matures and with increased dialysis blood flow, an increase in diameter of the cephalic vein with subsequent decrease in BFV is observed. Increased blood flow during hemodialysis evokes recirculation eddy’s which may result in endothermal damage and subsequent intimal hyperplasia unless the arterialized vein is able to adapt and remodel to the pressures and flows that are generated during hemodialysis.

Elderly Age Does Not Affect Long-Term Survival of Non-Transposed and Transposed Upper Extremity Arteriovenous Fistulae

Neville R. Dossabhoy,1,2 Peter Van,1,2 Renu Gupta,1,2 Clifton Frilot,2 Nephrology, Veterans Affairs Medical Center, Shreveport, LA; 1LSU Health, Shreveport, LA.

Background: The Fistula First initiative has successfully increased the placement of arteriovenous fistulae (AVF) for vascular access. Some authors have suggested that there is a higher failure rate of AVF in elderly patients. The purpose of this study was to determine if elderly age influences the overall survival of transposed brachial-basilic fistulae (TBBF) and non-transposed AVFs (NT) placed in the upper extremity (UE).

Methods: Our prospective, computerized clinical database was queried retrospectively to identify the survival outcomes of all upper extremity (UE) fistulae placed in CKD and ESRD patients over a 6-year period at our VA hospital. All fistulae were placed by a single surgeon, hence eliminating inter-operator variability. Patient demographics and comorbid conditions were noted from the electronic record. The primary end point was permanent failure of the access. Kaplan Meier survival analysis was performed using SPSS.

Results: 230 UE fistulae were placed, which were categorized into two groups by patient age at the time of AVF placement: < 75 years and 75 years and older. The table shows the distribution by access type and age.

<table>
<thead>
<tr>
<th>Age</th>
<th>Type of AVF</th>

</tr>
</tbody>
</table>

The figure shows that there was no difference in the Kaplan-Meier survival curves for the two age groups when NT and TBBF were analyzed collectively (P=0.833). Furthermore, there was no statistical difference between the survival curves when each group above was analyzed separately (P=0.996).

Conclusions: In conclusion, overall survival was similar for TBBF and NT AVF in our study and was not influenced by elderly age. This finding is contrary to popular opinion and some other reports.

TH-PO863

Peripherally Inserted Central Catheter (PICC) Placement in Hemodialysis Patients with Central Venous Catheters (CVC)

Rita L. McGill, Robin Ruthazer, Klemens B. Meyer, Dana Miskulin, Daniel E. Weiner. Tufts Medical Center, Boston, MA.

Background: PICC insertion threatens opportunities for AVF creation and may reduce achievement of AVF. Accordingly, we evaluated the incidence of PICC placement in ESRD patients after starting dialysis and in the 2 years prior to starting dialysis, and recognizing that AVF rates are lower in women, whether PICC rates differed by sex.

Methods: After restricting to patients with pre-dialysis Medicare claims, we used CPT codes to ascertain all PICCs placed during the 2 years before HD initiation and up to 12/31/2012 in the subset of adult HD patients entering USRDS in 2010 or 2011 with CVC as sole vascular access. Accounting for censoring due to death and ESRD modality treatment change, and using Poisson regression to adjust for age, race, BMI, diabetes and peripheral vascular disease, we calculated sex-based incidence ratios (IRR) using PICC per 100,000 patient months.

Results: PICC were placed in 2437 (14.6%) of women and 2250 (12.2%) of men.

<table>
<thead>
<tr>

<td>567</td>
<td>532</td>
</tr>
<tr>
<td>PICC TOTAL</td>
<td>3988</td>
<td>3331</td>
</tr>
</tbody>
</table>

Compared to men, crude and adjusted IRR of PICC for female sex were 1.35 [1.28-1.41] and 1.34 [1.27-1.41]. Multiple PICC (range=2 to 14) were placed in 648/2260 (29%) men and 803/2437 (33%) women who had any PICC.

Conclusions: Despite persuasive indications for PICC avoidance, people dialyzing via CVC frequently receive one or more PICC before and even after starting dialysis. The PICC rate was 35% higher in women, a difference not attenuated by adjustment for demographic and clinical factors. More frequent PICC placement may explain some of the lower fistula rate in women. Eliminating frequent PICC placements in patients with CVC may improve achievement of AVF.

Arteriovenous Fistula Outcomes in an Elderly UK Population

Agnes Masengu,1,2 Jennifer B. Hanko,1 Alexander P. Maxwell,1,2 Regional Nephrology Unit, Belfast City Hospital, Belfast, County Antrim, United Kingdom; 3Nephrology Research Group, Queen’s Univ Belfast, Belfast, County Antrim, United Kingdom.

Background: The merit of placing arteriovenous fistulas (AVFs) in the elderly is debated in the literature. We sought to investigate AVF outcomes in the population aged ≥ 65 years in our region.

Methods: The Northern Ireland Vascular Access Database incorporates vascular access data on patients with chronic kidney disease stage 4 and 5. The database includes information on all patients ≥ 65 years who had an AVF created during January 2009-December 2014 and had a functional outcome by the 1st March 2015. Functional AVF patency was defined as sustained 2-needle use on haemodialysis for at least 6 sessions. Failure to mature (FTM) was defined by either clinical examination or failure to sustain 6 sessions of 2-needle dialysis.

Results: During the study period 344 patients ≥ 65 years had an AVF created. One AVF failed immediately, three AVFs were ligated due to steal, 56 patients had not started dialysis by the study end-point and records were incomplete for 50 patients. A total of 254 patients (98% White) remained included for functional AVF patency analysis. Table 1: Clinical Characteristics of Patients ≥ 65 years with AVF Patency Outcomes (n=254)

<td>134 (53)</td>
</tr>
</tbody>
</table>

A total of 150 AVFs (59%) achieved functional patency and 105 (41%) FTM. Binary logistic regression revealed that a lower arm AVF in this elderly population was associated with FTM (p < 0.001, OR 0.23, CI 0.13-0.40).

Conclusions: Given their shorter life-expectancy, the goal of vascular access creation in the elderly should be to create one functional AVF using the best vessels identified. The greater risk of FTM with lower arm AVFs may mean preferential creation of an upper arm AVF if these vessels are better on clinical and ultrasound assessment.

Type of Vascular Access and Mortality in Japan: Comparison of Arteriovenous Fistula and Arteriovenous Graft on Patient Survival and Access Patency in Non-Elderly versus Elderly Population

**Background:** The National Kidney Foundation (NKF) Kidney Disease Outcome Quality Initiative (KDOQI) guidelines have recommended the use of AVFs at dialysis initiation of dialysis. However, it has been reported that the dialysis environment has been significantly different between Japan and the United States, and there are few people who continue hemodialysis with CVCs in Japan. The aim of this study is to examine the association between type of vascular access at dialysis initiation and mortality in Japan.

**Methods:** This study is retrospective, multicenter, cohort study which data was collected by "Aichi Cohort study of Prognosis in Patients" (AICOPP) newly initiated into dialysis. 18 tertiary care centers in Japan participating in the "AICOPP". This study enrolled 1,525 patients who started maintenance dialysis between October 1, 2011 and March 31, 2014. After exclusion of 129 patients who started peritoneal dialysis or without data, 1396 (87.1%) patients were enrolled. Cox regression was used to determine the effect of access type on total mortality. Type of vascular access was divided into four categories: AVFs, AVGs, CVCs changed to AVF during the course (CAVF), CVCs changed to AVG during the course (CAVG).

**Results:** This research showed prevalence of type of blood access in Japan.

Under multivariate analysis, CAVGs had a higher risk of mortality compared with AVFs group [hazard ratio (HR): 2.408; p value: 0.003]. No significant differences were observed compared AVFs with AVGs [hazard ratio (HR): 1.466; p value: 0.219] and CAVFs [hazard ratio (HR): 1.223; p value: 0.389].

**Conclusions:** As it is known, high AVF use was seen in Japan. Compared with AVFs, using CVCs changed to AVG during the course is associated with higher risks of mortality.

comparison of arteriovenous fistula and arteriovenous graft on patient survival and access patency in non-elderly versus elderly population

**Background:** Arteriovenous fistula (AVF) is generally known to be the ideal option as a vascular access. However, this consensus can be challenging in elderly population.

**Methods:** From August in 2008 to April in 2014, 1452 adult incident hemodialysis patients were included from Clinical Research Center registry for ESRD prospective cohort, from 31 centers in the South Korea.

**Results:** In the whole population, AVF vs. AVG use was associated with the better patient survival only in male (p < 0.001) and DM (p = 0.004) patients. Multivariate Cox regression analysis showed AVG (vs. AVF; odds ratio [OR] 2.308, 95% confidence interval [CI]: 1.031–4.829; p = 0.026), catheter vs. AVG (OR: 0.658, 95% CI: 5.379–21.19; p < 0.001) and age (OR 1.035, 95% CI: 1.012–1.058; p = 0.003) were significantly associated with poor patient survival. In the elderly patients (≥ 65 years old), the survival benefit by AVF use also existed in only male (p < 0.001) and DM (p = 0.009) patients, but AVG compared with AVG showed better access patency only in female (p < 0.001) and DM (p = 0.001) patients. Multivariate Cox regression analysis in the elderly population showed AVG (vs. AVF; OR 3.158, 95% CI: 1.080–9.238; p = 0.036), male (vs. female; OR 3.941, 95% CI: 1.031–15.066; p = 0.045) and the presence of peripheral vascular disease (OR 4.659, 95% CI: 1.389–15.626; p = 0.013) were significantly associated with poor patient survival. AVF showed the survival benefit compared with AVG in the even septuagenarian patients (≥ 70 years old), which is contrast to the previous reports about western population (p = 0.01). However, the superior access patency of AVF in comparison with AVG began to decrease in post-septuagenarian population.

**Conclusions:** In the Korean septuagenarian patients, AVF placement can be considered because of its survival benefit. However, it seems appropriate that AVG is preferably placed in the septuagenarian patients with multiple comorbidities.

**Type of Vascular Access and Mortality in Japan:** Toshikazu Ozeki,1 Shin Minatoguchi,1 Yukako Ohyama,1 Hideaki Shimizu,1 Yoshiro Fujita,1 Daisuke Inaguma.1 1Nephrology, Chubu Rosai Hospital, Nagoya, Japan; 2Nephrology, Nagoya Daini Red Cross Hospital, Nagoya, Japan.

Dilator-Assisted Banding and Beyond: Proposing an Algorithm for Managing Dialysis Access-Associated Steal Syndrome

Showen Wang, AKDHC Access Centers, Arizona Kidney Disease and Hypertension Center; Phoenix, AZ.

Background: Dialysis Access-associated Steal Syndrome (DASS) is a major complication of arteriovenous dialysis accesses and its proper management is of critical clinical importance. However, the reported approaches are diverse and general consensus is lacking. Unilateral, guided banding approaches have gained popularity, as they are minimally invasive. This report analyzes the clinical outcome of Dilator-assisted Banding (DAB), a simple technique initially described by the author for managing DASS.

Methods: This series included 30 patients that underwent DAB for DASS due to excessive dialysis access flow. Results: Of the 30 patients: 29 had upper arm fistulas or grafts and 1 had a forearm fistula; 23 had arteriogram - 3 of which required angioplasty ± stent for feeding artery stenosis. The DAB procedures included: intraluminal DAB (12/30), extraluminal DAB (14/30) and open fistula reduction plus DAB (4/30). After DAB, the average severity scores of ischemic symptoms was reduced from 2.8 ± 0.4 to 0.2 ± 0.4 for the fistula group (n=24, p<0.001) and from 3.0 ± 0.0 to 1.2 ± 1.2 for the graft group (n=6, p=0.041). Of the 24 patients with fistula, 19 had resolution of ischemic symptoms and 5 had minimal residual symptoms while 3 had finger necrosis that healed after DAB. Of the 6 patients with graft, 2 had resolution, 2 had minimal residual and 2 had no change of ischemic symptoms. These two DAB-ineffective patients underwent proximalization of arterial inflow (PAI) revisions that resulted in resolution of ischemic symptoms. During follow-up of 18.7 ± 14.5 months (range 1-50), all dialysis accesses remained functional. At 24-month post-DAB, the primary patency, primary-assisted patency and secondary patency rates of the fistula group were 72%, 91% and 100%, respectively. Conclusions: DAB is a simple, effective and versatile approach for managing DASS due to excessiveflow, especially in patients with fistula. In patients with failed banding, PAI can be effectively used for rescue. Based on the data in this series and the literature, an algorithm is proposed for managing DASS.

Outcomes of Vascular Access Creation in Incident Hemodialysis Patients in Singapore

Nicholette Ghob,1 Chielh-suai Tan,2 Shaam Achudan,1 Yi liang Tan,1 Kian Guan Lee,1 Hui-Lin Chooong,2 Tze tce Chong,1 National Univ of Singapore; 1Renal Medicine, Singapore General Hospital; 2Vascular Surgery, Singapore General Hospital.

Background: Hemodialysis is the main modality of renal replacement therapy for end-stage renal disease (ESRD) patients in Singapore. Vascular access is critical for effective therapy. This study evaluated the impact of pre-operative vein mapping on vascular access creation in patients newly initiated on hemodialysis in Singapore General Hospital.

Methods: Data of ESRD patients initiated on hemodialysis from January 2010 to December 2012 were retrospectively collected from electronic medical records. 708 patients (mean 62.8 ± 12 years, 61% male, 71.3% Chinese) who underwent surgical creation of their first vascular access were followed up for a mean of 2.3 ± 1.2 years. Results: 694 (98%) arteriovenous fistulae (AVF) and 14 (2%) arteriovenous grafts (AVG) were created. Successful AVF cannulation was established in 543 patients (78.2%). After 1 year, 511 (73.6%) remained patent with 43.5% (302/694) primary and 30.1% (210/694) secondary patency. 23 had arteriogram - 3 of which required angioplasty (AV) and 30 (4.3%) secondary patency. Upper arm AVFs had significantly higher patency rates (85.0% ± 76.4% vs. 80.0% ± 66.5% in the lower arm, p = 0.011). Pre-operative vein mapping was performed in 42.5% (295/694) patients. The mean vein diameter was 2.44 ± 0.21mm. Maturation rates with and without vein mapping were 72.2% and 62.2% respectively (p = 0.001). Between vein diameters of <2 and ≥2mm, there was no statistical difference in maturation rates (p = 0.001). Of the 24 patients with fistula, 19 had resolution of ischemic symptoms and 5 had minimal residual symptoms while 3 had finger necrosis that healed after DAB. Of the 6 patients with graft, 2 had resolution, 2 had minimal residual and 2 had no change of ischemic symptoms. These two DAB-ineffective patients underwent proximalization of arterial inflow (PAI) revisions that resulted in resolution of ischemic symptoms. During follow-up of 18.7 ± 14.5 months (range 1-50), all dialysis accesses remained functional. At 24-month post-DAB, the primary patency, primary-assisted patency and secondary patency rates of the fistula group were 72%, 91% and 100%, respectively. Conclusions: DAB is a simple, effective and versatile approach for managing DASS due to excessiveflow, especially in patients with fistula. In patients with failed banding, PAI can be effectively used for rescue. Based on the data in this series and the literature, an algorithm is proposed for managing DASS.

Chlorhexidine-Impregnated Transparent Dressing for Prevention of Catheter-Related Bacteremia in Hemodialysis Patients: A Quality Improvement Study

Vandana Niyvar1, Thronike W. Apatan,1 John Hanfelt2,1Nephrology/ Internal Medicine, Emory Univ, Atlanta, GA; 2Rollins School of Public Health, Emory Univ, Atlanta, GA.

Background: CRBSI are a major cause of morbidity in HD patients dialyzing with a CVC. A major route of catheter contamination is introduction of organisms from the skin to the catheter. Tegaderm-CHG is a transparent catheter dressing with an integrated gel containing chlorhexidine, designed to combine the benefits of transparent dressings; and the antecedial and bacteriostatic benefits of chlorhexidine. We conducted a QI project to assess the rates of catheter-related bloodstream infection (CRBSI) in three dialysis units following the introduction of chlorhexidine-impregnated transparent catheter dressings.

Methods: Our study was conducted in two phases. In the first phase (9/12 through 10/13), we introduced the intervention, Tegaderm-CHG, to EDC, one of the three Emory hemodialysis units. EDGB and EDNS were the control sites where standard gauze catheter dressings were maintained. The rates of CRBSI at each dialysis units during the 12-month intervention were compared against the rates of CRBSI for the 12 month pre-intervention period. CRBSI rates were also compared between the dialysis units. The second phase of the study started in 11/2013, with the extension of Tegaderm-CHG dressing to EDGB and EDNS (the control sites in Phase 1). Tegaderm-CHG was maintained at EDC.

Results: The three dialysis units were comparable in terms of age, sex, and race of patients. In phase 1, the catheter infection rate (per 1,000 catheter days) in EDC decreased by 51% (pre: 1.69, post: 0.82). At EDGB, the infection rate increased by 12% (pre: 1.80; post: 2.02) while the infection rate increased by 35% (pre: 0.91; post: 1.23) at EDN. However, none of these increases in infection rates were significant (i.e., p > 0.05). The infection rates at EDGB and EDN decreased significantly in phase 2 by 86% (pre: 1.86; post: 0.26), and 53% (pre: 1.89; post: 0.88), respectively. At EDC, the catheter infection rate did not change significantly in phase 2.

Conclusions: The use of Tegaderm CHG dressing was associated with decreased rates of CRBSI in Emory outpatient dialysis units. In-Patient Permanent Access Is Associated with Reduced Catheter Time for Emergent Start Hemodialysis Patients Catherine A. Moore,1 Richard E. Wing,2 Scott E. Lieberman.1 1Medicine- Nephrology Div, Univ of Rochester; Rochester, NY; 2Aurora Medical Group, Marinette Menominee Clinic, Marinette, WI.

Background: Hemodialysis initiation with a tunneled catheter carries increased risk of morbidity and mortality. Conversion from a hemodialysis catheter to permanent access at any time is associated with improved outcomes. This study investigates whether a strategy of placing permanent dialysis access in incident HD patients without permanent access while still hospitalized is associated with reduced exposure to hemodialysis catheters.

Methods: We conducted a retrospective cohort study of ESRD patients initiating Hemodialysis with a catheter while hospitalized at a single University Hospital Medical Center from October 2010 through June 2013. Patients were divided into two groups: those with permanent access placed during the hospitalization (N = 22) vs. those discharged without permanent access (N = 67). Our primary endpoint was removal of the hemodialysis catheter.

Results: Subjects who underwent permanent access placement while still hospitalized had a median catheter exposure time of 114 days compared with 241 days for those who did not. The median time with HD catheter in place was shorter by 127 days in the Inpatient Access group. There was no significant difference in length of hospital stay or early access loss.

Conclusions: The practice of placing permanent access while the patient is still admitted to the hospital is associated with greater likelihood of hemodialysis catheter removal.

TH-PO874
Factors Affecting Haemodialysis Arterio-Venous Fistula Maturation Hannah R. Wilson, Salman Ahmed, Joseph Russell, Nicola Ding, Maggi Steele, Ayeshia Iritza-Ali, David Makanjuola, Nihil Chitalia. Renal Unit, St. Helier Hospital, Surrey, United Kingdom.

Background: Arterio-venous fistulae (AVF) are the preferred access for haemodialysis (HD). Many AVFs however, fail to mature. We investigated the factors affecting maturation of AVFs in order to identify any characteristics which were predictive of AVF maturation.

Methods: All AVFs created between 2006 and 2014 were reviewed. Data analysis was performed using GraphPad. AVFs were deemed to have failed to mature if by 90 days post-creation, it was not possible to use them for HD. The patients were divided into 2 groups – those who had the AVF created pre-emptively (group 1) and those already on HD at the time of AVF creation (group 2). Characteristics reviewed were age, gender, ethnicity, co-morbidity scores, diabetes status and ethnicity had no impact on AVF maturation rates.

Conclusions: The timing of AVF creation is important; those formed pre-emptively are more likely to mature than those created when the patient is on dialysis. It is possible that the presence of a dialysis line might delay maturation, especially if it is ipsilateral to the AVF. It highlights the importance of prompt referral to nephrology services so that AVFs can be created in a timely manner.

Hand Held Ultrasound Device Solves Vascular Access (VA) Cannulation Problems Beth Adams, Vivek Soi, Jerry Yee, Lalathaksha Murthy Kumar. Henry Ford Hospital, Detroit, MI.

Background: The Fistula First Catheter Last workgroup coalition identifies VA cannulation as a fundamental “failure” point in optimizing arteriovenous fistula (AVF) usage. Infiltration from cannulation difficulties result in significant morbidity including loss of VA and cost. Cannulation success is reliant on cannulators’ skill and VA characteristics. Surface marking of VA to aid cannulation is frequently used but lacks real time information. Traditional ultrasound devices are expensive and need skilled operators rendering inapt for routine use in hemodialysis units. Sonic Window© (Analogic Ultrasound) is a coronal mode ultrasound device (CMUD) approved for VA cannulation. We present our early experience using this novel hand held CMUD for real time guidance of VA cannulation.

Methods: Three patients with cannulation failure defined as inability to achieve 3 needle cannulations leading to tunnel cuffed catheter (TCC) removal were identified. AVF was evaluated initially for 1-2 dialysis sessions with CMUD for course, depth from skin, optimal site for cannulation, needle length and size. Infiltration rates, subsequent procedures and hospitalizations were noted before and after CMUD use and cannulation failure days (days from initial VA clearance for use to TCC removal).

Reaching First Dialysis Quickly and Unassisted with Sirolimus Treated Fistulae – Serial Ultrasound Results and Clinical Outcomes
Maria V. DeVita,1 Eric S. Chemla,2 Konstantine B. Kipiani,3 Nutsa K. Beridze,3 Srram Iyer,1 *Nephrology, Lenox Hill Hospital, New York, NY; 1Vascular Surgery, St. George’s NHS Foundation Trust, London, United Kingdom; 2Vascular Surgery, Georgian Center of Angiology and Surgery, Tbilisi, Georgia; 3Vascular Therapies Inc, Cresskill, NJ.

Background: Neointimal hyperplasia (NH) resulting in a flow limiting stenosis within the juxta-anastomotic segment (JAS) of an AV Fistula (AVF), impairs increase in upstream vein diameter (VD), often requires supplementary procedures and prolongs time to 1st cannulation for dialysis (D). Sirolimus delivered locally to the vessel wall can suppress NH and preserve lumen patency (“sirolimus effect”).

Methods: 30 pts (29 on D) undergoing AVF surgery [22 Radiocephalic (RCF), 8 Brachiocephalic fistulae (BCF)] received a Sirolimus eluting collagen implant at and around the JAS. 1st cannulation was based on clinical evaluation.

Results: 18 males, mean age 50.8y, 20% diabetic. Analysis excludes 4/22 RCF that thrombosed ≤2 weeks; 18/22 RCF (88%) and all 8 BCF maintained Primary Patency (PP) prior to 1st cannulation (mean 49 days); 13 AVF were cannulated ≤6wks, 74% AVF maintained suitability for D with PP at 12mns. Table shows serial Ultrasound results.

</table>

Conclusions: Maximum % increase in VD occurred within 8hrs of surgery with gradual continued increments thereafter. At 4, 6 and 8wks, VD of 6mm was attained by 62%, 81% and 100% of the AVF respectively. 3. 26/30 AVF(87%) maintained PP before 1st cannulation, time to 1st dialysis for 13 AVF(50%) was ≤6wks and at 12mos 75% were functional with PP. 4.Results signal a “sirolimus effect” and will be tested in an upcoming randomized trial.

TH-PO877

Economic Burden to Medicare of Central Venous Catheter (CVC)-Related Blood Stream Infections (BSI) and Occlusions Among Incident Hemodialysis (HD) Patients
Scott Sibbel,1 Steven M. Brunelli,1 Abigail Hunt,2 Wendy Turemne,1 Antony E. Paffie,2 *DaVita Clinical Research, Minneapolis, MN; 1CorMedix Inc, Bedminster, NJ.

Background: Episodes of CVC-related BSI and occlusion in HD patients result in hospitalizations and vascular access-related procedures, with attendant increases in costs. We sought to quantify this burden to the payor among Medicare-enrolled patients at a large dialysis organization.

Methods: Patients received HD via CVC during 2011 and were enrolled in Medicare Parts A and B. In parallel analyses, patients who developed BSI (N=1413) or occlusion (N=793) were matched with controls who did not, on the basis of entry month and incident/prevalent dialysis status. Outcomes were assessed from date of BSI/occlusion (or corresponding date for controls) for 6 months or until censoring for modality change, transfer of care, loss of Medicare benefits or death. Comparisons were made using linear mixed models including fixed effects for exposure status and month, adjusted for covariates that were imbalanced at baseline.

Results: CVC-related BSI was associated with greater rate of hospitalization (incidence rate difference [IRD], 1.07 events/patient [pt]-year) and vascular-related procedures (IRD, 2.87 events/pt-year). Mean per patient per month (PPPM) costs were $2850 higher for BSI patients versus controls, driven primarily by increased inpatient costs. CVC occlusion was associated with modestly greater rate of hospitalization (IRD, 0.29 events/pt-year), but substantively greater rate of ambulatory procedures (IRD, 4.00 events/pt-year). Mean PPPM costs were $2354 greater for occlusion patients versus controls, driven by higher ancillary service and procedure costs.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
There was no difference in AVF survival between the groups (DPP4-I: 45.5 ± 7.2 pg/ml, p = 0.03). Among other drugs, no correlation was indicated between AVF dysfunction with insulin, RAS blocker, other antihypertensive drugs nor antplatelet agents. 

Conclusions: DPP4-I did not show any advantage in AVF outcome despite anti-inflammatory effect of lowering serum IL-6 level.

TH-PO881 

Background: The purpose of this article is to report our experience with drug-eluting balloon(DEB) for the treatment of failing Arteriovenous Fistula(AVF). Mean life expectancy of the vascular access after the procedure, influence on adequate dialysis parameters postintervention and percentage of complications.

Methods: DEB procedures made in our hospital were evaluated. Main objective was to analyze: a)Reason of consulting and vascular lesion found. b)Haemodialytic arteriovenous shunt type. c)Kt/V, Qb, PV d)Survival of the vascular access at the end of the study e)Complications related to the procedure.

Results: 9 angioplasty were made by DEB. Mean age:74,6 years, 50% male. 5 left native radiocephalic fistula and 1 humero-axillary prosthetic.Most of the patients had at least 4 previous interventions. Principal reason of consultation was low flow,being the most frequent arterial stenosis. No complications were found related to any procedure. Every vascular access is permeable at the actual time, mean life since the intervention: 24 months, being necessary only one reintervention in the target lesion. Blood flow, venous pressure and Kt/V improvement regarding to the basal was observed, after the procedure and at the end of the study.

Conclusions: There is limited experience with the use of drug-eluting balloon in haemodialysis arteriovenous fistula, an increase in average life expectancy of the vascular access with bad prognosis ( led to a new vascular access) was found, an improvement on adequate dialysis parameters was observed, preserving vascular system of the patient, decreasing costs and with no complications. More studies would be needed.

TH-PO882 
Alteplase Infusion as Rescue Therapy for Central Venous Haemodialysis Catheter Dysfunction Sanjana Gupta, Stephen B. Walsh, Karlene Thomas,1 Ravindra Rajakariar.1 1Barts Health NHS Trust; 2UCL Centre for Nephrology.

Background: Central venous haemodialysis catheters (CVHC) can become occluded or have poor blood flow (Qb). CVHC complication estimates are 35% and result in hospitalisation and interventional procedures. This study aimed to review alteplase infusion success and patency rates.

Methods: We undertook a retrospective review of all patients that had an alteplase infusion at the Royal London Renal Unit over a 15-month period. Patients who had failed an alteplase lock and 4mg alteplase was used in both lumens. Data was collected using the renal database.

Results: Baseline characteristics were identical between 2 groups in age, sex, blood pressure, body mass index, history of congestive heart failure and coronary artery disease. There was no difference in AVF survival between the groups (DPP4-I: 45.5 ± 7.2 pg/ml, p = 0.03). Among other drugs, no correlation was indicated between AVF dysfunction with insulin, RAS blocker, other antihypertensive drugs nor antplatelet agents. 

Conclusions: DPP4-I did not show any advantage in AVF outcome despite anti-inflammatory effect of lowering serum IL-6 level.
Results: There are 1002 haemodialysis patients; 412 diastole via a CVHC.

- Total uses / total patients (n) 94 / 74
- Repeat Alteplase, same CVHC n (%) 20 (21)
- Median age of CVHC (IQR) 147 days (77 - 300)
- Indication (occlusion / Poor Qb) n 31 / 63

CVHC age was statistically different depending on the indication; occluded CVHC age was 124 ± 22 vs 244 ± 27 days for low Qb (P=0.01). Rescued CVHC age was significantly lower than those in whom the alteplase was unsuccessful (147 ± 18.4 vs 269 ± 35.8; P=0.004). In 48% of patients with an occluded CVHC, flow was restored; the remaining 52% required further intervention. Low Qb CVHC success rate was 60% compared to 38% requiring further intervention, 2% were removed (arteriovenous fistula or transplant). There was no significant difference between success rates depending on the indication (P=0.34).

Alteplase infusion significantly increased litres processed in subsequent dialysis sessions, in whom the indication was low Qb (6.2 ± 1.16 litres; P < 0.0001). All of infusions undertaken; 1 month patency was 56%, 3 months 45% and 6% removed. No patient had an adverse bleeding event as a result of the alteplase infusion.

Conclusions: Alteplase infusion use is common; approximately once a week in our centre. Interestingly, complete occlusion of CVHC occurs early, possibly suggesting rapid growth of fibrin following insertion. Total litres processed improves after an alteplase infusion in over half of patients. This study demonstrates the safety and success rates of an alteplase infusion, providing evidence for its role prior to replacing the CVHC and importance in saving resources.

Temporal Evolution of Parameters Before and After Initiation of Hemodialysis

Jochen G. Raimann, John W. Larkin, Carly Van Zandt, Len A. Usyniak, Jeroen Koornman, Frank van der Sande, Barbara Cannon, Chad Sowers, Mark Stuart, Terry Ketchersid, Dugan Maddux, Peter Kotanko, Franklin W. Maddux.

1 Renal Research Inst; 2 Fresenius Medical Care North America; 3Maastricht Univ Medical Center; 4Ichim School of Medicine at Mount Sinai.

Background: Little is known about the dynamics of clinical and laboratory parameters during the transition before pre-dialysis chronic kidney disease and end stage kidney disease (ESKD). The goal of our research was to explore the temporal evolution of albumin (Alb), systolic blood pressure (SBP) and serum sodium (SnA) by analyzing monthly data before and after hemodialysis (HD) initiation.

Methods: We analyzed all available data from the de-identified Fresenius Medical Care CKD Data Registry to understand progression of clinical and laboratory markers before and after HD initiation. Average values of Alb, SBP and SnA were compared for 12 months prior and after HD initiation using t-test. To estimate the trends of the average values, we fitted a linear regression function through monthly averages.

Results: We studied 136846 patients (64/14 years, 56% male) over 48 months. Average SBP increased prior to HD initiation (1.2 mmHg/year), immediately decreased following HD initiation, and remained lower for the following 12 months (142.4±22.8 vs 136.1±23.2 mmHg; P<0.05). Before starting HD, Alb was found to be relatively unchanged, however an increase was observed after HD initiation (average Alb increased by 0.14 g/dL per year, levels were slightly higher 12 months after HD initiation [3.7±0.5 vs 3.8±0.4 g/dL; P<0.05]). Average SnA pre-ESKD had a declining trend (-0.5 mEq/L per year) and was lower compared to slightly higher 12 months after HD initiation [3.7±0.5 vs 3.8±0.4 mEq/L; P<0.05].

Conclusion: This study demonstrates a trend toward improvement in SBP and Alb following HD initiation. The etiology of the SnA decrease after HD initiation requires further investigation.

Accelerated Arterial Stiffening in Vitamin-K-Antagonist Treated Hemodialysis Patients

Christian D. Peters, Krista D Kjaergaard, J. Dam Jensen, Bente Jespersen. Dept. of Renal Medicine, Aarhus Univ Hospital, Aarhus, Denmark.

Background: Many hemodialysis (HD) patients are treated with vitamin-K-antagonists (VKA) in order to prevent thromboembolic events. A potential side effect to VKA treatment is an increase in soft tissue calcification due to the inhibitory effect of VKAs on the central (liver) and peripheral (e.g. vascular) carboxylation cycle synthesis of several vitamin K-dependant calcification-inhibiting factors. The aim of the present study was to investigate the impact of VKA-treatment on arterial stiffness in a longitudinal, prospective comparative study.

Methods: Seventy-five HD patients from the SAFIR study with urine output >300 mL/day and HD-vintage <1 year were divided into controls (n=67) and VKA-treated (n=8) and followed for one year. The groups were well matched according to age, sex, comorbidity, and intervention (placebo/irbesartan). Arterial stiffness was assessed with carotid-femoral pulse wave velocity (PWV) and pulse wave analysis using the SphygmoCor device.

Results: Blood pressure (BP), PWV, and glomerular filtration rate (GFR) were similar at baseline (controls/VKA-treated) systolic BP: 148±20/145±17 mmHg; PWV: 11.6±3.2/11.0±3.9 m/s; GFR: 53±5.3 vs 51±1.7 m/min. Dialysis treatment and BP-medication were also similar. During follow up, GFR decreased similarly in both groups (P<0.02). There was no significant difference in BP between the two groups over time although BP tended to decrease more in the controls. PWV decreased in the controls -0.9(-1.4; -0.3) m/s; P<0.004 and increased in the VKA-treated 1.6(0.0; 3.2) m/s; P<0.005. Mean difference among 12 months between the groups (DPPWV) was: 2.5(0.7; 4.2) m/s; P<0.006. DPPWV was gained significant after adjustment for ∆GFR, ∆MAP, age at baseline, and ∆BP-medication: 2.2(0.4; 4.0) m/s; P<0.02. Mean differences among 12 months between the groups in heart rate adjusted augmentation index and time to pulse wave reflection were: 7(-2; 15) %; P=0.11, (14±27; 21±2) ms; P<0.03 (TR).

Conclusions: Our findings indicate that VKA-treatment increases arterial stiffening significantly. We speculate that vitamin K-dependant calcification-inhibiting factors in HD patients may be inadvertently affected by VKA treatment.

Different Impact of Malnutrition-Inflammation and Metabolic Syndrome on Long-Term Mortality and Cardiovascular Events in Hemodialysis Patients

Naoki Nakaawag. Renal Div, Dept of Internal Medicine, Asahikawa Medical Univ, Asahikawa, Hokkaido, Japan.

Background: Malnutrition syndrome confers an increased risk of cardiovascular disease (CVD) in the general population. The relationship between adipocytokines, and clinical outcomes in hemodialysis patients remains controversial. We investigated whether adipocytokines, biomarkers of inflammation, nutrition status and clinical features predict the mortality of hemodialysis patients for 6 years.

Methods: We measured baseline plasma total and high-molecular-weight (HMW) adipocytokines, tumor necrosis factor (TNF-α) serum high sensitivity C-reactive protein (hsCRP), and clinical characteristics including visceral fat area (VFA) and the Geriatric Nutritional Risk Index (GNRI) in 133 hemodialysis patients.

Results: During the 6-year follow-up period, 41 (30.9%) patients died (heart failure, n = 13; acute myocardial infarction, n = 11; stroke, n = 2; infection, n = 10; and malignant cancer, n = 5). The deceased patients were significantly older, had more prior CVD and diabetes, higher TNF-α and hsCRP levels but lower GNRI, VFA, and total and HMW adipocytokin did not significantly differ between the two groups. TNF-α and hsCRP levels and GNRI score were significant for predicting all-cause and cardiovascular mortality in receiver operating curve analyses. The present ROC curve analysis for all-cause 6-year mortality found the predictive value of GNRI for mortality was 96. When stratified by a GNRI score of 96, Cox proportional hazards analyses identified TNF-α as a significant predictor of all-cause mortality (hazard ratio [HR] 1.23, P = 0.038) and hsCRP as a significant predictor of all-cause and cardiovascular mortality (HR, 2.32, P = 0.003; HR, 2.30, P = 0.012, respectively) after adjusting for age, sex, diabetes mellitus, and prior CVD, only in malnourished patients.

Conclusions: These results demonstrate that malnutrition and the inflammatory markers TNF-α and hsCRP, but not metabolic markers, including VFA and adiponectins have a significant impact on 6-year all-cause and cardiovascular mortality in hemodialysis patients.

Funding: Government Support - Non-U.S.

Non-Traditional Risk Factors Predict Atherosclerotic Events in Haemodialysis Patients – Post-Hoc Analyses of the AURORA Trial

Marit D. Solha,1,2 Geir Møyen,3 Patrick B. Mark,1,4 Hallvard Holdaas,1 Bengt C. Fellstrom,1 Alan G. Jardine,1,4 Inn of Cardiovascular and Medical Sciences, Univ of Glasgow, Glasgow, United Kingdom; Section of Nephrology, Univ Hospital North Norway; Dept of Transplantation Medicine, Oslo Univ Hospital, Oslo, Norway; Renal and Transplant Unit, South Glasgow Univ Hospital, Glasgow, United Kingdom; Dept of Transplantation Medicine, Oslo Univ Hospital Rikshospitalet, Oslo, Norway; Div of Nephrology, Uppsala Univ Hospital, Uppsala, Sweden.

Background: Patients on haemodialysis are at high risk for cardiovascular events, but heart failure and sudden death dominate and atherosclerotic events are less common. The AURORA trial was designed to assess the effect of rosuvastatin on myocardial infarction and death from any cardiac cause in haemodialysis patients. We studied predictors of the atherosclerotic, and not all cardiovascular, events in AURORA.

Methods: We re adjudicated all deaths and presumed myocardial infarctions according to stricter criteria to separate atherosclerotic from non-atherosclerotic cardiovascular events. The re adjudicated atherosclerotic endpoint included non-fatal myocardial infarction, fatal coronary heart disease, non-fatal and fatal non-haemorrhagic stroke, revascularisation procedures and death from ischaemic limb disease. Baseline predictors were assessed for the 2776 participants of the AURORA trial, and step-wise Cox regression analysis was applied.

Results: During a mean follow-up of 3.2 years, 716 patients experienced a re adjudicated atherosclerotic event. Baseline phosphate (HR 1.33; 95% CI 1.16-1.53 per 1 mmol/L increase), albumin (HR 0.93; 95% CI 0.91-0.96 per 1 g/L increase) and high sensitive CRP (HR 1.07; 95% CI 1.00-1.14 per mg/L increase) were significant predictors in addition to female sex, age, prevalent diabetes and cardiovascular disease. LDL cholesterol was not a significant risk factor.

Conclusions: Even with the use of strict criteria for endpoint definition, non-traditional risk factors, but not lipid disturbances, predicted atherosclerotic events in haemodialysis patients.

Funding: Pharmaceutical Company Support - AstraZeneca, Government Support - Non-U.S.

Proteomic Studies of Blood Plasma Using 2DE and Mass Spectrometry for Deeper View into the Mechanisms Involved in Atherosclerosis in Chronic Kidney Disease

Maria Wanick-Kosowska,1 Dorota Formatowicz,2 Elzbietaw Pawlczak,1 Dept of Nephrology, Transplantology and Internal Medicine, Poznan Univ of Medical Sciences, Poznan, Poland; Dept of Clinical Biochemistry, Poznan Univ of Medical Sciences, Poznan, Poland.

Background: The exact participation and association of particular risk factors and specific mechanisms that promote cardiovascular complications (CVD) in patients with chronic kidney disease (CKD) remain unclear. The close relationship between CVD and CKD is most likely due to the co-existence of both traditional and novel risk factors. To gain insight into better recognition of the mechanisms of CKD-related accelerated atherosclerosis, a comparative proteomic analyses have been performed.

Methods: Blood samples were taken from 90 patients (CKD1-2, CKD3-4, CKD5), 30 patients with CVD, but without CKD and 30 healthy volunteers. Plasma samples were depleted using affinity chromatography and divided into three fractions: high-abundance protein, low-abundance protein and low molecular weight protein. The first two fractions were analyzed by two dimensional gel electrophoresis and mass spectrometry, the last one has been subjected to direct MS/MS analysis. Differential accumulated proteins were confirmed by selected reaction monitoring analysis.

Results: 49 proteins (13 high and 36 low molecular mass) showed differences in accumulation levels. The proteomic profiles in CKD5 and CVD patients differed in the accumulation of four LAPs the relative accumulations of alfa -2-macroglobulin, second isoform of alfa 1 microglobulin and higher in CKD5 compared with CVD; fold changes 1.77, 4.14, 2.68 and 1.79, respectively. Moreover, the relative abundances of these proteins were up-regulated in CKD3-4 compared with CVD. CKD1-2 and CVD group differed in the accumulation of apolipoprotein A-4 and apolipoprotein A-1.

Conclusions: Our results definitely indicated similar proteomic profiles in CKD1-2 and CVD patients, in contrast to CVD and CKD5 patients, suggesting that mechanisms of CVD acceleration may be different in initial and advanced stages of CKD. It seems that it is related to chronic inflammation and immune disturbances, typical for CKD.

Hemodialysis-Induced Release of Microparticles

Liina Vassal,1 Inga Soeveri,1 Fairzbot Mobarrez,2 Tora Almqvist,3 Bengt C. Fellstrom,3 Dept of Medical Sciences, Uppsala Univ, Uppsala, Sweden; Dept of Medicine, Karolinska Inst, Stockholm, Sweden; Dept of Clinical Sciences, Danderyd Hospital, Karolinska Inst, Stockholm, Sweden.

Background: Microparticles (MPs) are 0.1 - 1.0 μm vesicles that are released from cells upon activation or during apoptosis. MPs are believed to be involved in the pathophysiology of atherosclerosis and thrombosis. Patients with cardiovascular risk factors have significant MP elevation. Measurements of MPs may uncover new insight into mechanisms behind the severe increased cardiovascular disease (CVD) risk in hemodialysis (HD) patients.

The aim was to study whether a hemodialysis session affects MP formation and release.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

297A
**Methods:** Plasma samples from 20 HD patients were drawn before and 1 h after the start of HD session. MPs derived from platelets (CD41+), monocytes (CD14+), endothelial cells (CD31+), and their expression of phosphatidlyserine (PS) and tissue factor (CD142) were measured by flow cytometry. P-selectin (CD62P) and CD40 ligand (CD154) were measured on platelet-MPs. In addition, Klotho and the receptor for advanced glycation end products (RAGE) were measured on MPs. Paired t-test was used.

**Results:** Mean age was 73.6 years (range 54-91), 5 patients were female, 14 had central dialysis catheter, 8 patients had diabetes and 14 had CVD.

Mean ± (SD) or (Median) range

**Conclusions:** The majority of MP levels increase significantly after the start of a HD session. Whether this is driven by patient or dialysis specific factors remains unclear. The clinical significance of MP release during HD needs to be evaluated. *Funding:* Government Support - Non-U.S.

**TH-PO891**

The Monocyte Subset of CD14+CD16+ Cells Plays a Key Role in Promoting Atherosclerosis in Hemodialysis Patients

**Methods:** Subjects included 62 HD patients and 30 healthy controls. Peripherial monocytes were isolated using magnetically labeled Whole Blood CD14+ microbeads. Transcriptional levels of CD14 and CD16 in circulating monocytes play a key role in promoting foam cell formation by binding and internalizing oxidized low-density lipoprotein. In addition, heterogeneity of monocytes and macrophage- colony stimulating factor (M-CSF) may facilitate the atherosclerotic process by SR over-expression.

**Results:** The CD14+CD16+ monocytes were expressed higher in HD patients than in those from controls (2.35 vs 1.29, p=0.0006). Moreover, it was higher in HD patients with CVD than in those without (2.79 vs 1.64, p=0.0023). Plasma concentration of M-CSF was measured with M-CSF ELISA kit. Additionally, CD16 protein expression was analyzed by a flow cytometry.

**Conclusions:** The CD14+CD16+ monocytes play a key role in promoting atherosclerosis in hemodialysis patients.

**TH-PO892**

Active Ghrelin Enhances the Association Between BMI and Clinical Outcome in Hemodialysis Patients Irrespective of Appetite Ilia Beberenvishev, Inna Sinutin, Ada Azar, Leonid Feldman, Shai Efrati. 1Nephrology, Assaf Harofeh Medical Center, Israel; 2Nutrition, Assaf Harofeh Medical Center, Zerifin, Israel; 3Nutrition, Assaf Harofeh Medical Center, Zerifin, Israel.

**Background:** Ghrelin, a gastric orexigenic peptide, and BMI are known as inversely associated with left ventricular hypertrophy and dysfunction, and may predict cardiovascular mortality in end-stage renal disease (ESRD) patients. This study was to evaluate the association of predialysis serum ghrelin levels with echocardiographic markers in ESRD patients.

**Methods:** Serum ghrelin, albumin, CRP, iPTH levels were obtained from predialysis blood samples at 123 incident HD patients. Echocardiographic parameters and left ventricular mass index (LVMI) and ejection fraction, ratio of peak early transmural flow velocity to peak early diastolic annular flow velocity (E/E’ ratio), ratio of peak early transmitral flow velocity to peak late transmitral flow velocity (E/A ratio), and mitral valve-deceleration time (DT).

**Results:** A direct correlation was found between PICP and Left ventricular mass index (r=0.308, P=0.002), between PICP and E/E’ ratio (r=0.236, P=0.009), between PICP and ratio of peak early transmural flow velocity to peak late transmural flow velocity (E/A) (r=0.285, P=0.002). A negative correlation was found between PICP and Left ventricular ejection fraction (r=−0.289, P=0.001), between PICP and mitral valve-deceleration time (r=−0.203, P=0.026). In the multivariate linear regression analysis, the PICP was independently positively associated with LVMI and E’ and negatively associated with Left ventricular ejection fraction. In the multivariate Cox regression analysis, previous CV event (HR 15.224, CI 3.26-71.04), and High PICP group (vs low PICP group) (HR 9.478, CI 1.10-81.82) were the significant prognostic factors cardiovascular event.

**Conclusions:** Serum predialysis ghrelin concentration is associated with left ventricular hypertrophy and dysfunction, and may predict cardiovascular event in incidential dialysis patient.

**TH-PO894**

Associations of Soluble Receptor for Advanced Glycation End Products with Cardiovascular Biomarkers and S100A12 (EN-RAGE) with Mortality in Long-Term Hemodialysis Patients Jun Yung Jung, Eul Sik Jung, Byoungcho Choi, Yun Jung Oh, Chungsik Lee, Ae Jin Kim, Han Ro, Jae Hyun Chang, Hyun Hee Lee, Wookyung Chung. 1Dept of Nephrology, Dept of Internal Medicine, Gachon Univ Gil Medical Center, Incheon, Republic of Korea; 2Dept of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea.

**Background:** Hemodialysis (HD) patients have been associated with vascular calcification and ultimately with high mortality rates. Formerly, we reported association of soluble receptor for advanced glycation end products (s-RAGE) and S100A12 (EN-RAGE) with mortality in end-stage renal disease (ESRD) patients. This study was to examine whether those biomarkers could be proposed for predicting cardiovascular morbidity and mortality in these subjects.

**Methods:** This is a prospective observational cohort study in 199 HD patients from extended analyses of our previous study. Serum S-RAGE, S100A12, comorbiddity, and other traditional risk factors were also investigated. The cumulative incidences for death using Cox proportional-hazards regression were evaluated in multivariable analyses. A mean observation period was 29 months.

**Results:** The patients were 57±14.3 years of age, 54.3% were male, 49.2% were diabetic, and 36.2% had a history of cardiovascular disease. During the observation period, 27 patients (13.6%) were died. Univariate analysis demonstrated that S100A12 was correlated with diabetes (P=0.04) and hs-CRP (P=0.01). In multivariable analyses, serum s-RAGE (HR [hazard ratio], 1.16; 95% CI [confidence interval], 0.61-2.19; P=0.65) and S100A12 (HR 1.05; 95% CI, 0.62-1.77; P=0.87) were not associated with mortality in hemodialysis patients, though traditional predictors for mortality including age, history of cardiovascular diseases, serum albumin and serum high-sensitivity C reactive protein (hs-CRP) were related to mortality. Powerful predictors for mortality were age, previous cardiovascular disease and serum albumin level.

**Conclusions:** Serum S-RAGE and S100A12 may be weak surrogate markers to predict all-cause mortality in patients receiving hemodialysis, even though S100A12 was partly related with diabetes and inflammation.
Impact of Sodium-Dependent Phosphate Co-Transport, Pit-1, in Peripheral Blood Mononuclear Cells on Cardiac Calcification in Maintenance Hemodialysis Patients: Minwen Ding, Mengjing Wang, Minmin Zhang, Jing Chen, Huashan Hospital, Fudan Univ.

Background: Vascular calcification (VC) is an important risk factor for cardiovascular disease in MHD patients, however, the mechanisms of which are still under investigation. The aims of this study were to explore the risk factors of VC in MHD patients, and to identify the expression of sodium-dependent phosphate co-transporter (Npt) in peripheral blood mononuclear cells (PBMCs) and assess its association with cardiac calcification and its possible impact factors.

Methods: This was a cross-sectional analysis of adult MHD patients who received at least 6-month regular MHD in our dialysis center. The coronary artery calcification (CAC) was measured by cardiac MSCT. The gene expression of Npt in PBMCs was measured by Real-time PCR and we tested serum TNF-α and IL-6 by ELISA. Multivariate logistic analysis was used to determine the risk factors of CAC. Correlation between the gene expression of Npt and other parameters was examined by Pearson's correlation analysis.

Results: 1,681 eligible patients were enrolled. 2. Three kinds of Npts were detected in PBMCs of MHD patients. They were type I Npt, Npt2b, type III Npt, Pit-1 and Pit-2, among which Pit-1 mRNA expression was significantly associated with extent of CAC. 3. The results of the logistic regression analysis were listed in Table 1. 4. Pearson's correlation analysis showed Pit-1 mRNA expression of PBMCs was significantly correlated with serum phosphorus (r=0.43, P<0.002), CAC score (r=0.63, P<0.001) and Pit-2 mRNA expression of PBMCs (r=0.53, P<0.001).

Table 1. Multiple logistic regression analysis of factors associated with CAC score tertile in MHD patients

Conclusions: Our result showed that longer dialysis vintage, diabetes, higher concentration of serum TNF-α and Pit-1 mRNA expression of PBMCs are the risk factors of CAC in MHD patients. Pit-1 mRNA expression of PBMCs was significantly correlated with serum phosphorus, CAC score and Pit-2 mRNA expression of PBMCs.

TH-PO898

HDL Subfractions in End-Stage Renal Disease (ESRD) Patients: Anna Gliba-Brozeka, Beata Franzczyk-Skora, Jacke Ryta, Dept of Nephrology, Hypertension and Family Medicine, Medical Univ of Lodz, Poland.

Background: Chronic kidney disease is a common disease associated with high cardiovascular risk. Recent studies have suggested that HDL not LDL may play the more important role in the progression of atherosclerosis in CKD patients. HDL from CKD patients was shown to become dysfunctional, lose its vasoprotective properties and begin to promote endothelial dysfunction and inflammation.

Methods: The aim of this study was to investigate the subfractions of HDL in ESRD patients, which is the first study investigating this phenomenon in dialysis patients. To our knowledge, this study included 50 ESRD patients (16 women, 34 men) on dialysis (WAM University Hospital, Lodz, Poland) and 20 healthy volunteers (14 women, 6 men). Blood samples were collected from all subjects and HDL subfractions were analyzed with the use of Lipoprint system. Moreover, all patients had IMT measured.

Results: This study revealed statistically significant differences in HDL subfractions between control and study group: HDL1 [5.6 (2.0-7.1) vs. 13.0 (8.2-15.8), P<0.0001], HDL2 [13.1 (3.5-14.9) vs. 15.2 (2.1-40.0), P=0.006], HDL3 [5.5 (0.8-8.6) vs. 9.4 (7.8-11.3), P<0.0001], HDL4 [8.5 (0.10-4.0) vs. 10.6 (9.5-12.0), P=0.003], HDL5 [9.2 (3.3-10.5) vs. 11.4 (9.9-12.1), P=0.01], HDL7 [7.6 (7.2-8.4) vs. 5.3 (4.2-7.2), P<0.0001], HDL8 [8.7 (8.0-9.5) vs. 4.8 (3.5-5.8), P<0.0001], HDL9 [7.0 (5.9-8.2) vs. 3.8 (3.0-4.8), P<0.0001], HDL10 [7.0 (6.2-8.7) vs. 4.3 (2.6-7.1), P=0.001] and large HDL [26.5 (17.5-29.2) vs. 40.3 (33.0-47.0), P<0.0001] and HDL Small [30.8 (22.3-43.2) vs. 12.8 (9.4-17.9), P<0.0001]. Significant differences were also observed in HDL7 [9.3 (6.6-12.9) vs. 13.4 (8.7-16.9), P=0.014], HDL6 [20.2 (18.0-23.2) vs. 17.6 (15.2-20.1), P=0.020], HDL Large [35.0 (23.7-56.8) vs. 41.4 (33.6-48.0), P=0.007] and HDL Medium [35.0 (22.2-51.7) vs. 45.8 (40.9-49.1), P=0.017] between HD patients with INT > 0.9 mm and < 0.9 mm.

Conclusions: This study revealed that ESRD influences HDL subfractions. Subfractions of large HDL are more abundant in patients with ESRD while small HDL fraction is more frequent in healthy persons. It is possible that the shift in HDL subfractions may be responsible for the increased risk of atherosclerosis in CKD patients.

TH-PO897

High Non-HDL Cholesterol as an Independent Risk Factor for Coronary Restenosis in Hemodialysis Patients Undergoing Percutaneous Coronary Interventions: Shoko Hasegawa, Toshiaki Nakano, Yasushi Mukai, Yuta Matsukuma, Ryusuke Yotsueda, Akiohiro Fujimoto, Kichiro Fujisaki, Kazuhiko Tsuruya, Takamaki Kitanazato, Department of Medicine and Clinical Science, Kyushu Univ Graduate School of Medical Sciences, Fukuoka, Japan; Dept of Cardiovascular Medicine, Kyushu Univ Graduate School of Medical Sciences, Fukuoka, Japan; Dept of Integrated Therapy for Chronic Kidney Disease, Kyushu Univ Graduate School of Medical Sciences, Fukuoka, Japan.

Background: It has been reported that patients with end-stage kidney disease (ESKD) have a higher risk of restenosis after percutaneous coronary intervention (PCI). The aim of this study was to investigate the risk factors of restenosis after PCI in hemodialysis (HD) patients.

Methods: From January 2007 to December 2014, we enrolled 54 consecutive ESKD patients undergoing HD (mean age: 66.5 +/- 10.1 years; 15 women, 39 men; mean HD duration: 3.7 years), who received PCI and follow-up coronary angiography (CAG) after about 6 months. The coronary restenosis was defined by the patient having target lesion revascularization on follow-up CAG.

Results: Of 54 patients who had received PCI, restenosis occurred in 22 patients (40.7%) within 5-12 months after PCI. In the univariable logistic analysis, serum levels of low-density lipoprotein cholesterol/high-density lipoprotein cholesterol ratio, serum levels of non-high-density lipoprotein cholesterol (non-HDL-C), and history of major adverse cardiovascular events (MACE) were significantly associated with the occurrence of coronary restenosis; odds ratio (OR) [95% confidence interval (CI)] was 1.89 [1.02-3.50], 8.7 [4.8-16.9], and 5.0 [2.9-8.7], respectively. In the multivariable logistic analysis, non-HDL-C and the history of MACE were significantly associated with the coronary restenosis; OR [95% CI] was 1.35 [1.08-1.69]/per 10 mg/dl increase in non-HDL-C) and 8.55 [1.38-8.85], respectively.

Conclusions: Non-HDL-C was an independent risk factor for the occurrence of coronary restenosis in HD patients undergoing PCI. This result suggests the significance and necessity of strict management of lipid metabolism after PCI in even HD patients.

Galectin-3 Does Not Correlate within Markers of Cardiac Structure and Function on Cardiac MRI: A Study in Haemodialysis Patients

Estrella.

Galectin-3 does not have a role in risk stratification of this patient group. Our results suggest that LVMI (r=-0.22 p=0.24), LVEF (r=0.08 p=0.65) or LVEDV (r=0.012 p=0.94). The previously diastolic volume 143.4ml was only associated with unintentional weight loss (OR=0.93; 95%CI: 0.88-0.98). FGF23 was only associated with self-reported exhaustion (OR=0.54, 95%CI: 0.30-0.95) while higher sKlotho was associated with lower odds of frailty (Table).

Methods: We conducted a cross-sectional study of incident HD patients enrolled in the Predictors of Arrhythmic and Cardiovascular Events (PACE) Study. Multivariable logistic regression models were used to estimate the association of S-Klotho and FGF23 with odds of frailty and frailty subcomponents.

Results: Of 336 individuals, 71% were black; 59% were male. Mean age was 55y. All had hypertension and 56% had diabetes, 38% CAD, and 37% obesity. Median sKlotho level was 364.4 pg/ml (IQR 272.5-494.6); mean FGF23 level was 656.2 U/ml (SD: 498). 40% of participants were frail. Adjusting for demographic factors, obesity, Charlson Comorbidity Index, hsCRP, serum albumin and Kt/V, higher sKlotho was associated with lower odds of frailty (Table). FGF23 did not predict arterial stiffness in dialysis-dependent CKD patients.

Conclusions: In this prospective cohort study, FGF23 did not predict arterial stiffness beyond known risk factors of age, mean arterial pressure, heart rate and the presence of diabetes. Our findings suggest that the excess cardiovascular mortality observed with elevated FGF23 in CKD is not primarily driven by effects on arterial stiffening.

FGF23 Is Not Associated with Arterial Stiffness in Patients with CKDSD

Kenneth J. Lim, Stephen M. Ting, Daniel Zehnder, Thomas F. Hiemstra, Stephen M.S. Ting, Tessa Kimberly Novick, Lucy A. Mecon, Stephen M. Sozio, Bernard G. Jaar, Larisa Tereschenko, Rulan S. Parekh, Michelle M. Estrella, Albert Einstein College of Medicine; Univ of Toronto; Johns Hopkins Univ; Univ of Oregon.

Background: Arterial stiffening is thought to be a key determinant of excess cardiovascular mortality in CKD patients. In CKD, the bone-derived phosphatonin fibroblast growth factor (FGF) 23 is elevated and has been implicated in the development of Cardiovascular disease. In this study, we sought to determine whether FGF23 is a predictor of arterial stiffness in dialysis-dependent CKD patients.

Methods: In this cross-sectional study, we enrolled 352 patients with advanced CKD and 150 healthy controls. Pulse wave velocity (PWV) was recorded by application tonometry, and blood pressure and biochemical parameters including plasma intact-FGF23 concentrations determined.

Results: Patients with CKD were significantly younger than controls (46±14 versus 49±11 years, p=0.02), had a higher blood pressure (MAP 97±14 vs 94±10 mmHg, p=0.003), and were more likely to be male (61% versus 49%, p=0.008). CKD patients had significantly higher FGF23 (605 pg/ml, IQR 112-1772 vs 40 pg/ml, IQR 33-49, p<0.001) and parathyroid hormone (25 pmol/L, IQR 13-56 versus 3.8 pmol/L, IQR 3.5-5.0 pmol/L, p<0.001). PWV was elevated in patients with CKD (8 ms/msec, IQR 6.9-9.6 vs 7.3 msec/m, IQR 6.6-8.4, p<0.0002). In a regression model adjusted for known predictors of PWV, FGF23 did not predict PWV (p=0.15, p=0.063), but was positively associated with the presence of CKD (p=0.009), age (p=0.001), mean arterial pressure (p=0.001) and heart rate (p=0.001).

Conclusions: In this prospective cohort study, FGF23 did not predict arterial stiffening beyond known risk factors of age, mean arterial pressure, heart rate and the presence of diabetes. Our findings suggest that the excess cardiovascular mortality observed with elevated FGF23 in CKD is not primarily driven by effects on arterial stiffening.

TH-PO900

Association of Klotho and FGF23 with Frailty in Patients Initiating Hemodialysis

Sahar T. Aghoghodaro, Lucy A. Mecon, Rulan S. Parekh, Michelle M. Estrella, Johns Hopkins; Univ of Toronto; Univ of Oregon.

Background: Frailty at dialysis initiation is associated with higher mortality. Both FGF23 and its co-receptor, klotho, have been implicated in the development of frailty. We aimed to evaluate the independent association of FGF23 and soluble klotho (sKlotho) with frailty in hemodialysis (HD) patients.

Methods: We conducted a cross-sectional study of incident HD patients enrolled in the Predictors of Arrhythmic and Cardiovascular Events in ESRD (PACE) Study. Frailty was defined by 3 of the following: unintentional weight loss >10 lbs in prior year, self-reported exhaustion, weakness (by hand grip strength), slowness (by walking distance) and self-reported low physical activity. Logistic regression was used to examine the associations of sKlotho and FGF23 with odds of frailty and frailty subcomponents.

Results: Of 336 participants, 71% were black; 59% were male. Mean age was 55y. All had hypertension and 56% had diabetes, 38% CAD, and 37% obesity. Median sKlotho level was 364.4 pg/ml (IQR 272.5-494.6); mean FGF23 level was 656.2 U/ml (SD: 498). 40% of participants were frail. Adjusting for demographic factors, obesity, Charlson Comorbidity Index, hsCRP, serum albumin and Kt/V, higher sKlotho was associated with lower odds of frailty (Table). TH-PO902

Differential Association of Fibroblast Growth Factor-23 and Soluble Klotho with Left Ventricular Hypertrophy

Tanya S. Johns, Esther D. Kim, Tessa Kimberly Novick, Lucy A. Mecon, Stephen M. Sozio, Bernard G. Jaar, Larisa Tereschenko, Rulan S. Parekh, Michelle M. Estrella, Albert Einstein College of Medicine; Univ of Toronto; Johns Hopkins Univ; Univ of Oregon.

Background: Fibroblast growth factor-23 (FGF23), a phosphaturic hormone, has been implicated in the pathogenesis of left ventricular hypertrophy (LVH) among patients with chronic kidney disease. Whether FGF23’s co-receptor, klotho, is independently associated with LVH is unclear.

Methods: To determine whether soluble klotho (sKlotho) is independently associated with LVH among incident hemodialysis patients, we conducted a cross-sectional study among participants who underwent baseline 2D echocardiograms in the Predictors of Arrhythmia and Cardiovascular Events (PACE) Study. Multivariable logistic regression models with FGF23, sKlotho, and both as primary predictors were constructed to estimate the odds of LVH (defined as LV mass index >116 g/m² in men and >104 g/m² in women).

Results: Of 391 participants who underwent echocardiogram, 371 and 387 had sKlotho and FGF23 levels available, respectively; 72% had LVH. Mean age was 54 years and 72% were black. All participants had hypertension with mean systolic BP 154 mm Hg. Median volume removed per HD session was 2.6L. (IQR: 1.6 – 3.7). FGF23 was not associated with LVH after adjusting for age, race, gender, BMI, systolic BP, serum albumin level, and ultrafiltration volume. In contrast, higher sKlotho was independently associated with lower odds of LVH (OR=0.51 per 1 log higher; 95% CI=0.28-0.96); this association remained robust with additional adjustment for FGF23 and Charlson Co-Morbidity Index.

Conclusions: sKlotho, not FGF23, is associated with a lower odds of LVH among incident hemodialysis patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only. Underline represents presenting author.

TH-PO903
Predictors of Arterial Stiffness in Incident Hemodialysis Patients
Stephanie M. Toth-Manikowski,1 Esther D. Kim,2 Lucy A. Meoni,3 Bernard G. Jaar,4 Tariq Shafi,1 Michelle M. Estrella,1 Rulan S. Parekh,4,7 Stephen M. Sozio,5 1Johns Hopkins Univ; 2Univ of Toronto.

Background: Premature vascular aging and arterial stiffening characterize CKD progression to ESRD and are associated with increased cardiovascular (CVD) morbidity and mortality. We identified predictors of arterial stiffness over time in HD patients.

Methods: In 339 incident HD patients in the Predictors of Arthrythmic and Cardiovascular Risk in ESRD (PACE) study, we examined the associations of baseline age, sex, race, comorbidities, CVD medications, and dialysis characteristics with longitudinal vascular stiffness measured by carotid-femoral pulse wave velocity (PWV) using generalized estimating equations. Annual change in PWV for up to 3 years was analyzed using linear regression.

Results: Mean age was 54, 58% male, 74% African-American, mean (SD) baseline PWV 10.7 (3.4) m/s, and annual PWV change 0.2 (2.6) m/s. Several factors were associated with higher PWV in univariate and multivariate longitudinal models. None were associated with PWV change.

| Table: TH-PO903 Predictors of Arterial Stiffness in Incident Hemodialysis Patients |
|--------------------------|--------------------------|
| Demographics             |                          |
| Age (10y)                 | 1.03 (0.81-1.24)         |
| Female                   | -0.35 (-1.03-0.32)       |
| African-American         | -0.62 (-1.39-0.14)       |
| Comorbidities            |                          |
| Diabetes                 | 2.62 (2.00-3.24)         |
| Coronary Disease         | 0.87 (0.71-1.56)         |
| Congestive Heart Failure  | 0.93 (0.26-1.60)         |
| LV Mass Index            | -0.03 (-1.03-0.04)       |
| Tobacco Use              | -0.51 (-1.18-0.17)       |
| Medications              |                          |
| Renin-Angiotensin Inhibitor | -0.01 (-0.70-0.67)     |
| Beta Blocker             | 0.83 (0.16-1.51)         |
| Clinical Characteristics  |                          |
| Pulse Pressure (10mmHg)  | 1.12 (0.88-1.37)         |
| Phosphorus (mg/dL)       | -0.24 (-0.57-0.10)       |
| iPTh (mg/dL)             | -0.01 (-0.02-0.00)       |
| Albumin (mg/dL)          | -0.38 (-1.11-0.34)       |

P-values: <0.001, <0.01, <0.05, <0.1, ns = not significant

Conclusions: Although PWV did not change significantly over time in incident HD patients, age, male sex, diabetes, and pulse pressure were independently associated with higher PWV. It may be difficult to modify PWV after HD initiation and clinical factors should be optimized prior to starting HD.

TH-PO904
Differences in Risk Factors for Coronary Artery Calcification Between Non-diabetic and Diabetic Hemodialysis Patients
Yoshiko Nishizawa,1 Sonoo Mizui,2 Kyoka Ono,1 Mariko Asai,1 Kazunori Yamashita,1 Kenichiro Shigemoto,1 Kohji Usui,1 Michiko Arita,1 Kiyoshi Fujita,1 Takao Masaki,1 1Div of Nephrology, Ichikyoi Harada Hospital, Hiroshima city, Japan; 2Ichiyokai Ichiyokai Clinic, Hiroshima city, Japan; 3Ichiyokai Ichiyokai Clinic, Hiroshima city, Japan; 4Ichiyokai Yokogawa Clinic, Hiroshima city, Japan; 5Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima city, Japan.

Background: The differences in risk factors for coronary artery calcification between nondiabetic and diabetic hemodialysis (HD) patients have not been fully explored.

Methods: We examined Agatston coronary artery calcium score (CACS) using MDCT, age, sex, presence of diabetes, dialysis vintage, smoking history, administration of phosphorus binders, geriatric nutritional risk index (GNRI), HbA1c, serum calcium, phosphate, iPTh, CRP, B2MG, LDL-cholesterol and triglyceride (TG) in 355 HD patients: 242 nondiabetics and 113 diabetics. Factors related to CACS were assessed by multivariate regression analysis using all of the above independent variables. Differences in the above parameters according to quartile (Q) of CACS were also assessed.

Results: Mean age (years), dialysis vintage (months), CACS (H) and serum phosphate (mg/dL) were 63.14 vs. 66.1 ± 12 (ns), 125.1 ± 100 vs. 133.5 ± 50 months (P<0.01), 1651 ± 2177 vs. 2177 ± 2533 (P<0.05), and 5.3 ± 1.3 vs. 5.0 ± 1.4 mg/dL in nondiabetics and diabetics, respectively. Patients with CACS Q4 showed higher prevalence of diabetes (40 vs. 19%), age (68.12 vs. 58.14 years), and CRP (0.7 ± 1.3 vs. 0.2 ± 0.4 mg/dl), but lower iPTh (1461 ± 133 vs. 193 ± 131 mg/dL) levels than patients with CACS Q1 (P<0.05), and other parameters were not significantly different except HbA1c. Significant associations were observed between CACS and age (P<0.001, β: 0.21), female (P<0.001, β: -0.21), dialysis vintage (P<0.001, β: 0.31), CRP (P<0.05, β: 0.16), TG (P<0.05, β: 0.13) in nondiabetics. However, CACS was significantly associated only with age (P<0.05, β: 0.30) and HbA1c (P<0.05, β: 0.26) in diabetics.

Conclusions: Risk factors for coronary artery calcification differ between nondiabetic and diabetic HD patients, and poor glycemic control is the major factor in the latter.

TH-PO905
Hemodialysis and Hemodilatation Improve Serum Calcium Propensity
Marijke J.E. Dekker,1 Andreas Pasch,2 Frank van der Sande,1 Constantijn Konings,2 Matthias Bachtl,1 Mauro Dionisi,3 Jeroen Kooman,1 Bernard J. Cauana,4 1Maastricht Univ Medical Center; 2Catharina Hospital Eindhoven; 3Univ Hospital Bern; 4Calcisco AG; 5Fresenius Medical Care.

Background: Calciprotein particles (CPPs) may play an important role in the calcification process. The calcification propensity of serum (Tc) is highly predictive of all-cause mortality in chronic kidney disease patients. Whether Tc is therapeutically improvable, by hemodialysis (HD) or even further by hemodilatation (HD), has not been studied yet.

Methods: We designed a cross-sectional single center study, and included prevalent patients on HD or HDF. Patients were divided into two groups based on dialysis modality. We included patients on a thrice-weekly schedule, with a dialysis vintage of >3 months and vascular access providing a blood flow rate of >300 ml/min. Calcium propensitity of serum was measured by the time of transformation from primary to secondary CPP (Tc, min), by time-resolved nephelometry.

Results: In total 64 patients were included and, Tc was measured in 376 pre- and post-dialysis samples of all-in-center dialysis sessions during one week. Tc levels improved in both the HD and HDF group with pre- and post-dialysis (mean (SD)) of 244±6(301±57) and 253±55(304±61) min respectively (P=0.43). The mean improvement of Tc was 26.29% in the HD group and 21.97% in the HDF group (P=0.61). The delta values (A) of calcium, phosphate (P) and albumin were equal in both groups. The DTA was mostly influenced by DP (P=0.280; P=0.01 HD and r=0.259; P=0.02 HDF).

Conclusions: HD and HDF patients present with same baseline vascular calcification risk values pre-dialysis. Calcification propensity is significantly improved during both HD and HDF. Tc should be a useful guide to optimize renal replacement strategy to improve the individual calcification risk in dialysis patients.

Association of Circulating Biomarkers with Vascular Stiffness and Coronary Artery Calcium in Incident Hemodialysis
Esther D. Kim,1 Stephen M. Sozio,2 Bernard G. Jaar,3 Lucy A. Meoni,2 Michelle M. Estrella,1 Rulan S. Parekh.1 1Univ of Toronto, Canada; 2Johns Hopkins Univ.

Background: Vascular calcification and stiffness are associated with higher mortality in hemodialysis. Studies examining the role of circulating biomarkers – specifically, FGF23, desphospho-uncarboxylated matrix GlA protein (dpuGMPI, Fetuin A, osteoprotegerin (OPG), and C-reactive protein (CRP) – in vascular calcification have reported contradictory findings, and the independent association of the biomarkers remains inconclusive.

Methods: In 392 incident hemodialysis patients in the Predictors of Arrhythmic and Cardiovascular Risk End Stage Renal Disease (PACE) study, we examined the associations of baseline FGF23, dpupGMPI, Fetuin A, OPG, and CRP with total coronary calcium score (Agatston) at baseline and vascular stiffness (pulse wave velocity [PWV]) at baseline and over 4 study visits. Baseline associations were determined using linear regression and repeated measures over visits were examined using mixed-effects models.

Results: At baseline, higher OPG was associated with increased odds of having a high coronary calcium score (>257), independent of other biomarkers (OR=1.11, 95%CI: 1.06,
1.6). The remaining biomarkers were not associated with high coronary calcium. Higher OPG was associated with higher PWV, and higher FGF23 was associated with lower PWV after adjusting for demographic factors, body mass index, comorbidity index, calcium phosphorus product, systolic blood pressure, and albumin.

∗P<0.05 †Adjusted for all biomarkers

OPG and FGF23 remained associated with PWV over follow-up and after additionally adjusting for all biomarkers (β=0.08, 95% CI: 0.01, 0.15 and β=−0.07, 95% CI: -0.13, -0.01).

Conclusions: Several vascular and phosphate biomarkers are associated with vascular calcification at baseline and/or stiffness longitudinally in incident dialysis patients. Further studies assessing interventions on these biomarkers are warranted.

Association of Arterial Stiffness with Cognitive Impairment in Incident Hemodialysis Patients

Methods: This study included 390 incident hemodialysis patients enrolled in the Predictors of Arrhythmic and Cardiovascular Risk in End-Stage Renal Disease (PACE) study. Arterial stiffness was measured using aortic pulse wave velocity (PWV) and augmentation index (Aix). Cognitive function was measured using time to complete Trail Making tests A and B (TMT A and TMT B) and the modified mini-mental state exam (3MS) score. Log-linear, Tobit, and logistic regression models were used to examine the baseline association of PWV with TMT A, TMT B, and 3MS, respectively. Changes in the scores over visits and mixed-effect models were used to examine association over time at 1 year follow-up.

Results: A baseline, higher PWV was associated with longer time to complete TMT A after adjusting for demographic factors, reading comprehension score, comorbidity index, systolic blood pressure, and atrial fibrillation (%TMT A=−3.12, 95% CI: 0.37−5.87). In the repeated measures analysis, higher PWV was still associated with longer TMT A time (%TMT A=2.05, 95% CI: 0.00−4.11), and higher Aix was associated with longer TMT B time (β=0.80, 95% CI: 0.01−1.58).

Conclusions: Vascular stiffness was not associated with 3MS.

TH-P0098

Close Relationship Between Vascular Endothelial Function and Serum Uric Acid Level in Hemodialysis Patients

Methods: We enrolled 48 patients undergoing maintenance HD at Ueda Kidney Clinic in Japan. No patient had a history of CVD. Reactive hyperemia index (RHI) as evaluated by Endo-PAT (Tamar Medical, Ltd., Caesarea, Israel) was used to assess VEF, whereby a higher RHI was indicative of better function. We also assessed for correlations between the natural logarithm of RHI (LnRHI) and clinical parameters.

Results: The median age of our patients was 67 years, the male-to-female ratio was approximately 2:1, and median LnRHI was low at 0.36. Analysis of Spearman’s rank correlation coefficient revealed a significant positive correlation between serum uric acid level (sUA) and LnRHI (r=0.372, p=0.009). As sUA is influenced by diet and dietary intake, we also performed multivariable linear regression analysis adjusted by age, body mass index, diagnosis by KiV, and normalized protein catabolic rate, and observed that sUA was significantly related to LnRHI (β=0.042, 95% CI: 0.007−0.078, p=0.006, r²=0.221).

Conclusions: The current study suggests that VEF is closely associated with sUA in HD patients. Although the precise mechanism is unknown, a marked decrease in sUA might be correlated with VEF impairment and should be avoided in individuals undergoing HD.

TH-P0099

Ambulatory Arterial Stiffness Index: An Early Marker of Cardiovascular Disease in Young Hemodialysis Patients

Methods: Retrospective review of 24-hour ambulatory blood pressure monitoring (ABPM) was performed in 11 pediatric patients on chronic HD (16±3.6yrs) and dialysis vintage of 32±18 months. AASI was calculated as 1-regression slope of the diastolic over systolic BP. Echocardiogram and bilateral carotid artery ultrasounds were performed to assess left ventricular mass index(LVMi) and carotid intimal medial thickness (cIMT). Carotid artery stiffness indices included distensibility coefficient(DC), stiffness index-β (SI-β) and PP. These were compared with reference values for healthy pediatric controls.

Results: AASI was significantly increased in HD patients compared to controls (2.02±0.1 versus 20±0.2; p<0.01). When matched to controls with similar BP’s and PP’s, the AASI detected increased vascular stiffness independent of PP. cIMT,LVMi, and DC were also significantly increased in HD patients (p<0.01).

Conclusions: Young HD patients demonstrate early surrogate markers of CVD including increased LVMi, cIMT and decreased vascular compliance. Increased AASI detected vascular stiffness that was independent of BP’s and PP’s. AASI may be an early non-invasive marker of vascular disease in young HD patients that merits further investigation.

Endovascular Renal Denervation Ameliorates Pathological Left Ventricular Dilatation in Dialysis Patients

Neil A. Hoye, 1 J. Christopher Baldi, 1 David L. Jardine, 2 John B.W. Schollum, 1 Gerard T. Wilkins, 1 Luke C. Wilson, 1 Robert J. Walker. 1 Dunedin School of Medicine, Univ of Otago; 2 Christchurch School of Medicine and Health Sciences, Univ of Otago.

Background: Endovascular renal denervation (RDN) ameliorates left ventricular hypertrophy and improves contractile function in resistant hypertension. Its cardiac effects on a dialysis population are unknown. We hypothesised that RDN would improve blood pressure (BP) control and sympathetic overload, resulting in improved ventricular function.

Methods: Nine dialysis patients with uncontrolled office BP (>140/90mmHg despite two or more agents at maximal tolerated doses) were recruited into this feasibility study. Office and ambulatory BP monitoring (ABPM) were performed before baseline, one and three months post RDN, along with supine muscle sympathetic nerve activity (MSNA). Echocardiography was performed at baseline and three months. Bilateral RDN was undertaken with an EnLightH™ catheter.

Results:

Baseline 1 Month 3 Months P-value
Office Systolic BP (mmHg) 179±28 156±24 152±25 <0.05
Office Diastolic BP (mmHg) 90±17 76±13 82±12 0.137
Mean Systolic ABPM (mmHg) 173±19 173±23 166±24 0.544
Mean Diastolic ABPM (mmHg) 92±11 89±13 88±11 0.906
MSNA Burst Frequency (bursts/ min) 59±12 59±15 59±13 0.872
LVIDd (mm) 54±6 50±7 <0.05
LV EDV (ml) 168±43 150±42 0.391
LV ESV (ml) 102±41 80±29 0.397
LV EF (%) 41±14 47±11 0.801
LVD mass/BSA (g/m2) 97±16 91±19 0.490
Diastolic Dysfunction Grade 2.0±0.7 1.1±0.4 0.003

Similar to previous, office systolic BP reduced and the effect on ABPM was attenuated. MSNA did not change, a novel finding. Despite lack of change in MSNA, LVIDd reduced, with an improving trend in diastolic dysfunction, another novel finding. There was no correlation between change in office systolic BP and ventricular dilatation (R=0.255) or dysfunction (R=-0.034), suggesting BP-independent effects.

Conclusions: RDN in dialysis patients improves office systolic BP and leads to a BP-independent improvement in ventricular dilatation and probably dysfunction. Further controlled studies are warranted in this population.

Temporal Loss of Bone Mineral Density Is Associated with Cardiovascular Diseases in Japanese Patients Starting Renal Replacement Therapy

Sawako Kato, 1 Shoichi Manayama, 1 Bengt Lindholm, 2 Yukio Yuzawa, 2 Yoshinari Tsuruta, 1 Seiichi Matsuo. 1 Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan; 2 Baxter Novum & Renal Medicine Karolinska Inst, Stockholm, Sweden; 3 Nephrology, Fujita Health Univ School of Medicine, Toyoake, Japan; 4 Miyoi Clinic, Toyohashi, Japan.

Background: Atherosclerosis, vascular calcification and alterations of bone metabolism are common aging disorders, which may be biologically linked via bone-vascular interactions. However, clinical studies on associations of temporal bone loss with cardiovascular disease (CVD) in dialysis patients are limited.

Methods: Seventy-six incident Japanese dialysis patients (46 males, age 60 ± 10 years) were enrolled and followed for a median of 3.8 years (range 1-5.8 years). Bone mineral density (BMD) of the lumbar spine was measured by dual X-ray absorptiometry at baseline and after 1 year.

Results: Baseline BMD, median value 1.05 (0.67-1.56) g/cm², negatively correlated to albumin (r=−0.28, P=0.015) and iPTH (r=−0.14, P=0.0002). When dividing patients into two groups according to delta BMD (defined as baseline - 1 year), those with high delta BMD had an increased mortality risk (Log rank 6.36, P=0.012) and time from dialysis initiation to the first CVD event appeared, although not significant, shorter in patients with high delta BMD (Log rank 2.81, P=0.094). Patients with high delta BMD had a significantly increased relative risk (RR; Cox hazard model) of mortality (10.9, 95% CI; 1.34-250.6) even after adjustments for age, gender, diabetes and smoking, compared with those with low delta BMD. RR of the first CVD event was 5.52 (95% CI; 1.15-73.8) with adjustments for age and gender.

Conclusions: Progressive loss of BMD associated with an increasing risk of CVD and mortality. Whereas in end-stage renal disease patients, BMD may have limited value as a predictor of a fracture risk, temporal changes of BMD, potentially reflecting bone-vascular interactions, may be useful as a marker of a CVD risk.

First in Man: Reduction of Inflammation with Medium Cut-Off (MCO) Membranes

Daniel Ziecker, 1 Ralf Schindler, 1 Markus Storl, 2 Kevin Willy, 2 Bogusz Trojanowicz, 2 Peter Martus, 3 Christof Ulrich, 3 Kristin Liehr, 3 Christian Henning, 5 Torsten Böhler, 6 Marcus A. Glomb, 5 Roland Fiedler, 7 Matthias Girndt. 1 Department of Nephrology and Internal Intensive Care Medicine, Charité Universitätsmedizin Berlin, Germany; 2 Dept of Internal Medicine II, Martin-Luther-Universität Halle, Halle, Germany; 3 Research & Development, Gambro Dialysatoren GmbH, Hechingen, Germany; 4 Inst for Epidemiology and Applied Biometry, Eberhard-Karls-Universität, Tübingen; 5 Inst for Chemistry, Food Chemistry, Martin-Luther-Universität Halle, Halle.

Background: High mortality in dialysis patients may be related to reduced clearance of cytokines with conventional dialysis membranes. Attempts to provide a better clearance with high cut-off membranes also leads to albumin loss. A new Medium-Cutoff membrane with better permeability for molecules up to 45 kDa but with limited permeability for albumin was tested clinically for the first time.

Methods: 50 patients were dialyzed with MCO and conventional high-flux (HF) membranes for four weeks following a randomized cross-over design. After the second phase, another 12-week-period was conducted to test for long-term effects. Serum samples were tested for inflammatory effects and cytokine concentrations. Support was granted by the German Federal Ministry of Education and Research (FKZ 13N11796-99).

Results: The primary end point mRNA content of TNF-α in leukocytes was reduced to a higher degree and significantly better after 4 weeks on MCO compared to HF (r=0.01). Interleukin-6 mRNA was markedly reduced with MCO (p<0.001). After a significant drop after four weeks of MCO dialysis, albumin concentrations stabilized after 12 weeks.

Vitamin D and Cardiac Autonomic Tone in End-Stage Kidney Disease: A Blinded, Randomized Controlled Trial
Sofiga B. Ahmed,1 Michelle C. Mann,1 Brenda Hemmelgarn,1 David A. Hanley,1 Tanvir Chowdhury Turin,1 Jennifer M. MacRae,2 David C. Wheeler,3 Sharanya Ramesh,3 Darlene Y. Sola,3 Derek Exner,1 1Univ of Calgary, Canada; 2Univ College London, United Kingdom.

Background: Importance: End-stage kidney disease (ESKD) patients are at high cardiovascular (CV) risk. Vitamin D deficiency is associated with depressed heart rate variability (HRV), a risk factor for CV death. Both vitamin D deficiency and depressed HRV are highly prevalent in ESKD.

Methods: Objective: To determine the effects of activated vitamin D (conventional) compared to activated and nutritional vitamin D (intensive) on HRV (low to high frequency spectrum; LF:HF) in patients with ESKD on hemodialysis (HD). Design: 2x2 crossover, blinded, randomized controlled trial in outpatient HD units. Fifty-six patients were randomized 1:1 to begin either conventional (0.25mg alfacalcidol and placebo 3 times/week) or intensive vitamin D therapy (0.25mg alfacalcidol 3 times/week and 5000U1 Erythropoietin weekly for 6 weeks). Main Outcomes: HRV is a surrogate index of cardiac autonomic nerve function and independently predicts CV mortality. The primary outcome was the change in LF:HF from the 1st to 6th week HD session. Secondary endpoints included individual changes in LF and HF, parameters of mineral metabolism and renin angiotensin system (RAS) activity.

Results: There was no difference in LF:HF from baseline to 6 weeks for either vitamin D treatment (conventional p=0.9; intensive p=0.07). There were no significant changes in any other measure of HRV, mineral metabolism or RAS activity. On exploratory subgroup analysis, participants who remained vitamin D deficient (25-hydroxyvitamin D<50nmol/L) after treatment had a significant increase in LF:HF (conventional: n=13, p<0.001 vs. insufficient and sufficient groups; intensive: n=8, p=0.001 vs. sufficient group).

Conclusions: Six weeks of treatment with conventional or intensive vitamin D did not alter LF:HF in ESKD patients. However, improved LF:HF was observed in the vitamin D-deficient subgroup. This finding may translate into decreased CV risk and should be considered hypothesis-generating and deserving of further study. Trial Registration: ClinicalTrials.gov NCT01774812. Funding: Private Foundation Support

The Validity of Left Ventricular Mass as a Surrogate Endpoint for Mortality Outcomes in Chronic Kidney Disease
Sunil V. Badve,1,2 Suetoona Palmer,1 Giovanni F.M. Strippoli,1,2 Matthew A. Roberts,1 Neil Borkon,1 Ali Ansari,1 Alan Cass,2 Carmel M. Hawley,2 Swapnil Hiremath,1 Elaine M. Pascoe,1 Vlad Perkovic,1 Gillian A. Whalley,1 Jonathan C. Craig,1 David W. Johnson,1 1Univ of Queensland; 2Princess Alexander Hospital; 3Univ of Otago; 4Univ of Bari; 5Monash Univ; 6Univ of Western Australia; 7Menzies School of Health Research; 8Univ of Ottawa; 9The George Inst for Global Health; 10Univ Inst of Technology; 11Univ of Sydney.

Background: Left ventricular mass (LVM) is increasingly used as a surrogate endpoint in trials involving chronic kidney disease (CKD) patients, as intervention-induced reductions in LVM are associated with improved outcomes. However, the prognostic value of LVM change and relative risk of mortality were estimated using random-effects models. Correlations between LVM change and mortality endpoints were summarized across all trials involving a bivariate random-effects Bayesian model together with 95% credible intervals (CrI).

Methods: The aim of this systematic review was to determine the validity of LVM as a surrogate endpoint for all-cause and cardiovascular (CV) mortality in trials involving chronic kidney disease (CKD) patients, as intervention-induced reductions to early mitral annulus velocity (E) called E/e’ is a less volume dependent, non-invasive index to estimate left ventricular (LV) filling pressure. However, the prognostic value of E/e’ has not been evaluated sufficiently in patients with end-stage renal disease (ESRD).

Results: The patients who newly started maintenance dialysis therapy between 2009 and 2012, had survived for at least 3 months after dialysis initiation, and had E/e’ data, were analyzed. E/e’ was calculated by pulse and tissue Doppler echocardiography. Cardiovascular (CV) composite endpoint comprised hospitalization for heart failure (HF), acute coronary disease (ACD) requiring intervention, ventricular arrhythmia, cerebral infarction or hemorrhage, and CV death. The patients were followed up until 2013.

E/e’ Calculated by Tissue Doppler Echocardiography and Cardiovascular Outcome in Incident Dialysis Patients
Jongha Park,1 Jongmin Lee,1 Kyung sun Park,2 Sang Hyeon Son,3 Shin-Jae Kim,4 Jong soo Lee,1 Hyun Chul Chung,4 1Ulsan Univ Hospital, Ulsan, Republic of Korea; 2Dongkang Medical Center, Ulsan, Republic of Korea; 3BHS Han-Sea Hospital, Busan, Republic of Korea.

Background: The ratio of early diastolic peak mitral flow velocity (E) to early mitral annulus velocity (e’), called E/e’ is a less volume dependent, non-invasive index to estimate left ventricular (LV) filling pressure. However, the prognostic value of E/e’ has not been evaluated sufficiently in patients with end-stage renal disease (ESRD).

Methods: The patients who newly started maintenance dialysis therapy between 2009 and 2012, had survived for at least 3 months after dialysis initiation, and had E/e’ data, were analyzed. E/e’ was calculated by pulse and tissue Doppler echocardiography. Cardiovascular (CV) composite endpoint comprised hospitalization for heart failure (HF), acute coronary disease (ACD) requiring intervention, ventricular arrhythmia, cerebral infarction or hemorrhage, and CV death. The patients were followed up until 2013.

Results: A total of 206 patients were analyzed (mean age 55.0±13.7 years old, female 51.5%). Median follow-up duration was 29.2 months (range 3.1-61.3). Forty-two CV events occurred during follow-up (15 HF, 17 ACD, 1 cerebral infarction, and 9 CV deaths). Mean E/e’ was 13.6±5.4 (range 5.3-29). After adjusting age, sex, diabetes, mean arterial pressure, LV ejection fraction, hemoglobin, serum albumin, C-reactive protein and volume status, one unit increase in E/e’ ratio was associated with 7% increase in the risk of CV composite endpoint (hazard ratio 1.07, 95% confidence interval 1.02-1.13, p=0.09). Adjusted hazard ratio linearly increased above 15 of E/e’ in Cox regression with cubic splines.

Non-Invasive Left Ventricular End-Diastolic Pressure (LVEDP) Measurement in Hemodialysis Patients: A Pilot Study

Background: Optimal volume status in dialysis patients is difﬁcult to assess. The Valuaversal maneuver is recognized as an bedside marker of central volume overload. A novel handheld device that combines ﬁnger photoplethysmography with Valuaversal maneuver can reliably estimate LVEDP (normal: <12mmHg). (Stieler H. PMID: 22893989). The goal of our pilot study is to determine the role of this non-invasive LVEDP measurement in managing volume in hemodialysis patients.

Methods: The LVEDP-Guided Volume Management Study is being conducted at 2 dialysis units in Baltimore. Baseline data collected includes demographics, medical history, KDQOL-36, NYHA dyspnea scale, intra/post dialysis symptoms, predialysis metrics [LVEDP, bioimpedance, blood pressure (BP) and echocardiogram]. We assessed the cross-sectional association of predialysis LVEDP with dyspnea symptoms and intradialytic hypotension (IDH, deﬁned as ≥20mmHg drop in systolic BP × nursing interventions).

Results: In the first 28 participants (mean age 56 years, 71% male, 82% black, median (25%, 75% percentiles) for predialysis LVEDP was 14 mmHg (12, 19), interdialytic weight gain (IDWG) was 1.7 kg (0.9, 2.9) and systolic BP was 150 mmHg (133, 164). LVEDP was signiﬁcantly higher in patients with dyspnea vs. those without. (Mean, 19 y vs. 14.6; p<0.03). IDH occurred in 5 (18%) patients and all had LVEDP £14 mmHg (Table). The unadjusted odds ratio for IDH per SD decrease in LVEDP was 4.37 (p=0.08). There was no signiﬁcant association between IDH and predialysis systolic BP or IDWG.

Conclusions: Non-invasive LVEDP measurements can identify hemodialysis patients with volume overload associated with symptoms (high LVEDP) and patients at risk for IDH (low LVEDP). Our ongoing study may help conﬁrm these initial ﬁndings and deﬁne the role of this measurement for volume management in dialysis patients.

Non-Invasive Left Ventricular End-Diastolic Pressure (LVEDP) Measurement in Hemodialysis Patients: A Pilot Study
TH-PO914

TH-PO915

TH-PO916

Conclusions: A higher E/e’ ratio, reflecting high LV ﬁlling pressure which is the main physiological ﬁnding of diastolic HF, may be associated with a higher CV risk in patients with ESRD.
TH-PO918

Background: Tallium-201 (201TI) washout rate of single photon emission computed tomography (SPECT) has been reported to correlate with coronary flow reserve which is an index of myocardial microcirculation and be useful to detect coronary artery disease and evaluate the severity. However, the evidence for its use in chronic kidney disease (CKD) has been lacking, and the association between 201TI washout rate and mortality is unknown. Therefore, a hospital-based, prospective, cohort study was conducted to evaluate the predictive ability of 201TI washout rate for mortality in CKD patients undergoing hemodialysis.

Methods: A total of 156 patients who had been started on maintenance hemodialysis undergoing pharmacologic stress thallium-201 SPECT within 1 year, 107 men and 49 women, with a median age of 67 years, were studied. The endpoint was defined as all-cause death. The Cox proportional hazards model was used to calculate hazard ratios (HR) and 95% confidence intervals (CI).

Results: During the mean follow-up period of 3.2 ± 2.4 years, 30 (19.2%) deaths occurred. The median (interquartile range) of 201TI washout rate was 45.1 (37.4 - 50.8)%. Cumulative survival rates at 5 years after starting dialysis, with 201TI washout rate levels above and below the median, were 76.7% and 63.8% (p = 0.992, log-rank test), respectively. Overall, the multivariate Cox regression analysis revealed that 201TI washout rate remained an independent predictor of death after adjusting by confounding variables (HR 0.95, 95% CI 0.90 to 0.99).

Conclusions: Among CKD patients undergoing hemodialysis, 201TI washout rate seems to be useful for predicting death.

TH-PO919
Research Cardiovascular Magnetic Resonance Imaging in Chronic Kidney Disease – Incidence, Significance and Implications of Unexpected Incidental Findings  Elaine Rutherford,1 Jonathan Weir,1 Rutherford Inst of Card Sci, Edinburgh, UK; 1Div of Cardiovascular & Diabetes Medicine, Univ of Dundee; 2Inst of Cardiovascular & Medical Sciences, Univ of Glasgow.

Background: Left ventricular (LV) mass on cardiac magnetic resonance imaging (CMR) is a common end point of clinical trials in nephrology. Incidental findings (IF) on research images have ethical & clinical implications. We retrospectively investigated the incidence of IF in research CMR & reviewed their impact on patient care.

Methods: 161 CKD patients underwent CMR for a 2002-2006 research study into transplant assessment. Images were used to assess LV mass & function. In our study a hospital-based, prospective, cohort study was conducted to evaluate the predictive ability of 201TI washout rate for mortality in CKD patients undergoing hemodialysis.

Results: During the mean follow-up period of 3.2 ± 2.4 years, 30 (19.2%) deaths occurred. The median (interquartile range) of 201TI washout rate was 45.1 (37.4 - 50.8)%. Cumulative survival rates at 5 years after starting dialysis, with 201TI washout rate levels above and below the median, were 76.7% and 63.8% (p = 0.992, log-rank test), respectively. Overall, the multivariate Cox regression analysis revealed that 201TI washout rate remained an independent predictor of death after adjusting by confounding variables (HR 0.95, 95% CI 0.90 to 0.99).

Conclusions: Among CKD patients undergoing hemodialysis, 201TI washout rate seems to be useful for predicting death.

TH-PO920
A Significance of Cardiothoracic Ratio for Mortality in Hemodialysis Patients: The Q-Cohort Study  Ryusuke Yotsuwa,1 Masahiro Erguchi,1 Shigeru Tanaka,2 Masatomo Taniguchi,1 Hideki N. Hirakata,1 Kazuhiko Tsuruya,1,2 Takanari Kitazono,1,2 Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 2Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 3Nephrology and Dialysis Center, Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan.

Background: Cardiothoracic ratio (CTR) of chest X-ray is commonly used to determine the volume status in hemodialysis (HD) patients. Thus, the present study was conducted to evaluate the significance of CTR in terms of longitudinal prognosis of HD patients.

Methods: A total of 3,347 Japanese HD patients aged 18 years were followed for 4 years. Patients were divided into four groups according to quartiles of CTR levels by sex. Risk estimates were calculated by a Cox proportional hazards model, adjusting for potential confounders. We investigated stratified analysis by sex, age, etiology of end-stage kidney disease, history of major adverse cardiac events (MACE) and blood pressure for subanalysis.

Results: The median values (interquartile range) of CTR were 0.49 (0.46–0.53) in male and 0.52 (0.48–0.56) in female. During the follow-up period, 564 patients (16%) died from any causes and the 4 years survival rate decreased significantly with higher CTR levels (p for trend <0.001). Compared with the lowest CTR quartile, the multivariable–adjusted hazard ratios (HRs) for all-cause mortality were 0.89 (95% confidence intervals, 0.66–1.21), 1.41 (1.07–1.86), and 1.52 (1.17–2.00) in subjects with low–intermediate, high–intermediate and highest quartile, respectively. Furthermore, the combination of higher CTR levels and history of MACE or lower blood pressure before HD (systolic blood pressure <140 mmHg and diastolic blood pressure <90 mmHg) synergistically increased the risk of all-cause mortality.

Conclusions: A higher CTR level is closely related to increased mortality in HD patients. This association is more remarkable in patients with history of MACE or lower blood pressure before HD.

TH-PO921
High Convection Volumes in Postdilution Online Hemodiafiltration (HDF) Are Feasible in the Vast Majority of ESKD Patients  Camiel LM de Roij van Zuijdewijn,1 Isabelle Chapdelaine,1 Men Jan Nub,1 Peter J. Blankenstijn,1 Constantijn Konings,2 Tonnis K. Kremer Hovinga,2 Neelke C. Van Der Weerd,3 Pieter M. Ter Wee,1 Muriel P. Grooteiman,1 1Nephrology, VU Univ Medical Center, Amsterdam, Netherlands; 2Internal Medicine, Catharina Hospital, Eindhoven, Netherlands; 3Internal Medicine, Martini Hospital, Groningen, Netherlands; 4Nephrology, Academic Medical Center, Amsterdam, Netherlands.

Background: Available evidence suggests a survival benefit for patients treated with high volume postdilution HDF (hvHDF) when compared to HD. Since these studies are limited by an observational design, we investigated whether hvHDF (>2L/session) is feasible in the majority of patients (>75%).
Methods: A prospective, multicenter study was performed (NCT01877499). HD (F) patients (n = 178) were eligible if treated 3 times/week for 36 weeks. Non-participating eligible patients formed a reference group to examine the representativeness of the study group. Treatment-related determinants of the convection volume were optimized in a stepwise fashion (treatment time [TT] up to 4 hours, blood flow rate [BFR] up to 400 mL/min and filtration fraction [FF] up to 33%). At the end of this protocol (T0) and 4 (T4) and 8 (T8) weeks thereafter, the convection volume was determined.

Results: Baseline characteristics were comparable in participants (n = 86) and references (n = 58). At T0 and at T4, 79/86 (92%) and 68/79 (86%) patients achieved hvHDF (mean 26.3 ± 3.56 and 26.3 ± 3.36L/session, resp). Hereafter, 2 patients died and 1 was transplanted. 83 patients remained; 66 (80%) reached hvHDF (mean 25.9 ± 3.53L/session, fig 1). Study discontinuation (n = 9), TT <4h (n = 4) or BFR £300 mL/min (n = 4) caused a convection volume <22L/session.

Conclusions: hvHDF is feasible in the vast majority of ESKD patients. As TT remained virtually unaltered, these findings were mainly due to a higher BFR and FF.

Physical Activity Among Patients with End-Stage Renal Disease: Use of the Exercise Vital Sign

Shayna L. Henry, Yi-Lin Wu, John J. Sim, Michael K. Gould.1 1Dept of Research & Evaluation, Kaiser Permanente Southern California, Pasadena, CA; 2Dept of Nephrology, Kaiser Permanente Southern California Los Angeles Medical Center, Los Angeles, CA.

Background: Exercise has been shown to improve physical functioning among ESRD patients. However, ESRD patients report exceedingly low levels of physical activity (PA) with only 13-34% engaging in recommended levels of PA. Although ESRD is characterized by substantial barriers to PA, low PA puts patients at risk for serious complications and higher mortality. Within Kaiser Permanente (KP), patients are administered the Exercise Vital Sign (EVS) just prior to dialysis treatment. The purpose of this study was to describe PA levels in ESRD patients using the EVS and to examine patient and caregiver priorities for outcomes in hemodialysis (HD).

Methods: ESRD patients (³18y) were eligible if treated 3x/week for ≥6 weeks. Non-participating eligible patients formed a reference group to examine the representativeness of the study group. Treatment-related determinants of the convection volume were optimized in a stepwise fashion (treatment time [TT] up to 4 hours, blood flow rate [BFR] up to 400 mL/min and filtration fraction [FF] up to 33%). At the end of this protocol (T0) and 4 (T4) and 8 (T8) weeks thereafter, the convection volume was determined.

Results: Baseline characteristics were comparable in participants (n = 86) and references (n = 58). At T0 and at T4, 79/86 (92%) and 68/79 (86%) patients achieved hvHDF (mean 26.3 ± 3.56 and 26.3 ± 3.36L/session, resp). Hereafter, 2 patients died and 1 was transplanted. 83 patients remained; 66 (80%) reached hvHDF (mean 25.9 ± 3.53L/session, fig 1). Study discontinuation (n = 9), TT <4h (n = 4) or BFR £300 mL/min (n = 4) caused a convection volume <22L/session.

Conclusions: hvHDF is feasible in the vast majority of ESKD patients. As TT remained virtually unaltered, these findings were mainly due to a higher BFR and FF.

Medicare Advantage (MA) Is Associated with Lower Rates of Mortality versus Medicare Fee-For-Service (MFFS) Among Incident End-Stage Renal Disease (ESRD) Patients

Steven M. Brunelli,1,2 Carey Colson,1 Scott Sibbel,1 Abigail Hunt,1 Allen R. Nissenson,2 Mahesh Krishnan.2

1DaVita Clinical Research, Minneapolis, MN; 2DaVita HealthCare Partners Inc, Denver, CO.

Background: Patients with ESRD have a high burden of comorbid illness and are complex to manage and may therefore benefit from programs like MA that facilitate care coordination. Currently, ESRD patients are barred from enrolling in MA after onset of ESRD; however, those already enrolled at the time of ESRD onset may remain enrolled.

Methods: Adult patients initiating hemodialysis (HD) or peritoneal dialysis (PD) between 01 Jan 2009 and 30 Jun 2011 who were enrolled with MA or MFFS as of ESRD onset were considered. MA patients were matched 1:1 to MFFS controls based on initial modality, access type, and propensity score (based on 26 demographic and clinical characteristics). Patients were followed from dialysis initiation until death, transplant, loss to follow up, change in benefits status, or end of study (31 Dec 2011). Mortality rates were compared using negative binomial models. Sensitivity analyses considering early and latent effects were performed using piecewise methods.

Results: Compared to MFFS, MA was associated with lower rates of mortality (64.3 vs 70.7 deaths/100 patient-years; incidence rate ratio, 0.91). Mortality effects were limited to MA patients and were attenuated after the first 24 months of dialysis.

Conclusions: Enrollment in MA was associated with substantially lower rates of mortality during 2009-2011.

Characteristics of Patients Receiving Dialysis at a Comprehensive Cancer Center and Outcomes

Ala Abudayyah,1 Jai prakash babu Thippai Jadegondanahalli,2 Rima N. Pai,1 Maria del Pilar Fernandez,2 Alvin H. Moss.3

1Section of Nephrology, UT MD Anderson Cancer Center; 2Nephrology and Hypertension, UT at Houston Medical School; 3Section of Nephrology, West Virginia Univ School of Medicine.

Background: With the increasing therapeutic options from the traditional cytotoxic therapies, small molecules for targeted therapies and more recently immunotherapies, cancer patients have been given a massive arsenal to tackle their cancer. With the associated renal toxicities from the chemotherapies, sepsis, infections, antibiotics, and obstruction we are often faced with decisions about the utility of dialysis. This is often the situation in the patients with advanced solid tumors that have failed multiple lines of treatment and are admitted with renal failure necessitating hemodialysis. Our hypothesis for this study is offering dialysis to advanced solid tumor patients will not improve overall survival and is not cost effective.

Methods: All patients diagnosed with Acute Kidney Injury in their last hospital admission with solid tumor and nephrology consult between 01/01/2005 through 12/31/2014 were identified using billing data. Patient demographic data for those records was extracted: date of birth, gender, race, financial class, vital status and last contact date. Our final study cohort is a total of 2,268 unique patient records.

Results: Out of 2,268 patients, 392 patients (17.28%) received dialysis and 1876 patients (82.72%) did not. A total of 1470 patients (64.81%) were discharged alive and 798 patients (35.19%) resulted in a hospital death. The hospital deaths included 269 patients (33.71%) that received dialysis and 529 patients (66.29%) that did not receive dialysis in the hospital.

Conclusions: Our preliminary data indicates that patients who survived their last hospitalization were less likely to have undergone dialysis (8.36%) when compared to patients that died during their last hospitalization (33.71%) dialyzed. Therefore, reaffirming that dialysis in advanced cancer patients would not likely add further benefit to their mortality.

Emergency Room Utilization by Dialysis Patients: A Population Based Study

Claudio Rigatto,1,2 James M. Zacharias,1,2 Bing Hu,1 Brett M. Hiebert,1 Navdeep Tangri,1,2 Paul Komenda.1,2 1Internal Medicine, Univ of Manitoba, Winnipeg, MB, Canada; 2Renal Health/Dialysis, Seven Oaks General Hospital, Winnipeg, MB, Canada; 2Renal Health/Dialysis, Winnipeg Health Sciences Centre, Winnipeg, MB, Canada; 3Manitoba Renal Program, Winnipeg Regional Health Authority, Winnipeg, MB, Canada.

Background: Patients with kidney failure are frail and have high rates of cardiovascular and infectious comorbidities. As a result, they are heavy users of non-dialysis acute health services such as the emergency department (ED). Despite this, accurate population based data on rates and patterns of ED visits by dialysis patients are lacking. The objective of the current study was to determine rates and patterns of ED utilization by adult dialysis patients vs. the adult general population.

Methods: We linked two large regional databases in Winnipeg, Manitoba, Canada (population 1.3 million), the Manitoba Renal Program Patient Registry and the Winnipeg Regional Emergency Program Admission Discharge Triage database. Data were analyzed for the years 2000-2010. Poisson Regression was used to compare rates.

Results: Over the study period, the linked dataset comprised >2.0 million visits in 1.2 million non-dialysis patients, and 17,738 visits in 3260 dialysis patients. Our key findings were 1) Age and Sex adjusted rates of ER visits were 8.5X higher among dialysis patients (153 vs 18 visits per 100 patient-years, p<0.001), with negligible variation year to year over the study period; 2) Rate of ER visits were 25% higher on Mondays and Tuesdays overall; this “post-weekend” risk phenomenon was more pronounced in dialysis patients vs. the general population (p<0.001 for interaction); 3) among dialysis patients, ER visits were 8X higher during the two weeks before and after initiation of dialysis, reflecting a period of heightened vulnerability for patients with kidney disease.

Conclusions: Our population based rates of ED utilization will help health administrators predict the “collateral” impact of a typical dialysis unit on the health system. Strategies to mitigate the high risk of ED utilization “post weekend” and around the time of transition to dialysis are urgently needed and should be a focus of future health systems research.

Development of a Clinical Risk Prediction Tool for Six-Month Mortality After Dialysis Initiation Among Older Adults

James Wick, Tanvir Choudhury Turin, Peter D. Faris, Jennifer M. MacRae, Robert G. Weaver, Brenda Hemmelgarn. Univ of Calgary, Calgary, AB, Canada.

Background: Early mortality after dialysis initiation is common among older adults. We sought to develop a tool to predict mortality within 6 months of dialysis initiation in an older adult population.

Methods: We linked administrative and dialysis registry data to define a cohort of older adults (age 65+) in Alberta, Canada who initiated chronic dialysis between May 2003 and March 2012. The outcome was all-cause mortality within 6 months of dialysis initiation. Potential predictors included demographics, comorbidities, health-system use, funding and care processes. The Cox model and adjusted risk ratios were computed. A risk score that predicts 6-month mortality was developed.

Conclusions: An intervention to improve discharge planning and case management for dialysis patients is needed to reduce early dialysis mortality.

Funding: Alberta Heritage Foundation for Medical Research, the Canadian Institutes of Health Research, the Canadian Health Services Research Foundation.

laboratory measurements and dialysis-related information. We used logistic regression and 10-fold cross validation to identify and validate a model of significant predictors. The Model discrimination and calibration were measured by c-statistic and Hosmer-Lemeshow goodness-of-fit respectively. A point system was created based on regression coefficients of predictors in the final model.

**Results:** 2,211 dialysis patients, of whom 386 (17.4%) died within 6 months. Significant predictors of 6-month mortality were: age > 69 years, vascular access with central venous catheter, baseline eGFR < 10.14-9 or > 31 ML/min/1.73m², normal proteinuria, atrial fibrillation, lymphoma and congestive heart failure (CHF). Model discrimination (C-Statistic: 0.73) and calibration (Hosmer-Lemeshow c²: 6.09, p=0.64) were good. A 40-point scale for 6-month mortality was created based on model coefficients with points assigned based on strength of each predictor as specified in Table 1.

Conclusions: We derived and internally validated a clinical risk prediction tool for 6-month mortality for older adults initiating dialysis, using age, vascular access, eGFR, proteinuria, atrial fibrillation lymphoma and CHF as predictors. The results require external validation prior to use in clinical practice. A tool such as this can guide decision making for older adults with kidney failure.

**Coping Strategies and Outcomes Among Hemodialysis (HD) Patients in the DOPPS**

**Elodie Speyer,1** Malomenstern,2 Peter G. Kerr,3 Antonio Alberto Lopes,4 Hugh C. Rayner,5 Bruce M. Robinson,6 Ronald L. Pisoni.7

1Arbor Research, USA; 2Univ of Michigan, USA; 3Monash Health & Monash Univ, Australia; 4Federal Univ of Bahia, Brazil; 5Birmingham Heartlands Hospital, UK.

**Background:** Although HD presents numerous psychological and physical challenges for patients, they cope with dialysis therapy and its impact on quality of life (QoL) and mortality is poorly understood.

**Methods:** Patients from 6 DOPPS countries completed the Coping Strategies Inventory-Short Form (CSI-SF), which we found to be reliable and valid in those countries for measuring 4 coping strategies: problem-focused engagement (PFE) and disengagement (PFD), and emotion-focused engagement (EFE) and disengagement (EFD); and summary measures of engagement (actions to confront stressors) and disengagement (avoiding exposure to stressors). Outcome was QoL (from SF-12 and KDQoL-SF), depression symptoms (from the CES-D), and all-cause mortality. Mixed linear and logistic models were used to estimate coping effects, adjusting for country and potential confounders.

**Results:** In general and whatever the exposure to stressors). Outcomes were QoL (from SF-12 and KDQoL-SF), depression symptoms (from the CES-D), and all-cause mortality. Mixed linear and logistic models were used to estimate coping effects, adjusting for country and potential confounders.

**Conclusions:** Engagement strategies appear to be beneficial and disengagement detrimental for HD patients. A better understanding of the coping strategies used by patients may have prognostic implications and may help to improve disease management by providing tailored care for each patient.

**Intradialytic Aerobic Cycling Exercise Improve Inflammation Status, Endothelial Progenitor Cells and Bone Density in Patients with End Stage Renal Disease on Maintenance Hemodialysis**

**Chi-chao W1,2**

1Div of Nephrology, Dept of Medicine, Tri-Service General Hospital, National Defense Medical Center; Taipei, Taiwan; 2Dept of Medicine, Cardinal Tien Hospital, School of Medicine, Fu Jen Catholic Univ, New Taipei City, Taiwan.

**Background:** Inflammation, endothelial dysfunction and mineral bone disease play critical roles of morbidities and mortalities in the hemodialysis (HD) patients. Physical exercise can improve inflammatory status and bone density reverse protein-energy wasting (PEW) and bone loss. We investigate the effects of intradialytic aerobic cycling exercise (TACE) during HD.

**Methods:** Forty end-stage renal disease patients undergoing HD will be randomly allocated into an exercise or control group for 3 months. The cycling session consisted of 5 minute warm-up, 20 minutes cycling at desired workload and 5 minutes cool-down during the three weekly dialysis sessions. Biochemical markers, inflammatory cytokines and nutritional status as well as serum endothelial progenitor cells (EPCs) count, bone mineral density and functional capacity were checked.

**Results:** There were no statistically differences in the baseline characteristics between groups. Biochemical and anthropometric parameters revealed improvement in serum albumin, body mass index and inflammatory cytokines in the exercise group. Statistically significant changes in numbers of CD133/CD34/KDR cells were observed in exercise group, whereas EPCs increased significantly during the study. The patients in exercise group showed a significantly greater 6-minute walk test than at baseline. Subjects who were able to walk faster showed greater increases in EPCs than other subjects. Bone loss at the femoral neck was significantly greater in the control group compared with the exercise group which essentially showed no change. The bone mineral density (BMD) change at the lumbar spine (L1 to L4) was not significantly different between the treatment groups.

**Conclusions:** In conclusion, an intradialytic aerobic cycling exercise program can decrease inflammation, increase nutritional status and bone mass index, improve 6-minute walk distance, and increase the number of EPCs in HD patients.

**TH-PO931**

**Multicenter Trial of Aerobic Exercise in Maintenance Hemodialysis Patients**

**Misa Miura,1 Akihirayama,2 Shigeru Owada,3 Yo Hirayama,4 Osami Ito,5 Masahiro Kohzuki,6 1Dept of Health, Tsukuba Univ of Technology, Tsukuba, Ibaraki, Japan; 2Dept of Internal Medicine and Rehabilitation Science, Tokohu Univ Graduate School of Medicine, Sendai, Miyagi, Japan; 3Asao Clinic, Kawasawa, Japan.

**Background:** Hemodialysis patients show reduced physical function and greater risk of arteriosclerosis because of hypertension, metabolic disturbances, and vascular calcification. Meanwhile, exercise training in hemodialysis patients improves fitness, physical function, quality of life, and markers of cardiovascular disease such as arterial stiffness. This study aimed to determine whether aerobic training and electrical stimulation to skeletal muscles for 12 weeks could improve physical function and dialysis efficacy in patients with end-stage renal disease (ESRD).

**Methods:** This was a multicenter trial. A total of 35 ESRD patients on three occasions (20 males, 15 females; age: 70.2±11.7 years) were randomized to receive 12 weeks of aerobic training exercise, during hemodialysis session (Ex-group: n=19), electrical stimulation to the lower limbs (ES-group: n=6), or no specific intervention (Cont-group: n=10). The Borg
scale was used to control the intensity of training. At baseline and study completion, the primary outcome measures were grip strength, quad muscle torque, workout time, activities, dialysis efficacy, HDL, LDL, CRP, IL-6 and blood pressure.

Results: In the Ex-group, handgrip, quad torque, and workout time increased significantly (P<0.05). Dialysis efficacy, HDL-cholesterol, LDL-cholesterol, CRP, and blood pressure on the morning of the dialysis day also improved significantly (P<0.05). These effects were not observed in the Cont-group. In the Es-group, quad muscle torque and dialysis efficacy increased significantly (P<0.05). IL-6 decreased significantly (P<0.05), compared to the other two groups.

Conclusions: In this study, the safety and efficacy of training and electrical stimulation during hemodialysis were confirmed without sudden drop of blood pressure or any other side effects. Therefore, training during hemodialysis session for 12 weeks might improve physical function with specific whole-body effects as well as local effects in ESRD patients.

TH-PO932
Glycemic Markers and 2-Year Non-Diabetic Hemodialysis Outcomes from the Glycemic Indices in Dialysis Evaluation Study
Mark E. Williams,1,2 Neal Mittman,1,2 Lin Ma,3 Julia I. Brennan,1 Curtis D. Johnson,4 Franklin W. Maddux,5 Eduardo K. Lacson,1,5 Jesse Diabetes Center, Boston, MA; 2Kidney Care of Brooklyn and Queens, Brooklyn, NY; 3Presbyterian Medical Care North America, Walltham, MA; 4Spectra Laboratories, Rockleigh, NJ; 5Physician, Lexington, MA.

Background: The ongoing GIDE (Glycemic Indices in Dialysis Evaluation) study includes data on nonDM hemodialysis (HD) patients (confirmed by HgbA1c <6.5%). Because nonglycemic factors may lower HgbA1c levels in ESRD, we previously reported their glycemic status/1-year outcomes using alternative glycemic markers [albumin-adjusted and unadjusted fructosamine (AlbF;F) and glycated albumin (GA) or percent GA (%GA)]. We now report 2-year study data.

Methods: 970 nonDM HD patients from 26 FMCNA facilities with glycemic markers from Jan-March 2013 were followed until April, 2015. Baseline AlbF, F, GA and %GA were used to classify patients as high or low glycemia using thresholds of AlbF<94 mmol/L, F<285 mmol/L, %GA<15.7%, and GA<300 mg/L. Standard and Time-dependent (TD) Cox models with case-mix adjustment for age, sex, race, ethnicity, BMI, HD catheter and baseline comorbidity were used to determine associations between each glycemic index and hospitalization/death risk.

Results: While 1% had HgbA1c<7%, high glycemic status was more commonly detected using F (59%), AlbF (4%), GA (15%) and %GA (29%). Elevated AlbF was significantly associated with 2-year mortality [Standard Cox: Hazard Ratio (HR)=2.53, 95% CI (1.31, 4.92), p=0.006; TD Cox: HR=3.55, 95% CI (1.97, 6.38), p=0.00001 and hospitalization [TD Cox: HR=2.49, 95% CI (1.70, 3.67), p=0.0001]]. For all other glycemic markers, no such associations were evident at the proposed thresholds using adjusted analyses in the Cox model.

Conclusions: These data support our previous findings of an association between poor glycemic status (high AlbF) and hospitalization/mortality outcomes in nonDM HD patients. High AlbF-glycemic status may have prognostic implications in nonDM HD patients.

TH-PO933
Association of Change in Serum HDL Cholesterol with Mortality in Hemodialysis Patients: Role of Gender
Sheila Mazdasyani,1 Elami Streja,1 Tae Hee Kim,1 Connie Rhee,1 Steven M. Brunelli,2 Matt L. Kashyap,2 Nosratola D. Vaziri,1 Kamyrant Kalantar-Zadeh,1 Hamid Moradi,1,3 UC Irvine; 2DaVita Clin Research; 3VA Long Beach.

Background: Elevated high-density lipoprotein cholesterol (HDL) levels, though protective in the general population, can be associated with higher mortality in hemodialysis (HD) patients. Association of HDL change over time with mortality has yet to be examined. Based on previous studies, we hypothesized that upward trends in HDL levels may be associated with higher mortality risk in HD patients.

Methods: We examined HDL change over time in 24,400 incident HD patients receiving care from a large dialysis organization in 2007-2011. Association of delta HDL (HDL change between the 1st and 2nd 91st day interval from dialysis start) and HDL trajectory with all-cause mortality were examined using mixed effect and Cox regression models and adjusted for demographics, comorbidities and baseline HDL. Delta HDL was treated both as a continuous variable using restricted cubic splines and in categories of<6, 6-<12, 12 -<18 (Rej), 2, 6, =18 mg/dL.

Results: Patients were 65±15 years old, 44% female, 31% black, 66% diabetic with a mean baseline HDL 40.5±13.9 mg/dL and HDL change 1.7±10.4 mg/dL. While male patients had no significant change in HDL over time, females had a significant decrease in HDL (mean -0.6 mg/dL/year). A<26 mg/dL increase or decrease in delta HDL was associated with a 7% and 37%, respective increase in all-cause mortality compared to reference group. Delta HDL-mortality associations did not differ across gender.

Conclusions: Decreased HDL over time was associated with worse outcomes and increased HDL was paradoxically associated with higher mortality. While HD treatment can be associated with a decrease in HDL, this effect was magnified in younger females. The novel and intriguing role of age and gender in association of HDL and survival needs further evaluation.

Differences in Perceived Kidney Disease Burden on Quality of Life by Race/Ethnicity in a Diverse Cohort of Hemodialysis Patients
Anna C. Porter,1 Rani Gallardo,2 Linda A. Schiffer,2 Denise M. Hynes,2,3,4 Dept of Medicine, Div of Nephrology, Univ of Illinois Hospital and Health Sciences System, Chicago, IL; 3Dept of Medicine, Div of Academic General Internal Medicine and Geriatrics, Univ of Illinois at Chicago, Chicago, IL; 4Inst for Health Research and Policy, Univ of Illinois at Chicago, Chicago, IL; 5Center of Innovation for Complex Chronic Healthcare, Edward Hines Jr., VA Hospital, Hines, IL.

Background: Low health-related quality of life (HRQOL) has been well-documented in patients with end-stage renal disease on hemodialysis (ESRD). While African Americans and Hispanics remain at increased risk for ESRD, HRQOL has been less well-described in these individuals compared to non-Hispanic whites.

Methods: Baseline HRQOL data was analyzed for participants enrolled in the Patient-Centered Medical Home for Kidney Disease study (PCMH-KD), a trial of a multidisciplinary, patient-centered primary care intervention in a population of hemodialysis patients at two dialysis facilities in Chicago. The Kidney Disease Quality of Life (KDQOL-36) instrument was used to assess HRQOL at baseline, and the following subscale scores were obtained: Physical, Mental, Burden of Kidney Disease, Symptoms and Problems, and Effects of Kidney Disease.

Results: Baseline data were available for 95 patients. Approximately, 52% of patients were African-American, and 45% were Hispanic. Significant racial/ethnic differences were observed among subscales of self-reported HRQOL.

Conclusions: Hispanic patients with ESRD on HD report disproportionate burden and effects of kidney disease on HRQOL and worse mental HRQOL compared to African American patients with ESRD on HD. Further exploration of these disparities may lead to strategies for improvement of HRQOL in Hispanic patients.

Relative Blood Volume and Mortality in Hemodialysis Patients

Linda H. Picciollo,1 Paul Balter,2 Mark Costanzo,3 Patrice B. Taylor,4 Claudio Mullon,5 Robert J. Kossmann.6
1Fresenius Medical Care North America (FMCNA), Waltham, MA; 2Renal Research Inst (RRi), New York, NY.

Background: A quality improvement project on fluid management using Crit-Line® Monitors (CLM) was conducted across multiple RRI facilities. Percent change in relative blood volume (RBV) was measured during routine hemodialysis (HD). Previous analyses of the same cohort have shown associations between RBV reduction and reduced hospital admission rate; the current analysis assesses mortality.

Methods: A retrospective analysis of HD treatments with RBV measurements was conducted over 6 months. RBV was calculated using: RBV= [(Hematocrit (admission rate; the current analysis assesses mortality.

Results: Patients were divided into RBV categories by 5% increments and compared on risk of deaths per patient months. Time to death was modeled with Cox proportional hazards model.

Conclusions: In a large cohort of HD patients with relative blood volume measured, patients with less reduction in percent change in relative blood volume at the end of dialysis had higher risk of death over 6 months when compared to patients with greater reduction. These patients may represent a subset of patients at high risk for adverse outcomes and may benefit from fluid management programs.

The Effect of Altitude on Erythropoiesis-Stimulating Agent Dose, Hemoglobin Level, and Mortality in Hemodialysis Patients

Scott Sibbald,1 Donna E. Jensen,1 John Alan Laich,1 Sarb Senghildi,2 Bradley J. Maroni,2 Steven M. Brunelli,1 DaVita Clinical Research, Minneapolis, MN; 1Akebia Therapeutics, Cambridge, MA.

Background: Prior studies have shown that hemodialysis (HD) patients residing at higher elevations have lower erythropoiesis-stimulating agent (ESA) utilization, possibly due to activation of hypoxia-regulated genes. We sought to better understand the impact of altitude on dosing of anemia medications and mortality following 2011 changes to the US epoetin alfa label and reimbursement policy.

Methods: We studied a cohort of prevalent nonverteran HD patients (vintage >6 months) treated at a large dialysis organization between 1 Jan 2012 and 31 Dec 2012. Patients were categorized across categories of longitudinal hemoglobin (Hb) level, ESA and intravenous (IV) iron dose, and mortality risk using mixed linear models. Associations were adjusted for baseline demographic and clinical characteristics.

Results: Compared to altitude of 0-1499 ft, higher altitude was incrementally associated with higher mean Hb and lower mean ESA dose; mean IV iron utilization did not differ. Altitude >1500 ft (vs 0-1499 ft) was independently associated with lower mortality risk: incidence rate ratio (IRR) was 0.74 with 95% confidence interval (CI) 0.63-0.88.

Conclusions: Among contemporary HD patients receiving treatment at >1500 ft, higher altitude was independently associated with greater Hb level despite lower ESA doses and comparable IV iron utilization. Altitude of >4500 ft was independently associated with a 26% lower mortality risk.
Results: Among subjects treated with PBO (n=9) or sotatercept 0.3 mg/kg or sotatercept 0.5 mg/kg, adverse events were mostly mild/moderate, unrelated to study drug, similar in type/severity between groups, and generally consistent with subject medical histories. Two deaths occurred in the PBO group. There were no dose-dependent changes in home BP. In the 225-day treatment phase, Hb was ~11 g/dL in 33%, 33%, 63%, and 78% of subjects treated with PBO or sotatercept 0.3, 0.5, or 0.7 mg/kg, respectively. Paired QCTs obtained in 4, 6, 5, and 6 subjects treated with PBO or sotatercept 0.3, 0.5, or 0.7 mg/kg showed <15% progression of VC in 33%, 80%, 80%, and 100%, and >2% increase in femoral neck cortical BMD in 0%, 20%, 40%, and 75%, respectively.

Conclusions: Sotatercept appears to be well tolerated with an acceptable safety profile in HD, without increases in home BP. There are beneficial dose-related responses to sotatercept in Hb, VC, and BMD. A larger dataset, with an ongoing 14-day dose group, will further substantiate these results.

Impact of CKD-MBD Composite Score on Mortality and Hospitalization: Dialysis Outcomes and Practice Patterns Study (DOPPS)
Douglas S. Fuller,1 Paul Dluzniewski,2 Kerry Cooper,3 Brian D. Bradbury,4 Mark D. Danese,5 Bruce M. Robinson,6,7 Francesca Tentori,2,3,8 Arbour Research Collaborative for Health, Ann Arbor, MI;9 Amgen, Thousand Oaks, CA;10 Outcomes Insights, Inc., Westlake Village, CA;11 Univ of Michigan, Ann Arbor, MI;12 Vandebilt Univ, Nashville, TN.

Background: The biochemistries associated with chronic kidney disease-mineral and bone disorder (CKD-MBD), parathyroid hormone (PTH), calcium (Ca), and phosphorus (P), are physiologically interrelated. We evaluated the impact of combinations of CKD-MBD parameters on mortality rates in HD patients.

Methods: We identified DOPPS 3-5 (2005-2014) pts in the US, Canada, and Europe (France, Germany, Italy, Spain, Sweden, and the UK) with ≥2 mos of follow-up. We assessed demographic and clinical covariates in study miss 9-12 and used Cox models to generate risk scores (DOPPS 5) by region based on pts with CKD-MBD parameters in target (MBD 0; P 3.5-5.5 mg/dL, Ca 8.4-10.2 mg/dL, PTH 150-600 pg/mL) and to compare event rates, adjusted for DRS, of mortality and a composite of death or hospitalization between MBD 0 and pts with 2-3 values outside target (MBD 2+).

Results: MBD 2+: prevalence, primarily due to high PTH and P, was 22.8%, 29.5%, and 26.9% in the US, Canada, and Europe, respectively. PTH above target was higher in the US (52%) compared to Canada (42%) and Europe (28%). Compared to MBD 0, MBD 2+ was associated with moderately higher mortality in the US (52%) compared to Canada (42%) and Europe (28%). Compared to MBD 0, MBD 2+ was associated with higher health care costs. Despite these differences, the majority of patients had CKD-MBD parameters within target ranges.

Conclusions: CKD-MBD parameters vary by region, perhaps resulting in differential risk of adverse outcomes. Our findings in this international cohort highlight the importance of simultaneous, rather than independent, control of CKD-MBD parameters within clinical guidelines.

US DOPPS Practice Monitor: Comparisons with CMS ESRD Databases
Douglas S. Fuller, Lindsay Zelpel, Keith McCullough, Brian Biber, Ronald L. Pisoni, Francesca Tentori, Bruce M. Robinson. Arbour Research Collaborative for Health, Ann Arbor, MI.

Background: Since August 2010, the Dialysis Outcomes and Practice Practices Practice Monitor (DPM; www.dopps.org/DPM) has leveraged its US Hemodialysis (HD) sample (now >200 facilities) to provide timely and detailed (>750 data tables) updates on national trends in HD care. Here we compare DPM estimates to available results from end-stage renal disease (ESRD) data sources collected by the Centers for Medicare and Medicaid Services (CMS).

Methods: Pearson correlations (r) were used to compare contemporary trends since Aug 2010 between DPM and the 2014 US Renal Data System Annual Data Report (ADR, through Dec 2012) and the Nov 2014 CMS Claims-Based Monitoring Project (CBMP, through Jun 2014). We also compared monthly DPM estimates with cross-sectional estimates from 2014 CrownWEB (CW, Dec 2013).

Results: DPM trends in ESA use and dose, IV iron use, and hemoglobin levels were highly correlated (r’s: 0.89-0.98) with ADR and CBMP trends. Compared to CW, DPM showed slightly higher fistula use, but slightly lower percent of patients with adequate Kt/V and URR values.

Reduced Free Triiodothyronine Is an Independent Predictor of Clinical Outcomes in Hemodialysis Patients with Low Albuminemia
Akihiko Kato,1 Masafumi Ono,2 Takeyuki Tsuzi,3 Naro Ohashi,4 Hideo Yasuda,5 1Blood Purification Unit, Hamamatsu Univ Hospital, Hamamatsu, Shizuoka, Japan; 2Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan.

Background: Low free triiodothyronine (fT3) and free thyroxine (fT4) are both related to malnutrition, inflammation and mortality in dialysis patients. Upper-normal thyrotrin (TSH) levels are also associated with a higher risk of total mortality in hemodialysis (HD) patients. However, it remains unclear which of thyroid-related hormones is most useful in predicting clinical outcomes. So, we aimed this study to compare the prognostic value of different hormones in prevalent HD patients.

Methods: We enrolled 339 HD patients (age: 64±13 years old, time on HD: 129±14 months), and measured basal fT3, fT4 and TSH. We then followed the patients for the next 42 months, and assessed the impact of fT3, fT4 and TSH on all-cause mortality and cardiovascular (CV) events or hospitalization. Patients were divided into the 4 groups based on the quartiles of fT4, fT3 and TSH. The associations of basal levels with clinical outcomes were examined with Cox proportional hazards models adjusted for demographic and classical factors and comorbidities.

Conclusions: Distributions of CKD-MBD parameters varied by region, perhaps resulting in differential risk of adverse outcomes. Our findings in this international cohort highlight the importance of simultaneous, rather than independent, control of CKD-MBD parameters within clinical guidelines.

Low Socioeconomic Status and Co-Morbidity Are Associated with Limited Health Literacy in RRT Patients – Results from the ATTOM Study

**Background:** Limited health literacy (LHL) is a risk factor for poor outcomes in chronic disease patients. Studies with limited patient numbers in RRT patients associate LHL with low socioeconomic status (SES), comorbidity and ethnicity.

**Methods:** This cross-sectional study used baseline data from the ‘Access to Transplantation and Transplant Outcome Measures’ (ATTOM) cohort. ATTOM recruited incident dialysis and transplant patients aged 18-75 years in the UK during 2011-2013 and also with patients similar to those transplanted (matched controls). Health literacy was measured by the question ‘How often do you need someone’s help to read instructions, leaflets, or other written material from your doctor or pharmacy?’ answered on a scale from 1-Never to 5-Always. LHL was defined as a score greater than 2. The three groups were analysed for associations between LHL and demographics, SES factors and comorbidity, using univariate and multivariate analysis, p<0.05.

**Results:** 6842 patients were recruited: 2621 incident dialysis (ID), 2262 incident transplant (IT) and 1959 matched controls (MC). 6373/6842(93%) completed the health literacy assessment. Prevalence of LHL was 20% in the ID, 12% in the IT and 15% in the MC group. In univariate analyses, in all groups, English not as first language, Asian ethnicity, low educational level, unemployment, absence of car or home ownership, increased comorbidity by modified Charlson index and mental illness were associated with LHL. In adjusted models, in all groups, the following factors were associated with LHL in patients receiving dialysis or at the point of transplantation, independent of first language. LHL may impact upon patients’ ability to engage with shared decision making with LHL in patients receiving dialysis or at the point of transplantation, independent of first language (OR>3.0 compared to employed) and absence of car ownership (OR 1.7). Low level of education (OR>2 for no qualifications compared to any), unemployment (OR>3.0 compared to employed) and absence of car ownership (OR 1.7). Age and sex were not associated with LHL of adjustment.

**Conclusions:** These findings suggest that low fT3 became an independent predictor of clinical outcomes in ID patients with low albuminemia.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only**
The reduction was most prominent in patients with longer dialysis vintage, patients who were younger, and those with lower pre-dialysis b2m levels. Similar results were obtained by propensity score-matched analysis. We also found that b2m clearance >80% may reduce risk of CTS.

Conclusions: The incidence of first-time CTS as proxy for DRA decreased significantly from 1998 to 2010. Several factors may have contributed to this decrease, including improved dialysis methods.

TH-PO947
Twice Weekly Hemodialysis and Clinical Outcomes in the China DOPPS
Yuecheng Yan,1 Mia Wong,2 Jia Qi Qian,1 Brian Bierer,3 Mei Wang,1 Nan Chen,1 Bruce M. Robinson,4 Shuchi Anand,4 Shanghai Renji Hospital;4 Arbor Research;4 Shanghai Ruijin Hospital;4 Stanford Univ.

Background: Outcomes related to 2 times weekly hemodialysis (HD), substantially practiced in China, remain understudied. Small, single-center studies have indicated better preservation of residual kidney function (RKF) and similar survival for 2 vs. 3 times weekly HD. We used data from the China Dialysis Outcomes Practice Patterns study (DOPPS) to evaluate survival and hospitalizations by frequency of HD.

Methods: We studied 1,433 patients from 45 HD units in China (2012-2015). Cox regression was used to model the association of 2 vs. 3 times weekly HD with clinical outcomes adjusting for patient and treatment characteristics.

Results: 270 patients (19%) were undergoing 2 times weekly HD in China. Compared with 3 times weekly HD, patients on 2 times weekly HD were more likely to be female and have shorter time on dialysis (4.3 vs. 2.6 yrs), more urine output, shorter dialysis session length (238 vs. 250 min) and longer travel times to facility. They were less likely to have diabetes or cardiovascular disease. Insurance coverage was similar in the two groups. During follow-up (median=1.7 years), 184 (13%) deaths and 516 (38%) hospitalizations occurred. No differences in mortality or hospitalization were found between the two frequency groups (Table). No interaction was observed with vintage (p=0.43).

Table: Progressive adjustment of mortality with twice weekly dialysis, in China

<table>
<thead>

<td>0.79</td>
</tr>
</tbody>
</table>

*1393 patients, 184 events. 
*a, age, gender, BMI, standardized, and vintage.

Conclusions: In this multi-center study with well-characterized patient and treatment data, outcomes of 2 vs. 3 times weekly HD were similar. Thus, it is possible that among carefully selected patients 2 times weekly HD may provide acceptable outcomes. An additional study is also need due to residual confounding, small sample size, and the changes in results with progressive adjustments.

TH-PO948
Initiation of a Chronic Kidney Disease Case Manager Program Is Associated with Better Outcomes in Incident Hemodialysis Patients
Joseph A. Kuhn,1 Patrick Bridge, John W. Larkin, Hao Han, Sheetal Chaudhuri, Len A. Usvyat, Terry Ketchersid, Franklin W. Maddux. Fresenius Medical Care North America, Waltham, MA.

Background: The Renal Care Coordinator (RCC) Program places chronic kidney disease (CKD) case managers in the Nephrology Practice to co-manage late stage CKD (4 and 5) patients for an optimal outpatient start to Renal Replacement Therapy (RRT). This program is performed through both physical and virtual RCCs. We compared outcomes in patients starting hemodialysis (HD) who were previously enrolled in the RCC program to CKD patients cared for in the nephrology practice, but were not in the RCC program.

Methods: All CKD 5 patients who transitioned to end stage renal disease (ESRD) requiring RRT between 1/1/2012 and 10/1/2014 at the nephrology practices that adopted the RCC program were analyzed. We compared outcomes in patients enrolled into the RCC program versus patients considered to have a “Timely Referral” for dialysis (i.e. were followed in a
nephrology practice for 4 months before starting RRT), but received no RCC interaction. The albumin (Alb) and hemoglobin (Hgb) levels were collected at the first outpatient HD treatment. We also computed the hospital days of mortality and the first 120 days of HD.

Results: 1,404 CKD 5 patients were identified for the analysis, where 51% of the population was enrolled in the RCC. Patients in the RCC had a lower % of catheters, higher days of HD. We also computed the rates of hospital days and mortality in the first 120 days of HD treatment. We also computed the rates of hospital days and mortality in the first 120 days of HD. We also computed the rates of hospital days and mortality in the first 120 days of HD.

P<0.05 (*)

Conclusions: This analysis demonstrates that placement of CKD case managers is associated with better outcomes, including anemia, access type, nutritional status and hospitalization in the first 120 days of HD.

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America

TH-P0949

Extracellular Overhydration Measured by Multifrequency Bioelectrical Analysis Is Associated with Increased Postdialysis Systolic Blood Pressure in Hemodialysis Patients Hae Yeul Park, 1 Seok-hyoung Kim, 1 Ah Ran Choi, 1 Jung eun Lee, 1 Hyung jong Kim, 2 Hoon Young Choi, 3 Sung-Kyu Ha, 1 Hyeong cheon Park. 1 Nephrology, Gangnam Severance Hospital, Yonsei Univ College of Medicine, Seoul, Korea; 2 Nephrology, Ross Medical Research Institute, Cleveland, Ohio; 3 Nephrology, University of Maryland School of Medicine, Baltimore, Maryland.

Background: Postdialytic hypertension is associated with increased morbidity and mortality for hemodialysis (HD) patients. Recent studies suggested that increased postdialysis extracellular volume may account for the rise in postdialysis systolic blood pressure (PDSBP).

Methods: Volume status assessments were performed during mid-week HD using multifrequency bioelectrical impedance (BIA, Inbody S10) in supine position. Demographic and routine biochemical data were collected and pre- and post-dialysis B-type natriuretic peptide (BNP) level was measured (Triage BNP test, Alere).

Results: We enrolled clinically stable 99 HD patients from 3 dialysis centers. Patients were divided into 3 groups based on a fall in SBP of 20mmHg or more (Hypotensive, 24.2%), an increased SBP of 10mmHg or more (Hypertensive, 32.3%), and a stable group (43.4%). The mean age was 55 ± 13.3 years in hypertensive, 58 ± 11.6 years in stable, and 62 ± 27.2 years in hypertensive group. Postdialysis BNP was 267 ± 251.1 pg/ml in hypertensive, 660 ± 913.9 pg/ml in stable and 212 ±197.8 pg/ml in hypertensive group. There were no differences in gender, dialysis prescriptions, and subjective global assessment score among the patient groups. The ECW/TBW ratio was significantly higher in the hypertensive group and positively correlated with PDSBP and delta SBP. The only independent risk factor affecting ECW/TBW ratio after dialysis was volume status.

Conclusions: HD patients who demonstrate increase in PDSBP should have their volume status reassessed and target dry weights adjusted using BIA, which is a promising new tool in assessing fluid status in patients on HD.

TH-P0950

Novel Phosphate Binder, Ferric Citrate Hydrate, Can Reduce Serum Phosphate Levels and Doses of Erythropoiesis Stimulating Agents in Japanese Patients on Hemodialysis Hironori Kuma, 1 Akihiro Nishimura, 1 Yosuke Umezaki, 1 Masafumi Sato, 2 Toru Kuma, 2 Daisuke Nishimura, 2 Taketoshi Uyama, 3 Yosuke Umezaki, 1,2,3 Nephrology, Nagoya University Hospital, Nagoya, Japan; 2 Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan.

Background: Ferric citrate hydrate (FC) has been available in Japan as a phosphate binder for patients on dialysis (HD) since 2014 although its effects have not been evaluated in detail in such patients. The present study aimed to determine the effects of FC on serum phosphate levels and anemia control in patients on HD.

Methods: Thirty-eight outpatients (mean age, 62.5 ± 7.7; hypertension, n = 29 [75.3%]; diabetes, n = 19 [50.0%]; secondary hyperparathyroidism, n = 15 [39.5%]) on maintenance HD were treated with FC for 6 months to control hyperphosphatemia. Serum concentrations of phosphate, calcium, hemoglobin, and ferritin levels, transferrin saturation (TSAT), and weekly epoetin (EPO) dose were monitored during the study.

Results: Mean phosphate levels were significantly decreased from 7.05 ± 1.11 to 6.19 ± 0.91 (p < 0.0001) and 6.14 ± 1.16 (p < 0.05) and 6.01 ± 1.11 (p = 0.0035) mg/dL at one, three and six months, respectively. Calcium, hemoglobin and ferritin levels did not significantly differ during the same periods. Transferrin saturation was significantly increased (26.7 ± 10.9% vs. 22.0 ± 9.5%, p < 0.05) and the weekly EPO dose was significantly decreased (2750 ± 2699 vs. 6801 ± 7406 IU/week, p < 0.05) after six months of FC therapy.

Conclusions: FC can decrease serum phosphate levels and the weekly EPO dose. Therefore, FC is useful for treating hyperphosphatemia and renal anemia in Japanese patients on HD.

Background:

TH-P0951

Geographic Variation of Potentially Avoidable Readmissions in Hemodialysis Patients Daniel W. Ross, 1 Kamyar Kalantar-Zadeh, 1 Steven Fishbane, 3 Anna Mathews, 1 BPI Division of Nephrology, Hofstra North Shore --LIJ School of Medicine, New York, NY; 2 Harold Simmons Center for Kidney Disease Research and Epidemiology, Div of Nephrology, Univ of California, CA.

Background: In 2011 in the United States, 36.3% of prevalent hemodialysis patients were readmitted within 30 days of an index hospitalization. These rates are approximately twice that of the general U.S. Medicare population. While some readmissions to hospital are unavoidable, it is probable that a substantial number could be prevented. In the present study, we describe inter-state variability in 30-day potentially avoidable readmissions (PAR).

Methods: The United States Renal Data System (USRDS) was used to identify prevalent hemodialysis patients (vintage ≥90 days) with acute hospitalizations in 2008. Exclusion criteria were transfer to rehabilitation or skilled nursing facility, unknown dialysis start date, and renal function recovery. PAR were identified using a validated, computerized algorithm (SQLape), and displayed geographically by state using Pitney Bowes MapInfo.

Results: 250,606 index hospitalizations were identified, with 37% readmissions within 30 days (n = 84,279). Nationwide, 24% of index hospitalizations were followed by a 30-day PAR (64.9% of all readmissions) (n= 59,803). PAR ranged from 12% to 31% by state. The figure shows the geographic distribution of potentially avoidable readmissions.

Conclusions: There is inter-state variability in PAR among chronic hemodialysis patients and may be related to regional differences in practice patterns or patient demographics. Further characterization of risk factors associated with PAR is the focus of our ongoing research.

TH-P0952

Unravelling the Relationship Between Mortality, Hyponatremia, Inflammation and Malnutrition in Hemodialysis Patients: Results from the INTERNATIONAL MONDO Initiative Marike J.E. Dekker, 1 Daniëlle Marcelli, 2 Bernard J. Canaud, 3 Constantijn Konings, 4 Karel M. Leunissen, 4 Nathan W. Levin, 4 Jochen G. Raimann, 5 Frank van der Sande, 6 Len A. Ustyayt, 7 Peter Kotanko, 8 Jeroen Koornman, 9 Catharina Hospital Eindhoven, 10 Maastricht Medical Center, 11 Fresenius Medical Care; 12 Renal Research Inst.

Background: Hyponatremia is a risk factor for mortality in hemodialysis patients. However, it is not well known to which extent comorbidities, such as malnutrition, fluid overload and inflammation are related to hyponatremia and influence the association between hyponatremia and outcomes.

Methods: We studied 8892 patients from the European subset of the MONDO Initiative. Nutritional and fluid statuses were assessed by multifrequency bioimpedance spectroscopy. Based on pre-dialysis fluid status, fluid depletion was defined as an extracellular water volume < -1.0L and fluid overload > +2.5L. Malnutrition was defined as a lean tissue index below the 10th percentile of age- and gender matched healthy controls. Hyponatremia and inflammation were defined as serum sodium levels ≤ 135 mEq/L and C-reactive protein levels > 10 mg/L, respectively.

Results: Hyponatremia was predicted by the presence of malnutrition (odds ratio (OR) 1.48 (95%CI 1.30-1.69) and inflammation (OR 1.44 (95%CI 1.26-1.64)), but not by fluid depletion (OR 1.38 (95%CI 0.98-1.93)) or fluid overload (OR 0.99 (95%CI 0.85-1.14)). Malnutrition (hazard ratio (HR) 1.39 (95%CI 1.23-1.58)), inflammation (HR 2.31 (95%CI 2.04-2.62)), fluid overload (HR 2.17 (95%CI 1.90-2.47)) and hyponatremia (HR 1.63 (95%CI 1.39-1.90)) were independent predictors for all-cause mortality.

Conclusions: In hemodialysis patients hyponatremia is associated with malnutrition and inflammation but not with denarged fluid status. Hyponatremia maintained predictive for all-cause mortality after correction for malnutrition, inflammation and fluid status abnormalities. Hyponatremia may aid efforts to identify hemodialysis patients at increased risk of death.
TH-PO953

Low Serum Sodium Concentration at the Induction of Maintenance Hemodialysis Predicts Higher Risk of Mortality: Yokako Ohyama, Hideaki Shimizu, Daio Inaguma, Yoshiro Fujita. 1Nephrology and Rheumatology, Chubu Rosai Hospital, Nagoya, Japan; 2Nephrology, Red Cross Nagoya Daini Hospital, Nagoya, Japan.

Background: Low serum sodium concentrations are associated with an increased risk of death in the general population because of underlying diseases such as congestive heart failure and cirrhosis. However, some papers report hyponatremia itself further increases the mortality risk. The prevalence of hyponatremia and the mortality risk of hyponatremia at the induction of maintenance hemodialysis (HD) have not been reported before.

Methods: This study is a retrospective cohort study which date was collected from “Aichi Cohort study of Prognosis in Patients” (AICOPP) newly initiated dialysis. After the exclusion of peritoneal dialysis (PD) patients, this study enrolled 1395 patients (mean age; 68 ± 13 years, mean eGFR level; 54 ± 2.2 ml/min/1.73m²) who started maintenance HD between 10/1/2011 and 11/30/2013. We divided the cohort to 4 groups by serum sodium concentration at the induction of HD adjusted by serum glucose concentration (Severe hyponatremia: Na<130, Mild hyponatremia: 130≤Na<136, Normal:136≤Na≤145, Hypernatremia: Na>145 mEq/L). The proportional hazard model was used to examine the association between serum sodium level and mortality.

Results: The prevalence of hyponatremia, defined as Na<136 mEq/L and <130 was at 23% and 5%, respectively. During 15.5 months’ mean follow up, 159 patients (11%) died. The lowest Na group was significantly associated with higher risk of mortality (figure1). Patients with serum sodium levels of <130 mEq/L were more likely to have multivariable-adjusted mortality hazard ratios (95% confidence interval) of 2.34 (1.31-4.15) compared to patients with serum sodium levels of 136-145 mEq/L.

Kaplan-Meier curves

Conclusions: Hyponatremia at the induction of HD is an independent predictor of higher risk for mortality.

TH-PO954

Frequency of Hyperkalemia Events in Dialysis Patients in a Large Dialysis Organization: Akeem Yusuf,1 Yan Hu,1 Bhupinder Singh,2 Alex Yang,2 James B. Wetmore.1 1Chronic Disease Research Group, MMRF, Minneapolis, MN; 2ZS Pharma, Inc, Redwood City, CA.

Background: Hyperkalemia is a major problem in dialysis patients. It is associated with increased risk of cardiac arrhythmias and sudden cardiac death. However, few studies have examined frequency of hyperkalemia episodes in a large population of dialysis patients.

Methods: A cohort of patients receiving thrice-weekly HD in 2010 was constructed using data linked between USRDS and a large dialysis organization (LDO). Patients were followed from first serum K measurement until death, transplant, change in dialysis modality, change in dialysis K concentration, loss of Medicare eligibility, loss to follow up, or Dec 31, 2010. Hyperkalemia was defined by serum K levels 5.5-6.0 mEq/L at 0.1 mEq/L intervals. Time-dependent Cox proportional hazards modeling was used to estimate the association between hyperkalemia occurrence and all-cause and cardiovascular mortality.

Results: Hyperkalemia defined as serum K ≥5.7 mEq/L was associated with all-cause mortality (adjusted hazard ratio [AHR] 1.1, 95% CI 1.01-1.28, P = 0.037, compared to K ≥5.0 mEq/L) after adjustment for demographic and clinical factors in time-dependent models; the AHRs increased progressively as the threshold for hyperkalemia rose (AHRs 1.18, P = 0.014, for K=5.8 mEq/L; 1.29, P = 0.001, for K=5.9 mEq/L; 1.37, P = 0.0002, for K=6.0 mEq/L). The pattern of the point estimates was similar for cardiovascular mortality, although the results did not reach statistical significance (AHRs 1.09 for K=5.7 mEq/L, 1.13 for K=5.8 mEq/L, 1.20 for K=5.9 mEq/L, 1.28 for K=6.0 mEq/L).

Conclusions: Hyperkalemia is associated with all-cause mortality beginning at K level ≥5.7 mEq/L, with mortality risk point estimates increasing in ordinal fashion through K level ≥6.0 mEq/L. A similar pattern was observed in the point estimates for cardiovascular mortality. This study may have identified a threshold at which point serum K becomes dangerous.

A Multicenter, Phase 2/3 Randomized, Double-Blind, Placebo-Controlled Trial of Nabumetone ER Tablets for the Treatment of Uremic Pruritus: Baseline Population Characteristics
Vandana S. Mathur,1 Jayant Kumar,1 Paul W. Crawford,1 Howard Halt,2 Thomas Sciascia.2 1MathurConsulting, Woodside, CA; 2Trevi Therapeutics, New Haven, CT. 1Renal Medicine Associates, Albuquerque, NM; 2Biostatistics, EdrivenConsulting, Wilmington, DE; 1Research by Design, Evergreen Park, IL.

Background: Uremic pruritus (UP) afflicts 30-40% of hemodialysis patients (HDP) and is associated with greater use of ESA and antibiotics. UP is hypothesized to be centrally-mediated via the reduction in endogenous κ/µ opioid ligand ratio. Nabumetone ER tablet (NAL), a κ-opioid agonist and µ-opioid antagonist, is being developed for treatment of UP.

Methods: 373 HDP with moderate or severe UP (Numerical Rating Scale, NRS itch intensity scores >4.5) were randomized to blinded placebo or NAL (60 or 120 mg BID) X 8-wks.

Results: Worsening itch intensity by baseline NRS quartile was monotonically associated with impaired QOL on all instruments as well as with sleep onset latency, anxiety, and depression, but not with age, gender, BMI, ethnicity, itch duration, IPTh, URR, or Kt/V. Black race appeared to be associated with higher NRS.

Conclusions: In addition to the 1st endpoint hypothesis that NAL will reduce itch intensity, the apparent associations between itch intensity and QOL measures at baseline warrant examination by treatment. Unblinded results will be presented.

TH-PO957
International Variation of Characteristics of Health Literacy and Its Association with Mortality in Dialysis
Kerri L. Cavanaugh,1 Mia Wang,1 Ken Wallston,1 Russell Rothman,1 Ali AlSahow,2 Patricia De Sequera,1 Takeshi Hasegawa,2 2Brian Bieber,2 Brian M. Robinson,2 Ronald L. Pisoni,2 Francesca Tentori.1,2
1Humber University; 2Abor Research; 1Jahra Hospital; 2Hospital Infantia Leonor; 1Fukushima Medical University.

Background: In patients receiving hemodialysis (HD), low health literacy (LHL) is associated with greater use of emergency care, more hospitalizations and higher mortality. Little is known about the characteristics of LHL in HD patients outside of the United States.

Methods: A total of 11,476 DOPPS participants completed the Brief Health Literacy Screen (BHLS) [0-12]. Descriptive statistics were performed overall and by country. Participants characteristics were examined between three health literacy categories using mixed, GEE, and multinomial logistic models. Cox models were applied to examine associations of LHL with mortality adjusting for the above variables and also potential effects of study phase, country, and facility clustering.

Results: LHL prevalence varied across countries (Figure). LHL was more likely in patients who were older, female, unemployed and in those who had fewer years on HD, lower education, and lower income (all P for trend<0.001). LHL was significantly associated with mortality when examined as a continuous score (HR=1.05; 95%CI=1.03-1.08 for each point decreased) or as a category (HR=1.65; 95%CI=1.28-2.12 Low vs. High), and with mortality when examined as a continuous score (HR=1.05; 95%CI=1.03-1.08 for patients who were older, female, unemployed and in those who had fewer years on HD, lower education, and lower income (all P for trend<0.001). LHL was significantly associated with mortality when examined as a continuous score (HR=1.05; 95%CI=1.03-1.08 for each point decreased) or as a category (HR=1.65; 95%CI=1.28-2.12 Low vs. High), and with mortality when examined as a continuous score (HR=1.05; 95%CI=1.03-1.08 for)

Conclusions: LHL is common worldwide among HD patients. Variability in LHL prevalence across countries may be in part explained by cultural differences as well as health care systems. Vulnerable patients are at highest risk of LHL, and LHL is an independent predictor of mortality. Further examining by country the role of health system practices may help to overcome LHL-related barriers to patient engagement and improve outcomes in hemodialysis.

Evaluation of a Vancomycin Weight-Based Dosing Protocol in Patients Undergoing High-Flux Hemodialysis
Katherine Desorges, Marieme N’Diaye, Robert Zoel Bell, Jean-Philippe Laferraine, Vincent Pichette, Michel Vallee.
Nephrology, Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.

Background: Hemodialysis patients are frequently subject to Gram-positive infections including Staphylococcus aureus and Methicillin-resistant Staphylococcus aureus (MRSA). Vancomycin is an antibiotic of choice in this population to treat these infections. The objective of this project was to validate the performance of a pre formatted individual prescription protocol of vancomycin in its capacity to reach target vancomycin serum concentrations of 10 to 30 mg/L for Gram-positive infections and 15 to 20 mg/L for MRSA infections.

Methods: The records of 84 patients diagnosed with end-stage renal disease undergoing a 4-hour, three times weekly high-flux hemodialysis treatment were analyzed retrospectively. All patients received vancomycin according to a weight-based dosing protocol between 2011 and 2014. Patients < 70 kg received a 1000 mg loading dose followed by a 500 mg maintenance dose at each dialysis session. Patients between 70 and 100 kg received a 1500 mg loading dose followed by a 750 mg maintenance dose. Patients > 100 kg received a 2250 mg loading dose followed by a 1000 mg maintenance dose.

Results: We collected and analyzed 189 dosages of 84 patients. For all assays, 95.2% achieved levels between 10 and 30 mg/L and 50.3% achieved levels between 15 and 20 mg/L. Stratified by weight categories, for the 10 to 30 mg/L target, 93.3% of patients < 70 kg, 100% of patients between 70 and 100 kg and 89.5% of patients > 100 kg achieved the target serum concentrations. For the 15 to 20 mg/L target, 49.3% of patients < 70 kg achieved the target serum concentrations (mainly below), 61.3% of patients between 70 and 100 kg achieved the target serum concentrations and 31.6% of patients > 100 kg achieved the target serum concentrations (mainly higher, but below 30 mg/L).

Conclusions: The vancomycin weight-based dosing protocol achieved target serum concentrations of 10 to 30 mg/L in 95.2% of patients. However, because half the dosages of patients < 70 kg were below the target of 15 to 20 mg/L, vancomycin bolus and maintenance doses should be adjusted upward in this subgroup. No dose change is suggested in the other subgroups.

Trends in Incident ESRD Counts Initiating Dialysis in Freestanding Facilities Have Regional Variation
David T. Gilbertson.1 Peer Kidney Care Initiative Investigators.1,2 CDRG, MRF, Minneapolis, MN; Peer Kidney Care Initiative.

Background: Overall rates of incident end-stage renal disease (ESRD) patients initiating dialysis in freestanding units have stabilized, and the growth in counts of incident ESRD patients began to slow by the beginning of this decade. We assessed trends in incident ESRD counts from 2004–2011, overall and geographically by the 9 US Census Divisions.
Methods: Data were ascertained from the Centers for Medicare & Medicaid Services ESRD database. For annual incident cohorts, we identified patients with their first outpatient dialysis within 3 months of initiating chronic dialysis in a freestanding facility.

Results: Yearly counts increased through 2010, with an average annual percent increase of 2.7% from 2004 to 2011. Between 2009 and 2011, this average percent increase was relatively unchanged (1.6%). However, there were regional differences, with increased New England Census Division experiencing the largest proportionate decrease in incident patients between 2009 and 2011, while the contiguous Middle Atlantic division averaged the highest increase during the same period by 2011.

Conclusions: Overall trends in dialysis incidence reveal substantial geographic variation that has not been explained, suggesting that an assessment based on overall U.S. counts may mask important regional differences. Whether these trends will continue in the face of increasing diabetes rates, an aging population and shifts in social demographic changes is uncertain and will require more detailed analysis.

Assocation of Intradialytic Hypoxemia with Hospitalization and Mortality: Results from a Large U.S. Hemodialysis Cohort

Nancy Ginsberg,1 Xiuling Ye,1 Stephanie Thijsen,1 Icahn School of Medicine at Mount Sinai, New York, NY; 1Renal Research Inst, New York, NY; 2Univ of Gruz, Austria; 3Univ of California - Santa Barbara, CA; 4Columbia University, New York, NY.

Background: While intradialytic hypoxemia is recognized since the early days of hemodialysis (HD), its associations with hard clinical outcomes have not yet been assessed.

Methods: We analyzed arterial oxygen saturation (SaO2) data obtained by Crit-Line™ monitor (CLM) in chronic HD patients treated between 1/2002 and 1/2015. An individual 6-month baseline with at least 10 CLM measurements preceded a 12-month follow-up. Prolonged intradialytic hypoxemia (PIH) was defined as SaO2 ≤ 90% for more than 1/3 of treatment time. Patients were stratified based on the presence or absence of PIH.

Results: We conducted Cox proportional hazards analysis with adjustment for age, gender, race, vintage, chronic obstructive pulmonary disease (COPD), congestive heart failure (CHF), diabetes, albumin, hemoglobin, erythropoietin (EPO) dose, neutrophil-to-lymphocyte ratio, interdialytic weight gain, post-HD systolic blood pressure, and ultrafiltration rate. PIH was associated with a higher hazard of hospitalization and mortality compared to patients without PIH (HR: 1.24, 95% CI: 1.11-1.38, p<0.001). The increases in hospitalization and mortality were most prominent in patients with both PIH and lower albumin and hemoglobin levels.

Conclusions: Prolonged intradialytic hypoxemia (PIH) is associated with increased risk for hospitalization and mortality. A better understanding of the pathophysiology of PIH, its clinical consequences and its medical management requires future basic and clinical research.

A New Poly methyl methacrylate Membrane (PMMA) Improves the Membrane Adhesion of Blood Components and Clinical Efficacy

Lauren J. Sexton,1 Donal J. Sexton,2 Scott Reule, Robert N. Foley, Medicine, Univ of Minnesota, Minneapolis, MN.

Background: Though the management of scleroderma continues to evolve it is unknown whether the burden of ESRD from scleroderma has changed.

Methods: We examined United States Renal Data System data (N = N = 1,557,117) for the years 1995-2010 to calculate incidence rates and outcomes of ESRD due to scleroderma. We conducted Cox proportional hazards analysis with adjustment for age, gender, race, vintage, chronic obstructive pulmonary disease (COPD), congestive heart failure (CHF), diabetes, albumin, hemoglobin, erythropoietin (EPO) dose, neutrophil-to-lymphocyte ratio, interdialytic weight gain, post-HD systolic blood pressure, and ultrafiltration rate. PIH was associated with a higher hazard of hospitalization and mortality compared to patients without PIH (HR: 1.24, 95% CI: 1.11-1.38, p<0.001). The increases in hospitalization and mortality were most prominent in patients with both PIH and lower albumin and hemoglobin levels.

Conclusions: Prolonged intradialytic hypoxemia (PIH) is associated with increased risk for hospitalization and mortality. A better understanding of the pathophysiology of PIH, its clinical consequences and its medical management requires future basic and clinical research.

Outcomes of Infants Receiving Chronic Peritoneal Dialysis

Hongying Dai,1 Laurel K. Willig,1 Bradley Warady,1 1Nephrology, Children's Mercy Hospital, Kansas City, MO; 2Research Development and Clinical Investigation, Children’s Mercy Hospital, Kansas City, MO.

Background: Outcome data for infants receiving chronic peritoneal dialysis (CPD) is limited and has been reported primarily by small voluntary registries. The impact of treatment era has also been poorly studied.

Methods: The USRDS database was reviewed for demographic features and outcomes of patients who initiated CPD in the first year of age from 1990-2014.

Results: A total of 1,730 infants (575 £1 month and 1155 >12 months) who initiated CPD at £12 months from 1990-2014 were identified. Overall, 68% of the infants were male and the most common primary diagnoses were obstructive uropathy (31.8%) and congenital renal dysplasia/hypoplasia (29.9%). Mean age at initiation of CPD was 0.4 months (±0.3 months) in infants £1 month and 5.2 months (±3.1 months) in infants >12 months.

Conclusions: The new PMMA (NF) membrane may improve the QOL of chronic dialysis patients by stabilizing the platelet and peripheral circulation.

Funding: Pharmaceutical Company Support - Financial support for Peer is provided by 13 participating dialysis provider organizations: American Renal Associates, Atlantic Dialysis Management Services, Centers for Dialysis Care, DaVita HealthCare Partners, Dialysis Clinic, Inc. TH-PO963

ESRD from Scleroderma in the United States 1995-2010

Donal J. Sexton,1 Scott Reule, Robert N. Foley, Medicine, Univ of Minnesota, Minneapolis, MN.

Background: Whether the burden of ESRD from scleroderma has changed.

Results: ESRD rates due to scleroderma in 1995-1996 were 0.6 per million per year in the overall population, with higher rates in age 40-64 (9.0) and ≥ 65 (14.1) years, females (0.8) and African Americans race (0.9). Standardized incidence ratios declined between 1995-1996 and 2009-2010 in the overall population (ratio 0.55), in those aged 40-64 yrs (0.49), 65+ yrs (0.62), in male (0.56) and female sex (0.55), in white AA (0.37). Characteristics of ESRD from scleroderma included age 40-64 (57.9% Vs. 41.3% yrs.), female sex (76.6% Vs. 45.1%) and white race (78.1% Vs. 65.2%). 74.3% of patients with scleroderma died over a mean observation period of 3.3 years, while 16.9% were
listed for renal transplant and 10.1% received a renal transplant. With matching for age, sex and race, overall mortality rates were higher in scleroderma cases than controls (22.3 vs. 15.5 per 100 person-years, P < 0.001). Overall rates of listing for renal transplant (8.4 vs. 8.5 per 100 person-years, P = 0.92) and rates of transplantation (4.1 vs. 4.3 per 100 person-years, P = 0.66) were similar in scleroderma cases and controls.

Results: The incidence of ESRD from scleroderma appears to have declined in the United States since 1995. Mortality rates on RRT are higher in scleroderma cases than controls taken from ESRD from other causes. However, listing for and receiving a renal transplant were as likely in scleroderma patients as matched controls.

TH-PO964

Background: As the prevalence and mortality associations of protein-energy wasting (PEW) syndrome criteria in the MHD population are not well established, we examined these in 1480 MHD pts in the HEMO Study, a multi-center RCT to examine the effects of dialysis dose and dialyzer flux on mortality.

Methods: The prevalence of International Society of Renal Nutrition and Metabolism PEW criterion (listed in the table) at the 12 m follow-up visit were examined. Subsequent mortality associations were examined in Cox models adjusted for demographics, duration of ESRD, Kt/V and flux groups, smoking and alcohol use.

Results: There were 632 deaths / 3390 yrs of follow-up. The prevalence of PEW criterion varied widely: 0% for low body fat% to 64% for low DEI (figure).

<table>
<thead>
<tr>
<th>PEW Criterion</th>
<th>All-cause mortality HR* (95% CI)</th>
</tr>
</thead>

TH-PO965
Primary Care Physician Involvement in the Care of Chronic Dialysis Patients in the U.S. Vahakn B. Shahinhian, Deanna Chyn, Yi Li, John Z. Ayanian, Richard Hirth, William H. Herman, Rajiv Saran. Univ of Michigan.

Background: Current health reform efforts aimed at improving quality and value center around delivery of good primary care. However, national patterns of primary care physician (PCP) involvement along with a nephrologist in the care of chronic dialysis patients are unknown.

Methods: Patients on chronic dialysis during 2010-11 with Medicare as the primary insurer were identified using US Renal Data System (USRDS) data. PCP involvement was defined based on a claim for an outpatient (non-dialysis) visit with a physician specializing in family practice, general internal medicine or geriatrics. Patients were characterized with respect to two aspects of preventive care: influenza vaccination and diabetes care.

Results: The sample included 179,645 patients, 81,272 of whom were diabetic. In 2010, 59% of patients had evidence of PCP involvement based on 1 outpatient visit. Patients with PCP involvement were older and more likely to be female, white and with diabetes as cause of ESRD (Table). Rates of vaccination and diabetes care were higher in those with PCP involvement, even after adjustment (ORs: 1.48 [1.45-1.51] for vaccination and 1.53 [1.48-1.58] for a composite of diabetes care).

By a more restrictive definition of ≥2 visits in 2010, 47% had PCP involvement; under a looser definition of ≥1 visit over 2 years (2010-11), vs 70%, had PCP involvement.

Conclusions: Even under the looser definition of PCP involvement, over one quarter of dialysis patients have no evidence of PCP involvement. Patients with PCP involvement have higher rates of preventive care, but further study should examine the impact on outcomes and costs.

Funding: NIDDK Support

TH-PO966
Are We Choosing Wisely? A Study of Colon Cancer Screening Practices Among Dialysis Patients in the United States Christopher A. Carlos, Chi-yuan Hus, Meda E. Pavkov, Nilka Rios Burrows, Vahakn B. Shahinhian, Rajiv Saran, Neil R. Powe, Kirsten L. Johansen. 1Univ of California, San Francisco, San Francisco, CA; 2Univ of Michigan, Ann Arbor, MI; 3Centers for Disease Control and Prevention, Atlanta, GA.

Background: Because estimated net gains in life expectancy are very small, the American Society of Nephrology recommended against routine cancer screening in asymptomatic dialysis patients. We aimed to determine how often colon cancer screening is performed in the U.S. and whether colon cancer screening is targeted toward healthier dialysis patients. Methods: We performed a retrospective cohort study of patients aged ≥50 years on dialysis between January 1, 2007 and September 30, 2012 using data from the United States Renal Data System (USRDS). Using multivariable Cox regression models, patients were divided into quartiles based on the risk of death and the likelihood of receiving a kidney transplant and, according to these quartiles of risk, we then assessed the likelihood of colon cancer screening (CCS) by fecal occult blood testing, sigmoidoscopy and colonoscopy from Medicare claims data.

Results: Of 391,616 patients, 13% received CCS over a median follow-up of 1.5 years (interquartile range 0.7-2.9). Screening was most common in patients with the lowest mortality risk (16%), compared with 9% of those with the highest mortality risk (HR 1.33;
Severe Sepsis Hospitalizations in Those on Maintenance Dialysis – National Trends and Outcomes
Ankit Sakhuja,1 Kianoush Banaei-Kashani,2 Hatem Amer,2 Robert C. Albright,1 Nephrology and Mayo Clinic.

Background: Severe sepsis (SS) is a life-threatening condition requiring early diagnosis and management. Incidence of SS is increasing in general population (GP) and mortality is declining; however, epidemiology and outcomes of SS have not been well studied in those on maintenance dialysis (MD). We designed this study to look at incidence and outcomes of SS in those on MD.

Methods: Using Nationwide Inpatient Sample database we included all hospitalizations (age ≥ 20 yr) with SS based on ICD-9-CM codes of severe sepsis, septic shock or blood stream infection with organ dysfunction from 2005 to 2010. Those on MD were identified based on ICD-9-CM codes. Age adjusted incidence of SS and mortality in subgroups was calculated by direct standardization to 2000 standard US population. Linear regression was used to assess trends over time and logistic regression to assess independent effect of MD on mortality.

Results: Of estimated 5,000,152 (95% CI: 4,798,520-5,201,784) hospitalizations with SS, 6.4% were on MD. Unadjusted incidence of SS was 145.4/1000 in MD compared to 3.5/1000 in GP with incidence rate ratio 40.9 (95% CI: 40.8-40.9). Age adjusted incidence of SS seems to be increasing in both subgroups though trend was not significant in MD (Fig 1).

Conclusions: Our findings suggest that screening was appropriately targeted to dialysis patients with longer life expectancies and away from those with the lowest chances of receiving kidney transplantation.

Funding: NIDDK Support, Other U.S. Government Support

TH-PO967

Unadjusted in-hospital mortality is higher in MD (30.3% vs 26.2%; p<0.001). Age-adjusted mortality is decreasing in both subgroups though trend was not significant in MD. Age-adjusted mortality continues to be higher in MD (Fig 1). MD is an independent risk factor for mortality with OR 1.26 (95% CI: 1.23-1.29).

Conclusions: Hospitalizations with SS are over 40 times more common in MD. Mortality is higher in MD and being on MD is an independent predictor of mortality in those admitted with SS. Though incidence of SS seems to be increasing, there is a trend towards decrease in mortality even in MD.

TH-PO968

Trends in Colorectal Cancer Screening in U.S. End-Stage Renal Disease Population
Kevin C. Abbott,1 Chyng-Wen Fuw,1 Paul L. Kimmel,1 Paul W. Eggers,1 Div of Kidney, Urologic Hematologic Diseases, NIDDK, NIH, Bethesda, MD; 2Social & Scientific Systems, Inc., Silver Spring, MD.

Background: Screening for colorectal cancer (CRC) has been recommended for those over 50 years old. Medicare coverage of CRC screening began in 2000. Dialysis patient care is shared by many practitioners, perhaps leading to therapeutic nihilism and insufficient screening. CDC data show almost 2/3 of patients at risk report CRC screening. We determined rates of CRC screening in ESRD hemodialysis (HD) patients, compared to a 5% Medicare sample, and to assess secular trends.

Methods: We used data from the 2001-2011 USRDS to describe trends in percentages of HD patients receiving CRC screening tests per year. We limited our study population to patients with Medicare Part A and B as primary payer to ensure complete Medicare claims data for CRC screening. Current Procedural Terminology /Healthcare Common Procedure Coding System (CPT/HCPCS) codes identified Medicare physician and supplier billing data for screening: colonoscopy (G0105 and G0121), sigmoidoscopy (G0104), and fecal-occult blood test (F0BT; G0107, G0328, and 82270). We compared HD data to a 5% Medicare sample.

Results: Overall, the proportion of HD patients having CRC screening decreased from 6.1% annually in 2001 to 3.5% in 2011 due to decreased use of FOBT. There was a persistent increase in the proportion of patients with colonoscopy or sigmoidoscopy for CRC screening in the 11-year study period, from 0.3% to 1.0% annually. In most years, male, black and age 50-75 patients were more likely to receive colonoscopy or sigmoidoscopy than female, white, and other age subgroups. In 2006, the most recent available comparable year, CRC screening in HD patients was less than that of the general Medicare population; 0.8% vs. 1.6% annually for colonoscopy and sigmoidoscopy, 0.4% vs. 8.1% including FOBT.

Conclusions: Screening for CRC in ESRD HD patients is less frequent than in the general Medicare population, and considerably less than CDC recommendations. Differences in ascertainment methods (CDC uses self-report) may account for most of the disparity from CDC estimates.

TH-PO969

Increasing Prevalence of Withdrawal from Dialysis: Trends from 2004-2011
James B. Wiener,1 Peer Kidney Care Initiative Investigators.2 CDCRG, MMRF; 2Peer Kidney Care Initiative.

Background: Voluntary withdrawal from dialysis, which frequently occurs when a patient perceives dialysis as having become unduly burdensome, is an area of increasing interest. How early withdrawal, defined as that occurring within 1 year of dialysis initiation, has changed over the past decade has not been fully explored.

Methods: Patients initiating dialysis between 2004 and 2011 were selected from the Centers for Medicare & Medicaid Services End-Stage Renal Disease (ESRD) database. Information on withdrawal was ascertained from the ESRD Death Notification Form by the presence of code 104 (“withdrawal”) in the 1st or 2nd position. The unadjusted cause-specific monthly mortality rate (deaths per 100 pt-years) was calculated for patients initiating in each year.

Results: Annual incidence counts ranged from 87,174 (2004) to 100,665 (2011). Overall, during the first year of dialysis, the withdrawal rate was highest soon after initiation, peaking at month 2 for all years except 2004. Rates then decreased until approx. month 9, stabilizing through month 12. Additionally, early rates more than tripled over the study period, from 1.9 per 100 pt-years at month 2 in 2004 to 5.9 in 2008 to 6.4 in 2011.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

319A
Conclusions: Withdrawal rates are high in the weeks immediately after dialysis initiation, a pattern more marked in recent years. Because patients who withdraw soon after initiation may be suboptimal dialysis candidates, future work should focus on determining whether a tailored approach, designed to identify individual patient goals and present the risks and benefits of dialysis and viable alternatives such as conservative care, might provide optimal patient-centric care.

In collaboration with the Chief Medical Officers of these organizations, the Peer Kidney Care Initiative is operated by the Chronic Disease Research Group, a division of the Minneapolis Medical Research Foundation, in Minneapolis, MN, Private Foundation Support

TH-PO970
The Dialysis Sodium Gradient – A Modifiable Risk Factor for Fluid Overload

Background: Fluid overload in patients on conventional hemodialysis is a frequent complication associated with increased hospitalizations, cardiovascular morbidity and all-cause mortality. There are multiple patient and physician-related factors that lead to fluid overload. Individualizing dialysate sodium prescription and minimizing the sodium gap are potential modifiable risk factors.

Methods: We performed a cross-sectional study on 111 prevalent stable conventional hemodialysis patients at the McGill University Health Center. The associations of sodium gradient with various hemodialysis parameters of fluid status including interdialytic weight gap, ultrafiltration (UF) rate, blood pressure (BP), intradialytic hypertension and intradialytic hypotension were analyzed.

Results: The mean serum sodium gradient was 4.6 ± 3.6 mEq/L with a mean pre-dialysis sodium of 137.4 ± 2.5 mEq/L and a mean dialysate sodium of 142.0 ± 3.6 mEq/L. There was a direct correlation between sodium gradient and interdialytic weight gain percentage (IDWG), ultrafiltration (UF) rate, blood pressure (BP), intradialytic hypertension and intradialytic hypotension were analyzed.

Sodium Thiosulfate Therapy Calcific Uremic Arteriolopathy: Mortality Outcomes with and without
Therapy
Chamberlain L. Obialo, Alexander Quarselle. Dept of Medicine, Morehouse School of Medicine, Atlanta, GA; Clinical Research Center, Morehouse School of Medicine, Atlanta, GA, Venezuela.

Background: Calcific uremic arteriolopathy (CUA) or Calcinosis is commonly seen in patients with end stage kidney disease (ESKD) and carries a high mortality risk. There is no definitive therapy for this condition but promising results have been reported in patients treated with intravenous sodium thiosulfate (STS). However, the mortality advantage of therapy with STS over therapy without STS remains unknown.

Methods: We retrospectively reviewed our ESKD patient’s records over a 10-year period and identified 45 biopsy confirmed cases of CUA. Associations between patients who received STS therapy and those who did not and various categorical end points were assessed using the Pearson chi-squared tests while differences in continuous end points were examined using Mann-Whitney- U tests. Survival analysis utilized Kaplan-Meier plots. All statistical tests were two-sided, and level of significance set at 0.05.

Results: The mean age of the 45 cases was 63, 60% female, mean body mass index was 34 and mean dialysis vintage was 4 years. Of the 45 cases, 23 (51%) received STS while 22 (49%) did not. The mean serum albumin, phosphorus and parathyroid hormone was 2.8 g/dl, 6.7 mg/dl and 989 pg/dl respectively. One – year mortality was 22% in STS vs. 50% in no STS cases, p = 0.05. The overall survival of the patients over the 2- year study period was significantly superior in the recipients of STS than in those who did not receive STS, p = 0.03.

Patients who did not receive STS were also more likely to have major surgeries than those who received STS, 86% vs. 52%, p = 0.01.

Conclusions: Sodium thiosulfate therapy appears to confer both short term and long term survival advantage over no STS. We encourage hospitals and dialysis companies to procure and make this agent more available to physicians.

Effect of High-Dose and High-Flux Hemodialysis on Markers of Inflammation in the HEMO Study
Kristen L. Nowak,1 Tom Green,2 Jian Ying,2 Alfred K. Cheung,2 Michel Chonchol,1 1Univ of Colorado Denver; 2Univ of Utah.

Background: Hemodialysis treatment induces markers of inflammation, which could affect clinical outcomes. This study sought to determine whether high-dialysis dose and high-flux dialysis would improve markers of inflammation compared with standard dialysis dose and low flux dialysis.

Methods: The HEMO Study was a randomized multicenter study of the effects of high-dose versus standard-dose and high-flux versus low-flux hemodialysis. Serum high sensitivity C-reactive protein (hs-CRP, pre-specified primary outcome for this set of analyses) and interleukin-6 (IL-6) were measured in stored serum samples in 1,846 HEMO participants. For each inflammatory marker we used a joint multi-state modeling approach to estimate the proportion of patients in 5 ordered states (S) over 3 annual assessments while accounting for mortality: S1=deceased (score=0), S2=alive in highest quartile (score=1), S3=alive in 2nd quartile (score=2), S4=alive in 3rd quartile (score=3), and S5=alive in lowest quartile (score=4). The average rank was computed over 3 yrs of follow-up and compared between the randomized groups.

Results: Randomized patients had high rates of coexisting conditions: 45% had diabetes, 80% had a history of cardiac disease. Characteristics of the patients in the two dose groups were similar, as were the characteristics of those in the two flux groups. The state distribution of hs-CRP in each year by dose (KTV) group and by flux group for hs-CRP are shown in Figure 1.

Comorbidity Data Source May Impact SMR/SHR Calculation

Jiannong Peng, 1  Mahesh Krishnan, 2  Jincheng Zhou, 1  Kimberly M. Nieman, 1  Yi Peng, 1  David T. Gilbertson, 1

CDRG, MMRF, MPLS, MN; 2 DaVita Healthcare Partners, Denver, CO.

Background: Standardized mortality and hospitalization ratios (SMRs and SHRs) are used to measure dialysis facility performance, with adjustment for demographics and comorbidities derived from the end-stage renal disease (ESRD) Medical Evidence (ME) Report. Sensitivities are low for ME-based comorbidities. We investigated the effect on SMR and SHR calculations by comparing ratios adjusted for claims-based comorbidities.

Methods: Using the USRDS ESRD database, we included US hemodialysis patients who initiated dialysis July 1-December 31, 2006-2010, had Medicare as primary payer, were aged ≥ 66 years, and had no prior transplant (TX). Patients were followed from dialysis initiation to the earliest of death, TX, modality change, or 1 year. SMRs and SHRs were calculated for patients in for-profit/non-profit and rural/urban facilities for ME-based and claims-based comorbidity, separately. Cox models were used for expected number of deaths and piecewise Poisson models for expected number of hospitalizations. Agreement of comorbidity between the two sources was measured by a kappa statistic.

Results: 73,950 incident hemodialysis patients were included. Kappas for comorbidity agreement were low, less than 0.5, except for diabetes (0.77). Percent of patients with claims-based comorbidity was similar for for-profit and non-profit facilities; ME-based comorbidity was lower for for-profit facilities. Differences between ME-based and claims-based SMR/SHR, claims-based ratios decreased 0.9%/0.6% for for-profit and 1.0%/0.7% for urban facilities and increased 3.4%/2.8% for non-profit and 5.9%/4.1% for rural facilities.

Conclusions: Comorbidity data source may impact performance evaluation. The impact is larger for smaller groups, and may increase with prevalent patients included.

Thematic Analysis of the Medical Records of a National Cohort of Patients Who Initiated Maintenance Dialysis: 2000-2009

Susan P.Y. Wong, 1  Elizabeth Vig, 1  Nilka Rios Burrows, 2  Chuan-fen Liu, 1  Desmond Williams, 2  Paul L. Hebert, 1  Ann M. O’Hare, 1

1Univ of Washington; 2Center for Disease Control.

Background: Little is known about how decisions to initiate dialysis take shape in clinical practice.

Methods: We performed a qualitative thematic analysis of the medical records of patients who initiated maintenance dialysis to understand factors that impact decisions to initiate maintenance dialysis as they occur in clinical context. We analyzed key care processes, patient-provider interactions and patient and/or provider concerns and considerations relevant to the decision to initiate dialysis as documented in the electronic medical records of a national random sample of patients for whom the decision to initiate maintenance dialysis was made at the Department of Veteran Affairs between 2000 and 2009 (n=1,691).

Results: We identified three dominant, overlapping themes pertaining to the decision to initiate dialysis: 1) dialysis initiation as process, which describes the decision to initiate dialysis as integrated with other treatment decisions and unfolding over time rather than an isolated decision occurring at a fixed point in time; 2) sources of momentum for dialysis initiation, which describes factors that appeared to hasten the process of dialysis initiation and included hospitalization for acute illness and efforts to optimize patients’ clinical status for future medical interventions; and, 3) push-pull dynamics between patients and providers, which describes the sometimes adversarial relationship between patients and providers during the process of dialysis initiation in which patients were often portrayed by providers as “resistant” to dialysis initiation while providers appeared paternalistic and safety conscious in their approach towards treatment decisions.

Conclusions: Our analysis of the medical record underscores the complexity of treatment decisions about dialysis initiation in real-world clinical settings and supports a re-conceptualization of dialysis initiation as a process that unfolds over time rather than as a discrete treatment decision occurring at a fixed point in time.

Trends in 30-Day Readmission Rates in Dialysis Patients During an Era of Medicare Payment Policy Changes, 1996-2012

Allan J. Collins, 1  Peer Kidney Care Initiative Investigators.

1MMRF; 2Peer Kidney Care Initiative.

Background: High hospital readmission rates, which may indicate inadequate quality of care and result in unnecessary expenditures, have been a recent focus for Medicare. Medicare has enacted payment-related policy changes: freezing the inpatient payment rate (1997), expanding “disproportionate share” hospital payments (early 2000s), tying

hsCRP did not differ significantly between dose (p=0.83) or flux groups (p=0.53). Similar results were obtained for IL-6.

Conclusions: Over 3 years, neither high-dose nor high-flux dialysis exhibited a beneficial effect on markers of inflammation.
reimbursement for outpatient hemodialysis services to the number of monthly visits (2004), introducing the new Medicare prospective payment system (2011), and instituting the “hospital payment penalty” (2012). Given evidence demonstrating links between these changes and readmission rates in the general population, we sought to examine changes in 30-day readmission rates in dialysis patients 1996–2012.

Methods: Data were obtained from the Centers for Medicare & Medicaid Services End-Stage Renal Disease database. Dialysis patients were assessed for discharges from short-term or critical access hospitals. Thirty-day readmission rates were calculated, without adjustment for differences in patient case-mix or hospital characteristics.

Results: All-cause readmission rates increased modestly over the period studied except for 2012. The rate was 32.8% in 1998; the rate increased to 34.6% in 2005, fell to 34.1% in 2009, and peaked at 34.8% in 2010. Discharge data in the first 6 months of 2012 showed further decrease (32.8%). In comparison, other studies show that the rate in the general Medicare population was generally stable 2007-2011 (19.0%), and decreased in 2012 (18.4%).

Conclusions: Thirty-day readmission rates were substantial in dialysis patients compared with general Medicare patients, possibly reflecting case-mix. How public policy changes may have affected potentially avoidable readmissions should be more fully explored. Cause-specific readmission rates might provide a better reflection of quality of care and should be examined.

TH-PO976

The Impact of Volume Status on Nocturnal Hypoxemia in Patients Undergoing Maintenance Hemodialysis Farhana Yousaf, Mittesh K. Patel, Sherbeth Marie C. Young, Chaim Charytan, Alla Goldberg, Bruce S. Spinowitz. New York Hospital Queens, flushing, NY.

Background: Hemodialysis patients experience changes in volume status according to hemodialysis schedule. Excess fluid volume may shift to the neck upon assuming a head-down position during overnight dialysis leading to edema of the soft tissues and peripharyngeal edema. We explored the impact of volume status on nocturnal hypoxemia in the hemodialysis population.

Methods: Following local IRB approval, adult hemodialysis patients who were undergoing regular chronic hemodialysis (HD) for at least 3 months were consented to complete two nights of nocturnal oximetry using Pulsox 300i wristwatch. HD night was defined as the night of HD treatment whereas non-HD night was defined as the night on which no HD was performed. The first hour of recording was deleted in efforts to capture changes and readmission rates in the general population, we sought to examine changes in 30-day readmission rates in dialysis patients 1996–2012.

For the 5 most common causes of hospitalization, the principal cause for readmission was in the same category as the initial admission, accounting for 18-32% of readmissions.

Conclusions: Thirty-day hospital readmission in Medicare recipients on dialysis is frequently linked to rehospitalization caused by the same underlying conditions. Additional research is warranted to further explore this phenomenon and develop preventive strategies.

TH-PO977

Hospital Readmission within 30 Days of Discharge Among Adults Receiving Dialysis Lorenzo D. Dalrymple, Barbara A. Grimes, Patrick S. Roman, Yi Mu, Danh V. Nguyen, Kirsten L. Johansen. 1 UC Davis; 2 UCSF; 3 UC Irvine, San Francisco VA.

Background: Hospital readmission is common in adults receiving dialysis. Few studies have examined the timing or causes of 30-day hospital readmissions.

Methods: We used the USRDS to examine adults initiating dialysis Jan 2009 through Dec 2010 who had Medicare as the primary payer. The cohort was followed from day 90 of dialysis for up to one year, with censoring for death, renal recovery or transplant. We classified the principal cause of the index hospitalization and hospital readmission using Clinical Classification Software.

Results: Our cohort consisted of 103,381 patients. During follow-up, 50,639 patients experienced 89,728 index hospital admissions; 5% resulted in in-hospital death. Of the 85,284 live hospital discharges, 25,792 (30%) were associated with 30-day readmission. The median time to readmission was 11 [5; 19] days. Leading causes of readmission by cause of index hospitalization are in Table 1.

Racial/Ethnic and Age Differences in Cause-Specific Deaths Among U.S. Dialysis Patients Alison J. Yu, Keith C. Norris, Alfred K. Cheung, Guofen Yan. 1 Univ of Southern California; 2 UCLA; 3 Univ of Utah; 4 Univ of Virginia.

Background: Recent research reported that Hispanics have the lowest all-cause mortality, African Americans (AAs) intermediate, and Whites the highest among U.S. dialysis patients over 30 years old. The objective of this study is to examine whether this risk pattern varied depending on the cause of death.

Methods: The study included 1,255,640 adult incident dialysis patients between 1995 and 2010 in the USRDS, with no prior kidney transplantation. We examined 5 major cause-specific deaths: cardiovascular (CVD), infection, malignancy, others, and unknown. Cause-specific hazards for each cause-specific death were compared among AAs, Hispanics, and Whites for overall and stratified by age groups.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

322A
Results: After adjustment for multiple covariates (Table), compared with Whites, in all age groups, Hispanics consistently had lower risks of cause-specific deaths for all major causes examined (HRs<1), while AAs also had lower risks except for the cause of infection, for which AAs had significantly higher risks in age groups of 50-70 years (HRs from 1.07-1.94).

</table>

Note: all significant at p<0.05 except the ones indicated by *.

Conclusions: The racial difference observed in all-cause mortality, in which Hispanics have the lowest risk, AAs intermediate, and Whites the highest, was also noted for major cause-specific deaths in most age groups, except for the cause of infection. Both younger and older AAs are at the greatest risk of death due to infection. Further studies are needed to explore the specific reasons responsible for the higher risk of infection-related death in AAs.

TH-PO979
Dialysis Therapy and Mortality in Older Heart Failure Patients with Advanced Chronic Kidney Disease: The Kaiser Permanente MATCH Study

David Law, Sijie Zheng, Sharina Belani, Jingrong Yang, Thida Tan, Juan Daniel Ordonez, Susan Kim, Alan S. Go. Kaiser Permanente Northern California.

Background: Heart failure (HF) and chronic kidney disease (CKD) often coexist and those with both have much worse outcomes than having either alone, with limited data to guide optimal management. We evaluated the outcome of dialysis therapy in a diverse elderly cohort with HF and advanced CKD.

Methods: In Kaiser Permanente Northern California, a large integrated healthcare system, we identified members ≥70 years with HF and estimated glomerular filtration rate (eGFR) £20 ml/min/1.73 m² between 2008-2012 and no prior renal replacement therapy, cancer, cirrhosis or organ transplant. Through 2013, we identified patients who started chronic dialysis and individually matched controls who were alive on the dialysis start date of the matched case along with age, gender, diabetes status, and high-dimensional propensity score to start dialysis. Demographics, clinical features and drug use were obtained from electronic records. We calculated rates of death through 2013 and examined the impact of dialysis on mortality using Cox regression.

Results: We identified 334 eligible HF-CKD cases who initiated dialysis and 899 matched control patients ≥20 years old matched on HF characteristics. Mean age was 80.1±4.8 yrs, with 51% women, 33% black and 72% diabetic. Case and control patients were well-matched across characteristics, except for controls being less likely to be Hispanic or have proteinuria, or to receive alpha blockers or thiazide diuretics; and more likely to have prior intracranial bleeding, liver disease, dementia and higher blood pressure, hemoglobin and mean eGFR (16.4 vs. 12.0 ml/min/1.73 m²). Incidence of death was 32 per 100 py in combined case and control patients. Among matched patients, after further adjustment for residual differences in patient features, dialysis was independently associated with a 47% lower rate of death (hazard ratio 0.53, 95%CI:0.41-0.67).

Conclusions: In older adults with HF and advanced CKD, dialysis was independently associated with a lower mortality. Randomized trials are needed to determine the net outcomes of dialysis related to both length and quality of life in the elderly with HF.

Funding: Private Foundation Support

TH-PO980
Gender, Poverty, and Dialysis Mortality in Adults with Sickle Cell Disease

Background: Chronic dialysis patients with sickle cell disease (SCD) have increased mortality compared with the general US dialysis population. The contributions of gender and neighborhood poverty to dialysis mortality in SCD patients are largely unknown.

Methods: Using USRDS data, we linked all US adults with SCD who initiated dialysis between 1995-2012 with zip-code level US Census neighborhood data. We performed multivariable Cox regression models with adjustment for age, dialysis type, BMI, and diabetes status to compare mortality between men and women, stratified by neighborhood poverty level. Neighborhoods with ≥20% of households living below the federal poverty level were defined as poor.

Results: The study cohort included 1,681 SCD patients on dialysis with 52% male, 94.7% black, mean age 42.5, and 55.9% living in poor neighborhoods. 1-, 5-, and 10-year mortality in this population were 26.1%, 67.9%, and 85.5%. Overall, men had similar mortality to women (aHR: 0.96, 95% CI: 0.86-1.07, p=0.45). However, men living in poor neighborhoods had a higher risk of death than women (aHR: 1.20, 95% CE: 1.04-1.40, p=0.015). (Figure 1) The median survival time from dialysis initiation for poor men with SCD was 2.37 years. In comparison, the median survival time for poor men without SCD was 3.77 years.

Figure 1. Dialysis Mortality in Sickle Cell Disease Patients by Gender and Neighborhood Poverty

Conclusions: Men with SCD who live in poor neighborhoods were at highest risk of death. Efforts to address socioeconomic barriers may be an important target for improving survival in this population.

TH-PO981
Peritoneal Dialysis (PD) Patient Outcomes Under the Dialysis Prognostic Payment System (PPS)

Marc Turecmen, Regina M. Baker, Jeffrey Pearson, Chad M. Cogan, Parma Mukhopadhyay, Elizabeth L. Cope. Arbor Research Collaborative for Health, Ann Arbor, MI.

Background: The use of PD was expected to be incentivized by the expanded Medicare PPS that was implemented in 2011. There is early evidence under the PPS of additional incident ESRD patients and dialysis facilities using PD (Hirth et al 2013; Turecmen et al 2014). More widespread PD use could have implications for PD outcomes due to potential changes in PD selection or in the experience of dialysis providers with PD. This study assessed PD patient outcomes before and after the new PPS was implemented.

Methods: This study included n=36,582 incident ESRD patients for whom PD was identified as the intended initial dialysis modality on the CMS ESRD Medical Evidence Form during 2008-12. We evaluated 1-year PD technique failure and PD patient mortality using data from Medicare claims, the Standard Information Management System, CRWNWeb, and the CMS Death Notification Form. PD technique failure was ascertained when hemodialysis was used for at least 60 days.

Results: Selection of PD increased from 5.8% to 8.4% of incident patients between 2008 and 2012 (see Figure).

Conclusions: Men with SCD who live in poor neighborhoods were at highest risk of death. Efforts to address socioeconomic barriers may be an important target for improving survival in this population.

Funding: NIDDK Support, Other NIH Support - NHLBI

TH-PO982
key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

323A
During this period, 1-year PD technique failure decreased from 18.8% to 16.1% of patients and 1-year PD patient mortality decreased from 9.4% to 8.6% (see Figure). Outcomes were relatively stable or improving across patient age, race, and Hispanic ethnicity subgroups and for patients in both urban and rural areas.

**Conclusions:** In the context of expanding PD use under the new PPS, there is no early evidence of worsening overall PD patient outcomes or of growing disparities in PD patient outcomes by demographic group or by urban/rural location. Instead, there were lower levels of PD technique failure and PD patient mortality in the initial years of the new payment system.

### TH-PO982

**Cognitive Impairment and Mortality in Adults on the Kidney Transplant Waitlist**  
**Mara McAdams-DeMarco, Hao Ying, Israel O. Olorundare, Dorry L. Segev. Johns Hopkins.**

**Background:** Older adults with poor cognitive function are at increased mortality risk. It is unclear whether ESRD patients of all ages with cognitive impairment are at increased mortality risk of while on the kidney transplant (KT) waitlist.

**Methods:** 918 ESRD patients being evaluated for and waitlisted for KT (no previous listings) at Johns Hopkins were enrolled in a prospective cohort study (11/2009-5/2014). The Modified Mini Mental Status (MMS), a test of global cognitive function (range 0-100, higher scores represent better function) was assessed at KT evaluation. Global cognitive impairment was defined as MMS score<80). Mortality risk by MMS score and cognitive impairment (separately) was estimated using an adjusted Cox proportional hazards model; participants were censored at the waitlist removal, time of KT or administrative end of follow-up.

**Results:** At KT evaluation, the mean (SD and range) age was 54 (14; 18-86), 57% were male, and 46% were African American. The mean (SD and range) MMS score was 82.6(11, 47-100) and 52% were classified as having cognitive impairment. 45 participants died over an average of 1.7 years of follow-up. Mortality risk was greater for adults on the KT waitlist who had worse MMS scores (1 point decrease in MMS score: HR=1.05, 95% CI: 1.02-1.08, P=0.003) and those with cognitive impairment (HR=2.51, 95% CI: 1.91-3.33, P<0.001) versus no impairment.

**Conclusions:** Among adults ESRD patients, impairment in global cognitive function more than doubled the risk of waitlist mortality. A simple screener for global cognitive function scores at the evaluation for first listing would not only identify adults with ESRD who have unrecognized cognitive impairment but also identify a high-risk population.

**Indications, Technique, and Outcome of Plasmapheresis in a Large Pediatric Dialysis Center**  
**Rainer Büscher, Lülbert Lübbers, Anja K. Büscher, Peter F. Hoyer. Pediatric Nephrology, Univ of Duisburg-Essen, Pediatrics II, Essen, Germany.**

**Background:** Plasmapheresis (PP) is a established therapeutic option for various indications in pediatric patients. However, there are only few reports with only little information on clinical outcome.

**Methods:** We performed a retrospective analysis involving 86 children and adolescents undergoing PP in our pediatric dialysis unit from 1997 to 2013.

**Results:** Within the observation period, 86 children (41 male), mean age 8.7±3.2 years (3 months to 18.9 years) received PP for a total of 652 sessions (1-33 sessions/patient; mean 6.4±3.1 sessions/patient). Most patients (30.2%) were treated for hematologic disorders. Complications during PP included encephalitis (5.5%), renal failure (1.2%), peritonitis (0.9%), and death (0.5%).

**Conclusions:** In the context of expanding PD use under the new PPS, there is no early evidence of worsening overall PD patient outcomes or of growing disparities in PD patient outcomes by demographic group or by urban/rural location. Instead, there were lower levels of PD technique failure and PD patient mortality in the initial years of the new payment system.

**Who Makes the Best Exit Site: Nephrologist or Surgeon?**  
**Vaihbrah S. Keskar, Mallory B. Byiani, Brian Blew, Jeffrey Warhen, Brendan McCormick. The Ottawa Hospital, Univ of Ottawa, Ottawa, ON, Canada.**

**Background:** Buried peritoneal dialysis (PD) catheters are placed months before dialysis is needed and the exit site is created at the initiation of dialysis by the nephrologist. In contrast, the exit site of an unburied catheter is created by the surgeon at the time of insertion. Our PD unit uses both methods of catheter placement. We undertook this study to compare the outcomes of the two methods of exit site creation.

**Methods:** The charts of all patients who initiation PD between Jan 2012 and Dec 2013 were reviewed. At each clinic visit, exit sites were graded by the PD nurse into standard predefined groups: perfect, good, equivocal and infected. Primary outcome was the frequency of perfect exit sites at 2, 6, and 12 months after initiation of PD. Secondary outcomes were exit site infections, peritonitis and technique failure due to exit site infection.

**Results:** 119 patients started PD during the period of interest and 114 remained on PD at 2 months. 52 patients had buried catheters externalized at the time of starting PD (group A) and 62 patients had unburied catheters (group B). Group A had more males (71% vs 48%), had higher mean age (65±14 vs 59±15) and had most of the patients as incident dialysis patients. Diabetic nephropathy was the most common underlying disease in either group (61.53% and 51.61%). Group B had a higher frequency of perfect exit sites at 2 months but this difference disappeared by 6 and 12 months. There was a trend towards more exit site infections in Group A but this did not translate into more technique failure.

**Conclusions:** Buried catheters are less likely to have perfect appearance at two months compared to unburied catheters; however this is no longer significant at six and 12 months. The trend towards more exit site infections with buried catheters suggests that there may be clinical consequences of the tissue trauma at time of exteriorization. Consideration should be given to the use of prophylactic antibiotics at exteriorization.

**Prevention of Peritoneal Dialysis Catheter-Related Infections – A Multicenter Randomized Controlled Trial**  
**Mercedes L. Veja, Paula López, Carmen Felipe, Jose Ramon Rodriguez-Palomares, Gloria Del peso, Francisco Javier Alfiajo, Fernando Tornero, Mar'a Jose Fernandez Reyes, Ana M. Tato, Maria Rosario Luque, Jose M. Portoles. Grupo Centro Diálisis Peritoneal, Spain.**

**Background:** Peritonitis, tunnel and catheter exit site (CES) infections are the most serious complications of peritoneal dialysis (PD). We studied the effect of antibiotic ointment (EU/DRAC: 2009-016835-36) on catheter-related infections (CRI) and morbidity.

**Methods:** Allocation was stratified in blocs of 4 centers. Ointment containing 2% colistin, tobramycin, amphotericin B and 4% vancomycin or normal saline were applied to the CES over 1 year. Follow-up period was 3 months after the last dose. Exit site infection (ESI) was defined as erythema, edema or local pain with purulent secretion and positive culture. Antimicrobial therapy was given according to local protocols.

**Results:** 140 patients were included, 6 didn’t meet entry criteria. Characteristics and dialysis parameters of the 65 in the control group (CG) and 69 intervention group (IG) patients were comparable.

**Conclusions:** In the context of expanding PD use under the new PPS, there is no early evidence of worsening overall PD patient outcomes or of growing disparities in PD patient outcomes by demographic group or by urban/rural location. Instead, there were lower levels of PD technique failure and PD patient mortality in the initial years of the new payment system.

324A
Mean study duration was 0.6 (IG) vs 0.6 (CG) years (ns). 26 episodes of CRF (11 ESL, 4 tunnel, 11 peritonitis) occurred in the CG and 12 in the IG (3 ESL, 0 tunnel, 9 peritonitis) (p=0.001). Etiology of ESI was Staphylococcus aureus (x7), Corynebacterium spp., Pseudomonas aeruginosa, E. coli, Serratia spp., caulase-negative S. (x2) and 1 negative culture in the CG and S. aureus (x1), 1 Gram-negative bacillus and 1 negative culture in the IG. Systemic or topical antibiotics were given for ESI in 11 (CG) and 2 patients (IG) (p=0.01), respectively. Hospital admissions were 23 (CG) and 15 (IG). Local side effects were significantly increased in the IG.

Conclusions: Local prophylaxis with a broad-spectrum antimicrobial ointment is associated with a significant reduction in ESI and systemic antibiotic use without associated bacterial resistance. Significant local side effects were observed.

Association Between Plasma Fibroblast Growth Factor-23 and Carotid Artery Atherosclerosis in Peritoneal Dialysis Patients

Nanmyi Liu
Jinmin Hospital of Shanghai.

Background: We investigate the association between plasma fibroblast growth factor-23 (FGF-23) level and carotid artery atherosclerosis of 125 stage 5 chronic kidney disease (CKD5) patients, who are doing continuous ambulatory peritoneal dialysis (CAPD) at renal division of Shanghai Jinmin Hospital in China.

Methods: A retrospective cohort study of individuals 15 years of age and older, divided into two cohorts according to carotid intima-media thickness (CIMT): C. normal cohort (CIMT<0.9mm) and CIMT thickening cohort (CIMT>0.9mm). Plasma FGF-23 concentrations were determined by ELISA. CIMT thickness and atherosclerotic plaques were measured by carotid ultrasound.

Results: Of the 125 PD patients, the CIMT was thickened in 82 patients (65.6%). Compared with the CIMT normal patients, plasma FGF-23 concentration was significantly increased (p=0.01) in the CIMT thickening cohort (Table 1). Linear regression analysis discovered an obvious positive correlation between plasma FGF-23 and CIMT (r=0.416, P=0.006) (Table 2). Multiple regression analysis indicated that plasma FGF-23 level was independent risk factor for CIMT (β=0.421, t=2.607, P=0.003) (Table 3).

Conclusions: The level of plasma FGF-23 was positively correlated with CIMT and played an important role in development of carotid artery atherosclerosis in peritoneal dialysis patients.

Atherogenic Index of Plasma Is Associated with Insulin Resistance in Non- Diabetic Peritoneal Dialysis Patients

My June Lee,1 Jae Eun Im,2 Meiyan Wu,2 Tae ik Chang,2 Tae-Hyun Yoo.1 1Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; 2Brain Korea 21 PLUS, Severance Biomedical Science Inst, Yonsei Univ College of Medicine, Seoul, Korea; 3Dept of Internal Medicine, NHIC Ilsan Hospital, Gyeonggi-do, Korea.

Background: Insulin resistance (IR) is an independent risk factor for cardiovascular morbidity and mortality. Although many factors including uremia, chronic inflammation, and abnormal adipokine levels are known to contribute to the development of IR, the role of pro-atherogenic lipoprotein on IR remains unknown in peritoneal dialysis (PD) patients. Therefore, we investigated the independent association between pro-atherogenic lipoprotein and IR in non-diabetic PD patients.

Methods: We conducted a cross-sectional study in 75 non-diabetic PD patients. Pro-atherogenic lipoprotein was assessed by the atherogenic index of plasma (AIP, log transformed triglyceride to high-density lipoprotein cholesterol ratio). IR was determined by homeostatic model assessment-IR (HOMA-IR). Patients were divided into the higher transformed triglyceride to high-density lipoprotein cholesterol ratio). IR was determined by homeostatic model assessment-IR (HOMA-IR). Patients were divided into the higher

Conclusions: IR was determined by homeostatic model assessment-IR (HOMA-IR). Patients were divided into the higher

Impact of Patient-Centred Automated Peritoneal Dialysis User-Interface on Operator Learning and Confidence

Catherine Firnnek, Mary Gellens, James A. Slood. Medical Affairs, Baxter Healthcare, Deerfield, IL.

Background: Automated peritoneal dialysis (APD) is an underutilized therapy for patients with end-stage renal disease (ESRD). The perception patients may not be able to manage their own treatment setups comes into play in choice of this treatment modality. Improvements to cyclergist technology may help to further simplify therapy for patients,
reducing barriers to uptake. This study aimed to determine whether a cycler-embedded, patient-centric interface offered an enhanced user experience compared to a conventional APD cycler.

Methods: 30 study participants (ages 29-84, mean 50 yrs, 67% male) diagnosed with ESRD were randomized into two groups using cycler with patient-centric user interface with advanced technology in development and a conventional APD cycler. Participants evaluated both cyclers on 2 non-consecutive days using a different cycler each day. Each participant was given a brief orientation, setup task, training session, break, followed by a setup task and questionnaire. Study results were analyzed via Fisher’s exact, Mann-Whitney and Exact binomial tests.

Results: The cycler with patient-centric user interface and advanced technology (in development) scored better on reduced reliance on printed instructions (p=0.001). Patients committed fewer deviations on the cycler in development vs the conventional cycler (2 of 19 vs 14 of 19 respectively) after training (p=0.004), including disinfecting hands (p=0.02) and line handling (p=0.01), and were more confident that they set up the cycler according to specifications (p=0.043). The new cycler scored higher in overall preference among study participants: The cycler with a patient-centric user interface was rated easier to learn (p=0.005) and to use (p=0.016), and users felt more confident operating the new cycler at home compared to conventional cycler interface.

Conclusions: A cycler with embedded, patient-centric interface was rated higher in terms of overall reliance on instructions, task competency, ease of use and learning, preference and overall confidence of using the cyclers. These findings indicate that APD cycler learning and confidence can be enhanced with a patient-centric user-interface.

THI-P0991
Single-Site Trans-Umbilical Peritoneal Dialysis Catheter Insertion
Mangalakumar Veerarasamy, Nephrology, KMCH, Coimbatore, Tamilnadu, India.

Background: Traditional laparoscopic peritoneal dialysis catheter placement requires two ports incision and this could lead to complications like leak and hernia at the port sites. We describe a novel approach of using single-site trans-umbilical ports that is associated with small scar (less than 1 cm) and reduced complications.

Methods: Under general anaesthesia pneumoperitoneum was created as per standard method. One 10mm port and one 5mm port was inserted through trans-umbilical route to guide peritoneal dialysis catheter insertion. Hernial orifices were inspected and if there was any adhesion present that was released to facilitate free fluid movement. The catheter was inserted through a small incision 1 inch below umbilicus. The catheter was positioned in the pouch of Douglas using lap instrument passed through the trans-umbilical port. The other end of catheter was tunnelled in the standard manner and brought out through the trans-facial port. The latter prevented the omentum migration or any mechanical complication that might require catheter reposition or change. Peritoneal dialysis catheter was inserted through a single-site trans-umbilical port. Hernial orifices were inspected and if there was any adhesion present that was released to facilitate free fluid movement. The catheter was inserted through a small incision 1 inch below umbilicus. The catheter was positioned in the pouch of Douglas using lap instrument passed through the trans-umbilical port. The other end of catheter was tunnelled in the standard manner and brought out through the trans-facial port. The latter prevented the omentum migration or any mechanical complication that might require catheter reposition or change. Peritoneal dialysis catheter was inserted through a single-site trans-umbilical port. Hernial orifices were inspected and if there was any adhesion present that was released to facilitate free fluid movement. The catheter was inserted through a small incision 1 inch below umbilicus. The catheter was positioned in the pouch of Douglas using lap instrument passed through the trans-umbilical port. The other end of catheter was tunnelled in the standard manner and brought out through the trans-facial port. The latter prevented the omentum migration or any mechanical complication that might require catheter reposition or change. Peritoneal dialysis catheter was inserted through a single-site trans-umbilical port. Hernial orifices were inspected and if there was any adhesion present that was released to facilitate free fluid movement. The catheter was inserted through a small incision 1 inch below umbilicus. The catheter was positioned in the pouch of Douglas using lap instrument passed through the trans-umbilical port. The other end of catheter was tunnelled in the standard manner and brought out through the trans-facial port. The latter prevented the omentum migration or any mechanical complication that might require catheter reposition or change.

Conclusions: A combined method of Single-site port placement, omentectomy and loop fixation of intra-abdominal segment of catheter offers the following advantages: small incision, hence risk of leak when catheter was used early after placement is low. The risk of hernia through port site is reduced and small scar will be welcome to image conscious patients. If there was any adhesion present that could be released with minimal trauma to peritoneum. Omentum was folded and pulled upwards to the left upper guardant and fixed to anterior abdominal wall using a trans-facial loop. The latter prevented the omentum wrapping diathesis catheter and causing malfunction. Then the port site was closed in three layers (Video available).

Results: 10 cases underwent catheter insertion with this approach (Male 7, Female 3) and the mean follow up period is 11 months. None of them developed leak or catheter migration or any mechanical complication that might require catheter reposition or change.

Conclusions: A combined method of Single-site port placement, omentectomy and loop fixation of intra-abdominal segment of catheter offers the following advantages: small incision, hence risk of leak when catheter was used early after placement is low. The risk of hernia through port site is reduced and small scar will be welcome to image conscious patients. If there was any adhesion present that could be released with minimal trauma to peritoneum. Omentum was folded and pulled upwards to the left upper guardant and fixed to anterior abdominal wall using a trans-facial loop. THI-P0992
Peritonitis and Survival following PD Catheter Insertion in Infants
Joshua Zaritsky, Coral D. Hanevold, Troy Richardson, Jonathan Rodean, John P. Lawlor, Raymond P. Quigley, Alicia Neu, Bradley Warady.

SCOPE Collaborative, CHA, Overland Park, KS.

Background: Chronic peritoneal dialysis (PD) is the dialysis modality of choice for children. However, there are limited outcome data in those who undergo PD catheter (cath) insertion in the 1st year of life. Using data from the Children’s Hospital Association Standardizing Care to Improve Outcomes in Pediatric End Stage Renal Disease (ESRD) Collaborative (SCOPE), we examined peritonitis rates and survival in 156 infants who had a PD cath placed in the 1st year of life. We describe a novel approach of using single-site trans-umbilical ports that is associated with small scar (less than 1 cm) and reduced complications.

Results: In hospital and overall peritonitis rates during the 1st year post cath insertion were 1.73 and 0.76 per-patient-year, respectively. Gran + organisms were responsible for 38.7% of infections (figure); 28% were culture negative. Polycystic kidney disease and pulmonary hypoplasia were more frequent in infants with peritonitis, whereas anuria did not differ between groups (table). Use of a cuffed catheter or plastic adaptor, nephrectomy prior to or concurrent with cath insertion, and G-tube insertion after cath placement were more common in pts with peritonitis, while number of cuffs, surgical technique, cath use within 14 days and cath revision did not differ between groups. Infants with peritonitis had longer initial hospital stays and lower survival compared with those without peritonitis.

THI-P0993
Risk Factors for All-Cause Unexpected Hospitalization After Peritoneal Dialysis Catheter Implantation
Zi Li, Zita C. Abreu, Joanne M. Bargman.

1Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China; 2Nephrology, Toronto General Hospital Univ of Toronto, Toronto, ON, Canada.

Background: Implantation of the peritoneal dialysis catheter (PDC), usually an elective procedure, may necessitate unexpected hospitalization due to multiple co-morbidities and inherent instability of the end-stage renal disease patient. This information is important for administrative planning for a PD program. However, information on hospitalization after PDC implantation is limited and details about the reason for hospitalization are lacking.

Methods: We performed a prospective cohort study in consecutive patients who underwent PDC implantation at a single institution from 2007 to 2013. Clinical characteristics of enrolled patients, technique of the implantation procedure and all-cause unexpected hospitalization and morbidity within 14 days after implantation were analyzed.

Results: A total of 246 patients receiving 252 PDC implantations during the 6 years were studied. After 39 procedures (15.5%), patients had an unexpected hospital stay due to operative complications (33.3%), worsening of comorbid disease (35.9%), or a single-night hospital stay for observation (30.8%). Compared to discharged patients, the unexpected hospitalization ones were older (P=0.001), had higher rates of previous episodes of heart failure (P<0.006) and heart disease (P<0.001), had more use of general anesthesia (P=0.046), had more added procedures during the implantation (P=0.02) and had more episodes of flow obstruction and peritonitis (P=0.012 and P<0.001). Multivariable logistic regression showed that age, cardiac morbidity, use of general anesthesia, PDC flow problems and peritonitis after implantation were independent predictors of all-cause unexpected hospitalization.

Conclusions: For the first time, our study has analyzed the rate of unexpected hospitalization after PDC implantation and identified the salient risk factors. Increased focus to identify patients at greatest risk for hospitalization, evaluation of processes of care, and implementation of preventive strategies may be helpful to reduce unplanned hospitalization after catheter insertion.
TH-PO994
Early Mechanical and Infective Complications in First Time Blind, Bedside, Midline Percutaneous Tenckhoff Catheter Insertion with Ultra Short Break-in Period: Setting New Standards
Succes Anjana,1 Ninoo G. George,2 Santosh Varughese.1 1Nephrology, Christian Medical College, Yellore, Tamil Nadu, India; 2Nephrology, Bilroth Hospitals, Chennai, Tamil Nadu, India.

Background: There are no large studies that have looked into ultra-short break-in period with blind, bedside, midline approach of Tenckhoff catheter insertion. Methods: 286 consecutive adult patients underwent catheter insertion for chronic peritoneal dialysis at our centre from January 2009 to December 2013. Those with history of midline laparotomy scars and hernias were referred for open surgical insertion. 245 patients (86.3%) underwent the percutaneous and 39 patients (13.7%) underwent surgical insertions. Results: The mean break-in period for the percutaneous group (PG) was 2.68 ± 2.63 days and for the surgical group (SG) was 11.19 ± 6.96 days, p <0.001. Poor catheter outflow was present in 22 (9%) of PG and in 4 (10.3%) of SG (p= 0.80).Primary catheter non-function was present in 24 (9.8%) of the PG and in 4 (10.3%) of the SG (p = 0.73). Catheter survival at one year was 164/241 (85.1%) in the PG. The various outcomes are:

Figure: Relevance of systolic blood pressure to vascular events and cause-specific mortality, by prior vascular disease or raised troponin.

Conclusions: The significantly shorter break-in period and smaller wound incisions reduce hospitalization and the need for bridging hemodialysis as well as having good patient and catheter outcomes.

TH-PO995
Comparing Outcomes of Percutaneous Peritoneal Dialysis Catheter Insertion by Nephrologist versus Open Surgical Insertion – Large Single Centre Experience
Louise E. Ross, Bhirgu Raj Sood. South West Thames Renal and Transplantation Unit, Carshalton, Surrey, United Kingdom.

Background: Several studies suggest that percutaneous insertion of peritoneal dialysis (PD) catheters by nephrologists improves the uptake of PD. Percutaneously inserted PD catheters by nephrologists improves the uptake of PD. Percutaneously inserted catheters in the percutaneous versus open surgical group. PD catheters requiring manipulation or replacement within the first year due to a functional problem was comparable in the percutaneously inserted catheters (9.2% versus 12.9%; p=0.327). There were no major complications in the form of visceral perforation or major hemorrhage in either group.

Conclusions: In our study, we found that infection related complications were better with percutaneous PD catheter insertion and mechanical failure rate was comparable to open surgical PD catheter insertion. We in our practice we have found that percutaneously inserted PD catheters are a safe means of increasing patient access to PD, enabling more patients to have a home-based therapy.

TH-PO996
Shared Decision-Making in Chronic Kidney Failure: The Retrospection of First Stage Dialysis Patients in India
Maxi Rohinski,1 Wilfried Mua,1 Andreas Wiencke,2 Matthias Girndt.1 1Inst of Rehabilitation Medicine, Martin Luther Univ Halle-Wittenberg, Halle (Saale), Germany; 2Inst of Medical Epidemiology, Biostatistics, and Informatics, Martin Luther Univ Halle-Wittenberg, Halle (Saale), Germany; 3Dept of Internal Medicine II, Martin Luther Univ Halle-Wittenberg, Halle (Saale), Germany.

Background: To date, little is known about the extent to which patients with chronic kidney failure feel involved in decision-making regarding the life-changing dialysis treatment. Previous studies on mortality yielded equivalence of peritoneal (PD) and hemodialysis (HD). However, only 5% of the patients in our study revealed, that although many patients are eligible for both options and entitled to unbiased counselling. Methods: In a nationwide multicenter study with federal funding (“CORETH-project”), we surveyed 781 patients on dialysis since 6 to 24 months with regard to their rating of shared decision-making (SDM) with their physician concerning the choice of renal replacement therapy. We used the “Shared Decision-Making Questionnaire” (Kriston et al., 2010), which is a highly reliable and well accepted measure. Furthermore, patients indicated the dominating reason for choosing their treatment as well as their treatment satisfaction (TS). Results: Data were compared between propensity score-matched groups of patients (p=0.7 vs p=0.246). Results: PD patients rated all aspects of SDM (for example, consideration of patient preferences or shared weighing of options) significantly more positive than HD patients (SDM-total score, p<.0001). PD patients predominantly (73%) indicated their independence as a motivation for the choice, whereas HD patients were largely (30%) subject to medical decisions only. Moreover, compared to HD, PD patients were more satisfied with the information received (p=.013). The SDM- and TS-total scores correlated significantly positive in the matched overall sample (r= .19, p<.0001). Conclusions: Our findings highlight awareness for an unbiased nephrological counseling-culture and provide indications for a successful SDM-process when choosing dialysis modality. According to the results, an effective SDM can pave the way for dialysis patients’ quality of life and treatment success. Funding: Government Support - Non-U.S.

TH-PO997
Depression and Cognitive Impairment in Peritoneal Dialysis: A Multi-Center Cross-Sectional Study
Jie Dong,1 Hai-chon Pi,2 Zaying Xiong,2 Jianlin Xiao,1 Hao Gui,1 Liang Liu,1 Yue-Ping Ren,1 Xing Bo,1 Liying Du,3 Zhao-xia Zheng.1 1Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China; 2Renal Div, Peking Univ Shenzhen Hospital, Shenzhen, China; 3Renal Div, The Second Hospital of Anhui Medical Univ, Hefei, Anhui, China; 4Renal Div, The Second Affiliated Hospital of Harbin Medical Univ, Harbin, Heilongjiang, China; 5Renal Div, Handan Central Hospital, Handan, Hebei, China.

Background: Depression and cognitive impairment have been identified as independent risk factors for mortality in peritoneal dialysis (PD) patients. The relationship between depression and cognitive functions in PD patients was investigated in this multi-center cross-sectional study. Methods: Study design: multi-center cross-sectional study. Setting & Participants: A total of clinically stable 458 patients who performed PD for at least 3 months from 5 PD units were included in this study. Only 5% of the patients in Germany choose PD, even though many patients are eligible for both options and entitled to unbiased counselling. Outcomes: Global and specific cognitive impairment. Measurements: Global cognitive function was measured by using the Modified Mini-Mental State Examination (3MS), specific cognitive function by executive function, immediate memory, delayed memory, visuospatial skill and language ability by subtests of Repeatable Battery for the Assessment of Neuropsychological Status. Depression was diagnosed if the depression severity index>0.5 by using Zung’s Self-rating Depression Scale. Results: The prevalence of depression and cognitive impairment evaluated by 3MS were 52% and 28.4% respectively. Patients with mild or moderate/severe depression had higher prevalence of general cognitive impairment, executive dysfunction, impaired immediate and delayed memory. After adjusting for demographic, comorbidity data and clinical parameters, depression scores were independently associated with lower scores of 3MS, immediate and delayed memory, and language ability, and longer completion time of Trails A and B. Even mild depression and HD independently predicted higher risk of CCI, executive dysfunction, impaired immediate and delayed memory after multivariable adjustments. Conclusions: Even mild depression plays an important role in global and specific cognitive functions in PD patients. Funding: Government Support - Non-U.S.

Proposed Model for the Care of Hospitalized Peritoneal Dialysis Patients

Cynthia R. Christiano, 1 Melanie I. Hames, 1 Pankaj Jawa, 1 Piper J. Hughes, 3 Maria H. Locklear. 2 Div of Nephrology, Brody School of Medicine at East Carolina Univ, Greenville, NC; 1Vidant Medical Center, Greenville, NC; 2Internal Medicine, East Carolina Univ, Greenville, NC.

Background: Peritoneal dialysis (PD) has been prescribed throughout the United States, yet the optimal model of care for hospitalized PD patients remains unknown. With a growing interest in home modalities and emphasis on quality, it is imperative that we identify an effective and efficient way to care for this patient population during hospitalization.

Methods: We describe a model successfully implemented at Vidant Medical Center (VMC) in 2008. Prior to this date, the primary hospital nurses performed PD care. Due to the high risk, low volume nature of inpatient PD, this resulted in inconsistent care as well as decreased physician, nursing, and patient satisfaction. In 2008, an inpatient PD nursing team was created. This team, consisting of nephrology nurses with specialized PD training, is managed by VMC’s self-maintained dialysis unit. Staffed with 2 nurses during the day and 1 nurse at night, they provide 24-hour care through the hospital, including the ICU and ED.

Responsibilities include patient education, exit site care, catheter flushes, and all manual and automated PD exchanges. Upon discharge, the outpatient unit is contacted to ensure appropriate transition back to the outpatient setting.

Results: This model provided several benefits: 1) PD treatments are consistently completed and charted, 2) Increased physician, nursing, and patient satisfaction, 3) Continuity of care, and 4) Cost reduction (personnel and supplies). Since inception, this team has grown to 13 nurses. During FY2014, 2568 (1572 adult / 996 pediatric) PD treatments were performed, the majority CAPD. To ensure appropriate utilization of nursing resources, most are cross-trained to perform hemodialysis.

Conclusions: In conclusion, the creation of a specialized nursing team has been instrumental in optimizing the care of our hospitalized PD patients. This sustainable model provides effective, efficient care and should be considered for implementation for hospitals providing PD services.

TH-PO999

Elderly Peritoneal Dialysis Compared with Elderly Hemodialysis Patients and Younger Peritoneal Dialysis Patients: Competing Risk Analysis of a Korean Prospective Cohort Study

Hyunsuk Kim, 1 Jung Nam An, 2 Dong Ki Kim, 1 Yong-Lim Kim, 1 Yun Kyu Oh, 2 Choon Soo Lim, 1 Yon Su Kim, 3 Jung Pyo Lee. 1 Internal Medicine, Seoul National Univ College of Medicine, Seoul, Republic of Korea; 2Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea; 3Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea.

Background: The outcomes of peritoneal dialysis (PD) in elderly patients have not been thoroughly investigated. We aimed to investigate the clinical outcomes and risk factors associated with PD in elderly patients.

Methods: We conducted a prospective observational nationwide adult end-stage renal disease (ESRD) cohort study in Korea from August 2008 to March 2013. Among incident patients (n=830), patient and technical survival rate, quality of life, and Beck’s Depression Inventory (BDI) scores of elderly PD patients (≥65 years, n=95) were compared with those of PD patients aged ≤49 years (n=205) and 50–64 years (n=192); and elderly hemodialysis (HD) patients (n=315). The patient death and technical failure were analyzed using cumulative incidence function.

Results: The patient survival rate of elderly PD patients was inferior to that of younger PD patients (P<0.001). However, the technical survival rate was similar (P=0.097). Compared with elderly HD patients, the patient survival rate did not differ according to dialysis modality (P=0.987). Elderly PD patients showed significant improvement in the BDI scoring compared with the PD patients aged <49 years (P=0.033). Low albumin, anemia, peritonitis, and low residual renal function were significant risk factors for the PD patient survival; and peritonitis was a significant risk factor for technical survival. Furthermore, low albumin and hospitalization were significant risk factors of patient survival among the elderly.

Conclusions: The overall outcomes were similar between elderly PD and HD patients. PD showed the benefit in BDI and quality of life in the elderly. Additionally, the technical survival rate of elderly PD patients was similar to that of younger PD patients. Taken together, PD may be a comparable modality for elderly ESRD patients.

TH-PO1000

Phosphorus Control and Phosphate Binder Pill Burden During Real-World Use of Sucroferric Oxyhydroxide in Peritoneal Dialysis Patients

Linda H. Ficociello, Vidhya Parameswaran, Mark Costanzo, Claudia Mullon, Franklin W. Maddux, Robert J. Kossman. Fresenius Medical Care North America (FMCNA), Waltham, MA.

Background: Achieving serum phosphorus (sPhos) control can be a challenge for dialysis patients (pts). This retrospective database analysis examined the real-world effectiveness of sucroferric oxyhydroxide (SO), an iron-based phosphate binder (PB), in adult peritoneal dialysis (PD) pts.

Methods: A cohort of PD pts prescribed SO as part of routine clinical care at FMCNA clinics was analyzed. Pts had ≥1 sPhos measured during SO and had been previously treated with sevelamer, calcium acetate, calcium carbonate or dual therapy. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and PB pills per day (PPD) were assessed 3-months before SO (baseline) and 3-months during SO (follow-up).

Results: Pts (n=328) were, on average, 53 years old, with a dialysis vintage of 3.9 years. At baseline, 56% of pts used sevelamer, 29% calcium acetate, 11% calcium carbonate, and 5% dual therapy. Pts in-range increased from 13.5 to 23.8% (76% increase). Mean sPhos decreased from 6.92 to 6.67 mg/dl, p<0.001. PB PPD was reduced from 8.4 to 3.8 pills (4.6 fewer pills, p<0.001). There was no significant change in sCa (9.1 to 9.0 mg/dl) or iPTH (335 to 555 pg/ml). TSAT and FER increased from 35.4 to 36.6% and 752.1 to 814.9 mg/ml, respectively. In pts not receiving IV iron (n=127), TSAT and FER did not change significantly (36.3 to 37.3% and 797.9 to 743.3 mg/ml, respectively).

Conclusions: In this large cohort of PD patients prescribed sucroferric oxyhydroxide as part of routine clinical care, a significant reduction in serum phosphorus (p<0.001) and a 76% increase in patients achieving in-range serum phosphorus (p<0.001) was observed. This was accomplished with a mean of 3.8 pills per day, a reduction of 4.6 pills (p<0.001).

Laparoscopic Findings of Visceral Peritoneal Injury in Patients Treated with Neutral pH Peritoneal Dialysis Solution Yudo Tanno, Nanae Matsuo, Izumi Yamamoto, Yasuuki Nakada, Ichiro Ohkido, Kettaro Yokoyama, Takashi Yokoo. Div of Kidney and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan.

Background: Encapsulating peritoneal sclerosis (EPS) is caused by a visceral peritoneal lesion, i.e., intestinal tract adhesion and encapsulation, it is important to evaluate changes in the visceral peritoneum. It has been reported that there was a decreasing trend of peritoneal injury with the use of PD solution with neutral pH as compared with acidic pH in the histopathological evaluation of the parietal peritoneum; however, there is no report evaluating changes in the visceral peritoneum, which is essentially important and should be evaluated. We previously reported laparoscopic approach for evaluation of EPS (KI 2012) in patients treated with PD solution with acidic pH. In this study, we examined macroscopic findings of the visceral peritoneum in patients treated with neutral pH solution alone for 4 years or more by laparoscopy.

Methods: 19 patients underwent laparoscopy at the time of PD catheter removal. Duration of PD in these patients was 64±18.8 months. Clinically, none of these patients had developed EPS by the time of the investigation. The findings of both parietal and visceral peritoneal tissues were categorized according to color changes, presence of neovascularizations and adhesions.

Results: It was found that longer the duration of PD, the worse the peritoneal injury. Although changes in the parietal and visceral peritoneum had heterogeneous distributions, the changes in the visceral peritoneum were milder, showing a discrepancy with the findings of the parietal peritoneum. As compared with laparoscopic findings in patients treated with PD solution with acidic pH, the degrees of color changes, presence of neovascularizations, and adhesions were all mild, however, severe adhesions were noted in patients with a history of PD peritonitis.

Conclusions: Although changes in the visceral peritoneum resulting from the use of PD solution with neutral pH show a decreasing trend as compared with acidic pH, there is a certain level of peritoneal change, suggesting the possibility of progression of peritoneal deterioration by long-term continuous use.

TH-PO1002

Background: Encapsulating peritoneal sclerosis (EPS) is the more dangerous complication of peritoneal dialysis (PD). The EPS can occur during PD (classic EPS), after kidney transplantation (TX) or rapid shift to hemodialysis (HD) as the mode of renal replacement therapy (RRT).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: Single-center retrospective analysis of PD transplanted patients in 35 years. Evaluation of the characteristics of the ESP presentation. Results: From July 1979 to December 2014, 173 PD patients underwent kidney transplantation (TX). They were diagnosed 5 cases (2.9%) of ESP: one after 6 months from the TX (typical posttransplant ESP), but the other 4 cases have occurred after more than 2 years after the kidney transplantation (maximum 207.2), and at least a long time of TX (median 227 ± 24 months, range 207-259), also after many years of cessation from the last period in PD. The median time of PD was 71±31 months (range 36-99). Two patients died after 10 and 41 months after diagnosis, respectively and after 332 and 367 months in RRT. In our center during the same period other 21 ESP cases (2.8%) were occurring among the 747 PD patients never transplanted. No cases of ESP was manifested after direct transfer from PD to HD. Conclusions: in our experience ESP prevalence in transplanted PD patients is not greater than that transplanted PD patients. In patients for many years in RRTs, ESP occurs even after a long time of the cessation of DP, especially after many treatments and long periods in PD. It is possible that the PD is acting only as a side event on the tissues affected by fibrotic processes formed for a long time in RRTs and/or due to the immunosuppressive therapy. To its features this form can be defined “composite ESP” and should also be considered in PD patients transplanted since many years.

Delta Neutrophil Index Is a Predictive Marker of Catheter Removal in Peritoneal Dialysis Patients with Peritonitis

Jae Eun Um,1 Sul A. Lee,1 Shin-Wook Kang.2 1Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea; 2Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Severe and prolonged peritonitis leads to peritoneal membrane failure and is the most common cause of technique failure in patients treated with peritoneal dialysis (PD). Recent studies reported that delta neutrophil index (DNI), which reflects the fraction of circulating immature granulocytes in the blood, is a practical severity marker of infection. This study investigated whether DNI could be a predictive marker of catheter removal PD patients with peritonitis.

Methods: Patients treated with PD peritonitis at Severance Hospital between January 2012 and January 2015 were enrolled. Demographic data, clinical, and laboratory parameters including DNI were collected at the time of peritonitis. DNI was calculated by automatic analyzer.

Results: A total of 125 PD peritonitis episodes in 92 patients were investigated. The mean age was 59.1 ± 12.0 years and 55 (44.0%) were male. PD catheter was removed in 31 (24.6%) patients. The median value of DNI in patients undergone PD catheter removal was significantly higher compared to that of patients who maintained PD catheters [DNI (interquartile range) 3.30 (0.0-6.50) vs. 0.70 (0.0-22.5), P<0.001]. DNI is significantly associated with percentage of segmented neutrophil (r=0.28) and serum albumin (r=-0.32), and dialysate leukocyte counts (r=0.20), but not with C-reactive protein (CRP) levels (r=-0.08). Multivariate logistic regression analysis revealed that DNI was an independent predictor for PD catheter removal in patients with PD peritonitis (odds ratio=1.08, 95% confidence interval=1.01-1.12, P<0.04) after adjustment for serum albumin, CRP, leukocyte count of dialysate effluent, and septic shock. The area under the ROC curve (AUC) of DNI for PD catheter removal was 0.69 (P<0.001), whereas the AUC of dialysate leukocyte count was not statistically significant (0.52, P=0.70).

Conclusions: DNI levels reflected the severity of peritonitis. Higher levels of DNI could be an independent predictor for PD catheter removal in patients with PD peritonitis.

TH-PO1004

Peritonitis Rates Among African Americans and Caucasians Undergoing Peritoneal Dialysis

Acceia Muqri, Russell Griffin, Eric L. Wallace. Univ of Alabama at Birmingham.

Background: African Americans (AA) are under-represented in the prevalent peritoneal dialysis (PD) population in the United States. There is relatively little conclusive data to explain the cause of this. One explanation is that AA may have higher rates of peritonitis than Caucasians leading to increased technique failure. This study aimed to determine if AA have higher rates of peritonitis than Caucasians. Despite this, technique survival between races did not differ. This study does not support the hypothesis that the underlying cause of decreased prevalent AA PD patients is due to increased technique failure from disproportionate peritonitis rates.

TH-PO1005

Factors Associated with Peritoneal Dialysis Technique Failure: A Single Center Study

Anoop Sheshadri, Ramesh Saxena. Dept of Nephrology, UTSW Medical Center, Dallas, TX.

Background: To review peritoneal dialysis (PD) technique survival and assess factors associated with PD technique failure at our center.

Methods: We performed a retrospective analysis of 315 patients with PD catheters placed between 01/2001 and 09/2009, reviewing medical records for demographic and clinical information. Primary outcome was PD technique failure, defined as permanent discontinuation of PD due to infectious or non-infectious complications, inadequate dialysis, or miscellaneous factors such as pain. Patients were followed at least 36 months after PD initiation. Survival analysis was performed using Kaplan-Meier methods. Covariates influencing survival were analyzed using Cox proportional hazards regression models.

Results: There were a total of 70 failures, 31 (44.3%) related to infectious complications, 22 (31.4%) to non-infectious complications (e.g. obstruction, leaks), 8 (11.4%) to inadequate dialysis, and 9 (12.9%) to miscellaneous factors. Overall survival at 36 months was 78.81%. Covariates significantly affecting technique failure include prior HD (1.83; 1.14-2.92), non-infectious complications (1.82; 1.28-2.59), DM (1.62; 1.00-2.63), HIV (2.52; 1.01-6.24), peritonitis (1.95; 1.29-3.12), and exit site infections (1.79; 1.09-2.92). Previous abdominal surgeries (90; 0.78-1.0) and BMI (1.005; 0.97-1.04) were not significantly associated with failure.

Conclusions: This is one of the largest single center studies of its type from a US PD program. It shows excellent 3 year PD technique survival, better than reported in similar studies. Our results confirm that diabetes mellitus, PD related infections, and non-infectious mechanical problems are independent risk factors for PD technique failure. Conversely, BMI, abdominal surgeries, and demographic characteristics such as race and gender do not have significant association and should not be considered barriers to PD initiation.

Effect of Early Peritonitis on Clinical Outcomes

Kristin M. Corap,1 Julia Beth Wenger,1 Jeffrey Perl,1 Sharon Nessim,1 Ishir Bhan,3 Joanne M. Bargman,2 1Nephrology, Massachusetts General Hospital, Boston, MA; 2Nephrology, St. Michael’s Hospital, Toronto, ON, Canada; 3Nephrology, Jewish General Hospital, McGill Univ, Montreal, QC, Canada; 4Nephrology, Toronto General Hospital, Toronto, ON, Canada.

Background: Infection is a source of significant morbidity and mortality for peritoneal dialysis (PD) patients. Previous studies suggest that early peritonitis is associated with shorter technique survival; however these studies are limited by small samples, restricted generalizability, and a lack of standardized definitions. We used data from a large dialysis database to determine if the timing of the first peritonitis episode is associated with adverse clinical outcomes.

Methods: US and Canadian data from 1996 to 2005 in the Baxter POET (Peritonitis, Organisms, Exits sites, Tunnel infections) database was analyzed. Patients who developed peritonitis within 6 months of PD initiation were identified as cases. Controls were patients whose first peritonitis occurred after 6 months. Patients who never developed peritonitis or who were on PD for less than 6 months were excluded. Patients were censored at the clinical inpatient, transfer to hemodialysis, or death.

Results: 920 cases and 2607 controls were identified.

Conclusions: AA when compared to non-AA, trended towards a higher risk of peritonitis than Caucasians. Despite this, technique survival between races did not differ. This study does not support the hypothesis that the underlying cause of decreased prevalent AA PD patients is due to increased technique failure from disproportionate peritonitis rates.
early mortality, occurrence of coronary heart disease and stroke, and incidence of peritonitis.

Secondary outcomes included all-cause mortality, cardiovascular and cerebrovascular
mortality, occurrence of coronary heart disease and stroke, and incidence of peritonitis.

Methods: In this retrospective cohort study, 348 incident PD patients (aged 48.2
± 15.5 years, 62% men) at Peking University Shenzhen Hospital from 2000 to 2014 were
included. BMI was calculated with height and weight first recorded within 2 to 6 months
after initiation of PD. Patients were categorized according to the World Health Organization
recommendation for Asians. All patients were followed until October 31, 2014. Primary
outcome was technical failure, defined as death or permanently transferred to hemodialysis.
Secondary outcomes included all-cause mortality, cardiovascular and cerebrovascular mortality,
incidence of coronary heart disease and stroke, and incidence of peritonitis. Data were analyzed using Cox proportional hazards models.

Results: BMI in this cohort was 22.1 ± 3.0 kg/m². During 2.5 (interquartile range:
1.0-4.0) years, 60 cases of technical failure occurred. Incidence of technical failure was higher in patients with low BMI (13.4/100 person-years) than those with normal BMI (5.2/100 person-years) and with high BMI (6.3/100 person-years). After adjustment of
date of age, sex, education, primary disease, and heart failure, hazard ratios (95% confidence
intervals) were 3.60 (1.53, 8.45) and 0.93 (0.49, 1.76) for patients with low and high BMI,
respectively, as compared to those with normal BMI. Similarly, the low BMI group had
significantly higher rates of total as well as cardiovascular and cerebrovascular mortality
than the normal BMI group, but such relationships did not exist in the high BMI group. No
associations of BMI with occurrence of coronary heart disease and stroke and incidence of
peritonitis were observed.

Conclusions: In incident PD patients, low BMI is associated with technical failure,
all-cause mortality, and cardiovascular and cerebrovascular mortality.

The Association Between Body Mass Index and Mortality in Peritoneal Dialysis Patients

Jin Ho Hwang,1 Guen jou Choi,2 Hyun Kang,2 Su Hyun Kim.1 1Internal Medicine, Chung-Ang Univ Hospital, Seoul, Republic of Korea; 2Anesthesiology and Pain Medicine, Chung-Ang Univ Hospital, Seoul, Republic of Korea.

Background: Unlike the general population, a higher body mass index (BMI) was consistently found to be a strong predictor of decreased mortality in patients with end-stage renal disease who receive maintenance hemodialysis (HD). This phenomenon has been referred to as the “Obesity paradox” or “reverse epidemiology.” Similar tendency has been observed in several studies with peritoneal dialysis (PD) patients, but the studies have reported conflicting results. We conducted this study to evaluate the association between BMI and all-cause mortality in PD patients.

Methods: A systematic search was conducted for published studies in Medline, EMBASE, and the Cochrane library databases from 1970 to April 2015. We identified studies

Patients with early peritonitis had a significantly higher peritonitis rate than controls (1.26 and 0.67 episodes/person-year, p<0.001). Early peritonitis was also associated with shorter technique and patient survival.

Conclusions: Our results suggest that patients with early peritonitis are at increased risk of adverse clinical outcomes such as future infection, technique failure, and death.

TH-PO1009

Is Obesity a Poor Prognostic Factor in Incident Peritoneal Dialysis Patients?

Hynju Jeong Cho,1 Hyo Jin Kim,1 Miseon Park,2 Dong Ki Kim,1 Kwon Wook Joo,1 Yon Su Kim,1 Curie Ahn,1 Kook-Hwan Oh.1 Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; 2Clinical Research Inst, Seoul National Univ Hospital, Seoul, Korea.

Background: Obesity is associated with an increased risk of death in the general population. Previous studies have demonstrated a discrepancy in the impact of body mass index (BMI) on mortality among peritoneal dialysis (PD) patients. We examined the effect of BMI on patient and technique survival in a prospective, incident PD cohort at a single center.

Methods: Subjects who started PD between 2000 and 2012 were enrolled in the study. Demographic and laboratory data were prospectively collected. Patients were categorized into four BMI groups: obese, ≤25 kg/m², overweight, 23.0–24.9 kg/m², normal, 18.5–22.9 kg/m² (reference category); and underweight, <18.5 kg/m². Patient and technique survival were compared using Cox proportional hazards models.

Results: A total of 632 incident PD patients were included in final analysis. The median follow-up period was 40 months (interquartile range, 19-64 months). Kaplan-Meier survival curve, patient survival was not statistically different among all BMI categories (p = 0.641, by log-rank test). The hazard ratio (HR) adjusted for age, sex, diabetes, comorbidities, albumin, hemoglobin for patient survival was not significant among BMI groups (p = 0.837). In contrast, technique survival was significantly poorer in obese patients than in patients having a normal BMI (p = 0.029, by log-rank test). The HR for technique failure was significantly greater for obese PD patients in comparison with the reference category [1.8, 95% confidence interval (CI): 1.2 to 2.8, p = 0.008]. The reasons for technique failure included recurrent peritonitis (34%), inadequate dialysis (17%), mechanical problem (17%) and refractory exit-site/tunnel infection (11%) in obese patients.

Conclusions: In our PD patients, patient survival was similar in all BMI categories. Therefore, obese patients should not be discouraged from receiving PD purely on the basis of BMI. However, technique survival was significantly poorer for obese PD patients. Further study is warranted to improve technique survival in obese patients.

TH-PO1010

Phosphate Clearance in Peritoneal Dialysis: Residual Renal Function and Dialysis Modality

Carmen Gonzalez corvillo,1 Mariangales Rodriguez Perez, Alejandro A. Suarez benjumea, Nuria Areste, Mercedes Salgueira lazo. Nephrology, Virgen Macarena-Rocio, Sevilla, Spain.

Background: Evaluate urinary and peritoneal excretion of phosphate and related factors in peritoneal dialysis(PD). Analyse phosphate clearance depending on PD modality and peritoneal membrane type.

Methods: Observational study, in a sample of 37 PD patients. Mean age 60±14 years. 24 patients on APD(16CCPD,8NIPD) 13 on CAPD.Mean Kt/ V: 1.8±0.6. Mean residual renal function(RRF):6.3±4.6 ml/min.Transmembranous peritoneal transport:6high(H),26high-average(HA) and Slow-average(LA).Renal and peritoneal phosphate clearance(ultrafiltration (UF) and diffusion(D)) was analyzed.Urinary and dialysate P-Cr. Weekly peritoneal P clearance(WPCl).Serum P/PTH.Use and dosage of phosphate binders and vitaminD analogs.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

330A
Results: Mean total P clearance=460±192mg/dl. Mean renal P clearance=286±201mg/dl and renal urine clearance=250±198mg/dl, respectively. When we analyzed Group A (18.4±1.2 weeks) and Group B (22.5±0.9 weeks) and by D 194:85±24/hr(1%). Mean urine and dialyze P concentration were 0±0.15 and 0.59±0.24 Mean WPCI=31.1±13.1/l/week. Mean serum P 4.5±1mg/dl and THPD24±166ppg/ml. 80±9% of patients were on Sevelamer and 22±calcium based binders.45% were on a vila min (P<0.03). Positive correlation between peritoneal clearance and UF (r=0.46, p<0.001) as well as between RRF and P elimination (r=0.53, p<0.001) was observed. WPCI was higher in patients on CAPD than on APD/39,47±27 vs 21±13/l/week p<0.05) being the many difference subjects performed to continuous vs discontinuous modalities (Kidney Int. 2013). It is still unexplained what factors predict RRF loss in the PD patients using BDPS. We investigated the relationship between clinical parameters at PD initiation and the change of RRF in the PD patients using BDPS. Methods: The data from patients who started PD as their first dialysis modality from 2001 to 2014 at The University of Tokyo Hospital were collected retrospectively. All patients were treated by automated PD (APD) using BDPS. To identify predictors of RRF decline, we analyzed data including clinical parameters measured at PD initiation. Residual GFR was calculated as the average of 24-hour urinary urea and creatinine clearances. The rates of urine volume and residual GFR decline were calculated by the least squares linear regression formula. The outcome of dialysis modality change was defined as switching to hemodialysis (HD) or combined therapy of PD and HD due to RRF loss. Results: 96 patients were analyzed in this study. On multiple regression analysis, the decline rates of urine volume and residual GFR were significantly correlated with proteinuria at PD initiation. When patients were divided into two groups according to urinary protein level, Kaplan-Meier analysis revealed the lower proteinuria group had higher persistence rate of APD and lower rate of dialysis modality change (Log rank; p = 0.011 and 0.004, respectively). On ROC analysis, urinary protein predicted the need of dialysis modality change within 2 years after PD initiation with statistical significance (AUC [95%CI]=0.78 [0.66-0.90]). Conclusions: Proteinuria at PD initiation may predict RRF loss and the need of dialysis modality change in the APD patients using BDPS.

TH-PO1012

Background: Although urgent start (US) peritoneal dialysis (PD) and traditional start (TS) PD have similar outcomes, it is not known if differences in outcomes exist based on race. The objective of this study was to determine if differences in PD outcomes exist when stratified based on race and type of PD start.

Methods: Retrospective data from an electronic database on incident PD patients collected between November 2012 and March 2015 was analyzed. Patients were analyzed by race and modality start: 3 groups-4 groups: Non-Asian (AA), Non-AA US, AA US and Non-AA US. Chi-square analysis was used to compare categorical variables, while ANOVA was used to compare means across groups. Exact mid-p was used to compare rates of hospitalization, peritonitis and catheter revisions. Survival curves were used to evaluate the probability of hospital free, peritonitis free, and technique survival. Patients were censored in the technique survival analysis for death or transplant.

Results: 114 patients were started on PD during the study period, 33 of which were US. When comparing US to TS, patients were matched for age, gender, and average days on PD. There were no significant differences in the incidence of infections, or technique failure, timing of peritonitis, timing of peritonitis, technique failure, catheter revision or hospitalization rates between TS and US groups. Sub-group analysis based on race stratification showed that age at PD start was younger in AA TS vs Non AA TS (50±13 vs 60±14 years respectively, p=0.02). 60% of AA TS patients were 60% more likely to have technique failure than Non-AA US (p<0.03). Peritonitis rates for AA TS, Non-AA TS, AA US, and non-AA US were 0.3, 0.14, 0.33, 0.36 per patient year respectively; catheter revision rates were 0.49, 0.3, 0.42 and 0.5 per patient year respectively with no significant difference among the subgroups.

Conclusions: There were no significant differences in outcomes among TS and US groups when stratified by race. Although AA TS patients have the least technique failure and hospitalization rates while AA TS have the highest, no significant differences were noted among race when stratifying by modality.

TH-PO1013

Background: In-center HD and PD are the 2 most common types of dialysis utilized in US. Few studies have examined characteristics of patients who changed dialysis modality. Kaiser Permanente Northern California is an integrated health care delivery system with 3.7 million members. We retrospectively examined the characteristics and disease burden of patients who switched from PD to HD.

Methods: Retrospective examination of EMR from Jan 2009 – Oct 2014. Disease burden was assessed by internally developed comorbidity point score, which predicts negative outcomes in the next 12 months, based on documented comorbidities and hospitalizations.

Results: From 2010-2014, dialysis population in our integrated health system increased from 4005 to 4491 patients, and PD population decreased from 621 to 1033. In this period, 11% of patients initiated dialysis modality switching. Majority of mode changes occurred within a year after dialysis initiation. 8% of HD patients switched to PD and 24% of PD patients switched to HD. Majority of patients who switched from HD to PD do so within 6 months of initiation. They have less comorbidities than those who stay on HD. They have a higher comorbidity score when they switch to PD but lower than repeated switching of those who switched from PD to HD. They were younger than those remaining on HD. Most patients who switched from PD to HD did so within a year. They have more comorbidities than those who stay on PD and have a higher comorbidity score when they switch to HD, even higher than the repeat score of those who switch from HD to PD. The difference in co-morbidity scores between the first and second measurement is higher in the PD to HD pattern. They have similar age to those who didn’t switch.

Conclusions: Patients who switched from HD to PD remain at approximately the same comorbidity score before and after switch. Comorbidity scores of patients who switched from PD to HD significantly increased, suggesting that change was influenced by decline in their overall condition. In our patient population, the switch from HD to PD is likely a patient’s decision, while the switch from PD to HD may be due to inability to continue PD.

TH-PO1014
Impact of Pre-Dialysis Immunosuppressive Treatment Time on Infectious Complications and Survival of Systemic Lupus Erythematosus (SLE) Patients on Peritoneal Dialysis Junbog Shi, Joanne M. Bargman. Dept of Nephrology, Peking Univ Third Hospital, Beijing, China; Div of Nephrology, Univ Health Network, Toronto General Hospital, Toronto, ON, Canada.

Background: SLE patients on peritoneal dialysis (PD) have a significant risk of infectious complications and poor outcomes.However, few studies have examined the relationship between pre-dialysis exposure to immunosuppressive (IS) therapy and the outcome of PD therapy. The objective of this study was to investigate whether pre-dialysis IS treatment time influences the infectious complications and outcomes of SLE patients on PD.

Methods: Twenty-six SLE patients were treated with PD in a major academic centre from May 1996 to May 2014. Demographics, diagnostic tests and IS treatment, comorbid conditions, hospitalizations. Few studies have examined characteristics of patients who changed dialysis modality.

Results: Two patients were lost to follow-up during the study period. Therefore, a total 24 patients were included for analysis. The SLE patients with longer duration of predialysis IS (n=17) were older than patients with shorter pre-dialysis IS (n=7) (83.6±11.0 vs 27.1±7.8, P<0.05), but there were no significant differences in sex, race, PD duration, PD sub-modality and biochemistry between the two groups (P<0.05). Seven patients died during the follow-up period and all the deaths were from the group with longer-pre-dialysis IS time (P>0.05). Three patients died from infections, two patients from cardiovascular disease, and two had sudden death at home. However, there were no significant differences in the incidence of other infections, or hospitalizations, infectious complications, hospitalizations and clinical outcomes during the study period were collected. Three years was chosen as the discriminant between longer and shorter duration of IS therapy.

Conclusions: SLE patients undergoing PD with longer pre-dialysis exposure to IS drugs have a greater mortality that appears to be related to both infectious and noninfectious causes. Although incident to PD, they should be considered a high-risk subgroup.

TH-PO1015
Predicting Peritoneal Dialysis Prescriptions with a Fast Peritoneal Equilibration Test Using PD Adequest J. Ken Levold, 1 Baris U. Agar, 2 James A. Sloand, 1 Mary Gellens, 2 1 Medical Products (Renal), Baxter Healthcare Corporation, Deerfield, IL; 2 Medical Products (R&D), Baxter Healthcare Corporation, Round Lake, IL.

Background: The fast peritoneal equilibration test (PET) is often used to determine parameters for peritoneal transport status, but its accuracy in predicting parameters of peritoneal dialysis (PD) therapy adequacy using computer software, like PD Adequest, has not been quantified. In the current study, the ability of a new version of PD Adequest was
examined to 1) compare mass transfer-area coefficients (MTACs) for urea, creatinine and glucose during fast and standard PETs and 2) use those parameters to predict PD therapy prescription adequacy.

**Methods:** Data from 104 PD (41 CAPD, 63 APD) patients who underwent a 4-hour standard PET and an overnight exchange with the same glucose concentration were used to determine the presented dialysis parameters. Calculated MTAC values for standard PET were compared with those for fast PET by using only data obtained at 4-hours during the standard PET and assuming a 200 mL residual volume in the prior exchange. The calculated membrane parameters were used to predict net ultrafiltration (UF), urea Kt/V and creatinine clearance (CrCl), and those predictions of therapy adequacy were also compared with the mean of 3 actual measurements of net UF, Kt/V and CrCl for each patient.

**Results:** Median urea, creatinine and glucose MTACs were 20.9, 10.1, and 9.1 mL/min during standard PET, and 21.0, 10.1 and 9.0 mL/min during fast PET; the corresponding median urea and creatinine clearance differences between MTACs for urea, creatinine and glucose were 0.6, 0.3 and 0.6 mL/min. Comparing predictions using standard and fast PETs, 81% of net UF were within 150 mL, 94% of Kt/V were within 0.1wk and 93% of CrCl were within 2 L/wk/1.73m². The percent of predicted and actual measured values of net UF within 300 mL, Kt/V within 0.2 wk and CrCl within 0.8 L/wk/1.73m² were 64%, 63% and 77% for standard PET and 38%, 64% and 77% using fast PET; these differences were not statistically significant.

**Conclusions:** These results suggest that the predictions of PD therapy adequacy using PD Adequest are clinically equivalent when either fast or standard PET is employed. **Funding:** Pharmaceutical Company Support - Baxter Healthcare Corporation

The Residual Diuresis Increases in Erythropoiesis in PD Patients

**Background:** Anemia in ESRD is attributed to impaired erythrocyte formation due to erythropoietin and iron deficiency. The accelerated clearance of erythrocytes may at least partially be due to enhanced erytpysis, a suicidal death of erythrocytes characterized by cell shrinkage and cell membrane scrambling with phosphatidylserine(PS)-externalization at the erythrocyte (RBC) surface. Exposed PS is recognized by macrophages that engulf and degrade the affected cells. Little is known about mechanisms underlying enhanced erythropysis in ESRD. At least in theory, erythropysis may be stimulated by some uremic toxins. The present study investigated erythropysis in peritoneal dialysis (PD) patients.

**Methods:** 46 PD patients (31 M, mean age:64±14yrs) and 17 healthy subjects (CTR) were enrolled. All measurements were made in isoethal RBCs. PS exposure was estimated from FITC-AnnexinV binding by flow cytometry.

**Results:** 27 patients were treated with CAPD and 19 with APD. The mean length of treatment was 39±29months. The PS externalization on surface was significantly higher in PD patients than in CTR (2.6%, 1.6±3.7 versus 0.8%, 0.7±1.3, p<0.01). The median percentage of erythropysis showed no significant differences between patients with(n=18) and without diabetes, treated with CAPD or APD and with a negative or positive (n=18) history of peritonitis. Erythropysis showed significantly lower levels in PD patients with residual diuresis (n=23) than in patients without (3.7%, 2.6±5.6 versus 5%, 3.1±6, p=0.03). A significant negative correlation was observed between percentage of erythropysis and Body Composition Monitor-BCM for hydration status (Spearman’s rho=-0.4, p<0.05). There was no a statistically significant relationship between erythropysis and months of PD, urea albumin and creatinine levels.

**Conclusions:** In conclusion, erythropysis has been shown to be significantly higher in PD patients than CTR. Our data suggest that the type and the length of PD treatment do not enhance erythropysis. On the contrary, the loss of residual diuresis lead to a significant increase of erythropysis: the residual diuresis may contribute to the elimination of potential uremic toxins that induce increased erythropysis.

Dialysate Losses of Vitamin 25(OH)D in a Cohort of Patients Treated with Peritoneal Dialysis Juen Carlos Ramirez-Sandoval, Maria Luisa Safar-Boueri, Jorge Jesus Silva, Olynka Vega-Vega, Ricardo Corea-Rotter, Reynero Fagundo, National Medical Sciences and Nutrition Inst Zubiran, Mexico City, Mexico.

**Background:** Peritoneal dialysis (PD) is associated with 25(OH)vitamin D deficiency. To our knowledge, there are no cohort studies about 25(OH)vitamin D dialysate losses in PD.Observative: To characterize 25(OH) vitamin D losses in peritoneal effluent (PE) and their relation with changes in serum 25(OH)vitamin D levels during 4 months in a cohort of incident PD patients.

**Methods:** 52 patients with <6 mths but >1 mth on PD were invited from 2011 to 2014. Those with severe infections, hospitalizations, and oral intake of D3 or D2 during follow up were excluded. Basal vitamin 25(OH) D in 24h PE and serum were measured. After 4 months, a 2nd assessment was performed. The principal outcome was the change in serum vitamin 25(OH) D levels.

**Results:** 43 patients were included, 22 (51%) men, median age was 39y (Interquartile range [IQR] 31-62), 29 (68%) had diabetes and 29 (67%) had some degree of renal residual function during all study. After 4 months of PD initiation, all patients had vitamin 25(OH) D levels <20 ng/mL, 13 of them with levels less than 10 ng/mL.

Fungal Peritonitis in the Standardizing Care to Improve Outcomes in Dialysis Not Associated With Peritoneal Transport Status in the Same Individual

**Background:** Recent studies have reported that peritoneal protein excretion (PPE) during peritoneal dialysis (PD) therapy is associated with cardiac disease and patient survival. However, little is known regarding the extent to which PPE can be influenced by PD prescription or peritoneal transport status.

**Methods:** The aims of this study were to compare PPE in the same individual with different PD prescriptions of either continuous ambulatory PD (CAPD) or nocturnal intermittent PD (NIPD), and to evaluate the correlation between PPE and dialysate to plasma creatinine ratio (D/P Cr). Seventeen patients, of whom 58.8% were male, were included in the study. A peritoneal equilibration test was performed and the amount of total protein (TP) loss in the dialysate was measured during CAPD or NIPD therapy in the same patient.

**Results:** The mean age of the patients was 59.4 ± 18.0 years, body mass index was 21.5 ± 3.4, serum TP (s-TP) was 5.8 ± 0.8 g/dL, serum albumin (s-Alb) was 3.0 ± 0.7 g/dL, C-reactive protein (CRP) was 0.4 ± 0.7 mg/dL, and D/P Cr was 0.76 ± 0.15. During NIPD therapy, PPE was correlated with peritoneal clearance ($\gamma = 0.63$, p = 0.006), effluent volume ($\gamma = 0.69$, p = 0.002), and PPE to effluent volume ratio ($\gamma = 0.80$, p = 0.000), but not with s-TP, s-Alb, CRP, or D/P Cr. During CAPD therapy, PPE was negatively correlated with s-TP ($\gamma = -0.62$, p = 0.007) and s-Alb ($\gamma = -0.58$, p = 0.014), positively correlated with effluent volume ($\gamma = 0.50$, p = 0.037) and PPE to effluent volume ratio ($\gamma = 0.72$, p = 0.001), but not with CRP or D/P Cr. On comparing NIPD and CAPD, there was no difference in effluent volume (7341 mg vs. 7209 mg, respectively); however, both PPE and PPE to effluent volume ratio were significantly lower during NIPD than during CAPD (5586 mg vs. 7779 mg (p = 0.004) and 0.74 mg/mL vs. 1.09 mg/mL (p = 0.044), respectively).

**Conclusions:** The current study demonstrated that PPE and PPE to effluent volume ratio were lower during NIPD than during CAPD in the same individual, independent of the peritoneal transport status.

Relation of Central and Brachial Blood Pressure to Volume Status in Peritoneal Dialysis Patients

**Background:** Euvolemia is an important predictor of outcome in peritoneal dialysis (PD), but chronic subclinical volume overload occurs frequently in PD patients. Even though volume overload is associated directly with hypertension, blood pressure (BP) not always reflect volume overload. Central BP has been shown to be a better predictor for target organ damages compared with brachial BP in general population. In this study, we evaluated comparative values of central BP and brachial BP for determining volume status in PD patients.

**Methods:** We enrolled 52 prevalent PD patients, and accessed variable status using Body Composition Monitor (BCM). Central BP was estimated using radial artery tonometry, and brachial BP measurement at office and 24-hour ambulatory blood pressure monitoring (ABPM) were performed. Volume overload was defined as an overhydration (OH) $\geq$ 1.1 L.

**Results:** Average office central systolic BP (cSBP), office brachial systolic BP (sSBP), and ambulatory brachial systolic BP (24-ssSBP) were 139.8±26.3, 140.7±19.2, and 142.5±22.0 mmHg, respectively. In overall, 41(78.8%) patients were in volume overload status. A stronger association of central BP with volume overload compared with brachial BP was observed in the receiver operating curve analysis (area under the curve (AUC) of cSBP, sSBP, and 24-ssSBP was 0.87±0.06, 0.78±0.09, and 0.83±0.06 respectively). In multivariate analysis adjusted for age, sex, PD vintage, diabetes, and cardiovascular disease, the odds ratio (OR) for central BP (OR 1.110; 95% CI 1.019-1.210) was higher than those for brachial BP (OR 1.085; 95% CI 1.014-1.161 for sSBP and OR 1.194; 95% CI 1.021-1.173 for 24-ssSBP).

**Conclusions:** Office central BP was more strongly related to volume status than out-of-office ambulatory brachial BP as well as office brachial BP, suggesting that central BP was more valuable than brachial BP in assessing volume status in PD patients.

Novel Regimen for Intrapерitoneal Cefazolin and Ceftazidime in Peritoneal Dialysis Patients

**Background:** Current guideline suggested that intraperitoneal (IP) antibiotics should be administered only in a long peritoneal dialysis (PD) dwell (>6 hours), which is not always practical because the long dwell might result in low ultrafiltration and volume overload. The objectives of this study were to develop a novel regimen for IP antibiotics in short dwell (<2 hours) during the automated PD cycling and examine the dialysate and plasma level of the most used empirical antibiotics for PD-related peritonitis, cefazolin and ceftazidime.

**Methods:** In the novel regimen, cefazolin and ceftazidime (20 mg/kg each) were added in a 5-liter bag of 2.5% dextrose PD fluid which was placed on the warmer of the PD cycling machine. Another 5-liter bag of PD fluid was connected to the machine, off the warmer. Patients underwent 5 exchanges of 2-liter PD fluid over 10 hours by the PD cycling machine without last fill or additional dwell. Cefazolin and ceftazidime concentrations in plasma and dialysate were determined by high performance liquid chromatography.

**Results:** Six PD patients without peritonitis were participated in the study. Dialysate cefazolin and ceftazidime were consistently high throughout the PD session in all patients (26-360 mg/L). Plasma cefazolin and ceftazidime exceeded the minimal inhibitory concentration (MIC) for susceptible organisms (8 mg/L) in 2 hours (cefazolin 28.5±8.0 and ceftazidime 12.5±3.4 mg/L at 2 hours), peak at 10 hours (51.1±14.1 and 23.0±5.2 mg/L) and then sustained well above the MIC at 24 hours (42.0±9.8 and 17.1±3.1 mg/L).

**Conclusions:** The novel regimen for IP cefazolin and ceftazidime in short dwell (<2 hours) during the automated PD cycling could provide adequate dialysate and plasma concentration and would become a standard regimen for peritonitis in PD patients already using PD cycling machine as well as those who temporarily need shorter dwells during peritonitis due to increasing peritoneal solute transport.

Is Automated Peritoneal Dialysis Better Than Continuous Ambulatory Peritoneal Dialysis in Quality of Life, Depression, and Renal Treatment Satisfaction? A Prospective Multicenter Propensity-Matched Study

**Methods:** Incident patients initiating APD and CAPD were prospectively enrolled from nationwide multicenters in Korea. HRQOL, depression, and renal treatment satisfaction were assessed at 1 and 12 months after the start of dialysis by Kidney Disease Quality of Life Short Form 36 (KDQOL-36), Beck’s Depression Inventory (BDI), and Renal Treatment Satisfaction Questionnaire (RTSQ), respectively. The mean changes of scores in APD and CAPD were compared by propensity score matching analysis.

**Results:** All 260 incident patients starting peritoneal dialysis (PD) from 11 centers were included in this study. A total of 170 patients were matched from 208 patients who completed all questionnaires and did not change PD modality during the 1-year follow-up period. The total scores at 1 month showed better HRQOL for APD than CAPD patients in symptom, patient satisfaction, pain, and social function domains. No differences were observed between the two groups in total scores of KDQOL-36 at 12 months. However, CAPD patients had a significantly greater improvement in symptom and social function domains. A significant improvement also occurred in BDI and RTSQ in CAPD patients.

**Conclusions:** APD is not better than CAPD in HRQOL, depression, and renal treatment satisfaction during initial first one year on dialysis. The relative positive effect of CAPD compared with APD on improvement of HRQOL, depression, and renal treatment satisfaction was confirmed.

**TH-PO1025**

Thyroid Functional Disease and Mortality in a National Peritoneal Dialysis Cohort

**Background:** Peritoneal dialysis (PD) patients have a high prevalence of thyroid dysfunction which may be due to 1) peritoneal effluent losses (vast majority of thyroid hormone is protein-bound) and 2) frequent exposure to povidone-iodine cleaning agents leading to iodine-induced hypo- and hyperthyroidism. In the general population thyroid dysfunction is associated with higher risk of cardiovascular (CV) disease and death. There has not been study of the association between hypo- or hyperthyroidism defined by TSH with mortality in PD patients.

**Methods:** We examined the association of thyroid functional status with all-cause mortality in a 5-year national cohort (1/2007-12/2011) of PD patients with at least one TSH measure. Thyroid functional status was defined as: hyper-, eu-, and hypothyroidism (TSH <0.5, 0.5-5, >5mIU/L). We examined time-dependent and baseline thyroid function to determine short- and long-term exposure–mortality associations, respectively, using Cox models with 3 adjustment levels: unadjusted, case-mix, and case-mix+laboratory adjusted.

**Results:** Among 1484 patients, 7% and 18% had hypo- and hyperthyroidism, respectively. In time-dependent analyses, hypo- and hyperthyroidism were each associated with higher mortality, suggesting short-term risk in PD patients. Further studies are needed to determine if CV pathways are implicated, and if thyroid-modulating therapies ameliorate mortality in this population.

**Conclusions:** Time-dependent hypo- and hyperthyroidism were each associated with higher mortality, suggesting short-term risk in PD patients. Further studies are needed to determine if CV pathways are implicated, and if thyroid-modulating therapies ameliorate mortality in this population.

**TH-PO1026**

A Tale of APOL1 Mutation and Parvovirus Infection

**Introduction:** We present a case of a first trimester pregnant woman with nephrotic range proteinuria and fetal demise in the setting of an acute parvovirus infection. Kidney biopsy revealed collapsing FSGS, and exome sequencing revealed mutations in APOL1. The relationship between Parvovirus and FSGS is one that clinicians might overlook, and perhaps may play a more prominent role in these progressive cases especially with APOL1 mutations.

**Case Description:** 37 yo Caribbean female presented at 8 weeks gestation with progressive swelling. Her daughter developed fifth’s disease one month prior. On presentation her BP was 146/95, HR 77 with pitting edema. Her creatinine was 6.3, BUN 43, albumin 1.5, and spot pt/ct 20.8. Parvovirus PCR was 2000 copies. Biopsy demonstrated collapsing FSGS secondary to Parvovirus B19 [Fig 1A 1B]
The hope was that this injury would improve with improvement in titers, so IVIG was started. A follow up PCR showed improvement to 200 copies but she remained nephrotic with proteinuria of 20-60 g. Re-biopsy revealed significant scarring and dialysis was initiated [Fig IC]. Patient is now being evaluated for transplant. Given the unusual severity of this case, and her possible African ancestry, a genetic susceptibility to podocyte injury was entertained. Whole exome sequencing identified the patient to have two APOL1 risk alleles.

**Discussion:** Parvovirus has been linked with collapsing FSGS, and in one study viral PCR was detected in 78% of kidney tissue with this diagnosis. The combination of B19 infection and APOL1 mutation likely made our patient particularly susceptible to injury. Our case raises the question of how often subclinical parvovirus infection may be involved in collapsing FSGS, and highlights how subtle and devastating it can be to the life of a prior healthy young woman.

**Podocyte Myeloid Bodies withoutConfirmed Genetic Mutation in a Female: Fabry’s Disease?**

Pravir V. Baxi,1 David J. Cimbaluk,2 David G. Warnock,3 Robert J. Descheny,4 William Luke Whittier,5 \*Nephrology, Rush Univ MC, Chicago, IL; 5Pathology, Rush UNC, Chicago, IL; 6Nephrology, UAB, Birmingham, AL; 7Genetics, Mt Sinai, New York, NY.

**Introduction:** Fabry’s disease (FD) is a X-linked lysosomal storage disorder caused by deficient alpha-galactosidase activity. A renal variant has been described with the R363H mutation. Due to random X-chromosomal inactivation, heterozygous females can present a diagnostic challenge. We report a case with a renal limited presentation, biopsy findings characteristic of FD but a negative whole blood DNA analysis.

**Case Description:** A 46-year-old Hispanic woman was evaluated for proteinuria. She was asymptomatic with no prior medical history or family history, and no exposure to silica, amiodarone, or hydroxychloroquine. Her exam was unremarkable: no neuropathy, skin changes, or corneal dystrophy. ScCr was 0.6 mg/dL, UA 2+ protein with P/C ratio of 1.94 g/L. Biopsy revealed diffuse enlargement of the podocytes with a foamy cytoplasmic appearance and on EM, prominent podocyte lamellated lipid inclusions with foot process effacement and minimal endothelial deposits.

**Figure 1:** Podocyte myeloid bodies; yellow line denotes foot process effacement, red star shows limited endothelial inclusion. Alpha-galactosidase activity was 0.187 U/L (lower limit of nl) and genomic sequencing of the GLA gene was negative. EKG, Echo, cardiac MRI, and brain MRI with and without gadolinium were nl.

**Discussion:** We present a pt with renal limited manifestations mimicking FD in the absence of known toxic exposure and a negative whole blood DNA mutation analysis. Treatment with enzyme replacement is not warranted without a positive genetic analysis. This case highlights the variable genotypic and phenotypic presentation, and raises the possibility that tissue-specific mosaicism could explain phenotypic variation in females with Fabry’s Disease.

**TH-PO1028**

**Relapsing Thrombotic Microangiopathy following Persistent Intravenous Use of Reformulated Oxycodone**

Melissa S. Nataatmadja,1,2,3 Baxi V. Pravir,4 Warnock, David G.,5 Descheny, Robert J.6, Whittier, William Luke.5

**Introduction:** Thrombotic thrombocytopenic purpura (TPP), with normal ADAMTS13 activity has recently been observed in persons injecting OxyContin (oxymorphone). This report supports the use of oxymethylene oxide (PEO), a tamper-proof coating added to the reformulated Oxycodone and Opna ER, as the causative agent, as TMA has now been observed following the use of two different medications but with the same PEO coating. Additionally, our case is the first to demonstrate relapse of TMA following persistent intravenous drug use of oxymethylene oxide. Given the rarity of this illness, it is possible that an unidentified genetic or immunologic susceptibility causes some individuals to develop TMA in response to these drugs, whilst others do not. We encourage clinicians to consider IV drug use in all patients presenting TMA, as treatment approach may differ and the role of plasma exchange is not yet clear.

**TH-PO1029**

**Iplilimum Associated Kidney Injury**

Andinet Gizaw, Jason M. Kidd, Nephrology, VCUHS, Richmond, VA.

**Introduction:** Melanoma is the most fatal form of skin cancer. Patients without surgically resectable disease require chemotherapy. Iplilimumab; a human monoclonal antibody against anti-CTLA-4 is an Immunomodulation agent, with proven benefit in overall survival in patients with unresectable, advanced (Stage 3) Melanoma. Cytotoxic T Cell Lymphocyte Antibody 4 (CTLA-4) is a negative regulator of T-Cell mediated anti-tumor immune response working as immune check points (down regulation). We present a case of acute kidney injury due to interstitial nephritis and minimal change disease from this drug.

**Case Description:** A 53-year-old woman with metastatic breast cancer, right atrial mass, status post resection, was seen for evaluation of acute kidney injury and nephrotic range proteinuria. He developed lower extremity swelling with rash about 02 weeks after receiving a third dose of ipilimumab. He had a baseline serum creatinine of 1.2mg/dL. At the time of consultation, his serum creatinine was 2.97mg/dL, 9 grams of proteinuria on 24 hours collection and serum albumin of 2.2. He was initially fluid resuscitated, however, creatinine increased to 5.2 mg/dL and he became oliguric. Urine microscopy was without casts and serology markers were negative. Renal biopsy was performed that showed an interstitial cast nephritis without giant cell interstitial inflammation and severe edema. Among most half of glomeruli were globally sclerotic, the others had minimally altered composition. Immunofluorescence was unremarkable. Electron microscopy showed diffuse effacement of podocyte foot processes. He was treated with high dose (2mg/kg) steroid and oral diuretics. Renal function has returned to his prior baseline and has a nephrotic proteinuria.

**Discussion:** This describes a case of nephrotic syndrome and interstitial nephritis related to the monoclonal antibody, Iplilimumab. Interstitial nephritis has been described with this drug before. However, this is the first case to our knowledge of the administration of Iplilimumab leading to acute kidney injury from interstitial nephritis and severe proteinuria from diffuse foot podocyte process effacement. Prompt recognition of this presentation is necessary to preserve renal function.

**TH-PO1030**

**Kappa Light Chain-Associated Crystal-Storing Tubulopathy, Podocytopathy, and Histiocytosis in GI Tract, in a Patient with Multiple Myeloma**

Michifumi Yamashita,1,2 Albert Q. Lam,3 Joseph V. Bonventre,2,3 Vanesa Bijo,2,4 \*Pathology, Brigham and Women’s Hospital, Boston, MA; 3Renal Division, Brigham and Women’s Hospital, Boston, MA; 4Harvard Medical School, Boston, MA.

**Introduction:** Multiple myeloma manifests with variety forms of kidney disease, such as amyloidosis, cast nephropathy, and light chain deposition disease. Among them, crystal-storing disease is a rare entity. We report an interesting case of a patient with extramedullary IgGk multiple myeloma, who presented with crystal-storing histiocytosis in GI tract, and subsequently developed crystal-storing tubulopathy and podocytopathy.

**Case Description:** A 65-year-old man with type 2 DM and HTN was found to have a 1 cm largeecal polyp on screening colonoscopy in 2009. The polyp showed diffuse infiltration by a plasma cell neoplasm and crystal-storing histiocytosis with k light chain (LC) restriction. At that time, the patient showed intact bone marrow, normal renal function and proteinaemia of 0.5 g/L. He was subsequently closely followed with endoscopy, SPEP, and renal function tests. In 2014, he developed nephrotic range proteinuria (>4g/24h), slightly rising Cre to 1.12 mg/dL, and increased serum free k LC (216 mg/L). Kidney biopsy was performed, revealing many proximal tubular epithelial cells containing PAS-positive PAS-negative granular materials in the cytoplasm. The glomeruli were unremarkable except for mild mesangial expansion. No significant immune deposits were present in glomeruli or tubulointerstitium, but there was slightly stronger background IF reactivity for k LC than l LC on frozen tissue sections. IF studies on protease-digested paraffin sections revealed strong k LC reactivity of the materials aggregated in the tubular epithelial cells and podocytes, whereas l LC was negative. EM revealed extensive intracytoplasmic accumulation of crystalline material of rhomboid and rectangular shapes in proximal tubular cells and podocytes.

**Discussion:** LC-associated crystal-storing disease is a rare kidney disease. To our knowledge, this is the first reported case of coexisting crystal-storing tubulopathy, podocytopathy, and histiocytosis in the GI tract in a patient with multiple myeloma.
Case Report of Obstructive Nephrolithiasis Secondary to Atazanavir

Dina Abdulwahab, Anusheer C. Shirali.

Introduction: Atazanavir, a protease inhibitor used in the management of human immunodeficiency virus (HIV), is associated with crystalluria and nephrolithiasis. While crystalluria is seen in 10-20% of patients on atazanavir treatment, frank nephrolithiasis is less common. We report a case of nephrolithiasis associated with atazanavir in an HIV patient on long-term highly active anti-retroviral therapy (HAART).

Case Description: A 56-year-old male with a past medical history of HIV on HAART, using dolutegravir, lamivudine, and abacavir to treat his HIV, presented with obstructive uropathy. His HAART regimen was switched to dolutegravir, lamivudine, and abacavir.

Discussion: This case clearly showed: (1) for the first time, Parvovirus B19 particles in glomeruli immunohistochemically and ultrastructurally, (2) Parvovirus B19 infection systemically and histologically preceding CG, and (3) when CG developed, serum Parvovirus B19 titer significantly decreased which could not be explained by the kidney tissue by EM or IHC. The evidence suggests that the direct or the indirect association between Parvovirus B19 infection and CG in kidney allograft.

A Case Report of Obstructive Nephrolithiasis Secondary to Atazanavir

Dina Abdulwahab, Anusheer C. Shirali.

Introduction: Atazanavir, a protease inhibitor used in the management of human immunodeficiency virus (HIV), is associated with crystalluria and nephrolithiasis. While crystalluria is seen in 10-20% of patients on atazanavir treatment, frank nephrolithiasis is less common. The evidence suggests that the direct or the indirect association between Parvovirus B19 infection and CG in kidney allograft.

Relapse of Kappa Restricted Chronic Lymphocytic Leukemia Associated with a Lambda Restricted Plasma Cell Clone Causing Renal Amyloidosis

Sunil Smita Mahendrakar, Anushree C. Shirali.

Introduction: Chronic lymphocytic leukemia (CLL) has been associated among many malignant diseases. Rarely, it has been associated with amyloidosis either as the sole clone responsible, or in association with a plasma cell clone possessing the same light chain. A 72-year-old man with ESRD due to DM and HTN, status post kidney transplantation. Delay in diagnosis and xanthine oxidase inhibitor treatment predisposes to recurrent disease in renal allograft, with allograft loss in over 25% cases. Though APRT is ubiquitous in all cells, extrarenal symptoms are uncommon in affected individuals. Our patient presented with crystalline keratopathy resolving completely after kidney transplantation.

Case Description: A 66 year old male, diagnosed with kappa-restricted CLL in 2009 achieved complete remission after 6 cycles of fludarabine, cyclophosphamide and rituximab. 5 years later, he presented with foamy urine, generalized swelling, and weight gain. Serum creatinine was 1.1. Initial spot urine protein / creatinine ratio showed proteinuria of 5g/g which later increased to 10g/g. During the previous year serum albumin fell from 3.8 to 1.5 g/dL, and the white blood cell count rose from 7.4 to 30 x10^9/L. During the previous year serum albumin fell from 3.8 to 1.5 g/dL, and the white blood cell count rose from 7.4 to 30 x10^9/L. While the lymphocyte frequency rose from 45% to 88%, serum free light chains were 45.1mg/L lambda, 21.5 mg/L kappa with a ratio of 0.48. Kidney biopsy showed AL-amyloidosis with immunofluorescence positive for lambda. Due to discrepancy in the clonality of previous circulating CLL expansion (kappa restricted) and renal amyloidosis (lamba restricted), a bone marrow biopsy was done. This showed a relapse of CLL with low level (<10%) plasma cell dyscrasia. Flow cytometry confirmed that the relapsed CLL population was kappa-restricted while the clonal plasma cell population expressed lambda. After 8 months of treatment with velcade, dexamethasone and revlimid, he showed minimal improvement in proteinuria.

Discussion: Though the co-existence of clonal plasma cells and CLL is known, the temporal association of this patient’s nephritic syndrome secondary to amyloidosis from a unique plasma cell clone expressing a different light chain supports the hypothesis that, in CLL, sharing the same microenvironment as non-tumor cells may activate bystander B-cells to express free light chains and in this case lead to amyloidosis.

Recurrent 2,8-Dihydroxyadenine Deposition Successfully Treated with Kidney Transplantation

Pamela A. Duran, Mohamran Narayanaj, Div of Nephrology, Yale Univ School of Medicine, New Haven, CT.

Introduction: Adenine phosphoribosyltransferase (APRT) deficiency is an autosomal recessive purine metabolism disorder where adenine is oxidized by xanthine dehydrogenase to 2,8-dihydroxyadenine (2,8-DHA), forming insoluble urinary crystals, nephrolithiasis, CKD and ESRRD. Literature reveals diagnosis of APRT deficiency is rare before kidney transplantation. Delay in diagnosis and xanthine oxidase inhibitor treatment predisposes to recurrent disease in renal allograft, with allograft loss in over 25% cases. Though APRT is ubiquitous in all cells, extrarenal symptoms are uncommon in affected individuals. Our patient presented with crystalline keratopathy resolving completely after kidney transplantation.

Case Description: A 41 y/o Caucasian female with recurrent 2,8-DHA nephrolithiasis since age 23 was maintained on Allopurinol. Clinical course was significant for obstructive uropathy requiring multiple stent placements, continued decrement in renal function and bilateral hydronephrosis. Treatment with xanthine oxidase inhibitor was initiated to prevent recurrent transplant kidney stone disease. She developed crystalline keratopathy, xanthine oxidase inhibitor treatment predisposes to recurrent disease in renal allograft, with allograft loss in over 25% cases. Though APRT is ubiquitous in all cells, extrarenal symptoms are uncommon in affected individuals. Our patient presented with crystalline keratopathy resolving completely after kidney transplantation.

Recurrence of CLL in a Patient with X-Linked Immunodeficiency Syndrome with Paraneoplastic Tumor-induced Osteomalacia (TIO) in Small Cell Carcinoma

M. Ahmed, Suneet Verma, Mandeep Samra, Jennine Michaud, Donghong Cai, Michael Yudd.

Introduction: Small cell carcinoma (SCCA) with diffuse sinusoidal pattern. Despite PO4 replacement, hypophosphatemia was found. Serum FGF-23, 577 RU/ml. No lab findings of Fanconi Syndrome . CT showed pulmonary weight loss. Labwork showed normal renal function, serum phosphorus (PO4) 0.8 mg/dl, immunohistochemical staining for FGF-23 in SCCA.

Discussion: Immunostaining of tumor cells from the lung and liver were positive for FGF-23. This is the first case with documented elevated serum FGF-23 and positive FGF-23 immunostaining of SCCA. Tumor-induced osteomalacia (TIO) is usually associated with benign tumors of mesenchymal origin, rarely with adenocarcinoma or small cell carcinoma. The syndrome is characterized by renal PO4 wasting due to excess FGF-23 from the tumor, leading to hypophosphatemia. There are at least 10 cases of SCCA with paraneoplastic PO4 wasting. Only for 1 case with documented elevated FGF-23 associated with tumors other than mesenchymal tumors: 2 cases of stage D2 prostate adenocarcinoma, one with metastatic colon cancer, and one with stage 4 ovarian cancer. All of these were advanced, metastatic disease. Of these, only the metastatic colon cancer case was documented with FGF-23 immunohistochemical staining in the hepatice metastases. Our case is the first case of FGF-23-positive immunostaining in tumor cells of small cell CA.

Paraneoplastic Tumor-induced Osteomalacia (TIO) in Small Cell Carcinoma

M. Ahmed, Suneet Verma, Mandeep Samra, Jennine Michaud, Donghong Cai, Michael Yudd.

Introduction: Small cell carcinoma (SCCA) with diffuse sinusoidal pattern. Despite PO4 replacement, hypophosphatemia was found. Serum FGF-23, 577 RU/ml. No lab findings of Fanconi Syndrome . Minimal Change Disease Diagnosing Relapsing Mantle Cell Lymphoma

Juan Calderon, Mark A. Perazella. Nephrology, Yale Univ School of Medicine, New Haven, CT.

Introduction: Glomerular lesions are linked with hematologic malignancies, with minimal change disease (MCD) commonly associated with Hodgkin’s lymphoma. Diagnosis of the underlying hematologic disorder often precedes development of the glomerulopathy; however, in rare cases, MCD precedes discovery of the lymphoma by several months. We present a case of a new onset nephrotic syndrome and AKI in association with undetected relapsing mantle cell lymphoma (MCL).

Case Description: A 74 yo man with history of stage IV mantle cell lymphoma in remission developed AKI and new onset edema. Chemotherapy completed 1 year prior to presentation induced complete remission on bone marrow and follow-up PET scans. On presentation he denied B symptoms, had no new lymphadenopathy, and only noted decreased appetite. The patient was edematous and hypertensive. Serum Cr was 2.4 mg/dl up from 1.3 mg/dl. High-grade, non-quantifiable urine protein was noted by the lab. Urine sediment was remarkable for numerous granular casts, oval fat bodies, and few uric acid crystals. Serum uric acid was 13.2 mg/dl. Therapy for tumor lysis syndrome was instituted due to concern for relapsing lymphoma in the setting of AKI. However, PET/CT scan was completely normal with no evidence for lymphoma. Furthermore, LDLH was within normal limits. Kidney biopsy revealed normal glomeruli on light microscopy with acute tubular injury. EM revealed global effacement of foot processes. A diagnosis of MCD with focal tubular injury was made and steroid therapy was started. Peripheral flow cytometry and later a bone marrow biopsy confirmed a 23% tumor burden compatible with relapsed MCL.

Targeted chemotherapy for MCL was initiated.

Discussion: We present the first report of MCD associated with relapsing MCL. Oncologic surveillance including PET scan failed to detect recurrent MCL. BM biopsy and flow study was pursued following the diagnosis of MCD. Initial therapy with steroids alone was associated with a reduction in proteinuria. This improved further with therapy directed at the relapsed MCL suggesting a pathophysiological relationship between these two disorders. Clinicians must remain cognizant of the possibility of malignancy when a suspicious glomerular lesion develops.

Renal Osteodystrophy

Hitarth S. Dave, Daniel E. Carl. Dept of Internal Medicine, Div of Nephrology, Virginia Commonwealth Univ School of Medicine, Richmond, VA.

Introduction: It is believed that mineral metabolism changes start as early as stage II chronic kidney disease (CKD). The spectrum of CKD-mineral and bone disorder (MBD) ranges from low-turnover anemic disease to high-turnover osteitis fibrosa.

Case Description: A 37-year-old female with end-stage renal disease (ESRD), currently undergoing hemodialysis, presented complaining of a 1-day history of inability to eat or drink. Prior to presentation, she had noticed 2-week history of difficulty speaking, and 8-month history of increasing facial size. On presentation, the blood pressure was 180/68 mm Hg, and the oxygen saturation 98% while breathing ambient air. The physical examination revealed significant bony hypertrophy of the maxilla and mandible with edema of the overlying soft tissue. Computed tomographic (CT) scans of the maxilla and mandible showed severe expansion of the mandible and hard palate with complete replacement of the osseous matrix and surrounding mass effect on the maxillary sinuses and oropharynx. This improved further with therapy directed at the relapsed MCL suggesting a pathophysiological relationship between these two disorders. Clinicians must remain cognizant of the possibility of malignancy when a suspicious glomerular lesion develops.

5-Oxoprolinuria: A Rare Cause of High Anion Gap Metabolic Acidosis due to Acetaminophen Ingestion

Aravind Manshadian, 1,2 Sreesh G. Iyengar, 1 Seyed-ali Sadjadi, 1 Lisa Aimee Hechanova. 1 Nephrology, Loma Linda Univ, Loma Linda, CA; 2 Nephrology, Jerry L Pettis Memorial Veterans Medical Center, Loma Linda, CA.

Introduction: Acquired 5-oxoprolinuria is a rare cause of high anion gap metabolic acidosis, with excessive accumulation of citrulline. It largely goes unrecognized because an assay for 5-oxoprolinuria is not widely available. The malnourished and chronically ill women with history of chronic acetaminophen ingestion are commonly affected. Acetaminophen levels are rarely in toxic range.

Case Description: A 57-year-old woman with a history of adipsia dolorosa was admitted for acute osteosclerotic. She was chronically taking acetaminophen containing aspirin. Her acetaminophen level was not elevated. Usual causes of anion gap acidosis were ruled out. Finally, a urine organic acid screen showed elevated 5-oxoprolinuria levels. Acetaminophen containing pain medication was stopped; she was given IV hydration and sodium bicarbonate. Her anion gap metabolic acidosis would quickly resolve.

Discussion: Acute and chronic acetaminophen ingestion can lead to high levels of 5-oxoprolinuria. The pathophysiology behind acquired 5-oxoprolinuria has been mostly explained by reduced glutathione in prior case reports. 5-oxoprolinuria is an intermediate in the gamma-glutamyl pathway, the metabolic cycle responsible for creating glutathione and shuttling amino acids into the cytosol. When glutathione levels are diminished, feedback inhibition ceases, causing an overproduction of 5-oxoprolin. Sepsis, amongst others eutologies, have been implicated in glutathione depletion. 5-oxoprolinuria clinically presents with altered mental status. One of the key aspects of diagnosing this disorder is the detection of 5-oxoprolin in urine. N-acetylcycteine may be an effective treatment that acts to restore intracellular glutathione levels. Extracellular fluid expansion with dextrose containing saline promptly improves symptoms. In conclusion, 5-oxoprolinuria should be considered in any patient with unexplained metabolic acidosis and recent acetaminophen ingestion. Overlooking the diagnosis can be costly.

Severe Tubulointerstitial Nephritis with Lymphoid Follicles in Sjögren’s Syndrome

Maiko Nagata, Takehiko Kawaguchi, Mao Watanabe, Takafumi Yamakawa, Moritoshi Kadomura, Hiroshi Kitamura, Toshiyuki Imasawa. Internal Medicine, National Hospital Organization Chiba-East-Hospital, Chiba, Japan.

Introduction: Patients with Sjögren’s syndrome (SS) are at increased risk for the development of lymphoma. The presence of acute tubular injury and lymphoid hyperactivity in SS may predispose patients to the development of lymphoma neoplasm. However, biopsy specimens from some of these patients do not meet histologic criteria for frank malignancy. We report a rare case of severe tubulointerstitial nephritis with lymphoid follicles in SS.

Case Description: A 66-year-old woman, who had developed general malaise for a few years, was admitted to our hospital, because of the rapid rise in the serum creatinine
Scleroderma renal crisis was diagnosed according to the pathology result. Lisinopril 20 mg once daily was started and a continued deteriorating leading to hemodialysis.

Discussion: Recognizing the early signs of kidney injury is important to initiate the treatment scleroderma renal crisis (SRC). Physicians should suspect for SRC once patients have signs of acute kidney injury regardless of elevated blood pressure or creatinine.

Acetaminophen Associated 5-Oxoproline Acidosis in an Anuric End-Stage Renal Disease Patient Michael Plam,1 Leslie F. Thomas,2 Christine Snozek,3 1Internal Medicine, Mayo Clinic, Phoenix, AZ; 2Nephrology, Mayo Clinic, Phoenix, AZ; 3Laboratory Medicine & Pathology, Mayo Clinic, Scottsdale, AZ.

Introduction: Also known as pyrogulatamic acid, 5-oxoproline is an intermediary in glutathione antioxidant metabolism. Reports of acetaminophen associated 5-oxoproline high–anion gap metabolic acidosis (HAGMA) has been slowly growing in the literature but remains under recognized in clinical practice.

Case Description: A 57 year old male with anuric end-stage renal disease (ESRD) was admitted for confusion and hypotension secondary to sepsis from infected lower extremity ulcers, poor oral intake, and excessive peritoneal dialysis. Laboratory evaluation revealed a depressed bicarbonate level of 17 mEq/L and an elevated albumin–corrected anion gap of 30 mEq/L. Despite correction of an elevated L–lactate with fluid resuscitation and antibiotics, his HAGMA persisted. An exhaustive investigation was unable to find a convincing etiology including common–ly attributable organic acids, D-lactate, paraproteinemia, toxic exposures, and medications. Further inquiry revealed a protracted course of therapeutic acetaminophen ingestion with a weighted average daily dose of 1.3 grams in the four weeks leading to presentation. Serum 5-oxoproline was elevated to >100.0 mmol/L (normal <2.5 mmol/L). Serum acetaminophen was undetectable. All medications and medications containing medications were subsequently stopped. His clinical course improved with supportive care and he was discharged home. After 5 weeks of acetaminophen cessation, his serum 5-oxoproline normalized to 27.1 mmol/L with anion-gap and bicarbonate levels returning to baseline.

Discussion: To our knowledge, we report the first case of acetaminophen associated 5-oxoproline acidosis in an anuric ESRD patient. Risk factors are thought to be related to glutathione deficiency which in turn favors the 5-oxoproline pathway of the γ-glutamyl cycle and results in accumulation. These risk factors include reactive acetaminophen metabolites, alcohol abuse, malnutrition, sepsis, renal dysfunction, and liver disease. As an under recognized entity in clinical practice, 5-oxoproline should be considered in adults with unexplained HAGMA and the above risk factors.

TH-PO1043

Renal Amyloidosis Associated with Apolipoprotein C-II Deposition Lohit Garg,1 Gerta Mane,2 Sami S. Zarouk,3 1Dept of Internal Medicine, Beaumont Health, Royal Oak, MI; 2Dept of Nephrology, Beaumont Health, Royal Oak, MI.

Introduction: A 62-year-old female with no family history of renal disease presented with a creatinine at 2.3 mg/dL and hypertension. Baseline creatinine was 1.2 mg/dL one year prior to presentation and she had 1+ proteinuria on urinalysis 3 years earlier. Serologic work up was negative for ANA, C3, C4, hepatitis B and C, HIV and SLE. Membranous gammapathy evaluation showed IgA kappa monoclonal protein as two bands in the beta globulin region. Random urine for protein electrophoresis showed a small amount of IgA and free kappa monoclonal protein. Her random urine protein/creatinine ratio was 6.3. A renal biopsy was consistent with amyloidosis in the mesangium that exhibited apple green birefringence on polarization microscopy after Congo Red staining. Immunofluorescent stains for kappa and lambda light chains were negative. Electron microscopy showed randomly arranged fibrils in the mesangium with features characteristics of amyloid fibrils. Bone marrow biopsy showed 6% plasmacytosis and minimal involvement with amyloidosis. Laser micro dissection and liquid chromatography mass spectrometry (LCMS) were performed on peptides extracted from Congo-red positive dissected areas. LCMS detected high levels of apolipoprotein C-II while analysis for lambda or kappa light chains, transferrin and serum amyloid A were negative. It was concluded that these findings are unequivocally consistent with apolipoprotein C-II amyloid. Genetic testing was performed by direct sequencing of apolipoprotein C-II and showed mutation in patient as well as her son but not her daughter.

Discussion: Apolipoprotein C-II is a component of very low density lipoprotein and readily aggregates in lipid free conditions to form homogenous amyloid fibrils due to their intrinsic structure. To the best of our knowledge, this is the first case of apolipoprotein C-II renal amyloidosis. This case highlights the importance of performing DNA sequencing of exons of interest and LCMS on known amyloidogenic proteins to accurately diagnose and type the renal amyloidosis, which is critical for prognosis, treatment and genetic counseling.

TH-PO1044

Membranous Nephropathy in a Young Child with IPEX-Like Phenotype and a Novel Fxo3 Mutation Olena Charnaya, Sun-Young Ahn, Asha Moudgil. Nephrology, Children’s National Medical Center, Washington, DC.

Introduction: Immune dysregulation, polyendocrinopathy, enteropathy, X-linked (IPEX) syndrome typically presents with heterogenous manifestations. The syndrome is characterized by numerous auto-immune diseases due to dysfunction in the Foxp3 gene, which plays a critical role in maintaining immune tolerance.
Reverse Pseudohyperkalemia in a Patient with Non-Hodgkin’s Mantle Cell Lymphoma

Case Description: A 44 y.o. male with ESRD was diagnosed in 11/2010 with CVID after developing pneumonitis. He had a history of recurrent sinusopulmonary infections and pneumococcal pneumonia. Immunoglobulin levels were undetectable and B and T NK cell numbers normal. He was treated with monthly IVIG infusions. In 3/2012, he underwent living unrelated kidney transplantation (KT). Immunosuppression consisted of basiliximab, methylprednisonelone, FK, MMF and prednisone. Baseline creatinine (Cr) post KT was 0.93 mg/dL and 1.06 mg/dL, Cr 1.06 mg/dL, urinalysis negative for blood, protein, and white blood cells. CT pain was so severe that he went to a local ER. Initial evaluation notable for BUN 10 mg/dL, Cr 1.06 mg/dL, urinalysis negative for blood, protein, and white blood cells. CT angiography revealed no evidence of acute tubular injury and transplant glomerulopathy with new diffuse (100%) C4d positivity. Rebiopsy showed resolution of ACR. However, he had chronic vascular rejection, focal intimal thickening and C4d positivity.

Discussion: Subsequent transthoracic echo showed no vegetation or shunt, appearing to exclude embolus from heart or lungs. Hypercoagulable work-up was negative. Patient is being managed conservatively with no anticoagulation, and is doing well. His Cr has drifted down from a peak of 1.16 mg/dL to a new baseline of 0.99 mg/dL, he has not developed hypertension, and his flank pain has resolved.

Conclusion: This case is notable because the FMD occurred in a male, and because renal infarction is a rare presentation of FMD. The actual cause of the infarction is most likely fat embolism syndrome (FES), which led to graft loss.

TH-PO1047

An Unusual Presentation of Fibromuscular Dysplasia

Case Report and Literature Review

Deepak Jasuja, Melissa D. Anderson. Div of Nephrology, Indiana Univ, Indianapolis, IN.

Introduction: Non traumatic causes of Fat Embolism Syndrome (FES) have been reported with bone marrow transplantation, osteomyelitis, pancreatitis, alcoholic fatty liver, and with liposuction. Etiology likely is fat particles entering the circulation with damage to capillary beds. Regardless of the mechanism initiating fat embolism, the end result is an intense inflammatory response. In the lungs, this induces lung injury that is indistinguishable from ARDS. FES can cause cerebral edema with raised intracranial pressure along with multi-organ failure and AKI.

Case Description: We present a 40- year-old African American lady who underwent non- myeloablative bone marrow transplant for Myelodysplastic anemia. One week after engraftment she developed sudden onset of respiratory distress leading to a cardio- respiratory arrest. She developed ARDS, multiple organ dysfunction syndrome and CVVH was initiated for oliguric AKI and Metabolic acidosis. Soon after initiating CVVH her filler clot was identified with white, creamy plaque which cleared after 2 successive filters. Patient met Gurd and Wilson’s criteria for diagnosis of Fat Embolism Syndrome. She had abundance of

Underline represents presenting author.
inflammatory cells on Broncho alveolar lavage including neutrophils and macrophages. Oil Red-O stain (stain for lipid) was performed to quantify macrophages displaying positivity. The initial Prep yielded 5 of 5 and the repeat prep yielded 11 out of 12 of macrophages positive for Oil-Red-O. CT brain was performed which revealed large acute strokes with midline shift compatible with subacute herniation. No cerebral blood flow was identified on nuclear scan and patient was declared brain dead and terminally weaned.

Discussion: With the absence of specific tests or criteria the diagnosis of FES is dependent on the clinical acumen of the physician. Lipid inclusion in 30%-70% of macrophages / inflammatory cells is more suggestive of FES. Only proven treatment is supportive. We propose that a clotting filter might be an earlier step to diagnose fat embolism syndrome and sending the filter for pathological analysis looking for lipid laden inflammatory cells is a less invasive approach as compared to quantification using Broncho-alveolar lavage.

TH-PO1049
Fetal Hyponatremia with Glycine Solution During Hysteroscopy – Proposal for New Mechanisms of Hyponatremia and Cerebral Edema

Introduction: We report a fatal case of severe symptomatic hyponatremia and cerebral edema following hysteroscopy.

Case Description: 39 y.o. woman underwent 70 mins hysteroscopic myomectomy, 6L of glycine solution used for distension, without documented deficits. 3 hours later she developed pulmonary edema. Hyponatremia of 117mEq/L, first noted 4 hours post surgery, baseline normal sodium. Course further complicated by agitation, vomiting, lethargy due to cerebral edema confirmed on C.T. Head 8 hours post-op, remained without brain stem reflexes. Post-op day 2 she also developed central diabetes insipidus. Remained brain dead, extubated and died after 12 days.

Discussion: Hyponatremia with glycine is iso-osmolar occurring as a result of dilution effect since glycine is retained in extra-cellular fluid before its metabolism by glycine cleavage enzyme. Two main postulations with the postulated explanation: 1) How does cerebral edema develop with iso-osmolar hyponatremia? 2) Why is hyponatremia often more severe than predicted? Proposed mechanisms: 1) Glycine can cross blood brain barrier (BBB) by passive diffusion, as shown in rats and cats. Sodium, however, does not exit brain via BBB as sodium transport across BBB occurs only inward. With glycotic toxicity, glycine accumulates in the brain cells after crossing BBB followed by water resulting in brain edema. Possibility of glycine metabolism to ammonia leading to cerebral edema cannot be ruled although high levels were not seen in our case.

TH-PO1050
Cytomegaloivirus-Induced Atypical Hemolytic Uremic Syndrome After Renal Transplant
Tinareen Kaar,1 Andrea G. Chiesa-votto,2 Leal C. Herlitzy,2 Richard A. Fatica.1 1Nephrology, Cleveland Clinic; 2Pathology, Cleveland Clinic, Cleveland, OH.

Introduction: Atypical hemolytic uremic syndrome (aHUS) may occur as de novo disease and recurrence of primary renal disease in kidney transplant recipients. Causes of de novo HUS includes immunosuppressive drugs, ischemia reperfusion injury, acute humoral rejection, and viral infections. Some patients have a genetic susceptibility to the disease from underlying mutations in the complement regulatory proteins. Cyto mengaloivirus (CMV) has been rarely reported as a trigger for de novo post-transplant aHUS.

Case Description: A 61 year old male underwent deceased donor kidney transplant for ESRD from presumed FSGS. 1 year following transplant he was admitted with profound diarrhea and weight loss due to CMV colitis and high grade CMV viremia (410,462 copies/ml). His immunity was reduced and he was discharged home on oral valganciclovir with near resolution of symptoms. He was re-admitted 1 week later with nausea, abdominal pain, and acute kidney injury (Creatinine of 3.8 mg/dL, baseline of 1.8 mg/dL). His repeat CMV viral load was significantly better at 70,000 copies/ml. Labs were suggestive of microangiopathic hemolytic anemia. Hb 8 g/dL, platelets 58 K/ul, LDH 586 U/L, haptoglobin <20mg/dL, and ADAMTS13 activity <67%. He received 4 sessions of plasmapheresis without improvement and required initiation of dialysis. Histologic features of acute and subacute endothelial injury, including segmental fibrin thrombosis of 2 arteries were present on transplant kidney biopsy. His aHUS genetic panel revealed several mutations in different genes. His CMV disease was identified. He was started on eculizumab. His hemolysis labs improved and he was taken off dialysis.

Discussion: CMV infection by way of endothelial injury can provoke aHUS in kidney transplant recipients and possibly be enhanced by genetic predispositions. Postulated mechanisms of CMV-induced injury include increased leakage and select perforation, endothelial expression of VWF, platelet adhesion, and intercellular adhesion molecule-1 and intracellular adhesion molecule-1. In our case, the aHUS process was halted by use of eculizumab.

TH-PO1051
Acute Interstitial Nephritis from Anti-PD-1 Therapy with Pembrolizumab in Two Patients with Advanced Non-Small Cell Lung Cancer
Heidi Mac G. Timbol, Anshuree C. Shirali, Internal Medicine, Section of Nephrology, Yale Univ School of Medicine, New Haven, CT.

Introduction: Immune checkpoint inhibition with monoclonal antibodies (mAb) targeted against programmed cell death receptor 1 (PD-1) is an emerging immunotherapy for various cancers. Pembrolizumab, an anti-PD-1 mAb, is being used in clinical trials with promising anti-tumor responses, but renal-specific adverse events are not clear. We report 2 cases of acute interstitial nephritis (AIN) in patients who received Pembrolizumab for advanced non-small cell lung cancer (NSCLC).

Case Description: Two female patients, both 69 years of age, with metastatic NSCLC were seen in outpatient nephrology clinic for acute kidney injury (AKI). Both patients were enrolled in a clinical trial with Pembrolizumab, and their cases had been complicated previously by auto-immune adenylasins. On labs, Patient A had an increase in creatinine to 2.1 mg/dL prior to cycle 16, up from a baseline of 0.9 mg/dL. Patient B had a creatinine peak of 1.9 mg/dL after cycle 6, up from a baseline of 1.1 mg/dL. Medications were significant for long-standing pantoprazole use in both patients. Urine sediment showed many WBC clumps without casts or RBCs. Renal ultrasound was unremarkable. Volume expansion with normal saline and cessation of potential nephrotoxins failed to reverse renal dysfunction in either case. Each patient underwent CT-guided renal biopsy, which showed diffuse AIN. Steroid therapy with prednisone 60 mg/day with a slow taper was started and creatinine improved to baseline.

Discussion: These two cases highlight a new association between AIN and Pembrolizumab, which to the best of our knowledge has not been previously reported. While both patients were on pantoprazole therapy prior to their AKI, this medication was not new. Rather, the time course of AKI best fits with initiation of pembrolizumab. Additionally, their pre-existing drug-related autoimmune adenylasins suggests a possible auto-immune component to AIN from anti-PD-1 therapy. With increasing use of these agents, clinicians should maintain a high index of suspicion for AIN as a cause of AKI and have a low threshold for kidney biopsy to confirm diagnosis and initiate early treatment.

TH-PO1052
Concurrent Anti-PLA2R and ADAMTS 13 Inhibitor – Coincidence or a Clue to Pathogenicity? Laith Al-Babadi,1 Moshe Shashar,2 Parikshit Duriseti,2 Ami Patel,2 Aala Jaberi,1 Ashish Upadhyay,1 Joel M. Henderson,1 Vipul C. Chitalia,1 David J. Salani,1 Laurence H. Beck,1 Boston Univ Medical Center; 2Mamata Medical College, India.

Introduction: Thrombotic thrombocytopenic purpura (TTP) is a hematologic emergency associated with a decrease in ADAMTS13 activity, most often due to the presence of an auto-antibody against ADAMTS13. However, patients with atypical hemolytic uremic syndrome (aHUS) have a low threshold for kidney biopsy to confirm diagnosis and initiate early treatment.

Case Description: Herein, we present a case of a 70 year old male who presented with generalized anasarca. Physical exam was remarkable for BP 180/100, and 2+ peripheral edema. Workup revealed Hgb 7.4, Pts 16, Creatinine 1.43, LD 742 and undetectable haptoglobin. His peripheral smear showed many schistocytes. These findings were consistent with thrombotic microangiopathy. Urine analysis showed 2+ blood, 3+ protein. Examination of the urinary sediment revealed oval fat bodies, and some RBCs. The patient was started on plasma exchange and prednisone (1 mg/kg). Further studies revealed a serum albumin of 2.2 and urine protein/Cr of 9. Kidney biopsy showed features of membranous nephropathy with many subepithelial deposits flanked by new basement membrane material (spikes). The deposits were immuno reactive for PLA2R, with IgG1 but no IgG4 reactivity. In addition, there was moderately severe arteriol and arteriolar sclerosis and segmentally prominent double contour formation in the glomeruli. These vascular changes suggest a primary form of endothelial injury and consistent with chronic thrombotic microangiopathy. VWF protease activity came back as less than 3% with an elevated inhibitor titer of 1.3 (spikes). Anti-PLA2R was detected in the serum at a titer of 40.3 IU/ml. Both were exclusively of the IgG1 subtype by western blotting, atypical of the usual IgG4 predominance for both autoimmune disorders.

Discussion: Although prednisone, plasmapheresis, and supportive therapy have thus far stabilized both diseases, rituximab would be our first choice for more definitive treatment of these concurrent autoimmune disorders. This unique case may help to further our understanding of the mechanistic pathways underlying both of these clinical entities.
Carfilzomib Associated Acute Kidney Injury Vladimir Liberman,1, Vivette D’Agati,2, Naveed N. Masani,1 Joseph Mattana, James Drakakis,1 Medicine, Winthrop-Univ Hospital, Mineola, NY, 2Pathology, Columbia Univ Medical Center, New York, NY.

Introduction: Carfilzomib is a selective proteasome inhibitor approved in 2012 for the treatment of relapsed and refractory multiple myeloma. A phase 2 trial of the drug showed an increased serum creatinine in 17.7% of patients but the mechanism has been incompletely understood. We report a case of biopsy proven acute tubular injury one week after carfilzomib administration. Case Description: A 60 year old man with IgG lambda multiple myeloma who received an autologous stem cell transplant 2 years ago presented to the hospital complaining of shortness of breath and chest discomfort. Physical examination revealed a blood pressure of 141/74, clear lungs, normal heart sounds with no murmurs and pitting edema of both lower extremities. Serum potassium was 0.6 mEq/L and creatinine was 3.4 mg/dL (baseline 0.8 mg/dL). Serum free lambda light chains were 3630 and free kappa light chains were 5.5. The patient was found in an injection of carfilzomib 7 days prior to his arrival. He had no history of nephrotoxic medications. Spot urine protein/creatinine ratio was 3 g/g with an albumin/creatinine ratio of 140 mg/g. Obstruction was excluded by ultrasonography and he received isotonic saline with only minimal improvement in kidney function at which point a kidney biopsy was performed. Renal biopsy showed focal mild myeloma cast nephropathy with diffuse acute tubular injury out of proportion to the sparse casts. The close temporal association with the initiation of carfilzomib suggests that it could have been responsible for the severe tubular injury given no other obvious insults. Discussion: Carfilzomib has been associated with kidney injury as one of its adverse effects in its phase 2 trial. Most of the kidney injuries were reported as grade 1 or 2 based on the NIH grading system. Grade 3 and 4 renal impairment was reported in 38 patients (7.2%). This case of biopsy proven acute tubular injury suggests a mechanism by which carfilzomib may cause acute kidney injury in patients with multiple myeloma.

Podocyte Infolding Glomerulopathy in a Patient of African Decent Matthew McCoy,1 Laurence H. Beck,2 and Stewart H. Lecker,3 Medicine, Beth Israel Deaconess Medical Center, Boston, MA.

Introduction: Podocyte infolding glomerulopathy (PIG) is a rare entity primarily described in Asians which is a form of membranous glomerulopathy (MG) from autoimmune diseases (i.e. lupus). It is not known whether PIG represents a new disease entity or a transient morphologic state of well-known diseases (i.e. a subset of membranous nephropathy or lupus nephritis). PIG has been exclusively described in Asian populations, with no cases reported in patients of African descent. PIG has been distinguished by its histologic features of podocyte membrane infolding into the basement membrane and the formation of microspikes and microtubules. The majority of cases do not contain electron-dense deposits, nor do they show any reactivity with IgG. Here we present the first reported case of PIG in a patient of African descent.

Case Description: A 58 year old Africa female from Ghana with history of systemic lupus erythematosus presented to the nephrology clinic for the evaluation of proteinuria. She was found to have a serum creatinine of 1.5 mg/dL and random urine protein to creatinine ratio of 1.5 g/g. Microscopic examination of the urine sediment did not reveal RBCs or casts. Other laboratory findings included a strongly positive anti nuclear antibody titers of 1:1280 and positive anti double stranded DNA. She underwent kidney biopsy. Light microscopy revealed thickened glomerular peripheral capillary walls, with numerous crater-like defects. Immunofluorescence was negative other than trace IgM and C3 reactivity along the basement membrane. Electron microscopy revealed thickened glomerular peripheral capillary walls, with numerous crater-like defects. The patient was referred for two years of stable, nephrotic-range proteinuria. Here we present the first reported case of PIG in a patient of African Decent.

Diabetes Insipidus Induced by Excessive Intake of Melatonin Rahul N. Pawar, Savneek S. Chugh, Amy R. Patel. Nephrology, Westchester Medical Center, Valhalla, NY.

Introduction: Melatonin is produced by the pineal gland and regulates the sleep/wake cycle in humans. Specific over the counter melatonin formulations can be used to treat circadian rhythm-related sleep disorders and age-related insomnia. Acute intoxication of melatonin and its deleterious effects have rarely been reported. We present the first case of diabetes insipidus due to excessive melatonin ingestion.

Case Description: A 24 year old female, with no known medical history, was brought to the hospital for altered mental status and possible drug overdose. Her vital signs were a Tmax of 101.8 F, HR 170, BP 150/103, and a pulse oximetry of 98% on 2L NC. On physical exam, she had mildly dilated and sluggishly pupils. Due to an altered sensorium, she was intubated for airway protection. Initial lab tests showed a sodium of 140 mEq/L, potassium 3.9 mEq/L, chloride 113 mEq/L, bicarbonate 25 mEq/L, BUN 8 mg/dL, and a creatinine of 0.6 mg/dL with no osmolar gap, but elevated AST 74 U/L, ALT 37 U/L and creatine phosphokinase of 2,460. Urine toxicology screen was negative for PCl, cocaine, MDMA, and opioids with an undetectable blood alcohol level. On day 1, she developed polyuria with a urine output of more than 13.5 liters, a serum sodium of 147 mmol/L and urine osmolality of 65 mosm/kg concerning for diabetes insipidus (DI). CT head and MRI of the brain were negative for intracranial lesions. Despite decreasing the rate of intravenous fluids, her urine output was more than 6L/day. Her urine osmolality increased to 444 mosm/kg suggestive of a partial central DI. With the administration of DDAVP, her urine output decreased to 2-3L/day. After tubulostomy, the patient reported ingestion of an excessive amount of melatonin for intracranial lesions. Despite decreasing the rate of intravenous fluids, her urine output was more than 6L/day. Her urine osmolality increased to 444 mosm/kg suggestive of a partial central DI. With the administration of DDAVP, her urine output decreased to 2-3L/day. After tubulostomy, the patient reported ingestion of an excessive amount of melatonin for intracranial lesions. Despite decreasing the rate of intravenous fluids, her urine output was more than 6L/day. Her urine osmolality increased to 444 mosm/kg suggestive of a partial central DI. With the administration of DDAVP, her urine output decreased to 2-3L/day. After tubulostomy, the patient reported ingestion of an excessive amount of melatonin for intracranial lesions. Despite decreasing the rate of intravenous fluids, her urine output was more than 6L/day. Her urine osmolality increased to 444 mosm/kg suggestive of a partial central DI. With the administration of DDAVP, her urine output decreased to 2-3L/day. After tubulostomy, the patient reported ingestion of an excessive amount of melatonin for intracranial lesions. Despite decreasing the rate of intravenous fluids, her urine output was more than 6L/day. Her urine osmolality increased to 444 mosm/kg suggestive of a partial central DI. With the administration of DDAVP, her urine output decreased to 2-3L/day. After tubulostomy, the patient reported ingestion of an excessive amount of melatonin for intracranial lesions. Despite decreasing the rate of intravenous fluids, her urine output was more than 6L/day. Her urine osmolality increased to 444 mosm/kg suggestive of a partial central DI. With the administration of DDAVP, her urine output decreased to 2-3L/day. After tubulostomy, the patient reported ingestion of an excessive amount of melatonin for intracranial lesions. Despite decreasing the rate of intravenous fluids, her urine output was more than 6L/day. Her urine osmolality increased to 444 mosm/kg suggestive of a partial central DI. Renal Transplant Dysfunction due to Calcium Casts following Parathyroidectomy. Maharanjan Raman, Rajkumar Chinnadurai, Grahame N. Wood, Jamil Choudhury, Philip A. Kalra. 1. Renal Medicine, Salford Royal NHS Foundation Trust, Salford, Manchester, United Kingdom; 2. Cellular Pathology, Salford Royal NHS Foundation Trust, Salford, Manchester, United Kingdom.

Introduction: Parathyroidectomy for renal hyperparathyroidism can lead to significant drop in calcium levels due to the hungry bone syndrome, which can lead to seizures, coma or fractures. Current practice is to pre-load patients with hydroxychloroquine and calcium supplements to maintain safe calcium levels in the post-operative period. We report a case of calcium cast nephropathy caused by significant renal dysfunction following parathyroidectomy.

Case Description: A transplant patient on Cincalacet for tertiary hyperparathyroidism underwent parathyroidectomy (PTX). Post-operatively her calcium levels were managed according to local protocol. Patient sub-acutely developed renal dysfunction and the trends in creatinine(Cr), corrected calcium(Ca) and parathyroid hormone levels(PTH) pre and post surgery are shown in the table below.

Virology screen, immunology screen, urine culture, urine PCR, DSA, Cyclosporin levels and renal ultrasound were normal with no change in patients haemodynamic status. Hence a kidney biopsy was performed to identify the cause, which showed evidence of calcium casts with surrounding inflammation with no evidence of rejection. Her steroid dose was transiently increased due to the inflammation seen on the biopsy and all her calcium and hydroxychloroquine supplements were suspended, which lead to recovery of her renal function to baseline.

Discussion: Our patient had mild hypercalcemia prior to parathyroidectomy with a stable renal function and following parathyroidectomy patient developed renal dysfunction despite similar levels of calcium, which can only be explained by intrageneric calcium supplementation based on the renal biopsy. Perhaps routine monitoring of urinary calcium may help us guide the amount of calcium given to such patients and aiming for lower levels of calcium post parathyroidectomy rather than normal levels may prevent such phenomenon.

TH-PO1059

Severe Ketoacidosis After Bariatric Surgery in a Patient Treated with Canagliflozin. Hossein Ghoftan, Christopher C. Wong, Miroslaw Smogorzewski. Div of Nephrology, Keck Hospital of USC, Los Angeles, CA.

Introduction: Euglycemic diabetic ketoacidosis is relatively uncommon and is usually caused by starvation and a lack of caloric intake. Sodium-glucose cotransporter-2 (SGLT-2) inhibitors have been very recently implicated as a cause of severe ketoacidosis. We report a case of euglycemic diabetic ketoacidosis in a patient who underwent bariatric surgery while taking an SGLT2 inhibitor, canagliflozin.

Case Description: A 38 year old male with a history of DM type 2 and morbid obesity presented with fatigue, acute dyspnea, decreased exercise capacity and 2-3 pillow orthopnea for two days. Canagliflozin 300 mg daily was initiated 3 months prior to his current presentation due to poorly controlled DM-2. Ten days prior to his hospitalization, he underwent gastric sleeve bypass surgery and was discharged on post-op day 1. Upon admission in the ICU, his physical exam was benign except for a PR 108/min, RR 29/min, and a normal BP 128/69 mmHg. ABG showed pH 6.9, pCO2 13mmHg, pO2 99mmHg, bicarbonate 5mg/dL. His anion gap was 37, and serum glucose 152 mg/dL, with normal kidney function. Urine toxicology and blood levels of lactic acid and creatinine were normal and urine ketones were negative. Urinalysis revealed pH 5.0, glucose >1000 mg/dL, and ketones>150 mg/dL. During the first day, he received 150 mg of sodium bicarbonate; his canagliflozin was held. He was intubated and started on a regular insulin drip along with 5% dextrose solution. He remained intubated for 5 days on an insulin drip. The past 2 days, he received pamidronate and extensive electrolyte replacement; blood glucose never exceeded 200 mg/dL while glycosuria persisted until day 7. C-peptide increased from 0.29 to 2.26 mg/L. Once anion gap was closed and patient stabilized, he was extubated and weaned off the insulin drip.

Discussion: We present a new case of severe euglycemic DM ketoacidosis caused by a combination of SGLT-2 inhibitor use and low caloric intake after bariatric surgery. Despite withdrawal of canagliflozin, its effect on glycosuria persisted for 7 days. Considering long biological effect of SGLT-2 inhibitors, they should be stopped weeks before a bariatric surgery to avoid ketoacidosis.

TH-PO1060

Severe Hypercalcemia in Erdheim-Chester Disease: A Rare Clinical Scenario. David H. Slade, 1, Esho Georges, 2 Ahmer Farooq, 2 Kavitha Vellanki. 1Dept of Medicine, Loyola Univ Medical Center, Maywood, IL; 2Dept of Nephrology, Loyola Univ Medical Center, Maywood, IL; 3Dept of Urology, Loyola Univ Medical Center, Maywood, IL.

Introduction: Erdheim-Chester disease (ECD) is a rare form of histiocytosis with highly variable clinical manifestations. Only a few cases have hypocalcemia, and even fewer have hypercalcemia. Here, we present a case of severe hypercalcemia, workup of which eventually led to the diagnosis of ECD.

Case Description: A 58 year old Polish male with chronic kidney disease due to obstructive urethral obstruction was transferred to our center for suspected pneumophlebitis. His course was complicated by persistent fevers with repeatedly negative infectious workup and severe hypercalcemia with ionized calcium levels peaking at 1.66 mm/L. Parathyroid hormone levels were appropriately suppressed. Work up for multiple myeloma showed no lytic lesions on bone scan, however, bilateral, symmetric, sclerotic lesions in the distal femurs and proximal tibiae were incidentally noted. Based on these findings, ECD was suspected. ECD was confirmed by biopsy which revealed multiple histiocytic and lymphomycic aggregates positive for the histiocyte marker CD68, but negative for CD1a (pathognomonic of the disease). He was subsequently started on BRAF (>raf murine sarcoma viral oncogene homolog B1) inhibitor, vemurafenib with marked improvement in clinical symptoms. While he received pamidronate for hypercalcemia during the hospital stay, his ionized calcium levels have since normalized and continue to be within normal range 6 months after the initial presentation.

Discussion: In conclusion, ECD is a rare disorder with varied clinical manifestations and diagnosis is often elusive, requiring a high level of clinical suspicion. Although skeletal involvement is seen in 96% of the patients with ECD, there have been no reported cases of hypercalcemia, and our case is the first to report such an association.

TH-PO1061

APOL1 Polymorphisms in Deceased Donors and Primary Glomerular Disease Post-Kidney Transplant: First Case Report. Pratik B. Shah, Alexander C. Wiseman, James E. Cooper. Renal Diseases and Hypertension, Univ of Colorado Medical Center, Aurora, CO.

Introduction: Genetic polymorphisms in APOL1 (G1/G2) are associated with glomerular disease and ESRD. An emerging issue is whether screening for APOL1 (G1/G2) should be performed in living or deceased kidney donors.

Case Description: A 46 year-old Caucasian male with a history of SLE received a deceased donor kidney transplant. The deceased donor was a 12-year old African American male. 9 months post-transplant, he presented with acute kidney injury following an elective acute CMV infection. The patient ultimately did not recover kidney function. The patient’s serum creatinine peaked at 2 g/g Cr, platelet count of 58000, LDH of 2022 U/L, haptoglobin of <14 mg/dl. Plasma CMV PCR was positive at 234000 copies/ml. The patient’s acute kidney injury was attributed to collapsing glomerulopathy induced by acute CMV infection. The patient ultimately did not recover kidney function.

Discussion: To our knowledge, this is the first case report of high risk variant APOL1 in a deceased donor with subsequent primary glomerular disease in both the recipients. This suggests that deceased kidney donor APOL1 genotyping may be informative in predicting graft outcomes. This also highlights the important question of whether routine screening of African American donors for high risk APOL1 variants before renal transplant is warranted.

This consideration must be balanced against the significant limitations in kidney availability.

Atypical HUS in an Infant due to a Novel Gene Mutation

Mohamed Alsefri, Robin Amy Kremsdorf, M. Khurram Faizan. 1 Rhode Island Hospital; 2 Hasbro Children’s Hospital; 3Hasbro Children’s Hospital.

Introduction: Atypical HUS (aHUS) is a rare genetic renal disease associated with over-activation of the alternative pathway of complement. A variety of mutations have been described in the complement pathway genes in patients with aHUS. We report a case of aHUS due to mutation in the Complement Factor B (CFB) gene.

Case Description: 10 months old Caucasian girl who presented with diarrhea, vomiting, and swelling in her extremities and face for 2 weeks preceded by an episode of cough, runny nose with non-bloody diarrhea. Upon presentation her BP was 150/90 mm Hg. Lab data showed Hb 6.4 g/dL, hematocrit 23%, leukocytosis to 100.4 x 10^9/L, anemia of chronic disease, serum creatinine, 0.3, Albumin 2.6 g/dL, LDH 632 IU/L, normal ADAMTS13 and C3 level 7.9 mg/dL. Urine revealed 32RBC/hpf with proteinuria, Urine Protein Creatinine ratio 19 g/g. Peripheral blood smear revealed schistocytes. Stool was negative for Shiga toxin. Clinical presentation was compatible with aHUS and patient was treated with Eculizumab. There was marked improvement in her clinical status with resolution of his symptoms.

Discussion: RRT was stopped after two weeks and she was discharged on ACEI with Eculizumab every 2 weeks.

TH-PO1063
Oxymorphone-Induced Thrombotic Microangiopathy and Acute Kidney Injury

Introduction: Intravenous (IV) administration of oral oxymorphone represents an emerging pattern of drug abuse with increasing popularity and unforeseen adverse consequences. Here, we present a case of IV oxymorphone abuse associated with thrombotic microangiopathy (TMA) and acute kidney injury (AKI).

Case Description: A 32-year-old man with a history of IV drug abuse presented with non-healing left arm wound. Physical examination was unremarkable except for a left forearm abscess. However, laboratory studies revealed a serum creatinine (SCr) of 2.3 mg/dL, blood urea nitrogen (BUN) of 55 mg/dL, creatinine 2.5 mg/dL, glucose 91 mg/dL, calcium 9.7 mg/dl,serum Osm 375 mOsm/kg, urine Osm 678 mOsm/kg, ADH level was 2.2 pg/ml(nl). Urinalysis: specific gravity 1.016, pH 5.5, 1+ protein, trace blood. A renal biopsy showed acute and chronic thrombotic microangiopathic changes consistent with aHUS. ADAMTS13 level was >100%. Kidney biopsy showed evidence of TMA supported by glomeruli filled with focal extravasated and crenated RBCs. Immunofluorescence (IF) was negative for immune complex deposition but C4d staining was positive. Conservative management including platelet transfusion, without plasma exchanges was successful.

Discussion: This patient presented with TMA, acute kidney injury, and normal serum ADAMTS13 activity. His urine oxymorphone was positive and he admitted to IV abuse of pulverized oxymorphone pills, which represents an emerging pattern of illicit drug abuse. The mechanism of oxymorphone-induced TMA remains unclear but it is suggested that the drug or some ingredients mixed in it triggers a cascade of immunological pathways leading to TMA. Previously reported cases had negative IF on kidney biopsy but positive C4d staining in this patient implies some degree of complement activation. Although PE was initially used in some cases, it has recently been shown that oxymorphone-induced TMA could successfully be managed without it. Based on this case coupled with previous reports, we suggest that health care providers should inquire about IV oxymorphone abuse in the setting of unexplained TMA and acute kidney injury.

TH-PO1064
IgG4-Related Tubulointerstitial Nephritis in a Young Patient with Enlarged Kidneys

Valerie Jorge Cabrera, Shirin Shirani, Joni H. Hansson. 1 Yale Nephrology, Yale School of Medicine, New Haven, CT; 2Nephrology, Yale New Haven Hospital/ST. Raphael Campus, New Haven, CT; 3Nephrology, Yale New Haven Hospital/ST. Raphael Campus, New Haven, CT.

Introduction: IgG4-related disease is a recently recognized entity characterized by the infiltration of tissues with IgG4-positive plasma cells. It occurs more commonly in middle-aged adults with a male predominance. IgG4-related diseases can be classified into two groups; those that can mimic tumors. We present the unique case of a young patient with a two year history of recurrent cellulitis, parotid gland enlargement, diffuse lymphadenopathy and nephrectomy.

Case Description: A 27 year old African American male presented with a rash and edema of his right lower extremity. He also reported night sweats and weight loss over 4 months. His past medical history included hypertension, recurrent cellulitis, nephrolithiasis, chronic kidney disease of unclear etiology, antithrombin III deficiency and pulmonary embolism. Hypothyroidism has shown thyrotropin, hypergonadotropic amenorrhea.

Discussion: A number of conditions can lead to kidney enlargement. Diabetes, HIV, amyloidosis, and leukaemia lymphoma are commonly included in the differential diagnosis. IgG4-related disease should also be considered in the differential diagnosis of patients presenting with kidney enlargement and recurrent infections.

TH-PO1065
Karyomegalic Interstitial Nephritis: A Rare Cause of Kidney Disease

Lindsay Sanders, 1 Maxwell L. Smith, 2 Ibrahim Qaqish, 1 Sumi Sukumar

1Nephrology and Hypertension, Mayo Clinic Arizona, Phoenix, AZ; 2Pathology, Mayo Clinic Arizona, Scottsdale, AZ.

Introduction: Karyomegalic interstitial nephritis (KIN) is a rare, progressive kidney disease associated with Fancconi–associated nüclease 1 (FAN1) mutation as well as exposure to heavy metal, ochratoxin, or viral pathogens. Less than 50 cases have been reported to date. Our patient is one of the few cases with a KIN and FAN1 mutation report.

Case Description: A 45-year-old man was seen for renal impairment first noted at age 40, with a serum creatinine of 1.6 mg/dL (eGFR 53 mL/min/1.73 m²). He had no known risk factors for chronic kidney disease. His only other personal medical history was for skin rashes but he had no history of heavy metal exposure. He had a history of recurrent upper respiratory tract infections. There is no known treatment.

Discussion: The diagnosis of KIN should be considered especially when there is evidence of delayed tubular function in addition to impaired thirst perception.

TH-PO1066
Hypodipsic Hypernatremia: An Unusual Manifestation of Paraneoplastic Syndrome

Sahar Siddiqui, Sun-Young Ahn, Asha Moudgil. Nephrology, Children’s National Medical Center, Washington, DC.

Introduction: Hypernatremia usually results from increased free water losses or impaired thirst perception.

Case Description: A 17-year-old female presented to the emergency room after an episode of syncope while waiting for school bus on a summer morning. She had intermittent episodes of slurred speech over the previous 2 weeks but denied polyuria, polydipsia, dizziness or headaches. She was diagnosed with primary amenorrhea one year ago. Physical Exam: Weight 46 kg (5%ile), height 150 cm (<3%ile), BP 92/58 mmHg and afebrile. She was Tanner III for breast & I for pubic hair. The remainder of her exam was normal. Laboratory evaluation showed hemoglobin 11.2g/dL, hematocrit 37.8%, platelet 100x10^9/L, sodium 177 mmol/l, potassium 4.3 mmol/l, creatinine 1.0 mg/dl, CO 2,32 mmol/l, BUN 55 mg/dl, creatinine 2.5mg/dl, glucose 91 mg/dL, calcium 9.7 mg/dl,serum Osm 375 mOsm/kg, urine Osm 678 mOsm/kg, ADH level was 2.2 pg/ml(nl). Urinalysis: specific gravity 1.016, pH 5.5, 1+ protein, trace blood. A renal ultrasound showed a right suprarenal mass which was confirmed to be an adrenal mass on CT scan. Despite adequate intravenous hydration, her hypernatremia persisted. Due to low LHR & FSH there was a concern for hypogonadotropic hypogonadism. However, brain MRI was normal. DDAVP was initiated with partial response. The patient underwent a right adrenalectomy. pathology was consistent with ganglioneuroma.

Discussion: The cause of hypernatremia in this case was likely an impaired thirst mechanism in a cognitively normal child. Her partial response to DDAVP suggests an additional contribution from partial diabetes insipidus. Essential hypernatremia and an unpredictable syndrome using sodium level sensors (Na+) were reported in a 6 year old child by Hyama et al. (2010; 66(4): 508-522). The mechanism of hypernatremia was postulated to be impaired thirst due to antibodies to Nax in the brain. A diagnosis of paraneoplastic syndrome should be considered in a patient with hypodipsic hypernatremia without structural hypothalamic lesions.
IgG4 Mediated Isolated Reteroperitoneal Fibrosis Causing Obstructive Uropathy in a Patient with Subclinical Ankylosing Spondylitis

Ahn M. Morgan, Vikram Aggarwal. Internal Medicine/ Nephrology Div, SUNY Upstate Medical Univ, Syracuse, NY.

Introduction: Retroperitoneal fibrosis is a rare manifestation of systemic autoimmune disease, characterized by the presence of inflammatory and fibrotic retroperitoneal tissue that often encases the ureters causing obstructive uropathy. Idiopathic retroperitoneal fibrosis is currently being recognized manifestation of IgG4-related disease. We report a case of histologically confirmed IgG4 related retroperitoneal fibrosis in a patient with subclinical Ankylosing spondylitis. This association has been rarely reported.

Case Description: A 70 year old male with PMH of HTN, diabetes and baseline creatinine of 1.2 mg/dl presented with weakness, vomiting and decreased urine output. Physical examination was unremarkable. Further evaluation revealed serum creatinine of 13.3 mg/dl and BUN=106 mg/dl. He also has mild hyperkalemia and anion gap metabolic acidosis. Urine analysis was negative for protein or RBC cast. A CT scan of the abdomen and pelvis, showed retroperitoneal mass, Aortitis, ankylosis of SI joint bilaterally with osseous fusion and bilateral mild hydronephrosis. Bilateral nephrostomy tubes were placed with excellent urine output as well as improvement of creatinine in baseline in 48 hours. He subsequently had a CT guided biopsy of the retroperitoneal mass. Histopathology revealed dense fibrous tissue with significant IgG4 positive plasma cell infiltrate. Immunological workup showed elevated level of IgG4 as well as positive HLA-B27. Hence this obstructive uropathy was confirmed to be due to IgG4 related retroperitoneal fibrosis. He also met the clinical and imaging criteria for Ankylosing spondylitis. Treatment with oral corticosteroids was initiated by rheumatology.

Discussion: Our hypothesis is that the patient had a subclinical Ankylosing Spondylitis which triggered IgG4 mediated disease that lead to retroperitoneal fibrosis which caused bilateral obstructive uropathy. Hence role of ankylosing spondylitis in development of idiopathic retroperitoneal fibrosis may be under appreciated. Further studies are needed to investigate and meta this criteria to be aware of this rather unusual presentation.

IgG4-Related Tubulo-Interstitial Nephritis with Low Complement C4, Circulating Immune Complexes and an Elevated IgG, Presenting as Unilateral Hydronephrosis and Prostatitis

Cornelius J. Doorenbos, Annemarie A. Van norel, Christiana F.M. Kloek, Peter Van den Tillaar. Nephrology, Deventer Hospital, Deventer, Netherlands; Radiology, Deventer Hospital, Deventer, Netherlands; Pathology, Deventer Hospital, Deventer, Netherlands; Urology, Deventer Hospital, Deventer, Netherlands.

Introduction: IgG4-Related Disease is characterized by infiltrates of IgG4-positive plasma cells and eosinophils in different organs and is a rare cause of tubulointerstitial nephritis (TIN) and idiopathic retroperitoneal fibrosis.

Case Description: A 67 year old white male had a creatinine increase from 0.90 to 2.06 mg/dl. He had fatigue and dyspepsia. Complement C3 was normal, C4 low 0.06 g/l, C1Q-BA 28% (N<8%), but ANA/ENA, DDNS, AST, ANCA, HBV, HCV and M-protein were negative. IgG4 3.0 g/l (N 0.08-1.40 g/l) Urine showed 3 RBC/HPF, protein 0.36 g, albumin 61 mg per 24h. On ultrasound both kidneys were 13 cm with right sided hydronephrosis and 300 ml urinary retention. CT-Urography showed obstruction of the right ureter at the iliac artery. A bladder catheter and ureteral stent did not improve renal function. A MAG-3I-I inferior vena cava showed a non-functioning right kidney without hydronephrosis. On autopsy, the CT showed soft tissue surrounding the aorta and the right iliac artery. A kidney biopsy showed TIN with a dense infiltrate of IgG4-positive plasma cells and eosinophils with impressive fibrosis, a vein showed obliterator phlebitis, consistent with IgG4-related TIN. TIN was treated with prednisone 40 mg daily and after 1 week he reported a dramatic clinical improvement, his creatinine decreased to 1.7 mg/dl.

Discussion: Hydronephrosis first dominated the clinical picture, delaying diagnosis, but the low C4, positive C1Q-BA and large kidneys suggested IgG4-related TIN. We found only one report of IgG4-related TIN with hydronephrosis, but that was after uraemic tract tuberculosis. Rare cases were reported of IgG4-related segmental ureteritis or prostatitis without TIN and the cases of IgG4-related TIN had no hydrenephrosis. The present case is the first with coincident biopsy-proven IgG4-related TIN, ureteral obstruction and prostatitis. Hydronephrosis does not exclude, but may be part of IgG4-related disease.

Monocolonal Light Chain Proximal Tubulopathy with Unique Ultrastructural Microtubular Inclusions

Introduction: Renal disease related to monocolonal gammopathies is common and varied. An uncommon lesion is proximal light chain tubulopathy (PLCT), which may present with Fanconi chain syndrome (FS) and variable degrees of renal failure. Most have ultrasonographic (US) findings of proximal tubule damage with crystalline inclusions of k LC’s within proximal tubular cells (PTC). A minority of PLCT do not have crystals; these may have LC restrictions. We describe a patient with a rare finding: PLCT with light chain (LC)-related microtubular inclusions.
Discussion: This is the second reported case of necrotizing and crescentic glomerulonephritis associated with IgG1-κ anti-GBM antibody. It is unknown if this disease is driven by an underlying autoimmune process or monochlonal gammopathy. Both cases are atypical for classic anti-GBM disease due to their relapsing nature.

TH-PO1072
First Reported Case of Collagenofibrotic Glomerulopathy in a Patient with Multiple Myeloma
Arum Rajasekaran,1 Indraneel Mogarla,2 Lilian W. Gaber,3 Jai Radhakrishnan,4 Alu Abaduyaeh 5
1Internal Medicine, UCF College of Medicine, FL; 2Div of Renal Diseases & Hypertension, UF Health College of Medicine; 3Division of Nephrology, Columbia Univ Medical Center, New York; 4Section of Nephrology, The Univ of Texas MD Anderson Cancer Center, Houston.

Introduction: Collagenofibrotic glomerulopathy is an extremely rare idiopathic glomerular disease characterized by abnormal accumulation of atypical spiralized and frayed type III collagen fibrils in mesangial and subendothelial areas, and elevated serum procollagen III and hyaluronan levels. Proteinuria (commonest feature), edema, hypertension, and occasional progression to ESRD are commonly seen. We report the first published case of Collagenofibrotic glomerulopathy in Multiple Myeloma.

Case Description: A 54 year old male with recent history of IgG kappa Multiple Myeloma (May 2011); with underlying CKD stage 3 and baseline Creatinine at 2 mg/dl, in remission status-post autologous stem cell transplant (January 2012) and on Lenalidomide maintenance therapy, presented with proteinuria of 4g. Kidney biopsy revealed Nodular and Focal glomerulosclerosis with IF weakly (+) for IgG, IgA, IgM, C3, C4, c1q, Kappa and Lambda light chains with +3 staining for IgM and c1q. EM showed patchy foot process effacement with massive deposition of collagen-III fibers. The weak and non-specific staining, along with massive collagen-III fiber deposition fitted with the description of Collagenofibrotic glomerulopathy, and made an immune mediated kidney injury less likely.

Discussion: Discussion: Collagenofibrotic glomerulopathy is an extremely rare disease characterized by massive intraglomerular atypical type III collagen fiber deposition. Proteinuria is the cardinal manifestation of this disease. Clinically, patients present with edema, hypertension and often progress to ESRD. Etiology and pathogenesis remains elusive. Most cases are seen in Japan and an autosomal-recessive mode of inheritance has been described. Definitive diagnosis is established by identifying collagen-III fibrils by IF and EM with special staining. No specific treatment is available unfortunately.

TH-PO1073
Severe Acute Kidney Injury (AKI) with Organomegaly in a 17 Days Old Newborn: When Pathology Makes the Difference
Marie-Michèle Gaudreault-Tremblay, Catherine Litilian, Natalie Patye, Aicha Merouani, CHU Sainte-Judeline, Montreal, QC, Canada.

Introduction: Acute tubulointerstitial nephritis (ATIN) is a significant cause of AKI in children and is often due to allergic drug reactions or infections. Diagnosis of ATIN is usually clinical and renal biopsy not routinely performed.

Case Description: A previously healthy 17 days old baby presented with decreased oral intake, vomiting and oligoanuria. His first laboratory results showed an elevated creatinine (1.7mg/dL) with metabolic acidosis, hypernatremia (Na 160mmHg), hyperkalemia (K 8.8 mEq/L) and thrombocytopenia (platelets 16x10^9/L). His urine analysis was abnormal (proteins 3gr/L, WBC 50000/hpf, RBC 20000/hpf, red blood casts). An ultrasound revealed bilateral hydronephrosis. Renal biopsy findings were consistent with severe ATIN. The most likely etiology for ATIN was drug reaction. The initial potential drug reaction was penicillin, which was stopped and the baby was put on ceftriaxone. The baby improved and was discharged home for a Foley catheter associated Escherichia coli urinary tract infection & E. coli confirmed on urine culture.

Discussion: This interesting case showed AL lambda amyloidosis in kidney transplant allograft as a cause of Massive Nephritie Syndrome with AKI that responded to chemotherapy. 51 year old African American female with history of ESRD secondary to APOD s/p DDKT in Oct 2010 with Thymoglobulin induction, maintained on 3 drug immunosuppression including tacrolimus, mycophenolate and prednison with baseline creatinine of 1.5, presented with anasarca and orthostatic hypotension. Her serum albumin was 1.2mg/dL. She underwent extensive investigations including Echo, transplant allograft ultrasound all of which came back unremarkable. She has sudden onset sub nephritic range proteinuria in Aug 2013 which progressed to nephritic range in Feb 2014. She has 34g of protein on a 24h urine collection 90% of which was albumin. Her UPCR gradually got worse from 10 to 32 with worsening in serum Cr from 1.5 to 5.5. She has poor response to IV Lasix with albumin infusion and has severe orthostatic symptoms. Her SPEP and UPAP were negative. Urine IFE showed lambda light chain. Serum free light chain showed elevated lambda levels. Due to worsening and explosive proteinuria with worsening anasarca renal allograft biopsy was done that showed lambda AL amyloidosis involving glomeruli, arterioles and arteries along with light chain proximal tubulopathy. Congophilic casts consistent with light chain cast nephropathy. Pt underwent bone marrow biopsy that did not show MM. She was treated with bortezomib combined with cyclophosphamide and dexamethasone and has good response with improvement in orthostatic hypotension, serum albumin level and lambda light chain got normal.

Pauci-Immunoglobulin Glomerulonephritis and Escherichia Coli Bacteremia: A Rare Coincidence or a True Causal Association?
345A

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

Discussion: ATIN is rare in neonates and usually drug-induced. This is the first report of a renal biopsy-proven ATIN in a neonate. Even if procedural risks of a renal biopsy are not negligible, it can make the difference in certain cases by dictating appropriate management.
She promptly responded to standard treatment of septic shock and her serum Cr improved to 1.6 mg/dL on discharge. Ten days later, she was readmitted to the hospital after a follow up visit to her primary physician where a routine blood work showed her serum Cr to be elevated to 6.8 mg/dL. Urine sediment revealed several RBCs and few granular casts. Anti-myeloperoxidase antibody was positive with a titer of 1:640. Other serological tests were negative. Her renal function declined further and she was initiated on hemodialysis. A renal biopsy was consistent with pauci-immune necrotizing and crescentic GN. She was treated with steroids, intravenous cyclophosphamide and plasmapheresis following which she came off dialysis & her serum Cr stabilized around 1.8 mg/dL. ANCA was checked and was positive for anti-MPO antibodies. Renal biopsy showed membranoproliferative glomerulonephritis with deposition of IgG kappa light chain cryoglobulins as well as immune complexes and/or paraproteins. Review of the literature reveals a small number of cases of PGNMID associated with CLL and cryoglobulinemia. The pathophysiology of GN in CLL is possibly due to glomerular deposition of immune complexes and/or paraproteins. Review of the literature reveals a small number of cases of PGNMID associated with CLL and cryoglobulinemia. We report a case of ANCA necrotizing vasculitis in a patient with CLL and cutaneous, renal and cerebral involvement due to monoclonal cryoglobulinemia. Despite leukemia treatment and regular hematocrit monitoring her clinical condition deteriorated and patient expired.

TH-PO1077
Cryoglobulinemic Vasculitis and Glomerulopathy Associated with Chronic Lymphocytic Leukemia
Narottam Regmi, Albert Braverman, Swaty Arora, Raavi Gupta, Subodh J. Saggi. Nephrology, SUNY Downstate Medical Center; Brooklyn, NY.

Introduction: Cryoglobulinemia manifests as ischemic or occlusive vasculopathy with or without renal involvement. Early stage Chronic lymphocytic leukemia (CLL) has not been reported with vasculitic lesions as its first manifestation. We report a rare case of Stage I CLL with cutaneous, renal and cerebral lesions due to monoclonal Type I cryoglobulinemia.

Case Description: A 60-year-old woman presented with abdominal pain due to retroperitoneal hematoma from a ruptured right gonadal artery, which was embolized. Labs included eucocytosis, anemia with mild azotemia. Flow cytometry was consistent with CLL. The patient was readmitted with a serum creatinine of 11.2 mg/dL and proteinuria and required hemodialysis. There were extensive lesions on her lower extremities and a necrotic left forearm ulcer. Renal biopsy revealed membranoproliferative glomerulonephritis with deposition of IgG kappa light chain cryoglobulins as well as intraluminal hyaline deposits (Figure 1), infiltrates consistent with CLL and thrombi in intrarenal arteries. Biopsy was complicated by hematoma leading to left nephrectomy. Plasmapheresis was initiated for cerebral infarcts related to cryoglobulinemia. Despite leukemia treatment and regular hemodialysis her clinical condition deteriorated and patient expired.

TH-PO1080
PGNMID in a Patient with Hepatitis C
Mohamed Alseiari, Susie L. Hu. Alpert Medical School of Brown Univ.

Introduction: Proliferative glomerulonephritis with monoclonal IgG deposits (PGNMID) is infrequently associated with hematological disease but more commonly presents like an immune-complex glomerulonephritis. Few have reported cases associated viral infections such as hepatitis C. We report a case of PGNMID in a patient with active HCV infection.

Case Description: A 56 year-old male with refractory hepatitis C (post treatment with interferon and Ribavirin), HTN and coronary artery disease presented with rising creatinine (peak 5.3 mg/dL) from baseline (0.9 mg/dL a year ago) and no kidney disease in family. He reported months of progressive fatigue, dyspnea on exertion, nausea, vomiting, and dark urine. He endorsed chronic Hepatoren use for leg pain. On examination BP was normal with clear lungs and no edema. Urinalysis revealed blood but minimal proteinuria with urine protein to creatinine ratio of 0.5 g/g and albumin 4.2 g/dL. Complements were low (C3 83 mg/dL, CH50 <10 U/mL). HCV-RNA quantification was 1.7 million copies. SPEP, plasma light-chains, ANA, ANCA, Anti GBM, HIV, Hep B serologies were normal. Bone survey was negative. Renal biopsy revealed diffuse linear staining of glomerular basement with monoclonal IgG/kappa immunoglobulin and endocapillary focal glomerulonephritis, chronic interstitial nephritis with ATN. Renal function did not improve until Prednisone was initiated, down to 3.3 mg/dL. Cyclophosphamide was started after discussion with his gastroenterologist. Antiviral therapy has been delayed until further improvement of renal function.

Discussion: We report a case of PGNMID associated with HCV. There are 2 other reports of HCV associated PGNMID however with membranous glomerulonephritis pathology. 30% of PGNMID patients have some heavy- and light-chain isoforms as the glomerular deposits. Membranoproliferative (57%) or endocapillary proliferative (35%) are the most two common histological variants. Nas et al in a series of 32 patients reported after an average of 30.3 months of follow-up, 38% had complete or partial recovery, 38% had persistent renal dysfunction, and 22% progressed to ESRD. Viral infection such as HCV associated immune disorders could be implicated in the pathogenesis. Currently, there is no consensus regarding the management of this entity.

TH-PO1079
Myeloma Cast Nephropathy with Acute Renal Failure, Skin Rash, Eosinophilia, and Low Complement C4 Level
Mustafa G. Aly,1 Mamoun Elhir Bashir,2 Irfan Warraich,3 Aumyot Prongdong,1 Weeaporn Sirisang,1 Internal Medicine, Nephrology Dept, Texas Tech Univ Health Science Center, Lubbock, TX; 2Pathology Dept, Texas Tech Univ Health Science Center, Lubbock, TX.

Introduction: We here report myeloma cast nephropathy with skin rash, eosinophilia and low complements which is a very atypical presentation of this renal condition.

Case Description: A 53y Caucasian female was admitted with 3 day confluent erythematous skin rash, acute renal failure with sCr 17.6 mg/dL. Five days prior, she was prescribed cephalexin for root canal infection. Initial diagnosis of acute interstitial nephritis was made but patient didn’t respond after stopping antibiotics and steroid course trial. urine exam showed WBC clumps and no casts. Serological biomarkers were done and reported Negative ANA, ANCA, cryoglobulins, Hepatitis B, Hepatitis C and HIV. Complement C4 was low with normal C3. Patient’s laboratory workup showed normocytic normochromic anemia and pseudohyponatremia per osmolality check, SPEP and SFLC ordered and was positive for M-spike with free light chain analysis showing predominant Lambda more than 4 g/L. Renal biopsy showed myeloma cast nephropathy.

Bone marrow biopsy confirmed MM with 80% plasma cell. Patient received bortezomib +dexamethasone + cyclophosphamide chemotherapy and her renal function completely improved after being dialysis dependent for about 12 weeks. Patient is being evaluated for BDM transplant after chemotherapy response.

Discussion: Multiple Myeloma can cause renal damage in many ways which sometimes can be misleading and very uncharacteristic. Up to our knowledge, this presentation is quite uncommon in literature and hence we suggest including myeloma related kidney injury in such clinical presentation.

Cases of Nephrotic Syndrome During Pregnancy

A Case of Thyroiditis and Nephrotic Syndrome During Pregnancy

Case Description: A 35-year-old pregnant woman presented with proteinuria and edema. Pregnancy-induced nephrotic syndrome (PINS) was diagnosed at 30 weeks gestation. She had a history of Graves' disease. The patient was treated with high-dose corticosteroids and plasma exchange. After treatment, proteinuria resolved, and she had a healthy delivery at 39 weeks gestation.

Discussion: PINS is a rare complication of pregnancy, affecting 1-2% of pregnant women. The pathogenesis involves the activation of the immune system, leading to glomerular injury. Treatment with corticosteroids and plasma exchange is effective in resolving proteinuria and improving maternal and fetal outcomes.

TH-PO1083
A Case of Cryoglobulinemic Nephropathy with Successful Childbirth After Recurrent Episodes of Nephrotic Syndrome During Pregnancy

Case Description: A 35-year-old woman was admitted due to recurrent albuminuria and nephrotic-range proteinuria during pregnancy. Renal biopsy revealed membranoproliferative glomerulonephritis (MPGN). She underwent plasmapheresis and immunosuppressive therapy with good efficacy. She delivered a healthy baby at term with a normal Apgar score.

Discussion: Cryoglobulinemic nephropathy is a rare cause of nephrotic syndrome in pregnancy. Cases often respond to aggressive immunosuppressive therapy. Early diagnosis and prompt treatment can lead to successful pregnancy outcomes.

TH-PO1084
A Case of Glomerular Lipidosis with Type III Hyperlipoproteinemia

Case Description: A 35-year-old woman was admitted with nephrotic-range proteinuria. Renal biopsy revealed lipid deposition in glomeruli. Genetic testing revealed a mutation in the APOE gene. She responded well to statin therapy and lifestyle modification.

Discussion: Glomerular lipidosis is a rare cause of nephrotic syndrome. It is associated with type III hyperlipoproteinemia. Early recognition and management can prevent progression to end-stage renal disease.
Londonderry, United Kingdom.

factors might be involved in causing nephrotic syndrome.

A Case of Autosomal Dominant Polycystic Kidney Disease and C3
TH-PO1087

Successful Treatment of Crescentic Glomerulonephritis (GN) in
Hycompomplectem Uticaria Vasculitis Syndrome (HYUV)
Ramchandur Bakhtian, Mark G. Parker. Nephrology, Maine Medical Center,
Portland, ME.

Introduction: HYUV is a rare autoimmune systemic disorder characterized by chronic urticaria, low complements and extracutaneous organ involvement. Kidney involvement is not uncommon (50% of cases), usually of benign nature. The glomerular injury pattern varies from mesangial proliferation to membranoproliferative glomerulonephritis (MPGN). Crescentic MPGN in HYUV is rare; only six cases have been reported in world literature, many with poor outcomes. We present a case of crescentic GN successfully treated with substantial remission.

Case Description: A 55-year-old Caucasian female with a previous episode of hives was admitted to hospital with features of both acute nephritic and severe nephrotic syndrome. She had 6 months history of persistent hives, fatigue, fevers, arthralgia, self-limited recurrent angioedema episodes, and generalized lymphadenopathy. Lymph node biopsy displayed reactive hyperplasia. Her serum creatinine was 4 mg/dl. Her protein to creatinine ratio was 23, serum bilirubin 1.4 mg/dl and total proteins 7.1 g/dl. Serum IgA was 1000 mg/dl, all other serum immunoglobulins were normal. ESR was 70 mm/hr. 12 urine casts/100 HPF. Serologic workup was positive for low C3 and C4 and ANA titer of 1:80. Anti-dsDNA, cryoglobulins, anti-SSA, anti-SSB, chronic hepatitis panel, and pupules for parvovirus, were all negative. C3 and C4 levels were normal. Anti C3d antibody was not performed. Renal biopsy revealed immune complex crescentic MPGN with IgG, IgA, IgM, C3 and C4 deposits on immunofluorescence. Treatment was started initially with high dose glucocorticoids followed by addition of mycophenolic acid and losartan. Her systemic symptoms and acute kidney injury resolved completely. Nephrotic syndrome improved slowly. After 6 months of therapy her proteinuria decreased to 4.5 g/dl and serum albumin increased to 3.8 g/dl.

Discussion: Crescentic GN associated with HYUV appears to convey a poor renal prognosis. Based on available information in five of six reported cases, three progressed to end stage renal disease; one had near complete renal recovery and another had partial recovery with persistent nephrotic range proteinuria. Relatively good outcome in our case may aid to our understanding of this uncommon and newly recognized disease process.

TH-PO1086

An Unusually Early Presentation of Pre-eclampsia
David Bennett, Renu Reginathan-Shenk, Maya K. Rao. Medicine, Div of Nephrology, Columbia University Medical Center, New York, NY.

Introduction: Pre-eclampsia affects approximately 3-6% of pregnancies in the United States. It is defined as new onset hypertension and proteinuria in pregnancy. By definition, it occurs after 20 weeks gestation. However, earlier cases have been reported in the literature.

Case Description: The patient is a 45 y/o woman, 16 weeks + 4 days pregnant with twins (IVF with donor embryo), with a PMHx significant for obesity and borderline HTN under control with anti-hypertensives. Termination of pregnancy was advised and performed. On post-discharge follow-up, her exam was notable for BP 193/122, 1+ upper extremity edema, 2+ lower extremity edema, and bibasilar crackles on lung exam. On labs, Cr 0.85, 3+ protein on UA (previously 1+), hemoglobin 10.5, WBC 13.4, platelets 254K, alanine transaminase 87 U/L, aspartate transaminase 112 U/L, alkaline phosphatase 251 U/L, total cholesterol 249 mg/dl, low density lipoprotein 116 mg/dl, high density lipoprotein 43 mg/dl, triglycerides 151 mg/dl, albumin 2.3. Serologic work-up including ANA, C3, C4, HIV, Hepatitis B, Hepatitis C, anti-dsDNA, cryoglobulins, anti-SSA, anti-SSB, chronic hepatitis panel, and workup for parvovirus, were all negative. Anti C3d antibody was not performed. Renal biopsy revealed immune complex crescentic MPGN with IgG, IgA, IgM, C3 and C4 deposits on immunofluorescence. Treatment was started initially with high dose glucocorticoids followed by addition of mycophenolic acid and losartan. Her systemic symptoms and acute kidney injury resolved completely. Nephrotic syndrome improved slowly. After 6 months of therapy her proteinuria decreased to 4.5 g/dl and serum albumin increased to 3.8 g/dl.

Discussion: Crescentic GN associated with HYUV appears to convey a poor renal prognosis. Based on available information in five of six reported cases, three progressed to end stage renal disease; one had near complete renal recovery and another had partial recovery with persistent nephrotic range proteinuria. Relatively good outcome in our case may aid to our understanding of this uncommon and newly recognized disease process.

TH-PO1088

To Deliver or Not to Deliver: The Dilemma of a Pregnant Patient with Medullary Cystic Kidney Disease Who Develops Acute Kidney Injury

Introduction: Achieving maternity is quite a challenge for women with chronic kidney disease (CKD). Pregnant patients with CKD of any stage but especially stages 3–5 are at increased risk for fetal loss, prematurity and pre-eclampsia.

Case Description: We present a case of a 31 year old pregnant female with a past medical history of CKD stage 3B secondary to medullary cystic disease (MCD) who presented with acute kidney injury at 31 weeks gestation. Her other co-morbidities include a history of diabetes and idiopathic thrombocytopenia (ITP). On admission, the patient had a creatinine of 2.32 mg/dl and was found to have 7 gm proteinuria. During this pregnancy, her baseline creatinine was 1.6-1.8 mg/dl and prior to pregnancy she had baseline proteinuria of 2 gm. Given her elevated creatinine and degree of proteinuria, there was concern that the patient could have pre-eclampsia. A management dilemma occurred and it was unclear whether the patient should have an emergency C-Section for questionable pre-eclampsia. Ultimately, the usual markers of pre-eclampsia such as proteinuria, increased creatinine, hypertension, low platelets, and elevated uric acid levels were all present in our patient. These markers however could be present in our patient due to her underlying medical conditions of CKD, ITP, and MCD. After a multidisciplinary meeting with the obstetrician, nephrologist, and hematologist occurred, it was felt that the patient truly did not have pre-eclampsia. A key decision was made and she was not induced. Her AKI was attributed to volume depletion and progression of CKD. Her creatinine eventually declined to 1.9-2 mg/dl and her proteinuria decreased to 3-5 grams. The patient is now 34 weeks pregnant and her pre-eclampsia has been maintained. As the weeks progress, there are increased chances of fetal development.

Discussion: Our case highlights that in patients with multiple co-morbidities and CKD, the diagnosis of pre-eclampsia can be challenging. Incorrectly labeling a patient as pre-eclampsic can lead to pre-term delivery and risks to the fetus. A multidisciplinary approach along with fetal monitoring can help differentiate pre-eclampsia from other diagnoses, prolonging delivery.

TH-PO1089

Development of Aggressive De Novo Henoch-Schönlein Purpura, 10 Years Post-Kidney Transplant
Kamel Hataba, Swati Rao, Avrum Gillespie, Mythili Ghanta, Serban Constantinescu, Xu Zeng, Iris J. Lee. 1Nephrology, Temple Univ School of Medicine, Philadelphia, PA; 2Temple Univ School of Medicine, Philadelphia, PA.

Introduction: Histologic recurrence of IgA deposits in renal allografts is as high as 60% in recipients with primary IgA nephropathy, however significant nephritis presenting as de novo Henoch-Schönlein Purpura (HSP) post-kidney transplant (KT) is rare with only a few cases reported. Our patient had biopsy proven idiopathic nephropathy (DN), yet presented with severe HSP with multi-system involvement 10 years post-KT.

Case Description: A 47 y/o female with DN receiving a living related KT in 2005 and was stably maintained on tacrolimus, prednisone, without mycophenolate mofetil (MMF) due to recurrent infections. 10-yrs post-KT, she developed diarrhea, melena and acute renal failure (Cr of 4.19 from 1.5) after completing a course of antibiotics for pneumonia. She developed diffuse purpuric rash and had hematolysis with severe abdominal pain. Abdominal CT scan showed enteritis of the small bowel. EGD demonstrated necrotic ulcers in the esophagus, stomach, and duodenum ulcerative jejunitis with narrowing, showing leukocytoclastic infiltration of vessels, and submucosa. Skin biopsy showed leukocytoclastic vasculitis. Urine had 4+ protein, leukocytes, red blood cells, but no casts. Extensive infectious and serologic workup was negative. KT biopsy demonstrated membranoproliferative glomerulonephritis changes without crescents, coupled with findings of DN and advanced interstitial fibrosis and tubular atrophy. Immunofluorescence showed +4 deposits for IgA and C3 and the patient was diagnosed with HSP. Due to severe GI involvement the patient was treated with pulse
Thrombotic Microangiopathy Secondary to Smoldering Myeloma: A Form
of MGRS

Case Description: A 64 year old AA female with chronic Hepatitis C, hypertension, diabetes mellitus came to our clinic for evaluation of AKI superimposed on chronic kidney disease. Laboratory data revealed serum creatinine of 2.24 mg/dl (baseline Cr 1.5 mg/dl), hypoaalbuminemia (3.2 gm/dL) with a spot urine protein/creatinine ratio of 3.3 (baseline of 1). Her AKI coincided with peripheral eosinophilia. Home medications included hydralazine, lansoprazole and simvastatin. She had recently completed eight weeks of treatment for Hepatitis C with Harvoni and her most recent viral load was undetectable. She denied using any NSAID, antibiotics, PPI or herbal supplements. Physical exam was normal. AKI workup revealed negative ANCA, normal complement, normal serum free immunoglobulin light chain ratio and negative ANA panel.

Discussion: Harvoni is a new combination pill consisting of ledipasvir with sofosbuvir approved by FDA in October 2014 for the treatment of chronic Hepatitis C genotype 1 virus infection. No cases of Acute Kidney Injury (AKI) have been reported with this agent thus far. We report the first case of Harvoni associated biopsy proven acute interstitial nephritis (AIN).

Harvoni Induced Acute Interstitial Nephritis

TH-PO1092

A Case of Leukocyte Chemotactic Factor 2 Associated Amyloidosis

Nada Bader, Saeed Kamaran Shaffi. Nephrology, Univ of New Mexico.

Introduction: Leukocyte chemotactic factor 2-associated amyloidosis (ALCT2) is a newly described form of nonhereditary amyloidosis. The disease usually presents with chronic kidney disease and bland urinary sediment with variable degrees of proteinuria. We describe a case of a young Hispanic female who presented with nephrotic syndrome without evident insufficiency.

Case Description: A 40 year old Hispanic female with history significant for uncontrolled type 2 diabetes, hypertension and rheumatoid arthritis, was referred to renal clinic for evaluation of nephrotic syndrome. Physical examination revealed peribulbar and bilateral lower limb edema. Pertinent diagnostic data are shown in figure 1.

Figure 1: Diagnostic Data

- Urinalysis: Protein
- Urine microscopy: Bland
- Serum creatinine (mg/dl): 0.5
- Serum albumin (g/dl): 1.4
- SLEP: No M component
- Renal ultrasound: Normal
- Normal kidney size with mild echogenicity

Renal biopsy showed extensive amyloidosis involving the glomeruli, interstitium and arterioles. Immunofluorescence was negative for immunoglobulins and amyloid associated protein. Proteomic typing of the amyloid revealed ALCT2 associated amyloidosis. The patient was started on linsopolone and splenolactone, but her proteinuria failed to improve and she had progressive deterioration of renal function. Two years later, she developed ascites and elevated liver enzymes. Her presentation was concerning for hepatic amyloidosis; therefore, she was transferred to a liver transplant center for further evaluation.

Discussion: Based on two large renal biopsy series, ALCT2 accounts for 2.5-2.7% of all cases of renal amyloidosis. In a multicenter study involving 72 patients with renal ALCT2, 92% were Hispanic, 2.8% were below the age of 50 and 91.4% had a serum creatinine > 1.2mg/dl. One third had nephrotic range proteinuria, but only 10% of all patients presented with nephrotic syndrome. Pathogenesis is not clear. It is postulated that inflammatory processes lead to excessive production of an amyloidogenic variant of ALCT2. Accurate identification of the amyloid protein is essential as disease modifying treatments are available for certain types of amyloidosis.

Complement Polymorphisms in Patients with Thrombotic Microangiopathy Associated with Intrahepatic Hepatitis: Implications for Nephrology

Joe Ghanem, Lukas Haragism, Satish Kumar. Nephrology, Univ of Oklahoma Health Science Center, Oklahoma City, OK.

Introduction: In 2012, the CDC reported 15 cases of unexplained renal failure and idiopathic microscopic polyangiopathy (TMA) in which all patients reported dissolving and intravenously injecting an oral preparation of oxymorphone (Opana) prior to presentation. Since then, 30 additional cases have been reported in the U.S. The mechanism of IV Opana-associated TMA is unclear. ADAMTS13 levels were normal. We report two patients with genetic polymorphisms of complement system proteins as a possible mechanism for Opana-associated TMA.

Case Description: Two patients, a 26 yo WM (Pt 1) and a 38 yo WM (Pt 2) presented with unexplained renal failure (serum creatinine 8.2 and 4.6 mg/dl respectively) in the setting of IV Opana Abuse. Both displayed a hematological constellation of microangiopathic hemolytic anemia, thrombocytopenia, consumed haptoglobin and elevated LDH. Both patients had normal INR/PT/PTT, ADAMTS13 (> 55%) and fibrinogen levels. ANA, HIV, and hepatitis profiles were negative. Renal biopsy showed intermediate sized vessels with mild thrombotic microangiopathy involving 20% of the glomeruli in both patients. Both received plasmapheresis for 5 days. Hematological microangiopathy resolved in Pt 2 but persisted in Pt 1. Both remained dialysis dependent. Genetic studies for complement-mediated HUS demonstrated both to be positive for a heterozygous polymorphism (IVSP-78 G>A) within an intron of the membrane cofactor protein (MCP/CD46) and for a homozygous polymorphism (p.His402Tyr) in the complement factor H (CFH). In addition, both patients had an additional CFH polymorphism (p.Val626Le; Pt 1 homozygous, Pt 2 heterozygous).

Discussion: Our patients suggest a 2 hit mechanism for IV Opana-associated TMA. Both had polymorphisms in complement system proteins MCP and CFH with a potential predisposition for complement-mediated HUS. The MCP/CD46 polymorphism has been shown to be enriched in patients with complement-mediated HUS. Polymorphisms in complement system proteins could cause hyperactivation and dysregulation of the complement system and provide a genetic predisposition for thrombotic microangiopathy, with IV Opana abuse acting as a trigger.

349A
Acute Kidney Injury due to an Excessive Dose of Rivaroxaban

**Case Description:** A 45 y/o man presented to his physician’s office with abdominal pain. Computed tomography (CT) of the abdomen was done and thrombosis of the portal, splenic, and mesenteric vein was identified. He was admitted to the hospital and discharged on coumadin 10 mg daily the next day. After 6 weeks, he was given a prescription for rivaroxaban 20 mg tab and told to take 1 tablet daily. He mistakenly took 2 tablets daily. After 5 days, he noticed painless gross hematuria for several days. He reported to his physician’s office and his serum creatinine had increased to 2.7 mg/dL from a baseline of 1.5. He had a prior history of warfarin use and he was started on dialysis and remained dialysis-dependent at last follow up.

Malignant Pleural Effusion

**Case Description:** A 56 year old female presented with microscopic hematuria (6-10 RBC), proteinuria (6.9 g) and acute kidney injury (creatinine 1.5 mg/dL). Her renal function deteriorated requiring hemodialysis treatment. Serology revealed mixed type III IgG/IgM cryoglobulins. Kidney biopsy showed mesangial proliferation, protein thrombi within capillary loops, reduplication of GBM and mesangial interpositioning, consistent with mixed membranous MPGN. She was treated with plasma exchange, Rituximab, and methylprednisolone. She was treated with plasma exchange, IgG, and is under evaluation for C3 glomerulopathy with nephrotic range proteinuria.

**Discussion:** Case 1: A 18 year old female presented with proteinuria (1.7 g), hematuria (44 RBC), proteinuria (6.9 g) and acute kidney injury (creatinine 1.5 mg/dL). Her renal function deteriorated requiring hemodialysis treatment. Serology revealed mixed type III IgG/IgM cryoglobulins. Kidney biopsy showed mesangial proliferation, protein thrombi within capillary loops, reduplication of GBM and mesangial interpositioning, consistent with mixed membranous MPGN. She was treated with plasma exchange, Rituximab, and methylprednisolone. She was treated with plasma exchange, IgG, and is under evaluation for C3 glomerulopathy with nephrotic range proteinuria.

**Case 2:** 18 year old female presented with proteinuria (6-10 RBC), proteinuria (6.9 g) and acute kidney injury (creatinine 1.5 mg/dL). Her renal function deteriorated requiring hemodialysis treatment. Serology revealed mixed type III IgG/IgM cryoglobulins. Kidney biopsy showed mesangial proliferation, protein thrombi within capillary loops, reduplication of GBM and mesangial interpositioning, consistent with mixed membranous MPGN. She was treated with plasma exchange, Rituximab, and methylprednisolone. She was treated with plasma exchange, IgG, and is under evaluation for C3 glomerulopathy with nephrotic range proteinuria.

**Discussion:** Patients with AIH should be monitored for proteinuria and active urinary sediment due to the risk of glomerulonephritis, despite treatment with prednisone and azathioprine. MPGN is a rare, but important, complication of AIH. Prompt diagnosis by biopsy and aggressive treatment of AIH associated MPGN is critical.

**TH-PO1097 Membranoproliferative Glomerulonephritis with Mixed Cryoglobulinemia in Patients with Autoimmune Hepatitis**

**Case 1: A 56 year old female presented with microscopic hematuria (6-10 RBC), proteinuria (6.9 g) and acute kidney injury (creatinine 1.5 mg/dL). Her renal function deteriorated requiring hemodialysis treatment. Serology revealed mixed type III IgG/IgM cryoglobulins. Kidney biopsy showed mesangial proliferation, protein thrombi within capillary loops, reduplication of GBM and mesangial interpositioning, consistent with mixed membranous MPGN. She was treated with plasma exchange, Rituximab, and methylprednisolone. She was treated with plasma exchange, IgG, and is under evaluation for C3 glomerulopathy with nephrotic range proteinuria.

**Case 2:** 18 year old female presented with proteinuria (1.7 g), hematuria (44 RBC), proteinuria (6.9 g) and acute kidney injury (creatinine 1.5 mg/dL). Her renal function deteriorated requiring hemodialysis treatment. Serology revealed mixed type III IgG/IgM cryoglobulins. Kidney biopsy showed mesangial proliferation, protein thrombi within capillary loops, reduplication of GBM and mesangial interpositioning, consistent with mixed membranous MPGN. She was treated with plasma exchange, Rituximab, and methylprednisolone. She was treated with plasma exchange, IgG, and is under evaluation for C3 glomerulopathy with nephrotic range proteinuria.

**Discussion:** Patients with AIH should be monitored for proteinuria and active urinary sediment due to the risk of glomerulonephritis, despite treatment with prednisone and azathioprine. MPGN is a rare, but important, complication of AIH. Prompt diagnosis by biopsy and aggressive treatment of AIH associated MPGN is critical.

**TH-PO1098 A Case of Chinese Herb (Aristolochic Acid) Nephropathy Leading to ESRD Complicated by Bladder Cancer**

**Case Description:** We report a 59 year old white female who had received Chinese herbs for one and half years before she developed progressive renal insufficiency that over a six month period led to ESRD requiring hemodialysis. A renal biopsy showed extensive tubular loss and collapse with interstitial edema and interstitial fibrosis consistent with the effects of tubular toxic damage caused by aristolochic acid. After one week of hemodialysis, the patient underwent a living unrelated kidney transplant from a friend. Alemtuzumab induction, steroid free maintenance on tacrolimus and mycophenolate (MMF) were started. She had no history of diabetes, hypertension or use of NSAIDS. She underwent monthly urinalysis and screening cystoscopy every six months to rule out urothelial malignancies. Twenty months post transplant she underwent right breast lumpectomy and radiation for intraductal carcinoma. Two and a half years after kidney transplantation, a cystoscopy revealed a bladder mass, a biopsy of which showed high grade urothelial carcinoma with squamous differentiation invading into submucosal connective tissue for which she underwent bilateral native nephrectomy, ureterectomy, cystectomy and transplant kidney ileal loop urinary diversion. One year later the patient was admitted with increased blood pressure and was found to have a malignant pleural effusion of undifferentiated primary which led to her demise. A sample of the Chinese herb that she had used was found to contain aristolochic acid.
Discussion: There has been a high risk of urethral malignancies associated with Chlamydia/aristolochic acid exposure with 40 – 45% of these patients developing multifocal high grade transitional cell carcinoma leading to a suggestions for either prophylactic bilateral native nephrectomy and ureterectomy at the time of renal transplantation or screening cystoscopies every 6 months to identify early stage urethral carcinoma. Our patient is a classic example of aristolochic acid associated nephropathy complicated with urethral cancer.

Anti-Tumor Necrosis Factor Therapy – A Trigger for Anti-Glomerular Basement Membrane Disease Carlos Antonio Cortes Sanchez, Hector R. Cordova, Krystahl Z. Andujar. Medical Service, VA Caribbean Healthcare System, San Juan, PR.

Introduction: Tumor necrosis factor (TNF) has a key pathological role in diseases such as rheumatoid arthritis (RA). Vasculitis and other autoimmune diseases have been associated with the use of anti-TNF agents such as Adalimumab.

Case Description: A 73-year-old man with of RA, Hypertension, Diabetes Mellitus type 2 and Non-Hodgkin’s Lymphoma in remission for 3 years complained of decreased urine output, dark urine, poor appetite, weight loss and peripheral edema for three weeks. He was on chronic low dose Prednisone and Adalimumab intermittently during the previous 21 months. Physical exam revealed bilateral lower extremity pitting edema but no skin lesions. Laboratories showed a serum creatinine of 9.5 mg/dl (baseline of 1.3 mg/dl). Urinalysis exhibited many RBC’s, proteinuria (2+) and pyuria without casts. The clinical picture suggested acute glomerulonephritis. Hemodialysis (HD) was started.

Throat swabs were compatible with Anti-Glomerular Basement Membrane Disease. Alveolar hemorrhage was not present. Plasmapheresis therapy decreased anti-GBM titers but there was no recovery of renal function. The patient continued using Adalimumab after discharge. He later returned with hemoptysis due to alveolar hemorrhage, which was resolved after the discontinuation of Adalimumab. The patient remained HD-dependent.

Discussion: The temporal association of the illness with anti-TNF therapy and worsening of symptoms upon reexposure suggest an etiologic role of Adalimumab in the development of Anti-GBM Disease in our patient. Patients receiving anti-TNF therapy should have renal function closely monitored to allow early detection of this infrequent but life-threatening side effect.

TH-PO1100

Severe Pauci Immune Crescent Glomerulonephritis Mimicking ANCA Related Vasculitis Caused by Clinically Silent Dental Abscess Leading to Bacterial Endocarditis Anil K. Chunduri, Maria Saleem Khan, Anthony Alvarado, Tibor Nadassy, Lee A. Hebert. Nephrology, OSUMC, Columbus, OH.

Introduction: Severe crescentic GN is usually categorized based on the cause if it is Anti GBM or IC mediated disease. However, it is not widely appreciated that some instances of pauci immune GN are actually the result of severe occult systemic infections. We present a case of severe pauci immune crescentic GN whose initial assessment for infection was negative. The patient was assumed to have idiopathic AAV and was treated with high dose steroids. Despite no obvious signs of infection, bacteremia was on our differential due to pancytopenia. These findings are rarely common, if ever, associated with AAV.

Case Description: 55 year old male with PMH of CAD presented to an outside hospital with fatigue. Initial labs revealed Hb: 7.6g/dL, WBC: 2.8 K/µL, Pt: 44 K/µL, Creat: 2.26 mg/dL. Infectious work up was negative. Autosome workup revealed: ANA positive (1:40), Anti GBM (<20), Anti PR3 (0.6), ANCA and Anti MPO: negative. C3: 77mg/dL, C4: 16.9 mg/dL (wmp). Cryoglobulin (<5), Urine PCR ratio was 1.2. Further workup included a bone marrow biopsy and kidney biopsy, which was suggestive of pauci-immune crescentic and necrotizing GN. He received treatment with steroids and was discharged on steroid taper. His creatinine upon discharge was 1.5 mg/dL. On follow up his creatinine was elevated to 3.5 mg/dL. He was transferred to our institution. Repeat Infectious work up revealed streptococcus viridians bacteremia, tricuspid and aortic valve endocarditis. A panoramic radiograph of his teeth showed periapical abscess. He was subsequently diagnosed with infection related acute pauci-immune crescentic necrotizing GN. Unfortunately this patient remained dialysis dependent at the time of discharge.

Discussion: It is well established but not widely appreciated that severe pauci-immune crescentic GN can be the direct result of infection. Thorough investigation is warranted even if the initial infectious workup is negative, if the patient does not have a positive response to conventional therapy to improve morbidity and mortality.

TH-PO1101

POEMS syndrome with Cast Nephropathy Amanda K. Hall, Josephine Abraham, Monica Patricia Revelo Penafiel, Frederic Clayton. ’Div of Nephrology and Hypertension, Univ of Utah, Salt Lake City, UT; ’Div of Pathology, Univ of Utah, Salt Lake City, UT.

Introduction: POEMS syndrome(Polynuropathy, Organomegaly, Endocrinopathy, Monoclonal protein, Skin changes) is a plasma cell disorder with peripheral neuropathy and any of the following features osteosclerotic bone, Castelmann’s disease, increased levels of serum vascular endothelial growth factor(VEGF), organomegaly, endocrinopathy, edema or skin changes. We report a case of POEMS presenting with acute renal failure due to cast nephropathy.

Case Description: A 63-year-old Caucasian female presented with a 3 month history of increasing weakness and was diagnosed with chronic inflammatory demyelinating polyneuropathy. She was also noted to have new onset diabetes mellitus and hypothyroidism. She was treated with intravenous immunoglobulin(IVIG) with minimal response. She was admitted with acute renal failure initially thought to be secondary to IVIG, progressive weakness, and shortness of breath. Serum beta 2 microglobulin was elevated and kappa/lambda ratio was abnormal with Bence-Jones proteinuria. Renal biopsy was deferred as the patient developed respiratory failure, subarachnoid hemorrhage, and a left middle cerebral artery stroke. Comfort measures were initiated. Bone marrow biopsy confirmed multiple myeloma. With 20% clonal plasma cells, azathioprine was stopped and an uneventful hepatomegaly, splenomegaly, and peripheral nerve demyelination with active axonal loss. Renal examination showed cast nephropathy with monoclonal kappa light chains.

These features are characteristic of POEMS given the multiple myeloma with neuropathy, organomegaly, rash and new onset diabetes mellitus and hypothyroidism.

Discussion: POEMS is a paraneoplastic syndrome associated with plasma cell dyscrasia. Polyneuropathy with plasma cell disorder should prompt evaluation for POEMS as outcomes have been excellent with diagnosis and treatment.

TH-PO1102

Acute Interstitial Nephritis Associated with a New Breast Cancer Chemotherapy Regimen Cory Handelsman, Michael T. Tanoue, Amy Kwon, Steven Salvatore, Jeffrey I. Silberzweig. ’Div of Nephrology, Weill Cornell Medical College; ’Dept of Medicine, Weill Cornell Medical College; ’Dept of Pathology, Weill Cornell Medical College, New York, NY; ’The Rogosin Inst, New York, NY.

Introduction: Acute interstitial nephritis (AIN) as a direct consequence of chemotherapy is infrequently described. A recent review implicated ifosfamide, tyrosine kinase inhibitors, and pemetrexed as culprits in this process. We describe a case of AIN related to the recently approved chemotherapy regimen of pertuzumab, trastuzumab, and docetaxel for HER-2 positive metastatic breast cancer. While diarrhea, rash, and pruritis are well-known side effects, this report is the first to show AIN as a consequence of this chemotherapy regimen.

Case Description: A 69-year-old woman recently diagnosed with HER-2 positive breast cancer and treated with six cycles of neoadjuvant pertuzumab, trastuzumab, and docetaxel was hospitalized for acute kidney injury after two days of diarrhea and vomiting. Admission labs demonstrated leukocytosis to 26,000/µL, serum creatinine of 5.9 mg/dL (baseline of 1.55 mg/dL), and elevated urinary “p” gap metabolic acidosis with a lactic acid of 4.5 mmol/L. Urinalysis showed pyuria with occasional granular casts. Fractional excretion of sodium was 1.88%. Renal sonogram showed normal resistive indices with no evidence of hydronephrosis or calculi. Infectious workup, including blood, urine, and stool studies, was unrevealing. Despite aggressive hydration and resolution of diarrhea and vomiting within 48 hours, her renal function worsened; her creatinine peaked at 9.0 mg/dL on hospital day 3. She was non-oliguric throughout the admission. A renal biopsy revealed moderate diffuse and subacute, interstitial inflammation characterized by lymphocytic infiltration with moderate eosinophilia and diffuse tubular injury. Some endothelial injury

Key: TH - Thursday; FR - Friday; SA - Saturday; OR-Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
was present as well. The patient was diagnosed with AIN secondary to chemotherapy and treated with prednisone. Two weeks later, her symptoms had fully resolved and her serum creatinine had returned to baseline.

**Discussion:** This is the first documented case of AIN related to combination chemotherapy with docetaxel, pertuzumab, and trastuzumab.

**TH-PO1103**

Sarcoidosis-Lymphoma Syndrome Presenting with Severe Refractory Hyercalcemia

Otsita W. Okechukwu,1 Barry M. Wall,2 Elvira Gomovanova,1 Deepak Nandikanti,1 *Nephrology Div, UTHSC, Memphis, TN; †Nephrology Section, VAMC, Memphis, TN.

**Introduction:** Sarcoidosis-lymphoma syndrome (SLS) is rare. Sarcoidosis (S) usually precedes lymphoma (L) by many months. Constitutional symptoms and hilar lymphadenopathy are key findings. We report a SLS case presenting with severe acute hyercalcemia and acute kidney injury (AKI).

**Case Description:** Case Report: A 70 yr-old Caucasian male was hospitalized with symptoms of generalized weakness, poor oral intake, and altered mental status. Examination was significant for dry mucous membranes, depressed mentation, evidence of bilateral pleural effusions, mild ascites, and 2cm well-delineated hyperpigmented erythematous plaques on anterior chest wall. Laboratory findings included a corrected serum Ca 19.4mg/dL (2 months prior: 9.3mg/dL), ionized Ca 2.3 mmol/L, BUN 35mg/dL, serum creatinine 2.5mg/dL (baseline 1.4 mg/dL), and mild anemia. Further work up revealed suppressed PTHrP (0.2pg/mL), normal 25D, TT3, TT4, serum urine electrolyte, calcium, calciotril, ACE, CEAl, PSA, and TSH. A working diagnosis of hypercalcemia of malignancy was made. Intravenous fluids, calcitomin, prednisone, and low dose pamidronate were initiated; however, his calcium continued to remain poorly responsive to conservative management. Calcium hemodialysis was required. Skin biopsy of chest wall lesion demonstrated non-caseating granulomatous dermatitis consistent with sarcoidosis. Thoracentesis was performed and pleural fluid cytology showed occasional plasmacytoid lymphoid cell and polyclonal T-cells on flow cytometry. However, flow cytometry of ascitic fluid was positive for monoclonal B cells. Computed tomography (CT) demonstrated diffuse soft tissue lung masses and abdominal carcinomatosis. Oesophageal survey was normal. CT-guided omental mass biopsy showed dense fibrous tissue with lymphoplasmacytic infiltrate. The diagnosis of SLS with associated B-cell lymphoma was made. Given poor functional status and widespread disease, the patient and his family opted for hospice care.

**Discussion:** Severe refractory hypercalcemia leading to AKI is unusual for sarcoidosis and should prompt investigation for concomitant lymphoma.

**TH-PO1104**

End Stage Renal Disease Secondary to Oxalate Nephropathy in a Patient with Undiagnosed Chronic Pancreatitis

Kalvany Chandras, Buri R. Don. *Div of Nephrology, UC Davis Medical Center, Sacramento, CA.

**Introduction:** Oxalate nephropathy is a rare, underdiagnosed, devastating disease characterized by extensive oxalate deposition, acute kidney injury and rapid progression to end stage renal disease (ESRD). Secondary hyperoxaluria occurs in enteric disorders associated with increased intestinal oxalate absorption and renal tubular injury. Chronic pancreatitis is a rare cause of oxalate nephropathy.

**Case Description:** A 66-year-old white man with history of diabetes mellitus, hypertension and recurrent kidney stones, was noted on routine labs to have an elevated serum calcium level (11.7 mg/dL, baseline 1.17 mg/dL, 6 months prior). He reported having chronic diarrhea, fatigue, loss of appetite and weight loss over the past 6 months. Workup revealed pancreatic calcifications consistent with chronic pancreatitis. Urinalysis and renal ultrasound were normal. Renal biopsy revealed acute tubular necrosis with extensive oxalate deposition. A 24 hr urine collection noted increased oxalate and reduced citrate excretion. Despite a 6 month course of a low oxalate diet, pancreatic enzymes, calcium supplementation, and sodium citrate to alkalize the urine, the patient’s renal function failed to improve, and he is preparing for home hemodialysis.

**Discussion:** Enteric hyperoxaluria can lead to acute oxalate nephropathy. It has been described in patients with post-gastric bypass surgery and inflammatory bowel disease. There are rare reports noting the association between chronic pancreatitis and oxalate nephropathy leading to chronic kidney disease (CKD) and rarely ESRD. The pathogenesis of hyperoxaluria in chronic pancreatitis remains uncertain, but it is postulated that fat malabsorption may increase the formation of fatty acids that inhibit the formation of calcium oxalate in the GI tract, combined with increased colonic mucosal permeability, leading to hyperoxaloremia, hyperoxaluria and oxalate crystalization in the kidney. Treatment remains largely empirical, aiming at decreasing oxalate burden to the kidney as was done in this patient. Oxalate removal with dialysis has not been shown to be beneficial. Oxalate nephropathy can be a late complication of chronic pancreatitis leading to CKD and ESRD.

**TH-PO1105**

mRNA Expression of Proinflammatory Mediators in Common Variable Immunodeficiency with Granulomatous Interstitial Nephritis: Case Report

Giacoamo Mori, Giulia Ligabue, Sara De biass, Milena Nasi, Andrea Cossarizza, Gianni Cappelli. *Univ Hospital - Modena.*

**Introduction:** Common Variable ImmuneDeficiency (CVID) impact on kidney function is poorly understood. We present a case of a woman, 39 years old, affected by CVID, expressing as hypogammaglobulinemia, anemia and chronic kidney failure secondary to granulomatous interstitial nephritis(IN).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only

Nephrotic Range Proteinuria without a History of Penicillamine Therapy in a Patient with Wilson’s Disease

Hideki Matsumura,1 Akira Ashida,1 Yuku Fuji1, Akihiko Shirai,1 Hyogo Nkakura,1 Motoshi Hattori,2 Hiroshi Tamai,3 1Pediatrics, Osaka Medical College, Osaka, Japan; 2Pediatric Nephrology, Tokyo Women’s Medical Univ, Tokyo, Japan.

**Introduction:** Wilson’s disease (WD) is a rare autosomal recessive genetic disorder of copper metabolism, characterized by hepatic and neurological abnormality. Although penicillamine is one of the key drugs for treatment of WD, in rare cases it may have a toxicogenic effect leading to nephrotic syndrome due to membranoproliferative glomerulopathy. Here, we report a case of WD in a patient who showed nephrotic range proteinuria clinically and focal segmental glomerulosclerosis (FSGS) histologically, without a history of treatment with penicillamine.

**Case Description:** We treated an 18-year-old girl who had been diagnosed as having WD at the age of 6 years and treated with trientine. She had normal liver function and normal urinalysis parameters. At the age of 16 years, she had developed acute liver failure due to poor drug compliance. Although her liver function subsequently recovered after plasma exchange and medications including zinc and trientine, slight proteinuria began to appear. As the proteinuria increased gradually to within the nephrotic range, we performed a kidney biopsy one year later. The patient had normal blood pressure, no edema, and her body mass index was 26.9. Blood examinations demonstrated no hypoproteinemia, no immunological abnormalities and normal kidney function. Although urinalysis revealed no hematuria, the urine protein/creatinine ratio was increased to 2.98. A kidney biopsy demonstrated perihilar FSGS and arteriolar intimal thickening, without tubular-interstitial or glomerular basement membrane changes. We diagnosed the patient as having secondary FSGS after successful treatment in response to WD medication.

**Discussion:** Although the kidney manifestations in WD include aminoacidurias and nephrocalcinosis, these were not observed in our patient. As her symptoms were relatively milder than those of typical FSGS and she had several known causes of secondary FSGS including arteriolar intimal thickening, our histological diagnosis was secondary FSGS. To our knowledge, this is the first report of histologically confirmed FSGS in a patient with WD.

**TH-PO1107**

Denosumab for the Treatment of Bishophosphate Refractory Hypercalcemia of Malignancy

Theresa L. Nilson, Tammy Wan, Erik Lawrence Lum. *Div of Nephrology, Univ of California, Los Angeles, Los Angeles, CA.

**Introduction:** Hypercalcemia is common in malignancy, occurring in 20-30% of patients. Volume expansion with normal saline is the mainstay of therapy, with the addition of bisphosphonates in cases of severe hypercalcemia. Here we describe a case of bisphosphate resistant hypercalcemia of malignancy and discuss potential treatment options for refractory cases.

**Case Description:** A 62 year-old male with T2 paraplegia following a fall 24 years ago presented to the ER for evaluation of a debucus ulcer. On arrival his vital signs were unremarkable, and physical examination demonstrated a 10x10 cm stage IV debucus ulcer with purulent drainage and exposed bone. Initial laboratory data demonstrated white blood cell count 18.7, hemoglobin 4.9 g/dL, normal basic metabolic panel and calcium 8.8mg/dL. He was transfused blood products and given antibiotic therapy. Bone biopsy demonstrated invasive squamous cell carcinoma. His calcium increased to 14.1mg/dL with elevated PTHrP 71pg/mL. He was diagnosed with humoral hypercalcemia of malignancy and treated with denosumab (20mg) and his calcium decreased to 9.32 mg/dL over the next four days. The response was sustained without additional need for administration over the next two months before the patient expired due to complications related to his debucus ulcer.
Discussion: This case illustrates the potential effectiveness of denosumab for the treatment of hypercalcemia refractory to bisphosphonates. Denosumab is a human monoclonal antibody against RANK-Ligand (RANKL) whose use has previously been described for management of hypercalcemia, but required multiple infusions. Recognition of this additional treatment, with effectiveness from a single infusion, is critical in managing refractory hypercalcemia, as the only other known option is hemodialysis. Increasing availability of options for management of refractory hypercalcemia may allow patients to avoid complications associated with hemodialysis.

TH-PO1108
Collapsing and NOS Focal Segmental Gомерulosclerosis (FSGS): Progression Along a Spectrum or Different Diseases? Suzanne L. Katsanos, Patrick H. Nachman, JulieAnne G. McGregor, Volker Nickeleit. UNC Kidney Center, Chapel Hill, NC.

Introduction: Minimal change disease (MCD) and some variants of FSGS (tip lesion and not otherwise specified NOS) are thought to represent a histologic spectrum of a same autoimmune pathogenic process (Habib, R. Proceedings Xth Int Cong of Neph). This contention has never been proven, however. Some cases of MCD are thought to be "unsampled" FSGS. A "transition" from MCD to FSGS is common in steroid-resistant forms (Tejani, A. Nephron 39). It has been proposed that collapsing FSGS is pathogenically and clinically distinct from other FSGS variants based on morphology, demographics, severity of nephrotic syndrome, and renal prognosis. The etiology has not been identified but viral agents, drugs, and cyclosporine toxicity have all been proposed.

Case Description: We present the case of a 37-year-old African American male with a complicated course of nephrotic syndrome. He was diagnosed with biopsy-proven MCD when 9 years old. He was treated with steroids followed by chlorambucil and then cyclophosphamide over the next several years. He was in complete remission off therapy for about 2 years until he re-presented with increased edema, proteinuria (3.8 g/d), hyperalbuninemia, and acute kidney injury (AKI). A repeat biopsy (23 glomeruli) showed FSGS NOS. He was treated with steroids followed by mycophenolate mofetil and cyclosporine, resulting in complete remission. 7 years later, he developed edema, proteinuria (21 g/d) and AKI. Repeat biopsy showed 25 glomeruli demonstrating segmental tuft collapse, activation of endothelial cells, and segmental marked activation and crowding of podocytes consistent with collapsing FSGS. HIV, hepatitis B, and hepatitis C were negative. The transition from MCD to FSGS NOS is common in the literature. However, the transition from FSGS NOS to collapsing FSGS is rarely reported. This patient’s case raises questions about this transition from NOS to collapsing variant. Glomerular undersampling is unlikely given 25 glomeruli were examined each time. This could represent a progressive, patient-related pathogenic process versus a de novo lesion (either related to a viral infection or medication, for example).

TH-PO1109
Lymphoma Associated Monoclonal Cryoglobulinemia in a Patient with Hepatitis C
Sangeeta Mutnuri, 1 Marjan Afrozian, 2 Hania Kassem. 3 "Dept of Nephrology, UTMB, Galveston, TX; 2 "Dept of Pathology, UTMB, Galveston, TX.

Introduction: We present a case of type I cryoglobulinemia and membrañoproliferative glomerulonephritis (MPGN) in a patient with hepatitis C infection (HCV), leading to the diagnosis of a marginal zone lymphoma.

Case Description: A 47 year old male with HCV and hypertension presented with two month duration of shortness of breath and decreased urine output. On examination he was hypertensive (blood pressure: 183/111 mm Hg), had lung crackles, lower extremity edema and hepatosplenomegaly. Laboratory tests were significant for hypercalcemia of 1.6 mg/dL, hyperphosphatemia of 4.8 mg/dL, hyperuricemia of 8.8 mg/dL, and low density lipoprotein (LDL) of 92 mg/dL. Renal biopsy revealed MPGN type II with deposits. Fluorescence microscopy favored kappa monoclonality. Electron microscopy of the deposits was consistent with cryoglobulins. Serum immunoelectrohoresis also confirmed IgM/Kappa monoclonality. As HCV is more commonly associated with polycylonal cryoglobulinemia this finding of monoclonality prompted a search for malignancy. A bone marrow biopsy showed lymphoid aggregates increase in number in the bone marrow and low density lipoprotein (LDL) was controlled on rituximab/dexamethasone based regimen. The creatinine trended down to 1.87 mg/dL.

Discussion: The transition from MCD to FSGS NOS is common in the literature. However, the transition from FSGS NOS to collapsing FSGS is rarely reported. This patient’s case raises questions about this transition from NOS to collapsing variant. Glomerular undersampling is unlikely given 25 glomeruli were examined each time. This could represent a progressive, patient-related pathogenic process versus a de novo lesion (either related to a viral infection or medication, for example).

TH-PO1110
A Lupus Nephritis Patient Accompanied with Storiform Fibrosis Characteristic in IgG4-Related Kidney Disease in the Absence of Serum IgG4 Elevation and IgG4-Positive Plasma Cell Infiltration

Introduction: IgG4-related kidney disease (IgG4-KD) usually presents as tubulointerstitial nephritis with IgG4-positive plasma cell (PC) infiltration and serum IgG4 elevation. IgG4-KD has characteristic histological findings called storiform fibrosis and nodular findings showing storiform density less than or equal to 60%. Recently, Hara et al. reported a case of IgG4-negative IgG4-KD (Mod Reumatol, 2014) which had a condition closely mimicking IgG4-KD despite the absence of serum IgG4 elevation and IgG4-positive PC infiltration. Here we report a patient diagnosed with lupus nephritis (LN) with IgG4-negative IgG4-KD.

Case Description: A 59-year-old Japanese man was referred to our hospital with chest pain and mild proteinuria. Thoracic biopsy was performed for abnormal lung shadow and interstitial pneumonia was diagnosed. Although ANA titer was elevated to 2560-fold, anti-DNA, anti-Sm, and anti-SS-A/B antibodies were all negative. Serum C3 and C4 levels and complement activity were decreased. Serum IgG and IgE levels were elevated, but serum IgG4 level was within normal limits. On contrast-enhanced CT, multiple low-density lesions were observed in kidney. Renal biopsy findings revealed lymphoplasmacytic infiltration with storiform fibrosis and small numbers of eosinophils. Immunostainings revealed CD138+ or IgG-positive PC infiltration without IgG4-positive PC. Immunofluorescence microscopy showed granular mesangial positivity for a “full-house” pattern. Electron microscopy disclosed mesangial and subendothelial dense deposition accompanied with virus-like particles. We diagnosed this patient with IgG4-negative IgG4-KD and LN (ISN/RPS II). After administration of 20 mg prednisolone, laboratory data was drastically improved.

Discussion: To our knowledge, this is the first report of a patient with LN and IgG4-negative IgG4-KD. IgG4-negative IgG4-KD may be a chronic burnout phase of IgG4-KD.

Further studies gathering similar cases would be needed to clarify whether or not IgG4-negative IgG4-KD is included in a category of IgG4-KD.

A Case of Acute Phosphate Nephropathy in a Kidney Transplant Recipient
Hetal Shah, M. Lee Sanders, Kelly A. Birdwell, Anthony J. Langone, Paisit Paueksakon, Beatrice P. Concepcion. Vanderbilt Univ Medical Center, Nashville, TN.

Introduction: Acute phosphate nephropathy has been described after large doses of phosphate, typically in laxatives and bowel cleansing preparations. We present a case of acute phosphate nephropathy in a kidney transplant recipient who was taking oral phosphorus supplementation for hypophosphatemia.

Case Description: A 26 year-old man with a living related donor kidney transplant in 2011 complicated by recurrent IgA nephropathy with a baseline creatinine of 1.9 mg/dl presented with nausea, vomiting, diarrhea, fatigue and elevated creatinine. Two weeks prior to presentation, he had been started on K-Phos-Neutral 500 mg three times a day for a hyperphosphatemia of 7.0 mg/dl. On the next day, his serum phosphate level increased to 10.4 mg/dl, phosphorus 9.7 mg/dl, calcium 9.6 mg/dl and iPTH 761 pg/mL. Urinalysis had a urine pH of 5, no red blood cells and trace protein. Renal biopsy was performed and pathology revealed 30 foci of intratubular calcium phosphate crystals with associated acute tubular injury involving 30-40% of tubular profiles, along with known recurrence of IgA nephropathy. The patient underwent acute hemodialysis for oliguric acute kidney injury. Given the high serum phosphorus, he was diazylzed for four consecutive days until phosphorus level was less than 4 mg/dl and did not rebound.

Patient was discharged requiring intermittent hemodialysis for an additional three weeks until he demonstrated renal recovery. His new baseline creatinine is 2.2 mg/dl and he has remained off hemodialysis.

Discussion: Hypophosphatemia is common in kidney transplant recipients. Although rare, acute phosphate nephropathy can occur in the setting of phosphorus repletion. This patient also had multiple risk factors, including baseline renal dysfunction, volume depletion and angiotensin receptor blocker use. Acute phosphate nephropathy can potentially lead to irreversible loss of renal function. While no specific treatment exists, in this case, aggressive hemodialysis to decrease serum phosphorus may have played a role in this patient’s eventual renal recovery.

TH-PO1112
Unusual Membranous Nephropathy in a Patient with Lupus
Iheanyichukwu Ogu, Julia Lewis, Agnes B. Fogo. Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.

Introduction: Membranous nephropathy (MN) is an immunologically mediated glomerular disease. Distinguishing between primary and secondary MN is important in guiding diagnosis and treatment. We present a case of a patient with systemic lupus with pathologic features in a repeat biopsy suggestive of primary MN.
A Case of Proliferative Glomerulonephritis with Monoclonal IgG Deposits Exhibiting Marked Nephrotic Syndrome Who Responded Well to the Renin-Angiotensin System Blockade Alone

Yoshishiko Nishisugih, Hideki Inoue, Tomoaki Onoue, Yutaka Kakizoe, Yuichiro Izumi, Takashige Kuwabara, Takuya Miyoshi, Masatake Adachi, Yushu Nakayama, Masashi Mukoyama. Nephrology, Kumamoto Univ Hospital, Kumamoto, Japan.

Introduction: Proliferative glomerulonephritis with monoclonal IgG deposits (PGNMD) is a newly recognized entity of glomerulonephritis caused by glomerular deposition of monoclonal IgG. The clinical and pathological features, treatment and prognosis of this entity remain elusive.

Case Description: A 79-year-old woman was admitted to our hospital due to hematuria and marked nephrotic-range proteinuria. Her serum creatinine level was 0.75 mg/dL and urinary protein excretion was 20.8g/24h. Renal biopsy showed a membranoproliferative feature without nodular formation. Immunofluorescence study showed capillary and mesangial deposits of IgG1, C1q and C3. Moreover, IgG-kappa deposits were strongly stained and IgG3 deposits were restrictedly stained for IgG heavy-chain subclass analysis. Electron microscopy revealed amorphous electron-dense mesangial and subendothelial deposits. Monoclonal proteins were not detected in serum or urine samples. Serum cryoglobulin titer was negative. Serum free light-chain assay showed a normal kappa/lambda ratio. These findings were consistent with the diagnostic criteria for PGNMD.

Considering her age and tolerability, we started monotherapy with angiotensin II receptor blocker. This case showed drastic reduction in proteinuria with stable renal function within 3 months. Considering her age and tolerability, we started monotherapy with angiotensin II receptor blocker. This case showed drastic reduction in proteinuria with stable renal function within 3 months.

Discussion: This report is the first case report of a patient with acute kidney injury in pregnancy from TMA secondary to pheochromocytoma. Patient made good renal recovery after resection of the tumor.

TH-POI116

Immune Reconstitution Inflammatory Syndrome and Hypercalemia with Acute Kidney Injury following Stribild Therapy

Caroline C. Garcia, Kelly H. Beers, Christine Miranda, Kamran Karimi, Yezina T. Nigatu, Nandi K. Wadhwia. Nephrology/Medicine, Stony Brook Medicine, Stony Brook, NY.

Introduction: Immune reconstitution inflammatory syndrome (IRIS) is an inflammatory disorder with paradoxical worsening of preexisting infections following HAART in HIV-infected individuals. We describe a case of IRIS following Stribild (elvitegravir, cobicistat, emtricitabine, tenofovir) resulting in hypercalcemia.

Case Description: A 33 year-old woman with acquired immunodeficiency syndrome (AIDS) who had been on StriBild for two months presented to the ED with acute kidney injury with a serum creatinine of 2.93 mg/dL and Ca of 15.2 mg/dL. Her CD4 count was 145 ul and viral load 35 copies/ml. Four months prior, she was treated with amphotericin for cryptococcal lung infection and Cryptococcosis. One month prior, a right lower lobe mass histology had revealed necrotic tissue with inflammatory cells. On examination, she was alert, in no acute distress, with unremarkable physical examination. Her temperature was 36.7 degrees Celsius, heart rate 72/minute, BP 108/64 mm Hg, respiratory rate 14/minute, and oxygen saturation 100% on room air. Chest X-ray showed an interval decrease in the right lower lobe mass. Serum intact PTH was 9.7 pg/mL, PTHr peptide, SPEP and UPEP were negative. Serum 25 (OH) D was 37 ng/mL, 1,25 (OH), D3 was 17 pg/mL, and 24 hour urine Ca was 270 mg. Urine fractional excretion phosphorus was 28% with no glucosuria. She was diagnosed with IRIS and Stribild was discontinued. She was treated with IV fluids and calcitriol with an improvement in her renal function and normalization of her serum calcium over a period of 4 weeks. Lab data summarized.

Discussion: IRIS is thought to be due to increased T-lymphocyte proliferation after HAART in AIDS patients. IRIS typically manifests as a granulomatous inflammation. Corticosteroids are treatment of choice in IRIS in the setting of excess 1.25 (OH) D3. In our case, serum 1.25 (OH) D3 was low suggesting possible other mechanisms.

TH-PO117

IgA-Dominant Postinfectious Glomerulonephritis: A Case Series Pranjali Sharma,1 Anitha Vijayan,2 Tingting Li.2 1Dept of Internal Medicine, Renal Div, Washington Univ in St. Louis, St. Louis, MO; 2Dept of Internal Medicine, Renal Div, Washington Univ in St. Louis, St. Louis, MO; 3Dept of Internal Medicine, Renal Div, Washington Univ in St. Louis, St. Louis, MO.

Introduction: IgA dominant post-infectious glomerulonephritis (PIGN) is a distinct clinicopathologic entity that typically occurs in diabetic patients and in association with a recent or active staphylococcal infection. Patients usually present with hematuria, proteinuria, and AKI. Renal pathology shows an immune-complex GN with various histologic patterns and IgA-dominance or co-dominance with IgG on immunofluorescence. Here we report the clinical characteristics and outcomes of 10 patients with IgA dominant PIGN.

Case Description: After obtaining approval from the local IRB, retrospective, single-center review of data was performed and 10 patients with IgA dominant PIGN were identified.

Majority was white males, and 6/10 were diabetic. Eight patients had a Staphylococcal infection and one had active Hep C infection. Only 3/10 had low complements. 6/10 required RRT and 4 developed ESRD, of which 2 died at 2 and 5 months after initiation of RRT. Five had left with varying degree of CKD and one was lost to follow up. Three patients were treated with immunosuppression in addition to antibiotics—all had significant improvement in renal function; one patient who was initially RRT-dependent was able to come off dialysis.

Table 1. Clinical features and outcomes of pts with IgA-dominant PIGN

Discussion: IgA-dominant PIGN is an increasingly recognized disorder that occurs most commonly in diabetic patients with Staphylococcal infections. Overall renal prognosis is poor. Treatment with immunosuppression in addition to antibiotics may be considered.

TH-PO1119

ANCA Negative Paeu-Immune Necrotizing Crescentic Glomerulonephritis in a Patient with Non Hepatitis C Mixed Essential Cryoglobulinemia Victor Nwazue,1 Ji ae Yoon,2 Balhinder S. Brar.3 1Medicine, Mercy St Vincent Medical Center, Toledo, OH; 2Nephrology, Univ of Toledo, Toledo, OH; 3Nephrology, Mercy St Vincent Medical Center, Toledo, OH.

Introduction: Mixed essential cryoglobulinemia (MC) is associated with a hepatitis C infection in 70-90% of patients and presents as membranoproliferative glomerulonephritis or rapidly progressive glomerulonephritis (RPGN) with or without crescents. We report an unusual presentation of type II MC without hepatitis C infection presenting as ANCA negative PNM and crescentic glomerulonephritis (GN). We report the clinical characteristics and outcomes of 2 different pathologically and pathogenically distinct disease entities. To our knowledge this is the first reported case with these unusual manifestations.

Case Description: A 64 year old male presented with AKI (creatinine of 5.4 from a baseline of 0.8 mg/dL, 2 weeks earlier), 12-18 month history of arthralgias, fatigue, joint pains, petchial and purpuric spots on his extremities. His symptoms were exacerbated in the winter months. Lab tests revealed elevated cryoglobulin level (338mg/dL), low C4 (5 mg/dL), positive rheumatoid factor, IgG monoclonal gammapathy (0.37g/dL). MPO ANCA, PR3 ANCA, ANA, hepatits B and C and HIV serologies were negative. Urinalysis showed 20-50 RBCs, no casts and proteinemia of 2.5. G bone marrow biopsy showed < 5% plasma cells and no T cell aberrancy or B cell monoclonality. A kidney biopsy revealed pauci-immune necrotizing C3GN. Electron microscopy (EM) showed no deposits or fibrillary or tubular structures in the glomeruli. The patient was treated with hemodialysis (HD), 5 sessions of plasmapheresis and oral cyclophosphamide for 3 months. He responded to treatment with near complete resolutions of his symptoms and near normalization of kidney function.

Discussion: Pauci-immune C3GN is associated with either microscopic polyanthus or granulomatous with polyanthus. These can present as RPGN and have either a positive MPO or PR3 ANCA but have no deposits on immunofluorescence and EM. C3GN in pauci-immune is an immunocomplex disease, has distinct tubulocapillary, fibrillary and tubular structures on EM. Our case was an unusual combination of 2 different pathologically and pathogenically distinct disease entities. To our knowledge this is the first reported case with these unusual manifestations.

TH-PO1120

Fibrillary Glomerulonephritis Presenting as Rapidly Progressive Crescentic Glomerulonephritis Pallavi D. Shirsat,1,2 Chi Chyi Chong,1,2 Ramesh Marahatta,1,2 Cherinet S. Adgeh,1,2 Neville R. Dossaboy.1,2 1Dept of Nephrology, Veterans Affairs Medical Center, Shreveport, LA; 2Dept of Nephrology, LSU School of Medicine, Shreveport, LA.

Introduction: Fibrillary glomerulonephritis is a rare disease of unclear etiology, known to be associated with malignancy, autoimmune disorders, lymphoplasmacytic disorders and hepatitis C. It is seen in 0.5 to 1.0% of native kidney biopsies.

Case Description: We report a case of a 62 year old Caucasian male veteran who had a past medical history of hepatitis C, hyperlipidemia, s/p coronary bypass, multiple colon polyps (rectal and CKA) stage 3. Patient, on a routine follow up appointment, was noted to have rapid worsening of kidney function, with creatinine increase from baseline of 1.4-1.8 up to 3.2 mg/dL. He was also noted to have 24 RBCs per HPF on urine microscopy. Urine protein:creatinine ratio was 4.5. Hepatitis C related membranous glomerulonephritis (GN) was high on the differential list. Hepatitis B and HIV serologies were negative. Complement, cryoglobulins, ANCA and serum protein electrophoresis were within normal limits. Patient underwent kidney biopsy, which showed crescentic GN, with linear pattern immunoglobulin deposition along the GBM (glomerular basement membrane) on light microscopy and immunofluorescence suggestive of anti-GBM disease. However, patient’s anti-GBM titer was negative! Electron microscopy showed thickening of GBM due to fibrillary deposits. Similar fibrillary deposits were also seen in the mesangium, with haphazard distribution of fibrils measuring about 15 nm, consistent with fibrillary GN. Conge red stain for amyloid was negative. Patient was also found to have a 2.8 x 2.5 cm well-circumscribed solid & cystic mass in right kidney on ultrasound, suspicious for renal cell carcinoma (RCC). A fine needle aspiration of the mass yielded cells consistent with RCC.

Discussion: Fibrillary GN is known to be associated with malignancy. It can rarely present clinically as rapidly progressive, crescentic GN, and masquerade as anti-GBM disease on immunofluorescence. Electron microscopy and serologic workup are needed to clinch the definitive diagnosis.

TH-PO1121

Pauci-Immune Necrotizing Crescentic Glomerulonephritis as the First Manifestation of Chronic Lymphocytic Leukemia Relapse S. Saadi Imam,1 Monia E. Werlang,1 Tatiana A. Thorn,2 Nabeel Aslam.1 1Dept of Medicine, Division of Internal Medicine, Mayo Clinic, Jacksonville, FL; 2Dept of Medicine, Div of Nephrology, Mayo Clinic, Jacksonville, FL.

Introduction: The association between hematological malignancy and auto-immune disease is a well-documented phenomenon. Chronic lymphocytic leukemia (CLL) patients have 5-10% risk of developing autoimmune cytopathies, and a rare subset of these CLL patients may present with anti-neutrophil cytoplasmic antibodies (ANCA) or Wegener’s with set of a vasculitis. Here, we present a case of a patient with treated CLL whose relapse was identified by the new diagnosis of ANCA-associated pauci-immune glomerulonephritis.
Case Description: A 73-year-old female with history of CLL, status post chemotherapy five years ago, presented with complaints of dyspea on exertion, fatigue, oral ulcers, hemoptysis, rash, arthralgias, edema, and tea-colored urine for 3 months duration. Exam showed BP 157/94, bibasilar rales and gingival ulcers. Labs showed Hb 5.4g/dL, platelets 113K, WBC 4.6k, S. creatinine 4.4mg/dL. Urinalysis showed 2+ protein, many RBCs and WBCs. ANCA, ANA, anti-PR3 and MPO were strongly positive. Kidney biopsy showed necrotizing crescentic pauci-immune glomerulonephritis in more than 50% of glomeruli. Taking into consideration the patient’s prior history of CLL, bone marrow biopsy was performed and showed scattered nodular lymphoid proliferation with flow cytometry confirming relapse of CLL. Given this finding, our patient was treated on the lines of CLL relapse with steroids and rituximab instead of using steroids, cyclophosphamide and plasmapheresis for the treatment of ANCA-associated vasculitis alone.

Discussion: The prevalence of ANCA positivity in CLL patients has been documented to be 20-25%. In our patient, ANCA-associated pauci-immune glomerulonephritis was the first manifestation of CLL relapse. Discovering CLL relapse mandated a change in the management from the standard treatment of pauci-immune glomerulonephritis to a regimen more appropriate for both conditions. Clinicians should be aware of this rare association of CLL with ANCA-associated vasculitis to choose the most appropriate treatment regimen for these patients.

TH-PO1124
A Case of Catastrophic Antiphospholipid Syndrome Treated with Plasma Exchange
Takesuki Takahashi, Fumihiko Furuya, Tetsuhiro Oku, Kenichiro Kitamura. Third Dept of Internal Medicine, Univ of Yamanashi.

Introduction: Catastrophic antiphospholipid syndrome (CAPS) is characterized by diffuse vascular thrombosis, leading to multiple organ failure within a few days and resulting to poor prognosis. Antiphospholipid syndrome (APS) is an autoimmune thrombotic syndrome with recurrent thrombosis and occurs in both artery and vein, and from large to micro vessels. CAPS is also defined as a fatal variant of APS and develop thrombosis of three different organ systems with histopathologic evidence of multiple small vessel occlusions and high titers of antiphospholipid antibodies. Treatment for CAPS has not been established, and intensive anticoagulation or immunosuppressive therapy is carried out.

Case Description: A 68-year-old female who had been diagnosed as lupus erythematosus and APS complicated with multiple cerebral infarctions and treated with 5 mg of oral prednisolone. After her admission, she developed de novo cerebral infarction and colonic perforation with ischemic enteritis. Following a partial colectomy, she developed gram-negative bacteremia, subsequently, multiple strokes, non-ST elevation myocardial infarction, renal failure, and pathological findings with multiple thrombi. These clinical findings indicated that patient’s features were consistent with CAPS. She was maintained with anti-bacterial agent, anticoagulant, and prednisolone. However, since renal failure and anuria had continued, she was treated with plasma exchange (PE) and hemodialysis. Thereafter the volume of urine output was gradually increased and her renal function was recovered.

Discussion: We report a case of CAPS with multiple organ failure and successfully treated with anticoagulant, prednisolone, and PE. The clinical manifestation of CAPS depends on the release of inflammatory cytokines from the affected organs by thrombosis and small vessel occlusion. Our patient’s successful course could be attributed to beneficial role of PE through the removal of excessive inflammatory cytokines.

TH-PO1125
Acute HIV in a HIV-Naïve Patient During Primary HIV Infection and High Viral Load
Amit N. Shah, Adam G. Winkler, Claude Bassil, Donald E. Wheeler, Jacques A. Durr. Div of Nephrology, Univ of South Florida, Tampa, FL.

Introduction: A hitherto healthy 42 yo AA male felt chills only 6 days earlier. He took a NQuil and skipped next day’s shift for body aches/GI cramps. He improved but again felt bad by HS, 48h later. Next AM in a local ER, his UA showed WBC/RBC, 3+ protein, and a SG of 1.030. Physical exam, chest X-ray, contrast abdominal CT, and eGFR, were normal. His WBC had worked full capacity again, but got admitted 48h later after a brief syncpe.

Case Description: Viral signs: T 103 °F, BP 100/60 mm Hg, and HR 76 bpm. He had transient mild diastolic. Serum albumin (Alb) was 2.1 g/d, creatinine (cr) 2 mg/dl, and WBC 3+103/ml. UA had WBC/RBC and >0.5 g/dl protein. UA was 21 mmol/l. His urine protein was ~12 g/24h. CRP was ~2 (<0.5 mg/dl), and ESR 50 mm/h. CPK was 8717 U/l and ~ half by 48h. BCP, and HIV-1/2 Ab screens were (-), but (+) for HIV p24 Ag. He had >3+106 HIV copies/ml, and 213 CD4+ cells/ml. US showed normal-sized kidneys, no obstruction, but some corticale echogenicity.

His cr first improved for 72h, but then rose to ~8 mg/dl in 1w. Dialysis and HAART were initiated. By then he had edema and Alb was 1.2 g/dl. Renal biopsy showed collapsing GN, podocyte hypertrophy/hyperplasia, microcystic tubular dilations, 3+ acute tubular injury, 2+ patchy (mostly lymphocytic) infiltrate with focal tubulitis, and no signs of chronicity. Prednisone was added. He seroconverted (HIV-1) 2w after his first chills.

Discussion: Of the case reports of primary renal HIV infection only 2 had biopsy-proven HIV. One was HIV Ab (+) but by EIA but not by Western blot, and had 70,000 HIV copies/ml (Szabo S et al. 2002). Both had advanced RF and already other infections. Our patient had normal eGFR until his acute HIV infection. The high HIV Ag load alone, not replication, is the sole likely cause for HIV, consistent with the view that a direct toxic effect of HIV gene products or podocyte dedifferentiation, since viral particle endocytosis readily occurs in podocytes (as their normal filter cleaning role?), but lack of HIV entry receptors precludes local replication (Khatua AK et al. 2010).
A Case of Hypercalcemia with Renal Failure: Renal Sarcoid?

Introduction: Sarcoidosis is a multisystem granulomatous disease of unknown etiology characterized by noncaseating granulomas in involved organs. Renal involvement occurs in 35-50%, manifested by hypercalculia, hypercalcemia, nephrocalcinosis, and nephro lithiasis. Granulomatous interstitial nephritis is the most typical histological finding usually in the setting of systemic disease and rarely in the absence of extrarenal sarcoid.

Case Description: A 54 y/o male presented with AKI superimposed on CKD and severe hypercalcemia (Calcium 13.5mg/dl, Ca×1.7mmol/L, creatinine=7.59mg/dl). Six months prior he had a kidney stone removed at which time his creatinine was 2.4mg/dl with Ca=1.1 but no further work up was performed. He was taking no medications and complained of back pain. Physical exam was unremarkable. A CT scan was negative for nephrolithiasis or hydronephrosis, chest X-ray revealed no abnormality. He was aggressively treated with IV NS and then Lasix with minimal improvement in the creatinine or the serum calcium. Work up for hypercalcemia included normal serum and urine immunofixation, negative PPD, normal PSA and normal skeletal survey. 25 Hydroxyvitamin D 27.8ng/ml (30-95ng/ml). He was started on prednisone 60mg/d with rapid resolution of the hypercalcemia and slow improvement in renal function (Creatinine 2.9mg/dl). A slow steroid taper over 1 year is planned.

Discussion: The diagnosis of sarcoid interstitial nephritis was strongly suggested by the renal biopsy given that other causes of granulomatous were ruled out. The patient was started on prednisone 60mg/d with rapid resolution of the hypercalcemia and slow improvement in renal function (Creatinine 2.9mg/dl). A slow steroid taper over 1 year is planned.

FR-PO002

Pediatric Chronic Refractory SIADH: Use of Tolvaptan

Cristin Kaspar, Nianzhou Xiao, Timothy E. Bunchman, Megan M. Lo. Pediatric Nephrology, Children’s Hospital of Richmond at Virginia Commonwealth Univ, Richmond, VA.

Introduction: The syndrome of inappropriate antidiuretic hormone (SIADH) is the most common cause of euvolemic hyponatremia in hospitalized patients, and standard therapies can be limited in their effectiveness. Arginine vasopressin receptor antagonists (AVR-A) oral tolvaptan and intravenous conivaptan have been FDA approved in adults, but reports on long-term use in pediatrics are lacking. We report on the dosing and safety of chronic AVR-A treatment in two patients with chronic SIADH. Dosing regimen was extrapolated from current pediatric and adult literature.

Case Description: Case A is a 13 year old, 43.5 kg female with a 12-year history of chronic A VR-A treatment in two patients with chronic SIADH. Dosing regimen was extrapolated from current pediatric and adult literature.

Discussion: Case A is a 13 year old, 47.3 kg female who developed refractory SIADH as her initial presentation of an olfactory neuroblastoma. She was treated with conivaptan load and infusion of 0.2 mg/kg/day, titrated off after 32 hours. She received tolvaptan starting at 0.15 mg/kg/day and discontinued once the mass was excised after 27 days.

Discussion: Stable tolvaptan dosing was reached at 0.15-0.3 mg/kg/day (7.5 mg daily or twice daily) and weaned to 0.08 mg/kg (3.5 mg) daily or every other day before being discontinued in both patients. Case B had elevation of serum creatinine when on IV conivaptan and fluid restriction. Neither patient had complications of hypokalemia, hypernatremia, or liver dysfunction. Both patients required frequent monitoring of serum sodium and regular titration of dose and oral fluid intake. We recommend starting tolvaptan at 0.5-0.3 mg/kg/day. The use of tolvaptan in an outpatient setting for chronic hyponatremia is safe and effective in adolescent patients with close monitoring.

FR-PO003

Congenital Pituitary Stalk Interruption Syndrome (PSIS) Newly Diagnosed in Case of Hyponatremia in the Elderly

Kenji Kajitani, Takahito Ito, Kaori Takakura, Yoko Tomiyama, Ikuo Nagayama, Masafumi Yamamoto, Akira Wada, Hirotugu Iwatani. Nephrology, Osaka National Hospital, Osaka, Japan.

Introduction: There are many diseases that cause hyponatremia. Among them, adrenal insufficiency (AI) is important due to its urgency. We present an extremely rare case of elderly-onset AI in congenital PSIS, which is highly suggestive of the mechanism of AI progression.

Case Description: A 72 year old female with a 24 year history of hypothyroidism and a 12 year history of diabetes mellitus type 2. She was diagnosed with hyponatremia (Na=115mEq/L) in December, 2015. She was admitted due to “severe” hyponatremia in March, 2016. She was transferred from another hospital where she was treated with fluid restriction and normal saline with an improvement in serum sodium but further fluid restriction caused her sodium level to fall below 120mEq/L. She was intubated and admitted to our hospital. She had a history of congestive heart failure, hypertension, hyperlipidemia, diabetes, gout, hypertension, and psoriasis.

Discussion: We present an elderly-onset AI in a congenital PSIS patient. We performed CRH/TRH/GHRH/LHRH stimulation test disclosed hypothalamic panhypopituitarism. The patient was started on hydrocoisone 60mg daily. We achieved an improvement in serum sodium level to 130 mEq/L. The improvements in serum sodium level were sustained with a daily dose of 30mg hydrocoisone. The patient’s condition improved and she was discharged home after a week of hospitalization.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

357A
the delivery of hypotensive hormones to pituitary, resulting in elderly-onset AI. Thus, blood flow disturbance of SHA can induce AI in PSIS. In conclusion, a con genital disorder can be the cause for elderly-onset adrenal insufficiency. This case suggests that pituitary stalk interruption syndrome should be taken into account as a differential diagnosis for hypopituitarism, even in the elderly, especially in short statured patients.

FR-PO005

A Family Case of Hypoparathyroidism, Deafness, and Renal Dysplasia Syndrome with a Novel Mutation of GATA3

Tomoo Yabuuchi, Shoichiro Kanda, Naoya Morisada, Keiichi Takizawa, Yuji Tomii, Naoto Kaneko, Hirotake Hama, Eiji Nakano, Norimasa Tada, Kiyonobu Ishizuka, Hiroto Chiba, Yoshihiro Kato, Yuki Tokoa, Kazumoto Iijima, Motoshi Hattori

1Dept of Pediatric Nephrology, Tokyo Women's Medical Univ, Shinjyaku-Ku, Tokyo, Japan; 2Dept of Pediatrics, Kobe Univ Graduate School of Medicine, Chuo-ku, Kobe, Japan.

Introduction: Congenital anomalies of the kidney and urinary tract (CAKUT), a major cause of end-stage renal disease in children, often present as a systemic disorder with extrarenal symptoms. Extrarenal symptoms and family history are helpful in the genetic diagnosis of CAKUT. We report here a family case of hypoparathyroidism, deafness, and renal dysplasia (HDR) syndrome with a novel mutation of GATA3.

Case Description: Soon after birth, a female patient was diagnosed as having bilateral cystic dysplastic kidneys by renal ultrasonography. She also had hearing impairment at the infancy. She received peritoneal dialysis at the age of 3 years and received a cadaveric kidney transplant at the age of 10 years. When she was 14 years old, she visited the emergency department because of acute abdomen. Detailed examinations showed hematometra associated with vaginal atresia. Branchio-oto-renal syndrome was considered as her diagnosis based on her hearing impairment, bilateral cystic dysplastic kidneys, and normocalcemia. However, we suspected that she had an HDR syndrome because we found that her mother had hypoparathyroidism after determining a detailed family history. Genetic analysis was approved by the central ethics board of Tokyo Women's Medical University and Kobe University. This analysis showed a novel mutation, c. 1013G>T (C338F) of GATA3, the causative gene for HDR syndrome.

Discussion: Our patient did not show any symptoms of hypoparathyroidism. However, based on the family history, we performed a genetic analysis and found a novel mutation of GATA3. She was then diagnosed with atypical HDR syndrome. Therefore, determining a detailed family history is important in the precise diagnosis of CAKUT patients.

FR-PO006

Hydropneumothorax: A rare cause of hypoxemia

Hirotaka Hama, Syuji Hiyamuta, Akiko Tsuchimoto, Kimichiro Fujisaki, Kumiko Torisu, Kosuke Masutani, Kazuhiko Tsuruya, Takanari Kitazono, Hiroyuki Hiyamuta, Yasuhiro Kawai, Kenji Ueki, Yuta Matsukuma

1Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka City, Japan; 2Dept of Integrated Therapy for Chronic Kidney Disease, Kyushu Univ, Fukuoka City, Japan.

Introduction: Hydropneumothorax is a very rare condition, usually associated with traumatic injuries, neoplasms, or infectious processes. In this case report, we present a patient with a non-traumatic hydropneumothorax and hypoxemia, which was successfully managed conservatively.

Case Description: A 45-year-old male patient was admitted to our hospital with a history of chest pain and shortness of breath. He was found to have a large left hydropneumothorax on chest X-ray. The patient was managed conservatively and underwent spontaneous resolution with no recurrence.

Discussion: Hydropneumothorax is a rare condition that can be caused by various etiologies. It is important to differentiate it from other causes of hypoxemia to ensure appropriate management. This case highlights the importance of a multidisciplinary approach in the management of such rare conditions.
hypokalemia, following the discontinuation of the medication, especially after prolonged use. Recent literature has knowledge, suggests this to be a case report demonstrating the association between HTN, hypokalemia and drospirenone.

Case Description: A 54 year-old Indian woman, previously normotensive, noted a new rise in home BP to 200/100 mm Hg and presented to the emergency department, where she was also noted to have mild hypokalemia to 3.1 mEq/L. Given the rather new onset of severe HTN and hypokalemia, work-up for secondary causes of HTN was done, which revealed normal aldosterone level (9 ng/dL), low plasma renin activity (PRA) (0.15 ng/mL/h) and high aldosterone/PRA ratio (60). Looking back into her history, it was noted that, the timing of symptoms was closely related to discontinuing Yasmin® (3 mg estradiol and 3 mg drospirenone), which she was taking for over 6 yrs. She was thought to have rebound effect with relatively excess mineralocorticoid activity, precipitated by the abrupt discontinuance of drospirenone. With the introduction of low dose spironolactone, her symptoms significantly improved.

Discussion: Drospirenone (an analogue of spironolactone), which has antimineralocorticoid and antiandrogenic activities similar to endogenous progesterone, counteracts the estrogen-mediated stimulation of the renin-angiotensin-aldosterone system (RAAS). Due to these effects, it has the potential to decrease blood pressure and also cause hyperkalemia. At a dosage of 400 mg daily, drospirenone causes mild natriuresis, which is followed by compensatory stimulation of the RAAS (comparable to a low sodium diet). When the prolonged ongoing suppression for the RAAS is removed, there might be a potential rebound effect with (relatively) high aldosterone state, resulting in sodium retention, leading to HTN. Spironolactone appears to be useful in this situation.

FR-PO010
Acthar Induced Hypokalemie Metabolic Alkalosis
Imran Quayyum, Neil W. Lyman. Dept of Nephrology, St. Barnabas Medical Center, Livingston, NJ.

Introduction: Acthar, an ACTH formulation from porcine pituitary gland, is an effective therapy for Membranous Nephropathy (MN). A rare adverse effect of hypokalemic alkalosis has been reported infrequently only. We present an atypical report of an 87 year old Caucasian female who developed severe hypokalemia and metabolic alkalosis with Acthar therapy, and concomitant diuretic use.

Case Description: The patient presented with severe bilateral leg edema. Lower extremity doppler was negative for DVT. Echo revealed normal EF. UA showed 4+ protein and 2+ blood. Spot protein/creatinine ratio was 20. Urine sediment had no RBC casts. Her scr was 1.99 mg/dL (baseline 1.34 mg/dL). Albumin was 2.3 g/dL. Workup for malignancy was negative. Her serologies were unremarkable and a renal ultrasound was negative. Anti-Phospholipid Antibody was positive. Renal function was normal. When this laboratory evaluation was done 2 months ago, the scr was 3.0 mg/dL and urinalysis was normal. She was referred due to her advanced age. Acthar 80 units 2x/week was added to her regimen of furosemide, amiloride, losartan and hydrochlorothiazide. Protein excretion decreased from 40 g/day to less than 5 g/24 hours. Of note, the patient is on continuous venovenous hemofiltration (CVVH) for end stage liver disease. She had previously been on dialysis for 2 months. 

Discussion: ACTH increases endogenous steroid production via MelanoCortin Receptor (MCR) type 2. It also exerts direct beneficial effects on podocytes and glomerular cells via other MCR subtypes. ACTH is an effective, alternative therapeutic modality for patients with MN who are non-responders to treatment with prednisone. The mechanism of action of ACTH has not been well described. We report a unique case of severe hypokalemia/metabolic alkalosis with the use of Acthar in a patient with MN. Clinical signs of hypokalemia and metabolic alkalosis are not typically seen in hyporeninemic hypoaldosteronism. Instead, ACTH-induced alkalosis can be explained by the increased aldosterone production, leading to hypokalemia. This case highlights the importance of evaluating the possibility of ACTH-induced hypokalemia in patients with MN and similar conditions.

FR-PO011
Polycthemia in a Patient with Bartter’s Syndrome and Medullary Nephrocalcinosis
Gorigle Singian Merdega, Medicine, Philippine General Hospital, Manila, Metro Manila, Philippines.

Introduction: Bartter’s syndrome is a tubular salt wasting disorder presenting with severe hypokalemic alkalosis, hyperchloremia, and hyperreninemia with normal blood pressure. Medullary nephrocalcinosis in this disorder is an infrequent finding and is still poorly understood. Polycythemia is an unusual presentation in patients with renal diseases, but has been described in literature among patients with nephrotic syndrome and distal tubal acidosis. It is noteworthy, however, that reports on secondary erythrocytosis among patients with Bartter’s syndrome is lacking. The exact mechanism for the polycythemia observed is uncertain, although it may be related to increased production of erythropoietin. The patient demonstrated, the concomitant use of ACTH and diuretic therapy can result in severe hypokalemic metabolic alkalosis. Clinicians should closely monitor serum electrolytes after initiating Acthar.

Case Description: A 27 year old Filipina male with recurrent bouts of severe hypokalemic alkalosis since childhood presenting as bilateral lower extremity weakness necessitating recurrent hospital admissions was diagnosed with Bartter’s syndrome based on metabolic alkalosis, hypokalemic alkalosis, slight hypernatremia with normal serum calcium and magnesium levels. He had normal blood pressure and no frank hypercalciuria. His creatinine was elevated but his ultrasound revealed normal sized kidneys with no evidence of nephrocalcinosis. He was treated with hemoglobin of 190 g/L, slight leukocytosis with no thrombocytosis. AK2 mutation was negative and a bone marrow biopsy revealed mildly hypercellular marrow with trilineage hematopoiesis, making polycythemia for which the patient was on iron supplementation. His lab hemoglobin was 15 g/dL. His symptoms resolved with bicalutamide. His labs showed serum sodium 139mmol/L, chloride 103mmol/L, creatinine 83mmol/L. His arterial blood pH was 7.37 with bicarbonate 21. His plasma renin activity was suppressed at 0.2ng/ml/hr and his serum aldosterone was raised at 534.4pmol/L. The transubtural potassium gradient was 3.87. Genetic analysis of the patient and affected family members revealed a missense mutation affecting exon 13 of the gene KLHL3 (c.1492C>T p.His498Tyr) affecting a residue located in the 5 kelch motif of the protein. The patient was treated with dietary salt restriction and a thiazide diuretic.

Discussion: This man illustrates classic findings in familial hypercalciemic hypertension including hypertension, hypercalciemia, metabolic acidosis and positive family history. Cases such as this gives us further insight into the molecular pathophysiology of blood pressure control. KLHL3 gene products play a key regulatory role in distal nephron Na reabsorption and may have potential as anti-hypertensive drug targets.

Renal Failure Run A-FUowl: Disseminated Histoplasmosis Eileen Smith, Rajeev Raghavan, Sreedhar A. Mandayam. Baylor College of Medicine, Houston, TX.

Introduction: In patients with fever of unknown origin (FUO) and glomerulonephritis, Histoplasma capsulatum should be considered.

Case Description: A 37-year-old man presented to the hospital with 3 weeks of fatigue, 15-pound weight loss, intermittent chest pain, dyspnea on exertion and 3 day history of erythematous pruritic rash on his neck. PMH included congenital aortic stenosis with AVR, complicated by endocarditis requiring repeat AVR. Physical exam found splenomegaly and a lacy erythematous rash on the neck and torso. On admission, creatinine was 3.15 mg/dL (baseline 1.7 mg/dL, last year) with gross hematuria, and new pancytopenia. Initial work-up for glomerular disease was non-diagnostic. He developed persistent cyclical fevers to 102°F during his hospital stay. Blood cultures, tagged WBC scan and TEE were negative. Kidney biopsy showed numerous electron-dense deposits suggestive of Membranopro-Proliferative Glomerulonephritis. H. capsulatum serology and culture were positive. CT scan of chest showed right hilar lymphadenopathy. The patient regularly cleaned a chicken coop. An infectious work-up found the patient to be strongly positive for the Histoplasma capsulatum urinary antigen. With itraconazole for histoplasmosis and concomitant steroid therapy for glomerulonephritis, he defervesced and his creatinine improved to 1.4 mg/dL.

Discussion: Infection Related Glomerulonephritis (IRGN) is an immune-mediated disease caused by non-renal pathogens. The incidence is higher in developing countries: for example, per 100,000 individuals, the incidence of cases per year is 39 in India and 0.78 in the United States. It is believed that sub-clinical IRGN is common and underdiagnosed. In a series of 1012 kidney biopsies, 10% had evidence of disease, such as subepithelial humps. Hematuria is present in > 80% of cases, and patients usually present with Nephritic Syndrome. Endemic mycoses as a cause of glomerular disease in humans are rare. An infection due to H. capsulatum can result from inhalation of aerosolized spores after disruption of chicken droppings harboring the fungus. We suspected endocarditis given his cardiac history, and kidney biopsy findings also supported infection. However, the splenomegaly, FUO, and exposure to fowls (FUOwls) established the diagnosis.

FR-P0015
Next Generation Sequencer Driven Exome Analyses Identified a MCKD1 Family with New Mutation Before VNTR Of MUC1 DNA Sequence, Suffering from Mucosal Dysfunctions Satoko Yamamoto, Jun-Ya Kaimori, Masaki Hatanaka, Naotsubo Ichiumi, Shiro Takahara, Hiroaki Rakugi, Yoshitaka Isaka. Dept of Advanced Technology of Transplantation, Osaka University Graduate School of Medicine, Suita, Osaka, Japan.

Introduction: Hereditary tubulo-interstitial nephritis (h-TIN) is characterized by family history, bland urine, normal size kidney, hyperuricemia, renal fibrosis and gradual renal function loss. MCKD1 type h-TIN is also recognized by the difficulty to identify mutant sequence by conventional Sanger Sequencer or next generation sequencing, because the cytoseine insertion mutation locates in the GC rich valuable number tandem repeat (VNTR) region. The mutant MUC1 DNA sequence is supposed to produce truncated type protein, which is inferred to be trafficking to the cell membrane. Because of the difficulty of identification, there may be lots of unknown symptoms in MCKD1.

Case Description: We identified 5 hereditary TIN patients in a family, three of those are renal transplant recipients, and the other was CKD. The CKD patient is 23 y/o female, whose renal function is gradually reducing for 10 years. Now her serum creatinin is over 3. Her renal MRI images showed normal size kidneys with no cysts. The patients are suffering from mucosal dysfunctions including GI ulcer, sinusitis, and dysphagia. We analyzed genome DNA sequence of hereditary TIN family by next generation sequence driven trio exome analyses. They revealed that the 2 bp deletion mutation were located before VNTR. Interestingly, consequently produced mutant MUC1 protein is a truncated protein with almost the same a.a. sequence repeats with previously reported mutant protein. The results were confirmed in the further analyses of other family members by conventional Sanger sequencer.

Discussion: We could identified the totally new mutation sequence of MCKD1 family, because it located before the GC rich VNTR sequence of MUC1. The newly identified mutant protein showed the almost same a.a. repeats sequence, suggesting these repeat sequence is implicated in the pathophysiology of MCKD1 type h-TIN.

FR-P0016
Propofol-Induced Hyperkalemia in a Hemodialysis Patient Ibrahim M. El-Ali, Chandana Shekar, Sarthak Virmuni, Ruchir D. Triivedi. Dept of Medicine, Div of Nephrology, Univ of Connecticut Health Center, Farmington, CT.

Introduction: Propofol induced hyperkalemia and propofol infusion syndrome are well described in the intensive care literature. Propofol induced sudden cardiac arrest, however, may be under recognized. We report a case in which a large bolus of propofol was associated with an acute increase in serum K+ precipitating potentially fatal cardiac arrhythmia.

Case Description: A 58 yo Caucasian male with a past history of hypertension presented a week after developing an acute hyperkalemia rash associated with fever, encephalopathy, and atrial fibrillation, which was preceded by a month history of intermittent night sweats, fever, and joint pain. The desquamating rash encompassed >30% BSA with mucosal involvement. Skin biopsy revealed acute vacuolar interface dermacits consistent with toxic epidermal necrolysis (TEN). Labs showed pancytopenia without evidence of hemolysis. Serum Cr was 2.14 mg/dL (recently 0.9) and urine Protein/Cr was 1.15. Urine microscopy showed numerous acanthocytes and a few RBC casts. Serologies revealed low C3 and C4, positive ANA 1:640 and ENA screen, but negative ANCA, cryoglobulins, infectious work up and antibodies to ds-DNA, Sm, RNP, Ro/SSA, La/SSB, Jol and Scl70. A kidney biopsy revealed acute tubular injury and mild mesangial and endothelial proliferation without crescents or tuft necrosis. Immunofluorescence revealed diffuse 1-2+ staining for IgG, IgA, IgM, C3, C1q, kappa and lambda in the mesangium and capillary walls. Electron microscopy showed mesangial and capillary deposits with 20nm non-branching fibrils. Congo red stain was negative and IgG subclass stain did not reveal monoclonality. The findings were classified as a fibribillary glomerulonephritis. After initial methylprednisolone pulse, treatment with oral prednisone and mycophenolate mofetil resulted in resolution of rash, encephalopathy, and recovery of renal function and cell counts. The unifying diagnosis was new onset SLE, with TEN (possibly precipitated by naproxen) and fibrillary glomerulopathy.

Discussion: This case illustrates an uncommon presentation of an immune complex mediated fibrillar glomerulopathy consistent with SLE in an older male patient who presented with TEN. SLE has been rarely implicated as a cause of SJS/TEN when associated with initial photodistribution, absence of genital involvement, and a prolonged course.

We report a case of SIADH associated with acute motor and sensory axonal neuropathy (AMSAN), a variant of GBS.

**Introduction:** Although lower urinary tract and kidney malformations account for 40% of childhood ESRD it is a rare cause of kidney failure in adults. Mutation in the HNF1α gene and homozygous loss-of-function mutation of muscarinic receptor M3 (CHRM3) were described. CHRM3 is the major receptor mediating urinary bladder contraction upon micturition. These patients have normal urethral patency on cystogram and detrusor hyporeflexia with high residual volumes after micturition seen on cystometry, identical to the findings in our report. This diagnosis in a 25 year old is rare, as most patients do not survive until adulthood or they are already ESRD.

**Case Description:** A 76-year-old woman with ADPKD was again admitted by infected (1L) renal cyst (7.3 cm) on ultrasonography (US) with similar episode, 1 yr ago. She presented with a fever, dysuria and left CVA tenderness. Despite clinical and laboratory improvement with sensitive antibiotics against Klebsiella pneumonia for 14 days, the size of the infected renal cyst was paradoxically enlarged (8.9 cm) on follow-up US. Thus, percutaneous catheter was inserted for drainage and after 1 wk, tubogram showed no evidence of dye leakage (figure1-A). Following complete clinical recovery, absolute ethanol sclerotherapy was performed to prevent further recurrent cyst infection. However, she complained of severe burning pain in low abdomen at the beginning of the procedure. Tubogram dye was shown in pelvicalveal system and ureter (figure1-B). Sclerotherapy was immediately stopped and saline irrigation was followed. Then, percutaneous catheter was remained into the cyst for further draining, and double-J catheter was inserted at ureteropelvic junction to prevent a ureteral stricture. Then, she underwent uneventful hospital course, and discharged on hospital day 42.

**Discussion:** Infected renal cyst wall, despite clinical recovery, could consist of already damaged tissue that may be easily broken by ethanol. Through this unexpected adverse complication, we learned that cyst ablation therapy with ethanol may not be an appropriate modality to prevent recurrent renal cyst infection in ADPKD.

**FR-PO019**

How ‘Idiopathic’ Is Idiopathic Hyperammonemia? Esho Georges, Kakitha Vellanki. Nephrology, Loyola Univ Medical Center, Maywood, IL.

**Introduction:** Idiopathic hyperammonemia is characterized by progressive elevations in serum ammonia of unknown etiology, ultimately leading to cerebral edema and death. It is a rare fatal syndrome described in transplant setting; lung transplant recipients having the highest risk. Calcineurin inhibitors are thought to play a role but the exact mechanism is not known. Here we report an unusual case of severe hyperammonemia that has been linked to donor transmitted Ureaplasma infection.

**Case Description:** A 59-year-old Hispanic man with idiopathic pulmonary fibrosis received bilateral lung transplant at our center. His induction regimen included thymoglobulin and methylprednisolone and was maintained on tacrolimus, mycophenolate and prednisone. He received intravenous antibiotics and improved clinically.

**Discussion:** Serum ammonia levels of such a magnitude despite aggressive dialysis is unheard of. It is a rare fatal syndrome described in transplant setting; lung transplant recipients having the highest risk. Calcineurin inhibitors are thought to play a role but the exact mechanism is not known. Here we report an unusual case of severe hyperammonemia that has been linked to donor transmitted Ureaplasma infection.

**Discussion:** In conclusion; underlying infection with urea splitting organisms need of further studies, it may be worthwhile to empirically treat with azithromycin for urea-splitting organism infections.

Pelvocalyceal Leakage on Ethanol Sclerotherapy for Recurrent Infected Renal Cyst in ADPKD Eunyoung Lee, Joo-Hark Yi, Sang-Woong Han, Ho-Jung Kim. Division of Nephrology, Dept of Internal Medicine, Hanyang Univ Guri Hospital, Guri-si, Gyeonggi-do, Republic of Korea.

**Introduction:** Though sclerotherapy has been commonly considered as a safe and effective treatment for symptomatic renal cysts, it’s effectiveness in recurrent infected renal cyst in autosomal dominant polycystic kidney disease (ADPKD) is rarely reported.

**Case Description:** A 76-year-old woman with ADPKD was again admitted by infected (1L) renal cyst (7.3 cm) on ultrasonography (US) with similar episode, 1 yr ago. She presented with a fever, dysuria and left CVA tenderness. Despite clinical and laboratory improvement with sensitive antibiotics against Klebsiella pneumonia for 14 days, the size of the infected renal cyst was paradoxically enlarged (8.9 cm) on follow-up US. Thus, percutaneous catheter was inserted for drainage and after 1 wk, tubogram showed no evidence of dye leakage (figure1-A). Following complete clinical recovery, absolute ethanol sclerotherapy was performed to prevent further recurrent cyst infection. A CD2AP Mutation (p.T374A) Associated with Cognitive Decline and Focal Segmental Glomerulosclerosis in Young Adulthood Dmitry Tsvekeyov,1 Yolanda Marie Anistan,1 Christian Harteneck,2 Maik Gollasch,1 Charité Univ Medicine Berlin, Nephrology/Intensive Care, Experimental and Clinical Research Center (ECRC) and Max Delbrück Center for Molecular Medicine, Berlin, Germany; 1Dept of Pharmacology and Experimental Therapy, Inst of Experimental and Clinical Pharmacology and Toxicology, Eberhard Karls Univ Hospitals and Clinics, and Interfaculty Center of Pharmacogenomics and Drug Research, Univ of Tübingen, Tübi.

**Introduction:** Mutations in CD2-associated protein (CD2AP) gene have been identified in patients with focal segmental glomerulosclerosis (FSGS); however, reports of CD2AP mutations remain scarce.

**Case Description:** We performed Sanger sequencing in a 32-year-old patient with steroid-resistant FSGS presented with a nephrotic syndrome (proteinuria >3.5 g/day). The patient reported that his mother and his only brother also have a kidney disease. Neurological examination showed a remarkable cognitive decline within the last 5 years. Therapy with steroid and low-intermediate doses of cyclosporine A led to a persistent reduction of proteinuria. Serum creatinine levels and glomerular filtration rate (eGFR) did not decline during this treatment.

**Discussion:** Our patient displayed mild cognitive decline, a phenotypic characteristic not previously associated with CD2AP-associated FSGS. His proteinuria was remarkably reduced by treatment with cyclosporine A. Our findings expand the genetic spectrum of CD2AP-associated disorders and broaden the associated phenotype with the co-occurrence of cognitive decline. Our case shows that cyclosporin A is a treatment option for CD2AP-associated nephropathy.

**FR-PO022**

Acute Motor and Sensory Axonal Neuropathy-Associated Syndrome of Inappropriate Antidiuretic Hormone Secretion Weeraporn Sirung,1 Aumyot Prongdong,1 Pavis Laengvejkal,2 Camilo Pena,1 Mustafa G. Aly,1 Sorot Phisitkul.1 Internal Medicine, TTUHSC; 1Neurology, TTUHSC.

**Introduction:** SIADH is associated with various conditions including Guillain–Barre’ syndrome (GBS). We report a case of SIADH associated with acute motor and sensory axonal neuropathy (AMSAN), a variant of GBS.
Case Description: A 36-year-old man presented with a 6-week history of progressive ascites, weight gain, and edema. Examination showed ascites with questionable weakness, more severe in the LLEs, muscle wasting, absent LE reflexes, dysesthesis and no cranial nerve involvement. MRI head/spine was unremarkable. CSF analysis showed albuminocytologic dissociation and ruled out infection. HIV, viral hepatitis and paraproteinemias were absent. SIADH and AMI were ruled out. However, G1 and GQ1b were negative. Nerve conduction study showed axonopathic pattern on motor and sensory fibers bilaterally. AMSAN was diagnosed. He received IV immunoglobulin with gradual improvement of his weakness. On admission, serum chemistry panel showed Na 115 mmol/L with normal Cr. Urine showed Na <20 mmol/L, and specific gravity 1.045. Urine Osm was not available initially. He received NS infusion for volume expansion. Interestingly, Na did not significantly improve after he became euvolemic. Fluid restriction was then tried with mild improvement. Endocrine work-up ruled out hypothryoidism and adrenal insufficiency. Repeat labs showed serum Na 124 mmol/L, urine Na 191 mmol/L and urine Osm 531 mOsm. Hence, SIADH was diagnosed. Other well-established causes of SIADH were ruled out thus AMSAN was believed to be the most likely cause of SIADH. Tolvaptan was started at 15 mg and resulted in significantly increased urine output (300-500 ml/hr). Na increased rapidly so DSW was started to prevent osmotic demyelination syndrome. Tolvaptan was restated at 7.5 mg 2 days later with prompt response. He was discharged on tolvaptan 7.5 mg daily with Na 130 mmol/L.

Discussion: Although GBS is a well-established cause of SIADH, but to our knowledge, AMSAN-associated SIADH has only been rarely reported in literature. We suggest that AMSAN should be high on the differential diagnosis for hyponatremia in patients with AMSAN, especially in the setting of euvolemia.

FR-P0023
Severe Renal Osteodystrophy as a Result of Fanconi Syndrome Rabie L. Adam-Eldien, Charles W. Heilig. Nephrology, Univ of Florida, Jacksonville, FL.

Introduction: Fanconi syndrome is a disease of the proximal renal tubules in which glucose, amino acids, uric acid, phosphate, bicarbonate and other substances are not reabsorbed and lost in the urine.

Case Description: 22 year old African American female with an autosomal dominant Fanconi syndrome. Her disease is clinically manifested by severe rickets and short stature. Her short stature has not responded to growth hormone. She has multiple stress fractures, and she amputates with a walker. Her disease is manifested chemically by generalized aminoaciduria, hyperchloremic metabolic acidosis, hyperphosphaturia, glucosuria, bicarbonaturia, and proteinuria. Her life compliance with the medication has been poor. She has a gastrostomy tube for medications administration. Her medications include Calcium Carbonate, Neutra-Phos, Rocaltopol, Polycitra and Zantac. Her physical examination showed: Height 98.5 cm, weight 15.8 kg, blood pressure 106/57, pulse 80. She can stand up with hips flexed and her trunk slightly forward because of the anterior and lateral bowing of the femur and the widening metaphyses of the knees and the wrists. She has rickety change, ankle prominence, and she has good range of motion. Extremities: Have severe rickety changes. Lower extremities are deformed with prominent femur curve bilaterally. The rest of her exam was uneventful.

Urinalysis shows glucose 100 mg/dL, ketones 40 mg, blood trace, pH 7, protein greater than 300 mg. Chemistry showed, Sodium 134, potassium 3.4, bicarbonate 31, chloride 112, glucose 142, BUN 5, creatinine 0.6, calcium 7.9, phosphorus 3.8. Osmolality 268.

Discussion: Acute intermittent porphyria (AIP) is a rare metabolic disorder. Polyuria is a common manifestation of many primary medical disorders. Here we present a case of Acute intermittent porphyria (AIP) with decreased urinary osmolality, and high urine sodium indicating a mechanism other than Diabetes insipidus. After the solute load was reduced the solute intake of the patient but first and foremost requires an accurate diagnosis.

FR-P0024

Introduction: Infective endocarditis can cause renal failure due to immune complex mediated glomerulonephritis. We present a case of Nontuberculous mycobacterium (NTM) endocarditis associated with acute glomerulonephritis with tubulointerstitial nephritis.

Case Description: Our patient was a 59 y/o Venezuelan man with a history of cocaine use who presented with generalized weakness, intermittent nausea, and a 40lbs weight loss. He denied taking any antibiotics or illicit drugs for the previous month. On examination, he was afibrile, HR 85, BP 112/43mmHg. Pulmonary exam was unremarkable, and heart rate was 85. Auscultation revealed a 3/6 holosystolic murmur at the right upper sternal border. JVP was not elevated. She was afebrile, HR 85, BP 112/43mmHg. Pulmonary exam was unremarkable, and heart rate was 85.

He denied taking any medications or illicit drugs for the previous month. On examination, his exam was unrevealing.

He has a gastrostomy tube for medications administration. Her medications include Calcium Carbonate, Neutra-Phos, Rocaltopol, Polycitra and Zantac. Her physical examination showed: Height 98.5 cm, weight 15.8 kg, blood pressure 106/57, pulse 80. She can stand up with hips flexed and her trunk slightly forward because of the anterior and lateral bowing of the femur and the widening metaphyses of the knees and the wrists. She has rickety change, ankle prominence, and she has good range of motion. Extremities: Have severe rickety changes. Lower extremities are deformed with prominent femur curve bilaterally. The rest of her exam was uneventful.

Urinalysis shows glucose 100 mg/dL, ketones 40 mg, blood trace, pH 7, protein greater than 300 mg. Chemistry showed, Sodium 134, potassium 3.4, bicarbonate 31, chloride 112, glucose 142, BUN 5, creatinine 0.6, calcium 7.9, phosphorus 3.8. Osmolality 268.

Discussion: Acute intermittent porphyria (AIP) is a rare metabolic disorder. Polyuria is a common manifestation of many primary medical disorders. Here we present a case of Acute intermittent porphyria (AIP) with decreased urinary osmolality, and high urine sodium indicating a mechanism other than Diabetes insipidus. After the solute load was reduced the solute intake of the patient but first and foremost requires an accurate diagnosis.

FR-P0025
Severe Hyponatremia in a Young Patient with Recurrent Abdominal Pain Dimpu M. Patel, Manish K. Saha, Ashita J. Tolwani. Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.

Introduction: Acute intermittent porphyria (AIP) is a rare metabolic disorder. Hyponatremia due to syndrome of inappropriate secretion of diuretic hormone (SIADH) during acute attacks of AIP requires prompt diagnosis and treatment of both AIP and hyponatremia.

Case Description: A 21yo Asian female presented to the ED with sharp intermittent abdominal and flank pain. Upon arrival to the ED, she had a generalized toxic-clonic seizure requiring intubation for airway protection. She denied any medications or illicit drugs for the previous month. Her only medications were trimethoprim-sulfamethoxazole and ibuprofen prescribed 2 days prior. Clinical exam revealed tender abdomen, right upper quadrant tenderness, and high urine osmolality (350 mOsm/kg). She was treated with a carbohydrate based diet and avoidance of medications known to precipitate an acute attack.

Discussion: AIP results from a deficiency of PBG deaminase, leading to accumulation of 5,10-dihydroxy-δ-aminolevulinic acid (ALA)-delta 7 and ALA-delta 6, which are degraded by PBG deaminase. Urinary ALA-delta 7 is increased. The metabolism of ALA-delta 7 and ALA-delta 6 are mediated by hematopoietic enzymes and it can be caused by a drug or accompanies another genetic disorder. In hereditary Fanconi syndrome, proximal tubular acidosis, hyperphosphatemic rickets, hypokalemia, polyuria, and polydipsia usually appear in infancy. If a patient is unable to keep up with the replacement of these substances secondary to compliance or lack of access, adverse permanent skeletal effects might result from that.

FR-P0026
A Case of Solute Diuresis Muhammad K. Qaseem, Elizabeth A. Gilliams, James L. Bailey. ’1 Emory Univ School of Medicine, At: ’EUH.

Introduction: Polyuria is a common manifestation of many primary medical disorders. Here we present a case of Argininosuccinate Lyase Deficiency(ASLD) who presented with altered mental status and later developed polyuria.

Case Description: A 24-year old male with history of ASLD was admitted to the Intensive Care Unit (ICU) for altered mental status with an ammonia level of 347mcnmol/L. He was started on Ammonia Scavenger therapy with Ammonium/arginine, Na-benzoate and bi-phenylacetate (BPA). On hospital day 10 he developed hypokalemia, hypernatremia and polyuria of 5L. His labs are listed below.

<table>
<thead>
<tr>

Urine studies showed urine Sodium of 253mmol/L, urine Potassium of 59mmol/L, urine chloride of 175 mmol/L, urine anion gap of 137, urine osmolality of 63 mOsm/kg and urine Creatinine of 63 mg/dL with a 5.3L of urine in 24 hours. He was receiving Normal Saline, Ammonium and Total Parenteral Nutrition(TPN). It was recommended to stop the infusion of ammonium to decrease the non-measured anions in the urine, stopping 5%normal saline and change the TPN to have less solute load. With these interventions his urine output and hypokalemia improved to almost back to normal.

Discussion: Argininosuccinate Lyase deficiency results in the breakdown of argininosuccinic acid to arginine and fumarate. ASLD can result in severe hyperammonemia. Treatment of acute decompensations with hyperammonemia involves discontinuing oral protein, using intravenous arginine and ammonia scavenging therapy. Polyuria in ASLD could be due to different mechanisms such as low BUN leading to poor urine concentrating ability with loss of free water or due to solute diuresis. Our patient’s high urine osmolality and high urine sodium indicated a mechanism other than Diabetes insipidus. After the solute content was decreased his urine osmolality decreased significantly along with his urine output. Hypernatremia also improved. Management of solute diuresis in this case was to reduce the solute intake of the patient but first and foremost requires an accurate diagnosis.
Life Threatening Hypokalemia and Metabolic Alkalosis Related to Paraneoplastic Cushing’s Syndrome
Chyi Chyi Chong, 1 Pallavi D. Shirsat, 1 Ramesh Marahatta, 1 Cheri N. Adgh, 2 Neville R. Dossabhoy. 2
1LSU Health Science Center, Shreveport; 2VA Medical Center, Shreveport.

Introduction: Paraneoplastic Cushing’s syndrome (CS) develops secondary to tumor-affected ACTH. In the case of severe hyponatremia, with metabolic alkalosis related to ectopic ACTH production.

Case Description: A 58 y/o African American male presented with complaints of feeling unwell, weight loss and frequent diarrhea for at least one month. On admission, he was normotensive. On physical exam, patient had mild wheezes at bases. Laboratory data was significant for Na 144 mEq/L, K 1.1 mEq/L, Cl 82 mEq/L, HCO3 50 mEq/L, BUN 14 mg/dl and Cr 1 mg/dl. Blood gas revealed pH 7.4, PCO2 92 mmHg, PO2 92.4 mmHg and HCO3 47 mmol/L. Pt unfortunately developed respiratory failure requiring intubation shortly after albuterol nebulizer treatment. He was also receiving Diamox in ICU. He required potassium supplement on average of 120 meq per day (Maximum 300 meq/day). Once diarrhea resolved and with discontinuation of Diamox, patient was still noted to be hypokalemic. Urine electrolytes performed: Na 31 mmol/L, K 107 mmol/L, Cr 41 mg/dL. Additional lab data: Renin <0.15 ng/ml/hr, Aldosterone <1 ng/dl, ACTH level 126 pg/ml and 24hr urine cortisol 3846 mg.

Discussion: This is a rare case of paraneoplastic CS associated with neuroendocrine carcinoma. Early recognition and appropriate treatment for this syndrome is important, although overall clinical outcome remains poor.

FR-PO28

Overcorrection of Hyponatremia Secondary to Diuresis in Postpartum
Maria Berenice Nava, 1 Maya K. Rao. 2 Div of Nephrology, Columbia Univ, New York, NY; Div of Nephrology, Columbia Univ, New York, NY.

Introduction: Previous case reports have described hyponatremia in pre-eclampsia particularly with twin gestations. Overcorrection in the post-partum period is a potential risk and complications manage.

Case Description: Case report.
30 yo woman G1P0 with intrauterine insemination with triplets presented at 30 weeks gestation with pre-eclampsia and nephrotic syndrome for emergent cesarean section. On presentation she was hypertensive, massively edematous found to have a serum sodium of (sNa) 126 mEq/L (no prior values), serum creatinine 0.5 mg/dL and albumin 2.4 g/dL. Urine osmolality was 159 mOsm/kg and the urine osmolality was 263 mOsm/kg, urine sodium 21 mEq/L. Spot urine protein:creatinine ratio 3.5 grams. By POD 2, her sNa decreased to a nadir of 119 mEq/L and spot protein: creatinine ratio was 0.458 grams. Free water restriction was started. She soon began to auto-diurese (2.6L in 4hrs) resulting in a rise in sNa to 127 mEq/L in 5 hrs with a urine osmolality of 159 mOsm/kg. She was started on DDAVP to 0.04IU/hr and sNa levels were checked every 4 hrs. Her subsequent sodium levels remained at 127 mEq/L over the next 12 hrs. On POD 0 she was noted to be hypokalemic. Urine output decreased to <100ml/hr on POD 4, urine osmolality was 217 mOsm/kg, therefore DSW was discontinued. She received 4 additional doses of DDAVP. The patient was ultimately discharged on POD/10 with a sNa of 143 mEq/L and off DDAVP.

Discussion: Hyponatremia in pre-eclampsia with nephrotic syndrome has been reported in the literature and it is thought to be secondary to low effective circulating plasma volume. In this case, we report rapid correction of serum sodium post-delivery likely due to volume redistribution and removal of ADH stimulus. Awareness of potential rapid correction and frequent monitoring of serum sodium is important in order to intervene early and prevent consequences of rapid sodium correction. Serum sodium post-delivery should be monitored very closely in cases such as these.

FR-PO29

Severe Hypocalemia in a Hemodialysis Patient

Introduction: Severe hypocalemia in a hemodialysis patient is rare in the absence of parathyroidectomy, vitamin D deficiency or calcitriol medications.

Case Description: A 58 year-old man was found to have severe asymptomatic hypocalemia (5.9 mg/dL) with prolonged QTC (547 ms) four weeks after starting hemodialysis. He had a history of prostate cancer treated with radical prostatectomy, bisphosphonates and a GnRH analog. Serum calcium prior to starting hemodialysis was 8.6 mg/dL; serum albumin 3.2 gm/dL, PTH 352 pg/mL, 25OH Vitamin D2 =<4ng/mL, 25OH Vitamin D3 12 ng/mL and phosphorus 6.3 mg/dL. His intravenous doxelcalciferol dose was titrated to 20 mcg thrice weekly; oral calcium carbonate and 1,25-dihydroxycholecalciferol were administered orally. Dialysate calcium concentration was increased to 3.5 mg/dL. However, despite these measures, pre-dialysis calcium was 6 mg/dL. On further review, it was found that he had been started on denosumab six weeks prior to initiation of hemodialysis for bone pain due to skeletal metastases. Denosumab is a monoclonal antibody against RANKL (a ligand for receptor of nuclear factor kappa-B ligand). Tumor cells in patients with skeletal metastases stimulate osteoblast to secrete RANKL, which stimulate osteoclast to promote osteolysis and increase calcium levels. Even after replenishing Vitamin D stores, our patient continues to need higher dialyse calcium.

Discussion: Common causes of hypocalcemia in dialysis patients include: vitamin D deficiency, autoimmune or surgical hypoparathyroidism, severe hyperphosphatemia due to tumor lysis or rhabdomyolysis and medications such as cinacalcet. Denosumab is an easily overlooked cause of hypocalcemia. Our patient had Vitamin D deficiency but normal calcium level prior to starting denosumab. It is important to replete vitamin D and calcium stores prior to initiating denosumab in patients with chronic kidney disease as they may have resistance to standard therapy for hypocalcemia. It is also recommended to check calcium levels regularly while on this medication.

FR-PO30

Central Diabetes Insipidus with Pituitary Atrophy from Chronic Lithium Use
Joe Ghata, Satish Kumar. Nephrology, Univ of Oklahoma Health Science Center; Oklahoma City, OK.

Introduction: Lithium use is commonly associated with nephrogenic diabetes insipidus (NDI) and rarely with central diabetes insipidus (CDI). The mechanism of Lithium associated CDI is unclear. We report a patient on chronic lithium therapy who developed CDI and partial NDI and who had atrophy of posterior pituitary atrophy on MRI.

Case Description: A 62 yo woman with diabetes mellitis 2 for 5 years, hypertension for 10 years, and bipolar disorder on lithium for 40 years was admitted to the ICU for altered mental status. ROS was negative for nausea, vomiting, diarrhea, acute intoxication or infectious prodrome. Physical exam was normal; she was clinically euvolemic. Urine output was 4-8 ml/hr and serum Na was 178 mEq/L. Serum creatinine was 4.84 mg/dL elevated from a baseline of 1.5 in 2012. Urine osmolality (U osm) was <100 mosm/L. Intravenous D5W at 200 ml/hour resulted in improved serum creatinine to 1.7 mg/dl but minimal reduction in serum Na. Water restriction produced a submaximal rise (<250 mosm/L) in U osm from 157 to 176. ADH levels were undetectable by RIA when serum Na was 165-175. Intravenous desmopressin produced submaximal elevation in urine osmolality from 80 to 153 (91.25%), consistent with partial NDI (U Osm = 250 mosm/L) and partial CDI (<15 to 99%). MRI demonstrated atrophy of the posterior pituitary with non-specific volume loss, straightening of the infundibulum, and absence of bright spot corresponding to the posterior pituitary. Final diagnosis was both central and nephrogenic DI associated with lithium use. Euthyremia was eventually achieved with intranasal DDAVP and liberal fluid intake.

Discussion: This is the first report of radiological evidence of posterior pituitary atrophy with lithium-associated central DI. Possible mechanisms of posterior pituitary atrophy may include “burn-out” from chronic hypersecretion of ADH caused by lithium induced nephrogenic diabetes insipidus or autoimmune hypophysitis from circulating autoantibodies developed in response to chronic high ADH levels.

FR-PO31

Iatrogenic Hyponatremia

Introduction: Vasopressin acts in the kidney via V2 receptors to regulate water resorption and on the vasculature via V1 receptors to regulate smooth muscle tone. It is often used in the management of shock, but rarely causes hyponatremia in hemodynamically unstable patients. We present here a case of a man who developed marked hyponatremia during vasopressin infusion.

Case Description: A 58 year old man with history of hypertension and coronary artery disease was admitted to intensive care unit for un-witnessed cardiac arrest. He was intubated and started on vasopressin and norepinephrine for cardiacogenic shock. His lab data on admission revealed normal serum sodium, blood urea nitrogen and creatinine. His inpatient course was significant for development of hyponatremia within 2 hours of initiation of vasopressin infusion. Patient’s sodium dropped from 142 mosm/L(normal range 136-146 meq/L) to lowest value of 124 meq/L associated with oliguria (urine output 20ml/hr). With cessation of vasopressin, urine output increased significantly to 500ml/hr and serum sodium increased from 124 meq/L to 142 meq/L. Dextrose infusion was started to prevent overly rapid correction. Please refer to graph for the changes in serum sodium and urine output with vasopressin infusion over time. Patient had normal cortisol levels and thyroid function.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Discussion: Vasopressin does not usually result in hyponatremia when used in management of shock. Possible explanations include lack of renal responsiveness secondary to cardiovascular hyperperfusion/acute kidney injury, or lack of intake of hypotonic fluids. In this case, the patient developed marked hyponatremia in setting of preserved renal function.

FR-PO032

Hyperkalemia Secondary to Octreotide Use in a Patient with Normal Kidney Function
Nephrology, Hofstra North Shore-LIJ School of Medicine, Great Neck, NY.

Introduction: Octreotide, a somatostatin analogue works by reducing blood levels of a variety of hormones (e.g. growth hormone, insulin) and chemical messengers (e.g. gastrin, vasoactive intestinal peptide). Octreotide therefore has been used as an effective medication for the treatment of sulphonylurea-induced hypoglycemia, acromegaly, VIPoma and carcinoid syndrome. Octreotide-induced hyperkalemia has rarely been reported in the literature. We report a patient with normal renal function who developed hyperkalemia secondary to octreotide use.

Case Description: A 70-year-old male with long standing history of DM (since 20 years), HTN, and metastatic neuroendocrine pancreatic cancer was referred by his oncologist for evaluation of severe hyperkalemia (serum potassium level of 6.6 mmol/L). Patient was diagnosed with pancreatic neuroendocrine tumor approximately 2 years prior to his presentation for which he underwent Whipple procedure. He was also receiving subcutaneous octreotide monthly for nearly 1.5 years prior to his presentation. There was no history of kidney disease or any urinary complaints. Other medications included aspirin, insulin, creon, levotiroxine and HCTZ. BP was normal and patient was noted to have bilateral lower extremity pitting edema on examination. Other labs done 5 days prior to presentation showed normal serum bicarbonate (25 mmol/L), normal serum creatinine (1.23 mg/dL), and elevated serum glucose (263 mg/dL). On reviewing medical records, our patient was noted to have chronic and persistent hyperkalemia over the previous six months that was medically managed by intermittent oral sodium polystyrene sulfonate and potassium diet. All other causes of hyperkalemia were clinically excluded. Serum potassium normalized after receiving medical management and holding octreotide treatment.

Discussion: We present a rare case of octreotide-induced hyperkalemia in a patient with normal renal function. We believe that hyperkalemia in our patient occurred as a result of octreotide-induced insulin suppression and resultant impaired cellular potassium uptake. Based on our experience, one should be aware of this potential life-threatening side-effect of octreotide therapy.

FR-PO033

Hypercalcemia and Acute Kidney Injury due to Immune Reconstitution Syndrome in an HIV Patient on HAART and MAC Therapy
Anand Achangti, Omar M. Shahateet, Karl Berthold Pemmbur, Nithin Karakala, Juan Carlos Q. Velez.
Nephrology, Med Uni of South Carolina, Charleston, SC.

Introduction: Hypercalcemia can occur in HIV-infected patients due to several conditions such as granulomatous diseases, lymphomas, and solid tumors. HIV patients are also susceptible to causes found in the general population, such as primary hyperparathyroidism, medications, and vitamin D supplementation.

Case Description: A 48 year old male with history of HIV and disseminated Mycobacterium avium complex (MAC) was sent to the hospital after being found to have a serum calcium of 15.5 mg/dL and serum creatinine of 5.8 mg/dL on routine labs. His only complaint was weakness. Five months prior to presentation, patient had an adjustment of his highly active antiretroviral therapy (HAART) with a viral load of 76,000 copies/mL, CD4 count of 36/CLMM, serum calcium of 9.6 mL/dL, and serum creatinine of 2.6 mg/ dL at that time. Previous renal dysfunction was caused by interstitial nephritis diagnosed 6 weeks prior. Patient reported increased compliance to his new regimen for several weeks prior to presentation, reflected by an increase in CD4 count of 138 (CLMM earlier and undetectable viral load upon presentation. Workup for hypercalcemia included: low PTH of 5.8 pg/mL, low PTH-rp of 0.7 pmol/L, and a high 1,25 Vitamin D of > 200 pg/mL. Serum and urine protein electrophoresis showed a restricted kappa lambda ratio and bone marrow biopsy were normal. Imaging was negative for lymphoma. The patient was managed with volume repletion, probenecid 600 mg/d, and IV pamidronate 60 mg with gradual improvement of his calcium to 8.8 mg/dL and creatinine to 2.8 mg/dL in 9 days. Steroids were tapered and the patient remained stable 6 months later.

Discussion: Our patient developed acute kidney injury secondary to severe hypercalcemia, likely due to renal vasoconstriction and volume depletion superimposed over interstitial nephritis. The etiology of hypercalcemia was likely immune reconstitution syndrome caused by the restoration of HAART. In patients with HIV and AIDS with history of granulomatous disease, it is important to monitor for hypercalcemia when initiating HAART therapy or adjusting therapy.

FR-PO034

Hypocalcemia in Severe Malnourishment, and Acute Pancreatitis Veils Vitamin D Intoxication
Nephrology, Stony Brook Univ Medical Center, Stony Brook, NY.

Introduction: Although vitamin D has a wide therapeutic index, a routine use of high doses of vitamin D intake can cause toxicity. We report a case with severe hypocalcemia likely due to malnourishment and pancreatitis related to alcoholism followed by hypercalcemia from vitamin D toxicity.

Case Description: A 43 year-old woman with alcoholism was admitted with rhabdomyolysis and alcohol induced acute pancreatitis. On initial examination she was in moderate distress with altered mental status and diffuse abdominal pain. Her blood pressure was 102/67 mmHg, heart rate 136/min and temperature 38.3°C. Her lab data revealed WBC 54.71 mm3, Hb 16.9 g/dL, PLTs 186 mm3, serum Na 129 mEq/L, K 3.5 mEq/L, bicarbonate 19 mEq/L, BUN 23.3 mg/dL, creatinine 1.3 mg/dL, sodium 133 mEq/L, potassium 1.7 mg/dL, CPK 1089 IU/L, albumin 2.9 g/dL. She received intravenous Ca, Mg, K and phosphorus in addition to oral supplements. On day 4, her serum Ca was 8.7 mg/dL, albumin 2.5 g/dL, phosphorus 4.0 mg/dL and K 3.9 mmol/L without any supplement. Her serum Mg remained low and continued to receive oral and intravenous Mg supplements. Serum Ca was not checked between days 9-14 of her hospitalization. On day 15, her serum Ca was 12.8 mg/dL, ionized Ca 6.4 mg/dL, vitamin D 25OH 370 ng/ml, vitamin D 1-25 OH 149 pg/ml and intact PTH 11.8 pg/ml. Her TSH, T4, ACE and vitamin A levels were normal. Her 24 hours urine revealed Na 140 mEq/L, K 70 mEq/L, creatinine 1110 mg, UN 4.1 g, Ca 462 mg, Mg 403 mg , phosphorus 931 mg. She admitted taking vitamin D 50,000 units daily for many months for her psoriasis on her own. Her hypocalcemia was treated and her serum calcium stabilized over one week to 9.4 mg/dL while her vitamin D 25OH and vitamin D 1-25 OH remained elevated over the next 6 weeks.

Discussion: Her unusual presentation of hypocalcemia masked vitamin D toxicity till she resumed regular nutrition. Her hypocalcemia was likely related to malnourishment due to chronic alcoholism and possible calcium deposition due to acute pancreatitis. With proper nutrition during her hospitalization and improvement of her underlying condition led to hypocalcemia due to vitamin D toxicity.

FR-PO035

Re-Defining the Speed Limit in Osmotic Demyelination Syndrome? Malrukh Rizvi, Rebecca D. Monk.
Nephrology, Univ of Rochester Medical Center, Rochester, NY.

Introduction: Osmotic demyelination syndrome (ODS) is a severe, debilitating, possibly fatal neuroanatomical condition that results from rapid correction of severe chronic hyponatremia. Imaging reveals central pontine myelinolysis (CPM). Potential added risk factors for ODS include Sodium (Na) < 120 mM/L, alcoholism, malnutrition and liver transplant. Current recommendations advise raising serum sodium by less than 9 mM/L in 24 hours. We present a case of ODS in a patient presenting with severe hyponatremia corrected at a maximum rate of 8mEq/dL in 24 hrs.

Case Description: A 37 year old man with a history of alcohol abuse was sent in to the hospital by police after a car accident for jaundice. He endorsed two weeks of worsening jaundice and right upper quadrant (RUQ) pain. Admission vital signs were stable. Physical exam revealed marked jaundice, abdominal distention and RUQ pain. Work up revealed severe alcoholic hepatitis with cirrhosis and metabolic derangements including a Na of 105 mM/L, chloride of 69 mM/L, Na urea nitrogen of 45 mg/dL, creatinine of 2.13 mg/ dL with unknown baseline. 3% saline with dDAVP was initiated for cautious correction of severe hyponatremia. Imaging reveals central pontine myelinolysis (CPM). Potential added risk factors for ODS include Sodium (Na) < 120 mM/L, alcoholism, malnutrition and liver transplant. Current recommendations advise raising serum sodium by less than 9 mM/L in 24 hours. We present a case of ODS in a patient presenting with severe hyponatremia corrected at a maximum rate of 8mEq/dL in 24 hrs.

FR-P0036  
A Case of Axenfield-Rieger Syndrome Presenting with Elevated Serum Bicarbonate  
Rudrick V. Ledesma, Maureen E. Brogan, Venkata Buddharaju, Rahul N. Pawar, Rajat Lamba.  Westminster Medical Center, NY.

Introduction: Elevated serum bicarbonate can often be misdiagnosed as metabolic alkalosis leading to improper management. Chronic respiratory acidosis caused by central hypoventilation can lead to elevated bicarbonate secondary to renal compensation. We present a case with alkalosis caused by cerebro-pontine lesion in a patient with Axenfield-Reiger syndrome (ARS).

Case Description: A 25 yo man with PMH of glaucoma, developmental delay, schizoid affective disorder sent to the ED for respiratory failure. He was seen earlier in renal clinic for treatment of elevated serum bicarbonate. He was complaining of fatigue and insomnia. Arterial blood gas was done and showed a pH of 7.30, pCO2 of 79, pO2 of 63 and HCO3 of 38.9. He was eventually admitted for further management. While in the hospital, he continuously needed bilevel positive airway pressure. Chest ultrasound showed little to no movement of his diaphragm. EMG was negative. PFT was suboptimal as he wasn’t able to follow the instructions. MRI brain showed a mass on his right cerebro-pontine angle. He was also diagnosed with ARS during his hospital stay. The mass was resected and progressive improvement was observed in his respiratory status. He was eventually weaned off bilevel positive airway pressure and was discharged home without any need for respiratory support.

Discussion: Elevated serum bicarbonate can often pose a diagnostic challenge. Evaluation should start with an ABG which would differentiate a primary metabolic alkalosis from a renal compensation of respiratory acidosis. Differential diagnoses for respiratory acidosis include central hypoventilation, primary lung pathology, neuromuscular disease and airway pathology. Central hypoventilation could be secondary to lesions in the respiratory center. ARS presents as a spectrum of developmental disorders resulting from abnormal migration and differentiation of neural crest cells with both ocular and systemic manifestations. The reason in the brain that may be affected are forebrain and pitorinary gland. Our case is interesting as he had ARS with epidermoid cyst which we believe has led to central hypoventilation and elevated bicarbonate as compensatory mechanism.

FR-P0037  
Signet-Ring Cell Carcinoma Presenting as Frequency of Urination  
Haya Waseem Siddiqui, Daniel E. Carl, Todd W. Gehr. Nephrology, Virginia Commonwealth Univ, Richmond, VA.

Introduction: Urinary tract obstruction may occur at any site in the urinary tract and is important to recognize early since it is readily reversible if quickly corrected.

Case Description: 45 year old male with obesity, history of gastric bypass surgery, hypertension and obstructive sleep apnea who presented to our institution for evaluation of frequency of urination. He developed progressively worsening frequency of urination, occurring every hour during the day and night for 3 months prior to presentation. During this time, his serum creatinine was 1.6 mg/dL. He had been seen multiple times by an Urologist and Primary Care Providers outside our institution, and was diagnosed with prostatitis despite negative urine cultures and no pyuria. During the work up, an outpatient CT scan revealed mild bilateral hydronephrosis and mild left hydroureter. Furthermore, an office cystoscopy revealed diffuse inflammatory cystitis of the bladder and no definitive bladder wall thickening. Over the ensuing 3-4 weeks, he developed acute kidney injury with a serum Cr that peaked at 6mg/dL. This prompted an admission to an outside facility.

He was again found to have mild bilateral hydrourerter, however, ureteral stents were attempted, but unsuccessful. A repeat cystoscopy revealed severely inflamed bladder tissue but no visible abnormality. Urinary bladder biopsy was done. Patient was transferred to VCU for placement of percutaneous bilateral nephrotoomy tubes by interventional. He had successful stent placement by IR followed by post obstructive diuresis treated with intravenous fluid hydration in the form of saline. His AKI improved as evidenced by peripheral edema evident on follow-up imaging study. His serum Cr improved to 1.3 mg/dL and repeat CT scan with intravenous contrast was obtained for staging which showed circumferential bladder wall thickening with asymmetric soft tissue prominence along the right anterior dome most consistent with bladder neoplasm. Outside pathology report was consistent with signet cell carcinoma of bladder.

Discussion: Signet-ring cell carcinoma a rare bladder tumor can result in acute kidney injury secondary to bilateral ureteral obstruction.

FR-P0038  
A Case of Tenofovir-Induced Nephrotoxicity  

Introduction: Tenofovir (TFV) is a nucleotide reverse-transcriptase inhibitor used for treatment of HIV and hepatitis B. Most studies suggest that TFV has only a modest effect on estimated glomerular filtration and severe nephrotoxicity is uncommon. We describe a case of tenofovir-induced nephrotoxicity.

Case Description: A 55 year old woman with HIV on TFV for several years, presented with vomiting and abdominal pain for 4 days. Physical exam was unremarkable. Laboratory data showed BUN 65 mg/dL, creatinine 9.07 mg/dL (baseline: normal), bicarbonate 12 mmol/L, glucose 137 mg/dL, HIV RNA: 21 copies/ml and CD4: 292 cells/ml, glycosuria and proteinuria (157mg/24 hours). Serological tests for autoimmune and infectious diseases were negative. Kidney biopsy showed proximal tubule (PT) injury and eosinophilic oval cytoplasmic inclusions on trichrome stain (fig a) with no definite glomerular or mesangial abnormalities. Electron microscopy (EM) showed PT cells with cytoplasmic swelling, loss of membrane integrity, accumulation of enlarged dysorphic mitochondria with intra-cristal widening and abnormal matrix appearance and loss of cristae (fig b) consistent with mitochondrial injury (MI) seen in TFV nephrotoxicity. Despite discontinuing TFV, she remained dialysis dependent.

Discussion: Currently available data supports renal safety of TFV in HIV patients. Severe renal dysfunction has only been reported sporadically. Although nucleoside reverse transcriptase inhibitors (adefovir) are known to impart mitochondrial reprogramming by interfering with DNA polymerase-γ, evidence linking TFV specifically to MI is limited. Our case implies that TFV can cause significant renal failure and MI. Monitoring renal function and urinalysis during TFV treatment is key for early detection of nephrotoxicity.

FR-P0039  
A Case of Severe Hypomagnesaemia in a Patient Treated with Trastuzumab  
Saifullah Kazi, Ghulam Akbar, Paul Robbins. Nephrology, Lankenau Medical Center, Wynnewood, PA.

Introduction: A case of invasive ductal carcinoma that was treated with chemotherapy including Trastuzumab found to have severe hypomagnesaemia requiring very aggressive repletion strategies.

Case Description: A 36 y/o non-alcoholic female with past medical history of hypertension well controlled on diet therapy, was diagnosed with invasive ductal carcinoma of the breast requiring initiation of chemotherapy with docetaxel and carboplatin with Trastuzumab. She received a total of 6 cycles of chemotherapy every three weeks and Trastuzumab was given weekly. After completion of chemotherapy, the dose of Trastuzumab was increased to 8mg per infusion every three weeks. Her serum magnesium level which was 2.1mg/dl in the beginning of chemotherapy was noted to be low at 0.5mg/dl when she presented with generalized weakness to the hospital six months into the treatment. At this time, she had completed her chemotherapy 2 months ago and now on Trastuzumab only. She was on lasix and proton pump inhibitors at that time, both of which were stopped immediately. However her serum magnesium remained low between 0.6-1.0 mg/dl persistently for next few months requiring intravenous infusions every week. On repeated testing, fractional excretion of magnesium remained high indicating renal magnesium wasting. Although patient was hypokalemic initially, it corrected immediately after stopping loop diuretics and remained normal following treatment using tubulopathies such as Gitelman or Bartter syndrome. She remained hypomagnesaemic despite completing one year course with Trastuzumab. She is receiving once a week intravenous infusions of magnesium 500mg with no further magnesium wasting. Although her serum magnesium remained low between 0.6-1.0 mg/dl persistently for next few months requiring intravenous infusions every week. On repeated testing, fractional excretion of magnesium remained high indicating renal magnesium wasting.

Discussion: Trastuzumab is a human epidermal growth factor (HER-2) inhibitor which belongs to the family of epidermal growth factor receptor (EGFR). EGFR is involved in increasing the magnesium absorption in the distal nephron by increasing the transcription of the genes regulating TRPM6 channel. Hypomagnesaemia has been well reported in other EGFR inhibitor with Cetuximab used in colon cancer and Erlotinib used in lung cancer, but not reported in patients taking Trastuzumab, especially after escalating to higher doses.

FR-P040  
Capecitabine Induced Acquired Bartter’s-Like Syndrome  
Eric A. Kirk, Jennifer Thompson, Juan Carlos Q. Velez, Nithin Karakala. Nephrology, MUSC, Charleston, SC.

Introduction: Many forms of chemotherapy carry a risk of electrolyte abnormalities. Capecitabine is an antimetabolite of the fluoropyrimidine carbamate class of chemotherapeutic agents. Phase I and II trials have reported hypomagnesaemia, hypokalaemia with hyperkaliemia as isolated electrolyte imbalances, and there are case reports of isolated hypomagnesaemia and reports of a relatively large number of patients with hypokalaemia. A Fanconi like pattern of electrolyte disorders has also been reported with capecitabine.

Case Description: A 68 year old female with neuroendocrine pancreatic cancer treated with capcitabine and temozolomide developed back spasms and was found to have severe hypokalaemia (2.4mmol/L), hypomagnesaemia (0.7mg/dL) hypocalcaemia (4.6mg/dL) and metabolic alkalosis (bicarbonate 30mmol/L) in the absence of vomiting or diarrhea 5 weeks after starting a 2 week course of capecitabine (1400mg/m2 divided twice daily). She had evidence of renal salt wasting with sodium 256.5mEq, potassium 51.8 mEq and calcium 500ng in a 24 hour urine collection. No evidence of hypoparathyroidism, with intact PTH 67.3pg/mL, 1,25 hydroxy vitamin D was 33pg/mL. Further capecitabine therapy was withheld. 24 hr urine collection was completed 1 week later with decreased renal loss of sodium, potassium and calcium and normalization of electrolytes.

Discussion: We present a case of life threatening hypokalaemia caused secondary to capcitabine. As the patient had metabolic alkalosis it was unlikely that the patient had Fanconi’s as described in some case reports. Our case is unique as this patient developed a combination of hypokalaemia, hypocalcaemia, hypomagnesaemia and metabolic alkalosis.
caused by capcitabine. The patient exhibited Barter’s like physiology with increased renal loss of calcium, magnesium, and sodium and evidence of metabolic alkalosis. Unlike the proximal tubulopathy associated with capcitabine, the pathophysiology of acquired Barter’s with is unknown but could be caused by direct inhibition of apical NaKCC or ROMK, or activation of the calcium sensing receptor on the basolateral surface in the thick ascending loop of Henle.

FR-PO041
Uncommon Case of Severe Hypercalcemia After Renal Transplantation Rapedrat Lekkham, Gitana Bradauskaite. Nephrology, Einstein Medical Center, Philadelphia, PA.

Introduction: Following renal transplantation, hypercalcemia is frequently caused by persistent hyperparathyroidism, but other causes should be kept in mind. We report a case of hypercalcemia after renal transplant from unregulated extrarenal 1,25-dihydroxyvitamin D synthesis from disseminated tuberculosis and cryptoccocus.

Case Description: The patient was a 59-year-old male with unknown etiology of ESRD who received a living unrelated kidney transplant. He was stable on low dose immunosuppressive agents for history of BK virus infection. At 10 months post-transplant, the patient diagnosed with disseminated cryptoccocosis with granulomatous mesentric mass and positive cryptoccoccal antigen. High dose oral fluconazole was started. 10 days later, he readmitted with severe hyperonatremia, severe hypercalcemia (corrected serum Ca peak at 14.72 mg/dl) and acute renal failure (serum Cr peak at 5.8 mg/dl from baseline 1.6 mg/dl). The iPTH level was suppressed to 2.8 pg/ml. The serum 1,25(OH)D level was elevated and levels of 25(OH)D fell. Serum phosphate rose and ALP levels were elevated. PTH-related peptide was negative. Serum immunoelectrophoresis with immunofixation showed elevated kappa monoclonal gammopathy with normal ratio of free kappa and lambda light chain. Kidney biopsy revealed acute tubular necrosis, no evidence of granulomatous or lymphoproliferative disease. CT chest revealed right upper lobe mass with calcified granuloma at lung base. Culture from lung biopsy showed strongly positive for Mycobacterium Tuberculosis. Anti-tuberculosis drugs were started and mycobacterium motefil was held. Elevated calcium levels were unresponsive to calcitonin, fluid neither helped. After his aperiodic AFB became negative, the oral prednisone was increased to 20mg/day. Hypercalcemia and hyperphosphatemia normalized upon one month follow up and remained stable until finished 6 months course of anti-tuberculosis drugs and the creatinine returned to baseline.

Discussion: Unlike persistent hyperparathyroidism, underlying diseases of PTH independent hypercalcemia after renal transplantation like a granulomatous disease can lead to significant morbidity and mortality. Early recognition and prompt treatment is necessary.

FR-PO042
Treatment of Malignancy-Associated Hypercalcemia with Low Calcium Hemodialysis Yields Several Benefits for Cancer Patient Rozina B. Ali, Akshitha Rao, Suzanne Boyle, Jesse M. Goldman. Div of Nephrology and Hypertension, Drexel Univ College of Medicine, Philadelphia, PA.

Introduction: Hypercalcemia of malignancy can be fatal. In literature, primary treatment remains forced saline diuresis while dialysis is seldom considered. We present a case of severe, refractory hypercalcemia associated with diffuse large B-cell lymphoma that was treated with low calcium (Ca) hemodialysis (HD).

Case Description: A 56 year-old male presented with 3 weeks of weakness and constipation. He noted a serum creatinine (Cr) of 1.45mg/dL, Ca of 2.1mg/dL, and ionized Ca of 2.3. Urine microscopy had granular casts. Cause of acute kidney injury (AKI) was attributed to hypovolemia, acute tubular necrosis and Ca-induced vasoconstriction. He had a PTH of 7pg/ml, PTH-ep of 2.1pmol/L, vitamin D 25,OH of 25.9ng/mL and 1,25(OH)2 of 18pg/mL. Non-contrast CT chest demonstrated diffuse lichenoid nephropathy with LN biopsy showing diffuse large B-cell lymphoma. On day 1, patient received several liters of normal saline, calcitonin, and pamidronate. Despite maximal medical therapy, he had delirium, persistent AKI with Cr peak to 2.6 mg/dL and elevated Ca at 15mg/dL. On days 3, 4, and 5, he received consecutive 4-hour sessions of intermittent HD with low Ca (2mg/L) dialysate using a 0180 high flux dialyzer with blood flow of 400mL/hr. On day 6, Ca decreased to 10.4 mg/dL and mental status improved. He received induction chemotherapy on day 13 with cyclophosphamide, doxorubicin, rituximab, and vincristine. At discharge, Cr was 1.66mg/dL and Ca level was 12mg/dL.

Discussion: Serum/urine Cr PCR: consecutively negative. Immunohistochemistry on tissue sections: positive for BK (SV40 T antigen which cross reacts with JC). In-situ hybridization for JC and BK viruses: positive in medullary tubular epithelial cell nuclei. Reduction in immunosuppression resulted in renal improvement.

FR-PO043
Case Description: 41 year old female with history of thyroidectomy for cancer, parathyroidectomy, hypothyroidism, and gastro-esophageal reflux disease (GERD) referred to our nephrology clinic for severe symptomatic hypokalemia for a decade. She has poor appetite and weighs around 330 pounds but denies vomiting or diarrhea. Home BP’s is low 90’s /60’s mmHg. She denies licorice, diuretic or excessive alcohol use. She was adopted as a child with unknown family history. She was admitted for further work up. Her serum potassium (K) was 3.5 and Mg was 1.2. 24 hour urine collection was done and levels of sodium, K, Mg and aldosterone were found to be 48 mmol, 21 mmol, 49.6 mmol, and 7.5 mg/di respectively. Fractional excretion of Mg using the formula FEMg = 100 * (UrineMg / PlasmaMg) / (0.7 * PlasmaMg + UrineCr) was 121% confirming renal Mg wasting. Her serum bicarbonate of 22mmol/L and absence of salt wasting ruled out Gitelman syndrome. Review of medications revealed that she was chronically on esomeprazole 40 mg daily for presumed GERD. Esomeprazole was stopped, and with continued magnesium supplementation her repeat K and Mg were within normal range as outpatient. Repeat 24 hour urinary Mg was pending at the time of abstract submission.

Discussion: The kidneys are highly efficient organs in Mg conservation with most of filtered Mg being reabsorbed in the thick ascending limb of the loop of Henle. It is speculated that patients who develop hypomagnesemia on long-term PPI treatment may harbor one or more heterozygous mutation(s) of the gene TMPRE6, FXVYD2, KCN310, or KCN1A1 involved in the modulation of Mg reabsorption in the distal nephron, leading to diminished efficiency of the encoded protein(s). This situation could involve a continuous low-grade Mg leak and facilitate the development of Mg depletion when combined with factors that decreases intestinal magnesium absorption.
FR-PO045
Successful Treatment of Anti-Angiotensin II Type 1 Receptor Antibodies Associated with Refractory Antibody-Mediated Rejection and AcuteCellular Rejection in Kidney Transplantation: A Case Report
Punlool Wiwattanatham, Atiporn Ingasitt, Nephrology Unit, Faculty of Medicine Ramathibodi Hospital, Mahidol Univ, Bangkok, Thailand.

Introduction: Angiotensin II type 1 receptor (AT1R) antibody has been proved that it can be detrimental to kidney allograft. Similar to HLA-antibody, patients who have AT1R antibody are at risk for rejection and poor allograft outcome. There is no standard treatment in this situation but the aim is to remove pathologic antibodies and suppress antibodies production. Outcomes after treatment are unsatisfactory and not well established. Herein we present a successful treatment kidney transplant patient who experienced AT1R antibody mediated rejection.

Case Description: A 50-year-old male with hypertension and ESRD underwent a disease donor kidney transplantation using a graft from acute kidney injury donor with peak serum creatinine of 1.24 mg/dl. No intraoperative complication occurred, urine flow rate of 300 ml/hr was observed immediate postoperative but abruptly decreased to 20 ml/hr at 8 hours posttransplantation. Acute rejection was suspected, thus allograft biopsy was done. The histopathological findings were compatible with acute cellular rejection combined with antibody-mediated rejection (ABMR). AT1-R antibody was detected at level of 15.0 ml/ml. Anti-rejection therapies were offered with steroid, IVIG, plasmapheresis, anti-thymocyte globulin and rituximab. At 8 weeks posttransplantation, rejection was well controlled with stable serum creatinine of 1.5 mg/dl.

Discussion: Although AT1R antibody associated rejection has rarely been reported, the outcomes after rejection are unsatisfactory. Early detecting rejection and rapid antibody removal seem to be the most effective treatment that prolong allograft function in present time. There are limited and controversial data about long term graft survival by treating patient with angiotensin receptor blocker.

Hemodiafiltration for Hepatic Encephalopathy Induced by Budd-Chiari Syndrome in a Patient with End-Stage Kidney Disease
Takuya Wakanatsu, Suguru Yamamoto, Takeshi Nakatsue, Junichiro J. Kazama, Ichiei Narita. Div of Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.

Introduction: Budd-Chiari Syndrome (BCS) is defined as portal hypertension caused by obstruction of the inferior vena cava at the liver. Severe BCS induces hepatic encephalopathy, and has been known to be exacerbated by HD due to removal of protein-bound tryptophan is removed by HD. Therefore, one of the reasons why HDF ameliorates hepatic encephalopathy is increased removal of protein-bound AAAs, leading to increased BCAA/AAA ratio.

FR-PO047
De Novo Lupus Nephritis in a Stable Kidney Transplant Recipient
Laura Panare, Karthik M. Ranganna, Alden Michael Doyle. Division of Nephrology & Hypertension, Drexel Univ Hahnemann Hospital, Philadelphia, PA.

Introduction: De novo Lupus Nephritis (LN) is an exceedingly rare complication in kidney transplant recipients. We present a case of histoplasmosis with clinical manifestations of SEL. The scarcity of autoimmune disease in this population is not fully understood, but has been attributed to the maintenance immunosuppression used to prevent allogreception and rejection.

Case Description: Herein we present de novo LN in a 55-year-old woman with post streptococcus glomerulonephritis and HTN; 28 years status-post living-related kidney transplant. The patient had no personal or family history of autoimmune disease at time of transplant. Three years ago, she began complaining of episodic carpo-pedal spasm and scoliosis; laboratory abnormalities included mildly low albumin and stable Ig proteinemia. Medications were stable and no potentially provocative antigens, vaccines or transfusions, were given during this period. Immunosuppression included cyclosporine and low dose prednisone. Seven months ago, the patient developed malar rash and hemo-proteinuria prompting immunological studies and kidney allograft biopsy. Anti-nuclear, double stranded DNA, Smith and histone antibodies were all strongly positive with low serum complement levels. Serum creatinine increased by 0.5 mg/dl; from baseline; urine protein to creatinine ratio revealed nephrotic range proteinuria peaking at 9.6grams. Immunofluorescence revealed granular “full house” pattern, C4d negative; Electron microscopy revealed intranembranous deposits. The patient was treated with high dose prednisone, continued cyclosporine and addition of mycophenolate mofetil.

Discussion: Although rare, de novo auto-immune disease should be considered for transplant patients despite maintenance immunosuppression.

FR-PO048
Atypical Hemolytic Uremic Syndrome Allograft Outcome in the Post Eculizumab Era
Laura Panare, Karthik M. Ranganna, Alden Michael Doyle. Division of Nephrology & Hypertension, Drexel Univ Hahnemann Hospital, Philadelphia, PA.

Introduction: Atypical Hemolytic Uremic Syndrome (aHUS) is an exceedingly rare etiology of renal failure. Two forms of HUS are often linked to underlying viral illness or particular classes of immunosuppression in transplant recipients. Exceedingly rare are genetic etiologies of aHUS for which transplantation is undesirable due to very high recurrence rates of disease.

Case Description: Herein we describe a case of misdiagnosis; 78 year old man initially diagnosed with rapidly progressive glomerulonephritis (RPGN) by kidney biopsy developed anuria necessitating hemodialysis. The patient had no family history of kidney disease. Immunological work-up was negative for Anti-nuclear or cytoplasmic antibodies; complement deemed within normal limits. Pt received a living-unrelated kidney transplant from a 40 year old healthy donor. Standard induction solumedrol and thymoglobulin. Initiation of maintenance calcineurin inhibitor (CNI), steroid, antimalabite. Favorable outcomes were observed, creatinine 1.77 mg/dl and urine output upon discharge. One week post-transplant, patient was observed to have increased creatinine, peak 4mg/dl, not amenable to discontinuation of CNI or typical offending agents; prompting renal biopsy. Histologically Thrombotic Microangiopathy (TMA), C4d (-) observed and deemed comparable to native biopsy slides. Laboratory studies confirmed aHUS (-) ADAMST13; low lactate dehydrogenase, elevated haptoglobin; peripheral smear hightocytes. Negative viral studies including Shiga toxin. Pt was treated with high dose solumedrol, plasma exchange and eculizumab; resolution of kidney function, creatinine 1.88 mg/dl, month post-transplant period. Interim six month follow-up, with twice monthly eculizumab reveal no recurrent TMA on biopsy; despite bouts of acute kidney injury related to CNI levels or viral fluctuations.

Discussion: aHUS, as presented above, may be misdiagnosed and therefore present at the time of post-transplant recurrence. With the advent of treatment, alternative pathway complement inhibitor eculizumab; a high degree of suspicion must be maintained when managing post-transplant dysfunction.

FR-PO049
An Unusual Manifestation of Disseminated Histoplasmosis in a Renal Transplant Patient
Kana N. Miyata, Lilly M. Barba. Nephrology, Harbor-UCLA Medical Center, Torrance, CA.

Introduction: Disseminated histoplasmosis is rare but can develop in immunocompromised patients. We present a case of disseminated histoplasmosis in a renal transplant patient with unknown origin with oral and gastrointestinal (GI) manifestations.

Case Description: The patient is a 42 year-old man with ESRD secondary to unclear etiology, who had a living related renal transplant from his cousin 4 years ago in Mexico. He was born in El Salvador, moved to California at age 7, and had traveled to Mexico and Cuba (last travel 1 year ago). His post-transplant course was complicated by antibody mediated rejection and borderline acute cell mediated rejection 2 years ago, for which he was successfully treated with IVIG, plasma exchange, and rituximab. His medication included tacrolimus, MMF, and prednisone. He presented with 2-3 weeks of fever and chronic abdominal pain after unsuccessful treatment with ciprofloxacin. He had a WBC of 38.7
It has been postulated that complement activation might have a role, but this patient had normal complement levels.

Hyponatremia, but low Na histoplasma antigen was positive. He improved soon after oral itraconazole was started.

Hemodialysis (HD) using a standard Na\textsuperscript{+} mEq/L to 131 mEq/L on day 2, and reached 137 mEq/L by day 3. The patient was then corrected of Na\textsuperscript{+} rise was > 0.5 mEq/hr or 6 mEq in 24 hrs. It was to be reduced if the correction

Introduction: Anuric acute kidney injury (AKI) with hyponatremia presents a therapeutic challenge. Hemodialysis (HD) using a standard Na\textsuperscript{+} bath can cause excessive correction of Na\textsuperscript{+}, and a risk of osmotic demyelination. We report the controlled correction of hyponatremia via continuous venous venous hemodialysis (CVVHD) against a standard bath using an infusion of dextrose 5% in water (DSW) to blunt the Na\textsuperscript{+} shift.

An 83 year old male with respiratory failure developed altered mentation and oliguria. Labs demonstrated severe hyponatremia with Na\textsuperscript{+} 119 mEq/L, K\textsuperscript{+} 6.8 mEq/L, and AKI with BUN 46 mg/dL, creatinine 3.08 mg/dL. Emergent renal replacement therapy (RRT) was required, but HD would have risked overly rapid correction of Na\textsuperscript{+}. Instead, we started CVVHD with a Na\textsuperscript{+} 140 mEq/L bath. The dialysate rate was 2 L/hr and blood flow rate was 200 cc/min. Net target was zero, with all drips included in the calculation. We simultaneously infused DSW at 100 cc/hour. [Na\textsuperscript{+}] was monitored every 4 hrs. The DSW flow was increased if the [Na\textsuperscript{+}] rise was > 0.5 mEq/hr or 6 mEq in 24 hrs. It was to be reduced if the correction was suboptimal. The patient’s [Na\textsuperscript{+}] rose from 118 mEq/L to 125 mEq/L on day 1, 125 mEq/L to 131 mEq/L on day 2, and reached 137 mEq/L by day 3. The patient was then safely converted to HD.

Discussion: CVVHD is a safer option for RRT than HD in the setting of severe hyponatremia, but low Na\textsuperscript{+} CVVHD is not available. Some have suggested adjusting the dialysate [Na\textsuperscript{+}] using sterile water to achieve the desired [Na\textsuperscript{+}] prior to treatment. This may produce a predictable response in Na\textsuperscript{+}, but there are concerns for infection and/or dosing error which makes this strategy problematic. Reducing dialysate or effluent flow, though effective, often results in unacceptable clearances. We demonstrated, that CVVHD with a standard Na\textsuperscript{+} bath, a separate D5W drip, and strict monitoring of [Na\textsuperscript{+}], can yield a predictable response in [Na\textsuperscript{+}], obviating the cumbersome and risky point of care manipulations of the dialysate formula.

Case Report: Renal Squamous Cell Carcinoma of a Native Kidney After Renal Transplant Adam Daniel Jakes,1 Poornam Jani,1 Mini Menon,1 Kate Adams,1 Matthew Edley,1 Stewart Fleming,1 Sunil Bhandari,1 1 Dept of Renal Medicine, Hammersmith Hospital, London, United Kingdom; 2 Hull York Medical School, Hull, United Kingdom; 3 Dept of Renal Medicine, Hull Royal Infirmary, Hull, United Kingdom; 4 Dept of Infection & Tropical Medicine, Castle Hill Hospital, Hull, United Kingdom; 5 St. James’s Univ Hospital, Leeds, United Kingdom; 6 Cellular and Molecular Pathology, Ninewells Hospital, Dundee, United Kingdom.

Introduction: Renal squamous cell carcinoma is a rare primary tumour of the kidney, which rapidly invades local structures and has a poor prognosis. Presentation is usually non-specific and is associated with renal stone disease and chronic infection. We present a case of squamous cell carcinoma of a native kidney in a renal transplant recipient, which has not previously been described in the literature.

Case Description: A 46-year-old white male with previous renal stones and recurrent urinary infections underwent a right nephrectomy and subsequent renal transplantation due to failure of the remaining kidney. Five years post-transplant, an abdominal ultrasound scan was performed due to recurrent urinary infections and ongoing pyuria. This was reported as normal, but he later developed a discharging sinus in his left flank. A CT scan revealed a right perinephric abscess with an associated cystic lesion. A left nephrectomy was performed and histological examination suggested an invasive squamous cell carcinoma of the renal pelvis. The patient later required major surgery for chronic infection, and further imaging revealed metastatic disease, resulting in the decision to treat him symptomatically.

Discussion: Renal transplant recipients are three-four times more likely to develop a malignancy than the general population. The patient also had renal stone disease and recurrent urinary infections; further increasing his risk of developing this condition. Abdominal ultrasound was suboptimal and only a later CT scan revealed the underlying malignancy. Given the non-specific nature of the symptoms and the poor prognosis, healthcare professionals should have a lower threshold for diagnostic imaging in these patients. This should be expedited if there is a persistent abnormality on urinalysis.

A Case of Hydronephrosis due to Adenovirus Hemorrhagic Cystitis following Peripheral Blood Stem Cell Transplantation for Malignant Lymphoma Rio Noto,1 Hideki Yokoi,2 Akhiro Yoshimoto,3 Motoyo Yanagita.2 1 Clinical Nephrology, Kobe City Medical Center General Hospital, Kobe, Hyogo, Japan; 2 Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.

Introduction: In patients receiving stem cell transplantation (SCT), adenoviral infection is associated with mortality and morbidity. Cystitis is the most common presentation of adenoviral urinar tract infection, which unusually causes inflammation of the upper urinary tract. We report a rare case of adenoviral urethritis accompanied by hydronephrosis due to autologous peripheral blood SCT.

Case Description: A 50-year-old female, who had undergone SCT 4 months ago for the treatment of nasal-type extranodal NK/T cell lymphoma and received tacrolimus as prophylaxis for graft-versus-host disease, developed fever, right back pain and dysuria. Computed tomography (CT) showed perirenal and periureteral fat heterogeneity and dilatation of the right ureter. He was diagnosed as pyelonephritis caused by ureteral stones (already dropped), but antibiotics did not relieve symptoms. In addition, he exhibited a left solitaiary pulmonary mass, which was diagnosed as Mycobacterium avium complex (MAC) infection by lung needle biopsy. Cystoscopy and retrograde pyelography revealed hemorrhagic cystitis and right ureteral stenosis, where a catheter was placed. Viral PCR test was performed for differentiating hemorrhagic cystitis, and adenovirus was detected both in urine and in blood. Symptoms and abnormal findings on CT were improved by the placement of a catheter and the decrease of tacrolimus dosage.

Discussion: Differential diagnoses were urethral carcinoma, recurrence of malignant lymphoma, retroperitoneal fibrosis and disseminated MAC disease. Urine cytology result was negative for malignant. Gallium scintigraphy excluded recurrence of malignant lymphoma. Fat heterogeneity disappeared after catheter placement, suggesting that malignant lymphoma and retroperitoneal fibrosis were unlikely. MAC was not detected from blood and urine cultures. Clinical course and laboratory data indicated that inflammation of adenoviral hemorrhagic cystitis spread to the right ureter, leading to ureteral stenosis and hydronephrosis in an immunocompromised patient after SCT.

Unusual Cause of Thrombocytopenia in a Dialysis Patient Rahul N. Pawar, Savneek S. Chugh, Amy R. Patel, Rudrick V. Ledesma, Rajat Lamba. Nephrology, Westchester Medical Center, NY.

Introduction: Hemodialysis (HD) is an invasive treatment with many adverse effects, thrombocytopenia being one of them. Most of the cases of thrombocytopenia on dialysis are related to the use of heparin creating auto-antibodies leading to heparin induced thrombocytopenia (HIT). Here we report a case of severe thrombocytopenia, which was initially thought to be due to HIT, but later revealed to be secondary to a specific dialyzer membrane.

An 81 year old female started on HD 2 months prior for progressive CKD was sent to the HD unit for excessive bleeding. She was on a new platelet (PLT) count of 27 K/uL. When she was first started on inpatient HD, she was found to be thrombocytopenic and heparin autoantibodies were weakly positive so she was started on argatroban. At the 1st outpatient HD unit, her PLT count increased to 200 K/uL. After transferring to a 2nd outpatient HD center, her PLT count, once again, dropped to 27 K/uL, along with recurrent bleeding at the catheter site. This prompted investigation of heparin exposure as a cause, but it was revealed that the patient never received heparin during any of her treatments. Despite being restarted on argatroban, her PLT count remained in the 20 K/uL range. The argatroban release assay was negative. It was noted that the hospital and the 2nd outpatient unit both used a F160NR dialyzer, different from the dialyzer used in the first outpatient unit. With the suspicion of a possible dialyzer reactor, the membrane was switched from F160NR to Gambro Revaclear. Her PLTs increased to 125 K/uL in 4 days. Discharge instructions were indicated that the patient must use a Revaclear dialyzer. A week later, repeat PLT count was noted to be 200 K/uL.

Discussion: This case demonstrates a rare dialyzer reaction, in which a specific dialyzer membrane leads to severe thrombocytopenia and bleeding. It has been postulated that complement activation might have a role, but this patient had normal complement levels.
FR-PO054

Calcium Free Dialysis for Hypercalcemic Crisis

Introduction:
Hypercalcemic crisis, a potentially life-threatening condition, has been defined as a calcium of 14 mg/dl or more with evidence of multi-organ dysfunction including cardiovascular, renal or CNS involvement. We describe a case of hypercalcemic crisis due to primary hyperparathyroidism treated with low calcium/calcium free dialysis.

Case Description:
A 62 year old healthy man was brought by his wife to the ED for lethargy, worsening confusion over 3 days, weight loss and constipation. On exam, he was hemodynamically stable, had flat jugular veins and dry mucous membranes. His corrected calcium was 23.58 mg/dl with a creatinine of 3.60 mg/dl. He was aggressively hydrated with normal saline and received a total of 2 doses of Calcitriol 240 IU IM with no improvement in his mental status or in his calcium levels. He was then given Denosumab 60 mg SQ and underwent a 3 hour session of low calcium dialysis (Ca bath 1.0 mEq/L). During the treatment, he was given NS boluses in addition to his maintenance NS 250 cc/hr to avoid hypotension. He subsequently underwent 3 additional treatments (Treatments 2 and 4- using calcium free dialysate and Treatment 3- using Ca 1.0 mEq/L) that were well tolerated. Following his 2nd treatment, his mental status improved significantly. After his 4th treatment, his calcium was 12.26 mg/dl. His intact PTH level was 1324 pg/mL. A Sestamibi thyroid scan showed a large left parathyroid mass. The patient underwent surgical resection of a 13 gm parathyroid adenoma after which his calcium normalized to 9.8 mg/dl. His clinical course and a blood pressure trend during hemodialysis is reported below.

Discussion:
Calcium free dialysis and the use of low calcium dialysate was tolerated with no hemodynamic instability. Aggressive hydration is important to maintain tolerability. It can be safely used as a bridge to definitive surgical treatment in the setting of primary hyperparathyroidism.

FR-PO055

Antineutrophil Cytoplasmatic Antibody Crescentic Allograft Glomerulonephritis following Sofosbuvir Therapy

Introduction:
Sofosbuvir is used for the treatment of hepatitis C virus infection. We report first case of ANCA/RPGN following Sofosbuvir in a kidney transplant recipient.

Case Description:
51 yo male had a living unrelated donor kidney transplant, received alentezumab induction, and tacrolimus and mycophenolate maintenance. sCr was 1.4, 1 week after transplant. 12 weeks post-transplant, sCr was 2.0; renal biopsy showed ATN and tubular isometric vacuolization. Tacrolimus was replaced with cyclosporine. His sCr stabilized at 1.6. He had HCV genotype 1a and high viral load. At week 40 after transplant, his sCr was started on ribavirin and sofosbuvir. At 12 weeks of HCV treatment, sCr was 3.7, UA with 30 protein and 131 RBCs, and PCR was 0.6. Allograft biopsy showed TMA. Therefore, sofosbuvir, ribavirin and cyclosporine were stopped. He was started on prednisone and continued on mycophenolate. His sCr was at 2.4. 70 weeks after transplant (30 weeks after initiation of sofosbuvir), he had a sCr of 1.4, p-ANCA titer was 1:320 and MPO ab >100. He was diagnosed with p-ANCA associated crescentic GN in the allograft. The patient was treated with sulfamethoxazole, trimethoprim and a course of plasmapheresis. He later started HD and Rituximab was added. He remains dialysis-dependent despite of our efforts in treating his RPGN.

Discussion:
Renal biopsy showed 3 different pathologies. Initially tubular toxicity of tacrolimus. After sofosbuvir and ribavirin, he had TMA, we stopped his HCV treatment, although the concurrent cyclosporine use was implicated. 30 weeks after the initiation of sofosbuvir and ribavirin therapy he had ANCA-associated crescentic GN. Ribavirin had no reported cases of ANCA vasculitis. Sofosbuvir was approved in 2013 and we suspect it as likely cause of ANCA vasculitis. Therefore, our case represents the first case of drug-associated ANCA vasculitis in an allograft kidney. Further drug monitoring is necessary to elucidate the degree of association and possible causal effect of sofosbuvir and p-ANCA vasculitis.

FR-PO056

Malignant PEComa Post Combined Kidney and Pancreas Transplantation

Case Description:
The patient was a 44-year-old Hispanic female with a history of DM type 1 with living related kidney transplant back in 1998 and followed by a pancreas transplant in 1999 with transplant pancreatectomy and retransplant of the second pancreas in 2010. Her immunosuppressive agents were mycophenolic acid, prednisone and tacrolimus. Fifteen years post-kidney-transplant, she developed fever with chronic cough for a month. CT of the chest revealed multiple, bilateral, solid, non-cavitating pulmonary masses with mediastinal lymphadenopathy. CT of the abdomen showed right native kidney mass measured 5.2x8x cm. Right lower lobe lung biopsy showed perivascular epithelioid cell neoplasm. The PEComas of the lung are traditionally considered benign. To investigate the nature of the renal mass, the patient underwent right open radical nephrectomy. Again, the right nephrectomy pathology showed malignant PEComa, 10 cm with pure epithelioid with carcinoma-like growth pattern, involving the entire kidney. The tumor is histologically identical to the patient’s lung mass and confirms that the kidney mass is the primary tumor and the lung tumor is a metastasis. The patient also found metastatic osteolytic lesions involved pelvis, proximal femurs, cervical and thoracic spines. After confirmed the diagnosis of malignant PEComas, mycophenolic acid was stopped. She was started on Temsirolimus 25 mg intravenous weekly, taclarim was changed to rapamycin and continue with oral prednisone. Unfortunately 3 weeks later patient became unresponsive, cardiac arrest and passed away.

Discussion:
Although the majority of PEComas is recognized as benign, but in the immunocompromised patient, especially with a history of multiple solid organ transplants like in our patient, the tumor could be presented in advance and aggressive way with fatal outcomes.

FR-PO057

A Case of Post-Transplant Kaposi Sarcoma Treated with Combination Chemotherapy and mTOR Inhibitor

Case Description:
A 43 y old African American male with history of ESRD s/p deceased donor kidney transplant in 2013 induced with alentezumab, maintained on tacrolimus, mycophenolate and prednisone was admitted with worsening shortness of breath and productive cough. His course was complicated by hypoxemic respiratory failure requiring intubation. He received broad-spectrum antibiotics initially and his anti-
FR-PO058

Warfarin-Related Nephropathy in a Kidney Transplant Patient
Nadeen J. Khoury, Gilbert W. Moeckel, Mark A. Perazella. 1  
1 Nephrology, Yale Univ, New Haven, CT; 2 Dept of Pathology, Yale Univ, New Haven, CT.

Introduction: Anticoagulant-related nephropathy is a new entity manifesting as AKI in the setting of excessive anticoagulation. Initial cases were related to warfarin use; however, more recently AKI is reported with direct thrombin inhibitors. We present biopsy-proven warfarin-related nephropathy (WRN) in a transplant patient on anticoagulation for atrial fibrillation with INR<2.

Case Description: A 69y old man with hypertension, atrial fibrillation (on warfarin), T2DM and ESRD s/p living unrelated kidney transplant with baseline sCr 2.0 mg/dL (on cyclosporine, mycophenolate and prednisone) presented with nausea, vomiting and abdominal pain. Acute cholecystitis was diagnosed and percutaneous cholecystostomy drainage performed. Initial labs revealed leukocytosis and AKI on CKD with sCr 2.7 mg/dL. INR was 1.8. Urinalysis revealed 3+ blood, 2+ protein with 179 RBCs/HPF, urine sediment 1-2 RBC casts/LPF. Transplant kidney ultrasounds was unremarkable. Complements were normal. Urine microscopy demonstrated persistent RBC casts and kidney biopsy was performed. Acute tubular injury with numerous occlusive RBC casts suggestive of WRN was observed. Kidney function slowly improved but sCr remained above baseline upon discharge. Warfarin was resumed due to high stroke risk.

Discussion: Our patient’s presentation with AKI in the setting of acute cholecystitis raised the possibility of sepsis-induced AKI. However, the presence of microscopic hematuria and numerous RBC casts suggested a glomerular process. Biopsy suggested WRN developing in the setting of CKD and anticoagulation. Our case is somewhat unusual given the INR<2. Most cases of WRN have an INR>3. However, the patient had risk factors that had been linked to WRN including CKD, diabetes mellitus and hypertension. Interestingly, INR levels several months prior were all consistently below 2 yet the patient had 2 bleeding episodes requiring hospitalizations (GI bleed and thigh hemATOMA) suggesting an underlying bleeding predisposition. It is reasonable to consider WRN in cases of unexplained AKI with RBC casts in a patient with INR<3 in the presence of other risk factors and bleeding tendency.

FR-PO059

Successful Preemptive Kidney Transplantation Using Rituximab Induction in a Young Patient with Focal Segmental Glomerulosclerosis and Nephrotic Syndrome – Case Report
Aurelius Kulonko, Grzegorz Piecha, Andrzej Wieczek. Dept of Nephrology, Transplantation and Internal Diseases, Medical Univ of Silesia, Katowice, Poland.

Introduction: Focal segmental glomerulosclerosis (FSGS) recurs in 30% of patients receiving their first kidney transplant and often leads to graft loss. In the past, patients with FSGS and overt nephrotic syndrome were rarely transplanted, mostly due to the worries about its relapse. Rituximab (RTX), an anti-CD20-specific monoclonal antibody, was previously reported to be a valuable option in resistant nephrotic syndrome and relapsing FSGS after second kidney transplantation. Hereby, we present a successful first kidney transplantation of a young patient with FSGS and full-blown nephrotic syndrome, treated with RTX induction.

Case Description: The patient is a 24-year-old woman, who developed nephrotic syndrome at the age of 4. FSGS was confirmed early by renal biopsy, she was treated with cyclosporine A, mycophenolate mofetil (MMF), and steroids, with no remission. She was referred to preemptive, deceased donor kidney transplantation despite of 10 y/day proteinuria. She received a kidney transplant with two doses of RTX (375 mg in ad 1 and 7, followed by tacrolimus 5 mg BID, MMF 500 mg BID, and steroids therapy after transplantation. We observed immediate kidney graft function and protein-absent diuresis since 6 day post-transplant. Pre-transplant soluble urokinase plasminogen-type activator receptor (suPAR) was 1750 pg/ml. His kidney function was at baseline. Imaging revealed diffuse lung 13th and was 2073 pg/ml at 6 months post-transplant. Steroids were tapered and discontinued at 10 months post-transplant. Twenty months after transplantation serum creatinine is 0.8 mg/dL and no proteinuria is observed.

Conclusion: Successful kidney transplantation in a patient with pretransplant overt nephrotic syndrome secondary to FSGS, using rituximab as an induction therapy strongly suggest the need for larger clinical trials in such patients.

FR-PO060

Black Appearing Peritoneal Effluent
Manjumith Ramachandran, Carol Motes Headley, Geeta G. Gaymanli, Adnan Naseer, Barry M. Wall. Nephrology, Veterans Affairs Medical Center, Memphis, TN.

Introduction: Endoscopic tattooing with India ink is a useful and safe tool for localizing small colorectal lesions.

Case Description: 60 year old man with End Stage Renal Disease due to Lupus Nephritis on continuous Ambulatory Peritoneal Dialysis (CAPD), developed black effluent from the peritoneal dialysis drain bag following screening colonoscopy. Findings included an ulcerated tumor occupying 25% to 49% of the colon circumference. There was no evidence of bleeding and multiple forceps biopsies were taken. The tumor area was marked using tattoos with 3 injections (5 ml each) of India ink. He returned CAPD and noticed his dialysate effluent was “black”. He presented to the ER with nausea, vomiting and black colored peritoneal fluid. Examination revealed a mild tender abdomen without rebound or guarding. Vitals were stable and he was afebrile. CT scan of abdomen revealed subcutaneous fluid, free intraperitoneal air and metastatic peritoneal disease. Peritoneal effluent cell count was elevated at 0.619 K/uL and WBC count of 5.5 K/uL. His presentation was consistent with peritonitis (cloudy dark-gray/black peritoneal effluent and elevated cell count)and empiric antibiotics were initiated with vancomycin, cefepime and metronidazole.

Within 48 hours the peritoneal effluent was clear (cell count down to 0.105 K/uL). The effluent culture grew Escherichia coli and Providencia Staurti. Dialysate remained normal. At the time of partial colectomy performed one month later, dark dye was still visible on mesenteric transverse colon, but no abscesses was identified.

Discussion: Complications associated with India ink tattooing include abscesses, inflammatory pseudotumor, focal peritonitis and peritoneal staining, most of which have been attributed to inadequate dilation or sterilization of the India ink dye. Dye spillage into the peritoneal cavity has been reported to occur at a rate between 2.4% and 13%. This occurrence has been attributed to injection technique (deep), and the possibility of trans- splanchnic migration of the dye. In our patient, drug administration, inadequate accurate drug site and bacterial peritonitis with gram-negative organisms is consistent with microperforation of the colon during the tattooing procedure.

FR-PO061

Sevelamer-Induced Colonic Ulceration – A Unique Case of Gastrointestinal Bleeding in End Stage Renal Disease Patient
Nivin Haroon,1 Unnikrishnan Ponnamma Kunjan Pillai,2 Zeenat Yousuf Bhat.1 1 Internal Medicine/ Nephrology, Wayne State Univ, Detroit, MI; 2 Internal Medicine/ Nephrology, Indiana Univ Ball Memorial Hospital, IN.

Introduction: End stage kidney disease patients experience significant morbidity and mortality. One common complication in this population is Gastro-intestinal bleeding(GIB). The causes of GIB in patients on chronic dialysis include use of aspirin and NSAIDs, Angiodysplasias and malignancies. Also medications like Sodium-poly-styrene-sulfonate can cause direct mucosa damage. We report a case of GIB in Hemodialysis-patient attributed to Sevelamer-induced colonic-ulceration.

Case Description: 56Y/0 ESRD-Hemodialysis patient with multiple comorbidities including hypertension, systolic cardiac-dysfunction, Atrial-fibrillation, H/o Breast Cancer s/p mastectomy/chemo(2005),presented to the hospital with passage of bright red blood per rectum,accompanied with syncope and shortness of breath. Her medications included Antibiotics, Aspirin, Baby-Aspirin, Carvedilol, Diltilazem, Pantoprazole, Sevelamer, Cinacalcet. Her clinical examination was unremarkable(excluding neurologic exam)except for palor. Orthostatic vital signs not checked due to dizziness, Significant labs findings were-hemoglobin-5.7mg/dl, Serum Potassium-5.5meq/L,BUN and Serum-Creatinine 46mg/dl, which were respectively and INR-1.1. CT head- no acute abnormalities, Mesenteric angiogram-no source identified, Endoscopic-Gastro-duodeno-scopy-normal, colonoscopy-no active bleeder, multiple diverticulosis1. Bleeding scan showed activity near the hepatic flexure. She underwent emergent right-hemicolecystectomy for the continued bleeding. Pathology report showed metastatic Carcinoma involving proximal Colon. Colonic-Mucosa inflammation and ulcerated,cluster of organophilic Fish scale like crystals suggestive of Sevelamer crystals were noted in colonic mucosa. Patient improved post surgery.

Discussion: There is only handful of literature on the Sevelamer colonic toxicity. This case highlight the fact that with widespread use of sevelamer in dialysis patient, physicians should be aware of this entity. Our understanding of Sevelamer-associated mucosal injury is limited and there are no known prevention strategies available.

FR-PO062

Successful Eculizumab Therapy in De Novo Atypical Hemolytic Uremic Syndrome in a Renal Transplant Recipient
Adil Mohammad Nazar, Matthew Edey, Martin Chanayireh, Sunil Bhandari. Hull and East Yorkshire Hospitals NHS Trust, Hull, United Kingdom.

Introduction: The use of terminal complement inhibitor eculizumab has not been well described in the treatment of de novo atypical hemolytic uremic syndrome (aHUS) post renal transplantation.

Case Description: We present a 47 years old female with end-stage renal disease due to reflux nephropathy who had received a living-donor renal transplant from her sister 18 months previously. Her maintenance immunosuppression medications included tacrolimus 6mg twice daily, mycophenolate sodium 720mg (AM) and 360mg (PM), and prednisone on Continuous Ambulatory Dialysis. Her prednisone was tapered and dehydrated. Admission biochemistry revealed stage III acute kidney injury with a serum creatinine of 640 µmol/l (baseline 90 µmol/l). She was anemic (Hb 90 g/l) and proliferative was held. His exam was unremarkable except for an exophytic gingival lesion on his right mandible. His blood work revealed a mild anemia, elevated liver function tests, and liver nodularities with bulky lymphadenopathy. An axillar lymph node biopsy was performed and was consistent with Kaposi sarcoma (HHV8+). Tacrolimus was stopped and the patient was transitioned to the mTOR inhibitor: sirolimus. He was initiated on liposomal doxorubicin for his extranodal disease and metastatic disease after four cycles. His renal function remained stable on sirolimus and prednisone.

Discussion: Post-transplant malignancies are common and constitute a major burden. Adjustment of immunosuppression is the mainstay of therapy in these cases. It is standard of practice to switch from calcineurin inhibitors to sirolimus upon the diagnosis of Kaposi sarcoma. However, there’s no literature regarding chemotherapy in transplant-associated Kaposi sarcoma. Most of the available data is from the AIDS population which we extrapolated to our patient. His bulky disease triggered us to explore aggressive therapy. Combination chemotherapy and sirolimus seem to be a good therapeutic strategy that should be considered in cases of disseminated post-transplant Kaposi sarcoma.

Underline represents presenting author.
370A
required multiple blood transfusions. Her trough tacrolimus level was raised to 22 ng/L. Stool microscopy and culture was negative for shiga-toxin producing bacteria. Blood film showed red cell fragments; serum lactate dehydrogenase was raised at 752 u/L. ADAMS-13 activity was normal. Renal biopsy was consistent with thrombotic microangiopathy. Complement genetic analyses (factors H, I, B and MCP tested) did not reveal any pathogenic mutations. Antibody H antibody was negative. She was treated, first with four cycles of plasma exchange and then commenced on eculizumab at 900mg infusion weekly for first four doses and then 1200mg fortnightly. Her renal and anemia parameters normally normalized.

hyperterglyceridemia, elevated LDL and D-dimer. Patient met the clinical criterion for HLRH. His nephrotic syndrome was attributed to HLRH associated with CMV infection. Treatment was started with anakinra 100 mg subcutaneously daily. Patient responded to the therapy with initial decline in serum Cr to 2.4 mg/dl. At 2 months follow up, proteinuria has improved to 2.1 g/g. ferritin to 1875 ng/ml, but Cr remains elevated at 3.6 mg/dl.

Discussion: Most cases of HLRH in kidney transplant recipients are triggered by CMV infection or other herpesviruses. This is a unique case of HLRH and nephrotic syndrome caused by CMV infection which is likely secondary to cytokine storm and histioctye proliferation. Treatment with anakinra could be beneficial in these patients.

BK Nephropathy in Allogeneic Stem Cell Transplant Recipient without Thrombotic Microangiopathy and Graft-Versus-Host Disease: A Unique Observation

Rima N. Paj1, Maria del Pilar Fernandez2, Jai Prakash Babu Thippaiah Jademgondahalli,3 William F. Glass,4 Sairah Ahmed,5 Ala Abdadyeyh.1 Section of Nephrology, UT MD Anderson Cancer Center; 2Nephrology and Hypertension, UT-Houston Medical School; 3Pathology, UT-Houston Medical School; 4Dept of Stem Cell Transplantation, UT MD Anderson Cancer Center.

Introduction: BK virus is emerging as an important pathogen in allogeneic stem cell transplant (SCT) recipients and more prevalent in patients of Graft versus Host Disease (GVHD) and Thrombotic microangiopathy (TMA). Due to immunosuppression, different drugs and/or drug combinations have been associated with BK nephropathy such as tacrolimus. BK virus causes chronic kidney disease, ureteral stenosis and hemorrhagic cystitis in stem cell transplant patients leading to increase mortality and long hospital stay. We present a unique case of BK nephropathy that has occurred in patient who was asymptomatic and without any co-infections, TMA, or GVHD. The patient was tapered off tacrolimus which showed improvement in the BK viral urine and serum load.

Case Description: A 31-year-old female with history of Acute Myeloid Leukemia (AML) underwent an allogeneic stem cell transplant a year ago. Patient was treated with 4 cycles of Fludarabine, IDArubicin, CYTarabine (FIA) and sorafenib regimen. Post-transplant course was complicated by GVHD of gastrointestinal tract and skin (Grade I). Patient was maintained on tacrolimus and later tapered off. She remained asymptomatic; however, kidney function worsened with elevated creatinine at 1.8. BK Serum viral Load of 10,800 was seen. Therefore, renal biopsy was done which was consistent with BK nephritis. With limited effective therapeutic options, immunosuppression by tacrolimus was tapered off and Leflunomide was started showing a decrease in viral load and creatinine stabilizing to 1.37.

Discussion: A definitive diagnosis of BK nephritis is confirmed with a kidney biopsy.

FR-PO066

Pharmacokinetics and Total Removal of Fosfomycin in a Patient with Chronic Kidney Failure Undergoing Haemodialysis

Julius Schmidt, Jan T. Kielstein. Nephrology, Medical School Hannover, Hannover, Germany.

Introduction: Fosfomycin shows bactericidal activity against various gram-positive, gram-negative and anaerobic pathogens, including antibiotic resistant S. aureus. However, dosing of fosfomycin in critically ill patients undergoing renal replacement is based on scarce data.

Case Description: A female chronic dialysis patient (76 years, BMI 20) was admitted to our hospital due to distinct dorsalgia. Computed tomography of the lumbar spine unveiled spondylodiscitis of the thoracic vertebrae 11/12. A punch biopsy of the affected bone region showed focal osteomyelitis. As the patient was allergic to penicillin, antibiotic therapy with cindamycin and fosfomycin sodium (8 g per day, 3 g before, 5 g after IHD session) was initiated. Maximum plasma concentration after the 3 infusion was 496 mg/L. IHD led to a distinct reduction of fosfomycin plasma levels of 61%, with a dialyzer clearance of 75 ml/min. The total amount of fosfomycin in the total collected dialysate was 2430 mg. Ccr after the additional administration of 5 g of fosfomycin after IHD treatment was 467 mg/L.
FR-PO067
Tumoral Calcification – A Rarely Seen Complication in Dialysis Patients
Lathika Raakesh, Raakesh Hassan, Christopher C. Wong, Chong Parke.
Nephrology, Univ of Southern California, Los Angeles, CA.

Introduction: Tumoral calcification is characterized by solitary or multiple painless, periarticular soft-tissue calcium deposits. Tumoral calcification was first described by Giard and Duret in 1898 and 1899. There are two categories, a familial variant also called Tschlaender disease and Secondary tumoral calcification also called Uremic tumoral calcification.

Case Description: Case : 50 year old female with end stage renal disease secondary to hypertension presented for evaluation of painful left shoulder mass. She has been on dialysis for 12 yrs. Has multiple painful swellings on her hands, elbow and feet. States that her shoulder mass appeared 2 years ago and has progressively increased in size. Also complained excruciating pain causing trouble carrying out her daily activities. Her surgical history significant for a right neck dissection for a neck mass, parathyroidectomy and a remote history of partial thyroidectomy.

Physical examination significant for multiple soft immobile nodular swellings on the left shoulder, dorsum of left foot, right elbow and index finger. Mass on the left shoulder about 12 X 10 cm in size, immobile, tender and firm to palpation. The swelling on the right elbow non tender to palpation and the one on the left index finger involved the distal and proximal interphalangeal joints. Imaging studies showed nodular swellings with significant calcification. Excision of the left shoulder mass showed exudation of a chalky white material. Pathology results were consistent with tumoral calcification.

Discussion: Secondary tumoral calcification is associated with high serum Ca X P in dialysis patients, secondary or tertiary hyperparathyroidism, aluminium intoxication and vitamin D overload. These lesions are painless but massive swellings can cause mechanical limitation, pain and neurovascular symptoms due to compression of adjacent structures. Management includes dietary phosphate restriction, noncalcemic phosphate binders, intense dialysis with a low-calcium dialysate and calcimetics. Surgical excision is indicated in symptomatic lesions. Parathyroidectomy recommended in patients with persistently elevated PTH levels. Tumoral calcification resolves after successful renal transplantation.

FR-PO068
Palate Nodule in a Hemodialysis Patient: A Long and Winding Road Until Diagnosis
Precil Diego Miranda de Menezes Neves,1 Ramaine Aparecida Bridi,2 Rosilene M. Elias,1 Fabio Luiz de Menezes Montenegro,1 Rosu M.A. Moyse.1,3 1Nephrology, Univ of Sao Paulo, Sao Paulo, Brazil; 2Univ Nove de Julho-UNINOFE, Sao Paulo, Brazil.

Introduction: Secondary hyperparathyroidism (SHPT) is a common condition in end-stage renal disease patients. We highlighted a complication that usually affects long bones, a brown tumor (BT). We report a case of a patient with SHPT, with a palate nodule, which diagnosis investigation led to a BT of maxilla.

Case Description: A 25 years-old female, previously hypertensive, who returned to hemodialysis after her kidney transplant failed. She was referred to our CKD-MBD service with a 3-month history of a progressively enlarging submucosal nodule with hard consistency on her posterior left palate. The mass was painful since the beginning, and presented progressive growth. She had no fever, neither consumptive symptoms nor palpable lymph nodes. Before coming to our service, she was referred to a maxillofacial surgery service, where a computed tomography (CT) and a biopsy were requested, as no initial suspected diagnosis was done. CT disclosed a lytic bone lesion located in alveolar process of maxilla, measuring 3.0 X 2.5cm, and damaging the superior molar roots, producing a bulging in the left maxillary sinus, nasal cavity and palate. Microscopy view evidenced the presence of multinucleated giant cells among ovoid and fusiform mesenchymal cells, large amount of hemorrhage and trabecular of lamellar bone tissue, being compatible with Brown Tumor. On review of her case, she confirmed that Sveveler's 1,8 g thrice a day, but the administration of Vitamin D analogs was not possible due to hyperphosphatemia. Her serum intact Parathormone levels were 1,500pg/ml, Vitamin D 36ng/ml, ionized calcium: 4,8mg/dl, phosphorus: 6,1mg/dl. Technetium sestamibi parathyroid scan revealed hyperactive glands at both superior thyroid lobes and at the low cervical region. The patient was submitted to total parathyroidectomy, and the lesion is progressively decreasing despite of other modalities of treatment.

Discussion: Brown Tumors must be kept in mind as a differential diagnosis in patients with SHPT even when these lesions are located in unusual sites such as the maxilla.

FR-PO069
A Case of Levofloxacin Toxicity Treated with Continuous Veno-Venous Hemofiltration
Karl Berthold Pembaur, Jennifer Thompson, Nithin Karakala.
Nephrology, MUSC, Charleston, SC.

Introduction: Levofloxacin is a commonly prescribed antibiotic. Multiple adverse events such as central nervous system and cardiovascular toxicity have been described. Cardiovascular toxicity, namely QT prolongation when present can be particularly dangerous and requires urgent management. Aside from stopping the drug there is paucity of data regarding other urgent treatment modalities such as CVVH when potential toxicity is suspected.

Case Description: A 53 year-old African American female with a history of ESRD on peritoneal dialysis (PD) for 2 years was admitted for concern of levofloxacin toxicity. She had been admitted to an outside hospital and discharged approximately 1 week prior to presentation with a levofloxacin prescription for presumed bronchitis. During initial evaluation, she admitted to taking levofloxacin 500 mg every 8h1 for the preceding 5 days. She admitted she had been performing PD every other day as she was concerned she was volume depleted. After 3 days she developed nausea, vomiting, left heel pain, left hand tremor, and palpitations. She had not performed peritoneal dialysis since the onset of her symptoms. Her initial physical exam was consistent for left hand tremor and Achilles tendon tenderness. Her QTc upon initial evaluation was 534. Serum levofloxacin level was ordered and a decision was made to start continuous veno-venous hemofiltration (CVVH) to increase clearance of levofloxacin. CVVH was stopped after clinical recovery of her symptoms and normalization of QTc. Her initial levofloxacin level was 36.65 mcg/mL (normal therapeutic range 8-12 mcg/mL) and serum creatinine was 1.7mg/dL. During the duration of treatment every 12 hours. Below is a graphical trend of her levofloxacin levels.

Discussion: Levofloxacin toxicity represents a unique and dangerous clinical challenge. This case report shows successful and effective treatment of critical toxicity with the use of CVVH.

FR-PO070
Utility of Cystatin C in the Setting of Urinoma
Lilian Saro-Nunez,1 Amrei Auferheide,2 Alan Perlman.1,2 Nephrology, Weil Cornell Medical College, NY, NY; 1Rogosin Inst, NY, NY; 2Technical Univ, Munich, Germany.

Introduction: Urinomas (i.e. presence of urine outside of the urinary tract) are common in the setting of urologic/pelvic surgery. Due to the resorption of extravasated urinary constituents such as urea nitrogen and creatinine, determination of renal function is typically confusing and often leads to the false impression of acute renal failure, a situation referred to as pseudo-renal failure. We describe the superior precision of cystatin C (CysC) vs serum creatinine (SCr) in estimating renal function in a patient with urinoma.

Case Description: 79 yo M with a history of urinary retention requiring a chronic indwelling Foley catheter presented with catheter obstruction leading to bladder rupture and apparent acute renal failure. Presenting Scr was 5.8mg/dl (baseline 1.5mg/dl). A cystogram was consistent with urinoma. Treatment of the bladder leak consisted of urinary catheter replacement and he maintained urine output > 2L/24h for several days. Scr decreased to 2.0mg/dl. A second episode of catheter obstruction subsequently occurred resulting in a significant increase of the extraperitoneal bladder leak and acute rise of creatinine to 4.6mg/dl. After placement of a larger catheter, his Scr decreased to 1.7mg/dl. During the second episode of urine leakage, simultaneous CysC levels were obtained. In contrast to
the marked variation of Scr during the onset and resolution of the urinoma, CysC levels demonstrated increasing modulating effect. In contrast, followed by return to near baseline level of 1.7 mg/L on catheter replacement. CysC-based eGFR values using CKD-EPI demonstrated similar relative stability, decreasing from 39 to 29 mL/min during the recurrent bladder rupture, followed by an increase to 36 mL/min after treatment. In contrast, the eGFR decline based upon Scr-based CKD-EPI equation was notably flatter declining from 20 to 11 mL/min during episode then increased to 38 mL/min with treatment.

**Discussion:** These findings imply superiority of CysC over Scr in estimating renal function in patients with urinoma and pseudo-renal failure. Discordant estimates of eGFR between CysC and Scr may be indicative of urinoma.

**FR-PO071**

Two Cases of Nonocclusive Mesenteric Ischemia Triggered by Intradialytic Hypotension

**Introduction:** Among dialysis patients, non-occlusive mesenteric ischemia (NOMI), defined as diffuse intestinal ischemia without any organic blood vessels occlusion, is rare (1%patient-year) but has a very high mortality (56-90%). The factors associated with mortality from this disease include age, diabetes, hypertension, intradialytic hypotension, atherosclerosis, medications, etc. Early diagnosis and treatment are important for improving survival in patients with this disease.

**Case Description:** We here report two cases of NOMI, who were triggered by hypotension during hemodialysis. Case 1: A 52-year-old man who had a left ventricular ejection fraction after cardiac infarction showed intradialytic prolonged hypotension. On physical examination, he was hypotensive with diffuse abrupt abdominal tenderness. The laboratory investigation showed a high blood white count of 20,000. Case 2: A 88-year-old woman on maintenance hemodialysis for 5 years had hemorrhagic shock. On physical examination, she was also hypotensive with mild abdominal tenderness. The laboratory investigation showed a high white blood count of 16,000. We performed multiple detector computed tomography (MDCT) and found patent mesenteric vessels in both cases. Subsequent surgical procedure revealed the necrosis of terminal ileum in case 1 and autopsy revealed necrosis of occluded in Case 2. Finally, we diagnosed them as having NOMI. The former underwent surgical procedure and was discharged alive from the hospital but the latter was dead.

**Discussion:** Considering the fact that NOMI is a very high mortality disease, early diagnosis and treatment is important. However, a diagnosis of this disease is very difficult because clinical manifestations are nonspecific. We speculated that the profile of hemodialysis is very different from other hospital but the latter was dead.

**FR-PO072**

Aggressive Renal Cell Carcinoma in a Renal Allograft

**Introduction:** Kidney cancers arising in renal allografts are very rare and most oncologic institutions lack experience in their management. We report a case of aggressive renal cell carcinoma (RCC) in a renal allograft in a patient with rare disease. Short post-transplantation.

**Case Description:** A 46-years-old man with a history of ESRD due to diabetic nephropathy underwent hemodialysis for one year prior to receiving a Living Un-Related Renal Transplant from his brother—in law, a 36 year healthy male in 2001. The patient had immediate graft function post-transplant and was maintained on MMF, Cyclosporine and Prednisone. He underwent renal allograft biopsy in 2004 for a gradual decline in renal allograft function; this biopsy showed chronic transplant glomerulopathy. The patient had very gradual decline in renal allograft (CKD G3a) until Jan 2015, when he developed mild lower abdominal pain over several weeks. Imaging including abdominal US and CT revealed a 14 X 12 X 12 cm mass arising from the transplant kidney with extensive regional adenopathy involving the right common iliac vein and IVC with evidence of lung metastasis. Biopsy showed RCC, clear cell type with extensive necrosis. The venous involvement precluded surgical excision. The patient was treated with sunitinib. Several weeks later, he developed extensive bilateral pulmonary embolism treated with heparin infusion. IVC filter was inserted and the initiation of treatment he developed grade 3 anemia. Alcoholic embolization of the tumor was then performed. Immunosuppressive medications were tapered and the patient returned to hemodialysis.

**Conclusion:** Characteristic of de novo kidney allograft RCC in a case currently unknown. These tumors can be de novo or transmitted by the donor and differentiation between these 2 modes of transmission may be difficult. The most common reported histologic type of graft tumor is papillary carcinoma; clear cell type as in our case is very rare. Tumors occurring in renal transplants are usually incidental, asymptomatic, low grade and small but may be symptomatic or with vapor clinical picture, high grade, aggressive and very large as in our case. Frequent and continued surveillance imaging of both the renal allograft and native kidneys is paramount.

**FR-PO073**

A Case of Acute Allograft Rejection Combined with BK Virus-Associated Nephropathy

**Introduction:** Rejection and BK virus-associated nephropathy (BKVAN) are major causes of renal allograft dysfunction. Treatment can be difficult when both conditions coexist, because potent immunosuppression is required in acute rejection and reduction of immunosuppressive agents is essential in BKVN. We present a case of acute allograft rejection combined with BKVN.

**Case Description:** A 41-year-old male with end stage renal disease because of hypertensive nephrosclerosis received a deceased donor renal transplantation. Immunosuppressive therapy was started with mycophenolate mofetil, tacrolimus, methylprednisolone, and anti-thymocyte globulin. On post-operative day (POD) 19, serum creatinine (Scr) level was 1.89 mg/dL but was elevated to 2.4 mg/dL on POD 25. Diffuse C4d staining in peritubular capillaries was noted on kidney biopsy and acute antibody-mediated rejection was diagnosed. Plasmapheresis was initiated and intravenous immunoglobulin (IVIG) and rituximab were administered. After 10 days of treatment, Scr was decreased to 1.5 mg/dL. Additional episodes of Scr elevation occurred and more sessions of plasmapheresis and IVIG administration were done, but Scr was elevated to 2.48 mg/dL on POD 67. Decoy cells were detected on urine cytology and high levels of vituria and viremia were found on polymerase chain reaction for BK virus DNA. On second kidney biopsy, findings of acute cellular rejection were noted and viral inclusion bodies in tubular epithelium were seen, suggestive of BKVN. For treatment of BKVN, reduction of immunosuppressive agents and administration of IVIG and leflunomide were performed. Steroid pulse therapy was done in regard of acute cellular rejection. Despite therapy, his renal function did not recover completely and Scr was elevated to 3.2mg/dL on POD 138.

**Discussion:** It is difficult to treat when BKVN and acute rejection coexist. In our patient, IVIG and leflunomide was administered and immunosuppression was reduced for BKVN while steroid pulse therapy was performed for acute rejection, but his allograft function deteriorated. Studies are required to optimize the management of these difficult cases.

**FR-PO074**

Decreased Ultrafiltration in an End-Stage Renal Disease Patient with Sickle Cell Anemia: A Potential Strategy to Facilitate Kidney Transplantation

**Introduction:** Sickle cell crisis (SC) leads to mortality and morbidity in sickle cell disease (SCD) patients. Vascular occlusion in a common precipitating cause. Volume overload may require increasing ultrafiltration(UF). We report a case of SCA patient with acute kidney injury (AKI) who suffered from recurrent episodes of SC and acute hemolytic anemia requiring blood transfusions after hemodialysis(HD) was initiated. She became more sensitized from blood transfusions. Decreased UF reduced episodes of SC and blood transfusions.

**Case Description:** A 39-year-old African American woman with a longstanding history of SCA presented with a severe episode of SC complicated by AKI requiring chronic HD 5 years ago. Since starting HD, she had more episodes of SC from once a year up to every other month and required more blood transfusions. She presented for a pre-kidney transplant evaluation. Her panel reactive antibody(PRA) increased from 28 and 0 to 44 and 10, for class I and II, respectively. Upon interview, she has HD 3 times/week. Her estimated dry weight was 62 kg and intradialytic weight gain was 2-2.3 kg. She sometimes had mild diastolic hypertension with BP of 90s/50s. As concern for over UF being a potential cause of volume depletion and subsequently precipitating SC, the UF was decreased. She had fewer episodes of SC and blood transfusions. She remained on the kidney transplant waiting list with this HD prescription and stable hemoglobin.

**Discussion:** Our patient presented with more frequent episodes of SC after HD initiation. Intradialytic hypotension indicates intravascular volume depletion which subsequently precipitating SC and hemolytic anemia. Volume management in SCA patients with ESRD is challenging and critical to avoid intravascular volume depletion. SC and acute hemolysis may be surrogate markers of over UF. Avoiding over fluid removal can prevent SC, acute hemolysis, and blood transfusion which potentially increases immunological barrier for kidney transplantation from sensitization.

**FR-PO075**

Recurrent Catastrophic Antiphospholipid Syndrome Treated with Eculizumab in a Peritoneal Dialysis Patient

**Introduction:** Antiphospholipid syndrome (APS) is a systemic autoimmune disease characterized by recurrent arterial and/or venous thromboses in presence of elevated titers of antiphospholipid antibodies (APL). These autoantibodies, promote thrombosis by activating endothelial cells and platelets. We describe a case of a clinical remission in recurrent APS via inhibition of terminal complement with Eculizumab in a Peritoneal Dialysis (PD) patient.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underlines represent presenting author.
Case Description: A 48-year-old man has shown recurrent CAPS characterized by diffuse vasculitis, glomerulonephritis, and infarction in the heart, kidneys, liver and lung tissues by positron of aPL. Angiography revealed a bilateral subclavian arterial thrombosis, a right iliac arterial stenosis that was treated with a stent and a left renal arterial occlusion. The patient’s renal function was decreased until End Stage Renal Disease, secondary to chronic thrombotic microangiopathy, and PD therapy was started. During 16 months, our patient presented 8 recurrent episodes of disease with pulmonary involvement characterized by multiple alveolar hemorrhages in concomitance with liver necrosis (biopsy proven) and myocardial ischemia. The patient was treated with high-dose pulse corticosteroids (methylprednisolone 500 mg/day IV followed byPrednisone (1 mg/kg/day), plasma exchange (5 series with a total of 74 sessions), IV immunoglobulin (400 mg/kg/day for 5 days), IV Rituximab (initial therapy and maintenance after 6 months), clopidogrel, aspirin and anticoagulation. Despite this standard therapy, we did not observe a sustained remission.

In conclusion of the literature, we chose to administer Eculizumab, a monoclonal antibody against complement C5, that blocks and prevents the generation of the proinflammatory molecules C5a and membrane attack complex C5b-9. The patient has been in remission with long-term Eculizumab treatment and anticoagulation therapy, without further thrombotic events during 1 year of follow-up.

FR-PO076
A Case Report of Post-Transplant Lymphoproliferative Disorder in Kidney Allograft
Dina Abdelwahab, Nadene J. Khoury, William S. Asch. Div of Nephrology, Yale New, Haven, CT.

Introduction: Renal tumors are rare in transplanted kidneys. Nephrectomy is the traditional approach for renal masses. We are reporting a renal mass that was found to be post-transplant lymphoproliferative disorder in the renal allograft which we chose to biopsy instead of using traditional surgical resection.

Case Description: A 63 year old female with past medical history of renal cell carcinoma (RCC), was postoperative kidney transplant by right nephrectomy. ESRD secondary to MPGN status post living donor kidney transplant presented with abdominal pain, fever and diarrhea. Ultrasound of renal allograft showed a solid appearing 4.8x5.6x4.3 cm mass in the upper pole of the transplanted kidney which was predominantly homogeneous with internal vascularity. MRI revealed a 6.2 x 4.9 x 4.5 cm mass with solid enhancing and non-enhancing components within the transplanted kidney concerning for renal cell carcinoma. Given her previous history of RCC there was an increased concern for recurrence. Nephrectomy would have been the traditional approach but that would have meant sacrificing her allograft and initiating hemodialysis. The mass was biopsied and pathology revealed post-transplant lymphoproliferative disorder. Microscopic description showed a small kidney portion with tubules and glomeruli overrun by a dense lymphoid infiltrate. Immunohistochemical stains revealed that the large atypical cells were positive for CD20, CD-2, Mum-1 and CD30 but negative for Bcl-2, Bcl-6 and CD138. C-myc stained approximately 10-20% of cells and Ki-67 30-40%. In situ hybridization for Epstein Barr virus encoded RNA (EBER) was positive. Patient received 6 cycles of R-CHOP, follow-up MRI showed decrease in mass size.

Discussion: The biopsy of renal tumors for the diagnosis of small masses has not been widely adopted despite recent safety reports with advanced techniques and physicians’ expertise. It has been shown to be safe and reliable and should be considered in all patients with small masses especially in transplanted kidneys to decrease the risk of unnecessary surgical intervention.

FR-PO077
Renal Replacement Therapy for Severe Hypoanamotra (PNA 99mEq/L), Using 5% Dextrose Solution Infusion Method
Masatatsu Hasegawa, Takuya Fujimura, Yuki Heath, Fumika Taki, Miyuki Futatsuyama, Masahiko Nagahama, Yasuhiro Komatsu. Nephrology, St. Luke's International Hospital, Tokyo, Japan.

Introduction: Dialysis therapy for patients with severe hypoanamotra poses risk of osmotic demeylination syndrome due to rapid correction of serum sodium concentration. To prevent rapid correction, low sodium dialysate or filtration fluid can be used; however, dialysate sodium concentration needs to be changed frequently as patient’s serum sodium concentration rises. Instead of using low sodium dialysate, infusion of 5% dextrose solution (DFW) to the dialysis circuit after dialyzer/hemofilter can adjust the serum sodium concentration of returning blood to the desired level (D5W infusion method). We successfully treated a patient with severe hypoanamotra therapy for severe hyperkalemia and acute kidney injury (AKI), using continuous venovenous hemofiltration (CVVH) with D5W infusion method.

Case Description: A 46 year-old woman presented to the emergency department with confusion and dysarthria, due to severe hypoanamotra (PNA 99mEq/L). She also had anuric AKI and severe hyperkalemia. Decision of dialysis therapy was made, but that would have been the traditional approach but that would have meant sacrificing her allograft and initiating hemodialysis. The mass was biopsied and pathology revealed post-transplant lymphoproliferative disorder. Microscopic description showed a small kidney portion with tubules and glomeruli overrun by a dense lymphoid infiltrate. Immunohistochemical stains revealed that the large atypical cells were positive for CD20, CD-2, Mum-1 and CD30 but negative for Bcl-2, Bcl-6 and CD138. C-myc stained approximately 10-20% of cells and Ki-67 30-40%. In situ hybridization for Epstein Barr virus encoded RNA (EBER) was positive. Patient received 6 cycles of R-CHOP, follow-up MRI showed decrease in mass size.

Discussion: The biopsy of renal tumors for the diagnosis of small masses has not been widely adopted despite recent safety reports with advanced techniques and physicians’ expertise. It has been shown to be safe and reliable and should be considered in all patients with small masses especially in transplanted kidneys to decrease the risk of unnecessary surgical intervention.

FR-PO078
Performing Chronic Hemodialysis Therapy in a Patient with Total Artificial Heart
Simona Pozzoli, Marco Simonini, Federico Pappalardo, Chiara Lanzani, Teresa Arcidiacono, Maria Teresa Sciaronne Alibrandi, Donatella Spotti, Paolo Manunta, Stefano Tentori, Giorgio Slaviero. San Raffaele Scientific Inst, Italy.

Introduction: Total Artificial Heart (TAH) is an implantable artificial heart usually used as a temporary bridge till heart transplantation. Recently a review showed that bleeding (47%), AKI requiring hemodialysis (40%) and infection (33%) are the most common complications following implantation of a TAH. Currently there are no data in the literature on long term renal function outcome and on management of ESRD related complications.

We present our experience on a patient with TAH in chronic hemodialysis therapy.

Case Description: A 55 years old Caucaisan man was admitted on 1st March 2012 at our Hospital ER with cardiac failure for AMI with rupture of the papillary muscle. His medical history included hypertension and dyslipidemia in good pharmacological control. On 9th March TAH has been implanted in order to replace the lost heart function. From the day of admission to ICU, the patient developed oliguric AKI and CRRT was started.

Subsequently, the patient was switched to four times a week haemodialysis. To maintain an appropriate circulating volume for the operation of cardiac device, atrial filling pressures were maintained between 5.5-5.5 mmHg and 6.0-6.5 mmHg in the right and left atrium respectively. At the same time it was decided to record the change of hematocrit which the patient was subjected during the dialysis sessions (via Blood Volume Monitor (BVM)) in order to identify the critical BVM value for the functioning of the cardiac device. In this way we were able to manage the patient’s dialysis sessions even once he was discharged from the hospital with the portable version of TAH.

Discussion: This patient received dialysis therapy four times a week in order to maintain a more constant and content weight till March 2015, when he underwent to combined heart and kidney transplantation. To the best of our knowledge this is the longer case of continuous dialysis therapy in a patient with total artificial heart. Total Artificial Heart is not considered a valid therapeutic option for those patients waiting for heart transplantation even for long periods of time.

FR-PO079
Severe Varicella Zoster Virus Encephalitis and Retinal Necrosis in a Renal Allograft Recipient
Jean Luc Franck, Srijita Mukherjee, Tina Thomas, Sharon M. Graves. Nephrology, Emory Univ, Atlanta, GA.

Introduction: Varicella zoster virus infection (VZV) has devastating potential complications and should be considered more often for testing by clinicians. Our case reflects the need to maintain a higher degree of suspicion for VZV by clinicians treating the immunosuppressed population.

Case Description: A 31-year-old man underwent living related renal transplantation in 2008 for chronic glomerulosclerosis. The clinical course was uneventful until January 2015, when he was diagnosed with grade 1A rejection after admitting to four months of nonadherence to his prescribed immunosuppression regimen, consisting of tacrolimus, mycophenolate mofetil, and prednisone. The rejection was addressed with pulse IV steroids and reumontation of his oral immunosuppressant regimen. Over the next four months, the patient sought medical attention for worsening and persistent occipital headache. Lumbar puncture was performed and suggested a viral etiology.MRI imaging was performed and revealed a large cerebellar infarct and diffuse vasculitis. Upon transfer to our institution, the patient underwent emergent neuroradiology evaluation which revealed hydrocephalus with decompressive craniotomy. Polymerase chain reaction (PCR) testing in the cerebrospinal fluid was positive for VZV. The patient was started on acetylov and steroids for treatment of VZV encephalitis and diffuse vasculitis. Ophthalmologic evaluation revealed retinal necrosis of the left eye, with PCR testing of the anterior chamber fluid also positive for VZV. After four weeks of acute care, the patient is currently in rehabilitation.

Discussion: Varicella Zoster Virus infection requires timely diagnosis and treatment for positive outcomes in the immunosuppressed patient. Clinical presentation can vary dramatically, from subtle rash to encephalitis. Therefore, clinicians caring for immunosuppressed patients should more routinely consider VZV as part of the differential diagnosis. Our case raises several questions including consideration for lengthening duration of VZV prophylaxis in allograft recipients and consideration for resuming VZV prophylaxis when resuming immunosuppression after extended periods of nonadherence.

FR-PO080
Hemodialysis Related Acute Thrombocytopenia During Pregnancy
Nikul Kumar Chandhuri, Belinda Bun Jim, Anjali Acharya. Dept of Nephrology, Jacobi Medical Center, Bronx, NY.

Introduction: Thrombocytopenia is not uncommon during pregnancy. It could be multifactorial and range from a mild asymptomatic condition to severe thrombocytopenia with fetal effects.

Case Description: A 29 year old woman with hypertension, CKD-IV from primary FSGS, presented at 10th week of gestation. Intermittent hemodialysis had to be initiated at 20th gestation week. Thrombocytopenia developed as described in the table below.

A Rare Case of Nephrocalcinosis Caused by Hereditary Renal Hypouricaemia

Three Months After Kidney Transplantation

Yo Komatsuzaki, Takashi Yokoo.

Introduction: Renal hypouricaemia (MIM: 220150) is a syndrome that involves a defect in urate transporter 1 (URAT1) for urate reabsorption at the brush border of the proximal tubule. Nephrocalcinosis and exercise-induced acute renal failure are two major complications affecting renal function. A C889T mutation in SLCA21A2 encoding URAT1 is the rare mutation in Japanese. Here we report a rare case of nephrocalcinosis caused by hereditary renal hypouricaemia three months after kidney transplantation.

Case Description: A 41-year-old man had undergone living-related kidney transplantation because of Henoch–Schönlein purpura nephritis. Three month protocol biopsy showed several localized nephrocalcinosis determined by either von kossa or Goldner’s stain (staining for urate crystals). The evaluation for nephrocalcinosis showed hypouricaemia at 1.9 mg/dl with a high fractional excretion of uric acid at 26.8% (normal range, 6–10%). DNA direct sequencing followed by restriction fragment length polymorphism showed that both the recipient and donor were heterozygous for C889T. This mutation induce stop codon, thereby subsequent immunostaining were performed to show that both the recipient and donor were heterozygous for C889T. This mutation induce stop codon, therefore subsequent immunostaining were performed to show that both the recipient and donor were heterozygous for C889T. This mutation induce stop codon, therefore subsequent immunostaining were performed to show that both the recipient and donor were heterozygous for C889T. This mutation induce stop codon, therefore subsequent immunostaining were performed to show that both the recipient and donor were heterozygous for C889T.

Discussion: The patient was asymptomatic throughout hospitalization. Hematological evaluation ruled out all routine causes of nephrocalcinosis during pregnancy such as gestational thrombocytopenia, preeclampsia, HELLP, TTP/ITP and autoimmune causes. Given the chronological correlation of plateau decrease and hemodialysis it was concluded that thrombocytopenia was induced by the mutation in URAT1. Patient was switched from a Frenesius dialyzer to Exeltra 210 high flux dialyzer.

FR-PO082
An Unusual Case of Lymphadenopathy in a Renal Transplant Patient

Anna Bertram, Marcus Hiss, Jan H. Bræsen, Philip F. Halloran, Gunilla Einecke.

Introduction: We report an uncommon cause of lymphadenopathy in a kidney transplant patient.

Case Description: The 28y old male patient presented 18y after living donor kidney transplantation with painful inguinal swelling. He had returned to dialysis 8 months ago due to repeated infection. He was diagnosed with his first renal allograft rejection 12y ago. He has been on blood and platelet transfusions with an immunosuppressive regimen consisting of a calcineurin inhibitor and corticosteroids. He had a history of nephrocalcinosis and renal hypouricaemia but did not show any symptoms. He had an ESRD from hypertension and DM2 and received a living donor kidney transplant 22mo ago. He took atorvastatin, tacrolimus, mycophenolate mofetil, and prednisone. He had fever, abdominal pain, diarrhea, bleeding episodes, neurological deficits, and thrombocytopenia. We performed a biopsy of the allograft with a calcineurin inhibitor and corticosteroids.

Discussion: This case illustrates that severe allograft rejection, confirmed on histopathological and molecular level, can in rare cases present with pronounced lymphadenopathy.

FR-PO083
Prevnar 13 Associated Immune Thrombocytopenic Purpura in a Renal Transplant Recipient

Sagar Gupta, Daniel C. Brennan. Renal, WashU, St. Louis, MO.

Introduction: ACIP recommends all adults with immunocompromising conditions should receive PCV13 to prevent invasive disease caused by 5serotypes of S. pneumoniae. We describe here a case of ITP associated with Prevnar 13 administration in a renal allograft recipient, which is the first reported case of its kind.

Case Description: A 77 year old Caucasian male presented with chief complaint of increased bruising at insulin injection sites for one week. There was no history of fever, abdominal pain, diarrhea, bleeding episodes, neurological deficits, new medications or insect bites. He had ESRD secondary to hypertension and DM2. He received a living unrelated kidney allograft 22mo ago. He was on tacrolimus, MMF, prednisone, MMF or insect bites. He had ESRD secondary to hypertension and DM2. He received a living unrelated kidney allograft 22mo ago. He was on tacrolimus, MMF, prednisone, MMF or insect bites. He had ESRD secondary to hypertension and DM2. He received a living unrelated kidney allograft 22mo ago. He was on tacrolimus, MMF, prednisone, MMF or insect bites. He had ESRD secondary to hypertension and DM2. He received a living unrelated kidney allograft 22mo ago. He was on tacrolimus, MMF, prednisone, MMF or insect bites. He had ESRD secondary to hypertension and DM2.

The isolated thrombocytopenia was diagnosed as ITP and was attributed to the Prevnar 13 vaccine. He was started on pulse prednisone and IVIG. He received 6 units platelets with counts increasing to 94000, later discharged on a prednisone taper. Weekly blood counts showed improvement to his baseline of 140,000 in 3 weeks.

Discussion: PCV13 contains the S. pneumoniae serotypes’ capsular polysaccharide covalently linked to an immunogenic carrier protein resulting in a T-cell dependent antigen that elicits a T helper-cell response. The pathogenesis of ITP involves antibody production driven by CD4+ helper T cells reacting to platelet surface glycoproteins. Antibodies formed during viral or bacterial infections may also cross-react with normal platelet antigens (a form of molecular mimicry). Isolated cases of ITP have been reported but are relatively rare. Our case is further unique to occur in a patient on immunosuppression with a calcineurin inhibitor and corticosteroids.

FR-PO084
Placement of a Tunneled Hemodialysis Catheter in the Superior Vena Cava for Multiple Central Venous Occlusions

Qinghua Yin, Tianlei Cui, Li Zhou, Ping Fu, Fang Liu. Div of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.

Introduction: A tunneled hemodialysis catheter is essential for dialysis access when the use of a functioning arteriovenous fistula is not possible. In extreme situations of multiple central venous occlusions, it remains a challenge to establish durable vascular access.

Case Description: A 49 year-old diabetic male who had been diagnosed with ESRD one year prior came to our medical center because of temporary catheter occlusion. CT venography revealed occlusion of the bilateral brachiopheliac, internal jugular and the common femoral veins, and central venography showed occlusion of the bilateral jugular and innominate veins. Guided by ultrasound, a percutaneous transhepatic route, as well as local ultrasound showed signs of chronic damage. Histology revealed severe ongoing cellular and AMR. Molecular analysis of the biopsy showed an unusually severe form of intimal hyperplasia and intima-media thickening (fig. 1A). De novo-associated thrombocytopenia and no sign of malignancy. Because the allograft in his right fossa iliaca was tender, we performed a biopsy, as well, although ultrasound showed signs of chronic damage. Histology revealed severe ongoing cellular and AMR. Molecular analysis of the biopsy showed an unusually severe form of intimal hyperplasia and intima-media thickening (fig. 1A) and it was performed. However, histology showed lymphangiitis and no sign of malignancy. Because the allograft in his right fossa iliaca was tender, we performed a biopsy, as well, although ultrasound showed signs of chronic damage. Histology revealed severe ongoing cellular and AMR. the SVC (Figure 2A). The puncture point of the skin was beneath and 0.5-1.0 cm outside of the middle third of the clavicle and the needle was guided to the direction of the subcutaneous tunnel was along the distal end of the SVC, which was marked by a 5F indwelling catheter. Under fluoroscopic guidance, a micro-21G needle (Cook) was used to puncture the stent occlusion of the SVC, dark red blood was drawn when the micro-21G needle (depth approximating 15 cm) met the stent indwelling catheter. Additionally, under anteroposterior and lateral fluoroscopic guidance, a 21G needle was punctured into the SVC (Figure 2B-C), and the tunnelled hemodialysis catheter (cuff to tip 23 cm, Bard) was then exchanged with a 0.035-inch guide wire in the SVC. Chest radiography showed positioning of the right atrium and hemodialysis catheter tip into the right atrium (Figure 2D). CT showed that the needle did not enter the chest.

Crystal Nephropathy in a Kidney Transplant Recipient due to Excessive Consumption of Oxalate Rich Diet and Vitamin C
C Sudeer Mudugunt,1 Padmavathi Mali,2 Sandesh Parajuli,1 Maha A. Mohamcel,3 Nephrology, Univ of Wisconsin School of Medicine and Public Health, Madison, WI; Internal Medicine, Marshfield Clinic, Marshfield, WI.

Introduction: Acute kidney injury due to crystal nephropathy has been reported mainly in patients with gastrointestinal (GI) malabsorption or GI surgery. We present a rare case of crystal nephropathy in the kidney transplant recipient (KTR) without obvious GI risk factors.

Case Description: 68 year old obese female, who is living-unrelated KTR for five years, with a stable post-transplant course and a baseline serum creatinine (sCr) of 1.1 mg/dl, presents to our hospital with tiredness and diarrhea for one week. She had extensive work up in the past for chronic diarrhea which is described as “soft stool”. 24 hour fecal fat, serum amylase and serum lipase were normal. Upon presentation, serum was 7.1 mg/dl which prompted us to perform an allograft kidney biopsy demonstrating multiple oxalate crystals deposited in the renal tubules. Reviewing her history further revealed that she was consuming 3 gm vitamin C (over the counter) daily for the last one month. Her preferred diet always consisted of oxalate rich foods (spinach). Renal functions improved in one month (sCr 2mg/dl) with hydration, discontinuation of vitamin C, and changes in dietary habits. Urine studies obtained after one week of treatment showed normal urine calcium, low urine oxalate and citrate.

Discussion: Oxalate nephropathy may occur from hyperoxaluria due to ingestion of oxalate rich diet or substances which metabolize to oxalate like vitamin C or from enteric causes like malabsorption. In our patient, we ruled out enteric causes and determined oxalate nephropathy was secondary to ingestion of oxalate rich diet and excess vitamin C. C renal functions improved with modification of diet, hydration and discontinuation of offending agents. Although vitamin C and high oxalate diet are rare causes of oxalate nephropathy in patients with normal renal function, it may cause significant nephropathies in KTR. KTR patients therefore, should follow low oxalate diet and avoid excessive vitamin C even with normal renal functions to avoid development of crystal nephropathy.

FR-PO086
The Conundrum of Dry Weight in a Pregnant Dialysis Patient

Introduction: The frequency of pregnancy in women bearing age who are on dialysis ranges from 0.3-1.5% per year. When a dialysis patient does become pregnant, nephrologists become extra vigilant to ensure a successful outcome for both mother and child. An important question that often arises is how to adjust a patient’s dry weight as pregnancy progresses.

Case Description: We present a case of a 23 year old pregnant dialysis patient who was admitted to the hospital with shortness of breath at 26 weeks gestation. She had a past medical history of a miscarriage, hypertension, and a failed deceased donor renal transplant.

At her outpatient dialysis unit, she was being dialyzed 6 times per week. Her dry weight was increased by 1.5 kg during the first trimester and during the second trimester by 1 pound a week to account for normal pregnancy weight gain. On this admission, her weight was 113.5 kg and her estimated dry weight was 114 kg. Her vital signs on admission revealed that she was mildly hypertensive with a blood pressure of 150/94 and her oxygen saturation was 90% on room air. After other etiologies were excluded, it was determined that the patient’s hypertension and hypoxia were due to volume overload despite the patient being below her expected dry weight. A feticard monitor was placed in the patient, which confirmed fetal activity every 24 hours. Approximately 2 weeks after discharge, the patient returned for her next dialysis with a weight of 108 kg, which was 6 kg below her expected dry weight. The patient delivered a baby weighing 5.4 lbs at 37 weeks with Appgar scores of 8 and 9 at 1 and 5 minutes, respectively.

Discussion: In a pregnant dialysis patient, it is difficult to distinguish between normal pregnancy weight gain and extra fluid. A fetal monitor and uterine artery doppler during dialysis are useful tools that nephrologists can employ to titrate ultrafiltration goals. Better volume management in turn could avoid pre-term delivery.

FR-PO087
A Rare Cause of AKI in a Renal Transplant Recipient
Ronald Brian Vigo,1,2 Sandra Barrow,1 Lillian W. Gaber,2 Wadi N. Sukl,1 Nephrology, Houston Methodist Hospital, Houston, TX; 3Pathology, Houston Methodist Hospital, Houston, TX.

Case Description: We present a 66 year-old African American woman who underwent pre-emptive living related donor kidney transplant for ESRD secondary to DMII and hypertension. She had immediate graft function and was discharged on the fourth post-operative day. Labs at discharge showed Na 136 mEq/L, K 3.5 mEq/L, Cl 102 mEq/L, HCO3 19 mEq/L, creatinine 1.3mg/dL and urine pH 7.0. Baseline renal biopsy was normal. Her medications on discharge included Prograf, Cilostat, Prednisone, Bactrim, Valcyte and sodium bicarbonate. She presented 10 days later with complaints of nausea, and vomiting as many as 10 times. Serum chemistries revealed the following: Na 136 mEq/L, K 5.9 mEq/L, Cl 105 mEq/L, HCO3 27 mEq/L, and total CO2 20 mEq/L, consistent with a high-anion gap metabolic acidosis (AG 21). Serum creatinine was 1.3 mg/dl and urinalysis revealed a urine pH of 7.5, pyuria and bacteriuria. Urine culture grew E. Faecalis and renal transplant ultrasound was normal. She was started on IV antibiotics and IV fluids, including sodium bicarbonate. Her chemistries revealed her anion gap metabolic acidosis had resolved, with total CO2 rising to 27 mEq/L. However, serum creatinine increased to 1.8 mg/dL, and continued to rise further despite treatment. A renal allograft biopsy was performed. Microscopic examination of the biopsy revealed widespread nephrocalcinosis with calcium-phosphate deposition. PT/INR at the time was 255 pg/mL, Ca 8.5 mg/dL, IP 4.1 mg/dL and fractional excretion (FE) of Ca 0.15%, FEIIP 29%, and urine anion gap was 29.

Discussion: We propose that our patient had developed post-transplant RTA, given the presence of a non-anion gap metabolic acidosis, low K, and urine pH of 7.0 in the immediate post-transplant period. Positive urine anion gap is suggestive of decreased ammonium excretion (although it should be confirmed with measurement of the urine osmolal gap and urinary Pco2). The combination of high urine pH, as a consequence of bicarbonate administration and decreased bicarbonate reabsorption, in conjunction with hyperparathyroidism and consequent increased phosphate excretion, provided the perfect medium for calcium phosphate precipitation.

FR-PO088
A Rare Case of Rabbit Anti-Thymocyte Globulin Induced Dissociated Intravascular Coagulation
Vasanthi Balaraman,1,2 Anup Patel,1 1Dept of Renal Transplant, Saint Barnabas Medical Center, Livingston, NJ; 2Dept of Nephrology, Newark Beth Israel Medical Center, Newark, NJ.

Introduction: Rabbit anti-thymocyte globulin (RATG) is a purified polyclonal immunoglobulin used for induction therapy in renal transplantation. Adverse effects include cytokine release syndrome, leukopenia, thrombocytopenia and serum sickness. We report a rare case of renal transplant recipient who developed severe coagulopathy and post-operative bleeding in whom RATG was used for induction.

Case Description: A 61 year old female with end stage renal disease received a deceased donor renal transplant. RATG (2 mg/kg) was initiated intraoperatively. Over the ensuing 2 hours, the patient became hemodynamically unstable with excessive bloody output from the surgical site drain. Exploration of the renal transplant revealed diffuse oozing from surrounding tissues but no bleeding from the arterial or venous anastomosis. Labs revealed an elevated prothrombin time of 27.0 sec, thrombin time of 36.4 sec, INR of 1.7, and fibrinogen level was 273 mg/dl, reduced thrombin level of 135 mg/dl and platelet count of 66000/cmcm. The RATG infusion was stopped. Multiple units of packed red blood cells, platelets, fresh frozen plasma and cryoprecipitate were transfused. There was persistent bloody output. A reexploration revealed persistent diffuse oozing which required packing of the transplant bed. On postoperative day 4, the patient’s condition improved.

Discussion: We suspect Dissociated Intravascular Coagulation(DIC) may be secondary to RATG in our case. The donor biopsy showed no evidence of DIC. Other causes including calcineurin inhibitors, hyperacute rejection and sepsis were ruled out. Only a few case reports of RATG induced coagulopathy exist in the literature. Weber et al reported 12 hematopoietic stem cell transplant patients having coagulopathy after using RATG therapy. These cases had elevated D-dimer, tissue factor, thrombin-antithrombin III complex, and thrombomodulin, but had no bleeding, thromboembolic or vaso-occlusive complications. We contemplate that DIC is a rare but potential life threatening complication of RATG induction and awareness of this potential complication is important.

FR-PO089
A Page Transplant Kidney
Supreet Sethi, Shalini Bumb, Scott Leonard Stange. 1Div of Nephrology, Dept of Internal Medicine, Duke Univ Health System, Durham, NC.

Introduction: Page kidney occurs by extrinsic compression of the renal parenchyma from a herniated or a mass, leading to activation of the renin-angiotensin-aldosterone system and resulting in systemic hypertension.

Case Description: A young-adult male, with ESRD of uncertain etiology underwent living related kidney transplantation 3-months prior to presentation. His post-transplant serum creatinine stabilized at 1.4 mg/dl. He was maintained on a low immunosuppressive regimen including tacrolimus, prednisone and mycopholic. The patient presented to the hospital with pain over allograft site and low grade fever.He reported an alteration with a family member without clear direct trauma to his right lower quadrant and subsequently referred to blunt trauma. Patient was hemodynamically stable with a blood pressure in the 170-180/100-110 mm Hg range. Labs revealed a Scr of 4.1 mg/dl, potassium of 5.7 mmol/L, hemoglobin of 10.8g/dl from a baseline of 12g/
FR-PO090
Black Colored Dialysate: A Rare Complication of Peritoneal Dialysis due to Cholecystitis
Yi Xin, Basmaah A. Abdulla, Pang-Yen Fan. Dept of Internal Medicine, Univ of Massachusetts Medical School; Dept of Nephrology, Univ of Massachusetts Medical School.

Introduction: We report a rare complication of black colored dialysate in a patient with ESRD on peritoneal dialysis (PD) with black cholecystitis.

Case Description: A 73 year old man was undergoing peritoneal dialysis for ESRD secondary to obstructive uropathy. He presented with black discoloration of his PD effluent due to a subcapsular renal transplant subcapsular/perinephric hematoma. The patient was managed conservatively and by hospital day 3, the renal function started improving. The patient was discharged with a SCr of 2.1mg/dl on hospital day 4 on his home regimen of amlopidine and labetalol. Most recently his SCr was 1.4mg/dl.

Discussion: The clinical syndrome of Page kidney in a kidney allograft due to subcapsular/perinephric hematoma following trauma or biopsy is characterized by acute hypertension with a concomitant acute decrease in kidney function. Our cases illustrates that this syndrome may occur without a history of direct trauma to the kidney, and that despite severe acute kidney injury, can be managed conservatively in some cases, with a good long term outcome.

FR-PO091
Acute Kidney Injury from Biopsy Proven Oxalate Nephropathy in a Combined Kidney and Lung Transplant Recipient
Minesh Patel, Saji Abraham. Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI.

Introduction: We report the only known case of late AON of a transplanted kidney in a combined kidney and lung transplant patient without CF after undergoing medical and surgical management of infective endocarditis.

Case Description: A 62 year old Caucasian male with a remote history of Hodgkin’s disease complicated by radiation-induced pulmonary fibrosis and aortic stenosis underwent a simultaneous double lung transplant and bioprosthetic aortic valve replacement (AVR) in February 2013. His post operative course was complicated by recurrent bronchopneumonias secondary to MSAA requiring prolonged oxacillin as well as ESRD secondary to presumed unrecovered acute tubular necrosis (ATN). The patient subsequently underwent a successful left deceased renal transplantation from his wife in October 2014 with baseline creatinine of 1.4mg/dl. Unfortunately, he developed E. faecalis bacteremia secondary to urosepsis and subsequent finding of multivalvular endocarditis with superior vena cava involvement. This was treated with a prolonged antibiotic course, but recurrent admissions thereafter for CHF and concomitant AKI necessitated a redo AVR along with mitral valve replacement and tricuspid valve repair, “Commando Procedure” on 3-9-2015. Immediate post-operative AKI occurred and was thought due to ATN given the presence of muddly brown casts on sediment exam along with hemodynamic instability requiring temporary intra- and post-operative vasopressor support. Amuric AKI persisted for four weeks leading to a surveillance kidney biopsy to investigate for superimposed rejection. Notable histologic findings were tubular injury consistent with ATN, but more prominent was that of extensive calcium oxalate deposits consistent with AON.

Conclusion: In summary we report the first known case of AKI due to AON in a lung and renal transplant recipient after infective endocarditis requiring prolonged antibiotics and the Commando heart procedure. Though the clinical presentation mimics ATN it is important for clinicians to include AON in the differential diagnosis.

FR-PO092
New-Onset Diabetes After Transplantation in a Pediatric Patient with Congenital Anomalies of the Kidney and Urinary Tract: The Role of Hepatocyte Nuclear Factor 1β
Naoto Kaneko, Naoya Morisada, Keichi Tukizawa, Tomoo Yabuchi, Hirohata Hama, Norimasa Tada, Eiji Nakano, Shoichiro Kanda, Kyiomyobu Ishizuka, Hiroko Chikamoto, Yuko Akioka, Jumpei Iijima, Motozaki Hattori. Dept of Pediatric Nephrology, Tokyo Women’s Medical Univ, Tokyo, Japan; Dept of Pediatrics, Kobe Univ Graduate School of Medicine, Kobe, Japan.

Introduction: Congenital anomalies of the kidney and urinary tract (CAKUT) are the most frequent cause of end-stage renal disease (ESRD) in children. New-onset diabetes after transplantation (NODAT) is one of the major complications following kidney transplantation (KTs). Mutations of hepatocyte nuclear factor 1β (HNF1B), a transcriptional factor involved in both the development of the liver and pancreas, have been reported to cause a multi-system disorder, including CAKUT, diabetes, liver dysfunction. We report a pediatric patient with renal hypodysplasia carrying a novel mutation of HNF1B who developed NODAT and liver dysfunction.

Case Description: The patient was a 14-year-old girl. She was diagnosed with bilateral hypodysplastic kidney in the newborn period. At the age of 3 years, she received living-related KTs from her mother preemptively. At the age of 4 years, a steroid pulse for acute rejection resulted in development of diabetes mellitus (NODAT). At the age of 13 years, she complained of acute right flank pain and fever. Laboratory data showed elevated transaminase levels and computed tomography showed malformation of the bile duct. The causes of NODAT were initially thought to be steroid and tacrolimus. However, based on her clinical features, including CAKUT, NODAT, and liver dysfunction, screening for a mutation of HNF1B was done by the central ethics board (Tokyo Women’s Medical University and Kobe University) was performed. Direct sequencing identified a novel splicing mutation of HNF1B, c.344+2T>C.

Discussion: CAKUT is the leading cause of ESRD in children and HNF1B is the most frequently mutated gene of CAKUT. Therefore, the contribution of HNF1B mutations to the development of NODAT appears to be large in the field of pediatric KTs. An oral glucose tolerance test and screening for HNF1B mutations may be advisable before KTs in CAKUT patients.
mice results in a concentrating defect in part related to a reduction of AVPR2 expression. As Pax2 and PTIP deletion, Pax2 and PTIP expression in the inner medulla, we hypothesized that Pax2 and PTIP are required for AVPR2 expression.

Methods: In IMCD-3 cells with control, Pax2 or PTIP deletion, we determined Pax2 and AVPR2 expression at the mRNA and protein level in response to normal and elevated osmolality. By ChIP analysis, we identified sites of Pax2 and PTIP enrichment on the AVPR2 promoter and determined changes in histone modifications, PolII occupancy in both IMCD and murine medulla tissue.

Results: Pax2 mRNA peaks 8 hours after an increase in osmolality, Pax2 protein peaks at 12 hours, and PTIP peaks at 20 hours. Pax2 deletion in the HMT activating complex localizes to a 100 bp fragment of the AVPR2 promoter, resulting in increases in activation marks, recruitment of PolII to this locus and an increase in gene expression in both cell lines and murine tissue. We identify the minimal promoter that Pax2 binds to and drives expression of the AVPR2 locus. Deletion of this 100 bp region of DNA results in lack of gene expression in the absence and presence of Pax2. Deletion of PTIP results in loss of gene expression even though Pax2 localizes to the promoter region, as histone activation marks are not increased and PolII is not recruited to this locus.

Conclusions: Thus, Pax2 and PTIP both regulate expression of AVPR2 in the murine inner medulla and in cells derived from this tissue. Pax2 provides the loci specificity for PTIP recruitment of the HMT activating complex and gene expression.

Adenine Downregulates NKCC2 and AQP2 in the Rat Kidney and Causes Early Nephrogenic Diabetes Insipidus

Hassane Amjal, Rose P. Webster, Ingrid Fernandes dos Santos. Internal Medicine, Univ of Cincinnati, Cincinnati, OH.

Background: Long-term feeding of adenine is extensively used to develop animal models of chronic renal failure with metabolic features resembling those observed in humans. However, the mechanisms by which adenine induces renal failure are poorly understood.

Methods: In this study, we examined the early effects of adenine (ADN) feeding on water metabolism and renal function in rats placed in metabolic cages. Rats were fed control diet or diet supplemented with 0.25% or 0.50% ADN, or 0.50% adenosine ad libitum with free access to dH2O, and monitored daily for food intake, water balance and urine osmolarity, and euthanized for blood an kidney collections after 7 days.

Results: ADN-treated rats exhibited a sharp polyuria and polydipsia and decreased urine osmolarity as early as 3 days, and the magnitude of these effects is dose-dependent. Further, ADN caused a significant reduction in food intake and body weight at 0.50% but not at 0.25%. None of these physiologic parameters was altered by adenosine treatment.

dDAVP treatment induced a significant increase in urine osmolarity in control but not in ADN-treated rats. Immunoblotting experiments demonstrated a sharp reduction in AQP2/actin expression (75%). Outer medulla (OM) and inner medulla (IM) tip/OM and inner medulla (IM) tip.

Conclusions: In conclusion, adenine acts on renal tubules as a signaling molecule in which AQP2 both regulates as a candidate NDI treatment. Metformin was used to stimulate AMPK activation in control and V2R-blocked rats. Immunochemistry showed that AQP2 and p-AQP2-Ser256 appear to be localized on the cell membrane with acute and chronic AMPK stimulation, both in control and V2R-blocked rats.

Conclusions: AMPK stimulation in V2R-blocked rats is able to reduce the urine concentrating defect by increasing UT-A1 and AQP2. These results indicate that specific AMPK pathway activators might provide a promising treatment for congenital NDI.

FR-PO097

HYAL2 Disruption Leads to Impaired Urinary Dilution Capacity in Mice

Vanessa Colombo, Inés Jadot, Anne-Emilie Deleclees, Isabelle Habsch, Bruno Flamion, Nathalie Caron. 1. Molecular Physiology Research Unit-URPhY, Univ of Namur, Namur, Belgium; 2. Laboratory of Experimental Nephrology, Univ Libre de Brussels, Brussels, Belgium.

Background: Hyaluronan (HA) is a glycosaminoglycan present in high amount in the inner medulla of the kidney but almost absent in the cortex. Hyaluronidase 2 (HYAL2) is one of the two major hyaluronidases acting synergistically to degrade HA. Recently, it has been shown that Hyal2−/−mice display HA accumulation in the kidney. Renal HA content is known to vary with hydration status. Therefore, our study was set up to characterize the renal excretory capacities and renal water handling in response to water deprivation and acute water loading in Hyal2−/−mice.

Methods: Experiments were performed in Hyal2−/−mice and in their wild-type controls. After appropriate acclimation, water deprivation was performed during 24 hours. The capacity to excrete a water load was tested on an hourly basis for the next 6h after i.p. injection of 2 ml of sterile water. Diuresis and urinary osmolarity were measured.

Results: After water deprivation, Hyal2−/−mice showed the same ability to concentrate urine as wild-type (WT) mice. On the other hand, Hyal2−/−mice had a significant delay in the diuretic response induced by an acute water load. As for renal HA content, Hyal2−/−mice maintained higher HA concentration than WT mice after both water deprivation and acute water loading. HA was present around tubules in all kidney zones including cortex. Pre-treatment with HA depletion, kidney AQP2 and kidney p-Ser75 AQP2 expressions were increased after water deprivation and decreased after acute water loading to the same extent in KO and WT mice.

Conclusions: HYAL2 deficiency and/or increased renal interstitial HA delays the diuretic response to acute water load without any increase in plasma AVP or lowering AQP2 expression.

FR-PO098

Phosphorylated AQP2 and NR3A Reduce NSAID-Induced Urinary Concentration Defect

Huiwen Ren,1 Baoxue Yang,2 Patrick A. Molina,1 Jeff M. Sands,1 Janet D. Klein,1 Medicine, Renal Div, Emory Univ School of Medicine, Atlanta, GA; 2. Pharmacology, School of Basic Medical Sciences, Peking Univ, Beijing, China.

Background: Vasopressin increases urine concentration through activation of aquaporin-2 (AQP2) in the collecting duct. Nonsteroidal anti-inflammatory drugs (NSAIDs) block PGE2 synthesis, and may suppress AQP2, producing a urine concentrating defect.

Methods: We treated rats with a nonselective NSAID, ibuprofen, and a COX-2-selective NSAID, celecoxib, daily for 3 days. Renal AQP2 and V2R expression was assessed using immunohistochemistry and immunoblotting. Results: After water deprivation, Hyal2−/−mice showed the same ability to concentrate urine as wild-type (WT) mice. On the other hand, Hyal2−/−mice had a significant delay in the diuretic response induced by an acute water load.

Conclusions: Results: Both NSAIDs significantly increased urine output and decreased urine osmolarity by days 7 - 14. Meloxicam significantly reduced total AQP2 in inner medulla (IM) tip to 64% and base to 63% of control. Ibuprofen decreased total AQP2 in IM tip to 76%, with no change in base. Meloxicam significantly increased the ratios of pSer256-AQP2 and pThr264-AQP2 to total AQP2 in IM tip (to 44% and 40%, respectively). Ibuprofen increased the ratio of pThr264-AQP2 to total AQP2 in IM tip but did not affect pSer256-AQP2 total AQP2. Both NSAIDs increased pSer256-AQP2 and pThr264-AQP2 ratios in IM tip and base. Ibuprofen increased UT-A1 levels in IM tip, but not base. NR3A, present in rat IM tip and base, was significantly decreased in the meloxicam and ibuprofen treated IM mice (37% and 20%, respectively), but unchanged in IM tip. AQP2 and UT-A1 abundances were decreased both in wild type (AQP2: 76%, UT-A1: to 62%) and NR3A−/− mice (AQP2: 52%, UT-A1: to 33%) by ibuprofen treatment. Meloxicam did not show any changes either in wild type or in NR3A−/− mice. Notably, ibuprofen treatment caused AQP2 and UT-A1 to decrease more in NR3A−/− mice than in wild type mice.

Conclusions: We conclude that NSAIDs reduce AQP2 abundance contributing to decreased urine concentrating ability. In compensation, p-AQP2 increases, resulting in increased AQP2 membrane insertion. The beneficial effects of NR3A may reflect the altered Ca2+ entry that could be limiting dephosphorylation of AQP2 and promoting improved water homeostasis.

AMPK Activation Increases Urine Concentrating Ability in a Rat Model of Congenital Nephrogenic Diabetes Insipidus

Orhan EK, Huwien Ren, Lauren M. Lorocque, Janet D. Klein, Jeff M. Sands. Medicine, Renal Div, Emory Univ School of Medicine, Atlanta, GA.

Background: The urine concentrating mechanism is primarily regulated by vasopressin which activates NKCC2 and urea transporters to generate a hypertonic interstitium that promotes water reabsorption through AQP2. Congenital nephrogenic diabetes insipidus (NDI) is caused by vasopressin V2 receptor (V2R) mutations. Present treatment options are limited. We studied AMPK as an alternate pathway to stimulate transporters involved in urine concentration.

Methods: Tolbutam (10 mg/kg/day), a selective V2R antagonist, was given by oral gavage to rats for 4 days, +/- metformin (800 mg/kg/day). Urine volume and osmolarity were measured daily. Following sacrifice, kidneys were dissected into inner medullary tip, base and outer medulla, and UT-A1, AQP2, and NKCC2 were analyzed by Western blot. Immunohistochemistry was used to localize AQP2, pAQP2, pAMPK, and NKCC2.

Results: Tolbutam was used to produce a rat model of NDI. Urine volumes of tolbutam-treated rats increased 105% within 24 h. Metformin was used to stimulate AMPK as a candidate NDI treatment. Metformin decreased urine volume by 110% back to control levels in 3 days. Urine osmolarity in control rats (mean: 210 mOsm/kg) was decreased by tolbutam (mean: 1303 mOsm/kg, p<0.05) and returned to near control levels by metformin (mean: 2335 mOsm/kg, p<0.05). Metformin increased protein abundance of IM tip UT-A1 by 61% in tolbutam treated rats (p<0.05). IM tip AQP2 was also increased 44% but failed to reach statistical significance (p=0.057). In contrast, IM base UT-A1 and AQP2 protein levels were not changed with AMPK stimulation. Outer medullary NKCC2 abundance was increased 117% with AMPK stimulation in control rats (p<0.004) but not in V2R-blocked rats. Immunochemistry showed that AQP2 and p-AQP2Ser256 appear to be localized on the cell membrane with acute and chronic AMPK stimulation, both in control and V2R-blocked rats.

Conclusions: AMPK stimulation in V2R-blocked rats is able to reduce the urine concentrating defect by increasing UT-A1 and AQP2. These results indicate that specific AMPK pathway activators might provide a promising treatment for congenital NDI.

The Role of Klotho in Renal Sodium and Water Transport
Talita R. Sanches,1,2 Fernando O. Coelho,1 Leticia Jorge,1 Leticia U. De Castro,1 Makoto Kuro-o,2 Lucia Andrada,1,3* 1Div of Nephrology, Univ of Sao Paulo, Brazil; 2Jichi Medical Univ, Japan.

Background: Klotho (Kl), a transmembrane protein hormone, counteracts aging. Aging is often paralleled by dehydration, which could promote age-related disorders, because it decreases renal KI protein abundance, as well as increasing plasma osmolarity, antidiuretic hormone (ADH), aldosterone, and 1,25 vitamin D. ADH and aldosterone decrease Kl transmembrane in HEK293 cells and are elevated in the sera of Kl knockout mice. We explored the effects of Kl deficiency on renal transporters.

Methods: 8-12 week old male Kl−/−, Kl−/- and Kl+/- mice (n=6/group) were fed standard mouse chow and given to aquatic access to tap water. We evaluated serum levels of Na, K, Cl, Mg, creatinine and urea. We immunoblotted for sodium/hydrogen exchanger isoform 3 (NHE3), renal outer medullary potassium channel (ROMK), the Na-K-Cl cotransporter (NKCC2), alpha subunit of the epithelial sodium channel (αENaC) and aquaporin 2 (AQP2) measured in many clinical water-balance disorders as a potential biomarker for diagnosis and treatment. However, Kl knockout mouse present reduced sensitivity to elevated plasma aldosterone levels with no increase in oENaC or ROMK protein expression. A lack of Kl can deregulate the adaptive response (FAPESP).

Results: Data are mean±SEM.

Conclusions: In Kl knockout mice, there seems to be normal regulation of NKCC2 and trafficking of AQP2 to the apical plasma membrane in response to ADH. However, Kl knockout mouse present reduced sensitivity to elevated plasma aldosterone levels with no increase in oENaC or ROMK protein expression. A lack of Kl can deregulate the adaptive response (FAPESP).

Inhibition of EGFR Activity Increases Aquaporin 2 Phosphorylation and Increases Water Reabsorption in Lithium Treated Mice
Pui Cheung, Naohiro Nomura, Anil V. Nair, Hua Ann Jenny Lu, Richard Bouley, Dennis Brown. Medicine, Massachusetts General Hospital, Boston, MA.

Background: Impairment of vasopressin (VP) receptor type 2 signaling in the kidney is detrimental to water homeostasis. However, strategies targeting cAMP signaling to treat diseases associated with water balance have so far been unsuccessful in humans, prompting a search for alternative pathways that modulate AQP2 trafficking.

Methods: The effect of erlotinib (Erl) oral gavage in a lithium induced nephrogenic diabetes insipidus mice model was analyzed by measuring urine volume and osmolality. The effect of Erl on aquaporin 2 trafficking and expression in kidneys was studied by immunostaining and western blot analyses. EGFR and Erl regulation of AQP2 trafficking and phosphorylation were studied using selective kinase inhibitors and phospho-specific antibodies on AQP2-expressing LLC-PK1 cells.

Results: Erl alone had only a subtle effect on AQP2 trafficking, but it exerted a significant antagonizing effect on VP-induced AQP2 phosphorylation and membrane accumulation. Conversely, erlotinib (Erl), an EGFR inhibitor, led to a VP-independent increase of apical AQP2 accumulation in collecting ducts, and significantly reduced urine volume by more than 40% after 4 days of treatment in lithium-induced NDI mice. Erl enhanced AQP2 plasma membrane localization in cells by increasing AQP2 exocytosis and decreasing endocytosis. This effect was cAMP, cGMP, and PKA independent. Despite apparently bypassing cAMP pathways, Erl resulted in AQP2 phosphorylation in a dose dependent manner at serine 256, an essential step in VP-induced AQP2 membrane accumulation. We propose that EGFR has a tonic inhibitory effect on VP action, and that relief of such inhibition enhances AQP2 phosphorylation and results in membrane accumulation.

Conclusions: We showed a crosstalk between EGFR and VP in the modulation of AQP2 trafficking. EGFR inhibition increases AQP2 membrane expression bypassing the canonical VP/CAMP/PKA pathway and ameliorates lithium-induced NDI in mice. This study improves our understanding of the diversity of mechanisms that regulate water reabsorption in the body, and uncovers a novel pathway for potential therapeutic targets for NDI.

ChiP-seq Analysis of Genomic Binding Sites for the Transcription Factor E11 in mmpCkd Cells
Hyun Jun Jung, Viswanathan Raghu Ram, Jae Wook Lee, Mark A. Knepper. Systems Biology Center, NHLBI, NIH.

Background: Collecting duct cells selectively express a number of transport proteins (aquaporins and ion channels) vital to water and electrolyte balance. Previous studies of tissue-specific gene expression in collecting duct cells have implicated Ets family transcription factors (TFs) (Yu et al. PNAS 2009;106:2441). We integrated data from prior proteomics and transcriptomics studies of mouse mpkCCD cells using Bayes’ Rule to create a probability-based ranking of all known TFs with regard to likelihood of a role in collecting duct-specific gene expression. Among the top-ranked TFs were several Ets family TFs including E11.

Methods: To identify genomic binding sites for E11 in mmpCkd cells, we carried out ChiP-seq analysis using an antibody successfully employed in the Mouse ENCODE Project. The mmpCkd cells were treated with the vasopressin analog dDAVP (100pM) for 24 hr prior to crosslinking and chromatin immuno-precipitation (ChiP) (n=3). DNA libraries were prepared from immunoprecipitated DNA and sequenced using an Illumina HiSeq 2000 sequence to identify TF-enriched genomic regions. Control ChiP was carried out with nonspecific IgG.

Results: The analysis (MACS peak-calling software) identified >2000 binding sites seen in all three replicates and not seen in IgG-only controls. The identified sites mapped to within 2000 bp of annotated transcription start sites (TSSs) of several genes whose transcript abundances were previously demonstrated to be regulated by vasopressin including Id3, Tgfb1, Nfkb1 and Spag9 (Sanches et al. Plos One 2011;6:10110). There was no E11 binding in the vicinity of any aquaporin or any ENaC subunit, indicating that any role of E11 in regulating these targets is likely to be indirect. However, E11 binding was mapped to additional TFs that are predicted to bind within 1000 bp upstream of TSSs for aquaporin-2, β-ENaC or γ-ENaC (Genomatix motif analysis). These TFs were C/EBP, Gata3, Sox4, Junb, Sp1, Sp3, Gabpa, Nkhi1, Hmxbox1, Breb1 and Rrma.

Conclusions: These data provide an initial step in identification of the transcriptional network that determines cell-type-specific expression in renal collecting duct cells.

Deletion of Aquaporin 11 in Transgenic Mice prior to Post-Natal Day 12 Results in Proximal Tubule Injury and Cyst Formation 

Soren Nielsen,1 Mads Vammen Damgaard,1,2 Michael R. Rutzler,1 Robert A. Fenton,2 Aleksandra M. Rojek,3 Dept of Health Science and Technology, Aalborg Univ, Aalborg, Denmark; 1Dept of Biomedicine, Aarhus Univ, Aarhus, Denmark.

Background: AQP11 is expressed in the proximal tubule (PT). Neutone AQP11 KO mice show PT vacuolization and cysts, resulting in renal failure and death. This study examined whether the kidney injury is important for PT injury and cyst formation, and whether the cyst formation is related to the recycling of AQP11 to PT, as reported in the literature (J Am Soc Nephrol. 16: 1985, 2005), the expression of Casps was examined by real-time PCR in the kidney of AQP11 null mice before the polycyst development. We speculated that cisplatin may play an important role in the development of cisplatin nephrotoxicity. The enhancing the AQP11 expression in the kidney will be a renoprotective strategy in cisplatin nephrotoxicity.

FR-PO106 Development of a Model on Chronic SIADH: Effect of Water Challenge and Treatment on Behavior, Learning, Memory and Brain Edema 

Marta Tejedor, Ana Duran Vila, Carmen Grande, Margarita Fernandez, Teba Gonzalez, Maria Melendo, Ana Morales, Cristina Vila, Juan Carlos Jado, Ignacio Lizardo, Alberto Tejedor Jorge, Nephrology, Hospital_Gregorio_Mara, Madrid, Spain.

Background: AIM: to develop a model on chronic SIADH and study the effects of acute water overload on behavior, brain edema and response to treatment.

Methods: We induced chronic SIADH by daily injection of ddAVP and water over a 3-5 day period to balb-c mice. We induced acute on chronic SIADH by giving an acute i.p. water challenge of 5% of body weight. We assessed behavioral changes by filming spontaneous ambulations of mice and under challenge conditions in a Morris water maze. We also studied brain edema by means of continuous Perfusor gradients to fraction grey and white brain substance. We administered tolvaptan to evaluate their effects in the abovementioned conditions.

Results: ddAVP administration alone was able to induce significant changes in spontaneous behavior despite minimal changes in natriuresis (3%)(2). These changes were earlier and more severe if a chronic water overload was given. Overall, learning and memory improved over time with training, measured by times of resolution (p<0.004) and trajectory (p<0.002) in a water maze. This was more evident in the control group than in the SIADH group (learning (p=0.06), memory (p=0.08)). The mean trajectory length to resolve the maze was 185.5±5 cm in the control group, 360±44 cm in SIADH with no acute water overload (p<0.05) and 808±94 cm in SIADH with an acute water challenge of 5% (p<0.05). Treatment with tolvaptan significantly shortens the length of the trajectory to nearly baseline values. The SIADH group who received a 5% water challenge developed significant brain edema which was reduced by tolvaptan. No significant changes were seen in animals who did not receive the water challenge. An acute water overload of 5% in SIADH was equivalent to a 10% one in controls, as shown by similar worsening in the water maze.

Conclusions: ddAVP injection alone is enough to induce subtle behavioral changes, even in the absence of significant hypotension. Acute on chronic SIADH significantly worsens brain edema and resolution of a water maze, and such changes can be reverted by tolvaptan.

FR-PO107 Warburg-Like Proliferation Underlies Lithium-Induced Nephrogenic Diabetes Insipidus 

Teun de Groot, Peter M.T. Deen, Mohammad Alsady, Dept of Physiology, Radboud Univ Medical Center, Netherlands.

Background: Lithium is the first-choice medication for treatment of bipolar disorders and is used by 0.1% of the western population. Unfortunately, lithium treatment is associated with development of severe renal side effects. In approximately 50% of treated patients, lithium causes an urinary concentrating defect, which develops in 20% of patients into symptomatic Nephrogenic Diabetes Insipidus (NDI). This disorder is characterized by polyuria and polydipsia and is caused by downregulation of AQP2 water channels in principal cells of the renal collecting duct. Furthermore, lithium induces proliferation of the renal collecting duct and in vivo. Cell proliferation is often characterized by aerobic glycolysis (Warburg effect). Here, we investigated whether lithium may induce Warburg-like aerobic glycolysis and whether inhibition of this Warburg effect may rescue lithium-induced-NDI (Li-NDI).

Methods: Polarized mouse cortical collecting duct (mCCkD) cells were cultured as a 2D transwell model and exposed to lithium chloride on the apical side (10 mM) and basolateral side (1 mM) to mimic clinical conditions in patients. C57BL/6J mice were fed a normal rodent diet or a diet with lithium chloride in a concentration of 40 mM/kg of chow for the last 48 hours of the experiment, mice were housed in metabolic cages in order to determine water intake and urine output/osmolality during the last 24 hours.

Results: Lithium induced proliferation of mCCkD cells as shown by increased levels of the proliferation markers PCNA and cyclin D1. In addition, lactate and succinate, main products of the Warburg effect were increased in lithium-treated mCCkD cells and mice. This was accompanied by a decrease in the ratio of phospho-pyruvate dehydrogenase (pPDH)/PDH, confirming the induction of aerobic glycolysis by lithium in mice. Interestingly, inhibition of lithium-induced glycolysis with 2-deoxyglucose (2DG) attenuated lithium-induced AQP2 downregulation in mCCkD cells.

Conclusions: Our results reveal that lithium induces aerobic glycolysis in mCCkD cells and mice. Targeting of aerobic glycolysis with 2-deoxyglucose rescued lithium-induced AQP2 downregulation and may represent a potential therapy for Li-NDI.

Funding: Government Support - Non-U.S.

Background: Vasopressin escape is a protective mechanism that limits hyponatremia in the syndrome of inappropriate antidiuresis (SIADH). In vasopressin escape, transcripts of aquaporin-2 and aquaporin-3 were significantly downregulated at day 1, 2, and 4. Among downregulated transcripts were transcription factors (Hes1, Hmx2, Hosb5, Hosb6, Hosb7, Jun, and Fox3) and a cyclin-dependent kinase inhibitor (Cdk1b).

Methods: FR-PO111 Mouse Monocarboxylate Transporter 9 Functions as a Urate Transporter Promu itself, Radikul. Otake, Motoshik Ouchi, Naohiko Anzai. Dept of Pharmacology and Toxicology, Dokkyo Medical Univ School of Medicine, Mibu, Tochigi, Japan.

Background: Monocarboxylate transporter 9 (MCT9/SLC16A9) has been suggested to be involved in the onset of hyperuricemia or gout by genome-wide association studies (GWAS). Since no experimental data about MCT9 function has been reported, we tried to clarify its physiological roles.

Results: The expression of SLC16A9 was investigated by quantitative RT-PCR (qRT-PCR) against human tissue cDNAs. Using oocyte expression system, we injected mouse MCT9 (mMCT9) cRNA to perform the functional characterization of mMCT9.

Methods: The expression of SLC16A9 was investigated by quantitative RT-PCR (qRT-PCR) against human tissue cDNAs. Using oocyte expression system, we injected mouse MCT9 (mMCT9) cRNA to perform the functional characterization of mMCT9.

Results: mMCT9 cRNA injection did not cause hyperuricemia in mice. However, mMCT9 cRNA injection resulted in a significant decrease in the plasma uric acid levels and increased plasma levels of several phosphatidylcholine and sphingomyelin species; and (iv) a significant reduction in plasma carnitine levels, a significant decrease in the expression levels of carnitine palmitoyl transferase (CPT1) and crestdinase, a significant decrease in the expression levels of carnitine palmitoyl transferase (CPT1) and crestdinase. These results revealed a separate, hitherto undescribed heterozygous mutation in SGLT2 (c.265G>A; p.Glu89Lys) in a patient with juvenile cataracts, microcornea and glucosuria. While the MCT12 mutation co-segregated with the eye phenotype, poor correlation with the glucosuria phenotype questioned a pathogenic role of the mutation in the kidney. Here we show that MCT12 resides on basolateral membranes of proximal tubule epithelial cells. Therefore, MCT12-mediated cellular creatine efflux contributes to the kidney phenotype.

Results: Results revealed 13 genes whose expression was relevant for the AQP2 redistribution. One of them is a recently identified member of the cyclin-dependent kinase family. Its knockdown blocks the AQP2 translocation and simultaneously increases the AQP2 protein abundance.

Results: Results revealed 13 genes whose expression was relevant for the AQP2 redistribution. One of them is a recently identified member of the cyclin-dependent kinase family. Its knockdown blocks the AQP2 translocation and simultaneously increases the AQP2 protein abundance.

Conclusions: Our approach contributes to understanding the molecular mechanisms underlying the control of AQP2 trafficking and to identify potential therapeutic targets for the treatment of diseases caused by or associated with aberrant AVP-mediated water reabsorption such as diabetes insipidus or heart failure.

NaDC1 Knockout: Effects on Blood Pressure and Urine pH
Federico Jose Teran,1 Wei Tao Huang,1 L. Lee Hamm,1,2 Kathleen S. Herings-Smith.1 1Nephrology, Tulane Univ School of Medicine, New Orleans, LA; 2Research, SLVHCS, New Orleans, LA.

Background: NaDC1 reabsorbs filtered citrate (Cit); thus its regulation is important in preventing calcium nephrolithiasis. Importantly NaDC1 reabsorbs other Krebs cycle intermediates such as succinate (Suc) and αKG. Recently Suc and αKG have been found to be potent in paracrine signaling as their luminal presence stimulates distal nephron G-protein coupled receptors GPRC9R and GPCR9 respectively. Luminal Suc via GPCR9 has been found to stimulate renal renin; while αKG via GPCR9 stimulates bicarbonate secretion by type I intercalated cells. The purpose was to determine whether knockout of NaDC1 produces hemodynamic or urine pH changes that might be anticipated by activation of these receptors.

Methods: Adult NaDC1 KO, heterozygous (Het), and wild-type mice (WT), under normal or acid diet for 72 hr, were studied using standard clearance techniques. After anesthetization different measurements of hemodynamic parameters were determined and rats were allowed to recover for 24 hr. Urine, blood and tissue were collected for assessment of NaDC, Cit, αKG, and pH.

Results: NaDC1 KO produced 2, 4, and 10-fold increases in urine Suc, Cit, and αKG, respectively. There was substantial residual reabsorption of Cit and Suc in KO mice, indicating other transporters involved in reabsorption of these substrates. Despite the increase in normal αKG there was no significant increase in urine pH (normal or acid diet); in fact on normal diet urine pH was lower in KO mice (5.10 ≤ 0.04 vs 5.90 ± 0.13 WT; p < 0.001). The lower urine pH in KO mice on normal diet may be a response to loss of potential driving force for increased Krebs cycle intermediate excretion. There was no change in the ability of KO animals to excrete acid. In regard to potential hemodynamic effects mediated by NaDC1 KO and increased urine Suc, no change in MAP was determined comparing WT, Het or KO either on normal or acid diet.

Conclusions: In sum, NaDC1 is responsible for significant reabsorption of normal αKG and Suc, but knockout of NaDC1 does not impair acid-base homeostasis or BP changes on normal or acid diets. Funding: NIDDK Support

FR-PO114
The Ablation of Dendritic Cells Prevents the Upregulation of the Intrarenal Renin-Angiotensin System and Renal Sodium Transporters in Response to Angiotensin II and High Salt Diet
Patricia A. Araras,1 Daniel E. Hevia,1 Carolina E. Prado,1 Eugenia L. Fuentes,1 Rodrigo Pacheco,1 Luis F. Michea.1 1Univ de Chile, Chile; 2Fundación Ciencia y Vida, Chile.

Background: Blood pressure depends on the renal sodium reabsorption mediated by the tubular transporters that are modulated by the intrarenal renin-angiotensin system (iRAS). Angiotensin II (AngII) and a high salt diet (HS) cause hypertension (HT) and the hemodynamic effects mediated by NaDC1 KO and increased urinary Suc, no change in MAP was determined comparing WT, Het or KO either on normal or acid diet.

Methods: CD11c DOG mice, for selective loss of DCs (CD11cLy), and CD11c COL% mice were euthanized 14 days after induction of HTN. Heart weight/body weight (H/BW) ratios were calculated and kidney leukocyte infiltration was analyzed by flow cytometry. We conclude that DCs are required for the modulation of iRAS and TLR4, renal NF-κB and plasma IL-6.

Conclusions: Interleukin-6 Inhibition Attenuates Hypertension and Proteinuria in Dahl Salt-Sensitive (SS) Rats
Shireen Hashmat,1 Scott K. Van Why,1 Shieen Hashman,1 Justin M. Abais-Battad,1 Hayley Lund,1 Scott K. Van Why,2 David L. Mattson. 1Pediatrics, Medical College of Wisconsin; 2Physiology, Medical College of Wisconsin, Milwaukee, WI.

Background: Interleukin-6 (IL6) inhibits the inflammatory response to injury. The current study is to determine whether prior splenectomy (SPLX) significantly alters tissue inflammation; however the effect of SPLX on HTN remains unclear. Therefore, the objective of the current study is to determine whether prior splenectomy influences the development of HTN in 2 different mouse models.

Methods: Mice underwent SPLX or sham surgery 7 days prior to the induction of HTN using angiotensin-II (AngII, 400ng/kg/d) or nitric oxide synthase inhibition using L-NAME (30mg/kg/d). Systolic blood pressure (SBP) was measured by tail-cuff manometer daily and mice were randomized 14 days after induction of HTN. Heart weight/body weight (H/BW) ratios were calculated and kidney leukocyte infiltration was analyzed by flow cytometry.

Results: Mice with prior SPLX+AngII had significantly lower (P<0.05) SBP at both week 1 (148±7) and week 2 (135±7) as compared to Sham+AngII (174±7/173±7mmHg). Similarly, SPLX+AngII mice had significantly smaller (P<0.007) H/BW (4.3±0.3) as compared to Sham+AngII treated mice (5.2±0.4mg/g BW). Interestingly, no difference was observed in renal CD45+ (9.8±3 vs 10.6±3x10^5 cells/g, P=0.64) or CD3+ T-cell infiltration (8.8±0.2 vs 9.6±0.1x10^5 cells/g, P=0.64) between Sham+AngII and SPLX+AngII treated mice respectively. Furthermore, SPLX did not appear to influence the development of L-NAMe HTN. SPLX+L-NAMe mice had similar P=0.84 SBP (145±9mmHg) as the Sham+L-NAMe group (146±4mmHg, n=6) after 2 weeks. Relative heart weights were also similar (P=0.45) between SPLX+L-NAMe (4.9±0.2) and Sham+L-NAMe treated mice (4.8±0.3mg/g BW).

Conclusions: Our data suggests that the full pressor response to AngII is dependent on the spleen. However, the effect of the spleen appears to be independent of renal inflammation. Moreover, the protective effect of the spleen is specific to AngII-dependent HTN and does not appear to be generalizable to all mouse models of hypertension. Further studies are needed to understand the putative link between lymphoid organs (such as the spleen), renal inflammation, and the development of chronic HTN.

Salt Overload Promotes Severe Renal Injury and Activates AngII, Renal NF-κB and Other Components of Innate Immunity in a Model of Arterial Hypertension
Víctor F. Ávila,1 Orestes Foresto-Neto, Simone CA Arias, Camila Fanelli, Flavia G. Machado, Mariliza V. Rodrigues, Claudia R. Sena, Viviane D. Faustino, Líssiény CT Rempel, Gizely CS Moreira, Vivian L. Viana, Denise M. Malheiros, José E. Krieger, Roberto Zutz, Clarice K. Fujihara. 1Univ de Sao Paulo, Sao Paulo, Brazil.

Background: Hypertension (HTN) develops in rats that received the NF-κB inhibitor pyrrolidinedithiocarbamate (PDTC) during lactation. High salt (HS) and uninephrectomy (UNx) aggravate HTN, increase renal AngII and lead to severe renal injury. Here, we further investigated the mechanisms of renal injury and the effect of Lactotransferrin (L) in this model.

Methods: Munich-Wistar pups received PDTC (PDTClact), or no treatment (C) during lactation. At 10 weeks of age, all rats underwent UNx and were divided in: C, given normal salt diet (NS); PDTClact; given HS; PDTClact+HS; given HS and L; 50 mg/kg/d. After 3 mo, we assessed: tail-cuff pressure (TCP, mmHg), glomerulosclerosis (GS), interstitial collagen (COL), arteriolar lesions (AL), interstitial AngII+, macrophages (Mo) and lymphocytes (Ly), cells/mm², TLR4 and nuclear NF-κB (nC) in serum IL-6 (ng/mL).

HS+UNx led to severe HTN and renal vascular injury, intense Mo Ly infiltration, increased AngII+ and TLR4, and NF-kB activation, with increased plasma IL-6, all correlating positively with TCP. L strongly attenuated renal damage, normalizing renal TLR4, renal NF-kB and plasma IL-6.

Conclusions: In PDTC l, renal injury caused by HS+UNx involves activation of renal AngII and innate immunity, including the NF-kB system. FAPESP/CNPq.
Methods: Experiments were performed to assess the potential role of IL-6 in Dahl hypertensive rats. In these experiments, rats were administered anti-IL-6 neutralizing antibody (anti-IL-6; 4 μg/day; IP: R&D Systems, Minneapolis, MN) or normal goat IgG control (4 μg/day, IP) for 11 days.

Results: The MAP and urine protein excretion rates (Up) were similar between the groups of SS rats (n=13-16/group) when fed low salt (0.4% NaCl) chow. Following 11 days of high salt (4% NaCl) chow, the rats receiving anti-IL-6 demonstrated a significant reduction in intraocular IL-6 in the renal medulla compared to control group (954±133 pg/ml vs 1802±336 pg/ml). Moreover, the increase in MAP following 11 days of 4% NaCl intake was significantly attenuated in treated (MAP=138±3 mmHg) vs control group (MAP=172±3 mmHg). Anti-IL-6 also attenuated IS-induced expression of CCL5 (4-fold), TNFα mRNA expression 1.25-fold. Moreover, the increase in MAP following 11 days of 4% NaCl intake was significantly attenuated in treated (MAP=138±3 mmHg) vs control group (MAP=172±3 mmHg). Anti-IL-6 also attenuated IS-induced expression of CCL5 (4-fold), TNFα mRNA expression 1.25-fold.

Conclusions: These results suggest that IL-6 may play an important role in the development of SS hypertension and end-organ damage by mediating the infiltration of leukocytes into the kidney.

Indoxyl Sulfate Uregulates Aortic Expression of (Pro)renin Receptor by Reactive Oxygen Species and Activation of AhR/NF-κB Pathway in Vascular Smooth Muscle Cells
Maimaiti Yisirevili,1 Toshimitsu Niwa,2 Cardiology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan; 1Faculty of Health and Nutrition, Shabun Univ, Ichinomiya, Aichi, Japan.

Background: Chronic kidney disease (CKD) is considered major causes of death in cardiovascular disease (CVD) patients. (Pro)renin receptor (PRR) is significantly expressed in the vascular smooth muscle cells (VSMCs).

Methods: CKD rats and IS-administrated rats were subjected for in vivo experiments. Human aortic smooth muscle cells (HASMCs) was treated with or without indoxyl sulfate (IS).

Results: Indoxyl sulfate (IS) significantly increased NOS and PRR expression at all time points. IS significantly activated AhR and NF-κB in HASMCs.

Conclusions: IS stimulates aortic expression of PRR and NOS, and hence, may contribute to the physiological response to high dietary salt and salt-sensitive hypertension.

Role of Skin and Endothelial Surface Layer Heparan Sulfates in Blood Pressure Regulation
Rik Hg Olde Engberink,1 Naomi Van Vliet,2 Bert-Jan Van den Born,3 Ed van Bavel,4 Liffert Vogt.1 Nephrology, AMC, Amsterdam, Netherlands; 2Laboratory of Genetic Medicine, AMC, Amsterdam, Netherlands; 3Vascular Medicine, AMC, Amsterdam, Netherlands; 4Biomedical Engineering and Physics, AMC, Amsterdam, Netherlands.

Background: Besides the skin, the endothelial surface layer (ESL) contains many glycosaminoglycans (GAGs) that can osmotically inactivate Na+ and may affect blood pressure (BP). GAGs regulate heparan sulfate (HS) polymerization, the predominant ESL GAG. In mice with heterozygous loss of EXT1 and EXT2 (EXT), and wildtype (WT) mice, we investigated the role of HS in the skin and ESL in BP regulation after an acute and chronic NaCl load.

Methods: We investigated BP effects of a 7-d normal (0.3%), NSD and high (8.0%) HS). NaCl diet, with tail cuff measurements, and an acute 1.8% NaCl load (8 μl/g) with intracardiac measurements. We used intravital microscopy to estimate ESL thickness in <40 µm crenal vessels on both diets. We used high performance liquid chromatography-mass spectrometry to measure skin HS disaccharide concentration.

Results: Baseline BP was equal in WT and EXT mice (p=0.9), with no difference between NSD and HSD. Relative to WT, acute NaCl infusion increased BP in EXT mice (p=0.02), while heart rate remained equal (p=0.5). After a NSD and HSD, EXT mice had a 78% reduction of ESL thickness compared to WT mice (Fig A). HSD increased ESL thickness in WT, especially in 20-40 µm vessels, but not in EXT mice (Fig BC). Skin HS concentration and sulfation patterns were equal between diets in WT mice (Fig DE). On NSD, EXT mice had more highly sulfated HS compared to WT (Fig DE). Ext mice on a HSD had the highest skin HS concentration, of which most were low-sulfated.

Conclusions: An intact ESL is pivotal to prevent a BP increase during acute NaCl excess. Skin GAGs may be particularly important to prevent detrimental NaCl effects on the long-term, especially when the ESL is damaged.

Adenosine A1 Receptor Exacerbates Water-Sodium Retention in Deoxycorticoesterone Acetate-Salt Hypertensive Mice Janet Yanqing Mei,1 Xiaoxiao Shi,1 Dongli Tian,1 Xiaoyan Peng,1 Wei Chen,2 Limeng Chen.1
1Nephrology Dept, Peking Union Medical College Hospital, Beijing, China; 2Cardiology Dept, Peking Union Medical College Hospital, Beijing, China

Background: Adenosine receptor (A1AR) engages in tubuloglomerular feedback; its activation is followed by increased secretion of atrial natriuretic peptide (ANP) in the heart. We aim to study the function of A1AR in water-sodium retention.

Methods: DOCA-salt hypertensive model was established by removal of left kidney, implantation of a DOCA pellet (200mg, 60-day release), and feeding with high salt diet (8%NaCl). Arterial blood pressure and heart rate were measured by tail-cuff method. Urine samples were collected using metabolic cage. The CD73 (an adenosine synthetase), A1AR, ANP and Corin (a protease cleaves pro-ANP, producing ANP) mRNA expression were measured by real-time PCR.

Results: Wildtype DOCA-salt mice showed higher blood pressure (124.7±20.3 vs. 105.8±14.1 mmHg, P<0.01), slower heart rate (562.0±90.8 vs. 681.5±90.1, P<0.01), and increase in 24h urine output (3606.2±2359 vs. 1399:752 ml, P<0.01). The adenosine pathway was activated in DOCA-salt mice evidenced by increased CD73 (2.22 and 17.7 times increased expression in kidney and heart, P=0.034 and 0.009). The cardiac mRNA expression of ANP and Corin were also significantly higher in DOCA-salt mice (176.6 and 30.93 times increased expression, P=0.030 or 0.005). The A1AR mice showed no significant changes in blood pressure or heart rate between DOCA-salt and sham group. The elevation of 24h urine output (7003:3742 vs. 3606.2±2359 ml, P=0.031) and 24h sodium excrection (1246.5±860.5 vs. 1479.7±48.9 mmol/d, P=0.028) was more prominent compared to wildtype DOCA-salt mice. There was no change in either ANP or Corin mRNA expression.

Conclusions: A1AR may exacerbate water-sodium retention in salt sensitive hypertension. The reduction in glomerular hyperperfusion and hyperfiltration through podocyte injury, abnormally increased filtered load of Na and Cl transport and induces neuroexcitation, both of which may increase blood pressure. Here we tested the hypothesis that fructose-fed rats fed a high salt diet is a critical component of fructose-induced salt-sensitive hypertension.

FR-PO123

Dietary Fructose Increases Renal Sympathetic Nerve Activity in Response to High Salt Diet in Awake Freely Moving Rats Noreen F. Rosal,1,2 Lorenz Sellin,1,2 Pablo A. Ortiz,1,2 William H. Beierwaltes.1,2
1Nephrology, Wayne State Univ School of Medicine, Detroit, MI; 2Physiology, Wayne State Univ School of Medicine, Detroit, MI

Background: High consumption of fructose containing foods is increasingly prevalent. Fructose intake is associated with metabolic syndrome including hypertension. Fructose upregulates renal Na and Cl transport and induces neuroexcitation, both of which may increase blood pressure. Here we tested the hypothesis that fructose-fed rats fed a high salt diet will have higher plasma renin activity (PRA), renal sympathetic nerve activity (RSNA) and mean arterial pressure (MAP) than glucose-fed rats on similar diet.

Methods: Male Sprague Dawley rats were instrumented for telemetric MAP and RSNA measurements. They were placed on 20% glucose (GF) or 20% fructose (FF) in drinking water. Blood pressure (BP) were measured for 3 weeks by radiotelemetry, starting one week prior to implantation. Histological and mRNA analysis were performed at the end of the observation period. Renal vascular function was evaluated in the isolated perfused kidney.

Results: Blood pressure in FF rats was 120.1±9.1 mmHg vs. 106.4±7.5 mmHg in GF rats (P<0.05). FF rats had higher plasma renin and MAP, however no differences were seen in heart rate. FF rats had higher RSNA than GF rats (P<0.05).

Conclusions: These indicate that, in podocyte injury, abnormally increased filtered load of Agt is reabsorbed via proximal tubular cells mainly dependently on melanin. In the present study, we tested whether melanin is involved in intrarenal AGT generation. For this purpose, we generated proximal tubule specific melanin knockout (KO) mice by crossing melanin-loxp, Ndr1-Cre, and Kap-Cre mice. Renal AngII contents were measured by radioimmunoassay.

Results: In melanin KO mice (n=12), renal melanin mRNA was decreased to 2.5% of that in control mice (n=16). Renal Agt staining was markedly diminished, with increase in urinary Agt in KO mice. However, renal Agt levels were similar between KO and control mice (108±11 vs. 101±17 fmol/g). We next tested the effect of melanin KO on intrarenal Agt generation in fructose-fed rats. Rats with abnormally increased filtered load of Agt in mice with podocyte-specific injury, by crossing with NEP25 mice. Control NEP25 mice (n=10) showed markedly intense renal Agt staining and enhanced renal Agt level (450±61). Melanin KO/NEP25 mice (n=12) showed diminished renal Agt staining and significantly attenuated renal Agt level (119±23, p<0.01). KO/NEP25 mice showed similar renin and Agt mRNA, and more presence of cRNA in the kidney.

Conclusions: These indicate that, in podocyte injury, abnormally increased filtered load of Agt is reabsorbed via megalin by proximal tubular cells and induces the inappropriate activation of intrarenal renin-angiotensin system, which may be involved in the progression of tubulointerstitial damage secondary to podocyte injury.

Funding: Government Support - Non-U.S.
Results: At baseline systolic BPs were similar in CNTF-KO and WT mice (119 ± 2 vs. 124 ± 1 mmHg). CNTF deficiency significantly attenuated BP increase under Ang II infusion (week 1: 139 ± 3 vs. 153 ± 3 mmHg; week 2: 151 ± 5 vs. 168 ± 4 mmHg; n = 19; P < 0.01). Strikingly, in the CNTF-KO group significantly less animals died of cardiovascular causes (4.2% (KO) vs. 29.2% (WT) P < 0.05). In accordance, end organ damage (cardiac hypertrophy, renal vascular fibrosis and tubulo-interstitial damage) was attenuated in the CNTF-KO group. In the isolated perfused kidney, pressor response to Ang II was significantly attenuated in CNTF-KO mice. Administration of CNTF (0.5nM) nearly restored the Ang II dependent pressor response. This effect was mediated through a JAK2/STAT3 dependent pathway as renal vascular fibrosis and tubulo-interstitial damage) was attenuated in the CNTF-KO group (3.4 ± 0.6 vs. 29.2% (WT) P < 0.001). Sodium excretion was unchanged (veh: 3.46 ± 0.6 vs. 3.38 ± 0.6 mmol/24h). There were no changes in proximal fractional reabsorption (Veh: 57 ± 2%, Veh: 59 ± 0.6%) and distal fractional reabsorption (Veh: 83 ± 3%, AII: 87 ± 2%). UMOD expression in the renal medulla was 3 fold higher in Ang II treated rats compared to vehicle rats.

Conclusions: Our data demonstrate that AngII increases UMOD expression and excretion independent of blood pressure and alterations in tubular reabsorption. These results suggest that the interaction of AngII with UMOD precedes Na+ transport alterations and therefore can be an important mechanism involved in the development of hypertension.

FR-PO127
Angiotensin II AT1 Receptor Potentiates Prostaglandin E2 Vasconstrictor Effects
Maria Palazzo Kraemer, Fred S. Lamb, Richard M. Breyer. Div of Nephrology and Hypertension, Dept of Veterans affairs and Vanderbilt Univ, Nashville, TN; Dept of Biochemistry, Vanderbilt Univ, Nashville, TN; Dept of Pediatrics, Vanderbilt Univ, Nashville, TN.

Background: Prostaglandin E2 (PGE2) is a vasomodulator that has vasopressor and vasodepressor effects. Our previous results have demonstrated that sub-threshold concentrations of Ang II can synergize with PGE2 to modulate Na transport. The present study was performed to determine the mechanism of elevated blood pressure in ATRAP-KO mice after 5/6 Nx, plasma volume and Na/K measurements. On day 3 proximal and distal reabsorption were measured by metabolic cages for 24 h and urine was collected for UMOD and Na/K measurements. On day 3, proximal and distal reabsorption were measured by methylene blue injection and the renal medulla was harvested for determination of UMOD expression by western blot.

Results: Blood pressure was unchanged after 3 days of AngII (veh: 89 ± 1; AII: 81 ±1 mmHg). AngII treated rats had significantly increased UMOD expression compared with control rats (Veh: 17.6 ± 2.19; AII: 28.9 ± 3.6, mg/24h, p < 0.05). Sodium excretion was unchanged (veh: 3.46 ± 0.6; AII: 3.38 ± 0.6 mmol/24h). There were no changes in proximal fractional reabsorption (Veh: 57 ± 2%; AII: 59 ± 0.6%) and distal fractional reabsorption (Veh: 83 ± 3%, AII: 87 ± 2%). UMOD expression in the renal medulla was 3 fold higher in AngII treated rats compared to vehicle rats.

Conclusions: Our data demonstrate that AngII increases UMOD expression and excretion independent of blood pressure and alterations in tubular reabsorption. These results suggest that the interaction of AngII with UMOD precedes Na+ transport alterations and therefore can be an important mechanism involved in the development of hypertension.

Funding: Government Support - Non-U.S.
increased blood pressure and plasma volume after 5/6 Nx compared with WT mice. Therefore, endogenous ATRAP may exert a protective function against pathological blood pressure elevation in CKD.

FR-PO131
In Vivo Action of Angiotensin II Type 1a Receptor in Renal Injury Induced by Deoxycorticosterone Acetate-Salt Hypertension  
Mikako Hisamichi, Atsuko Romori,1 Takashi Sugaya,1 Daisuke Ichikawa, Kenjiro Kimura, Yugo Shibagaki.1 1Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Japan; 1Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Japan; 1Dept of Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.

Background: The AT1α receptor plays a major role in the renal action of Ang II and is expressed in vascular smooth muscle cells of the afferent arterioles. In this study, we investigated the morphological change in deoxycorticosterone acetate (DOCA)-salt hypertensive nephropathy in L-FABP-+/− mice to confirm the in vivo function of the AT1α receptor against renal damage due to hypertension.

Methods: To examine urinary L-type fatty acid binding protein (L-FABP) as an indicator of tubulointerstitial damage, we used healthy L-FABP transgenic mice in addition to disrupting the AT1α receptor gene (L-FABP−/− AT1α−/−). L-FABP−/− AT1α−/− and L-FABP−/− AT1α+/- mice were administered DOCA tablets plus 1% NaCl water for 28 days.

Results: In the DOCA salt hypertensive model with L-FABP−/− AT1α−/− (L-FABP−/− AT1α−/− DOCA), slight expansion of the glomerular area and tubulointerstitial damage were observed, but not glomerular sclerosis. In the AT1α knockout mice administrated DOCA-salt (L-FABP−/− AT1α−/− DOCA mice), glomerular sclerosis with expansion of the mesangial area was found, and the degree of tubulointerstitial damage was more severe compared with L-FABP−/− AT1α−/− DOCA mice. In L-FABP−/− DOCA mice, L-FABP+/- mice were significantly higher in the L-FABP−/− AT1α−/− DOCA mice than in the L-FABP−/− AT1α−/− DOCA. This renal damage induced in the L-FABP−/− AT1α−/− DOCA mice was significantly attenuated by reduction of blood pressure using Hydralazine. Activation of the AT1α receptor may contribute to myogenic response of the afferent arteriole involved in the renal autoregulatory mechanism.

Conclusions: In conclusion, kidneys without AT1α receptors exhibited an increased vulnerability to hypertension, and therefore activation of the AT1α receptor inhibited the transmission of the elevated systemic pressures to the glomeruli.

FR-PO132
Renal Blood Flow and Oxygenation During Renin-Angiotensin-Aldosterone System Activation – Two Sides of the Same Coin?  
René van der Bel,1 Aart J. Nedernev,2 Bram F. Coolen,2 Wouter V. Potters,1 Hein J. Verberne,1 Lottfert Vogt,1 Erik Stroes,1 C.T.P. (Paul) Krediet.1 1Internal Medicine, AMC, Univ of Amsterdam, Netherlands; 1Radiology, AMC, Univ of Amsterdam, Netherlands; 1Nuclear Medicine, AMC, Univ of Amsterdam, Netherlands.

Background: In chronic kidney disease, renal hypoxia and renin-angiotensin-aldosterone system (RAAS) activation may augment each other. Although renal oxygenation (RO) measured by Blood Oxygen Level Dependent (BOLD) MRI is not correlated to Glomerular Filtration Rate (GFR), recent data suggest that RO relates to inter-individual variability in RAAS. Further explore this we measured the effects of Angiotensin II (Ang-II) on renal blood flow (RBF) and RO in healthy humans.

Methods: After a 30 min baseline phase, 8 healthy volunteers (age 19-22 years) were subjected to continuous Ang-II infusion at 0.3, 0.9 and 3.0 ng/kg/min for 12 minutes per dose. RBF were assessed by BOLD and phase contrast MRI, respectively (Ingenia, 1.5T, 7.1%, p=0.016; 24±4.5%, p<0.001). RBF and RO varied proportionately (R=0.48, p=0.017).

Conclusions: Ang-II causes a dose dependent DRBF. The observed DRO seem to differ between cortex and medulla. Only for the cortex BOLD may provide an index of tissue perfusion.

FR-PO133
Chloride Contributes to Hypertension and Renal Injury in Aldosterone-Salt Treated Rats  
Takahiro Yamauchi, Shigehiro Doi, Toshiaki Doi, Kensuke Sasaki, Toshihito Ueno, Ayumu Nakashima, Takao Masaki. Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.

Background: Aldosterone-salt treatment is known to induce renal inflammation and play a role in the development of hypertension, as well as elevating blood pressure. In addition to sodium, chloride has recently been reported to be involved in renal damage, raising the possibility that sodium-bicarbonate may ameliorate renal injury and hypertension in the rats treated with aldosterone-salt combination.

Methods: Following a left nephrectomy, 8-week-old male Sprague-Dawley rats were implanted with an osmotic infusion pump and then allocated to the following 3 groups: 1) drinking a 1% NaCl solution with aldosterone infusion (NaCl-aldosterone treated group), 2) drinking a 1% NaClO solution with aldosterone infusion (NaClO-aldosterone treated group), and 3) drinking water with vehicle infusion. Blood pressure levels were measured by tail cuff method. After 8 weeks, the rats were sacrificed and their renal tissues examined by immunoblotting and immunohistochemistry.

Results: The NaCl-aldosterone group had higher blood pressure levels than the NaClO-aldosterone group. Protein expression of eNOS and Pendrin in the membrane fractions of the aldosterone increased in NaCl-aldosterone group compared with the NaClO-aldosterone group. In addition, the NaCl-aldosterone group had high protein levels of NCC and phosphorylated NCC in the whole protein and membrane fractions. On the other hand, the expression of inflammatory (CD3, CD68, IL17A, IL-23 receptor) and fibrotic markers (α-smooth muscle actin, collagen I) were greater in the NaCl-aldosterone group.

Conclusions: These findings suggest that chloride plays an important role in the development of NaCl-aldosterone-induced hypertension and renal injury.

FR-PO134
RAGE-DNA Aptamer Improves Aldosterone-Induced Renal Injury Possibly via Inhibition of Rac1-MR Axis in Mice with Hypertensive Nephropathy  
Kensei Taugh-eight,1 Sho-ichi Yamagishi,2 Yuichiro Higashimoto,2 Yosuke Nakayama,1 Katsuhiko Asanuma,3 Seiji Ueda,1 Kei Fukami.1 1Div of Nephrology, Dept of Medicine; 2Dept of Pathophysiology and Therapeutics of Diabetic Vascular Complications; 3Dept of Chemistry, Kurume Univ School of Medicine, Kurume, Japan; 1Div of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.

Background: Advanced glycation end products (AGEs) stimulate the generation of reactive oxygen species (ROS) and subsequent enhancement various intracellular pathways through the interaction with receptor for AGEs (RAGE). Although AGEs-RAGE axis has been mainly investigated in diabetic nephropathy, its pathophysiological role in hypertensive nephropathy (HN) is unknown. In addition, recent evidence has suggested that aldosterone (ald) mineralocorticoid receptor (MR) system plays a crucial role for the pathogenesis of HN. In this study, we examined whether AGE-RAGE system could interact with ald-MR axis in deoxycorticosterone acetate (DOCA)-induced HN in mice. Further, we explored the inhibitory effects of DNA-aptamer directed against RAGE (RAGE-aptamer).

Methods: Uninephrectomized 8-week-old C57Bl/6J male mice were divided into three groups; 4% salt diet (control), 4% salt diet with DOCA (50mg/kg), and DOCA with hydralazine (Hyd). RAGE-aptamer constructed by SELEX method was continuously administrated with osmotic mini pump.

Results: DOCA elicited-UAE was independent of blood pressure. Renal ROS generation, RAGE protein expression and plasma carboxymethyl lysine (CML) levels were elevated in DOCA/salt mice. RAGE was colocalized MR in podocytes by immunohistochemical analysis. Further, GTP-bound Rac1 activation and MR overexpression were observed in DOCA/salt mice. DOCA-elicited increase in UAE, renal ROS generation and RAGE expression, plasma CML levels were improved by RAGE-aptamer independent of blood pressure. Interestingly, RAGE-aptamer suppressed GTP-bound Rac1 activity and MR activation in DOCA/salt mice.

Conclusions: AGES-RAGE axis and Rac1-MR pathway could be correlated with each other, which could lead to podocyte injury in HN. RAGE-aptamer may be a novel therapeutic strategy for the progression of HN.

FR-PO135
Dipeptidyl Peptidase-4 Inhibitor Ameliorates the Aldosterone-Induced Renal Fibrosis  
Kang-Yung Peng, Vincent Wu. Dept of Internal Medicine, National Taiwan Uni, Taipei, Taiwan.

Background: Renal fibrosis is considered a common outcome of a wide variety of chronic kidney diseases with diverse causes. However, no antifibrotic agent has been approved in clinical practice yet. In this study, we examined the effect of dipeptidyl peptidase-4 (DPP-4) inhibitor on aldosterone-induced fibrosis by aldosterone.

Methods: Human proximal tubular epithelial cells (HK2) were used to examine the inhibitory effect of DPP-4 inhibitor on aldosterone induced epithelial-mesenchymal transition (EMT). Besides, aldosterone infusion mice were used to evaluate the effect of DPP-4 inhibitor, linagliptin, on aldosterone induced renal fibrosis. Expression of TGF-β, OPN and molecules involved in EMT were examined using western blot and immunohistochemistry. Although AGEs-RAGE axis has been mainly investigated in diabetic nephropathy, its pathophysiological role in hypertensive nephropathy (HN) is unknown. In addition, recent evidence has suggested that aldosterone (ald)-mineralocorticoid receptor (MR) system plays a crucial role for the pathogenesis of HN.

Results: In vitro studies showed that aldosterone significantly increases the expression of TGF-β, OPN, and markers of the epithelial-mesenchymal transition in HK2 cells, while these effects were decreased in that treated with DPP-4 inhibitor. Similarly, the aldosterone-infused mice exhibited severe kidney fibrosis. The expression of TGF-β, OPN, vimentin and α-SMA were induced by aldosterone, and oral DPP-4 inhibitor ameliorated the kidney fibrosis and lessened the increase in fibrotic proteins without significant changes in blood pressures.

Mitochondrial Oxidative Stress-Activated Renal Local RCS Promotes the Expression and Function of NCC in Proteinuric Kidney Disease

Songming Huang, 1 2 Yibo Zhuang, 1 Guixia Ding, 1 Zhanjun Jia, 1, 2 Aihua Zhang, 1, 2 Nephrology Dept, Nanjing Children Hospital, Nanjing Medical Univ, Nanjing, China; ‘Nanjing Key Laboratory of Pediatrics.

Background: The fluid retention and hypertension are common complications of kidney diseases, whose pathogenic mechanisms remain elusive.

Methods: Kidney tissues from mice subjected to albumin overload via i.p injection for 12 days and renal biopsy specimens were analyzed.

Results: Following albumin overload, we found a striking increase of Na+ -Cl cotransporter (NCC) expression by 2.3-fold in mouse kidneys determined by Western blotting and qRT-PCR. To evaluate NCC function in these mice, we examined key components of RCS and found a striking elevation of angiotensinogen (AGT) and angiotensin converting enzyme (ACE) by 2-3 folds in line with enhanced urinary AngII excretion. In proteomic mice, we also observed 4-fold upregulation of NCC and remarkable stimulation of ACE detected by immunohistochemistry in accord with significantly increased urinary Ang II output. To further investigate the role of RCS in NCC upregulation, we did primary culture of renal tubular cells and observed that albumin directly increased NCC paralleled with significant induction of AGT, ACE, and Ang II. Strikingly, administration of specific ACE inhibitor captopril to the cells remarkably abolished albumin-induced enhancement of NCC and RCS components. Additionally, albumin overload significantly reduced mitochondrial superoxide dismutase (SOD2) by 60%, and administration of a SOD2 mimic (MnTBAP) entirely abolished the stimulation of NCC, ACE, and AGT in mice with albumin overload.

Conclusions: The findings demonstrated an important role of albuminuria in upregulating RCS expression via a renal mitochondrial oxidative stress-initiated stimulation of renal local AGT/ACE/Ang II, which may contribute to the fluid retention and hypertension in proteinic kidney disease to some extent.

Prophylactic and Therapeutic Tenapanor Are Vascular Protective in a Rat Model of CKD

1 Ann-Catherine Jönsson-Rylander, 1, 2 Margareta Behrendt, 1, 2 Craig F. Plato, 2 Denise L. Schwabauer, 3 Peter J. Greenslade, 4 Astrazeneca R&D, Möln达尔, Sweden; 5 Biopharma Inc., Denver, CO.

Background: Tenapanor (AZD1722), an inhibitor of the Na+ /H+ exchanger NHE3, reduces absorption of gut sodium and phosphate. It is being developed for renal and constipation-related indications.

Methods: 5/6 nephrectomized Sprague Dawley rats were fed 4% NaCl chow to induce salt-sensitive arterial hypertension. Oral tenapanor (1 mg/kg/day) was initiated either at the start of NaCl intake (prophylactic; Px) or 2 weeks later (therapeutic; Tx), and was administered for up to 6 weeks. Disease controls (DCs; vehicle-treated) and healthy controls (HCs; sham operated, normal chow) were included to enable assessment of disease progression. Systemic hemodynamics and urinary and plasma biomarkers were assessed every 2 weeks. Ex vivo vascular function (isometric tension recording) or arterial stiffness (pulse wave velocity) was evaluated to include assessment of disease progression. Systemic hemodynamics and urinary and plasma biomarkers were assessed every 2 weeks. Ex vivo vascular function (isometric tension recording) or arterial stiffness (pulse wave velocity) was evaluated to include assessment of disease progression.

Results: Compared with DCs, rats in the Px and Tx groups had reduced urinary albumin, sodium and phosphorus excretion (p<0.05), and looser stools. Systolic, diastolic and mean BP increased in DCs but were normalized in the Tx group. Arterial stiffness was reduced by Px and Tx tenapanor (p<0.05). Compared with HCs, DCs had impaired aortic vasoconstrictor and vasodilator function at 2 weeks (p<0.05) and significant endothelial dysfunction at 6 weeks. Px tenapanor normalized, and Tx tenapanor attenuated arterial hypertension, vascular stiffness, vasoconstrictor and endothelium-dependent and independent vasodilator function (Table).

Funding: Government Support - Non-U.S.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Tenapanor prevented most of the maladaptive consequences in a rat model of renal insufficiency-induced salt-sensitive arterial hypertension and CKD. The benefit of Tx treatment was similar to that elicited by PxB use, suggesting disease modification. Funding: Pharmaceutical Company Support - AstraZeneca

Urinary Exosome Profiling in Thiazide Induced Hyponatremia

Sarah Kiran Channavajhala,1 Theresa Peltz,2 Wenjing Jia,1 Ian Hall,1 Kevin O’Shaughnessy,3 Matthew A. Bailey,1 James W. Dear,1 Mark Glover,1 1Therapeutics and Molecular Medicine, Univ of Nottingham, United Kingdom; 2Clinical Pharmacology Unit, Univ of Cambridge, United Kingdom; 3Centre for Cardiovascular Science, Univ of Edinburgh, United Kingdom.

Background: Thiazides are one of the most widely used and cost-effective class of anti-hypertensive medication. Thiazide-Induced Hyponatremia (TIH) is one of their major adverse effects and the leading cause of drug-induced hyponatremia requiring hospitalization. A priori TIH must result from excessive saliuresis and/or water reabsorption. The water and electrolyte transporter composition of urinary exosomes (UE) reflects their cellular origin and are a promising way to study renal dysfunction. This study assessed the expression of AQP2 and NCC in the UE of TIH patients.

Methods: 100 patients admitted to hospital with severe TIH donated urine samples during acute TIH and at two months post TIH cessation. Matched normotensive controls were recruited both on and off thiazides (groups 1 & 2 respectively). UE from a representative sample of each patient group were isolated and AQP2 and NCC were evaluated by Western blotting and Nanoparticle Tracking Analysis (NTA). AQP2 and NCC expression was normalized by urinary creatinine. Immunoblots were also corrected for total protein and results expressed as units of optical density/µg.

Results: Westerns showed that UE expression of AQP2 was higher in cases during acute TIH compared to convalescent (32.93 vs 28.71, P<0.01) and compared to both control groups 1 and 2 (15.61 and 15.09 respectively, P<0.001). NCC expression was lower in TIH patients acutely compared to convalescent (17.72 vs 31.86, P<0.05) and compared to both control groups (30.32 and 31.17, P<0.05). NTA also demonstrated increased AQP2 expression in acute & convalescent TIH.

Conclusions: This study highlights the utility of UE analysis to probe the molecular pathophysiology of TIH. Increased AQP2 and reduced NCC expression suggests that TIH results from increased water reabsorption and sodium wasting in the distal nephron. TIH studies may further understand of renal physiology and inform the design of new thiazide medicines less prone to cause hyponatremia. Funding: Government Support - Non-U.S.

Epigenetic Modulation of Renal Arterioles Induced by DOCA-Salt Loading in Mice

Hiroaki Inoue, Kazutoshi Miyashita, Masaaki Sato, Kentaro Fujii, Aika Hagiwara, Masanori Tamaki, Hiroshi Itoh. Internal Medicine, School of Medicine, Keio Univ, Tokyo, Japan.

Background: The relationship between salt intake and development of hypertension is familiar; however, the mechanism for the onset has not been fully revealed. Our previous report showed that the medial hypertrophy of renal arterioles after transient salt loading in spontaneous hypertensive rat caused lasting elevation in blood pressure. The present study investigated the significance of epigenetic modulation of the gene expressions which are relevant to the medial hypertrophy after transient salt loading.

Methods: Male 6 week old C57Bl6 mice were implanted deoxycorticosterone acetate (DOCA) pellets and given drinking water containing 1% NaCl for 2 weeks for generation of MetS+RAS. Sham served as controls (n=7 each). Single-kidney renal blood flow (RBF) and glomerular filtration rate (GFR) were studied in-vivo, and microvascular architecture (micro-CT) and interstitial fibrosis ex-vivo.

Results: EVs were detected in the stenotic-kidney 4 weeks after injection. RBF and GFR did not increase and BP did not recover reflecting an absence of increase in reflex SNA. Histological examinations of the kidney were performed during and after the salt loading. Gene expressions in the kidney such as matrix metalloproteinases (MMPs), which promote the medial hypertrophy, were quantified. Epigenetic modulation of the genes were analyzed.

Results: Transient salt loading caused elevation in blood pressure during the loading period. Blood pressure after stopping salt-loading was also significantly higher than that before salt loading. Salt loading caused medial hypertrophy of renal arterioles, and it remained after stopping salt loading, as to cause lasting renin elevation. Real time PCR revealed that MMP2 and MMP9 were increased during the salt loading. CGN5, CBF and p300, which are histone acetyltransferases, were elevated. Sir1, Sir3, HDAc1 and HDAc3, which are histone deacetylases, were decreased. Histone H3K9 and H4K16 acetylations in the MMP2 gene were enhanced by the salt loading.

Conclusions: The last medial hypertrophy and renin elevation after transient salt loading were suggested to be caused by the increased expression of MMPs along with augmented histone acetylations by the salt loading. Increased expressions of acetyltransferases along with decreased expressions of Sirs and HDAcS by transient salt loading would be involved in the enhancement of the histone acetylations.

Radio-Frequency Catheter-Based Renal Denervation in Hypertensive Sheep with Chronic Kidney Disease Impairs Responses to Hemorrhage

Reetu R. Singh,1 Karen M. Moritz,2 Kate M. Denton.1 1Physiology, Monash Univ; Clayton, VIC, Australia; 2School of Biomedical Sciences, The Univ of Queensland, St. Lucia, QLD, Australia.

Background: Renal sympathetic nerves medulate kidney function and blood pressure (BP). Trials using catheter-based renal denervation (cDNX) in hypertensive patients yielded results both in support of and, against its efficacy in lowering BP. A critical question is whether cDNX has adverse consequences, in situations of clinical challenge, such as hemorrhage in denervated patients where intact nerves would be required. This study examined consequences of cDNX 1) on BP and renal function and 2) on reflex activation of sympathetic nerve activity (SNA) in hypertensive sheep with chronic kidney disease (CKD).

Methods: Sheep with established hypertension and renal dysfunction (CKD group) with an appropriate control group were used. At 10 months of age, some animals underwent cDNX (CKD-cDNX; control-cDNX) while the remaining underwent sham procedure (CKD-intact; control-intact). Al 2 months post-cDNX, BP, renal function, and plasma renin activity (PRA) were assessed before, during and after hemorrhage (20% blood volume withdrawn over 15 minutes).

Results: CKD sheep had higher BP compared to all groups but CKD-cDNX sheep had similar BP to control sheep. Basal renal function was not further reduced. In response to hemorrhage, BP fell in all groups but the greatest decrease occurred in CKD-cDNX. In Control-intact sheep this fall in BP gradually recovered, associated with increase in PRA reflecting an increase in reflex SNA. In contrast, in Control-cDNX and CKD-cDNX groups, PRA did not increase and BP did not recover reflecting an absence of increase in reflex SNA.

Conclusions: cDNX effectively reduced BP at 2 months post-cDNX in previously hypertensive sheep but had no effect on renal function. However, the lack of reflex activation of neural mechanisms observed during hemorrhage suggest, that cDNX may impair a patient’s ability to adequately respond to physiological challenges. Funding: Government Support - Non-U.S.

Interleukin-10 Mediates the Renoprotective Properties of Mesenchymal Stem Cells-Derived Extracellular Vesicles in Porcine Metabolic Syndrome and Renal Artery Stenosis

Alfonso Eirin,1 XIang-yang Zhu, Christopher M. Ferguson,2 Scott Riester,2 Andre J. Van Wijnen,3 Amir Lerman,1 Lilach O. Lerman,1 1Divs of Nephrology and Hypertension, Mayo Clinic 2Orthopedic Surgery, Mayo Clinic 3Cardiovascular Diseases, Mayo Clinic, Rochester, MN.

Background: Mesenchymal stem/stromal cells (MSCs) are immunomodulatory and have unique potential to restore the renal microvasculature, but may generate safety concerns. MSC-derived extracellular vesicles (EVs) emerged as a novel non-cellular alternative. Using a swine model of metabolic syndrome (MetS) superimposed on renal artery stenosis (RAS) we tested whether intrarenal injection of EVs attenuates renal injury and if this capacity is mediated by their cargo of the anti-inflammatory cytokine IL-10.

Methods: Mesenchymal stem cells (MSCs) were cultured and if this capacity is mediated by their cargo of the anti-inflammatory cytokine IL-10. Using a swine model of metabolic syndrome (MetS) superimposed on renal artery stenosis (RAS) we tested whether intrarenal injection of EVs attenuates renal injury and if this capacity is mediated by their cargo of the anti-inflammatory cytokine IL-10. Using a swine model of metabolic syndrome (MetS) superimposed on renal artery stenosis (RAS) we tested whether intrarenal injection of EVs attenuates renal injury and if this capacity is mediated by their cargo of the anti-inflammatory cytokine IL-10.

Results: EVs were detected in the stenotic-kidney 4 weeks after injection. RHF and GFR, which increased in Mes cDNX compared to Lean, fell in Mes+RAS. Yet, the lack of reflex activation of neural mechanisms observed during hemorrhage suggest, that cDNX may impair a patient’s ability to adequately respond to physiological challenges. Funding: Government Support - Non-U.S.

Role of Mitochondrial Dysfunction and ROS Production in Ang II-Induced NLRP3 Inflammasome Activation

Wen Yi, Liu Yiran, Tang TAotao, Bi Cheng Liu. Inst of Nephrology, Southeast Univ, Nanjing, Jiangsu Province, China.

Background: The type 1 angiotensin (AT1) receptor plays an important role in maintaining blood pressure. Previous studies suggested that the activation of immune responses by angiotensin (Ang) II during hypertension may aggravate renal damage. NLRP3 inflammasome activation promotes renal inflammation and contributes to chronic kidney injury. Further investigation should be performed to explore the correlation between the RAS and NLRP3 inflammasome activation, and possible mechanisms.

Methods: C57BL/6 AT1R-/- and NLRP3-/- mice underwent left nephrectomy followed 1 week for recovery. Blood pressure measurements were recorded at baseline and following 4 weeks of chronic Ang II or saline infusion. At the end of the experiment, the kidney were harvested and fixed. AT1R siRNA and mito-TEMPO treatment were performed before the Ang II stimulation in HK2 cells. The expression levels of NLRP3 inflammasome and mitochondrial dysfunction were measured.

Results: Ang II significantly induced kidney injury and NLRP3 inflammasome activation. Mitochondria swelling and fragmentation were observed by transmission electron microscope. AT1R-/- blocked Ang II-induced hypertension, inhibiting the mitochondrial dysfunction and NLRP3 expression. Deficiency of NLRP3 attenuated kidney injury in hypertension with no significant influence to blood pressure. In vitro studies showed that Ang II stimulation increased the mitochondrial damage and NLRP3 activation in dose- and time- dependent manner. AT1R siRNA and mito-TEMPO treatment were performed before the Ang II stimulation in HK2 cells. The expression levels of NLRP3 inflammasome and mitochondrial dysfunction were measured.

Conclusions: Ang II stimulation increases NLRP3 inflammasome activation through AT1a receptor. Ang II-induced NLRP3 activation is mediated by mitochondrial dysfunction, with overproduction and accumulation of ROS. NLRP3 inflammasome activation plays an important role in kidney injury, and blocking it can be a potential therapeutic target for hypertension-associated kidney damage.

The Endoplasmic Reticulum Stress Inhibitor 4-Phenybutyric Acid Prevents the Development of Essential Hypertension in Young Spontaneously Hypertensive Rats

Sajad Naseer, Chao Lu, Jeffrey G. Dickhout. Medicine, McMaster Univ, Hamilton, ON, Canada; ‘St. Joseph’s Healthcare Hamilton, Hamilton, ON, Canada.

Background: Essential Hypertension is the leading global risk factor for premature death. This complex multifactorial disease has no known cause and has been shown to contribute to the progression of chronic kidney disease (CKD). Mechanistically both Endoplasmic Reticulum (ER) stress and the Unfolded Protein Response (UPR) have been implicated in the pathobiology of this disease. A small molecular chaperone, 4-phenylbutyric acid (4-PBA), is known to inhibit ER stress. In our previous studies, we found that 4-PBA is able to lower blood pressure in animal models of hypertension. It remains unclear however if ER stress is a cause of hypertension or a consequence.

Methods: Young spontaneously hypertensive rats (SHR) were used in this study and Wistar Kyoto (WKY) rats were used as its normotensive control. High blood pressure begins to develop in the young SHR at 4-weeks of age. Radio-telemetry transmitters (HE7-X1 transmitter, Data Sciences International) were implanted to monitor blood pressure development, heart rate and ECG activity in both SHR and WKY. SHR and WKY were both randomized into 4-PBA (1 g/kg/d) or vehicle groups at 4-weeks of age to determine

Macrophage Endothelin-B Receptors Clear Endothelin-1 and Regulate Blood Pressure

Nechri Dhaun. Queen’s Medical Research Inst, University of Edinburgh.

Background: Hypertension is common. Its cause remains unclear in the majority of those affected. Recent data suggest that macrophages (Mφ) contribute to, and protect from, hypertension. Endothelin-1 (ET-1) is the most potent endogenous vasoconstrictor with additional pro-inflammatory properties. The effects of ET-1 on Mφ biology are not well studied.

Methods: To examine the interactions between the ET and Mφ systems we administered incremental doses of intravenous ET-1 to C57BL/12-nephrin toxin receptor (CD11b-DTR) mice – given diphtheria toxin (DT) and to target ET-B receptors – on the myeloid lineage. Mφ depletion or loss of function – CD11b-DTR mice given DT and lYsMET-5- mice – were not associated with a difference in baseline BP or endothelial dysfunction. In both, administration of ET-1 resulted in an exaggerated hypertensive response compared to controls. At a dose of ET-1 1nmol/kg the maximal change in BP was –2 fold greater in Mφ deficient mice compared to control groups. In vitro, bone MDM and human Mφ possess both ET-B and ET-A receptors. Whereas stimulation of mouse and human Mφ with exogenous ET-1 did not polarize Mφ to a classical or alternative phenotype, both displayed chemokines to ET-1. This was reduced by selective ET-B receptor mediated antagonism.BMDM stimulation with LPS/INFγ led to an increase in the concentration of ET-1, an effect that was blocked by phosphoramidon, an inhibitor of endothelin converting enzyme. Importantly, using pharmacological and gene targeting studies we show a novel clearance mechanism for ET-1 through ET-B receptor mediated dynamin-dependent endocytosis present in both murine and human Mφ. Finally, patients receiving Mφ depleting therapy we show that BP is higher and the ET system more activated than in those receiving non-depleting therapies.

Conclusions: Overall, these data suggest that Mφ and ET-1 may play an important role in BP control and potentially have a critical role as a therapeutic target in hypertension.

FR-PO147

Role of the Myeloid Endothelin-B Receptor in Angiotensin II Mediated End-Organ Damage

Background: Hypertension is common and in the majority of cases its cause remains unknown. Recent interest has focused on the role of macrophages (Mφ) in blood pressure (BP) regulation. Endothelin-1 (ET-1) is the most potent endogenous vasoconstrictor mediating its effects through two receptors – the endothelin-A receptor (ET-A) and endothelin-B (ET-B) receptor. The ET-B receptor has a specific role in ET-1 clearance. We investigated the role of the Mφ ET-B receptor in a model of angiotensin (AngII)-mediated end-organ damage.

Methods: Mφ ET-B receptor deficient mice (lYsMET-5-) and controls were exposed to Ang II infusion for 6 weeks under a high salt diet. We assessed BP via telemetry, cardiac structure and function and endothelial function by Doppler ultrasound, end-organ injury and plasma and urine ET-1.

Results: At baseline, components of BP did not differ between groups and increased similarly with Ang II. Whereas after 6 weeks of Ang II lYsMET-5- and controls had similar left ventricular hypertrophy and cardiac insufficiency, endothelial function was better in lYsMET-5- at both baseline and after Ang II (% dilation of basilar artery in response to CO2/CO2 vs. controls: baseline: 20 ± 1%, p<0.01; at 6 weeks: 11 ± 0.2% vs. 0.5 ± 0.1%). Baseline renal function and proteinuria did not differ between groups. After Ang II, lYsMET-5- showed similar renal function compared to controls but less proteinuria (urine albumin/crea, mg/mmol: 20.8±10 vs. 530±25, p<0.01), glomerulosclerosis (34±0.2 vs. 61±0.4%, p<0.01), and fewer renal Mφ compared to controls (F4/80 staining per high power field, lYsMET-5- vs. controls: 1.1±0.7 vs. 3.2±0.5%, p<0.02), although similar levels of CD3+ cells. Plasma ET-1 was no different at baseline but increased more in lYsMET-5- with Ang II vs. controls after 6 weeks Ang II: 3.7±0.7 vs. 1.4±0.2pg/ml, p<0.03). Urine ET-1 was similar baseline and 6 weeks.

Conclusions: Deletion of the Mφ ET-B is associated with a blunting of the effects of systemic Ang II infusion as reflected by less endothelial dysfunction, reduced inflammation and end-organ damage. The mechanisms for these effects are the focus of ongoing research.

A Novel Reduced Uterine Perfusion Pressure (RUPP) Model of Preeclampsia in Mice

Tomofumi Fushima,1 Yuji Oe,2 Emiko Sato,1  Sadasathy Ito,2 Hiroshi Sato,1,1 Nobuayuki Takashita.1,2 1Graduate School of Pharmaceutical Sciences, Tohoku Univ, Sendai, Miyagi, Japan; 2Div of Nephrology, Endocrinology, and Vascular Medicine, Tohoku Univ, Sendai, Miyagi, Japan.

**Background:** Preeclampsia (PE) is a pregnancy-related hypertension with proteinuria that typically develops after 20 weeks of gestation. PE is caused by a reduction in uterine blood flow due to abnormal trophoblast invasion of the spiral arteries. The ischemic placenta releases anti-angiogenesis factors such as sFlt-1, leading to maternal hypertension and proteinuria. The reduced uterine perfusion pressure (RUPP) model is widely used in rats, but not in mice, hindering the clarification of genetics of PE. The aim of the present study is to establish a novel PE model using an improved RUPP method in mice.

**Methods:** As shown in the Figure, 1 uterine vessels of pregnant ICR mice were ligated at 14.5 dpc, and BP, renal phenotype and pregnancy outcome were analyzed.

**Results:** RUPP in mice increased blood pressure. B.B’ ligation mice showed increased urinary albumin excretion, mesangial expansion and endotheliosis as shown by the reduction of glomerular open capillary area. RUPP increased the risk of miscarriages but not in mice, hindering the clarification of genetics of PE. The aim of the present study is to establish a novel PE model using an improved RUPP method in mice.

**FR-PO149**

Sildenafil Treatment Is Protective against Progression of Renal Injury in the Preeclamptic Dahl Salt Sensitive Rat

Ellen Elizabeth Gillis, Jennifer N. Mooney, Michael R. Garrett, Jennifer M. Sasser. Pharmacology and Toxicology, Univ of Mississippi Medical Center, Jackson, MS.

**Background:** Preeclampsia, a hypertensive disorder of pregnancy, is characterized by transient glomerular damage and increased risk for kidney disease later in life. Recent studies in our lab have identified the Dahl salt sensitive (Dahl S) rat on a 0.3% NaCl diet as a spontaneous model of superimposed preeclampsia. We hypothesized that sildenafil treatment would result in an improvement in renal function during the preeclampsia pregnancy exhibited by the Dahl S rat.

**Methods:** Female Dahl S rats (n=4-9) were mated, and rats were randomly divided into control and sildenafil treated groups. Sildenafil was administered to the treated group via food on gestational days 10-20 at a dose of 50 mg/kg/d. Rats were placed in metabolic cages on gestational day 19 for 24-hr urine collection, and blood and tissues were harvested via food on gestational days 10-20 at a dose of 50 mg/kg/d. Rats were placed in metabolic cages on gestational day 19 for 24-hr urine collection, and blood and tissues were harvested via food on gestational days 10-20 at a dose of 50 mg/kg/d.

**Conclusions:** We developed a novel RUPP mouse model that recapitulates the phenotype of PE. This model is expected to be useful for investigating pathogenesis of PE and evaluating its new therapies.

Recessive Mutations of the Interaction Partners, TENC1, DLC1 or MAGI2, Cause Nephrotic Syndrome in Humans

Shazia Ashraf,1 Jia Rao,1 Merlin Airik,1 Svjetlana Lovric,1 Jennifer A. Lawson,1 Weizhen Tan,2 Carolin Sadowski,1 Werner Lukas Pabst,1 Daniela A. Braun,1 Heon Yung Gee,1 Richard P. Lifton,2 Martin Zenerker,1 Friedhelm Hildebrandt,1,4 1Div of Nephropathy, Boston Children’s Hospital, Boston, MA; 2Dept of Genetics, Yale Univ School of Medicine, New Haven, CT; 3Inst of Human Genetics, Univ Hospital Magdeburg, Magdeburg, Germany; 4HHMI.

**Background:** Identification of monogenic causes of nephrotic syndrome (NS) has furthered the understanding of its pathogenesis. However, many genes and disease mechanisms remain unknown.

**Methods:** We performed homozygosity mapping (HOM) and whole exome sequencing (WES) in individuals of consanguinous families with NS to identify the underlying mutations. To identify additional families, we performed microfluidic PCR (Fluidigm Access Array™) and next generation sequencing (NGS) to screen worldwide cohort of ~2000 individuals with severe NS.

**Results:** By WES in consanguineous family A1358, we identified a homozygous missense mutation (p.R292Q) in the TENC1 (Tenascin-J) gene in an amino acid residue conserved since Ciona intestinalis. By microfluidic PCR and NGS, we detected additional mutations in TENC1 in three unrelated families with NS. Later, we also discovered mutations in 2 different families with NS in DLC1 gene, a known binding partner of TENC1. Interestingly, most of the individuals with TENC1 or DLC1 mutations had steroid sensitive NS or histologically showed biopsy of MCNS. Furthermore, in 2 families with NS and neurological impairment, we identified 2 different homozygous truncating mutations in MAGI2 gene. Deficiency of Tenc1 or Magi2 has been previously shown to cause NS in mice. By Co-IP, we now show that TENC1 and DLC1 interact with MAGI2 in HEK293T cells and these interactions are abrogated in one of the MAG2 mutant. Knockdown of TENC1, DLC1 or MAGI2 in cultured podocytes exhibited an altered podocyte migration rate. Immunofluorescence microscopy showed that TENC1 and DLC1 colocalize with phosphotyrosine at the focal adhesions in cultured human podocytes.

**Conclusions:** We, thus, identified mutations of TENC1, DLC1 and MAGI2 as three novel single-gene causes of NS revealing a potential new pathogenic pathway for NS.

Genes Encoding Nuclear Pore Outer Ring Components NUP85, NUP107, and NUP133 Are Mutated in Patients with Nephrotic Syndrome Svijetlana Lovric,1 Weizhen Tan,2 David Schapiro,2 Shazia Ashraf,3 Daniela A. Braun,1 Jia Rao,1 Richard P. Lifton,4 Heon Yang Gee,1 Friedhelm Hildebrandt,1,3 1Div of Nephrology, Boston Children’s Hospital, Harvard Medical School, Boston, MA; 2Dept of Genetics, Yale Univ School of Medicine, New Haven, CT; 3Howard Hughes Medical Inst, Chevy Chase, MD.

Background: Steroid resistant nephrotic syndrome (SRNS) almost invariably progresses to end-stage kidney disease. Although more than 30 single-gene causes of SRNS are known, a large proportion of SRNS remains unexplained. Recently, mutations in genes encoding proteins of the nuclear complex (NPC) have also been implicated in nephrotic syndrome. Study of these proteins has implicated SMAD signaling in the pathogenesis of nephrosis.

Methods: To identify additional novel causes of nephrotic syndrome, we performed a candidate screen of 17 nuclear pore complex (NPC) genes in an international cohort of >900 individuals with SRNS using microfluidic multiplex PCR (Fluidigm Access Array)1 and next generation sequencing (Illumina MiSeq)2,3.

Results: In two families we identified two homozygous missense mutations, p.A777V and p.R645W, (conserved to S. cerevisiae) in the NPC outer ring protein NUP133. We then sequenced the exons of 1,000 additional families in genes encoding other outer ring proteins and found mutations in NUP107 (3 families, p.Y889C, conserved to C. elegans) and NUP133 (2 families, p.S974R and p.R231G, conserved to D. rerio). Although the structure resolution of the NPC 3D complex is incomplete, we modeled the interacting portions of the Y-subcomplex proteins NUP107 and NUP133. Two of the mutations, p.S974R in NUP133 and p.Y889C in NUP107, are located in the interacting alpha helix between the two proteins. 5 of 6 families demonstrated FSGS on biopsy.

Conclusions: As a novel cause of SRNS we identified mutations in 3 different NPC outer ring proteins NUP85, NUP107, and NUP133 that form an integral part of the Y-subcomplex. Further functional studies are needed to illuminate how the defect of NPC contributes to the pathogenesis of nephrotic syndrome.

Defining the Genetic Epidemiology of a Phenotypically Well-Characterized Adult-Onset Focal and Segmental Glomerulosclerosis Cohort Moumita Barua,1 Daniel C. Catran,1 Heather N. Reich,1 Michelle A. Hadunezhad,1 Mark Leung,1 Weili Li,1 Andrew D. Paterson,2 York P. Pei,1 Nephrology, Toronto General Hospital, UHN, Toronto, ON, Canada; 1Biology, Univ of Waterloo, Waterloo, ON, Canada; 2The Centre for Applied Genomics, Hospital for Sick Children, Toronto, ON, Canada; 3Dalla Lana School of Public Health, Univ of Toronto, Toronto, ON, Canada; 4Genetics and Genome Biology, Hospital for Sick Children, Toronto, ON, Canada.

Background: The genetic epidemiology underlying adult-onset sporadic FSGS has not been well characterized and rigorous correlation of rare genetic forms of disease with clinical outcomes is also lacking. We defined the genetic epidemiology of the phenotypically well-characterized sporadic and familial Toronto GN FSGS cohort using next-generation sequencing.

Methods: We have ascertained the clinical information and performed whole exome sequencing in adult-onset disease of 90 sporadic FSGS cases, 41 steroid-sensitive nephrotic syndrome (SSNS) cases, and next generation sequencing in adult-onset disease of 90 sporadic FSGS cases, 41 steroid-sensitive nephrotic syndrome (SSNS) cases. In contrast, in 4 of 23 autosomal dominant and 4 of 23 autosomal recessive families with FSGS, a disease-causing mutation was identified in the following genes: NIP12, TRPC6, LMX1B and ADCK4. Mutations in the known FSGS genes were found in 7.8 and 17.4% of sporadic and familial cases of adult-onset disease, respectively, but none were discovered in patients with SSNS.

Conclusions: Our results are consistent with extensive genetic heterogeneity in FSGS. We will test the association of rare variants with phenotype. Clinical outcomes will be described.

A Novel Mouse Mutant with a Point Mutation in Laminin α5 Exhibits Chronic Nephrotic Syndrome Sara Falcone1, Thomas Nicol,1 Cheryl Scudamore,2 Frederick W.K. Tam,3 Charles D. Pusey,4 Jeffrey H. Minner,5 Steve Dm Brown,1 Paul K. Potter,1 Mammalian Genetics Unit, MRC Harwell, Harwell, Oxfordshire, United Kingdom; 2Mary Lyon Centre, MRC Harwell, Harwell, Oxfordshire, United Kingdom; 3Renal Sciences, Imperial College, London, United Kingdom; 4Renal Div, Washington Univ, St. Louis, MO.

Background: Diseases associated with ageing pose an increasing social and financial burden on society and represent an imperative for research in the biomedical sciences. We are undertaking the first large-scale project to investigate the interaction between genetic variation and the pleiotropic effects of ageing, employing random mutagenesis and phenotyping to generate new models of late onset or age-related disease.

Methods: Mutant mice are being aged to 18 months and undergo comprehensive phenotyping across a wide range of disease areas at several time points throughout the life of the mice. To date we have identified lines with a variety of late onset phenotypes which are being characterised in detail.

Results: Mutant mice were identified at 6 months of age with elevated creatinine and urea levels, which reached end stage renal failure at approximately 10 months of age. Mapping and whole genome sequencing identified a Lama51562 mutation in the L4a domain of Lama5. Time course studies of Lama51562 homozygotes showed reduced serum albumin (18.0 ± 1.2 vs 24.9 ± 3.1 g, mean SD) and proteinuria from 12 weeks of age with a gradual loss of renal function over time. Affected mice also have significantly elevated cholesterol levels and a progressive nephropathy leading to diffuse glomerular fibrosis, dilated protein filled tubules and pigment deposition suggesting this is a model of nephrotic syndrome. The mutation does not affect expression of the LAMA5 protein within the glomerular basement membrane.

Conclusions: We have identified a novel mouse mutant with a missense mutation Lama5 resulting in nephrotic syndrome. Recent patient sequencing data suggests LAMA5 mutations are associated with focal segmental glomerulosclerosis. Further functional studies are needed to determine how the mutation affects the expression of LAMA5 and whether this mutation predisposes to other glomerular diseases.

Analysis of the remaining 20 families (65%) did not reveal any gene with rare segregating mutations present in multiple independent families.

Conclusions: Mutations in genes known to be associated to FSGS are identified in a small proportion of cases. Mutations with focal segmental glomerulosclerosis in children with kidney disease can result in defects that present as FSGS. These findings can point to a correct genetic diagnosis and the identification of mutations in genes involved in CAKUT suggests that glomerular sclerosis could be the manifestation of a maladaptive reaction to reduced glomerular mass from whatever cause.

Background: Steroid Resistant Nephrotic Syndrome (SRNS) is a rare disease characterized by glomerular filter malfunction. Analysis of inherited cases has identified mutations in >50 genes. However, clinical data can be limited and the true pattern of inheritance difficult to verify. In light of recent advances in next generation sequencing (NGS) and rare disease genetics, we re-examined CD2AP, a gene considered to cause autosomal dominant SRNS in an in vivo model.

Methods: In-house whole exome sequencing (WES) data on 200 deeply phenotyped SRNS patients was tested to assess the ability of CD2AP mutations to act as autosomal dominant. All protein altering CD2AP variants detected with a MAF < 0.05 were selected for further examination in the Exome Aggregation Consortium (ExAC) database. Samples with likely pertinent variants in CD2AP were also analysed for causal mutations in other SRNS genes.

Results: Variants with a frequency of >1 in 1000 in the ExAC database were considered unlikely to cause autosomal dominant SRNS based on frequency of SRNS in populations. Two rare CD2AP variants remained after filtering but one case also demonstrated a rare heterozygous non-syndromic disease causing variant in SYNPO (allelic frequency 0.0002179 in ExAc, non-homogeneous) and the other a variant in NPHS2 (not seen in ExAc). SYNPO interacts with CD2AP and combined, these genes cause FSIG in mice. The NPHS2 variant neighbourd a mutation linked previously to bighemogenic heterozygosity with CD2AP in SRNS.

Conclusions: Some heterozygous CD2AP variants occurred in normal controls or were detected incidentally during sequencing variants. This indicates that mutations behaving as a dominant negative in a small number of cases may in fact demonstrate more complex inheritance on interrogation of a larger cohort. Computational analysis of WES provides a useful adjunct to rapidly examine and ascertain actual heritability in rare disease populations, especially in seemingly sporadic cases.

Chemical Chaperone 4-PBA Is Not Nephroprotective in Experimental Podocin Nephropathy

Tania Tamara Wlodkowski, 1 Manoureh Tabatabaeifar, 2 Geert-Jan Mollet, 2 Corinne Antignac, 2 Franz X. Michaelis. 1Pediatric Nephrology, Div. Heidelberg Univ Hospital, Germany; 2Inserm U983, Hospital Necker, France.

Background: 4-PBA has been demonstrated to improve protein trafficking from ER to plasma membrane and function of mutant AF508-CFTR protein in cystic fibrosis. In hereditary nephrotic syndrome the most common NPHS2 (podocin) mutation, R138Q, leads to retention of podocin in the ER and therefore to defective intracellular protein trafficking. In order to investigate beneficial effect of chemical chaperone in podocin nephropathy, we administered 4-PBA to knock-in mice carrying this mutation. Analogous to human disease, these mice develop heavy proteinuria, podocyte loss, focal segmental glomerulosclerosis and progressive renal failure.

Methods: 12 mice in C57Bl/6 mice with Nphp2 wild type or Nphp2 R138Q were used. After 8 weeks of age, 4-PBA (100 mg/kg) or PBS was administered i.p. for 4 weeks. Weight and proteinuria were monitored weekly. Biochemical and histopathological changes were examined after 4 weeks of treatment.

Results: All animals developed massive proteinuria (116% of untreated controls). Hypoalbuminemia at 4 weeks was slightly ameliorated (21.1 (Co) vs. 24.7 g/dl; n.s.). Serum urea, cholesterol and creatinine levels were deteriorated by 4-PBA treatment. Podocyte loss (podocytes per glom.: 93% (Co), 69% (4-PBA) of healthy animals, n.s) and glomerular sclerosis index (1.75(Co), 1.824-PBA) were unchanged, whereas an increase in tubulointerstitial fibrosis was noted in 4-PBA treated animals (1.36 (Co) vs. 3.82 (4-PBA).

Conclusions: In an in vivo model of hereditary podocin nephropathy, prophylactic 4-PBA treatment showed no beneficial effect on proteinuria and podocyte loss but aggravated tubulointerstitial fibrosis and renal failure. Our findings argue against a nephroprotective action of 4-PBA in this hereditary podocytopathy.

Prominent Renal Complications in the c.80A>G in MMACHC Gene

Fang Wang, Xiaoyu Liu, Huixue Xiao, Yong Yao, Jie Ding, Yanqin Zhang. Dept of Pediatrics, Peking Univ First Hospital, China.

Background: MMACHC C defect is a clinically heterogeneous disease caused by mutations in the MMACHC gene. The aim of the present study was to delineate renal phenotype in Chinese children with MMACHC C defect.

Methods: Detailed clinical data were collected and analyzed, and all coding exons of MMACHC gene were PCR-amplified and sequenced from genomic DNA.

Results: Four unrelated Chinese children (1 female, 3 male) with unexplained microscopic hematuria and proteinuria were included. The onset age of renal symptoms ranged from 9 months to 4 years. Two patients had nephrotic-level proteinuria in their initial visit, and renal dysfunction was detected in 2 patients in 3 months and 6 months after onset, respectively. Only 1 patient had hypertension in 6 years after onset. All patients had metabolic acidemia, and megaloblastic anemia was present in 2 patients. None of 4 patients had thymoglobulinemia or pancytopenia. One of 4 patients had mild development backward. Four patients had hyperhomocysteinemia, and 2 of 4 patients presented with remarkable elevated urinary methylnalamic acid. Renal biopsy in 3 patients showed thronoblastocromatinic acid. Mutations in MMACHC gene was found in four patients. Two patients were a compound heterozygote for c. 658_660delAAG and c.80A>G, and one patient was a compound heterozygote for c.80A-G. Three patients were in follow up. After vitamin B12 [in the form of hydroxycobalamin (OHCbl), folic acid and L-carnitine betaine supplementation, urine protein became negative in 2 patients and reduced in 1 patient, and renal function in 1 patient was improved. In all 3 patients, hemoglobin increased to normal, plasma homocysteine decreased and still was abnormal. In 2 patients with remarkable elevated urinary methylnalamic acid was normal in 1 patient and decreased in another patient. Blood pressure of the patient with hypertension was well-controlled using calcium channel blocker.

Conclusions: Prominent renal complications can be found in c.80A-G in MMACHC gene, and treatment resulted in improvement of renal and hematological signs.

The Susceptible Human Leukocyte Antigen Class II Genes and the Encoding Amino Acid Residues on Major Histocompatibility Complex Molecules to Primary Membranous Nephropathy

Li-Lan Xie, 1,2,3,7 Zhou Qu, 1,2,3 Gang Liu, 1,2,3 Yun-hua Liao, 1,2,3 Ming-hui Zhao. 1Renal Division, Peking Univ First Hospital, Beijing, China; 2Div of Nephrology, the First Affiliated Hospital, Guangxi Medical Univ, Nanning, China.

Background: Primary membranous nephropathy (MN) is an organ-specific autoimmune disease. M-type phospholipase A2 receptor (PLA2R) appears to be the specific target antigen, which needs to be presented by major histocompatibility complex (MHC) Class II to activate immune system. In genome wide association studies, risk alleles at PLA2R loci and single nucleotide polymorphism (SNP) (rs2187668) within HLA-DQA1 closely associate with the disease. However, the full association of HLA class II genes and MHC molecule amino acids has not been investigated in MN.

Methods: We genotyped 860 Chinese individuals, including 261 primary MN patients and 599 healthy controls, for DRB1, DQAI, DQBI and DPBI, 4 digits resolution HLA alleles, and extracted the encoding amino acid sequences from IMGT/HLA database. Circulating anti-PLA2R antibody was detected in all patients.

Results: We found that DRB1*1501 (OR=3.49, P=1.77×10^-13) and DRB1*0301 (OR=3.34, P=3.46×10^-10) were both significantly higher risk alleles for MN. In patients with positive anti-PLA2R antibodies, DRB1*1501 (OR=6.06) and DRB1*0301 (OR=92) showed even higher risk for the disease. The SNP (rs2187668) is the tag SNP of DRB1*0301. After conditioning on DRB1*1501 and DRB1*0301, no other HLA allele showed significant association with MN. At amino acid level, the most significant and independent associations were mapped to amino acid position 13 (P=5.78×10^-12) and position 71 (P=7.99×10^-12) on MHC DRB1 chain. After conditioning on these positions, no other amino acid position showed significant association with MN. Alamine on position 71 and Arginine on position 13 were encoded by DRB1*1501; lysine on position 13 was encoded by DRB1*0301. These amino acids were susceptible to MN and showed positive association with the presence of anti-PLA2R antibodies (P<0.001).

Conclusions: We concluded that two alleles of HLA class II genes, and the encoding three amino acid residues on two positions at the epitope-binding pockets of MHC DRB1 chain, were responsible for higher risk to MN.

Somatic Mosaicism and Variant Frequency Detected by Next Generation Sequencing in X Linked Alport Syndrome

Naohiro Kamivoshi, 1 Kandai Nozu, 1 Tomohiko Yamamura, 1 Takeshi Ninchoji, 1 Yuko Shima, 1 Koichi Nakashimi, 1 Norishige Yoshikawa, 1 Kazumoto Ijima. 1Pediatrics, Kobe Univ Graduate School of Medicine, Kobe, Hyogo, Japan; 2Pediatrics, Wakuama Kita Medical Univ, Wakayama, Japan; 3Pediatrics, National Center for Child Health and Development, Tokyo, Japan.

Background: Alport syndrome is a hereditary disorder of type IV collagen, characterized by chronic kidney disease progressing to end-stage renal disease, sensorineural hearing loss, and urinary abnormalities. Approximately 85% of Alport syndrome patients show X-linked inheritance (XLAS) and variants in the type V collagen, a5 gene (COLA5), which encodes the type IV collagen α5 chain. Although male patients with XLAS usually develop end-stage renal disease before 30 years of age, some male patients with a milder phenotype and develop end-stage renal disease later in life. However, the molecular mechanisms associated with this milder phenotype have not been fully identified.

Methods: We genetically diagnosed 186 male patients with suspected XLAS between January 2009 and August 2014. Genetic examination involved: 1) extraction and analysis of genomic DNA using polymerase chain reaction and direct sequencing using Sanger’s method for all patients; and (2) next-generation sequencing to detect variant allele frequencies for four patients who suspected somatic mosaic variants.

Results: We identified somatic mosaic variants in the COLA5 in four patients. Interestingly, two of these four patients with variant frequencies in kidney biopsies or urinary sediment cells of ≥50% showed hematuria and moderate proteinuria, while the other two with variant frequencies of <50% were asymptomatic or only had hematuria.

A New Non-Invasive Method to Examine Collagen α5(IV) Expression Using Plucked Hair Follicles: Analysis of an X-Linked Alport Family with a Novel COL4A5 Splice Region Variant Andrew E. Maloney, Steven Daniel Funk, Jeffrey H. Miner. Renal Div; Dept of Medicine, Washington Univ, St. Louis, MO.

Background: Alport syndrome is a hereditary disease caused by mutations in COL4A5 in 85% of cases. Many different mutation types in this gene have been described. Levels and patterns of type IV collagen deposition are variable in the glomerular basement membranes of Alport kidneys. As COL4A5 is also expressed in the skin, we sought to characterize COL4A5 deposition in the basement membrane of plucked hair follicles from a family with a novel COL4A5 variant as a way of confirming the functional significance.

Methods: Whole-exome sequencing was done on the proband of a family with biopsy proven Alport syndrome. Sanger sequencing was performed on all affected family members and a married-in unaffected individual. Immunofluorescence microscopy was performed on whole mount and sectioned hair follicles co-stained with monoclonal antibodies to collagen α2 and α5(IV). Staining intensity between males and females, affected and unaffected, was analyzed.

Results: Family WU1 is a 3 generational family with chronic kidney disease secondary to Alport syndrome. Affected are in each generation, and both males and females are asymptomatic. Whole-exome sequencing of affected individual 3227 revealed a novel splice region variant c.1780-6G>C in COL4A5. There were no other potentially pathogenic variants found in COL4 or other podocyte genes. This variant was confirmed by Sanger sequencing and segregated with disease. Reduced and abnormal expression of COL4A5 protein was confirmed in affected family members by immunofluorescence microscopy of hair follicles.

Conclusions: We confirmed linkage of a novel splice region variant in COL4A5 to Alport syndrome in a family with a typical X-linked inheritance pattern; this variant may be pathogenic. We developed and validated a new approach to characterize the expression of COL4A5 protein using immunofluorescence microscopy of plucked hair follicles. Furthermore, we demonstrated variability of COL4A5 expression between patients in this family, suggesting intermittent failure of splicing and/or variable lyonization in females.

X-Linked Alport Dogs Demonstrate Mesangial Filipodial Invasion of the Capillary Tuft as an Early Event in Glomerular Damage Sabrina D. Clark,1 Mary B. Nabity,1 Rachel Bianzio,1 Brianna M. Dufek,1 Dominic E. Cosgrove,2 Veterinary Pathobiology, Texas A&M Univ, College Station, TX; 2Veterinary Biosciences, The Ohio State Univ, Columbus, OH; 1Genetics, Boys Town National Research Hospital, Omaha, NE.

Background: X-linked Alport syndrome (XLAS), caused by a mutation in the type IV collagen COL4A5 gene, accounts for approximately 80% of the cases of human Alport syndrome. Dogs with XLAS have a similar clinical progression. Prior studies in autosomal Alport mice demonstrated early mesangial cell invasion as the source of laminit 211 in the glomerular basement membrane (GBM), leading to podofibril loss. Thus far, these findings have not been confirmed in a large animal model.

Methods: XLAS dogs and unaffected littermates were monitored with serial clinicoopathologic data and renal biopsies. Biopsies were obtained at the onset of microalbuminuria (MA), overt proteinuria (urine protein:creatinine (UPC) > 2), onset of azotemia, moderate proteinuria, and at euthanasia. Glomeruli were analyzed by immunohistochemistry.

Results: With disease progression, XLAS dogs showed a progressive decrease in renal function (based on serum creatinine, symmetric dimethylarginine (SDMA), UPC, and oxohedrin clearance) and increased in interstitial fibrosis and glomerulosclerosis (based on light microscopy and/or immunostaining for ASMA and fibronectin). The only identifiable structural abnormality at the time of MA was segmental multilamination of the GBM observed on transmission electron microscopy (TEM), which was more extensive when overt proteinuria developed. Co-localization studies showed that mesangial laminin 211 and integrin α6β1 accumulate in the GBM, which was identified with laminin 212. This was first observed when overt proteinuria developed and coincided with evidence of mild cellular interpositioning on TEM, consistent with invasion of the capillary loops by mesangial cell processes.

Conclusions: These findings confirm, in a large animal model, the induction of mesangial filipodial invasion of the glomerular capillary tuft leading to the irregular deposition of mesangial laminin 211 as an early initiating event in Alport glomerular pathology.

Drug Repurposing for the Treatment of Experimental Alport Syndrome Vanessa R. Williams,1 Ana Konvalinka,2 Xuewen Song,2 Eun Hui Bae,2 Fei Fang,1 Rohan John,3 York P. Pei,1 James W. Scholroy,1,2 1Inst of Medical Science, Univ of Toronto, Canada; 2Diy of Nephrology, Univ of Toronto, Canada; 3Internal Medicine, Chonnam National Univ Medical School, Korea; 2Pathology, Univ of Toronto, Canada.

Background: Alport Syndrome (AS) is a hereditary nephropathy caused by mutations in genes that encode type IV collagen, leading to progressive injury and eventually end-stage renal disease. Currently there are few effective therapies for AS. Therefore we applied a drug repurposing strategy, utilizing data on drugs currently approved for use in humans, to identify a novel AS treatment.

Methods: 129/SvCola3(F0) and wild-type (WT) mice were studied at 4 and 7 weeks (N=8/group). Histological analyses of formalin-fixed mouse kidney sections were performed. Plasma and 24-hour urine samples were collected. Global gene expression profiling of RNA from renal cortex was performed with the Affymetrix Mouse Gene 2.0 ST Array. Significance Analysis of Microarrays (SAM) was used to identify differentially expressed genes. In silico drug repurposing with the Connectivity Map (CMap) was used to identify drugs expected to effectively treat murine AS.

Results: Mice with AS developed a progressive rise in albuminuria and serum creatinine. These changes were associated with glomerulosclerosis and tubulointerstitial fibrosis. SAM was used to generate a disease signature of differentially expressed genes, comparing 7-week-old KO versus WT mice. The disease signature was used to query the CMAP. Vorinostat, a lysine deacetylase inhibitor, was the top drug predicted to reverse the signature. KO mice were treated with vehicle or vorinostat daily from 4 to 7 weeks of age. Vorinostat treatment induced hyperacetylation of kidney lysine residues. This was associated with reduced albuminuria, decreased α5α4 protein expression, and reduced gene expression of inflammatory cytokines.

Conclusions: In silico drug repurposing identified a novel therapeutic approach to AS. Further testing of the putative therapy showed that vorinostat exerted a renoprotective effect. Further studies will better define the mechanisms underlying the protective effect of this novel therapy.

KCTD1 Mutations in Scalp-Ear-Nipple (‘Finlay-Marks’) Syndrome: A Further Cause of Thin Basement Membrane Nephropathy Dongmo Wang,1,2 Peter Diakumis,3 Melanie Bahlo,3 Deb J. Colville,3 Judith A. Savige.1 1Medicine, The University of Melbourne (Menzies Health), Melbourne, VIC, Australia; 2Bioinformatics, WEHI, Melbourne, VIC, Australia.

Background: Scalp-Ear-Nipple syndrome is a ectodermal dysplasia, with a scalp defect, thinning of ears and absent breasts. It results from mutations in KCTD1, an inhibitor of the transcription factor, AP2. AP2 regulates the expression of the collagen IV α3 and α4 chains, which are major components of the glomerular, corneal and retinal basement membranes. This study characterised the clinical phenotype in Scalp-Ear-Nipple syndrome and how mutations caused disease.

Methods: Two unrelated families with Scalp-Ear-Nipple syndrome were examined by a renal physician and an ophthalmologist. One family member provided a skin biopsy that was used to derive a fibroblast cell line. Urine specimens from two family members were used to study the expression of the collagen IV α3 and α4, and laminin α5 and b1 transcripts. The ER size was measured using immunohistochemistry before and after treatment with PBA, a chemical chaperone.

Results: Seven family members had developed renal cysts and impaired renal function by late adulthood, and all 14 who were examined had astigmatism. A renal biopsy demonstrated a thickened glomerular membrane. One individual had a thinned cornea and the two who were examined with optical coherence tomography had a small optic disc, and thinned retinal nerve fibre layer.

Discussion: Reduced transcription of the collagen IV α3 and α4 chains in the urine. The fibroblast cell cultures confirmed reduced laminin transcripts. ER size was increased in the fibroblast cells in vitro but PBA chaperone treatment reduced ER size. However no KCTD1 mutations were identified in 20 individuals with Thin membrane nephropathy and no 141A1 COL4A4 mutations nor in 20 individuals with familial astigmatism.

Conclusions: The clinical features of Scalp-Ear-Nipple syndrome are due to KCTD1 mutations that affect basement membrane collagen IV and laminin expression. Chemical chaperones represent a potential treatment to delay renal failure.

Podocyte Globotriaosylceramide (GL3) Accumulation in Fabry Disease Is Influenced by Age and Genotype Behzad Najafi,1 Camilla Tondel,2 Einar Svarstad,2 Michael L. West,1 Michael Mauer,1 1Univ of Washington; 2Univ of Bergen; 2Dalhousie Univ; 1Univ of Washington.

Background: Podocyte injury plays a key role in Fabry nephropathy, a major complication of Fabry disease. Identification of factors affecting podocyte injury may help to understand the pathophysiology of Fabry nephropathy. We studied effects of age and genotype on podocyte GL3 accumulation in Fabry patients.

Methods: Kidney biopsies from 55 male Fabry disease patients, age 25 [4-65] (median [range]) years were studied using electron microscopic stereology. Podocyte GL3 volume

A Founder Haplotype of APOE-Kyoto Mutation Associated with Lipoprotein Glomerulopathy

Background: The Canadian Fabry Disease Initiative (CFDI) is a multicentre prospective study of outcomes with enzyme replacement therapy (ERT) in Fabry disease. ERT has been shown to be of benefit in reducing Fabry cardiac and renal disease. There is uncertainty as to the benefits of ERT in older patients. We compared outcomes of ERT in patients over 65 years of age with the overall CFDI population.

Methods: Patients are reviewed every 6-12 months as to clinical status. ERT is provided every 2 weeks according to national guidelines with intravenous dose agalsidase alfa (0.2 mg/kg), with a maximum dose of 1.0 mg/kg. Cardiovascular risk factor modification is promoted with use of ASA, statins and ACEi/ARB. Clinical outcomes are defined as stage 5 CKD, stroke/TIA, acute deafness, cardiac arrest, CHF, arrhythmia, unstable angina, MI, PTCA, pacemaker/ICD, AVR/CABG and death.

Results: As of Jan 2015, 429 subjects were enrolled. There were 51 patients over 65 yr, 68.6% female, and 60.8% on ERT with mean age 71.8 y. There were no differences in mean age, cardiac variant genotype, or time in the CFDI between those on ERT and those not. Compared with patients not on ERT, those on ERT had lower GFR, greater proteinuria and higher LVM at both baseline and 6 y later. Three patients not on ERT had 5 clinical events, prevalence 15%, no deaths with clinical event rate of 1/34.5 patient years. Twenty patients on ERT had 5 deaths, 38 clinical events, prevalence 64.5% and clinical event rate of 1/9.3 patient years.

Conclusions: Older patients with Fabry disease continue to have clinical events, mainly cardiac, despite ERT but appear to be living longer. Use of the Canadian Fabry Disease guidelines appears to successfully target high-risk older patients. ERT use in this subgroup appears to be of benefit.

Outcomes of Patients Over 65 in the Canadian Fabry Disease Initiative Study

Steve Doucette, 1 Christiane Auray-Blaiz, 1 Kaye Lemoine. 4 Medicine, Dalhousie Univ, Halifax, NS, Canada; 2 Medicine, Univ of Montreal, Montreal, QC, Canada; 3 Genetics, Univ of Calgary, Calgary, AB, Canada; 4 Emeritus, Univ of Toronto, Toronto, Canada; 4 Medicine, Univ of British Columbia, Vancouver, BC, Canada; 2 Dept of Community Health and Epidemiology, Dalhousie Univ, Halifax, NS, Canada; 1 Pediatrics, Univ of Sherbrooke, Sherbrooke, QC, Canada; 2 Nursing, Nova Scotia Health Authority, Halifax, NS, Canada.

Results: We report 11 pregnancies in 4 women (table 1). Two had an established diagnosis of aHUS prior to the first pregnancy (case 2 and 3). Case 1 presented with end-stage renal disease due to TMA (biopsy-proven) 12 months after her first delivery and case 4 presented postpartum after her uncomplicated first delivery. In 8 pregnancies females received preventive plasma infusions (PI, 200-1600 mL) 2 to 4 weeks apart. After kidney transplantation case 1 received a maintenance therapy (PIs once a month), which was intensified during the II pregnancy to every other week. Two pregnancies (case 2, case 4) are currently ongoing without evidence of a disease flare so far. Nine pregnancies went without any complication and the offspring are healthy. One pregnancy (c.3, II) without PIs resulted in an intrauterine fetal death at gestation week 36, without signs of TMA in the mother.

Lifton,\textsuperscript{4} Martin Zenker,\textsuperscript{4} Friedhelm Hildebrandt,\textsuperscript{4,} 5\textsuperscript{ Dept of Medicine, Boston Children’s Hospital, Harvard Medical School, Boston, MA; 5 Dept of Surgery, Kuwait Univ, Safat, Kuwait; 6 Dept of Genetics, Yale Univ School of Medicine, New Haven, CT; 7 Dept of Human Genetics, Otto von Guericke Univ, Magdeburg, Germany; 8 Howard Hughes Medical Inst, Chevy Chase, MD; 9 These authors contributed equally to this work.\textsuperscript{a} Background: Congenital anomalies of the kidney and urinary tract (CAKUT) are the leading cause of end-stage kidney disease in children. The morphogenesis of kidney and urinary tract is modified by genetic mutations that lead to CAKUT. Identifying these mutations will not only provide deeper insight on disease mechanisms but also aids in improving diagnosis. TUBAL3 was identified as a potential candidate gene for causing CAKUT.\textsuperscript{b} Methods: Homozygosity mapping with whole exome sequencing (WES) was performed in 20 consanguineous families with CAKUT from India. Homozygous recessive mutations within the homoyzogous region were further evaluated as the strongest candidates. Furthermore, we screened an additional cohort of 900 patients with CAKUT for additional mutations with a barcoded array based multiplex exon PCR (48x48 Fluidigm Access Array\textsuperscript{TM}) followed by next generation sequencing (Illumina MiSeq\textsuperscript{TM}). All identified mutations were confirmed by Sanger sequencing.\textsuperscript{c} Results: A homozygous truncating mutation (p.Tyr179*) in the gene TUBAL3 was identified in the consanguineous Indian family A3838 using WES. We then independently detected another mutation homoyzogously (p.Gly10Ser) in the gene TUBAL3 in a family A1347 of Kurdish descent. TUBAL3 (Tubalin, alpha-like 3) is a protein coding gene and is very conserved across species. Tubulin is the major constituent of microtubules.\textsuperscript{c} Conclusions: We identified recessive mutations in TUBAL3 as a novel single-gene cause of CAKUT. Further genetic information and functional studies will help understand disease mechanisms and the role of TUBAL3 in the pathogenesis of CAKUT.

Whole Exome Sequencing Reveals Mutation of PAPLN as a Novel Cause of Congenital Abnormalities of the Kidney and Urinary Tract (CAKUT)\textsuperscript{1} Jing Chen,\textsuperscript{1,} Asaf Vivante,\textsuperscript{1} Julian Jakob Schulz,\textsuperscript{2} Shirlee Shirl,\textsuperscript{2} Stefan Kohl,\textsuperscript{2} DAW-yang Hwang,\textsuperscript{2} Eljah O. Kehinde,\textsuperscript{4} Velibor Tasic,\textsuperscript{4} Friedhelm Hildebrandt,\textsuperscript{4,} 5

\section*{Methods:} To identify novel monogenic causes of CAKUT we applied homozygosity mapping with whole exome sequencing (WES) to 36 families with CAKUT. Then we investigated a worldwide cohort of ~1,600 families with CAKUT with a barcoded array based multiplex exon PCR (48x48 Fluidigm Access Array\textsuperscript{TM}) and next generation sequencing (Illumina MiSeq\textsuperscript{TM}).

\section*{Results:} In a consanguineous family with isolated CAKUT we detected a homozygous protein truncating mutation (p.Arg480*) in the PAPLN gene by WES. PAPLN encodes papillin, a component of the extracellular matrix (ECM) that plays a role in ECM development and interacts with ADAMTS metalloproteases. Papillin contains several thrombospondin type 1 domains homologous to ADAMTS-1, in which mutations leads to protein truncating mutation (p.Arg480*) in the PAPLN gene. PAPLN mutations were detected in another patient, of which 19 patients with CAKUT were screened using next-generation sequence analysis, and candidate mutations were confirmed using Sanger sequencing. The correlation between mutations and clinical manifestation was evaluated.

\section*{Methods:} To investigate the incidence and effects of mutations of PAX2 and 25 related genes, 25 patients with CAKUT were screened using next-generation sequence analysis, and candidate mutations were confirmed using Sanger sequencing. The correlation between mutations and clinical manifestation was evaluated.

\section*{Results:} Thirty patients, including two family cohorts (n = 5 and 2), 19 patients with sporadic CAKUT, and 4 coloboma only control cases were evaluated in the present study. Screening the sequences of PAX2 and 25 other genes identified 46 nonsynonymous single nuclear changes and 9 indels. Among these candidate gene abnormalities, eleven PAX2 mutations were detected in another patient, of which KIF26B mutation was novel. Kidney function and proteinuria were more severe in patients with PAX2 mutations than in those without themutation. Moreover, the coloboma score was significantly higher in patients with PAX2 gene mutations. Three out of five patients with PAX2 mutations had focal segmental glomerulosclerosis diagnosed from kidney biopsies.

\section*{Conclusions:} Our data indicate that PAX2 mutation is a key mutation in CAKUT and may make a major contribution to the pathogenesis of kidney and eye abnormalities. However, other factors and gene mutations may play a role, and further human and animal studies will be required to define the mechanism of pathogenesis of CAKUT.

\section*{Conclusions:} We identified recessive mutations in TUBAL3 as a novel single-gene cause of CAKUT. Further genetic information and functional studies will help understand disease mechanisms and the role of TUBAL3 in the pathogenesis of CAKUT.
Methods: To identify causative genes for CAKUT we investigated consanguineous families with CAKUT by applying whole exome sequencing (WES) combined with homozygosity mapping.

Results: In one family we detected a homozygous loss-of-start-mutation in the gene TCT25 (tetratricopeptide repeat-containing 25). This mutation (p.MetThr; c.2T>C) was present in a consanguineous family with a posterior urethral valve, vesicourethral reflux and bilateral hydrourephrosis. TCT25 plays a role in ciliogenesis, pronephric cilia function and signal transduction in the sonic hedgehog pathway (Hayes, J. M. et al., 2007. Dev. Biol. 312: 115; Xu Y et al., 2015. PLOS ONE 10(4): e0124378). The latter has been shown to coordinate bladder as well as urethra formation in mice (Haraguchi R et al., 2007. Development 134(3):525; Haraguchi E et al., 2012. PLOS ONE 7(1): e42245).

Conclusions: By WES and homozygosity mapping we identified TCT25 as a novel monogenic CAKUT-causing gene if mutated.

Phenotypic Analysis of a Cohort of Patients with Hepatocyte Nuclear Factor 1 Beta (HNF1β) Mutations and Correlation with Established Scoring Systems

Emma Kave Montgomery,1 John Andrew Sayer,1,2 1Renal Services Centre, Newcastle Hospitals NHS Foundation Trust, Newcastle upon Tyne, Tyne and Wear, United Kingdom; 2Inst of Genetic Medicine, International Centre for Life, Newcastle Univ, Newcastle upon Tyne, Tyne and Wear, United Kingdom.

Background: Hepatocyte nuclear factor 1 beta (HNF1β) mutations may lead to a wide spectrum of clinical phenotypes including developmental defects of the kidney, pancreas, liver, and Mullerian duct. HNF1β mutations account for Renal Cysts and Diabetes (RCAD) syndrome. We reviewed patients with known HNF1β mutations to determine the range of phenotypes encountered and identified if these patients would have been detected based on established scoring systems.

Methods: We selected patients who had been screened for HNF1β mutations from 2009 to 2014 within our hospital. Serum magnesium, potassium, urate and creatinine levels were noted along with renal morphology based on imaging. All positive and negative patients for HNF1β mutations had their phenotypes quantified and correlated with published HNF1β scoring systems and screening criteria.

Results: 135 patients were screened over 5 years. The cohort included 17 patients from 10 families with confirmed HNF1β mutations. The majority of these patients had CKD stage 3, with a mean creatinine of 144 umol/L. Only 35% of mutation positive patients had both renal cysts and diabetes. 57% of patients had hypomagnesaemia, 50% of the patients had hyperuricaemia and 4 patients had clinical symptoms of gout with 75% of these patients having hyperuricaemia and 4 patients had clinical symptoms of gout with 75% of these patients presenting with gouty symptoms before the age of 30. Using a published HNF1β scoring system, 16 patients reached a threshold score of ≥8, sufficient for a presumed diagnosis, validating the sensitivity of the scoring system in our cohort. Based on alternative screening criteria, all 17 patients would have been identified for screening.

Conclusions: The majority of patients with HNF1β mutations demonstrated hypomagnesaemia (50%), hyperuricaemia (53%) and deranged liver function tests (59%). RCAD remains a misnomer and patients with HNF1β mutations have a wide phenotypic spectrum, with only one third having renal cysts and diabetes. The use of a HNF1β scoring/screening system will help to improve detection rates.

CTNS Gene Mutations and Variants in Adult Hemodialysis Patients

Craig B. Langman,1 Paul C. Grimr,1 Elena N. Levchentko,1 Krishna R. Polu,4 Feinberg Sch Med, Northwestern U;1 Stanford U. Sch of Med; 2Univ of Leuven,2 Raptor Pharmaceuticals, Novato, CA.

Background: Nephropathic Cystinosis (NC), a rare, systemic, autosomal recessive disease due to CTNS gene mutations causes end-stage renal disease (ESRD). While most cases of NC are recognized in infancy (95%), late-onset NC with ESRD is rare but might be under-diagnosed. NC is rarely diagnosed in African-Americans (AA). Objective: To identify CTNS mutations and possible pathogenic variants (A) in a representative sample of adult patients (pts) in the US.

Methods: Genomic DNA was extracted from whole blood from 4007 adult hemodialysis pts from the Davita biorepository. Fluidigm’s Access Array IFC was used for the CTNS target enrichment. Enriched DNA was sequenced on the Hiseq 2500 using 2 x 100bp read length.Reads were mapped to the human genome version hg19 using the BWA aligner. Mutations and Δ were called using both GATK and Samtools and confirmed by Sanger sequencing.

Results: 16 pts had homozygous (HoZ) and 52 pts had compound heterozygous (HTZ) CTNS sequence Δ. 168 pts had a known diagnosis of NC (W138X). In HoZ pts, 6 had known mutations in CTNS (V42I/G66 were AA) consistent with NC. 9 had upstream promoter mutations (UPM) (7 with -294C>T and 2 with -295G>C, a mutation locus with known disease association), and 3 of these pts were AA. In 52 HTZ CTNS sequence Δ, 2 AA pts had UPM. The other 50 had combinations of changes in the CTNS coding sequence & promoter region.

Conclusions: The unexpected frequency of CTNS gene mutations & Δ suggest that late-onset NC may be underrecognized in ESRD. These CTNS alterations need further study to determine pathogenicity and association with NC. In addition, CTNS mutations & Δ in AA subpopulation signals a need for evaluation for a diagnosis of late onset nephropathic cystinosis in ESRD.

Sixteen Monogenic Genes Cause 20% of Early-Onset Urinary Stone Disease

Jennifer A. Lawson,1 Daniela A. Braun,1 Heon Yung Gee,1 Jan Halbritter,2 Shirlee Shril,1 Weiizen Tan,1 John Andrew Sayer,2 Danko Milosevic,3 Michelle Baum,3 Velibor Tasic,3 Friedhelm Hildebrandt,1,2 1Nephrology, Boston Children’s Hospital, Boston, MA; 2Inst of Genetic Medicine, Newcastle Univ; Newcastle upon Tyne, Tyne and Wear, United Kingdom; 3Dept of Pediatric Nephrology, Univ of Zagreb Medical School, Zagreb, Croatia; 4Medical Faculty Skopje, Univ Children’s Hospital, Skopje, Macedonia, The Former Yugoslav Republic of; 5Howard Hughes Medical Inst, Chevy Chase, MD.

Background: Urinary stone disease (USD) is a prevalent condition that affects 10-15% of adults in their lifetime. It is associated with high morbidity due to colicky pain, the necessity for surgical intervention, and sometimes progression to chronic kidney disease. In recent years, multiple monogenic causes of USD have been identified. However, the prevalence of each monogenic gene has yet to be systematically studied in a pediatric urinary stone cohort.

Methods: To determine the proportion of cases that can be explained molecularly by mutations in 1 of 30 known urinary stone genes, we conducted a high throughput exonic sequencing analysis in an international cohort of consecutively recruited individuals from three renal stone clinics. The cohort consisted of 143 individuals under 18 year of age, with nephrolithiasis (n=123) or isolated nephrocalcinosis (n=20).

Results: We detected likely causative mutations in 16 of 30 analyzed genes, leading to a molecular diagnosis in 20% (29 of 143) of affected individuals; 14 of the 32 detected mutations were not previously described as disease causing (43.8%). We show that mutations in recessive genes are more likely to cause infantile onset disease, whereas mutations in dominant genes are more likely to manifest later.

Conclusions: We present the first exclusively pediatric cohort examined for monogenic causes of urinary stone disease, and our data demonstrates that important therapeutic and preventative measures may result from mutational analysis in individuals with early-onset USD.

Mild Inhibition of Alanine-Glyoxylate Aminotransferase Translation as a Possible Treatment of Primary Hyperoxaluria Type I

Yuacov Frishberg,1 Bodo B. Beck,2 Ruth Belostotsky,1 Pediatric Nephrology, Shaare Zedek Medical Center, Jerusalem, Israel; 1Inst of Human Genetics, Cologne, Germany.

Background: Primary hyperoxaluria type I (PH1) is a kidney stone disease, often leading to ESRD, caused by absence, deficiency or mistargeting of the liver peroxisomal alanine-glyoxylate aminotransferase (AGT), encoded by AGT. The most frequent mutation G170R, responsible for 30% of PH1 cases in Caucasians, results in aberrant mitochondrial localization rather than catalytic inactivity. Modulating AGT maturation and folding has long been perceived as a therapeutic approach. Yet, numerous attempts over the years failed to rescue AGT mutants. We propose mild translational inhibition as a novel approach to rescue AGT mutants. We propose mild translational inhibition as a novel approach to modulate AGT translation in a dose-response fashion. Mild inhibition of AGT translation would allow AGT partial resurfacing in the mitochondrial (major) versus peroxisomal (minor) subpopulations of mutated AGT.

Methods: Using a short-term treatment with low concentrations of emetine showed statistically significant increase of the peroxisomal (minor) subpopulations of mutated AGT we developed the self-assembly split-GFP-based assay for detecting peroxisomal subpopulation of AGT. To ensure selective and specific discrimination between the mitochondrial (major) and peroxisomal (minor) subpopulations of mutated AGT we developed the GlowAGT,WT-AGT but not G170R-AGT was detectable by GFP fluorescence, although both variants were visible by indirect immunofluorescence. Long-term treatment with low concentrations of emetine showed statistically significant increase of fluorescent subpopulation of G170R-AGT. GFP fluorescence was exclusively co-distributed with the peroxisomal staining in all cases.

Conclusions: We have developed and applied successfully GlowAGT as a unique self-assembly split-GFP-based assay for detecting peroxisomal subpopulation of AGT. Using GlowAGT we show that mild translation inhibition by emetine is a novel therapeutic approach for PH1 caused by AGT misfolding/mislocalization.

Functional Analysis of CLCNKB Mutations Causing Bartter Syndrome Type III
Yohan Bignon, Mathilde Keck, Stéphane Lourdèl, Rosa Vargas-Poussou, Jacques Teulon, Olga Andrini, Metabolism and Physiology Renales, Centre de Recherche des Cordeliers, UPMC, Paris, France; 2Dept of Human Genetics, Hopital European Georges Pompidou, Univ Paris 5, Paris, France.

Background: Bartter Syndrome type III is a human autosomal recessive disease characterized by salt wasting, hypokalemic metabolic alkalosis and secondary hyperaldosteronism. Therefore, patients affected by Bartter syndrome type III display the clinical triad characterized by salt wasting, hypokalemic metabolic alkalosis and secondary hyperaldosteronism. Therefore, patients affected by Bartter syndrome type III display the clinical triad.

Methods: We characterized the electrical activity, total protein expression, surface expression and subcellular localization of mutated forms of ClC-Kb in X. laevis oocytes and mammalian cell lines.

Results: Currents produced by G424R and G437R CIC-Kb channels were reduced by 50%, in proportion to membrane targeting without any change in total protein abundance. A204T mutants did not produce any current but their membrane insertion was only partially reduced (50-80%). Protein abundance of A210V was decreased by half. Conversely, that of P216L was comparable to WT CIC-Kb, suggesting that the P216L mutation might alter channel gating. Finally, A204T seems to be electrically functional, well rather inserted into the plasma membrane and protein level is comparable to that of wild-type CIC-Kb.

Methods: a. Fetal kidneys were exposed to maternal hyperglycemia using Streptozotocin (STZ). Posteriorly these sections were immunostained to detect apoptosis (active caspase3) in the CM (Six2 and NCAM) and nascent neprons (Lefl and NCAM). b. Glycoseis inhibihet ex vivo in E12.5 kidneys by pharmacetical inhibition of PFKFB3 (YN1 5-25nM). c. Glycoseis and oxidative phosphorylation were measured in NIDDK Support, Other NIH Support - NIH-NIGMS newborn kidneys of Six2-GFP-gfp3/2, a genetic model of impaired cap mesenchyme renewal.

Results: a. CM of P0 kidneys of STZ-treated females showed increased apoptosis and reduction in nascent nephron number (Lefl+ and NCAM+). b. Glycoseis inhibition resulted in a smaller dispersed CM, accelerated but not ectopic differentiation of the NPC with up to a 50% increase in Lhex+ nascent nephrons 24-48h post-treatment, and decreased Citedl expression by QPCR in isolated NPC. UB tip and branch numbers were unchanged. Thus, increased nephrogenesis was independent of UB branching. Expression of Wnt4 was unchanged. c. Conditional deletion of p53 in NPC resulted in dispersed CM, depletion of the Citedl+V2+ NPC dependent of apoptosis, and hypoplastic kidneys with fewer nascent nephrons. Isolated mutant cells showed reduced basal oxygen consumption rate and decreased maximal respiratory capacity. Accordingly, the mutant cells exhibit a significant, nearly two-fold decrease in ATP (p<0.005, n=3).

Conclusions: Our data are consistent with the idea that the metabolic status of the NPC is a critical determinant of NPC renewal and differentiation.

Prorenin Receptor Signaling Promotes Nephron Induction During Mouse Kidney Development
Renfang Song,1 Graeme James Preston,1 Laura R. Kidd,2 Ihor V. Yospyi1,1 Pediatric Nephrology, Tulane Univ, New Orleans, LA;1 Pathology, Tulane Univ, New Orleans, LA.

Background: Deficient nephrogenesis is the major factor contributing to congenital renal hypoplasia (RHD), one of the leading causes of childhood end-stage kidney disease. Nephron induction is driven by reciprocal interactions between progenitor cells of the cap mesenchyme and the ureteric bud (UB).

Methods: To determine the potential role of the prorenin receptor (PRR) in nephrogenesis, we generated mice with a conditional deletion of the PRR in nephron progenitors using Six2-Cre;ROSA-RFP.

Results: Inactivation of PRR in nephron progenitors caused a marked decrease in the number of developing nephrons, severe congenital RHD with collapsed glomeruli and an enlarged Bowman’s space (such as those seen with a collapsing FSGS), podocyte foot process effacement and early postnatal death within 48 hours from birth. UB branching was greatly reduced, likely secondary to decreased nephrogenesis. Reduced congenital nephrogen endowment resulted from premature depletion of nephron progenitor cell population due to impaired progenitor cell proliferation and loss of normal molecular inductive response to canonical Wnt/β-catenin signaling within the metanephric mesenchyme. At 2 months of age, heterozygous Six2+RFP+ mice exhibited focal glomerulosclerosis, decreased kidney function and massive proteinuria.

Conclusions: Collectively, these results are consistent with a cell-autonomous requirement for the PRR within nephron progenitors for progenitor maintenance, induction of nephrogenesis, normal kidney development and function. Thus, PRR is a potential candidate for future genetic screening studies in patients with congenital RHD and proteinuric kidney disease.

FR-PO183

Functional Dissection of Enhancers for Bmp7 in Kidney Development
Taro Tsujimura,1,2,3 Osamu Takase,1,2,3 Masami Nangaku,1 Keizhi Hishikawa,1,2,3 Advanced Nephrology and Regenerative Medicine, The Univ of Tokyo Hospital, Tokyo, Japan;1 Div of Nephrology and Endocrinology, The Univ of Tokyo Hospital, Tokyo, Japan;1 Div of Tissue Engineering, The Univ of Tokyo Hospital, Tokyo, Japan.

Background: Bmp7 is a critical player in the kidney development, as shown by its severe retardation in the KO mice of the gene and their subsequent perinatal lethality due to the malfunction. Previous studies identified two potential enhancers for the Bmp7 expression in the developing kidney around the lona: one residing inside the 1st intron of Bmp7 for expression in the developing ureteric bud; the other located downstream of the 3’nd end of Bmp7, which is rather active in the metanephric mesenchymal cells. Consistently, Bmp7 is also expressed in these two distinct domains. However, neither the requirement of these elements nor the influence of Bmp7 secreted from these different cell types for the kidney development has been uncovered so far. In this study, we aimed to characterize the roles of the two enhancers to better understand the cis-regulation of Bmp7 and the kidney development.

Methods: We established and analyzed homozygous mice carrying a large genomic deletion of the downstream region of Bmp7 including the mesenchymal enhancer.

Results: We found that they have significantly smaller body size than their wild type littermates, although they are viable unlike the KO mouse of Bmp7. We previously showed that the above deletion also disrupts the topological partition of the chromatin conformation between the Bmp7 domain and the neighboring one of another developmental gene, Tjp2/c, resulting in a merger between them (Tsujimura et al. PLAS Genetics 2015). Interestingly, upon this deletion, we scored significant up-regulation of Tjp2/c in the kidney probably by the effect of the intron enhancer.

Conclusions: These results suggest that the endogenous genomic context guarantees robustness in the regulation of the kidney development by linking the more important ureteric bud enhancer to Bmp7 tightly. The differential roles of the two enhancers will be further discussed based on the histological and functional analysis of the kidney in the homozygous deletion mice.

BMP7 Regulates Expansion of the Postnatal Nephron
Mary E. Tuilenti,1,2,3 Seymouros Rosen,3 Jordan A. Keidberg,1,2,4 1Dept of Medicine, Boston Children’s Hospital, Boston, MA; 2Dept of Pathology, Beth Israel Deaconess Medical Center, Boston, MA; 3Dept of Pediatrics, Harvard Medical School, Boston, MA; 4Harvard Stem Cell Inst, Cambridge, MA.

Background: The factors that regulate the expansion of nephrons after their initial induction and differentiation are largely unknown. Bone morphogenetic protein 7 (BMP7) is a crucial factor driving proliferation and self-renewal of nephron progenitor cells during the development of the embryonic kidney. In this study we investigated a potential role for BMP7 as a regulator of post-induction nephron growth and differentiation.

Methods: The Bmp7 gene was conditionally mutated in progenitor cells using Six2-GFP-Cre. Kidneys from mutant and control mice were analyzed using a novel approach to quantitatively proximal tubule expansion as an indicator of nephron growth in the postnatal mouse.

Results: Kidneys of Bmp7 conditional mutant mice were smaller with reduced numbers of nephrons. Bmp7 was expressed in developing nephron tubules of control kidneys and was absent from mutant kidneys. Proximal tubule growth, as determined by computationally measuring the area of lectin-stained proximal tubules in postnatal kidneys, was reduced in mutant kidneys. However, the proximal tubule area per glomerulus was increased in mutant kidneys, indicating that those nephrons that were induced underwent hypertrophy. Hypertrophy, as defined by Kdo2×Glomerular size, increased in both mutant and control mice but was greater in mutants than in control by P10.

Conclusions: Loss of Bmp7 in progenitors leads to low nephron number. Bmp7 appears to be an important driver of postnatal nephron expansion. This phenotype is similar to hypogonadism and may be used to understand the basis for nephron hypotrophy in low nephron number situations.

Funding: NIDDK Support

FR-PO185

Grainyhead-Like 2 (Grhl2) Regulates Collecting Duct Barrier Function, Aquaporin 2 Expression and Urinary Concentration
Christian Hinze,1,2 Janett Ruffert,1,2 Katharina Walentin,1 Max Werth,1 Jonathan M. Barasch,1 Andong Qiu,1 Kerim Mutig,1 Sebastian Bachmann,1 Kai M. Schmidt-Ott,1,3 1Dept of Nephrology, Charité-Universitätsmedizin, Berlin, Germany; 2Max Delbrueck Center for Molecular Medicine, Berlin, Germany; 3Div of Nephrology, Columbia Univ, New York; 4Dept of Anatomy, Charité-Universitätsmedizin, Berlin, Germany; 5Urological Research Laboratory, Charité-Universitätsmedizin, Berlin, Germany.

Background: Osmotic homeostasis is tightly regulated by the kidney and its collecting ducts which form tight barriers, thereby maintaining steep concentration gradients and allowing transcellular reabsorption of water via aquaporins. The transcription factor grainyhead-like 2 (Grhl2) is highly expressed in renal collecting ducts. Using cultured collecting ducts, we recently showed that Grhl2 regulates epithelial barrier formation and lumen expansion via a target gene set comprising the transcription factor Ovo-like 2 (Ovol2), the small GTPase Rab 25 (Rab25) and the tight junction component claudin 4 (Cldn4). The role of Grhl2 in the collecting duct in vivo is unknown.

Methods: To investigate the role of Grhl2 in the renal collecting duct, we generated a collecting duct-specific knockout with Hoxb7-Cre;Grhl2+-/lox mice, which exhibit a deletion of Grhl2 protein in most of the collecting ducts. The molecular and cellular alterations in their kidneys and their response to water deprivation were analyzed.

Results: Transcriptional profiling of Hoxb7-Cre; Grhl2+-/lox mice kidneys and control littermates showed deregulation of Ovol2, Rab25 and Cldn4, but also differential expression of Aquaporin 2 (Aqp2). Following water deprivation, Grhl2-deficient mice displayed significantly lower urinary osmolality at 6 hours (P<0.001) and 24 hours (P<0.04) when compared to control mice. Moreover, Grhl2-deficient mice had more than 35% more urine volume during the first 24 hours in response to water deprivation when compared to controls (P<0.005).

Conclusions: Our data indicate that Grhl2 critically participates in water homeostasis, epithelial barrier function and Aqp2 expression. This might be of relevance to diseases involving defective renal responses to water deprivation.

Loss of the Transcription Factor Te2f2 in the Renal Struma Leads to Polyuria and Defects in Tubular Development
Shintaro Ide,1 Yoshio Macawa,1 RizaIpy P. Scott,1 Tuncer Onay,1 Kana Ide,1 Minoru Takemoto,1 Koutaro Yokote,1 Susan E. Quiggan,1 1Clinical Cell Biology and Medicine, Chiba Univ Graduate School of Medicine, Chiba, Japan; 2Feinberg Cardiovascular Research Inst and Div of Nephrology and Hypertension, Northwestern Univ, Chicago, IL.

Background: Renal stromal cells serve as a supportive framework for nephrons and the collecting duct network, produce erythropoietin, and contribute to renal fibrosis when they undergo myofibroblast-like transformation. Te2f2/Pod1 is a BHLH transcription factor

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
strongly but not restrictively expressed in the developing renal stroma. Conventional Tcfl1 knockouts (KO) mice survive and have maldifferentiated renal stromal and pericytes without signs of the renal interstitium. However, the precise function of Tcfl1 within renal stromal cells has yet to be clarified as Tcfl1 is also expressed within the condensing metanephric mesenchyme during development.

Methods: In order to characterize the role of Tcfl1 in stromal development and function, we bred floxed Tcfl1 mice with Foxd1-Cre mice allowing specific inactivation of Tcfl1 within the developing renal stroma and its derivatives.

Results: Mice lacking Tcfl1 in the renal stroma (Tcfl1<sup>fl/fl</sup>) do not have an overt phenotype at birth, but renal stromal arterioles branching in embryonic kidney explant cultures. However, by 4 weeks postnatal, Tcfl1<sup>fl/fl</sup> mutant mice develop polycyria similar to diabetes insipidus. Polyuric mutant mice produce urine with significantly reduced osmolarity and creatinine levels but with higher levels of sodium and chloride relative to control littersmates. Mutant kidneys are smaller, have a disorganized interstitium, and shriveling of the medullary rays due to a reduction in the loops of Henle and collecting ducts, whereas proximal tubule densities appear undisturbed.

Conclusions: Specific inactivation of Tcfl1 in the stroma causes polycyria underscoring an important role of the renal interstitium in regulating postnatal development of tubules critical for urine concentration.

Genetic Deletion of Cyclooxygenase-2 Impairs Glomerular Silt Diaphragm Formation During Late Stages of Kidney Development

Kirsten Madsen, 1,2 Niels Marcussen, 2 Bryce Jensen. 3
1 Dept of Cardiovascular and Renal Research, Univ of Southern Denmark, Odense, Denmark; 2 Dept of Pathology, Odense Univ Hospital, Odense, Denmark

Background: Renal cyclooxygenase-2 (COX-2) expression is necessary for normal glomerular development. Impaired COX-2 activity has been associated with decreased expression of VEGF, a vascular growth factor of significant importance for glomerular capillary development. Therefore experiments were designed to test the hypothesis that COX-2 expression supports glomerular development through stimulation of capillary loop formation.

Methods: Kidney tissue was collected from a developmental series of COX-2 knockout (KO) mice and wild-type littersmates (WT).

Results: Renal COX-2 expression showed developmental regulation with significantly higher COX-2 expression at postnatal (P) days 1 and P7 than at any later time points (P14, P21 and P40). Quantitative unbiased stereology at P2 showed significantly reduced glomerular number in COX-2 KO mice compared to WT littersmates (8188 ± 781 and 12251 ± 454 glomeruli/kidney respectively, P=0.0001). Subcapsular accumulation of small and immature glomeruli was seen in COX-2 KO mice whereas glomeruli deeper in the cortex towards the medullary junction appeared normal. Tissue abundance of VEGF, angiopoietin-1 and -2 mRNAs was significantly reduced in COX-2 KO mice compared to WT at P7. By electron microscopy at P28, immature subcapsular glomeruli showed normal appearance of fenestrated endothelial cells but severe podocyte foot process effacement and absence of mesangial cells. Normal morphology was confirmed in glomeruli deeper in the cortex. At P7, COX-2 KO mice showed reduced expression of silt diaphragm proteins nephrin and podocin but not syndecanopin compared to WT. In summary, deletion of COX-2 leads to decreased renal expression of VEGF, a key growth factor for renal stromal and mesangial cells, with severe podocyte foot process effacement and absence of mesangial cells.

Conclusions: In summary, deletion of COX-2 leads to decreased renal expression of VEGF, a key growth factor for renal stromal and mesangial cells, with severe podocyte foot process effacement and absence of mesangial cells.

Functional Cross Talk Between Tyrosine Phosphorylation of Crumbs Homolog 2 and Mechanistic Target of Rapamycin Complex 1 in Developing Podocyte

Sho Hamaguchi, Yukino Nishibori, Kunitaka Yam. 3 Dept of Pediatrics, Kyorin Univ School of Medicine, Mitaka, Tokyo, Japan

Background: Mutation of crumbs homolog 2 (CRB2) is a novel cause of congenital nephrotic syndrome (cNS). We have previously characterized transplantation of kidney and liver tissues from CRB2 deficient mice. However, how CRB2 functions in podocyte development is unknown.

Methods: MKC cells expressing mouse full-length CRB2 or mutated-CRB2 lacking tyrosine phosphorylation site were established. Specific antibodies against CRB2 intracellular domain (CRB2-Ab) or tyrosine phosphorylation site (pY-CRB2-Ab) were generated. The samples from cultured cells and rat kidneys were subjected to Western blot and immunofluorescence microscopy.

Results: Int-CRB2Ab determined CRB2 to locate at the apicobasolateral membrane in wild-CRB2 cells. Specificity of pY-CRB2Ab was confirmed by using samples from mutated-CRB2 cells and wild-CRB2 cells treated with protein tyrosine phosphatase inhibitor. Int-CRB2Ab identified that CRB2 expression commenced at the comma-shaped body stage, observed in the apical side of glomerular epithelium. CRB2 in the S-shaped body was still visible at the apical side of immature podocytes, then translocated along the lateral side of mature podocytes. At the mature stage, CRB2 was observed in the podocyte foot processes. In contrast, phosphorylation of CRB2 was determined faintly in immature podocyte at the S-shaped body stage, intensely at the mature stage and then decreased in the proximal distal convoluted tubule (P.05). CRB2 tyrosine phosphorylation may regulate energy system of developing podocytes through suppressing excessive mTORC1 activation.

Conclusions: CRB2 tyrosine phosphorylation may regulate energy system of developing podocytes through suppressing excessive mTORC1 activation.

Epithelial Cell Fate in the Nephron Tubule Is Mediated by the Etv5a Transcription Factor During Zebrafish Kidney Development

Amanda N. Marr, Rebecca A. Wingert.
Biological Sciences, Univ of Notre Dame, Notre Dame, IN.

Background: Kidney development requires the differentiation and organization of discrete nephron epithelial lineages, however the genetic and molecular pathways involved in these events remain poorly understood. The embryonic zebrafish kidney, or pronephros, provides a simple and useful model to study nephrogenesis.

Methods: The pronephros is comprised of two types of epithelial cells: transportive and multi-ciliated cells (MCCs). Transportive cells occupy distinct tubule segments and are characterized by expression of solute transporters, while MCCs function in fluid propulsion and are dispersed in a “salt-and-pepper” pattern in the tubule. Epithelial cell identity is related by a pathway between Notch signaling pathway and retinoic acid (RA) signaling, where RA promotes MCC fate by inhibiting Notch signaling in renal progenitors, while Notch activity acts downstream to trigger transportive cell formation and restrict MCC identity. Previous research has shown that etv5a and its ETS family members are required for ciliogenesis in other zebrafish tissues.

Results: Here, we mapped etv5a expression to renal progenitors that occupy domains where MCCs later emerge. Thus, we hypothesized that etv5a is required for ciliogenesis of MCCs in the nephron. etv5a loss of function produced a decline of MCC number and reduced expression of the MCC markers odf3b and centrin, where rescue experiments partially restored wild-type MCC number. In epistatic studies, exogenous RA treatment expanded the etv5a domain, indicating that etv5a acts downstream of RA. Additionally, treatment with exogenous RA partially rescues the reduced MCC phenotype after loss of etv5a. Further, abrogation of Notch with the small molecule inhibitor DAPT increased etv5a expression, while overexpression of Notch using a transgenic line reduced the etv5a domain, suggesting Notch acts upstream to inhibit etv5a.

Conclusions: Taken together, these findings provide novel insights about the mechanisms of epithelial cell development during nephrogenesis.

Emx1 Is Essential for Distal Segment Development During Nephrogenesis

Elin E. Morales, Rebecca A. Wingert.
Biological Sciences, Univ of Notre Dame, Notre Dame, IN.

Background: Vertebrate kidneys are comprised of functional subunits called nephrons that typically have three basic parts: a renal corpuscle, a tubule with proximal and distal segments, and a duct. The developmental pathways that establish nephron segment identities from renal progenitors remain poorly understood.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

399A
Methods: The zebrafish embryo forms a simple two-nephron pronephric kidney that provides an ideal model system with which to study cell-fate decisions with high anatomical and genetic resolution. emx1 is a homeobox gene that, along with its paralog emx2, is known for playing essential roles in brain development. While both genes are expressed in the pronephros, their roles in nephrogenesis have not been established. Using whole mount in situ hybridization, we found that emx1 and emx2 were dynamically expressed in renal progenitors, and became localized to the distal and proximal renal segments, respectively.

Results: In knockdown studies, emx1 morphants formed a normal distal domain, marked by cranx, but within it formed an expanded distal early (DE) segment, marked by slc2a12a. These data suggest that emx1 is essential to promote the DL, and may restrict the DE and/or negotiate the site of the DE/DL boundary. Furthermore, emx2/2 expression is responsive to changes in retinoic acid (RA), which is essential to induce proximal segments and repress distal segments during nephrogenesis. RA treated embryos had a restricted emx1/1 domain and expanded emx2 domain, while exposure to the RA biosynthesis inhibitor DEAB conversely expanded emx1 and restricted emx2 expression. These data suggest that RA signaling acts upstream of both genes in renal progenitors, positively regulating emx1 and negatively regulating emx2.

Conclusions: Future studies will define the role of emx2, independently explore emx1/2 nephron patterning functions with CRISPR-Cas lines, and assess the relationship of these emx genes to other factors, such as irx3, that have been shown recently identified to be components of the gene regulatory networks that direct nephron segmentation. Preliminary data looking at factor interactions suggest that emx genes may be located downsteam of others who regulate independent pathways.

Prostaglandins as Regulators of Nephron Proximo-Distal Cell Fate Decisions Shahram Jevin Pourcetzecht, Christina N. Cheng, Rebecca A. Wingert. Biological Sciences, Univ of Notre Dame, Notre Dame, IN.

Background: To date, there have been a number of important discoveries furthering our understanding of nephron segmentation. Despite this, the factors that direct nephron cell-fate decisions remain largely unknown. Danio rerio, the zebrafish, possess an embryonic kidney composed of two nephrons and a blood filter that share a remarkable degree of genetic, structural, and functional homology with the human nephron and when coupled with genetic tractability, ex utero development, and optically transparent embryos make it a cutting-edge model to study nephrogenesis.

Methods: The zebrafish embryonic kidney, the pronephros, is organized in a proximal-distal pattern of contiguous segments much like the human kidney. The proximal segments, the proximal convoluted tubule (PCT) and the proximal straight tubule, share a name with their mammalian counterpart counts; the distal segments, the distal early (DE) and the distal late (DL) – are homologous to the mammalian thick ascending limb (TAL) and distal convoluted tubule (DCT) respectively. We performed a chemical genetic screen using zebrafish embryos during nephrogenesis and analyzed the effects on segmental patterning.

Results: Interestingly, a large number of prostaglandin (Pg) pathway components were identified among our hits. Prostaglandins (Pgs) are fast-acting lipids necessary for an array of physiological functions. We discovered that treatment with bioactive Pg agonists restrict the PCT and DL, while inducing an expansion of the PST. Genetic knockdown and small molecule inhibition of the Pg producing Cox1/2 enzymes or the Pg Ep G-protein receptors triggered an expansion of the DE segment at the expense of the DL. Further, we saw that modest levels of Pj pathway with higher vertebrates. emx1 is a homeobox gene that, along with its paralog emx2, is known for playing essential roles in brain development. While both genes are expressed in the pronephros, their roles in nephrogenesis have not been established. Using whole mount in situ hybridization, we found that emx1 and emx2 were dynamically expressed in renal progenitors, and became localized to the distal and proximal renal segments, respectively.

Conclusions: Thus, we show here for the first time that Pg signaling has an impactful role in nephron cell-fate decisions, suggesting that Pgs may have considerable implications for kidney development and disease.

FR-PO193
Cloning of the Zebrafish Kidney Mutant Zeppelin Reveals That Bra2/Fancl1 Is Essential for Renal Development Paul T. Kroeger, Rebecca A. Wingert. Biological Sciences, Univ of Notre Dame, Notre Dame, IN.

Background: Zebrafish kidneys are conserved with other vertebrates, making them an excellent genetic model to study renal development. The kidney collects metabolic waste using a blood filter with specialized epithelial cells known as podocytes. Podocyte formation is poorly understood but relevant to many kidney diseases, as podocyte injury leads to proteinuria, which is characteristic of renal disease.

Methods: zeppelin (zep) was isolated in a forward screen for kidney mutants and identified as a homoygous recessive lethal allele, which has a loss of podocyte numbers, deficient filtration, and fluid imbalance. Addition of retinoic acid did not rescue the zep mutant phenotype. Although mutants had normal formation and cell death, the interrenal gland was increased in size, suggesting a possible cell fate switch between these related lineages. This data was corroborated by interrenal gland volume identified by FISH analysis. 3β-HSD staining indicated the interrenal gland produced more hormones in the zep mutants, potentially suggesting an alternate mechanism of an endocrine feedback loop leading to proliferation of interrenal cells.

Results: Meiotic mapping and whole genome sequencing of zep identified a splicing mutation in breast cancer 2, early onset (bra2)/fancl1, which was confirmed by sequencing of bra2/fancl1. Several independent bra2 morpholino phenocopy zep, causing edema and podocyte reductions, as well as an increase in the size of the interrenal gland. Additionally, 3β-HSD staining suggests that morphants have an increased number of cells that generate hormones, similar to zep. Histological analyses of the adult kidney in zep heterozygotes, bra2+/−, 3β-HSD+ juveniles and adults showed renal pathologies associated with glomerular defects. Taken together, these data suggest for the first time that bra2/fancl1 is essential for kidney development and homeostasis.

Development of the Vasculature in the Bladder Julia K. Schaffer,1 Kenneth A. Walker,2 Caitlin M. Schaefer,2 Daniel S. Bushnell,3 Elna Mukherjee,1 Sunder Simis-Lucas,2 Carlton M. Bates,2 1Div of Newborn Medicine, Univ of Pittsburgh; 2Div of Nephrology, Univ of Pittsburgh, Pittsburgh, PA.

Background: Developing bladder consists of differentiating outer muscle, middle stromal, and inner epithelial layers. To date, formation of the bladder vascular network has not been determined. Aim: To determine vascular patterning through bladder development.

Methods: We examined developing bladder vasculature from embryonic day (E) 11.5 through postnatal day (P) 30 by genecis histology and immunohistochemistry (including morphometry with GSL1 lectin staining). We performed quantitative realtime PCR (qPCR) for genes associated with vascular formation (e.g. Angiopoietin 1 and Vegfa ligands and Tie2 and Vegf2 receptors) and hypoxia inducible factors (Hifs).

Results: In early bladder development (E11.5-13.5) vascular branches from the umbilical arteries grow towards a network of developing vessels within the primitive bladder mesenchyme. However, by E15.5, connections between the umbilical arteries and primitive bladder vasculature network are diminished and a vascular remodeling. Perfusion (presence of red blood cells) of most bladder vessels was identified even at early developmental time points. Morphometric assessment revealed a peak in relative vascular tissue content in the bladder at E15.5, which regressed with further maturation. This reduction in vascular content after E15.5 suggests vascular pruning and further remodeling. qPCR revealed that Angiel1 and Vegf2 expression peaked during early embryonic development, whereas expression of the Angiel receptor, Tie2, peaked in early postnatal mice. The Vegf2 ligand Vegfa displayed consistent expression at all ages. Interestingly, Hif1a and Hif2a demonstrate inverse mRNA expression profiles with Hif1a highest in embryonic bladders and Hif2a expression peaked in adult bladders.

Conclusions: Unexpectedly, bladder vasculature appears to arise from angiogenic vessels that arise from the umbilical artery. Subsequently, early bladder vessels undergo pruning with age. Key molecules that regulate vascular development, including hypoxia inducible factors, have differential expression patterns.

Exploring the Relation Between Cells and Extracellular Matrix in the Developing Human Fetal Kidney Astrik Petrovska,1 Estefanie Rodriguez,1 Ruby Kim,1 Hasmik Soloyan,1 Brendan Grubbs,2 Matthew Edward Thornton,2 Roger E. De Filippo,1 Laura Perin,1 Stefano Da Sacco,3 1Urology, Children's Hospital Los Angeles, Los Angeles, CA; 2Div of Developmental Biology, University of Pittsburgh, Pittsburgh, PA.

Background: It is widely accepted that, during development, the renal compartment undergoes dramatic changes in regards to cell specification and differentiation, matrix deposition and spatial organization. However, despite the growing number of studies focusing on kidney mouse development, very little is known of changes, including cell differentiation and extracellular matrix (ECM) deposition, occurring during human development. To fill this gap, we have characterized human embryonic kidneys (hEK) at different weeks of gestation to better understand renal progenitor biology and cell-matrix interactions.

Methods: Histological analysis were carried out on hEK between 11-22 weeks of gestation for ECM components (such as collagen IV a1-6 chains, collagen I, fibronectin) and progenitor/mature renal cells markers such as WT1, Pax-2, Six-2, Cited1, VE-Cadherin, a-SMA.

Results: We observed dynamic changes in the ECM throughout the progression of the gestational ages. In particular, decrease in nephrogenic zone size along with a higher presence of C- and S-shaped structures and fully developed glomeruli and tubules was observed. Interestingly, Hif1a and Hif2a demonstrate inverse mRNA expression profiles with Hif1a highest in embryonic bladders and Hif2a expression peaked in adult bladders.

Conclusions: Our data suggest that, during hEK development, cell specification is accompanied by marked changes in ECM composition. This characterization might increase our knowledge of reparative processes enabling investigations focused on matrix remodeling and progenitor cell activation, thus ultimately enhancing the chances to treat renal damage.

Enalapril Treatment Modulates Lymphangiogenesis and Fibrogenic Machinery in the Developing Rat Kidney
Kee Hwan Yoo, Hyung Eun Yim, In Sun Bae, Byungkwon Kim, Young Sook Hong, Joo Won Lee.
Dept. of Pediatrics, Korea Univ Medical Center, Seoul, Republic of Korea.

Background: The renin angiotensin system plays a pivotal role in both renal development and progressive renal disease. Lymphangiogenesis occurs during normal organ development and pathological processes. In this study, we aimed to investigate the effect of angiotensin II inhibition on the expression of fibrogenesis-related molecules and lymphatic vessels in the developing rat kidney.

Methods: Newborn rat pups were treated with enalapril (30 mg/kg) or vehicle for 7 days after birth. We investigated the intrarenal expression of fibroblast growth factor (FGF)-1, FGF-2, FGF receptor (R)–1, Fibroblast-specific protein (FSP)-1, intercellular adhesion molecule-1, toll-like receptor (TLR)-2, and TLR-4 with Western blotting and immunohistochemistry at postnatal day 8. For the determination of lymphatics, the lymphatic vessel markers of vascular endothelial growth factor (VEGF)-C, VEGFR-3, and podoplanin were assessed. For the detection of cell proliferation and collagen fibers, Ki-67 and Sirius red stainings were performed.

Results: In the enalapril-treated group, intrarenal FGF-1, FGF-2, FGF-1 and VEGF-C protein expression were decreased, compared to the controls (P < 0.05). Immunohistochemistry for the lymphatic vessel markers of VEGF-C, VEGFR-3, and podoplanin showed reduced lymphatic immunostainings in the enalapril-treated kidneys. However, FSP-1 expression was prominent in the interstitium and glomeruli in enalapril-treated kidneys. While cell proliferation was reduced in the enalapril-treated group, collagen deposition was enhanced in the enalapril-treated kidneys (P < 0.05). Intercellular adhesion molecule-1, TLR-2, and TLR-4 protein expression showed no differences between the two groups.

Conclusions: Enalapril treatment during postnatal 7 days may induce perturbations in FGF/FGF signals, cell proliferation, and lymphangiogenesis required for renal development and maturation and activate in part the fibrogenic machinery in the developing rat kidney.

The Effect of Prenatal Hypoxia and a Postnatal High Salt Diet on Renal Structure in the Aged Mouse
Sarah L. Walton, 2 Reetu S. Singh, 2 Joan Li, 1 Helle Bielefeldt-Ohmann, 3 Tamara Paravicini, 3 Melissa H. Little, 1 Karen M. Moritz. 1
1 School of Biomedical Sciences, Univ of Queensland, Brisbane, Queensland, Australia; 2 Dept of Physiology, Monash Univ, Melbourne, Victoria, Australia; 3 Inst for Molecular Bioscience, Univ of Queensland, Brisbane, Queensland, Australia. 5 School of Veterinary Science, Univ of Queensland, Gatton, Queensland, Australia.

Background: Chronic fetal hypoxia leads to growth restriction and increased risk of adult disease. This study examined the long-term renal outcomes of offspring prenatally exposed to hypoxia, and whether a postnatal high salt diet could exacerbate impairments.

Methods: Pregnant CD1 mice were housed in a hypoxic chamber (12.0% O2; N=8, HYP). For control (21% O2; N=8, CON) environment from embryonic day (E) 14.5 to birth (E) 20.5. A subset of male pups was randomly allocated to a control diet (0.2% NaCl, NS) or high-salt diet (5% NaCl; HS) from 10 weeks of age. Blood pressure was measured at 12 months of age and kidneys were collected. Kidney sections were examined for nephron number, glomerulosclerosis, interstitial fibrosis, renal vascular remodeling, and alpha-smooth muscle actin (α-SMA) expression by a researcher blinded to treatment groups.

Results: Prenatal hypoxia led to a decrease in nephron number and elevated blood pressure. Kidneys of HYP offspring showed expansion of the mesangial matrix, thickening of glomerular basement membranes and increased glomerulosclerosis compared to CON. These changes were exacerbated by the HS diet. Interstitial fibrosis and renal vascular remodeling scores were increased in CON and HYP offspring fed the HS diet, with the effect greatest in HYP offspring. α-SMA staining of CON kidneys was confined to vascular structures, whereas in HYP kidneys α-SMA expression was prominent in the interstitium and glomeruli in enalapril-treated kidneys. Since ureteric branching, and global DNA methylation. Also, blockade of DNA methyltransferase inhibited ureteric branching in organ culture. Since ureteric branching, and global DNA methylation. Also, blockade of DNA methyltransfarase (FR-PO199)
A Perinatal Switch in Iron Utilization Determines Postnatal Chronic Kidney Disease
Rongjia Deng, 1 Rosemary V. Sampogna, 1 Andong Qiu, 2 Jonathan M. Barash. 1
1 Columbia Univ; 2 Tongji Univ, China.

Background: Iron deficiency affects 2 billion people world-wide and is a threat to embryonic and early postnatal development. Periconceptual maternal iron deficiency (PM-ID) results in hydropic postnatal kidneys but it is not clear whether PM-ID causes cell-lineage or cell-stage specific hypoplasia, nor which species of iron is involved.

Methods: We investigated a mouse model of dietary iron deficiency and a series of deletions of the transferrin receptor, TIR1 (cell autonomous transferrin iron deficiency, ATF-ID) in different cellular lineages using a novel TIR1-flox/lox construct.

Results: Severe PM-ID depleted both T1 iron and NTBI (non-transferrin bound iron) resulting in severely hypoplastic proximal tubules and even anephric during gestation, whereas the overall structure of uretic bud was maintained. Milder PM-ID resulted in surviving but severe postnatal kidney hypoplasia, disruption of the growth of the proximal tubule and TALH and increased mortality before weaning. To determine the mechanism of hypoplasia we examined mesenchymal, ureteral and stromal ATF-ID with different Cre drivers. Mesenchymal ATF-ID (SisCre or KspCre) demonstrated increasing demand for transferrin by the time of birth, resulting in worsening proximal tubule hypoplasia, remarkable cystic transformation and interstitial fibrosis, and even anephria (ProPax3Cre) after birth, the timing of which coincided with accelerated segment-specific growth. The combination of ATF-ID and PM-ID further worsened nephropen development. In contrast, the collecting ducts (HoxB7Cre) and stroma (Foxd1Cre) did not depend on transferrin.

Conclusions: In sum, NTBI supported prenatal and postnatal stromal and ureteric development and the initial stages of metanephric development, whereas T1 iron was required for perinatal maturation of the nephron. T1 iron depletion resulted in hypoplasia, cysts, and fibrosis, the timing and specificity of which was the result of a sequence of utilization of NTBI followed by T1 iron. We propose that a peri-natal switch in the mechanism of iron utilization during the compaction and segmentation of the kidney is reflected changing cellular control of iron delivery. Iron deficiency is a cause of CKD.

Troy/TNFRSF19 Marks a Progenitor/Stem Cell Population in the Kidney
Frans Schutgens, 1, 2 Maarten B. Rookmaaker, 1 Robert Vries, 3 Marianne C. Verhaar, 2 Hans Clevers. 1 Nephrology and Hypertension, UMC Utrecht, Utrecht, Netherlands; 2 Hubrecht Inst, Utrecht, Netherlands.

Background: Segment committed stem cells play a crucial role in renal development and regeneration. Identification of these stem cells is an important step towards the development of new diagnostic and therapeutic strategies for renal diseases. In this study, we evaluated Troy, an adult stem cell marker in other organs, as a marker for segment committed stem cells in the developing and adult kidney.

Methods: Renal Troy expression was assessed during embryonic development and adult turnover using Troy-GFP mice. The contribution of Troy+ cells to renal development and turnover was investigated using in vivo lineage tracing with Troy-GFP-CreERT2;Rosa-LacZ reporter mice. Troy+ cells were labeled with tdTomato and their clonal expansion in Troy+ cells were assessed.

Results: During embryonic development Troy+ cells were present in the ureteric bud [1A], whereas in adult kidney Troy+ cells were present in the papilla. After p1 induction, Troy+ cells gave rise to tubular structures by clonal expansion that persisted up to 2 years after induction [1B-1E]. Immunohistochemistry revealed predominant co-staining with the kidney marker AQP2 [1C]. Troy+ cells were co-localized to collecting ducts formation after cessation of nephrogenesis. Finally, Troy+ cells had a higher in vitro sphere forming capacity than Troy+ and Troy- cells [1F-1H].

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

Conclusions: These data show that Troy marks a stem/progenitor population for the collecting duct in the developing kidney. Moreover, our data also suggest a role for Troy+ progenitor cells in the adult kidney.

Preserved Nephrogenesis following Partial Nephrectomy in Early Neonates
Yuhei Kirita,1 Daisuke Kami,2 Ryo Ishida,3 Tetsuro Kusaba,1 Takaomi Adachi,1 Satoshi Gojo,2 1 Nephrology, Graduate School of Medical Science, Kyoto Prefectural Univ of Medicine, Kyoto, Japan; 2 Regenerative Medicine, Graduate School of Medical Science, Kyoto Prefectural Univ of Medicine, Kyoto, Japan.

Background: For a long time, although the appendage regeneration has been limited to non-mammalian vertebrates, the rodent neonates demonstrated the capability to regenerate the resected cardiac apex. In this study, we hypothesized that neonatal kidney could maintain the capability of neoprogenesis.

Methods: One sixth-partial resection at the inferior pole of right kidney was performed on neonatal rats at postnatal day 1 (P1) and day 4 (P4) under the hypothermic anesthesia. The animals were sacrificed with time to examine by pathology and quantitative PCR, including limited tissue availability, phenotypic alterations due to immortalisation and a lack of genetic diversity. With the dawn of induced pluripotent stem cell (iPSC) technology,

Conclusions: The locations of LRCs were different if BrdU was administered in different periods of kidney development. Most of BrdU-retaining cells were quiescent, few of them in the proximal tubule and papilla may be the renal progenitor cells.

Tissue-Specific Transport and Injury Response in Kidney Tubules Derived from Human Pluripotent Stem Cells
Benjamin S. Freedman,1,2,3 Craig R. Brooks,1,2 Albert Q. Lam,1,2 Ryui Morizane,1,2 Joseph V. Bonventre,1,2 Brigham and Women’s Hospital; 1 Harvard Medical School; 1 Univ of Washington School of Medicine.

Background: Human pluripotent stem cells (hPSCs) can differentiate into cells expressing markers of kidney proximal tubules, but the functional capacity of these structures remains poorly understood. We developed a new, adherent, 3D culture system to evaluate transport and injury characteristics in hPSC-derived kidney tubules, compared to undifferentiated hPSCs.

Methods: hPSCs sandwiched in extracellular matrix were maintained in pluri-potency-sustaining media to form undifferentiated cavitated spheroids (SOX2+ OCT4+), or differentiated with growth factors into nephron progenitor cells (PAX2+SIX2+) and subsequently proximal tubules (LTL+LRP2+). hPSC spheroids or differentiated tubules were incubated with small molecule fluorescent probes to monitor transport into lumens, or with nephrotoxic chemicals to assess upregulation of kidney injury molecule-1 (KIM-1).

Results: Kidney tubule lumens selectively accumulated rhodamine-dextran (RD) and fluorescein methotrexate (MTX) transport cargoes. Inhibition of actin polymerization with Latrunculin B, or permeabilization of tight junctions with EDTA, significantly reduced cargo fluorescein methotrexate (MTX) transport cargoes. Inhibition of actin polymerization with Latrunculin B, or permeabilization of tight junctions with EDTA, significantly reduced cargo fluorescein methotrexate (MTX) transport cargoes. Inhibition of actin polymerization with Latrunculin B, or permeabilization of tight junctions with EDTA,
many of these disadvantages could potentially be overcome. To this end we have been attempting to develop a protocol to produce proximal tubule-like cells from human iPSCs with xenobiotic transport capabilities.

Methods: Human iPSCs were differentiated into the intermediate mesoderm (IM) using Wnt and retinoic acid activation (CHIR99021 and TNNBP). Cells were further differentiated using combinations of different growth factors.

Results: The derived cells exhibit cobble stone morphology and express certain proximal tubule proteins such as claudin-2. Additionally, the cells can be maintained for up to 4 weeks in culture. Preliminary results demonstrate the ability of the differentiated cells to form tubule-like structures (DI-10-ASP) and organic anions (6-CF) and to extrude p-glycoprotein substrates (calcein-AM).

Conclusions: While further characterization will be needed, the initial results are promising, indicating that proximal tubule-like cells derived from iPSCs could be a new tool for screening the nephrotoxic potential of compounds.

The Direct Differentiation Method of Renal Tubular Cells by Synthetic mRNA of Transcription Factors Identified from TF-Inducible Human ES Bank

1 Ken Hiratsuka, 1,2 Toshiaki Monkawa, 1 Shintaro Yamaguchi, 1 Ryuji Morizane, 1 Shigeru H. B. Ko, 1 Minoru S. H. Ko, 1 Hiroshi Itoh, 1 1 Dept of Internal Medicine, Keio Univ School of Medicine, Shinjuku-ku, Tokyo, Japan; 2 Dept of System Medicine, Keio Univ School of Medicine, Shinjuku-ku, Tokyo, Japan.

Background: To find transcription factors which promote differentiation towards renal tubular cells, we utilize the human ES line with doxycycline-controllable transcription factors (TF-inducible hES bank). To establish the differentiation method of renal tubular cells, we transfect the synthetic human mRNA of the target transcription factors into human ES cells.

Methods: We performed exhaustive search for DNA microarray data after TF induction in the hES bank, and analyzed them in silico to find the specific transcription factors, which expressed in kidney epithelial cells. We synthesized the synthetic human mRNA of the target transcription factors. By using the lipofection method, we transfecated the synthetic mRNA of target transcription factors to human ES cells, and cultured them. The morphological changes, mRNA expressions, and protein expressions were analyzed.

Results: Transcription factors, which expressed in human kidney epithelial cells, were identified by in silico analysis. We successfully made synthetic mRNA of candidates of transcription factors. Five days after the transfection of the synthetic mRNA to human ES cells, we were able to observe characteristic morphological changes in the differentiated cells. The mRNA expression of OSR1, ITGA8, AQP1, and MEGALIN were increased. Moreover, the protein expression of AQP1 and LTL were also detected in the differentiated cells.

Conclusions: We identified specific transcription factors for differentiation toward kidney (especially, proximal tubular cells), and demonstrated that the differentiation of proximal tubular cell phenotype from human ES cells by a novel method using synthetic mRNA.

Differentiation of Human iPSC into Functional Podocytes

1 Anja Wilmes, 1 Elisabeth Feifei, 1 Georg Korn, 2 Paul Jennings, 1 Gerhard Gstraunthaler.

1 Innsbruck Medical Univ; 2 Innsbruck Medical Univ; 1 Innsbruck Medical Univ; 1 Innsbruck Medical Univ.

Background: Podocyte injury and subsequent loss of glomerular integrity is a major cause for chronic kidney disease (CKD). Two-thirds of patients with CKD suffer from disorders that arise from the glomerulus, mainly due to podocyte injury. Podocytes are highly specialized cells with a complex cytoarchitecture composed of foot processes that form the glomerular filtration barrier. The study of the molecular processes of glomerular transition and senescence. In a 3D MPS, hPSC-derived RTECs formed tubular structures comparable to primary RTECs. Immunofluorescence staining demonstrated positive signals for the tubule transporters SGLT2 and OAT3 as well as the epithelial markers CD113 and E-cadherin.

Conclusions: We have shown that hPSC-RTECs can propagate in vitro and maintain their differentiated characteristics, with morphology and markers similar to primary RTECs. hPSC-RTECs are grown in a 3D MPS, they maintain an epithelial phenotype and express membrane transporters essential for functions including glucose reabsorption and organic anion secretion. This system establishes a platform in which to optimize hPSC-RTEC expansion and function in a 3D, microfluidic context, with relevance for human disease modeling in vitro and for the generation of regenerative medicine.

Sourcing of Renal Tubular Epithelial Cells from Human Stem Cell-Derived Kidney Organoids

Elijah Weber, 1 Benjamin S. Freedman, 1 Jonathan Himmelfarb, 2 Edward J. Kelly, 3 1 Pharmaceutics, Univ of Washington, Seattle, WA; 2 Nephrology, Univ of Washington, Seattle, WA; 3 Kidney Research Inst, Univ of Washington, Seattle, WA.

Background: Human pluripotent stem cells (hPSCs) provide a self-renewing, reproducible source of kidney cells for laboratory investigation and regenerative medicine approaches. While we tested the potential of hPSC-derived renal tubular epithelial cells (RTECs) to grow and maintain differentiation in 2D and 3D cultures, compared to primary RTECs from adult kidneys.

Methods: hPSCs were treated with growth factors to promote differentiation into nephron progenitor cells (PAZ2-SIX2) and subsequently proximal tubules (LTL-ZO1-LRP2). RTECs purified from tubular organoids were re-plated on tissue culture plates with or without extracellular matrix. RTECs were analyzed for proliferation, kidney-specific marker expression, and their capacity to seed a ‘kidney on a chip’ 3D microphysiological system (MPS).

Results: RTECs purified from hPSC organoids grew to confluent monolayers in minimal RTEC growth media on extracellular matrix. hPSC-derived RTECs resembled primary RTECs morphologically. Marker immunofluorescence analysis revealed that purified hPSC-RTECs possessed ZO1 tight junctions and reacted with LTL. Sub-cultivation was limited to 2-3 passages, after which hPSC-RTECs underwent epithelial-to-mesenchymal transition and senescence. In a 3D MPS, hPSC-derived RTECs formed tubular structures comparable to primary RTECs. Immunofluorescence staining demonstrated positive signals for the tubule transporters SGLT2 and OAT3 as well as the epithelial markers CD113 and E-cadherin.

Conclusions: While further characterization will be needed, the initial results are promising, indicating that proximal tubule-like cells derived from hPSCs could be a new tool for screening the nephrotoxic potential of compounds.

Genome-Wide Methylation Analysis of Epigenetic Memory in Human Kidney Derived iPS Cells

Osamu Takase, Tao Tsujimura, Masao Nangaku, Keichi Hishikawa.

Dept of Advanced Nephrology and Regenerative Medicine, The Univ of Tokyo, Tokyo, Japan.

Background: Epigenetic memory such as DNA methylation signature of iPS cells derived from parental cells was reported to determine the differentiation fate of the iPS cells (Nature 2012). Last year, we reported the result of kidney specific induction protocol (Nature Commun, 2013) by using two different kind of human iPS cells established from human fibroblast (F-iPS) and human kidney epithelial cells (K-iPS). Last year, we reported the result of kidney specific induction protocol (Nature 2012). Last year, we reported the result of kidney specific induction protocol (Nature Commun, 2013) by using two different kind of human iPS cells established from human fibroblast (F-iPS) and human kidney epithelial cells (K-iPS), and demonstrated more efficient induction of markers of kidney development (WT1, Pax-1, Sall-1) and differentiation (AQP-1, Nephrin) in K-iPS as compared with F-iPS cells.

Methods: In this study, we performed a genome-wide methylation analysis of i-KIPS and F-iPS cells, and tried to clarify the mechanism of kidney lineage specific induction of human iPS cells.

Results: Among 27,578 sites, we focused on high Cpg promoter methylation (GC<0.55, Cpg>0.75). 56 sites such as Kid1 and SOD2 were strongly methylated in F-iPS than in K-iPS cells such as KCNK12 and GATA4 were strongly methylated in F-iPS. In F-iPS, the markers of kidney development were strongly methylated in F-iPS than in K-iPS cells (Pax-2; 23.6 vs 2.1, Sall-1; 18.7 vs 4.3). However, the marker of differentiation was strongly methylated in K-iPS (AQP-1; 1.7 vs 1.1).

Conclusions: These results demonstrate that epigenetic memory in parental cell determine the induction of human iPS cells toward kidney lineages, and the role of key genes in kidney lineage specific induction will be discussed.

Mechanism of Kidney Repair in the Omentum-Kidney Model – Tubulogenesis and Differentiation of Free-Lying WT-1 Cells to Podocytes Occurring in the Fusion Zone

Igancio Garcia-Gomez, 1 Krishnamorthy P. Gudehithlu, 1 Peter D. Hart, 1 Jose A.L. Arruda, 1 Ashok K. Singh, 1,2 Hektoen Inst of Medicine, Chicago, IL; 1 Div of Nephrology, John H. Stroger, Jr Hospital of Chicago; Chicago, IL; 2 Div of Nephrology, Univ of Illinois at Chicago, Chicago, IL; 1 Internal Medicine, Rush Univ Medical College, Chicago, IL.

Background: When activated omentum was fused to the injured kidney it induced glomerular repair and ameliorated chronic kidney disease (Garcia-Gomez et al JASN 2014). The fusion zone between the omentum and the injured kidney was highly proliferative (high BrdU uptake), with abundant free-lying nephrin precursor WT-1 cells. In this study, we examined the fusion area to further understand the mechanism of repair in this model.

Methods: In 5/6 surgically nephrectomized rats, polyethylene glycol was intraperitoneally injected to activate the omentum and fuse to the injured kidney. Nephrectomized rats with complete omentectomy were used as control. Kidney tissues were examined 1-3 weeks after injury by histology and immunofluorescence (Pax-2, WT-1 and podocalyxin).
E15 embryonic rat kidney served as control for immune-staining. Two-week fusion zone tissue and tissue far from fusion zone, control and normal was quantified for mRNA for selected developmental genes (WT-1, Wnt-4, Podl1, Lim1, HNF-6, BMP-7) by RT-PCR.

Results: We found that the fusion zone tissue showed proliferation and expansion of collecting ducts, as evidenced by intense staining for Pax2, in a pattern similar to that seen in E15 embryonic rat kidney. Further, several islands of WT-1 cells in the fusion zone differentiated to podocytes, as judged by co-expression of podocalyxin. mRNA for Wnt-4 and WT-1 increased by 10-20 folds and mRNAs for other developmental genes increased by 2-5 folds in the fusion zone. Control tissue did not show the above changes.

Conclusions: The fusion zone tissue between the injured kidney and omentum appears to be a highly active tissue with proliferation and differentiation of kidney progenitor cells (WT-1, Pax-2, podocalyxin) taking place, and thus providing a healing environment to the injured kidney.

FR-PO211

Functional Alterations of Adipose-Derived Mesenchymal Stem Cells from Human with Atherosclerotic Renovascular Disease Under Hypoxic Conditions

Background: Atherosclerotic renal vascular disease (ARVD) induces microvascular loss and interstitial inflammation, ultimately leading to ischemic injury. Mesenchymal stem cells (MSCs) can induce angiogenesis, decrease inflammation, and limit apoptosis in experimental animals. Aging and co-morbid conditions may blunt these properties in older human subjects. This study tested the hypothesis that hypoxic preconditioning of adipose tissue-derived MSCs would modify expression of MicroRNAs (miR) associated with MSCs survival, angiogenic, and anti-inflammatory properties.

Methods: MSCs obtained from subcutaneous tissue of 7 patients with ARVd (Age 75±3±4) were cultured under normoxic or hypoxic conditions (%50±10) for 4 days. Hypoxic MSCs were returned to normoxia thereafter. Levels of the pro-survival and pro-angiogenic factors vascular endothelial growth factor (VEGF) and insulin-like growth factor (IGF) were measured in the supernatant by ELISA. Expression of MiRs-210, 21 and 145 in MSCs was measured by quantitative rt-PCR and apoptosis by flow cytometry for Annexin V.

Results: Hypoxic conditions increased VEGF and IGF (p<0.05) in MSC supernatant, but had no effect on apoptosis.

Conclusion: Hypoxic conditions induced VEGF and IGF (p<0.05) in MSC supernatant while apoptosis was not affected.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
**Conclusions:** Intra-arterial autologous aMSCs were tolerated with no adverse effects. This low dose, delivered without renal revascularization, was associated with increased tissue oxygenation and cortical RBF, consistent with improved renal microcirculation. Our results provide first-in-humans evidence to support a role for aMSC to restore local blood flow and oxygenation in ARVD.

**Cell Therapy with Serelaxin Promotes Angiogenesis and Anastomosis which Is Critical for the Preservation of Vascular Integrity After Kidney Injury**

**Brooke M. Huuske,¹ Alexander Ruvantha Pinto,² Chrisian S. Samuel,² Sharon D. Ricardo.³ Dept of Anatomy and Developmental Biology, Monash Univ, Clayton, Victoria, Australia; ²Australian Regenerative Medicine Inst, Monash Univ, Clayton, Victoria, Australia; ³Dept of Pharmacology, Monash Univ, Clayton, Victoria, Australia.

**Background:** We previously reported that the combination of mesenchymal stem cells (MSCs) and serelaxin (Rln) attenuates ureteral obstruction (UO)-induced fibrosis. However the affect on endothelial cell regeneration is yet to be elucidated. Here we tested the hypothesis that a mechanism of repair after fibrosis is induced via endothelial angiogenesis and sprouting in the presence of MSCs and Rln.

**Methods:** Live cell imaging of human bladder endothelial cells (HBECs) and human umbilical vein endothelial cells (HUVECs) in tube forming assays were conducted with MSC-conditioned media and Rln (1-100ng/mL) to observe their affects on angiogenesis. Spheroid assays determined the effects of MSC and Rln on HBECs and HUVECs sprouting in vivo. Proliferation of HBECs and HUVECs in the presence of MSCs and Rln was investigated. AqPCR for angiogenic genes was performed on MSCs cultured with or without Rln (10ng/mL). Endothelial integrity was visualized using CD31 protein localization in kidneys from mice 3, 5 and 7days post-UUO, with or without MSCs Rln (n=4-6/group).

**Results:** Angiogenesis of HBECs was modulated in the presence of MSC-conditioned media and Rln with tube number and branch length increased compared to control. HUVECs readily formed sprouts in culture, which was enhanced when both Rln and MSCs were present. The migration capacity of MSCs towards injured HBECs was significantly increased when Rln was added. Rln induced the expression of angiogenic genes from the MSCs. Immunofluorescence microscopy of CD31 determined a decrease of endothelial integrity in a time-dependent manner in vivo. However the administration of MSCs and Rln preserved the vascular integrity.

**Conclusions:** These results suggest that both angiogenesis and sprouting is enhanced only when both MSCs and Rln are used in combination. This may be in part due to Rln-induced release of angiogenic factors from MSCs which may aid in revascularization of the fibrotic kidney.

**Effects of Adipose Derived Stem Cells in a Model of Chronic Renal Hypoxia**

Cristiane Saveriano Rubio, Jose Tarcisio Giffoni, Rosemara Silva Ribeiro, Milene Subtil Ormanji, Vanessa A. Varela, Mirian A. Boim. Nephrology, Federal Univ, Sao Paulo, Sao Paulo, Brazil.

**Background:** Chronic renal artery stenosis causing chronic hypoxia may lead to irreversible damage of the kidney with progressive deterioration of renal function. Due to reduced regenerative abilities of the kidney, mesenchymal stem cells (MSC) emerge as an alternative therapy. The aim of this study was to investigate the effects of MSC, isolated from adipose tissue (ASC) on renal fibrogenesis induced by chronic renal artery stenosis.

**Methods:** Left renal artery of male Wistar rats was partially occluded and ASC were injected through caudal vein. ASC were characterized by their immunophenotype/multipotentiality. To analyze the migration and retention time, labeled ASC were injected 6 weeks after renal occlusion (RO) and analyzed 24, 48, 72 hours or 15 days after injection by flow cytometry. Caudal systolic blood pressure (SBP) was weekly estimated. Renal function and mRNA expression levels of collagen I (Col I), Fibronectin (FN) and TGF-β were determined by qPCR, 6 weeks after renal artery occlusion in the following groups: Sham; Stenotic control (StC), receiving PBS i.v.; Stenotic + ASC (S+ASC). ASC were injected 3 and 5 weeks after RO i.v.

**Results:** After 48 hours cells were retained in both kidneys, stenotic and contralateral followed by heart and lung. After 15 days the presence of ASC decreased significantly in the lungs and heart but they were still present in the kidneys. SIC animals showed progressive increase in SBP while the S+ASC rats had a stabilization of SBP with no further increase after 15 days. Plasma renin concentration was similar among groups and developed proteinuria which was reduced by ASC treatment. There was an increase in the expression of Coll, FN and TGFβ in the stenotic kidney (cortex and medulla) which was reversed by ASC treatment.

**Conclusions:** In conclusion ASC prevented further increase in SBP and reduced the expression of molecules induced-fibrosis. ASC migration and retention in the clipped and contralateral kidneys can be potentially beneficial to restore damaged tissue and to preserve the function of the contralateral kidney.

**Funding:** Government Support - Non-U.S.

**Therapeutic Effects of Erythropoietin Producing Kidney Mesenchymal Stem Cell Derived Microparticles on Anemia in Chronic Kidney Disease Mice**

Hee Young Choi, Minah Lee, Yui Kang, Ah Ran Choi, Sung-Kyu Ha, Hyeong Cheon Park. Dept of Internal Medicine, Gangnam Severance Hospital, Yonsei Univ College of Medicine, Seoul, Korea.

**Background:** Progression of chronic kidney disease (CKD) results in aggravation of erythropoietin (EPO)-dependent anemia. Microparticles (MPs) shed from kidney mesenchymal stem cells (KMSC) have been demonstrated to confer protective effects against acute kidney injury and kidney fibrosis via transfer of messenger RNA. Previous studies have demonstrated improvement of renal anemia by EPO transfected MSC. We investigated whether MPs derived from EPO producing KMSC can exert therapeutic effects on anemia in CKD mice.

**Methods:** Mouse model of CKD and renal anemia was induced by the electrocoagulation of right renal cortex and sequential left nephrectomy. Six weeks post-nephrectomy, CKD and anemia was confirmed via blood urea nitrogen (BUN) and hemoglobin measurements as well as renal histology. Stable human EPO-producing KMSC (EPO-KMSC) and their MPs isolated by differential ultracentrifugation were injected intraperitoneally into established CKD mice and followed for 2 weeks (EPO-KMSC: 1×10^9 per mouse, MP: 2×10^8 per mouse). BUN and hemoglobin were evaluated and degree of renal tubulointerstitial damage was examined for 2 weeks after CKD.

**Results:** EPO secretion from EPO-KMSC was confirmed to sustain over 4 weeks in vitro and RT PCR reviewed the presence of EPO mRNA within MPs. Injected EPO-KMSC-derived MPs were demonstrated within tubulointerstitial area. Animals that received EPO-KMSC and MPs demonstrated significantly lower BUN levels compared to CKD control mice (60±2, 62.7±2.7 vs.83.7±7.5 mg/dL, P<0.05, respectively). Importantly, hemoglobin levels were significantly higher in CKD mice treated with EPO-KMSC and MPs compared to CKD control mice (11.7±0.1, 11.3±0.5 vs.9.7±1.0 mg/dL, P<0.05, respectively).

**Conclusions:** The use of EPO secreting MSC is a viable strategy for cell therapy in renal anemia. Our results suggest that EPO-KMSC derived MPs as well as EPO-KMSC can improve renal function and renal anemia in CKD mice.

**Transplantation of Human Embryonic Mesenchymal Stem Alleviates Lupus Nephritis in MRL/lpr Mice**

Yuan Li, Jianhui Fan, Shi Hui, Chen Xiao Lan, Yuan Yuan. ¹Affiliated Hospital of Nantong Univ, Nantong, China; ²Affiliated Hospital of Nantong Univ, Nantong, China; ³Affiliated Hospital of Nantong Univ, Nantong, China; ⁴Affiliated Hospital of Nantong Univ, Nantong, China.

**Background:** Com pared with bone marrow derived MSC, embryo-derived MSC have greater expansion and differentiation potentials. T helper cell 17(Th17) and interleukin 17(IL-17) is closely related to the occurrence and development of Lupus. The glial cell-derived neurotrophic factor (GDNF) which is closely related to the kidney development and is produced by the kidney injury and chronic hypoxia. We investigated the effects of human embryonic MSC (iMSCM) in lupus nephritis in MRL/lpr mice.

**Methods:** The MRL/lpr mice were divided into 2 groups: Control, iMSCM group. iMSCM were injected at one dose of 1×10^9/200ul twice (at the 16th, 19th weeks of age) through tail vein. Mice were sacrificed at 24 weeks of age.

**Results:** Multi-treatment of iMSCM was able to increase the survival, decrease the levels of 24-h proteinuria, and anti-double-stranded DNA (dsDNA) antibody. iMSCM treatment decreased the content of renal Th17 and interleukin 17(IL-17) is closely related to the occurrence and development of Lupus. The glial cell-derived neurotrophic factor (GDNF) which is closely related to the kidney development and is produced by the kidney injury and chronic hypoxia. We investigated the effects of human embryonic MSC (iMSCM) in lupus nephritis in MRL/lpr mice.

Ctns−/− mice. However, while PTC rescue andare reported to be effective in treatment of various diseases. The aim of this study is to investigate the therapeutic potential of T-MSCs in the treatment of AKI induced by GM.

**Methods:** Twenty male Sprague-Dawley rats were divided into four groups: Control, GM (140 mg/kg/day, ip for 10 days), GM-T-MSCs (1x10^5 cells, intravenous injection at 1 day after the 1st GM injection) and T-MSC group. To examine the intra-renal localization of T-MSCs, T-MSCs were labeled with PKH-26 red fluorescence before infusion. Measurement of BUN, Cr, proteinuria and histologic analysis including TUNEL staining were performed on 16 days of GM injection. Effect of T-MSC on renal tubular cells was also evaluated using a transwell co-culture system of NRK cells and T-MSC. Intracellular reactive oxygen species measured by measuring NOX activity, H2O2, generation, NOx mRNA expressions with DCF-DA staining.

**Results:** PKH-26-labeled T-MSCs were observed in renal tubular cells in GM-T-MSCs group. The infusion of T-MSCs preserved renal function with a decrease in proteinuria. T-MSCs also alleviated renal tubular dilatation and reduced apoptosis of renal tubular cells in the rats with GM-induced AKI. The infusion of T-MSCs downregulated the expression of Bax, Cytochrome c, Cleaved caspase-9 and -3 and upregulated Bcl-2 of renal cortical tissue. In-vitro study revealed an amelioration of GM-induced oxidative stress and apoptosis of NRK cells by T-MSC.

**Conclusions:** Our results suggest that T-MSCs protect the kidney from GM-induced AKI, possibly via the mechanism of modulation of oxidative stress and apoptosis.

**Funding:** Government Support - Non-U.S.

Exosomes Secreted by Human Urine-Derived Stem Cells Could Prevent Kidney Complications from Type I Diabetes in Rats

Zhenzhen Jiang, Yumei Liu, Ying Fan, Jing Zhang, Yang Fei, Niansong Wang.

Dept of Nephrology and Rheumatology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China.

**Background:** Stem cells are currently the main candidates for the development of new treatments for diabetic nephropathy, as they may exert their therapeutic effects mainly through endocrine mechanisms. Therefore, exosome-derived from stem cells have been reported to play an important role in kidney injury.

**Methods:** Exosomes from conditioned medium of human urine-derived stem cells (USCs-Exo) were isolated using ultra-filtration and purification methods. USCs-Exo was then verified by morphology characteristics and specific biomarkers. After the establishment of the streptozotocin (STZ) induced Sprague - Dawley (SD) rats' model, the effects of USCs-Exo on kidney injury were observed via tail intravenous injection of USCs-Exo or control weekly until 12 weeks. In vitro, podocytes cultured in high glucose medium were treated with USCs-Exo to test the protective effect of USCs-Exo on podocyte apoptosis.

**Results:** USCs were cultured and were verified by positive markers of CD29, CD73, CD90 and CD44 antigens, and negative markers of CD34 and HLA-DR. Intravenous injections of USCs-Exo could potentially reduce the urine volume and urinary microalbumin excretion, prevent podocytes and tubular epithelial cells apoptosis, suppress the caspase-3 overexpression and increase glomerular endothelial cells proliferation in diabetic rats. In addition, USCs-Exo could reduce podocyte apoptosis induced by high glucose in vitro.

**Conclusions:** USCs-Exo may have the potential effect to prevent kidney injury from diabetes by inhibiting podocytes apoptosis and promoting vascular regeneration.

**Funding:** Government Support - Non-U.S.
Conclusions: In conclusion, HSC transplantation can repair and preserve near-normal kidney function. Understanding mechanisms underlying kidney repair could spur the development of novel stem cell-based therapies for degenerative renal disorders.

Towards the Clinical Application of Gene-Modified Hematopoietic Stem Cell Transplantation for Cystinosis
Tatiana Vm Lobry, Jay Sharma, Sarah Ul, Celine Rocca, Betty Cabrera, Stephanie Cherqui. Pediatrics, Univ of California San Diego, San Diego, CA.

Background: Cystinosis is an autosomal metabolic disease caused by mutations in the CTNS gene, encoding a lysosomal cystine transporter, leading to cystine accumulation and multi-organ failure. Affected individuals present before 2 years of age with a Fanconi syndrome and eventually progress to end-stage renal failure. Treatment with cysteamine does not prevent these complications. We showed previously that wild-type HSC transplantation could treat cystinosis in the Ctns-/- mice. Thus, we developed an autologous transplantation strategy of HSCs genetically modified ex vivo to express a functional CTNS gene. Preclinical studies using a SIN-lentivirus vector containing CTNS to transduce Ctns-/- HSCs and transplanted in Ctns-/- mice led to cystine reduction in all tissues and kidney function improvement.

Methods: Pharmacological and toxicological studies are in progress. We established the optimal conditions to transduce human CD34+ HSCs with our lentiviral vector to obtain a Vector Copy Number (VCN) included between 1 and 3. We performed Colony Forming Unit (CFU) assays to ensure normal proliferation and differentiation of transduced human CD34+ HSCs from healthy donors and cystinotic patients and the In Vitro Immunomobilization (IVIM) assay, a genotoxicity test. Serial transplantations in the Ctns-/- mice will assess the safety of our vector in vivo.

Results: While we obtained VCN within the range for healthy donors CD34+ HSCs, the VCN for the CTNS-/- CD34+ HSCs is below 1, requiring further optimization. CFU assays did not show aberrant differentiation of the transduced CD34+ cells from the healthy donors and cystinotic patients. Finally, no immortalized clones were observed with the IVIM assay suggesting a good safety profile of our vector. These results will be included in our IND for a phase 1 clinical trial for cystinosis. The in vivo serial transplantations are in progress.

Conclusions: This work represents the first stem cell and gene therapy treatment strategy for cystinosis and should lead to a phase 1 clinical trial.

FR-PO222
Mesenchymal Precursor Cell Therapy for Diabetic Nephropathy: 24 Week Results from a Phase 2A Randomized Controlled Trial
David K. Packham, Ian R. Fraser, Peter G. Kerr, Silviu Itescu, Karen R. Segal. MRRG, Melbourne, VIC, Australia; Epworth H, Melbourne, VIC, Australia; Dept Neph, Monash M C, Melbourne, VIC, Australia; Mesoblast PLC, NY, NY.

Background: Renal inflammation and endothelial dysfunction contribute to the etiology of diabetic nephropathy (DN). Bone marrow derived mesenchymal precursor cells (MPC) can modulate both inflammatory cells and microvasculature. We conducted a randomized, placebo (PBO) controlled, dose-escalating trial of allogeneic MPC in 30 subjects with type 2 DN.

Methods: Patients (24 men, 6 women) with an estimated glomerular filtration rate (eGFR) of 20-50 ml/min/1.73m2 and on a stable regimen of renin-angiotensin inhibition were randomized to a single IV infusion of PBO (saline) or 150 million (M) or 300M MPCs (N=10 per group). Patients have been followed-up for 24 weeks. Baseline mean age was 70 years mean eGFR was 34.6, 35.7 and 34.6 ml/min/1.73 m2 for PBO, 150M and 300M, and 19/30 patients had eGFR<30.

Results: There were no treatment-related adverse events. For eGFR change from baseline at 24 weeks, the least square mean (LSM) differences from PBO were 3.2±2.3 (8.1%) in both 150M and 300M groups. PBO-adjusted treatment differences were greater in pooled MPC with baseline eGFR<30: 4.9±2.3 (+12%) at 24w. The LSM differences from PBO for mean individual annualized slopes of eGFR change over 24w was 6.8±4.8 in both treatment groups. Baseline IL-6 levels correlated with SCR and eGFR improvement at 12 w in the MPC groups (r=0.57 and 0.50; both p<0.05) but not in PBO. The LSM differences from PBO for mean individual annualized slopes of eGFR change over 24w was 7.8±4.8 ml/ min/1.73 m2 in pooled MPC, understanding baseline IL-6=3.5 pg/dl and 5.6±0.5 in PBO in patients with baseline IL-6≤3.5 pg/dl, suggesting greater preservation or improvement in eGFR relative to PBO in the presence of elevated IL-6.

Conclusions: In this first in humans study, a single MPC infusion improved or stabilized GFR over 24w. Baseline eGFR<30 and high IL-6 levels suggest two biomarkers that may predict efficacy with MPC treatment. Positive response to MPC therapy may be enhanced by the presence of non-fibrotic, but at-risk, renal tissue and aberrant pro-inflammatory milieu.

Long-Term Effect of Methylprednisolone Pulse and Autologous SFV (Stromal Vascular Fraction) Therapy in Severe IgA Nephropathy with CKD Stage III
Yvonne Koon Cho, Yumi Choi, Jin-Soo Suh. The Medical Hub Kidney Center, MIRAE ENG Research Inst, Seoul, Republic of Korea; Dept of Pediatrics, Gwangmyeong Sang-Ae Hospital, Gwangmyeong-si, Gyeonggi-do, Republic of Korea; Dept of Pediatrics, College of Medicine, The Catholic Univ of Korea, Bucheon-si, Gyeonggi-do, Republic of Korea.

Background: Up to date there is no specific method of treatment in severe IgA nephropathy with CKD, but giving ACE inhibitor, angiotensin II receptor blocker(ARB), omega-3 etc. and eventually almost all cases fall into CKD V and need KTP or dialysis. Cell-based therapy is an emerging field in nephrology field especially aspose derived stem cells(ASCs). The beneficial effects of mesenchymal stem cell occur through differentiation-independent pathways include increased cell survival and proliferation, decreased inflammation, immune modulation, tissue regeneration etc.

Methods: We tried methylprednisolone(MP) pulse therapy followed by autologous SFV(stromal vascular fraction), which contained ASCs in severe IgA nephropathy with CKD stage III. This case was 44years old female patient, Renal biopsy finding showed Grade IV(Lee’s classification) with CKD stage 3. MP pulse was tried 6 cycles followed by autologous SFV were injected through intravenously 4 times at 3 weeks interval.

Results: Initial renal biopsy findings before treatment(Tx) showed 61% sclerotic glomeruli, however follow up renal biopsy 18 months after Tx showed 41% sclerotic glomeruli and disappeared immune deposits, The serum creatinine level before Tx was 1.77mg/dl with GFR 35/ml/min, however 18 months after Tx serum creatinine was 1.03mg/dl with GFR 61/ml/min.

Conclusions: In conclusion MP pulse therapy with autologous SFV treatment in intractable IgA nephropathy might be a promising therapeutic means without any notable side-effect or complications especially in early stage CKD, although the efficacy and safety, of SFV infusion therapy needs long term studies.

Extracellular Vesicles in Glomerular VEGF Homeostasis
Sargis Sedrakyan, Stefano Porta, Hasmik Soloyan, Nikita Tripuraneni, Roger E. De Filippo, Benedetta Bussolati, Laura Perin. Children's Hospital Los Angeles; Univ of Turin.

Background: Strict regulation of VEGF signaling between podocytes and glomerular endothelial cells (GEC) is critical for GEC survival and function, therefore, loss of glomerular VEGF homeostasis during disease progression can impact GEC integrity leading to decline in glomerular function. Importantly, recent studies have described extracellular vesicles (EVs) to play important role in stem cell mediated paracrine modulation, including in kidney. We have already established that amniotic fluid stem cells (AFSC) are reproactive, and we hypothesize that EVs released within damaged glomeruli are involved in VEGF regulation. Herein, we investigate the impact of AFSC derived EVs in the maintenance of glomerular VEGF homeostasis.

Methods: Using qPCR and ELISA we measured VEGF expression along the course of disease progression in isolated glomeruli of mice affected by Alport Syndrome (AS). Endothelium morphology was evaluated by HIS and TEM. GEC were FACS sorted from a GEC specific Tek reporter mice and studied by gene and protein arrays for VEGF/VEGF-R, oxidative stress, and apoptotic pathways. Co-cultured GEC and ASFV were loaded with EVs. Delivery of ASFC derived EVs normalized VEGF expression and ameliorated endothelial damage. Importantly, the soluble receptor of VEGF, sFlt1—involved in regulating VEGF signaling—was also modulated upon treatment, indicating a VEGF/sFlt1 mechanism of regulation by EVs. In vitro experiments further confirmed the direct role of EVs in VEGF/sFlt1 regulatory mechanism.

Conclusions: In conclusion, our data demonstrate for the first time the alteration of VEGF signaling within AS glomeruli. We further showed that ASFC derived EVs play an important role in maintaining glomerular homeostasis of VEGF signaling, so critical to maintain GEC integrity and function, presenting with a potent for new targeted therapies in CKD.

FR-PO225
Renal Exosomes Store and Transfer the Ischemia Preconditioning State and Protect Rats with Severe Renal Ischemia
Katherine J. Kelly, Jesus H. Dominguez, Medicine, Indiana Univ Medical School, Indianapolis, IN; Medicine, Veterans Administration, Indianapolis, IN.

Background: Acute Kidney Injury (AKI) is a risk factor for chronic kidney disease (CKD) and end-stage renal disease (ESRD). We have reported that intravenous renal cell transplants (IRCT) improve outcomes in rats with AKI (APJ 303:F357, 2012). IRCT action was mediated by relatively small number of anchored and retained cells, and we have hypothesized that cells amplified renal protection by releasing exosomes (EX) acting at a distance.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Methods: We tested if renal EX from cultured cells used for hRCT improved AKI. Nontransgenic male Sprague Dawley rats (SD, n = 4–7) were subjected to 45 minutes of bilateral ischemia/reperfusion (IRI). Renal exosomes (600 µg/protein/rat) were then given intravenously.

Results: There were 5 groups of rats: 1) sham, no IR; 2) renal ischemia (IR) untreated (NO-EX); 3) IR treated with heat inactivated EX (HI-EX); 4) IR treated with normal EX (NL-EX) and 5) IR treated with EX prepared by kidney cells subjected to ischemia/reperfusion injury (IPC-EX). In sham, serum creatinine was 0.3±0.03 at 24 hrs and 0.3±0.02 at 48 post-surgery. In NO-EX it was 2.1±0.6 and 1.7, post IR, respectively. In HI it was 2.2±0.1 and 1.6±0.3. However, in NL-EX it was 2.4±0.4 and 0.78±0.1. The most striking effect was found in IPC-EX: 0.7±0.2, and 0.50±0.1, p<0.05 vs. all including NL-EX. Kidney weight (mg/gm body weight) 6 days post IR was also improved by EX: 3.8±0.1 in sham; 6.7±0.6 in NO-EX; 6.7±0.6 in HI; 5.2±0.2 in NL-EX 5.2±0.2, and 4.8±0.2 in IPC-EX, which was significantly lower than all IR groups, including NL-EX. Neutrophils (PMN) in IPC-EX were also reduced by 65 % (p<0.05) when compared to NL-EX. IPC-EX reduced renal C3 expression in glomeruli and tubules by 73 % and 82 % respectively (p < 0.05 for both). IPC-EX also protected 76 % of renal tubules when compared to NO-EX.

Conclusions: IPC is effective but impractical. However, given IV can communicate the IPC state, reach the kidneys, modulate inflammation and protect function and structure following severe IR.

The Impact of Preexisting Chronic Kidney Disease on the Severity and Recovery of Acute Kidney Injury
Sun Young Lim, Young Ju Na, Myung-gyu Kim, So-young Lee, Sang-Kyung Jo, Won-Yong Cho.
Dept of Nephrology, Korea Univ Hospital, Seoul, Korea; Dept of Nephrology, Eulji Univ Hospital.

Background: Recent observational studies have shown that a substantial proportion of patients with acute kidney injury (AKI) have often progression to chronic kidney disease (CKD). Among several risk factors for the development of CKD after AKI, decreased baseline glomerular filtration rate (GFR) represents an important risk factor. However, precise mechanisms involved in the development of fibrosis after AKI with preexisting CKD have not been completely ascertained. Here in this study, we assessed the impact of preexisting CKD on the severity and recovery of AKI in mouse model of 5/6 nephrectomy.

Methods: Male CD-1 mice underwent 5/6 nephrectomy or sham operation, and 6 weeks later ischemia reperfusion injury (IRI) was performed. On day 1, 7 and 28 after IR, functional, histological, and molecular parameters were compared between them.

Results: Twenty minutes clamping of renal pedicle in 5/6 nephrectomized mice did not provoke more severe functional, histological deterioration compared to normal mice on day 1 and 7. Similar elevations in SCR were observed in both groups until day 7 after IR; however, SCR remained higher on day 28 in 5/6 nephrectomized mice compared to normal mice, suggesting that preexisting CKD does not modify severity of AKI but adversely affect the recovery process. From day 7 to 28, mRNA expression of p21, and protein level of pH3, both representing cell cycle arrest were significantly increased in 5/6 nephrectomized mice compared to sham (AKI) mice. Treatment with p53 inhibitor after IRI resulted in not only decreased p21 and pH3 protein level, but also fibrosis in CKD+AKI mice, suggesting that epithelial cell cycle arrest is partially responsible for impaired recovery from AKI in 5/6 nephrectomized mice.

Conclusions: Taken together, reduced nephron mass do not seem to increase severity of AKI, but have negative effect on repair process, leading to development of fibrosis.

Impaired Functional Recovery from Acute Kidney Injury in Rats with Preexisting Chronic Kidney Disease Predicts the Severity of De Novo Hypertension
Aaron J. Polichnowski, Karen A. Griffin, Mana Dissadace, Anil K. Bidan, Edward Hines Jr, VA Hospital, Hines, IL; Medicine, Loyola Univ Medical Center, Maywood, IL.

Background: The mechanisms by which AKI accelerates the progression of CKD remain poorly understood. We have recently demonstrated that preexisting CKD predisposes to impaired recovery from AKI as evidenced by exaggerated levels of tubulointerstitial fibrosis and modest elevations in blood pressure at 4 weeks post injury. However, a rigorous examination of the relationship between impaired functional recovery from AKI and the development of hypertension has not been examined.

Methods: Male SD rats underwent normotensive 3/4 nephrectomy (3/4 NX) and were chronically instrumented with a BP radiotelemeter. Two weeks later, rats were subjected to 40 min IR (n=20) or sham IR (n=8). BP was assessed every 10 min, 24 hr/day for 4 weeks and glomerular filtration rate (GFR) was then assessed in the conscious state (FITC-imulin).

Results: As compared to baseline values, systolic BP was significantly elevated (P<0.05) in rats at 4 weeks post IR (134±2 vs. 149±5 mmHg, respectively) but not sham IR (139±4 vs. 140±2 mmHg, respectively). GFR was significantly less (P<0.05) in rats subjected to IR vs. sham IR (1.1±1 vs. 1.4±1 ml/min, respectively). As shown in Figure 1, a very strong negative correlation was observed between GFR and the increase in systolic BP over the 4 week protocol. Systolic values 48 hours post AKI did not correlate with either GFR or the change in systolic BP at 4 weeks post AKI, indicating that the development of hypertension following IR was due to impaired recovery from AKI as opposed to a greater severity of AKI.

Conclusions: The development of hypertension following AKI in the presence of preexisting CKD is likely to significantly contribute to the subsequent progression of CKD.

Exocytosis of Endothelial Lysosome-Related Organelles Hair-Triggers a Patho-Loss of Glycocalyx at the Onset of Sepsis
Tala F. Azar, Yan-yi Yen, Min Zhang, Brian R. Ratliff, J. Michael S. Goligorsky.

New York Medical College; The City College of The City Univ of New York; Ulsan Medical College, Seoul, Republic of Korea.

Background: Endothelial surface glycocalyx (ESG) is a well-known regulator of leukocyte surveillance, vascular permeability, and a sensor of shear stress. ESG is degraded during sepsis, thus contributing to systemic multiorgan involvement. Our previous demonstration of a very early post-stress exocytosis of lysosome-related organelles (LRO) with their lytic enzymes led us to hypothesize that exocytosis of LRO may catapult a synchronized deregulation of ESG.

Methods: To test this hypothesis we first analyzed the time-course of exocytosis of Weibel-Palade bodies and secretory lysosomes after application of lipopolysaccharides (LPS) to endothelial cells.

Results: Time-lapse video microscopy revealed that LROs undergo agitation and vectorial movement with a time course of a few minutes after LPS. In addition, spectrophotometry measurements illustrated an increase of lysosomal cargo, cathepsin B, within the media after 10min of LPS exposure. Two therapeutic maneuvers, a nitric oxide intermediate, NG-hydroxy-L-arginine (NOHA), and culture media conditioned by endothelial progenitor cells (ECM-CM) reduced the directionality and motility of LRO. The patch loss of ESG occurring with the similar fast kinetics was confirmed using confocal fluorescence microscopy and Stochastic Optical Reconstruction Microscopy. The loss of ESG was blunted by pretreatment with NOHA or ECM-CM. Moreover, these treatments resulted in a significant reduction of mortality of septic mice.

Conclusions: In summary, above studies provide the first demonstration of the very early patchy disintegration of ESG which can be prevented by pretreatment with NOHA and ECM-CM, maneuvers that reduced exocytosis of LRO. Data support the hypothesis assigning to stress-induced exocytosis of these organelles the role of a hair-trigger for local degradation of ESG that in turn initiates leukocyte infiltration, increase vascular permeability, and partially accounts for the later morbidity and mortality.

Vitamin D Deficiency Contributes to Vascular Damage in Sustained Ischemic Acute Kidney Injury
Ara C. de Braganca, Rido A. Volpin, Purvi Mehrotra, Carlie M. Ivanic, Lucia Andrade, David P. Basile.

The City College of The City Univ of New York; Unives of Sao Paulo School of Medicine, Sao Paulo, SP, Brazil; Cellular and Integrative Physiology, Indiana Univ School of Medicine, Indianapolis, IN.

Background: It has been shown that injury to the renal vasculature may play an important role in the pathogenesis of ischemic acute kidney injury (AKI). Reductions in microvascular density may play a critical part in the progression of chronic kidney disease (CKD) following AKI-induced ischemia/reperfusion injury (IRI). Vitamin D deficiency (VDD) is associated to tubulointerstitial damage and fibrosis progression following IRI-AKI. We evaluated the effect of VDD in sustained IRI-AKI, hypothesizing that VDD contributes to vascular damage.

Methods: Wistar rats were fed 25(OH)D3-free or standard diets for 35 days. On day 28, rats were randomized into four groups: control (sham), VDD, bilateral IRI and VDD. Rats were analyzed 7 days after the surgeries.

Results: VDD rats showed impaired capillary density (by cbin1 staining) and reduced VEGF expression, even in the absence of injury. In addition, VDD IRI rats manifested a remarkable capillary rarefaction and also had increased RW/BW, tissue injury scores, FSP-1.

Exosomes-Mediated Delivery of Pro-Survival MicroRNA-486-5p in Acute Kidney Injury

Methods: We have previously reported that up-regulation of miR-21 contributed to the protective effect of delayed ischemia preconditioning (IPC) in renal ischemia/reperfusion injury (IR). The role of vascular endothelial cells in the protective effects of miR-21 in renal delayed IPC is less well understood. In the present study, we examined the role of vascular endothelial cells in the protective effects of miR-21 in renal delayed IPC.

Results: We provide evidence that the deficiency of MR in the SMC protects against the development of acute kidney lesions induced by IR, however MR deficiency in SMC did not impact the appearance of CKD induced by IR, suggesting that MR in other cell types is involved.

Funding: Private Foundation Support

FR-PO231

The Role of Vascular Endothelial Cells in the Protective Effect of Delayed Ischemic Preconditioning in Renal Ischemia/Reperfusion Injury

Xianjun Xu, Xiaoyan Jiao, Nana Song, Xiaoqiang Ding. Div of Nephrology, Zhejiang Hospital, Shanghai, China.

Background: We have previously reported that up-regulation of miR-21 contributed to the protective effect of delayed ischemia preconditioning (IPC) in renal ischemia/reperfusion injury (IR). The role of vascular endothelial cells in renal IR is not well-understood. In the present study, we examined the role of vascular endothelial cells in the protective effects of miR-21 in renal delayed IPC.

Methods: For the delayed IPC and IR model, 4 d after IPC (15 min ischemia) or sham surgeries, preconditioned mice were subjected to 35 min occlusion of bilateral renal pedicles, followed by 24 h reperfusion. Human umbilical vein endothelial cells (HUVECs) were treated with cobalt chloride for hypoxia model in vitro. Locked nucleic acid (LNA) modified anti-miR-21 or anti-scrambled was transfected into cells or delivered into the mice via tail vein injection less than 1 hour prior to IPC. Vascular permeability was determined by the Evans Blue dye. Cell apoptosis was estimated by Annexin V/FITC apoptosis detection. Expression of programmed cell death 4 (PDCD4) protein and miR-21 was examined by western blot and real-time PCR, respectively.

Results: Compared with the Sham+IR group, mice in the IPC+IR group showed significant improvement of renal function and histology injury (P<0.01). MiR-21 was up-regulated in the IPC+IR group with concomitant decline of PDCD4 (P<0.05) and improvement of vascular permeability (P<0.05). In vitro, miR-21 in HUVEC was increased in hypoxia, but PDCD4 expression was decreased. Knockdown of miR-21 by LNA anti-miR-21 abrogated the protective effect of IPC with concomitant up-regulation of PDCD4 (P<0.05) and exacerbated renal vascular permeability (P<0.05). Cell apoptosis significantly decreased after knockdown of miR-21 in vitro.

Conclusions: Up-regulation of miR-21 in renal delayed IPC improved the apoptosis of vascular endothelial cell by inhibiting its target PDCD4. This may be another mechanism underlying the protective effect of the delayed IPC.

Role of Vascular Mineralocorticoid Receptor in Renal Ischemia/Reperfusion

Jonatan Barrera-Chimal,1 Alan Le Mercier,1 Sonia Prince,1 Soumya El Moghribi,2 Norma Bobadilla,2 Frederic Jaisser.1 INSERM U1118, Centre de Recherche des Cordeliers, Paris, France;1 Inst de Investigaciones Biomédicas UNAM and INNSZ, Mexico City, Mexico.

Background: Renal ischemia/reperfusion (IR) is a major cause of acute kidney injury and is associated with chronic kidney disease (CKD) development. Mineralocorticoid receptor (MR) antagonism prevents the acute and chronic consequences of renal IR. Whether the benefit of the MR antagonists is due to the blockade of the MR in the vessels is unclear.

Therefore we want to study the specific contribution of endothelial and smooth muscle cells (SMC) MR in acute and chronic consequences of renal IR.

Methods: To inactivate MR in endothelial cells (MR−/− mice), floxed MR mice (MRflox) were crossed with mice expressing the inducible Cre recombinase under the Vcadence promoter. To allow inactivation MR in smooth muscle cells (MRflox/mice), MR−/− mice were crossed with mice expressing the inducible Cre recombinase under the Sma promoter. Sham surgery or bilateral renal IR for 20 min was performed in MR+/− and KO mice and the animals were studied at short term (24 h) and long term (30 days) after reperfusion.

Results: In MR−/− mice, IR induced renal dysfunction (plasma creatinine from 8.9±0.3 in sham to 33.8±6.8 μmol/L in IR), tubular injury and increased mRNA levels of kin-1 (400-fold) and NGAL (220-fold). The MR−/− mice displayed similar alterations induced by IR as MR−/− mice. In contrast, after 24 h of IR, the MRflox/mice presented normal renal function (plasma creatinine was 9.6±0.7 and 14.0±1.9 μmol/L in sham and IR, respectively), absence of histological alterations and reduced kin-1 and NGAL levels.

After 30 days, the MR−/− mice developed CKD characterized by renal dysfunction (plasma creatinine from 10.5±0.1 in sham to 15±0.8 μmol/L in IR), tubular-interstitial fibrosis and increased mRNA levels of fibronectin and Galexin-3 (2-fold). The MRflox/mice developed similar alterations.

Conclusions: We provide evidence that the deficiency of MR in the SMC protects against the development of acute kidney lesions induced by IR, however MR deficiency in SMC did not impact the appearance of CKD induced by IR, suggesting that MR in other cell types is involved.

Renal Vein Hydrodynamic Fluid Delivery Ameliorates Established Renal Injury following Ischemia/Reperfusion Injury

Jason Andrieu Collet,1 Purvi Mehrrotta,2 David P. Basile,2 Robert L. Bacallao,27 Cellular and Integrative Physiology, Indiana Univ School of Medicine, Indianapolis, IN;1 Div of Nephrology, Indiana Univ School of Medicine, Indianapolis, IN;2 Richard L. Roudebush VA Medical Center, Indianapolis, IN.

Background: Past and current treatment for Acute Kidney Injury (AKI) is mainly supportive in nature; no therapeutic modalities to date have shown efficacy in improving the condition. While numerous experimental approaches can prevent AKI, there are few potentially translatable studies which may influence the course of established AKI. The goal of this study was to target vascular congestion and inflammation, which contribute to impaired renal perfusion and renal damage, following the established injury. We hypothesized that high-pressure retrograde hydrodynamic delivery (HD) of saline will improve established AKI, in part, by improving vascular congestion.

Methods: Male Sprague Dawley rats underwent left unilateral ischemia (35 min) and right unilateral nephrectomy or bilateral IRI (35 min) and reperfusion for 24 hours to induce AKI. 0.5mL of isotonic saline was then injected into either the vena cava (VC) or retrograde to left kidney via the renal vein (RV) under high pressure (~60mHg). Recovery was evaluated via serum creatinine and accumulation of immune cells were evaluated using FACS.

Results: Average serum creatinine at 24hrs was similar between groups (sCre=3.3mg/dl), however, RV-HD treated rats showed a rapid improvement in serum creatinine over the following 24 hours vs VC HD rats (24 to 48 h a serum creatinine ≤0.54 mg/dl vs. ≤0.6375 mg/dl, p=0.0237). To evaluate effects on inflammation, bilateral IRI rats subjected to left-RV HD resulted in a significant reduction in C4d (54%±18; p=0.05), CD68 (60%±8; p<0.05), B cells (56%±3.5; p<0.05) and DC/Macs (71%±13; p<0.05) compared with VC rats.

Conclusions: These results indicate that high pressure retrograde hydrodynamic delivery HD may provide a novel and effective therapeutic strategy for the treatment of AKI and transition of AKI to CKD.

**Human Adipose Stromal Cells Ameliorate Renal Injury and Attenuate Capillary Rarefaction following Ischemia-Reperfusion**

**Background:** Acute kidney injury (AKI) is a syndrome characterized by the rapid loss of the kidney’s excretory function, resulting in excess in 17 million hospital admissions a year. Although the tubular epithelium is the primary target of ischemic injury, early damage to endothelial cells contribute to AKI by resulting in impaired perfusion. Moreover, renal capillary density is permanently compromised in rats following AKI induced by ischemia reperfusion (IRI), which is hypothesized to promote CKD. Therefore, to preserve capillaries may impact both short-term recovery and long-term function post-AKI. Adipose tissue resident stromal cells (ASCs) have proangiogenic and anti-inflammatory properties. It is hypothesized that ASCs facilitate repair by capillary preservation, revascularization of damaged endothelium and decreased inflammation.

**Methods:** Male Sprague Dawley rats were subject to bilateral IRI (40 min). At the time of reperfusion, ~2×10^4 ASCs (hASCs, n=15) or vehicle (n=14) were injected into the suprapenal abdominal aorta. Recovery was evaluated via serum creatinine and capillary specific staining. Accumulation of immune cells in the kidney were evaluated using FACS.

**Results:** hASC-treated rats had a 90% survival by day 7, compared with 70% for vehicle. Serum creatinine showed a significant reduction in hASC-treated rats vs vehicle at 48 hrs, (35%, p=0.0008). By day 7, vehicle-treated rats showed a reduction in renal capillary density relative to sham (43%), which was significantly attenuated in hASC-treated rats (28%). Additionally, hASCs-treated rats exhibited a significant decrease in C4D (62%, ±16.8) and C5b-9 (72%, ±3.5) Tecil infiltration (p<0.05). Further, IL-17 cytokine secreted by CD4+T cells was reduced by ~40% in hASC-treated rats (185±66) as compared to vehicle (292±83.9). Conversely, the number of regulatory T cells was increased in hASC-treated rats compared with vehicle (35%, p=0.05).

**Conclusions:** These data suggest that ASCs may ameliorate AKI, at least in part, by preserving capillary density, decreasing inflammation and restoring renal function.

**Studying the Effect of Induced Expandable Human Kidney Progenitor Cells on Renal Function Using Transcutaneous Assessment**

**Background:** Mitochondrial dysfunction causes various mitochondrial diseases and mitochondrial repair. The process of creating new mitochondria to replace damaged mitochondria, is a potential therapeutic target for AKI. Our laboratory has demonstrated that LY344864, a selective 5-HT<sub>1F</sub> receptor agonist, promotes recovery from AKI as demonstrated by an increase in MB and reduced BUN and Kimm in a mouse model of ischemia reperfusion. While the 5-HT<sub>1F</sub> receptor is a G<sub>B</sub> coupled GPCR, the mechanism of 5-HT<sub>1F</sub> receptor mediated MB is unknown.

**Methods:** Mechanism of 5-Hydroxytryptamine 1F Receptor Stimulation of Mitochondrial Biogenesis in the Kidney

**Results:** 5-HT<sub>1F</sub> receptor agonist, promotes recovery from AKI as demonstrated by an increase in MB and reduced BUN and Kimm in a mouse model of ischemia reperfusion. While the 5-HT<sub>1F</sub> receptor is a G<sub>B</sub> coupled GPCR, the mechanism of 5-HT<sub>1F</sub> receptor mediated MB is unknown.

**Conclusions:** These studies report the novel finding that G<sub>B</sub> heterodimer initiates MB and does so through a new pathway. Specifically, 5-HT<sub>1F</sub> stimulation of G<sub>B</sub> activates Akt and eNOS, leading to the induction of MB. The identification of this pathway provides additional therapeutic targets for a drug intervention which could treat AKI.

**Indole Anagols Have Novel Therapeutic Effects on Mitochondrial Diseases and Kidney Injury**

**Background:** Mitochondrial dysfunction causes various mitochondrial diseases and kidney injuries. Anti-oxidant quinones have been used clinically to prevent the disease progression but the effectiveness is yet to be established. We recently found that an indole-derivative increased ATP levels in Hep3B cells and analyzed 41 newly synthesized indole derivatives. Among these compounds, we focused on the most potent derivative #5A (MA-5). The aim of this study was to clarify the effects of MA-5 in mitochondrial diseases and kidney injury.

**Methods:** Fibroblasts from patients with mitochondrial diseases (Leigh syndrome, MELAS, Leber disease, and Kearns-Sayre-syndrome) were cultured in ROS generating condition with BSO(β-lithionine (S)-retinoxime) and cell viabilities, cellular ROS and glutathione levels were measured. The redox property of MA-5 was examined by cyclic voltammetry. The site of MA-5 distribution was visualized by fluorescence-labeled MA-5 (MA-5FRET). MA-5 was exposed to kidney slices for 3 hr before they were exposed to kidney ischemia (26 min) reperfusion injury (IRI) or cisplatin (20 mg/kg body weight). Plasma creatinine (Cr), blood urea nitrogen (BUN) and renal pathology were assessed.

**Results:** MA-5 improved mitochondrial disorders in cultured human fibroblasts in a dose-dependent manner in mitochondrial disease fibroblasts. MA-5 exhibited irreversible oxidation peaks by cyclic voltammetry, suggesting that MA-5 did not have antioxidant property like anti-oxidant quinones. MA-5 did not affect the cellular ROS or GSH levels. MA-5 FL co-localized with the mitochondrial marker. In IRI mice model, after ischemia (60 min), MA-5 treated group showed a reduction in renal injury and tubular cell injury were significantly reduced in MA-5 treated group. BUN (70.9 + 10.1 vs 101 + 13.0 mg/dl) and tubular injuries, at 96 hr after cisplatin injection, were significantly reduced in Indole #5 treated groups.

**Conclusions:** MA-5 exhibited therapeutic effects in fibroblasts from mitochondrial disease patients as well as renoprotective effects in both IRI and cisplatin nephrotoxicity.

**Formoterol Induces Renal Mitochondrial Biogenesis Through G<sub>B</sub>-Dependent Signaling**

**Background:** Acute kidney injury (AKI) carries a high mortality and morbidity with no effective treatments beyond renal replacement therapy. AKI is characterized by mitochondrial dysfunction, particularly in the renal proximal tubule cells (RPTC). The induction of mitochondrial biogenesis (MB) is a therapeutic target for AKI. Our group has shown that formoterol, a β<sub>2</sub> adrenoceptor agonist, can induce MB in vitro and in vivo, and stimulate recovery of mitochondrial and renal function following AKI in mice. However, the signaling events leading to formoterol-induced MB remain unknown.

**Methods:** Formoterol increased Akt phosphorylation in RPTC at 30 min, and this increase was augmented by the G<sub>B</sub> inhibitor gallicin. Gallicin also augmented formoterol-induced increases in FCCP-OER, a biomarker of MB. Formoterol increased the phosphorylation of eNOS, a downstream target of Akt, at 1 hr, and pretreatment with the Akt inhibitor MK2206 blocked Akt and eNOS phosphorylation. Additionally, treatment with the NOS-inhibitor L-NAME attenuated formoterol-induced increases in FCCP-OER.

**Conclusions:** This study demonstrates that formoterol-induced MB occurs via β<sub>2</sub>-adrenoceptor coupling to G<sub>B</sub>, G<sub>B</sub> leads to the activation of Akt and eNOS, promoting MB. Stimulation of these signaling pathways represents an attractive therapeutic target for AKI.

Identification of Slow-Cycling Cells in the Kidney Using TetOP-H2B-GFP Mice
Shunusuke Takahashi, Akito Maeshima, Masao Nakasatomi, Hidekazu Ikeuchi, Toru Sakairi, Yoriaki Kaneko, Keiju Hiromura, Yoshishida Nojima. Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Gunma, Japan.

Background: Renal tubular epithelium can regenerate after a variety of insults. During tubular regeneration, survived tubular cells proliferate, migrate and differentiate into mature cells. After several cell divisions, kidneys were removed for analysis. Localization of GFP-positive cells was examined by immunostaining with several nephron markers and their cell number was quantitatively assessed.

Results: 1) After a pulse of doxycyline, GFP-positive cells were found in the kidney of TetOP-H2B-GFP mice. Most GFP-positive cells were AQP-1 positive tubular cells. As pulse periods become longer, the number of GFP-positive tubular cells increased (pulse 8h-0.5%, pulse 24h-10%, pulse 72h-18%, pulse 3 weeks-5%). After a short pulse (8h) of doxycyline with no chase, all GFP-positive cells were present as a single cell, but after 2 weeks or 4 weeks chase periods, GFP-positive cells were found in clusters of two cells or three cells. 2) In TetOP-H2B-GFP mice treated with a long pulse (3 week) of doxycyline, the number of GFP-positive cells decreased according to chase periods (Chase 2h-50%, Chase 4h-40%, Chase 8h-5%).

Conclusions: These data suggest that slow-cycling cells cannot be detected as GFP-positive cells using TetOP-H2B-GFP mice under doxycyline control. This model will be applicable for selective isolation and in vitro characterization of slow-cycling tubular cells.

FR-PO240

Renal ERK1/2 Regulates PGC-1a and Mitochondrial Biogenic Homeostasis Physiologically and During Renal Injury
Justin B. Collier, Ryan Whit Tucker, Rick G. Schneilmann. Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.

Background: Acute kidney injury (AKI) is defined as a sudden decline in kidney function and the outcomes of AKI have not changed in the past few decades. Previous studies demonstrated that persistent disruption of mitochondrial homeostasis (e.g. peroxisome proliferator-activated receptor gamma coactivator-1α (PGC-1α), a master regulator of mitochondrial biogenesis (MB),) is an important contributor to renal ischemia reperfusion (IR) injury and repair. While the MAPK extracellular-regulated kinases 1/2 (ERK1/2) regulates numerous cell signaling pathways, the role of ERK1/2 activation in MB physiologically and as a consequence of renal IR injury remains limited.

Methods: Renal proximal tubule cells (RTCP) were treated with the specific MEK1/2 inhibitor trametinib (10nm) for various time points. Control mice were treated with trametinib (1mg/kg). Trametinib was administered 1 hour before 18 min of bilateral IR. Mitochondrial respiration was measured in primary renal proximal tubules (RPTC) using the Seahorse XF96 Extracellular Flux Analyzer. I/R injury was induced in male C57BL/6 mice aged 8-10 weeks by bilateral clamping of the renal pedicle for 19 minutes. Mice received daily treatment with saline vehicle or BAY 58-2667 (0.1 mg/kg) beginning at 24 h after IR.

Results: Treatment of RPTCs with BAY 58-2667 increased FCCP-uncoupled respiration, a marker of MB. BAY 58-2667 also increased mitochondrial gene and protein expression and mtDNA content in the renal cortex of naïve mice. Beginning 24 h after IR injury, daily treatment with BAY 58-2667 accelerated recovery of renal function evidenced by reduced BUN and renal expression of NGAL and KIM-1 at 6 d. Histological examination demonstrated reduced renal tubular necrosis in BAY 58-2667 treated mice at 6 d. Increased renal expression of growth factors and anti-fibrotic cytokines TGF-α and IL-10, and reduced oxidative DNA damage. These changes were associated with the recovery of renal MB signaling evidenced by increased mRNA expression of PGC-1α, NRF1, D10X, COX1 and ATP5F6, as well as mtDNA content and protein expression of PGC-1α and COX1. In addition, mitochondrial function was recovered as renal ATP returned to sham control levels. Finally, BAY 58-2667 blunted the progression of renal fibrosis evidenced by reduced COL1A2 and aSMA expression.

Conclusions: These data demonstrate that activation of guanylyl cyclase by BAY 58-2667 promotes recovery from AKI by stimulation of MB, reduction of inflammatory and oxidative damage, and inhibition of renal fibrosis.

Funding: NIDDK Support

FR-PO241

The Guanylyl Cyclase Activator BAY 58-2667 Stimulates Mitochondrial Biogenesis and Promotes Recovery from Ischemia-Reperfusion Induced AKI
Rick Whitaker, Rick G. Schneilmann. Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.

Background: Mitochondrial dysfunction is an important pathophysiological component of acute kidney injury (AKI). As reduced mitochondrial function can impair energy-dependent renal repair processes following AKI, stimulation of mitochondrial biogenesis (MB), the generation of new, functional mitochondria, could promote renal energy-dependent repair processes following AKI. This study was utilized the transgenic mouse with doxycyline-inducible expression of an H2B-GFP fusion protein (TetOP-H2B-GFP mice), in which divisions can be labeled with GFP under doxycyline control.

Methods: TetOP-H2B-GFP mice were treated with doxycyline for the indicated periods, kidneys were harvested, and kidneys were harvested for analysis. Localization of GFP-positive cells was examined by immunostaining with several nephron markers and their cell number was quantitatively assessed.

Results: 1) After a pulse of doxycyline, GFP-positive cells were found in the kidney of TetOP-H2B-GFP mice. Most GFP-positive cells were AOP-1 positive tubular cells. As pulse periods become longer, the number of GFP-positive tubular cells increased (pulse 8h-0.5%, pulse 24h-10%, pulse 72h-18%, pulse 3 weeks-5%). 2) After a short pulse (8h) of doxycyline with no chase, all GFP-positive cells were present as a single cell, but after 2 weeks or 4 weeks chase periods, GFP-positive cells were found in clusters of two cells or three cells. 3) In TetOP-H2B-GFP mice treated with a long pulse (3 week) of doxycyline, the number of GFP-positive cells decreased according to chase periods (Chase 2h-50%, Chase 4h-40%, Chase 8h-5%).

Conclusions: These data suggest that slow-cycling cells cannot be detected as GFP-positive cells using TetOP-H2B-GFP mice under doxycyline control. This model will be applicable for selective isolation and in vitro characterization of slow-cycling tubular cells.

Conclusions: MSC administration offers renoprotection from AKI on CKD when given immediately post insult. Early, specific biomarker-guided diagnosis of AKI identifies the optimal time for MSC-based therapy. Another clinical trial in high-risk cardiac surgery patients showed that giving MSCs 24-48 hrs post insult, based on the late and non-specific rise in SCr, abolished their protective effects.

FR-PO244
Improved Survival of Graft Bone Marrow-Derived Mesenchymal Stem Cells in the Ischemia-Reperfusion-Induced Injured Kidney with Overexpression of Heme Oxygenase-1
Nanmei Li, Jinn Hospital of Shanghai.

Background: one marrow-derived mesenchymal stem cells (BMSCs) transplantation offers therapeutic potential for acute kidney injury (AKI), but with limited efficacy. This study investigated the effect of HO-1 overexpression on the donor BMSCs’ survival, and its impact on the repair of AKI was also observed.

Methods: Ischemia/reperfusion (IR)-AKI kidney homogenate supernatant (KHS) was prepared. SD BMSCs, eGFP-BMSCs and HO-1-BMSCs were harvested and treated by the AKI-KHS. Cell viability, apoptosis and cell cycle were evaluated. Activities of oxidant stress-related enzymes, expression of p65 and the protein levels of Caspase-3 and Bcl-2 in BMSCs were tested. Survivals of the implanting BMSCs in the AKI rat model as well as the renal function were also assessed.

Results: HO-1-BMSCs showed a higher expression of HO-1 and AKI-HKS treatment further enhanced this level. This increased HO-1 expression promoted BMSCs survival under the AKI microenvironment with decreased apoptotic cells as well as less proportion of G0/G1 cells. AKI-KHS induced reduction of SOD activity and GSH-Px in BMSCs with increased MDA and AOXD levels, however, HO-1 overexpression changed this phenomenon. Activation of NF-xB p65 was inhibited in HO-1-BMSCs. Western blot showed decreased Caspase-3 expression and increased Bcl-2 expression in HO-1-BMSCs. The in vivo study showed increased survival of HO-1-BMSCs in the AKI kidneys, which was associated with improved renal function.

Conclusions: HO-1 overexpression could enhance survival of BMSCs under the IR-AKI microenvironment both in vitro and in vivo as the result of ROS elimination. Activity of NF-xB p65 and Caspase-3/Bcl-2 signal transduction pathways were involved in this process.

Induced Pluripotent Stem Cell-Conditioned Medium Mitigates Renal Ischemia-Reperfusion Injury by Suppressing Oxidative Stress We-Cheng Tseng, Der-Cherng Tang. Div of Nephrology, Dept of Medicine, Taipei City Hospital Heping-Fuxue Branch, Taipei, Taiwan; Div of Nephrology, Dept of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.

Background: Ischemic acute kidney injury (AKI) carries high mortality and current treatment remains unsatisfying. Induced pluripotent stem cell (iPS) is a promising therapeutic option for AKI; nonetheless, teratoma formation addresses critical safety concerns for iPS cell transplantation. iPS-derived conditioned medium (iPS-CM) is comparable with iPS cells on ameliorating acute lung injury but the beneficial role of iPS-CM on AKI remains unclear.

Methods: Rat model of renal ischemia-reperfusion injury (IRI) and NRK52E cells subjected to hypoxia-reoxygenation (HR) were used to explore the role of iPS-CM on AKI. BUN, creatinine, tubular cell apoptosis, level of reactive oxygen species (ROS), expressions of proinflammatory cytokines and animal survival were investigated.

Results: Administration of iPS-CM intraperitoneally significantly improved renal function and decreased tubular cell apoptosis after renal IRI. Moreover, elevated ROS level in IRI-rat kidneys was markedly attenuated by iPS-CM. Co-culture of NRK52E cells with iPS-CM also significantly diminished HR-induced apoptosis and ROS production. Furthermore, iPS-CM downregulated both H-Ras and IRI-stimulated expressions of p38 MAPK, TNF-α, NF-xB and caspase 3. Additionally, the IRI-related IL-6 and MCP-1 expression were also suppressed by iPS-CM. Finally, after being subjected to renal IRI, the rats treated with iPS-CM demonstrated better survival as compared those treated with phosphate-buffered saline or normal control medium.

Conclusions: iPS-CM decreases renal IRI-related lethality by suppressing ROS, inflammation, and tubular cell apoptosis. iPS-CM may be a potential therapeutic option for kidney repair in ischemia.

Vascular Adhesion Protein-1 (VAP-1) Inhibition Ameliorates Cisplatin Induced Acute Kidney Diseases and Disorders (AKD)
Daisuke Katagiri, Yoshifumi Hamasaki, Kento Doi, Kousuke Negishi, Takeshi Sugaya, Masaoomi Nangaku, Eisie Noiri. Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; Apheresis and Dialysis, The Univ of Tokyo, Tokyo, Japan; Emergency and Critical Care Medicine, The Univ of Tokyo, Tokyo, Japan; CMIC Ltd, Tokyo, Japan.

Background: Cisplatin (CP) is a platinum compound that is used as an effective chemotherapeutic agent for many malignancies. Its nephrotoxicity is dose dependent, which often limits its use. Research in the field of acute kidney diseases and disorders (AKD), including acute kidney injury (AKI), is important to prevent their progression to chronic kidney disease (CKD).

Methods: A new clinically relevant animal model using multiple low doses of CP was used to evaluate AKD. Human liver fatty acid-binding protein (L-FABP) transgenic (Tg) mice were administered 10 mg/kg of CP (three times, at 0, 1, 3 weeks) for four weeks. Vascular adhesion protein-1 (VAP-1) inhibitor that was recently reported to prevent fibrosis in organs was studied in this model. For treating group, mice received 2 mg/kg/day of PXS-4728A, a selective VAP-1 inhibitor, starting 3 weeks after the first CP administration.

Results: Moderate renal interstitial fibrosis occurred with multiple CP administration. Urinary L-FABP, one of the promising AKI biomarkers, increased about 10-fold one week after every CP injection. Although no further elevation of L-FABP was observed at 3W, following the omission of CP at 2W, L-FABP did not revert to baseline levels. Treatment of PXS-4728A for one week attenuated interstitial fibrosis in this model. VAP-1 inhibitor treatment remarkably reduced 4-HNE- and 8-OHdG-positive areas. The mRNA expressions of TP53, VEGF, VEGFR2, and MMP2 in the kidney were increased significantly by multiple CP treatments and attenuated by VAP-1 inhibitor treatment. Further, the inhibition of lipid accumulation in the S3 segments, together with L-FABP suppression was confirmed.

Conclusions: Multiple treatments with CP lead to moderate kidney dysfunction with increased AKI biomarkers and renal fibrosis. As a standing point of onco-nephrology, VAP-1 inhibitors are promising candidates for the prevention of CKD in patients using CP for the treatment of malignancy.

Pulsed Focused Ultrasound Improves Mesenchymal Stem Cell Therapy for Acute Kidney Injury by Upregulating Renal Interferon-Gamma to Stimulate Stem Cell Production of Interleukin-10
Scott R. Burks, Matthew Nagle, Michele Breuler, Saejung Kim, Bierta Milo, Joseph A. Frank. Frank Lah, NIH Clinical Center, Bethesda, MD.

Background: Pulsed focused ultrasound (pFUS) to kidneys enhances mesenchymal stem cell (MSC) homing to kidneys and improves outcomes when treating early or established acute kidney injury (AKI) compared to MSC infusions alone. However, mechanisms of improved combination therapy are unclear.

Methods: AKI was induced in C3H or interferon-γ (IFNγ)-deficient mice with cisplatin (15 mg/kg), pFUS (40W, 5%da) was delivered to kidneys –3hr before infusion of 10 human MSC. MSCs were observed by immunostaining for human mitochondria. For some experiments, MSCs were treated in culture with recombinant IFNγ or siRNA against IL-10. Cytokines were analyzed by mouse- and human-specific ELISAs. Serum creatinine and blood urea nitrogen values were measured spectrophotometrically.

Results: Proteomic profiling of AKI kidneys revealed that pFUS upregulated renal IFNγ and after MSC homed to pFUS-treated kidneys, they produced more human IL-10 compared to MSC in kidneys without pFUS. MSCs were observed by immunostaining for human mitochondria. For some experiments, MSCs were treated in culture with recombinant IFNγ or siRNA against IL-10. Cytokines were analyzed by mouse- and human-specific ELISAs. Serum creatinine and blood urea nitrogen values were measured spectrophotometrically.

The purpose of this study is to clarify the therapeutic effects of SHED on AKI induced by IRI.

Methods: Seven days after heminephrectomy, the renal artery and vein were clamped for 20 min to induce ischemia in male C57BL/6 mice. SHED or PBS as a control was administered subcapsularly after the reperfusion. Blood, urine and tissue samples were collected. In order to confirm renoprotective potential of conditional media of SHED (SHED-CM) in vitro, H2O2 stimulation assay and scratch wound assay using mouse tubular epithelial cells (TECs) were also performed.

Results: Serum creatinine and BUN levels and urinary KIM-1 excretion were significantly decreased in SHED-treated group. In inflammatory cell infiltrations and aSMA was reduced in animals receiving untreated and SAHA pretreated cells. In addition, postischemic renal function declined after renal ischemia and remained unaffected in all groups. A significant increase in GTP-Arf6 and GTP-Rac1 levels when compared to kidney sections from HGF treated IRI mice. Additionally, SecinH3 counteracted the renal reparative effects of HGF.

Conclusions: SHED administration successfully attenuated mouse IRI-induced AKI. Our results indicate that SHED exerted anti-inflammatory activity in early stage of inflammation and promote cell proliferation by paracrine effect, thereby renoprotective effect in a mouse model of ischemic kidney injury. These results suggest that SHED might offer novel stem cell resource, which can be applied for the treatment of ischemic kidney injury.

Endothelial Autophagy and Endothelial-Mesenchymal Transition (EndoMT) in EPC Treatment of Ischemic AKI

Background: Autophagy potentially prolongs the cellular lifespan. Early Endothelial Progenitor Cells (eEPCs) protect mice from ischemic AKI. The mid-term prognosis in AKI critically depends on vascular remanifaction and interstitial fibrosis with the latter partly induced by mesenchymal transdifferentiation of endothelial cells (EndoMT). Aim of the study was to determine the impact of eEPC preconditioning with different autophagy inducing agents (SAHA / Temsirolimus - Tems) in ischemic AKI.

Methods: Male C57/B16 mice were subjected to bilateral renal ischemia (40 min) followed by 45 min of reperfusion. Mice were analyzed 48 hours and 4 weeks later. In addition, cultured EPCs were treated with TGFB +/- SAHA, autophagy (perinuclear LC3-II) and Stress Induced Premature Senescence (SIPS - SA-b-Gal) were evaluated 96 hours later.

Results: Cultured EPCs showed reduced perinuclear density of LC3-II+ vesicles and elevated levels of SA-b-Gal after treatment with TGFB-alone, indicating impaired autophagy and aggravated SIPS. These effects were completely abrogated by SAHA. Systemic administration of either SAHA or Tems pretreated EPCs resulted in elevated intrarenal endothelial p62 at 48 h and 4 weeks. This effect was most pronounced after injection of SAHA treated EPCs. At 4 weeks endothelial expression of mesenchymal αSMA was reduced in animals receiving untreated and SAHA pretreated cells. In addition, SAHA treated cells reduced fibrosis at week 4. Tens in contrast aggravated EndoMT. Postischemic renal function declined after renal ischemia and remained unaffected in all experimental cell treatment groups.

Conclusions: In ischemic AKI, intrarenal endothelial autophagy may be stabilized by systemic administration of pharmacologically preconditioned eEPCs. Early EPCs can reduce postischemic EndoMT and fibrosis in the mid-term. Autophagy induction in eEPCs may either increase or decrease the mesenchymal properties of intrarenal endothelial cells. Thus, endothelial autophagy induction in ischemic AKI is not a renoprotective event per se.

Impact of Timing Administration of Mesenchymal Stromal Cells on Serum Creatinine following Renal Ischemia/Reperfusion in Rats

Pascal Rowart,1 Laurence Poma,1 Jean-marie H. Krzesinski,1,2 Olivier Detry,1 François Jouret,1,2 Nephrology, Univ of Liege Hospital (ULg CHU), Liege, Belgium; 1GIGA Cardiovascular Sciences, Univ of Liege, Liege, Belgium; 2Abdominal Surgery and Transplantation, Univ of Liege Hospital (ULg CHU), Liege, Belgium.

Background: Experimental models of renal ischemia/reperfusion (IR) have suggested protective effects of mesenchymal stromal cells (MSC) therapy. Still, parameters of MSC, including volume, route and timing of cell administration, remain largely debated. Particularly, MSC infusion in mice has been shown to be beneficial “a priori” but deleterious “a posteriori” of renal I/R injury.

Methods: In order to further investigate the influence of the timing of MSC administration on renal injury, we used 10-week-old Lewis rats categorized in 4 groups. Groups 1 (MSC D-7, n=10) and 2 (MSC D-1, n=7) received caudal i.v. injection of MSC (1.5×10⁶ in 1 mL of saline) 7 days before or 1 day after renal I/R, respectively. Control groups 3 (saline D-7, n=6) and 4 (saline D-1, n=6) received equal volume of saline at similar time points. Left renal ischemia was induced by clamping the renal pedicle below the renal hilus and nephrectomy was simultaneously performed. Blood sample was collected from inferior vena cava at 48 hours post reperfusion. MSC phenotype was confirmed by FACS analysis.

Results: In groups 1 and 3, serum creatinine (Scr) reached 1.4 ± 0.7 versus 2.4 ± 0.8 mg/dL, respectively (p<0.001). In groups 2 and 4, Scr was 4.9 ± 0.7 versus 3.3 ± 0.9 mg/dL, respectively (p<0.001). Furthermore, Scr levels were statistically worse when MSC were administered after renal I/R in comparison to a priori infusion (p<0.0001).

Conclusions: MSC administration 7 days prior to renal I/R may attenuate kidney injury in comparison to (i) saline infusion or (ii) MSC infusion 1 day after renal I/R. Conversely, on the basis of Scr levels, MSC therapy performed after renal I/R worsens kidney injury in rats.

Cytosolic Phospholipase A2 Regulates the G2 to M Transition by Modulating the Activity of Tumor Suppressor Sirtuin 2

Sadat Movahedi naini, Joseph V. Bonventre. Brigham and Women Hospital, Renal Division, Boston, MA.

Background: SIRT2, a tumor suppressor gene, contributes to the control of the G2 to M transition checkpoint of the cell cycle under cellular stress. However, the mechanisms underlying both SIRT2 activation and the regulation of the G2 to M transition remain largely unknown. Here, we describe the regulatory function of cPLA2α on SIRT2 activity and G2 to M transition.

Methods: G2 to M transition in vitro was evaluated in LLC-PK1 cells overexpressing SIRT2 or cPLA2α and in mouse embryonic fibroblasts (MEFs) derived from cpla2α-/- mice. G2 to M transition in vivo was assessed in cpla2α-deficient mice during moderate I/R and under severe stress induced by colchicine. G2 and mitotic cells were identified by staining with pH1 and MPM-2 antibodies, respectively. Analysis of the phosphorylation state of SIRT2 was carried out in the presence or absence of cPLA2α in vitro by kinase assay and in vivo using a SIRT2 ser331 phosphospecific antibody.

Results: cPLA2α, SIRT2, and cyclo-CaCd2 form a multiprotein complex at the G2/M transition in vivo and in vitro. cPLA2α acts as a bridge in this complex to promote binding of SIRT2 to cyclo-CaCd2. Cyclo-CaCd2 then phospho-activated SIRT2 at ser331. Phosphorylation of SIRT2 at ser331 diminishes its catalytic activity and reduces its binding affinity to centromeres and mitotic spindles. This detachment of SIRT2 from mitotic spindles in the presence of cPLA2α promotes G2 to M transition. In cpla2α-/- MEFs and kidney tubular cells SIRT2 was hypophosphorylated at the G2/M transition. Lack of cPLA2α in these cells resulted in a reduction in the number of mitotic cells in response to mitotic stress.

Conclusions: cPLA2α is a regulator of the G2 to M transition in vitro and during ischemia/reperfusion injury in kidney epithelial cells. This function of cPLA2α may be further exploited to better understand the important link between cPLA2α and tumorigenesis and between inflammation and the age-related disorders such as Alzheimer’s disease, in which SIRT2 has been implicated.

The Cytosine Guanosine Exchange Factors Are Required to Promote HGF-Mediated Renal Recovery After Acute Kidney Injury in Mice

Background: The lack of current treatment and preventable measures for acute kidney injury (AKI) in hospitalized patients results in an increased mortality rate of up to 80% and elevated health costs. The molecular aspects of kidney injury and repair are still under investigation, with a focus on inflammation and the age-related disorders such as Alzheimer’s disease, in which the molecular aspects of kidney injury and repair are still under investigation.

Methods: We used an ischemia and reperfusion injury (IRI) mouse model to analyze the role of modulating this signaling pathway on kidney recovery. We treated IRI mice with either HGF, the cytosine inhibitor SecinH3, or a combination of both. Kidney function was assessed by measuring creatinine (Cre) and blood urea nitrogen (BUN) levels. Standard H&E staining was used to detect kidney structure and immunohistochemistry was performed to detect active-Rac1 and active-Arf6.

Results: Simultaneous treatment with SecinH3 and HGF blocks the ability of HGF to promote kidney recovery as evidenced by Cre and BUN levels. Immunohistochemistry showed that HGF treatment promoted recovery of tubule structure, and had enhanced levels of active, GTP-bound Arf6 and GTP-Rac1 levels when compared to kidney sections from HGF treated IRI mice. Additionally, SecinH3 counteracted the renal reparative effects of HGF.

Conclusions: We show that HGF-dependent damaged kidney recovery requires the function of a cytosine-dependent signaling module, and that inhibiting cytosine DNA methylation counters HGF-stimulated recovery. In addition, we demonstrate that HGF treatment of ischemic mice promotes the activation of Arf6 and Rac1 in the recovering kidneys in a cytosine-dependent manner, and that cytosine activity is required to promote epithelial repopulation of kidney tubules and thus kidney recovery.

Regulation of Kidney Injury Molecule-1-Mediated Efferocytosis by Rho GT-Pases

Ola Ismail, Xiaohong Zhang, Lakshman Gunarathnam.

Department of Medicine, Western University, London, ON, Canada; ‘Matthias Muller Centre and Lawson Research Inst, London Health Sciences Centre, London, ON, Canada.

Background: Kidney injury molecule 1 (KIM-1) is a phagocytic receptor for apoptotic cells that is specifically upregulated on the apical membrane of proximal tubule cells (PTCcs) after acute kidney injury. KIM-1-mediated clearance of apoptotic cells (efferocytosis) protects from interstitial fibrosis during acute kidney injury by down-regulating innate immunity and inflammation. As cytoskeletal remodeling is essential for phagocytosis, we examined the relative importance of Rac1 and RhoA, two key Rho GT-Pases that mediate actin remodeling, in KIM-1-dependent efferocytosis. We also investigated a possible link between KIM-1, which we previously identified as a KIM-1-interacting protein, and these Rho GT-Pases.

Methods: To study the role of Rac1 and RhoA in KIM-1-mediated uptake of apoptotic cells, we utilized chemical inhibitors or plasmids encoding dominant negative forms of Rac1 or RhoA proteins and measured the uptake of apoptotic cells by flow cytometry. Using commercially available GT-Pase pull-down assays, we measured the endogenous Rac1 and RhoA activity in KIM-1-expressing cells after apoptotic cell-stimulation. To decipher whether these Rho GT-Pases are down-stream mediators of Gal2-KIM-1 signaling, we silenced Gal2 using siRNA and measured Rac1 and Rho GT-Pase activity.

Results: Inhibition of Rac1 resulted in a significant decrease in KIM-1-mediated phagocytosis, whereas inhibition of and RhoA increased it. RhoA activity gradually increased during phagocytosis and peaked during the later stages of phagocytosis, whereas Rac1 activity remained constant over the entire course of phagocytosis. Furthermore, silencing a key KIM-1-interacting protein, Gal2, caused a significant decrease in RhoA activity.

Conclusions: We conclude that Rac1 and RhoA play opposing roles during KIM-1-mediated efferocytosis, whereby RhoA serves to mediate signaling by KIM-1 and its interacting partner, Gal2.

Funding: Government Support - Non-U.S.

Periostin Increases Kidney Fibrosis After Ischemia-Reperfusion Injury via Rac1 and RhoA Proteins

Boramae Medical Center; Chung-Ang Univ Hospital, Republic of Korea.

Rac1 and RhoA mediate phagocytosis, whereas inhibition of and RhoA increased it. RhoA activity gradually increased during phagocytosis and peaked during the later stages of phagocytosis, whereas Rac1 activity remained constant over the entire course of phagocytosis. Furthermore, silencing a key KIM-1-interacting protein, Gal2, caused a significant decrease in RhoA activity.

Conclusions: We conclude that Rac1 and RhoA play opposing roles during KIM-1-mediated efferocytosis, whereby RhoA serves to mediate signaling by KIM-1 and its interacting partner, Gal2.

Acute Kidney Injury Improves Functional Recovery and Prevents Renal Fibrosis

Florence Lilian Johnson, Nimesh Patel, Massimo Collino, Christoph Thiemermann.

Translational Medicine and Therapeutics, The William Harvey Research Inst, Queen Mary Univ of London, London, United Kingdom; ‘Dep of Drug Science and Technology, Univ of Turin, Turin, Italy.

Background: Acute kidney injury (AKI) is a major risk factor for the development of chronic kidney disease (CKD). Renal ischemia may cause post-inflammatoyy scarring leading to loss of nephron function. Development of new therapies targeting key factor (NF-kB) is a family of transcription factors activated post-inflammation, but its role in the progression of chronic kidney disease to CKD is unknown.

Methods: Male Wistar rats were subject to a RH nephrectomy and L1 unilateral renal ischemia for 15 min, or nephrectomy (sham) (n=6) (sham) (n=6) (sham) (n=6) (sham) (n=6). Animals subjected to unilateral ischemia were randomly divided into 5 groups: normal control (control animals), rats subjected to unilateral ischemia for 15 min, rats subjected to unilateral ischemia for 15 min and treated with anti-NF-kB agents (NF-kB) is a family of transcription factors activated post-inflammation, and the level of fibrosis at 2d.

Conclusions: Inhibiton of NF-kB at 24h post AKI (at peak creatinine values) improves renal functional recovery at 48h post AKI, and reduces the degree of fibrosis observed at 2d.

Funding: Government Support - Non-U.S.

The Peroxisome Proliferator-Activated Receptor γ (PPAR-γ) Agonist Pioglitazone Prevents Acute Kidney Injury (AKI) Progression to Chronic Kidney Disease (CKD) via Activation of Foxp3+ Regulatory T Cells (Tregs)

Jung Pyo Lee, Yuhong Tao.

Department of Internal Medicine, Western Univ, London, ON, Canada; ‘Kidney Research Inst, 414A

Postn null mice compared within WT mice. Furthermore, Postn null mice compared to in WT mice.

Conclusions: Periostin is related to the progression via p38 MAPK activation in cisplatin nephrotoxicity by reducing p65 acetylation through AMPK-SIRT1/P300 pathway. Treatment in cisplatin nephrotoxicity were attenuated by the PPAR-γ antagonist GW9662.

Results: Compared to sham-operated rats, rats subjected to unilateral renal ischemia developed AKI (increases in serum creatinine and decreases in the estimated creatinine clearance). The delayed administration of IKK16 at 24h post AKI (at peak creatinine values) significantly improved renal functional recovery and structural injury at 48h post AKI, compared to sham-operated rats, rats culled at 7d post AKI demonstrated significant increases in α smooth muscle actin (α-SMA) and CD68+ staining for myofibroblasts and macrophages, respectively. IKK16 administration significantly decreased α-SMA and CD68+ staining at 7d post AKI. Rats culled at 28d post AKI demonstrated a significant increase in Sirius red staining compared to sham rats, indicating the development of fibrosis. Administration of IKK16 at 24h significantly attenuated Sirius red staining, and therefore the level of fibrosis at 2d.

Conclusions: Inhibition of IKK at 24h post AKI (at peak creatinine values) improves renal functional recovery at 48h post AKI, and reduces the degree of fibrosis observed at 2d.

Funding: Government Support - Non-U.S.

Acute Kidney Injury Improves Functional Recovery and Prevents Renal Fibrosis

FR-PO256

Competitive Inhibition of CD95L Reduces Inflammation, but Only Modestly Improves Outcomes in Experimental Ischemia-Reperfusion Injury
Luis Eduardo Becker, Clara Daschner, Martin G. Zeier, Christian Morath.
Nephrology, Univ of Heidelberg, Heidelberg, Germany.

Background: After previous encouraging results in CD95L (FasL) mutant mice in ischemia-reperfusion injury (IR) models, we sought to investigate the effect of the competitive pharmacologic inhibition of CD95 (FAS) in kidney IR using APG101, an orally administered drug developed for the treatment of recurrent glomeruloma, which has shown a good patient tolerability in phase I and II clinical studies.

Methods: C57BL/6 mice treated with different dosages of APG 101 (10, 30 or 100 μg/kg-body weight, single-dose, 12h before IR) or vehicle (PBS) alone were submitted to a 2h period of ischemia by clamping both renal pedicles. Sham-operated mice treated with the highest dosage of APG101 dose or PBS. The experiment was further divided into two observation periods: day 2 (injury phase) and day 7 (recovery phase). Serum and kidney tissue analyses were performed focusing on function recovery, cell proliferation, macrophage infiltration and renal structure. Results are given as mean±SEM.

Results: Optimal serum CD95L saturation was only achieved in the APG 100μg/kg group (98.4±0.35%) and 96.9±1.3% at day 2 and 7, respectively, so that experiments were further conducted with this dosage. At day 2, serum creatinine was significantly higher in the IR PBS group, but not in the IR APG group compared to sham-op (0.26±0.12 and 0.20±0.07 vs. 0.09±0.03 mg/dl P<0.05), a similar pattern was seen in macrophage infiltration and MCL-1 mRNA expression in the kidney, both persisting until day 7. Apoptosis, however, was similar between the IR groups in both observation periods. APG treatment markedly reduced cell proliferation in both sham and IR animals compared to PBS (0.510.9 vs. 8.4±5.7 Ki67 positive cells/hpf, p=0.0004), which was observed at day 2, but didn’t persist until day 7.

Conclusions: Despite an anti-inflammatory effect, the APG101-induced impairment of the tubular cell proliferation may have hampered the early recovery phase after IR leading to the modest results.

FR-PO259
Oral Treatment with PBI-4050 Reduces Ischemia-Reperfusion-Induced Fibrosis
Jean-Francois Thibodeau, Mikael Tremblay, Brigitte Groux, Lilianne Geerts, Alexandra Felton, Francois Sarra-Bourrew, Pierre Laurin, Lyne Gagnon.
ProMetic BioSciences Inc., Laval, QC, Canada.

Background: PBI-4050, a novel first-in-class orally active compound which is currently in clinical phase II/III in CKD patients, displays anti-fibrotic activities via a novel mechanism of action. In a double-blind ascending dose (400 to 2400 mg) clinical phase I trial, PBI-4050 was found to be safe and well tolerated up to 2400 mg without any significant side effects. Clinically relevant fibrosis is a leading cause of acute kidney injury (AKI), which may result from a variety of conditions, such as decreased cardiac output, renal vascular occlusion or obstruction, and kidney transplantation. The aim of this study was to investigate the anti-fibrotic activity of PBI-4050 in a mouse model of acute ischemic kidney injury.

Methods: Renal ischemia-reperfusion (IR) injury was induced by the clamping of the left renal pedicle for 60 minutes in C57BL/6 mice (6-8 week old). Mice were treated with vehicle or PBI-4050. At day 14, mice suffering from renal IR demonstrated the anti-fibrotic activity of PBI-4050 in a mouse model of acute ischemic kidney injury.

Results: There was a significant increase in BUN, Scr and serum NGAL in mice treated with Cis+U0126 vs. Cis only. Tumor weight and volume was decreased in mice treated with vehicle+U0126 vs vehicle alone demonstrating that U0126 decreases tumor growth. Tumor weight and volume was decreased in mice treated with Cis+U0126 vs Cis alone demonstrating that U0126 significantly increased the therapeutic effect of cisplatin.

Conclusions: U0126 decreased cisplatin-induced AKI. In addition, U0126 decreased tumor growth and improved the therapeutic effect of cisplatin. Discovery of a drug that decreases cisplatin-induced AKI and improves the therapeutic effect of cisplatin would be a significant finding for patients with cancer.

FR-PO260
Cisplatin Acute Kidney Injury and Conversion to Chronic Kidney Disease
Robert L. Safranstein,¹² Heino Velazquez,¹ Richard Tortora,¹ Gilbert W. Mocek,² Gary V. Desir.¹²°⁶ Nephrology, FACT HealthCare System, West Haven, CT, ¹Nephrology, Yale Univ, New Haven, CT.

Background: Chronic Kidney Disease (CKD) develops in humans after repeated doses of cisplatin (CP). We report on a new model to investigate the mechanism of this form of CKD.

Methods: 8-week old C57Bl6 mice were given either a single or double dose (2 weeks post dose) of CP (15 mg/kg) and studied 1,2,4,6 and 16-25 weeks after the first dose. GFR was measured by inulin clearance followed by intravascular perfusion-fixation. Immunohistochemistry and Multiphoton Microscopy (MPM) were applied to the fixed tissue.

Results: GFR fell precipitously to below 50% controls 2 weeks after the second dose and progressed without hypertension, loss of glomerular number, or glomerulosclerosis. Kidney weight fell as a result of loss of cortical tissue. Collagen deposition increased but was mainly restricted to peritubular locations along the cortico-medullary region. Influx of macrophages, increased cell cycle activity (Ki67) and apoptosis (TUNEL) were followed by vascular rarefaction. Ki67 failed to increase after the second dose as it did after a single dose. The cyclopin-dependent kinase inhibitor protein p21 increased and paralleled the lack of cell cycle activity. Abnormal glomerulotubular junctions (GTJ) developed only after the second dose, which included loss of megalin positive parietal epithelial cells and the formation of atubular glomeruli. These changes correlated well with the development of progressive renal insufficiency.

Conclusions: MPM uncovered abnormalities of the GTJ that marked the transition from AKI to CKD in CP-induced CKD. Coupled with the failure of the proximal tubule (PT) to re-enter the cell cycle suggests a causal relationship between failed repair of this segment and the conversion of AKI to CKD. The increased expression of the p21 gene seen here and its demonstrated role in progression in the renal ablation model of CKD suggests its sustained activation may cause the conversion of AKI to CKD. Understanding why injured PT cells fail to re-enter the cell cycle following the second dose of CP is likely to yield new means to prevent CP-induced CKD, which may be applicable to other forms of AKI to CKD conversion.

Glycogen Synthase Kinase-3 Regulates Fibroblast Activation and Development of Fibrosis following Renal Ischemia/Reperfusion in Mice
Shailendra Singh, ¹ Shixin Tao,¹ Timothy A. Fields, ¹ Raymond C. Harris,² Reena Rao.¹ ¹The Kidney Inst, Dept of Medicine, Univ of Kansas Medical Center, Kansas City, KS; ²Dept of Medicine, Vanderbilt Univ Medical Center, Nashville, TN.

Background: Glycogen synthase kinase-3β (GSK3β) is a serine/threonine protein kinase that plays an important role in renal tubular injury and regeneration in acute kidney injury. However its role in the development of renal fibrosis, often a long-term consequence of acute kidney injury is unknown. Using a mouse model of renal fibrosis induced by ischemia/reperfusion (IR) injury, we demonstrated increased GSK3β expression and activity in fibrotic kidneys.

Methods: Bilateral I/R was carried out on male C57BL6/J mice; both renal pedicles were exposed by flank incision and clamped for 30 minutes at 37°C. GSK3 inhibitor (TBDZ-3) was administered by daily IP injection at 1mg/Kg BW. dose starting 1h before (TBDZ-pre) or 48h after (IR/TBDZ-post). Studies were also carried out in rat fibroblast NRK-49F cells. In vivo: TBDZ-3 was added to cell culture medium. In vitro: GSK3β expression and activity increased significantly starting 48h after IR and remained high in the fibrotic kidneys 12 days after IR. GSK3β was detected in renal myofibroblasts and tubules. GSK3 inhibition suppressed fibrosis, with significantly reduced myofibroblast population, extracellular matrix deposition, inflammatory mediators and TGF-β binding in TDZD-pre and TDZD-post treatment groups compared to vehicle treated group. In vitro: TGF-β treatment increased GSK3β expression in NRK-49F cells and GSK3 inhibition abolished TGF-β induced SMAD-3 activation and α-SMA expression. Importantly, overexpression of constitutively active GSK3β stimulated α-SMA expression.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

even in the absence of TGF-β1 treatment. These results suggest that TGF-β1 regulates GSK3β expression, which in turn is important for TGF-β1 SMAD3 signaling and fibroblast-to-myofibroblast differentiation.

**Conclusions:** The study thus demonstrates that GSK3 could promote renal fibrosis by activation of TGF-β signaling and the use of GSK3 inhibitors might represent a novel therapeutic approach for progressive renal fibrosis that develops as a consequence of AKI.

Regulating Cx43 and TRPC6 Expression Protects Renal Epithelial Damage in a Rat AKI Model

Zhang Li, Wei Wang, Juan Wang, Lining Wang.

**Dept of Nephrology, First Affiliated Hospital of China Medical Univ, Shenyang, Liaoning, China.**

**Background:** Intracellular Ca$^{2+}$ homeostasis plays an essential role in maintaining normal cell function. Connexin43 (Cx43) and transient receptor potential channel (TRPC6) has been reported to regulate Ca$^{2+}$ entry in some pathologic conditions. The aim of this study was to elucidate whether the modifier protein of glyceraldehyde-3-phosphate dehydrogenase (MP) and ATP-MgCl$_2$, could regulate Cx43 and TRPC6 in a rat model of acute kidney injury (AKI).

**Methods:** Male Sprague-Dawley rats were divided into the following groups: normal control, gentamicin-treated, MP plus gentamicin-treated, ATP-MgCl$_2$ plus gentamicin-treated (n=15 for each), as well as control group for MP and ATP-MgCl$_2$ alone (n=5 for each). Levels of serum creatinine (sCr) for each group were measured on the 14th days of treatment. The “in vivo cryotechnique” was used for preparing kidney specimen as before.

**Immunohistochemistry staining for Cx43 and TRPC6 was performed.** Western blotting of the gentamicin-treated group showed a significant increase in sCr compared to the normal control group. Co-treatment of gentamicin with MP and/or ATP-MgCl$_2$, produced marked decreases preventing the increase of sCr. Under light microscope, the gentamicin-treated group showed tubular epithelium damage indicating AKI. This was attenuated by MP and/or ATP-MgCl$_2$, co-treatment. Immunohistochemistry staining indicated that MP and/or ATP-MgCl$_2$, co-treatment prevented gentamicin-induced down-regulation of Cx43 and TRPC6 in renal epithelial cells using the “in vivo cryotechnique”. Furthermore, the expressions of Cx43 and TRPC6 in gentamicin-treated group showed much weaker intensity using conditional fixation method compared to that using “in vivo cryotechnique” suggesting there might be artificial damage during the conditional fixation procedure.

**Conclusions:** Using a rat model of AKI, MP and ATP-MgCl$_2$, were able to prevent the down-regulation of Cx43 and TRPC6, which might reduce Ca$^{2+}$ entry and its downstream signaling, thus minimizing the damage in the renal epithelial cells.

S-Glutathionylation of TAZ Might Contribute to Acute Kidney Injury and Repair

Rajesh Kumar Gandhirajan, 1 Benedikt Bernd Walla, 1 Manaswita Jain, 1 Malte P. Bartram, 2 Markus M. Rinschen, 1 Thomas Benzing, 1, 2 Bernhard Schermer, 1, 2 Dept. of Medicine and Center for Molecular Medicine, Univ of Cologne, Cologne, NRW, Germany; 1Cluster of Excellence on Cellular Stress Responses in Ageing-Associated Diseases (CECAD), Univ of Cologne, Cologne, NRW, Germany;

**Background:** The clinical syndrome of acute kidney injury (AKI) is one of the most important diseases in nephrology and associated with increased morbidity and mortality. Kidney displays a remarkable potential for repair even after severe acute injury. Recent studies identified the Hippo pathway as a master regulator of organ growth and proliferation and uncovered the importance of the two mammalian Hippo-signaling effector molecules YAP and TAZ as regulators of proliferation and apoptosis during kidney development. The objective of the current study is to demonstrate that TAZ undergoes redox regulation via s-glutathionylation.

**Methods:** Immunoprecipitation, reporter gene assay, XTT assay, cycloheximide assay.

**Results:** Our findings indicate that exposure to hydrogen peroxide (H2O2) increased TAZ/TEAD transcriptional activity without affecting YAP/TEAD. Consistently, TAZ/TEAD interaction was slightly enhanced upon H2O2 exposure. Furthermore, H2O2 exposure increased nuclear localization of TAZ in a stable NIH3T3-Fip-in cell line expressing TAZ-GFP. We confirmed s-glutathionylation using recombinant TAZ protein in vitro and biotinylated glutathione ester in cell culture. To identify cysteine residues undergoing s-glutathionylation we generated TAZ C>A mutants. Reporter assays revealed that TAZ C358A showed increased transactivation of TEAD, the effect on cell proliferation and migration was also enhanced in TAZ C358A mutant. Finally, cycloheximide chase assay revealed that all of the TAZ mutants exhibited increased stability following 6h incubation.

**Conclusions:** Our data indicate a novel mechanism how pro-proliferative TAZ activity is regulated by ROS via s-glutathionylation, which could play an important role in tissue injury and repair. Currently, we are following the hypothesis that ROS derived from constitutively active NOX4 could modulate TAZ activity in the kidneys and we are investigating the importance of s-glutathionylation of TAZ in vivo.

Bud-Like Structure Capable of Developing to Lamellipodia in Wound Healing of Tubular Epithelium – A Scanning Electron Microscopic Approach

Kiyoko Inui, 1 Hiroyuki Morita, 2 Yoshiko Inoue, 1 Shinya Omiya, 1 Tomoki Miyazaki, 2 Ashio Yoshimura. 1 Div. of Nephrology, Showa Univ Fujigaoka Hosp, Yokohama, Kanagawa, Japan; 2 Div. of Endocrinology and Metabolism, Aichi Medical Univ School of Medicine, Nagakute, Aichi, Japan.

**Background:** Cell migration is essential in wound healing during which filamentous (F)-actin assembly plays a pivotal role. Cell biological approaches, using confocal microscopy, succeeded in identifying molecules regulating the assembly, such as the Arp2/3 complex, N-WASP, cofillin, and profilin. Although cells form filopodia (microspike) and lamellipodia (membrane), and move forward, much remains to be seen in the ultrastructure of these processes.

**Methods:** Rat tubular epithelium (NRK-52E) was cultured, grown to confluency, and scratched. The cells were subjected to scanning electron microscopy (SEM) at various time points. In separate experiments, immunoelectron microscopy was performed using an antibody against Arp3. Lastly, 60% confluent NRK-52E cells were cultured in the presence or absence of si-RNA for Arp3, grown to confluency, and scratched. The cells were observed periodically at the SEM levels, and, the length of time for complete recovery was compared.

**Results:** As shown in the figure, SEM elucidated elaborated network of filopodia containing “bud-like structure” (bud) that may develop to lamellipodia. Arp3 was expressed in filopodia and lamellipodia but not in a bud. The Si-RNA knockdown significantly prolong the length of time for the recovery. It at least partially inhibited the formation of filopodia network and lamellipodia but not the formation of a bud.

Inhibition of Microtubule Dynamics Delays Kidney Recovery After Ischemia/Reperfusion Injury in Mice

Sang Jun Han, 1 Jee in Kim, 1 Kwon Moo Park. 1 Dept. of Anatomy and BK21 Plus, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; 2Dept of Molecular Medicine and MRC, Keimyung Univ School of Medicine, Daegu, Republic of Korea.

**Background:** Ischemia/reperfusion (I/R) is a major cause of acute kidney injury (AKI). If recovery from AKI is delayed, kidney progresses toward chronic renal failure. Microtubules, a component of the cytoskeleton, contribute to cell damages, cell shape, cell motility, and cell division. Here, we investigate that the role of microtubule network on the kidney injury, recovery and progression of fibrosis after I/R injury.

**Methods:** Mice were subjected to 30 minutes of bilateral renal ischemia, and mice were sacrificed 16 days after ischemia. Some mice were administered either saline (vehicle) or paclitaxel (taxol), a microtubule stabilization agent; 1 day before ischemia (pretreatment) or from 1 day after ischemia until sacrifice every 2 days (post-treatment).

**Results:** Pretreatment of taxol did not affect post-I/R renal function compared with vehicle-treated I/R group. Post-treatment of taxol delayed renal functional and histological recovery with retardation of tubular regeneration, and accelerated proliferation of interstitial cells after ischemia. Post-treatment of taxol from 24 hours after ischemia enhanced cell cycle arrest, progression of fibrosis, and macrophage infiltration into the kidney. Furthermore, post-treatment of taxol suppressed reguloparization of primary cilia in tubular epithelial cells.

**Conclusions:** In conclusion, our results demonstrate that microtubule stabilization or inhibition of cell proliferation delays kidney tubule cell restoration after ischemic injury, whereas interstitial cell proliferation is accelerated, leading to kidney fibrosis. It suggests that regulation of microtubule dynamics is critical to repair from AKI and progression of AKI to chronic kidney disease.

Tubulin Acetylation in the Kidney Tubular Cells After Ischemia/Reperfusion Injury

In Hyo-mee Kim, Sang Joon Han, Kwon Moo Park. Dept. of Anatomy and BK21, Kyungpook National Univ, Daegu, Korea.

Background: Acetylation of tubulin is known to play an important role in the stabilization of microtubules. Kidney ischemia/reperfusion (I/R) is a major cause of acute renal failure. I/R causes damage to the cytoskeleton in the tubular epithelial cells.

Aim: To study the acetylation of tubulin in kidney tubular epithelial cells after I/R injury using western blotting and immunohistochemical staining. Mice were subjected to either 30 min of ischemia or sham-operation. Kidneys were harvested at various times after ischemia.

Results: Acetylated tubulin expression dramatically decreased 24 hours after ischemia and then gradually increased over time. However, total α-tubulin expression was not significantly changed after I/R. In normal kidney, immune-reactivities of kidney epithelial cell to acetylated α-tubulin antibody were different in tubules; the orders were the descending order: duct distal tubules and the proximal tubule. Twenty-four hours after ischemia, acetylated α-tubulin expression increased in the proximal tubule and the distal tubule with strong expression in the nuclei of the tubular cells. In the glomerulus, acetylated α-tubulin was also observed and the expression was very strong in the podocyte and Bowman's capsule. Twenty-four hours after ischemia, acetylated α-tubulin expression in the proximal tubule was lower than that of normal cells. Nine days after ischemia, acetylated α-tubulin expression in the podocyte and interstitial cell increased. Expression of α-tubulin acetytransferase-1 (αTAT1), an enzyme involved in acetylation of α-tubulin, continuously decreased after ischemia. Histone deacetylase 6 (HDAC6), an enzyme involved in deacetylation of tubulin, also decreased acetylation of α-tubulin.

Conclusions: Ischemia/reperfusion reduced tubulin acetylation in renal tubular cells, suggesting that R/I-induced decrease of tubulin acetylation is associated with reduction of stability of microtubule in cells.

Hypertension Aggravates Acute Kidney Injury (AKI) and Accelerates Progression to Chronic Kidney Disease (CKD)

Anja Thorenz, Hypertension Aggravates Acute Kidney Injury (AKI) and Accelerates Progression to Chronic Kidney Disease (CKD)

Background: Hypertension is a major risk factor for AKI and its progression to CKD. However, the mechanisms by which hypertension aggravates AKI and accelerates CKD progression are poorly understood. Injured or dying cells release products, or Danger signals, that activate the NLRP3 inflammasome, process pro-IL1 and pro-IL18 to their active secreted forms and activate TLR2/4 and MyD88 dependent transcription of immune genes in non-immune kidney cells. NLRP3 inflammasome activation in injured non-immune cells can result in pyroptotic cell death.

Aim: To study the role of impaired tubulo-interstitial fibrosis and the interplay between immune cell signaling and tubulo-interstitial fibrosis.

Methods: Mice were randomized into control, CD1, and C57Bl/6 strains. After induction of AKI, CD1 mice had significantly more inflammation and fibrosis compared to C57Bl/6 mice.

Results: CD1 mice show severe blood pressure elevation in ischemia induced AKI. Ischemia-reperfusion mouse models: 1) unilateral ischemia reperfusion injury in the kidney (IRI) and contralateral nephrectomy (DCN) on day 9, fibrosis and injury evaluation on day 28 (UIR DCN). 2) I/R with delayed contralateral nephrectomy (DCN) on day 9, fibrosis and injury evaluation on day 28 (UIR DCN D28).

Conclusions: The up-regulation of Gadd45-gamma protects against acute kidney injury, however, maladaptively increases the expression of pro-fibrotic molecules.
Canonical BMP Signaling via BMPR1A and Smad1/5/8 Mediates the Transition to Fibrosis After Renal Ischemia Reperfusion Injury

Emilia Vigolo,1 Lajos Marko,2 Christian Hinze,1 Dominik N. Müller,2,3 Ruth Schmidt-ullrich,1 Kai Schmidt-Ott,2,3,1 Max Delbrueck Center for Molecular Medicine, Berlin, Germany; 1 Experimental and Clinical Research Center, Charité-Universitätsmedizin, Berlin, Germany.

Background: Ischemia reperfusion injury (IRI) of the kidney leads to acute kidney injury (AKI) and frequently precipitates the development of tubulointerstitial fibrosis. Bone morphogenic protein (BMP) signaling has been implicated in the pathogenesis and progression of the disease, but its tubular-specific role is unclear.

Methods: We induced IRI in mice by clamping the left renal pedicle for 25 minutes. The severity of injury was measured by histology scoring, elevated mRNA expression of renal injury markers NGAL and KIM-1 and increased urinary NGAL (uNGAL) excretion 24h post-ischemia. Activation of canonical BMP signaling was detected by nuclear pSmad1/5/8 immunostaining and Western blotting. To achieve a doxycycline-dependent Cre-mediated inactivation of BMP receptor 1a (Bmpr1a) in renal tubules, we generated Pax8Rta;LC1;Bmpr1aCreloxP mice (Bmpr1a cKO).

Results: Canonical BMP activity, as revealed by pSmad1/5/8, was widely detected in healthy wild-type (wt) mouse kidney tubules. IRI caused a sustained injury in wt kidneys as shown by elevated NGAL and KIM-1 expression and increased uNGAL excretion. In a 2.7-fold increase in BMP-7 expression, 42.7% decrease in fibroblast activation, and 63.7% decrease in renal fibrosis. These findings demonstrate that HAC1 and HAC2 are responsible for the loss of BMP-7 expression and its renal protective functions in the injured kidney. Furthermore, our study suggests that Class I HDAC inhibitors have a tremendous therapeutic potential for stimulating kidney repair and inhibiting disease progression following chronic renal injury.

Conclusions: BMP-7 expression and its renal protective functions in the injured kidney. Furthermore, our study suggests that Class I HDAC inhibitors have a tremendous therapeutic potential for stimulating kidney repair and inhibiting disease progression following chronic renal injury.

Gli2 in Perivascular MSC Is Required for Kidney Fibrosis and Can Be Targeted Pharmacologically

Rafael Kramann, Susanne V. Fleig, Steven L. Fabian, Omar H. Maarouf, Jane Wittkopp, Yicong Ikeda, Benjamin D. Humphreys. Renal Div, Brigham and Women's Hospital, Boston, MA.

Background: We recently demonstrated that perivascular mesenchymal stem cell (MSC)-like cells are defined by expression of Gli1 and are critical myofibroblast precursors. We now investigate the role of Gli transcriptional activators in myofibroblast progenitors during kidney fibrosis and value as therapeutic targets.

Methods: We utilized mouse genetics, drug binding, RNAi and retrovirual overexpression to dissect the roles of Gli1 vs. Gli2 in myofibroblast activation and fibrosis. We pharmacologically targeted Gli proteins with Darinaparsin, an arsenical, and GANT61, a small molecule Gli inhibitor. We evaluated them in two separate mouse CKD models. We measured hedgpathway activity and expression of Gli in human kidney fibrosis specimen.

Results: In vitro knockdown of Gli1 had no appreciable effect whereas knockdown of Gli2 induced a G0/G1 cell cycle arrest of mouse fibroblasts. Conversely, Gli2 overexpression rescued this cell-cycle effect and drove proliferation. In vivo, knockout of Gli1 showed no effect on fibrosis severity after UUO whereas either conditional knockout of Gli2 or overexpression of the Gli3 repressor in Gli1−/−pericytes ameliorated fibrosis and induced a G1/G0 cell cycle arrest specifically in myofibroblasts, consistent with our in vitro results. We show that darinaparsin directly binds to Gli2, lowers Gli2 protein levels and induces a G0/G1 cell cycle arrest. This effect of darinaparsin absolutely requires Gli2, and Gli2 overexpression rescued the cell cycle defect. When administered in a therapeutic dosing strategy after UUO or IRI, darinaparsin potently reduced Gli1 and Gli2 expression, myofibroblast specific Gli3 expression, induced cell cycle arrest, and ameliorated fibrosis and reduced tubular injury (GANT61, structurally unrelated to darinaparsin, showed the exact same effects. In human kidneys with fibrosis there is strong upregulation of Gli1 and Gli2 mRNA, suggesting this pathway is conserved in humans.

Conclusions: Gli2 is a critical driver of myofibroblast proliferation and a novel therapeutic target in kidney fibrosis.

FR-PO274
Class Ia HDAC Inhibitors Restore BMP-7 Expression and Inhibit the Pathogenesis of Renal Fibrosis following Chronic Renal Injury

Qiusha Guo,1 Scott R. Manson, Kateynn H. Moore, Paul F. Austin. Dept of Surgery, Div of Urology, Washington Univ, St. Louis, MO.

Background: BMP-7 is a potent anti-fibrotic cytokine that is also required for the repair of renal injuries. However, chronic renal injury leads to the loss of BMP-7 and fibrogenic genes. We utilize a model of unilateral ureteral obstruction (UUO) to examine potential therapeutic strategies for stimulating the innate repair mechanisms of the kidney.

Methods: BMP-7 expression was studied in vivo in inner medullary collecting duct (IMCD) cells and in vivo in a mouse model of unilateral ureteral obstruction (UUO). The therapeutic effects of broad spectrum histone deacetylase (HDAC) inhibition with Trichostatin A (TSA) and Class Ia HDAC inhibition with MS-275 were evaluated by assessing renal pathology.

Results: UUO results in an 83.1% decrease in BMP-7 mRNA expression that is paralleled by a 63.0% decrease in the acetylation of histone proteins in the proximal Bmp7 promoter, a process that results in gene repression. These changes are HDAC-dependent and blocked by treatment with TSA. An in vivo pharmacological screen in IMCD cells revealed that TSA and MS-275 stimulates BMP-7 expression, while inhibitors of other HDAC isoforms have no effects. These results were confirmed by using siRNA-mediated genetic ablation to demonstrate specificity and chromatin immunoprecipitation to show binding of the Class Ia HDAC proteins HDAC1 and HDAC2 to the Bmp7 promoter. MS-275 also stimulates anti-fibrotic functions of BMP-7 in vitro by suppressing the expression of the TGF-β-dependent pro-fibrotic genes COL1A1 and aSMA by 68.2% and 97.6%, respectively. Finally, these results extend to the obstructed kidney in vivo where HDAC inhibition results in a 2.7-fold increase in BMP-7 expression, 42.7% decrease in fibroblast activation, and 63.7% decrease in renal fibrosis.

Conclusions: These findings demonstrate that HDAC1 and HDAC2 are responsible for the loss of BMP-7 expression and its renal protective functions in the injured kidney. Furthermore, our study suggests that Class I HDAC inhibitors have a tremendous therapeutic potential for stimulating kidney repair and inhibiting disease progression following chronic renal injury.

Klotho Influences the Fate of Fibrosis in Cardio-Renal Protection

Steven M. Weldon,1 Hu Sheng Qian,1 Nestor X. Barrezaeta,1 Jorge L. Villalona,1 R. Paul Fracasso,1 Glenn A. Reinhart,1 Jian Xie,2 Chou-Long Huang,2 Noelwyn Oliver,1 1CardioMetabolic Disease Research, Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT; 2Univ of Texas SW Medical Center, Dallas, TX.

Background: Soluble Klotho is an endogenous hormone produced predominantly by extracellular domain shedding of membrane Klotho in the kidney. Although Klotho is known to provide cardio-renal protection through its regulation of ion transport and growth factor signaling, specific cellular localization and function of Klotho in the normal and diseased kidney are not clearly defined.

Methods: We evaluated Klotho expression and localization in human and mouse kidney via in situ hybridization (ISH), immunohistochemistry (IHC) or RNAseq. Cardio-renal protective effects of soluble human Klotho administration were studied in mouse unilateral ureteral obstruction (UUO; 5 day) and isoproterenol-induced cardiac hypertrophy (ISOP, 5 mg/g/d x 10d) models.

Results: In normal adult human kidney (fresh nephropatony and autopsy, n=9), Klotho was highly expressed in distal tubules (DT) and in both cortical and outer medulla collecting ducts (CD). Proximal tubule and podocyte expression was low but detectable. Following UUO, renal Klotho RNA was decreased 61% and protein content was reduced greatly in the corticomedullary vs Sham group. Klotho treatment (10 µg/kg, QD, IP) attenuated UUO-induced tubulointerstitial fibrosis (picrosirius red stain, n=10) by 67%∗ (p<0.05) and 418A

Kidney Interstitial Cell Derived Tenascin C Plays an Important Role in
Promoting Injury-Repairing of the Kidney by Stimulating Cell Proliferation
Min Zhang, Qionghong Xie, Xiaoyi Mao, Da Shang, Chunming Hao. Div of Nephrology, Huashan Hospital, Shanghai, China.

Background: Tenascin-C (TNC) is a glycoprotein expressed in extracellular matrix during development and injury repairing. This study explored the role of TNC in acute kidney injury (AKI).

Methods: A TNC promoter driven inducible CreERT2 knock-in mouse line with EGFP reporter (IRE-EGFP) as generated (TNC-CreERT-eGFP). AKI was induced by 40 minutes of ischemia followed by reperfusion in unilateral nephrectomized mice (UN+UIR). Cell lineage tracing was conducted in TNC-CreERT2,R26-mTOMato mice to examine the origin of TNC expressing cells. The effect of TNC on cell proliferation was examined using a cell count kit in cultured HK2 cells. TNC expression was also examined in human biopsies with IRB approval.

Results: In normal kidney, TNC was restricted in renal papilla in both mice and human. Following IR, TNC was markedly induced in renal cortex, particularly in injured areas. TNC reporter showed that induced TNC expression is localized in interstitial cells, but not tubular epithelial cells. TNC induction was also shown in human biopsies with AKI. Co-staining IF showed that TNC was expressed by the PDGFRβ (+) renal interstitial cells, but not NG2 (+) pericyte, F4/80 (+) macrophage and FSP-1 (+) cells. Lineage tracing revealed that TNC expressing cells following IR were not derived from the renal medullary interstitial cells that constitutive express TNC, suggesting new TNC induction. To examine the role of TNC induction following AKI, TNC-/- mice were generated. TNC deletion resulted in significantly increased kidney weight, kidney collagen and alpha-smooth muscle actin staining. Since UUO resulted in a dramatic loss of TAZ and YAP expression in NRK52E cells, we examined if TNC could repress TAZ/YAP expression. In vitro, TNC significantly increased cell proliferation by 50%.

Conclusions: TNC is induced in renal interstitial cells after IR-induced AKI, protecting the kidney from injury. The protective effect of TNC on AKI may be associated with promoting renal recovery by stimulating epithelial cell proliferation.

FR-PO278
TAZ and YAP Are Mechanoregulators of TGF-β-Smad Signaling and Renal Fibrogenesis

Background: Fibrosis is a final common injury pathway responsible for the progression of most forms of CKD, for which no specific treatments exist. Driven largely by TGF-β signalling, fibroblast-myoﬁbroblast transdifferentiation is crucial for ﬁbrosis. While it is known that ﬁbroblast activation is mechanosensitive, with soft matrix akin to a healthy kidney, impairing TGF-β responsiveness, the underlying mechanisms remain poorly understood. TAZ and YAP are homologous transcription co-factors with TGF-β regulatory activity, whose nuclear localization and activity are regulated by matrix stiffness. Here, our aim was to examine how stiffness regulates TGF-β signalling via TAZ/YAP, and to test if TAZ/ YAP inhibition can attenuate renal ﬁbrosis.

Methods: The effects of matrix stiffness on TAZ/YAP localization and TGF-β/Smad signalling were examined in rat renal ﬁbroblasts (NRK49Fs) cultured on soft (2 kPa) and stiff (100 kPa) gels. To test the effect of TAZ/YAP inhibition, NRK49F cells and mice were treated with verteporfin (VP), a drug used as a macular degeneration treatment with reduced described TAZ/YAP and matrix properties.

Results: In NRK49F cells, stiff matrix resulted in nuclear TAZ/YAP localization and enhanced TGF-β signalling. Growth on soft matrix, in contrast, lead to reduced TAZ/ YAP nuclear localization, and impaired TGF-β-induced Smad2/3 nuclear accumulation and transcriptional activity. In NRK52E cells, knockdown of stiffer resulted in a dramatic loss of TAZ/YAP, leading to a similar inhibition of TGF-β/Smad signalling. VP-induced TAZ/YAP loss also enhanced pro-fibrotic Smad2/3 degradation following TGF-β stimulation. In vivo, VP similarly reduced renal TAZ/YAP and Smad2/3 levels in UUO mice, leading to diminished myoﬁbroblast accumulation and interstitial collagen deposition.

Conclusions: Our data suggest that renal ﬁbrosis is regulated by a novel mechanical stimulus (stiffness) that, through control of the mechanosensory proteins TAZ and YAP, modulates TGF-β/Smad signalling. Furthermore, we hypothesise that verteporfin is a potential anti-ﬁbrotic treatment that interferes with this pro-fibro-mechano-chemo-synthetic axis.

FR-PO279
Targeted Deletion of Numb from Proximal Tubules Attenuates Interstitial Fibrosis by Mitigating G2/M Arrest
Fengxin Zhu, Jing Nie. Div of Nephrology, Nanfang Hospital, Guangzhou, Guangdong, China.

Background: Progressive tubulointerstitial fibrosis (TIF) is the final common pathway leading to end stage renal disease. Tubular epithelial cells (TECs) have a crucial role in the pathogenesis of TIF. Numb is a multifunctional protein involved in diverse cellular processes. However, little is known about the physiologic and pathologic role of Numb in kidney.

Methods: We examined the expression and distribution of Numb in normal adult male mouse kidney as well as in mouse model of renal fibrosis induced by unilateral ureteral obstruction (UUO). We previously showed that Numb’s role in renal fibrosis, we generated a conditional knockout mouse model in which Numb is selectively ablated from proximal tubules (PEPCK-Numb-KO). To confirm the role of Numb in regulating cell cycle, Numb was overexpressed in NUR77 cells by infecting with a Numb adenovirus (Ad-Numb) and endogenous Numb was knocked down by siRNA in HK-2 cells before aristolochic acid (AA) treatment. To examine the role of p53 in Numb-induced G2/M arrest, Ad-Numb infected HK-2 cells were incubated with pifithrin-α, a p53 inhibitor.

Results: Numb is expressed in renal tubules and glomeruli. The expression of Numb in renal tubules was significantly increased after UUO. After UUO, PEPCK-Numb-KO mice exhibited significantly attenuated TIF. Ectopic expression of Numb increased the fraction of cells in G2/M stage and upregulated the expression of TGF-β1 and CTGF in NUR77 cells. Knocking down endogenous Numb attenuated AA-induced G2/M arrest and profibrotic cytokines production. Furthermore, G2/M arrest and expression of profibrotic cytokines were significantly reduced in PEPCK-Numb-KO mice after UO. Inhibiting p53 activity dramatically mitigated Numb-induced G2/M arrest and profibrotic cytokines production.

Conclusions: In summary, our studies demonstrate that Numb has a profound effect on prone to G2/M arrest of TECs through stabilizing p53 protein. Depletion of Numb markedly attenuates G2/M arrest of proximal tubules which in turn reduces TIF. Collectively, these data indicate that targeting Numb might be a novel therapeutic approach for the treatment of fibrotic kidney diseases.

Identification of a New Aldosterone Synthase Inhibitor with Anti-Fibrotic Activity in Animal Models

Background: The renin-angiotensin-aldosterone system (RAAS) plays a critical role in renal physiology. Inhibitors of ACE and ARBs are currently the mainstay in the treatment of management of chronic kidney disease (CKD). Despite initial success in reducing aldosterone, concentrations return to pretreatment levels in 30-40% of patients. This "aldosterone escape" significantly limits the therapeutic effectiveness. Through mineralocorticoid receptor dependent and independent processes, aldosterone is thought to directly accelerate renal damage by sustaining inflammation and fibrosis. An attractive approach to deal with aldosterone escape is to inhibit aldosterone synthase (AS), the enzyme responsible for aldosterone production (encoded by the CYP11B2 gene).

Methods: We have identified a promising series of potent and selective small molecule inhibitors of AS. Lead compound ANG3586 has 7 mM potency against AS and excellent selectivity against other P450 enzymes. It is orally bioavailable in rodents and appears to be well tolerated. ANG3586 was tested in the rat remnant kidney model (25 mg/kg, po, bid) and the mouse unilateral ureteral obstruction (UO/O) model (25 mg/kg, po, bid, ten days). In vivo, the rat remnant kidney model, animals with overt renal dysfunction were treated with vehicle or ANG3586. The elevated blood pressure in 5/6 nephrectomized animals was reduced to normal by compound treatment. ANG3586 also markedly reduced kidney collagen content and improved renal histology. Renal function, as determined by serum BUN and creatinine levels, urine albumin to creatinine ratio and urine NGAL, was found to be markedly improved. In the mouse UO model, ANG3586 reduced the increase in kidney weight, kidney collagen and alpha-smooth muscle actin staining. Since UO does not result in distinctly increased blood pressure, the anti-fibrotic activity appears independent of blood pressure lowering activity of ANG3586.

Conclusions: Taken together, ANG3586 shows promise as a potential novel anti- fibrotic agent.

Tubulointerstitial Fibrosis Increases Peritubular Capillary Permeability and Induces Subsequent Hypoxia
Jun Zou, Jae Won Yang, Haiyun Yang, Agnes B. Fogo. Dept of Pathology, Microbiology, and Immunology, Vanderbilt Univ, Nashville, TN; Div of Nephrology, Xinhua Hospital, Shanghai, China.

Background: We previously showed that folic acid-induced tubulointerstitial injury significantly increased peritubular capillary permeability. In this study, we utilized kidney slices of different species to study the behavior of peritubular capillaries and oxygen supply changes contribute to this cross-talk of tubular to glomerular injury.

Methods: Co-luciferase mice, which have luciferase inserted in the collagen I promoter were mated with Numb mice, which have a phosphoglycerate dehydrogenase (GAPDH) promoter in podocytes, and develop glomerulosclerosis when immunotin is administered. Mice were treated with folic acid (FA, 240mg/kg BW, i.p.) or vehicle (VEH). At day 42, Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author. 419A

Funding: NIDDK Support.
mice were sacrificed to assess interstitial fibrosis, peritubular capillary number (CD31 staining) and renal fibrotic factors, which were subjected to unilateral ureteral obstruction (UUO). Renal pathological changes were assessed in tissue sections stained with Masson and Collagen I staining. Kidney tissues were removed. HK-2 cells were cultured in DMEM containing DL-Hcy. The expression of G9a and Collagen I were examined by Western blot and qPCR. Renal fibrosis and collagen type I mRNA transcription, showed higher density in folic acid vs. VEH 5.3±0.6 fold (P=0.05). Renal expression of nephrin influenced morphology, adhesion complex composition and ECM adhesion might ultimately inform therapeutic strategies to correct or repair glomerular barrier function.

Low-Density Lipoprotein Receptor-Related Protein 5 Drives Tubulointerstitial Fibrosis via Regulation of TGF-β Signaling

Xueming He, Rui Cheng, Jian-xing Ma. Dept of Physiology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.

Background: Low-density lipoprotein receptor-related protein 5 (LRP5), a co-receptor of the canonical Wnt/beta-catenin pathway, was recently reported to drive idiopathic pulmonary fibrosis through activating beta-catenin. In this study, we examined the potential role of LRP5 in the regulation of TGF-β signaling in tubulointerstitial fibrosis.

Methods: LRP5-deficient (LRP5-/-) mice and age-matched wild-type (WT) mice were subjected to unilateral ureteral obstruction (UUO). Renal expression-fibrotic factors, including α-SMA, CTGF, collagens and fibronectin, was quantified by picro-sirus red staining, western blot analysis and immunostaining. Primary tubular epithelial cells (PTECs) were cultured from LRP5-/- and WT mice. Co-Immunoprecipitation was performed in a human proximal tubular epithelial cell line (HKC-8) over-expressing LRP5 and TGF-β receptors.

Results: LRP5-/- mice with UO showed ameliorated renal fibrosis and alleviated TGF-β signaling compared with WT mice with UO. However, activation of the Wnt/beta-catenin signaling was not different between LRP5-/- mice and WT mice, indicating that attenuated tubulointerstitial fibrosis in LRP5-/- mice was not due to mitigated activation of the fibrotic Wnt-beta-catenin pathway.

Conclusion: LRP5 promotes tubulointerstitial fibrosis via regulation of the TGF-β signaling. This activity is independent of its role in the Wnt/beta-catenin pathway.

Loss of Endothelial Nitric Oxide Augments Smad3 Linker Phosphorylation and Precedes Insulin Resistance in High-Fat Diet Induced Obesity

Yu bo yang Sun, Xinli Qu, Jinhua Li. Anatomy and Developmental Biology, Monash Univ, Melbourne, Victoria, Australia.

Background: Deficiency of endothelial nitric oxide synthase (NOS3/enOS) confers susceptibility to diet-induced obesity and its complications. eNOS-derived nitric oxide (NO) acts as a potent vasodilator, enhances insulin sensitivity and also inhibits inflammation. TGF-βSmad signaling plays an important role in regulating glucose and energy homeostasis. Smad3 deficient mice are protected from diet-induced obesity and obesity-related kidney injury. This study investigated whether the loss of endothelial-derived NO promotes Smad3 activation, which precedes insulin resistance in high-fat diet (HFD) induced obesity.

Methods: C57BL/6J wild type, eNOS deficient (eNOS-/-) with C57BL/6J background mice were given HFD or normal diet (ND) treatment for 1, 5, 7 days and 4, 8 or 16 weeks. Results: Within 7 days of HFD treatment in WT mice, Western blotting showed a marked decrease in total eNOS level and its complications. eNOS-derived nitric oxide (NO) acts as a potent vasodilator, enhances insulin sensitivity and also inhibits inflammation. TGF-βSmad signaling plays an important role in regulating glucose and energy homeostasis. Smad3 deficient mice are protected from diet-induced obesity and obesity-related kidney injury. This study investigated whether the loss of endothelial-derived NO promotes Smad3 activation, which precedes insulin resistance in high-fat diet (HFD) induced obesity.

Hyaluronidase-2 Dependent Regulation of CD44 Variant Expression in Anti-fibrotic versus Pro-Fibrotic Cells

Funding: Other NIH Support - National Natural Science Funds of China (Grant No.81100515)
Methods: Fibroblasts & renal epithelial cells were incubated with TGFβ1 to induce myofibroblast differentiation. In comparison to cells incubated with TGFβ1 alone, Vpr induction led to increased extracellular matrix production and reduced collagen deposition. This effect was mediated by inhibition of AMPKα1 in pericytes/myofibroblasts.

Results: In vitro experiments demonstrated that the presence of doxycycline inhibited Vpr induction. In Vpr mice compared with control mice, renal cortex FGF2 content was significantly reduced compared to untreated Vpr mice. In vivo experiments confirmed that administration of FGF2 antagonist decreased albuminuria in Vpr mice at day 21 (0.47 ± 0.9) versus 2.3 ± 0.6). In contrast, FGF2 treatment in glomeruli, biotinylated FGF2 was administered intravenously and detected with fluorescent streptavidin. Vpr mice and control mice received FGF2 (5 mg/animal/weekly for 4 weeks) or FGF antagonist (PD173074, 50 mg/animal/bi-weekly for 4 weeks).

Conclusions: FGF2 plays a crucial role in inflammatory and fibrotic conditions. Our findings suggest that inhibition of the FGF2 signal pathway in pericytes/myofibroblasts leads to inhibition of Wnt activation and reduced renal fibrosis.

Role of AMP-Activated Protein Kinase Signaling in Fibroblast Activation and Renal Fibrosis

Yuyan Wang, Yanlin Wang. Medicine, Baylor College of Medicine, Houston, TX.

Background: Renal fibrosis is a common manifestation of chronic kidney disease resulting in progressive loss of kidney function. Although activated fibroblasts are responsible for the production and deposition of the extracellular matrix, the molecular mechanisms underlying fibroblast activation are not fully understood. In this study, we examined the functional role of AMP-activated protein kinase a1 (AMPKα1) in the activation of fibroblasts and the development of renal fibrosis.

Methods: We investigated the role of AMPKα1 in fibroblasts and renal epithelial cells by examining AMPKα1 expression and activity.

Results: We found that AMPKα1 expression and activity were significantly increased in fibroblasts and renal epithelial cells treated with TGF-β1. Inhibitors of AMPKα1 significantly reduced collagen deposition and suppressed extracellular matrix production, suggesting a potential role for AMPKα1 in the modulation of renal fibrosis.

Conclusions: Our findings suggest that targeting AMPKα1 signaling may be a potential therapeutic strategy for the prevention and treatment of renal fibrosis.

Increased Expression of Complement C1 from Pericyte/Mycoblasts Contributes to Renal Fibrosis Via Activation of Wnt/β Catenin Signaling

Sandhya Xavier, Susan G. Landes, Amandeep Bajwa, Jing Yu, Jeremy Stuart Duffield, Didier Portilla. Department of Medicine and Center for Immunology, Inflammation and Regenerative Medicine, Univ of Virginia, VA; 1Univ of Virginia; 2Biosign Idee.

Background: Pericytes/fibroblasts are progenitors of scar-forming cells known as myofibroblasts. We have characterized the inflammatory nature of pericytes/fibroblasts isolated from UUO mice. We have also shown that Wnt/β-catenin signaling is activated during kidney fibrosis. Role of complement C1 on pericyte function or in Wnt activation remains unknown.

Methods: We used the unilateral ureteral obstruction (UUO) and folic acid nephropathy models. Pericytes were isolated using magnetic beads containing anti-PDGFR receptor. Ab expression of C1 complex was examined by western blotting, immunofluorescence, and real-time PCR in tissue and in cell lysates and supernatants obtained from pericytes cultured from sham, day 3 and day 10 UUO mice kidneys. Topflash reporter assays were used to study Wnt signaling.

Results: Expression of C1q chains a,b,c as well as subunits Clr and C1r were increased during fibrosis along with increased expression of TGF-β, n-SMA and Wnt target genes wisp1 and 2. Immunostain showed C1q localization in the mesangial compartment of UUO but not in sham mice consistent with PCR and western blot data. In cultured pericytes, C1 complex component C1q protein was increased in culture supernatants of Day 3 and Day 10 but not in shams. Expression of C1q proteins was absent in supernatants of UUO pericytes isolated from C1qKO mice. Topflash reporter assays for Wnt signaling showed that pericytes from UUO kidneys had pronounced activation of the reporter following Wnt3a treatment as compared to shams, and this effect was blunted in pericytes isolated from C1qKO mice.

Conclusions: We demonstrate both in vivo and in vitro that increased expression of the C1 complex occurs in response to kidney injury along with activation of Wnt signaling. In vivo/in vitro data, showing that inhibition of C1 complex using C1INH prevented renal fibrosis, we conclude that its inhibition in pericytes/fibroblasts leads to inhibition of Wnt activation and reduced renal fibrosis.

FR-PO294

The Role and Association of Inflammatory and Apoptotic Caspases in Tubulointerstitial Fibrosis

Chun Zhang, You Ke, Hua Su. Nephrology, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.

Background: Caspases are a family of cysteine proteases with pivotal functions in apoptotic and inflammatory signaling. According to their difference of structures and functions, 14 mammalian Caspases are classified into three categories, which are apoptosis activator, apoptosis executor and inflammatory mediator. Caspase-1 is an inflammatory caspase, and Caspase-7 belongs to apoptosis executor. The roles and association of these two distinct types of Caspases in tubulointerstitial fibrosis (TIF) are not well understood.

Methods: Unilateral Ureteral Obstruction (UUO) animal model was constructed on wild-type(WT) and caspase-1 knockout (KO) mice. In vitro study, the cultured tubular epithelial cell line NRK-52E (TECs) were employed and the expression of caspase-1 and caspase-7 was modulated by transfection of Lentiviral expression vector.

Results: In current study, we found both Caspase-1 and Caspase-7 protein levels were elevated in UUO WT mice. While in UUO mice with Caspase-1 KO background the increased Caspase-7 was suppressed significantly along with the minimized extracellular matrix accumulation which was demonstrated by western blot, immunohistochemistry and Masson trichrome staining. In vitro TGF-β1 stimulation promoted the expression of Caspase-1 and Caspase-7 simultaneously in TECs. Notably, genetic deletion of either Caspase-1 or Caspase-7 could abrogate TGF-β1 driven TECs' transdifferentiation and apoptosis. In addition, knocking down Caspase-1 impaired Caspase-7 upregulation in TGF-β1 treated TECs which was consistent with in vivo study. However genetic deletion of Caspase-7 did not influence Caspase-1's abundance.

Conclusions: Our observation firstly links inflammatory and apoptotic Caspases together in TIF and further elucidates Caspase-1 activation is an upstream event of apoptotic Caspase-7 induction during TIF and TECs' transdifferentiation and apoptosis.

FR-PO295

MAD2B-Sno-Smad3 Signaling Pathway Is Implicated in Fibroblast Activation and Tubulointerstitial Fibrosis

Chun Zhang, Hui Tang, Hua Su. Nephrology, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.

Background: Mitotic arrest deficient protein MAD2B, an anaphase-promoting complex (APC)/cyclosome inhibitor, is indispensable for mitotic checkpoint control. Previously we found MAD2B was expressed in glomerular and tubulointerstitial compartment. In addition our data indicated MAD2B was involved in podocyte injury triggered by high glucose. But its role in renal fibrosis remains elusive.

Methods: The object of this study included patients with renal tubulointerstitial fibrosis (TIF) (secondary glomerulonephritis and interstitial nephritis were excluded), Unilateral Ureteral Obstruction(UUO) mice and in vitro cultured tubular epithelial cell line (NRK-52E) and renal fibroblast cell line (NRK-49F). In vivo gene silencing of MAD2B was carried out using Lentiviral gene delivery.

Results: 1. The results of our study indicated patients with renal tubulointerstitial fibrosis (TIF) (secondary glomerulonephritis and interstitial nephritis were excluded), Unilateral Ureteral Obstruction(UUO) mice and in vitro cultured tubular epithelial cell line (NRK-52E) and renal fibroblast cell line (NRK-49F). In vivo gene silencing of MAD2B was carried out using Lentiviral gene delivery.

Conclusions: Our observation firstly links inflammatory and apoptotic Caspases together in TIF and further elucidates Caspase-1 activation is an upstream event of apoptotic Caspase-7 induction during TIF and TECs' transdifferentiation and apoptosis.

Funding: Government Support - Non-U.S.
Results: By immunohistochemistry and western blot, it showed the expression of Markers of cell differentiation in TIF patients, which allowed us to identify the types of cells contributing to the elevated MAD2B abundance. It is well known that TECs and fibroblast are the main culprits in TIF. Our data suggested that TGF-β1 exposure to the level of MAD2B in NRK-52E was not altered, whereas in NRK-49F MAD2B was upregulated in a time- and dose-dependent manner. Furthermore TGF-β1 induced fibroblast activation can be abrogated by MAD2B genetic deletion. Intriguingly, Snod, a repressor of Smad3, was decreased in NRK-49F cells treated with TGF-β1 which could be alleviated by MAD2B knocking down. Consistently, in UUO mice the expression of Snod was significantly increased in the renal cortex accompanying with enhanced activation of Smad3 and locally genetic deletion of MAD2B by Lenti viral transfection preserved Snod’s abundance and consequently suppressed Smad3 signaling which finally dampened the fibroblast activation and ECM accumulation in UUO mice.

Conclusions: Our observation proposes that MAD2B participates in fibroblast activation and tubulointerstitial fibrosis by repressing Snod and subsequently activating Smad3 signaling pathway. Regulation of MAD2B-Snod pathway may be a promising strategy for tubulointerstitial fibrosis. However, the regulatory mechanisms between MAD2B and Snod and still need further investigation.

Funding: Government Support - Non-U.S.

FR-P0298

FHL2 Promotes Tubular Epithelial-to-Mesenchymal Transition by Regulating β-Catenin Activity Ting Cai, Danqin Sun, Chunshan Dai, Junwei Yang, Weichun He. Center for Kidney Disease, 2nd Affiliated Hospital of Nanjing Medical Univ, Nanjing, Jiangsu, China.

Background: Fibrotic kidneys exhibit aberrant activation of β-catenin signaling, one of the main pathways that play a critical role in mediating tubular epithelial-to-mesenchymal transition (EMT). FHL2 (four-and-a-half-LIM-IM only protein 2), an adapter protein, is an endogenous regulator of β-catenin activity.

Methods: To determine whether FHL2 is also involved in the EMT process, we investigated its regulation and function during TGF-β1-stimulated EMT.

Results: TGF-β1-induced FHL2 mRNA and protein expression in rat proximal tubular epithelial cells (NRK-52E) in a time- and dose-dependent manner was significantly dependent on intracellular Smad signaling. Overexpression of FHL2 suppressed E-cadherin, increased α-smooth muscle actin (α-SMA), vimentin and fibronectin expression, whereas knockdown of FHL2 via small interfering RNA partially reduced TGF-β1-mediated α-SMA, vimentin and fibronectin expression, and restored E-cadherin. TGF-β1-induced FHL2 physically interacts with β-catenin in the nuclei in NRK-52E cells. Ectopic expression of FHL2 promoted β-catenin nuclear translocation, induced β-catenin-mediated gene transcription, and upregulated the expression of β-catenin target genes such as plasminogen activator inhibitor-1 (PAI-1) and Twist. Conversely, downregulation of FHL2 expression reduced β-catenin nuclear translocation, abolished β-catenin-mediated gene transcription, and inhibited PAI-1 and Twist expression in the basal and TGF-β1-stimulated conditions. In a mouse model of obstructive nephropathy, FHL2 expression increased in a time-dependent manner, suggesting that it may play a role in tubular EMT and renal fibrosis in vivo.

Conclusions: We speculate that, through manipulating β-catenin activity, FHL2 may be a potential future therapeutic target to prevent progression of renal fibrosis.

PBI-4050 Inhibits the Development of Renal Fibrosis in a Model of Tubulointerstitial Fibrosis Ming-Zhi Zhang,1 Lyne Gagnon,2 Raymond C. Harris.1 1Medicine, Vanderbilt Univ, Nashville, TN; 2ProMetic Biosciences, Laval, QC, Canada.

Background: Kidney fibrosis occurs in chronic kidney diseases and leads to gradual loss of kidney function. Although the etiology of kidney fibrosis is multifactorial, there is increasing evidence linking chronic inflammation to kidney fibrosis. PBI-4050, a novel first-in-class orally active low molecular weight compound currently in phase II clinical trials, has anti-fibrotic and anti-inflammatory properties in different models.

Results: In vivo, we used α-SMA-GFP mice to visualize fibroblast-to-myofibroblast transition (EMT). PBI-4050 (200 mg/kg/day) by daily gastric gavage from 4 to 14 weeks of age. Immunohistochemical analysis showed that in untreated homozygous HB-EGF mice, α-SMA expression levels of the pro-fibrotic and fibrotic components including CTGF and TGF-β, α-SMA (a marker of myofibroblasts), fibronectin, collagen I and IV were increased in Sirt1 mutant kidneys compared to control kidneys, suggesting that pericyte detachment and subsequent pericyte-myofibroblast transition are augmented in Sirt1 mutant kidneys, resulting in excessive fibrosis.

Conclusions: Functional depletion of Sirt1 in endothelial cells aggravates capillary rarefaction and tissue fibrosis following kidney injury. Consistent with this finding, detachment of PDGFβR+ pericytes was increased in Sirt1 mutant kidneys compared to control kidneys, suggesting that pericyte detachment and subsequent pericyte-myofibroblast transition is augmented in Sirt1 mutant kidneys, resulting in excessive fibrosis.

Losartan Reduces Renal Fibrogenesis by Up-Regulating Klotho in Uremic Rats Edgar Maciquzquez,1 Josse Carla Paterno,2 Gabriel H. Polokony,1 Mariana S. Perez,3 Nestor Schor, Mirian A. Boim.

1Nephrology, UNIFESP; 2Sao Paulo, Brazil.

Background: Klotho is a transmembrane protein expressed mainly in the kidney. Soluble Klotho (sKlotho) is an anti-aging hormone factor with diverse functions through mechanisms involving Wnt and TGFβ1 signaling. Renal fibrosis is the end stage of the progressive chronic kidney disease (CKD) and renal klotho is markedly decreased in CKD patients. Renin angiotensin system (RAS) blockade is a relevant therapy to reduce CKD progression and the beneficial effects go further to the anti-inflammatory effect. The aim of this study was to investigate a possible link between RAS and Klotho by evaluating the effects of losartan on Klotho/Wnt signaling in 5/6 nephrectomy model of CKD in rats.

Methods: Adult male Wistar rats were underwent 5/6 nephrectomy (Nx). The Nx animals were separated into three groups: control, with no treatment (Nx), treated with losartan (LOS; 25 mg/kg/day, p.o.) or propranolol (PROP; 25mg/kg/day, p.o.). Results were compared with SHAM group. Blood pressure was measured by tail-cuff plethysmography. After 8 weeks, animals were sacrificed and the remnant kidney was removed to determine the renal expression of collagen, fibronectin, epithelial-to-mesenchymal transition (EMT) markers (FPSP1 and a-SMA) and Klotho signaling (Klotho, Wnt5 and GSK3β) by real time PCR.

Results: Nx rats presented hypertension that was blunted by both losartan and propranolol. The expression levels of collagen and fibronectin were increased in Nx group, which was reverted only in LOS group. The presence of the EMT markers, FPSP1 and a-SMA , was observed in Nx group which was decreased with losartan treatment. Klotho was reduced in Nx animals and LOS but not propranolol significantly increased klotho expression. Nx animals showed upregulation of GSK3β, Wnt 7a and Wnt 3. LOS treatment prevented the decrease in Wnt 7a and GSK3β but not Wnt 3.

Conclusions: These data suggest that the beneficial effect of losartan on renal fibrosis is independent of blood pressure reduction and may be, at least in part, due to upregulation of klotho. In conclusion, losartan induced no change in klotho expression. The interaction between the RAS and Klotho could inactivate the Wnt pathway.

Funding: Government Support - Non-U.S.
In vitro treatment of TGF-β1-activated fibroblasts with EPC extract prevented reversion of fibroblastic phenotype but did not reverse expression of endothelial markers. In two distinct models of renal fibrosis, unilateral ureteral obstruction (UUO) and chronic phase of folic acid-induced nephropathy (FAN), subcapsular injection of EPC extract to the kidney prevented and reversed accumulation of α-SMA-positive myofibroblasts and reduced collagen deposition. The expression of ECM marker for cytokine-induced myofibroblasts was reduced in EPC treated rats. Interestingly, TGF-β1 was mediated via a 130-kDa MT1-MMP pathway resulting in induction of pluripotency transcription factors KLF4, C-Myc, OCT4, and Nanog in association with the open chromatin confirmation.

Conclusions: EPC extract does not reverse endothelial-mesenchymal transition, but it prevents and reverses fibroblast-to-myofibroblast transition and renal fibrosis. The component of EPC extract, LIF, is capable of preventing development of the contractile phenotype of activated fibroblasts, but does not eliminate TGF-β1-induced collagen synthesis in cultured fibroblasts and models of renal fibrosis. LIF component of EPC extract is a participant of its antifibrotic effect, but not the sole one, as other yet undiscovered factors contribute to the antifibrotic effect of the extract.

FR-P0301
Mitochondrial Metabolic Switch to Glycolysis in Proximal Tubular Epithelial Cell in Fibrotic Kidneys
Lei Jiang, Jianwei Yang. Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ; Nanjing, Jiangsu, China.

Background: Renal proximal tubule is susceptible to hypoxic injury since its reliance on aerobic oxidative metabolism. Mitochondrial dysfunction contributes to progression of chronic renal disease. However, the profile of the energy metabolism of renal tubule in progression of fibrosis is uncertain, and the relationship between the change of energy metabolism and tubular epithelial cell damage is unclear.

Methods: Gene expression profiles related to energy metabolism of the proximal tubule in fibrotic kidneys were analyzed. 2-Dexoyglucos (2-DG) was given to CD-1 mice under UUO intraperitoneally. Primary tubular epithelial cells (PTC) cultured from normal CD-1 mice renal cortex was used. 2-DG (inhibitor of glycolysis), bromopyruvic acid (inhibitor of hexokinase), dichloroacetate (inhibitor of glycolysis), oligomycin (inhibitor of oxidative phosphorylation), etomoxir (inhibitor of fatty acid oxidation), DOH (inhibitor of gluconeogenesis, w), PAK RNAi or HIF-1α siRNA was used in PTC with or without TGF-β1 stimulation. The oxygen consumption rate (OCR) and extracellular acidification rate (ECR) were detected by Seahorse Metabolic Analyzer.

Results: I. Glycolysis was upregulated in the proximal tubule in fibrotic kidney. 2. Genes related to glycolysis were upregulated, however, genes related to oxidative phosphorylation, fatty acid metabolism and glutamine metabolism were downregulated. The key limiting-rate enzymes for glycolysis were upregulated in the fibrotic kidney. 3. 2-DG could block the renal fibrosis under UUO. 4. OCR was decreased under TGF-β1 stimulation in PTC, however, ECAR was increased after TGF-β1 stimulation. 5. Inhibiting oxidative phosphorylation, fatty acid oxidation or glutamine metabolism could increase the lactate production in PTC. Lactate could directly induce PTC damage. 6. Inhibiting glycolysis could ameliorate the damage of PTC under TGF-β1 incubation.

Conclusions: The mitochondrial metabolism including oxidative phosphorylation, fatty acid oxidation and glutamine metabolism is defective in proximal tubular epithelial cell in fibrotic kidney. The metabolism is switch to glycolysis, and the glycolytic pathway further aggravates the injury.

The Effects of CCN3/NOV on the Formation of Extracellular Matrix in Human Mesangial Cells
Haifei Liu, Long Chen, Hong Liu, Bi-Cheng Liu. Dept of Nephrology, Zhong Da Hospital, Southeast Univ; Nanjing, Jiangsu, China.

Background: Glomerulosclerosis is characterized by mesangial cells proliferation and accumulation of extracellular matrix (ECM) in glomeruli. ECM accumulation is a variety of damage factors, leading to ECM deposition. ECM accumulation is the net result of the balance between synthesis and degradation. CCN3, a matricellular protein of the CYR61-Ctgf-NOV (CCN) family, associates specifically with ECM. A recent study found that treatment with the matricellular protein CCN3 can block and/or reverse fibrosis development in obesity with diabetic nephropathy. However, whether CCN3 can alleviate the formation of glomerulosclerosis by inhibiting the production of ECM and/or promoting the degradation of ECM is still unknown. This study aims to explore the potential role of CCN3 in ECM accumulation of mesangial cells induced by TGF-β1.

Methods: Human mesangial cells lines were stimulated with TGF-β1 (2ng/ml) and CCN3 for different concentration (5 to 500 ng/ml) after 24 hours of serum starvation. The expressions of fibronectin (FN), type I collagen (COLI), matrix metalloproteinase-2 (MMP-2), matrix metalloproteinase-9 (MMP-9) and tissue inhibitor of metalloproteinase-1 (TIMP-1) were identified by Western blot analysis. In vivo study: Urinary unilateral obstruction model was induced in adult male B6 mice (6 months, 20–25 g). Mice with UUO were given with intra-peritoneal Syk inhibitor (20 and 40 mg/kg, bid) or saline daily, one day prior the uro surgery. Both obstructed and contralateral kidneys were harvested 7 days after surgery. Kidney tissues were prepared for further pathological and molecular biological analysis.

Results: Our results demonstrated that the inhibition of Syk in NRK49F cells inhibited the stimulation effect of TGF-β1 leading to fibroblast to fibroblast transition, but it prevents and reverses fibroblast-to-myofibroblast activation and also reduces the tubulointerstitial fibrosis in UUO mice. The mechanism may be related to anti-inflammatory effects and down-regulate MAPK-p38 pathway.

Conclusions: In conclusion, we demonstrated that Syk inhibitor ameliorates TGF-β1 induced kidney myofibroblast activation and also reduces the tubulointerstitial fibrosis in UUO mice. Both obstructed and contralateral kidneys were harvested 7 days after surgery. Kidney tissues were prepared for further pathological and molecular biological analysis.

Optimization of Identification of the Glomerular Extracellular Matrix Proteome
Liliang Hobeika, Michelle T. Barati, Jon B. Klein, Kenneth R. McLiech, Michael Merchant. Medicine, Univ of Louisville; Dept of Veterans Affairs, Louisville, KY.

Background: Increased glomerular extracellular matrix (ECM) is present in many glomerular disorders, eg, diabetic nephropathy and FSGS. Defining the ECM proteome by mass spectrometry (MS) offers the opportunity to determine the mechanism for increased ECM and identify disease specific markers. The optimal conditions for ECM isolation and MS analysis have not been determined. This study compared three extraction techniques in glomeruli isolated by laser capture microdissection (LCMD) from two types of tissue preparation.

Methods: Frozen (FR) and formalin-fixed paraffin embedded (FFPE) tissue from the same human kidney were cut into 10mm sections, stained with hematoxylin, glomeruli in glomeruli isolated by laser capture microdissection (LCMD) from two types of tissue preparation.

Results: The total protein yield and number of proteins identified were determined in various conditions of ECM (ECM) isolation of glomeruli. The ECM isolated by LCMD was enriched in LIF and VEGF. Only LIF was capable of reducing fibroblast-to-myofibroblast transition and renal fibrosis. Screening the composition of EPC extract for cytokines revealed that it is associated with down-regulation of MAPK-p38 pathways.

Conclusions: In conclusion, we demonstrated that Syk inhibitor ameliorates TGF-β1 induced kidney myofibroblast activation and also reduces the tubulointerstitial fibrosis in UUO mice. The mechanisms may be related to anti-inflammatory effects and down-regulate MAPK-p38 pathway.

BMP-7 Inhibits Renal Akt Signaling
Debra F. Higgins, Catherine Godson. School of Medicine, Conway Inst, Univ College Dublin, Dublin, Ireland.

Background: Bone morphogenetic protein-7 (BMP-7), a member of the TGFβ superfamily, counteracts pro-fibrotic TGFβ, and protects from fibrosis in acute and chronic renal injury models.

Methods: Using the chronic fibrosis model, unilateral ureteral obstruction (UUO), we investigated exogenous-rhBMP-7 on signaling pathways involved in hypoxia and TGFβ-induced fibrosis. Mice undergoing UUO were treated with either vehicle or rhBMP-7 (300ng/kg.i.p.), kidneys were harvested on day 8 post-obstruction and analysed for markers of renal fibrosis and activation of SMAD, MAPK, and PI3K signaling. Results: rhBMP-7 response to UUO, SMAD1/5/8 activity was lost in vehicle-treated kidneys yet maintained in BMP-7-treated kidneys. Collagen accumulation was significantly increased in obstructed kidneys of vehicle-treated animals compared with contralateral and this response was not observed in BMP-7-treated obstructed kidneys. Immunohistochemical analysis of type I, III, and IV collagen revealed that accumulation of type I collagen was significantly impaired in BMP-7-treated obstructed kidneys. Activation of SMAD2, SMAD3, ERK, p38 and Akt signaling pathways occurred during fibrogenesis and BMP-7 significantly attenuated SMAD3 and Akt signaling in vivo. In the kidney, inner medullary collecting duct and tubular epithelial cells are responsive to BMP-7. Analysis in mouse inner medullary collecting duct (mIMCD) and human tubular epithelial (HK-2) cells stimulated with either TGFβ, hypoxia (1% oxygen) to induce Akt activation provided further evidence that BMP-7 could specifically inhibit PI3K / Akt signaling.

Conclusions: These data demonstrate an important mechanism by which BMP-7 orchestrates renal protection through Akt inhibition and strengthens the argument for use of Akt inhibitors as anti-fibrotic therapeutics.

Prevention of Renal Interstitial Fibrosis by Simultaneous Deletion of Bax and Bak
Hee-Seong Jang, Babu J. Padanilam. 1,2 Cellular and Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE; 1,2 Internal Medicine, Section of Nephrology, Univ of Nebraska Medical Center, Omaha, NE.

Background: Proximal tubular injury and apoptosis are key mediators of development of kidney fibrosis, a hallmark of chronic kidney disease. However, the molecular mechanism by which tubular apoptotic cell death leads to kidney fibrosis is poorly understood.

Methods: Here we tested the roles of Bax and Bak, two crucial proteins involved in intrinsic apoptotic cell death, in progression of kidney fibrosis. Mice with proximal tubular deletion of Bax or Bak and double deletion of Bax and Bak were subjected to unilateral ureteral obstruction (UUO).

Results: Dual deficiency of Bax and Bak inhibited tubular apoptosis and atrophy. Consistent with decreased tubular injury, dual ablation of Bax and Bak suppressed UUO-induced inflammation and kidney fibrosis with decreased tubular cell cycle arrest, expression of fibrogenic and inflammatory cytokines, and oxidative stress in the kidney. Bax or Bak deficiency was insufficient to prevent apoptosis and all other aforementioned malevolent effects, suggesting compensatory mediation by each in the respective signaling pathways.

Conclusions: These data suggest that dual ablation of Bax and Bak in the kidney is required to prevent UUO-induced tubular apoptosis and the consequent kidney inflammation and fibrosis.

Investigating the Role of Cilia in Regulating Fibrosis in the Kidney and Liver Using PKD Mouse Models

Background: Cystic kidney disorders are frequently caused by mutations in cilia associated proteins (intratubular lagular transport, IFT) or ciliary signaling proteins (polycystin-1 or polycystin-2). Comorbidities commonly associated with renal cysts include biliary abnormalities with associated fibrosis in both tissues. In the kidney of cilia mutants, ischemia-reperfusion (IR) injury greatly exacerbates the rate of cyst development; however, it is not known whether IR injury will similarly affect the liver and how loss of cilia affects injury induced fibrosis.

Methods: To address these questions, we are utilizing Oak Ridge Polycystic Kidney (ORPK) mice that have a congenital hypomorphic IFT88 mutation and conditional mutant mice where cilia are disrupted in the kidney (CaggCreER). The conditional mutant mice used in IR injury studies were injected with rhadenosine-rhBMP-7 on proliferation and inflammation responses and production of extracellular matrix (ECM) and pro-fibrotic factors.

Results: Our preliminary studies in the kidney indicate that IFT88 mutant mice receiving IR injury have increased ECM transcription (Col Iα2, Col IIIα1, and fibronectin) compared to the sham operated kidney. Despite the increased ECM production, the pro-fibrotic growth factor TGF-β, which is frequently associated with fibrosis, was not significantly elevated in mutant mice. However, another TGF-β family member, inhibin βA, was increased in the injured kidney of mutant mice suggesting a possible mechanism for ECM production. ORPK mice have a noticeable liver phenotype characterized by biliary hyperplasia and, similar to the kidney, an increase in Col Iα4 and Col IIIα2 transcripts. ORPK mutant mice also have increased transcript levels of the microcotranscript protein, MCP1, and the pro-inflammatory cytokine, IL-1β.

Conclusions: Together, our preliminary data suggest that defects in cilia formation promote fibrotic disease progression possibly through altered cytokine production and enhanced recruitment of infiltrating monocytes.

Klotho Suppresses Epithelial-Mesenchymal Transition (or Transformation in Adriamycin Nephropathy
Tsuneo Takenaka, Tsutomu Inoue, Matsuhiro Hayashi. 1,3 International Univ of Health and Welfare; 3Saitama Medical Univ; 1Keio Univ.

Background: Klotho interacts with various proteins to alter their function. Klotho may bind to the receptor for WNT and TGFbeta, inhibiting their signals.

Methods: Experiments were performed to assess how klotho protects kidney from its injury. Adriamycin (5 mg/kg) was injected into rats to induce nephropathy. Human reconstituent klotho (K, 50 micro-g/kg/day), 4-benzyl-2-methyl-1,2,4-thiadiazole-3,5-dione (GSK3beta blocker, 0.2mg/kg/day) and vehicle (V) was administered. Rats which were untreated with Adriamycin were used as control (U). Animals were killed 8 weeks later. Renal expressions of Wnt1, GSK3beta, Tbeta1, and collagen I were assessed by RT-PCR against GAPDH. Western blot was used for p-GSK3beta and beta-actin.

Results: Adriamycin increased albuminuria, renal expression of Wnt1, p-GSK3beta, TGF and collagen I in comparison to the control. Klotho and T beta suppressed increased albuminuria and the phosphorylated GSK3beta in the kidneys, with decreased elevations of Wnt1, supporting that klotho inhibits Wnt signaling without changes in Wnt level. While klotho and T reduced TGFbeta, klotho preferentially ameliorated collagen I in comparison to T.

The Molecular Mechanism of miR-382 in the Pathogenesis of Renal Tubulointerstitial Fibrosis
Yi Fane, 1,2 Ting Xie, 1 Hui Zhang, 1 Sheng Wu. 1 Nephrology, Zhongshan Hospital Fudan Univ, China; 3Shanghai Key Laboratory of Kidney Diseases and Blood Purification.

Background: To investigate the roles of microRNA-382 (miR-382) in the pathogenesis of renal tubulointerstitial fibrosis.

Methods: Human kidney epithelial (HK2) cells that transfected with a miR-382 inhibitor (antagomir-382) was used to examine the effect of miR-382 abundance on cell polarity, as well as to test the complementary relationship between miR-382 and its predicted target gene, heat shock 60kDa protein 1(HSPD1), which was further verified by site-directed mutagenesis. We also examined the in vivo role of miR-382 in the development of renal interstitial fibrosis, in a mouse unilateral ureteral obstruction (UUO) model. Locked nucleic acids (LNA) and anti-miR-382 was intravenously delivered via tail vein less than 30minutes prior to UUO, and repeated the dosage 24 hours after the surgery. For clinical verification, renal biopsy specimens from 12 IgA nephropathy (IgAN) patients were collected, 6 with moderate to severe tubulointerstitial fibrosis (TIF) and 6 with no TIF. The relative abundance of miR-382 and HSPD1 protein was analyzed using in situ hybridization and immunohistochemistry.

Results: HSPOD1 was confirmed to be a new, direct target gene of miR-382 by in vitro transfect technique and mutation experiments. The development of epithelial transformation or renal interstitial fibrosis was accompanied with up-regulated abundance of miR-382. Down-regulation of miR-382 was associated with significant reductions of interstitial fibrosis, but increase protein expression of HSPD1 and thioeodizin, both in the obstructed mouse kidneys and renal biopsy specimen from IgAN patients.

Conclusions: MiR-382, a profibrotic microRNA, is up-regulated with the development of renal interstitial fibrosis. The down-regulation of miR-382 and HSPD1 protein was used analyzing in situ hybridization and immunohistochemistry.

Assessing the Role of Gremlin-1 on Renal Fibrosis In Vitro Marcela Herrera, Liuhan Liang, Asha Seth, Carol Patricia Moreno Quinn. Cardiovascular & Metabolic Diseases, Medimmune, Cambridge, United Kingdom.

Background: Bone Morphogenic Proteins (BMPs) signal through SMAD-1/5/7 to upregulate genes that antagonize fibrosis. The endogenous antagonist gremlin-1 binds to BMPs and antagonizes extracellular BMPs, inhibiting their anti-fibrotic effects. Gremlin-1 is upregulated in the proximal tubular (PT) of DN patients. We hypothesized that Gremlin-1 participates in the development of renal fibrosis by inducing a pro-fibrotic phenotype in proximal tubules and renal interstitial fibroblasts.

Methods: To test this hypothesis we used HK-2 (human PT cell line) and NRK49F (rat renal fibroblasts) cells where the pro-fibrotic phenotype was induced by Transforming Growth Factor b1 (TGFb1: 2.5 ng/mL, 72 hrs). Gremlin-1 secretion and protein expression was measured by Western blotting and gene expression by qPCR.

Results: In PT cells, TGFb stimulated gremlin-1 protein secretion by 2.3 fold (from 57 ± 3 to 134 ± 8 ng/mL) and mRNA expression of (Gremlin-1: p = 0.05), increased expression of fibronectin (FN, an extracellular matrix component) by 50% (p < 0.05) and reduced expression of c-aldh (c-CAD, an epithelial marker) by 95% (p = 0.05). All changes also occurred at the mRNA level. Gremlin-1 sRNA significantly reduced gremlin-1 mRNA expression and efficiently blocked the TGFb-induced Gremlin-1 release by 100%. However, Gremlin-1 knockdown did not prevent the pro-fibrotic changes of TGFb. In contrast to PT cells, TGFb did not induce gremlin-1 secretion in renal fibroblasts. TGFb increased FN and a-smooth muscle actin (aSMA, marker of fibroblast activation) in a dose-dependent manner. Addition of gremlin-1 (mimicking the in vivo setting) did not exacerbate fibrosis at any dose of TGFb. Addition of recombinant BMP2 was not sufficient to prevent TGFb-induced fibrosis in either cell type. Recombinant BMP2 alone (1 nM) increased SMAD5 phosphorylation and the expression of ID1 (a marker of BMP signalling) at 1 and 24 hrs post treatment. The stimulatory effect of BMP2 was blocked by pre-treatment with recombinant Gremlin-1 (2 mM). These data confirm intact BMP2/gremlin-1 signalling in both cell types.

Conclusions: Our data does not support the participation of gremlin-1 in TGFb-dependent renal fibrosis in vitro.

Vitamin (Vit) D Repletion Ameliorates Muscle Wasting and Muscle Fibrosis in Mice with Chronic Kidney Disease Wei Ding, Wei W. Cheung, Mary Christine Esparza, Ping Zhou, Richard L. Lieber, Robert H. Mak. Pediatric Nephrology, Univ of California, San Diego, La Jolla, CA

Background: Cachexia presenting as muscle wasting and weakness is prevalent in CKD patients and may impact their quality of life. We investigated the effects of vitamin D repletion in a mouse model of CKD-associated cachexia and vitamin D deficiency.

Methods: CKD in c57BL/6 mice were induced by 5/6 nephrectomy. CKD and sham mice were treated with 25VitD (25 mg/kg/day), 1.25VitD (40 ng/kg/day) or vehicle (V) for 6 weeks via a subcutaneous osmotic pump. CKD-V mice were fed ad libitum while other groups of mice were pair-fed to CKD+V mice. Parameters of energy homostasis, skeletal muscle histomorphometry and in vivo muscle function were measured. The expression of key molecules implicated in myogenesis and fibrosis pathway was assessed using a focused PCR array.

Results: Serum 25VitD and 1.25VitD levels were significantly lower in CKD than sham mice (p < 0.01) and was increased, within the physiological range, by 25VitD and 1.25VitD repletion in CKD mice. CKD mice exhibited reduced weight gain, increased body mass index (BMI) and increased expression of the BMI-related gene, leptin. Increased energy expenditure in CKD mice was associated with upregulation of uncoupling proteins (UCPs) in skeletal muscle and adipose tissues. Soleus muscle fiber area, soleus collagen content as well as aberrant gene expression involved in muscle function was significantly reduced in CKD mice than sham mice (p < 0.01). Skeletal muscle fibrosis, a major pathological hallmark of myopathies, is evident in CKD mice. Soleus collagen content was significantly increased in CKD than sham mice (p < 0.01). Gene expression of myogenesis and fibrotic pathways were increased in CKD than sham mice (p < 0.01). Perturbations in weight gain, energy expenditure, UCPs, lean mass decrement and muscle function tests, soleus muscle fiber area, soleus collagen content as well as aberrant gene expression involved in myogenesis and muscle fibrotic pathway in CKD mice were normalized by 25VitD but only partially attenuated by 1.25VitD repletion.

Conclusions: 25VitD and 1.25VitD repletion have differential effects on muscle wasting and muscle fibrosis in CKD mice.

The Effect of Cell Culture Surface Coating on Glomerular Endothelial Cell Phenotype Kamilla Campanholle,4 Signe Holm,4 Kamilla Tove Skrede,4 Signe Camilla Holm,4 Kamilla Aasa Campanholle,4 Kamilla Ritsuko Campanholle,4 Holm,4 Southern Denmark Univ, Odense, Denmark.

Background: Renal interstitial fibrosis is characterized by dysregulated extracellular matrix turnover and protease activity. ECM protein fragments generated by protease cleavage can be measured by specific ELISAs, providing a protein fingerprint of the disease. The aim of this study was to set up an ex vivo model for renal interstitial fibrosis in order to investigate the ECM turnover profile in the fibrotic kidney.

Methods: 14 male 12 weeks old Sprague-Dawley rats underwent Unilateral Ureteral Obstruction (UUO) surgery by ligation of the right ureter. The left kidney (contralateral) was used as internal control. 6 rats were sham-operated and used as control group. Rats were terminated 2 weeks after the surgery, when advanced fibrosis is known to be present. The kidneys were excised and processed to tissue slices (PCTS) were cultured for 5 days in serum free medium. Markers of collagen type I formation (P1NP), collagen type III degradation (C3M) and α-smooth muscle actin (α-SMA) were measured in the PCTS supernatants. The extent of tubulointerstitial fibrosis was evaluated by histology.

Results: P1NP, C3M and α-SMA were significantly increased in supernatants of tissue slices from the UUO ligated kidneys compared to the contralateral kidneys (p < 0.001) and to sham operated animals (p > 0.0001). However the markers had a high inter-individual variability in the UUO group. When comparing the levels of the markers from the UUO kidney to those from the corresponding contralateral kidney, animals with pronounced differences were those presenting advanced fibrosis in histology.

Conclusions: The UUO PCTS ex vivo model provides a valuable translational tool for investigating the ECM remodeling associated with renal interstitial fibrosis. Since the ECM content is not measured, the markers measured in the supernatants also in circulation and in urine, these markers have the potential to accurately and non-invasively describe the tissue remodeling during fibrosis.

Collagen Degradation Profile in a Nephrotic Nephritis Model Signe Holm Nielsen,1, 2 Daniel Guldgard Kring Rasmussen,1, 2 Gabriela Campanholle,1 Robert V. Martinez,2 Morten Asser Karsdal,1 Federica Genovesi,1 1Fibrosis Biology and Biomarkers, Nordic Bioscience, Herlev, Denmark; 2System Biology, Denmark Technology Univ, Kgs. Lyngby, Denmark.

Background: The nephrotic nephritis (NTN) mouse model is characterized by a rapid onset of nephritis, followed by tissue destruction and progression to renal scarring. We aimed at identifying markers for early disease onset that were directly linked to the events of scar formation in the kidney.

Methods: Neo-epitope degradation fragments of collagen type I, III and IV generated by MMP cleavage were measured by specific ELISAs (namely C1M, C3M and C4M) in urine of NTN and healthy mice terminated at 7 and 21 days after injury (NTN: n=21, Controls: n=6). Urinary albumin/creatinine (A/CR), urinary proteinuria, plasma creatinine and blood urea nitrogen (BUN) were measured as markers of renal function. Intestinal fragments of glomerulosclerosis were evaluated by histology and quantification of α-SMA and collagen type I in immunohistochemistry.

Results: While C1M levels in urine were not different between NTN mice and controls, C3M levels were elevated in NTN rats at 7 days (p < 0.05) and decreased to levels close to the controls at 21 days. This elevation was also reflected in proteinuria, peaking at 7 days, but not in BUN and plasma creatinine. C4M levels were elevated at 21 days and not at 7 days (p > 0.01), and correlated with the extent of interstitial fibrosis.

Multi-Clonal Population of Cells of Renin Lineage (CoRL) Transdifferentiate into Podocytes and PECs in Experimental FSGS

Natalya V. Kaverina,1 Diana G. Eng,1 Jeffrey W. Pippin,2 Michael E. Rusinak,2 Kenneth W. Gross,2 Stuart J. Shankland.3 1Devision of Nephrology, Univ of Washington, Seattle, WA; 2Dept of Molecular and Cellular Biology, Roswell Park Cancer Inst, Buffalo, NY.

Background: Focal segmental glomerulosclerosis (FSGS) is secondary to podocyte injury and loss. Because adult podocytes cannot proliferate, their replacement by progenitors is critical for their repair and regeneration in disease. Here we explored whether single or multiple clones of cells of renin lineage (CoRL) serve as a local progenitor source to replace damaged podocytes in experimental FSGS.

Methods: Experimental FSGS was induced following abrupt podocyte depletion by administration of a cytotoxic anti-podocyte antibody in two confetti mouse reporters. First, to confirm adult podocyte regeneration following abrupt depletion, podocytes were genetically fate-mapped in adult NPHP2+/CreConfetti1/1VGF reporter mice with experimental FSGS. Second, to prove that adult podocyte regeneration by CoRL was multi-clonal, CoRL were fate mapped in RenCre / Confetti1/1VGF reporter mice with experimental FSGS. Results: FSGS in NPHP2+/Confetti1/1VGF mice was characterized by marked podocyte depletion (45% decrease) on d7. A multi-clonal repopulation of podocytes resulted in an increase in their overall number to 77% of normal by d28. No podocyte proliferation was detected by BrdU staining. In RenCre / Confetti1/1VGF mice, a multi-clonal expansion of 4-color-labeled CoRL (GFP, RFP, CFP, YFP) was detected in glomeruli at FSGS d28. A subset of all clonal reporters co-expressed 5 podocyte markers (podocin, synaptopodin, p57, WT-1, nephrin). CoRL were also observed usingBowman’s capsule and capsule-adjacent PEC markers (PA2X, claudin-1). BrdU staining did not co-localize with CoRL reporters. Conclusions: Following an abrupt depletion of adult podocytes in experimental FSGS, their number was increased in the absence of podocyte proliferation. Regeneration of adult podocytes was likely in part due to multiple clones of CoRL serving as local progenitors.

Macula Densa-Derived Factors Control Glomerular Cell Remodeling

Anne Riquier-brison,1 Donna Ralph, Jasmine Ann Arevalo Castillo, Janos Peti-Peterdi.1 1Physiology and Biophysics, Univ of Southern California, Los Angeles, CA.

Background: Macula densa (MD) cells are strategically positioned at the vascular entrance of the glomerulus and control renal hemodynamics and renin. In this study, we addressed a novel, non-traditional role of MD cells regulating glomerular cell plasticity/remodeling by mesenchymal progenitor cells.

Methods: For genetic cell fate tracking, tamoxifen-induced NG2CreERT2-Tomato mice were fed either a control or salt-deficient + ACE inhibition (SD+ACEi) diet, for 2 weeks to achieve strong MD stimulation. We observed a 5-fold increase in renal interstitial density of NG2-derived (+) cells (5.9±1.1 cells per field in control, 30.2±4.5 in SD+ACEi), and the homing of NG2+ cells to the mesangium under the MD and into the glomerulus. This effect was blunted by the selective COX-2 inhibitor SC38236 (COX-2i) or the nNOS inhibitor 7-NI (13.2±2.2 cells per field with COX-2i+7-NI and 11.6±1.7 with 7-NI). Immunofluorescence (IF) of Claudin-1 showed a 4-fold increase in the number of NG2+ cells in the glomerular parietal layer (0.5±0.2 cells per glomerulus in control, 2.0±0.4 in SD+ACEi). Podocin IF identified a few NG2+ podocytes. NG2+ cell homing was blunted by COX-2i and 7-NI (SD+ACEi, 0.1±0.2 cells per glomerulus with COX-2i+7-NI). Co-localization of endogenous NG2-Tomato fluorescence with IF of renin revealed an increase in the proportion of NG2+ renin-expressing cells from 22.0±6.6% to 70.6±7.4% after SD+ACEi, inhibited by COX-2i. Similarly, the density of proliferating cells expressing Ki67 increased after treatment (11.7±1.0 cells per field with control, 23.3±2.8 with COX-2i+7-NI). In the vicinity of the juxtaglomerular area, inhibited by COX-2i (5.6±1.0) and 7-NI (2.7±0.3).

Conclusions: Our results suggest that NG2+ pericytes may be an important progenitor cell population in the kidney. In response to MD-derived (from COX-2 and nNOS) paracrine factors, MD cells rapidly recruit cells from the renal interstitium proliferate and migrate towards the MD along the arteriolar territory and via the vascular pole into the glomerular epithelium and mesangium. In conclusion, MD cells play new important roles in the maintenance and remodeling of the glomerulus.

A Novel Method for Assessing Podocyte Depletion in Whole Glomeruli

Victor G. Puelles,1 James William Van den Wolde,1 Lisa Cullen-McEwen,1 Keiht B. Schaefer,2 Jonathon M. Besley,1 Kieran M. Short,1 Georgina Carruma,1 Stacey Hokke,1 Stephen D. Firth,1 Ian S. Harper,2 Dick J. Nikolice-Paterson,2 John F. Bertram.1 1Dept of Anatomy and Developmental Biology, Monash Univ; Melbourne, Victoria, Australia; 2Monash Micro Imaging, Monash Univ, Melbourne, Victoria, Australia; 3Dept of Nephrology, Monash Medical Centre, Melbourne, Victoria, Australia.

Background: Podocyte depletion plays a major role in the development and progression of glomerulosclerosis. Given that glomerulosclerosis is often focal, affecting some but not all glomeruli, our aim was to develop a rapid, accurate and precise method for quantifying podocyte depletion in whole glomeruli.

Methods: Pod+ iDTR mice, in which expression of the human diphtheria toxin (DT) receptor is driven by the podocin promoter, and iDTR mice (controls) (mice controls) were injected with 3.6x107 (TUNel)/kg). Tissue was collected at day 35 for podocyte analysis (n=3 mice per group). A 100μm thick kidney slice from the pronephros and synaptopodin. Slices were cleared with benzyl alcohol, benzyl benzote (BABBB). An SP8 confocal microscope (Leica, Germany) fitted with a BABB objective (NA: 0.95; working distance: 2mm) was used. Total podocyte number was obtained by manual counting and used to calculate percent podocyte depletion in each glomerulus.

Results: In iDTR mice (controls), total podocyte number per glomerulus was almost identical between manual counts (66.6±1.92) and Imaris (65.47±9.26; P=0.65). In Pod+ iDTR mice, total podocyte number was also similar between manual counts (52.96±1.17) and Imaris (53.5±11.35; P=0.81). With both methods, podocyte counts were obtained in less than 2 minutes per glomerulus, a significant time reduction compared to existing methods. Imaris also facilitates the estimation of podocyte and glomerular volumes for a more accurate assessment of podocyte morphology in the glomerulus and synaptopodin. Slices were cleared with benzyl alcohol, benzyl benzoate (BABBB). An SP8 confocal microscope (Leica, Germany) fitted with a BABB objective (NA: 0.95; working distance: 2mm) was used. Total podocyte number was obtained by manual counting and used to calculate percent podocyte depletion in each glomerulus.

Conclusions: This is the first method to combine immunofluorescence, BABB-clearing and confocal microscopy to count podocytes in whole glomeruli. The method is accurate, precise and rapid, and provides a novel approach for podocyte morphometrics in settings where sufficient tissue is available for analysis.

Identification and Validation of Fluid Flow Shear Stress (FFSS)-Induced Changes in Podocyte Signaling Pathways Using Bioinformatic Tools

Tarak Srivastava,1 Hongying Dai,2 Ashraf El-Meawary,1 Ellen T. McCarthy,1,2 Vishal Virdi,1 and Mukut Sharma1

1Dept II for Internal Medicine, Univ Hospital Cologne, Cologne, NRW, Germany; 2Dept of Pediatrics, Univ Hospital Cologne, Cologne, NRW, Germany; 3Cologne Excellence Cluster on Cellular Stress Responses in Aging-Associated Diseases, Univ of Cologne, Cologne, NRW, Germany.

Background: In Fabry disease the deficiency of the enzyme α-galactosidase A leads to an accumulation of globotriaosylceramide (Gb3). An enzyme replacement therapy with agalsidase alfa (Replagali®) or beta (Fabrazyme®) is licensed since 2001. The establishment of an α-galactosidase A-deficient human podocyte cell line has already been published by our group. These podocytes accumulate Gb3, exhibit dysregulated AKT and mTOR signaling and dysregulated autophagy. We analyzed changes in cellular signal transduction by our group. These podocytes accumulate Gb3, exhibit dysregulated AKT and mTOR signaling and dysregulated autophagy. We analyzed changes in cellular signal transduction

Methods: We performed microarray analysis (Affymetrix GeneChip Mouse Exon 1.0 ST Array) on immortalized podocytes without FFSS (Control), immediately after FFSS (End-FFSS), 2 hours (post-2hr FFSS), and at 24 hours (post-24hr FFSS) after cessation of FFSS at 2 dynes/cm² for 2 hr. Mouse exon 1.0 ST Array has ~4 probes/exon and ~40 probes/gene. Data from the microarray were log transformed, normalized and filtered to generate a set of 17,494 genes. Genes that were significant at p<0.01 were analyzed using Ingenuity Pathway Analysis (IPA) and Enrichr Program to identify key pathways.

Results: IPA showed Akt, COX-2, and AMPK (at End-FFSS); TGF-β (at post-2hr FFSS) and p38MAPK, ERK1/2 (at post-24hr FFSS) in the main network. Enrich Kinase Enrichment Analysis showed GSK3β, ERK1/2 in all three treatment groups compared with the control group. ChiP-X Enrichment Analysis identified transcription factor β-catenin. Western blotting, fluorescence microscopy and immunocytochemistry were used to validate changes in these signaling molecules.

Conclusions: Increased FFSS affects pathways that mediate podocyte survival and inflammation, and provide targets to address the mechanism of hyperfiltration-mediated glomerular injury.

FR-PO321

A Podocyte-Based Screening Assay Identifies Paulowne-Derivatives as Novel Podocyte Protective Agents

Ha won Lee, Samia Khan, Mohd Hafeez Faridi, Teresa D. Geraghty, Mehmet M. Altintas, Jochen Reiser, Vincet Gupta. Dept of Internal Medicine, Rush Univ Medical Center, Chicago, IL.

Background: Podocyte injury and loss is an early hallmark in the pathogenesis of a variety of glomerular diseases. Therefore, podocytes are an excellent cellular target for the development of kidney directed therapeutics. We recently described a novel cell-based high content screening (HCS) assay for quantifying podocyte damage in vitro. Here, we describe utilization of this HCS assay to identify a family of small molecules that significantly protect podocytes from injury.

Methods: We utilized cultured murine podocytes in an HCS assay using 96-well imaging plates to screen drugs for quantifying podocyte damage in vitro. Here, we describe utilization of this HCS assay to identify a family of small molecules that significantly protect podocytes from injury. We modified our drug screening platform for high throughput imaging (HT-Imaging pipeline) and automated drug screening for thousands of podocytes per condition. Identified hits were confirmed and a number of biochemical and cell biological assays were used to validate the findings.

Results: We identified a family of small molecules, Paulowne, as highly potent agents that protected podocytes. Among these, three other podulates (paullone, 1-azakenpaullone, and alsterpaullone) showed dose-dependent protection of podocytes from PAN-damage induced loss in F-actin fibers. Among the four paulonines identified, 1-azakenpaullone and alsterpaullone showed the highest level of protection. At cellular level, alsterpaullone reduced the elevation in the expression of Desmin, a podocyte damage marker, and inhibited PAN-induced podocyte migration. While PAN treatment reduced AKT phosphorylation in podocytes, alsterpaullone maintained the levels of phosphorylated AKT in podocytes.

Conclusions: Employment of our newly described podocyte-based screening assay results in the discovery of podocyte-directed therapeutics for treating a number of glomerular diseases. Paulonines represent a family of small molecules that show podocyte protection from damage. We also describe a proposed molecular mechanism for the efficacy of these novel agents. We hope that these methodologies will lead to the development of novel types of specific kidney protective drugs.

NovoNordisk Podocyte Quantification Assay to Ascertain Patient Serum Toxicity

Elena Kuznetsova,1 Nadezda Vasilieva,1 Chen-Fang Chung,2 Sima Babayeva1

1Novo Nordisk, Inc., Princeton, NJ; 2Dept of Medicine, McGill Univ-McGill Univ Health Center, Montreal, QC, Canada.

Background: Septicemia/renal failure is a common indication for dialysis or renal transplantation. In > 50% of patients, the disease is idiopathic and may recur post-transplant suggesting the presence of a pathogenic toxic factor(s) circulating in the blood. The identity of this factor and the pathogenic mechanisms remain enigmatic. Recent in vitro studies from our lab showed that plasma from recurrent FSGS patients disturbs the human podocyte cytoskeleton and focal adhesion complexes (FACS). We developed a novel unbiased assay to quantify the toxic effects of patient plasma and nephrotoxic drugs on cultured human podocytes and to identify strategies that block serum toxicity.

Methods: Cultured human differentiated podocytes are exposed to adriamycin, recombinant TNFa or human sera from patients with various forms of FSGS. FACS are visualized with anti-vinculin antibody, and cell images are analyzed to define the number of FACS/1000μm² cell area. We analyzed sera from 12 patients: 2 with idiopathic, 4 recurrent FSGS, 4 non-recurrent FSGS and 2 de novo FSGS.

Results: Both adriamycin and recombinant TNFa disrupt podocyte actin cytoskeleton and FACS in a dose-dependent manner. Comparing to healthy control, sera from patients with de novo FSGS (no known mutations identified), FSGS and de novo FSGS post-transplant drastically reduces FACS number, yet sera from mFSGS post-transplant does not statistically affect FACS. In ~60% of the patients with serum toxicity, these effects on podocytes can be averted by TNFa pathway blockade.

Conclusions: Our in vitro podocyte assay provides, for the first time, means to reliably identify those patients with idiopathic FSGS who are at high risk of recurrence post-transplant. It may also identify FSGS patients who may be candidates for anti-TNFa therapy that could prevent progressive glomerular injury.

Loss of Robo2 in Podocytes Protects Adult Mice from Acute Glomerular Injury

Anna Pisarek-Horowitzi, Xueping Fan, Hila Milo Rasouly, Stefanie Chan, Hui Chen, Ramon G. Bonegio, Joel M. Henderson, David J. Salant, Weining Lu. Renal, Boston University Medical Center; Boston, MA.

Background: SLIT2 and its receptor ROBO2 play an important role during kidney development. We have recently found that ROBO2 is expressed in developing glomerular podocytes. However, the role of ROBO2 in the adult mouse kidney, particularly under acute glomerular injury conditions, is not clear.

Methods: To test the hypothesis that loss of Robo2 in glomerular podocytes affects the outcome of acute glomerular injury, we applied two in vivo acute glomerular injury models induced by nephrotoxic serum (NTS) injection and proteinuric saline (PS) perfusion, in Robo2 podocyte specific knockout mice (Robo2 KO) and wild type controls. Kidney glomerular ultrastructure was analyzed by scanning and transmission electron microscopy before and after injury. Podocyte foot process width and slit diaphragm density were measured to quantify the severity of the glomerular injury. Urine albumin to creatinine ratio was measured in the NTS model. Podocyte specific gene expression was analyzed using TaqMan real time PCR for mRNA and Western blot for protein levels.

Results: Robo2 podocyte specific knockout mice developed less proteinuria after the NTS injury with lower urine albumin/creatinine ratio as compared to the wild type controls. Electron microscopy showed that Robo2 KO mice have milder foot process effacement and less defects in the slit diaphragm induced by either NTS or PS injury. TaqMan and Western blot analyses revealed that nephrin, a crucial transmembrane component of the podocyte slit diaphragm, was significantly up-regulated at both mRNA and protein levels in the Robo2 KO mice before NTS injury and at the late stage of heterologous phase after the NTS injury. In addition, the mRNA levels of Robo2 and Slit2 in the wild type kidneys were also upregulated after the NTS injury.

Conclusions: SLIT2-ROBO2 signaling pathway plays an important role in the adult mouse kidney and loss of Robo2 in podocytes from acute glomerular injury. Our findings suggest that SLIT2-ROBO2 signaling might also have a negative impact on nephrin expression during podocyte injury and be a potential therapeutic target.

Inducible Knockdown of Shroom3 Induces Proteinuria with Podocyte Dedifferentiation

Madhav G. Menon, Chengwen Wei, Karen Lok Yee Keung, Ilana Greene, Weijia Zhang, John C. He, Barbara T. Murphy. Medicine, Icahn School of Medicine at Mount Sinai; New York, NY.

Background: Intrinsic loci in Shroom3 have been associated with CKD and CAN. A role for Shroom3 in the podocyte cytoskeleton has been shown. However Shroom3 knockout mice die neonatally with neural tube defects and detailed renal phenotypes are unknown. Here we report our findings from Doxycycline (DOX) inducible, shRNA-mediated shroom3 knockdown mice.

Methods: In these mice Shroom3-specific shRNA expression was induced upon DOX feeding, with RTTA expression in all cells driven by CAGS-promoter. Six-wk old mice were fed DOX-feed/water. Non-DOX fed littermates were controls (n=6 each). At 4- and 8-weeks, renal tissue was obtained for histology. Twenty-five glomeruli were analyzed per mouse and quantification was used imaging.

Results: DOX-mice developed significantly increased Albumin-to-creatinine ratios starting at 2 weeks compared to controls.

Proteinuria persisted at 8 weeks of DOX feeding. No light microscopic changes were detectable on PAS-stained sections in Shroom2 knockout mice or control mice. Kidney mesangial matrix expansion or intratubular protein casts was observed up to 8-weeks of DOX feeding. Assessment of WT-1 stained nuclei/glomeruli by immunofluorescence (IF) showed no reduction in podocyte number at 4- or 8-weeks in DOX-mice compared to controls (p>0.05). By 8-weeks, however, IF staining revealed that area and intensity of glomerular synaptopodin staining was observed by 4 weeks in DOX-mice compared to controls (p<0.001; n=3 each at 4-wks, Fig 2). Electron microscopic studies are ongoing.

Conclusions: Our preliminary findings suggest that inducible and global knockdown of Shroom3 induces podocyte dedifferentiation features of podocyte dedifferentiation without evidence of podocyte loss. Further studies are needed to elucidate the precise role of Shroom3 in proteinuria and its function in the glomerular filtration barrier.

FR-PO326

Protective Role of Cyclodextrin in Focal Segmental Glomerulosclerosis (FSGS)

Alla Mitrofanova, 1 Patricia R. Wahl Pristau, 1 Ximena A. Morales, 1 Mayrin Correa-Medina, 2 Christopher E. Pedigo, 1 Gloria Michelle Ducasa, 1 George William Burke, 2 Sebastian Martini, 2 Matthias Kretzler, 2 Sandra M. Merscher, 1 Alessia Fornoni, 1 Katz Family Drug Discovery Center, Nephrology and Hypertension, Univ. of Miami, FL; Surgery, Univ. of Miami, FL; Internal Medicine, Nephrology, Univ. of Michigan, MI; 1Computational Medicine and Bioinformatics, Univ of Michigan, MI.

Background: We recently demonstrated that cholesterol accumulation contributes to podocyte injury in diabetic kidney disease (DKD), where 2-hydroxypropyl-β-cyclodextrin (CD) protects podocytes from cholesterol-dependent damage in vitro and in vivo. We hypothesize that lipid related genes are affected in glomeruli of patients with primary FSGS and that these genes are associated with experimental podocytes high in CD.

Methods: Microarray analysis on glomerular transcripts of lipid-related genes from patients with FSGS (n=54) and from normal living donors (n=6) were obtained from patients enrolled in NEPTUNE, a longitudinal observational cohort looking at individuals with proteinuria. 5-week-old BALB/c female mice were injected with a single intravenous dose of adriamycin (ADR, 11 mg/kg) to develop FSGS-like lesions. 24-hours after ADR injection, osmotic pumps with CD in 0.9% saline solution (40 mg/kg/day) were implanted under the skin for 10 weeks. Measurements of body weight and urine collections for ACR (Albumin/creatinine ratios) were performed weekly. At time of sacrifice, serum creatinine and Blood Urea Nitrogen (BUN) were determined and kidneys collected for histological analysis.

Results: Microarray analysis of the glomerular transcripts in the NEPTUNE cohort demonstrated that cholesterol efflux related genes, such as PLIN3, S1PR2, S1PR1, S1PR1, and lipid dysmetabolism related genes, such as SCD, LDLR, ABCG1, were increased in FSGS. CD administration reduced mesangial expansion as well as ACR and BUN observed at 10 weeks in the ADR+CD group compared to the ADR group (p<0.05). No changes in body weight were found.

Conclusions: We demonstrated that glomerular lipids are altered in FSGS and that 2-hydroxypropyl-β-cyclodextrin protected podocytes in an experimental model of FSGS. Our data suggest that CD could be used as a safe and effective drug therapy in FSGS patients.

Podocyte-Derived Cxcl12 Has a Dual Role in Glomerular Injury and Regeneration

Simone Romoli, Santhosh Kumar Ve, Shrikant R. Mulay, Hans J. Anders. Nephrologisches Zentrum, Klinikum der Univ Muenchen; Munich, Bavaria, Germany.

Background: Stromal-derived factor (SDF)-1/CXCL12 is a homeostatic chemokine facilitating homing and activation of stem cells. Podocytes constitutively produce CXCL12, hence, we speculated on a role of CXCL12 in glomerular regeneration upon injury.

Methods: Glomerular injury was induced by a single i.v. injection of 13mg/kg adriamycin (ADR) in male Balb/c mice, which received either the CXCL12 inhibitor NOX-A12 or the inactive control s.c. at 13.4mg/kg thrice a week. Renal progenitor cell properties (RPC) were used for in vitro studies.

Results: ADR-induced podinuria peaked at day 7 (injury phase), which subsequently declined without returning back to baseline and being associated within FSGS lesions after 14 days (repair phase). CXCL12 blockade aggravated ADR-induced A/C and podocyte loss at day 7, which implies an autocrine role of CXCL12 for podocyte survival. In contrast, CXCL12 blockade reduced A/C levels and the glomerular sclerosis scores as well as increased podocyte numbers at 14 days indicating a beneficial effect of CXCL12 blockade during the repair phase. The pro-survival effect of CXCL12 on podocytes was further confirmed in a model of dipheria toxin-induced podocyte depletion using CXCL12 blockade. To investigate the dual effect of CXCL12, we focused on the Notch signaling pathway. ADR injection reduced native Notch expression, which was reversed following CXCL12 blockade. In vivo studies with RPC revealed that CXCL12 suppressed RPC proliferation, which was reversed with CXCL12 inhibitor. Similar results were obtained when RPC were exposed to supernatants from necrotic podocytes. CXCL12 blockade also increased the capacity of RPC to differentiate into podocytes.

Conclusions: Podocyte-derived CXCL12 has a dual role in glomerular injury. CXCL12 protects podocytes during the injury phase in an autocrine manner by suppressing Notch signaling, which otherwise triggers mitotic catastrophe and podocyte loss. Podocyte-derived CXCL12 assures Notch-mediated quiescence of RPC. Our data also demonstrate that therapeutic CXCL12 inhibition in glomerular injury can improve long term outcomes possibly by enforcing the intrinsic regenerative capacity of RPC.

FR-PO328

Shank2 Modulates Glutamatergic Signaling in Podocytes

Eugenia Dobrinskikh, 1 Linda Lewis, 1 R. Brian Doctor, 2 Judith Blaine, 1 Medicine, Univ of Colorado, Aurora, CO; 2Biology, Univ of Mississippi, Oxford, MS.

Background: Shank2 is a large scaffolding protein that is a master regulator of glutamate receptors at the neuronal postsynaptic density. Knockout (KO) of Shank2 in mice leads to autistic behaviours and abnormal glomerular filtration. Shank2 is also known to be expressed in podocytes. Shank2 has been shown to express functional N-methyl D aspartate (NMDA) and metabotropic glutamate receptor 1 (mGluR1) receptors which are both members of the glutamate receptor family.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

429A
Results: We have found that podocytes express Shank2 in vivo and in vitro. Since Shank2 plays an important role in regulating glutamate receptor function, we examined the effect of Shank2 knockout on NMDA and mGlur1 expression and function in podocytes. Shank2 KO resulted in decreased expression of NMDA and mGlur1 receptors in glomeruli. We isolated podocytes from wild type and Shank2 knockout mice and created conditionally immortalized Shank2 KO podocytes. Conditionally immortalized Shank2 KO podocytes also demonstrated decreased expression and altered localization of glutamate receptors. In neurons, activation of glutamate receptors modulates intracellular calcium levels by allowing calcium influx into the cell (NMDA receptors) or release of calcium from intracellular stores (mGlur1). Fluo-4, a calcium sensing dye, we examined intracellular calcium levels in wild type and Shank2 KO podocytes. At baseline, Shank2 knockout podocytes had significantly fewer calcium spikes than wild type podocytes. Treatment with NMDA and gluta-mate increased the number of calcium spikes in both wild type and Shank2 KO podocytes but the number of spikes in the KO podocytes was significantly reduced compared to wild type. Podocytes have been shown to communicate with each other via calcium waves. To examine podocyte to podocyte communication after injury, we “burned” a podocyte using high intensity laser power and then examined calcium wave propagation from the site of injury. After burning, wild type podocytes exhibited calcium waves emanating from the injured podocyte whereas no waves were seen in the knockouts.

Conclusions: Taken together these data indicate that Shank2 regulates glutamate receptor function in podocytes.

FR-PO329
Podocytes Transcytose Albumin and IgG Using the Neonatal Fc Receptor (FcRn) In Vitro and In Vivo
Evgenia Dobriniskikh,1 Linda Lewis,2 Jeffrey B. Kopp,3 Judith Blaine.1 Medicine, Univ of Colorado, Denver, CO; 2Kidney Disease Section, NIDDK, NIH, Bethesda, MD.

Background: Proteinuria is strongly associated with kidney disease progression. Podocytes are key constituents of the glomerular filtration barrier (GFB), which determines the selectivity of protein filtration. By even the most conservative estimates between 2 and 9 g of serum proteins a day normally pass through the GFB. The molecular mechanisms whereby podocytes handle albumin and IgG remain to be fully determined.

Results: We have found that transcytosis is the major pathway whereby cultured podocytes handle albumin and IgG. In other epithelial cell types, the neonatal Fc receptor (FcRn) is required to transcytose endocytosed albumin and IgG, thereby salvaging these proteins from degradative pathways. To examine the role of FcRn in albumin and IgG transcytosis in podocytes, we knocked down FcRn in cultured podocytes using lentiviral short hairpin (shRNA). FcRn knockdown (KD) resulted in a 71 ± 9% decrease in FcRn expression compared to control. In an in vitro transcytosis assay, FcRn KD increased intracellular accumulation and decreased appearance of albumin and IgG in the supernatant, suggesting impaired transcytosis, but the differences were not statistically significant, possibly due to residual FcRn. We therefore isolated podocytes from wild type (WT) and FcRn knockout (KO) mice and created conditionally immortalized WT and KO podocyte lines. Knockout of FcRn resulted in significantly increased intracellular accumulation, assessed by immunostaining and Western blot (demnetometric analysis of intracellular protein 1 hr after loading showed 0.37 ± 0.1 (WT) vs 0.97 ± 0.2 (KO), p<0.05 for albumin and 0.52 ± 0.04 (WT) versus 1.03 ± 0.19 (KO), p<0.05 for IgG), and decreased appearance of supernatant albumin or IgG, indicating defective transcytosis. We extended our studies to an in vivo model by creating a podocyte-specific FcRn KO mouse. Podocyte-specific FcRn KO mice demonstrated impaired transport of endocytosed albumin or IgG by 8 weeks of age, assessed by immunostaining. Studies of albuminuria are in progress.

Conclusions: Taken together, these studies indicate that podocytes in vitro and in vivo transcytose albumin and IgG using FcRn.

FR-PO330
Transcriptional Reprogramming by Wilms' Tumor 1 and FoxC2 in Glomerular Disease
Sandrine Synge,1 Christian Schrader,2 Jochen Reiser,1 Ellen Kruithof,1 Ellen Gahr,1 Ellen Kruithof,2 Marius Vischer,1 Martin G. Zeier,1 Ellen Kruithof,2 Ellen Kruithof,1 Ellen Kruithof,1

Background: Wilms’ Tumor-1 (WT1) and FoxC2 have been associated with glomerular disease. WT1, which is important for barrier function. We detected a filamentous pattern of the hantaviral cytoskeleton, because the filamentous pattern protein has been associated with glomerular disease.

Methods: We now use ChIP-Seq to study the DNA binding of WT1 to target genes in the context of Adryanicism-induced podocyte injury that is considered a model for human FSGS. WT1 ChIP-Seq was performed using isolated glomeruli from 6 days post-injection or control Balb/C mice. FoxC2 binding was determined by direct ChIP-qPCR.

Results: Expression of WT1 and FoxC2 decreased in podocytes, as did binding of WT1 and FoxC2 to their common targets. WT1/FoxC2 target gene expression was also reduced. In contrast to these WT1/FoxC2 target genes that represent a set of genes normal for podocyte function, we identified a second set of WT1-bound genes, not bound by FoxC2, including Hduc5 and 7, whose expression increased after podocyte injury and whose binding decreased, suggesting that WT1 acts as a repressor for a distinct set of target genes.

Conclusions: These results suggest a model whereby WT1 and FoxC2 activate gene expression in normal podocytes, while WT1 represses other genes in normal podocytes independently of FoxC2.

FR-PO331
A Basophilic Kinase Site at the N-Terminus of TRPC6 Controls Channel Activity
Hennig Hugmann,1 Markus M. Rischmehl,1 Alexander Kuczkoowski,1 Stuart E. Dryer,1 Bernhard Schermer,1 Thomas Benzing,1 Paul T. Brinkkoetter.

1Nephrology, Univ Hospital Cologne, Cologne, Germany; 2Bichemistry, Univ of Houston, Houston, TX.

Background: The non-selective cation channel TRPC6 plays a pivotal role in the development of proteinuric kidney disease. Hyperactivity of TRPC6 either through gain of function mutations, increased total protein levels or membrane abundance of the channel protein has been associated with glomerular disease.

Methods: To investigate regulation of the TRPC6 channel activity we conducted mass spectrometry experiments to screen for phosphorylation sites in the TRPC6 protein. We identified several new actions as previously known phospho-peptides. The serine residues in position 13 and 14 of the human TRPC6 protein are phosphorylated and embedded in a basophilic kinase motif. Substitution of the serine residue in position 14 with alanine (S14A) leads to a reduction of TRPC6 conductance in voltage clamp experiments in Xenopus oocytes.

Results: The atypical cyclin-dependent kinase (Cdks), a serine- threonine kinase expressed in the podocyte, is directed to basophilic motives. In the podocyte, Cdks is activated by the specific activators p35, p25, and Cyclin L1 in cell culture experiments a direct phosphorylation of TRPC6 by Cdks/p35 at position S14 could be confirmed with mass spectrometry and radioactive in vitro kinase assays. Co-expression of Cdks/p35 and TRPC6 enhanced channel conductivity of TRPC6 in voltage clamp experiments. This effect was abrogated by the amino acid substitution S14A.

Conclusions: A basophilic kinase site at the N-terminus of TRPC6 was identified which controls channel activity. As exemplarily shown for Cdks/p35, basophilic kinases phosphorylate TRPC6 at serine 14 and affect channel function. This site may serve as a molecular switch for TRPC6 activity and as a potential future drug target.

Hantaviruses Associate with Actin Fibers and Cause Podocyte Damage
Stefan Hägels,1 Alexandra Kowalski,1 Jochen Reiser,1 Martin G. Zeier,1 Ellen Kruithof,1 Ellen Kruithof,1

1Nephrology, Univ Hospital Heidelberg, Heidelberg, Germany; 2Dept of Internal Medicine, Rush Univ Medical Center, Chicago, IL.

Background: Characteristic for the clinical picture of Old World hantaviruses is an acute renal failure with often massive non-selective proteinuria. Previously, we showed that cell-to-cell contact proteins were disrupted and levels were decreased in infected human renal cells, correlating with the clinical picture. However, the exact mechanisms driving hantaviral pathogenesis are not well characterized.

Methods: Renal biopsies of patients with acute hantavirus infection were analyzed by electron microscopy. A human podocyte cell line was used for infection with Hantaan virus (HTNV). Cell-to-cell contact proteins were analyzed by immunoblotting, qRT-PCR and immunofluorescence. The cytoskeleton was examined by confocal microscopy and by depolymerising drugs. Cell motility was measured by migration assays.

Results: Analysis of renal biopsies revealed podocyte foot process effacement with loss of cell-to-cell contacts. To examine the underlying mechanism of hantavirus-induced alterations, we performed in vitro infection studies. We showed that HTNV had no influence on transcription levels of cell-to-cell contact proteins, indicating another mechanism of cell-to-cell contact disruption. Next, we focused on an impact on the cytoskeleton which is important for barrier function. We detected a filamentous pattern of the hantaviral nucleocapsid (N) protein which was associated with actin fibers. This N protein localization depends on the integrity of the actin cytoskeleton, since the filamentous pattern disappeared after actin depolymerization. Correspondingly, we measured decreased viral release waves after loss of N protein filaments. During infection, we revealed impaired podocyte motility as a functional consequence due to hantavirus-induced effects on actin dynamics and focal adhesions.

Conclusions: These results demonstrate that hantavirus infection leads to podocyte injury by morphological changes. Disruption of cell-to-cell contacts may be caused by the association of N protein and actin leading to changes in podocyte motility. These findings provide useful insights into the mechanism inducing renal failure.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

430A
Results: The mice showed variable levels of proteinuria and GS. p110γ-positive cells per glomerulus were correlated significantly with glomerular COL1A2 mRNA content. In culture, p110γ KD podocytes, but not WT cells, demonstrated increased membrane ruffling along with distinct Rac1 staining at the membrane, and KD podocytes were resistant to in vitro ADR treatment. WT cells expressing constitutively active p110γ showed decreased cytoskeletal stress and DEATH early after injury was detected, suggesting that p110γ activity directly mediates podocyte dysfunction.

Conclusions: p110γ expression in podocytes correlates with degree of GS, and therefore, a potential maker for GS. p110γ activity mediates podocyte damage by affecting signals that is critical for cytoskeletal structure.

Effects of FSGS-Associated Mutations on the Stability and Function of Myosin II

Turgay Moeller. Turgay Moeller, Ralf Hausmann, Thiago Strieder, Jürgen Ofenloch, Marcus J. Moeller. Nephrology and Immunology, Univ Hospital RWTH Aachen, Aachen, NRW, Germany.

Background: Myosin is expressed in podocytes and plays a key role in regulating the integrity of their cell-cell junctions, however, the effects of FSGS mutations on MyoII motor activity and stability have not been directly tested. In this study, we used a simple model organism, fission yeast Schizosaccharomyces pombe, to test the effects of FSGS-associated mutations on myosin activity. Fission yeast has only one class I myosin, MyoII, which is involved in actin patch assembly at the sites of endocytosis.

Methods: The amino acid residues mutated in the FSGS patients are conserved between human MyoII and yeast MyoII, which allowed us to introduce equivalent mutations into yeast myosin and use the resulting mutant strains for functional analysis. MyoII-GFP localization and stability was analyzed using fluorescence imaging and Western blotting, while MyoII functional activity was tested using growth and endocytosis assays.

Results: Yeast strains expressing mutant MyoII exhibited defects in growth and endocytosis similar to those observed in the myoII deletion strain. These mutations also disrupted MyoII localization to endocytic actin patches and resulted in mis-localization of MyoII to endosomes, linear membrane microdomains found in yeast cells. While both mutants examined in this study showed loss of function, one of these mutants was also characterized by the decreased protein stability.

Conclusions: Using the yeast model system we were able to determine that the kidney disease-associated mutations impair myosin functional activity and have differential effects on protein stability. This study provides the first example of using fission yeast as a model system to test the effects of FSGS mutations on MyoII function. This novel system allowed us to definitively establish for the first time the connection between the myosin motor activity and its ability to support normal glomerular filtration.

Vinculin Bind Zonula Occludens-1 (ZO-1) and Is Required for Podocyte Stabilization of the Slit Diaphragm following Injury

Xuefei Tian, Kazunori Inoue, Shutu Ishibe. Dept of Internal Medicine, Yale Univ School of Medicine, New Haven, CT.

Background: Cell-matrix interactions and intercellular junctions in podocytes are important factors to prevent protein leakage through the glomerular filtration barrier. Vinculin, a cytoplasmic protein, links the actin filaments to integrin-based cell-matrix proteins and cadherin-based intercellular junctions. We have observed that vinculin is highly expressed in podocytes, and appears to be critical in maintaining slit diaphragm integrity following injury through its interaction with ZO-1.

Methods: Wild type and Vcin−/− mice were analyzed to determine the role of vinculin in vivo, and primary podocytes were isolated for in vitro studies.

Results: Podocyte specific ablation of Vcin resulted in no significant difference in body weight, albuminuria, and kidney histology up to 18 months when compared to littermate controls. However, Pod−/−KO mice had significantly increased albumin/creatinine ratios following lippopolysaccharide (LPS) or rabbit anti-mouse glomerular basal membrane (NTS) induced podocyte damage respectively (284±40 vs 411±31 mg/mg, and 205±28 vs 314±38 mg/mg, P<0.05). In addition, loss of Vcin in podocytes resulted in worsened foot process effacement. Co-immunostaining of ZO-1 with Vcin in primary podocytes and isolated glomeruli with ZO-1 in the primary podocytes and isolated glomeruli respectively. Cell fractionation of control and Pod−/−KO podocytes treated with either LPS or proteinase sulfate (PS) revealed a mislocalization of ZO-1 and nephrin to the cytoplasm in the mutant podocytes when compared to the control. These findings were further validated by immunofluorescence imaging of the primary podocytes following LPS or PS-stimulation and from isolated glomeruli following LPS or NTS-stimulation. No changes in cell adhesion or focal adhesion number were observed between the control and Pod−/−KO podocytes following LPS or PS stimulation on various substrates.

Conclusions: Our results reveal an association between vinculin and ZO-1 in podocytes. Loss of Vcin in podocytes results in the mislocalization of slit diaphragm proteins ZO-1 and nephrin following injury, thus exacerbating proteinuria.

mRNA and protein expressions of Cytochrome P450 Family 24 (CYP24A1), VDR and vitamin D receptors. Proteins of co-repressors, proteins-activators of co-repressors, proteins-activators of co-activators and protein interactions in these complexes were evaluated by immunoprecipitation (IP) studies followed by Western blot analysis. Role of proteosomal degradation of VDR in AMs was determined.

Results: Both AT1R-BLK and VDA stimulated VDR complexes formation that differed in their composition and in their functionality. AT1R-BLK-induced VDR complexes contained unliganded VDR, SMRT, and phospho-histone deacetylase (HDAC3), whereas, VDA-VDR complexes were constituted by liganded VDR and CBP/p300. AT1R-BLK-induced complexes attenuated podocyte acetylin- histone (Ac-H3) levels and CYP24A1 expression, whereas VDA induced increasing and repressive expressions. On the other hand, VD-VDR complexes not only increased podocyte Ac-H3 levels but also enhanced CYP24A1 expression, thus suggesting their acetylating and gene activation properties. AT1R-BLK-induced podocyte SMRT inhibited expression of the pro-apoptotic gene BAX through down regulation of WIP1, and phosphorylation of Chk2 in high glucose milieu. Since SMRT-depleted podocytes lacked AT1R-BLK-mediated protection against DNA damage, it appears that SMRT is necessary for DNA repairs during AT1R-BLK.

Conclusions: AT1R-BLK provides podocyte protection in AMs predominantly through VDR expression and partly through unliganded VDR expression in 1, 25(OH)2D deficient states, on the other hand, AT1R-BLK contributes to liganded VDR expression in 25(OH)2D sufficient states.

FR-P0341

Background: Missense mutations in the NPHS2 gene, encoding podocin, are a major cause of familial and sporadic forms of steroid-resistant nephrotic syndrome (SRNS). Among them, those encoding endoplasmic reticulum (ER)-resident mutant proteins, e.g. R138Q, correlate with the most severe cases of SRNS.

Methods: We generated two human podocyte cell lines stably expressing 2HA-podocin or 2HA-podocinR138Q to perform comparative studies on podocin post-translational modifications and podocin degradation.

Results: We detected increased podocin S-nitrosylation and N-glycosylation in 2HA-podocinR138Q vs. 2HA-podocinwt podocytes, which may modify podocin topology, degradation and trafficking. We also suggest that a further interaction of podocinR138Q with the NADPH oxidase complex may contribute to its ER-retention.

Conclusions: These findings show podocin S-nitrosylation for the first time and suggest that increased S-nitrosylation and N-glycosylation may contribute to the defective trafficking and degradation of podocinR138Q, the product of the most frequent human podocin missense mutation and possibly of other pathogenic podocin missense mutants.

RAS Inhibition Enhances Proliferation and Migration of Cells of Renin Lineage (CoRL) as Progenitors in Experimental FSGS Julia Lichtnerk, Diana G. Eng, Jeffrey W. Pinnick, Kenneth W. Gross, Stuart J. Shankland.

1Div of Nephrology, Univ of Washington, Seattle, WA; 2Dept of Molecular and Cellular Biology, Roswell Park Cancer Inst, Buffalo, NY.

Background: RAS inhibitors are used therapeutically in proteinuric glomerular diseases. In focal segmental glomerulosclerosis (FSGS) where podocyte number is depleted, recent data showed that ACE-Inhibitors could improve podocyte number. Because adult podocytes cannot proliferate, their replacement by renal progenitors is critical for their regeneration in disease. The impact of RAS blockade on adult podocyte progenitors is not well understood.

Methods: Experimental FSGS characterized by podocyte depletion was induced by an antipodocyte antibody in two strains of Cells of Renin Lineage (CoRL) reporter mice (RenCre and RenCreER) where CoRL are fate mapped. Diseased mice were randomized at day 3, when podocyte number was depleted by 40%, to receive Enalapril or Losartan, or an anti-podocyte antibody in two strains of Cells of Renin Lineage (CoRL) reporter mice

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

432A
Conclusions: Following the abrupt depletion of adult podocytes in experimental FSGS, RAS inhibition induced slight regeneration of their progenitors. This regeneration of adult podocytes is likely in part due to proliferation and migration of CoRl progenitor cells into the glomerular compartment. We show the first time that RAS inhibition has the potential to stimulate progenitor cells necessary for kidney repair and regeneration following podocyte depletion.

SheCa Influences Nephrin Endocytosis and Protects from Glomerular Injury Claire E. Martin,1,2 Kelly A. Petersen,2 Lamine Aoudjijt,3 Tomoko Takano,2 Nina Jones.1 1Molecular and Cellular Biology, Univ of Guelph, Guelph, ON, Canada; 2Dept of Medicine, McGill Univ, Montreal, QC, Canada.

Background: The transmembrane protein nephrin is a key component of the slit diaphragm (SD). It has recently been postulated that nephrin turnover plays a key role in maintaining a healthy SD, and multiple theories regarding the role of nephrin phosphorylation in endocytosis are emerging. Tyrosine phosphorylation of the cytoplasmic tail of nephrin facilitates recruitment of several signaling proteins that regulate podocyte shape and thereby permselectivity of the SD. Previous work from our lab has identified and mapped the interaction between nephrin and the SheCa adaptor protein and demonstrated an early requirement for SheCa in maintenance of the filtration barrier in mice. Given SheCa's established role in endocytosis, we now hypothesize that SheCa may regulate nephrin endocytosis to ultimately maintain filtration barrier integrity.

Methods: Multiple approaches were used to measure the influence of SheCa and SheCa domain mutants on the levels of surface nephrin and signaling downstream of nephrin. Paroxynin aminocellulose (PAN) nephrin was induced in Sprague-Dawley rats for 0, 4, 7, or 14 days and nephrin endocytosis was monitored via biochemical analysis and immunofluorescence experiments.

Results: We demonstrate that SheCa expression is increased in podocytes in response to PAN injury, which is accompanied by activation of the stress-activated p38 and JNK MAP kinases. Interestingly, we found that transactivation of AP-1, which occurs downstream of nephrin activation as well as p38 and JNK, is attenuated by SheCa, and this effect is reversed by mutation of the SheCa SH2 domain, which mediates nephrin binding. Further investigation revealed that SheCa promotes nephrin endocytosis in a phospho-dependent manner by enhancing Src-mediated nephrin phosphorylation, its own binding to nephrin and endocytosis into EEA1-positive endosomes both in vitro and in PAN-treated rats.

Conclusions: Together these findings suggest a protective effect of SheCa in podocytes by influencing phospho-dependent nephrin endocytosis and possibly attenuating nephrin-mediated p38/JNK signaling in response to injury.

Podocyte Specific Response to Complement Challenge AnneKatrin Dettmar,1,2 Magdalena Riedl,2 Fred G. Pluthero,2 Moin Saleem,2 Jun Oh,2 Christoph Licht.1 1Dept of Pediatrics, Univ Medical Center Hamburg-Eppendorf; 2Dept of Pediatric Nephrology, Hospital for Sick Children; 3Academic Renal Unit, Univ of Bristol.

Background: There is a multilayered system of fluid phase and surface bound complement regulatory proteins, which ensure that complement activation occurs only on specific sites and spares the body’s own organs. Unrestricted complement activation is a main cause for damage in complement-mediated glomerulopathies such as CSG or membranous nephropathy (MN). In MN, podocytes, key components of the glomerular filtration barrier, are target of overshooting complement activation. The aim of this study was to characterize the complement defense mechanisms in podocytes and their response to complement challenge (CC).

Methods: We analyzed complement regulators by immunofluorescence, flow cytometry and qRT-PCR in immortalized human podocytes and compared them to blood grown endothelial cells (BOECs). Functionality of secreted complement factor H (CFH) was tested via a cofactor assay. In a model for CC (sensitization with antibodies against grown endothelial cells (BOECs). Functionality of secreted complement factor H (CFH)

Results: Inhibition has the potential to stimulate progenitor cells necessary for kidney repair and regeneration following podocyte depletion.

Ephrin-B1 Is Essential for the Formation and the Maintenance of the Integrity of the Silt Diaphragm Component: Inducible Podocyte-Specific Ephrin-B1 Deletion Causes Irregular Localization of Nephrin, NEPH1, CD2AP and ZO-1 Yoshiyasu Fukushima, Hiroshi Kawachi. Dept of Cell Biology, Inst of Nephrology, Nippon Univ Graduate School of Medical and Dental Sciences, Nigata, Japan.

Background: Ephrin and eph function as receptor-ligand pairs, and are reported to play multiple functions in several tissues. We have reported ephrin-B1 was expressed at the podocyte slit diaphragm (SD) and had an interaction with nephrin, a critical component of the SD (Kidney Int 72: 934, 2007). However, the function of ephrin-B at the SD is not well defined. In this study, the role of ephrin-B at the SD and the functional association of ephrin-B expression on podocytes were elucidated.

Methods: (i) The expression of the SD components (nephrin, NEPH1, podocin, CD2AP and ZO-1) were analyzed in tamoxifen-inducible podocyte-specific Ephrin-B1 knockout (KO) mice (Podocin-CreERT2; Ephrin-B1 fox/fox). (ii) The effect of the nephrin secretion on the molecular conformation of ephrin-B was analyzed.

Results: (i) Tamoxifen-induced inactivation of the ephrin-B1 gene at E18.5 resulted in the dislocalization of nephrin, NEPH1, CD2AP and ZO-1, although podocin dislocalization was not detected. These alterations of the molecular arrangement of the SD components were also detected in the mice of which ephrin-B1 was deleted at 3 month-old with tamoxifen (KO vs. cont, n=5: nephrin, score 3.11 vs 3.40, p<0.01; NEPH1: 2.97 vs 3.36, p<0.05; CD2AP, 3.01 vs 3.24, p<0.05; ZO-1: 3.28 vs 3.66, p<0.05). (ii) Not only nephrin but also ephrin-B was phosphorylated in the rat nephritic model caused by the injection with the antibody against nephrin, although phosphorylation of these molecules was not detected in SD of normal kidneys. The phosphorylation of these molecules were detected already at 1 h after the antibody injection. The ephrin-B phosphorylation was also induced by the treatment with the anti-nephrin antibody in HEK293 cells co-transfected with ephrin-B and nephrin. Conclusions: Ephrin-B1 is essential for the formation and the maintenance of the proper arrangement of the SD molecules. The stimulation to nephrin by the antibody phosphorylated not only nephrin but also ephrin-B, indicating ephrin-B is functionally associated with nephrin.

Ubiquitin C-Terminal Hydrolyse-L1 Deficiency in Podocytes Protects from Immune Complex Nephritis in Mice Julia M. Fechter,1 Marlies Sachs,2 Thorsten Wiech,2 RoFA. Stahl,2 Catherine Meyer-Schwesinger,1 Nephrology, University Clinic Hamburg, Hamburg, Germany; 2Pathology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Background: Ubiquitin C-terminal Hydrolyse-L1 (UCH-L1) is a central deubiquitinating enzyme of the neuronal ubiquitin proteasomal system. UCH-L1 is thought to regulate the intracellular pool of monoubiquitin in neurons. Recently we identified a de novo expression of UCH-L1 in podocytes of patients with membranous nephropathy. Upregulation of UCH-L1 correlated with disease progression, accumulation of ubiquitinated proteins and increased expression of podocyte-specific proteins in human and rodent podocytes. Inhibition of UCH-L1 enzymatic function in a rat model of membranous nephropathy decreased the abnormal protein accumulation and ameliorated the clinical course of disease. We generated mice with podocyte-specific UCH-L1-deficiency to investigate the role of UCH-L1 on novel expression in podocytes.

Methods: Mice with podocyte-specific UCH-L1-deficiency were generated by Cre-Lox technology and back-crossed into the C57/Bl6 background. Podocyte phenotype were evaluated by morphological (immunohistochemistry, electron microscopy) and biochemical techniques (Western blotting, proteasomal activity assays, real-time PCR) in unchanged and anti-podocyte antibody challenged wildtype and knockout mice.

Results: Unchanged podocyte-specific UCH-L1-deficient mice exhibited normal podocyte morphology throughout life and delayed age-related proteinuria accompanied by a decreased accumulation of poly-ubiquitinated proteins. Following induction of anti-podocyte nephritis, podocyte-specific UCH-L1-deficient mice showed decreased signs of podocyte injury and decreased proteinuria despite a comparable immunologic reaction to the injected anti-podocyte antibodies. Podocyte-specific proteins such as nephrin and podocin were increased and protein accumulation was decreased. UCH-L1-deficiency resulted in increased proteasomal capacity and activity in injured podocytes.

Conclusions: Podocyte-specific UCH-L1-deficiency protects podocytes from age-related degenerative changes and from immune complex nephritis through increased proteasomal capacity.

Adhesion and Repulsion of Podocytes: Role of EphB-Receptors Eva Koenjehausen, Julius Hoffacker, Lukas Ludwig Peter Heimann, Nils Tim Haep, Magdalena Woznowski, Ivo Quack, Lars C. Rump, Lorenz Sellin. Univ Hospital Duesseldorf.

Background: Eph-receptor kinases mediate cell adhesion and repulsion at specialized cell contacts. Eph-receptor kinases bind to their cell-membrane bound ligands, the ephrines. EphB1 and EphB4 have been localized at the slit diaphragm. The molecular function of the EphB1,2,3 receptors in podocytes is unknown so far. Permeability is a hallmark for
glomerular disease and results from disruption of the glomerular filter. The slit diaphragm is a specialized intercellular domain of EphB2 as EphB2.DC-YFP cells adhere to ephrinb1-CFP and vice versa) occurs in both cell types during repulsion. The repulsion is dependent on the intracellular domain of the EphB2 receptor and ephrinb1 ligand, truncated mutants of EphB2 (ephrinb1.CDC-CP) were analyzed.

**Results:** Human podocytes as well as murine glomeruli express EphB1, 2 and 3 receptors. Co-cultures of differentiating EphB2-YFP and ephrinb1-CFP podocytes show repulsion between the two cell types. Transendoxytosis (YFP particles in CFP cells and vice versa) occurs if both cell types during repulsion. The repulsion is dependent on the intracellular domain of EphB2 as EphB2.DC-YFP cells adhere to ephrinb1-CFP and ephrinb1.DC-CFP cells. However, repulsion is maintained in co-cultures of EphB2-YFP with ephrinb1.DC-CFP cells. Co-culture experiments of differentiated, confluent podocytes confirm the results presented above.

**Conclusions:** EphB2 receptors mediate podocyte repulsion upon binding to their ligand ephrinb1. The EphB2 receptor cytoplasmic domain seems to be crucial for repulsion. Maintaining the correct podocyte distance within the highly organised glomerular architecture is not well understood. These cell culture data provide a promising concept of potential regulation of podocyte distance in vivo.

Overexpression of the Splice Isoform VEGF165b Is Sufficient for Kidney Function in Mice When VEGF Receptors Are Depleted

**Background:** Podocyte over-expression of VEGF isoforms is low during normal physiological conditions. However, it is increased in renal pathologies like diabetic nephropathy and glomerular microaneurysms. VEGF isoforms increase podocyte permeability. Electron microscopy was used to examine the ultrastructure of the glomeruli, and immunofluorescence microscopy to determine the expression levels of podocyte and endothelial-specific proteins. Glomerular endothelial cells (GEnCs) in culture were used to determine the mechanism of action of VEGF isoform through VEGFR-2.

**Methods:** Podocyte-specific VEGF-A KO was induced via doxycycline for 10-14 weeks in WT, VEGF-A-KO and VEGF-A KO n/n-VEGF-A-b mice. In situ hybridisation confirmed a knock-down of VEGF-A. The kidney functional phenotype was determined through the urinary albumin creatinine ratio (uACR) and measurement of glomerular water permeability. Electron microscopy was used to examine the ultrastructure of the glomeruli, and immunofluorescence microscopy to determine the expression levels of podocyte and endothelial-specific proteins. Glomerular endothelial cells (GEnCs) in culture were used to determine the mechanism of action of VEGF isoform through VEGFR-2.

**Results:** The VEGF-A isoform alone is sufficient to increase the expression of anti-angiogenic VEGF-b, those studies suggest that VEGF-b is protective in renal function in diabetic rodent models. This study aimed to investigate whether constitutive podocyte over-expression of VEGF-b is able to rescue the injury phenotype seen in the inducible podocyte-specific VEGF-A KO mouse. The mechanism of action of VEGF-b within the glomeruli was also investigated.

**Conclusions:** Our study indicates that VEGF-A splice isoform manipulation could be a novel therapeutic avenue in chronic glomerular disease.

Deletion of the Major Soluble Flt1 Isoform from Mice Reveals New Vegf Decay Variants

**Background:** VEGF is an angiogenic cytokine that can induce vasculogenesis and angiogenesis in many different cell types. However, VEGF is also known to have anti-angiogenic effects, especially in the kidney. The mechanism of action of VEGF-A is complex and involves multiple isoforms. Ultra structural studies show glomerular basement membrane thickening and thickening of the basement membrane. Measurement of glomerular water permeability confirmed a knock-down of VEGF-A. The kidney functional phenotype was determined through the urinary albumin creatinine ratio (uACR) and measurement of glomerular water permeability.

**Methods:** To determine function of the soluble variant of Flt1 in the glomerulus, we generated a conditional KO model for the single sFlt1 (sFlt1 cKO) isoform reported in mice (removal of intron 13). Renal phenotype was examined by evaluating kidney function and histology. qPCR and Northern blot were used to identify splice variants of Flt1; 3’RACE was used to clone the spliced genes. Proteins of splice variants were generated by BacMam system.

**Results:** We generated sFlt1 cKO mice, and confirmed the deletion of Flt1 intron 13 using Southern blot. Surprisingly, it did not result in any overt kidney phenotype by 6 months of age. Northern blot and Western blot analyses revealed the existence of a major compensatory isoform, previously reported as human-specific. We also confirmed the existence of 17 new sFlt1 isoforms in RNA isolated from mice and 12 from human primary podocytes as well as mouse and human placenta samples. We present that the existence of these isoforms compensates for the loss of sFlt1 in our transgenic model. The functions of these isoforms warrant further investigation and may provide insight into regulation of Vegf levels, podocyte function and preeclampsia.

**Funding:** Government Support - Non-U.S.

Polarity Signaling at the Kidney Filtration Barrier: Questioning the Function of Par3A

**Background:** The slit diaphragm (SD) represents the only cell-cell contact in between neighbouring podocytes. Classical adherence as well as tight junction proteins are part of this protein-protein supercomplex including ZO-1, occludin, catenins and cadherins. Polarity signaling is critical to maintain the SD complex as the Par3/Par6/aPKC complex clusters at the SD via direct interaction of Par3 with nephrin via its PDZ-domains.

**Methods:** To understand the role of the Par3 proteins at the slit diaphragm, we generated a novel podocyte specific Par3A knockout mouse model where exon 6 is flanked by loxP sites. Following podocin:cre mediated recombination expression of all known Par3A clusters at the SD via direct interaction of Par3 with nephrin via its PDZ-domains.

**Results:** Mice were born in predicted Mendelian frequency. Par3A-/-mice were born as heterozygous Par3A+/− mice at birth and did not show any signs of disease in their later life. Even challenging Par3A-/- mice with the albumin overload model did not result in an overt glomerular phenotype. Therefore, we performed additional immunoprecipitation experiments for aPKCota out of immortalized mouse podocytes and carried out in LCM/MS analysis to identify the aPKCota podocyte interactome. Interestingly, the most abundant aPKCota interacting proteins were Par6 and Lgl1/2.

**Conclusions:** Our results challenge the current view of the aPKCota/PAR6 complex and its role at the slit diaphragm. In contrast to tight junctions where aPKC-signaling diagnosis clustering by Par3A, its role at the SD is independent of Par3A. Here Lgl1/2 seem to be the predominant interactors clustering aPKCota at the SD.

FR-PO352
Focal Segmental Glomerulosclerosis (FSGS) Permeability Factor (FSPF) Interacts with Glomerular Filtration Barrier Through Glycoconjugates Ram Sharma,1 Ellen T. McCarthy,2 Tarak Srivastava,2 Virginia J. Savin,3 Mukut Sharma.1 1Renal Research, KC VA Medical Center - MBRF, Kansas City, MO; 2Kidney Inst, KU Medical Center, Kansas City, KS; 3Renal Div, UMKC Children’s Mercy Hospital, Kansas City, MO.

Background: Galactose (Gal) blocks the FSGS serum-unduced increase in in vitro glomerular albumin permeability (P_{a}) (Trans Res 2008, 151:288-292) and decreases proteinuria in some patients with recurrent FSGS (NDT 2009, 24:2938-2940). Thus, the interaction of FSPF with glomerular cell surface glycoconjugates may play an essential role in its effect on the filtration barrier.

Methods: We selected sugars and lectins to model the interaction between glomerular glycoconjugates and FSPF. We used, (a) affinity techniques to evaluate the binding of FSPF with immobilized sugars (b) immunodeaminase to assess its significance in FSPF-induced increase in P_{a} and (c) Gal/N-acetyl Gal (GalNac)-specific lectin to determine the site of action of FSPF as FSPF mimetics.

Results: Plasma FSPF activity was retained by immobilized Gal, GalNac or galactosamine. Gal dose-dependently blocked FSPF-induced increase in P_{a} and partially reversed the effect of FSPF on P_{a} (p<0.01). In contrast, glucose, glucosamine or mannose did not interact with FSPF. Removal of sialic acid by neuraminidase diminished the FSPF-induced increase in P_{a}. We screened twenty Gal/GalNac-specific lectins as potential mimetics of FSPF. Only Dolichos biflorus agglutinin (DBA, 10 mg/mL) and Helix pomatia lectin (10 mg/mL) increased P_{a} to 0.65 and 0.55, respectively (p<0.001). The increases in P_{a} were like that induced by FSPF were blocked by Gal (100 µM) (p<0.001).

Discussion: The interaction of FSPF with glomerular cell surface glycoconjugates may play an essential role in its effect on the filtration barrier. Our novel findings regarding the affinity of FSPF for select sugars, the loss of activity after removal of sialic acid and the direct effect of certain lectins on barrier function provide new information regarding the molecular composition of FSPF and its interaction with glomerular proteins/glycolipids.

FR-PO353
EPB41L5 Is a Critical Regulator of the Kidney Filtration Barrier Christoph Schell,1 Martina Suhm,1 Manuel Rogg,1 Martin Helmstaedter,1 Mariko Hirano-Kobayashi,2 Tobias B. Huber.1 1Dept of Nephrology, Univ Medical Center Freiburg, Freiburg, Baden-Württemberg, Germany; 2Laboratory for Vertebrate Body Plan, Center for Developmental Biology - RIKEN, Kobe, Kobe, Japan.

Background: Podocyte loss represents the final common pathway of various glomerular pathologies. Hence, tightly regulated adhesion towards the glomerular basement membrane is a fundamental biological process of podglomerulopathy.

Methods: Based on podocyte single cell isolation and a mass-spec candidate approach the composition of podocyte focal adhesions was resolved. A combinatorial nephropathy model with a newly generated conditional mouse model and various high resolution microscopy techniques (TEM, STORM) the candidate protein EPB41L5 was analyzed.

Results: Knockdown of the EPB41L5 homolog Yurt in drosophila nephropathy resulted in abnormal glomeruli and decreased podocyte capacity. Evaluation of a condition laminin knockout model revealed a rapid loss of podocytes implicating its role in podocyte adhesion. Employing immunoglobulin electron microscopy and STORM super resolution microscopy EPB41L5 was clearly localized towards the basal compartment of podocytes, in close proximity to INTEGRIN-beta1. Further functional experiments revealed that loss of EPB41L5 resulted in decreased activation of INTEGRIN-beta1, reflected by altered migratory behavior of primary podocytes.

Conclusions: Our findings indicate that EPB41L5 is a highly conserved, specific regulator of podocyte adhesion by modulating focal adhesion composition and function. Future studies will need to clarify its potential implications in genetic and acquired glomerular pathologies.

FR-PO354
The Effect of Anti-PLA2R Autoantibodies on Human Podocytes In Vitro Marvline Fresaquet,1 Rachel Lennnon,2 Paul E. Brenchley.1 1Wellcome Trust Centre for Matrix Research, Univ of Manchester, Manchester, United Kingdom; 2Inst of Cardiovascular Sciences, Manchester Royal Infirmary, Manchester, United Kingdom.

Background: PLA2R was identified as a major target antigen in idiopathic membranous nephropathy. 70% of patients have circulating autoantibodies which bind this receptor on the podocyte leading to immune complex deposition in the glomerular basement membrane. We recently characterized the interaction on PLA2R antibodies. Herein, we present the first 3D model of PLA2R, domains and demonstrated that autoantibodies are of high affinity. We seek to understand if affinity-pure anti-PLA2R alone in the absence of complement can modulate podocyte function.

Methods: We prepared affinity-purified human anti-PLA2R (91% IgG4, 9% IgG2) and assessed podocyte morphology following autoantibody treatment using immunofluorescence staining of actin and measurement of cell surface area and circularity. Integrity of the filtration barrier was assessed by Electric Cell-substrate Impedance Sensing and the response of a confluent monolayer of differentiated podocytes to 10mg/ml purified human anti-PLA2R and apoptosis was measured by cleaved caspase-3 staining in podocytes and oxidative stress was measured with CellROX reagent in differentiated podocytes challenged with the autoantibody.

Results: We have developed an in vitro podocyte model to define mechanisms of anti-PLA2R effects on cell morphology and function. Purified anti-PLA2R altered podocyte shape, with rounding and loss of actin stress fibres within 24 hours. Integrity of a confluent podocyte monolayer was significantly reduced at 72 hours by anti-PLA2R but not by the IgG control. Within 30 minutes of anti-PLA2R treatment, there was evidence of caspase-3 cleavage in podocytes peaking at 6 hours promoting apoptosis. In the same time frame anti-PLA2R induced free radical generation (P<0.0001, treated v. untreated), triggering oxidative stress which could be neutralised using a scavenger.

Conclusions: Anti-PLA2R in the absence of complement activation modulates podocyte cell function by inducing changes in cell shape and monolayer permeability, activation of free radical production and apoptosis.

FR-PO355
Deletion of the Ste20-Like Kinase, SLK, in Podocytes Induces Injury Andrey V. Cybulsky,1 Elena Torban,2 Joan Papillon,1 Julie Guillermette,2 Natalya Belkina.1 1Medicine, McGill Univ, Montreal, QC, Canada; 2NIH, Bethesda, MD.

Background: SLK is essential for embryonic development, and may play a key role in wound healing, tumor growth and metastasis. Expression and activation of SLK is increased during recovery from ischemic acute kidney injury. Overexpression of SLK in glomerular epithelial cells/podocytes in vivo induces injury and proteinuria. Conversely, reduced expression of SLK protects against acute kidney injury and modulates cytokine expression and, motility. Tight regulation of SLK expression thus appears to be critical for normal renal structure and function. We address the role of SLK in podocyte function.

Methods: Podocyte-specific SLK knockout (KO) mice were produced by breeding mice with an FSPF transgenic mouse bearing exon 8-7 with podocin (NPHS2)-Cre mice. Loss of expression results in deletion of the kinase domain. Deletion of SLK exon 4-7 in glomeruli was confirmed with PCR.

Results: Podocyte-specific deletion of SLK resulted in albuminuria at 4-5 months of age in male mice, and 8-9 months in female mice, which persisted for up to 13 months (albumin/creatinine in KO was 2-3-fold above control). At 11-12 months, KO mice did not show renal histologic abnormalities by light microscopy, and glomerular area of KO was comparable to control. However, by electron microscopy, KO mice showed focal foot process effacement and microvillous transformation of podocyte plasma membranes. Mean foot process width was ~2-fold greater in KO, compared to control. By immunofluorescence microscopy, WT1-positive cells were reduced by 35% in KO mice compared to control, and staining for nephrin and podocytin was reduced in KO mice by 20-30%. SLK is reported to phosphorylate ezrin. Staining for phosphorylated ezrin/radixin/moesin (ERM) was reduced by 20% in KO glomeruli, in keeping with reduced SLK catalytic activity in glomeruli; however, tubular phospho-ERM staining was comparable in KO and control.

Conclusions: Podocyte-specific deletion of SLK leads to albuminuria, loss of podocytes and morphologic evidence of podocyte injury. Thus, SLK is essential to the maintenance of podocyte integrity as mice age. The mechanism may, at least in part, relate to ezrin phosphorylation and cytoskeletal integrity.

A Podocyte-Specific Knockout of the DNA Repair Gene Ercle Leads to Proteinuria and Focal Segmental Glomerulosclerosis Fabian Braun,1 Roman Aaron Akbar,1 Björn Schumacher,2 Wilhelm Bloch,1 Berhard Scherner,1,2 Thomas Benzing,1,2 Christine E. Kurschat,1,2 1Nephrology, Univ Hospital Cologne, Cologne, Germany; 2CECAD, Univ Hospital Cologne, Cologne, Germany; 3German Sport Univ Cologne, Cologne, Germany.

Background: The prevention and therapy of aging-related diseases will become a major public health problem. Among elderly patients mild to severe impairment of kidney function is common. Models to study renal aging have not been established yet. In a previous study, we identified a progeria mouse model of Ercc1-deficiency to exhibit expression profiles similar to those of glomerular aging in wt mice. Erc1 is involved in nucleotide excision repair, facilitating 5’ incision around bulky DNA lesions. In humans, the lack of Erc1 leads to a progeria phenotype. Thus, a podocyte-specific knockout of Erc1 may help us gain new insights into glomerular and podocyte aging processes.

Methods: Erc1fl/fl mice were bred in a mixed CD1/FVB background with CD1 mice to produce the Cre recombinase under the podocin promoter. We analyzed weight, urine and serum of animals at 7, 9, 11 and 13 weeks of age. Kidneys were fresh-frozen in OCT, fixed in paraformaldehyde and embedded in paraffin or prepared for electron microscopy.

Results: Erc1fl/fl mice are born in normal median rations and show no developmental abnormalities. We detected an onset of proteinuria at week 8 in aged animals. The normal weight curve compared to controls until week 11 to 18. 7 week old kidneys showed no morphological changes in light or electron microscopy. Male and female mice develop foot process effacement and focal segmental glomerular sclerosis at 9 weeks of age. This phenotype is aggravated by the knockout of Erc1 and kidney function showed sclerosis, interstitial fibrosis with tubular atrophy and tubular protein casts. We observed an increase in DNA damage shown by positive pH2A.X staining in glomerular nuclei at week 11.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Our study reveals a critical role for nucleotide excision repair in murine podocytes. This finding underscores the importance of podocyte DNA maintenance in these postmitotic cells. In ongoing studies we will characterize the role of Ercc1 in a podocyte cell culture model.

Mice Heterozygous for Rac1 in the Podocyte Are Protected against Nephrototoxic Serum Nephritis-induced Albuminuria, but Knockout Mice Are Not

Hila Roshanravan, Stuart E. Dryer.

Pathology, Univ of Michigan, Ann Arbor; MI; Renal Section, Boston Univ Medical Center, Boston, MA.

Background: Podocyte injury, either by genetic or acquired abnormalities, can lead to progressive proteinuria and glomerulosclerosis. Current treatments are not designed to specifically target the podocyte but are used for broader immunotherapeutic or anti-inflammatory purposes, thus podocyte-targeted therapies are needed. Rac1, a member of the Rho GTase family, has been suggested as a therapeutic target for podocyte injury. However we previously demonstrated that podocyte-specific Rac1 knockout mice have exacerbated albuminuria with a hypertensive injury model. We hypothesize that partial reduction of podocyte Rac1 is protective.

Methods: We employed the nephrotic serum (NTS) nephritis model, which causes predominant podocyte injury and high-grade proteinuria without appreciable inflammation, in wild-type (WT), podoRac1-KO (podoRac1-KO), and podocyte-specific Rac1 heterozygote mice (podoRac1-HET). A separate group of NTS-treated WT mice were given EHT1864 (40mg/kg), a Rac inhibitor. Mice were injected with NTS (1.5 mg/kg body weight) (n=8-10 mice per group) and placed in metabolic cages for 1 or 2 days for daily urine collection. Urine albumin was measured by SDS-PAGE gel with standard curve, normalized by urine creatinine.

Results: NTS treatment resulted in robust albuminuria in wild-type mice on days 1 and 2 with albumin-to-creatinine ratios (ACR) of 400-500 µg/mg. However, podoRac1-KO mice showed an equally robust albuminuric response on day 1, but less on day 2 compared to wild-type, suggesting accelerated recovery. In contrast, NTS treated podoRac1-HET mice demonstrated nearly 70% reduction in ACR compared to wild-type (130 versus 390 µg/mg, P<0.01). The Rac inhibitor EHT1864 was equally effective.

Conclusions: These results demonstrate that a partial reduction in Rac1 activity, through genetic or pharmacologic inhibition, provides a protective effect against NTS-mediated podocyte injury, whereas Rac1 deletion is not beneficial. Our findings should help guide the development and assessment of Rac1 inhibitors to target podocyte injury.

The Ectodomain of Syndecan-4 Increases Surface Expression of Podocyte TRPC6 Channels: An Essential Role for Integrin Signaling

Eunyoung Kim, Hila Roshanravan, Stuart E. Dryer. Biology and Biochemistry, Univ of Houston, Houston, TX.

Background: Excessive activation of podocyte TRPC6 channels has been implicated in glomerular diseases. Syndecan-4 (Sdc-4) is a type-1 single-pass proteoglycan that can be cleaved to produce a soluble product capable of paracrine and autocrine signaling. A previous study (1) showed that the Sdc-4 core protein increases the surface expression of TRPC6 in podocytes. Here we show that the Sdc-4 ectodomain can also modulate TRPC6 channels and describe some of the pathways that surround this effect.

Methods: Cell surface expression of TRPC6 was monitored using surface biotinylation assays and whole-cell patch clamp recordings from cultured mouse podocytes. Signaling pathways were examined using assays for activated components and selective inhibitors. Protein interactions were examined by co-immunoprecipitation and confocal microscopy.

Results: We have confirmed previous studies showing effects of over-expression and knockdown of Sdc-4 core protein on podocyte TRPC6 (1). In addition, exposing podocytes to Sdc-4 ectodomain caused an increase in the surface abundance of TRPC6, accompanied by an increase in cationic currents evoked by diacylglycerol (DAG). Sdc-4 ectodomain increased the generation of reactive oxygen species (ROS) and effects of Sdc-4 on TRPC6 were blocked by the ROS quencher TEMPOL. Exposure to Sdc-4 ectodomain caused activation of NFAc1 and Rac1, inhibition of RhOa, and increased the total abundance of b3-integrin in its severally phosphorylated forms. Hyperosmotic effects on TRPC6 persisted after inhibition of calcineurin or NFAT. The Sdc-4 core protein immunoprecipitated and co-localized with b3-integrin in podocytes. Moreover, effects of Sdc-4 ectodomain were inhibited by cileintide, an inhibitor of outside-in signaling through av-containing integrins. Exposure to TNF caused a marked increase in shedding of Sdc-4 ectodomain from podocytes into the surrounding medium. This also occurred after over-expression of Sdc-4 core protein.

Conclusions: Locally produced Sdc-4 ectodomain may play a role in regulating podocyte TRPC6 channels and may contribute to glomerular pathology. (1) Liu et al. (2012). Atheroscler Thromb Vasc Biol 32: 378-385.

Regulation of Fascin-1 by Mechanical Stress in Podocytes

Christian Scharf, Sandra Schordan, Elisabeth Rumpel, Katrin Darm, Silke Vogelgesang, Kerstin U. Amann, Henny Wegner, Jürgen Giebel, Karlheinz Endlich, Nicole Endlich. Anatomy and Cell Biology, Univ Medicine of Greifswald, Greifswald, Germany; ENT, Univ Medicine of Greifswald, Germany; Pathology, Univ Medicine of Greifswald, Germany; Nephropathology, Univ Hospital of Erlangen, Germany.

Background: Glomerular hypertension causes glomerulosclerosis via the loss of podocytes, which are challenged by an increased mechanical load. We and others have demonstrated that podocytes are mechanosensitive cells. However, the response of podocytes to stretch remains incompletely understood.

Methods: Using 2D fluorescence gel electrophoresis (2D DIGE), we analyzed the proteome of cells of our mouse podocyte cell line that were cultured on flexible membranes with or without cyclic biaxial mechanical stress (0.5 Hz, 5% linear strain, 3 d).

Results: Mechanical stress profoundly altered the podocyte proteome. Several spots containing the actin-bundling protein fascin-1 were differentially regulated by mechanical stress. By immunofluorescence, fascin-1 was found to colocalize with nephrin in mouse kidney sections. The presence of fascin-1 in foot processes was confirmed by immunoelectron microscopy. Knockdown of fascin-1 in cultured podocytes increased the cell loss in response to mechanical stress. The mRNA levels of fascin-1 were not affected by mechanical stress. However, mechanical stress resulted in an almost complete dephosphorylation of fascin-1. It is known that phosphorylation at Ser-39 regulates the bundling activity of fascin-1, e.g. required for filipodia formation. Podocytes expressing wild type GFP-fascin-1 and non-phosphorylatable GFP-fascin-1-S39A showed marked filipodia formation, being absent in podocytes expressing phosphorymorphic GFP-fascin-1-S39D. Finally, the immunofluorescence signal of phosphorylated fascin-1 was strongly reduced in glomeruli of patients with diabetic nephropathy as compared to glomeruli of healthy controls.

Conclusions: In summary, mechanical stress dephosphorylates fascin-1 in podocytes thereby increasing the actin-bundling activity of fascin-1. Fascin-1 may play an important role in the adaptation of podocytes to mechanical stress.

Deletion of the Vps34 Downstream Effector PIKfyve Establishes Milder Endocytic Dysfunction in Healthy Glomerular Podocytes Compared to Proximal Tubular Cells

Madhusudan Venkatareddy, Rakesh Verma, Sanjeevkumar R. Patel, Puneet Garg. Internal Medicine/Nephrology, Univ of Michigan, Ann Arbor, MI.

Background: The mechanisms by which the glomerular filtration barrier prevents the loss of large macromolecules and at the same time maintain the filter remain poorly understood. Recent studies have proposed that podocytes play an active role in both endocytosis of filtered macromolecules and maintaining the filtration barrier.

Methods: We generated podocyte and proximal tubular specific deletion of PIKfyve using the cre-loxP system. Indirect IF and immune EM was used to assess the endocytic pathways.

Results: Deletion of a key endosomal trafficking regulator, the class III phosphoinositoid 3-kinase or Vps34 in podocytes results in aberrant endosomal membrane morphology and podocyte dysfunction. We recently demonstrated that the vacuolation phenotype in cultured Vps34-deleted podocytes is due to the absence of a substrate for the Vps34 downstream effector PIKfyve. PIKfyve is a Fyve finger domain containing phosphoinositide 5-kinase that phosphorylates Vps34-generated phosphatidylinositol (PtdIns)3P to produce PtdIns(3,5)P2. PIKfyve perturbation and PtdIns(3,5)P2 reduction have been shown to result in massive membrane vacuolation along the endosomal system. We show here that deletion of PIKfyve in endocytically active proximal tubular cells resulted in the development of large cytoplasmic vacuoles that appear as a result of arrested endocytic traffic progression at a late-endosome stage. In contrast, deletion of PIKfyve in podocytes did not alter significantly the endosomal morphology even in aged, 18-month-old mice. However upon culturing, the PIKfyve-deleted podocytes obtained from the knockout mouse developed massive cytoplasmic vacuoles. Measurement of phosphoinositides using HPLC shows reduction of both PtdIns(3,5)P2 and PtdIns(3)P in PIKfyve deleted podocytes in vitro confirming reduced PIKfyve enzymatic activity following deletion. Using double fluorescent mtnmG mouse we were able to confirm Cre-mediated gene deletion in both podocytes and proximal tubular cells in vivo.

Conclusions: In summary, these data suggest that healthy podocytes have a low level of endocytic flux in vivo.

Albumin-Induced Podocyte Injury Can Be Endocytosis-Independent
Shipra Agrawal,1 Xiaojie Nie,1 Tetsuya Kitao,2 Melinda A. Chanley,1 William E. Smoyer,2 1Clinical and Translational Research, Research Inst at Nationwide Children's Hospital, Columbus, OH; 2Pediatrics, Ohio State Univ, Columbus, OH.

Background: Endocytosis plays a crucial role in podocytes in nephrotic syndrome, wherein podocytes are exposed to serum levels of albumin. We have previously reported an association between podocyte exposure to albumin (and its associated factors) and podocyturia, cell injury and induction of pro-inflammatory genes. We thus hypothesized that albumin-induced podocyte injury can also be partially endocytosis independent.

Methods: Endocytosis was analyzed by fluorescent microscopy and fluorometry in cultured differentiated podocytes at varying temperatures and times and in the absence or presence of inhibitors of clathrin- and caveole-mediated endocytosis. Cells were analyzed for viability, activation of major kinases (p38, ERK1/2, JNK, MK2), and expression of pro-inflammatory, heat shock, and glucocorticoid-regulated genes.

Results: Endocytosis occurred at 37°C, but not at 4°C, and was attenuated by inhibitors for both clathrin- and caveole-mediated endocytosis. Inhibition of endocytosis, however, did not correlate with reductions in kinase activation or pro-inflammatory gene induction. While albumin exposure resulted in lower endocytosis in murine vs. human podocytes, murine cells activated kinases, induced pro-inflammatory genes and exhibited cell death more than human podocytes.

Conclusions: Inhibition of both clathrin- and caveole-mediated albumin endocytosis did not correlate with activation of kinases and induction of pro-inflammatory genes in podocytes. Moreover, disparate responses were identified in human vs. mouse podocytes with regard to albumin endocytosis, cell injury, kinase activation, and pro-inflammatory gene induction. Taken together, our data suggest that podocytes endocytose albumin in both clathrin- and caveole-mediated manners, albumin-induced podocyte injury can occur in an endocytosis-independent manner.

Genome-Modeled Pluripotent Stem Cells Reveal a Critical Role for Podocalyxin in Human Podocyte Morphogenesis
Benjamin S. Freedman,1,2 Craig R. Brooks,1 Jing Zhou,1 Joseph V. Bonventre,1,2 Brigham and Women’s Hospital; 2Harvard Medical School; 3Univ of Washington School of Medicine.

Background: Human pluripotent stem cells (hPSCs) can self-renew extensively and differentiate into diverse tissues. We investigated the potential of hPSCs to differentiate into kidney podocytes, and used CRISPR/Cas9 gene editing to explore the function of podocalyxin, an apical sialomucin altered in glomerular disease states.

Methods: Cas9 nucleases and guide RNAs targeting PODXL were transfected into hPSCs. PODXL+ clones were identified by chromosome and immunoblot analysis. hPSCs were differentiated stepwise with growth factors into kidney progenitor cells (Six2+PAX2+) and subsequently kidney tubular organoids. Podocyte marker expression was investigated by confocal microscopy in unmodified or PODXL- organoids of otherwise identical genetic background.

Results: In kidney organoids, podocyte markers including podocalyxin, WT1, and synaptopodin were strongly expressed in tight clusters of spherical cells, which resembled capillary or early-stage podocytes by electron microscopy. These cells did not react with LTL, but arose in capsule-like termini in LTL LRP+ proximal tubules. Podocalyxin coated the plasma membrane, whereas ZO-1, synaptopodin, and β-catenin co-localized in linear tracks between adjacent cells. PODXL- hPSCs differentiated into similar clusters, which did not express podocalyxin. In PODXL+ clusters, ZO-1, synaptopodin, and β-catenin failed to organize into linear tracks, instead migrating laterally in a diffuse expression pattern. This correlated with a ~ 40 % decrease in intercellular distance between nuclei, compared to unmodified isogenic controls.

Conclusions: hPSCs can differentiate into cells resembling immature podocytes. Podocalyxin is dispensable for podocyte specification, but is required for proper organization of junctional complexes and podocyte spacing. Our findings suggest a functional role for podocalyxin in the establishment of human podocyte architecture. Genome-modified hPSC-podocytes present a new tool for investigating human podocytes, with potential for ‘disease in a dish’ models and therapeutic screens.

Molecular Targeting of Nephi 1 Signaling: A Therapeutic Approach to Protect Podocyte Injury
Deepak Nihalani,1 Eshetam Ari,2 Fru Ashish,3 Lawrence B. Holzman,1 1Medicine, Univ of Pennsylvania, Philadelphia, PA; 2Proteomics, Inst of Microbial Technology, Chandigarh, India; 3Medicine, Temple Univ, Philadelphia, PA.

Background: Glomerular injuries that induce podocyte dysfunction are the leading causes of renal malfunction. Podocyte proteins Nephrin and Nephrin are essential components of the glomerular filtration barrier and signaling from these proteins is involved in maintaining podocytes structure and function. Thus understanding the mechanisms that regulate signaling and organization of these proteins are therapeutically valuable.

Methods: This study presents a novel hypothesis that attenuating Nephrin in Nephrin and Nephrin signaling is therapeutically significant in protecting podocytes from injury. Consistent with this hypothesis, using a unique protein transduction approach, we recently demonstrated that inhibiting Nephrin signaling protected podocytes from injury. Since we first reported the structural properties of Nephrin1-PODXL-67, we used recombinant novel molecules or compounds that can specifically bind Nephrin and target its interactions.

Results: Using a novel approach of targeting protein-protein interaction, we identified many potential molecules and to test the proof of principle and the validity of this approach, we evaluated compounds ID (sodiumcitrate) was commercially procured and investigated. Biochemical experiments suggested that addition of ID under in vitro and in vivo conditions significantly increased and stabilized the interaction between Nephrin and ZO-1. As a consequence, induction of glomerular injury by PAN (purnomycinaminonucleoside) did not significantly increase expression of Nephrin or podocyte cell death. Addition of ID to these cells resisted injury induced changes in their actin cytoskeleton. Furthermore, using an in vivo zebrashif model system, we demonstrated that pre-treatment with ID rescued zebrasfish from adriamycin induced toxicity and preserved their renal filtration system.

Conclusions: Collectively, this is the first study that provides compelling evidence that molecular approaches can be used to directly target slit diaphragm proteins to prevent podocyte damage.

Extracorporeal Mesenchymal Stromal Cell Therapy for Critical Care
Biju Parekkadan, Surgery (Bioengineering), Harvard Medical School, Massachusetts General Hospital, Boston, MA.

Background: Human mesenchymal stromal cells (MSCs) metabolette and secrete anti-inflammatory and regenerative factors that can be of systemic benefit to acute, critical injury. When transplanted MSCs are limited in dose and rapidly cleared by the host when they are prohibited or reduced, we investigated if this therapy for the development of a bioreactor technology to maintain MSC viability at high fidelity and continuously deliver secreted factors into the blood stream in a clinical setting.

Methods: MSCs were integrated into hollow-fiber bioreactor devices whereby the cells, separated by a permeable membrane, can directly and dynamically provide systemic therapy without entering the body. We present a human scale prototype of the technology that has shown sustained cell viability and function throughout cGMP manufacturing in preparation for a Phase I human trial set to begin in 2015.

Results: The presentation will also report encouraging in vivo therapeutic trials in a large animal (canine) model of ischemic acute kidney injury (AKI) where 91% of animals survived compared to 50-60% in control arms. Pharmacological analysis of this bioreactor technology in vivo allowed for an unprecedented look at MSC function during product use and verified potency that is unattainable by conventional intravascular delivery of MSC.

Conclusions: A combined approach to optimize MSC therapy that employs pharmacology principles and cell delivery strategies will be essential to translating this cell therapy product to humans for AKI and other critical organ dysfunction syndromes.

Extracorporeal Diffusive Clearance of Silicon Nanopore Membranes in a Pulmonary Porous Blood Circuit
Steven Kim,1 William Moses,1,2 Juchyun Park,3 Clarence Chow,4 Charles Blaha,1 Zohora Iqbal,1 Rishi Kant,1 Benjamin Chui,1 Ken Goldman,4 William Henry Fissell,4 Shuvo Roy,1,3 1Nephrology, UCSF; 2Surgery, UCSF; 3Bioengineering, UCSF; 4Silicon Kidney, LLC; 5Ben Chui Consulting; 6H-Cubed; 7Nephrology & Hypertension, Vanderbilt Univ.

Background: Silicon nanopore membranes designed for hemofiltration (HF-SNMP) have demonstrated increased permeability compared to polymer membranes. Previously, we reported in-vitro data showing a 3-fold improvement in diffusive clearance using SNMP optimized for diffusion (HD-SNMP). Here we test the diffusive clearance of HD-SNMP vs HF-SNMP in an extracorporeal pore model without a blood pump.

Methods: A microelectromechanical systems fabrication technique was used to decrease the SNMP thickness (HD-SNMP 100 µm vs HF-SNMP 400 µm). Polyethylene glycol coated HD-SNMP (n=3) and HF-SNMP (n=3) with sub-10nm pore sizes were tested in a single channel flow circuit (h=1mm). Vascular access was obtained by placing tunneled catheters within the carotid artery and jugular vein of healthy ~50kg pigs. Blood flow was achieved via the arterial-venous pressure differential (35-120ml/min). Dialysate was recirculated in a counter-current fashion (30ml) and flow rates were adjusted to ensure 0 transmembrane pressure. Dialysate creatinine concentration was measured hourly and serum creatinine was measured at time 0 and hours thereafter. The pore size of each SNM was measured before and after blood exposure using hydraulic permeability.

Results: Blood flow was maintained via the arterial-venous pressures differential with <5mmHg pressure drop. The average plasma creatinine concentration was 1.38±0.1mg/dL. The creatinine clearance was 37.2±3.9ml/min/m² (HF-SNMP) vs 126.0±27.1ml/min/m² (HD-SNMP) at 92.5±36.6ml/min. There was no detectable albumin transport into the dialysate and HD-SNMP maintained the mechanical integrity at over 250mmHg in vitro. These pore size changes following blood exposure was 1.4±2.3nm to 1.9±1.2nm for HF-SNMP and HD-SNMP, respectively.

Conclusions: This study demonstrates the successful transport of creatinine in an extracorporeal circuit without a blood pump. We also showed a ~3-fold improvement in diffusive clearance of creatinine using HD-SNMP in a blood circuit.

Hemofilter Design Based on Computational Simulations of Pulsatile Flow
Amanda Buck,1 Joseph J. Groszek,2 Clark David Kensinger,1 Daniel Colvin,1 Shuvo Roy,2 William Henry Fissell.2 1Dept of Radiology and Radiological Sciences, Vanderbilt Univ; 2Div of Nephrology and Hypertension, Vanderbilt Univ; 1Dept of Surgery, Vanderbilt Univ; 2Dept of Bioengineering and Therapeutic Sciences, Univ of California San Francisco.

Background: In the US, the ratio of patients with end stage renal disease (ESRD) on dialysis to annual kidney transplants for ESRD is 20:1 (USRDS 2014 Annual Data Report), underscoring the grave need for an artificial kidney alternative. Hypothesis: For the development of a hemofiltration device, computational fluid dynamics (CFD) simulations can predict potentially thrombogenic zones [e.g. low and high wall shear stress (WSS) areas, associated with stasis and shear induced cell damage, respectively] and can be used to refine device design to minimize such areas.

Methods: CFD simulations of pulsatile blood flow through a prototype hemofilter were validated in vitro using MR velocimetry. Hemofilters were implanted in large animals (n=4) for 30 days or until thrombosis and then explanted. Based on the CFD results, a subsequent flow path was devised to minimize predicted thrombogenic regions, and simulations were conducted on the second design.

Results: The in vitro and in silico models showed strong agreement. Pulsatile CFD simulations of the prototype device demonstrated zones of low WSS, and clot formation occurred in two of the four implants at the CFD-predicted sites. Flow simulations of the second-generation design showed reduced areas of low WSS.

Conclusions: Thrombogenic low WSS regions predicted in silico correspond with clot formation in vivo. In addition to predicting areas of thrombogenicity, CFD can be used to guide hemofilter device design to minimize these sites.

FR-PO367
Characterization of Dialyzer Membranes by MALDI-Mass-Spectrometric Imaging Techniques
Joachim Jankowski, Vera Jankowski. Inst of Molecular Cardiovascular Research, Univ Hospital RWTH, Aachen, Germany.

Background: Dialyzer polymer membranes are grossly classified as cellulose-based and synthetically produced membranes. Although cellulose membrane's clearance and mechanical properties qualify it for use in dialyzer membranes, hydroxyl groups of these membranes lead to strong activation of the complement system. Therefore, recent membranes are manufactured from synthetic polymers.

Methods: For physical and chemical characterization of these materials of dialyzer membranes a wide range of analytical methods is available. Over the last few years, MALDI mass-spectrometric analysis with imaging as additional spatial information has developed as a powerful tool for space-resolved analysis, not least because of its mass accuracy and high sensitivity. MALDI imaging techniques combine the potential of mass-spectrometric analysis with imaging as additional spatial information with relevance for biocompatibility of the dialyzer membranes. MALDI imaging enables the visualization of localization and distribution of biomolecules, chemical compounds and other molecules on different surfaces.

Results: In this study, surfaces of polymeric dialyzer membranes, consisting of polysulfone (PS) and polyvinylpyrrolidone (PVP) were investigated, regarding to chemical structure and compound's distribution. According to the manufacturing process laminar and abulmen membrane surfaces are characterized by differences in chemical composition and physical characteristics. MALDI imaging demonstrated that the abluminal membrane surface is more consisting of polysulfone than polyvinylpyrrolidone, the luminal membrane surface displayed more PVP than PS. The addition of PVP as hydrophilic modifier to polysulfone-based membranes increases the biocompatibility of the dialysis membranes. The analysis of polymer distribution is a relevant feature for characterization of dialysis membranes.

Conclusions: In conclusion, MALDI imaging is a powerful technique for polymer membrane analysis, regarding not only detection and identification of polymers but also localization and distribution in membrane surfaces, which has strong impact on the biocompatibility of the dialyzer membranes.

FR-PO368
Effect of Peristasis with Pediatric Catheters
Anna Lorenzin, Francesco Garzotto, Claudio Ronco. Nephrology and International Renal Research Inst Vicenza, St. Bortolo Hospital, Vicenza, Italy.

Background: Thanks to the technological advances of the last years, Continuous Renal Replacement Therapy CRRT machines have been upgraded and equipped with circuits specific for pediatric patients. To date, to treat these patients the most used catheter is the small T-French, however with a neonate this is inadequate for the dimensions. It is not clear if it is possible to use a smaller catheter with adult CRRT machine or a specific pediatric machine is needed. We set up a dedicated circuit to assess the usability of a peristaltic blood pump designed for adults and compare it with a pediatric pump in terms of access pressure. Frequency of pump was performed in vivo test with the pediatric pump and in vitro test with the adult pump.

Methods: A bilumen catheter was implanted in four adult patients with a venous pressure sensor. The device was validated in vitro using MR velocimetry. Hemofilters were implanted in large animals (n=4) for 30 days or until thrombosis and then explanted. Based on the CFD results, a subsequent flow path was devised to minimize predicted thrombogenic regions, and simulations were conducted on the second design.

Results: The in vitro and in silico models showed strong agreement. Pulsatile CFD simulations of the prototype device demonstrated zones of low WSS, and clot formation occurred in two of the four implants at the CFD-predicted sites. Flow simulations of the second-generation design showed reduced areas of low WSS.

Conclusions: Thrombogenic low WSS regions predicted in silico correspond with clot formation in vivo. In addition to predicting areas of thrombogenicity, CFD can be used to guide hemofilter device design to minimize these sites.

FR-PO369
Hemodialysis with CARPEDIEM Machine: An In Vitro Test
Anna Lorenzin, Dario Galaceo, Stefania Areu, Francesco Garzotto, Claudio Ronco. Nephrology and International Renal Research Inst Vicenza, St. Bortolo Hospital, Vicenza, Italy.

Background: Despite the development of continuous renal replacement therapies machines, their employment still remain unsuitable in new born and infants. This gap has been filled thanks to the coming of a specific pediatric dialysis machine CARPEDIEM. To date it is set up only for continuous hemofiltration CVVH: to provide a wider range of applications, specific filters have been conceived to implement a continuous hemodialysis CVVHD. We tested a prototype kit to evaluate its performance in terms of clearance K.

Methods: We performed in vitro test with plasma for the 3 filters HD010 HD020 HD050 (surface 0.1, 0.2, 0.35m²). Fibers were put manually into the housing of CVVH filters. CVVHD in cocurrent configuration: otherwise a longer circuit is required. We set up a dedicate circuit to assess the usability of a peristaltic blood pump designed for adults and compare it with the adult pump in terms of access pressure.

Results: We are presenting the data of the two pumps with 5Fr catheter and 15ml/min flow rate. Analyzing the arterial pressure values, we found that the spikes are more frequent with the CARPEDIEM pump than with the adult one. The min and max value are respectively (-50, -28mmHg) and a mean Dp = 18mmHg with CARPEDIEM pump; (-61, -20mmHg) and a mean Dp = 40mmHg with adult pump (Fig.1).

Conclusions: We can notice that there is an high discrepancy in terms of Dp between the two pumps: high values of Dp lead to an high shear stress. As the shear stress is one of the main causes of hemolysis, it seems that a specific pediatric machine is advisable for neonates that need small catheter. Further investigation have to be perform with blood to confirm our results.
FR-PO370

Removal of Protein-Bound Uremic Toxins: Simulating the Effect of Toxin Displacement versus Increase in Dialyzer Clearance

Vaibhav Maheshwari, Stephan Thijsen, Doris H. Fuertinger, Franz Kappel, Peter Kotanko. Renal Research Inst, NY; Univ of Graz, Austria.

Background: Protein-bound uremic toxins (PBUT) exert numerous deleterious effects. Their removal with standard hemodialysis (HD) is poor. Meyer et al. have modeled the impact of increasing dialysate flow rate and dialyzer mass transfer area coefficient on PBUT removal [JASN, 2004]. Here, we compare those results to a novel approach based on PUBT displacement by infusion of binding competitors [Tao, Blood Purif, 2015].

Methods: We developed a multi-compartment patient model and a dialyzer model depicting spatiotemporal dynamics based on law-of-mass-action kinetics. We chose indoxyl sulfate (IS) as a prototypical PUBT and ibuprofen as the binding competitor. We modeled IS removal during a 4-hr HD (Q_{d}=250 mL/min, Q_{f}=750 mL/h, initial total IS 100 µmol/L, initial free fraction of IS 8%), with IS dialyzer clearances from 150 to 200 mL/min. This was compared to IS removal achieved by ibuprofen infusion (800 µg/200 mL) into the arterial line at 50 mL/hr (IS clearance 150 mL/min).

Results: IS removal during HD with a clearance of 150 mL/min was 438 µmoles (plasma reduction ratio 34%), which conforms to literature data [Niwa, Blood Purif, 2012]. With IS clearance of 200 mL/min, removal improved by 8.7% to 476 µmoles. With ibuprofen infusion (IS clearance back at 150 mL/min), removal improved by 11.2% to 487 µmoles.

Conclusions: Our model yields predictions of IS kinetics that agree with empirical and modeled data [Niwa et al.; Meyer et al.]. Of note, a mere 8.7% improvement in IS removal would require an increase in dialysate flow rate from 800 to 1350 mL/min plus a 70% increase in membrane surface area. The modeled ibuprofen infusion alone yields an 11.7% improvement even absent an increase in dialyzer clearance. The use of binding competitors holds great promise. These results require validation in vivo.

FR-PO372

Membrane versus Peristaltic Blood Pumps for Extracorporeal Therapies: Comparison on Index of Hemolysis

Francesco Garzotto, Sean M. Bagshaw, Claudia Ronco. Nephrology and IRRIV, St. Bortolo H., Italy; Critical Care Medicine, Univ of Alberta Hospital.

Background: Hemolysis during extracorporeal treatments mainly occurs as a consequence of mechanical stress on the blood. Red blood cell deterioration is undetected because it is far from any acute hemolytic threshold but represents a potential harm for patients. A new membrane-piston driven pump has been recently proposed on the S.A.M.(©Spectral Medical Inc, Toronto) device designed for continuous renal replacement therapies (CRRT). Aim of this investigation is to compare the membrane with peristaltic pumps by measuring the Normalized Index of Hemolysis NIH during in vitro testing.

Methods: Three sessions of hemoperfusion with a line inserted in place of a hemofilter were performed both with SAM and Prismaflex (©Baxter International). A single pool of fresh heparinized bovine blood (Heparin 500 UI/L, Hb 122 g/dL, Base Excess 0±5 mmol/L) were split into three aliquots containing 900 mL (Control, SAM, Prismaflex) and circulated for 6 hours/session. Blood:total samples were drawn at baseline, 30 min and every 1 hour. NIH were calculated as median hourly variation of free hemoglobin and used for comparison. Data was compared with two tailed Student’s t-test based on F-Test results.

Results: NIH values of 0.12±0.03 and 0.13±0.09 mg/100L for SAM and Prismaflex respectively are lower than those reported in literature due to the simplified circuit used (no vascular access and filter). Creation of hemoglobin between sam and control, and prisma and control are non-significant fig 1a. Slope of the curves that describe the creation of hemolysis are nearly identical with a slow rate of production of free hemoglobin.

FR-PO371

Membrane Driving Blood Flow for Extracorporeal Therapies

Francesco Garzotto, Sean M. Bagshaw, Anna Lorenzin, Mauro Neri, Claudia Ronco. Nephrology, St. Bortolo H.

Background: From the first application of Continuous Venovenous Hemofiltration CVVH, the blood flow has been driven by a peristaltic pump. Several attractive alternatives, with both advantages and disadvantages, have been proposed for many years. SAM (Spectral Medical Inc.; Toronto, Canada) is a novel instrument, in which the pumping of whole blood and fluids is performed through the use of pistons, chambers and valves. A plastic cartridge blood circuit system fig 1b incorporates all of the pumps, air trap system, pressure monitors and clamps. This circuit is covered on one side by a plastic membrane adhered to the pumping pistons via a drawn vacuum. Aim of the present is to evaluate the new pumping system.

Methods: We set up the machine for CVVH. An 11.5 Fr 20 cm catheter was connected to the lines. We ran the machine for 6 hours in order to characterize the performance of the system. During the first cycle, suction generated by the drawing back of the piston, moves the blood into the arterial-chamber AC. Positive pressure generated by the piston then drives the blood through the circuit. The camshaft design can allow different profiles for Withdrawal and infusion flows. The largest Priming volume measured (both the ACs full), is 98 ml with a stroke volume for each AC of 14ml.

Conclusions: CVVHD with CARPEDIEM seems to be effective for diffusion transport of small molecular weight solutes, according to specific clinical needs. In the light of these findings CARPEDIEM can be a promising alternative to peritoneal dialysis, i.e. in treating electrolyte imbalance with accurate fluid removal. Limitation: handmade filters could induce variability in the results due to disposition and variable number of fibers.

FR-PO375

Comparison of Blood Flow Profile Between a Two-Chamber Piston Pump and a Peristaltic Pump

Stephan Thijssen, Doris H. Fuertinger, Franz Kappel, Peter Kotanko. Renal Research Inst, NY; Univ of Graz, Austria.

Background: Protein-bound uremic toxins (PBUT) exert numerous deleterious effects. Their removal with standard hemodialysis (HD) is poor. Meyer et al. have modeled the impact of increasing dialysate flow rate and dialyzer mass transfer area coefficient on PBUT removal [JASN, 2004]. Here, we compare those results to a novel approach based on PUBT displacement by infusion of binding competitors [Tao, Blood Purif, 2015].

Methods: We developed a multi-compartment patient model and a dialyzer model depicting spatiotemporal dynamics based on law-of-mass-action kinetics. We chose indoxyl sulfate (IS) as a prototypical PUBT and ibuprofen as the binding competitor. We modeled IS removal during a 4-hr HD (Q_{d}=250 mL/min, Q_{f}=750 mL/h, initial total IS 100 µmol/L, initial free fraction of IS 8%), with IS dialyzer clearances from 150 to 200 mL/min. This was compared to IS removal achieved by ibuprofen infusion (800 µg/200 mL) into the arterial line at 50 mL/hr (IS clearance 150 mL/min).

Results: IS removal during HD with a clearance of 150 mL/min was 438 µmoles (plasma reduction ratio 34%), which conforms to literature data [Niwa, Blood Purif, 2012]. With IS clearance of 200 mL/min, removal improved by 8.7% to 476 µmoles. With ibuprofen infusion (IS clearance back at 150 mL/min), removal improved by 11.2% to 487 µmoles.

Conclusions: Our model yields predictions of IS kinetics that agree with empirical and modeled data [Niwa et al.; Meyer et al.]. Of note, a mere 8.7% improvement in IS removal would require an increase in dialysate flow rate from 800 to 1350 mL/min plus a 70% increase in membrane surface area. The modeled ibuprofen infusion alone yields an 11.7% improvement even absent an increase in dialyzer clearance. The use of binding competitors holds great promise. These results require validation in vivo.

Enhanced Molecule Molecule Clearance by a Biomimetic Dialyzer Membrane
Joseph J. Groszek,1 Jin Cheng,1 Charles Blaha,2 Rishi Kant,2 Jaehyun Park,2 Benjamin Chui,3 Ken Goldman,4 Shuvo Roy,2 William Henry Fissell,1
1Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN; 2Bioengineering and Therapeutic Sciences, Univ of California, San Francisco, San Francisco, CA; 3Ben Chai Consulting, Sunnyvale, CA; 4H-Cubed, Inc, Olmstead Falls, OH.

Background: Although polymer dialyzers attain very high small solute clearance rates, polydispers pore sizes limit middle molecule clearance by conventional polymer dialyzers. We hypothesized that a biomimetic membrane with uniform slit pores would enhance middle molecule clearance.

Methods: Thin film silicon membrane samples (surface area 1.4 x 10^4 m^2) with monodisp pore size of 5-8 nanometer pores (“SNM-HD”) were manufactured as previously described, surface-modified with polyethylene glycol and mounted in a custom designed cartridge. Membrane pore size was estimated from hydraulic permeability measurements. Human blood was spiked with PABA and fluorescent-labelled Ficol, a polyanl sucrose globular polysaccharide. Blood flow was set at 100 ml/min and dialysate flow varied between 70 and 140 ml/min. Blood and dialysate concentrations of PABA and Ficol were measured by size-exclusion chromatography. Clearance as a function of dialysate flow rate was extrapolated to estimate Kea as a function of molecular weight.

Results: B2M clearance in high-flux dialyzers is typically 5-8% of the value of urea clearance. PABA clearance was 139 ml/min/m^2. 15.7Angstrom Ficol (same radius as B2M) clearance in the SNM dialyzers was 16.9 ml/min/m^2, 3.5 fold higher than reported B2M clearance in polymer dialyzers.

Conclusions: A biomimetic membrane of uniform slit pores potentially offers much higher middle molecule clearance than conventional polymer dialyzers.

FR-PO374
Anti-Fouling of Silicon Nanopore Membranes Using SLIPS Bas Meusen,1,2 Steven Kim,3 Zohora Iqbal,1 Charles Blaha,2 William Henry Fissell,1 Shuvo Roy.1 1UCSF, 2Univ of Eindhoven; 3Silicon Kidney; 4Vanderbilt Univ.

Background: Silicon Nanopore Membranes (SNM) have been developed for application in an implantable bioartificial kidney. However, SNM are subject to fouling and thrombosis with continuous blood exposure. Thin polymer coatings have been applied to SNM as a strategy to limit cell adhesion and protein adsorption. Slippery Liquid Infused Porous Surface (SLIPS) is a biotriposed “omniphobic” surface coating that has been reported to prevent thrombosis and fouling on arteriovenous shunts. Here we present the application of SLIPS coating to SNM and evaluate protein adsorption in vitro.

Methods: SNM with –10 nm pores were coated with SLIPS and incubated with BSA-FITC (2 mg/ml in PBS) for 24 hours at 37°C. Uncoated (bare) silicon substrates served as controls. Fluorescence microscopy and ellipsometry were used to evaluate the surfaces and water transport through the SNM was tested using established hydraulic permeability assays.

Results: SLIPS strongly reduced BSA-FITC adsorption on SNM compared to bare silicon. Ellipsometry confirmed the presence of SLIPS coating with a thickness of 0.5±0.2mm, which is theoretically thin enough to keep open the pores open in the membrane. However, hydraulic permeability testing revealed no ultrafiltration through the SNM for at least 24 hours and transmembrane pressures of up to 5 psi.

Conclusions: SLIPS is a promising and easy-to-apply protein repellent coating, but its highly omniphobic characteristic prevents ultrafiltration even through pores that are over 5x the coating thickness. For use in the bioartificial kidney, SLIPS has relevant implications as an anti-fouling coating where an ultra-thin blood compatible, but non-filtering surface is desired.

FR-PO375
Measuring Spatial Trends of Single Nephron Filtration with Molecular MRI
Edwin Baldegger1, Jennifer R. Charlton,2 Kevin M. Bennett,1 1U. of Hawaii, Honolulu, HI; 2U. of Virginia, Charlottesville, VA; 3U. of Hawaii at Manoa, Honolulu, HI.

Background: To better develop drugs to treat kidney disease their physiologic mechanisms during development, noninvasive techniques to measure whole kidney function at the level of the single nephron are needed. We investigated the combined use of two MRI contrast agents, cationic ferritin (CF) and Gd-DTPA, to measure local (voxel) macromolecular uptake and glomerular filtration rates of single nephrons over the whole rat kidney with 3D MRI using the isolated, perfused rat kidneys under physiological conditions.

Methods: Krebs-Ringer (KR) bicarbonate solution with 7.5 mg/100mL of Fraction-V BSA and a bubbling infusion of carbonate was perfused into isolated rat kidney. Temp was maintained at 37°C. CF in KR solution (0.071 mg/mL of CF), was infused into the system first. Next, a bolus of 0.25 mmol Gd-DTPA in 10mL of KR solution was infused into the perfusion system. (All rates = 5ml/min) Kidneys were imaged during the perfusion with MRI. Voxel time courses were then fitted to a bi-exponential model.

Results: Glomeruli were distinguished by uptake of CF and a distribution of CF accumulation rates and gd-DTPA elimination rates was visible. (Fig 1a-b) We used the location of the glomeruli in 3D and the time course of CF labeling (Fig 1c-d) to discern spatial trends in uptake rate of CF. Time course structures also mapped well with the different morphological structures in the kidney (Fig 1e).

Conclusions: Our results demonstrate that automated quantification is capable of not only distinguishing between anatomical features of kidneys, but also characterizing the degree of abnormality in diseased tissue.

440A
Results: the developed contrast agent (µ-Angiofil) turned out appropriate for µCT ex vivo with superior perfusion and contrast-to-noise features. The obtained µCT datasets were of superior quality and allowed clear visualization of the microvasculature and glomeruli.

In kidney, modern high-resolution microCT (SkyScan-1172) provided the whole mouse kidney vasculature in 3D with the spatial resolution of approx. 2 µm. The sample is fixed prior the micro-CT-scan and therefore can be processed for the histological evaluation after the scan. This circumstance brings multiple advantages, including much easier localization of the µCT-findings in the post-scan histological sections.

Conclusions: using µ-Angiofil we obtained 3D-µCT datasets of superior quality, which are sufficient for estimation of relevant kidney morphometry parameters. The developed angiographic approach will substitute the existing golden-standard. Besides classical kidney morphometry, it provides the data on the vasculature through the whole kidney in 3D what makes the technique even more beneficial.

Rising Accuracy of Transcutaneous GFR Measurement Jochen Friedemann,1 Ralf Heinrich,1 Yury Shullevich,1,2 Johannes Pill,1 Daniel Schock-Kusch,1,2 1Mannheim Univ of Applied Sciences, Inst for Process Control and Innovative Energy Conversion, Germany; 2Mannheim Pharma & Diagnostics GmbH, Germany; 2Freudenberg New Technologies SE & Co. KG, Weinheim, Germany.

Background: Transcutaneous measurement of GFR (GFR) is now getting used frequently in animal studies. tGFR allows consecutive GFR measurements in the same clearance, automatically correcting influences like bleaching of skin fluorescence.

Methods: Bolus clearance (GFR was measured in awake Spraque Dawley (SD) rats using the commercially available NIC-Kidney system, immediately followed by a blood sampling based constant infusion clearance (cGFR). GFR was calculated by a one compartment model (GFRexo), GFRnew and cGFR. Also 46 GFR measurements in SD rats were reevaluated by GFRexo.

Results: Results are given in table 1. Mean values of the three methods are comparable with no significant difference. The accuracy (larger STD) of GFRexo is lower compared to GFRnew and cGFR. This finding was verified by the 46 measurements in SD rats (GFRexo: 0.97 ± 0.18 ml/min/100g b.w.; GFRnew: 0.95 ± 0.14 ml/min/100g b.w.).

<table>

Conclusions: The results indicate that GFRexo yields data in comparable accuracy as cGFR. For an apriori estimation of the sample size to detect a change in GFR of 10% in the SD rats investigated, the effect size rises from 0.55 (GFRexo) to 0.73 (GFRnew). The required sample sizes in fig. 1. illustrate the strong contribution of GFRexo to the concepts of refining and reduction of animal studies.

FR-PO379
Quantification of the Progressive Fibrosis Development in Mouse Kidney Unilateral Ureteral Obstruction Model Using Fluorescence Lifetime and Second Harmonic Generation Imaging Microscopy

Funding: Government Support - Non-U.S.

Background: Renal fibrosis is considered to be the final common pathway for most forms of chronic kidney disease (CKD) and involves glomerular sclerosis and/or tubulointerstitial fibrosis. There is great interest in identifying renal fibrosis in the early stages of CKD to predict progression. Unilateral ureteral fibrosis (UUO) is a well-characterized model of CKD and renal fibrosis. Kidney injury and fibrosis usually are assessed by Picrosirius Red staining or immunohistochemistry for collagen isoforms.

Methods: The goal of this study is to compare histologic measures of renal fibrosis to Fluorescence Lifetime Imaging (FLIM) and Second Harmonic Generation (SHG) techniques in our deep imaging microscope DIVER.FLIM and SHG allow quantification of collagen in unstained tissue and can be adapted for live animal imaging. Male C57BL/6 mice were subjected to UUO of right kidney. At 7, 14 and 21 days, both kidneys were harvested. The uninjured left kidney was used as a control. Serial sections of both kidneys were analyzed by Picrosirius Red staining or FLIM with SHG.

Results: We performed quantification of Picrosirius Red stained-kidneys using polarized light. This showed progressive increase for the number of positive pixels for fibrosis in the left kidney 9631.9 ± 1626.2, 16167.8 ± 6647.7 and 20511.5 ± 5727.6 compared to 5625.3 ± 770.6, 3909.3 ± 2395.9 and 4493.8 ± 2011.8 in the control kidney respectively. Using the Phasor approach to FLIM, comparisons between the two kidneys show that the auto fluorescence lifetime signature give rise to two well separate phaser clusters. Quantification of ten different fields of view for each kidney at the above time-points for SHG signal confirms Picro-Sirius Red scoring.

Conclusions: Finally, the combined FLIM and SHG images let us establish a criterion for quantitative determination of fibrosis directly from the microscopic images.

Chemical Imaging: A Novel Approach to Obtaining Label-Free Biochemical Information in Renal Transplant Patients with Recurrent Diabetic Nephropathy

Background: The main treatment for end-stage renal disease is kidney transplantation, which over time undergo chronic rejection including changes in the glomerular, tubulointerstitial and vascular compartments. Also, recurrence of disease in diabetics can mimic transplant glomerulopathy. We have identified biochemical markers using Chemical imaging that were associated with recurrent diabetic nephropathy. Chemical Imaging is an emerging approach to obtain images of the biochemical composition of tissue biopsies in a label-free fashion.

Methods: An initial study focused on identifying patients with no evidence of diabetic nephropathy and patients with advanced diabetic nephropathy in native kidneys. Serial sections were acquired and stained with PAS or imaged using chemical imaging. IR spectra were extracted to identify biomarkers associated with diabetic nephropathy progression. A second study identified transplanted patients who underwent very rapid recurrent diabetic nephropathy and patients with no evidence of diabetic nephropathy.

Results: Biomarkers were identified that were changed in renal structures associated with the progression of diabetic nephropathy, including increased levels of glycation. These biomarkers were found to be increased in the cohort of transplant patients that underwent rapid diabetic nephropathy recurrence. In addition, the early biopsies from the patients that underwent later diabetic nephropathy progression were biochemically different from the non-progressive patients, suggesting that chemical imaging may identify pre-histological biomarkers that will predict outcome.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: We have identified a number of biomarkers that are associated with the advancement of diabetic nephropathy and that we can track the early recurrence of diabetic nephropathy in surveillance biopsies. In addition, we have highlighted a 'biochemical signature' that may be predictive of the later progression of diabetic nephropathy recurrence.

Contrast-Enhanced Ultrasound Characterizes Kidney Lesions with Accuracy Comparable to Contrast-Enhanced CT or MR

Emily H. Chang,1 Sandeep Kasoji,2 Paul Dayton,1 Wui K. Chong,1 Kimryn Rathmell1 1Univ of North Carolina, Chapel Hill, NC; 2North Carolina State Univ, Raleigh, NC.

Background: Incidental kidney lesions are often detected on imaging performed for other reasons. Indeterminate lesions are further characterized with a contrast-enhanced computed tomography (CT) or magnetic resonance imaging (MRI). These tests have many limitations and are contraindicated in patients with allergies to contrast, metallic hardware and chronic kidney disease (CKD). An accurate alternative study is needed. Contrast-enhanced ultrasound (CEUS) is one potential alternative. CEUS uses microbubbles, non-contrast, gas filled bubbles with lipid or albumin shells, as the contrast agent. We investigated the accuracy of CEUS for malignancy in patients with incidental kidney lesions.

Methods: CEUS was performed on 33 patients. Results were independently interpreted by 2 blinded readers and risk-stratified by the Bonniah classification system. Sensitivity, specificity and predictive values were calculated for lesions with histologic diagnosis as the gold standard. As histology was available for 58 lesions only, we performed secondary analyses using an expanded gold standard definition that included clinical recommendation.

Results: Of the 33 patients, 12 had CKD and 14 had histologic diagnoses. There was 100% inter-reader agreement in the primary analysis (Figure 1A) and 97% agreement in the secondary analysis (Figure 1B). Sensitivities (94-100%), positive (70-93%) and negative predictive (90-100%) values for CEUS were comparable to CT (83-100, 50-67 and 77-100%, respectively) and MRI (81-100, 60-78 and 80-96%, respectively). CEUS specificity (0-56%) was lower than MRI (71-100%).

Figure 1. Diagnostic accuracies based on gold standard of histologic diagnosis (A) and histologic diagnosis or clinical recommendation (B).

Conclusions: CEUS has excellent potential as an alternative diagnostic tool for kidney lesions among patients with CT/MRI contraindications. Further evaluation is needed.

Lead-Free Drape Aided to Xray Detector Significantly Decreased Radiation Scatter During Access Intervention

Jie Cui,1 Fengyong Liu,1 Zubin Irani1 1Nephrology Dept, Massachusetts General Hospital, Boston, MA, China; 2Interventional Radiology Dept, Chinese People’s Liberation Army General Hospital, Beijing, China; 3Div of Vascular Imaging and Intervention, Massachusetts General Hospital, Boston, MA, China.

Background: Exposure from scattered radiation can be very high during access interventional procedures because of the relatively closer operative position. The purpose of this study is to evaluate whether applying a lead-free, sterile, disposable drape can decrease scatter radiation exposure during access intervention.

Methods: An upper extremity phantom was placed on the angiography table to mimic real-time patient’s upper extremity access. Using this model, measurement of scatter radiation was made every one foot away from the phantom before and after applying the drape using a collimated and low-output condition. The scattered radiation dose was measured three times in each spot. And the measurement was taken at 0.9m (waist level) and 1.5m (neck level) as well as neck level (1.5m). Statistical significance was compared using t-test.

Results: Scatter radiation was attenuated throughout the measurement field when the drape was applied. The degree of scatter radiation reduction was distance and height dependent. Scatter radiation decreased 61.6% at the waist level and 81% at the neck level (P<0.05).

Conclusions: The application of this sterile, lead-free drape can significantly reduce scatter radiation in the procedure room. This novel technique can be used to reduce exposure radiation dose to the operators.

FR-PO383

Pathogenesis of Brain Damages in Chronic Kidney Disease and Clues for Early Diagnosis

Yao-ping Lin,1,2 Der-Cheng Tarn1,2 1Medicine, National Yang-Ming Univ, Taipei, Taiwan; 2Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.

Background: There is globally increased prevalence of chronic kidney disease (CKD). Vigorous efforts have been devoted to ameliorate renal deterioration and prevent cardiovascular morbidity/mortality. However, patients also have enough incubation time to develop deranged cognition that severely disturbs quality of life. Neurological pathology/damages may occur in CKD patients long before any overt clinical symptoms can be noticed. Given the similar embryological development as brain, the eyes can be the windows to pinpoint the initial brain pathology. Herein we employed proteomics, animal model and behavior analysis to investigate the possible overlapping biological signatures in the eyes and brain of CKD.

Methods: Subtotal nephrectomized rats were established as CKD model. Open field and object recognition tests were adopted as neurological screen. Brain and eyes were harvested for proteomic analysis. Western blotting and immunohistochemistry were used to confirm and localize the identified proteins. To elucidate the global protein changes in the brain and eye of SNX rats, the data was analyzed by Ingenuity Pathways Analysis (Ingenuity Systems, http://www.ingenuity.com/).

Results: The eye pathology appeared in parallel with the brain damages. The significantly dysregulated proteins in the SNX rat eyes were spectrin beta 3, 26S proteasome non-ATPase regulatory subunit 2, 6-phosphofructokinase, dihydroyirimidinase-related protein, and the heat shock 70, 90a, and chaperonin containing Tep1, subunit 6a (Zeta 1).

All these proteins have been linked to the neuro-degeneration in humans.

Conclusions: There were overlapping eye and brain biological networks. Our results might pave the way for early diagnosis of CKD-neurological pathology via eye examinations, and targeted interventions towards the neurological diseases.

Funding: Government Support - Non-U.S.

FR-PO384

Metabolomic Profiling of Chronic Kidney Disease Using a Local Exhaustive Exploration Approach

Mathias Luck,1 Eric Thvert1, Cécilia Dannon1, Nicolas Pallet1 1Nephrology, Georges Pompidou European Hospital, Paris, France; 2Hypercube Inst, Paris, France.

Background: 1H Nuclear Magnetic Resonance (NMR)-based metabolomic profiling is useful for the diagnosis of CKD stages. Due to the high dimension of NMR spectra datasets and the complex mixture of metabolites in biological samples, the identification of discriminant biomarkers of a disease is challenging. None of the widely used chemometric methods in NMR metabolomics performs local exhaustive exploration of the data.

Methods: We developed a descriptive and easily understandable approach searching for discriminant local phenomena. We selected the most discriminant features from the dataset based on both the normalized mutual information and the chi-2 test. We studied the local distribution of the patient subgroups with identical degree of CKD severity on each feature, using the proprietary algorithm HyperCube, which searches for local overdensities of an explanatory variable modality, and identifies a combination of variables as well as their value ranges that give the optimal prediction of the outcome of interest. Further, logistic regression on these discriminant features was used to build a predictive model of the CKD severity stage.

Results: We explored a complex dataset that includes 1H-NMR urinary metabolomics, clinical, demographic, clinical chemistry and histo-pathological variables, in a cohort of 110 individuals with a CKD. The HyperCube algorithm combined with logistic regression supports the discriminant metabolites obtained with standard Orthogonal Projection to Latent Structure Discriminant Analysis (O-PLS-DA) model. Unlike the O-PLS-DA model, HyperCube algorithm provided clues into the distribution of the CKD severity subgroups.
with respect to spectral data. The built predictive model identifies metabolomics profiles containing metabolic pathways such as citrate/citrate, dimethylsulfoxide, trigonelline and glycine. The majority of the predictive variables were urinary metabolites identified by 1H-NMR, indicating that CKD significantly impacts the urinary metabolism.

**Conclusions:** Our findings indicate that HyperCube is a valuable analytical method for the description of CKD severity phenotypes.

**RNA-seq Profiling in Unip nephrectomized Rats**  
Jaee Woook Lee, Mark A. Knepper. NHILB, NIH, Bethesda, MD.

**Background:** Renal hypertrophy occurs as a compensatory response to reduction in nephron mass. To identify early gene expression changes in renal hypertrophy, we profiled whole-kidney transcriptome in the contralateral kidney of unip nephrectomized rats using RNA-seq.

**Methods:** 5-week-old male Sprague-Dawley rats received right uninephrectomy (UNx; n=4 at each time point) or sham surgery (S, n=4 at each time point). Rats were sacrificed at 24, 48, and 72 hours after surgery. 1.5 µg of total RNA from the left kidney was used to make cDNA libraries for Illumina sequencing. Reads were mapped to Ensembl genes and 103 downregulated transcripts were identified in UNx. Among upregulated transcripts were cell cycle genes including centromere proteins (Cenpa, Cenpf, and Cenpc); MMC helicase subunits (Mmc3, Mmc5, and Mmc8); cyclins (CcnA, CcnA, Ccna, and Ccna); cyclin-dependent kinase (Cdk1); and polo-like kinase (Plk1). Among downregulated transcripts at 48 h were transcription factors (Jun, Hmz2, Klf15, Foxa5, Zfp36, Zfp354a, Zbtb16, and Zic3). At 72 h, 769 transcripts were upregulated and 704 downregulated in UNx. Upregulated transcripts included Cgfl, Rgs1, and Tsc22d2, which may trigger this response. The urine and plasma samples were collected at the time of renal biopsy from 50 patients at Imperial College Renal & Transplant Centre, London, UK and compared with healthy volunteers. All samples were measured by FTIR spectrometer and analysed by the established method. The biochemistry results such as urine protein/creatinine ratio (uPCR), Scr and renal histopathology were collected.

**Results:** Total RNA yields did not differ significantly between UNx and sham kidneys. Each library had 35-42 million reads and more than 80% of reads were uniquely aligned. At 24 h, 45 transcripts were upregulated and 72 downregulated in UNx. Upregulated transcripts included connective tissue growth factor (Ctgf), regulator of cell cycle (Rgcg), serum/glucocorticoid-regulated kinase (Skg1), glucocorticoid-induced leucine zipper protein (Tic22d3), a zinc finger transcription factor (Zbtb16), and genes related to steroid biosynthesis (e.g. Insg1). At 48 h, 183 transcripts were upregulated and 103 downregulated in UNx. At 72 h, 769 transcripts were upregulated and 704 downregulated in UNx. Upregulated transcripts included Cgfl, Skg1, Zbtb16, and cyclins (CcnB1, CcnA2, and CcnB1). Interestingly, Cgfl, Skg1, Zbtb16, and Tic22d3 showed a triplication response, upregulated at 24 h and 72 h and downregulated at 48 h, consistent with an undamaged control sample. The urine and plasma samples were collected at the time of renal biopsy from 50 patients at Imperial College Renal & Transplant Centre, London, UK and compared with healthy volunteers. All samples were measured by FTIR spectrometer and analysed by the established method. The biochemistry results such as urine protein/creatinine ratio (uPCR), Scr and renal histopathology were collected.

**Results:** In comparison with healthy volunteers, patients with GN, diabetic nephropathy (DN), membranous nephropathy and FSGS exhibited significantly higher levels of the urine 1545 cm⁻¹ marker. Furthermore, this urine spectral marker correlated with the degree of interstitial fibrosis, tubular atrophy and Scr (p<0.05). There was significant elevation of the plasma 1545 cm⁻¹ marker in all the disease groups compared with healthy volunteers.

**Conclusions:** Our results show the use of the specific urine and plasma FTIR biomarkers will be a novel approach to investigate progressive kidney diseases, including GN and DN, without chemical manipulation of samples.

**Funding:** Private Foundation Support

**FR-PO387**  
**Omics Investigation of Urine Samples with and without Addition of a Protease Inhibitor**  
Claire Boulanger, Ilse M. Roed, Petra Züriég, Manuja Kaluarachchi, Elaine Holmes, Franz S. Schaefer, John C. Lindon, Jack F. Wetzels, Jeroen Deegens. Metabolomers Ltd, London, United Kingdom; Dep of Nephrology, RadboudUMC, Nijmegen, Netherlands; Mosaïques Diagnostics GmbH, Hannover, Germany; CSM, Dep of Surgery & Cancer, Imperial College London, London, United Kingdom; Dep of Nephrology, Univ of Heidelberg, Heidelberg, Germany.

**Background:** Urine is an ideal biofluid for biomarker discovery. To conserve the protein profile integrity, samples are stored with a protease inhibitor (PI). It is unknown whether the PI alters the metabolomic and proteome profiles. This study aimed to test the influence of the PI on metabolomic and proteomic analysis of urine samples.

**Methods:** We collected 10 urine samples from normal controls (NC, n=4) and membranous nephropathy patients (MN; n=6) and the samples were aliquoted. A PI (mini complete, Roche) was added to an aliquot of each sample. Urine samples were stored at -80°C. For metabolomics, samples were analyzed by 1H NMR spectroscopy and HILIC-UPLC-MS. Multivariate analysis (MVA) was used to elucidate any PI effect in normal urine and proteinuria. For peptidomics, capillary electrophoresis-coupled mass spectrometry was used to profile the low molecular weight proteome in urine.

**Results:** Unsupervised MVA of urine metabolic profiles showed clear discrimination between NC-PI, NC+PI, MN-PI and MN+PI. Supervised MVA of PI+ and PI- samples revealed subtle changes in metabolite levels and the presence of intense signals between 3.63 to 3.91 ppm in the PI+ samples, obscuring endogenous metabolite peaks. Unsupervised MVA of HILIC-UPLC-MS data showed discrimination between MN-PI and NC-PI. Supervised MVA of PI+ and PI- samples showed no detectable difference between the two sample types. For peptidomics, MVA between PI+ and PI- resulted in no statistically significant peptide differences. Further validation with a proteome classifier for CKD (CKD273) showed no statistical significant difference between samples with and without PI.

**Conclusions:** The PI addition did not affect the distinction between MN and NC in the metabolome and proteome analysis. However, PI may affect the analysis of metabolic subcategories using UMR. Therefore, samples with PI can be used, but with caution.

**Funding:** Other NIH Support - The research leading to these results has received funding from the European Union’s Seventh Framework Programme (FP7/2007-2013) under grant agreement no. 305608 (EURenOmics).

**CNVkit – Software Tools for Analyzing Genomic Structural Variants**  
David Fasel, Miguel Verbitsky, Simone Sanna-Cherchi. Medicine, Columbia Univ Medical Center, New York, NY.

**Background:** Copy number variations (CNVs) are increasingly recognized as genetic susceptibility factors for kidney disease. Determining whether CNVs are pathogenic or associated with a specific phenotype is challenging and few tools exist to aid in this process. Here we describe new software tools that provide semiautomated and flexible annotation and interpretation of CNVs, including array CGH, DNA SNP microarrays, and NGS, and to perform joint analyses. It was also used to identify copy number variant regions by using a sliding window approach to detect regions or genes that are enriched for deletions or duplications.

**Results:** CNVkit was recently used as a key component of a study (Verbitsky, JCI 2015), which compared CNVs in 419 children with chronic kidney disease against those found in 21,575 controls, and against predefined coordinates of known genomic imbalances. The software was used to homogenize results and output from different detection platforms, including array CGH, DNA SNP microarrays, and NGS, and to perform joint analyses. It was also used to identify copy number variant regions by using a sliding window approach to detect regions or genes that are enriched for deletions or duplications.

**Conclusions:** Structural variants are major susceptibility factors to congenital kidney malformations and pediatric kidney disease, and should be considered when investigating the cause of genetic disorders. CNVkit provides freely available and easy-to-use tools to help CNV annotation and interpretation.

Quantifying Uropathogenic Bacteria Infection in 3D  Neal A. Paragana,1 Alexander Klose,a,2 1Medicine, Univ of Washington, Seattle, WA; 2In Vivo Analytics, Inc, New York, NY.

Background: Urogenital tract infection is a disease that annually affects more than 250 million people worldwide; however, the number of antibiotic resistant strains have been increasing while newly validated antibiotics have been lagging behind. We have developed a method to monitor and quantify a uropathogenic bacterial infection with multispectral bioluminescence tomography (BLT) of a novel bioluminescent uropathogenic E. coli (UPEC-lux).

Methods: We modeled pyelonephritis by transurethral injection of UPEC-lux. First, we acquired bioluminescence images with a bioluminescent optical imaging at four different spectral windows centered at 575, 655, 695 nm and with bandwidth of 50 nm. The multi-orientation images were acquired using a mirror gantry for simultaneous imaging of the dorsal and ventral view. The animal was placed in a fixed position into a novel body shape conforming animal mold, placed onto the mirror gantry and spectral images were acquired. In vivo bacterial quantification, a novel calibration device using tissue mimetic material was used. The light intensity imaging data became input to a novel BLT reconstruction algorithm based on an expectation-maximization (EM) method and the simplified spherical harmonics (SPH) equations for modeling in vivo light propagation. Post reconstruction, we calculated the total photon emission density of a volume of interest (VOI). We then calculated the in vivo organ bacterial load by registering it to a novel organ probability map.

Results: The EM method reconstructed the 3D photon emission density of the UPEC-lux and mapped the signal to a novel organ probability map. We analyzed these UPEC-lux in a model of pyelonephritis and we were able to determine the bacterial load in the kidney by BLT which correlated to CFUs from serial dilution of kidney homogenate (Pearson correlation coefficient R2=0.92). For the first time, we could demonstrate the feasibility of determining the bacterial burden in the kidneys.

Conclusions: The ability to monitor bioluminescent signal non-invasively will be a powerful tool to understand the pathophysiology of urinary tract infections and a new method to test novel antibiotics.

FR-PO390
Public Engagement of Kidney Related Health Information on the Internet Samir Sulaiman, Joseph A. Vassalotti, Vijay Lapsia. Medicine, Icahn School of Medicine, New York, NY.

Background: The National Kidney Disease Education Program (NKDEP), a part of the National Institutes of Health (NIH) provides an authoritative, up-to-date and trusted consumer health information resource for patients with kidney disease. We hypothesized that the US government (GOV) supported websites would have the highest consumer engagement of kidney related health information on the internet.

Methods: We used traffic rank based on publicly available data obtained from alexa. We modeled pyelonephritis in the genitourinary disorders group. The NKDEP had fewer unique US visitors (59,408) compared to Davita. We hypothesized that the US government (GOV) supported websites would have the highest consumer engagement of kidney related health information on the website.

Results: In the general health category, the NIH website ranked at the top; however, the NIH website was the only kidney related website. Cancer was the only disease category with more than 1 website in the top 25 (7 total). The NKDEP ranked 8th in the genitourinary disorders group. The NKDEP had fewer unique US visitors (59,408) compared to Davita. We modeled pyelonephritis by transurethral injection of UPEC-lux. First, we acquired bioluminescence images with a bioluminescent optical imaging at four different spectral windows centered at 575, 655, 695 nm and with bandwidth of 50 nm. The multi-orientation images were acquired using a mirror gantry for simultaneous imaging of the dorsal and ventral view. The animal was placed in a fixed position into a novel body shape conforming animal mold, placed onto the mirror gantry and spectral images were acquired. In vivo bacterial quantification, a novel calibration device using tissue mimetic material was used. The light intensity imaging data became input to a novel BLT reconstruction algorithm based on an expectation-maximization (EM) method and the simplified spherical harmonics (SPH) equations for modeling in vivo light propagation. Post reconstruction, we calculated the total photon emission density of a volume of interest (VOI). We then calculated the in vivo organ bacterial load by registering it to a novel organ probability map.

Results: The EM method reconstructed the 3D photon emission density of the UPEC-lux and mapped the signal to a novel organ probability map. We analyzed these UPEC-lux in a model of pyelonephritis and we were able to determine the bacterial load in the kidney by BLT which correlated to CFUs from serial dilution of kidney homogenate (Pearson correlation coefficient R2=0.92). For the first time, we could demonstrate the feasibility of determining the bacterial burden in the kidneys.

Conclusions: The ability to monitor bioluminescent signal non-invasively will be a powerful tool to understand the pathophysiology of urinary tract infections and a new method to test novel antibiotics.

Media Awareness and Reporting of Dialysis Disruptions and Death from Natural Disasters in the United States Samir Sulaiman, Lindsay E. Jebult, Vijay Lapsia. Medicine, Icahn School of Medicine, New York, NY.

Background: Patients receiving in-center hemodialysis are particularly vulnerable during and after disasters. Evidence of morbidity/mortality from disruption to dialysis in a disaster is limited and is so far based on statistical inference. We investigated media awareness and reporting of dialysis disruptions and death during natural disasters in the US.

Methods: We identified all major disaster declarations by the US Federal Emergency Management Agency. Disasters since 2000, excluding man-made and wildfires, with at least 1 known death were included. We then conducted a systematic Google News search to identify articles within 30 days of each disaster in the electronic mass media (media).

Results: Of 887 natural disasters from 2000-2015, 120 had at least 1 reported death (total 4,383 deaths). Of 19 hurricanes incidents, 13 articles referred to dialysis, reporting 7 dialysis disruptions, 4 dialysis deaths and 12 instances of potential disruptions to dialysis. Only 1 of the 61 deaths reported during 3 winter storms was dialysis related, with 2 instances of dialysis disruptions and 3 instances with potential for dialysis disruption. Tornadoes, which occurred most often and resulted in the second highest mortality had no coverage in the media during its aftermath.

Conclusions: Based on media reports, hurricanes and winter storms are major contributors of treatment disruption and mortality in patients on dialysis. Media reports can help identify the magnitude of disruption to dialysis operations as well as deaths.

FR-PO392
A Comparison of Physician Reporting versus Computer Algorithms for CMS Data Reporting on Form CMS-2728 Mohammed Said Malas,1,2 Ranjani N. Moothi,1 Jon D. Duke,2 Sharon M. Moe,1 1IU, Indianapolis, IN; 2RI, Indianapolis, IN.

Background: The CMS-2728 form (ESRD Medical Evidence Report) assesses 23 comorbidities chosen to reflect poor outcomes and increased mortality risk. Previous studies have questioned the validity of physician data entry on forms CMS-2728 and the relationship to hard outcomes. We hypothesize that reporting of comorbidities by a computer algorithm identifies more comorbidities and therefore is superior to physicians’ completion of the forms.

Methods: We collected data from CMS-2728 forms for all 296 patients who had included an ESRD diagnosis and received chronic dialysis between 2005 and 2014 at Indiana University outpatient dialysis centers. We analyzed patients’ data from electronic records systems that collated information from multiple sources. Previously utilized computer algorithms or natural language processing was used to extract data on 10 comorbidities (Table) for a period of up to 10 years prior to ESRD incidence. These algorithms incorporate billing codes, prescriptions, and other elements that are relevant to each comorbidity. We compared the presence of these comorbidities on the forms to the determined presence according to the algorithms.

Results: The computer algorithms had higher reporting of comorbidities compared to physician completion of the forms (Table). This remained true when decreasing the data span to one year and using only single health center data sources.

Kidney Dashboard: An Integrated Support Tool for Clinical Care and Research Involving Kidney Patients
Jamie S. Hirsch, 1, 2 Hojat Salmasian, 2 Amy Y. Chan, 3 David Vawdrey, 1 Matthew Fred, 3 Krzysztof Kiryluk, 1 1 Div of Nephrology, Dept of Medicine, Columbia Univ, New York, NY; 2 Dept of Biomedical Informatics, Columbia Univ, New York, NY; 3 NewYork-Presbyterian Hospital, New York, NY.

Background: Large amounts of data are contained in electronic health records (EHR), and retrieval of relevant information for nephrology patients is cognitively complex and time-consuming. This results in inefficiencies, missed opportunities to improve care, and difficulty adhering to complex clinical guidelines. We developed a Kidney Dashboard, an integrated tool that gathers and analyzes information to facilitate the care and research of kidney patients.

Methods: Relevant clinical data were catalogued and categorized, including visit history, billing data, vital signs, labs, imaging, pathology, and medications. We automated generation of derived data, such as estimation and trend of eGFR, proteinuria, and automated CKD-staging. We implemented a comprehensive rule-based alert system based on KDIGO guidelines to provide real-time clinical decision support.

Results: The Dashboard was created within the clinical information system at NewYork-Presbyterian Hospital, incorporating inpatient and outpatient data from multiple sources. It uses a tile layout, where each tile represents a relevant section of data that matches clinician workflow, e.g., renal function, anemia, bone and mineral metabolism, glomerulonephritis, etc. Repeat eGFR and proteinuria data are presented as interactive timelines. The Kidney Dashboard aims to improve care and facilitate research by consolidating all relevant EHR data at the point-of-care and generating phenotypic decision support and creates a portable phenotypic patient profile for genetic and epidemiologic research in kidney disease.

Conclusions: The Kidney Dashboard aims to improve care and facilitate research by consolidating all relevant EHR data at the point-of-care and generating phenotypic profiles of kidney patients. This project promotes precision nephrology, exemplifying the new generation of “smart” EHR tools. Following its public release, effectiveness of the Dashboard will be studied in focus groups and by time-motion studies and audit log analyses. The improvement in adherence to KDIGO guidelines will be tested prospectively.

FR-PO394
Forecasting a Renal Prognosis of IgA Nephropathy Using Machine Learning: Validation Study
Haejoong Lee, 1 Junhyung Noh, 1 Hyosang Kim, 1 Won Seok Yang, 1 Yong Su Kim, 1 Dong Ki Kim. 1 Internal Medicine, Seoul National Univ Hospital; 2 Computer Science and Engineering, Seoul National Univ College of Engineering; 3 Internal Medicine, Asan Medical Center.

Background: We aimed to develop and validate individual outcome prediction models in IgAN patients using machine learning.

Methods: We included adult IgAN patients from Seoul National University Hospital (SNUH, n = 1,540) and Asan Medical Center (AMC, n = 1,044) at the time of renal biopsy. They were divided into development (followed up >10 years) and prediction (follow up <10 years) sets, respectively. The outcome was 10-year renal survival (10YRS) probability. We developed predictive models from SNUH test set by using logistic regression (LR) with Lasso method, a classification and regression tree (CART), and neural network (NN) using 16 clinico-pathologic variables. We also used bagging, random forest (RF) and boosting for ensemble learning. Finally, those models were validated internally in SNUH prediction set and externally in AMC development and prediction sets.

Results: Considering missing data, 1,514 and 847 patients were included from SNUH and AMC cohorts. In the LR model, eGFR, hemoglobin, proportions of GS and SS, interstitial fibrosis (IF) were selected as predictors for 10YRS. The CART model, eGFR 53.3 ml/min/1.73m2 was proved to be a watershed for 10YRS, followed by proportion of GS and SS, IF, hemoglobin and proteinuria, sequentially. In addition, the ensemble learners showed good performance (accuracies of bagging, 0.868; RF, 0.874; boosting, 0.882). These individual learners were validated internally with good performance (sensitivities of LR, 0.855; CART, 0.921; NN, 0.952; bagging, 0.857; RF, 0.921; boosting, 0.921). And finally, we proved the robustness of those models from external validation. Good performances of both development (sensitivities of LR, 0.847; CART, 0.867; NN, 0.855; bagging, 0.852; RF, 0.872; boosting, 0.851) and prediction sets (sensitivities of LR, 0.980; CART, 0.929; NN, 0.941; bagging, 0.882; RF, 0.902; boosting, 0.922) were showed.

Conclusions: We developed robustness of prediction models using machine learning for the individual’s likelihood of 10YRS in IgAN with both internal and external validation.

FR-PO395
Quantifying the Gender Reimbursement Gap in Nephrology
Sadeen Ali, Xiangming Fan, Pankaj Jawa, Tejas P. Desai. Nephrology, East Carolina Univ; Greenville, NC.

Background: 2015 Medscape Compensation Report suggests that female providers earn less than male providers but the sample size was 1695; only 1% Nephrologists. To analyze the financial disparities, we compared total Medicare reimbursements paid to males & females.

Methods: We obtained reimbursement data from 2014 Medicare Provider Utilization & Payment Data Physician Public Use File. We consolidated all reimbursements by NPI number & categorized them by specialty & sex. We adjusted reimbursement differentials against number of Medicare beneficiaries seen & services provided. Linear regression models were used to compare reimbursements.

Results: We analyzed 246,996 providers in 13 specialties; 5% were Nephrologists. Female Nephrologists were reimbursed less $41,776.96 (unadjusted); the 6th worst female-reimbursement differential. In the adjusted analysis, female Nephrologists had the worst reimbursement differential: less $17,971.66.

Female Reimbursement Deficits ($). Lower & Upper Refer To 95% Confidence Interval Bounds.

Conclusions: When adjusted for the number of beneficiaries seen & services provided, female Nephrologists endure the largest reimbursement gap by sex in any specialty. Steps should be considered to close his gap.

FR-PO396
Protein Engineering for Renal Delivery of Molecular Therapies
Pan Liu, Jing Jin. Dept of Medicine-Nephrology/Hypertension, The Feinberg School of Medicine, Chicago, IL.

Background: Targeted delivery of therapeutic enzymes to the kidney is desirable for treatment of renal diseases and beyond. Previously, approaches that exploit the renal excretion of low-molecular weight proteins (LMWP) have been attempted. However, these carriers can only deliver chemical compounds, and their efficiency is further hampered by in vivo clearance. In order to deliver enzyme cargos, we designed carrier proteins for specific and long-lasting renal delivery. We engineered a fusion protein comprised of a kidney-targeting polybasic tag (PBT) and an Fc segment for extended stability.

Methods: PBT-Fc and Fc-only control were produced as recombinant proteins. We used in vitro parameters as an ULMWP control for alternative means of renal targeting through excretion. The probes were then separately labeled with a radionuclide 111In-Technetium (**In-Tc) tracer. Following i.v. injection of the probes to rats, we performed SPECT in whole body scanning. Radiograms were obtained in a time series for up to 1 hour. In parallel, we performed histology studies of kidney sections to determine the sub-anatomical patterns of the injected probes.

Results: Prominent and sustained kidney localization of **In-PBT-Fc (>95%) was observed by SPECT, a pattern in contrast to that of the **In-Fc control that was mainly in blood circulation during the course of observation (only <5% is in the kidney). **In-Tc-
Duramycin reached the kidney quickly and then followed through urinary excretion to the bladder in less than 20 minutes, leaving only 5% remaining in the kidney. The imaging results were consistent with IHC findings from mouse kidney following probe injections, which shows the PBT-Fc, but not FC-alone, binding the glomeruli and tubule basement membrane shortly after injection. PBT-Fc sustained in the kidney for at least 10 days.

Conclusions: Our engineered PBT-Fc carrier exclusively targets kidney through binding to the glomeruli and tubule basement membrane. This recombinant probe also achieves long-lasting kidney retention (days as compared to minutes for LMWP), yet another desirable property for targeted therapeutic delivery. This vehicle potentially be useful for delivery of molecular therapies, particularly enzyme proteins, to the kidney.

FR-PO397

Dynamic Culture on an Orbital Shaker Alters the Phenotype of Primary Human Renal Tubular Epithelial Cells
Nicholas J. Ferrell, Jin Cheng, Siemng Miao, William Henry Fissell,1 Nephrology, Vanderbilt Univ Medical Center, Nashville, TN; 2Biomedical Engineering, Vanderbilt Univ, Nashville, TN.

Background: Primary cells cultured in vitro gradually lose features characteristic to the in vivo cell type, variously termed “senescence” or “culture stress.” Culture conditions that help maintain cell-specific phenotype are advantageous for cell biology and tissue engineering. Here we evaluated the phenotype of primary renal tubular epithelial cells after applying apical fluid shear stress using an orbital shaker.

Methods: Human renal tubular epithelial cells were isolated from donor kidneys not suitable for transplant. Cells were cultured on Transwell inserts under static conditions or on an orbital shaker at a frequency producing fluid shear stresses of 2 dyn/cm². Transphesitapillary resistance was measured daily. After 2 weeks in culture, cell density was analyzed by counting DAPI stained nuclei, and expression of tubule-specific markers was measured by PCR and western blotting.

Results: Dynamic culture significantly increased steady state transphesitapillary resistance from 344±31 to 544±32 Ω·cm² (p<0.001) and resulted in a 21.5±2.1% (p<0.001) increase in cell density. Gene expression of tubule epithelial cell markers (GTG1, COL4A1, COL4A2, NHE3, and NAPP2) increased with fold changes in expression of 4.3 ± 0.4, 3.1 ± 0.2, 2.1 ± 0.4, and 1.9 ± 0.2, respectively. Cells grown under shear also showed increased protein expression of gamma-glutamyl transpeptidase.

Conclusions: Primary renal tubular epithelial cells grown on an orbital shaker with physiological levels of fluid shear stress appear to express proximal tubule markers more than cells grown in static conditions. This may be due to increased nutrient delivery and waste removal with improved mixing at the apical brush border, or due to specific gene regulation related to mechanotransduction. Further mechanistic insight may allow investigators to develop improved in vitro culture systems for cell biology and tissue engineering and more accurate in vitro models of disease.

CRISPR/Cas9-Mediated Site-Specific Mutation in Rat Angiomotin Gene via Direct Injection of One-Cell Embryos
Yaochun Zhang, Zakir Hossain,2 Bo Lan,1 Chang-Yien Chan,1 Hui Kim Yap,1 Kar Hui Ng.1 1Dept of Paediatrics, National Univ of Singapore, Singapore; 2Cancer Science Inst of Singapore, National Univ of Singapore, Singapore.

Background: Genetically modified animals represent a crucial tool for understanding gene function in development and disease. The recently developed CRISPR/Cas9 system is an efficient gene-targeting technology to generate genetically modified animals. We have performed exome sequencing in a Singapore Chinese family with X-linked recessive membranous nephropathy associated with Fanconi syndrome and anti-tubular basement antibodies, and identified AMOT, coding for angiomotin, as a novel candidate gene with a putative disease-causing mutation p.S50G in the N-terminal of the p130-AMOT isoform. Preliminary work confirmed the expression of angiomotin in renal tubular cells. This study aimed to introduce the mutation into rat genome via direct injection of CRISPR/Cas9 into one-cell embryos, establishing rat models for downstream pathological studies.

Methods: The tracrRNA:crRNA fused single guide RNA (sgRNA, 20ng/µl) and a single-stranded oligonucleotide (ssODN, 3ng/µl), which encodes the p.S50G mutation of angiomotin and serves as template for HDR-mediated repair, was introduced into the rat pronucleus via microinjection. Pups produced from the injected one-cell embryos, establishing rat models for downstream pathological studies.

Funding: Government Support - Non-U.S.

FR-PO399

Double Transduction of a Cre/LoxP Lentiviral Vector: A Simple Way to Generate Cell-Specific Knockdown Mice
Shin-Wook Kang, Bo Young Nam, Meiyan Wu, Tae-Hyun Yoo. Brain Korea 21 PLUS, Severance Biomedical Science Inst, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Genetically engineered mice have been used to elucidate the function of specific genes. Transgenic mice via conventional knockout techniques using oocytes or embryonic stem cells are most commonly used to downregulate genes, but this method has certain limitations. Therefore, a novel method to knock down specific genes in a cell specific manner in adult mice was devised by lentivirus (LV)-assisted transfer of short hairpin RNA.

Methods: In vitro, the LV suspension containing LV-Hoxb7 Cre and/or LV-Aquaporin 3 shRNA (LV-AQP3) was added to primary mouse renal collecting duct cells (CDs) and mouse mesangial cells (MMCs). In vivo, first, LV-Hoxb7 Cre was injected into the intrapleural injection site to check the Hoxb7 promoter efficiency. Second, LV-loxP shAQP3 was injected into the Hoxb7 Cre transgenic mice to check shAQP3 function. Third, consecutive injections of LV-Hoxb7 Cre and LV-loxP shAQP3 were made to C57BL/6J mice.

Results: In vitro, LV-Hoxb7 Cre worked only in CDs due to the presence of Hoxb7 in CDs but not in MMCs. Furthermore, combined injection of CDs with LV-Hoxb7 Cre and LV-loxP shAQP3 significantly inhibited the protein expression of AQP3 with the disappearance of EGFP protein expression, suggesting that LV-Hoxb7 Cre and LV-loxP shAQP3 used in this study worked together effectively. In vivo, kidney CD-specific AQP3 knockdown mice were generated by consecutive injection of LV-Hoxb7 Cre and LV-loxP shAQP3 in adult C57BL/6J mice. In mice treated with LV-Hoxb7 Cre alone, mCherry protein expression occurred only in CDs, while LV-loxP shAQP3 injection alone led to an increase in EGFP expression in all cells. In the kidney, AQP3 expression in mice injected with LV-Hoxb7 Cre or LV-loxP shAQP3 alone did not differ, but consecutive injection of LV-Hoxb7 Cre and LV-loxP shAQP3 significantly reduced AQP3 expression. However, the expression of AQP3 in other organs did not differ between the groups.

Conclusions: Double transduction of Cre- and loxP-based LV can be a simple way to generate cell-specific knockdown mice, and this method may also be applicable to other species.

FR-PO400

Local Delivery of Interleukin-10 via Injectable Hyaluronic Acid Hydrogels to Prevent Local and Systemic Injury in Ischemic Acute Kidney Injury
Danielle Soranno,1 Chris Altmann,2 Sarah Faubel,2 Ana Andres-hernando,2 Pediatrics & Bioengineering, Nephrology, Univ of Colorado, Aurora, CO; 2Medicine, Nephrology, Univ of Colorado, Aurora, CO.

Background: AKI is pro-inflammatory and causes systemic complications via IL-6. Here, we use injectable hyaluronic acid (HA) hydrogels to deliver IL-10, an anti-inflammatory cytokine, to improve local and systemic outcomes of AKI.

Methods: Four treatment groups were followed for 28 days following AKI (15 µL of therapy delivered 3 days status-post AKI), and compared to healthy and untreated AKI controls (n=5): IL-6 in saline delivered under the kidney capsule (LK IL-6); IL-10 suspended in HA delivered subcutaneously (SQ gel IL-10); HA with or without IL-10 injected under the left kidney capsule (LK gel, LK gel IL-10); HA hydrogels were developed as previously reported. Serial measurements of blood urea nitrogen and creatinine were followed for 4, 14, and 28 days. Serum IL-6 was measured at sacrifice. Immunohistochemistry (IHC) was performed to identify collagen type III deposition. Positive cells were quantified (20 images/section, in cortex). ANOVA with Dunnett’s posthoc was used to determine significance.

Results: All treatment groups normalized BUN, Cr and serum IL-6 by day 28 while the untreated AKI cohort had a persistent increase in BUN, Cr and IL-6. All treatment groups showed a significant reduction in collagen deposition in both left and right kidneys compared to untreated AKI, with variable effect depending on the mode of HA/IL-10 delivery.

Substrate Stiffness Regulates Renal Epithelial Cell Cilia Formation via Autocrine TGFβ Signaling

Mingfang 2

Shuvo Roy, 1

Dong Ki Kim. 1, 2

Background: The primary cilium senses the extracellular environment. Malformation of primary cilia has been shown to result in kidney disease. Although much is known regarding ciliogenesis, the role of mechanical features of the microenvironment in cilia formation is poorly understood.

Methods: Human primary proximal tubule epithelial cells (HRECs) and LLC-PK1 cells were plated on collagen-coated polyacrylamide gels with different stiffness (0.5 kPa, 1 kPa, 10 kPa and 40 kPa) and grown for 5 to 7 days. Cilia formation was analyzed by immunofluorescence staining of AC-tubulin followed with microscopy imaging. Protein expression was measured by immunoblotting. Recombiant TGFβ 1 and an inhibitor of TGFβRII SB431542 were used for TGFβ signaling modulation. LiCl was utilized to stimulate P-GSK3b.

Results: Stiff gels (10 kPa and 40 kPa) gave rise to higher ciliary density than compliant gels (0.5 kPa and 1 kPa) did (60% vs 20%). Furthermore, this phenotype could be altered by manipulation of transformation growth factor beta (TGFβ) signaling: addition of TGFβ 1 could increase the cilia frequency even when the cells were on compliant gels; similarly, inhibition of TGFβ receptor II impairs cilia formation in the context of stiff substrates. Further supporting a role for TGFβ, substrate stiffness was associated with increased SMAD2 and GSK3B phosphorylation. Incubation with LiCl also increased GSK3B phosphorylation and cilia formation independent of TGFβ.

Conclusions: Substrate stiffness determines cilia formation through TGFβ signaling via downstream GSK3β phosphorylation. This work highlights that substrate mechanical properties have a strong influence on markers of differentiation. This has relevance for tissue engineering efforts and also suggests a mechanism of disease progression in the scurvy kidney. This may broaden researches on kidney disease and contribute to disease therapy.

An Additive Role of Microfluidics on KLF 15-Induced Differentiation of Human Primary Podocyte

Seung Hoe Yang, 1

Eunjin Bae, 2

Sejoong Kim, 2

Kwon Wook Joo, 1, 2

Choon Soo Lim, 1, 2

Yon Su Kim, 1, 2

Dong Ki Kim. 1, 2

Kidney Research Inst; Internal Medicine, Seoul National Univ College of Medicine, Seoul.

Background: Podocyte de-differentiation is one of major problems during the process of primary podocyte culture. Recently, much interest has been focused on the topic, yet length and technical process hinder a progress. Kringel-like factor (KLF 15) was reported to be a novel transcriptional regulator of podocyte differentiation and its expression was increased by retinoic acid (RA) which promotes the differentiation of podocytes. But, the duration of podocyte differentiation process remains long. Here, we present a novel in vitro protocol to induce podocyte differentiation.

Methods: To mimic in vivo biological environment of glomerulus, a polydimethylsiloxane (PDMS) microfluidic device was used. The human primary podocytes were cultured in the 500 mm by 130 mm microfluidic channel and were stimulated with a laminar fluidic shear stress of 0.5 dyn/cm2 for 5 days. Various dose of RA was used to promote podocyte differentiation.

Results: In this research, we were able to reduce the time required for podocyte differentiation with higher shear stress and higher dose of RA. A couple of tests were conducted to verify the podocyte differentiation through the protocol. First, the phenotype of podocytes changed from cobblestone like shape to arborized cells. Through immunofluorescence staining, the increased expression of cytosplasmic synaptopodin and intercellular junction ZO-1 was confirmed. Moreover, KLF 15 expression was also increased. These molecules were also quantified with mRNA expression through real-time PCR. The size of podocytes became larger and the height of podocytes increased by a factor of 2.3 fold. Lastly, the podocytes aligned with the direction of flow.

Conclusions: In conclusion, we were able to promote podocyte differentiation in the shorter processing time with microfluidics and RA. Yet, more effort to mimic biological aspects of kidney such as complex structure with multiple cell layers and round surface is necessary.

Background: Microarray analysis of renal tissue from patients with antineutrophil cytoplasmatic antibody (ANCA)-associated neutrophilic glomerulonephritis (GN) revealed the CC chemokine ligand 18 (CCL18) as the highest up-regulated chemokine. The renal production of CCL18 was associated with fresh glomerular lesions and impairment of renal function. The cellular sources of CCL18 were identified as macrophages and dendritic cells. CCL18 serum levels were elevated in patients with newly diagnosed ANCA GN as well. In order to test whether CCL18 might serve as a biomarker of relapsing renal ANCA disease, we prospectively analyzed CCL18 serum levels.

Methods: Hundred thirty-five patients with biopsy proven ANCA GN were prospecively analyzed for CCL18 serum levels. Patients included in the study were in remission on maintenance therapy (n=117) or without immunosuppressive treatment (prednisolone 5mg or less was accepted) (n=18). Serum levels of CCL18 were measured by ELISA every three months. Renal relapse was defined as either rising serum creatinine with urinary red cell casts or biopsy-confirmed active ANCA-associated glomerular lesions (i.e. fibrinoid necrosis and/or cellular crescents) accompanied by an intensification in immunosuppressive treatment.

Results: During a mean follow up time of 11.6 ± 8.3 months, 16 patients developed a renal relapse. CCL18 levels were higher in relapsing patients when compared with patients who were in remission (p=0.001; 167.5±34.6 ng/ml vs. 83.17±46.38 ng/ml). CCL18 serum levels increased at the time of relapse and decreased after immunosuppressive therapy was restarted or intensified (n=16; ANOVA; p<0.001).

Conclusions: CCL18 serum levels are associated with disease activity in patients with ANCA GN and might serve as a marker of renal relapses in the surveillance of these patients.

Prognostic Value of Persistent Hematuria and Proteinuria in ANCA-Associated Vasculitis: Data from the European Vasculitis Study Group (EUVAS) Therapeutic Trials

Alexandre Karras, 1, 3

Thomas F. Hiemstra, 3

Rachel B. Jones, 2

Dr. R. W. Jayne, 2

Nephrology, HEGP Hospital, Paris, France; 2Nephrology, Addenbrooke’s Hospital, Cambridge, United Kingdom; 3On behalf of the EUVAS Study Group.

Background: Renal involvement is frequent ANCA-associated vasculitides (AV), due to crescentic glomerulonephritis (CGN). Hematuria (Hu) and proteinuria (Pu) are detected during the initial and active phase of CGN but the prognostic value of the persistence of these urinary abnormalities during the remission phase of AV is still controversial.

Methods: Data were combined from three EUVAS trials (IMPROVE, RITUXV AS, MUCYCYC), providing data for Hu and Pu at month 6 (M6) following initiation of immunosuppression and patient follow-up until month 18 (M18). Hu was defined as urine protein >0.1 RBC/mm3. Proteinuria was evaluated by protein-to-creatinine ratio (PCR, g/gmml).

Results: Data concerning 337 patients were available for analysis. ANCA specificity (PR3/MPO) was 58.37%, renal involvement was present in 73% of cases and initial mean eGFR was 46.3±2 mL/min/1.73m2. Hu was still positive at M6 in 27% of cases, although 96% of patients were in AV remission. Positivity of Hu at M6 was associated with more severe initial nephropathy but was not predictive of renal dysfunction at last FU (mean eGFR at M18 was respectively of 55.24 and 60.24 mL/min for Hu+ and Hu- patients, p=0.03). Proteinuria at M6 was <0.03 g/mmol in 53% of cases, between 0.03 and 0.1 g/mmol in 25%, >0.01 g/mmol in 22%. Among patients with M6 Pu <0.1 g/mmol, 29% had CKD stage 4 or 5 at M18, vs 3.5% and 11.5% respectively for patients with M6 PCR <0.03 and 0.03-0.1 g/mmol. Multivariate analysis using a mixed effects model demonstrated that the presence of eGFR at M18 and at the marker of renal relapse were independently associated with age (p=0.001), baseline eGFR (p=0.001) and M6 proteinuria (p=0.002), but not with M6 haematuria (p=0.284) nor ANCA specificity (p=0.82).

Conclusions: Persistence of micro-hematuria during the remission phase of AV is associated with more severe initial renal involvement but does not predict poor renal outcome. Degree of proteinuria at M6 reflects more severe kidney damage and is an independent predictor of CKD progression in AV nephropathy.
Methods: Retrospective analysis of AAV pts treated w/ new SI regimen: RTX 1gm Q2wk x 2, doses oral CYC 3mg/Kg/d x 1 wk and 1.5mg/Kg/d x 2, mtx (adj) for eGFR, and pulse pulsedmethylone followed by a rapid prednisone (pred) taper to 15mg pred by 5wk. Remission defined as BV AS-WG 0 and pred dose <7.5 mg/d. Pts received SI alone or SI+ plasma exchange (PE).

Results: 74 pts treated with SI and 35 pts w/SI+PE (table 1). Time to remission in the SI and SI+PE was 117±53 and 122±39 days, respectively (p=0.06). Cumulative incidence plots (Figure 1). Among survivors, 100% of SI and 97% of SI+PE achieved remission. 3 pts (4%) in SI and 1 (3%) in SI+PE died during induction. There were 0.04 treatment-related adverse events/p't month in both groups.

Conclusions: RTX with low-dose bridging CYC allows for successful induction of remission in essentially all AAV pts while attenuating exposure to high dose GC. Treatment-related adverse events were minimal. Our data provide an impetus for a randomized trial comparing this new regimen with the standard of care.

FR-PO408

Pulse Methylprednisolone for Induction of Remission in Severe ANCA Associated Vasculitis Is Associated with an Increase in Adverse Events but No Improvement in Outcome

Dimitrios Choumouzis,4 Julie Anne G. McGregor,4 Alan D. Salama,4 Vladimir Tesar,5 Martin Egfjord,4 Zdenka Hruskova,5 Charles McAdoo,1 1Imperial College London; 2Lund Univ; 3Univ of North Carolina Kidney Center; 4Renal Research Group, Dept of Medicine, Haukeland Univ Hospital, Bergen, Norway; 5Renal Research Institute, Imperial College, London.

Background: Intensive pulse methylprednisolone (MP) is frequently used as part of remission induction in severe ANCA associated vasculitis (AAV). However, there are no studies assessing its efficacy in the setting of AAV, while treatment related complications remain the main source of morbidity.

Methods: We retrospectively analysed outcomes of 114 patients that presented with severe AAV at 5 large centers in the United Kingdom, United States and Denmark between 2000-2013. All patients received high dose oral corticosteroids, cyclophosphamide and plasma exchange. Rituximab treated patients were excluded. The chi square and Mann-Whitney U tests were used for statistical analysis.

Results: Fifty-two patients received MP (median dose 1.5 g over 3 days) in addition to standard therapy while 62 did not. Patient characteristics and disease severity were comparable between the two groups. There was no difference in survival at 3 months (MP: 94.2% vs non MP: 91.9%, p=0.633) or 12 months (84.6 vs 80.6%, p=0.579). Renal recovery amongst survivors (63.5 vs 72.6%, p=0.297) and relapse rates at 12 months (11.6 vs 8.6%, p=0.617) were similar. MP therapy was associated with more infections per patient at 3 months (0.7 vs 0.3, p=0.005) and more new onset diabetes (28.6 vs 6.6%, p=0.002).

Conclusion: Within the limitations of this study we found that the addition of MP to standard therapy for remission induction in severe AAV led to a significant increase in adverse events, with no improvement in survival, renal recovery or relapse rates. Our results question the currently widespread use of MP in severe AAV and suggest that a randomized controlled trial is urgently needed in order to definitively address this issue.

FR-PO409

Serum B Lymphocyte Stimulator (BLYs) Levels as Markers of Disease Activity in Anti-Neutrophil Cytoplasm Antibody (ANA) Associated Vasculitis (AAV)

Background: B lymphocyte stimulator (BLYs) has been implicated in the pathogenesis of AAV. Previous studies have shown elevated levels in active disease, and following anti-CD20 therapy. Antineutrophil cytoplasm antibodies (ANCA) are not reliable predictors of disease activity and relapse and alternative markers are needed in order for immunosuppressive therapy. The aim of this study was to determine the clinical significance of serum BLYs levels in our patients with AAV.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

448A
Methods: Serum samples were obtained from patients with AAV at our centre, and BlyS levels detected using sandwich ELISA. Clinical data were obtained by review of patient records.

Results: Samples were collected from 68 patients with AAV and 13 healthy controls. Thirty one patients were male, 44 Caucasian and 21 Indoasian. Fifty patients had granulomatosis with polyangiitis, 13 patients had microscopic polyangiitis and 5 had eosinophilic granulomatosis with polyangiitis. Significantly higher BlyS levels were found in patients with active disease than those in remission and healthy controls.

Thirty seven patients who had been treated with Rituximab had significantly higher BlyS levels (p<0.0001). Eighteen patients had relapsed at 1 year following recruitment. These relapsing patients had significantly higher BlyS levels than those patients who did not relapse (p<0.0016).

Conclusions: This study supports the role of BlyS in the pathogenesis of AAV. BlyS levels could be used as markers of disease activity and predictors of relapse. With increased use of rituximab in AAV, further studies are needed to assess the impact of B cell depletion on B cell survival factors. These findings highlight the potential role for BlyS in the maintenance of remission of AAV.

Predictors of Renal Histopathology in Antineutrophil Cytoplasmic Antibody Associated Glomerulonephritis Sophia Lionaki, 1 Clio Marvagni, 2 George Liapis, 1 George Somarakis, 4 John N. Boletis, 3 Alexandros Drosos, 4 Athanasios Tzioufas, 3 Haralampos Moutsopoulos, 2 *Nephrology, Laiko Hospital, Athens, Greece; 2Pathophysiology, Univ of Athens, Greece; 3Pathology, Laiko Hospital; 4Rheumatology, Univ of Ioannina.

Background: Prompt, aggressive therapy is vital foranti-neutrophil cytoplasmic antibody (ANCA)-associated glomerulonephritis (GN) asdelays in diagnosis of renal histopathological changes may compromise patient outcomes. We aimed to identify predictors of distinct renal histopathological classes 6 months after diagnosis.

Methods: A single-centre cohort of patients with biopsy-proven ANCA-associated GN was studied retrospectively. Demographics, clinical, laboratory, serological and radiological parameters were analyzed. Patients were classified on the basis of renal histopathology, according to the report by Berden et al (JASN 2010) for ANCA-associated GN by a renal pathologist into: focal class, crescentic class, mixed class and sclerotic class. A risk score was developed for each histopathological class using univariate and logistic regression analyses. Patients were classified on the basis of renal histopathology.

Results: Variables independently associated with focal class included disease duration up to diagnosis < 8 weeks, absence of red blood cell (RBC) casts by urine microscopy and eGFR > 49ml/min/1.73m2; with crescentic class > 40 erythrocytes/hpf, identification of RBC casts in urine, ear nose and throat (ENT) involvement and eGFR < 49ml/min/1.73m2; with mixed class age > 54 years, male gender, and absence of ENT involvement. In the presence of 2 or 3 risk factors a predictive risk score of each histopathological class was calculated: odds ratio (OR), 95% confidence intervals (CI), for focal class (2 risk factors) 17.5 (95% CI [4.9-62.9]), 38.0 (6.8-213.7) for crescentic class (3 risk factors), and 8.3 [1.0-67.5] (2 risk factors) for mixed class.

Conclusions: We propose a predictive algorithm of specific histopathological classes of ANCA-associated GN, which might provide a crude estimation of the disease activity in the glomeruli at presentation. This tool might assist the clinician in making decisions regarding the level of intensity of inductive immunosuppressive therapy at clinical diagnosis.

FR-PO411

Rituximab as a Cyclophosphamide Sparing Agent for Patients with Multi-Relapsing ANCA-Associated Small Vessel Vasculitis Sophia Lionaki, 1 George E. Fragoulis, 2 Alice Venetanapouloou, 2 John N. Boletis, 3 Panagiotis Vlachogiannopoulos, 3 Haralampos Moutsopoulos, 2 Athanasios Tzioufas, 3 *Nephrology, Laiko Hospital, Athens, Greece; 2Pathophysiology, Univ of Athens, Greece.

Background: To evaluate the clinical efficacy and outcomes, of patients with multi-relapsing ANCA-associated Vasculitis (AAV), who received induction therapy with rituximab for a new disease relapse.

Methods: We retrospectively studied all patients with biopsy proven AAV, who were treated with rituximab upon a new relapse. A control group consisted of patients from the era prior to the initiation of rituximab in the treatment of AAV, was selected using the following criteria: i/history of relapse, ii/organ involvement at relapse, iii/treatment with the standard regimen. Patients and controls were matched for age, gender, and disease duration. Comparisons of disease outcomes along with the frequency and severity of adverse events were performed between groups. Rituximab was used with high dose glucocorticoids and depending on the organ involvement a short course of cyclophosphamide was added.

Results: Of 147 patients with AAV and a mean total follow up time of 78.2 months, 18 patients (12.2%) received induction treatment with rituximab for disease relapse. Time to 1-relapse from the 1st diagnosis of AAV was shorter in the rituximab group and the mean number of relapses per patient was significantly higher in this group. The mean BVAS score was similar between groups at study entry while 13/18 patients received a 3-month course of cyclophosphamide in addition to rituximab.

Conclusions: Rituximab was shown efficacious in patients with multiple relapsing AAV including cases with renal and pulmonary involvement. It allowed us to minimize the ultimate exposure to cyclophosphamide in these patients, which is crucial, as they accumulate remarkable toxicity in long-term.

FR-PO412

Differences Between Patients with Definite and Suspected ANCA-Associated Vasculitis in a Secondary Care Hospital Eline Houwen, 1 Willem A. Bax, 3 Walentina A. Sliker, 2 Bastiaan Van Dam, 1 Femeneke C.P. Frerichs, 1 Gideon Verhave, 1 Dept of Nephrology, MCA-Gemini Group, Alkmaar, Netherlands; 2Laboratory of Clinical Chemistry, Hematology and Immunology, MCA-Gemini Group, Alkmaar, Netherlands.

Background: ANCA-associated vasculitis (AAV) is a rare disease with a broad spectrum of symptoms. Therefore, diagnosing AAV is often challenging. In an effort to provide guidance for clinicians, we aimed to identify differences between ANCA positive patients with a definite and suspected diagnosis of AAV.

Methods: In this retrospective study, all patients that tested positive for MPO and/or PR3 ANCA between 2005 and 2015 in a secondary care hospital in the Netherlands were analyzed. Patients were divided into subgroups according to clinical diagnosis and the Birmingham Vasculitis Activity Score (BVAS). Possible predictors for AAV, such as patient characteristics, clinical symptoms and ANCA titers were identified. Patients were also screened for commonly used exclusion criteria in trials.

Results: We included 240 patients with a positive MPO and/or PR3 ANCA, of which 120 patients were clinically diagnosed with AAV (group 1); all had a BVAS ≥ 3. Of the patients without the diagnosis AAV, 50 had a BVAS ≥ 3 (group 2) and 70 had a BVAS < 3 (group 3). In group 2, 29 patients had an alternative diagnosis, including other rheumatic diseases and infection. In a multivariable linear regression model, higher ANCA titers, higher BVAS and Ear Nose Throat (ENT) symptoms were predictive for AAV (all p<0.001). Of the patients diagnosed with AAV, 21 (18%) would have been excluded from most trials, based on a malignancy (n=13) or drug use associated with vasculitis (n=8). Notably, characteristics of these patients did not differ significantly from the other AAV patients.

Rituximab and Low-Dose Cyclophosphamide Therapy for Renal ANCA-Associated Vasculitis: Long-Term Follow-Up
Nicholas R. Medieval-Thomas,1,2 Nicholas D. Mansfield,1 Stephen Paul McAdoo,1,2 Anisha Tanna,1,2 Megan Griffith,1,2 Jeremy B. Levy,1 Tom H. Cairns,1 Terrence Cook,1 Alan S. Dalama,3 Ruth M. Tarzi,2 Charles D. Pusey,2 1Imperial College Renal and Transplant Centre, 2Imperial College Healthcare NHS Trust, London, United Kingdom; 3Imperial College London, London, United Kingdom.

Background: The previously reported study of rituximab (RTX) and low-dose cyclophosphamide (CYP) followed by azathioprine maintenance for ANCA-associated renal vasculitis (AAV), suggested it was efficacious in inducing remission and has an acceptable side-effect profile (N Mansfield et al 2011). We have followed the cohort for over seven years and report the regimen’s efficacy and safety profile.

Methods: Long-term outcomes were retrospectively ascertained from all 23 previously treated patients.

Results: Mean time since starting the treatment regimen was 83 months; twenty-one patients started the regimen more than five years ago. All patients achieved clinical remission within six weeks, with depletion of circulating CD19-positive B cells and significant reduction in median anti-PR3-MPOANCA titre. After 84 months follow-up, five renal and four non-renal relapses were observed and treated in five patients. Median eGFR improved from 28 ml/min (range 11-63) at presentation to 49 ml/min (range 1.87) after one year and was maintained at 50 ml/min (8-90) at five years (n=21) and 46ml/min (22-76) at seven years follow-up (n=9). To date, three infections requiring hospital admission and four malignancies have been recorded.

Conclusions: This rituximab-based low-dose cyclophosphamide regimen followed by maintenance therapy provides safe and effective long-term treatment at more than five years follow-up.

FR-PO414
The Histopathologic and Clinical Determinants of the Change in GFR During the 1st Year of Treatment in ANCA-Associated Vasculitis
Pierre-Luc Lavoie,1 Remi Goupil,2 Michelle Goulet,2 Maxime Rheumae,2 Soumeya Brachemi,3 Stephan Troyano.1 1Nephrology, Hôpital du Sacré-Coeur; Univ. de Montréal, Montréal, QC, Canada; 2Internal Medicine, Hôpital du Sacré-Coeur; Univ. de Montréal, Montréal, QC, Canada; 3Nephrology, CHUM, Montréal, QC, Canada.

Background: Identifying the predictors of the change in GFR in ANCA-associated vasculitis (AAV) is helpful to avoid prolonged immunosuppression in those where no benefit exists and to consider modifying therapy in those who should improve but fail to do so.

Methods: We retrospectively reviewed cases of AAV with a renal biopsy in 3 hospitals to determine predictors of the change in GFR (deltaGFR) during the 1st year of treatment. We considered demographics, pathology findings, treatments and complications incurred. In particular, we addressed the histopathologic classification (Berden JASN 2010) proposing focal, crescentic, mixed and sclerotic subsets.

Results: Of 120 patients with AAV, 71 had a renal biopsy and received immunosuppression. They presented at an age of 59±13 with 48% female, 49% anti-MPO+ and a GFR of 32±30 ml/min including 22 patients on dialysis. Induction consisted of cyclophosphamide (93%), rituximab (6%), plasma exchange (27%) and pulse methylprednisolone (69%) in addition to oral corticosteroids. During the first year, patients recovered 15±20 ml/min/1.73m2 with 11 no longer requiring dialysis. The deltaGFR increased up until 6 months, although it varied greatly individually. Age, hypertension, MPO positive serology, the extent of crescentic and sclerotic glomeruli, tubular atrophy and the histopathological classification were associated with a lower GFR at diagnosis. However, at one year only the histopathologic classification and the number of admissions for treatment-related complications predicted a lower deltaGFR. The focal, crescentic, mixed and sclerotic subsets experienced a 19±5, 20±10, 26±10 and ±2±2 ml/min deltaGFR respectively (p=0.026, trend test).

Conclusions: The change in GFR during the 1st year of treatment in AAV increased 15±20 ml/min. It appeared maximal at 6 months into therapy. The histopathologic classification helped predict the deltaGFR at 12 months, with a reduced benefit of therapy in the sclerotic subset.

FR-PO415
Analysis of Clinical Features in ANCA-Associated Vasculitis: 30 Years Single Center Experience – Relationship Between RPGN and Renal Prognosis
Soko Kawashima, Shinya Kaname, Yoshinori Komagata, Yoshihiro Arimura. First Kyorin Univ School of Medicine, Mitaka, Tokyo, Japan.

Background: The clinical features of AAV, with respect to rapidly progressive glomerulonephritis (RPGN), have been changing, but were not well examined in Japan, where MPO-ANCA-associated vasculitis (MPO-AAV) are dominant in contrast to the Western countries. Thus, we retrospectively analyzed the clinical database of the 179 patients with AAV who were admitted to our hospital for the last 30 years.

Methods: At the onset, all patients fulfilled the Chapel Hill Consensus Conference (CHCC) classification criteria for MPA, GPA and EGPA. We divided the AAV patients into the 4 groups based on the presence or the absence of RPGN and hemodilution and compared the clinical features and renal prognosis. Among 179 AAV patients, 166 cases (92.7%) were MPO-ANCA positive and 14 cases (7.8%) were PR3-ANCA positive.

Results: RPGN was observed in 100 (55.9%) of the 179 patients, including 49 cases of maintenance hemodialysis group (A), 2 cases of temporary dialysis group (B) and 49 cases of non-dialysis group (C), in addition to 79 cases without RPGN and dialysis (D). Significant differences were observed in BVAS, CRP, eGFR and serum Cr concentration. There were no differences for treatment choice, rate of kidney biopsy and frequency of relapses among the groups. Comparison among the different periods for every 10 years show the tendency of an increase in age of onset and the downward trend of serum Cr concentration, rate of RPGN and maintenance hemodialysis, BVAS scores, and frequency of relapses and mortality.

Conclusions: These results have clearly shown the changing features of AAV in Japan, with an earlier detection and the improvement of renal and patient survival during the periods.

FR-PO416
The Effect of Race on 5-Year Survival Outcomes in ANCA-Associated Renal Vasculitis
Luxme Nadarajah, Vasantha M. Muthuppalaniapan, Ravindra Rajakariar. Nephrology, Barts and The London NHS Trust, United Kingdom.

Background: Anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis is a multi-systemic autoimmune disease characterized by inflammation of microscopic vessels. Renal involvement occurs in 70% of patients, with 1 year mortality rates exceeding 15%. With a prevalence of two cases per 100,000 populations there is a significant preponderance to Caucasians (C). Little is known about the outcomes in patients from Indo-Asian (IA) and Afro-Caribbean (AC) race despite an increasing number of cases seen with the disease.

Methods: We performed a single center, retrospective study, observing 5-year survival outcomes and relapse rates between C, IA and AC in ANCA-associated renal vasculitis. Electronic case notes over a 10-year period (2004-2014) were used collect data to include age at time of diagnosis, Birmingham vasculitis activity score (BVAS) at presentation, race, presence of diabetes and renal function. 5-year survival outcomes were analyzed using a cox proportional hazard model.

Results: In total 121 patients were included in the study, there were 84 (70%) C’s, 31 (25%) IA’s and 6 (5%) were of AC background. Median age was 66 years, 56% were men, 20% were diabetic and average BVAS score at presentation was 5. One-year relapse rates were low with 8 (6%) relapses seen. No significant difference in 5-year survival outcome was found between the races. Age at presentation significantly affected survival outcomes (p=0.007).

5-year survival outcomes dependent on race

Caucasian
Afro-Caribbean
Indo-Asian

Conclusions: We conclude that survival outcomes for IA and AC are not worse compared to those of C origin. Age remains to be a significant predictor in determining mortality outcomes. This study provides valuable clinical information in an area that has not been well studied.

FR-PO417
Possibility of Increasing Prevalence of Otitis Media with ANCA Associated Vasculitis in Japan
Takeshi Nakatani,1 Yukiko Norawa,2 Hiroe Sato,2 Yoko Wada,1 Takeshi Kuroda,2 Masaaki Nakano,2 Ichiei Narita.1 1Div of Clinical Nephrology and Rheumatology, Graduate School of Medical and Dental Sciences, Niigata Univ, Niigata, Japan; 2Health Administration Center, Niigata Univ; Niigata, Japan; 2Dept of Medical Technology, School of Health Sciences, Faculty of Medicine, Niigata Univ, Niigata, Japan.

Background: A new disease concept, otitis media with ANCA associated vasculitis (AAV), has been advocated.

Methods: One hundred and fifty seven patients (74 males and 83 females) with AAV (81 microscopic polyangiitis, 54 granulomatosis with polyangiitis (GPA), and 22 eosinophilic GPA) were admitted to Niigata University Hospital from 1989 through 2014. Twenty seven patients (17%, 13 males and 14 females) with AAV were reviewed. Their clinical presentation was compared to those of C origin. Age remains to be a significant predictor in determining mortality outcomes. This study provides valuable clinical information in an area that has not been well studied.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author. 450A
Conclusions: OMAAV is increasing. Chest X ray, urinary test, and measuring ANCA should be considered in refractory otitis media.

FR-PO418
Temporal and Spatial Clustering of Anti-Glomerular Basement Membrane Disease
Mark N. Canney,1,2 Paul O’Hara,1 Caitriona M. McEvoy,1 Aileen C. Niland,1 Mark Alan Little.1 Irish Anti-GBM Study Group; 1Trinity Health Kidney Centre, Trinity College Dublin.

Background: An environmental trigger has been proposed as an inciting factor in anti-glomerular basement membrane (anti-GBM) disease. We aimed to define country-wide incidence of anti-GBM disease, investigate clustering of cases in time and space and to assess the impact of spatial variability in incidence on outcomes.

Methods: National multicentre observational study of anti-GBM disease cases diagnosed in Ireland 1.6.2003-31.5.2014. We ascertained cases by screening immunology laboratories for instances of positive anti-GBM antibody and the national renal histopathology registry for biopsy-proven cases. We defined the population at risk using census figures. A variable-window scan statistic was used to detect temporal clustering. A Bayesian autoregressive spatial model was used to provide standardised incidence ratio (SIR) estimates for each county. Patient and renal survival were assessed using Kaplan-Meier and log-rank test.

Results: Seventy-nine cases were included. National incidence was 1.64 (95% CI 0.82-3.35) pmp/year. A temporal cluster was identified (n=10) in a 3 month period in early 2013; 6 (60%) were resident in the southeast. Spatial analysis revealed wide regional variations in SIR (fig 1A) and a cluster (B,C) in the northwest (n=7, SIR 1.71, 95% CI 1.02-3.06).

However, being in a cluster or distance from diagnosis site to treating center did not significantly impact on patient (HR 1.8, 95% CI 0.9-3.8) or renal survival (HR 0.7, 95% CI 0.4-1.1).

Conclusions: Country-wide incidence of anti-GBM disease is higher than reported by single centre studies. We detected clustering of cases in time and space supporting the hypothesis of an environmental trigger. Wide regional variation in incidence highlights the need for country-wide epidemiological studies of anti-GBM disease to further our understanding of its aetiology.

FR-PO419
Venus Thromboembolism in ANCA Vasculitis Is Associated with Elevated Microparticle Tissue Factor Activity
Elizabeth J. Brant,1 Carmen E. Mendoza,1 Yichun Hu,1 Susan L. Hogan,1 Ronald J. Falk,1 Patrick H. Nicholson,1 Vimal K. Dossaii,1 Donna O. Bunch.1 UNC Kidney Center, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.

Background: Venous thromboembolism (VTE) is a severe complication of ANCA vasculitis (AAV). Mechanisms of VTE are not known, but tissue factor (TF)-bearing microparticles (MPs) from activated or apoptotic cells may play a role. We hypothesized that elevated microparticle tissue factor activity (MPTFa) is associated with VTE in AAV.

Methods: Patients without VTE (VTE-) were enrolled prospectively during active disease. Patients with VTE (VTE+) were included whether active or in remission at the time of VTE. Longitudinal platelet-free plasma (PPP) samples from 28 patients and 16 healthy controls (HC) were assayed for MPTFa. All patients had >3 samples spanning 112 months. MPs (mean ± SD) were enzymatically derivatized with Factor Xa inhibitor X. Absorbance was measured after addition of Factor Xa chromogenic substrate. Recombinant relipidated human TF was used as a standard. Values were expressed as a percent of MPTFa from a positive control (FFP from LPS-stimulated HC blood). Fisher’s exact tests and Wilcoxon tests were used to compare categorical and continuous variables, respectively.

Results: Demographics were similar among patients and HC. VTE+ and VTE- patients did not differ in ANCA serotype or titer, BVS, D-dimer, other laboratory data, or organ involvement. VTE+ patients had significantly higher peak MPTFa than VTE- (HR 10.5 (95% CI 2.8, 40.5) p<0.001) most strongly associated with peak D-dimer (HR 2.1, 95% CI 1.0-4.5, p=0.03) (fig 1, 2). All VTE+ patients had peak MPTFa above normal (mean ± 2SD of HC = 6.5) versus 2/20 VTE- patients (p<0.0001).

Conclusions: Patients with AAV who develop VTE have a notable propensity for increased MPTFa at times both near and remote from VTE. Conversely, those without VTE rarely exhibit MPTFa significantly higher than healthy controls during their disease course. Further study is needed to determine if elevated MPTFa can identify AAV patients at high risk for VTE and whether MPTFa contributes to thrombogenesis.

FR-PO420
C9B0 and Angiopoietin-like 4 in Glomerulopathies
Gabriel M. Cura-Fuentes,1 Alfonso Segarra,1 Eduardo H. Garin.1 1Pediatr-Div of Nephrop, Univ of Florida, Gainesville, FL; 1Nephrology, Vall D’Hebron, Barcelona, Catalonia, Spain.

Background: Proteinuria in MCD is thought to be due to an increased C9B0 podocyte expression. Recently, podocyte angiopoietin-like 4 (Ang4) has been suggested to induce proteinuria in MCD. Objective: To determine the pattern of C9B0 and Ang4 in MCD and other glomerulopathies.

Methods: 34, 30 and 32 patients with biopsy-proven MCD, FSGS and MN respectively, were enrolled. Urinary and serum C9B0 and Ang4 were measured by Elisa. Differentiated human podocytes were incubated for 6 h with 15% of serum from MCD patients in relapse or in remission. Podocyte expression of C9B0 and Ang4 was measured by Western-Blot analysis. Urinary Ang4 pl was measured by 2D electrophoresis Statistical analysis: Mann-Whitney U test, Wilcoxon matched-pairs signed rank test for comparison of paired groups, and Spearman correlation.

Results: Urinary C9B0 was increased in MCD patients during relapse, but not in patients with FSGS or MN, or normal controls. Serum C9B0 was lower in patients with glomerulopathies during relapse compared to normal controls. Urinary Ang4 pl was increased in patients with glomerulopathies compared to normal controls, whereas serum Ang4 pl was higher in normal controls compared to patients with glomerulopathies. Both urinary C9B0 and Ang4 pl correlated with proteinuria in MCD, FSGS and MN. Podocytes exposed to sera from MCD patients in remission showed a significant increase in C9B0 expression but not Ang4 pl when compared to MCD patients in remission. Urinary Ang4 pl was 5.4.

Conclusions: 1) Decreased serum C9B0 and Ang4 pl in nephrotic syndrome is likely due to increased urinary losses. 2) Increased urinary C9B0 was only observed in MCD patients in relapse while increased urinary Ang4 pl was seen in all the glomerulopathies. 3) Podocyte C9B0 but not Ang4 expression was increased by serum from MCD patients in relapse. 4) Urine Ang4 pl in MCD has a pl of 5.4, suggesting no role on Glomerular Basement Membrane charge. 5) While C9B0 seems to play a role in proteinuria in MCD, Ang4 detected in urine in MCD and other glomerulopathies is likely the result of an increased glomerular permeability.

Apol I Polymorphism Determines HIV Boarding in Human Podocytes
Pravin C. Singhjal,1 Xiqian Lan,1 Ashwani Malhotra,1 Karl Leon Skorecki,1 Joanna Mikulak,3 1Dept of Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; 1Medicine, Rambam Health Care Campus, Haifa, Israel; 3Clinical and Experimental Immunology, Humanitas Clinical and Research Center, Milan, Italy.

Background: Patients of African ancestry with untreated HIV infection, carrying the G1 or G2 kidney disease risk variant (Vs) at the APOL1 gene are at a >10-fold greater risk for developing HIV-associated nephropathy (HIVAN) compared to patients of other races. Although the association of APOL1 alleles with kidney disease risk variants. Although podocyteopathy in HIVAN has been attributed to the direct effect of HIV infection, the mechanistic contribution to kidney injury of the APOL1 allelic state remains to be elucidated.

Methods: We evaluated the priming effect of IL-1β on human podocyte (HP) APOL1 expression. To evaluate the effect of IL-1β on HIV-1 processing in podocytes, HPs were pre-stimulated with human recombinant IL-1β for 6h and then incubated with HIV-1 followed by analysis for the HIV-1 strong stop DNA by qPCR analysis. HPs treated under similar conditions were evaluated for Nef receptor knockdown and expression of TLR-4 (VR-1 entry) expression. To determine the effect of over expression of APOL1 (G6) and APOL1 variants (G1/G2) HPs were either transfected with APOL1G6/G1/G2 plasmids, or HPs were pre-stimulated with 10 ng/mL of IFNγ and then incubated with HIV-1 and analyzed for HIV-1 strong stop DNA concentration at various time points and also measured for their lysosomal bioactivity.

Results: APOL1 expression increased after incubation of podocytes with the HIV. In turn, APOL1 expression was further enhanced in response to augmented entry of virus compared to controls, demonstrating enhanced expression of TLR-4 and IL-1β treatment, consistent with viral load dependency. Podocytes over-expressing the non-risk APOL1 gene (G0), either through
FR-PO424

Use of Spot Urine Protein Creatinine Ratio to Predict Proteinuria in Nephrotic Syndrome in NEPTUNE. Marie C. Hoogan, 1 Jonathan P. Troost, 2 Peter J. Nelson, 3 Heather N. Reich, 4 Sharon G. Adler, 5 Daniel C. Catran, 5 Gerald B. Appel, 6 Debbie S. Gipson, 4 Wenjun Ju, 2 Matthias Kretzler, 2 John C. Lieske. 1

Background: Random urine protein creatinine ratio (UPC) is used to estimate 24 hr protein excretion (24P) yet little data are available wrt sensitivity & specificity, especially in pts with glomerular proteinuria.

Methods: The Nephrotic Syndrome Study Network (NEPTUNE) studies newly diagnosed patients with MCD, FSGS, & MN. Total protein, alb & creat are measured in random & 24 hr urine collections at a central biobank at postbiopsy baseline & subsequent visits within 2 yrs of dx.

Results: Of 603 participants, 302 have same day spot & 24 hr ur samples with a total of 827 samples across all visits eligible for this analysis. Urine protein excretion (g; median; 25, 75%); was higher in adults (1.0, 0.3, 2.3) than peds (0.2, 0, 0.7); Spot UPC correlated better with 24 hr UPC than 24P in both adults (r=0.79 vs 0.66) & peds (r=0.84 vs 0.67). Using these data we derived equations to predict 24P from spot UPCs: for adults 24P = [10−0.88(log10 [Spot UPC])]; & for peds was 24P = [10−0.16(log10 [Spot UPC])]. The efficiency (AUC) of spot UPC to accurately predict 24P values above thresholds of 0.5, 1.0, 2.0, 3.0, 6.0 & 10.0 ranged from 0.83-0.97 in adults & peds.

In subgroup analysis the correlation between log-transformed UPC and log-transformed 24P was similar in all age ranges & diseases, but stronger in obese vs. normal wt subjects (bMean=0.78 (0.69, 0.88); bMedian=0.85 (0.78, 0.93); bT25=0.93 (0.85, 1.0) p<0.001).

Conclusions: Among MCD, FSGS, & MN pts UPC correlates only moderately with 24P. 24P is best derived from spot UPC using a non-linear estimating equation. Wu influences reliability of spot UPC. Our data also suggest UPC can be used with caution to identify those pts with 24P above clinically relevant cut points. As 24P is susceptible to collection errors & implications of threshold values may be dependent on patient size, additional studies to evaluate spot UPC vs 24P and clinical outcomes are warranted.

Podocyte Depletion in Alport Syndrome Complex. Larvya T. Wielman, 1 Jeffrey B. Hodgkin, 1 Su Qing Wang, 1 Farsad Afshininia, 1 David B. Keshaw, 1 Roger C. Wiggins. 1 Univ of Michigan.

Background: Increasing evidence suggests that podocytes may play a role in Alport Syndrome Complex (ASC) progression of renal disease. We previously reported that podocyte detachment rate measured in urine is increased in ASC, suggesting that podocyte depletion could play a role in causing progressive loss of kidney function. This result therefore raised the question as to whether progression in ASC could be due to progressive podocyte depletion from glomeruli.

Methods: To address this question we measured podocyte nuclear number, density and cell area (Glepp1 positive) in the same 3m thick formalin-fixed paraffin-embedded histologic section. Twenty six kidney biopsies from 21 patients were collected. Of these 20 were designated as ASC including both classic Alport Syndrome (with thin and thick GBM segments and lamellated lamina densa [n=20]) and Thin GBM [n=6]. Twenty protocol biopsies from deceased kidney transplant donors were used as age-matched controls.

Results: When compared to controls, podocyte number per glomerulus, % podocyte depletion, nuclear density and cell area density were all decreased in the ASC cohort (P<0.01). The mean podocyte volume (MPV) was correspondingly larger for ASC than control (P<0.05) representing podocyte hypertrophy to compensate for reduced podocyte number and density. Podocyte depletion was present in ASC biopsies prior to detectable histologic abnormalities. No abnormality was detected by light microscopy at <5% podocyte depletion, minor pathologic changes (mesangial expansion and adhesions to Bowman’s capsule) were present at 30-50% podocyte depletion, and FSGS was progressively present above 50% podocyte depletion. Estimated GFR did not change measurably until >70% podocyte depletion. Low level proteinuria was an early event at about 25% podocyte depletion and increased in proportion to podocyte depletion.

Conclusions: These data support the concept that progressive podocyte depletion occurs from an early stage in ASC leading to FSGS-like pathologic changes and eventually to End Stage Kidney Disease. Early intervention to reduce podocyte depletion is projected to prolong kidney survival in ASC.

FR-PO425

Rituximab in Steroid Dependent and Calcineurin Inhibitor (CNI) Dependent/Intolerant Adult Idiopathic Minimal Change Disease and Focal Segmental Glomerulosclerosis. Harbir Singh Kohli, 1 Raja Ramachandran, Vivekanand Jha, Krishan L. Gupta. 1 Dep of Nephropathy, Post Graduate Inst of Medical and Research, Chandigarh, India; 2 Dep of Nephrology, Post Graduate Inst of Medical and Research, Chandigarh, India.

Background: Steroid dependent (SD) nephrotic syndrome (NS) is managed with CNIs but the long-term results are limited by CNI nephrotoxicity and dependence. This prospective study was done to evaluate the effect of rituximab in those SD-NS who were either CNI dependent or had CNI induced nephrotoxicity.

Methods: This prospective study was undertaken in patients of SD MCD/FSGS patients were given initially CNI ( tacrolimus). Of these, who were either tacrolimus (TAC) dependent (relapse NS on tapering or stopping after 1 year at least) or had TAC induced nephrotoxicity (rise in serum creatinine >2 times the baseline) were enrolled for rituximab administration during Oct 2013 to Oct 2014. Patient with at least 6 months follow-up were analysed. After achieving remission with oral prednisolone the steroids were tapered to stop in 8 (66.7%). Mean age was 21.8±1.57 gm/day, 2.52±0.78 gm/dl and <2 gm/day or <50% of baseline with normal serum albumin (³3.5 gm/dl).

Results: A total of 12 cases, 10 Tac dependent (duration of TAC-35±12 months) and 2 with nephrotoxicity were studied. Basic disease was MCD in 4 (33.3%) and FSGS in 8 (66.7%). Mean age was 21.8±1.57 yrs. Mean proteinuria, serum albumin and serum creatinine prior to enrollment in the study were 3.24±1.57 gm/day, 2.52±0.78 gm/dl and 0.79±0.15 mg/dl respectively. All achieved target CD-19 (<1%) with single infusion and 4 (33.3%) cases had risen in their CD 19 at 3 months and were given second dose. At 6 months, CR and PR was achieved in 9 (75%) and (8.3%) respectively. There were 2 non-responders (16.6%). Of the 10 responders,3 have completed 1 yr of follow-up and are in remission.

Conclusions: Rituximab appears to be a promising agent in the management of adult CNI dependent or intolerant NS due to MCD/FSGS with minimal short-term adverse events.
FR-PO426

Treatment and Outcomes in Minimal Change Disease: Experience of a Single UK Centre

Anthony Fenton, Stuart W. Smith, Peter Hewins.
Dept of Renal Medicine, Univ Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.

Background: Minimal change disease (MCD) accounts for 10–25% of nephrotic syndrome in adults. We retrospectively reviewed the treatment and outcomes of MCD patients in our centre.

Methods: We identified adults who had undergone renal biopsy between June 1996 and March 2012 which was reported as being consistent with MCD, and who had at least 12 months of follow-up. Electronic hospital records were used for data collection.

Results: There were 78 cases, with median follow-up of 72 months. Baseline and treatment details are shown in the table (averages are mean, or median where distribution is skewed). 27% had a history of nephrotic syndrome in childhood. All but one patient (who entered remission spontaneously) were treated with prednisolone, and 97% achieved complete remission at a median time of 33 days (6–309), although 12% needed a second-line agent to do so. Mean number of relapses during the first 24 months was 1.0. 88% experienced at least one relapse, and 45% patients required second-line agents at some point. Regarding complications: 12% developed thromboembolic disease, 14% had an admission-requiring infection, and 41% had at least one episode of AKI. Mean follow-up creatinine was 91 mmol/L, but significantly higher in those who had had AKI (104 vs 85 P=0.04) and those who had received an ACEI (99 vs 78 P=0.01). Of 16 patients who underwent subsequent biopsy (all of whom had received a CNI), 8 showed evidence of CNI damage, and 5 were consistent with FSGS. Diabetes mellitus developed in 12% cases, and 8% patients died during follow-up.

Conclusions: Almost all treated adult MCD patients enter remission, although second-line agents are frequently required. Despite therapy, complications remain common, including AKI which is associated with residual reduced excretory function.

FR-PO427

Predictors for Relapse in Adult Minimal Change Disease

Haijooong Lee, Dong Ki Kim, Kwon Wook Joo, Yon Su Kim, Chun Soo Lim.
Internal Medicine, Seoul National Univ Hospital.

Background: Minimal change disease (MCD) is well-known benign primary glomerulonephritis in adults because of their distinct rare renal progression to end-stage. However, their relapse-associated morbidity has been underestimated. In this study, we aimed to explore the predictors of relapse in adult MCD patients. Methods: We reviewed clinical and pathologic characteristics of adult primary MCD patients from Seoul National University Hospital from 1979 to 2013. Patients who were presented by nephrotic syndrome and followed up more than 12 months were included. Patients were classified as either relapsers or non-relapsers. Initial treatment regimens, their response, and complication were also reviewed. The number of relapse were classified as follows, no relapse, 1-2 relapses (relapse group 1), and ≥ 3 relapses (relapse group 2).

Results: A total of 195 patients were included in the final analysis. Among them, median age at the time of diagnosis was 38 (23–53) years and 113 (57.9%) were men. During median follow up of 81 (44–153) months, more than 90% of patients reached to remission after initial treatment. However, only 64 (32.8%) patients did not experience any relapse. Remaining 131 patients, 69 (35.4%) relapsed once or twice and 62 (31.8%) relapsed more than three-times. The younger, the more relapse was found. In addition, severity of nephrotic syndrome data were shown in the table. Multivariate analyses found that younger age, lower serum albumin, mesangial proliferation and treatment duration remained as independent risk factor for relapse.

Conclusions: We proved that patients with younger age, severe nephrotic syndrome, lower mesangial proliferation and shorter treatment duration were prone to relapses. Moreover, relapse is morbidity due to higher thromboembolic events in adult MCD patients.

FR-PO428

Rituximab in Relapsing Minimal Change Glomerulonephritis: Clinical Outcomes and Financial Analysis

Kevin William Loudon, Clare Morlidge, Suresh Mathavakannan, Ken Farrington, Barbara Thompson, Paul Warwick.
Dept of Renal Medicine, Lister Hospital, United Kingdom.

Background: Minimal change disease (MCD) accounts for 10-15% of adult nephrotic syndrome, with frequent relapses or steroid-dependency occurring in 25-30%. Glucocorticoids and calcineurin inhibitors are the mainstay of treatment, but can be associated with significant toxicity. Rituximab holds potential to induce long term remission in these patients, but in the United Kingdom is currently not funded based on perceived excessive cost.

Methods: Nine patients with frequently relapsing MCD (histologically confirmed) were given total dose Rituximab 1g – 2.4g divided into two - four doses from 2012 - 2014. Time from diagnosis to first Rituximab dose was 140 months (10 – 336). Cost effectiveness of Rituximab was assessed based on comparing annual relapse rates; inpatient/outpatient attendances and immunosuppressant medication in the two years prior, and one year post Rituximab. Data was obtained retrospectively using hospital finance records, NHS standard tariff and the British National Formulary (2015) respectively.

Results: In all patients Rituximab induced complete remission. All steroid-sparing agents were discontinued. Four patients remain on low dose prednisolone (less than 4mg). Mean follow-up was 15 months (6 – 30) with only one relapse at 19 months. Annual relapse rates fell from 1.83/year (0.5 – 6.0) to 0.12/year (0.0-0.57). Inpatient days fell from a mean of 4.2 days/year (0-9.6) to 1.7 days/year (0-4.5). Outpatient consultations fell from 12.5/year (5-26.4) to 7.3/year (4.5-28). Mean annualised pre-Rituximab costs were £172 and post Rituximab, £5046, in 6/9 patients with sufficient length of follow up for comparison. No major complications were noted following treatment.

Conclusions: In patients with relapsing MCD, Rituximab proved to be cost effective and well tolerated. Burden of medication with attendant side effects, as well as inpatient and outpatient attendance were significantly reduced. Annualised costings showed a modest saving post Rituximab. Further randomised studies are required to confirm and extend these findings.

FR-PO429

Long-Term Outcomes of Nephrotic Syndrome, from Childhood into Adulthood

Rebecca C. Hjorten, Frederick J. Kaskel, Kimberly J. Reidy.
Pediatrics, Div of Nephrology, Albert Einstein College of Medicine, Children’s Hospital at Montefiore, Bronx, NY.

Background: Steroid Resistant Nephrotic Syndrome (SRNS) is known to have several long term sequelae including chronic and End Stage Kidney Disease (CKD and ESKD). However there are few studies on the long-term outcomes of steroid sensitive nephrotic syndrome. Presented here is a single center, retrospective case series from an urban, ethnically diverse population in the Bronx.

Methods: We utilized a medical record data mining tool to identify patients by ICD-9 code (1) with a diagnosis of nephrotic syndrome prior to age 18 (2) with a documented albumin <3.5 g/dl or random urine protein >1 g/dl and (3) with at least one hospital encounter after age 18. Patients with a history of renal biopsy or who received immunosuppressant medication other than steroids were termed complicated nephrotic syndrome (CNS). All others were termed simple nephrotic syndrome (SNS). Patients with a diagnosis of asthma prior to age 18 with at least one hospital encounter after the age of 18 were used as controls. Each cohort was evaluated for diagnosis of hypertension, osteoporosis, cataracts, infertility and malignancy. Their last height, weight and creatinine were used to evaluate their height and weight percenttile, BMI and estimated GFR by the MDRD equation.

Results: All three groups – SNS (n=173), CNS (n=169) and control (n=18225) had similar age at diagnosis, length of follow-up. Both the SNS and CNS groups had a greater proportion of short stature, cataracts, infertility and malignancy (Chi square statistic p < 0.05) [table 1]. In addition they had a greater percentage of patients with CKD by eGFR than the controls. Mean BMI of patients with SRNS and CNS were similar to the controls.

Conclusions: Our results show that even patients with uncomplicated nephrotic syndrome are at risk for significant outcomes, including chronic kidney disease. Further study is needed, however it implies that all patients with a diagnosis of nephrotic syndrome will need to be counseled regarding the risks associated with their diagnosis and should have long term monitoring for these outcomes, including worsening renal function, hypertension and malignancy.

Apolipoprotein CI Levels Are Associated with the Urinary Protein/Urinary Creatinine Levels in Pediatric Idiopathic Steroid-Sensitive Nephrotic Syndrome

Jun Odaka, Takahiro Kanai, Takane Ito, Jun Aoyagi, Takariki Yamagata. Pediatrics, Jichi Medical Univ, Shimotsuke, Tochigi, Japan.

Background: Various humoral factors have been proposed as causal agents of idiopathic steroid-sensitive nephrotic syndrome (ISSNS). In the present study, we analyzed serum proteins using mass spectrometry (MS) in a search for proteins that might be related to ISSNS pathophysiology.

Methods: We collected serial serum samples from 33 children with ISSNS. The serum samples were collected in each phase as follows: Phase A1 [the acute phase prior to steroid treatment (STx)], Phase A2 [remission with STx], and Phase A3 [remission without any medication]. We also included two control groups comprised of children with normal urinalysis (Group B) and children with a nephrotic syndrome other than ISSNS (Group C). The urinary protein/urinary creatinine (UP/UCr) ratios were not statistically different between Phase A1 and Group C. We used surface-enhanced laser desorption/ionization time of flight MS to analyzed samples.

Results: A total of 207 peptide ion peaks were detected in the range of m/z 2000–10000. Four peptide ions (m/z 6444, 6626, 8695, and 8915) were significantly correlated with UP/UCr levels. The m/z 6626 was identified as apolipoprotein CI (Apo CI).

A1 compared with Phase A2, Phase A3, and Group C. The intensities of m/z 6626, 8695, and 8915 were significantly correlated with UP/UCr levels. The m/z 6626 was identified as a protein associated with the UP/UCr levels in pediatric ISSNS. Our findings provide new insight into elucidating the pathophysiology of ISSNS.

Conclusion: Apo CI was detected as a protein associated with the UP/UCr levels in pediatric ISSNS. Our findings provide new insight into elucidating the pathophysiology of ISSNS.

Ofatumumab in Two Nephrotic Syndrome Children

Marina Vivarelli,1 Manuela Colucci,1 Alice Bonanni,2 Francesco Emma,1 Gian Marco Ghiggeri,2 1Nephrology and Dialysis, IRCCS Bambino Gesù; 2Pediatric Hospital, Rome, Italy; 2Nephrology and Dialysis, Gaslini Pediatric Hospital, Genova, Italy.

Background: Rituximab (RTx), an anti-CD20 monoclonal antibody, is an effective treatment in patients with frequently-relapsing or steroid-dependent nephrotic syndrome (Ravani, JASN 2015). However, some patients develop adverse reactions. We describe the use of a humanized anti-CD20 monoclonal antibody, ofatumumab (OFA), as a viable alternative.

Methods: Patient 1 is a 3-year-old boy who presented at 18 months with NS initially resistant to treatment with oral prednisone. He was then treated with 3 iv boluses of methylprednisolone followed by cyclosporinaA, with remission. Upon steroid discontinuation, NS relapsed. Prednisone was restarted and a single dose of RTx was planned, but was never completed as at start of infusion a severe allergic reaction (urticaria, dyspnea) occurred. Patient 2 is a 14-year-old boy with SDNS since the age of 2 years treated with oral prednisone, cyclosporinaA and micophenolate mofetil (MMF), with the development of severe obesity. A first infusion of RTx at age 12 was well tolerated and allowed prednisone discontinuation for over 2 years. Then a prolonged (>30 days) relapse occurred under treatment with oral prednisone, MMF and cyclosporinA. Therefore, a second RTx infusion was attempted, but the child presented severe dyspnea and it was interrupted. The use of OFA at 1.5 g/1.73 m2, described in steroid-resistant NS children (Basu, NEJM 2014), was attempted. In patient 2 OFA was preceded by three boluses of iv methylprednisolone to induce remission.

Results: In pt 1, OFA infusion was uneventful. In pt 2, a mild allergic reaction was observed and treated. Remission was maintained during the follow-up period (9 months for pt 1, 5 months for pt 2), despite the interruption of prednisone treatment in both patients, and in pt 1 of cyclosporinaA, while in pt 2 of MMF with ongoing cyclosporinaA at last follow-up. After OFA infusion, CD19+ B cells reappeared at 7 months in pt 1, while remained depleted (0%) at 5 months in pt 2.

Conclusions: OFA could be a therapeutic option in managing severe forms of drug-resistant nephrotic syndrome in patients who have developed intolerance to RTx.

Population-Based Identification of Children with Primary Nephrotic Syndrome: Kaiser Permanente Nephrotic Syndrome Study

Alan S. Go,1 Dongjie Fan,1 Thida Tan,1 Janet M. Wojcicki,2 Jirong Yang,1 Juan Daniel S. Go,1 Kaiser Permanente Northern California; 2Univ of California, San Francisco; 1Stanford Univ.

Background: Few population-based data exist about children with primary nephrotic syndrome (NS) in the US. We identified a cohort of children with primary NS in a large integrated healthcare system.

Methods: Kaiser Permanente Northern California cares for >750,000 children. We identified members age<18 yrs between 1996-2012 who had nephrotic range proteinuria (UACR>3500 mcg/mg, PCR>3 mg/mg, 24-hr protein>3500 mg, dipstick>300 mg/dL) or diagnosed NS (ICD-9 581.x) in electronic records and lab databases. Nephrologists reviewed records for clinical presentation, lab and biopsy results to confirm primary NS.

Results: We identified 179 children with NS due to minimal change disease (72%), focal segmental glomerulosclerosis (23%) or membranous nephropathy (5%). Incidence was 1.47 per 100,000 (95% CI 1.27-1.70). Biopsies were available in 40% of cases. Baseline features at diagnosis are shown by cause of NS.

Abatacept Treatment and B-1 Immunostaining in Patients with Primary and Post-Transplant FSGS

Kutger J. Mass,1 Brigitte Willemsen,2 Henry Dijkstra,3 Catharina M. Haring,1 Jeroen Deegens,1 Jack F. Wetzels,1 1Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; 2Pathology, Radboud Univ Medical Center, Nijmegen, Netherlands; 3Nephrology, Deventer Hospital, Deventer, Netherlands.

Background: Podocyte B7-1 expression has been implicated in the pathogenesis of idiopathic nephrotic syndrome for many years. Recently, podocyte B7-1 was described as a potential therapeutic target by demonstrating efficacy of B7-1 blocking agent abatacept in five patients with primary and post-transplant FSGS (Yu et al. New Engl J Med 2013). The authors speculated that patients who will respond to abatacept can be identified by positive B7-1 immunostaining on kidney biopsy. Here, we report our experience with abatacept and B-1 staining in patients with FSGS.

Methods: Patients with no or partial proteinuria remission after plasmapheresis for treatment of FSGS received abatacept (2 or 3 doses of 10 mg/kg). After several trials of unsuccessful immunofluorescence staining, we performed B7-1 immunohistochemistry on paraffin embedded tissue with a primary antibody mouse anti CD80 (R&D systems).

Results: Three patients with post-transplant FSGS, and one patient with FSGS in the native kidney (Table, Patient 4) were treated with abatacept. All transplant patients had developed nephrotic proteinuria immediately after transplantation. Patient 1 had been treated with plasmapheresis for many years, and was previously unresponsive to B7-1 blocking agent belatacept. None of the patients had proteinuria remissions after abatacept, nor did we observe positive podocyte B7-1 immunostaining.

Conclusions: In our hands B7-1 staining was absent in patients with FSGS. Our data caution against too much optimism regarding the efficacy of abatacept.
Steroid Resistant Nephrotic Syndrome: A Prospective, Open Label Study of the Safety and Efficacy of Combination Tacrolimus and ACTH

**Background:** Steroid resistant nephrotic syndrome (SRNS) in adults is associated with increased risk for progression to ESRD. Tacrolimus is a calcineurin inhibitor (CNI) that is an alternative to steroids, but is associated with progressive fibrosis and loss of GFR. ACTH gel has shown benefit in the treatment of SRNS. To investigate additive effects, we followed 23 SRNS patients receiving combination therapy with Tacrolimus and ACTH Gel.

**Methods:** 23 patients with SRNS (IMGN 8, 11 FSGS and 4 other) receiving ACEi/ARB and 8 weeks of oral steroids prior to combination therapy of ACTH and Tacrolimus. Eleven patients received 2 or more drug therapies. Of the 23, 17 (71%) initially received IMGN therapy followed by Tacrolimus. Duration of ACTH/TAC therapy averaged 6.2 months (range 1-12 months). Complete or partial responses were defined as UP/Cr ratio of < 0.30, <0.5, <1.0, <2.0, <5.0, and <10.0, respectively (all p<0.0001). After adjustment, differences were attenuated but remained statistically significant for demographic, socioeconomic, and comorbidity differences.

**Results:** Of the 23 patients, 6 (26%) achieved a complete response; a partial responses were observed in 11 (48%) for an overall response of 74%. Proteinuria levels (expressed as a UP/Cr ratio) before and after treatment are listed in the Table. There was no difference in the rate or time to complete or partial remission between IMGN and FSGS (IMGN: 82%; 6.1 ± 0.8 mths; FSGS: 75%; 7.0 ± 1.5 mths). Complete or partial remission was achieved in 92% (21) of patients with IMGN. Of the 23 patients, 6 (26%) achieved a complete response; a partial responses were observed in 11 (48%) for an overall response of 74%. Proteinuria levels (expressed as a UP/Cr ratio) before and after treatment are listed in the Table. There was no difference in the rate or time to complete or partial remission between IMGN and FSGS (IMGN: 82%; 6.1 ± 0.8 mths; FSGS: 75%; 7.0 ± 1.5 mths). Complete or partial remission was achieved in 92% (21) of patients with IMGN.

**Conclusions:** In the Tac cohort a higher remission rate was demonstrated and a suggestion of fewer adverse events although numbers are small. However the baseline parameters show the GFR was significantly lower in the prednisolone group. Patients treated with Tac had a longer duration of treatment but appeared to have a better adverse event profile overall. A randomised controlled trial is required to investigate this further.

**FR-PO436**

**Differences in Initial End Stage Renal Disease (ESRD) Treatment Modality Across Glomerulonephritis Subtypes**

Michelle M. O’Saughnessy,1 Maria E. Montez-Rath,2 Richard A. Lafayette,2 Wolfgang C. Winkelmayer3

**Background:** Kidney transplantation (Tx) is the treatment of choice for end-stage renal disease (ESRD). Hemodialysis (HD) and peritoneal dialysis (PD) outcomes are largely equivalent. Whether access to these modalities is equal across glomerulonephritis (GN) subtypes has not been established.

**Methods:** We identified all patients in the US Renal Data System 18-75 years who initiated ESRD treatment with Tx, HD, or PD (1996-2011) and had ESRD attributed to 6 GN subtypes [focal segmental glomerulosclerosis (FSGS), IgA nephropathy (IgAN), membranous nephropathy (MN), membrane-proliferative GN (MPGN), lupus nephritis (LN), vasculitis]. Odds ratios (ORs) for PD vs HD and for Tx vs HD were computed using multinomial logistic regression (IgAN as reference group), with multivariate adjustment for demographic, socioeconomic, and comorbidity differences.

**Results:** Among 75,278 patients studied, demographic, socioeconomic, and comorbidity characteristics differed considerably across GN subtypes. In unadjusted analyses, patients with FSGS, MN, MPGN, LN, and vasculitis were significantly less likely to receive Tx or PD as a first ESRD treatment modality than patients with IgAN: OR for Tx 0.52, 0.35, 0.48, 0.23, and 0.13, respectively; OR for PD 0.77, 0.66, 0.59, 0.48, and 0.30, respectively (all p<0.0001). After adjustment, differences were attenuated but patients with secondary GN subtypes (LN, vasculitis) remained significantly less likely to receive Tx or PD as compared to patients with IgAN (figure).

**FR-PO435**

**Treatment of Nephrotic Syndrome Secondary to Primary FSGS – Prednisolone or Tacrolimus? A Two Centre Experience**

Hannah R. Wilson,1 Thomas M. Connor,2 Tom Cairns,2 Mona Saleh Wahba,2 Marie B. Condon,1 Megan Griffith.3

**Background:** Focal segmental glomerulosclerosis (FSGS) is a significant cause of end-stage renal failure. Patients with nephrotic syndrome have a worse prognosis. Current guidelines advise prolonged prednisolone (pred) at 1mg/kg. Tacrolimus (Tac) is an alternative for patients, but long-term therapy is often necessary, and there are concerns about toxicity.

**Methods:** Retrospective review of all patients with nephrotic syndrome secondary to primary FSGS treated with a minimum of 12 mths follow-up at 2 centres. All patients received standard therapy with max tolerated ACEi +/- ARB. Complete remission (CR) was defined as normal serum albumin with PCR <50; partial remission (PR) as proteinuria ≤50% baseline. Results described as Median (Range); p value <0.05 significant.

**Results:**

FR-PO437
Non Collapsing Focal and Segmental Glomerulosclerosis in Patients with HIV

**Background:** With the improvement of the treatments against HIV, non collapsing focal and segmental glomerulosclerosis (FGS) has become more frequent than HIV associated nephropathy (HIVAN). However, the pathophysiology of non-collapsing FSGS among HIV patients remains poorly understood. We thus aimed to compare patients with HIV and non-FSGS patients with HIVAN and with non HIV patients with FSGS.

**Methods:** HIV patients with a kidney biopsy in our center between 2000 and 2012 (24 non collapsing FSGS and 13 HIVAN) and two control groups (10 primary and 12 secondary FSGS) were included. Clinical and biological data were collected; viral load in serum and urine was assessed, and patients underwent anticoagulation.

**Results:** Clinical and biological features of HIV patients with non-collapsing FSGS were close to those of controls with secondary FSGS. Among HIV patients, the prevalence of cardiovascular risk factors was greater in those with non collapsing FSGS than in those with HIVAN (79% vs. 38%, p=0.01) but was comparable to the one in controls with secondary FSGS (100% vs. 79%, NS). HIV patients with non collapsing FSGS and controls with secondary FSGS had more frequently arteriolosclerosis on the biopsy than patients with HIVAN (75% and 82% vs 36%, p<0.01). Visceral epithelial cells expression of PCNA showed that, despite a stronger staining in collapsing lesions, it can be found among all patients groups and in any FSGS lesion type. The majority of HIV patients with non collapsing FSGS had undetectable viral load in serum and urine.

**Conclusions:** Major clinical, biological and histological differences between HIV patients with non collapsing FSGS and HIVAN support the hypothesis that the diagnosis of HIVAN needs to be excluded among patients at risk for FSGS. An association between idiopathic FSGS and HIVAN is suggested, and the risk of collapsing FSGS should be considered among patients with HIVAN.

**Funding:** Private Foundation Support

FR-PO438
Diabetic Glomerulosclerosis or Idiopathic Nodular Glomerulosclerosis – Role for Insulin Resistance

**Background:** Diabetic nephropathy (DN) is characterized histologically by nodular mesangial sclerosis, a thickened glomerular basement membrane, and hyalinized arterioles. Differential diagnoses by light microscopy (LM) include membranoproliferative glomerulonephritis, amyloidosis, monoclonal immunoglobulin deposition disease, and fibrillary or immunofluorescent glomerulopathy. These can readily be excluded by special staining, immunofluorescence (IF) and electron microscopy (EM). Idiopathic nodular glomerulosclerosis (ING) is the term used to denote classic DN confirmed by LM, IF, and EM, but in the absence of diabetes mellitus (DM). Case reports suggest insulin resistance (IR) as a possible cause.

**Methods:** Data was collected retrospectively on 21 cases of diabetic glomerulosclerosis or ING biopsied due to proteinuria (>1 g on urinalysis to 12.3 g/days), or with or without renal insufficiency (creatinine 0.6-4.4 mg/dL).

**Results:** 13 patients were male with majority of patients being African American (10) and non-Hispanic white (7). 1 patient was post renal transplant and another post liver transplant. None of these patients were diagnosed with DM, although some had intermittently elevated blood glucose and borderline HbA1c. All patients had hypertension, but only 5 were active tobacco users and 8 were former smokers. BMI range was 21-43kg/m². Hemoglobin A1c range was 4.6-6.1% in 10 patients and 6 patients denied DM by telephone survey. The remaining 5 patients had no history of DM per records with few elevated random plasma glucose levels found on 24h iodixanol. None of them fulfilled current diagnostic criteria for DM. Metabolic syndrome (MS) defined by Adult Panel III criteria was evident in 11 patients.

**Conclusions:** The pathogenesis of ING remains unclear. It involves the interplay of hypertension, obesity, and heavy smoking. We feel that IR is critically important, whether evident as subtle, prediabetic elevations of blood glucose, MS, or elevated HOMA-IR score being the only manifest feature. Insulin sensitivity assessed by HOMA-IR score is possibly an important predictive factor in pathophysiology of ING and needs to be tested routinely.

FR-PO439
Association of Serum Albumin Level and Venous Thromboembolic Events in Seven-Thousand Patients with Nephrotic Syndrome

**Background:** Prior studies have shown that low serum albumin in patients with nephrotic syndrome (NS) is associated with an increased risk of venous thromboembolic (VTE) events. This is based on small studies with a low number of thromboembolic events and short term follow-up.

**Methods:** From a nationally representative cohort of over 3 million US veterans with baseline estimated glomerular filtration rate (eGFR) ≥60 ml/min/1.73m², we identified 7037 patients with NS based on ICD-9 codes. Association between serum albumin level and risk of incident VTE events (based on ICD9 codes) was assessed using Cox regression analysis with adjustments for age, gender, race, comorbidities, eGFR, BMI, and anticoagulant treatment.

**Results:** Mean age was 57±11 years, and patients were 96% male, 32% African-American and 60% diabetic. There were a total of 158 VTE events over a median follow-up was 8.1 years (16 events (4.1%, event rate (ER): 8.5/1000 patient-years(PY)) in patients with albumin < 2.5 g/dl, 18 events (3.4%, ER: 5.7/1000 PY) in patients with albumin 2.5-2.99 g/dl, 89 events (2.5%, ER: 3.4/1000 PY) in patients with albumin 3-3.99 g/dl and 55 events (1.4%, ER: 1.9/1000 PY) in patients with albumin ≥ 4 g/dl. Compared to patients with albumin < 2.5 g/dl, those with albumin levels of 3-3.99 g/dl (adjusted HR: 1.51; 95%CI: 1.01-2.26), 2.5-2.99 g/dl (2.24, 1.24-4.05) and < 2.5 g/dl (2.79, 1.45-5.37) experienced a linearly higher risk of VTE events.

**Conclusions:** Lower serum albumin is a strong incremental risk factor for VTE events in NS. The risk increases proportionately with declining albumin levels. Our finding may have important clinical implications regarding initiation and duration of prophylactic anticoagulation.

**Funding:** NIDDK Support, Veterans Administration Support

FR-PO440
Hypercoagulopathy Is Directly Correlated with Disease Severity in Nephrotic Syndrome

**Background:** Nephrotic syndrome (NS), a leading cause of end stage kidney disease, is characterized by massive proteinuria, hypoalbuminemia, and an increased risk for venous thromboembolism (VTE). We recently reported that hypercoagulopathy is proportional to the severity of both proteinuria and hypoalbuminemia in two animal models of NS. This study was designed to determine if this relationship translates to human NS.

**Methods:** Aliquots of plasma anticoagulated with 0.32% (final concentration) sodium citrate were obtained from the NEPTUNE biorepository (n=147 patients), along with corresponding clinical lab data (e.g. urine protein/creatinine (uPC), serum albumin (sAlb)). Samples collected from a local patient cohort (n=21) were used to validate biorepository

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
specimen integrity. Endogenous thrombin potential (ETP) was determined using the
Technochromin TGA kit and RC Low reagent after 2.1 dilution with buffer. Plasma antithrombin
(pAT) activity was measured by the amidolytic method.

Results: As expected, NEPTUNE patients exhibited a wide range of proteinuria values
(median (range) uP:C: 1.85 mg/mg (0-17.6)). Hypoalbuminemia and proteinuria severity were
proportional to ETP (R=-0.252 & 0.128, respectively, P<0.001). These correlations were stronger in
the subset of patients with uP:C>2 (R=-0.331 & 0.157, respectively, P<0.001). Plasma AT activity
was also significantly correlated to hypoalbuminemia and proteinuria severity (R=(-0.125 & 0.031, P<0.03, respectively). There was no correlation between TA AT activity and ETP. Results were similar in the validation cohort.

Conclusions: Both hypoalbuminemia and proteinuria severity in humans with NS is
significantly, albeit weakly, correlated to ETP (an established marker of thrombotic risk).
Adjusting these data for clinical variables (e.g. smoking status, BMI, etc.) may aid in the modeling and development of evidence-based cut-offs to guide indications for prophylactic anticoagulation.

FR-PO441

Successful Social Media Recruitment into the NephCure Kidney Network, a Rare Disease Patient Registry

Laura Hay, Jennifer H. Mariani, Joanna Dauber, Chelsey Fix, Alyssa Fisher, Jane Shen, Lalita Subramanian, Marilyn Hairperin, Elizabeth L. Cope, 1 Arbor Research Collaborative for Health, NephCure Kidney International.

Background: Participation in clinical research for primary nephrotic Syndrome (NS) has been
limited by the rarity of the disease. There is growing interest in leveraging social media to expand
geographic and demographic reach for recruitment. Because of the妮志ing nature of rare
diseases, patients turn to social media for support, creating online communities that, if accessible, could potentially serve as a resource for recruitment.

Methods: The NephCure Kidney Network (NKN) is a web-based patient opt-in registry for
recruiting patients into clinical trials. Participation is in whole, including kidney disease history, demographics and research participation preferences. Recruitment efforts launched in March 2014 relied on email campaigns to contacts of the patient advocacy group, NephCure Kidney International (NKI), but then expanded in September 2014 to include social media. Weekly posts were made to NKN’s Facebook page, with analysis of performance based on impressions (# of people reached) and engagements (likes, clicks, shares, comments). Relationships with other closed Facebook kidney disease groups were established and posts made to their sites.

Results: 45,151 impressions and 2,927 engagements were made from 9/2014-6/2015. Of
patients who participated, 54% were recruited through social media.

Conclusions: A recruitment strategy which includes social media is an efficient, cost-
effective opportunity to engage rare disease patients across a wide geography, including
those who have not previously participated in research.

FR-PO442

The Expression of Podocyte Protein PREX2 in Glomerular Diseases

Anna Levin, 1 Julia Wijkström, 1 Jenny Hulko, 1 Jenny C. Nystrom, 2 Kerstin Ebefor, 3 Annette Bruchfeld, 1 Jaakko Patrakk, 4 Kjell Hultenby, 1 Anniika Wernerson, 3 CLINTEC, Karolinska Inst (KI), Stockholm, Sweden; Dept of Physiology, Sahlgrenska Academy, Gothenburg, Sweden; 2 Dept of Molecular and Clinical Medicine, Sahlgrenska Academy, Gothenburg, Sweden; 3 Dept of Medicine, KI, Stockholm, Sweden; 4 LabMed, KI, Stockholm, Sweden.

Background: Phosphatidylinositol-3,4,5-trisphosphate-dependent Rac exchange factor
(PREX2) is a 183 kDa protein that functions as a RAC guanine nucleotide exchange factor (GEF), activating Rac proteins. It has been discovered in several tissues, e.g. brain, lung, liver and kidney. The specific function of PREX2 in the kidney is unknown. The aim of the present study was to investigate the localization of PREX2 in the kidney and the possible role in renal disease.

Methods: RT-PCR, Western Blot and immunohistochemistry (IHC) was used to identify the
localization of PREX2 in renal tissue. The mRNA expression in diseased kidney was
analyzed by microarrays on isolated glomeruli from patients with IgA Nephropathy (IgAN), Membranous Nephropathy (MN) and normal tissue. Immuno electron microscopy (IEM) was used to semiquantify PREX2 in renal biopsies from patients with IgAN (n=6), Minimal Change Nephropathy (MCN, n=5) and control tissue from healthy kidney donors (n=5).

The morphology was correlated to proteinuria at time of biopsy.

Results: RT-PCR and Western Blot showed the presence of PREX2 in glomerulus, IHC and IEM revealed that PREX2 was localized to podocyte foot processes. In disease samples, mRNA levels were not changed in IgAN and MN. Semi-quantitative IEM showed a significantly lower expression of PREX2 in IgAN and MCN compared to controls. A tendency towards a negative association between PREX2 and proteinuria was seen, although this was not significant.

Conclusions: We found that PREX2 is a new podocyte-associated protein. Although no difference in mRNA levels were found, the expression of PREX2 was significantly
lower in IgAN and MCN compared to controls. The function of PREX2 in the glomerular formation is still unknown but it will now be further investigated in an extended patient cohort and in genetically modified animals.

FR-PO443

Urinary and Serum Soluble Urokinase Receptor Levels Predict the Therapeutic Response of Nephrotic Syndrome

Kohei Fujimoto, Yuki Matsui, Norifumi Hayashi, Junko Imura, Hiroki Adachi, Hideki Yamaya, Hitoshi Yokoyama. Div of Nephrology, Kanazawa Medical Univ, Uchinada, Ishikawa, Japan.

Background: It is necessary to develop noninvasive biomarkers to predict the treatment response for nephrotic syndrome (NS), and to differentiate their histological types in the initial phase.

Methods: The subjects were 32 patients with primary NS [8 with focal segmental
glomerulosclerosis (FSGS), 12 with minimal change nephrotic syndrome (MCNS), 10 with membranous nephropathy (MN), and 2 with membranoproliferative glomerulonephritis]. Using ROC analysis, we examined whether or not it is possible to differentiate refractory NS from non-refractory NS, and MCNS from FSGS based on the pretreatment values of clinical markers [urinary protein (UP), serum/urinary soluble urokinase receptor (su-) uPAR, urinary L-FABP, and eGFR], and values and changes (Δ) after 2 months (2M).

We also examined the renal expression of activated b3 integrin (AP-3) by immuno-staining in
primary NS and normal tissues.

Results: The following parameters were useful for differentiating refractory NS from
non-refractory NS: 2M (AUC=0.968, p=0.001), 2Ms-suPAR (AUC=0.913, p=0.002), D2Ms-suPAR (AUC=0.906, p=0.007), D2Ms-suPAR (AUC=0.881, p=0.005), and D2MUP (AUC=0.833, p=0.014). On the other hand, D2Ms-suPAR (AUC=0.905, p=0.007) and D2Ms-suPAR (AUC=0.816, p=0.048) were useful for differentiating MCNS from FSGS. In addition, u-suPAR before treatment was positively correlated with UP (p=0.501, p<0.003) and urinary L-FABP (p=0.427, p=0.017). The expression of activated b3 integrin was primarily strong in the proximal tubular epithelial cells in FSGS or MN, but, weak in MCNS and normal tissues. Otherwise, there was no expression of activated b3 integrin on podocytes in both normal and diseased tissues.

Conclusions: It may be possible to evaluate the treatment response of NS and to
differentiate MCNS from FSGS based on changes in u-suPAR within 2 months after the start of treatment. As a mechanism involved in proteinuria in NS patients, u-suPAR may inhibit protein reabsorption in the proximal tubules through the activation of b3 integrin.

FR-PO444

Turkish Atypical Hemolytic Uremic Syndrome Registry: Initial Pediatric Results

Nesrin Besbas, 1 Oguz Soylenmezoglu, 2 Bora Gulhan, 1 Z birsin Ozcaner, 3 Emine Korkmaz, 4 Fatih Ozatins. 1 Pediatric Nephrology, Faculty of Medicine Hacettepe Univ, Ankara, Turkey; 2 Pediatric Nephrology, Faculty of Medicine Gazi Univ, Ankara, Turkey; 3 Pediatric Nephrology, Ankara Univ Faculty of Medicine, Ankara, Turkey; 4 Nephrogenetics Laboratory Dept of Pediatric Nephrology, Hacettepe Univ, Ankara, Turkey.

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare, genetic, life-
threatening disorder of chronic complement activation leading to systemic thrombotic
microangiopathy and end-organ damage. The national aHUS registry was initiated in November 2013 and collects information on the progression and treatment of disease.

Methods: A clinical diagnosis of aHUS is required for inclusion. Demographic, medical histories, treatments, efficacy and safety outcomes data are collected initially and every 3 months.

Results: By May 15, 2015, 122 pediatric patients (55.8% female and 44.2% male) were
enrolled from 22 centers covering all the country. Mean age at diagnosis was 4.38±4.23 years. A total of 90 patients (74.6%) had oliguria or anuria at the time of diagnosis. Serum complement 3 was low in 49 patients (40.2%). Neurologic system involvement was present in 34 patients (27.2%). Renal biopty was performed in 37 patients (30.7%). Renal replacement therapies (RRT) were initiated in 61.5 % of the patients at administration where only 10% of the patients were discharged with RRT. Genetic studies including the complement pathway, DGKE and factor H antibodies were studied in 73% of patients. Plasma infusion or plasma exchange was the initial treatment in 82% of patients and 59% of patients (n=72) had eculizumab treatment. At the time of discharge after initial management, 78 patients (63.9%) and 92 patients (75.4%) achieved renal and hematological remission, respectively. Four patients died at the acute stage of the disease. Mean duration of follow-up was 2.28±2.30 years. During follow-up, eculizumab was stopped in 18 patients and re-started in four of them due to relapse.

Conclusions: The pediatric aHUS Registry will provide data to help increase our
knowledge of the aHUS patient with different genetic background and also evaluate the
long-term safety and efficacy of treatment options including the eculizumab.
FR-PO445

Long-Term Outcomes of Thrombotic Microangiopathy Treated with Plasma Exchange – A Systematic Review

Background: The adoption of plasma exchange as standard treatment for thrombotic microangiopathy, more patients are surviving and longer-term outcomes have greater relevance.

Methods: We conducted a systematic review of observational studies between 1980 and 2013 that reported outcomes of adults with thrombotic microangiopathy at least 6 months after initiating plasma exchange. We searched several databases from 1980 to 2013 for eligible articles published in any language. We abstracted data in duplicate and assessed the methodological quality of each study using an assessment tool developed based on recommended validity criteria.

Results: We screened 6672 articles, reviewed 213, and included 34 studies totaling 1182 patients (study median range, 24 [10-118]). The (mean or median) follow-up ranged from 6 months to 13 years. The cumulative incidence of relapse and mortality was highly variable and ranged from 3 to 84% and 0 to 61%, respectively. The incidence of other outcomes across 10 studies also varied (outcomes included hypertension, kidney disease, preeclampsia, stroke, seizure, severe cognitive impairment, and depression); in 3 other studies long-term neurocognitive function and health-related quality of life were significantly lower than the general population.

Conclusions: In summary, patients who survive an episode of thrombotic microangiopathy may be susceptible to long-term vascular complications including chronic kidney disease, but the magnitude of this risk and how to mitigate it remains unclear from prior studies.

FR-PO446

Eculizumab Prevents Thrombotic Microangiopathy in Atypical Hemolytic Uremic Syndrome Patients: Long-Term Follow-Up

Background: In previous studies of patients (pts) with aHUS, ECU effectively treated and prevented thrombotic microangiopathy (TMA) and improved renal function and hematological parameters for up to 2 yrs.

Methods: An observational, multicenter, long-term follow-up study of aHUS pts treated with ECU in 5 prior clinical studies. The primary endpoint was exposure/follow-up TMA event rate post-parent study on-(ON) and off-treatment (OFF; among pts who were treated and prevented thrombotic microangiopathy (TMA) and improved renal function and hematological parameters for up to 2 yrs.

Results: 85 pts enrolled (Table); of these, 74 pts had ON and 37 pts had OFF treatment periods with median follow-up of 24.6 and 16.6 months, respectively. The TMA event rate was 6.7 per 100 pt-yrs for ON pts, and 23.5 per 100 pt-yrs for OFF pts. The rate of TMA events while on or off-label and standard dose and quality of life were significantly lower than the general population.

Conclusions: In summary, patients who survive an episode of thrombotic microangiopathy may be susceptible to long-term vascular complications including chronic kidney disease, but the magnitude of this risk and how to mitigate it remains unclear from prior studies.

FR-PO447

An Update on Tailored Eculizumab Maintenance Treatment in Patients with Atypical Haemolytic Uremic Syndrome

Background: Atypical hemolytic uremic syndrome (aHUS) is a severe, systemic thrombotic microangiopathy often related to mutations in the genes encoding complement regulatory proteins. Since 2009, Eculizumab (ECU) has been successfully used in patients (pts) with aHUS. The standard maintenance treatment suggests ECU administration every two weeks (wks), life-long but the best treatment schedule is not yet defined. To update on our experience on individualized ECU treatment schedule for preventing relapses based on drug biological activity, with the rational of improving the patient’s quality of life, reducing the risk of adverse reactions and reducing the heavy costs of the treatment.

Methods: Pts undergoing ECU treatment at our Center were addressed to a progressive extension of the interval between ECU doses from the standard 2 wks to 3 or 4 wks with a strict monitor of global complement activity. APS0 was routinely determined before each ECU administration and the interval between doses was adjusted with the target of maintaining APS0<25%. Strict monitoring of indicators of disease reactivation, namely blood in the urine with home dipstick, was regularly performed.

Results: The interval between doses was extended in 33 pts (13 ≤ 18 yrs) with a median age of 28.1 yrs (5-62), 17 F, 21 with native kidney and 12 with graft. Identified mutations were: CFI-15, CFI-2, CD46-1; MCP-1; CFI-3; C9H2; CFB1; CFBH1 homoz. deletion with (3) or w/o (1) antiFHAb;4; multiple mutations;3; Idiopathic:7. In 19 pts the optimal interval between ECU doses was 4 wks while in 14 pts it was 3 wks. No relapses was observed after discontinuation of ECU compared with 748 mos (mean 23 mos/pt).

Conclusions: In patients with aHUS, our experience supports the possibility of tailoring ECU maintenance treatment schedule based on global complement activity. In a cohort of 10 adult pts the described novel approach leads to an average estimated saving >2 million USD/yr.

FR-PO448

Chemokines as Potential Biomarkers of Renal Involvement in Scleroderma

Background: Renal disease in scleroderma (SSc) remains a major clinical challenge. Previous studies showed up to 50% of SSc patients have CKD. We sought to gain insight into the progression of SSc renal disease by examining markers of disease in serum and urine.

Methods: We collected urine and serum from 80 SSc patients, with or without renal disease, for comparison with patients with CKD of other causes (n=10) and healthy controls (n=12). We performed multiplex analysis of candidate markers of disease activity or severity in SSc and renal injury: MCP-1, MCP-3, IL-6, IL-18, TNF-a, and VEGF.

Results: 40 SSc patients had CKD defined by eGFR and urinalysis. Serum MCP-1 was increased in SSc compared with controls, with SSc-CKD significantly lower than SSc without CKD. Mean serum MCP-1 was 132 pg/ml (95% CI 105-162) for SSc with normal renal function compared with 65 pg/ml in SSc-CKD (p<0.001 for this comparison).

Conclusions: MCP-1 was not increased in CKD of other causes (mean 47 pg/ml, 23-85) compared with

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
controls (mean 53 pg/ml, 25-85, p=0.848). Conversely, urine MCP-1:creatinine ratio was higher in SSc-CKD (mean 64, 32-111) than in SSc with normal renal function (mean 23, 18-28, p=0.046). MCP-3 was upregulated in the urine of patients with SSc with or without CKD (mean MCP-3:creatinine ratio 3.6, 2.5-4.6) compared with healthy controls (mean 0.9, 0.5-1.4, p=0.016). There was no difference between groups in serum MCP-3.

**Conclusions:** This is the first study to measure MCP-1 and MCP-3 in the urine of SSc patients. Elevated urine MCP-1 in SSc-CKD suggests increased expression in the renal tract and may help define organ-specific effects of this potential pathogenic mediator that has previously been reported to be increased in serum in association with pulmonary complications. In contrast to MCP-1, other markers of SSc severity (e.g. IL-6) or renal injury (e.g. IL-18) did not differentiate between groups. Our findings support further investigation of urine concentrations of chemokines MCP-1 and MCP-3 as markers or mediators of CKD in SSc.

Towards a Deeper Understanding of Fibrillary Glomerulonephropathies: Clinicalopathologic Analysis of Patients in a Long-Term Inception Cohort

Caroline J. Poulton, Yichun Hu, Harsharan Kaur Singh, Volker Nickeleit, William Franklin Pendergraft, UNC Kidney Center, UNC Chapel Hill, Chapel Hill, NC; UNC Pathology, UNC Chapel Hill, Chapel Hill, NC.

**Background:** Fibrillary glomerulonephritis is an uncommon primary glomerular disease. Accordingly, there are no clinical trials to guide treatment making this a challenging disease to manage. Here, we report clinical characteristics and treatment outcomes of patients with fibrillary glomerulonephropathies diagnosed and/or treated at UNC or through the Glomerular Disease Collaborative Network and compare them to a previously published cohort from Mayo clinic.

**Methods:** Patients were identified through the UNC Division of Nephropathology database. Clinical data were extracted from the electronic medical records starting at the time of initial diagnosis.

**Results:** There were 31 patients with fibrillary glomerulonephritis who were treated at UNC and another 245 patients who were diagnosed by the UNC Division of Nephropathology.

**Conclusions:** This clinicopathologic analysis of patients with fibrillary glomerulonephritis is the largest study of its kind in the literature to date. The patients in our cohort were more ethnically diverse than the Mayo clinic group but presented with similar degrees of kidney impairment and nephrotic range proteinuria. Fibrillary mesangiocapillary is an understudied glomerular disease that portends a poor prognosis warranting the need for prospective multi-center treatment studies to determine durable therapeutic avenues.

Clinical, Histologic, and Genetic Predictors of Response to MMF in C3 Glomerulopathy

**Background:** Membranoproliferative glomerulonephritis C3 Deposits: Clinicopathological study. Uriel A. Gaviria, Luis A. Castilla, Eduardo I. Navarro, Ismael Lopez, Kelly Camacho, Maia Olivero, Ismael Lopez, Gustavo Arcoa Martinez, Henry J. Gottlieb, Janet Raul Gonzalez, Marianella, Clínica de la Costa, Barranquilla, Atlántico, Colombia; Medicine, Univ Simón Bolívar, Barranquilla, Atlántico, Colombia.

**Results:** Membranoproliferative glomerulonephritis (MPGN) is a pattern of damage characterized in the light microscopy by mesangial hypercellularity, thickening of the glomerular basement membrane and mesangial interposition in the capillary wall. Recent advances in the understanding of its underlying pathogenesis led to a classification scheme based on the findings in the immunofluorescence. Alteration complement regulation has proven to be a risk factor for the development of MPGN.

**Funding:** Cross-sectional study. The data were extracted from NefroRed®, a software platform that contains the socio-demographic, anthropometric, clinical and laboratory data of 1200 patients with kidney biopsies from 2008 to 2014. It was selected for the study those patients that showed the pattern of glomerulonephritis and membranoproliferative and C3 deposits only or preponderant. Each biopsy was studied by light microscopy and immunofluorescence, light microscopy included hematoxylin-eosin, PAS, and Jones for basement membrane. Immunofluorescence was performed using antibodies directed against IgG, IgA, IgM, C1q, C3, albumin, fibrinogen, Lightweight Kappa and Lambda chains.

**Results:** Mean age of men was 42.3 years and women was 36.7 years. The minimum age was 18 years. The maximum age was 69 years; 51.8% (n = 14) of patients were women. 1200 biopsies showed 58 injuries MPGN (5%) of these 58 cases only 27 (32%) lesions showed C3 deposits only or preponderant.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Conclusions: 30% of patients with GMP have as pathogenic mechanism the complement activation with complement C3 deposition in the glomerulus. Our research group has found C3 deposition causally related to GMP. The most common clinical presentation is nephrotic syndrome.

FR-PO453
Steroids Alone for the Treatment of C3 Glomerulonephritis with Monoclonal Gammopathy
Sanjeev Sethi,1 Insara Jaffer Sathick,1 Ladan Zand,1 Samih H. Nasr,2 Sanjeev Sethi,2 Fernando C. Fervenza,1 Nelson Leung,1,2 1Div of Nephrology and Hypertension, Mayo Clinic; 2Div of Anatomic Pathology, Mayo Clinic.

Background: C3 glomerulonephritis (C3GN) is a rare disease with no trial data to direct treatment. In patients with C3GN with monoclonal gammopathy, steroids alone may be a viable treatment option.

Methods: We present our experience in managing C3GN with monoclonal gammopathy with prednisone.

Results: 5 patients presented to our institution from 2011 to 2014 with biopsy proven C3GN and underlying monoclonal gammopathy. Median age of this cohort was 63 years. Median estimated GFR by MDRD equation was 35.4 ml/min1.73m2 and median proteinuria was 2 g/day at presentation. All patients had IgG kappa monoclonal gammopathy. Patient 5 required renal replacement therapy but recovered renal function. All patients were treated with Prednisone 60mg/day tapering to zero in all except one. Patient 2 and 4 continue on 2.5-5mg/day. Median duration of follow up was 26.9 months. Median estimated GFR at presentation was 40.16 ml/min1.73m2. All patients showed improvement in proteinuria. 3/5 patients showed improvement in proteinuria. 3/5 patients showed improvement in kidney function.

A Prospective Evaluation of Renal Contrast-enhanced Ultrasound (CEUS) in the Detection of Pyelonephritis

Florian Buchkremer,1 Daniel Drozdog,2 Werner C. Albrich,3 Andreas H. Bock,4 Div of Nephrology, Kantonsspital Aarau, Aarau, Switzerland; 5Div of Infectious Diseases, Kantonsspital St. Gallen, St. Gallen, Switzerland.

Background: Contrast-enhanced ultrasound (CEUS) has been described as a promising method for detecting acute pyelonephritis (PN) and its complications. We evaluated its value in diagnosis and risk stratification in the setting of a randomized controlled trial (RCT).

Methods: Immunocompetent adults with community-acquired urinary tract infection (UTI) presenting in the emergency department of Kantonsspital Aarau were enrolled in a RCT designed to evaluate the performance of a PCT/pyuria guided algorithm versus standard guidelines (Drozdov et al. BMC Medicine 2015). Outcomes included antibiotic exposure, duration of therapy, persistent infections and recurrences/re-hospitalizations.

As part of the protocol, all hospitalized UTI patients with fever and/or flank pain were to undergo renal CEUS in addition to standard greyscale and Doppler examination within 48 hours of admission. CEUS findings were defined as: uncomplicated UTI; hyoperfused areas (HAs); or renal perfusion abnormalities (RPA).

Results: Of 70 UTI study patients hospitalized with fever and/or flank pain, 41 (59%) underwent the ultrasound study. Dropout reasons included missing consent (5%), early discharge (6) or technical (18%). Examined and non-examined patients did not differ significantly in baseline characteristics or outcome. Findings suggestive of PN were found in 5/41 (12%). In 3 patients, this was evident in greyscale/Doppler already, in 2 additional patients, critical findings were only present in CEUS. The presence of PN-suggestive findings was not predictable from any baseline clinical characteristic. Patients with and without PN-suggestive findings did not appear to differ in outcome.

Conclusions: Ultrasound evidence of pyelonephritis is rare in patients hospitalized for UTI. Adding CEUS to base greyscale and Doppler ultrasound may substantially increase the number of positive findings.

ISN 0by25 AKI Global Snapshot Project: AKI Disposition

Michael V. Rocco,1 Ravindra L. Mehta,1 Giuseppe Remuzzi,2 Jing Zhang,3 Melanie Godin,4 Michael V. Rocco,5 U Sao Paulo; 6U California San Diego; 7Mario Negri Inst; 8Sherbrooke U; 9Wake Forest U.

Background: The 0by25 AKI Global Snapshot Project (GSP) was a point prevalent survey of AKI pts seen in health care facilities throughout the world.

Methods: A web-based survey tool was used to obtain data from individual clinicians on AKI pts who had a confirmed diagnosis of AKI based on KDIGO criteria. Detailed methodology may be found in the ISN GSP abstract on provider characteristics. Countries were defined by gross national income per capita (GNI): Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC).

Reasons: A web based survey tool was used to obtain data from individual clinicians about AKI pts with AKI based on KDIGO criteria. Detailed methodology may be found in the ISN GSP abstract on provider characteristics. Countries were defined by gross national income per capita (GNI): Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC).

Results: Nephrology management of AKI was more common in LLMIC (85.1%) versus HIC (59.4%) or UMIC (59.8%). Location of pts 7 days after AKI diagnosis varied by GNI category. Death rate was significantly different in dialyzed (17%) vs. non-dialyzed (9%) pts (p<0.0001). Among dialyzed pts, the mortality rate was similar in countries of different GNI categories. The main reason to start dialysis was solute control, with a similar distribution among country categories.

FR-PO458

ISN 0by25 AKI Global Snapshot Project: Indications for Initiating and Withholding Dialysis in AKI Worldwide

Etienne Macedo,1 Ravindra L. Mehta,1 Giuseppe Remuzzi,2 Jing Zhang,3 Melanie Godin,4 Michael V. Rocco,5 U Sao Paulo; 6U California San Diego; 7Mario Negri Inst; 8Sherbrooke U; 9Wake Forest U.

Background: The 0by25 AKI Global Snapshot Project (GSP) was a point prevalent survey of AKI pts seen in health care facilities throughout the world.

Methods: A web based survey tool was used to obtain data from individual clinicians on AKI pts who had a confirmed diagnosis of AKI based on KDIGO criteria. Detailed methodology may be found in the ISN GSP abstract on provider characteristics. Countries were defined by gross national income per capita (GNI): Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC). We analyzed the frequency of AKI requiring dialysis and the reasons for starting or withholding dialysis.

Results: Of 3855 pts, 768 (20%) were dialyzed. Mortality rate was significantly different in dialyzed (17%) vs. non-dialyzed (9%) pts (p<0.0001). Among dialyzed pts, mortality rate was similar in countries of different GNI categories. The main reason to start dialysis was solute control, with a similar distribution among country categories.

INS 0by25 AKI Global Snapshot Project: Differences in Location and Process of Care Among AKI Patients Around the Globe

Etienne Macedo,1 Rudvinda L. Mehta,2 Giuseppe Remuzzi,3 Jing Zhang,4 Melanie Godin,4 Michael V. Rocco,5 1U Sao Paulo; 2U California San Diego; 3Mario Negri Inst; 4Sherbrooke U; 5Wake Forest U.

Background: The Global Snapshot (GSP) was a prospective cross-sectional study designed to capture standardized information on incidence, causes and treatment of AKI in all health care settings throughout countries of diverse economic status. Methods: A web based survey tool was used to obtain data from AKI based on KDIGO criteria in 72 countries. Detailed methodology is found in the ISN GSP abstract on provider characteristics. We analyzed the characteristics of patients and process of care by gross national income (GNI) country levels. Countries were defined as: Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC).

Results: Based on GNI, 23 countries were classified as LLMIC, 20 as UMIC and 29 as HIC. In LLMIC, 58% of patients were classified as AKIN stage 3 at AKI diagnosis. sCr was significantly higher in these patients (3.26 mg/dL) compared to 2.43 in patients from HIC and 2.3 in patients from UMIC.

Conclusions: BS cr was often present in patients from HIC and UMIC, where 1/3 of AKI cases occurred in CKD patients. Absence of BS cr was a common issue in LLMIC, associated with higher levels of sCr and KDIGO stage at AKI diagnosis. UO is often not computed in patients who develop AKI. Systematic assessment of urine output in high-risk patients could help identify AKI earlier.

Funding: Pharmaceutical Company Support - Astute Medical (San Diego, CA, USA), Danone Nutricia Research (Palaiseau, France) and Bellco (Mirandola, Italy), Private Foundation Support

FR-PO461

INS 0by25 AKI Global Snapshot Project: Risk Factors for AKI

Ravindra L. Mehta,1 Giuseppe Remuzzi,2 Jing Zhang,3 Melanie Godin,3 Michael V. Rocco,4 Jorge Cerda,5 John Feehally,6 Fredric O. Finkelstein,7 Nathan W. Levin,8 Marcello Tonelli,9 1U California San Diego; 2Mario Negri Inst; 3Sherbrooke U; 4Wake Forest U; 5Albany Med Coll; 6Yale U; 7Renal Research Inst; 8U Calgary.

Background: The 0by25 AKI Global Snapshot Project (GSP) was a point prevalence survey of AKI pts seen in health care facilities throughout the world. Methods: A web based survey tool was used to obtain data from individual clinicians about AKI patients with AKI based on KDIGO criteria. Detailed methodology is found in the ISN GSP abstract on provider characteristics. Countries were defined by gross national income per capita (GNI): Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC).

Results: Participants were distributed from North East Asia 26.4%, South Asia 18.9%, Latin America/Caribbean 14%, Africa 13.4%, North America 7.3%, Western Europe 6.2%, Oceania/South East Asia 4.3%, Russia/Commonwealth Independent States 3.9%, Middle East 3.4%, Eastern/Central Europe 2.2%. Ethnic groups included 53% Asian, 19% Caucasian, 9% Hispanic, 8% African, 7% Middle Eastern and 1.5% Native/Aboriginal. Causes of AKI varied by GNI and were compared by Kruskal-Wallis test.

ISN 0by25 AKI Global Snapshot Project: Evaluation and Treatment

Jorge Cordeira,1 Rodrigo G. da Cunha,2 Giuseppe Remuzzi,3 Jing Zhang,4 Melanie Godin,5 Michael V. Rocco,6 Emmanuel A. Burdman,7 Guillermo Garcia-Garcia,7 Vivekanand Jha,7 Andrew J.P. Lewington,8 Raul Lombardi,9 Albert M. Hsue,10 U’California San Diego; 11 Mario Negri Inst; 12 Sherbrooke U; 13 Wake Forest U; 14 U Sao Paulo; Hosp Civil de Guadalajara; 15 George Inst Global Health; 16 Leeds Teaching Hosp; 17 Servicio Medico Integral.

Background: The 0by25 AKI Global Snapshot Project (GSP) was a point prevalent survey of AKI pts seen in health care facilities throughout the world.

Methods: A web based survey tool was used to obtain data from individual clinicians about pts who had AKI based on KDIGO criteria. Detailed methodology may be found in the ISN GSP abstract or provider characteristics. Countries were defined by gross national income per capita (GNI): Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC).

Results: Initial evaluation of AKI included urinalysis in 73.6%, ultrasound in 55% and renal biopsy in 4.1%, with all three more commonly being performed in LLMIC. Initial treatment of AKI included fluids in 74.3%, vasoressors in 23.8%, diuretics in 41.4%, antibiotics in 63.8% and urinary diversion in 19.5%. The receipt of dialytic therapy occurred in 790 of 4018 pts (19.7%), with use in 18.8% in HIC, 14.3% in UMIC and 28.0% in LLMIC. In 244 instances where dialysis was recommended but not performed, futility was cited in 58.6% and cultural beliefs were cited in 25.4%. Unavailability of staff or material resources to perform dialysis was reported in 1.4% of HIC, 3.8% of UMIC and 16.4% of LLMIC. Inability to afford therapy was 1.4% in HIC, 1.9% in UMIC and 16.4% in LLMIC (p<0.001). The ratio of pts not able to receive dialysis by those that did receive dialysis was 0.21 in HIC, 0.25 in UMIC and 0.18 in LLMIC. There were significant differences in the renal modality used.

Conclusions: Lack of resources, staff or finances to perform dialysis was most prevalent in LLMIC. When dialysis was provided, it was less likely to be CRRT and more likely to be SLED in LLMIC.

ISN 0by25 AKI Global Snapshot Project: Provider Characteristics

Melanie Godin,1 Rodrigo G. da Cunha,2 Giuseppe Remuzzi,3 Jing Zhang,4 Michael V. Rocco,6 Nathan W. Levin,5 Andrew J.P. Lewington,7 Etienne Macevedo,7 Marcello Tonelli,9 Sherbrooke U; U’California San Diego; Mario Negri Inst; Wake Forest U; Albany Med Coll; George Inst Global Health; Renal Research Inst; Leeds Teaching Hosp; U Sao Paulo; U’ Calgary.

Background: The ISN 0by25 AKI Global Snapshot Project (GSP) was designed to determine the spectrum of AKI pts seen in health care facilities throughout the world.

Methods: Health care providers joined the GSP after gaining approval from their local IRB. Providers chose one “index” day between 9/29/2014 and 12/7/2014 to provide data on AKI pts under their care. De-identified data on pts who met criteria for AKI by modified KDIGO criteria were entered through a secure website using a standard questionnaire developed by the 0by25 AKI workgroup. Data collected included pt demographics, initial clinical data, diagnostic, treatment and outcome information. Countries were grouped into three categories based on gross national income per capita (GNI); high income with GNI >US$12476, low and lower middle income with GNI <US$4035, and upper middle income with GNI between levels 1 & 3.

Results: 324 surveys from 72 countries were received describing 4024 pts with AKI. Providers included 248 nephrologists, 20 nephrology fellows, 14 intensivists, 26 pediatric nephrologists. Location of facilities by region included 52 from Africa, 47 from Latin America & Caribbean, 45 from North America, 45 from South Asia, 40 from North and East Asia, 34 from Western Europe, 19 from Russia/Commonwealth of Independent States, 17 from Oceania & South East Asia, 14 from Middle East and 11 from Eastern & Central Europe. Size of catchment population for each facility was: >5 million in 28%, 0.5-1.5 million in 26%, 0.1-0.5 million in 19% and 1.5-3 million in 11%. Type of facility was institute in 47%, public hospital or health care concern in 37%, private multispecialty group in 14%. Dialysis was available in 97% of facilities.

Conclusions: This project is the first worldwide point prevalent survey of AKI. It demonstrates the feasibility of obtaining data on AKI using a secure website from practitioners in varied health care settings from six continents.

Postoperative Acute Kidney Injury in Non-Cardiac Surgery

Dong Ki Kim, Kwon-Woon Joo, Yo Sun Kim, Hajeong Lee.

Background: Prevention of acute kidney injury (AKI) and amelioration of its severity remain important issues of improving surgical patient outcomes. Therefore, preoperative renal risk evaluation and patient optimization is crucial for nephrologists. Although there are several studies dealing with postoperative AKI in cardiac surgery, they have been seldom studied in non-cardiac surgery.

Methods: We included adult (age ≥ 18 years) patients who received major non-cardiac surgery in Seoul National University Hospital from 2004 to 2013. We extracted their clinical data from our electronic medical record system. Acute Kidney Injury Network criteria (AKIN) was used to define and classify AKI.

Results: Among a total of 95,266 operations, 1,560 cases (1.64%) developed AKI. Patients with AKIN stage I were 964 (1.01%), stage II, 117 (0.12%), and stage III, 479 (0.50%). AKI was most prevalent in urologic surgery, followed by general surgery, orthopedic surgery, and neurologic surgery. Patients who developed AKI tended to be older (53.7 vs. 58.9 years), and male (45.6% vs. 65.6%). Patients with AKI had higher prevalence of underlying diseases such as liver/heart/hematologic/vascular and neurologic disease than those without. Moreover, they showed higher baseline systolic blood pressure and lower baseline diastolic blood pressure than those without. Baseline renal function was lower in AKI-developed patients than the others (0.90 vs. 1.13 mg/dL, P<0.001). Multivariate logistic regression analyses found that older age, male sex, lower baseline renal function, presence of hypertension, longer duration of surgical time and orthopedic or urologic surgery were significant risk factors for postoperative AKI in noncardiac surgery.

Conclusions: In this study, we demonstrated the incidence of postoperative AKI in non-cardiac major operations. Moreover, we found clinical risk factors for postoperative AKI development. Further investigation of prediction models for postoperative AKI in major non-cardiac surgery should be warranted for development of preoperative renal optimization strategy.

FR-PO465

Impact of Hospital CABG Volume and AKI Needing Dialysis on CABG Hospitalizations

Ankit Sakhuja,1 Jesse D. Schold,2 Edward G. Soltész,2 Sevag Demirjian.3 1Div of Nephrology, Univ of Michigan; 2Nephrology and Hypertension, Cleveland Clinic; 3Thoracic and Cardiovascular Surgery, Cleveland Clinic.

Background: Acute Kidney Injury (AKI) is common after Coronary Artery Bypass Grafting (CABG) and associated with poor outcome. Increased hospital procedure volume has been associated with better outcomes. We examined (1) impact of number of annual CABG procedures per hospital (CABG-vol) on AKI needing dialysis (AKI-D) and mortality, and (2) if it modifies the relationship between AKI-D and mortality.

Methods: Using Nationwide Inpatient Sample database from 2000-2010 we identified admissions with CABG using ICD-9-CM codes. Those with AKI-D were identified and those with kidney transplant or on maintenance dialysis were excluded. Multivariable logistic regressions were used to assess impact of CABG-vol on AKI-D and mortality. We used restricted cubic splines to account for non-linear relationship between CABG-vol and mortality. A priori interaction term between CABG-vol & AKI-D was assessed in model 2.

Results: Of estimated 3,373,292 (95% CI: 3,103,610-3,570,973) hospitalizations for CABG, 0.7% (24,126) had AKI-D. Those with AKI-D were older, more females (37.5% vs 29.1%; p<0.001) and blacks (7.4% vs 5.5%; p<0.001). On adjusted analysis, CABG-vol was correlated with AKI-D (0.99; 95% CI 0.99-1.00) but was associated with mortality (Fig 1).
AKI-D was a significant predictor of mortality with OR 13.75 (95% CI: 11.37-16.64). Interaction term between CABG-vol & AKI-D was not significant (p=0.8).

**Conclusions:** Lower annual CABG hospital procedure volume is significantly associated with higher mortality but not with higher incidence of AKI-D. AKI-D is associated with higher mortality in those undergoing CABG, however, there is no differential effect of hospital volume on adjusted odds of mortality due to AKI-D.

**FR-PO467**

Changes of Epidemiology and Influencing Factors of Acute Kidney Injury After Cardiac Surgery – A Five-Year Study from 2009 to 2013 Zahouping Zou,1,2 Jiaren Xu,1,2 Wenli Lv,1,2 Bo Shen,1,2 Yi Fang,1,3 Jianzhou Zou,1,4 Jie Teng,1,2 Xiaoping Ding,1,2 1Dept of Nephrology, Zhongshan Hospital, Fudan Univ, Shanghai, China; 2Shanghai Inst for Kidney and Dialysis, Zhongshan Hospital, Fudan Univ, Shanghai, China; 3Shanghai Key Laboratory of Kidney Disease and Blood Purification, Zhongshan Hospital, Fudan Univ, Shanghai, China.

**Background:** Cardiac surgery is a common cause of acute kidney injury (AKI). We collected the epidemiological data of patients with AKI from 2009 to 2013 in order to explore the influencing factors of changes of epidemiology after cardiac surgery. **Methods:** Clinical data of patients undergoing cardiac surgery, which included demographic data of preoperative, intraoperative, postoperative, and laboratory data was collected in our hospital from January 2009 to December 2013. The main endpoint was poor prognosis which included overall mortality and abandonment of treatment. The second point was renal outcome. **Results:** A total of 1,1693 patients enrolled, including 6637 males and 5056 females. The overall AKI incidence was 34.5% (n=4030). The AKI incidence increased during the five years from 34.2% to 36.5% (P<0.05). There was no significantly statistical differences in AKI-RRT incidences during the five years (P=0.360). The hospital mortality of AKI decreased from 6.3% in 2009 to 3.8% in 2013. The incidence of poor prognosis in AKI was 8.3%, 7.5%, 6.8%, 5.1%, 8.0% (P=0.196). The mortality of AKI-RRT decreased from 47.1% to 29.5%, but there was no statistical difference (P=0.230). The incidence of non-progression in RRT decreased from 66.7% to 57.4%, also no significantly statistical difference (P=0.825). Multivariate logistic regression analysis showed that male age (every additional 10 years), body mass index (every additional 5 kg/m²), hypertension, chronic heart failure, pre-operative serum creatinine >115 mmol/L, CPB (every additional 30 min) were the risk factors of AKI after cardiac surgery. **Conclusions:** The incidence of AKI after cardiac surgery increased from 2009 to 2013 and the rate of poor prognosis did not change. The incidence of AKI-RRT and the rate of poor prognosis remained high. The prevention and treatment of AKI still need improvement. **Funding:** Government Support – Non-U.S.

**FR-PO468**

The Very Long-Term Co-Morbidity Adjusted Impact of AKI following Cardiac Surgery: A 15-Year Follow-Up Study Alejandro Ferreiro,1 Raul Lombardi,2 1Nephrology, INCC, Facultad de Medicina, Montevideo, Uruguay; 2Critical Care Medicine, SMI, Montevideo, Uruguay.

**Background:** AKI is a frequent complication of cardiac surgery (CS) associated to high mortality. The co-morbidity adjusted residual impact on very long-term mortality (>12 years) of AKI, excluding the initial catastrophic impact on early mortality has never been addressed before. **Objectives:** To evaluate the net attributable impact of AKI after CS on long-term survival. **Methods:** All adult patients submitted to CS between 1/1/2000 and 31/12/2013 (n=7755) were enrolled. The INCC prospective-collected database with more than 750 variables (demographics, comorbidities, type of CS, intraoperative and postoperative variables, peri-operative support and short time outcomes) was used. Long-term survival (up to 15 year by December 2014) was obtained by systematic telephone survey (minimum 1-year follow-up) and the National Population Registry. AKI stages were defined according to KDIGO definition. Demographics, logistic EuroSCORE (and their single components), type of CS, baseline renal function (Cockcroft-Gault formula) were used for comorbidity risk-adjustment. Statistical analysis: "t" test, Kruskal-Wallis test, Kaplan-Meier curves with long-rank test and Cox regression for multivariate survival analysis. Only patients alive after the first year follow-up entered in the long-term survival analysis (n= 9050). **Results:** AKI incidence: 38.4%. RRT: 1.7%. Long-term (15 years) actuarial survival after 1 year follow-up: no AKI 0.58; AKI I: 0.47; AKI II: 0.39; AKI III: 0.27 (P<0.001). In multivariate Cox regression analysis, AKI stages I, II and III (OR 1.17; 1.24; 1.62 respectively) were independently associated with mortality between 1 year after CS and 15 year follow-up, even after adjustment with logistic EuroSCORE (OR 1.02), age (OR 1.038), diabetes (OR 1.58), pre-operative eGFR (OR 0.996) and no-isolated coronary bypass surgery (OR 1.24). **Conclusions:** AKI and its severity are independently associated with very long-term mortality, even after discarding short term events (1 year), in cardiac surgery. Should AKI be causative or a surrogate marker of late events in the long-term follow up is a matter of concern to be evaluated.

**FR-PO469**

Incidence and Influencing Factors of Cardiac Surgery-Associated Acute Kidney Injury Based on the KDIGO Criteria: A Retrospective Cohort Study Changchun Cao,1 Xiangcheng Xie,1 Xin Wan,2 1Nanjing Hospital Affiliated to Nanjing Medical Univ (Nanjing First Hospital); 2Nanjing Hospital Affiliated to Nanjing Medical Univ (Nanjing First Hospital).

**Background:** The incidence and influencing factors of cardiac surgery-associated acute kidney injury (CSA-AKI) based on the KDIGO criteria have not been well studied. This study was aimed to evaluate the incidence, risk or protective factors of acute kidney injury (AKI) in patients after cardiac surgery.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: A retrospective analysis of 2575 patients undergoing first documented cardiac surgery with cardiopulmonary bypass (CPB) between January 2008 and December 2012 in our hospital was conducted. Perioperative variables were collected and analyzed. Univariate and multiple logistic regression models were used for determining the association between the development of AKI and risk factors.

Results: Of 2575 patients, 931 (36%) developed AKI. A total of 38(1.2%) patients required renal replacement therapy. The overall in-hospital mortality rate was 1.5% (38 of 2575). CSA-AKI was significantly associated with in-hospital mortality (adjusted HR: 2.22, 95% CI 1.16-4.24, P = 0.016), especially in patients needing RRT (adjusted HR: 18.68, 95% CI 8.58-40.68, P < 0.001). The independent risk factors identified by multivariable analysis were shown in Table 1.

FR-PO470

Acute Kidney Injury Post-Major Orthopaedic Surgery: A Single Centre Experience

Tracey Ying, Samantha Chan, Stephen E. Lane, Christine A. Somerville. 1Dept of Renal Medicine, Univ Hospital Geelong, Geelong, Victoria, Australia; 2Warwick Health Biostatistics Unit, Univ Hospital Geelong, Geelong, Victoria, Australia; 3School of Medicine, Deakin Univ, Geelong, Victoria, Australia.

Background: Given the increasing incidence of AKI and the burden this places on the medical system, there is a clear need to expand the practice of ‘preventative nephrology’ – the optimisation of renal function through minimisation of potential insults. Renoprotection is particularly critical in the perioperative setting, a period of high renal vulnerability. However, there is currently little evidence regarding numerous theoretical risk factors for postoperative AKI.

Methods: All patients undergoing MOS at our centre between 2008 and 2014 were included. Of 2277 surgeries audited for AKI using comparisons of preoperative and postoperative creatinine, 164 cases were identified (per RIFLE criteria) and matched to controls 2:1 for age, sex, procedure and chronic kidney disease stage. Their records were reviewed for established and proposed risk factors for postoperative AKI: diuretic, non-steroidal anti-inflammatory (NSAID) and angiotensin converting enzyme inhibitor (ACEI) or angiotensin receptor blockers (ARB) use. Associations of proven and hypothetical risk factors were estimated using conditional logistic regression.

Results: Controlling for known risk factors, both diuretic and ACEI or ARB use were found to be associated with an approximately twofold increased risk of AKI (diuretic – OR 2.06 95%CI 1.30-3.26, p<0.005, ACEI/ARB – OR 2.09 95%CI 1.31-3.32, p<0.005). A dose-effect model accounting for preoperative, intraoperative and postoperative NSAIAD administration demonstrated a linear relationship between the number of times NSAIADs were given and postoperative AKI risk (OR 1.35 95%CI 1.05-1.73, p<0.05).

Conclusions: Perioperative diuretic, NSAIAD and ACEI or ARB use were shown to be significantly associated with postoperative AKI, indicating that these medications should be used with caution in MOS. Further prospective studies are required to confirm this.

FR-PO471

Incidence of In-Hospital Acute Kidney Injury by Surgery and Invasive Surgical Procedures Among Non-Emergency Hospital Admissions

Joshua Taylor Swan,1,2 Beverly A. Shirley,1 Linda W. Moore,1 Wadi N. Suki,1 A. Osama Gaber,1,3 1Houston Methodist Hospital; 2Texas Southern Univ; 3Weil Cornell Medical College.

Background: This study aimed to identify non-emergency invasive surgical procedures that are associated with the highest burden of in-hospital AKI.

Methods: Urgent and elective admissions to a quaternary teaching hospital in 2012-2013 with a principal procedure within 1 day of admission were included. Principal procedures were categorized using AHRQ’s Clinical Classifications Software (CCS).

Conclusions: This study assesses the incidence of AKI after invasive surgical principal procedures, and this data will help prioritize research to prevent in-hospital AKI. Non-kidney transplant, heart valve, and CABG surgical procedures were associated with the highest number of AKI cases at this single center, and non-kidney organ transplants were associated with a high severity of AKI.

FR-PO472

Risk Factors Associated with Post-Operative AKI After General Surgery

Pradeep Pradeep,1,2 Nader Zadeh,1,2 1Div of Nephrology, VAMC, Buffalo, NY; 2Anesthesiology, VAMC, Buffalo, NY; 3Surgery, VAMC, Buffalo, NY.

Background: AKI after cardiac and vascular surgery has been extensively studied. However, there is no study which has evaluated the factors associated with development of stage 1 AKI by AKIN criteria in general surgery patients.

Conclusions: This study assesses the incidence of AKI after invasive surgical principal procedures, and this data will help prioritize research to prevent in-hospital AKI.
Methods: We conducted a cohort study using a prospective database of patients undergoing non-cardiac and non-vascular surgery performed at Mount Sinai Health System which are in part reported to the National Surgical Quality Improvement Program (NSQIP). Demographic, social history, comorbid diseases, including coronary artery disease (CAD), congestive heart failure (CHF), chronic obstructive lung disease (COPD), peripheral vascular disease (PVD), cerebrovascular accidents (CVA), hypertension, and diabetes, were prospectively entered into the Veterans Affairs Surgical Quality Improvement Program (VASQIP) database at the time of surgery. Preoperative laboratory data were also entered for each participant. Univariate and multivariate logistic regression were performed to estimate the odds of AKI after surgery.

Results: A total of 13300 patients who underwent non-cardiac and non-vascular surgery whose data was available to define AKI between 2000-2014 were included in this analysis. A total of 1621 patients developed AKI stage 1. In univariate analysis, increasing age, male gender, ASA class, poor functional status, presence of COPD, peripheral vascular disease (PVD), cerebrovascular accidents (CVA), hypertension, and diabetes were prospectively entered into the Veterans Affairs Surgical Quality Improvement Program (VASQIP) database at the time of surgery. Preoperative laboratory data were also entered for each participant. Univariate and multivariate logistic regression were performed to estimate the odds of AKI after surgery.

Conclusions: AKI is associated with increased length of hospital stay and mortality. Efforts to recognize and intervene in preoperative modifiable factors to prevent AKI will improve outcomes in general surgical patients.

FR-PO474

The Comparison of the Incidence of Acute Kidney Injury Post Coronary Artery Bypass Graft versus Percutaneous Coronary Intervention: National Inpatient Sample Experience

We extracted total 485742 cases from National Inpatient Sample (NIS) to create a propensity-score matched cohort of patients who had multivessel coronary disease and underwent first-time CABG or PCI between 2004-2012. Patients received concomitant valvular repair or both CABG and PCI on same admission, history of organ transplant, CKD stage IV or V, or RRT on dialysis were excluded. Both groups were matched for age, gender, race, payer, prior MI, unstable angina, heart failure, CVA, stroke or TIA, peripheral arterial disease, atypical or aortic valve disease, atrial fibrillation/bradycardia, ventricular fibrillation or tachycardia, CKD, diabetes, HTN, dyslipidemia, smoking, cirrhosis, obesity, anemia and in-hospital GI bleeding. The odds ratios were estimated by logistic regression analysis.

Results: The incidence of AKI in CABG group was higher than PCI group (8.41% vs. 0.40%; OR 2.07, 95% CI 2.00-2.15, P< 0.001). The incidence of severe AKI requiring RRT were similar in both groups (0.95% vs. 0.91%, P=0.147). Compared with PCI group, CABG group had higher total in-hospital mortality (1.99% vs. 1.48%, OR 1.34, 95% CI 1.24-1.40, P<0.001). The in-hospital mortality in patients with AKI was higher in CABG (0.92% vs 0.59%, P<0.001).

Conclusions: Patients received CABG were at higher risk of developing AKI and associated with higher total in-hospital mortality. The in-hospital mortality in patients with AKI was higher in CABG.

FR-PO475

Diagnosis-Required Acute Kidney Injury Among Hospitalized Adults with Documented Hepatitis C Virus Infection: A Nationwide Inpatient Sample Analysis

We identified a total of 4,603,718 adult hospitalizations with associated HCV from 2004-2012, of which 51,434 (1.12%) were complicated by AKI-D. The proportion complicated by AKI-D increased significantly from 0.86% in 2004 to 1.28% in 2012. Trend was similar when stratified by cirrhosis and paralleled that in HCV negative hospitalizations.

Figure 1. Temporal Trends in the Incidence of Acute Kidney Injury (AKI) Requiring Renal Replacement Therapy among Hospitalized Adults with and without Documented Hepatitis C Virus Infection

In-hospital mortality was significantly higher in hospitalizations complicated by AKI-D vs. those without (27.38% vs. 2.95%; adjusted odds ratio 2.09, 95% Confidence Interval 1.74-2.51) which remained stable over the study period.

Conclusions: The proportion of HCV hospitalizations complicated by AKI-D increased significantly between 2004-2012. Similar to observations in the general population, AKI-D was associated with two-fold increase in odds of in-hospital mortality. These results highlight the burden of severe AKI in hospitalized adults with HCV infection.

Temporal Trends of Burden of Dialysis Requiring Acute Kidney Injury in Cerebrovascular Accident Hospitalizations

**Methods:** We used the Nationwide Inpatient Sample to evaluate the yearly incidence of AKI-D in AIS and ICH admissions from 2002 to 2011. We also evaluated the trend of impact of AKI-D on in-hospital mortality and adverse discharge utilizing adjusted odds ratios (aOR) after adjusting for demographics and comorbidity indices. Results: We extracted a total of 3927267 AIS and 704648 ICH admissions, AKI-D occurred in 1.5 and 3.5 per 1000 in AIS and ICH admissions respectively. Incidence of admissions complicated by AKI-D doubled from 0.9/1000 to 0.17/1000 in AIS and from 2.1/1000 to 4.3/1000 in ICH admissions.

Conclusions: The proportion of DC hospitalizations with AKI-D increased from 2006-09 & although, this was stable from 2009-12, there was an increase in absolute case number. These results elucidate burden of AKI-D on DC hospitalizations & excess associated mortality as well as highlight the importance of prevention, early diagnosis & testing of novel interventions in this vulnerable population.

Long-Term Healthcare Utilization and Mortality After Acute Kidney Injury in Critically Ill Children

**Methods:** Retrospective cohort study of children admitted to two Montreal, Canada PICUs, 2003-2005 (N=2500). Exclusions: no health number, deceased in PICU. Clinical chart data was merged with provincial administrative health data. AKI (main exposure): by Kidney Disease Improving Global Outcomes serum creatinine (SCr) definition (if no PICU-SCr drawn, non-AKI was assumed). 5-year outcomes: all-cause mortality; healthcare utilization (HCU), defined as the number of hospitalizations, emergency room (ER) and physician visits per 100 person years. AKI-outcome relation was evaluated with multivariate logistic (mortality) and linear regression (HCU), adjusting for gender, age, cardiac surgery, PRISM (mortality) score, vasopressors and infection.

Results: Of 2407 children (mean±SD age=6±5.7 yrs; PRISM = 8.2±5.9); 56% male; 448 (18.6%) developed AKI. AKI (yes/no) was associated with mortality in univariate (p=0.05) but not multivariate analysis. Stage 2 AKI or worse was associated with 5-year mortality (adjusted aOR=1.9, 95% CI 1.1-3.2). AKI (yes/no) was associated with increased 5-year hospitalizations (adj p=0.05) and physician visits (adj p=0.001), but not ER visits (adj p=0.8). There was a graded increase in 5-year HCU with higher AKI severity.

Conclusions: PICU-AKI is associated with long-term increased mortality risk and HCU. Research should evaluate cost-effective interventions to improve child AKI treatment and evaluate effects on late outcomes.

**Funding:** Government Support - Non-U.S.

**FR-PO479**

Acute Kidney Injury: A 12 Month Follow, the Incidence and Mortality

**Methods:** Patients who were admitted between the time periods of August 2012 until January 2013 were included in this study. Liaising with the biochemistry department, all patients who had a rise in their creatinine based on the Acute Kidney Injury Network Criteria received an e-alert sign on the computer system. Clinical outcomes were obtained from each patient record.

Conclusions: PICU-AKI is associated with long-term increased mortality risk and HCU. Research should evaluate cost-effective interventions to improve child AKI treatment and evaluate effects on late outcomes.

**Funding:** Government Support - Non-U.S.
Results: There were a total of 36,957 patients admitted during that 6 month time period of which a total of 358 cases of AKI were identified. There was total of 183 male patients and 171 female patients. Four of the male patients had a further AKI alert during the same hospital admission. The mean age was 72.18 years. Pre-renal causes were identified as the main contributors to the cases. Majority of the AKI alerts were Stage 1 AKI which was 70.7%, Stage 2 AKI was 25% and Stage 3 AKI was 4.3% of the total cases. The data also revealed that the average length of stay (ALOS) did not differ in each of the stage. A patient ALOS for Stage 1 AKI was 23.3 days, Stage 2 AKI 24 days and Stage 1 AKI 21 days. Of the total number of cases of patients with AKI, 50.6% (179/354) of the patients had died within the 12 months period. Looking into the mortality rate of each individual stages of AKI the mortality rate at 12 months for Stage 1 AKI is 46.5%. For Stage 2 AKI, 62.7% and for Stage 3 AKI, 47.6%.

Conclusions: From the data collected, it shows that the degree of AKI does not affect the length of stay of patients. Despite the different stages of AKI indicating the severity of the injury, mortality rate for Stage 1 and Stage 3 did not differ. This indicates that AKI carries a high mortality rate regardless of the severity of the injury. Early recognition leads to early intervention in the prevention of AKI.

FR-PO480
Acute Kidney Injury: Adding Informatics to Injury – (Electronic Injury Alerts)
Conor Patrick Moran, Ying C. Kuan, Patrick Lm Lynch, Francis Mccarroll. 1 Dept of Nephrology, Altnagelvin Hospital, Londonderry, United Kingdom; 2 Dept of Clinical Chemistry, Altnagelvin Hospital, Londonderry, United Kingdom.

Background: Acute Kidney Injury, (AKI), is common with a variably reported mortality, (15-60%). UK national audit reported that up to 30% of cases were avoidable and that as much as 43-61% of post-admission AKI experienced an unacceptable delay in recognition of insult. There has been a paucity of work with regards to AKI recognition and prevention. National guidelines have recommended the use of electronic alerts (e-alerts) for AKI detection.

Methods: We introduced AKI e-alerts with accompanying electronic guidance in late October 2014 and prospectively collected data on the patients identified with severe AKI. Data collection was carried out for 3 months, (n=110). The demographics of this cohort were compared with a historical cohort of severe AKI (n=89).

Results: Mean age, (72 years vs. 73 years), gender distribution, (M:F: 46% / 54% vs. 47% / 53%), and median time to death, (10 days vs. 9 days), were comparable. Thirty day mortality was similar with regards to hospital acquired AKI, (27.3 % vs. 26.1%). 30 day mortality was significantly lower for community-acquired AKI, (10.7%). Mean and median age was demonstrated to be higher in the group of patient who died, (Mean: 80.1 years vs. 75.7 years), (Median: 82 years vs. 82 years) – negative skew due to outliers.

Conclusions: Although our initial data suggests an electronic AKI alert has a discernable effect on 30 day mortality rate and time to death. We feel that e-alerts with the addition of further Quality Improvement work will eventually result in a steady reduction in AKI mortality.

FR-PO481
Tenofovir Nephrotoxicity Is an Important Cause of Acute Kidney Injury in HIV Infected Inpatients

Background: Tenofovir disoproxil fumarate (TDF) is widely prescribed as a first choice therapy for HIV infection, because of its convenient dosing schedule, efficacy and relatively low side effects. However, renal toxicity may lead to acute kidney injury (AKI), chronic kidney disease (CKD), and proximal tubular injury. Here we describe clinical characteristics and outcomes of AKI associated to TDF.

Methods: In a retrospective cohort (between Mar/2011 to Feb/2015), we have described AKI alerts in patients with TDF nephrotoxicity, defined as an elevation of Cr by ≥ 0.3 mg/dl during a 14 day period after administration of cisplatin (peak Cr) compared with baseline (bl Cr). Patients with bl Cr of >1.5 were excluded.

Results: Of the 1979 patients in our study, 55% were male with a mean ± SD of age of 61.6 ± 12.8. A bl Cr was 0.9 ± 0.2. 241 of 1979 (12.2%) patients developed CaN. However, it ranged from 7.8% in the medium dose group (cisplatin dose 75-130 mg) to 18.2% in the high dose group (>130mg) without a clear dose response relation.

Conclusions: CaN associated to TDF nephrotoxicity was prevalent in the HIV infected inpatients and showed high morbidity, including almost a third of patients requiring dialysis and more than a half not recovering renal function after withdrawing the drug.

FR-PO482
Cisplatin-Associated Nephrotoxicity: Not as Frequent as Previously Reported
Shiveta S. Motwani, Sushrut S. Waikar, Benjamin D. Humphreys, Gary C. Curhan. Nephrology, Brigham and Women’s Hospital, Boston, MA.

Background: Cisplatin-associated nephrotoxicity (CaN) is a frequent problem amongst patients with various cancers. Most older studies have reported 25-30% of patients who receive cisplatin experience acute kidney injury. However, these data have not been re-evaluated systematically recently despite rapid advances in oncologic care. Therefore, we examined the proportion of patients who develop acute kidney injury after exposure to the first cycle of cisplatin in a large patient database. We also examined the frequency of kidney injury stratified by sex and cisplatin dose regardless of cancer type.

Methods: We collected data on patients ≥ 18 years of age who had received cisplatin as a primary, secondary or adjuvant or neo-adjuvant therapy at a tertiary-care medical center (Massachusetts General Hospital) between 2006 and 2014. Detailed data regarding cisplatin dose, demographic characteristics, concurrent medical history and laboratory data including serum creatinine (Cr) and electrolytes were collected. CaN was defined as an elevation of Cr by ≥ 0.3 mg/dL during a 14 day period after administration of cisplatin (peak Cr) compared with baseline (bl Cr). Patients with bl Cr of >1.5 were excluded.

Results: Of the 1979 patients in our study, 55% were male with a mean ± SD of age of 61.6 ± 12.8. A bl Cr was 0.9 ± 0.2. 241 of 1979 (12.2%) patients developed CaN. However, it ranged from 7.8% in the medium dose group (cisplatin dose 75-130 mg) to 18.2% in the high dose group (>130mg) without a clear dose response relation.

In addition, a significantly lower frequency of CaN was noted amongst females compared with males (9.3% vs 14.5%, p<0.001).

Conclusions: Cisplatin-associated nephrotoxicity occurs less frequently than previously reported. This may reflect changes in preventive care such as more aggressive hydration with electrolyte-rich solutions.

Long-Term Follow-Up of Children with STEC-HUS Caused by E. coli O104:H4 (German HUS Outbreak 2011): A GPN Registry

Markus J. Kemper,1 Wiebke Aubert,1 Thurid Ahlensiel-Grunow,2 Brigitta Kranz,3 Jun Oh,1 1Pediatric Nephrology, Univ Medical Center Hamburg- Eppendorf, Hamburg, Germany; 2Pediatric Nephrology, Medizinische Hochschule, Hannover, Germany; 3Pediatric Nephrology, Univ Hospital, Münster, Germany.

Background: In 2011 E. coli O104:H4 caused the largest outbreak of HUS in adults and children. A total of 90 children were affected, of whom 64 (71%) required dialysis for a median of 11 days.

Methods: Currently following data are available from 60 of 90 children (67%), 31 girls from 11 pediatric centers in Germany. Median follow-up is 2.7 range 1.2-3.8 years, median current age of patients is 14.7 (3.4-18.7) years.

Results: Median current serum-creatinine is 0.7 (0.3-8.9) mg/dl. In two patients (2.2%) with CKD stage 3 and 4 at discharge GFR improved and they are now in CKD Stage 2. One patient remained dialysis dependent initially and one reached ESRD after 3.5 years; both underwent successful living-related kidney transplantation. All these 4 patients were treated with eculizumab in the initial phase of STEC-HUS including 2 who also received plasmapheresis. Proteinuria is currently present in 17 (19%) patients and 9 (10%) require treatment for hypertension. Three patients have neurologic symptoms (headache, performance deficit, spasmodic movement disorder) and 3 patients have EEG abnormalities without symptoms.

Conclusions: Long-term follow-up is important after O104:H4 associated STEC- HUS. CKD stage 3-5 at discharge is a risk factor for ESRD, however some children show a spontaneous improvement over time. Patients with proteinuria and hypertension need long-term follow-up. Follow-up studies after STEC HUS should include neurologic investigations.

FR-PO488

SOFA Scores as Predictors of Mortality and Dialysis Dependency in Acute Kidney Injury

V. Shane Pankratz,1 Christos Argyropoulos,1 Khaled Abdel-Kader,2 Kelly V. Liang,3 Paul M. Palevsky,3 Mark L. Unruh.1 1Dept of Internal Medicine, Div of Nephrology, Univ of New Mexico School of Medicine, Albuquerque, NM; 2Dept of Medicine, Div of Nephrology and Hypertension, Vanderbilt Univ School of Medicine, Nashville, TN; 3Dept of Medicine, Renal- Electrolyte Div, Univ of Pittsburgh School of Medicine, Pittsburgh, PA.

Background: The Sequential Organ Failure Assessment (SOFA) score measures the severity of organ failure, and baseline SOFA scores have been used to predict mortality in patients with Acute Kidney Injury (AKI). We evaluated whether SOFA scores, either upon initiation of dialysis or clinically updated, predict mortality and dialysis dependency following AKI.

Methods: Data from patients enrolled in the Acute Renal Failure Trial Network (ATN) study, a randomized multicenter trial of the intensity of renal support in AKI, were used in Cox proportional hazards regression and multinomial logistic models to assess the degree to which SOFA scores predict mortality and dialysis dependency.

Results: SOFA scores were associated with increased mortality risk following AKI among the 1,124 ATN participants, but the concordance statistic was low, at 0.651 (standard error [se]=0.014). When time-dependent analyses were used to take advantage of prospectively updated SOFA scores, the concordance statistic increased to 0.753 (se=0.013). When time-dependent analyses were used to take advantage of prospectively updated SOFA scores, the concordance statistic increased to 0.753 (se=0.013).

FR-PO490

Comparison of Clinical Characteristics of Patients with Acute Kidney Injury After Intraoperative Versus Inhaled Colistin Therapy

Hvinnia Yoon,1 In O Sun,2 Kwang Young Lee,1 A young Cho.1 Div of Nephrology, Dept of Internal Medicine, Presbyterian Medical Center, Jeonju, Jeonbuk, Republic of Korea.

Background: The aim of this study is to investigate the incidence and clinical characteristics of intraoperative or inhaled colistin associated acute kidney injury (AKI) using the RIFLE and AKIN criteria.

Methods: From 2010 to 2014, 160 patients were treated with inhaled or intraoperative colistin. Of these, we included 139 patients who received colistin for >72 h, and compared the incidence and clinical characteristics of patients in the inhaled (n=120) and intraoperative (n=19) groups.

Results: The patients included 116 men and 23 women, with a mean age of 68 years (range, 20-91). Patients were infected with either A. baumannii (54%) or P. aeruginosa (46%), and pneumonia (91%) was the most common type of infection. The mortality rate was 43.9%, and AKI occurred in 83 (60%) patients. At the end of therapy, bacteriologic cure rate was 64%. There were no differences in the clinical characteristics between the intraoperative and inhaled groups except for age. In comparison with patients in the intraoperative group, the patients in the inhaled group were older (74 ± 6 vs 67 ± 14 years, p=0.03). The incidence of AKI was not different between the two groups (62% vs 47%, p=NS), and there was no difference in the severity of AKI according to the RIFLE criteria. Of the 83 patients with AKI, 8 and 1 patients underwent renal replacement therapy.

Conclusions: In our study, the incidence of AKI in patients undergoing colistin therapy was 60%, and there was no difference in safety between the intraoperative and inhaled colistin groups. Therefore, it is also important to monitor renal function during colistin therapy regardless of the route of administration.

FR-PO491

Acute Kidney Injury following Coronary Angiography

Dadi Helgason,¹ Jörð E. Long, ¹ Gísl H. Sigurdsson,² Martin I. Sigurdsson,² Olafur S. Indridsson, ³ ¹Dept of Medicine; ²Department of Anesthesia, Landspitali; ³Dept of Anesthesia, Brigham and Women’s Hospital, Boston, MA; ⁴Div of Nephrology, Landspáli - The National Univ Hospital of Iceland, Reykjavik, Iceland.

Background: Acute kidney injury (AKI) is a known complication of coronary angiography (CA). The aim was to study the incidence, risk factors and outcome of AKI following CA in a whole nation.

Methods: This was a retrospective analysis of data from all CA in Iceland during a 9 year period. AKI was diagnosed according to the creatinine based KIDGO criteria and survival status for all patients was verified at Statistics Iceland. The epidemiology and clinical outcomes were compared between three 3-year periods using Chi-squared and Kaplan-Meier method, and multivariate logistic regression was performed to find predictors of AKI.

Results: From Jan 1st 2005 to Dec 31st 2013 10713 patients underwent 13890 CA of whom 40% entailed an intervention. Median (range) age was 65 (19-96) years and 70.7% were men. AKI was diagnosed in 214 patients (1.5%; 168 (1.2%), 270(2.2%) and 19 (0.1%) of stage 1, 2 and 3, respectively. There was a trend towards a decreasing incidence of AKI: 1.8% in the first 3 year period, 1.3% in the second and 1.4% in the last (p=0.05). AKI was more common in the intervention group, 2.2% vs. 1.1% (p=0.0011). Patients with AKI were older (p=0.04), had more prior intervention of AKI, more coronary disease and prior eGFR compared to non-AKI patients. In multivariate analyses age over 70 years (OR=1.01, 95% CI=1.007-1.016), angiography with intervention (OR=1.01, 95% CI=1.003-1.019), COPD (OR=1.01, 95% CI=1.003-1.025), liver disease (OR=1.03, 95% CI=1.014-1.058) and prior history of AKI (OR=1.07, 95% CI=1.051-1.080) were independent predictors of AKI after CA. One year survival of AKI patients did not differ between time periods: 67.0%, 63.1% and 69.0% in the first, second and third, respectively, p=0.3.

Conclusions: There is a trend towards a decrease in AKI incidence following CA in recent years. Aged patients with multiple co-morbidities and prior history of AKI need special attention in connection with this fact.

Risk Factors of Acute Kidney Injury and In-Hospital Mortality in Adult Patients Receiving Extracorporeal Membrane Oxygenation (ECMO)

Sung Woo Lee,1 Seon Ha Back,2 Jae Yoon Park,2 Shin-Young Ahn,1 Sejoong Kim,1 Ho Jun Chin,1 Dong-Wan Chae,1 Ki Young Na.1 1Seoul National Univ Bundang Hospital; 2Seoul National Univ Hospital.

Background: Although acute kidney injury (AKI) is the most frequent complication in patients receiving extracorporeal membrane oxygenation (ECMO), little has been studied about the risk factors of AKI and in-hospital mortality. Thus we performed the study to identify factors associated with AKI and in-hospital mortality.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Acute Kidney Injury in the First Hundred Days After Hematopoietic Stem Cell Transplantation: Experience with 222 Transplanted Patients in a Single Center Miguel A. Sols, Sandra Tejedor, Isidro Torregrosa, Carmen Ramos, Isabel Juan, Patricia Tomas, Patricia Zambrano Esteves, Juan José Guzmán Herrera, Maria Jesus Puchades, Alfonso M. Carrasco. Nephrology, Univ Clinic Hospital, Valencia, Spain.

Background: Hematopoietic stem cell transplantation recipients are at an increased risk of Acute Kidney Injury (AKI) or Chronic Kidney Disease (CKD). An earlier diagnosis could dramatically improve the patients’ prognosis. Objective. To analyze the incidence of AKI in the first 100 days of Hematopoietic stem cell transplantation recipients and the relationship with mortality.

Methods: We carried out a retrospective study including 222 adult patients who underwent Hematopoietic stem cell transplantation between 2006 and 2010 at our institution. AKI was defined using the RIFLE criteria in the first 100 days after transplantation. Results: 222 patients were included in the study, 137 males and 85 females. Median follow-up was 30 months, range 1-60 months. In the first 100 days after transplantation AKI developed in 78 patients according to the RIFLE criteria (35.1%). A total of 85 patients died during follow-up vs 47 who had developed AKI (38.2% versus 61%, p<0.05). Detailed patients’ characteristics are summarized in table 1.

Overall Mortality 85 (38.2%)

Mortality in AKI 47 (61%)

Conclusions: AKI incidence in hematopoietic stem cell transplantation recipients is very high. There is a statistically significant relationship between AKI and death in these patients. Earlier AKI identification could prevent kidney damage progression and improve patient outcome over time.

FR-PO493

STOP-Acute Kidney Injury (AKI): A Streamline Approach to the Management AKI Leads to Reduction of Mortality Rates Hsu-phen Chong, Thangavelu Chandrasekar. Nephrology, Aintree Univ Hospital, United Kingdom.

Background: Acute Kidney Injury (AKI) has a mortality rate of 30%, greater than common conditions such as myocardial infarction (8%) and stroke (9%). It is estimated that 15% of all inpatients at University Hospital Aintree (UHA), Liverpool, UK, suffer an AKI making it a condition of considerable importance in everyday practice. Through clinical audit, it was found that mortality rate of AKI in UHA was 33% on wards other than renal ward (9%).

Methods: To reduce AKI mortality by 30% and length of stay by 20% over a 12 month period from Oct 2013 using standardised, evidence based approach. Using plan, do, study act (PDSA) methodology, we developed and tested an automated e-alert diagnostics system, an AKI treatment bundle and a patient information leaflet. The STOP-AKI project was launched. Our Primary drivers were early and accurate identification of AKI, effective intervention and monitoring, staff and patient engagement. Initially, trialled at ward level, the project was scaled up to admission areas (Accident and Emergency Department and the Medical Assessment Unit) becoming part of routine management for all admitted patients.

FR-PO494

Race and Risk of Acute Kidney Injury (AKI) in VA Patients Michael Hugue, Diane Steffick, Deidra C. Crews, Neil R. Powe, Sharon Saydah, Meda E. Pavkovic, Kara Zivin, Rajiv Saran. 1Univ of Michigan; 2Johns Hopkins Univ; 3Univ of California San Francisco; 4Centers for Disease Control and Prevention; 5VA Ann Arbor Health System.

Background: African Americans (AA) are at increased risk for AKI compared to Caucasians (C); potential explanations include differences in risk factors, genetic susceptibility and socioeconomic factors. We explored the influence of race on AKI risk in the Veterans Administration (VA), an integrated healthcare system.

Methods: Retrospective cohort analysis of all hospitalizations for VA patients with known AA or C race in 2011. AKI was defined by KDIGO criteria (≥ 0.3 mg/dL increase in serum creatinine from pre-admission baseline). Modified Poisson regression models estimated the effect of AA race on risk of AKI, adjusting for age, sex, baseline eGFR, comorbidities (DM, HTN, coronary heart disease,CHD; CHF), geographic region and severity of illness during hospitalization. Additional models including albuminuria were run for those with available data.

Results: We identified 180,429 VA hospitalizations. Compared to C, AA had higher prevalence of DM (43.1% v. 41.1%, P<.001), lower prevalence of CHD (45.7% v. 58.8%, P<.001), lower Charlson comorbidity scores (1.4 v. 1.6, P<.001) and higher baseline eGFR (89.2 v. 81.7, P<.001). AKI occurred in 19.5% of admissions (35,134) involving 23.2% of AA and 18.5% of C. In adjusted models, AA race remained an independent risk factor for AKI (RR 1.26, 95% CI 1.24-1.28). In the subgroup with albuminuria data (40,668), the risk was slightly attenuated (RR 1.20, 95% CI 1.16-1.24). A similar increased risk of hospital-acquired AKI in AA compared to C (RR 1.19, 95% CI 1.15-1.23) was found.

Conclusions: Although AA Veterans had higher baseline eGFR and lower comorbidity scores compared to C, AA had an increased risk of developing AKI, even after accounting for differences in risk factors & geographic region. This increased risk for AKI in AA persisted when examining AKI that developed during hospitalization. Given that VA patients have similar healthcare access and benefits, our results suggest that the increased AKI risk seen in AA is unlikely to be fully accounted for by disparities in access to care.

FR-PO495

Mortality Risk Factors in Mexican Patients with Acute Kidney Injury Luis Alberto Evangelista-Carrillo,1 Enrique Rojas-Campos,2 Salvador Mendoza Cabrera,1 Benjamin Gomez-Navarro,1 1Nefrologia y Trasplantados, IMSS, Guadalajara, Jalisco, Mexico; 2Unidad Médica de Investigación en Enfermedades Renales, IMSS, Guadalajara, Jalisco, Mexico.

Background: Acute kidney injury (AKI) data in Latin American is scarce.

Methods: Aim: To determine patient survival, mortality risk factors and treatment in AKI patients from a tertiary hospital. Methods: Prospective cohort Dec 2010-2012 of 275 patients with AKI who need Nephrology consultation. Recollected data at admission, follow-up, months. Results: Fall in mortality rates from a baseline of 24% to 18.5 %, representing an overall reduction in mortality of 23%. Length of stay fell by 11% equating in a 2.0 day reduction in length of stay.

Conclusions: The STOP-AKI project led to the development of an AKI bundle in Oct 2013. This has achieved not only a significant reduction in patient mortality and length of stay but in addition a more structured and streamlined way of approaching the patients with AKI in our hospital. With the bundle being rolled out to primary care and the rest of our inpatient wards, we anticipate a further reduction in mortality.
Nephrologists consultation and 30 days follow up included demographics and biochemical variables, time between AKI onset and Nephrology consultation, fluid balance, mortality scale, treatment and date of death or patient discharge.

Results: The overall mortality was 49%. Mean age 58 years. The principal diagnosis at admission was coronary syndrome. The AKI at the moment of consultation was 3 in the 64%.

*p<0.05

Mortality predicted analysis.

Conclusions: This is the first report of epidemiology of AKI in Mexico. The conservative treatment is associated with mortality. The consultation with nephrology was late. Use of diuretic, vasopressor and urea less than 1 liter per day at the nephrology consultation time were associated with mortality.

FR-PO496

Cast Nephropathy versus Acute Tubular Necrosis in Newly Diagnosed Multiple Myeloma: A Comparative Study

Insara Jaffer Satiajik, 1 Samih H. Nasr, 2 Nelson Leung, 1,3

1 Div of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 2 Div of Anatomic Pathology, Mayo Clinic; 3 Div of Hematology, Mayo Clinic, Rochester, MN.

Background: Myeloma cast nephropathy (MCN) and acute tubular necrosis (ATN) are recognized causes of acute kidney injury (AKI) in newly diagnosed multiple myeloma patients. However it is currently not known if there is a difference in outcomes between these two groups. We conducted a retrospective study to compare the clinical characteristics and renal response rates in patients presenting with acute kidney injury at the time of myeloma diagnosis.

Methods: We included all patients with AKI at the time of multiple myeloma diagnosis with biopsy-confirmed diagnosis of MCN or ATN between 1998 and 2013. Patients with chronic kidney disease (estimated GFR by MDRD equation=45ml/min/1.73m2) and relapsed multiple myeloma were excluded. We assessed survival and renal outcomes. Six month landmark survival analysis was done with Kaplan Meier estimates. Renal response was classified according to IKMG consensus criteria.

Results: Out of a total of 51 patients who were included in the study, 42 had MCN and 9 had ATN. Baseline characteristics were not significantly different between the groups except urine albumin percentage of >6% was predictive of ATN.

Conclusions: Our data suggests that AKI due to ATN at the time of myeloma diagnosis is more likely to recover compared to MCN with a faster time to response. However this does not seem to affect overall survival.

FR-PO497

Hospital Manifesting AKI Presents Worst Outcome Than Community Acquired AKI

Xose Luis I. Perez-Fernandez, 1 Florentina E. Siclsen, 1 Joel Sabater Riera, 1 Kathleen D. Liu, 2 John A. Kellum, 3 Servei de Medicina Intensiva, Hospital Univ de Bellvitge, L’Hospital de Llobregat, Barcelona, Spain; 2 Critical Care, Univ Pittsburgh Medical Center, Pittsburgh, PA; 3 Nephrology & Critical Care, Univ California San Francisco Parnassus MC, San Francisco, CA.

Background: The objective of this study was to evaluate outcomes in critically ill patients with severe community-acquired AKI (CA-AKI) and hospital-manifesting AKI (HM-AKI). Secondary objectives were to identify characteristics that differ between patients with CA-AKI and HM-AKI to design future preventive strategies.

Methods: Observational retrospective study conducted at two tertiary care hospitals between 2000-2008 (UPMC, Pittsburgh, USA) and 2006-2012 (HUB Barcelona, Spain). Those with CA-AKI met criteria for KDIGO Stage 3 AKI at hospital admission whereas those with HM-AKI did not have AKI at hospital admission. HM-AKI subjects met KDIGO Stage 3 AKI criteria within 24 hours of ICU admission, with at least 72 hours elapsing between hospital admission and ICU admission. The relationship of type of AKI (CA-AKI, HM-AKI) with 90-day survival was analysed using Cox regression models controlling for differences between survivors and non-survivors.

Results: 354 patients met inclusion criteria. 92.5% of these patients required RRT at some point during ICU admission. 189 (35.4%) patients had AKI manifest while in hospital, especially those who presented with severe comorbidity. HM-AKI remained an independent risk factor for death compared to CA-AKI (HR 1.5; 95%CI (1.1 – 2)). Analysis, HM-AKI remained an independent risk factor for death compared to CA-AKI.

Conclusions: AKI manifesting after hospital admission has significantly worse outcomes compared to AKI present at hospital admission even among patients progressing to stage 3 by ICU admission. Future interventions should be directed to prevent AKI in hospital wards.

FR-PO498

Assessing Patient Awareness in Moderate to Severe Acute Kidney Injury

Sharidan Parr, Marcus G. Wild, Swee-Ling Levea, Talat Alp Ikizler, Edward D. Siew, Kerri L. Cavanaugh, Vanderbilt University Medical Center, Nashville, TN.

Background: We aimed to evaluate awareness and knowledge of kidney disease in patients experiencing moderate to severe AKI, which is important for implementing targeted patient self-care risk-reduction strategies.

Methods: We surveyed 150 hospitalized patients in one academic medical center who experienced KDIGO Stage II or III AKI. We characterized patients’ awareness that AKI is more likely to recover compared to MCN with a faster time to response. However this does not seem to affect overall survival.

Conclusions: AKI due to ATN at the time of myeloma diagnosis is more likely to recover compared to MCN with a faster time to response. However this does not seem to affect overall survival.
Results: Median participant age was 54 years; 53% were male; 81% were white; 90% had high school education or higher; 30% had health literacy scores ≤6; baseline serum creatinine (Scr) was 0.9 mg/dL; peak Scr was 2.9 mg/dL; 50% had Stage 2 AKI and 50% had Stage 3 AKI. In total, 80% of patients were unaware that they experienced AKI, including 7 patients requiring dialysis. Predictors of awareness included female gender (71% vs 41%), peak serum creatinine (4.5 vs 2.7), Stage-III AKI (82% vs 42%); nephrology consultation (68% vs 31%), dialysis (29% vs 6%), duration of injury (6 vs 3 days), discharge Scr (2.2 mg/dL vs 1.5 mg/dL), and reporting a diagnosis of AKI with a provider during the hospitalization (43% vs 21%) (p values <0.05 for all comparisons). We found poor patient recognition of preventable causes of AKI and most patients desired more information [Figure 1].

Conclusions: Most patients with moderate to severe AKI are unaware of their condition, lack understanding of risk factors for future AKI, and desire more information about AKI. Optimizing AKI awareness and understanding to promote patient-centered communication and care will require targeted educational strategies during and after hospitalization.

Early and Late Auto Kidney Injury in Severely Burned Patients

Stanislaw Niemczyzk,1 Wojciech Witkowski,2 Wojciech Klimm,2 Agnieszka Surowiecka-Pastewka,2 Marek Kawecki,2 Katarzyna Szamatoluska,2 1Dept of Internal Medicine, Nephrology and Dialysotherapy, Military Inst of Medicine, Warsaw, Poland; 2Dept of Burns, Plastic and Reconstructive Surgery, Military Inst of Medicine, Warsaw, Poland; 3Dept of Treatment of Burns, Centre for the Treatment of Burns, Słomczanowskie Slaskie Szpitali Specjalistyczne w Patrymo, Dept of Epidemiology and Biostatistics, Inst of Mother and Child, Warsaw, Poland; 4Dept of Emergency Medicine, Faculty of Health Sciences, Academy of Technology and Humanities, Bielsko-Biala, Poland.

Background: Evaluation of factors influencing early and late acute kidney injury (AKI) in severely burned patients and assessment of the relationship between time of occurrence of AKI and mortality.

Methods: Retrospective analysis of severely burned patients with ≥30% total body surface area (TBSA), admitted to two centers for the treatments of burns. We selected and analysed 239 severely burned patients. Renal function was evaluated at three points: admission, critical middle point of hospitalization and the endpoint death or discharge from the center. AKI criteria: decrease in glomerular filtration rate (GFR)<60 ml/min at admission, decrease in GFR<75% compared to baseline, decrease in the daily diuresis<500 ml.

Results: At admission 15.1% of the patients had GFR <60 ml/min. AKI occurred in 38.5%. The occurrence of AKI was associated with: elderly age (p<0.001), female gender (p<0.017), overweight and obesity (p=0.055), extented depth of burns, respiratory failure, low protein concentration (for all p<0.001), low blood pressure (p=0.014) and high white blood cells count (WBC) (p=0.010). Early AKI was detected in 28% Mortality was 100% with the initial GFR<60 ml/min, 100% with the initial GFR<60 ml/min and early development of renal function, 50% with the initial GFR<60 ml/min and early developing, and 60% with the initial GFR<60 ml/min and no worsening. Late AKI was observed in 10% of patients and mortality was 79.2%. Mortality in the group with AKI was 88.0% versus 24.5% without AKI.

Conclusions: The frequent occurrence of AKI, especially early, worsens the prognosis for survival. The assessment of renal function should be included in the prognostic scales for burned patients.

FR-PO502

Acute Kidney Injury and Risk of Incident Heart Failure Among U.S. Veterans

Nisha Bansal,1 Michael Edwin Matheny,2 Svetlana Eden,3 Robert Grevey,2 Shariah Purr,2 James Fly,2 Khaled Abdel-Kader,2 Jonathan Himmelstfarb,1 Ian H. De Boer,1 Talat Alp Ikizler,2 Edward D. Siew.2 1UW; 2Vanderbilt.

Background: Acute kidney injury (AKI) is common and associated with poor long-term outcomes. Heart failure (HF) is a leading cause of cardiovascular disease among patients with chronic kidney disease (CKD). The relationship between AKI and HF remains unknown and may identify a novel endpoint and link between kidney and cardiovascular disease.

Methods: We studied a national retrospective cohort of 111,488 U.S. Veterans hospitalized between 2003-2012 without history of HF. AKI was defined as a 0.3 mg/dl or 50% increase in serum creatinine using the difference between peak hospitalization and baseline creatinine (as determined by mean of outpatient creatinine over previous year and staged according to Kidney Disease Improving Global Outcomes (KDIGO) criteria using change in serum creatinine. Incident HF was defined as ≥1 hospitalization or ≥2 visits with a diagnosis of HF, as determined from validated ICD9 codes, through 2012. Propensity score matching of 37 relevant inpatient and outpatient covariates were generated and patients with and without AKI were matched 1:1. Cox proportional hazards were used to determine the association of AKI with risk of incident HF, adjusting for baseline age, eGFR, coronary heart disease and hypertension. Patients who died or had an outcome after the end of the study were censored.

Results: There were 17,272 matched pairs with and without AKI in the study. Patients with and without AKI during the index hospitalization were well matched with median

Acute Kidney Injury Increases Medical Costs Even in the Pre-AKI Stage

Jeonghwan Lee, 1 Seon Ha Baek, 2 Shin-Young Ahn, 3 Ho Jun Chin, 4 Ki Young Na, 5 Dong-Wan Chae, 6 Sejoong Kim. 2 Internal Medicine, Hallym Univ Hangang Sacred Heart Hospital, Seoul, Republic of Korea; 3Internal Medicine, Seoul National Univ Bundang Hospital, Seongnam, Gyeonggi-do, Republic of Korea.

Background: Early detection of acute kidney injury (AKI) is important to prevent the progression of AKI and to improve clinical outcomes. However the significance of mild increase in serum creatinine below AKI stage is not well established. In this study, we defined pre-AKI as the 25-50% increase in serum creatinine levels from the baseline levels. We aimed to investigate the influence of AKI stage including pre-AKI on clinical outcomes.

Methods: All clinical and laboratory data were retrieved from electronic medical record database.

Results: We enrolled a total of 2816 patients who admitted Seoul National University Bundang Hospital from January 1, 2013 to December 31, 2013. We excluded patients who had not checked serum creatinine levels during admission or who were on dialysis due to end-stage renal disease.

Results: The proportion of patients who had AKI during admission were 21.6% (pre-AKI), 15.8% (AKI stage 1), 5.9% (AKI stage 2), and 3.2% (AKI stage 3). In-hospital mortality increased according to the stage of AKI [log-rank P < 0.001; HRs 1.878 (1.189-2.966) AKI stage 1; 6.039 (3.948-9.239) AKI stage 2; 12.064 (7.992-18.210) AKI stage 3].

Conclusions: We suggest that outpatients should be monitored for AKI, given its unexpected incidence and increased medical costs during admission. Clinical significance of pre-AKI should be paid attention.

Impact of Fluid Overload on Acute Kidney Injury Diagnosis and Associated Outcomes in Critically III Patients: A Retrospective Cohort Study

Luis Ignacio Bonilla, 1, 2 Sara Simoni, 3 Maria Fernanda Golzarri, 4 Salvador Rodriguez, 5 Jordana S. Lemus, 1, 2 Guillermo Cardenas, 4 Claudio Rotonc, 2 Internal Medicine, Hospital General Dr. Manuel Gea Gonzalez, Mexico City, Mexico; 1IRRIV, International Renal Research Inst Vicenza, Vicenza, Italy; 3Nephrology, National Inst of Cardiology, Mexico City, Mexico; 4ICU, Hospital General Dr. Manuel Gea Gonzalez, Mexico City, Mexico.

Background: Fluid overload/FO changes the volume of distribution of creatinine, which is equivalent to total body water(TBW),this can alter the serum creatinine(sCr) concentrations,higher TBW result in lower sCr leading to underestimation of AKI.

Methods: We made a retrospective analysis of 120 records of pts from 2 centers. We calculated daily fluid balance and divided it by the body weight to obtain a percentage of FO.Pts were divided into 2 groups,A and B,with <2.5% and >5% of FO,respectively.

Results: We made a retrospective analysis of 120 records of pts from 2 centers. We calculated daily fluid balance and divided it by the body weight to obtain a percentage of FO.Pts were divided into 2 groups,A and B,with <2.5% and >5% of FO,respectively.

Conclusions: Fluid overload/FO changes the volume of distribution of creatinine, which is equivalent to total body water(TBW),this can alter the serum creatinine(sCr) concentrations,higher TBW result in lower sCr leading to underestimation of AKI.

Placental Growth Factor (PLGF) is the Novel Predictor of CKD Progression: The Results from NARA-CKD Study

Masaru Matsui, Katsuhiko Morimoto, Miho Tagawa, Ken-ichi Samejima, Yasuhiro Akai, Yoshikazu Saito. First Dept of Internal Medicine, Nara Medical Univ, Kashihara, Japan.

Background: PLGF plays a critical role in arterio genesis through vascular inflammation. We have already reported an independent association of PLGF with survival and cardiovascular risk in the patients with chronic kidney disease (CKD study), we performed Assessment of Risk management for Atherosclerotic diseases in CKD (NARA-CKD) study; however, the relations between circulating levels of PLGF and the progression of CKD remains unknown.

A prospective cohort study of 402 participants undergoing renal biopsy was conducted to elucidate the predictive value of PLGF on renal prognosis in the patients with CKD.
Results: Histologically, elevated PI GF was significantly associated with the severity of glomerulointerstitial damage and the intimal thickening of small renal arteries. During a median follow-up of 2.7 years, 82 patients reached primary end-points which were defined as the requirement of replacement renal therapy (38 patients) and the decline of eGFR by more than 25% from baseline (44 patients). Although baseline eGFR was not statistically different among patients in all PI GF quartiles, the rate of eGFR decline in the patients with the highest PI GF quartile was significantly faster than those with other quartiles. With adjustment of known confounding factors, PI GF was significantly associated with the risk of deterioration of renal function with the adjusted hazard ratio of 1.75 (1.38–2.26) for each quartile increment of PI GF. The combined use of eGFR and PI GF significantly improved the predictive accuracy for CKD progression compared with eGFR alone (c statistics from 0.689 to 0.772, p<0.001).

Conclusions: Elevated PI GF is a novel and independent predictor of renal prognosis in the patients with CKD.

FR-PO508

Steep Decline in Renal Function After a Hypertensive Disorder of Pregnancy: A Longitudinal Study

Methods: Data from the PREVEND study, a population based prospective cohort with median follow-up of 11 years, were used to identify women without and with self-reported HDP (non-HDP, n=1805 and HDP, n=977). A case cohort, 10 years post-partum was created by record linkage, with subgroups: normal pregnancy (control, n=202), pregnancy-induced hypertension (PIH, n=56) and preeclampsia (PE, n=29). Renal function and the prevalence of CKD were compared.

Background: Hypertension in pregnancy can be associated with renal injury which may be masked by gestational change. Postpartum assessment is an opportunity to detect persistent renal abnormalities. However previous studies are small and often exclude those with pre-existing hypertension, a risk factor for CKD. Aim: To determine the postpartum prevalence of renal abnormalities in women with chronic hypertension, pregnancy induced hypertension (PIH) or preeclampsia (PE) in a previous or current pregnancy.

Methods: Women with singleton pregnancies referred to a hypertension pregnancy clinic (Feb 2011-Nov 2014) attending postpartum review (offered to all) were included. Those with previously diagnosed CKD were excluded. Demographics, 24-hour urine protein, estimated GFR (CKD-EPI) and blood pressure after six weeks postpartum were recorded.

Results: Overall 120 (29.7%) of women were found to have features of renal disease postpartum. Subgroup analysis according to hypertensive groups is shown in Table 1.

Conclusions: A substantial proportion of women with hypertension in pregnancy have renal abnormalities after six weeks postpartum. Identification of risk factors for progression of CKD in this population through longitudinal studies is needed.

FR-PO509

Pregnancy Outcomes in Women with Chronic Kidney Disease in South Australia

Methods: Data was obtained from the PREVEND study, a population based prospective cohort with median follow-up of 11 years, were used to identify women without and with self-reported HDP (non-HDP, n=1805 and HDP, n=977). A case cohort, 10 years post-partum was created by record linkage, with subgroups: normal pregnancy (control, n=202), pregnancy-induced hypertension (PIH, n=56) and preeclampsia (PE, n=29). Renal function and the prevalence of CKD were compared.

Results: eGFR was lower at baseline and during follow-up in HDP vs non-HDP (A). In addition, the decline in eGFR was steeper in HDP vs non-HDP (B). At baseline and during follow-up there were more anti-hypertensive drug use, including ACEi in the HDP group. 24-h albuminuria at baseline was higher in HDP vs non-HDP and remained steadily higher in HDP during follow-up. A trend towards increased risk of CKD was observed in HDP. FR-1.13 (1.13-1.16) (C). In the case cohort, eGFR was significantly lower (C) and 24-h albuminuria significantly higher (p<0.003) in the PE vs controls. 7.8% of the controls, 10.6% of the PIH and 12.9% of the PE group met the criteria for CKD.

Conclusions: We report a lower renal function and a steeper renal function decline over time after HDP. Women with severe hypertensive disorders of pregnancy (PE) have the highest risk for renal function loss.

FR-PO511

Changes of Markers of Prothrombotic State in Membranous Nephropathy Complicated with Type 2 Diabetes

Methods: Patients were enrolled if they were diagnosed with MN and T2DM during the time period of 2005-2014. All patients were treated with immunosuppressive therapy and followed up until December 2015. The study population was divided into two groups: (1) MN patients with T2DM (MN+T2DM, n=14); (2) MN patients (pure MN, n=6). Differences in the biomarkers of vascular function and markers of thrombosis were evaluated at baseline and after 6 months of treatment. The primary endpoint was to assess the changes in thrombotic and anti-thrombotic markers.

Results: There were no significant differences in baseline characteristics between the two groups. After 6 months of treatment, there were significant differences in levels of proteinuria (>150 mg/d: MN+T2DM vs pure MN, p<0.05), homocysteine (MN+T2DM vs pure MN, p<0.05), proteinuria (MN+T2DM vs pure MN, p<0.05), and vWF levels (MN+T2DM vs pure MN, p<0.05). The levels of proteinuria, homocysteine, proteinuria, and vWF were significantly lower in MN+T2DM group compared to pure MN group.

Conclusions: The changes in markers of prothrombotic state were significantly different between MN patients with T2DM and pure MN patients treated with immunosuppressive therapy. The changes in these markers may contribute to the pathogenesis of MN in patients with T2DM.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusions: Under NS state, MN+DM patients existed more serious prothrombotic state compared to primary MN+DKD. The mechanism is related to disorders of plasminogen activation function, coagulation function, as well as fibrinolytic function. More attention should be paid to treatment of prothrombotic state in MN+DM patients.

Serum C3 and Renal Outcome in Patients with Primary Focal Segmental Glomerulosclerosis
Tian Li,
Jingyuan Xie,
Jun Tong,
Hong Ren,
Weiming Wang,
Nan Chen.
Dept of Nephrology, Rui Jin Hospital,
Shanghai Jiao Tong Univ,
School of Medicine,
Shanghai, China.

Background: The role of complement in the pathogenesis or progression of FSGS is uncertain. The aim of this observational cohort study was to identify the clinical implications of serum C3 levels and to investigate their utility as predictor of renal outcomes in patients with FSGS.

Methods: 591 biopsy-proven primary FSGS patients were recruited. Clinical, histological and progression data were recorded. Decreased serum C3 level was defined as C3 <85 mg/dl. The study endpoint was end-stage renal disease (ESRD).

Results: Of the patients, there were 117 patients (21.5%) with low serum C3. At the time-point of renal biopsy, compared to patients with C3 ≥85 mg/dl, those with C3 <85 mg/dl had higher level of serum creatinine, lower levels of eGFR, proteinuria, hemoglobin, triglyceride, cholesterol, IgA, more severe segmental sclerosis, tubular atrophy and total suPAR serum level for the prediction of recurrent FSGS.

Conclusions: Complement activation may occur in patients with FSGS. It is associated with clinical and histological severities. Low serum C3 is an independent risk factor for the decline of eGFR, and is associated with poor renal outcome in patients with FSGS.

Funding: NIDDK Support

Nada Alachkar,
Changli Wei,
Changkyu Gu,
Jochen Reiser,
Nephrology, Massachusetts General Hospital, Charlestown, MA; Univ of Louisville School of Medicine, Louisville, KY; Nephrology, Johns Hopkins Univ School of Medicine, Baltimore, MD; Medicine, Rush Univ Medical Center, Chicago, IL.

Background: Primary FSGS is a kidney disorder that leads to end stage renal disease and affects tens of thousands people annually. Several studies suggest the soluble urokinase-type plasminogen activating receptor (suPAR) to be a predisposing circulating factor and prognostic marker of FSGS through its interaction with αvβ3 integrin.

Methods: We collected serum samples from kidney transplant recipients with FSGS. We also analyzed sera from healthy controls and patients with sepsis and on peritoneal dialysis. These sera were used to assess integrin activation in podocytes. Western blot identified a fragment of suPAR containing the D2-D3 only in the subset of sera from patients with recurrent FSGS. In vitro, the EC50 response of D2-D3 for activating integrin αvβ3 was approximately ten fold than for D1-D2-D3. Exposure of podocytes to physiological concentrations of the D2-D3 increased the amount of surface uPAR and facilitated podocyte motility. Injections of the D2-D3, but not full-length suPAR, induced transient proteinuria in mice. Transgenic mice for D2-D3 developed rising serum suPAR levels and a variable degree of proteinuria. A composite risk analysis score was developed that included presence of the D2-D3 in patient serum, podocyte integrin activation capacity, and total suPAR serum level for the prediction of recurrent FSGS.

Conclusions: suPAR D2-D3 fragment is a prognostic marker and risk factor for recurrent FSGS.

Background: Lupus nephritis is the most common glomerulonephritis in the Colombian Caribbean region, despite there is less published information about its evolution and clinico-pathological aspects. Objective: To evaluate prognosis, survival and renal function of patients with LN residing in the Colombian Caribbean region controlled between 2000 - 2014.

Methods: 229 patient study with LN corroborated by histology according to the International Society of Nephrology Classification / Renal Pathology Society (ISN/ RPS. 2003) treated with induction and maintenance therapy and with a systemized following of at least 2 years. The pharmacological treatments included prednisolone, azathioprine, and Cyclophosphamide mycophenolate mofetil in isolation or combined and the clinical laboratory and histopathology variables were correlated as predictive value of therapeutic response. To achieve this as methodology a non-parametric descriptive statistics ANOVA (k-w) was used and canonical correspondence analysis.

Results: 229 patients in total of 34±12 of age, which 88% women, whose evolution were controlled during 24±6 months. The most common form of clinical presentation was nephrotic syndrome and asymptomatic hematuria-proteinuria (68.07%) the type III and type IV patients under 25 years and negative response to treatment. The estimated glomerular filtration rate measured by MDRD showed a significant improvement at 24 weeks with regard the baseline figure of 74.36.

Conclusions: The early detection and reference of NL patients allows an early approach and therapy. Which will prevent chronic kidney disease.

Association of ABO Blood Group with Progression of IgA Nephropathy
Meng Yang,
Jingyuan Xie,
Yan Ouyang,
Xiaoyan Zhang,
Xiao Li,
Wen Zhang,
Weiming Wang,
Nan Chen.
Dept of Nephrology, Ruijin Hospital,
Shanghai Jiaotong Univ School of Medicine, Shanghai, China.

Background: ABO blood group antigens are major histocompatibility antigens and little is known about its association with progression of IgA nephropathy (IgAN).

Methods: Biopsy-proven primary IgAN patients were retrospectively recruited. Clinical, histological and progression data were recorded. Patients with eGFR<15ml•min^-1•1.73m^-2 at time of biopsy were excluded. Renal tissue was semi-quantitative scored according to the Oxford scoring system. ABO blood group was determined by standard erythrocyte antiserum agglutination method. All patients were divided into B antigen group (type B and AB) and non-B antigen group (type A and O) based on their ABO types.

Results: Among the 752 IgAN patients recruited in this study, 210 patients were type A (27.9%), 221 were type B (29.4%), 72 were type AB (9.6%) and 249 were type O (33.1%). When renal biopsy was performed, patients in B antigen group had higher eGFR (82.44 ± 65.68 ml/min), lower systolic blood pressure (125.36 ± 129.29 mmHg), and uric acid (373.59 vs. 393.93 mmol/l) than patients in non-B antigen group. No significant difference was detected between histological lesions and these two groups. Totally, 100 patients progressed to end-stage renal disease (ESRD) after a median follow-up period of 51.05 months, including 32 (15.2%) type A, 18 (8.1%) type B, 2 (2.8%) type AB and 48 (19.3%) type O patients. Kaplan-Meier analysis showed that median ESRD-free survival time in patients in B antigen group was significantly longer than patients in non-B antigen group (148.2±5.5 months vs. 138.8±7.5 months, p<0.001). Furthermore, patients in B antigen group were associated with a decreased risk of ESRD (HR=0.56, 95%CI 0.33-0.94) after adjusted by age, sex and clinical variables including eGFR, sbp, serum albumin, urine protein and hemoglobin by Cox proportional hazards model.

Conclusions: Our data suggested that B antigen had an independent protective effect against the progression of IgAN.

Background: Primary IgA nephropathy (IgAN) is one of the most common glomerular diseases in China. In this study we try to investigate the clinical characteristics and the relationship between CKD stages and long-term outcomes of patients with primary IgAN through the retrospective analysis of their clinical data.

Methods: Patients with biopsy-proved primary IgAN from 2002 to 2013 were included in the retrospective analysis. They were older than 18 years old and their follow-up time was more than 12 months. We collected their medical history, laboratory test reports and other clinical data. Then we enrolled 297 patients who were followed up for 5 years for further research. Kaplan-Meier method was used to calculate the renal survival rate of the patients.

Variability of GFR Decline in Alport Syndrome: Insights from a Provincial Database
David Langsford,1 Mila Tang,2 Ogjenka Djurdjevic,3 Lee Er,4 Aedera Levin,1,3 *UBC; 2BC Renal Agency.

Background: Alport syndrome (AS) is one of the inherited causes of CKD due to mutations in the collagen genes making up the glomerular basement membrane collagen. Design of clinical trials for intervention in AS proves challenging without a clear understanding of renal progression over time as observational data is lacking due to small sample size. We present here the utilization of population based data in a simulation to mimic clinical trial recruitment and endpoints to provide insights in trial designs for AS.

Methods: AS patients were identified within a provincial CKD clinical database (PROMIS) in British Columbia, Canada for this observational simulation study. Patients were excluded if they had fewer than 4 GFR-MDRD measurements or 2 as a study entry point to generate 100 random samples. Primary outcome was annual rate of GFR change over 2 years categorized into: > -5 mL/min/yr (progressor), -5 to 2 mL/min/yr (stable), < -2 mL/min/yr (regressor).

Results: 37 pts met inclusion criteria; median follow-up was 48.2 months, and median age of 36. The sample sizes for each random sample at the 3 enrolment gFR levels were: 11, 12 and 10 respectively. Of those that ’enrolled’ at gFR 45-60 mL/min, 72.7% (IQR:63.6%,81.8%) progressed, and 22.7% (IQR:9.1%, 36.4%) remained in stable state. The five-year renal survival rate of patients in CKD3b stage was 85.3%, while it is only 65.3% for patients in CKD4 stage.

Conclusions: Five-year and ten-year renal survival rate of patients with IgAN was 92% and 88%, respectively. Patients in CKD3b or CKD4 stage at biopsy may have a lower renal survival rate and a worse outcome. At the time of renal biopsy, patients with impaired renal function, mass proteinuria, hypertension, anemia and low serum albumin may have a greater risk of progressing to end-stage renal disease.

Micronas as Predictive Biomarkers of Chronic Kidney Disease (CKD) in Patients (Pts) Undergoing Radical Nephrectomy (RN) for Kidney Cancer
Francesco Trevisani,1 Michele Ghidini,1 Jens C. Haehne,2 Andrea Lampis,3 Paolo Manunta,4 Maria Teresa Sciarrone Alibrandi,5 Giacomo Dell’Antonio,6 Lorena Citerio,7 Laura Zagato,8 Francesco Montorsi,9 Fabio Benigni,10 Alberto Brigante,11 Roberto Bertini,11 Andrea Solonia,10 Cristina Carracino,12 Massimo Rugge,10 Paolo Rigotti,10 Giovambattista Capasso,10 Luciano Cascione,13 Chiara Braccon,12 Nicola Valeri.1 1ICR, London, United Kingdom; 2San Raffaele Inst, Milan, Italy; 3Univ of Padua, Padua, Italy; 4Univ of Naples, Naples, Italy; 5IOR, Bellinzona, Switzerland.

Background: MicroRNAs (miRs) are small non-coding RNAs involved in cell homeostasis and disease. Our study identified clinical and molecular markers associated with increased risk of developing CKD after RN for renal clear cell carcinoma(RCC).

Methods: 80 pts who underwent RN for RCC at a single institution between 2008-2011 were included. Inclusion criteria: normal renal function at surgery time (gFR > 60 mL/min CKD-EPI formula 2009, serum creatinine <1.1 mg/dL, no proteinuria). No pre-existing glomerulopathy. No evidence of metastatic disease. Minimum follow-up: 12 months post-surgery. FEPE normal adjacent tissue to RCC(-)sm was micro-dissected to isolate cortex(10 glomeruli) and medulla and was subject to RNA extraction. miRs analysis was performed using Nanostring nCounter and validated by Real-time, droplet PCR and in situ hybridization(SH). Cox regression analyses were used to define variables associated with increased risk of CKD.

Results: 47.4% of pts developed CKD(stage 3a-3b-4 KDIGO) 12 months after RN. At multivariable Cox Regression, type II diabetes(pvalue:0.009),basal serum creatinine(pvalue:0.002) and miR-193b over-expression(pvalue:0.017) were independently associated with increased risk of developing CKD after RN for renal clear cell carcinoma(RCC).

Conclusions: Tissue and urinary miRs deregulation may represent an early marker of kidney dysfunction and may anticipate clinical and laboratory evidence of CKD providing an important tool for personalized follow-up and prevention in pts undergoing RN for RCC.

Urinary Angiotensinogen to Creatinine Ratio Is a Specific Biomarker for Renal Progression in Autosomal Dominant Polycystic Kidney Disease
Hayne C. Park,1 Hyunjin Ryu,1 Myeun Han,2 Hyun Suk Kim,2 Kook-Hwan Oh,1 Young-Hwan Hwang,1 Curie Ahn,1 *Internal Medicine, Armed Forces Capital Hospital, Seongnam-Si, Gyeonggi-Do, Korea; 2Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; 3Internal Medicine, Eulji General Hospital, Seoul, Korea.

Background: Urinary angiotensinogen to creatinine ratio (AGT/Cr) is elevated in autosomal dominant polycystic kidney disease (ADPKD), but whether AGT/Cr is a specific biomarker of ADPKD progression is not known. This study was performed to measure urinary AGT/Cr in subcohorts according to primary renal disease (glomerulonephritis (GN), diabetic nephropathy (DN), hypertensive nephropathy (HTN), ADPKD) and to demonstrate urinary AGT/Cr in subcohorts according to primary renal disease. First-voided morning urine was collected from all patients upon enrollment and stored at -80°C until measurement. Urinary AGT was measured by commercial sandwich enzyme-linked immunosorbent assay (ELISA). Urinary AGT/Cr levels and associated factors were compared among CKD subgroups.

Methods: Nine nephrology centers recruited adult subjects with chronic kidney disease (CKD) stage 3a-4 and classified them into subgroups according to primary renal disease as shown in Table 1. First-voided morning urine was collected from all patients upon enrollment and stored at -80°C until measurement. Urinary AGT was measured by commercial sandwich enzyme-linked immunosorbent assay (ELISA). Urinary AGT/Cr levels and associated factors were compared among CKD subgroups.

Results: A total of 1528 patients were enrolled in KNOW-CKD cohort study (NCT 01630486) from Apr 2011 to Dec 2013. Among them, 153 patients were excluded (71 unclassified subgroups, 71 without urinary AGT measurement, 9 without available eGFR) and a total of 1375 (519 GN, 310 DN, 292 HTN, 254 ADPKD) patients were included in the final analysis. The mean age was 51 years and baseline serum creatinine was 1.9 ± 1.2 mg/dL. The GN and ADPKD subgroups showed younger age and earlier elevation.

CKD: Risk Factors for Incidence and Progression - II
Poster/Friday
of urinary AGT/Cr levels according to CKD stages. When we performed the risk factor analysis separately in GN and ADPKD subgroups, the highest quartile of urinary AGT/Cr was associated with GN subcohort, female gender, hypertension, decreased eGFR, decreased plasma Hb, and higher degree of albuminuria. However, in multivariate logistic regression analysis, ADPKD subcohort demonstrated higher urinary AGT/Cr compared to GN subcohort after adjusting other co-factors.

**Conclusions:** Urinary AGT/Cr is greatly increased in ADPKD independent of albuminuria and renal function.

**Using Biomarkers to Predict Progression to End-Stage Renal Disease within 6 Months of Liver Transplant**

**Joseph T. Bahng,1 Kimberly Autumn Forde,1 Peter Abt,1 Michael R. Bennett,2 Anirban Ganguli,3 Mary Ann C. Lim,1 Debra J. Mccorriston,1 Mary C. Shaw,4 Deirdre L. Sawinski,1 1Perelman School of Medicine at the U. of Pennsylvania; 2Cincinnati Children’s Hospital.

**Background:** Liver transplant (LT) recipients are at increased risk for CKD and progression to ESRD. Creatinine, the standard for assessing renal function, provides limited prognostic information for recovery from AKI. Our aim is to create a predictive model for progression to ESRD within 6mos of LT incorporating clinical data and biomarkers.

**Methods:** We enrolled 202 patients, of whom 138 have 6mos follow up. 13 patients progressed to ESRD, defined as GFR<20 ml/min; dialysis, or transplant evaluation. Logistic regression models evaluated neutrophil gelatinase-associated lipocalin, IL-18, Cystatin-C, Kidney Injury Molecule-1, & liver fatty acid binding protein for inclusion. Receiver operating characteristic curves and concordance statistics were used to assess the models.

**Results:** In one model, MELD score at LT, pre-LT AKI, pre-LT renal replacement therapy, and highest creatinine 6mos pre-LT were associated with ESRD at follow-up (p<0.05). In another model with biomarkers, only urinary IL-18 was included for its association with progression to ESRD. Creatinine, the standard for assessing renal function, provides limited prognostic information for recovery from AKI. Our aim is to create a predictive model for progression to ESRD within 6mos of LT incorporating clinical data and biomarkers.

**Conclusion:** Our predictive model for progression to ESRD within 6mos of LT incorporating clinical data and biomarkers is associated with higher MELD score at LT, pre-LT AKI, pre-LT renal replacement therapy, and highest creatinine 6mos pre-LT.

**Detection of Inflammatory BioMarkers in Urine Using a Dried, Shelf Stable Transport Device, ViveST**

**Daniel R. Mcclernon,1 Timothy W. Murray,2 Anita M. Mcclellon,1 bioMONTR Labs, Research Triangle Park, NC, 2Vivebio LLC, Alpharetta, GA.

**Background:** Current medical practice assesses health of implanted kidneys by monitoring non-specific signals (serum creatinine) after rejection has started and gold standard diagnostic method is invasive kidney biopsy. Studies of non-invasive biomarkers (CXCL9) have shown utility (CTOT-01) in identifying subsets of patients at risk for acute rejection. A urine based test for post surgical evaluations to pinpoint rejection and expedite therapeutic intervention is needed. Here we describe detection of CXCL9/MIG and CXCL10/IP-10 in urine in combination with a novel collection device ViveST, eliminating need for cold chain transport and storage.

**Methods:** Urine collected and centrifuged (4°C)at 2,000xg (30 min). Supernatant decanted into clean tubes and diluted 1:1 with proprietary diluent buffer. Reconstituted Human, A.99/MIG and CXCL10/IP-10 (R&D Systems) was reconstituted using molecular grade water to concentrations of 10,000pg/ul and serially diluted. Urine was spiked with diluted reconstituted human MIG or IP-10. 1ml aliquots were loaded onto ViveST and dried. ViveST samples were reconstituted with 1ml of molecular grade water and analyzed concurrently with frozen aliquots using quantitative sandwich enzyme immunoassay techniques for MIG or IP-10. Linear regression analysis from seven levels of calibration standard used to calculate MIG and IP-10 concentration.

**Results:** ViveST samples yielded MIG or IP-10 concentrations similar to corresponding frozen aliquots (see table). Replicate aliquots gave similar results.

**Conclusions:** MIG and IP-10 can be detected in urine as inflammatory biomarker to assess risk of transplant rejection. ViveST can be used as ambient storage and transport device eliminating need for cold chain storage. Additional studies warranted assessing detection of biomarkers at therapeutically relevant concentrations.

**Albuminuria-Induced Apoptosis in Children with Nephrotic Syndrome Is A Result of the Dysbalance in Apoptosis Controlling System**

**Yejevnia Burlaka, Dept of Pediatrics No.4, National O.O. Bogomolets Medical Uni, Kyiv, Ukraine.

**Background:** Albuminuria promotes cell death, and is associated with faster progression of chronic kidney disease (CKD). However, the molecular mechanisms regulating cell death in response to albuminuria are not fully understood.

**Methods:** 53 patients aged 10-15 years with active stage of nephrotic syndrome were included in the study. Immunohistochemical staining of anti-apoptotic factor Bax, anti-apoptotic factor Bcl-xl, number of apoptotic cells in kidney biopsy specimens were done. Comparison of the level of these parameters between the different segments of nephrone at different stages of glomerulosclerosis has been performed.

**Results:** Measurement of the pro-apoptotic factor Bax in kidney slices obtained from children with morphological form of nephrotic syndrome focal segmental glomerulosclerosis (FSGS) showed presence of high level of Bax in both glomerular and tubule-interstitial segments. Higher immunosignals of Bax was evaluated in glomeruli with FSGS I-II st. as compared to tubular segment. When FSGS III-IV st. observed higher expression of Bax was detected in surrounding tubule-interstitial segment. Expression of the anti-apoptotic factor Bcl-xl was studied. Higher expression of Bcl-xl was recorded in tubule-interstitial segment as compared to glomeruli when FSGS I-II st. occurs. When FSGS III-IV st. occurred higher immunosignals of Bcl-xl is localized in surrounding tubule-interstitial segment with almost complete absence in glomeruli. The number of apoptotic cells was analysed. Quantitative analysis of apoptosis in kidney sections of patients with FSGS I-II st. revealed higher apoptotic index (AI) in glomeruli as compared to tubule-interstitial component. In kidney sections with FSGS III-IV st. higher AI was found in tubule-interstitial compartment.

**Conclusions:** Thus, progression of kidney injuries in nephrotic syndrome is associated with increased activity of pro-apoptotic factor Bax and simultaneous reduction of anti-apoptotic factor Bcl-xl. The level of the expression of Bax and Bcl-xl depends on the stage of FSGS and indicates the step-dependent manner of glomerular and interstitial injuries development upon the chronic influence of albuminuria.

**eGFR, Renal, and Cardiovascular Risk and Nucleosome/Nucleotide Backbones of Human Immunodeficiency Virus Patients in the USA**

**Jonathan A. Winston,1 Grace McConney,2 1Icahn School of Medicine at Mount Sinai; 2Case School of Medicine.

**Background:** HIV treatment involves choices in complex environments, and must balance disease management and potential safety issues (kidney and Cardiovascular diseases (CVD)) in an aging population. This study examined renal, CVD and comorbid conditions, and treatment of HIV patients.

**Methods:** Patients diagnosed with HIV using ICD-9 codes were selected from the Quintiles database (33M patients). Patients enrolled for ≥ 1 year during 2012-14, maintaining a single antiretroviral therapy, and for whom baseline eGFR could be computed were stratified based on backbone: regimens including tenofovir disoproxil fumarate (TDF), abacavir (ABC), or other (OTH). eGFR and rate of CV comorbidities at baseline were assessed.

**Results:** 14,942 HIV patients (mean age: 43; 76% male) were included; 85% TDF, 7% ABC, 8% OTH. Mean baseline eGFR was 99 ml/min/1.73 m², with differences observed among regimens (102 TDF, 82 ABC, 87 OTH). Classified by degree of kidney impairment at baseline, regimen was highly correlated with level of impairment, with normal or mild impairment (eGFR<60) more likely to be treated with TDF, and patients with moderate to
severe impairment (eGFR<60) more likely to be on ABC. Several CVD risk factors were more prevalent in ABC patients compared to TDF, hypertension (25% v 13%), dyslipidemia (30% v 16%), and diabetes (12% v 5%) (p<0.001 in all) being the most common.

Conclusions: HIV patients often present with prevalent CVD risk and reduction in kidney function. Physicians make treatment choices that reflect concern for kidney function, consistent with labeling. This choice may come with cost, with more CVD risk factors correlated with alternative choices of NRTIs. As some antiviral regimens may be associated with CVD while others with kidney disease, understanding CVD risk profile versus kidney function protection may help optimize care of patients.

Liveview tool provides the best compromise between accuracy and time required.

Renal Reserve: Development of a Kidney Stress Test Kyle Rodenbach,1 Dana F. Fuhrman,1 Paula S. Maier,1 Katherine D. Shaw,1 George J. Schwartz.1 1Peds, Univ of Rochester, Rochester, NY; 2Peds, Univ of Pittsburgh, Pittsburgh, PA.

Background: Renal reserve (RR) is the difference in stimulated versus baseline glomerular filtration rate (GFR); it might predict future kidney health. The purpose of this study was to compare a meat versus liquid protein load in a cystatin-C-based (Cys-C) RR test using cystatin-C-mediated creatinine clearance (CrCl) and iohexol infusion clearance (IoCl) for validation.

Methods: Participants (N=18) were screened for health status, blood pressure, and proteinuria. They followed a low protein diet and took cysteine (20 mg/kg) for two days prior to the study. Water loading was used to maintain urine flow, and two hours were allowed for a stable steady state to be established. Participants 1-10 received a burger (1 g/kg protein); 11-15 received a ProCel® shake (1 g/kg protein); and 16-18 received a high dose ProCel® shake (1.5 g/kg protein). Data were analyzed for significance of RR. Cystatin-C estimated GFR (Cys-C eGFR) was calculated using the CKD-EPI Cys-C formula (Inker NEJM 2012) following IVC catheter calibration (ERM-DA471).

Results: Participants (N=18) had a mean (SD) age of 22 (2) years and were 39% male and 72% white. Baseline GFR (SD) in mL/min/1.73m² averaged 103.4 (14.7) for CrCl; 108.9 (9.0) for IoCl (N=8); and 117.4 (6.1) for Cys-C eGFR. For the burger group (N=10), mean RR (SD) in mL/min/1.73m² was 17.1 (11.6) for CrCl (P=0.001); 8.4 (4.3) for IoCl (P<0.001); and 4.7 (2.4) for Cys-C eGFR (P<0.001). For 1-0.1 g/kg shakes (N=8), mean RR (SD) in mL/min/1.73m² was 15.8 (5.8) for CrCl (P<0.001), 11.7 (9.0) for IoCl (P=0.008), and 2.4 (2.9) for Cys-C eGFR (P=0.05). The burger and shake groups did not differ significantly in RR determined by CrCl, IoCl, or Cys-C but Cys-C-based RR was significantly less than Io-o-based RR for both groups. There were no differences in post-load versus pre-load CrCl clearance ratios.

Conclusions: Cys-C-based RR following a burger provides a simple stress test of kidney function which was validated by classical renal clearances and can be applied to those who recover from acute kidney injury. Why Cys-C-based RR was smaller than Io Cl, the reference standard, is a topic for future investigation.

FR-PO527

Background: Despite the clinical recovery of an acute kidney injury (AKI) episode, progression to chronic kidney disease (CKD) could be observed on long time follow-up. The mechanisms are poorly understood. To analyzed if angiotensin II receptor blockade (ARB) before the ischemic insult is effective in abrogating the severity of the AKI episode and/or the progression to CKD.

Methods: Male Wistar rats were divided into 4-groups of rats: sham; sham plus losartan 3-d before surgery; bilateral renal ischemia for 45-min (UTxI); and losartan administration (3-d) before ischemia (Los+Pre). Animals were studied after 1, 3, 5, 15 days of 9-months. At the end of each experimental period, physiological, histopathological, immunohistochemistry, biochemical and molecular studies were performed.

Results: UTxI group developed CKD characterized by renal dysfunction, proteinuria, renal hypertrophy, glomerulosclerosis, tubular atrophy and tubulointerstitial fibrosis. At the ultra-structural glomerular level, foot process effacement was observed, which was associated a reduction in immune-gold staining for nephrin. Renal injury was mediated by increased oxidative stress, inflammation and up-regulation of TGFÎ¬, aSMA, and Collagen I protein levels. TGFÎ¬ overexpression was mainly observed in epithelial cells. Interestingly, in spite of ARB did not prevent or reduced AKI severity, it was enough effective to prevent CKD. The renoprotection conferred by ARB was associated with the early recovery of renal blood flow, lesser inflammation and greater nuclear hypoxic inducible factor 1Î± (HIF1Î±) staining.

Conclusions: Our data shows that in spite of, losartan pre-treatment did not protect the rats against AKI, it was effective to prevent the transition to CKD. The mechanisms by which losartan prevented CKD were in part due to the early renal blood flow recovery, lesser inflammation and greater HIF1Î± nuclear translocation within the 15 days post-ischemia.

Specific Endothelial Heparin-Binding EGF-Like Growth Factor Deletion Ameliorates Renal Injury Induced by Chronic Angiotensin II Infusion
Fenfua Zeng, Lance A. Kloepfer, Raymond C. Harris. Medicine, Vanderbilt Univ, Nashville, TN.

Background: Transactivation of EGFR by angiotensin II (Ang II) plays important roles in the initiation and progression of chronic kidney diseases (CKD). In vitro studies suggested that HB-EGF may be a critical mediator in this process, whereas its role in vivo has not been reported.

Methods: Age-matched male littermates of HB-EGF−/− mice with endothelial-SCL-Cre-ER (T) (+) or (-) were used. Tamoxifen injections produced control (HB−/−) and mice with specific deletion of HB-EGF from endothelium (HB−/−/−), which underwent untreated hyperlipidemia and systolic minipump-mediated infusion with saline or Ang II for 8 weeks. Systolic blood pressures (SBP) were measured by tail-cuff. Renal injury was evaluated by albuminuria using urinary albumin/creatinine ratios and by morphology with periodic acid-Schiff (PAS) staining. Renal EGFR activation was determined by immunoblotting and immunostaining. Endothelium/podocyte injury, inflammation and renal fibrosis were evaluated by immunostaining.

Results: Compared to control, kidneys from HB−/− mice with Ang II-infusion had significantly reduced EGFR activation. Endothelial HB-EGF deletion did not significantly prevent the hypertension induced by Ang II infusion, albeit lower SBP was detected in HB−/− mice compared to HB−/−/− mice. However, it decreased Ang II-infusion related renal injury, as demonstrated by 1) less albuminuria; 2) less glomerulosclerosis with glomerular score of 0.793 versus 1.652 in the control; 3) preserved endothelial integrity and decreased podocyte injury shown by more glomerular tufts area and WT1 positive cells; and less apoptotic cells measured by cleaved caspase 3 and TUNEL staining; 4) reduced inflammation in perivascular area and interstitium measured by F4/80 and CD3 immunostaining; and 3), reduced renal fibrosis, as shown by α-SMA immunostaining.

Conclusions: Shedding of HB-EGF from endothelium plays an important role in Ang II induced renal injury by linking Ang II-ATIR with EGFR transactivation. Inhibition of HB-EGF shedding could be a potential therapeutic strategy for CKD.

Effects of Acute Kidney Injury (AKI) Severity and Co-Morbidities on Chronic Kidney Disease (CKD) Progression
Gregory John Wilson,1,2 Andrew Lawrence Kark,1,2 Andrew John Mallett,1,2,3,4 Alan Salisbury,1,2,3,4 Zaimin Wang,1,2 Helen G. Healy,1 Wendy E. Hoy,1,2,4 Kidney Health Service, Royal Brisbane and Women’s Hospital Queensland, Australia; 1Inst for Molecular Biology and School of Medicine, UQ, Australia; 2Centre for Chronic Disease, UQ, Australia.

Background: AKI is a common and important cause of CKD. It remains unknown how AKI severity influences CKD progression. Which co-morbidities influence the progression of CKD also remains undefined.

Methods: We aimed to explore whether AKI severity and patient co-morbidities influence CKD progression. Patients with AKI associated with a clinical diagnosis of AKI were identified in the Royal Brisbane & Women’s Hospital cohort (n=1150) of the Queensland registry. AKI events were confirmed through historical creatinine values (2005 month plasma samples frozen from a phenotypically characterized cohort of patients with AKI Stage 3 and below from a prior Probiotic Renalys1 study. NMR spectral data of baseline and 6 month plasma samples were analyzed after identical treatment of all samples. A total of 24 baseline samples were differentiated by a change in their BUN. Principal components analysis and orthogonal partial least squares discriminant analysis was used to analyze the data and determine the metabolites that best differentiated the phenotypic groups.

Results: Characteristics of the cohort population were age 57.7 ± 14 yrs, mean BMI 31.3 ± 6.1 Kg/m2, 10 males and 14 females, 20 with HTN, 8 with DM, 11 Caucasian and 9 AA, 3 other, 1 unknown. 16 patients who had a decrease in BUN after 4 months of probiotics treatment could be differentiated based on baseline samples from those whose BUN increased or did not change. The majority of the metabolites that differentiated the groups were microbial related metabolites.

Conclusions: Metabolomics analysis revealed a signature of metabolites that were associated with a decrease in BUN, and holds promise for use in predicting individuals with CKD that would most benefit from use of probiotics. The majority of the metabolites important to the differentiation of groups map to pathways involved in microbial metabolism.

Association Between Gut Microbiome and Cardiovascular Risk in Chronic Kidney Disease Patients with Type 2 Diabetes Mellitus
Ruchi Singh, Tetyana L. Vasylyeva. Pediatrics, Texas Tech Health Sciences Center, Amarillo, TX.

Background: Diabetes is one of the leading causes of CKD. It is well established that patients with T2DM often experience persistent low-grade inflammation leading to microvascular deterioration and progression of vascular complications along with impaired gut motility, which impacts their microbomes. The aim of this study was to study the assessment of gut microbiota, plasma zonulin, and inflammatory cytokines (TNF-α, IL-6, IL-10) in conjunction with FGF-23, ET and levels of LPs in CKD (stage 4 and 5) patients with Diabetic Nephropathy (DN).

Methods: Healthy controls were matched by age and gender. Their dietary habits have not been observed. Total of 40 subjects participated in this study. IL-6, FGF-23, LPS. ET-1 and zonulin, levels were measured by ELISA and quantitative analysis of gut microbiota composition (454 pyro sequencing).

Results: Higher circulation serum zonulin, TNF-α, and IL-6, FGF 23, LPS, ET-1 levels were noted in the CKD (stage 4 and 5) patients with DN compared with HCs. Patients with advanced CKD was substantially different from healthy population with increased percentage of LPs producing bacteria. Significant diversity was observed in gut microbiota in study subjects compared to control group. CKD patients had high serum concentration of ET-1 and TNF-α. Zonulin concentration was found positively correlated with LPs, inflammatory markers and FGF-23.

Conclusions: Gut microbiota is a modifiable factor and zonulin could be a future potential target to control chronic inflammatory responses. Gut microbiota and increased gut permeability in patients with advanced CKD secondary to DN results in high level of LPs that mediates chronic inflammation which was implicated in deterioration of cardiovascular health.

FR-PO531
Metabolomics of Chronic Kidney Disease in Cohort of Patients Given Probiotics
Subodh J. Saggi,1 Eli A. Friedman,1 Natarajan Ranganathan,2 Kelly Mercier,2 Susan Meritech,2 Susan Summer,2 1Nephrology/Medicine, SUNY Downstate Medical Center, New York, NY; 2Metabolomics, Research Triangle Inst, Research Triangle Park, NC; 3Kibow Biotechnol Inc., Kibow Biotechnol Inc., Newtown Square, PA.

Background: Persistent reduction in Glomerular Filtration Rate (GFR) below 60 ml/min/1.73 m² 3 years over 3 months are hall marks of Chronic Kidney Disease (CKD). Urea is strongly linked to major uremic toxicity, clinically despite the description of middle molecules as being toxic. Persistent elevation of BUN may accompany reductions in GFR in some patients. We were specifically interested in obtaining pilot data identifying metabolites that differentiated patients with CKD whose BUN decreased after 4 months of probiotics treatment from those whose BUN remained stable.

Methods: Broad spectrum 1H-NMR metabolomics was used to analyze baseline and 6 month plasma samples frozen from a phenotypically characterized cohort of patients with CKD Stage 3 and below from a prior Probiotic Renalys study. zonulin, TNF-α, IL-6, FGF 23, LPS, ET-1 levels were noted in the CKD patients.

Results: Thirty-three metabolites and 31 proteins were identified. Among them, 17 proteins. The data was analyzed with statistic and bioinformatic methods.

Conclusions: Metabolomics analysis revealed a signature of metabolites that were associated with a decrease in BUN, and holds promise for use in predicting individuals with CKD that would most benefit from use of probiotics. The majority of the metabolites important to the differentiation of groups map to pathways involved in microbial metabolism.
FR-PO533

AST-120 Affects the Level of Circulating TNF-Alpha Receptors That Predict Both Renal and Cardiovascular Outcomes in Patients with Advanced Renal Dysfunction

Ran-hui Cha,1 Dong Ki Kim,2 Yon Su Kim.1 1Internal Medicine, National Medical Center; Seoul, Republic of Korea; 2Internal Medicine, Seoul National Univ College of Medicine, Seoul, Republic of Korea.

Background: Tumor necrosis factor alpha and its two receptors have a critical role in kidney diseases. We aimed to establish the role of circulating TNF-alpha receptors (cTNFRs) as a new biomarker of renal disease and to identify the impact of AST-120 on the level.

Methods: 579 patients from 11 medical centers in Korea were prospectively recruited and followed up for 36 months after randomization into AST-120 and control arms. A total of 6 gram of AST-120 was given to participants in AST-120 arm as well as conventional therapy. Major adverse cardiovascular events (MACE) occurred more frequently in patients with higher baseline cTNFRs change of cTNFRs was also independently associated to the more occurrence of composite renal outcomes by the intermediate tertile of cTNFRs after the adjustment for traditional risk factors. More MACEs occurred in patients with higher baseline cTNFRs than those with lower cTNFRs. AST-120 was effective to lessen the increase of cTNFRs.

Conclusions: Baseline and change of cTNFRs did not improve the predictability of composite renal outcomes in comparison with classic biomarkers. But cTNFRs predicted renal outcomes. AST-120 affects the level of circulating TNF-Alpha Receptors that predict both renal and cardiovascular outcomes in patients with advanced renal dysfunction. And AST-120 was effective to lessen the increase of cTNFRs.

FR-PO534

Swimming Exercise Training (EXE) Normalize Blood Urea Nitrogen (BUN), Decrease Glomerulosclerosis, and Attenuates the Loss of Myokine IL6 in Rats with Chronic Kidney Disease (CKD) by 5/6 Nephrectomy (5/6Nx)

Rafael Luiz, Rodolfo Rosso Rampeto, Kleiton Augusto Santos Silva, Luciana Jorde, Edson Andrade Pessoa, Maria A. Gloria, Mario Luis Ribeiro Cesaretti, Nestor Sehor. Nephrology, Federal Univ of SÃ£o Paulo, SÃ£o Paulo, Brazil.

Background: The aim of this study was to evaluate the EXE effects on renal function, glomerulosclerosis and myokine IL6 has been associated with stimulation of hypertrophic muscle growth and myogenesis through regulation of the proliferative capacity of muscle stem cells in rats with 5/6Nx.

Methods: Adult Wistar rats were divided in groups (n=8): Control (CS), Control+EXE (CE), Sedentary 5/6Nx (NS) and 5/6Nx+EXE (NE). The protocol was employed in 5/6Nx rats after 7 days from the surgical procedures. EXE periods were 60min/day 5 days/week during 8 weeks. It was evaluated arterial pressure (AP), maximal exercise test (MExtest), creatinine clearance (CrCl), BUN, proteinuria (uProt), glomerulosclerosis, myokine IL6 (by Lumixen) as well mortality rate.

Results: EXE did not modify the increment in MAP but prevent, at least in part, a lower decline in the MExtest caused by 5/6Nx (29.1 ± 16.2 m/min, p<0.05). A higher CrCl in NE was observed compared with NS (2.27±0.33 vs 0.96±0.20 m/min, respectively (p<0.05). BUN was normalized in NE (43.6±2.73 mg/dL). Proteinuria was not significantly different in NE vs NS group (36.87±3.53 vs 40.13±2.35 mg/24h). Glomerulosclerosis was 48% higher in NS vs NE. Myokine IL6 (pg/m) was decreased in NS (286±40.14) and attenuated the loss in NE (384.00±20.82). A higher mortality rate was observed in NS (70%) vs NE group (39%, p<0.05).

Conclusions: Results suggested that the EXE minimize the impact of 5/6Nx, by decreasing glomerulosclerosis and reducing the impact on CrCl(42%). Finally, attenuating myokine IL6 in NE, the decreasing mortality rate in NE vs NS and by minimizing the impact of 5/6Nx on CrCl indicate that EXE in this protocol, induced protection on renal function. Thus, it is reasonable to suggest that EXE could be an additional strategy to be employed in CKD.

FR-PO535

Does Autophagosome-Proteolysis Contribute to CKD-Induced Muscle Atrophy? Zhen Su,1 Haidong Wang,2 Janet D. Klein,3 William E. Mitch,2 Xiaonan H. Wang.1 1Dept of Nephrology, The First Affiliated Hospital of Wenzhou Medical Univ, Wenzhou, Zhejiang, China; 2Nephrology, Baylor College of Medicine, Houston, TX; 3Renal Medicine, Emory Univ, Atlanta, GA.

Background: CKD-induced muscle wasting results from activation of the ubiquitin proteasome system (UPS). Since FoxO3a modulates the UPS but also activates autophagosomes, we hypothesized that autophagosome-induced proteolysis may contribute to CKD-induced muscle wasting.

Methods: CKD model in mice: subtotal nephrectomy for one month. Muscle overloading model: removal of gastrocnemius and soleus to overload the plantaris muscle (overloading exercise) in normal and CKD mice. Acupuncture with low frequency electric stimulation (Acu/LFES) was applied 15 minutes daily for 2 weeks (Hu, JASN, 26:626 2015). Electrical stimulation used a consistent pulse, electric frequency 20Hz, current 1mA.

Results: Both exercise and Acu/LFES reduced CKD muscle mass. In muscles of CKD mice, mRNAs related to autophagy-lysosomal function, Binp3, Atg12, Atg8, LC3II and Beclin-1, were upregulated and Binp3, Beclin-1 and LC3II proteins were increased. Acu/LFES treatment reversed these changes. Exercise in control mice also increased autophagy-lysosomal related protein LC3-II, Beclin-1, P62 and Yop34. The levels of these mediators were not additive to changes observed in mice with CKD. We cultured C2C12 myotubes in uremic serum and found increased autophagy markers, indicating activation of autophagosomes. Acidification alone did not stimulate autophagy markers. Based on these results, the UPS, but not autophagosomes, is responsible for degradation of structural proteins (myosin and actin).

Conclusions: 1) autophagosome-mediated proteolysis occurs in CKD-induced muscle atrophy. In mice with CKD, the UPS was principally involved in muscle proteolysis; the role of autophagosomes was convoluted. 2) Prevention of muscle atrophy by exercise is not due to inhibition of the autophagy-lysosomal proteolysis pathway in CKD. 3) Muscle atrophy cannot be equated with increased autophagy markers. 4) Acu/LFES and exercise promote different autophagy consequences.

FR-PO536

Indoxyl Sulfate, a Uremic Toxin, Accelerates Skeletal Muscle Atrophy in CKD Condition Yuki Emori,1 Hiroshi Watanabe,2 Masafumi Fukagawa,3 Toru Maruyama.1 1Dept of Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kumamoto Univ, Kumamoto-shi, Japan; 2Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara-shi, Japan.

Background: Skeletal muscle atrophy is often observed in chronic kidney disease (CKD) patients, especially in patients undergoing hemodialysis. Uremic toxins has been known to link to CKD complications. However there has been no report on the relationship between uremic toxins and skeletal muscle atrophy. The purpose of this study is to investigate the involvement of uremic toxins on skeletal muscle atrophy observed in CKD condition.

Methods: In vitro cytotoxicity of uremic toxins on cell proliferation and differentiation was evaluated by using a mouse myoblast cell line (C2C12). The effect of uremic toxin on proteolysis and protein synthesis system in C2C12 was also evaluated. In the animal study, we examined the contribution of uremic toxin on muscle atrophy using uremic toxin overloaded half- or 5/6-nephrectomized mice.

Results: We focused on six protein bound solutes including indoxyl sulfate (IS), indole acetic acid, p-cresyl sulfate, hippuric acid, kynurenic acid and 3-carboxy-4-methyl-5-propyl-2-furanpropanoic acid. Among these uremic toxins, IS significantly inhibited proliferation and differentiation of C2C12 myoblast cell, and decreased phosphorylation of Akt. Moreover, IS significantly increased atrophy-related genes expression but it did not affect differentiation-related genes expression. In the animal experiments, IS-overload reduced body weights and skeletal muscle weights of half- or 5/6-nephrectomized mice, and consequently weakened its muscular endurance. IS-overload mice showed increased skeletal muscle atrophy-related genes expression. In the same experimental condition, IS also induced the expression of inflammatory cytokine and transforming growth factor-b in skeletal muscle cells.

Conclusions: IS is the potent uremic toxin inducing skeletal muscle atrophy associated with CKD by increasing muscle atrophy-related genes.

FR-PO537

Myostatin Stimulates Progenitor Cells to Differentiate into Fibrocytes Leading to Muscle Fibrosis in Chronic Kidney Disease Liping Zhang,1 Jingling Dong,2,4 William E. Mitch.1 1Medicine/Nephrology, Baylor College of Medicine, Houston, TX; 2Life Science & Engineering College, Northwest Univ for Nationalities, Lanzhou, Gansu, China.

Background: In chronic kidney disease (CKD), fibrosis develops in damaged kidneys leading to loss of functions. Fibrosis in muscle also complicates CKD but the identity of cells developing into fibrocytes and mechanisms causing fibrosis are not defined. The potential precursors of muscle fibrosis are mesenchymal progenitor cells (fibrotic and adipogenic progenitors (FAPs)) while mechanisms causing fibrosis include myostatin as

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
CKD raises its expression and muscle injury can stimulate injured muscles to develop fibrocytes. Our hypothesis is that CKD stimulates myostatin expression causing FAPs to differentiate into fibrocytes.

**Methods:** 1) we isolated and cultured FAPs, adding recombinant myostatin to determine if it causes FAPs to proliferate and differentiate into fibrocytes. 2) We isolated GFP-labelled FAPs from transgenic, GFP-expressing mice and transplanted them into tibialis anterior (TA) muscles of CKD mice. We assessed conversion of FAPs into GFP-fibrocytes using α-SMA expression. 3) CKD mice were injected with an anti-myostatin peptibody to determine if myostatin stimulates muscle fibrosis. 4) Interactions between myostatin signaling and FAP conversion to fibrocytes were tested by knockdown Smad3 with a lentivirus expressing Smad3 SiRNA.

**Results:** 1) In cultured FAPs, myostatin stimulated their proliferation and conversion into fibrocytes and there is proliferation of FAPs in injured muscles of CKD mice. GFP-labelled FAPs differentiated into TA muscles of CKD mice differentiate into fibrocytes identified as expressing the fibrosis maker, α-SMA. FAP proliferation and muscle fibrosis were prevented in CKD mice injected with the anti-myostatin peptibody. Finally, Smad3 knock-down blocked FAP differentiation into fibrocytes indicating that a myostatin to Smad3 pathway is essential for the conversion of FAPs to fibrocytes.

**Conclusions:** 1) Myostatin stimulates myostatin production to activate FAPs which differentiate into fibrocytes. The process is blocked by an anti-myostatin peptibody, providing a new target for preventing muscle fibrosis as a complication of CKD.

**Effect of Methoxy Polyethylene Glycol – Epoetin Beta on Plasma Levels of IL-1β, TNF-RI, TNF-RII, sFAS, sFASL, TGFβ, MMP-9 in Patients with CKD**

**Patients with CKD** Piotr Bartnicki, Ewa Majewski, Zbigniew Baj, Jacek Rysz.

**Background:** In patients with CKD are observed disturbances of immune cells function and endothelium dysfunction with high tissue fibrosis. ESAs using in these patients, beyond anemia correction seem to have renoprotective effect and slow progression of CKD. In this study we aimed to determine effect of methoxy polyethylene glycol – epoetin beta (Mircera) on plasma levels of selected parameters in predialysis patients with CKD.

**Methods:** 28 patients with CKD and anemia, treated with Mircera, were enrolled to the study. The healthy control group included 15 volunteers. Plasma levels of evaluated parameters were measured with available enzyme- linked immune-sorbent assay (ELISA) kit.

**Results:** The results of our study are shown in the table.

*p < 0.05 to control group, **p < 0.05 to CKD before treatment

**Conclusions:** Plasma concentrations of evaluated parameters are significantly higher in CKD patients in comparison to control group. After ESA treatment plasma level of TNF-RI was significantly higher and MMP-9 was significantly lower in CKD patients. These data suggest that Mircera used in correction of anemia in CKD might influence on immune cells function, apoptosis and tissue fibrosis.

**FR-PO539**

**Qualitative Changes in Erythrocytes in Chronic Kidney Disease**

Ken Aizawa, Ryohi Kawasaki, Yoshihito Tashiro, Michinori Hirata, Koichi Endo, Ken-ichi Serizawa, Yasushi Shimonaka.

**Product Research Dept, Chugai Pharmaceutical Co., Ltd., Kamakura, Japan.**

**Background:** Therapeutic control of anemia in chronic kidney disease (CKD) is assessed by monitoring hemoglobin (Hb) levels. However, monitoring Hb alone could potentially fail to reveal pathological changes in erythrocytes, because erythrocyte lifespan is shorter in CKD. Shortening of erythrocyte lifespan may attenuate erythropoietin responsiveness, resulting in poor prognosis of CKD. Erythrocyte lifespan are thought to be shortened by qualitative changes such as deterioration of deformability and stability, but it is not clear which of these aspects are changed in CKD.

**Methods:** To assess qualitative changes in erythrocytes we first confirmed in a rat model of iron-deficiency anemia. Deformability was quantified by laser diffraction electactometry and stability was quantified by hemolysis test. We next produced CKD model rats using 1.1 antibody injection plus uninephrectomy. Epoetin beta pegol (C.E.R.A., 25 mg/kg) was intravenously injected the day after surgery. At 11 wks, Hb levels, erythrocyte deformability and stability, plasma urea nitrogen (UN) and creatinine (pCre) were assessed.

**Results:** Iron-deficiency rats showed significant anemia and had impaired erythrocyte deformability and stability. These changes in erythrocytes were almost normalized by administration of iron sucrose. In the CKD model, Hb level was significantly decreased and deformability and stability of erythrocytes were significantly impaired. Stability significantly recovered and deformability tended to recover in the C.E.R.A. group, although there was no significant difference in Hb levels between the disease group and C.E.R.A. group. Kidney function (UN and pCre) correlated significantly with stability, but not with deformability. Morphologic parameters (mean corpuscular volume and red cell distribution width - standard deviation) did not reflect changes in deformability and stability.

**Conclusions:** Deformability and stability of erythrocytes were impaired in CKD rats, and may be linked with kidney dysfunction. Focusing on qualitative aspects of erythrocytes may provide a better understanding of pathological conditions and therapeutic benefit in anemia.

**Eryptosis in Chronic Kidney Disease**

Grazia Maria Virzi, Anna Clementi, Alessandra Brocca, Massimo de Cal, Claudio Ronco.

**Nephrology-IRRIV.**

**Background:** Even though anemia in CKD results mainly from the lack of erythropoietin, accelerated erythrocyte death(eryptosis) seems to be a contributor factor. Eryptosis is characterized by cell shrinkage and cell membrane scrambling with phosphatidyserine(PS)-exposure at the erythrocyte (RBC) surface. Eryptosis may be triggered by some urmic toxins. P-cresol is an urmic toxin which has negative cardiovascular and cytopathic effects. This study explored if eryptosis is triggered by p-cresol and if different stages of CKD may influence erythrocyte death.

**Methods:** RBCs from healthy subjects were incubated in buffer at a hematocrit of 0.4% in RPMI with different concentrations of p-cresol (0-2.5-5-10-20-40ng/mL) and with plasma from CKD patients (3 for each stage) for 24hours. PS exposure was estimated from AnnexinIV binding in flow cytometer.

**Results:** Increasing concentrations of p-cresol modified significantly the percentage of PS exposure on RBC surface, thus suggesting that increasing concentrations of p-cresol may stimulate eryptosis in vitro. Moreover, there was no significant difference in terms of median values of eryptosis between CKD stages, but a positive trend was evident: eryptosis increase with CKD progression.

**Conclusions:** In addition to its known cardiovascular and cellular effects, p-cresol seems to stimulate eryptosis in vitro and increasing concentrations of this urmic toxin may be responsible for higher levels of eryptosis in vivo. Our data show that CKD plasma contains components able to trigger eryptosis and different stages of CKD may be responsible for different levels of RBC death, thus suggesting that progression of CKD may increase eryptosis in vivo. These results suggest a role of urmic toxicity in the genesis of eryptosis and renal anemia. It is necessary to increase the sample size to validate our hypothesis.

**Palmitate Exacerbates Renal Anemia: Suppression of Renal Erythropoietin Production via Endoplasmic Reticulum Stress**

Reiko Inagi, Tirthun Anusornvongchai, Yu Ishimoto, Akira Okada, Norio Suzuki, Masayuki Yamamoto, Masaoi Nangaku.

**DiV of CKD Pathophysiology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan; DiV of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan; Tohoku Univ School of Medicine, Sendai, Japan.**

**Background:** Derangement of erythropoietin (EPO) production in renal EPO-producing (REP) cells causes renal anemia. Palmitate induces endoplasmic reticulum (ER) stress, which contributes to glomerular and tubular cell damages. Thus, we evaluated the effect of palmitate-ER stress axis on EPO production in REP cells.

**Methods:** C57/B6J or the mice, in which the renal EPO gene was replaced with GFP or REP cells were lineage labeled with tdTomato, were daily injected with palmitate

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author. 482A
hypoxia (HIF activation with CoCl
 in CKD patients, fibrosis marker α-SMA was downregulated. silenced SIRPα in muscle cells treated with a cytokine mixture, containing cytokines present with CKD vs. control mice. In order to determine a cause and effect relationship, SIRPa significantly increased in cardiac muscles of mice with CKD, with reduction in tyrosine with a heart weight to body weight that is significantly larger vs. control mice. SIRPa was and cardiac muscle cell lysates.

2 months hearts were harvested and left ventricle muscle samples were examined for SIRPα, to contradict vitro experiments, the reason of this phenomenon may be that many neonatal with mild lesion group, E-cad staining in moderate lesion group and severe lesion group HK2 cells group were lower than control-shRNA HK2 cells, in contrast, CTGF and α-SMA westernblot; immunofluorescence was used in different degrees of tubulointerstitial lesions.

to the degree of tubulointerstitial lesion, kidney specimens were divided into 3 groups: mild lesion, moderate lesion, and severe lesion. We handle normal kidney portions as controls. The expressions of integrinβ4, E-cad, CTGF and α-SMA were assessed by qRT-PCR and western-blot; immunofluorescence was used in different degrees of tubulointerstitial lesions.

Results: (1) Compared with negative control, integrinβ4 and E-cad were significantly lower, however, CTGF and α-SMA were increased (2) Integrinβ4 and E-cad in β4-shRNA HK2 cells group were lower than control-shRNA HK2 cells, in contrast, CTGF and α-SMA were increased; integrinβ4 and E-cad with TFb1 treatment were significantly lower than without TFb1 groups, CTGF and α-SMA expressions were increased. (3) Compared with mild lesion group, E-cad staining in moderate lesion group and severe lesion group reduced, α-SMA staining and integrinβ4 staining increased. After being further analyzed, the most of integrinβ4 staining located in neocapillary renal tubules.

Conclusions: integrinβ4 is decreased in the process of EMT, and reduced integrinβ4 can exacerbate HK2 cells from epithelial cell transition to mesenchymal cells, therefore loss of integrinβ4 may be the marker of TIF. However, the results of vivo experiment appeared to be different with vitro analysis, the reason of this phenomenon may be that many neonatal renal tubules possess the ability of proliferation.

Conclusions: These results imply that SIRPα increases fibrosis, and suggesting that SIRPα may have important influences on cardiac muscle fibrosis via a new pathway in chronic kidney disease. Ultimately blocking SIRPα in heart muscle may improve cardiac fibrosis associated with chronic kidney disease.

FR-PO544 Retinal Microvascular Abnormalities and Incidence and Progression of Chronic Kidney Disease Charumathi Sabanayagam,1,2 Peng Guan Ong,1 Boon Wee Teo,1 Carol Y. Cheung,2 Ching-Yu Chung,2 Ecosse L. Lamoureux,2 Tien yin Wong,1,2 Singapore Eye Research Inst, Singapore; 'Office of Clinical Sciences, Duke-NUS Graduate Medical School, Singapore; National Univ of Singapore, Singapore.

Background: To examine the longitudinal association of a panel of retinal vascular parameters, markers of microvascular damage, with the incidence and progression of chronic kidney disease (CKD) in middle-aged Asian adults.

Methods: The population consisted of a cohort of Malay adults aged 40-80 years examined from 2004-06 and again from 2010-2012 (n=1464; 1306 free of CKD and 158 with pre-existing CKD). The outcomes were incidence (estimated glomerular filtration rate [eGFR]=60 mL/min/1.73m²+25% decrease in eGFR) and progression of CKD (drop in eGFR category ≥60, 30-59, 15-30, <15=+25% decrease in eGFR or an annualized eGFR rate/3=3 mL/min/1.73m²/year). Retinal vascular parameters (arteriolar and venular caliber, tortuosity, branching angle, and fractal dimension were measured from baseline retinal photographs using a computer-assisted program (Singapore I Vessel Assessment, SIVA). Retinopathy was graded using a standard protocol. Associations were examined using Cox proportional hazards regression models adjusting for age, sex, blood glucose, systolic blood pressure and baseline eGFR.

Results: Over a median follow-up of 6.6 years, 6.4% (70% had diabetes) developed incident CKD and 26.6% (62% had diabetes) developed progressive CKD. In multivariable models, retinal arteriolar narrowing, retinal venular widening, and presence of retinopathy were significantly associated with increased risk of CKD. The HR (95% CI) of incident CKD was 1.31 (1.01-1.72) per SD decrease in arteriolar caliber, 2.20 (1.10-4.41) for tertile 3 vs. tertile 1 of venular caliber; 2.06 (1.24-3.44) for retinopathy. Increased arteriolar tortuosity alone was associated with progressive CKD (1.57 [1.04-2.37] per SD decrease. All associations were consistently present among those with diabetes.

Conclusions: Retinal vascular abnormalities increased the risk of CKD by more than two times in Asian adults. Our findings provide evidence that retinal imaging may be a useful tool to improve risk stratification for CKD.

Funding: Government Support - Non-U.S.

FR-PO545 Relationship Between Serum Bilirubin and Hyalinization of Renal Arterioles Yusushi Miyagi,1 Kentaro Kohagura,2 Yusuke Ohya,3 Kunitoshi Iseki,1 Department of Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyu, Nishihara-cho, Okinawa, Japan; 2Dialysis Unit, Univ of the Ryukyu, Nishihara-cho, Okinawa, Japan.

Background: It has been suggested that there is a relationship between serum bilirubin and renal hyalinosis. In the present study, we examined the relationship between serum bilirubin levels and the hyalinization of renal arteries in patients with chronic kidney disease (CKD).

Methods: We reviewed the clinical records of 138 patients with CKD (mean age: 44 years) who underwent renal biopsy at our department during a 3-year period starting in 2010. Patients who were receiving calcineurin inhibitors were excluded. The subjects were divided into three groups based on their total serum bilirubin levels: tertile group 1 (0.2-0.4 mg/dl; 40 patients), tertile group 2 (0.5-0.7 mg/dl; 61 patients), and tertile group 3 (0.8-1.4 mg/dl; 37 patients). Using the pathological specimens obtained from renal biopsies, the hyalinization of renal arterioles was semiquantitatively evaluated, and the mean score of renal arteriolar hyalinization grade was used for analysis.

Results: Tertile group 1 had markedly higher urinary protein levels and markedly lower serum hemoglobin (HB) levels than tertile group 3. We defined total serum bilirubin levels under 0.5 mg/dl (tertile group 1) as low levels and divided them into two groups of values under and above 0.5 mg/dl. These were set as explanatory factors, and a multiple regression analysis was performed, with the degree of hyalinization of renal arterioles as the objective variable. A low serum bilirubin level was a significant risk factor for the hyalinization of renal arterioles (R² = 0.45, β = 0.26, p = 0.003), even when adjustments were made for age, sex, HbA1c levels, mean blood pressure, history of smoking, and LDL cholesterol levels. Furthermore, even when the explanatory factor of serum HB level was added, the results of the analysis remained the same.

Conclusions: Low serum bilirubin levels may be a risk factor for the hyalinization of renal arterioles independent of classical risk factors of cardiovascular disease.
FR-PO546

Autonomic Nervous Dysfunction in Predialytic Chronic Kidney Disease: 3 Years Observational Follow-Up Study

Suh Min Park, Sang Heon Song, Eun Young Seong, Ihm Soo Kwak, Harin Rhee, Il Young Kim, Woo Jin Jung, Jong Man Park, Dong Won Lee, Soo Bong Lee, Min Jung Kim, Joo Hui Kim. Internal Medicine, Pusan National University School of Medicine, Busan, Republic of Korea.

Background: Generally, sympathetic overactivity and impairment of the parasympathetic system are often seen in patients with dialytic CKD, COPD, RA as well as elderly. Also, arterial stiffness and edema have been related with mortality in patients with cardiovascular disease. However, to date, few data regarding autonomic nervous system, vascular stiffness, edema in pre-dialytic CKD was proposed. This study was designed to explore the interrelationship of those parameter in pre-dialytic CKD (G3, 4) and uncover the risk factor related with renal functional deterioration.

Methods: Thirty-three patients were enrolled. Hydration status (extracellular water [ECW]/total body water [TBW]) was determined by bioimpedance analysis. Brachial-ankle pulse wave velocity (baPWV) and neck ultrasonography for carotid plaque and intima-media thickness were conducted for checking up of vascular status. CAN was scored using Ewing’s method and we also expressed the standard deviation of normal-to-normal interval (SDNN), low frequency/high frequency ratio (LF/HF ratio). Serial creatinine change over a median follow-up of 3 years was used for assessment of renal function.

Results: Of the 33 patients, 14 (42%) have suffered with CAN. Patients with CAN have higher progressive declining rate of renal function, baPWV, systolic BP compared with patients without CAN. The group having declining renal function has higher CAN score, baPWV and lower SDNN compared with preserved renal function group. CAN score correlated positively with ECW/TBW (r=0.405, p<0.019), mean PWV (r=0.623, p<0.001) and SBP (r=0.513, p<0.002). CAN score correlated negatively with declining rate of renal function (r=0.471, p<0.006), HbaA1c (p<0.001) and albumin (r=-0.484, p<0.004).

Conclusions: Autonomic nervous dysfunction including lower SDNN and increased arterial stiffness associated with CAN may be important risk factors for deterioration of renal function in pre-dialytic CKD patients. Also, autonomic nervous dysfunction was related with arterial stiffness and edema.

FR-PO547

Inhibition of EGFR Alleviates the Development and Progression of Hyperuricemic Nephropathy in Rats

Na Liu,1 Li Wang,1 Andong Qiu,2 Shouqiang Zhuang.1,3 1Nephrology, Shanghai East Hospital, Tongji Univ School of Medicine, Shanghai, China; 2School of Life Science and Technology, Advanced Inst of Translational Medicine, Tongji Univ, Shanghai, China; 3Dept of Medicine, Rhode Island Hospital and Brown Univ School of Medicine, Providence.

Background: Hyperuricemia is an independent risk factor for chronic kidney disease and contributes to kidney fibrosis. In this study, we investigated the effect of epidermal growth factor receptor (EGFR) inhibition on the development of hyperuricemic nephropathy (HN) and the mechanisms involved.

Methods: In this experiment, we did Cell Culture and Treatments, processed the establishment of Hyperuricemic nephropathy (HN) model, assessment of serum uric acid, renal Function and other biochemistry index, performed Immunoblot Analysis, Immunohistochemical Staining, as well as ELISA analysis.

Results: In a rat model of HN induced by feeding a mixture of adenine and potassium oxonate, increased EGFR phosphorylation and severe glomerular sclerosis and renal interstitial fibrosis were evident, accompanied by renal dysfunctions and decreased urinary microalbumin excretion. Administration of gefitinib, a highly selective EGFR inhibitor, prevented renal dysfunction, reduced urinary microalbumin and inhibited activation of renal interstitial fibroblasts and expression of extracellular proteins. Gefitinib treatment also inhibited hyperuricemia-induced activation of the transforming growth factor-beta-1 (TGF-β1) and nuclear factor-kB (NF-kB) signaling pathways and expression of multiple profibrogenic cytokines/chemokines in the kidney. Furthermore, gefitinib treatment suppressed xanthine oxidase activity, which mediates uric acid production, and preserved expression of organic anion transporters 1 and 3, which promotes uric acid excretion in the kidney of hyperuricemic rats.

Conclusions: Thus, blocking EGFR can attenuate development of HN via suppression of TGF-β1 signaling and inflammation, and promotion of the molecular processes that reduce uric acid accumulation in the body.

FR-PO548

Probiotic and Yogurt Consumption Is Associated with a Lower Prevalence of Albuminuria: A Cross-Sectional Analysis of NHANES

Rabi Yacoub, Girish N. Nadkarni, Deepak Kaji, Shanti N. Patel, John C. He, Steven G. Coca, Jaime Uribarri. Medicine/Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Animal data suggest that probiotic supplements may retard CKD progression. Yogurt is the most widely available probiotic food in the United States. However, the relationship between frequent yogurt consumption or probiotic use, and kidney parameters has not yet been evaluated. We aimed to study this association in the National Health and Nutrition Examination Survey (NHANES) database.

Methods: We utilized NHANES data with reported one year yogurt consumption frequency and probiotic use (2003-2005). The “consumers group” was defined as either yogurt consumption ≥ thrice weekly or regular use of probiotic, and we analyzed its association with albuminuria and eGFR after adjustment for demographic and clinical parameters.

Results: We had complete data on 6853 participants (mean age 48.3±20.45.2% male), of which,1359 (20.3%) were frequent consumers and 918 participants (12.2%) had detectable albuminuria (Median=67.1, IQR =-41.6-157.1 mcg/mg). Frequent consumers had a trend towards lower mean UACR compared to non-consumers (mean difference [MD]: -12.3, 95% CI -29.8 to 5.2, P=0.17) that was attenuated after complete adjustment. On the other hand, frequent consumers had decreased odds of albuminuria (UACR > 30 mcg/mg) compared to non-consumers (adjusted Odds Ratio 0.79; 95% CI 0.63-0.97; P=0.05).

FR-PO549

Assessment of Serum Levels of Heavy Metals in Patients with Chronic Kidney Disease of Unknown Etiology

Om Prakash Kalra,1 Akash Gupta,1 Alpana Raizada,1 Sunil Agarwal,1 Basu Dev Banerjee.1 Medicine, UCMS and GTB Hospital, Delhi, India; 2Biochemistry, UCMS and GTB Hospital, Delhi, India.

Background: Chronic kidney disease (CKD) encompasses a wide spectrum of different etiological processes associated with abnormal kidney function and gradual progressive decline in glomerular filtration rate. CKD of unknown etiology (CKDs) has emerged as an important entity accounting for approximately 10% of CKD patients worldwide. Of the environmental toxins implicated in causation of CKDs, heavy metals form an important group. In the present study, we estimated the serum levels of lead, cadmium, arsenic and chromium in patients with CKDs and evaluated their role in the etiopathogenesis of CKDs.

Methods: The study was conducted in the Departments of Medicine and Biochemistry at University College of Medical Sciences and GTB Hospital, Delhi from December 2013 - April 2015. It was a case control, cross sectional study. Ninety subjects in the age group 18 – 60 years of either sex were divided into 3 groups: Group I: Healthy controls (n=30), Group II: Individuals satisfying case definition of CKD(n=30) and Group III: Individuals having CKD of known etiology (CKD)(n=30). Detailed history, complete physical examination, routine investigations, urine albumin excretion (UAER) estimation was done. Estimation of serum level of heavy metals was done using Atomic Absorption Spectrophotometry.

Results: The median levels of lead, cadmium and chromium were significantly higher in patients of group II and this difference was statistically significant as compared to subjects of group I and III. The median levels of arsenic in patients of group II and III were similar but significantly higher than patients of group I. The levels of arsenic, cadmium and chromium were also found to be significantly higher in the health controls (group II) compared to healthy population. Consequently, the UAER levels in patients of group II and III were similar but significantly higher than patients of group I.

Conclusions: As compared to healthy controls, the serum levels of lead, cadmium, and arsenic were found to be significantly higher in patients of CKDs. The study indicates a possible role of heavy metals in causation of CKDs.

FR-PO550

High Prevalence of Elevated Molybdenum Levels in CKD Patients

Guido Filippi,1,2 Vladimir Belostotsky,1 Marta Caroline Kobrzyński,1 Shili-Han Shiau,1 Li Yu Yang,1 Power Resources, University of Western Ontario, London, ON, Canada; 2Pathology and Laboratory Medicine, University of Western Ontario, London, ON, Canada; 3Paediatrics, McMaster Univ, Hamilton, ON, Canada.

Background: Molybdenum (Mo), atomic number 42 is an essential trace element present in water and is crucial for human survival because four mammalian enzymes harbor a pterin-based Mo cofactor (Moco) at their active site and are Mo-dependent. Mo can be lethal in high doses, and chronic toxicity in animals leads to stunted growth, skeletal abnormalities, anemia, and histological changes in the kidney and liver. There is no information about Mo levels in patients with CKD.

Methods: After approval by the ethics board, and as part of a larger study on zinc supplementation in CKD, we studied 87 plasma Mo and copper (Cu) levels in 50 children with an eGFR <90 and >15 mL/min/1.73 m² using the Schwartz formula. Where available,
we also recorded the cystatin C eGFR using the Filler formula in 35 children. Mo and Cu levels were measured using High Resolution Magnetic Sector Inductively Coupled Plasma Mass Spectrometry (HR-ICP-MS).

Results: The mean Schwartz eGFR was 46±23 and the Cystatin C eGFR was 48±20 mL/min/1.73 m². The median Mo level was 2.26 (interquartile range 1.7, 3.3 ug/L, mean 2.78±1.70 ug/L), significantly higher than the upper reference interval of 1.4 ug/L, and with an exponential increase with lower eGFR.

Conclusions: With worsening kidney function, Mo levels accumulate.

Funding: Clinical Revenue Support

FR-PO551

High Prevalence of Elevated Vanadium Levels in CKD Patients

Guido Filler, 1,2,4 Vladimir Belostotsky, 1 Marta Caroline Kobrzynski, 1 LiJu Yang, 1 Paediatrics, Univ of Western Ontario, London, ON, Canada; 2Pathology and Laboratory Medicine, Univ of Western Ontario, London, ON, Canada; 4Paediatrics, McMaster Univ, Hamilton, ON, Canada; 3Medicine, Univ of Western Ontario, London, ON, Canada.

Background: Vanadium (V, atomic number 23) is an essential trace element present in many industrial products, especially in steel, which can be very toxic if levels are too high. The excretion of vanadium by the kidneys is rapid with a biological half-life of 20-40 hours in the urine. Chronic poisoning is associated with respiratory symptoms, nervous disturbances, vegetative symptoms, tremors, palpitation of the heart, extrastrioles, anemia, leukopenia, and punctate basophilia of the erythrocytes. While adult data suggest that V is accumulating in dialysis patients, there is no information about V levels in patients with CKD.

Methods: After approval by the ethics board, and as part of a larger study on zinc supplementation in CKD, we studied 87 plasma V levels in 50 children with an eGFR <90 mL/min/1.73 m² and > 15 mL/min/1.73 m². The median Mo level was 2.26 (interquartile range 1.7, 3.3 ug/L, mean 2.78±1.70 ug/L), significantly higher than the upper reference interval of 1.4 ug/L, and with an exponential increase with lower eGFR (r=−0.57, p=0.0002).

Conclusions: With worsening kidney function, Mo levels accumulate, while Cu levels remain unaffected.

Chronic Nicotine (Ch-Nic) Exacerbates Subpressor Angiotensin II (SP-AngII) Induced Renal Dysfunction in Part via the Renal Sympathetic Nervous System

Kiran B. Chandrashekhar, 1 Rodrigo Maranon, 1 Arnaldo F. Lopez-Ruiz, 2 Andrea F. Soljancic, 1 Istvan Arany, 1 Luis A. Juncos, 1 Nephrology, UMMC, Jackson, MS; 2Physiology, UMMC, Jackson, MS.

Background: Ch-Nic exacerbates SP-AngII-induced renal dysfunction and vascular remodeling while having minimal changes on blood pressure. However, the mechanisms are incompletely understood. Because Ch-Nic activates the renal sympathetic nervous system, we hypothesized that this activation contributes to nicotine’s deleterious effects on SP-AngII-induced renal dysfunction and injury.

Methods: Sprague Dawley rats underwent either sham or renal denervation (RD) surgery and then subdivided to get nicotine (12 g/ml) or vehicle (saccharine 2%). These were randomized to get either SP-AngII (SQ, 200ng/kg/min) or vehicle (saline). Hemodynamics were measured in anesthetized animals and tissue collected for biochemical analysis.

Conclusions: Renal denervation ameliorated SP-AngII-induced HTN, renal dysfunction, inflammation and injury. While RD did not appear to provide additional benefit to blood pressure control in Ch-Nic+SP-AngII group, it provided protection against the renal effects of Ch-Nic in the SP-AngII rats. These results support a role for the sympathetic nervous system in SP-AngII-induced renal dysfunction, as well as in the exacerbating effect of Ch-Nic on SP-AngII mediated renal dysfunction.

FR-PO553

Elevated Plasma Chymase Is Associated with Risk of Chronic Kidney Disease

Jing Chen, 1,2 L. Lee Hamm, 1,2 Damodor R. Kumbala, 1 Chung-shian Chen, 1 Kevin K. Wu, 1 Swapna G. Kallu, 1 Ravi Siriki, 1 Shilpa Gadde, 1 Arnold B. Alper, 1 Myra A. Kleinpeter, 1 Vecchi Batuman, 1 Eric E. Simon, 1 Gabriel Navar, 1 Jiang He, 1,3 Medicine, Tulane School of Medicine, New Orleans, LA; Epidemiology, Tulane School of Public Health and Tropical Medicine, New Orleans, LA; Nephrology, Ochsner Health System, New Orleans, LA.

Background: Chymase is the primary enzyme that mediates angiotensin II formation independent of angiotensin-converting enzyme and also play a role in activating transforming growth factor-βeta and matrix metalloproteinase-9. Experimental studies suggest that it may cause renal and cardiac fibrosis. However, the association of circulating chymase with chronic kidney disease (CKD) is not well studied.

Methods: We investigated the association of chymase and the risk of CKD in 163 CKD patients and 186 controls without CKD. CKD was defined as estimated glomerular filtration rate (eGFR)<60 mL/min/1.73 m² or presence of albuminuria. Multivariable analyses were used to examine the relationship of plasma chymase and CKD.

Results: The multivariable-adjusted medians (interquartile ranges) were 1.6 (1.1, 2.1) in patients with CKD vs. 1.2 (0.7, 1.9) pg/mL in controls without CKD (p<0.002 for group difference) after adjusting for age, gender, race, physical activity, smoking, drinking, systolic blood pressure, glucose, low-density lipoprotein cholesterol, body mass index, and history of cardiovascular disease. After adjustment for the above risk factors, the odds ratio for CKD comparing the highest to the lowest tertile of chymase was 2.85 (95% confidence interval, 1.41-5.76).

Conclusions: These data indicate that elevated circulating chymase is associated with risk of CKD.

The Superoxide Urokinase-Type Plasminogen Activator Receptor Serum Levels in Adults with Nephrotic Syndrome

Qiuling Fan, Nephrology, The First Hospital of China Medical Univ.

**Background:** The serum levels of soluble urokinase type fibrinolytic enzyme activators receptor (suPAR) in adults with nephrotic syndrome were analyzed.

**Methods:** The serum levels of soluble urokinase type fibrinolytic enzyme activators receptor (suPAR) in 70 nephrotic syndrome patients with membranous nephropathy, diabetic nephropathy group, lupus nephritis, minimal change kidney disease and focal segmental glomerular sclerosis group was detected by enzyme-linked immunosorbent assay. The relationship between the parameters and suPAR levels were analyzed.

**Results:** Serum soluble urokinase receptor levels of nephrotic syndrome patients are significantly higher than the normal control group (P < 0.01). The serum suPAR levels of FSGS and MN patients were significant higher than MCD patients (P < 0.05). Serum suPAR level was positively correlated with serum creatinine, blood urea nitrogen (r = 0.401, p = 0.001; r = 0.186, p = 0.029) and negatively correlated with eGFR (r = -0.265, p = 0.026; r = -0.373, p = 0.018; r = -0.424, p = 0.007; r = -0.400, p = 0.009).

**Conclusions:** Serum suPAR level was positively correlated with age, serum creatinine, blood urea nitrogen, and negatively correlated with eGFR. The serum suPAR levels of FSGS and MN patients were significantly higher than MCD patients and may be a potential marker to distinguish FSGS and MCD.

FR-PO556

**Urinary Sodium: Impact on Blood Pressure and Progression of Chronic Kidney Disease**

Adriano Luiz Ammirati, Maria Eugenia F. Canziani, Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil.

**Background:** Chronic kidney disease (CKD) is characterized by chronicity and progression of renal damage. The presence of hypertension is related to the progression of renal damage. Diets high in salt have been associated with an increased risk of hypertension. Sodium analysis in the urine of 24 h is considered the standard method to estimate the daily intake of this mineral. The aim of this study was to evaluate the impact of sodium intake estimated by urinary sodium in the urine of 24 hours (Nau24hs) on renal outcomes and their impact on hypertension.

**Methods:** Data were collected from medical records of 118 patients with CKD in conservative treatment, that had one Nau24hs dosage and a follow-up of at least five years. Information collected initially and after 5 years were: demographics, etiology of CKD; comorbidities, blood pressure, routine laboratory tests and estimated creatinine clearance (eGFR-Cr). The Nau24hs values were classified into two groups by the median and also divided into tertiles and compared with the rate of progression of CKD (fall of the estimated clearance greater than 20% in 5 years) and the change in blood pressure.

**Results:** Patients had a mean of 186 ± 64 Meq/L of Nau24hs which represented a Na intake of 5.4 g/day. Patients with Nau24hs ≥ 200 Meq/L had higher systolic blood pressure and those with Nau24hs> 200 Meq/L had higher systolic and diastolic blood pressure when compared to other patients. In addition, patients with higher Nau24hs present significant decrease in systolic blood pressure over 5 years. The decrease in creatinine clearance over 5 years (29% of patients) were more frequent in diabetics and those who did not use converting enzyme inhibitors and are associated with the presence of proteinuria. There was no association of Nau24hs with the progression of renal dysfunction.

**Conclusions:** In conclusion, Nau24hs > 200 mEq/L had higher systolic and diastolic blood pressure when compared with subjects with Nau24hs ≤ 200 mEq/L and a follow-up of at least five years.

Methods: Patients with ≥5 years of potential follow-up were identified from the ChronicKidney Disease Stages Implementation Study (CRISIS). 5-year RRT risk was estimated using a logistic regression model incorporating age, gender, eGFR, albuminuria, PO4, Ca2+, HCO3, and albumin.

Results: 728 patients were included in this analysis (median follow-up 4.4 [IQR 2.4-5.6] years), with 118 patients (16%) progressing to RRT. Mean baseline age was 64±14 years and eGFR 34±14 ml/min/1.73m2.

Time to RRT presented as mean (standard deviation). Percentages represent the proportion of patients within that risk group.

Effect and Safety of Sofosbuvir (SOF) Containing Direct-Acting Antiviral (DAA) Hepatitis C Virus (HCV) Therapy in a Real-World Population with Chronic Kidney Disease (CKD)

Guillermo Ortiz,1 Gregory L. Hundemer,1 Elke Backman,2 Ravi I. Thadhani,3 Raymond T. Chung,3 Meghan E. Sisc,1 Nephrology Div, MGH, Boston, MA; 2Pharmacy, MGH, Boston, MA; 3Gastrointestinal, MGH, Boston, MA.

Background: Early trials of SOF-based regimens excluded patients with CKD, thus little is known about safety, efficacy, and effect on kidney function.

Methods: We retrospectively evaluated 72 patients with CKD starting DAA treatment (tx) between 11/2013-12/2014. CKD was defined by average eGFR <60ml/min or albuminuria >30mg/g 6 months prior to tx. Safety, tolerability and laboratory results were assessed by chart review. Models predicting sustained virological response (SVR) were performed.

Results: Subjects were aged 61±8 years, 60% white, 22% black, 12% Hispanic, and 74% male. 50% were diabetic, 39% cirrhotic, 54% HCV tx naïve, 39% had prior liver or kidney transplant, and 7% were HIV/HCV coinfected. DAA regimens were: SOF/simeprevir 50%, SOF/ledipasvir 13%, SOF/ribavirin 28%, other SOF regimens 10%, 8% had a transient creatinine rise >0.5mg/dL during tx. Average eGFR on tx was similar to baseline (mean [95% CI]: 57 [52-62] vs. 53 [51 - 63] ml/min, respectively P=0.26). SVR was 77% (95% CI 66-88). 76% experienced at least 1 adverse effect (AE); only 5 (7%) discontinued tx due to an AE.

Conclusions: SOF-containing DAA regimens are effective and relatively safe in patients with CKD. Although AEs were common, serious AEs or significant nephropathy were rare. Lower eGFR at baseline predicted an increase likelihood of HCV cure with SOF-based regimens.

FR-PO561

Risk of Liver Injury After Glucosidase Inhibitors Therapy in Advanced Chronic Kidney Disease Patients: A Population-Based Study

Vincent Wu,1 Chih-chin Kao,1 Yu-Ying Chiu,1 Internal Medicine, National Taiwan Univ Hospital, Taipei; Internal Medicine, Taipei Medical Univ Hospital.

Background: α-glucosidase inhibitors (AGIs) are commonly used to control postprandial blood glucose. However, AGIs-related liver injury has been reported, but whether the relationship of AGIs and liver injury applies to advanced chronic kidney disease (CKD) patients remains uncertain.

Methods: In the nationwide case-control study, we recruited advanced diabetic CKD patients, who has taken AGIs from January 1, 2000 through December 31, 2010 as cases and those with relationship of AGIs and liver injury applies to advanced chronic kidney disease (CKD) patients remains uncertain.

Results: Subjects were aged 61±8 years, 60% white, 22% black, 12% Hispanic, and 74% male. 50% were diabetic, 39% cirrhotic, 54% HCV tx naïve, 39% had prior liver or kidney transplant, and 7% were HIV/HCV coinfected. DAA regimens were: SOF/simeprevir 50%, SOF/ledipasvir 13%, SOF/ribavirin 28%, other SOF regimens 10%, 8% had a transient creatinine rise >0.5mg/dL during tx. Average eGFR on tx was similar to baseline (mean [95% CI]: 57 [52-62] vs. 53 [51 - 63] ml/min, respectively P=0.26). SVR was 77% (95% CI 66-88). 76% experienced at least 1 adverse effect (AE); only 5 (7%) discontinued tx due to an AE.

Conclusions: SOF-containing DAA regimens are effective and relatively safe in patients with CKD. Although AEs were common, serious AEs or significant nephropathy were rare. Lower eGFR at baseline predicted an increase likelihood of HCV cure with SOF-based regimens.

Conclusions: Few patients with CKD had the full set of laboratory results needed to employ a validated ESRD risk prediction model for population health management. Urine ACR and serum phosphorous results were often unavailable. To improve risk stratification, efforts are needed to more frequently obtain these laboratory tests during clinical care or to develop refined models that use more readily available information.
**FR-PO562**

Add-On Renoprotective Effect of Pentoxifylline in Pre-Dialysis Advanced Chronic Kidney Disease Treated with Renin-Angiotensin-Aldosterone System Blockade – A Nation-wide Database Analysis

**Background:** Pentoxifylline decreases proteinuria in patients with glomerular disease due to its anti-inflammatory and anti-fibrotic properties. A combination therapy of pentoxifylline with an angiotensin converting enzyme inhibitor (ACEI) or an angiotensin II receptor blocker (ARB) decreased proteinuria and the glomerular filtration rate (GFR) decline in early chronic kidney disease (CKD). Whether adding pentoxifylline to ACEI/ARB provides additional benefits on renal outcome or survival is unclear in CKD stage 5 patients who have not yet received dialysis (CKD 5 ND).

**Methods:** A prospective cohort study was conducted based on the Taiwan National Health Insurance Research Database. From January 1, 2000 to June 30, 2009, we enrolled 14,117 CKD 5 ND patients with serum creatinine levels >6 mg/dL and hematocrit levels <28% and who have been treated with ACEI/ARB. All patients were further divided into two groups with or without pentoxifylline within 90 days after starting erythropoiesis-stimulating agent (index date). Patient follow-up took place until dialysis, death before initiation of dialysis or December 31, 2009.

**Results:** With a mean follow-up of 12 months, 9,867 patients (69.9%) required long-term dialysis and 2,805 (19.9%) died before progression to end-stage renal disease requiring dialysis. After propensity score-matching, add-on use of pentoxifylline was associated with a lower risk for long-term dialysis or death in those treated with ACEI/ARB (HR, 0.94; 95% CI, 0.90-0.97) or ARB (HR, 0.91; 95% CI, 0.86-0.97).

**Conclusions:** Pentoxifylline exhibited an add-on renoprotective effect in reducing the risk for long-term dialysis in CKD 5 ND patients who received renin-angiotensin-aldosterone system blockade. Randomized studies are needed to validate this association.

**FR-PO563**

Novel Therapy Regimens Have Reduced the High Risks of Bladder and Haematological Malignancies in ANCA-Associated Vasculitis

Chinar Rahmattulla,1 Annelies Eva Lin Berden,2 Sophie-Charlotte Wäcker,1 Marlies Reinders,1 Ernst C. Hagen,1 Ron Wolterbeek,1 Jan A. Bruijn,1 Ingeborg M. Bajema,1 1Leiden University Medical Center; 2Leiden University Medical Center

**Background:** The introduction of immunosuppressive therapy has dramatically improved the prognosis of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). As a result, attention has shifted to long-term complications in patients. In this study, we investigate the incidence of malignancies in AAV patients. Additionally, we investigate the effect of therapy on malignancy incidence.

**Methods:** We included patients with histopathologically-proven AAV diagnosed at a large university hospital. Malignancy incidence was assessed with the Dutch National Pathology Database, which covers all the histologically confirmed malignancies diagnosed in The Netherlands. We used the Netherlands Cancer Registry incidence rates for comparing the malignancy incidence in our AAV cohort to that of the general Dutch population.

**Results:** Thirty-six of 138 patients with AAV developed a total of 85 malignancies during a mean follow-up of 9.7 years. We observed 61 non-melanoma skin cancers (NMSCs), three colon carcinomas, three breast carcinomas, three prostate carcinomas, two lung carcinomas, two soft tissue sarcomas, two unknown primary malignancies, and a variety of malignancies that occurred only once. The gender-, age-, and calendar year-adjusted malignancy risk was 2.21-fold (95% CI: 1.64–2.92) higher than that of the general population. Only the incidence of NMSCs was significantly increased compared to the general population (standardized incidence ratio: 4.23, 95% CI: 2.76–6.19). Malignancy risk was associated with the duration of cyclophosphamide therapy, and was not increased in patients that received cyclophosphamide for less than 1 year.

**Conclusions:** AAV patients have a higher risk of malignancies than the general population, but this risk is accounted for solely by NMSCs. Throughout the years, the risk of other malignancies—specifically bladder and haematological malignancies—has decreased in patients with AAV. This finding reflects the beneficial results of ongoing efforts to reduce cyclophosphamide exposure by developing new therapy regimens.
FR-PO566

**Lactobacillus plantarum 299v Reduces the Incidence of Clostridium difficile Infection in Patients Treated with Antibiotics in the Nephrological and Transplantation Department**

Marcin Adamczyk, Agata Kutycz, Katarzyna Kwiecień, Sylwia Małgorzata Dudek, Magdalena Gaspka, Andrzej Wieczek. Dept of Nephrology, Transplantation and Internal Medicine, Medical Univ of Silesia, Katowice, Poland.

**Background:** Lactobacillus plantarum 299v (LP299v) has been introduced into the clinical practice in order to reduce gastrointestinal symptoms during antibiotic exposure. However, it remains controversial whether or not probiotics are also effective in the prophylaxis of Clostridium difficile infections in patients receiving antibiotics. The aim of this clinical, retrospective, single-centre study was to analyze the effects of Clostridium difficile infections among patients receiving antibiotics and hospitalized in the period before and after initiation of LP299v routine use, as a prevention of CDI, in the nephrology and transplantation ward.

**Methods:** Among 3533 patients hospitalized in Department of Nephrology, Transplantation and Internal Medicine, Medical University of Silesia in Katowice during two years (October 2012 – October 2013 and December 2013 – December 2014) 23 patients with CDI were diagnosed and enrolled in this study. Since November 2013 prevention of C. difficile infection with the oral use of LP299v was performed in all patients treated with antibiotics and who were at a high risk of developing CDI (patients after organ transplantation and receiving immunosuppressive drugs for any other reasons). For the further analysis the observation period was divided into two twelve-months intervals before (October 2012 to October 2013) and after initiation of LP299v use as the prophylactic manoeuvre against CDI (December 2013 to December 2014).

**Results:** It was found a significant reduction of the number of cases of C. difficile infection after beginning of LP299v routinely used (n=2, 11% of all hospitalized patients) compared with the previous twelve-months period of observation (n=21, 12% of all hospitalized patients).

**Conclusions:** Routine use of Lactobacillus plantarum 299v during treatment with antibiotics may prevent C. difficile infection, particularly in patients at high risk of CDI in the nephrology and transplantation ward.

FR-PO567

**In Patients with Chronic Kidney Disease, Comanagement by Nephrologists is Associated with Lower Risk of Medication Errors**

**Background:** Patients with chronic kidney disease (CKD) are commonly prescribed drug doses that are excessive for their kidney function. Many CKD patients are followed by a nephrologist alone or in consultation with a family physician (i.e. comanagement) versus family physician alone is associated with more anti-hypertensive drugs, lower BMI, blood pressure, the number of anti-hypertensive drugs, ACEI/ARB use, Hb, Alb, corrected Ca, iPTH, and FGF23. We also employed 1:1 (k=1-6) propensity-score full matching, where one BB user matched to at most k non-users.

**Results:** BB users showed significantly-lower eGFR, more proteinuria, higher BMI, more anti-hypertensive drugs, lower Alb, higher 1-84 PTH, higher FGF23, and lower 25OHD levels, most of which suggested a poor risk for CDV at baseline. During a median follow-up period of 190 patient-years, 109 patient reached the outcome. Of those, 12 patients died by RRT, 71 reached a doubling of Cr, and 26 started dialysis. A multivariable Cox model with covariates that were significantly-different between BB users and non-users at baseline showed non-significant HR of 1.58 (C.I. 0.86 – 2.90). We also evaluated a fully-adjusted model and a parsimonious model with a stepwise backward-elimination method; however, the results remained non-significant. The 1 (k=1-6) full matching using propensity score did not show significant results, either. (0.93 (0.52 – 1.68)).

**Conclusions:** The BB therapy was not associated with renal outcomes in CKD patients without prior CDV. Confirmation in a larger study is required.

FR-PO568

**Variation in Co-Medication Use According to Kidney Transplant Immunosuppressive Regimen: Application of Integrated Registry and Pharmacy Claims Data**

**Background:** While modern immunosuppressive therapies (ISx) have substantially reduced acute rejection, ISx medications have many side effects, and transplant recipients must take an array of “co-medications” to help mitigate complications. Co-medication utilization patterns are not well described in large, representative samples due to lack of available data.

**Methods:** We designed national U.S. transplant registry data with pharmacy records (2005-2010) from a large pharmaceutical claims clearinghouse to examine treatments for anemia, metabolic disorders and infections according to ISx regimen in mo 6-12 post-transplant (N=22,433). Associations of ISx with co-medication use (adjusted odds ratio, aOR) were examined with multivariable logistic regression including adjustment for recipient, donor and transplant factors.

**Results:** Compared to a reference regimen of tacrolimus (Tac), mycophenolate (MPA) and prednisone, rapamycin-based ISx was associated with significantly (P<0.05) higher use of ESAs (aOR 2.52), iron (aOR 2.26), statins (aOR 1.47), fibrates (aOR 2.35), and phosphorous binders (aOR 2.85) (Figure). Cyclosporine-based ISx was associated with lower use of ESAs compared to those taking triple ISx, recipients of tacrolimus-based dual and mono-therapies had lower use of statins, ACEI/ARBs, and anti-bacterial agents. Recipients of steroid-free ISx were less commonly treated for new onset diabetes.

**Conclusions:** Co-medication use should be considered in the cost-effectiveness and individualization of ISx regimens.

**Funding:** NIDDK Support

FR-PO569

**Association of Urinary Biomarkers of Injury and Repair with Incident Chronic Kidney Disease in Type 2 Diabetes: An Ancillary Study of the ACCORD Trial**

Girish N. Nadkarni,1 Vecna Rao,2 Faramarz Ismail-beigi,3 Vivian A. Fonseca,4 Sudhir V. Shah,5 Michael S. Simonson,6 Prasad Devarajan,7 Chirag R. Parikh,3 Steven G. Coca.1 Mount Sinai; 1 Yale Univ; 2 Case Western Reserve Univ; 3 Tulane Univ; 4 UAMS; 5 Univ of Cincinnati.

**Background:** Urinary kidney injury molecule (KIM-1), monocye chemoattractant protein (MCP)-1, interleukin (IL)-18, & YKL-40 are biomarkers representing renal injury, kidney fibrosis, and inflammation. We evaluated their association with incident CKD3b in the ACCORD trial.

**Methods:** We designed a case-cohort study of 721 participants & measured KIM-1, MCP-1, IL-18, & YKL-40 from baseline to 4.3 years. 194 eligible participants, 64% were inappropriate dosing. Exposure was defined as one or more outpatient visit with a nephrologist in the 1 year prior to antibiotic prescription. A multivariable logistic regression model was used to determine the independent association between comanagement and inappropriate dosing. Results: 21,348 eligible prescriptions studied, 64% were inappropriate dosing. The patients were 82 (IQR 76-87) years of age with comorbidities including: hypertension (89%), diabetes (49%), coronary artery disease (49%), and congestive heart failure (38%). 77% of all prescriptions were prescribed by family physicians and 2% were prescribed by nephrologists. Multivariable analysis revealed that patients with appropriate prescriptions were more likely to have seen a nephrologist in the one year prior with an unadjusted odds ratio of 1.07 (95% CI 1.01-1.14, p=0.02), adjusted odds ratio 1.23 (95%CI 1.15-1.32, p<0.001).

**Conclusions:** In patients with stage 4 or 5 CKD prescribed an antibiotic, those with an appropriate dose were 23% more likely to have been cared for by a nephrologist in the previous year. Although we cannot conclude what caused the improved prescribing practice, this improvement may, in part, explain the improved patient outcomes associated with seeing a nephrologist in observational studies.

**Funding:** ACCORD Trial

1 Estimated % difference in α1m attributable to each TDF exposure variable, adjusted for demographics, traditional kidney risk factors, and HIV-related factors.

**Conclusions:** In HIV-infected men, TDF exposure was strongly associated with higher urine α1m levels. α1m is a promising biomarker for the detection and monitoring of TDF-associated tubular toxicity.

**Impact of Kidney Function and Urinary Protein Excretion on Pulmonary Function**  

**Yusuke Nakade,1,2,3 Tadashi Toyama,3 Shinti Kitajima,2 Yasuyuki Shinozaki,2 Akinori Haru,2 Mito Shimizu,2 Yasunori Iwata,2 Norihiko Sakai,2 Kengo Furuchi,2 Takashi Wada,2,3  
**Clinical Laboratory, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan; 2Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan; 3Dept of Laboratory Medicine, Kanazawa Univ Hospital, Kanazawa, Ishikawa, Japan.**

**Background:** Although the cardiorenal relationship in patients with chronic kidney disease (CKD) has been investigated, information about the lung-kidney relation is limited. Here, we investigated the impacts of kidney function and urinary protein excretion on pulmonary dysfunction.

**Methods:** The data of pulmonary function tests (PFTs) and kidney function tests from 1 April 2005 to 30 June 2010 were selected from our laboratory database. Data were classified into 4 categories according to eGFR and proteinuria. Category 1: eGFR ≥ 60 ml/min/1.73 m² and urinary protein < 0.3 g/gCr; Category 2: eGFR < 60 ml/min/1.73 m² and urinary protein < 0.3 g/gCr; Category 3: eGFR ≥ 60 ml/min/1.73 m² and urinary protein ≥ 0.3 g/gCr; Category 4: eGFR < 60 ml/min/1.73 m² and urinary protein ≥ 0.3 g/gCr. Pulmonary function data were evaluated according to these 4 categories.

**Results:** A total of 133 participants without major respiratory disease, abnormal computed tomography and smoking history were enrolled. Hb-adjusted %DLCO was strongly correlated with eGFR in participants with a lower eGFR. 

**Conclusions:** This study suggests that eGFR and urinary protein excretion were associated with pulmonary function (Hb-adjusted %DLCO).
FR-PO572
Renal Biomarkers in Diabetes, Role Beyond Retinopathy, Relation to Nephropathy

Background: Diabetic nephropathy and retinopathy remain two of the most frequent complications of diabetes and is the leading cause of end-stage renal disease (ESRD) and blindness worldwide. The concordance rate between both complications is often present in diabetic patients.

Methods: We tried to study the relation between renal biomarkers including serum creatinine (SCr), urinary albumin/creatinine ratio (ACR), serum cystatin-C (cysC) and urinary NGAL (uNGAL) with diabetic retinopathy (DR) in 100 diabetic patients. Patients were classified according to severity into 3 stages: no diabetic retinopathy (No DR), Non-Diabetic Retinopathy (NDPR) and proliferative DR (PDR).

Results: Urinary ACR, serum cysC and uNGAL were higher significantly among patients with DR (NDPR & PDR) than patients without, while SCr showed a non significant rise with progression of retinopathy. All markers were higher among PDR than NDPR group.

Conclusions: Renal biomarkers namely urinary ACR, serum cysC and uNGAL may point to a more advanced stage of diabetic retinopathy, which might be an aid to identify the degree of retinopathy beside the traditional fundus examination in diabetic patients.

FR-PO573
Prognostic Importance of Urea and Urea: Creatinine Ratio for Mortality as Compared to Creatinine Concentrations Alone in the General Population
Ronan Casacub,1,2,3 Peanut G. Stack,1,2,3 John P. Ferguson.1 1Nephrology, Univ Hospital Limerick, Ireland; 2Graduate Entry Medical School, Univ of Limerick, Ireland; 3Health Research Inst, Univ of Limerick, Ireland.

Background: High Creatinine (Cr) concentrations reflect poor kidney function and are associated with a higher risk of death. It is unclear whether other measures of kidney function such as blood urea nitrogen (BUN) concentration and BUN/creatinine ratio, are better predictors of mortality in the general population.

Methods: A cohort of 15,773 non-pregnant subjects age >20, representative of the U.S. population, were identified from the Third National Health and Nutrition Examination Survey (1988-1994). Vital status was obtained through linkage with the National Death Index through to 2006. Subjects were classified into categories of Cr, BUN and BUN/Creatinine ratio (B/Cr). Weighted multivariable Cox regression models, compared hazard ratios [HR] and 95% CI for death among the decile groups and the prognostic capacity of Creatinine Ratio (B/Cr). Weighted multivariable Cox regression models, compared hazard ratios [HR] and 95% CI for death among the decile groups and the prognostic capacity of Creatinine Ratio (B/Cr).

Results: In multivariable analysis, BUN was found to be the most important single function such as blood urea nitrogen (BUN) concentration and BUN/creatinine ratio, are better predictors of mortality in the general population.

Conclusions: The term protein-energy wasting (PEW) implies a state of depleted protein and/or energy stores. An International Society of Renal Nutrition and Metabolism (ISRN) panel proposed objective criteria for the definition of PEW syndrome. However, the extent to which these variables used in PEW syndrome definition are indicative of low protein or energy stores is unknown. Muscle is the largest protein store and fat mass is the largest energy store in the body. Therefore, we examined the associations of these variables with low body mass index (BMI) and fat mass (FM) measured by DXA scans in 11,834 participants in the 1999-2004 National Health and Nutrition Examination Survey (NHANES).

Methods: Definitions of PEW variables are summarized in the table. The associations of each PEW variable with BMI and FM in the entire cohort and CKD (CKD-EPI eGFR < 60) sub-population were examined in linear regression models using svy suite in STATA 13.

Results: Mean age was 46.0 yrs, 50.3% were male, 9.5% were black. 6.7% had CKD. Unintentional weight loss and low levels of serum albumin, serum cholesterol, BMI and MAMC were associated with lower LBM and FM. On the other hand, low protein and energy intakes were associated with higher LBM and FM.

Conclusions: Both BUN and Creatinine Concentrations Alone in the General Population. Among patients with malnourished states (Low BUN), higher SC were associated with lower mortality. In contrast, among patients with normal-high BUN concentrations, higher Cr was associated with elevated death risk. Risk Prediction models should take BUN levels into consideration when estimating future death risk.

Kazuhiro Tsuruya,1 Takana Kitaizono,2 Yuuta Kiyohara,1 Takahiro Nominomiya,1,3 1Dept of Environmental Medicine, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 2Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 3Center for Cohort Studies, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.

Background: Growing evidence suggests that high serum uric acid (SUA) levels are causally related to an increased risk of kidney dysfunction. However, the association remains inconclusive in general Asian populations. Additionally, there are limited studies investigating the influence of SUA levels on the development of albuminuria.

Methods: A total of 2,059 community-dwelling Japanese subjects aged ≥40 years without chronic kidney disease (CKD) were followed for 5 years. CKD were defined as eGFR <60 mL/min/1.73m² or urine albumin/creatinine ratio (UACR) ≥30 mg/g. The odds ratios (ORs) for the development of CKD and the rates of decline in eGFR were estimated according to quartile of SUA (≤40, 4.1-4.9, 5.0-5.8, ≥5.9 mg/dL).

Results: During follow-up period, 396 subjects experienced CKD, of whom 125 had eGFR <60 mL/min/1.73m² and 312 had UACR ≥30 mg/g. The age- and sex-adjusted incidence of CKD increased significantly with higher SUA levels (p for trend <0.001). Compared with those with SUA of ≤40 mg/dL, the multivariable-adjusted ORs for the development of CKD were 1.21 (95% confidence intervals, 0.84-1.74), 1.47 (1.01-2.17), and 2.10 (1.37-3.23) in subjects with SUA of 4.1-4.9 mg/dL, 5.0-5.8 mg/dL, and ≥5.9 mg/dL, respectively. Likewise, there were positive associations of SUA levels with the adjusted risk of developing eGFR <60 mL/min/1.73m² (OR 1.00 [reference] in ≤40 mg/dL, 2.30 [1.10-4.82] in 4.1-4.9 mg/dL, 2.81 [1.34-5.88] in 5.0-5.8 mg/dL, and 3.73 [1.65-8.44], in ≥5.9 mg/dL) and UACR ≥30 mg/g (1.00 [reference], 1.12 [0.76-1.65], 1.35 [0.90-2.03], and 1.91 [1.14-2.87], respectively). Additionally, higher SUA was significantly associated with a greater decline in eGFR (p for trend = 0.002).

Conclusions: Higher SUA level is a significant risk factor for the development of both kidney dysfunction and albuminuria in a general Japanese population.

Conclusions: Serum chemistry, body weight and muscle mass PEW criteria appear to be dependent upon both protein stores (as indicated by LBM) and energy stores (as indicated by FM). Dietary variables are not reflective of protein or energy wasting. A modified PEW syndrome definition without the dietary variables would be a better indicator of PEW syndrome.

Low-Proteinuric CKD and Risk of ESRD in Nephrology Clinics: Emerging Role of Serum Phosphorus
Luca De Nicola, Michele Provenzano, Paolo Chiodini, Giuseppe Conte, Roberto Minutolo, Nephrology, Second Univ, Naples, Italy; Med Stat, Second Univ, Naples, Italy.

Background: In low-proteinuric (LP) CKD, factors other than proteinuria (Uprot) likely act as predictors of ESRD. However, comprehensive assessment of epidemiologic features of LP versus high-proteinuric (HP) patients is still lacking. This information is critical in renal clinics where LP patients are common.

Methods: We pooled three prospective cohorts that in 2000-2010 enrolled 2,488 CKD patients stage III-V under stable care from ≥6 months in 40 Italian renal clinics. Patients were followed for ESRD (chronic dialysis-transplant) up to 12/2014. Patients were classified in two groups, LP (56%) and HP (44%), by Uprot ≥0.5 vs <0.5 g/24h, respectively.

Results: Besides lower Uprot (median, IQR: 0.15, 0.06-0.28 vs 1.20, 0.78-2.05 g/24h), LP differed from HP because male gender (55 vs 62%), diabetes (28 vs 35%) and use of anti-RAS (73 vs 78%) were less frequent. In LP, moreover, (70 vs 12) (p<0.05) (14 vs 14) (p=0.001), GFR-EPN (35.2 ±13.3 vs 26.6±13.2 mL/min/1.73m²) and Hb (12.7±1.7 vs 12.3±1.8 g/dL) were higher while systolic BP (137±18 vs 140±18 mmHg) was lower. Serum phosphorus (P) was lower in LP group (1.33±0.83 vs 1.68±0.70 mg/dL, P<0.05). GFR-EPN and Hb (10.0, 8.50-0.97 and anti-RAS (0.74, 0.60-0.91) had a prognostic role exclusively in HP. A negative interaction P*Uprot was detected in HP (β=-0.064, P=0.004). Results were consistent across cohorts.

Conclusions: In renal clinics, LP patients are prevalent and characterized by nontrivial renal risk despite higher GFR. Risk factors for ESRD are peculiar; in particular, results in LP and HP suggest that lower Uprot allows full expression of the negative role of P, the effect being evident for P levels mostly normal.

Trends in CKD Awareness in the U.S. Population, 1999-2012, Overall and by KDIGO Risk Groups
Yunnuo Yu,1 Tanushree Banerjee,1 Delphine S. Tuot,1 Jennifer L. Bragg-Gresham,2 Mark Eberhardt,3 Sharon Saydah,4 Rajiv Saran,5 Neil R. Powe,6 UCFSC,7 UM,8 CDC.

Background: Despite medical knowledge of chronic kidney disease (CKD) as a risk factor of cardiovascular disease, hypertension, and progression to kidney failure, a majority of patients are not aware of their disease. Early identification and management of CKD can decrease its rate of progression.

Methods: We used cross-sectional National Health and Nutrition Examination Survey data (1999-2012) of non-pregnant adults aged ≥20 years with CKD who had complete urinary albumin and creatinine data (N=8,480-10,296). CKD stages 1-4 were classified using KDIGO's prognosis of CKD risk levels based on GFR and albuminuria. The risk categories range from low to very high risk and predict the risk of CKD progression, ESRD, and mortality. eGFR was estimated using the MDRD equation. CKD awareness was defined by answering “yes” to the question “Have you ever been told that you had weak or failing kidney function?”. The incidence rate of patients are not aware of their disease. Early identification and management of CKD may be reaching those at greatest risk and acceleration might help mitigate CKD progression and associated comorbidities.

Funding: Other U.S. Government Support

FR-PO578

Intermittent Abnormal Kidney Function and Mortality in Community Dwelling Individuals
Donal J. Sexton,1 Scott Reule,2 Robert N. Foley,3 1Medicine, HRB Clinical Research Facility, NUIGalway, Galway, Ireland; 2Medicine, Univ of Minnesota, Minneapolis.

Background: The health implications of permanently abnormal kidney function as measured by estimated glomerular filtration rate and spot urinary albumin excretion has been well characterized to date. However little data is available regarding the implications of intermittent abnormalities in these tests as defined by established thresholds.

Methods: We evaluated the frequency of intermittent abnormal kidney function and its association with all-cause mortality in the US general population using the National Health and Nutrition Examination Survey III, 1988-1994. Mortality linkage data were available through December 2006. Estimated glomerular filtration rate (eGFR) calculated using the CKD-EPI equation and urinary albumin-creatinine ratios (ACR) were measured twice, a mean of 17 days apart (N=1161).

Results: Proportions of abnormal tests included: for eGFR <60 ml/min/1.73m² either test 7.32 %, first test 5.94%, second test 6.86%, first test only 1.64%, second test only 1.38%, both tests 4.31%. Compared to participants with eGFR ≥60 ml/min/1.73m² on both testing occasions, adjusted hazard ratios were 1.8 (95%CI 1.3, 2.4) for intermittent and 1.7 (95%CI 1.1, 2.5) for persistent abnormal eGFR. Proportions with ACR ≥30 mg/g were as follows: either test 16.54%, first test 11.63%, second test 13.55%, first test only 3.19%, second test only 4.91%, both tests 8.44%. Compared to those with ACR <30 mg/g on both occasions’ mortality hazard ratios for intermittent abnormal function was 2.1 (95%CI 1.6, 2.7), and persistent abnormal 2.0 (95%CI 1.5, 2.8). Models were adjusted for age, sex, race, diabetes mellitus, cardiovascular disease (congestive heart failure, previous myocardial infarction or stroke), current smoking, self reported hypertension, systolic and diastolic blood pressure, total cholesterol and body mass index.

Conclusions: CKD as defined by established thresholds may be persistent or intermittent in community dwelling individuals. Participants with intermittently abnormal kidney function as defined by current thresholds were at similar mortality risk to those with persistent abnormal function on both occasions.

FR-PO579

Renal Outcome of APRT Deficiency Presenting in Childhood
Hafnhildur L. Runolfsdottir,1 Runolfur Palsson,1,2 Inger Maria Agustsdottir,1 Olafur S. Indridason,1 Vidar O. Edvardsson,1,3 Faculty of Medicine, Univ of Iceland; 2Div of Nephrology, 3Children’s Medical Center; Landspitali – The National Univ Hospital of Iceland, Reykjavik, Iceland.

Background: Adenine phosphoribosyltransferase (APRT) deficiency is an inherited disorder of purine metabolism that leads to nephrolithiasis and chronic kidney disease (CKD). APRT enzyme data are available on APRT deficiency presenting in childhood.

Methods: All patients in the APRT Deficiency Registry of the Rare Kidney Stone Consortium who presented with clinical manifestations of the disorder and/or were diagnosed with the disease before age 18 years were included in the study. Presenting features, time to diagnosis and disease course were examined. Glomerular filtration rate (eGFR) was estimated with the modified Schwartz equation in children and the MDRD equation in adults. CKD was defined as eGFR <60 ml/min/1.73 m² and acute kidney injury (AKI) according to the KDIGO criteria. Data are presented as median (range).

Results: Eighteen children presented at the age of 1.6 (0.2-16.5) years. Presenting features included redness-brown diabetic spot in 11 patients (55%), kidney stones in 8 (42%), lower urinary tract symptoms in 8 (42%) and AKI in 2. The diagnosis was promptly made in 7 patients, while it was delayed in 12 (63%) patients for 15.2 (0.3-39.2) years. One patient, who did not receive drug treatment, developed ESRD at age 11 years. Twelve patients were placed on allopurinol at the age of 2.1 (0.6-16.5) years. During follow-up of 18.9 (1.7-31.5) years, 3 of these patients developed 4 kidney stone events and AKI occurred in 2 patients during episodes of volume depletion; none had developed CKD. Six patients did not begin pharmacotherapy until age 29.8 (20.5-42.4) years. At last follow-up, at 43.9 (32.5-56.9) years of age, 3 had experienced a total of 9 kidney stone events, 2 had suffered AKI, 3 had stage 3 CKD and one had progressed to ESRD at the age of 44 years.

Conclusions: A substantial proportion of patients with APRT deficiency present in childhood. The commonly observed delay in diagnosis and treatment may have grave consequences. APRT deficiency must be excluded in all children with kidney stones, renal dysfuction and redness-brown diabetic spot.

Funding: Other NIH Support - This study was supported by the Rare Kidney Stone Consortium (U54DK088780), a part of the National Center for Advancing Translational Sciences (NCATS) Rare Diseases Clinical Research Network (RDCRN). RDCRN is an initiative of the Office of Rare Diseases Research (ORDR). The Rare Kidney Stone Consortium is funded through collaboration between NCATS and National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK).
Association of Chronic Kidney Disease with Increased Risk of Recurrence of Upper Urinary Tract Urothelial Cancer – A Population-Based Study

Methods: We conducted a population-based cohort study through Taiwan National Health Insurance Research Dataset. Incident UTUC patient was extracted from Taiwan Cancer Registry Database and linked to data status. Status of CKD including non-dialysis CKD, dialysis ESRD, and renal transplant were identified before the index date of UTUC. Recurrence was defined as either new tumor lesion in bladder, or at the other site of urinary tract, or occurrence of distant metastasis within 3 months after first surgery. Differences of characteristics between CKD and non-CKD group was described as mean ± standard deviation or percentage and tested by independent t test and chi-square test. Competing risk approach was used for estimating cause-specific hazard ratio (C SHR) and 95% confidence interval ( CI ).

Results: Totally, 4,002 UTUC patients from 2001 to 2005 were included and tracked until disease recurrence or end of 5 years after the index date of UTUC. Near half patients accompanied with various stages and status of CKD at index date. UTUC patients with CKD were younger, more female, and had more co-morbidities than patients without CKD. After adjusting factors of age, tumor grade, and co-morbidities, CKD significantly increased risk of UTUC recurrence in female (C SHR: 1.72, 95% CI: 1.33-2.21, p = 0.001); but not in male (C SHR: 0.91, 95% CI: 0.44-1.86, p = 0.79).

Conclusions: CKD increases risk of recurrence in female UTUC patient and is an important prognostic indicator. (This study was granted by the Ministry of Science and Technology (NSC 102-2314-B-037-015-MY3) and by the Ministry of Health and Welfare (MOHW103-TD-B-111-05, MOHW104-TDU-B-212-124-003, budget from health and welfare surcharge of tobacco product). Single Centre Experience of Late Referral and Achievement of Useable Dialysis Access Over a 9-Year Period
Mohamed Salah Eldin Khogali, Renal Dept, Dorset County Hospital; Dorchester, Dorset, United Kingdom; Renal Dept, Dorset County Hospital, Dorchester, Dorset, United Kingdom.

Background: We describe a single centre, retrospective analysis of late (≤ 90 days) referral for dialysis over a 9 year period from April 2003 till March 2012. Factors that contributed to late referral and success in creating permanent dialysis access were determined.

Methods: Data on adult patients referred ≤ 90 days from dialysis were collected including patient demographics, source of referral, mortality, reason for late referral, creation of permanent dialysis access and use of permanent dialysis access at first dialysis.

Results: One hundred and twenty-seven patients were referred in ≤ 90 days over the 9 year period. Ninety-nine (78%) patients were referred within 30 days prior to dialysis and (22%) patients within 30 – 90 days. Their median age was 63 years and 60% (39) patients were male. Twenty-five (20%) patients were diabetic. Forty (33%) patients died within the first year after referral, 25 (21%) patients within the first 6 months and 15 (12%) patients between 6 months and 1 year (figure1). Fifty-six patients (51%) presented late due to acute renal failure (myeloma 24, vasculitis 14, irreversible acute kidney injury 10, renal cell carcinoma 5, glomerulonephritis 3 and others 9). Twenty-nine patients (23%) referred by physicians and surgeons, and 24 patients (19%) referred by GPs were late referrals of patients with known chronic renal failure. Nine patients (7%) presented late due to lack of understanding of their disease, denial, and fear of the unknown. One hundred and ten patients had permanent dialysis access created and 17 patients no permanent access procedures. The average time to create permanent dialysis access was 44 days post-dialysis commencement. Six permanent haemodialysis accesses were created pre-dialysis, 56 post-dialysis; 19 peritoneal dialysis accesses were created pre- dialysis, 29 post-dialysis.

Conclusions: Overall the number of patients presenting late for dialysis has decreased. Late referral has a poor 1 year survival and most patients require haemodialysis long-term. Only a minority of patients referred late have permanent dialysis access created and used at their first dialysis.

Fr-POS82

Abnormal Global Glomerular Sclerosis Rate in Remnant Kidney of Ipsilateral Nephrectomy to Covariate the Risk of End-Stage Renal Disease within Five Years in Patients of Upper Urinary Tract Urothelial Carcinoma
Sheng-Chen Shyu, Shih-Wei Lin, Pei-Ih Liang, Shih-Ming Yeh, Ming-Yen Lin, Shang-Jyh Hwang, Wen-Jeng Wu, Kaohsiung Medical Univ, Taiwan; National Health Research Insts, Miaoli, Taiwan.

Background: Taiwan has significantly high incidence of upper urinary tract urothelial cancer (UTUC) and end-stage renal disease (ESRD). UTUC coexisted with chronic kidney disease (CKD) may deteriorate cancer progression and increase mortality risk. The aim of study was to explore the association of CKD with the risk of UTUC recurrence.

Methods: This cohort study included 132 cases of non-dialysis UTUC patients post ipsilateral nephrecterectomy from 2002 to 2010. We collected clinical and laboratory data before surgery, tumor size, whether into dialysis after surgery, and followed up to dialysis or to December 31, 2014. Renal histopathology was read by 3 specialists: nephrologists or pathologist. We used logistic regression for studying tubuleinterstitial fibrosis score and global glomerular sclerosis (GGS) rates and Cox regression to investigate factors associated with renal survival.

Results: There was no significant factor associated with tubuleinterstitial fibrosis, but advanced CKD was significantly related to GGS rate adjusted with age and gender [OR (95%CI): 4.8(1.4-16.9), p = 0.014]. Kaplan-Meier survival curve showed five-year renal survival rate was 86.3%. Factors affect five-year renal survival were hypertension (HR[95%CI]): 4.0(1.15-2.52), p = 0.043 and GGS rate [HR(95%CI): 17.4(2.4-124.1), p = 0.004].

Conclusions: Our findings demonstrated that UTUC patients with hypertension before surgery or abnormal GGS rate in remnant kidney have higher risk of entering dialysis within five years post ipsilateral nephrectoerectomy. (This study was granted by the Ministry of Science and Technology (NSC 102-2314-B-037-012-MY3) and by the Ministry of Health and Welfare (MOHW103-TD-B-111-05, MOHW104-TDU-B-212-124-003, budget from health and welfare surcharge of tobacco product). The Epicdemic of Chronic Kidney Disease in Rural and Remote Canadian First Nations: Results from Manitoba’s FINISHED Screening Program Paul Komenda, Barry Ad Lalavalle, Thomas W. Ferguson, Navdeep Tangri, Allison Dart, Bing Hu, Audrey Gordon, Caroline D.Chartrand, Lorraine M. Mcleod, Claudio Rigatto, Medicine, Univ of Manitoba, Winnipeg, MB, Canada; Diabetes Education Project, Winnipeg, MB, Canada; Convention Health Sciences, Univ of Manitoba, Winnipeg, MB, Canada; Seven Oaks General Hospital Research Centre, Winnipeg, MB, Canada.

Background: Chronic Kidney Disease (CKD) is a global epidemic affecting 10-15% of the general population. Canadian First Nations children and young adults are known to suffer from a high rate of proximate risk factors for CKD, in particular elevated rates of diabetes. The rates of CKD are not well defined in this population. We used data from The First Nations Community Based Screening to Improve Kidney Health and Prevent Dialysis (FINISHED) project, a 3-year initiative completed in 2015 that accomplished community wide screening in 11 rural and remote First Nations communities in Manitoba, Canada.

Methods: Detailed methods of the FINISHED study have been previously published (Lalavalle et al. CJRHD, 2015). An interdisciplinary team screened for CKD in adults and children aged 10+ using both urine albumin-to-creatinine ratio (AUCR) and eGFR in 11 communities across 2 tribal councils. We present here the data on demographic variables, risk factors for CKD, and the prevalence and severity of CKD in the adult (age 18+) screening cohort.

Results: 3346 adults were screened. 26.7% of those screened had CKD defined as elevated urine ACR (micro- or macroalbuminuria) or eGFR < 60 ml/min/1.73m². Road access communities had a lower prevalence of CKD (18.6%) than remote air access communities (36.0%). Macroalbuminuria (urine ACR > 300 mg/g) was present in 5% of those screened (2.8% in road access and 7.5% in air access communities).

Conclusions: Rural and remote Canadian First Nations suffer up to a 3-fold higher prevalence of CKD than the general population and a nearly 5-fold higher prevalence of macroalbuminuria. This prevalence is comparable to high-risk populations such as those with diabetes, hypertension, and CHF, respectively. Given these risks and road access, screening and treatment interventions may be cost-effective, as they have been shown to be in other high-risk populations.

FR-PO585
Age and Gender Specific Lifetime Risk of Renal Replacement Therapy Jan A.J.G. van den Brand, Maria Pippas, Vianda S. Stel, Jack F. Wetzels, Kitty J. Jager, Dept. of Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; ERA-EDTA Registry, Academic Medical Centre Univ of Amsterdam, Amsterdam, Netherlands.

Background: Kidney transplantation is the preferred treatment of end stage renal disease (ESRD). Graft and patient survival are highest after transplantation with a graft from a living donor. However, persons who donate a kidney are themselves at risk of ESRD. Personalized risk prediction requires age and gender specific risk estimates. Here, we report lifetime risk of renal replacement therapy (RRT) for ESRD by age and gender across Europe. Lifetime risk of RRT is lower in persons with normal eGFR compared to men. These data offer a basis to provide personalized prediction of lifetime ESRD risk when evaluating a potential kidney donor. The estimates presented here are population averages. We expect that lifetime risk is lower in persons with normal eGFR and no albuminuria.

Methods: We investigated a retrospective cohort of all adult type 2 diabetic patients receiving care in an integrated health care system in central Pennsylvania during the period 1/1/2004-12/31/2014. Patients were risk stratified using the 2002 NKF and, separately, the 2012 KDIGO CKD classification systems. We compared the predictive performance of the two classification systems for death and ESRD using Akaikes Information Criterion (AIC) obtained from multivariate, Cox proportional hazards models. Using only the KDIGO 2012 classification system, we then investigated patients categorized as stage G1 or G2 (with ‘high’ or ‘very high’ albuminuria) for the presence of modifiable risk factors.

Results: 17,385 type 2 diabetes comprised the study population (median follow-up 6.8 years). Median age and eGFR were 60 years and 95 ml/min/1.73m², respectively. 53% were male, 44% had a smoking history, and 16% and 5% had a history of coronary disease and CHF, respectively. Although both classification systems discriminated reasonably well, the KDIGO 2012 system—incorporating uACR—had lower AIC scores and was more likely to minimize information loss. Across all risk factors examined, less than half the population was receiving recommended care.

FR-PO586
Characterizing Risk Among Type 2 Diabetics with Preserved eGFR and Abnormal Urinary Albumin Excretion Robert M. Perkins, Alex R. Chang, H. Lester Kirchner, 1 Bayer HealthCare, Whippany, NJ; Geisinger Medical Center, Danville, PA.

Background: Updated CKD risk stratification guidelines promote earlier identification of higher-risk patients. Two conditions are required to improve outcomes among such patients: robust risk characterization, and the presence of modifiable factors.

Methods: We investigated a retrospective cohort of all adult type 2 diabetic patients receiving care in an integrated health care system in central Pennsylvania during the period 1/1/2004-12/31/2014. Patients were risk stratified using the 2002 NKF and, separately, the 2012 KDIGO CKD classification systems. We compared the predictive performance of the two classification systems for death and ESRD using Akaikes Information Criterion (AIC) obtained from multivariate, Cox proportional hazards models. Using only the KDIGO 2012 classification system, we then investigated patients categorized as stage G1 or G2 (with ‘high’ or ‘very high’ albuminuria) for the presence of modifiable risk factors.

Results: 17,385 type 2 diabetes comprised the study population (median follow-up 6.8 years). Median age and eGFR were 60 years and 95 ml/min/1.73m², respectively. 53% were male, 44% had a smoking history, and 16% and 5% had a history of coronary disease and CHF, respectively. Although both classification systems discriminated reasonably well, the KDIGO 2012 system—incorporating uACR—had lower AIC scores and was more likely to minimize information loss. Across all risk factors examined, less than half the population was receiving recommended care.

FR-PO587
Detecting Bowel Cancer in Chronic Kidney Disease (CKD): The Detect Study Germaine Wong, Univ of Sydney, Australia.

Background: CKD confers a 20% higher risk of colorectal cancer (CRC) than the general population, and has a very poor prognosis, with less than 50% of kidney transplant recipients surviving one year after diagnosis. The benefits and harms of screening for advanced colorectal neoplasms in CKD are unknown. We aim to determine the prevalence and spectrum of advanced colorectal neoplasms in CKD, and to evaluate the test performance characteristics of immunochemical faecal occult blood testing (iFOBT) for screening advanced colorectal neoplasms in CKD.

Methods: Participants with CKD stages III-V, on dialysis and with a kidney transplant, aged between 35 and 74 years were recruited from 10 centres in Spain, Canada, Australia and New Zealand. All received two screening iFOBTs, and those with at least one or more positive screens underwent colonoscopy, with test negatives verified by clinical follow up and data linkage.

Results: Of the 1602 patients recruited to the study, [CKD stages III-V: n= 734 (45.8%); dialysis: n=392 (24.7%) and transplant n=476 (29.7%)], 345 (21.5%) had one or more positive screens. Of the 1602 patients recruited to the study, [CKD stages III-V: n= 734 (45.8%); dialysis: n=392 (24.7%) and transplant n=476 (29.7%)], 345 (21.5%) had one or more positive screens. Of the 1602 patients recruited to the study, [CKD stages III-V: n= 734 (45.8%); dialysis: n=392 (24.7%) and transplant n=476 (29.7%)], 345 (21.5%) had one or more positive screens. Of the 1602 patients recruited to the study, [CKD stages III-V: n= 734 (45.8%); dialysis: n=392 (24.7%) and transplant n=476 (29.7%)], 345 (21.5%) had one or more positive screens. Of the 1602 patients recruited to the study, [CKD stages III-V: n= 734 (45.8%); dialysis: n=392 (24.7%) and transplant n=476 (29.7%)], 345 (21.5%) had one or more positive screens. Of the 1602 patients recruited to the study, [CKD stages III-V: n= 734 (45.8%); dialysis: n=392 (24.7%) and transplant n=476 (29.7%)], 345 (21.5%) had one or more positive screens. Of the 1602 patients recruited to the study, [CKD stages III-V: n= 734 (45.8%); dialysis: n=392 (24.7%) and transplant n=476 (29.7%)], 345 (21.5%) had one or more positive screens.

Conclusions: This investigation confirms the feasibility of early risk characterization among patients with preserved eGFR and abnormal urinary albumin excretion. Care gaps are highly prevalent among these individuals and may serve as targets to improve long term outcomes.

Subclinical Pulmonary Congestion Is Pervasive in Nephrotic Syndrome

Francesca Mallamaei, 1,2 Francesco Marino, 2 Carmela Martorano, 2 Rocco Tripeti, 1 Marianna Bellantoni, 1 Giovanni Tripeti, 1 Carmine Zoccali, 1 National Research Council of Italy, Inst of Clinical Physiology, Reggio Cal Cal, Italy; 2Nephrology, Transplantation and Hypertension Unit United Hospitals, Reggio Calabria, Italy.

Background: In patients with Nephrotic Syndrome (NS) the lung is considered as an organ protected from the risk of edema. However information on objectively measured lung water in NS patients is lacking.

Methods: We measured lung water with an ultrasound technique (US) and with standard transthoracic impedance in an incidence of series of 42 asymptomatic patients with active NS. Eleven of these patients were submitted during NS remission. Transthoracic impedance was measured on 3 healthy volunteers that formed the control group. US lung studies were performed after 5 and 60 minutes of supine resting and after 5 minutes of standing. Transthoracic impedance was measured after 30 min of supine resting only.

Results: In patients with active NS the median number of US-B lines (a metric of lung water) after 5 min in supine position was markedly higher [12; Interquartile range: 7-25; p<0.001] than in healthy subjects [4; 2-9]. The difference between patients [16, 11-35] and controls [4; 2-9] amplified (p<0.001) after 60 min of supine resting and attenuated after 5 min of standing [9, 7-25 vs 4, 3-5, p=0.001]. After NS remission, the number of US B lines reduced to 5 (4-18) at 5 min and to 6.5 (2-22) at 60 min (P=0.001) approaching the normal range. Lung congestion in patients with active disease was fully confirmed by transthoracic impedance measurements (p<0.001 vs healthy controls).

Conclusions: Asymptomatic pulmonary congestion is pervasive in patients with NS. A clinical trial is needed to assess the usefulness of the application of this technique for the management of patients with NS.

The Incidence of Malignancies prior to the Diagnosis of ANCA-Associated Vasculitis (AAV) Is Not Increased in Comparison to the Incidence in the General Population

Emma Elisabeth Van Daalen, 1 Chinuin Rahmatullah, 1 Ron Wolterbeek, 2 Jan A. Bruijn, 1 Ingeborg M. Bajema, 1 Pathology, Leiden Univ Medical Center, Leiden, Netherlands; 2Medical Statistics and Bioinformatics, Leiden Univ Medical Center, Leiden, Netherlands.

Background: Several studies have found an increased malignancy risk before the diagnosis of AAV, especially in granulomatosis with polyangiitis (GPA), whereas data on microscopic polyangiitis (MPA) are scarce. It has been hypothesized that malignancies and AAV have common pathways in their pathogenesis (Ann Rheum Dis 2004, Rheumatology 2014). Several studies have found an increased malignancy risk before the AAV diagnosis. To further elucidate this hypothesis, we retrospectively retrieved data on 138 patients with biopsy-proven AAV diagnosed in the Netherlands. Malignancies prior to AAV diagnosis were identified using the Dutch National Pathology Database. The malignancy incidence was compared to the incidence in the general population, as reported by the Netherlands Cancer Registry. The Standardized Incidence Ratios (SIRs) were calculated, matching for gender, age and calendar time period. Separate analyses were performed for GPA and MPA.

Results: Twelve patients were diagnosed with cancer before the AAV diagnosis (mean follow-up: 11.8 years). Overall malignancy risk was not increased (SIR: 0.92, 95%CI: 0.48-1.61). Malignancy risks were also not increased for malignancies of the skin, bladder, kidney, lung, stomach, rectum and uterus (SIRs ranging from 1.71 to 4.77, not significantly increased). There was no difference in malignancy risk between GPA (SIR: 1.23, 95%CI: 0.49-2.53) and MPA (SIR: 0.98, 95%CI: 0.27-2.50) patients (relative risk: 1.26, 95%CI: 0.32-5.38).

Conclusions: We did not find an increased incidence of malignancies prior to AAV diagnosis compared to the general population. This is in contrast with previous studies, in which GPA was associated with preceding renal cell carcinoma, bladder cancer and non-melanoma skin cancer. Most other studies have not included microscopic polyangiitis patients, for which malignancy risk was not increased in our study. Our findings do not support the hypothesis that malignancies and AAV have a shared pathogenic pathway.

Gastrointestinal Symptoms and Hypoalbuminemia in Chronic Kidney Disease Patients

Xuehan Zhang, 1 Nisha Bansal, 1 Alan S. Go, 1 Chi-juan Hou, 1,2 1Peking Union Medical College Hospital; 2Univ of California-San Francisco; 3Univ of Washington; 4Kaiser Permanente Northern California.

Background: Hypoalbuminemia is an important risk factor for adverse outcomes in patients with CKD. Little is known about the relationship between gastrointestinal (GI) symptoms and serum albumin level in CKD.

Methods: This is a cross-sectional study of participants (N=3599) in the Chronic Renal Insufficiency Cohort (CRIC) study which collected information regarding potential uremic symptoms. For each of the 4 following symptoms: “bad taste in mouth,” “loss of appetite,” “nausea,” “vomiting,” we created a severity score by multiplying the number of symptomatic days in the past month by a severity score of 1 to 3 (mild, moderate and severe). We then summed up the individual severity score for an overall severity score. Dietary protein intake was measured via 24-hour urine. The main outcome was severe). We then summed up the individual severity score for an overall severity score. Dietary protein intake was measured via 24-hour urine. The main outcome was low serum albumin levels. The main outcome was low serum albumin level. Dietary protein intake was measured via 24-hour urine. The main outcome was low serum albumin levels.

Results:

<table>
<thead>
<tr>
<th>Symptom</th>
<th>Odds Ratio (95% CI)</th>
</tr>
</thead>
<tbody>
<tr>
<td>A bad taste in your mouth?</td>
<td>1.0 (reference)</td>
</tr>
<tr>
<td>Loss of appetite?</td>
<td>1.0 (reference)</td>
</tr>
<tr>
<td>Nausea or being sick to your stomach?</td>
<td>1.0 (reference)</td>
</tr>
<tr>
<td>Vomiting?</td>
<td>1.0 (reference)</td>
</tr>
</tbody>
</table>

Odds ratios were adjusted for demographic variables, smoking, and smoking status.

Conclusions: Increased prevalence of GI symptoms become apparent among CKD patients at relatively high eGFR levels (45 ml/min/1.73m²). These symptoms correlated with important nutritional parameters.

Obstructive Lung Function in CKD: NHANES 2007-2012

Sankar D. Navaneethan, 1 Susana Arriagin, 2 Mahboob Rahman, 1 Jesse D. Schold. 3Cleveland Clinic; 2CWRU.

Background: Lung diseases are one of the leading causes of death in the general population. We aimed to study the prevalence of obstructive lung function in those with CKD. In addition, factors associated with obstructive lung function were examined.

Methods: Participants aged 20-79 years from the National Health and Nutrition Examination Survey (NHANES) 2007-2012 who underwent spirometry testing using spirometry protocols were included in this analysis. Global Initiative for Chronic Obstructive Lung Disease classification of COPD (FEV1/FVC <0.7) based on post-bronchodilator spirometric results was used to establish the prevalence of obstructive lung function weights adjusted for non-response to spirometry. CKD was defined as presence of eGFR <60 ml/min/1.73 m² and/or UACR >30 mg/g. Factors associated with obstructive lung function were identified using logistic regression model for the entire cohort, CKD and non-CKD groups separately using (based on spirometry).

Results: Out of 11,995 participants (CKD=1563; Non-CKD=10,432) who completed the spirometry testing, 1,098 participants were eligible for both and only 1049 complete bronchodilator spirometry. Prevalence of obstructive lung function using baseline spirometry data were 25% in CKD and 13% in non-CKD and GOLD criteria were 17% in CKD and 8% in non-CKD. Each 5 ml/m lower eGFR and proteinuria were associated with higher odds of having obstructive lung function in the entire cohort.

Table. Factors associated with obstructive lung function in the study cohort

Association of Serum Osteoprotegerin with Bone Loss in Chronic Kidney Disease

From the KNOW-CKD Study
Chang Seong Kim,1 Eun Hui Bae,1 Seong Kwon Ma,1 Kook-Hwan Oh,2 Curie Ahn,1 Soo Wan Kim1
1Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Republic of Korea; 2Dept of Internal Medicine, Seoul National Univ, Seoul, Republic of Korea.

Background: Osteoprotegerin (OPG), a potent inhibitor of osteoclast activation, deactivates the osteoclasts protective and trophic mineral density. This study examined the association between serum OPG and bone loss in patients with chronic kidney disease (CKD), a condition associated with increased risk of bone fracture and mineral and bone disorders.

Methods: BMD at the lumbar spine, total hip and femur neck was assessed by dual energy X-ray absorptiometry; and serum OPG was measured at baseline in 1,423 CKD patients in the prospective KoreaN Cohort Study for Outcome in Patients With Chronic Kidney Disease. Osteoporosis was defined to T score ≤ –2.5 in patients aged over 50. Results: Mean quartiles of serum OPG were significantly associated with lower BMD (lumbar spine, total hip and femur neck) compared with the lowest quartile of serum OPG. Multivariable linear regression model indicated that serum OPG was independently associated with decreased lumbar spine and total hip BMD (B = –0.489; 95% confidence interval [CI], –0.883–0.095; P = 0.015, B = –0.349; 95% CI, –0.672–0.027; P = 0.027, respectively) but femur neck BMD was not associated with serum OPG in women. No independent association was found between serum OPG and BMD in men after adjustments. In multivariable logistic regression analysis, serum OPG was associated with increased risk of osteoporosis in women, but was not in men (odds ratio [OR], 4.01; 95% CI, 1.27–12.67; P = 0.018; OR, 95% CI, 0.16–1.52; P = 0.311, respectively).

Conclusions: Serum OPG was independently associated with lumbar spine and total hip BMD and increased risk of osteoporosis in female CKD patients. However, these associations were not found in male CKD patients.

Growth in Children with Chronic Kidney Disease: A Report from the KNOW-Ped CKD (Korean Cohort Study for Outcome in Patients with Pediatric Chronic Kidney Disease)
Fujin Park,1 Yo Han Ahn,2 Kyoung Hee Han,2 Seong heon Kim,1 Joo Hoon Lee,2 Young seo Park,1 Hee Gyung Kang,1 Hae Il Cheong,1 Curie Ahn,1 IL Soo Ha,1 1Dept of Pediatrics, Seoul National Univ Children’s Hospital, Seoul, Korea; 2Dept of Pediatrics, Jeju National Univ School of Medicine, Jeju, Korea; 3Dept of Pediatrics, Pusan National Univ Children’s Hospital, Yangsan, Korea; 4Dept of Pediatrics, Asan Medical Center; Univ of Ulsan College of Medicine, Seoul, Korea; 5Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Korea.

Background: Growth impairment is common in children with chronic kidney disease (CKD) and can negatively impact psychosocial impact. We investigated the characteristics of growth in Korean children with CKD.

Methods: Clinical characteristics along with anthropometric measurements were examined in subjects of KNOW-Ped CKD, Korean cohort Study for Outcome in Patients with Pediatric Chronic Kidney Disease. Findings of 322 children (M/F: 218:104), who were enrolled to the study from July 2010 to December 2013 in seven major pediatric nephrology centers of Korea, were analyzed to investigate the characteristics of growth in Korean pediatric CKD.

Results: Mean height- and weight- z scores of Korean pediatric CKD patients were -0.88±1.43 and -0.91±1.65. Mean BMI- z score was -0.36±1.25. Height deficit was observed from early stage of CKD with mean height- z score -0.42 in CKD stage I. Short stature (z score < -1.88, 20% of the subjects) and underweight (z score < -1.65, 28% of the subjects) were associated with female sex, age younger than 2-year-old at enrollment, co-morbidity, and advanced CKD stage. Low BMI was associated with high blood pressure, co-morbidity and younger age. The final height- z score was -0.86±1.19, which is shorter than predicted adult height- z score (-0.33±0.7) calculated from their parental height.

Conclusions: Growth failure is one of the most important complications in pediatric CKD patient. More profound height, weight and BMI impairment were associated with younger age and co-morbidity. Children with these findings need close attention on their growth and may require earlier intervention to avoid severe growth impairment.

Risk of Early Preterm Delivery in Pregnant CKD Patients – A Model for Counseling – The TOCOS Cohort (Torino Cagliari Observational Study)
Giorgia B. Piccoli,1 Rossella Attini,1 Gianfranca Cabiddu,2 Antonello Pani,2 Tullia Tedros,2 1Ss Nefrologia Dept of Clinical and Biological Sciences, Univ of Turin, Italy; 2Dept of Surgery, Univ of Turin, Italy; 3Nephrology, Brotzu Hospital, Cagliari, Italy.

Background: Chronic kidney disease (CKD), whose prevalence almost equals preeclampsia in pregnancy, increases the risks of adverse pregnancy outcomes; the degree of decrease of serum OPG was significantly associated with lower BMD (lumbar spine, total hip and femur neck) compared with the lowest quartile of serum OPG in women. A homogeneously followed-up, low-risk preganant population served as controls. So far there are no largest Italian cohort dedicated to the multidisciplinary follow-up of CKD in pregnancy. Patients: Pregnant women with CKD: 503 live-born singletons in CKD: 835 low-risk controls (2000-2013). Measurements: Outcome: early pre-term delivery. The candidate variables were readily measurable, available, inexpensive (hypertension, proteinuria, kidney disease and function). Bootstraping was used for internal validation.

Results: Early preterm delivery was more frequent in CKD (12.5% vs controls (1%) (p<0.0001). The most parsimonious model (Likelihood ratio test p<0.0001; McFadden’s pseudo R²<0.2290) summarized various combinations of CKD stages, hypertension and proteinuria and defined a scale of risk. First step included CKD stage 1, normotension and proteinuria <1g/24h (OR:2.8); second step included CKD stages 2-5 without hypertension and proteinuria, and CKD stage 1 with either hypertension or proteinuria (OR:19.5 and 20.9); third step included CKD stages 2-5 with either hypertension or proteinuria (OR:44.7); the combination of hypertension and proteinuria was associated with the highest risk, but the low number of cases prevented precise quantification. Limitations: the study was performed in two Centers only. The number of cases with severe CKD is small.

Conclusions: The model may support counselling and clinical management by grading the risk for adverse pregnancy outcomes. Further studies are needed to externally validate the model.

Funding: Government Support - Non-U.S.

FR-PO595

Solitary Kidney Is Associated with a Higher Risk of Adverse Outcomes in Pregnancy
Jessica B. Kendrick,1,2 John R. Holmen,1 Gerard John Smits,1 Michel Chonchol,3 1Univ of Colorado Denver, Aurora, CO; 2Denver Health Medical Center, Denver, CO; 3Intermountain Health Care, Salt Lake City, UT.

Background: Chronic kidney disease is associated with adverse outcomes in pregnancy. Data regarding the effect of decreased glomerular filtration rate on pregnancy in women with a single kidney primarily has come from studies of kidney transplant recipients and living kidney donors. We set out to determine the risk of adverse outcomes in women with a single kidney from etiologies other than donation.

Methods: Using data from an integrated health care delivery system from 2000 through 2014, we conducted a study of 1,556 pregnant women hospitalized for childbirth. A total of 333 women had a single kidney with normal kidney function and were matched 1:3 by age and race to women with two kidneys. Adverse pregnancy outcomes included preterm delivery, delivery via cesarean section, preeclampsia/ eclampsia, length of stay at hospital and low birth weight (<2,500 g). Multivariable logistic regression analysis was used to examine the association between a single kidney and adverse pregnancy outcomes.

Results: Of the women with a solitary kidney, the mean (SD) age and mean (SD) gestational age at delivery was 28±6 years and 38±2 weeks, respectively. Compared to women with two kidneys, those with a single kidney had an increased risk of preterm delivery (OR 2.33, 95% CI 1.61-3.38), delivery via cesarean section (OR 1.85, 95% CI 1.33-2.56), and preeclampsia/eclampsia (OR 1.87, 95% CI 1.23-2.85). Women with a single kidney also had an increased risk of a length of stay < 3 days in the hospital (OR 1.50, 95% CI 1.01-2.20) and low infant birth weight (OR 2.99, 95% CI 1.95-4.59).

Conclusions: Women with a solitary kidney from causes other than kidney donation have a higher risk of adverse outcomes in pregnancy.

Funding: NIDDK Support

FR-PO596

Thiamine Deficiency in Non-Dialysis CKD Patients
Yukako Ohyama,1 Toshikazu Ozeki, Shun Minatoguchi, Hideaki Shimizu, Yoshiro Fujita,1 1Department of Nephrology and Rheumatology, Chubu Rosai Hospital, Nagoya, Japan.

Background: Thiamine deficiency is associated with malnutrition, alcoholism and chronic diseases such as cancer. Long use of diuretics also induces thiamine deficiency, which is due to an increased urinary loss of thiamine. Some papers report that thiamine tend to accumulate because of decreased urinary flow in chronic kidney disease (CKD) patients. Others report that a protein restricted diet causes thiamine deficiency in CKD patients. This study aimed to examine the prevalence and factors associated with thiamine deficiency in CKD patients.

Methods: This is a single center cross-sectional study in patients with non-dialysis CKD under regular follow-up in nephrology center of Chubu Rosai Hospital from July 1, 2014 to January 31, 2015. Patients who meet the CKD criteria of Japanese Society of Nephrology were selected. We used the data from the national renal, questionnaire, and nutrition surveys.

Results: The study population consisted of 149 patients aged 71.2 ± 10.9 years with estimated glomerular filtration rate <33 ± 2.1 (mean ± standard deviation) (1.73mL/min/1.73m2). They were divided into low thiamine group (serum thiamine level<30ng/ml) and high thiamine group (serum thiamine level³30ng/ml). In univariate comparisons, patients with low thiamine group had significantly lower protein intake which is estimated by the nutrition survey. The use of loop diuretics was not associated with thiamine deficiency. In multivariate analyses, high age, low eGFR and low protein intake, especially less than 0.8g/kg, were independently associated with thiamine deficiency.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

transplant and 25 glomerulonephritis, predominantly lupus). Most women were considered:

Pregnancy outcomes were analysed.

A year, renal biopsy, disease flare or rejection, and conversion back to mycophenolate.

Protein restriction for CKD patients especially with high age and low eGFR have a high risk of thiamine deficiency.

FR-PO597

Controlled Attenuation Parameter Measured by FibroScan Is Closely Associated with Microalbuminuria in CKD Patients.

Background: Hepatic steatosis can be determined by the measurement of liver controlled attenuation parameter (CAP) using FibroScan. Although the practical methods predicting the risk of metabolic syndrome (MS) development are lacking, recent studies report that this parameter is closely correlated with the presence of MS in the general population. Therefore, we investigated whether CAP measured by FibroScan could predict the presence of MS in chronic kidney disease (CKD) patients.

Methods: A total of 468 CKD patients evaluated. MS was defined by using the Modified National Cholesterol Education Program (Adult Treatment Panel III) criteria. Multivariate logistic regression analysis was used to identify the independent association between CAP and MS.

Results: The mean age of the patients was 57.5 years and 225 patients (48.1%) were female. The mean value of CAP was 241.7 dB/m. CAP was independently associated with body mass index (β=7.818, P<0.001), triglyceride (β=0.246, P=0.002) and estimated glomerular filtration rate (eGFR) (β=0.581, P=0.005). MS was diagnosed in 142 (30.3%) patients. In patients with MS, diabetes was more prevalent (59.9 vs. 25.8%, P<0.001), hemoglobin (13.1±2.4 vs. 12.6±2.1 g/dL, P=0.026) and CAP (262.0±60.6 vs. 232.9±40.0 dB/m, P=0.001) levels were significantly higher, while eGFR (82.9±27.5 vs. 91.6±26.0 mL/min/1.73m², P=0.001) was lower compared with patients without MS. Multivariate logistic regression analysis revealed that high CAP levels were independently correlated with the increased risk of MS (per 1 dB/m increase, odds ratio=1.010, 95% confidence interval=1.002-1.018, P=0.014) after adjustment for confounding factors.

Conclusions: High CAP levels measured by FibroScan were significantly associated with an increased risk of MS in CKD patients. These data suggest liver FibroScan could be a practical method for evaluating the risk of MS development in CKD patients.

FR-PO598

Outcomes in Women Switched from Mycophenolate to Azathioprine in Advance of Pregnancy.

Background: Mycophenolate is teratogenic and should be replaced in advance of pregnancy. There is concern that this change may have adverse consequences including transplant rejection and disease flare. The aim of this study was to determine the risk of adverse outcome in women switched from mycophenolate to azathioprine.

Methods: Records of women attending regional renal pre-pregnancy counselling clinics 2011-2014 were examined. Women taking mycophenolate were included and the decision to switch to azathioprine was reviewed. Outcomes were a decline in eGFR within a year, renal biopsy, disease flare or rejection, and conversion back to mycophenolate. Pregnancy outcomes were analysed.

Results: Data were available for 60 women (31 kidney transplant, 4 kidney-pancreas transplant and 25 glomerulonephritis, predominantly lupus). Most women were considered eligible for a switch to azathioprine and one woman chose to switch against advice.

Conclusions: Protein intake is an important factor for thiamine levels of CKD patients. Protein restriction for CKD patients especially with high age and low eGFR have a high risk of thiamine deficiency.

FR-PO599

Controlled Attenuation Parameter Measured by FibroScan Is Closely Associated with Microalbuminuria in CKD Patients.

Background: Hepatic steatosis can be determined by the measurement of liver controlled attenuation parameter (CAP) using FibroScan. Although the practical methods predicting the risk of metabolic syndrome (MS) development are lacking, recent studies report that this parameter is closely correlated with the presence of MS in the general population. Therefore, we investigated whether CAP measured by FibroScan could predict the presence of MS in chronic kidney disease (CKD) patients.

Methods: A total of 468 CKD patients evaluated. MS was defined by using the Modified National Cholesterol Education Program (Adult Treatment Panel III) criteria. Multivariate logistic regression analysis was used to identify the independent association between CAP and MS.

Results: The mean age of the patients was 57.5 years and 225 patients (48.1%) were female. The mean value of CAP was 241.7 dB/m. CAP was independently associated with body mass index (β=7.818, P<0.001), triglyceride (β=0.246, P=0.002) and estimated glomerular filtration rate (eGFR) (β=0.581, P=0.005). MS was diagnosed in 142 (30.3%) patients. In patients with MS, diabetes was more prevalent (59.9 vs. 25.8%, P<0.001), hemoglobin (13.1±2.4 vs. 12.6±2.1 g/dL, P=0.026) and CAP (262.0±60.6 vs. 232.9±40.0 dB/m, P=0.001) levels were significantly higher, while eGFR (82.9±27.5 vs. 91.6±26.0 mL/min/1.73m², P=0.001) was lower compared with patients without MS. Multivariate logistic regression analysis revealed that high CAP levels were independently correlated with the increased risk of MS (per 1 dB/m increase, odds ratio=1.010, 95% confidence interval=1.002-1.018, P=0.014) after adjustment for confounding factors.

Conclusions: High CAP levels measured by FibroScan were significantly associated with an increased risk of MS in CKD patients. These data suggest liver FibroScan could be a practical method for evaluating the risk of MS development in CKD patients.

FR-PO600

The Assessment of Incidental Risk for Microalbuminuria According to the Level of Depression Scale.

Background: Depression is one of the most common psychiatric disorders. The observed difference for depression goes beyond function and extends to somatic health. A growing body of evidence shows that depression is significantly associated with chronic kidney disease. Nonetheless, the incidental relationship between microalbuminuria and depression was not identified yet. Therefore, we conducted this study to investigate incidental relationship of microalbuminuria with depression scale.

Methods: This study was conducted for 45,293 Korean men and their spouses without microalbuminuria who got medical health check up in Kangbuk Samsung Total healthcare center in 2010. To assess the degree of their depression, Center for Epidemiologi Studi-EndoScale (CES-D) was used (CES-D ≤ 15: normal, CES-D 16-20: moderate risk group, CES-D > 21: high risk group). On the basis of CES-D score in 2010, they were classified into 3 groups (normal, moderate, high risk group) and monitored for the development of microalbuminuria from January, 2011 to April, 2015.

Results: While the general incidence was 1.7%, the incidence of microalbuminuria increased in proportion to the risk score of depression evaluated by CES-D (CES-D ≤ 15: 0.4%, CES-D 16-20: 1.8%, CES-D > 21: 3.6%). When the hazard ratio (HR) of normal group (CES-D ≤ 15) was set to reference value (HR: 1.00), the HRs for microalbuminuria also increased according to the score of CES-D scale. In addition, these associations were preserved even after adjusting for the various metabolic covariates such as age, physical activity, total cholesterol, LDL-cholesterol, triglyceride, body mass index, and obesity (CES-D 16-20: 1.98, CES-D > 21: 3.37).

Conclusions: Our study showed that the risks of microalbuminuria in proportion to the severity of depression. These findings imply the clinical role of the depression for
FR-PO601
Outcomes in CKD Patients with Hospital Acquired Complications
Babak Bohloulia, 1 Terri Jurgens Jackson, 2 Marcello Tonelli, 3 Scott Klassen. 1
1 Medicine, Univ of Alberta, Edmonton, AB, Canada; 2 Northern Clinical Research Centre, Univ of Melbourne, Epping, Vic, Australia; 3 Medicine, Univ of Calgary, Calgary, AB, Canada.

Background: Patients with CKD are at increased risk of hospital acquired complications (HACs) including those considered preventable. The impact of HACs on patient and health system outcomes has not been well described.

Methods: Subjects hospitalized from April 1, 2003 to March 31, 2008 from a population based cohort (Alberta Kidney Disease Network) were studied. Outpatient eGFR and proteinuria (protein/creatinine ratio or dipstick) in the year prior to index hospitalization were used to define CKD status. Co-morbid conditions were identified using validated algorithms applied to administrative data. ICD 10 CA was used to classify reason for admission. A specific diagnostic indicator (type II) was used to identify hospital acquired complications (HACs) that were sub-classified as “potentially” and “always” preventable.

We studied the following outcomes: re-admission within 90 days of discharge, all cause mortality at 90 days, and index hospitalization costs. Multivariable regression models examined the association of HACs with re-admission, mortality, and incremental health care costs, accounting for confounders.

Results: Of 536,549 subjects, 45,377 (8.5%) with CKD were hospitalized. In patients with HACs, the OR of re-admission and death at 90 days was 1.37 (95% CI: 1.32 – 1.43), and 3.11 (95% CI: 3.06 – 3.58) respectively compared with those without HAC. Hospitalizations with any HAC were associated with incremental health costs of $4028 (95% CI: $3898 – $4158). A graded association was observed for those outcomes with increasing number of HACs and severity of CKD. Similar results were noted when only potentially preventable HACs were considered.

Conclusions: Complications occurring during hospitalization in patients with CKD is independently associated with an increased risk of hospital re-admission, health care costs, and mortality. Targeted strategies to reduce HACs in this patient population may have a significant benefit.

FR-PO602
Plasma Proteins Associated with Declining Renal Function in Patients with Type 1 Diabetes: Results of a Global Proteomic Analysis Using SOMAscan Platform
Andrew L. Schialfa, Monika A. Niewcza, Marcus G. Pezzolesi, Andzej S. Krolowski, Joslin Diabetes Center, Boston, MA.

Background: Increases in serum creatinine and cystatin C are considered measures of declining renal function in patients with diabetes.

Methods: To search for other proteins correlated with declining renal function, we conducted a follow-up study, following 30 patients with T1D and proteinuria for 1-3 years. Mean eGFR was 67 ml/min at baseline, and was 59 ml/min at the end of follow-up. Plasma samples were stored at -80°C. Proteins were measured on the SOMAscan platform at baseline and at the end of follow-up. The platform measured 954 proteins for each of the 30 patients, with median limit of detection (LOD) of 1.6pg/mL/dynamic range of 8 logs, and median coefficient of variation (CV) of 5% for individual proteins measured repeatedly in replicate runs of plasma samples.

Results: Renal function change during follow-up in each patient was expressed as the difference between eGFRcre at baseline and at follow-up and was referred to as ∆GFR in replicate runs of plasma samples. 30 patients, with median limit of detection (LOD) of 1.6pg/mL,dynamic range of 8 logs, mean eGFR was 67 ml/min at baseline, and was 59 ml/min at the end of follow-up. Mean eGFR was 67 ml/min at baseline, and was 59 ml/min at the end of follow-up. Spearman rank correlation coefficient between ∆GFR and the percent change in the protein’s level (RFU) (mean: -7.7 ml/min, range: -44 ml/min to 11 ml/min). For each protein, the Spearman rank correlation coefficient between ∆GFR and the percent change in the protein’s level (RFU) (mean: -7.7 ml/min, range: -44 ml/min to 11 ml/min).

Conclusions: In conclusion, increasing or decreasing concentrations of plasma proteins with cold grant loss may reflect worsening renal function, as is the case with cystatin C. However, changes in plasma concentration of these proteins may represent the extent and intensity of the disease process underlying progressive renal decline, which is most likely the case with IL-1β and the TNFR-β.

FR-PO603
Mass Spectrometry Imaging Reveals Disease Specific Alterations in Protein Abundance in Human Diabetic Nephropathy
Haijun Yang, 1 Audra M. Judd, 2 Michelle Reyerz, 1 Jeremy L. Norris, 3 Richard M. Caprioli, 4 Raymond C. Harris, 3 Agnes B. Fogo. 1 Pathology, Microbiology and Immunology, Vanderbilt Univ; 2 Mass Spectrometry Research Center, Vanderbilt Univ; 3 Nephrology, Vanderbilt Univ; 4 Nashville, TN.

Background: Diabetic nephropathy (DN) is a major complication in diabetic patients. However, the progression and development of DN are characterized by multiple pathophysiologic changes. We examined MALDI mass spectrometry imaging (MSI) to discover alterations in protein expression in human DN glomeruli and compared to the morphology and clinical features.

Methods: DN biopsies (n=36) and normal kidney (n=9) were assessed. Complete nephrobiology findings were divided into mild, moderate and severe, based on biopsy findings. Follow-up was available in 23 patients, and patients were sub-grouped into stable DN (decreased eGFR 50-70 ml/min/1.73 m², progressive 50-70 ml/min/1.73 m², and fibrotic DN). Matrix-assisted laser desorption/ionization mass spectrometry (MALDI) is a technology that acquires molecular information from thin tissue sections in a spatially-defined manner. We examined MALDI mass spectra to discover alterations in protein expression in human DN glomeruli and compared to the morphology and clinical features.

Results: DN patients had reduced eGFR and increased proteinuria, compared to normal. Mass spectrometry showed 168 peptide peaks, with 8 peaks increased and 21 peaks decreased in DN compared to Normal. Moderate and severe DN showed more nodular glomerulosclerosis than mild DN by study design (moderate 2.13±0.10, severe 2.17±0.22 vs. mild 0.43±0.30, 0.4+ scale, p<0.05) and mesangial expansion (moderate 1.97±0.09, severe 2.28±0.15 vs. mild DN 1.21±0.15, p<0.05). Peptide maps were more similar in moderate vs severe DN groups, compared to mild DN. Thirteen of 168 peptide peaks were significantly different between the three groups. In progressive DN, 10 peptide peaks were decreased and 1 was increased, compared to stable DN. Of note, these peaks differed from those associated with the morphologic phenotype.

Conclusions: We conclude that different peptide maps correlate with DN onset, severity and prognosis, and that clinical and morphological phenotypes have differing proteomic correlates. These peptides will now be further validated and identified by MS/ MS fragmentation and database searching.

FR-PO604
Urine Metabolomic Profiling Reveals a Unique Signature for Type 2 Diabetes
Jane J. Kim, Rintaro Saito, Satoshi Miyamoto, Minya Pu, Loki Natarajan, Kumar Sharma. Univ of California, San Diego.

Background: Increases in circulating branched chain amino acids (BCAA) are associated with type 2 diabetes (T2D) and insulin resistance. However, it is not clear whether increased plasma BCAA concentrations result from increased synthesis, or impaired degradation or excretion. Here, we employ a targeted metabolomics approach to evaluate diabetic patients without overt kidney disease to identify urine metabolites associated with T2D, presenting potential urine biomarkers for clinical prediction and further insight into disease pathogenesis.

Methods: We measured 105 urine metabolites by GC/MS in a screening T2D cohort (n=27), validation T2D cohort (n=14), and healthy control group (n=23). We also examined kidney cortex of db/db and control db/+ mice to measure gene expression by Illumina microarray and protein expression by western blot.

Results: Following FDR correction, 57 metabolites were found to be different in the screening cohort compared to controls. When these 57 metabolites were carried forward for analysis in a validation T2D cohort, 24 of these urine metabolites were confirmed to be different from controls using Bonferroni adjustment for multiple comparisons. 16 of the 24 confirmed metabolites were amino acids, and 8 of these represented BCAA degradation products. To further investigate BCAA metabolism, we examined kidney tissue from db/db mice and found that the gene expression of key enzymes related to BCAA catabolism was decreased. Western blot studies confirmed that renal expression of branched-chain ketoacid dehydrogenase, a mitochondrial enzyme complex that catalyzes an irreversible step in BCAA catabolism, was reduced in db/db mice compared with controls.

Conclusions: Prior studies have reported impaired mitochondrial BCAA metabolism in adipose, muscle and liver. However, our results show a robust pattern of increased BCAA concentrations, likely reflecting increased BCAA catabolism and/or increased metabolic flux. The reduced renal expression of BCAA enzymes supports a role for dysregulated BCAA metabolism by the kidney. The elevated BCAA metabolism may have an effect on regulating insulin resistance and the development of kidney disease with T2D.

Urineary Matrix Metalloproteinase Activities Are Associated with Renal Hyperfiltration in Adolescents With Type 2 Diabetes
Petter Bjornstad, Laura Simmons, Margaret Snell-berge, Karen L. Mueller, Kristin Nadeau. 1 Barbara Davis Center for Diabetes; 2 Univ of Colorado Denver; 3 Children’s Hospital Colorado.

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal disease. Matrix metalloproteinases (MMP) modify extracellular matrix during vascular remodeling and are known to be elevated in diabetes, and associated with DN in type 1 diabetes. We hypothesized that activities of latent MMP and neutrophil gelatinase-associated lipocalin (NGAL) proteins in urine would be associated with microalbuminuria and hyperfiltration in adolescents with type 2 diabetes (T2D).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
498A
Methods: 295 adolescents with T2D (14.0±1.8 years, <2 years duration, BMI ≥85%, and HbA1c ≤5%) in the Treatment Options for Type 2 Diabetes in Adolescents and Youth (TODAY) study had urine and blood evaluated at baseline and annually for 5 years. MMP2, MMP9 and NGAL activities were measured by gelatin zymography and normalized to urine creatinine. Microalbuminuria was defined as albumin-to-creatinine ratio (ACR) ≥30mg/g. Estimated GFR was calculated by Schwartz (eGFR=36.5height/creatinine) and hyperfiltration defined as ≥135mL/min/1.73m². Mixed models evaluated the longitudinal relationships between MMP-2, MMP9 and NGAL with eGFR, ACR, hyperfiltration and microalbuminuria respectively. MMP2, MMP9 and NGAL-MMP9 activities were natural log-transformed (ln) due to skewed distribution.

Results: MMP2, MMP9 and NGAL-MMP9 were associated with eGFR, but not ACR over time after adjusting for age, sex, HbA1c, SBP and treatment group. One standard deviation increase in ln MMP2, ln MMP9 and ln NGAL-MMP9 was each associated with 0.03, 0.046 and 0.001 decrease in ln ACR, respectively. MMP2, MMP9 and NGAL-MMP9 activities were each associated with 1.2, 1.0 and 1.2 increase in ln MMP2, ln MMP9 and ln NGAL-MMP9, respectively. MMP2, MMP9 and NGAL-MMP9 activities were each associated with 0.03, 0.046 and 0.001 decrease in ln ACR, respectively. MMP2, MMP9 and NGAL-MMP9 activities were each associated with 1.2, 1.0 and 1.2 increase in ln MMP2, ln MMP9 and ln NGAL-MMP9, respectively.

Conclusions: Inclusion, urinary MMP and NGAL activities were associated with early DN in adolescents with T2D over time. Moulton) and K23 RR020038 (K. Nadeau).

FR-PO606
A Serum Metabolite Classifier Predicts Response to ARBs in Diabetes
Michelle Pena, Bernd Mayer, Andreas Heinzel, Peter Rossing, Hildo Jan Lambers Heerspink.

Background: Individual patients show a large variability in albuminuria response to Angiotensin Receptor Blockers (ARB). Identifying novel biomarkers that predict ARB response may help optimize treatment. We aimed to discover and validate a novel serum metabolite classifier that predicts response in urinary albumin excretion (UAEx) to ARBs in diabetes.

Methods: Flow injection analysis/liquid chromatography-tandem mass spectrometry based targeted metabolomics was performed on serum samples from type 2 diabetes patients (n=49) enrolled in a clinical study assessing the effect of irbesartan 300mg/day. Individual serum metabolites were selected with LASSO regression to predict UAEx response to irbesartan. The classifier was developed with ridge regression. Improvement in risk prediction was tested on top of a control model (age, sex, HbA1c, SBP, GFR, UAE) by assessing differences in explained variation (R2) between the control model and the classifier model. The classifier was externally validated in a clinical study in type 1 diabetes patients (n=50) testing the effect of losartan 100mg/day. Metabolite mapping was performed on a molecular model of diabetic kidney disease to identify underlying molecular processes contributing to ARB response.

Results: The classifier included 21 metabolites. Median reduction in UAEx was -42% [-69.8 to 1.9] in type 2 diabetes. The classifier was significantly associated with UAEx response to irbesartan (p<0.001) and significantly improved prediction of UAEx response on top of the control model (R2 increase from 0.10 to 0.69, p<0.001). In the external validation cohort, median reduction in UAEx was -43% [-62.2, 23]. The classifier significantly improved prediction of UAEx response to losartan (R2 increase from 0.17 to 0.52, p<0.001). Metabolites included in the classifier were assigned to stress/inflammation pathways and downstream consequences of fibrosis and extra cellular matrix remodeling. Moreover, ADMA, impacting eNOS activity, appears to be a specific factor relevant in ARB response.

Conclusions: A classifier of 21 serum metabolites was identified and externally validated to significantly improve prediction of albuminuria response to ARBs in diabetes.

FR-PO607
Is Urinary Proteomics Useful to Predict Retinopathy in Type 2 Diabetic Patients in the DIRECT Study
Mig K. Eickhoff, Marie Frimodt-Moller, Morten Lindhardt, Mohammed Dakna, Harald Mischak, Direct Steering Group, Peter Rossing, Steno Diabetes Center, Gentofte, Denmark; Mosaïques Diagnostics GmbH, Hannover, Germany; BHF Glasgow Cardiovascular and Renal Research Centre University of Glasgow, Glasgow, United Kingdom; HEALTH, Univ of Aarhus, Denmark; Univ College London, London, United Kingdom.

Background: Diabetic microvascular complications affect the kidney and the eyes, being a leading cause of renal failure and blindness. Urinary proteomics has shown promise as an early indicator of future development of diabetic nephropathy. Here we investigate if this could also predict progression of diabetic retinopathy.

Methods: In a post-hoc study of the DIRECT 2 study, a randomized, controlled clinical trial of candesartan for prevention of retinopathy, we studied patients with type 2 diabetes and normoalbuminuria (n=792), followed for a mean of 4.7 years. We address the predictive value of urinary exosomal gelatinase and ceruloplasmin expression based on urine and blood assessed at recruitment of 273 urinary peptides (CE-MS). We also assessed the possibility of a new EYEscore based on discriminative features chosen out of 1161 peptides in a training set of 528 patients. Progression were either 2 step (E2) (primary) or 3 step (E3) (change in retinopathy on the concatenated Early Treatment Diabetic Retinopathy Study severity scale).

Results: Progression of retinopathy was seen in 37% of E2 and 19% of E3 patients. None of the peptides were significantly differently expressed in cases vs control. In Cox models five peptides were associated with E3 but not E2 in the training set but were not validated. The CKD classifier was able to predict E3 (HR 1.54 95% CI 1.02 to 2.13, p=0.042) but not E2 (HR 1.14 p=0.34) during follow-up, independent of treatment (candesartan/placebo), age, gender, systolic BP, baseline UAER, baseline eGFR, HbA1c, and diabetes duration.

Conclusions: In this cohort of patients with type 2 diabetes and normoalbuminuria from a large intervention study, the CKD classifier was an independent predictor of severe but not mild progression in retinopathy. It was not possible to develop a retinopathy specific marker panel with clinically relevant accuracy.

FR-PO608
Urinary Exosomal Analysis Reflects Underlying Kidney Pathology Better Than Whole Urine Analysis
Kristofamurthy P. Gudehithlu, Ignacio Garcia-Gomez, Jane Vernick, Carolyn S, Brodin Min, Mark A. Krane, Javid J. Cimbulaik, Peter D. Hart, George Dunea, Jose A. L. Arruda, Ashok K. Singh, Div of Nephrology, John H. Stroger, Jr. Hospital of Cook County, Chicago, IL; Dept of Internal Medicine, Rush Univ Medical College, Chicago, IL; Section of Nephrology, Univ of Illinois at Chicago, Chicago, IL; The Hektoen Inst of Medicine, Chicago, IL.

Background: Predicting or diagnosing underlying kidney pathology by analyzing whole urine has remained unrealized. This is because whole urine mostly represents proteins from the plasma and little from the kidney. Urinary exosomes, on the other hand, being kidney-derived, contain proteins of the kidney. We experimentally tested the hypothesis, ‘urine exosomal proteome more truly represents the underlying pathology of kidney disease than a whole urine based analysis.’ Comparison between whole urine and urine gelatinase and ceruloplasmin, two kidney disease markers, was performed on normal and diabetic kidney disease patients.

Methods: Urinary exosomes were separated from urine by ultra-centrifugation. Gelatinase, an enzyme which measures matrix degrading activity collectively from whole urine and exosomes (mainly MMP-2, 9) was measured using fluorosceinated gelatin as the substrate, and ceruloplasmin, an oxido-reductase enzyme involved in iron metabolism, was measured by sandwich ELISA. Biopsies were immunostained for MMP-9 and ceruloplasmin.

Results: We found that changes in both, gelatinase (decreased activity; 20-50%; p<0.05) and ceruloplasmin (increased levels; 300%; p<0.05), in the urinary exosomes of diabetic kidney patients were in agreement with the alterations of these two proteins in the kidney tissue as judged by immune-staining. In contrast, the levels of these two proteins in the whole urine were highly variable (p>NS) and in disagreement with the results of immune-staining.

Conclusions: In conclusion, our findings support our hypothesis that protein markers found in urinary exosomes better reflect the changes in the kidney than protein measurements carried out in whole urine samples.

FR-PO609
Neutrophil Gelatinase Associated Lipocalcin as an Early Biomarkers of Nephropathy in Diabetic Patients and Effect of RAAS Blockade on NGAL as Marker of Tubular Damage in Diabetic Nephropathy
Anupama Kaul, Dharmendra Bhaduria, Narayan Prasad, Amit Gupta, Raj K. Sharma, Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, India.

Background: T2DM is the primary cause leading to kidney disease. Novel, more sensitive biomarkers that may be used to detect diabetic nephropathy at an early stage, and possibly also detect disease progression or regression after drug therapy.

Methods: 150 Diabetic patients were enrolled in the study from nephrology and endocrinology OPD at Sanjay Gandhi Post Graduate Institute Of Medical Sciences, Lucknow India from 2012-14, 50 each of normo-, micro- and macroalbuminuric with 50 normal healthy control. Serum NGAL and cystatin C were measured at enrollment and after 12-15 months. ACEI as intervention was given in all normo hypertensive ,microalbuminuric and macroalbuminuric Diabetics. After follow up period 1 year repeat NGAL levels assessment. Normoalbuminuric ,normotensive individuals with raised NGAL at the baseline and follow up after 1 year were assessed.

Results: As compared to control population the normoalbuminuric Diabetics had higher levels as well as urinary NGAL levels but lesser than microalbuminuria.Mean NGAL levels were not significantly different between Normoalbuminuric and diabetics. At re-evaluation, mean NGAL value and mean eGFR value in patients with diabetes had increased (p=0.078 and p=0.006 respectively). At both baseline and reevaluation, NGAL positively correlated with cystatin C (p<0.001) and creatinine (p<0.010). NGAL correlated negatively with eGFRr (r= -0.26, p=0.049). Among micro,macroalbuminuric diabetes the baseline urine albumin excretion rate was significantly correlated with the rate of eGFR
Mechanism of Increased Urinary Full-Length Megalin Excretion in Type 2 Diabetes Mellitus Patients with Nephropathy

Shankhait Dey, Shoji Kuwahara, Michihiro Hosozuma, Tomomi Ishikawa, Ryoho Kasada, Yusuke Yoshida, Ichieti Narita, Takahiro Ochiya, Akibiko Saito, Clinic Nephrol & Rheumatol, Niigata Univ, Niigata, Japan; Applied Mol Med, Niigata Univ, Niigata, Japan; Clinic Nutr Sci, Niigata Univ, Niigata, Japan; Mol & Cell Med, NCCRI, Tokyo, Japan; Health Admin Center, Niigata Univ, Niigata, Japan.

Background: Megalin, an endocytic receptor of proximal tubule cells (PTCs), is excreted into urine in both of the extracellular domain and the full-length forms. Previously we developed urinary ELISA systems to measure the two forms of megalin and found that the excretion of the full-length form, mainly present in the insoluble urinary fraction, may be a candidate biomarker for the progression of diabetic nephropathy (DN). We thus aimed to investigate the molecular mechanism of urinary excretion of the full-length form of megalin.

Methods: Megalin content of urinary extracellular vesicles (EVs) from normal control and type 2 diabetes mellitus (T2DM) patients with different albuminuria stages were measured by western blotting. By immunoelectron microscopy and Nanoparticle Tracking Analysis using NanoSight®, we characterized the size and number of the EVs. To study increased EVs' excretion in vitro, we cultured immortalized rat proximal tubule cells (IRPTCs) and treated with advanced glycation end products-modified bovine serum albumin (AGEs).

Results: The number of urinary EVs' excretion is increased in T2DM patients in comparison with the normal control subjects in a correlation with the progression of DN. By immunoelectron microscopy we found that megalin is excreted through the smaller vesicles which are likely to be excreted through AQP5 and AQP2, expressed at the plasma membrane, thus allowing their quantitation in urine samples.

Conclusions: Exocytosis-mediated urinary excretion of full-length megalin via exosomes might be a useful biomarker for early detection and progression of DN.

Funding: Government Support - Non-U.S.

Urinary Neutrophil Gelatinase-Associated Lipocanal as Complementary to Albuminuria Biomarker of Early Stage Diabetic Kidney Disease in Type 2 Diabetes

Agnieszka Galu-Bladzinska, Paulina Dumnicka, Agnieszka Zylka, Beata Kustierz-cabala, Marek Kuzniewski, St Queen Jadwiga District Hospital No 2, Rzeszow, Poland; Dept of Medical Diagnostics, Jagiellonian Univ Medical College, Krakow, Poland; Dept of Diagnostics, Chair of Clinical Biochemistry, Jagiellonian Univ Medical College, Krakow, Poland; Dept of Nephrology, Jagiellonian Univ Medical College, Krakow, Poland.

Background: Two clinical phenotypes of diabetic kidney disease (DKD) have been reported, i.e. with or without increased albuminuria. The aim of this study was to assess the usefulness of uNGAL for the preclinical diagnosis of DKD in the course of diabetic mellitus type 2 (DM2).

Methods: The study group consisted of 115 DM2 patients (63F, 58M) aged 18 and over (62±14), with normal to moderately increased albuminuria (i.e. urine albumin/creatinine ratio (UACR) <300 mg/g) and eGFR (CKD-EPI) ≥60ml/min/1.73m. Control group included 22 non-diabetic persons with comparable age (57±14; p=0.1) and sex (9F, 13M; p=0.5), and with similar comorbidities. Urine concentrations of uNGAL, albumin and creatinine (uCr) were measured in the first morning urine sample. Urine albumin/creatinine ratio (UACR), and analogically, uNGAL/uCr were calculated.

Results: In control group, maximum UNGAL/uCr was 39.64 μg/g. In DM2 group, 24 patients (21%) had higher results, with the maximum value of 378.6 μg/g. Twenty three (20%) of DM2 patients had UACR >30 mg/g; of those, 11 had uNGAL/uCr >39.64 μg/g. Among patients with uNGAL/uCr >39.64 μg/g, 13 did not have markedly increased albuminuria (UACR in those patients ranged from 2.35 to 16.10 mg/g). Women with DM2 had significantly higher uNGAL/uCr than men (median 28.06; IQR 9.55-65.60 versus 11.40; 3.36-18.02 μg/g; p=0.001), without significant difference in UACR (p=0.09). uNGAL/uCr in DM2 patients correlated significantly with Hba1C (R=0.28; p<0.013), however, it did not correlate with eGFR (R=0.54; p=0.1), age (R=0.14; p=0.1), or time from DM2 diagnosis (R=0.13; p=0.1).

Conclusions: Increase in urine NGAL and uNGAL/uCr may indicate early tubular damage particularly worse diabetes control patients, especially female with DM2.

The Expressions of Vitamin D and Its Receptor in Patients with Diabetes Associated with Proteinuria and Diabetic Nephropathy

FR-PO615

**Methods**: The prospective follow-up study; 114 diabetes patients were followed for 5.0 ± 1.1 years. Patients were divided at baseline into three groups according to their urinary albumin-to-creatinine ratio (UACR): 68 patients with normoalbuminuria (UACR < 30 mg/gCr), 31 patients with microalbuminuria (30 mg/gCr ≤ UACR < 300 mg/gCr), and 17 patients with macroalbuminuria (UACR ≥ 300 mg/gCr). Progression of albuminuria was the main outcome. Omentin was measured by ELISA, and the values were adjusted for age, BMI, and sex before analysis.

**Results**: Progression either to the next albuminuria level in 16 patients or to end-stage renal disease (ESRD) occurred in 5 patients. No difference in adiponectin concentrations was observed between progressors and nonprogressors in patients with normoalbuminuria. In the patients with microalbuminuria and macroalbuminuria, progression of albuminuria was associated with higher omentin. Progression to ESRD was also associated with estimated glomerular filtration rate (eGFR). When these covariates were included in a Cox regression analysis, eGFR and omentin were significantly associated with progression of albuminuria.

**Conclusions**: Increased serum omentin levels predict the progression from microalbuminuria to macroalbuminuria and progression of albuminuria was associated with higher omentin. Progression to ESRD was also associated with estimated glomerular filtration rate (eGFR). When these covariates were included in a Cox regression analysis, eGFR and omentin were significantly associated with progression of albuminuria.

The Firts Affiliated Hospital of Zhengzhou Univ, Zhengzhou, Henan, China.

**Background**: Vitamin D receptor (VDR) is a member of the nuclear receptor superfamily, and there was no report about the expression of Vitamin D and its receptor in patients with diabetes associated with proteinuria and diabetic nephropathy. So, this study aimed to test the expression trends of VDR in blood, urine specimens and renal tissues of diabetic nephropathy patients, and the relationship with urinary protein, to explore the role of VDR in diabetic nephropathy.

**Methods**: 1. 65 patients who had been diagnosed with T2DM (with or without albuminuria) were enrolled in this study and 25 healthy control subjects were enrolled (NC group). The patients were classified according to the ratio of urinary excretion of albumin/creatinine (ACR). Diabetic patients without proteinuria (DM group, ACR: less than 30 mg/g, n = 25), with microalbuminuria (DN group, ACR: 30 to 300 mg/g, n = 24) and clinical proteinuria (DN2 group, ACR: more than 300 mg/g, n = 18). 2. The expressions of VD and VDR levels in the plasma and urine supernatant were measured by ELISA, and the VDR in blood cells was measured by qRT-PCR. The expressions of VD in kidney tissue were measured by immunohistochemical staining.

**Results**: Plasma VD and VDR levels were significantly lower in DN2 and DN3 groups as compared with NC group (plasma VD 0.78±0.24 and 0.88±0.29 vs. 2.32±1.33 mg/ml P<0.05, VDR 157.52±98.36 and 164.20±64.50 vs. 325.33±194.68 mg/ml P<0.05).[cite2] Urinary VD and VDR levels were significantly elevated in DN2 and DN3 groups as compared with NC group (urinary VD 1.34±0.58 and 1.42±0.44 vs. 1.18±0.56 mg/ml P<0.05, VDR 83.60±31.78 and 88.40±28.10 vs. 60.93±12.03 mg/ml P<0.05). The expressions of VD in kidney tissue in DN groups were obviously lower than those in control groups, differences were statistically significant (P<0.05).

**Conclusions**: These results verify that VDR declined with the increase of the amount of urine protein. Based on these results, VDR may play a role of renal protection in diabetic nephropathy.
FR-PO619
Macrophage Accumulation and Phenotype in Human Diabetic Nephropathy

Ying Yang, Yinfeng Guo, Zhihia Song, Min Zhou, Xiaoiaoning Zhang. **Southeast Univ.**

**Background:** Macrophage, especially its distinct phenotype is involved in the progress of DN. M1 is characterized with pathogenic function, while M2 displays anti-inflammatory. This study tries to examine the macrophage phenotype and its relationship to the renal function and histological changes in human DN.

**Methods:** We studied retrospectively 46 patients with DN who were confirmed by diagnosis of renal biopsy. Biopsies were divided into I Ha Ib III IV classes according to the pathologic classification of DN. Patients with renal trauma or renal tumor were considered as control group. Serum creatinine, proteinuria were calculated. Kidney tissues were used to assess histological changes and the presence of macrophage marker CD68, M1 marker iNOS, M2 marker CD206, Arg-1, TREM1 and TREM2.

**Results:** In biopsy renal tissue of human DN, Expression of CD68, M1 were significantly increased in the glomeruli (2.835±1.045/gcs VS 1.203±0.547/gcs for normals P<0.031; 2.330±1.343/gcs VS 0.896±0.548/gcs for normals P=0.046) and interstitium (0.037±0.142%area VS 0.019±0.02%area P=0.016; 0.018±0.08%area VS 0.009±0.05%area P=0.023). While M2 were mainly observed in the interstitium (0.019±0.008%area VS 0.010±0.004%area P=0.038). Interstitium M2 correlated strongly with interstitium M1 infiltration. Additionally there was a positive correlation between the glomerular CD68, M1 numbers and serum creatinine (r=0.619, p=0.001; r=0.463, p=0.017), proteinuria (r=0.641, P=0.000; r=0.508, P=0.008), mesangial matrix, interstitial collagen deposition. Likewise, the expression of interstitial CD68, M1, M2 also correlated strongly with serum creatinine (r=0.638, P=0.000; r=0.606, P=0.001; r=0.520, P=0.006), proteinuria (r=0.749, P=0.000; r=0.651, P=0.000; r=0.694, P=0.000), mesangial matrix, interstitial collagen deposition. Besides TREM1,2-positive cells were apparent in the interstitium and the expression levels significantly correlated with interstitium M1,M2 expression respectively.

**Conclusions:** Macrophage infiltration and polarization participate in the development of diabetic nephropathy.

FR-PO620
Risk of Diabetes Increased According to the Level of Urinary Albumin Excretion Even Within Normal Range

Dong-Yong Lee, Beom Kim, Kyoung Hyoub Moon, Kyoung Hyoub Moon, Sung Keun Park, Younjo Jung. **Internal Medicine, VHIS Medical Center, Seoul, Republic of Korea:** Total Health Care Center, Kangbuk Samsung Hospital, Sanggyunkwan Univ, School of Medicine, Seoul, Republic of Korea.

**Background:** Urine albumin creatinine ratio (UACR) as a reliable index of urinary albumin excretion is getting great attention on its predictive role for various diseases related with diabetes. Nevertheless, predictive value of UACR within normal range was not clarified for diabetes yet. Therefore, this study was aimed at examining the clinical association between normal range of UACR and development of diabetes.

**Methods:** We identified 1,274 non-diabetic Korean men within normal range of UACR in 2005, and followed them up until 2010. All subjects were classified into three categories corresponding to normal range of UACR and development of diabetes.

**Results:** During follow-up, diabetes developed in 97 out of 1,274 subjects (7.6%). Incidence rate of diabetes increased in proportion to the levels of UACR (tertile 1: 4.9%, tertile 2: 7.3%, tertile 3: 10.6%, P<0.001).

**Conclusions:** Elevated UACR, even within normal range, was significantly associated with the future development of diabetes.

FR-PO621
Albuminuria Is Positively Associated with Elevated Numbers of Circulating Endothelial Pre- and Mature Cells, but Inversely Associated with Circulating Fibrocytes

Tine Hansen, Bernt Johan Illum von Scholten, Alexander Rosendahl, Regine Berghold, Peter Rosing. **Steno Diabetes Center, Gentofte, Denmark; ’Novo Nordisk A/S, Målev, Denmark.**

**Background:** Diabetic nephropathy is characterized as a microvascular disease with enhanced vascular leakiness in the kidney and aberrant tissue remodelling. Abnormal number and function of endothelial cells, stem cells and activation of leukocytes is considered as contributing mechanisms to the “kidney-micro”-vascular leaky syndrome. We determined if circulating endothelial pre- and mature cells, fibrocytes or monocyte sub-populations were abnormally regulated in type 2 diabetic patients with albuminuria.

**Methods:** Cross-sectional study of 37 type 2 diabetic patients; 18 with normalalbuminuria (<30mg/24h) and 19 with albuminuria (30mg/24h). 8-color flow cytometry analysis of peripheral blood was performed. ANCOVA compared expression of cell markers and absolute number of specific cell populations in patients with normoalbuminuria vs. albuminuria.

**Results:** Expression of VEGFR2 was significantly enhanced in patients with albuminuria (p=0.009). Also, the total number of circulating mature endothelial cells (CEC) was significantly enhanced in albuminuria (p=0.001). Circulating fibrocyte number and collagen-1 expression was inversely associated with albuminuria (p=0.037) and TGFbeta stabilizing and M2-associated galectin-3 expression on M1-like and M0-like monocytes was positively associated with albuminuria (p=0.029). In contrast, expression of the M1-associated marker CD11c (p=0.042) was inversely associated with albuminuria on all monocytes, particularly on M0-like macrophages (p=0.014).

**Conclusions:** The enhanced number of CEC together with elevated expression of VEGFR2 may indicate an aberrant function of the CEC with reduced capacity to seal the kidney microvascular disease. The imbalanced M2-polarization of monocytes and aberrant fibrocyte count may favour improper repair leading to excessive tissue fibrosis. Hence therapeutic approaches addressing migratory pattern of CEC, providing adjuvant activating signals or restoring the immune balance might provide novel individualized treatment regimes.

**FR-PO622
Prognostic Value of Tubulointerstitial Lesions and Urinary N-Acetyl-b-D-Glucosaminidase in Patients with Type 2 Diabetes and Biopsy-Proven Diabetic Nephropathy

Koki Hoshino, Tatsuya Suwabe, Kenmei Takaichi, Yoshifumi Ubara. **Nephrology Center, Toranomon Hospital Kajigaya, Kavasaki, Kanagawa, Japan; ‘Nephrology Center, Toranomon Hospital, Tokyo, Japan.**

**Background:** Recently, it has been reported that some biomarkers of renal tubular injury are useful to predict the renal prognosis in the early stage of diabetic nephropathy (DN). However, how closely such biomarkers reflect actual tubulointerstitial damage remains unknown.

**Methods:** Among 210 patients with type 2 diabetes and biopsy-proven DN, 152 patients were enrolled, 89% of whom had overt proteinuria. The endpoint was defined as a 50% or more decrease of the estimated glomerular filtration rate (eGFR) from baseline to the outcome even after adjustment for those covariates (+1 for IFTA score, HR: 2.20 [95% CI: 1.50-3.21]). On the other hand, the IFTA score was significantly related to the outcome even after adjustment for those covariates (+1 for IFTA score, HR: 0.87 [95% CI: 0.66-1.13]). On the other hand, the IFTA score was significantly related to the outcome even after adjustment for those covariates (+1 for IFTA score, HR: 2.20 [95% CI: 1.50-3.21]).

**Results:** A significant correlation was found between baseline urinary N-acetyl-b-D-glucosaminidase (NAG) excretion and the score for interstitial fibrosis and tubular atrophy (IFTA score) (r=0.39, P=0.001). The influence of urinary NAG on the renal prognosis was attenuated after adjustment for known promoters of progression (+1SD for log NAG, HR: 0.87 [95% CI: 0.66-1.13]). On the other hand, the IFTA score was significantly related to the outcome even after adjustment for those covariates (+1 for IFTA score, HR: 2.20 [95% CI: 1.50-3.21]).

**Conclusions:** The assessment of urinary NAG excretion did not improve the prognostic power of known indicators of progression, whereas the IFTA score did. The IFTA score may be more useful for predicting the renal prognosis than current tubulointerstitial markers, especially in patients with advanced DN.

Is There Any Benefit of Performing Renal Biopsies in Patients with Diabetic Nephropathy when No Other Diagnosis Than Diabetic Nephropathy Is Found?

Rosa M. Montero,1 Dimitrios Anestis Moutzouris,2 Ranmith Perera,2 David Goldsmith.1  
1Nephrology & Transplantation, Guy’s & St Thomas’ NHS Foundation Trust, London, United Kingdom; 2Histopathology, Guy’s & St Thomas’ NHS Foundation Trust, London, United Kingdom.

**Background:** The risk of renal biopsy has long been thought to outweigh the benefit of performing these on patients with diabetes mellitus (DM) leading to small numbers of renal biopsies in this population. Those biopsied have a propensity to more proteinuria or haematuria precipitating biopsy. Glomerular lesions alone have long been the hallmark of diabetic nephropathy (DN) however looking back at the biopsy can there be more to see?  

All native renal biopsies diagnosed with DN from 2009-2014 were retrieved from archive at Guy’s & St Thomas’ NHS foundation trust. Renal biopsies were performed in patients with DM who had heavy proteinuria or haematuria on presentation. Biopsies with a DN diagnosis alone were identified and Tervaert’s new DN classification was applied. Clinical outcome data was collected from electronic patient records. Cox regression models were used to perform statistical analysis.  

**Results:** 3000 native kidney biopsies were performed from 2009-2014. 34 DM patients had DN alone on renal biopsy, 12 T1DM and 22 T2DM. 20 male, 14 females. Ethnicity: 35% white, 35% black, 3% asian, 27% other. Age range: 24-86 years (median 55). UPCR: 13.492 mg protein/mmol creatinine (median 392) eGFR: 7-74.9 (median 23). 8.8% 5 year mortality. Glomerular IV and Interstitial fibrosis III lesions were significant predictors of mortality. Glomerular IV and Interstitial fibrosis III lesions were significant predictors of mortality. Glomerular IV and Interstitial fibrosis III lesions were significant predictors of mortality.  

**Conclusions:** Interstitial fibrotic lesions are as important as glomerular lesions in predicting renal survival. Determining the significance of the compartments in predicting outcome may be more sensitive; however few biopsies are undertaken in this population. The role of an earlier renal biopsy showing less well established features in the DN population that could be reversed may need to review our practice unless sensitive and specific biomarkers are found to correlate with the underlying histopathology.

Understanding the Relationship Between Histopathology and Renal Function in Hypertension and Diabetes

Matthew Palmer,1 Jordana B. Cohen,2 Mandy Liang,2 Steven S. Pullen,2 Katalin Suszka.1  
1Pathology, Univ of Pennsylvania, Philadelphia, PA; 2Nephrology, Univ of Pennsylvania, Philadelphia, PA; 3CardioMetabolic Research, Boehringer Ingelheim, Ridgefield, CT.

**Background:** Much of the literature relating clinical and pathologic variables in patients with diabetes mellitus (DM) and hypertension (HTN) has relied on biopsy series. To gain unbiased insight into the degree of interstitial fibrosis (IF) and glomerular sclerosis (GS) associated with decline of renal function in DM and HTN, we have correlated histopathology with renal function, DM and HTN status in patients undergoing tumor nephrectomies.  

**Methods:** Data and renal tissue were collected on nephrectomy patients from 7 centers. We used Spearman correlation coefficients to compare eGFR with pathologic assessment of IF and GS (manual count). Bivariate linear regression was used to test the association between log-transformed percent IF or GS and eGFR, stratifying by presence of DM or HTN.  

**Results:** Of 251 patients, there were 60 without DM or HTN, 89 with HTN alone, and 102 with DM (+/- HTN). Median age was 62, 42% were female, 60% were Caucasian, median systolic blood pressure was 134 mmHg, and median eGFR was 66.5. There was a significant association between decline in eGFR and both IF (rho=-0.50, p<0.01) and GS (rho=-0.53, p<0.01). eGFR of 60 was associated with a geometric mean (95% CI) IF and GS of 7.3% (5.1-10.3) and 8.3% (5.7-12.1) for patients without DM or HTN, 9.2% (7.5-11.2) and 9.9% (8.1-12.1) for patients with DM or HTN, and 10.9% (8.8-13.5) and 9.6% (8.0-11.6) for patients with DM and HTN. Stage 3 CKD was associated with a median IF and GS of 10% (IQR 8.7-10.8) for patients with HTN, and 10.9% (8.8-13.5) and 9.6% (8.0-11.6) for patients with DM. Stage 3 CKD was associated with a median IF and GS of 10% (IQR 5-15) and 11.3% (IQR 5.7-18.8) overall, and with median IF and GS of 10% (IQR 5-20) and 11.9% (IQR 5.7-20.8) in DM.  

**Conclusions:** While IF and GS are similar at a given eGFR, patients with DM have a trend toward a greater degree of IF and GS at the same level of eGFR compared to those with isolated HTN. Stage 3 CKD is associated with median IF of 10% though there is high inter-individual variation. This highly variable histopathology should be considered when patients with DM are included into clinical studies, and kidney biopsies might be useful to include in categorization.

Efferent Arterioles Are Special Target for Obesity

Noriiko Usugi, Michio Nagata.  
Kidney and Vascular Pathology, Faculty of Medicine, Tsukuba Univ, Tsukuba, Ibaraki, Japan.

**Background:** The link between obesity and renal disease is unclear. Hyperfiltration is suspected to induce arteriolar hyalination and glomerular hypertrophy in moderate to severe obesity. To assess morphological changes in the outer circle, we investigate human normal renal tissue from 7 mild obese cases (Ob)(BMI 27) and 3 lean cases (Le)(BMI 19) with hypertension and compared with 7 hypertensive case (HT) and 4 control(Con).  

**Methods:** Total 130 of serially cut paraffin sections were double immunostained with CD34 as endothelial marker, and smooth muscle actin as medial marker, followed by PAS stain. Incidence of hyalinosis in afferent and efferent arterioles, intraglomerular cystic dilation connecting to efferent arterioles, segmental sclerosis, sclerotic glomeruli(GS) and average size of glomeruli were assessed using 30-40 glomeruli per case.  

**Results:** The morphological data were as follows; average glomerular diameter 203±26, 181±19, 156±14 um, incidence of arteriolar hyalinosis 43±13%, 47±29%, 20±16% in control, respectively (*P=0.05 vs Con, **P=0.05 vs Con and HT). Higher incidence of cystic dilatation near efferent arterioles was noticed in Ob (21±15%) than HT and Con (2±15%, 0%, respectively(**P=0.05). Obese cases revealed neither significant intimal thickening nor distortion in the interlobular arteries, no segmental sclerosis, low incidence of GS (11%) and minimal interstitial damage(<10%).  

**Conclusions:** Efferent arterioles are targets for obesity, which suggest that specific mechanism of glomerular hyperfiltration involves obese cases, even in mild form.  

**Funding:** Government Support - Non-U.S.

A Pathological Scoring System to Predict Renal Outcome in Diabetic Nephropathy

Junichi Hoshino, Koki Mise, Toshiharu Ueno, Keichi Sumida, Masayuki Yamanouchi, Noriko Hayami, Tatsuya Suwabe, Shigeko Hara, Yoshifumi Ubara, Kenmei Takaichi, Nephrology Center, Toranomon Hospital, Tokyo, Japan.

**Background:** With association between diabetic nephropathy (DN) and renal outcome increasingly clear, we aimed to create a new DN pathological scoring system that could predict renal outcome.  

**Methods:** We studied 205 patients with DN confirmed by renal biopsy between March 1998 and January 2010 who met inclusion criteria. Renal biopsy included clinical parameters and Tervaert classifications. Hazard ratios (HRs) for end-stage renal disease (ESRD) were estimated by adjusted Cox regression. Overall pathological risk score (D-score) was calculated by summing the products of beta-coefficient and bootstrap-inclusion fractions, its predictive utility evaluated by Kaplan-Meier methods and c-statistics with 10-fold cross-validation for the year of risk of ESRD.  

**Results:** D-scores of glomerular classes 1, 2A, 2B, 3, and 4 were, respectively, 0, 3, 4, 6, and 6. Those of interstitial fibrosis and tubular atrophy classes 0, 1, 2, and 3 were 0, 7, 9, and 11, and those of interstitial inflammation classes 0, 1, and 2, respectively, 0, 3, and 4. D-score of hyaline class 2 was 3 and that of arteriosclerosis class 2 was 1. So a patient’s D-score could be 0-25.

**HRs for ESRD in patients with D-score £14, 15-18, 19-21, and 22-25 were, respectively, 1.00 (ref) (1.61) (1.84-1.90), 19.78 (2.15-182.40), and 45.46 (4.63-446.68) after adjusting for clinical factors. When comparing c-statistics, a model that included D-score in addition to age, eGFR, and proteinuria, showed a slight improvement from 0.901 (0.861-0.942) to 0.932 (0.898-0.965). The net reclassification index also showed better reclassification (0.24 <0.02 to 0.49).”  

**Conclusions:** In addition to clinical parameters, D-score may have improved prediction of 10-year risk of ESRD. Patients with D-score £14 had excellent renal prognosis.  

**Funding:** Private Foundation Support
Methods: A total of 396 patients with T2D and biopsy-proven DN from Nanjing DN registration system who were followed-up for at least 1 year were recruited and median 5-year follow-up. Renal outcomes were defined by progression to end-stage renal disease and doubling of serum creatinine.

Results: Of the participants, the mean baseline eGFR was 73.86 ± 33.52 mL/min per 1.73 m². The levels of the urinary tubularinterstitial injury markers including the NAG, RBP and NAGL were significantly different among quartiles of serum phosphorus (P < 0.01). The participants whose eGFR >90 mL/min per 1.73 m² had a higher rate of tubulointerstitial injury (interstitial fibrosis tubular atrophy scores of 2 and 3, P = 0.005; interstitial inflammation scores of 1 and 2, P = 0.035) in hyperphosphatemia (>1.45 mmol/L) group than in lower phosphorus group (<1.17 mmol/L). Participants with baseline levels of serum phosphorus in higher quintiles had a higher cumulative incidence of ESRD (log-rank, P < 0.01). In the analyses adjusted by age, sex, diabetes status, BP, FBG, BMI, proteinuria, cholesterol, and eGFR, the relationship between higher serum phosphorus and an increased risk of ESRD remained. The association between serum phosphorus and ESRD risk persisted and was stronger when the sample was restricted to those with a baseline eGFR equal to 60-90 mL/min per 1.73 m², but not when it was restricted to patients with a baseline eGFR of 30-60 mL/min per 1.73 m².

Conclusions: These findings indicated the baseline serum phosphorus is associated with tubulointerstitial injury of T2DN patients. And serum phosphorus >1.45mmol/L is an independent risk factor of ESRD in T2DN, especially in the patients with eGFR>60 mL/min per 1.73 m².

Longitudinal Changes in Estimated Glomerular Filtration Rate in Youth with Type 1 Diabetes: Insights From the SEARCH for Diabetes in Youth Study

McClain, T.D., Wieschogle, G., Fino, M., Afrakian, D., Maahs, A., Mott, A.F. for the SEARCH for Diabetes in Youth Study; 1Univ of North Carolina; 2Wake Forest School of Medicine; 3Univ of Washington; 4Univ of Colorado Denver.

Background: Diabetes is the leading cause of kidney disease in the US. The natural history of kidney function early in type I diabetes (T1D) is relatively unknown.

Methods: SEARCH for Diabetes in Youth is a multicenter cohort study of incident diabetes in youth <20 yrs at diagnosis. Cystatin C (CysC) was measured at two study visits; values were calibrated for assay drift and standardized to the reference material. GFR was estimated using the CysC-based Filler equation, the only pediatric equation validated in hyperfiltration. Participants were stratified by change in eGFR: gain of >3.5 mL/min/1.73m², loss of >3.0 mL/min/1.73m², or stable. Nominal multinomial regression was used to predict eGFR gain vs stable, eGFR loss vs gain, and no albuminuria. Multivariate logistic regression analysis was performed to determine risk factors, including DR, associated with DN in the Korean population.

Results: Among the 971 DM patients, the prevalence of microalbuminuria was 93.3% and that of macroalbuminuria was 5.5%. The prevalence of eGFR <60 mL/min/1.73m² was 9.1%, and half of those were nonproteinuric DKD. We observed a prevalence of 20.0% for DR and 3.8% for proliferative DR/PDR. Multiple logistic regression analysis revealed that HbA1c ≥7.5% (OR = 1.24; 95% CI = 1.12–1.39), and PDR (OR = 2.80; 95% CI = 1.32–5.96) were independent risk factors associated with diabetic kidney disease, and the older age [adjusted odds ratio (aOR) = 1.19; 95% confidence interval (CI) = 1.09–1.31] and the presence of hypertension [aOR = 5.90; 95% CI = 1.37–22.71] were significantly associated with nonproteinuric DKD.

Conclusions: Nonproteinuric renal dysfunction in type 2 DM is not rare. PDR is associated with proteinuric DKD, however, DR and PDR are not significantly associated with nonproteinuric DKD.

FR-PO629

A Cross-Sectional Study for Evaluating the Diagnostic Accuracy of Cystatin C and N-Acetyl β-D Glucosaminidase in Predicting Diabetic Nephropathy

Background: Diabetic nephropathy (DN) is classified into V stages. Amongst which, stage I and II reclassifies proximal tubule damage, stages III and IV in stage III reclassifies irreversible glomerular damage stages. The inability of creatinine and microalbuminuria to detect early reversible stages urges the necessity of new efficient diagnostic biomarkers. Thus, we have selected proximal tubule originated proteins, cystatin c (cyst c) and N-acetyl β-D Glucosaminidase (NAG) to study their efficacy in detecting early manifestations of DN.

Methods: Uriminary serum cyst c and NAG were estimated in total 491 age-matched patients enrolled for our cross-sectional study. Their efficacy was compared with urinary microalbuminuria, serum creatinine and eGFR in patients with varying type 2 diabetes (T2DM) duration and various stages of DN.

Results: Patients with 5-10 years of T2DM duration showed a significant increase in cyst of proteinuria. However, urinary NAG increased in DN in patients with varying type 2 diabetes duration. The ROC curve signifies diagnostic efficacy of urinary cyst c (AUC 0.820) over urinary NAG (AUC 0.678), in detecting T2DN patients susceptible to develop DN.

Figure 1: Comparison of urinary Cystatin c and NAG in various groups

Conclusions: Urinary cyst c in comparison to urinary NAG plays a significant role in predicting the early renal decline in T2DM patients with varying duration of diabetes. Furthermore, the presence of such low molecular weight protein and renal origin enzyme indicates pathogenesis of proximal tubule in early stages of DN.

The Relationship Between Diabetic Retinopathy and Diabetic Kidney Disease in a Population-Based Study in Korea (KHNANES V2-3)

Min-jong Lee,1,2 Won-jun Lee,1,3 Seiran Kim1,4,5 Gyu Tae Shin,1,2 Heungsoo Kim,1,6,7 Dept of Nephrology, Ajou Univ School of Medicine, Suwon, Republic of Korea; 2Dept of Ophthalmology, 102 Replacement Depot, Republic of Korea Army, Chancheon, Republic of Korea.

Background: Previous studies of the association between diabetic kidney disease (DKD) and diabetic retinopathy (DR) used only albuminuria/proteinuria as chronic kidney disease (CKD) markers and, hence, did not consider eGFR. This study aimed to evaluate the prevalence of DKD and the association between DKD, as evaluated by both proteinuria and eGFR, and DR in the large cohort of patients with type 2 diabetes from the Korean National Health and Nutrition Examination Survey (KNHANES).

Methods: From the fifth (2011, 2012) KHNANES, 971 participants with type 2 diabetes were included. Selected samples were weighted to represent the entire civilian population in Korea. DKD was defined as diabetes with the presence of albuminuria and/or impaired GFR. Nonproteinuric DKD was defined as estimated glomerular filtration rate (eGFR) calculated by Modification of Diet in Renal Disease (MDRD) equation < 60 ml/ min/1.73m² and no albuminuria. Multivariate logistic regression analysis was performed to determine risk factors, including DR, associated with DN in the Korean population.

Results: Among the 971 DM patients, the prevalence of microalbuminuria was 93.3% and that of macroalbuminuria was 5.5%. The prevalence of eGFR <60 mL/min/1.73m² was 9.1%, and half of those were nonproteinuric DKD. We observed a prevalence of 20.0% for DR and 3.8% for proliferative DR/PDR. Multiple logistic regression analysis revealed that HbA1c ≥7.5% (OR = 1.24; 95% CI = 1.12–1.39), and PDR (OR = 2.80; 95% CI = 1.32–5.96) were independent risk factors associated with diabetic kidney disease, and the older age [adjusted odds ratio (aOR) = 1.19; 95% confidence interval (CI) = 1.09–1.31] and the presence of hypertension [aOR = 5.90; 95% CI = 1.37–22.71] were significantly associated with nonproteinuric DKD.

Conclusions: Nonproteinuric renal dysfunction in type 2 DM is not rare. PDR is associated with proteinuric DKD, however, DR and PDR are not significantly associated with nonproteinuric DKD.

Funding: Government Support - Non-U.S.

A Decrease in Blood Pressure During Follow-Up Is Associated with an Increased Risk of All-Cause Mortality in Patients with Type 2-Diabetes and Renal Impairment – The Swedish National Diabetes Register (NDR)

Hann Almgren,1,2 Stefan Franzen,1,2 Ann-marie Svensson,1 Bjorn Eliasson,1 Maria Svensson,1,2 Nephrology, Skaraborg Hospital, Skivle, Sweden; 3Center of Registers, Gothenburg, Sweden; 4Medicine, Sahlgrenska Univ Hospital, Gothenburg, Sweden.

Background: A U-shaped relationship between systolic blood pressure (SBP) and risk of all-cause mortality has been found in patients with type 2 diabetes (T2D) and renal impairment (RI). We here assess the association between time-dependent mean SBP, change in SBP during follow up and risk of all-cause mortality.

Methods: 27,322 patients with T2D and RI (eGFR<60 mL/min/1.73m² MDRD) classified into 10 mmHg intervals according to SBP at baseline were followed for 4.7 years. The risk of all-cause mortality was estimated using time-dependent mean SBP and change in SBP from last observation by time-dependent adjusted cox model. A smoothing spline describe the influence of mean SBP and the change in SBP on the hazard function.

Results: During follow-up 8265 deaths occurred. Using SBP 130-139 mmHg as a reference group a time-dependent mean SBP <130 mmHg was associated with increased risk of all-cause mortality in all (HR 1.28, 95% CI 1.20, 1.36) and in patients without
previously congestive heart failure (n=23 799) (HR 1.26, 95% CI 1.18, 1.36). In addition, a 25-50 mg/mL decrease in SHP from the last observation was associated with an increase in risk of all-cause mortality (HR 1.44, 95% CI 1.33, 1.56) compared to a change in the range -10 to 30 mmHg.

Conclusions: A systolic blood pressure < 130 mmHg and a decrease in systolic blood pressure during follow up with or without previous congestive heart failure, is associated with an increase the risk of all-cause mortality in patients with type 2-diabetes and renal impairment. Intensity of hypertensive medication and co-morbidities are important confounders and will be further evaluated.

FR-PO632

Increased Expression of WNT5a in Renal Tubules Is Associated with Diabetic Nephropathy in Humans, Malik Asad Anjum, An Xiao, Dean Troyer, Michael J. Solhaug, Anca Dobrian, Jerry L. Nadler, Liwei Huang, Internal Medicine, Eastern Virginia Medical School, Norfolk, VA; 2Pathology, Sentara Norfolk General Hospital, Norfolk, VA.

Background: Diabetic nephropathy (DN) is the leading cause of end stage renal disease worldwide. In recent years, convincing data has come forward suggesting that inflammatory pathways play a pivotal role in the pathogenesis and progression of DN. Identification of these inflammatory pathways and associated biomarkers may help in the early diagnosis of DN and development of novel targeted therapeutic strategies to help prevent, treat and even slow the progression of DN. Wnt5A, a secreted glycoprotein, plays an important role in normal kidney development and is also a pro-inflammatory factor which has been associated with renal fibrosis and disruption of matrix metabolism. The objective of our study was to investigate the expression of WNT5A in diabetic kidneys in humans.

Methods: 11 subjects with biopsy confirmed DN were included in our experimental group. Normal kidney tissues from non-diabetic subjects who underwent nephrectomy for renal cell carcinoma were used as controls. Exclusion criteria for the experimental group were HIV positivity, chronic/acute inflammatory diseases (including hepatitis C) and steroids/immunosuppressant medication. WNT5a expression was evaluated in paraffin embedded tissues.

Results: Immunohistochemical analysis of WNT5a expression showed positive staining on the apical side of the plasma membrane of the renal tubular epithelial cells in control kidney tissues. The intensity of the staining is increased in patients with DN compared to normal kidney control tissues. In patients with DN, WNT5a expression is localized both in the cytoplasm and on the apical side of the plasma membrane of the renal tubular cells. WNT5a is also expressed on glomerular cells, but there are no differences in Wnt5a expression between the tissues from diabetic subjects and controls.

Conclusions: Our results suggest that WNT5a expression in renal tubules might have a pathogenic role in the development of human renal tubular fibrosis. These studies are the first to demonstrate an increase in WNT5a expression in renal tubules in DN.

FR-PO633

Accuracy of Serum Creatinine and Glomerular Filtration Rate Estimation for Adjusting Metformin Prescription in European Type 2 Diabetics, Olivier Muranne, Coralie Fafin, Pierre Delanaye, Martin Flament, 1Nephrology, CHU, Nice, France; 2Nephrology, Hospital, Liege, Belgium; 3Physiology, APHP, Paris, France.

Background: There is a debate in the literature about the thresholds of serum creatinine (Scr) above which the drug is contraindicated (1.5 mg/dL in men & 1.4 mg/dL in women). For KDOQI, recommendation is a dose-adjustment between 45 and 30 mL/min and a withdrawal below 30 mL/min. However, in DM2, estimation of renal function based on Scr alone or on eGFR may vary from the true renal function (mGFR). The purpose of our study was to define the performance of the GFR assessment method (Scr or eGFR calculated with Cockcroft-Gault (CG) or CKD-EPI) in terms of metformin dose adjustment in DM2 who underwent a GFR measurement.

Methods: In 243 DM2 patients, GFR was measured by urinary clearance of ¹⁵⁃TcDTPA. Non indexed GFR was used. We analyzed the agreement between classification of patients based on mGFR and, first, Scr alone with a cutoff value of 1.5 mg/dL in men and 1.4 mg/dL in women, second, on eGFR with threshold values of 45 or 30 mL/min. When both methods classified the patient in the same subgroup, the data were considered concordant otherwise overprescription (underprescription) was defined for discordance according to mGFR.

Results: Age was 61 ± 12 y/o, median mGFR was 42 [30-61] mL/min. Based on mGFR, the distribution of the patients according the following GFR class: [90-45] 11045%), [44-30] 74(30%), < 30: 59(24%). In patients with a Scr above the cutoff value, mGFR(mL/min) was < 30 mL/min in respectively 23:40 women and 33:106 men. With a threshold of 45 mL/min then 30 mL/min, concordance was found in 80%85% then 8888% of the patients for the CG and CKD-EPI. With a threshold of 30 mL/min, discordance was an overestimation (or understimation) in 22%(9) and 19%(8) or (14%6) and 11%(5)% of the patients with the CG and CKD-EPI.

Conclusions: In this population creatinine-derived equations outperformed Scr alone in correctly classifying the patients in prescription subgroups. However, even with creatinine-based equations, discordance with mGFR occurs in 1220% of the patients. New strategies such as drug concentration monitoring may be necessary to improve appropriate prescription of metformin in DM2.

FR-PO634

Background: Change in albuminuria may have useful prognostic value. We sought to assess the association between change in urine albumin-to-creatinine ratio(UACR) and the risk of all-cause death, cardiovascular disease(CVD), and end-stage renal disease(ESRD) in the ADVANCE trial.

Methods: We defined UACR change(baseline to 2 years) as >30% decrease, <30% decrease to >30% increase(minor change); reference, and >30% increase. Follow-up for outcome ascertainment commenced at the second UACR measurement. We used Cox regression to estimate the hazard ratio(HR), after adjustment for demographics, ADVANCE randomized treatment assignments, comorbidities, laboratory measurements(including baseline UACR), and drug use.

Results: From baseline to 2 years, 34% of 9195 patients experienced a UACR decrease of >30%, 36% experienced a minor change, and 40% experienced an increase of >30%. Over the next 2.9 years(median), 526 deaths, 524 CVD events, and 12 ESRD events were recorded. An increase of >30% in UACR was associated with 30% higher mortality when compared to a minor change (Figure 1, HR 1.30, 95%CI:1.18-1.49). Increase in UACR was associated with increased CVD or ESRD, although the direction of effect was similar. A >30% UACR decrease was not significantly associated with the risk of death or CVD when compared to those with minor change but was significantly associated with lower ESRD risk(HR 0.10, 95%CI:0.01-0.79).

Conclusions: In type-2 diabetes patients, >30% increase in albuminuria predicted higher mortality while >30% decrease was associated with decreased ESRD risk. Our results suggest change in albuminuria may be a potential prognostic marker for clinical outcomes in type-2 diabetes.
Results: QTc interval was prolonged significantly at the end of HD in all sessions (p<0.001). Change in glucose level (mean±SD -1.8±4.2 vs -1.7±3.0) did not have a significant effect on the change in QTc interval (p=0.396), which was not different in diabetic subjects compared to non-diabetic group (p=0.390). Serum K+, Mg2+ and Ca2+ levels dropped significantly (p<0.001) during all 3 HD sessions. There was no significant difference in heart rate level and the drop in K+, Mg2+ and Ca2+. The change in Mg2+ (p<0.05) and Ca2+ (p<0.05) levels but not K+ (p=0.202) were more pronounced in diabetic subjects. The change in Mg2+ levels in diabetic subjects was associated with QTc prolongation (p<0.05).

Conclusions: Significant QTc prolongation occurs at the end of HD in people with and without diabetes, often reaching abnormal levels and appears to be related more to changes in blood electrolytes than glycaemia. The fall in serum Mg2+ levels during HD had a larger effect on QTc than K+ or Ca2+ and this appears to have a more pronounced effect in diabetic subjects. The changes in QTc may increase the risk of cardiac dysrhythmia and sudden death in HD patients.

FR-PO636
Markers of Inflammation and Endothelial Dysfunction Are Associated with Cardiovascular Morbidity and Mortality in Type 2 Diabetic Patients with Microalbuminuria
Bernt Johan Illum von Scholten,1 Henrik Reinhardt,1 Tine Hansen,1 Casper Schalkwijk,1 Coen Stehouwer,2 Hans-Henrik Parving,2 Peter Karl Jacobsen,2 Peter Rossing,1 1Steno Diabetes Center, Denmark; 2Maastricht Univ Medical Center, Netherlands; 3Rigshospitalet, Denmark.

Background: Accumulating evidence suggests that inflammation and endothelial dysfunction link type 2 diabetes (T2D) to cardiovascular disease (CVD). We evaluated the predictive value of markers of inflammation and endothelial dysfunction for combined fatal and non-fatal CVD and for all-cause mortality in patients with T2D and microalbuminuria but without known coronary artery disease (CAD).

Methods: Prospective study including 200 patients. All received intensive multifactorial treatment. Markers of inflammation (TNF-α, ICAM-3, hsCRP, SAA, IL-1α, IL-6, IL-8) and endothelial dysfunction (thrombomodulin, VCAM-1, ICAM-1, E-selectin, P-selectin) were measured at baseline. Adjusted score models included sex, age, total cholesterol, smoking, HbA1c, creatinine, systolic blood pressure and urinary albumin excretion. Fully adjusted models additionally included NT-proBNP and coronary artery calcium score (CAC).

Results: Participants were 76% men, age (± SD) 59 ±9 years, HbA1c was 7.9 ±1.3% and UAER (IQR) was 103 (39–230) mg/d. Occurrence of CVD (n=40) and mortality (n=26) was traced after 6.1 years (median). In adjusted Cox analysis, higher TNF-α predicted the CVD endpoint and mortality (p=0.002). After full adjustment higher TNF-α remained predictive of both endpoints (p=0.007). Higher thrombomodulin and ICAM-3 were associated with risk of CVD and mortality in adjusted analyses (p=0.05) and predicted mortality after fully adjustment (p=0.001). Higher VCAM-1 and ICAM-1 were associated with risk of mortality in adjusted (p=0.002) and fully adjusted models (p=0.005). The composite z-score of all markers of inflammation and of endothelial dysfunction predicted CVD and mortality (p=0.008).

Conclusions: In patients with T2D and microalbuminuria without known CAD, biomarkers of inflammation and endothelial dysfunction were independently associated with risk of CVD and mortality. Especially TNF-α was a robust predictor, even after adjusting for albuminuria, NTproBNP and CAC.

FR-PO637
Predictors of Glycemic Status and Associations with Mortality in Incident Diabetic Hemodialysis Patients
Connie Rhee,1 Steven B. Kim,1 Rajnish Mehrotra,1 Elani Streja,1 Danh V. Nguyen,1 Steven M. Brunelli,2 Gregory Brent,1 Csaba P. Kovessy,1 Kamyar Kalantar-Zadeh,1 UC Irvine; 2Univ Washington; 1DaVita Clinical Research; 3UCLA; 4UTHSC.

Background: In the general population, intensive glycemic targets confer higher mortality in diabetics with cardiovascular risk. In diabetic hemodialysis (HD) patients, some but not all studies show that lower glycemic levels defined by HbA1c are associated with higher mortality. We sought to examine predictors of low glycemic status in HD patients, and hypothesized that lower glycemic levels are associated with higher mortality.

Methods: In a 5-year national cohort (1/2007-12/2011) of incident diabetic HD patients with or without known CAD measures during the 1st 91-days of dialysis, we examined predictors of low HbA1c (<6%; ref 6–<8%; ≥8% separately examined) using logistic regression. We then examined the association of HbA1c with all-cause mortality. Baseline and time-dependent HbA1c as a proxy of long-term and short-term exposure—mortality associations, respectively, were examined using case-mix laboratory adjusted Cox models.

Results: Among 63,607 diabetic HD patients, 37% had low HbA1c levels. Female gender and non-Hispanic race/ethnicity; lower BMI and nPCR; and higher serum bicarbonate, creatinine, and albumin were associated with higher risk of low HbA1c. Baseline HbA1c levels <7% were associated with lower mortality. However, time-dependent HbA1c levels <5% were associated with higher mortality.

Conclusions: Baseline HbA1c levels <7% were associated with lower mortality, suggesting that moderately low glycemic status has long-term benefits in diabetic HD patients. Yet time-dependent HbA1c levels <5% were associated with higher mortality, suggesting that very low glycemic status carries short-term risk. Further studies are needed to determine if pharmacotherapies targeting these glycemic ranges reduce mortality in diabetic HD patients.

FR-PO638
Waist-Hip Ratio Is Associated with Renal Hyperfiltration in the Non-Diabetic, Middle-Aged General Population
Vidar T. N. Stefansson,1 Jorgen Schel,1 Trond G. Jansen,1 Toralf Melsom,1 Bjorn Odvar Eriksen,1,2 1Metabolic and Renal Research Group, UiT the Arctic Univ of Norway, Tromsø, Norway; 2Section of Nephrology, Univ Hospital of North Norway, Tromsø, Norway; 3Dept of Organ Transplantation, Oslo Univ Hospital, Oslo, Norway.

Background: Renal hyperfiltration (RHF) is a maladaptive response to increased metabolic stress in the kidneys which may result in chronic kidney disease. Diabetes causes RHF, but whether obesity in non-diabetic persons is a cause of RHF has not been adequately studied in the general population. This study aimed to establish whether RHF assessed by measured glomerular filtration rate (GFR) is associated with obesity independently of metabolic and cardiovascular risk factors.

Methods: We performed a cross-sectional study of a representative sample of 1594 persons recruited from the general population of the municipality of Tromsø, Norway, aged 50-62 without prevalent cardiovascular disease, diabetes or renal disease. GFR was measured by iohexol clearance. Obesity was classified according to body mass index (BMI), waist circumference (WC) and waist-hip ratio (WHO). RHF was defined as >90th percentile of residuals from a linear regression of absolute GFR on age, sex, weight and height.

Results: In multivariable adjusted logistic regression models, the odds ratios (95% confidence intervals) for RHF were 1.56 (1.11-2.18) per 0.10 increase in WHO, 0.82 (0.51-1.32) per 5kg/m2 of BMI and 1.23 (0.92-1.65) per 10 cm of WC. WHR was consistently associated with RHF across different models. Higher BMI and WC were significantly associated with RHF only when an alternative definition of RHF, not adjusted for body weight, was used. Higher BMI, WC and WHO were also independently associated with increasing GFR analyzed as a continuous variable.

Conclusions: Central obesity measured as WHR is associated with RHF and higher GFR independently of age, sex, body weight, metabolic indices (including fasting glucose,
insulin and HbA1C) and cardiovascular risk factors (including ambulatory blood pressure, antihypertensive medication and smoking status). WHR may be a better indicator of the renal effects of obesity than BMI or WC.

Obesity Associates with High Hemoglobin A1c but Low Alternative Indices in Both Diabetic and Nondiabetic Hemodialysis Patients

Mark E. Williams,1 Neal Mittman,2 Lin Ma,3 Julia I. Brennan,4 Chiniu M. Jani,5 Curtis D. Johnson,6 Franklin W. Maddux,7 Eduardo K. Lacson.1,8,9 Joslin Diabetes Center, Boston, MA;1 Kidney Care of Brooklyn and Queens, Brooklyn, NY;2 Fresenius Medical Care North America, Waltham, MA;3 Spectra Laboratories, Rockleigh, NJ;4 Physician, Lexington, MA.

Background: The GIDE (Glycemic Indices in Dialysis Evaluation) study is evaluating several glycomic markers in hemodialysis (HD) cohorts with and without diabetes. We have reported that alternative glycemic indices may be elevated out of proportion to hemoglobin A1c (HgbA1c). Because obesity is known to affect markers of glycemia, we examined its association with these indices.

Methods: A combined cohort of 2,394 active HD patients (1,424 with diabetes, 970 without) from 26 U.S. FMCNA facilities had baseline indices [HgbA1c; albumin-adjusted and unadjusted fructosamine (AlbF; F) and glycated albumin (GA) or percent GA] measured Jan-Mar 2013 and monthly until April, 2015. Mean of body mass index (BMI) was determined for the entire cohort. Obesity—BMI³30kg/m². Cox models adjusted by age, sex, race, ethnicity, vintage, HD catheter, baseline comorbidity and laboratory albumin values were utilized to determine associate between obesity with death outcome.

Results: Average BMI (kg/m², mean±SD) by risk as determined by indices (low=within target range, high=above target range) are shown in (table 1).

The Hazard Ratio (HR) for death was reduced with obesity [HR=0.76, 95%CI (0.62, 0.94), p=0.01].

Conclusions: Obesity is positively correlated with HgbA1c but negatively correlated with other glycemic indices in hemodialysis patients. Further studies are needed to elucidate underlying mechanisms and assess the relationship of these findings to superior survival outcomes in obese HD patients.

FR-PO640

BMI and Causes of Death in Chronic Kidney Disease

Sankar D. Navaneethan,1 Jesse D. Schold,2 Susana Arrigain,1 John P. Kirwan,3 Joseph V. Nally,1 Nephrology, Cleveland Clinic;2 Quantitative Health Sciences, Cleveland Clinic;3 Pathobiology, Cleveland Clinic.

Background: Chronic kidney disease (CKD) is associated with higher risk for cardiovascular related death. In CKD, a higher body mass index (BMI) is associated with a lower risk for death, but cause specific death details are unknown across the BMI range.

Methods: We included 54,306 patients with CKD (two estimated glomerular filtration rate <60 ml/min/1.73 m² 90 days apart; January 2005 – December 2012) from our institutional electronic medical record-based CKD registry. We examined the associations between various causes of death (cardiovascular, malignancy and non-cardiovascular/ non-malignancy related deaths obtained from the State of Ohio mortality files) across the BMI range using the Cox proportional hazards model.

Results: During a median follow-up of 3.7 years (25th percentile-75th percentile: 1.8-5.8), 14,518 patients died. In the multivariable model, an inverted J-shaped association was noted between BMI and overall, cardiovascular, malignancy-related, and non-cardiovascular/ non-malignancy related deaths.

Similar associations were noted for BMI 25-29.9, 30-34.9, and 35-39.9 kg/m² categories. BMI>40kg/m² was not associated with cardiovascular and non-cardiovascular/ non-malignancy related deaths in CKD. Sensitivity analyses yielded similar results even after including only those with ≥2-year follow-up, adjusting for proteinuria, and excluding diabetes and hypertension from the models. However, the inverse associations between higher BMI and cardiovascular deaths were not observed among smokers.

Conclusions: In those with CKD, compared to BMI of 18.5-24.9 kg/m², those who are overweight, class 1 and 2 obesity are associated with lower risk for cardiovascular, malignancy-related and non-cardiovascular/ non-malignancy related deaths. Future studies are needed to confirm these findings.

Funding: Pharmaceutical Company Support - CCF CKD registry creation was supported by an unrestricted grant from Amgen to the Department of Nephrology and Hypertension at Cleveland Clinic

FR-PO641

Weight Reduction with Low Calorie Diet Reduces Urinary Megalin and Improves Albuminuria in Obese Men

Tetsuro Takeda,1 Akihiko Saito,2 Nephrology, Dokkyo Medical Univ Koshigaya Hospital, Koshigaya, Saitama, Japan;2 Applied Molecular Medicine, Niigata Univ, Niigata, Japan.

Background: Megalin, an endocytic receptor in proximal tubules, is involved in the mechanisms of albuminuria in diabetic nephropathy. A urinary full-length megalin (C-megalin) assay is linked to the severity of diabetic nephropathy and IgA nephropathy. Also, albuminuria is a frequent sign of obese individuals and could be reduced by losing body weight. We investigated the relationship between level of urinary C-megalin and albuminuria on a weight reduction program in obesity.

Methods: Thirty-three obese male volunteers (age 36.6 ± 6.9 years, BMI >25 kg/ m²) were enrolled but 30 subjects completed the 12-week weight reduction program. The program consisted of replacement of evening meal by a low caloric formula food (MICRO-S®) for first 4 weeks and followed by bi-weekly dietary counseling session with nutritionist. Of these, 20 subjects with metabolic syndrome were included (based on the Japanese criteria). Urinary albumin/Cr ratio (ACR) and urinary C-megalin were measured at baseline and after the program.

Results: The mean weight loss was 5.2 ± 2.9 kg (5.6% of the original BW). The baseline ACR ranged from 2.8 to 52.9 mg/gCr. After the program, BMI, waist circumference, BP, total cholesterol, and FFA were significantly decreased. HDL-cholesterol and adiponectin were significantly increased. Overall, ACR was not changed (11.9 ± 12.4 vs 8.8 ± 5.3 mg/gCr). However, in the cases with ACR >8 mg/gCr at baseline (n=11), ACR was more effectively reduced (22.9 ± 15.1 vs 12.7 ± 6.4 mg/gCr) without a change in eGFR. The reduction of ACR was correlated with the reduction of urinary C-megaltn. No other parameters like insulin resistance were associated with the reduction of ACR or C-megaltn.

Conclusions: Losing BW with a formula food is effective in reducing urinary ACR in obese men. This improvement of ACR is related to the reduction in urinary C-megaltn. Since albumin is excreted into urine by its increased glomerular leakage and/or decreased proximal tubular reabsorption via megalin and cubulin, our observations suggest that megalin metabolism in proximal tubules may determine albuminuria in obesity.

FR-PO642

Obesity Management in Patients with Chronic Kidney Disease (CKD): A National Survey

Christopher Lawrence,1 Helen L. MacLaughlin,2 Ken Farrington,1 Andrew H. Frankel.1 1Lister Hospital, United Kingdom; 2Kings College London, United Kingdom; 3Imperial College London, United Kingdom.

Background: Obesity contributes to the development and progression of CKD and may be a barrier to, or increase risks of, transplantation. Evidence for how the renal multi-disciplinary team (MDT) should proceed is limited and sometimes counterintuitive i.e. association of increased weight and better survival on haemodialysis. The study assessed approaches to obese patients with CKD across the UK and describes the availability of, and extent of co-working with, bariatric services.

Methods: An online survey tool was designed and sent by the British Renal Society to UK renal clinical directors and dieticians. The survey focused on patients with CKD stage ≥ 3, with proteinuria and co-existent Obesity stage II (BMI > 35kg/m²) as these patients are most likely to progress to ESRD.

Results: 58/71 (82%) of UK units responded with respondents split between dieticians (53%) and nephrologists (47%). Most respondents (78%) thought the prevalence of obesity has increased over the last decade. There was no consensus on the BMI cut off for kidney transplantation: 30%, 16%; 35%, 71%; ≤40, 12%; none, 2%. The 3 most common actions for initial obesity management were: to provide education/motivation (81%); dietary referral (69%) and test fasting glucose and lipids (43%). Thereafter only 33% would refer to bariatric services. The main perceived barriers to weight loss were: lack of patient motivation (79%); no funding (60%); lack of services (53%). 54% of renal units co-locate with bariatric services. Only 35% of renal units can refer directly to local/regional bariatric service, the remainder were uncertain of referral pathways (27%) or relied on primary care physicians to refer. Only 5 units (9%) have a joint care pathway for obese patients with CKD undergoing bariatric surgery.

Conclusions: The response to obesity in CKD falls short of National (NICE) guidelines. The increasing prevalence of obesity is a challenge to the renal MDT. Strategies to tackle this include wider recognition of the problem; identifying and sharing best practice and alleviation of hyperfiltration. However, there are also concerns about deleterious effects associated with cardiovascular complications. To prevent progression of systemic cardiovascular complications in DM patients, glycemic control is important. However using of anti-diabetic agents was restricted in patients with renal impairment. In this study, we examined the efficacy and safety of the glucagon-like peptide analogue, liraglutide to treat type 2 DM patients with renal impairment.

Methods: Twenty type 2 diabetes patients with renal insufficiency (Age; 65.4y; DM duration;11.9y, eGFR,21.6ml/min/1.73m²) were enrolled. Anti-diabetic agents were switched to liraglutide from others. Prior to liraglutide therapy, 9 patients used insulin, 8 used oral antidiabetic agents, and 3 were only diet therapy. During 24 months liraglutide use, we examined the change of blood pressure and renal function. Echocardiography was examined at baseline and 24 months after liraglutide initiation.

Results: Hemoglobin A1c, and systolic/diastolic blood pressure levels were gradually decreased with liraglutide use. Renal function indicated by eGFR was not changed (table1), and the slope of the reciprocal of serum creatinine was improved after use of liraglutide (p<0.001). Moreover Liraglutide induced ameliorating left ventricular function(LVMI and EF).

FR-PO643

Effects of Renin-Angiotensin Blockade (RASB) on the Components of Early Interstitial Expansion in Patients (pts) with Type 1 Diabetes (T1D)

Zarah Khan, Michael Maurer, Maria Luiza A. Caramori. Medicine and Pediatrics, Univ of Minnesota, Minneapolis, MN.

Background: Interstitial expansion is important for GFR loss in the later stages of a variety of disease processes, including diabetic nephropathy (DN). The Renin-Angiotensin System Study (RASS; NEJM 2009;361:40) considered whether RASB with enalapril or losartan compared to placebo could slow progression of early DN lesions over 5 years (yrs) in 285 normoalbuminuric (NA), normotensive (NT), normal GFR T1D pts. RASS found no difference between the treatment groups in albuminuria or eGFR at 5 yrs. However, this early DN study was limited by a single research center, 7 from each treatment group, with a wide range of change in Vv(Int). The response to obesity in CKD falls short of National (NICE) guidelines.

Methods:

- At baseline, 49% of the Int was made up by Col, 12% by C, 26% by PTC, 7% by S, and 2% by artifact. Overall there was no change in Int composition during RASS. Compared across treatment groups, there were no statistically significant effects of treatment group on the Vv of any of the Int components. Rv (171.5 cm³) remained stable in all groups.

Conclusions: RASS found that NA, NT, normal GFR T1D pts had surprisingly rapid increases in Vv(Int/Cortex). The response to obesity in CKD falls short of National (NICE) guidelines.

No adverse events were seen.

Conclusions: These findings suggest that liraglutide therapy for type 2 diabetes patients with renal impairment was safe and effective for decreasing glucose levels and blood pressure. Moreover it preserved renal function and improving left ventricular function.

FR-PO645

Do SGLT2 Inhibitors Affect GFR and Albuminuria in Diabetic Patients? A Systematic Review and Meta-Analysis

Xiao Xu, Yang Li, Peng Xia, Limeng Chen. Dept of Nephrology, Peking Union Medical College Hospital.

Background: SGLT2 inhibitors are a new class of antihyperglycemic drugs that lower blood glucose levels by inhibiting renal glucose reabsorption. SGLT2 inhibitors can have potential renoprotective capacities through modulation of tubuloglomerular feedback and alleviation of hyperfiltration. However, there are also concerns about deleterious effects on renal function caused by volume depletion.

Methods: We performed this systematic review and meta-analysis to assess the effects of SGLT2 inhibitors on estimated GFR (eGFR) and urinary albumin/creatinine ratio (ACR) in diabetic patients. We conducted a systemic search of Pubmed, Embase, Cochrane Central Register of Controlled Trials and Sinomed through April 2015 to identify published randomized double-blind controlled trials of SGLT2 inhibitors reporting renal outcomes. Two reviewers worked independently to extract data and assess the quality of included studies. Random effects model were used in data synthesis.

Results: We retrieved 2279 studies, 53 of which met the predefined criteria. Among included studies, 33 studies examined short-term effect with follow up less than 26 weeks, and 20 studies examined long-term effects with follow-up longer than 48 weeks. 4 studies included subjects with CKD 2-4. SGLT2 inhibitors did not cause statistically significant changes in eGFR (mean change,-0.19 ml/min/1.73m², 95% CI, -0.86 to 0.47) or in ACR (mean change, -23.76 mg/g, 95% CI, -66.75 to 19.23).

Effects of Statins on Diabetic Kidney Disease in Patients with Type 2 Diabetes

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

**Background:** Renoprotective properties of statins have received much attention; however, a recent large cohort study found no beneficial effect of statins on diabetic kidney disease (DKD). Furthermore, whether there are differences among statins in their effects on the kidney remains unclear.

**Methods:** This was a single-center historical cohort study of Japanese adult ambulatory patients with type 2 diabetes. We studied 412 patients who were newly prescribed one of the following 4 statins: pravastatin, rosuvastatin, atorvastatin and pitavastatin, and who had estimated glomerular filtration rate (eGFR) >30 mL/min/1.73 m². As the control group, 946 patients without a prescription history of statins were enrolled. Two outcomes were defined: 1) annual decline in eGFR and 2) progression to a more advanced stage of albuminuria. To adjust for the effects of confounding factors, we used the propensity score (PS) as the covariate. PS was estimated using a multinomial logistic regression model that included 18 clinical parameters. Furthermore, to take into account the varying number and spacing of eGFR measurements, and the variable follow-up period for each individual, we conducted the linear mixed-effects model regression analysis. The intercept and slope were treated as random effects.

**Results:** During the median follow-up period of 5.3 years (range, 2.0–8.6 years), the adjusted eGFR decline (±standard error) in the control group (1.6 ± 0.1 mL/min/1.73 m²/year) was significantly slower than that in rosuvastatin (2.4 ± 0.2, p=0.001), atorvastatin (2.6 ± 0.3, p=0.003) and pitavastatin group (2.3 ± 0.3, p=0.036), but not in pravastatin group (1.7 ± 0.2, p=0.780). Next, during the median follow-up period of 4.2 years (range, 0.1–8.5 years), 138 patients showed progression of albuminuria stage. The adjusted hazard ratio (vs. control group) for the albuminuria progression was 0.85 (p=0.690), 0.86 (p=0.670), 1.01 (p=0.980), and 0.69 (p=0.462) in pravastatin, rosuvastatin, atorvastatin and pitavastatin group, respectively.

**Conclusions:** Statins may have no beneficial effect on the progression of DKD. Instead, some statins are likely to be associated with faster renal function decline.

Glucose Targets for Preventing Diabetic Kidney Disease and Its Progression: A Meta-Analysis

**Methods:** Using standard Cochrane methods, we did a systematic review and meta-analysis of randomized controlled trials that evaluated intensive versus standard glycemic control admistered to adults and children with type 1 or type 2 diabetes with or without kidney disease. Intensive glycemic control was defined by a treatment targeting an HbA1c level <7.0% or fasting glucose levels <120 mg/dL. Effect sizes were calculated using a random-effects model. Studies were critically appraised using Cochrane methods.

**Results:** 10 studies involving 28,885 participants were eligible for inclusion. In studies at low risks of bias, intensive glycemic control had uncertain effects on doubling of serum creatinine (0.91; CI 0.34-1.47) and end-stage kidney disease (1.21, CI 0.12-11.98). Tight glycemic control reduced the onset (0.82, CI 0.71-0.93) and progression (0.56, CI 0.36-0.87) of microalbuminuria. In absolute terms, treating 1000 patients with tight glycemic control for 1 year might prevent 7 experiencing new-onset albuminuria and 22 with worsening albuminuria.

**Conclusions:** Intensive glycemic control among adults with diabetes had very uncertain effects on doubling of ESKD and progression of kidney failure, while providing small clinical benefits on the onset and progression of microalbuminuria.

Patient Benefits and Cost Savings Predicted for Mineralocorticoid-Receptor Antagonist Treatment of Early and Advanced Diabetic Kidney Disease

**Background:** Exploratory studies suggest that mineralocorticoid-receptor antagonists (MRA) may improve outcomes in patients with diabetic kidney disease (DKD). Finerenone (BAY 94-8862) is a selective, potent and non-steroidal MRA for the treatment of patients with DKD and is currently being studied in two clinical phase III trials, “FIDELIO” and “FIGARO”.

**Methods:** A Markov cohort model was used to emulate disease history, treatment effects, and outcomes for DKD patients with various disease severities (by albuminuria, measured by urinary-albumin-creatinine ratio [UACR], and chronic kidney disease [CKD] stage, measured by estimated glomerular filtration rate [eGFR]). Efficacy of finerenone is accomplished by reducing albuminuria evidenced by phase 2 trial data. The model has US...
blood and 24-hour urine samples were collected at baseline (pre, days -2 to 0) and the last 3 diet days (on, +19 to +21). Each subject’s tests were averaged by period, and the group averages analyzed by one-way ANOVA and between groups by t-test. Urinary N excretion was adjusted per 70 kg. Body composition [total (T), fat free mass (FFM), kg] was measured by bioimpedance (BIS).

**Results:** mean±SD. ADA or Paleo pre-on; a, p<0.05; Δ Paleo vs Δ ADA: b, p<0.1; c, p<0.05; d, p<0.01.

Both groups had equally modest nonsignificant declines in weight.

**Conclusions:** The higher acid diet had significantly greater loss of fat free mass associated with a greater loss of urinary urea and ammonium. A plant based low acid weight loss diet may be better in maintaining lean body mass compared to a usual acid diet.

**Independent Association of Systolic Blood Pressure and Hemoglobin A1c Levels on Clinical Outcomes in Diabetic Patients with Normal Kidney Function**

Aidar Gmosman,1 Jun Ling Lu,1 Miklos Zsolt Molnar,1 Keichii Sumida,1 Praveen Kumar Potukuchi,1 Kamary Kalantar-Zadeh,2 Csaba P. Kovedsy,3 1Univ of Tennessee Health Science Center, Memphis, TN; 2Univ of California, Irvine, CA; 3VA Medical Center, Memphis, TN.

**Background:** Systolic blood pressure (SBP) goal of <140mmHg is recommended for majority of patients with diabetes mellitus (DM). It is however unknown if glycemic control modifies the association of uncontrolled hypertension (HTN) with mortality and morbidity in DM patients.

**Methods:** We examined 894,661 US veterans with DM and baseline eGFR >60 ml/min/1.73m² (mean age 66.6±10.9 years, 97% males, 17% African-Americans). The association of mutually exclusive combined categories of hemoglobin A1c (AIC: <6.5, 6.5-6.9, 7.0-7.9, 8.0-8.9, 9.0-9.9, and 10%) and SBP (<120, 120-139, 140-159, 160-179, and >180mmHg) with the risk of all-cause mortality, incident CKD, coronary heart disease (CHD), and stroke was examined in Cox models adjusted for baseline characteristics, statin use, and co-morbidities, using patients with A1c 6.5-6.9% and SBP of 120-139 mmHg as referent.

**Results:** A total of 221,983 (25%) patients died, and 178,628 (20%), 43,374 (5%) and 29,536 (3.5%) developed incident CKD, CHD and stroke, respectively, during a median follow up of 7.4 years. SBP displayed a U-shaped association with mortality in each A1c category. Conversely, SBP >120-139 mmHg was associated with a monotonous increase in the risk of CKD, CHD and stroke in all A1c categories. A1c levels were linearly associated with worse outcomes for all end points and in all SBP categories.

**Conclusions:** SBP above 120-139 mmHg and higher A1c levels were associated with higher mortality and morbidity in diabetic patients, independent of each other. Tight glycemic control may reduce mortality and morbidity across all SBP categories in patients with normal kidney function.

**High Acid Diets Increase Urinary Nitrogen Excretion and May Decrease Muscle Mass in Obese Diabetics**

Lynda A. Frassetto, Umesh Masharani, Anthony Sebastian. UCSF, San Francisco, CA.

**Background:** We have previously shown that decreasing dietary acid loads with bicarbonate supplements lowers urinary nitrogen (N) excretion in postmenopausal women. Here we examined whether we could lower urinary N excretion in obese diabetics by increasing plant food intake (“Paleo diet”) compared with a “usual” acid diet (America Diabetes Association diet).

**Methods:** 12 obese well controlled type 2 diabetes (7 Paleo, 5 ADA) were enrolled in a 21 day no-weight loss controlled metabolic diet study. Daily protein intake per 2500 kcal averaged 116 g on the Paleo and 127 g on the ADA diets (p=0.7). Fasting arterialized

**Clinical Benefit of Pre-Dilution On-Line Hemodiafiltration for Removal of Low-Molecular-Weight Proteins and Fibrobast Growth Factor-23 in Patient with Diabetic Nephropathy**

Kenji Sakurai,1 Takeshi Saito,1 Fumi Yamauchi,1 Hiroshi Hosoya,1 Yoshitaka Kurihara,1 Daiisuke Ishii,1 Kazunari Yoshida,1 Kenichi Kobuko,2 Akihiro C. Yamashita.3 1Hashimoto Clinic, Kanagawa, Japan; 2Urology, Kitasato Univ, Kanagawa, Japan; 3Organ Transplant Medicine, Kitasato Univ, Kanagawa, Japan; 4Medical Engineering and Technology, Kitasato Univ, Kanagawa, Japan; 5Chemical Science and Technology, Hosei Univ, Tokyo, Japan.

**Background:** Increased concentration of fibroblast growth factor 23 (FGF-23) is reportedly associated with increased risk of cardiovascular complication and mortality in dialysis patients. Therefore, there is a possibility that reduction of FGF-23 levels may improve prognosis of diabetes patients with elevated its levels. We compared the removal performance of low-molecular-weight proteins (LMWP) and FGF-23 between pre-dilution on-line hemodiafiltration (HDF) and hemodialysis (HD) with super high-flux dialyzer.

**Methods:** The study involved 31 patients (15:HDF, 16:HD, 4 hrs, Qd:600 mL/min). Blood flow rates were 284±20 for HDF, 281±14 mL/min for HD. Replacement fluid volume in HDF was 49.2±9 L/session. Removal rates (RR,%) and removal amounts (RA,mg) of urea nitrogen (UN), creatinine, β2-microglobulin (β2-M, MW:11.8Kda), α1-microglobulin (α1-M, 33KDa) and FGF-23 (32KDa) were examined. We followed the changes in FGF-23 levels of patients for 4 month period.

**Results:** Ks/V, RR's of UN and creatinine were significantly higher in HD than in HDF, whereas RR's and RAs of β2-M, α1-M, and FGF-23 were significantly higher in HDF. RRs of β2-M and α1-M were 80.3±3.7 and 42.0±6.1 for HDF, 73.5±4.1 and 25.0±6.8 for HD, respectively. RR and RA of FGF-23 were 66.0±6.5 for HD, 51.1±8.3 for HD and 0.11±0.01 for HD, respectively.

**Conclusions:** The results confirmed that HDF was superior to HD in removing LMWP and FGF-23, which are removed mainly by convection. The convection volume can be much easily controlled in HDF than HD because HDF utilizes internal filtration. The RRs of FGF-23 were 24 points higher than those of α1-M in both modes despite the small difference in MW, suggesting that distribution volume of FGF-23 was smaller than that of α1-M. No clear tendency was detected in changes of FGF-23 during 4-month observation period.

### FR-PO653

**Comparison of Removal Performance of Small- to Large-Molecular-Weight Substances Between Pre-Dilution On-Line Hemodiafiltration and Hemodialysis with Super-High-Flux Dialyzer**

Kenji Sakurai,1 Takeshi Saito,1 Fumi Yamauchi,1 Hiroshi Hosoya,1 Yoshitaka Kurihara,1 Daiisuke Ishii,1 Hashimoto Clinic, Sagamihara Kanagawa, Japan; 2Urology, Kitasato Univ, Sagamihara Kanagawa, Japan.

**Background:** In pre-dilution on-line hemodiafiltration (HDF), net dialysate flow rate is reduced, because replacement fluid accounts for 30 to 50% of total dialysate flow (Qdtotal). Therefore, removal efficiency of small-molecular-weight substances by diffusion is reduced, whereas that of low-molecular-weight proteins (LMWP) by convection is...
improved. In hemodialysis (HD) using super high flux dialyzer, the increased blood flow rate (QB) increases amount of fluid filtration, thereby improving the removal efficiency of LMWPs. In this study, we compared the removal efficiency of small- to large-molecular-weight substances between HDF and HD to verify the superiority of HDF.

**Methods:** The study involved 62 patients (31: HD, 31: HDF). Super high flux dialyzers for HD and high-performance hemofilters for HDF were used. Qd was 500 for HD and Qdtotal was 600 mL/min for HDF. Replacement fluid volume for HDF was 44.4 ± 10.0 L per session. QB was 256 ± 23, 257 ± 25 mL/min and Treatment time was 4.1 ± 0.2, 4.0 ± 0.1 hours in HD and HDF, respectively. Removal rates (RR) of β2-microglobulin (β2-M:1.18kDa), protein (PRL:23kDa), α1-microglobulin (α1-M:33kDa) and α1-acid glycoprotein (AGP:44kDa) were investigated. Kt/V for urea and plasma clearances (CL) of β2-M, PRL and α1-M were measured.

**Results:** RR (%) of each substance was significantly higher in HDF than in HD (P < 0.005). BM:79.8 ± 3.2 vs. 70.8 ± 4.7, PRL: 75.3 ± 5.5 vs. 69.2 ± 6.6, α1-M: 40.0 ± 4.1 vs. 31.5 ± 6.4, α1-AGP: 11.9 ± 4.3 vs. 7.4 ± 4.8. Kt/V was 1.56 ± 0.22 (HDF) and 1.51 ± 0.19 (HD). Plasma CLs (mL/min) of β2-M were 95.7 ± 3.6 and 73.6 ± 3.7, those of PRL were 57.3 ± 4.3 and 28.1 ± 5.5 in HDF and HD, respectively.

**Conclusions:** The performance of HDF in removing LMWPs was superior to that of HD and there was no significant difference in Kt/V in both modes. An increased conversion by HDF greatly contributed to improved removal of LMWPs and appropriate control of dialysate flow rate improved the removal efficiency for small molecular substances to the level achieved by HD.

The Effect of Increasing Kt/V<sub>ema</sub> in the HEMO Study on Levels of Non-Urea Solute Toxins

Timothy W. Meyer<sup>1</sup>, Tammy L. Soltet<sup>2</sup>, Tariq Shafi<sup>1</sup>, Tanushree Banerjee<sup>1</sup>, Neil R. Powe<sup>3</sup>, Thomas H. Hostetter<sup>4</sup>, Johns Hopkins, MD; <sup>2</sup>Med, Stanford, CA; <sup>3</sup>Med, UCSF, CA; <sup>4</sup>Med, Case Western, OH.

**Background:** In the HEMO study, outcomes were no better in patients randomized to “high dose” thrice weekly hemodialysis providing spKt/V<sub>ema</sub> 1.73 than in those randomized to “standard” hemodialysis providing spKt/V<sub>ema</sub> 1.32.

**Methods:** This study assessed whether “high-dose” treatment lowered levels of non-urea solutes. Solutes were measured by LC/MS/MS in plasma samples obtained at least 3 months after randomization in 1281 HEMO subjects.

**Results:**

</tr>
</tbody>
</table>

Increasing Kt/V<sub>ema</sub> caused statistically significant but only modest reductions in the levels of trimethylamine oxide, phenylacetylglutamine, and symmetric dimethylarginine. Mathematical modeling showed that limited reduction in the levels of these solutes was a predictable consequence of the intermittency of treatment. Their reduction ratios with standard treatment were high and the increased intensity of treatment reflected by a 30% increase in Kt/V<sub>ema</sub> in HEMO’s high dose arm could not remove much more solute. Remarkably, increasing Kt/V<sub>ema</sub> in HEMO caused no reduction in the levels of asymmetric dimethylarginine or p-cresol sulfate, two solutes which have been associated with cardiovascular disease in dialysis patients. Modeling showed that stability of their plasma levels could be accounted for by increased solute production accompanying the increase in Kt/V<sub>ema</sub> and/or the presence of non-dialytic clearance.

**Conclusions:** Levels of non-urea solutes may fall only slightly or not at all when Kt/V<sub>ema</sub> is increased above standard levels for thrice weekly treatment. Treatments that are more effective in reducing solute levels may be required to improve outcomes.

**FR-PO655**

Improved Protein-Bound Uremic Toxins Dialytic Removal with Use of Albumin Binding Competitors: An In Vitro Human Whole Blood Study

Xia Tao<sup>1</sup>, Stephan Thijssen<sup>2</sup>, Peter Kotanko<sup>2</sup>, Chih-Hu Ho<sup>2</sup>, Michael E. Henrie<sup>3</sup>, Eric W. Stroup<sup>1</sup>, Garry J. Handelman<sup>1</sup>,<sup>1</sup> Univ of Massachusetts, Lowell, MA; <sup>2</sup>Renal Research Inst, NY, NY; <sup>3</sup>Fresenius Medical Care, Ogden, UT.

**Background:** Protein-bound uremic toxins (PBUT) are intensively studied retained solutes that accumulate in chronic kidney disease patients. Efficient removal of PBUTs is critical to improving the dialytic removal of PBUTs by increasing their free fractions with use of protein binding competitors.

**Methods:** The binding properties of indoxyl sulfate (IS), indole-3-acetic acid (IAA) and hippuric acid (HIAA), and their binding competitors, iopropen (IBU), furoxicidone (FUR) and tryptophan (TRP) were studied by rapid equilibrium dialysis (RED) to select suitable model compounds for the HD study. The method was then tested in an in vitro HD experimental model with human whole blood spiked with PBUTs. After 10 min baseline test, the binding competitors were introduced upstream of dialyzer blood inlet. The removal of urmicotoxins was estimated as the amount leaving dialysate outlet relative to the amount entering blood inlet.

**Results:** The infusion of IBU and FUR mixture (647±100µmol/l and 126±100µmol/l in blood, respectively) in the HD model increased removal of IS from 6.3 ± 0.1 to 15.2 ± 0.3 % (mean ± standard deviation) (2.4-fold) and IAA removal increased from 15.9 ± 0.2 to 29.8 ± 0.6 % (1.9-fold). TRP (1mmol/l in plasma) infusion increased the removal of IS and IAA to 9.4 ± 0.1% and 26.0 ± 0.3% (1.4- and 1.3-fold, respectively). Only moderate effects were observed in the change of HIPA removal.

Variable Recovery Time After Hemodialysis Treatment

Antonia Harford<sup>1</sup>, Susan Pain<sup>2</sup>, Ronald Schrader<sup>3</sup>, Ambreen Gul<sup>4</sup>, Dana Miskulin<sup>5</sup>, Philip Zager<sup>2</sup>,<sup>1</sup> UNM, 2DCI, Tufts.

**Background:** Prolonged recovery time after hemodialysis (HD) may predict adverse clinical outcomes. In the Frequent Hemodialysis Network a patient’s response to the Recovery Question was consistent over time. To determine if this consistency is also present among patients undergoing thrice weekly HD we compared responses to the Recovery Question after each treatment in a given week.

**Methods:** We asked 256 patients in 3 DCI HD facilities “How long did it take you to recover after your last treatment?” The number of patients who answered the question on the 1st, 2nd, and 3rd treatment was 221, 207, and 200, respectively; 148 patients (57.8%) answered the question on all 3 occasions. Recovery time was categorized as <0.5 hours (h), 0.5 to 6 hours and ≥ 6h.

**Results:** Among the 148 patients who answered the Recovery Question 3 times, recovery times were 6.9, 4.5 and 9.3 hours after the 1st, 2nd, and 3rd treatment was 221, 207, and 200, respectively; 148 patients (57.8%) answered the question on all 3 occasions. Recovery time was categorized as <0.5 hours (h), 0.5 to 6 hours and ≥ 6h.

**Conclusions:** This method increases the removal of PBUTs and has no effect on non-protein-bound solutes. Achieving higher dialytic removal of PBUTs by infusion of binding competitors is feasible and efficient to apply in current HD settings.

511A
Among the patients with consistent short vs. long recovery, there were no differences in age, race, and vintage. There was a trend for women (59%) to be more likely to have recovery ≥ 6 h (p=0.09). After the 1st dialysis of the week, recovery was more likely (40%) to be ≥ 6 h among patients dialedy with a dialysate sodium concentration (DNa) <140 mEq/L vs. with a (DNa) ≥ 140 mEq/L (22%). However, similar differences were not observed for the 2nd and 3rd treatments.

Conclusions: There is significant variability among individual patients answers during the week when the recovery question is asked after each treatment.

FR-PO657
Quality Control and Improvement Union of Hemodialysis Centers: A New Management Model
Lijieying Han, Mei Wang. Dept. of Nephrology, Peking Univ People’s Hospital, Beijing, China.

Background: With the increasing incidence of end stage renal disease (ESRD) in China, more dialysis facilities are being opened. There are huge variations of patient care staffing levels and quality of care. How to maximize the utilization of existing health resources, optimize the management of hemodialysis patients and improve quality control are important issues. The aim of this study was to investigate the feasibility and effects of quality control and improvement union comprised of best hospitals and basic hospitals on patients’ medical quality control and improvement.

Methods: The HD union was constructed and specific measures were determined including, 1) Quarterly continuous quality improvement (CQI) meetings, 2) education based on typical cases including extensive discussions, guidelines and latest research results introductions, 3) lectures focusing on key questions, 4) opening green channel and construction of two-way referral system. Paired t-test was used to compare the differences of medical parameters of each hemodialysis center before and two-years after construction of HD union.

Results: The leading center of HD union was the HD center from Peking University People’s Hospital. Cooperating centers were other eight centers from class three and class two hospitals. After quarterly CQI meetings, all union members learned how to do medical quality control and improvement, constructed standards and procedures for diagnosis, cure and nursing of their HD center, established the institutions of lab exam and regular round frequency, added necessary examinations and implemented all-around management of HD patients. Green channel for intractable cases transfer were applied successfully. Thereafter, MMT appears to be a feasible and acceptable intervention for CKD patients and home practice. There were no significant between-group differences in affective response, anxiety, depression, self-reported health or coping skills at baseline or in change over time. Retention rate was 91.7% overall and 83.3% for the MMT group.

Conclusions: MMT appears to be a feasible and acceptable intervention for CKD patients during HD, although effectiveness remains to be demonstrated. Small sample size and low baseline distress levels in the study population limited the power to establish effects of MMT. Further research is needed to determine if abbreviated MBRS is sufficient to benefit tolerability of HD in this population. Focus on patients with higher baseline distress levels in future research would increase the likelihood of observing clinical benefit.

FR-PO659
Fluid Management Parameters Are Associated with Dialysis Recovery Time in Conventional Dialysis Patients
Wael F. Hussein,1,2 Rohini Arramredddy,1,2 Marc Reiterman,1 Sumi J. Sun,1 Brigitte Schiller,1,2 1Dept of Medicine, Division of Nephrology, Stanford Univ, Palo Alto, CA; 2Satellite Healthcare, San Jose, CA.

Background: Longer dialysis recovery time (DRT) is associated with increased mortality and shorter time to hospitalization. We studied the association of fluid management and hemodynamics with recovery time in conventional hemodialysis (HD) patients.

Methods: Self-reported DRT, obtained by asking “How long does it take you to recover from a dialysis session?”, was recorded for 2,689 patients undergoing thrice weekly adequate HD in 46 centers in 3 states. Ordinal logistic regression was used to study the association between patient and dialysis characteristics with DRT. Statistical adjustments were made for age, gender, race, vintage and baseline distress levels in the study population likely limited the power to establish effects of MMT. Further research is needed to determine if abbreviated MBRS is sufficient to benefit tolerability of HD in this population. Focus on patients with higher baseline distress levels in future research would increase the likelihood of observing clinical benefit.

FR-PO660
Different Adsorptive Properties of Hemodialysis Membranes May Cause Selective Depletion of Plasma Proteins
Jan Mares, Lukas Kielberger. Nephrology, Charles Univ, Plzen, Czech Republic.

Background: During hemodialysis (HD) session, plasma proteins are adsorbed to the surface of HD membrane. The resulting biofilm affects both dialyzer permeability and biocompatibility. The aim of this study was to analyze its composition in different HD membranes.

Methods: Twelve long-term HD patients were assigned to 4 HD with three different dialyzers in a cross-over design: ethylene-vinyl-alcohol/EVAL (KF-201-1.8C, Asahi Kasei), polysulfone (F8 HPS, Fresenius), and vitamin E-substituted polysulfone (ViE-18, Asahi Kasei). After HD session, the biofilm was eluted with acetic acid. Obtained proteins (200 µg) were separated by 2-dimensional electrophoresis and fractions showing distinct abundance across groups were identified by tandem mass spectrometry. Blood was sampled along the session to enable subsequent confirmatory studies (ELISA).

Conclusions: Long DRT affects a large proportion of HD patients. Optimizing UFR and controlling IDH are critical measures to improve quality of life for these patients.

FR-PO668
Feasibility of Mindfulness Meditation Training During Dialysis for Patients with Chronic Kidney Disease and Effect on Tolerability of Sessions
James C. Wasserman,1 Daniel Schupack,2 Andrew E. Williams,3 Paul K. Han,4 George K. Dreher,5 Mary Bitterauf.1 1Div of Nephrology, Maine Medical Center, Portland, ME; 2Center for Outcomes Research and Evaluation, Portland, ME; 3Maine Medical Center, Portland, ME; 4Maine Medical Center Research Inst, Portland, ME; 5MaineHealth, Falmouth, ME.

Background: Hemodialysis (HD) for CKD entails >/= 12 h of weekly treatment, creating significant distress for patients. Mindfulness-Based Stress Reduction (MBSR) has effectively helped patients with other chronic diseases cope with distressing symptoms and treatments. An abbreviated form of MBSR (Mindfulness Meditation Training, MMT) was incorporated into HD sessions to explore its feasibility, acceptability and potential effects on distress.

Methods: 12 patients were randomly assigned to MMT during HD or usual care. The MMT group underwent weekly 1-h individual sessions during HD for 4 wk. Within-session change in affective response was assessed with the Self-Assessment Manikin (SAM), validated measure of affective valence, arousal and dominance. Anxiety, depression, self-rated health and coping skills were also assessed with validated measures. Patient perceptions were assessed with qualitative interviews at study’s end.

Results: In qualitative interviews, patients reported improved tolerability of HD session length, positive intention to continue meditation and no significant issues with MMT sessions or home practice. There were no significant between-group differences in affective response, anxiety, depression, self-reported health or coping skills at baseline or in change over time. Retention rate was 91.7% overall and 83.3% for the MMT group.

Conclusions: MMT appears to be a feasible and acceptable intervention for CKD patients during HD, although effectiveness remains to be demonstrated. Small sample size and low baseline distress levels in the study population limited the power to establish effects of MMT. Further research is needed to determine if abbreviated MBRS is sufficient to benefit tolerability of HD in this population. Focus on patients with higher baseline distress levels in future research would increase the likelihood of observing clinical benefit.

Mathematical Model of Protein Transport and Plasma Refilling in Hemodialysis
Bengt Lindholm,1 Mauro Pietriibiasi,2 Małgorzata Debowska,2 Alicja Wojcik-Zaluska,2 Wojciech T. Zaluska,2 Jacek Waniewski,2 ‘Baxter Novum & Renal Medicine, Karolinska Inst, Stockholm, Sweden; 2Inst Biocybernetics & Biomedical Engineering, Warsaw, Poland, Rehabilitation and Physiotherapy, Med Univ Lublin, Lublin, Poland; ’Nephrology, Medical Univ Lublin, Lublin, Poland.

Background: Mathematical modeling offers a way to estimate quantities we cannot access directly during hemodialysis (HD). Here we propose a whole-body model of vascular refilling describing water and protein shifts across the capillary membrane during HD. The model was applied to reproduce profiles of plasma volume and serum total protein concentration in patients (pts) undergoing HD. Methods: The double-compartment model (vascular and interstitial space) was based on balance equations of protein mass and water volume in each compartment. The net transport across the capillary wall is the sum of the flow through the membrane’s pores and lymphatic flow. The capillary membrane is described according to the three-pore theory. Two transport parameters of the model, the relative number of large pores (Lp) and the total permeability surface area product (LpS) of the capillary membrane, were estimated from volumetric data and blood samples collected in 20 stable, non-diabetic pts during 60 HD sessions. Results: Lp and LpS were estimated to 10.0 ± 8.4 mL/min/mmHg and 0.062 ± 0.041. The model predicted profiles of plasma volume and serum total protein concentration with an average root-mean-square error < 2%, with larger errors only in pts with very high initial drop in blood volume. When increasing the assumed value of interstitial/serum protein ratio from 0.3 to 0.6, while the total refilling rate remained similar, the value of individual pore flow changed so that filtration through large pores at its peak was 40% smaller and absorption through small and ultrasmall pores was 80 and 60 % higher, respectively. Conclusions: The model proposes a mechanistic interpretation of fluid transport processes induced by ultrafiltration during HD. The estimated values of individual flows through each kind of pore and lymphatic absorptive represent the relative impact of these not-measurable quantities on total vascular refilling. Effect of Computationally-Optimized Vibration on Clearance of Solutes During In Vitro Hemodialysis
Katherine N. Ghabrian,1 Susan J. Lewis,1 Joseph L. Bull,2 John J. Pirte,1 Bridgett A. Scoville,1 Thomas Veloseni,1 Brad Urrerant,3 Selim Perkins,4 Bonnie A. Malley,5 ‘Coagulation Laboratory, Univ of Michigan, Ann Arbor, MI; 2Dept of Biomedical Engineering, Univ of Michigan, Ann Arbor, MI; 3St Alexius Medical Center, Hoffman Estates, IL; 4Dept of Physiology and Pharmacology, Western Univ, London, ON; 5Dept of Mechanical Engineering, Univ of Michigan, Ann Arbor, MI.

Background: Our previous in vitro studies demonstrated that the addition of vibration enhances dialytic clearance of solutes by a median of 18% during CVVHD. In this study, we applied computational fluid dynamics to determine vibration’s effects during hemodialysis and correlated them using an in vitro hemodialysis model. Methods: Based on predictions of a computational fluid dynamic models, two vibration settings (120 Hz/0.176 mm [360 Hz/0.075 mm] were selected and applied to a F8 dialyzer (1.8 m² Fresenius) during in vitro hemodialysis using blood-dialysate flow rates of 300/600 mL/min, respectively. Mean transmembrane clearances were analyzed for six solutes: urea, creatinine, gentamicin, vancomycin, indoxyl sulfate, and hippuric acid. Albumin, free hemoglobin, and LDL concentrations were measured after 4 hours of dialysis with applied vibration to assess blood and dialyzer integrity. Results: A one-way ANOVA revealed no significant difference between the control group and non-control vibration groups in solute clearance: urea, F(2,27)=1.801, p=0.184; creatinine, F(2,27)=2.525, p=0.099; gentamicin, F(2,27)=0.273, p=0.763; vancomycin, F(2,27)=0.003, p=0.997; indoxyl sulfate, F(2,27)=0.390, p=0.680; hippuric acid, F(2,27)=0.398, p=0.675. Four hours of vibration had no significant effect on blood and dialyzer integrity as measured by concentrations of albumin (F(1,22)=0.185, p=0.675), hemoglobin (F(1,22)=1.038, p=0.319), and LDL (F(1,22)=0.185, p=0.672). Conclusions: Although vibration has been shown to enhance solute clearance in patients, in this study we were unable to reproduce these results using our in vitro hemodialysis model using flow rates typically seen with intermittent hemodialysis. Sevelamer Hydrochloride Improves Oxidative Stress in Maintenance Hemodialysis Patients
Siren Sezeg, Bahar Gurlekdemirci, Cihat Burak Sayin, Emre Tutal, Zeynep Bal, Fatma Nurhan ozdemir Acar. ‘Dept of Nephrology, Baskent Univ Faculty of Medicine, Ankara, Turkey.

Background: Oxidative stress plays a key role in the pathogenesis of cardiovascular diseases. Superoxide dismutase (SOD) and malondialdehyde (MDA) are well-known antioxidant enzymes that detoxify advanced glycation end products (AGEs). We thought that avoiding calcium intake and through pleiotropic effects, sevelamer hydrochloride might be a differential influence in terms of oxidative stress. The aim of this study is to examine the effects of phosphate binders (PBs) on the components of the oxidative stress and clinical and biochemical parameters including pulse wave velocity in our maintenance hemodialysis (MDH) patients. Methods: A total of 111 patients (mean age: 52.2 ± 14.3 years; mean duration of dialysis: 9.7 ± 4.8 years) undergoing maintenance hemodialysis and using the same PBs at least one year were enrolled into the study. Patients were divided into two groups according to usage of PBs as sevelamer based PB (group 1; n = 84 and calcium based PB (group 2; n=27). Biochemical parameters were assessed from monthly clinical visits. Serum AGE, MDA and SOD levels were determined by ELISA method. Pulse wave velocity (PWV) was determined by using the SphygmCor system. Results: Groups were similar in means of demographic characteristics and URR levels. Patients in group 1 had significantly lower AGE (p: 0.018), higher MDA (p: 0.027) and SOD (p: 0.012) levels. Although both baseline and first year PWV values were similar in two groups, PWV values significantly decreased in group 1 (p<0.001) where increased in group 2 (p: 0.021) in the second year analysis. In linear regression analysis, serum AGE levels were detected as the unique predictor of DPWV (p: 0.005). For each 1 mL/min of increased level of AGE resulted in 0.53 cm/sec of increased level of PWV (p: 0.005, CI: 0.016-0.089).

Conclusions: Despite similar phosphorus levels and dialysis adequacy, sevelamer decreases serum AGE and increases serum MDA and SOD levels as well as improves PWV. Thus, sevelamer improves the oxidative stress and cardiovascular risk by pleiotropic effects when compared to calcium based phosphate binders.

Preliminary Study About Optimal Dosage of Heparin Locking Solution to Maintain the Patency of Hemodialysis Catheter Jung-woo Noh, Eunjung Kim, Ja-Ryong Koo. Internal Medicine, Nephrology, Hallym Univ Medical Center, Hallym Kidney Research Inst, Seoul, Korea.

Background: Hemodialysis catheters (HC) are routinely heparin locked to maintain patient patency. This practice may cause bleeding episodes. The amount of heparin for heparin locking solution at many dialysis centers has been decreased recently to reduce the risk of bleeding. However, the effect of this change on patency of HC is unknown. We compared the patency of HC between four types of heparin amount of 4000, 5000, 7500, and 15000 units (U).

Methods: This observational study included 126 chronic hemodialysis patients using HC in Hallym University Medical Center from March 2011 to July 2014. 29 patients received a 4000 U, 41 patients received a 5000 U, 44 patients received a 7500 U and 41 patients received a 15000 U of heparin. The primary outcome was composite outcome: frequency of thrombolytic instillation, change of hemodialysis line due to dysfunction of HC and HC obstruction due to thrombosis. We also compared activated partial thromboplastin time (aPTT) levels between groups just before and 10 minutes after the end of each hemodialysis.

Results: The composite outcome were 2.44±5.42, 1.06±3.46, 0.40±1.18 and 0.52±1.16 episodes/100 catheter-days, respectively (p=0.03). 4000U group showed especially high rate of occurrence of events compared to other groups receiving more than 5000 U of heparin. However, event rate of HC obstruction due to thrombosis was not significantly different: zero episodes/100 catheter-days for 4000U and 15000U groups, 0.01±0.05 episodes/100 catheter-days for 5000IU group and 0.14±0.61 episodes/100 catheter-days for 7500 IU group. At 10 minutes after heparin lock, prolonged aPTT was observed in all groups. When 10 minutes aPTT levels between 4000 U group and other groups are compared, those of 7500 U (p=0.007) and 15000 U (p=0.004) groups were significantly prolonged. But there were no bleeding complications in those groups.

Conclusions: Low concentration heparin lock solution with total amount of 4000 U do not increase HC obstruction due to thrombosis, but increase in thrombolytic instillation and set change. Higher concentration heparin lock solution with total amount over 7500 U prolonged the aPTT without bleeding complication.

Association Between Depressive Symptoms and Dependency with Mortality in Hemodialysis Patients After 5 Years of Follow-Up Joaquín Manrique, María del cielo Mena, Eva Cerdán, Laura Catalan. Servicio de Nefrología, Complejo Hospital de Navarra, Pamplona, Spain; Nursing Staff. Servicio de Nefrología, Complejo Hospital de Navarra, Pamplona, Spain.

Background: The prevalence of depression and its role in mediating survival of patients with end-stage renal disease (ESRD) has been highly controversial. Moreover, according to the population ages, their limitations in performing daily activities affect their wellbeing.

Methods: We have evaluated depressive symptoms and dependency associated with mortality in a longitudinal study of 148 hemodialysis (HD) outpatients followed for 5 years. Depressive symptoms were assessed using the Beck Depression score (BDs), and dependence by Barthel scale (BS) performed by nursing HD staff.

Results: Depressive symptoms are common among patients on hemodialysis. Both of them may as well as increase the burden on caregivers and the use of health services.

Conclusions: Our study shows that the disability in self-care and the presence of depressive symptoms are associated with increased mortality and decreased survival of patients on hemodialysis.

Limitations of Access Recirculation due to a Low Access Flow Rate on Middle Molecule Clearance During Post-Dilution Hemodiafiltration J. Ken Leypoldt, Markus Storr. Renal Therapeutic Area, Baxter Healthcare Corporation, Deerfield, IL; Research & Development, Gambro Dialyssatoren GmbH, Hechnigen, Germany.

Background: Post-dilution hemodiafiltration (HDF) with a high convective volume (CV) is associated with lower overall patient mortality, potentially due to high middle molecule (MM) clearance from the patient (Kp). A higher CV can most readily be achieved by extending the treatment time or increasing the blood flow rate (BFR); however, the effect of access recirculation due to a low access flow rate (AFR) when increasing the BFR on MM Kp during HDF has not been previously quantified.

Methods: A theoretical mass balance model for assessing the effect of a low AFR on MM Kp was formulated. Access recirculation was assumed to occur when the BFR exceed the AFR. The model demonstrates that higher MM Kp is dependent on HDF membrane properties, AFR, BFR, CV and the fluid removal rate from the patient (FRR).

Results: Sample results are tabulated for a patient with a hematocrit of 33% at different AFRs and BFRs maintaining a fixed filtration fraction of 25% during a 4-hour HDF treatment with a FRR of 0.5 L/hour. MM filter clearance was assumed to depend on CV with a diffusive clearance of 75 mL/min and a sieving coefficient of 0.7.

When the AFR is higher than the BFR, MM Kp increases with increasing CV. At low AFR, increasing the BFR above the AFR results in a lower MM Kp than expected. Indeed, increasing the BFR above the AFR can even lead to a reduction in MM Kp.

Conclusions: High convective volumes during post-dilution HDF achieved by using high blood flow rates may not result in higher middle molecule clearance if the access flow rate is low. Routine assessment of access recirculation or access flow rate may be necessary during post-dilution HDF with high blood flow rates to improve patient outcomes.

Protein Biofilm and Its Relation to Dialyzer Permeability for Middle Molecular Weight Markers in Three Polysulfon Membranes Lukas Kielberger, Jan Mares. 1st Dept of Internal Medicine, Charles Univ Teaching Hospital, Plzen, Czech Republic.

Background: Membrane permeability, particularly in terms of middle molecular clearances, is largely dependent in vivo on the formation of a protein biofilm. Our aim was to assess its dynamics during HD session together with molecular composition of the biofilm.

Methods: 12 HD patients were assigned in a cross-sectional design to Xevonta® HD2® (B-Braun, 2.3 m²), CorDiax FX100® ( Fresenius, 2.2 m²) and Polyflux® 210H (Gambro, 2.1 m²) dialyzers. Blood pre- and post-dialysis was sampled at 0, 15, 60, and 240 min; spent dialysate was collected from the dialyzer and produced for analysis.

Results: At the beginning, Xevonta and FX dialyzers showed significantly higher in vivo sieving coefficients for all MWs up to 26 kDa (ml/min) then Polyflux dialyzer (p<0.01). After 15 min, Xevonta and FX permeability decreased significantly (p<0.01) in all MW classes while in Polyflux, only MW<21 kDa (BFRP) were affected (p<0.01). The total protein content of membrane biofilm was similar in all three dialyzers: 118±85, 41±10, and 40±17 mg protein per dialyzer for Xevonta, FX, and Polyflux, resp. Significant differences in protein composition were captured in 48 out of 231 protein fractions. Among them, complement factor H-related protein 3 (FHR3), insulin-like growth factor binding protein 4 (IBP4), or multiple fibrin fragments (FDP) were identified. While FDP and IBP4 were prevalent in eluates from FX and Xevonta dialyzers (p=0.005 and 0.001, resp.), FHR3 was abundant in Xevonta only (p=0.01).

Conclusions: Even with modern biocompatible dialyzers, in vivo permeability decreases along HD session, probably due to biofilm formation. The decrease occurred irrespective of total protein adsorbed, compromising rather membranes primarily more permeable and higher MWs. Differences in biofilm composition are complex and may impact both dialyzer permeability and biocompatibility.

Protective Effects of Intravenous L-Carnitine (LC) Administration on Development of Cardiomyopathy in Hemodialysis (HD) Patients Takahisa Uchino, 1 Jyunichiro Hashiguchi, 1 Satoshi Funakoshi, 1 Hiroshi Ichinose, 2 Osamu Sasaki, 1 Kenji Sawae, 1 Miki Yano, 1 Yutaka Morita, 1 Kazunori Utsunomiya, 1 Yoko Obata, 2 Tomoya Nishino, 7 Miwa Shirahama, 1 Takashi Harada, 2 Nagasaki Kidney Center, Nagasaki, Japan; 2Nagasaki Univ School of Medicine, Nagasaki, Japan.

Background: Due to loss via dialyzer patients on maintenance HD often suffer from dialysis-related cardiac deficiency, causing various clinical symptoms. Cardiomyopathy Consensus Conference in 2003 convened by The National Kidney Foundation had reported that the level of evidence was “moderate” for cardiomyopathy. Recent studies have shown that L-carnitine can improve left ventricular (LV) function in HD patients. In this study, we aimed to investigate whether intravenous administration of LC can prevent the development of cardiomyopathy in HD patients as assessed by M-mode ultrasound cardiography (UCG).

Methods: Thirty-eight HD patients without reduced left ventricular function were treated with intravenous administration of 1000mg/kg body of LC at the end of every HD session for 12 months. M-mode UCG assessments were undergone in all subjects at the three points: 1 year prior to the treatment, the start of LC administration and year after the treatment.

Results: As shown in Figure 1, average %FS (fractional shortening) significantly declined during 1 year before the start of LC, then stabilized after the treatment, suggesting LC administration might protect the progression of LV contraction impairment. Average early diastolic filling velocity (E) / atrial filling velocity (A) ratio showed similar pattern, suggesting LC treatment could be protective in LV diastolic disorder. LC treatment also might delay LV hypertrophy progression.

Conclusions: Intravenous LC administration can be a candidate therapy for protection of the development of cardiomyopathy in HD patients.

Symptoms and Quality of Life Among Patients Receiving HD Mark L. Unruh, 1 Kim J. Cox, 1 Stephen H. A. Hernandez, 2 Sanah Parvez, 2 Mark Parshall. 2 "Div of Nephrology, Univ of New Mexico; 2College of Nursing, Univ of New Mexico.

Background: Health-related quality of life (HRQOL) assessment is a required condition of coverage for HD providers, but standard measures may not adequately reflect the impact of symptoms and treatment on QOL for patients receiving HD or the concerns that matter most to them. The purpose of this qualitative study is to more fully characterize patients’ perspectives on the symptoms and treatment experiences affecting their QOL.

Methods: We conducted semi-structured interviews with a diverse sample of 50 HD patients (48% Female; 42% Hispanic; 30% American Indian; 14% Black; 12% Non-Hispanic White) to elicit their experiences with diagnosis and treatment of ESRD and the symptoms and aspects of treatment that have the greatest impact on their QOL. Interviews were audio-recorded, transcribed, and analyzed for themes using an interpretive-approach.

Results: Participants recalled that the initial diagnosis of ESRD was received with shock and denial. Over time, patients reported that QOL was associated with “taking control” of some features of their treatment. Common symptoms associated with HD, such as cramping and fatigue, were described as potentially manageable when patients were able to participate in decisions about fluid removal and scheduling of HD treatments. Patients who formed a partnership with their providers to negotiate fluid removal reported fewer episodes of severe cramping and improved QOL. Similarly, being able to choose among a variety of days and shifts for HD treatment enabled patients to manage fatigue, work hours, travel, and attendance at social events. These factors were critically important to the QOL in our relatively young sample (median age = 53; median duration of HD treatment = 4 years).

Conclusions: This is one of the largest and most diverse qualitative studies of symptoms among patients undergoing HD. There were few differences in symptoms or the impact of treatment on QOL among racial and ethnic groups. Findings highlighted the importance of fluid management and fatigue to patient experience.

Association of Time-Averaged Concentration of Hemoglobin with Mortality: Results from a Large U.S. Hemodialysis Cohort

Hanie Zhang, Stephan Thijssen, Peter Kotanko. Renal Research Inst, New York, NY; Icahn School of Medicine at Mount Sinai, New York, NY.

In hemodialysis (HD) patients the time averaged concentration of hemoglobin (Hb_tac) can be estimated from pre- and post-HD hemoglobin (Hb) levels. It has been suggest that Hb_tac may be an appropriate indicator for anemia management (Siga, Int Urol Nephrol 2014). However, the association between Hb_tac and mortality has not yet been evaluated.

Methods: We analyzed hemoglobin data obtained by Crit-Line™ monitor (CLM) in chronic HD patients. A 6-month baseline period with at least 10 CLM measurements preceded a 12-month follow-up during which outcomes were noted. We used Hb values from HD sessions following a short interdialytic interval. Hb_tac was computed as follows (Krisper, NDF 2000): Hb_tac = 0.5 × Hb_post + 0.38 × 1.28. We defined Hb_post as the average Hb between minutes 5 to 20 from the start of the CLM recording, and Hb_post as the average of Hb between minutes 5 to 20 from the end of the CLM recording. The relation between Hb_tac during baseline and mortality was explored by spline analysis of hazard ratio (HR).

Results: We studied 982 patients (136) with a total of 19,142 CLM measurements. Average Hb_tac was 10.72 g/dL (SD 0.81, range 7.27 – 14.62 g/dL). The mortality rate during follow-up was 11.6 per 100 patient-years. The minimal HR (figure 1B) was 0.82 at Hb_tac of 10.87 g/dL. The solid line represents mean HR, the dotted line 95% confidence intervals.

Conclusions: Hb_tac is associated with mortality, levels around 10.9 g/dL are associated with the lowest mortality risk. Studies are required to further explore methods to estimate Hb_tac based on Hb measurements by the CLM and the usefulness of Hb_tac for mortality prediction.

FR-PO676
Prediction of Changes in Serum Albumin Levels Among Hemodialysis Patients by Serum Neutrophil Gelatinase-Associated Lipocalin Levels

Hirotsuka Imaizumi, Akira Ishii, Hideki Yoko, Masato Kasahara, Keita P. Mori, Takashige Kuwabara, Kazuwa Nakao, Masashi Mukoyama, Motoko Yanagita, Kiyoshi Mori. Dept of Nephrology, Graduate School of Medicine, Kyoto Univ; Kyoto, Japan; Inst for Advancement of Clinical and Translational Science, Kyoto Univ Hospital, Kyoto, Japan; Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; Medical Innovation Center, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.

Circulating concentration of neutrophil gelatinase-associated lipocalin (NGAL) or LCN2 is elevated in acute and chronic kidney diseases. Recently, we reported that, in a cross-sectional study, serum NGAL concentrations in maintenance hemodialysis (HD) patients were determined independently by % creatinine generation rate, white blood cell count and anion gap, indicating that NGAL is a marker of good nutritional conditions. Clinical impact of NGAL was further evaluated in a prospective analysis.

Methods: Correlations of baseline nutritional indices with baseline and follow-up serum albumin levels and with changes in albumin levels after a year were investigated among 87 HD patients using linear regression analysis.

Results: Follow-up albumin levels were positively correlated to baseline NGAL, serum albumin levels and rank of variables in the risk model.

Conclusions: Serum NGAL level in HD patients appears to be a unique biomarker allowing prediction of alteration in serum albumin levels in a year.

FR-PO677
Race, Health-Related Quality of Life and Mortality in a Large Cohort of Brazilian Multiracial Hemodialysis Population

Marcelo Barreto Lopes, Priscila S. Carvalho, Janaína M. de O. Paula, Jeane M. Monteiro, Gildete Barreto Lopes, Antonio Alberto Lopes. Federal Univ of Bahia, Salvador, BA, Brazil.

Background: Studies developed in patients undergoing maintenance hemodialysis (MHD) in the United States (US) indicate that the survival and the health-related quality of life (HRQOL) are better in African Americans and other racial minorities than in Whites. Similar to the US, Brazil is a country with a diverse racial population. There is a lack of studies to investigate if there are differences in HRQOL and mortality by race in Brazilian MHD patients. The present study developed in a multiracial Brazilian MHD population investigated associations of race (Whites as reference) with HRQOL and survival.

Methods: A prospective cohort of 1084 MHD patients (11.8% White, 61.3% mixed race, 26.1% Black) enrolled in the Prospective Study of the Prognosis of Chronic Hemodialysis Patients (PROHEMO) developed in nephrology clinics of Salvador, Brazil. The predictor variable was race (White as reference). Outcomes were mortality and HRQOL scores, using the KDQOL-SF. Multivariable linear regression was used for differences in scores and Cox regression for mortality. Associations were adjusted for age, sex, diabetes, heart failure, blood hemoglobin and vintage.

Results: Mean age was significantly lower (P<0.001) in Blacks (49.2±14.0 yrs) and mixed races (47.6±14.5 yrs) than in Whites (55.0±13.7 yrs). In the multivariable linear regression differences were not observed by race for PCS, MCS, disease burden and effects of kidney disease. For symptoms/problems, a significantly (P=0.043) higher adjusted score (difference=3.6) was observed in Whites (than in Blacks). In the Cox model with complete adjustment for covariates, the hazard ratio (HR) was 0.95 (95% confidence interval (CI) 0.66-1.35) for the comparison between mixed race and White and 1.10 (95% CI=0.75-1.61) for the comparison between Blacks and Whites.

Conclusions: In disagreement with studies developed in the United States, this study developed in a multiracial Brazilian hemodialysis did not show worse HRQOL and higher mortality in whites as compared to patients of mixed race and Blacks.

FR-PO678
Low Lymphocyte Counts Are an Independent Predictor of Mortality in Chronic Hemodialysis Patients: A Retrospective Cohort Study

Background: Mortality in chronic hemodialysis populations remains high. Lymphopenia has been associated with increased cardiovascular risk in the general population but few data are available on the effect of low lymphocyte counts on long-term survival of hemodialysis patients.

Methods: Retrospective study of a single-center cohort of 689 hemodialysis patients using monthly laboratory results and dialysis parameters extracted from a center database and a national registry. The effect of baseline and time-changing lymphocyte counts on overall mortality was studied using the Kaplan Meier and Cox proportional hazard methods.

Results: Lymphopenia (<1200 µL) was present in approximately one third of incident hemodialysis patients and correlated with older age, lower creatinine, lower phosphorous, higher Kt/V and a positive history of ischemic heart disease. Lymphopenia was not associated with classical markers of malnutrition-inflammation complex such as albumin, normalized protein catabolic rate, BMI and CRP. Baseline lymphopenia was associated with classical markers of malnutrition-inflammation complex such as albumin, hemoglobin, BMI, CRP and Kt/V and history of ischemic heart disease.

Conclusions: Lymphopenia is highly prevalent in hemodialysis patients and is a strong predictor for patient death. The association was stronger when lymphocyte counts were considered as a time-changing variable and independent of other risk factors for patient death. Lymphopenia was not associated with markers of the malnutrition-inflammation complex such as albumin, CRP and Kt/V and history of ischemic heart disease.

FR-PO679
Current Status of Hemodialysis in China
Li Zhang, Delong Zhao, Xueying Cao, Xiang-Mei Chen, Guangyan Cai. Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases.

Background: In May 2010, the first nationwide, web-based prospective renal data registration platform, the Chinese Renal Data System (CNRDS) was launched in China. The purpose of this study was to determine the current status of hemodialysis in China by analyzing the data from CNRDS.

Results: (1) There were 4047 domestic hemodialysis centers and 339748 survival patients were registered by the end of 2014. (2) In the 339748 patients, 58.85% were male. The average age was 54.9 years and average dialysis duration was 42.2 months. The three leading causes of ESRD were glomerulonephritis, diabetic nephropathy and hypertensive renal diseases. (3) 4322 patients died in 2014, with an average of 61.9 years and average dialysis duration of 39.7 months. The main causes of death were cardiovascular events and stroke, followed by infection and gastrointestinal bleeding. (4) In the patients, 44.1% had predialysis blood pressure less than 140/90mmHg; 55.4% had hemoglobin concentration ≥100g/L and 80.3% had albumin levels ≥35g/L. 39.6% had serum calcium between 2.10 and 2.50mmol/L; 34.7% had serum phosphorus between 1.13-1.78mmol/L; 53.9% had PTH between 130 and 600pg/ml.

Conclusions: As Chinese National Health and Family Planning Commission have enhanced the basic medical security system on hemodialysis, both the population and the quality of hemodialysis have increased in recent years.

FR-PO680
Outcomes and Quality of Care in Rural versus Urban Managed Dialysis Patients
James M. Zachariah, Allison Dart, Harvey M. Chochinov. 1 Dept of Medicine, Univ of Manitoba, Winnipeg, MB, Canada; 2 Dept of Pediatrics, Univ of Manitoba, Winnipeg, MB, Canada; 3 Dept of Psychiatry, Univ of Manitoba, Winnipeg, MB, Canada.

Background: A proportion of patients are managed in remote satellite units in Manitoba, Canada. Urban nephrologists oversee all dialysis care; however family physicians (FP) co-manage patients. This study examines outcomes and quality of care indicators in rural vs urban managed patients.

Methods: Prospectively collected clinical data from the Manitoba Renal Program and administrative health data housed at the Manitoba Centre for Health Policy were analyzed retrospectively. All adult (~1990 to 2010) and pediatric patients (~90 days to 2010) were included. Individuals dialyzing in rural satellite units (n=510) more than 50% of the time were compared to their urban (n=2629) counterparts. Differences in cohort characteristics were analyzed at baseline as well as differences in primary care and quality indicators. Regression analyses examined differences in hospitalizations and days in hospital. Cox proportional hazard models were performed to examine differences in survival.

Results: Patients in rural satellite units vs urban were younger, 58 ± 6 yrs (p=0.002), but were more likely to have DM 69.4 vs 55.3% (p<0.0001), PVD 9.4 vs 4.0% (p<0.001) and HDL (1mM, Angiogram or PTCA) 42.8 vs 34.2% (p=0.002). More rural patients accessed a FP at least once per year 85.7% vs 67.3% (p<0.0001) and 85.3% vs 68% (p<0.001), after controlling for sex, income, Charlson, era, age and region at the start of dialysis.

Conclusions: Survival in a cohort of patients dialyzing in remote satellite units was found to be superior to their urban counterparts, after controlling for co-morbidities. A potential reason might be increased primary care involvement, although differences were not seen in traditional quality of care indicators.

FR-PO681
Applying Hemodialysis Clinical Quality Indicators to Individual Patients: A Useful Mortality Prognostic Tool in Clinical Practice?

Background: Hemodialysis (HD) care is routinely assessed by a set of clinical and laboratorial parameters, known as Clinical Quality Indicators (CQI). CQI registry and monitoring constitutes an instrument to evaluate the quality of care provided at each HD unit. The purpose of this study was to determine whether CQI, applied on an individual patient basis, is a predictor of mortality.

Methods: Retrospective study that included 334 patients of a HD Unit from 2011 to 2014. Demographic, clinical and laboratory data were collected. The CQI considered were eleven, which included target variables: spgKtV ≥ 1.4; weekly dialysis time ≥ 720 minutes; Albumin ≥ 3.5 g/dL; Hemoglobin between 10 and 12 g/dL; phosphatemia between 2.5 and 5.5 mg/dL; Ca×P product < 55 mg²/dL; PTH levels between 150 and 600 pg/ml; Ferritin between 200 and 800 mg/dL; Mean arterial pressure < 105 mmHg; Intelectal weight gain (IWG) ≥ 4% and fistula as vascular access. Single CQI were rated in a binary form (0 = not reached target/1 = reached target) at each monthly evaluation and the average were determined. Ultimately, the eleven parameters were added in a single variable for each patient (CQIP).

Results: During follow-up, 33% of patients died. In the Cox regression model, age (HR 1.09; CI 1.07-1.11; p<0.001), diabetes (HR 2.88; CI 1.92-4.32; p<0.001), peripheral arterial disease (HR 1.65; CI 1.09-2.44; p= 0.016) and CQIP (HR 0.73; CI 0.62-0.87; p<0.001) were shown to be independent predictors of mortality, after adjustment for other clinical and demographical factors. When CQIP was replaced by its constituent variables, albumin (HR 0.06; CI 0.08 -0.32; p<0.001), PTH (HR 2.8; CI 1.10-3.93; p = 0.023), IWG (HR 0.34; CI 0.14-0.83; p = 0.018) and fistulae presence (HR 0.61, CI 0.4-0.93, p = 0.021) presented statistical significance.

Conclusions: A set of parameters, generally applied as a quality care indicators, proved to be an independent predictor of death when applied to individual patients. This should be regarded as an easy and practical prognostic tool to be applied in current practice.

FR-PO682
Association of Estimated Glomerular Filtration Rate at Commencement of Maintenance Dialysis with Mortality Among Patients with Advanced Chronic Kidney Disease in Singapore
Tazeen H. Jafar,1 Jin Ai Zhen,1 John C. Allen,1 Saeideh Tavajoh,1 Khuan yew Chow.1 'Duke-NUS Graduate Medical School Singapore; 2National Disease Registry Office, Health Promotion Board, Singapore.

Background: Recent evidence suggest that higher estimated glomerular filtration rate (eGFR) at commencement of dialysis may be associated with increased mortality. However, there is scarcity of data on patients of Southeast Asian origin. We analyzed and compared mortality risk in patients with early and late start dialysis as measured by kidney function at dialysis initiation among Southeast Asian population of Singapore.

FR-PO683
Enhanced the basic medical security system on hemodialysis, both the population and the quality of hemodialysis have increased in recent years.

Funding: Government Support - Non-U.S.
Methods: We performed a retrospective analysis of patients enrolled in the Singapore Renal Data System database from 2008 to 2011. Patients were classified into groups by eGFR at dialysis initiation.

Results: In this total incident population (n=3708), a total of 1510 individuals died during a median follow-up period of 2.8 years. The hazard ratio (HR) and 95% CI associated with different levels of eGFR at commencement of RRF are shown in table below. The main multivariable model (n=3189 without missing information on covariates) associated with the eGFR at dialysis initiation within the groups: age, gender, level of education, smoking, presence of diabetes, ischemic heart disease, cerebrovascular disease, and peripheral vascular disease, malignancy, hepatitis B, hepatitis C, kidney transplant, and modality of dialysis. Additional models accounted for serum albumin (n=2657), and serum ferritin (n=2462), and serum calcium (n=1628).

The results were consistent after accounting for serum albumin, serum ferritin, and serum calcium in the multivariable models.

Conclusions: Late initiation of dialysis is associated with a lower risk of mortality in comparison with early dialysis initiation in Southeast Asians in Singapore.

FR-PO683
Predicting Mortality for Patients Who Are on Hemodialysis–A National Cohort Study in Taiwan
Jinn-Yang Chen, Div of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan.

Background: Comorbid conditions and medical history provide prognostic information for dialysis patients. The objective of this study was to develop a prognostic model to predict short-term (6-months) and 1-year) and long-term (2.5-years) survival for incident hemodialysis (HD) patients.

Methods: Incident Taiwanese hemodialysis patients from 2006 to 2010 were extracted from National Health Insurance claim records. Prognostic model was developed by using combined conditions (summarized as Taiwan index), monthly income and medical history during one year before initiation of dialysis. Somner’s D statistic was used to assess the discrimination ability of our model.

Results: A total of 36,875 incidence HD patients were included in this study and the last follow-up day was December 31, 2011. More comorbid burden, male gender, history of acute kidney injury, dementia, admitting to intensive care unit, staying at nursing home and ever using ventilator were significant prognostic factors. Monthly income only had marginal effects on survival at 2.5 years. For discrimination ability, our model has Somner’s D statistics of 0.76, 0.76, and 0.75 for 6-months, 1-year, and 2.5-years survival, respectively.

Conclusions: Three prognostic models with same covariates for short-term and long-term survival in HD patients were found in this study. The consistency in model performance helps clinicians and patients to make decision.

Funding: Government Support - Non-U.S.

FR-PO684
Twice Weekly Treatment Eligibility for Incident Hemodialysis (HD) Patients
Suresh Appassamy, Andrew I. Chin, Thomas A. Depner. Div of Nephrology, Univ of California, Davis, Sacramento, CA.

Background: KDOQI guidelines advise that hemodialysis treatments constitute a conservative criteria, half of these were judged ineligible because of US requirements or HD-induced symptoms. Opportunity exists for incremental HD in a significant number of incident patients.

In the 225 patients who could achieve the target stdKT/V with 2/week HD, the mean spKT/V required was 0.83±0.36. A total of 105 or 25% of patients with measured Kru met all 4 criteria.

Conclusions: Urine collections disclosed that 225 or approximately 30% of 734 incident patients were eligible for 2/week HD based on solute kinetics alone. Using conservative criteria, half of these were judged ineligible because of US requirements or HD-induced symptoms. Opportunity exists for incremental HD in a significant number of incident patients.

FR-PO685
The Relationship of Diabetes and Congestive Heart Failure to Costs of Care in End Stage Renal Disease Patients
Sheetal Chaudhuri, Jane Brzozowski, Hao Han, Len A. Usyut, John W. Larkin, Mahathi Mothali, Terry Ketchersid, Franklin W. Maddux. Fresenius Medical Care North America, Waltham, MA.

Background: Many Medicare patients (Pts) with end stage renal disease (ESRD) are known to have co-morbidities of diabetes mellitus (DM) and/or congestive heart failure (CHF). Total costs of care for ESRD Pts are likely to be dependent on patient comorbidities and likely to vary by geography. We investigated the relationship of DM and CHF based on Pts’ geographic location.

Methods: ESRD Pts with evidence of dialysis at any time during Jan 1, 2010 through Dec 31, 2011 and Medicare as their primary payer were analyzed. Pts were stratified based on Metropolitan Statistical Areas (MSA) and Medicare Part A and B costs were calculated from 100% Medicare data. T-test comparisons were performed for quartiles of total cost of care for four groups: based on vintage (incident [≥90 days on dialysis] or prevalent [≥3 years on dialysis]), as well as, comorbidities (no DM and no CHF, DM and no CHF, no DM and with CHF and with both DM and CHF).

Results: Claims for 107,659 Pts were analyzed. Total cost of care increased significantly as the percent (%) of Pts with CHF and DM increased; cost of care declined significantly as the % of Pts with neither DM nor CHF increased by MSA. Cost of care did not change with the increase in % of Pts without DM and with CHF. Yet, costs of care declined as % of Pts with DM and without CHF increased by MSA. These patterns were observed in both incident and prevalent Pts.

Figure 1. Costs of care by MSA (per member per month)

Incident Patients
Prevalent Patients

Results: These results identify differences in association between ESRD related co-morbidities and total costs of care: the % of Pts with both DM and CHF is higher in areas with higher total costs. Surprisingly, costs of care are lower in areas where the % of Pts with DM but without CHF is higher. Risk Adjustments should be considered.

FR-PO686
Long Term Outcomes Over 2 Years following a Dialysis Adequacy Quality Improvement Initiative
Sajida Yousoufi, Philip A. Karla, Janet Hegarty. 1,2
1 Royal Free NHS Foundation Trust; 2 Manchester Academic Health Sciences Centre.

Background: Dialysis adequacy is known to correlate with clinical outcomes such as mortality. Evidence based guidelines recommend that haemodialysis patients should achieve a urea reduction ratio of >65%. UK Renal Registry data shows wide variation in facility attainment of target URR. In 2010 the Salford Renal Network implemented an ambitious programme to uplift attainment of key quality of care indicators to within the top 10% in the UK; dialysis adequacy was a target in 2 phases of improvement in 2010-2012.

Methods: Our network implemented a quality improvement programme using collaborative methodology. We set four teams a different clinical indicator to work on over 12 months cycles for 2 successive years, guided by QI facilitation input. Unit A worked on URR in phase 1 and developed a package of changes using plan-do-study-act (PDSA) testing that was used for improvement by Unit B in phase 2. We analysed the long-term outcomes in these units for a further 2 years until May 2014.

Results: Both units reached their aim of >90% of patients achieving target URR>65% within their improvement year. Both units sustained the improvements for 2 years with no additional resource input after the collaborative. Changes included protocolled nurse-led changes to dialysis prescriptions, multidisciplinary review of vascular access, a nurse-led anticoagulation protocol, blood sampling protocol, and monthly reports.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: Longer term outcomes from QI interventions are underreported with limited evidence on sustainability. We implemented multifaceted interventions to improve dialysis adequacy in our network to within the top 10% in the UK. Implementing evidence-based changes led by frontline staff trained in QI has sustained these improvements for 2 years after a formal QI intervention, improving quality of care for our patients.

FR-PO687
Clinical Effectiveness of Intermittent Infusion Hemodiafiltration (I-HDF) Compared with Conventional Hemodialysis: A Multicenter Clinical Trial
Michio Mineshima, Kei Eguchi. Clinical Engineering, Tokyo Women’s Medical Univ, Tokyo, Japan.

Background: Intermittent infusion hemodiafiltration (I-HDF) using backfiltration of an ultrapure dialysis fluid has been developed to improve the peripheral circulation of the patient receiving a typical hemodialysis (HD) with repeated intermittent infusion by an automated dialysis machine, GC-110N (JMS Co. Ltd., Tokyo, Japan). In a typical HD treatment, excessive water removal often induces hypotension and muscle spasm. In the I-HDF, some 200-300 mL ultrapure dialysis fluid was infused into the blood component through the dialysis membrane at a rate of 100 mL/min, every 30 min. I-HDF, namely, means a HDF treatment with small amount of infusion volume, 1.4 to 2.1 L (200-300 mL × 7 times)/session.

Methods: In this paper, clinical effectiveness of I-HDF was evaluated in comparison with conventional HD (CHD) during a multi-center clinical trial that twenty chronic renal disease patients participated.

Results: A significantly lower value for time-averaged blood volume reduction was obtained with I-HDF compared with CHD in spite of there being no difference in the total amount of water removal. It was due to a higher plasma refilling rate in I-HDF. In addition, increasing peripheral blood flow rate in the patient’s toe was detected by a laser flowmeter for each infusion in many patients. The cleared space value defined as amount of normalized solute removal during a treatment were higher with I-HDF than CHD for many patients.

Conclusion: Intermittent Infusion HDF using an automated dialysis machine was effective for improvement of the peripheral circulation of patients receiving conventional HD.

FR-PO688
Impact of Post-Hospital Phone and Telehealth Care Management to Reduce Admissions: Experience from 28 US Dialysis Clinics
Rachel L. Wingard, Billie Axley, Kathryn A. McDougal, Andrew D. Howard, Joelle Heilemann, Perry Parlier, Sophia Rosen, Len A. Usvyat, Alexis Porras, Franklin W. Maddux. 1Fresenius Medical Care, Waltham, MA; 2Metropolitan Nephrology Associates, Clinton, MD.

Background: 2012 day 30 readmissions for hemodialysis (HD) patients (pts) were high at 35% in 2012 (USRDS). The Right Trac (RT) program aimed to address readmissions by telephone calls and dialysis team visits. In 28 clinics from Feb-Nov ‘14, RTCMs attempted weekly phone calls to pts at home or dialysis clinic, or via telehealth in the clinic for 30 days post hospitalization.

Results: In 28 clinics from Feb-Nov ‘14, RTCMs attempted weekly phone calls to pts at home or dialysis clinic, or via telehealth in the clinic for 30 days post hospitalization. RTCM rates ranged between 2.5 to 95%. RTCM calls during 30 days post-hospital showed significantly lower 60-day readmits ppy for pts with initial and >=1 follow-up calls. Telehealth also had lower 90-day readmits ppy vs. phone calls, although not significant. Further study is needed, especially in view of high RTCM rates.

FR-PO689
Reduced Hemodialysis (HD) Patient Hospital Admissions and Readmissions Associated With Right Trac™ Care Transitions Program
Rebecca L. Wingard, Billie Axley, Kathryn A. McDougal, Andrew D. Howard, Cathleen Ockee, Sharon Deluca, Janice B. Sitzlar, Len A. Usvyat, Franklin W. Maddux. 1Fresenius Medical Care, Waltham, MA; 2Metropolitan Nephrology Associates, Clinton, MD.

Background: 30-day readmissions for HD patients (pts) are high at 35% in 2012 (USRDS). The Right Trac (RT) Program addressed factors in the complex process of care transitions, with the aim to reduce hospital admissions and readmissions.

Methods: 26 HD clinics (3682 pts) were in RT. Interventions deployed in 3 phases (Apr ’13-Nov ’14). I: Pre- and post-hospital checklists for clinicians to manage pt teaching, anemia, nutrition, medications, and dry weight. II: Telephonic case management for 30 days post-discharge. III: Dialysis Link™ centralize clinical info exchange among providers, admission and readmit data from per pt per year (ppy) for “baseline year” (2012) vs. “full intervention year” (2014) were compared to 18 control clinics (2449 pts) matched for clinic size, admission and readmission rate, and urban vs. rural location at baseline. Poisson models with random effects for pty and clinic, adjusted for age, vintage, race, gender, ethnicity, DM, CHF, and COPD were constructed to assess the difference between baseline and intervention and between RT and control clinics.

Results: 30-day readmissions ppy declined from baseline to full intervention year in RT (0.88 to 0.65, p<0.001) and controls (0.73 to 0.6, p<NS); comparison of the change between groups was not significant (Fig 1). Admissions ppy declined from 2.5 to 95 for RT (p<0.001), and 2.14 to 1.9 for controls (p<NS); comparison of the change between groups was significant with greater decline for RT (p<0.001, Fig 2).

Conclusions: RTCM calls during 30 days post-hospital showed significantly lower 90-day readmits ppy for pts with initial and >=1 follow-up call. Telehealth also had lower 90-day readmits ppy vs. phone calls, although not significant. Further study is needed, especially in view of high RTCM rates.

FR-PO690
Predicting Early Mortality Among Hemodialysis Patients Using USRDS Data
Eugene Wang, Zhi He, Jennifer L. Bragg-Gresham, Yuan Yang, Haoyu Gu, Yi Li, Kamyar Kalantar-Zadeh, Elani Streja, Rajiv Saran. 1Div of Nephrology-Dept of Internal Medicine and KECC, Univ of Michigan, Ann Arbor, MI; 2Renal Div Dept of Medicine, Peking Univ First Hospital, Beijing, China; 3Dept of Biostatistics and KECC, Univ of Michigan, Ann Arbor, MI; 4Univ of California Irvine, Orange, CA; 5Harold Simmons Center, Orange, CA.

Background: Higher early mortality of hemodialysis (HD) is recognized. We sought to quantify the risk of early mortality and develop a robust prediction model which could potentially guide clinical decision-making.

Methods: The 2007-2012 data from the United States Renal Data System (USRDS) on incident HD patients, age >18 years, were randomly split as ‘training’ and ‘validation’ samples. Cox proportional hazards model with piece-wise constant coefficients was used to model all-cause mortality during day 0-90 and day 91-365 of HD. Those transferred to peritoneal dialysis or transplantation were censored. The resulting model was validated by C statistic.

Results: The mean age (n=611,094) was 63.61±14.9 years, with 130,473 deaths during the first year of HD. Mortality rates were 35 per 100 person-years in the first 90 days and 21 per 100 person-years during day 91-365. The discrimination p-values for day 0-90 and day 91-365 showed very good ability involved 23 variables including demographics characteristics, pre-ESRD care, laboratory values, co-morbidities as well as institutionalization status. In adjusted analyses, selected variables with significant time-varying effects are listed in the Table.
FR-PO691

Recent Evidence on the Impact of Medicare’s Bundled, Prospective Payment System for Renal Dialysis

Richard Hirth1, Tammine A. Nahra1, Adam S. Wilk1, Marc Turenne2, John Wheeler1, Kathryn Sleeman1, Wei Zhang1, Jonathan H. Segal1

1University of Michigan; 2Arbor Research Collaborative for Health.

Background: Medicare implemented an expanded prospective payment system (PPS) in 2011, including services previously paid by fee-for-service. One intent of the PPS was to incentivize providers to be more efficient in the mix of services provided.

Methods: We used Medicare claims to assess monthly trends from 1/2010-12/2014 for injectable drugs that were previously billed separately. For 2010, we assessed actual spending. For 2011-14, we projected spending based on reported utilization.

Results: ESA use declined in the months immediately pre- and post-PPS, continuing to decline through 2012. In 2013, ESA use leveled off. Use of iron products, often improving medication utilization overall and the use of lower cost therapies. These incentives seem to incentivize providers to be more efficient in the mix of services provided.

Conclusions: The expanded bundle dialysis PPS provided incentives for both lower medication utilization overall and the use of lower cost therapies. These incentives seem to have motivated an immediate movement toward lower cost methods of care. Facilities have been able to maintain a lower cost of care over the last two years. CMS continues to monitor facility costs and will continue to make a reduction to the ESRD PPS Market Basket through CY 2018, in accordance with section 217 of PAMA.

FR-PO692

Effect of Medicare’s Payment Adjustment for Low-Volume Dialysis Facilities on Facility Closures

Richard Hirth1, Tammine A. Nahra1, Adam S. Wilk1, Marc Turenne2, Jonathan H. Segal1, John Wheeler1, Kathryn Sleeman1, Wei Zhang1

1University of Michigan; 2Arbor Research Collaborative for Health.

Background: Small dialysis facilities may face higher per-treatment costs due to economies of scale. Since 2011 a low-volume payment adjustment (LVPA) raised Medicare payments to facilities with <4000 treatments in each of the 3 prior calendar years. A goal of this policy is to preserve access to care by preventing the closure of small facilities.

Methods: We tested the hypothesis that the LVPA prevented closures by examining the year-to-year closure rates of U.S. dialysis facilities during 2007-2013, before and after the policy, comparing facilities providing <4000 and >4000 annual treatments. Analyses with linear regression relate facility outcomes to prior year size, ownership, for-profit status, hospital affiliation, patient mix, regional location, modality mix and county characteristics, to examine the effect of the LVPA on 8 of treatments provided by facilities.

Results: Among low-volume facilities, year-to-year closure rates declined from 3.8%, 4.9% and 4.0% pre-LVPA, falling to 1.1%, 0.5% and 0.8% post-LVPA. Among facilities with >4000 treatments, closure rates also decreased, but to a much smaller extent (from 1.0%, 1.2% and 0.8% pre-LVPA to 0.6%, 0.2% and 0.3% post-LVPA).

Conclusions: In Medicare’s bundled payment system, closure rates decreased overall, with a much larger absolute reduction among small facilities. The gap in closure rates between small and large facilities fell from about 3% points before the policy to about 0.5% points after. LVPA appears to have helped prevent small dialysis facility closures, but it may also motivate some small facilities to avoid growing in order to retain the LVPA. Emphasizing a dialysis facility’s importance for patient access rather than size alone may help inform payment policy modifications.

FR-PO693

Delayed Thrombectomy Increases Risk for Dialysis Catheter Placement

Scott Reule1, Sunil Akkina1, Andrew J. Esten1, Paul E. Drawz1

Dept of Medicine, Univ of Minnesota, Minneapolis, MN.

Background: Arteriovenous dialysis accesses (fistulas or grafts) are associated with significant rates of thrombosis. Though timely thrombectomy may have a significant impact on immediate and long-term access survival, it is not always readily available. The goal of this study was to evaluate whether delayed thrombectomy increases risk for loss of dialysis access and subsequent placement of a dialysis catheter.

Methods: All patients at the Fairview Health System with thrombectomy as the primary reason for admission between January 2008 and April 2015 were included in this retrospective observational study. The electronic medical record was reviewed to evaluate type of access, timing of admission and declot, and access on discharge and 6 and 12 months after discharge. Baseline characteristics and proportions were determined for the overall population as well as stratified by tertile of time to thrombectomy, defined as the time from admission to the declot procedure. The outcomes of interest included need for dialysis catheter at discharge and 6 and 12 months after discharge. Logistic regression was used to evaluate the risk for delay of thrombectomy catheter use adjusting for prior intervention, access type, and time to thrombectomy.

Results: Of 444 patients identified using procedural codes, 122 were admitted primarily for thrombectomy. The mean age was 60.4 years, 65% were male, and 44.3% utilized arteriovenous fistula for access. Mean time to thrombectomy was 0.45 days (range: 0.05-1.13 days). Fifteen patients utilized a catheter for hemodialysis on discharge. Delayed thrombectomy was associated with a two-fold increase in requirement for catheter at discharge (OR 2.02; CI 1.19-3.43) and at 6 months (OR 2.04; CI 1.20-3.48). This association remained present at 12 months (OR 1.75; CI 1.02-3.00).

Conclusions: In this study of patients cared for within a large academic health system, a one day delay in thrombectomy doubled the risk for need for a dialysis catheter at discharge and 6 and 12 months after discharge. These results indicate that a clotted dialysis access should be considered a medical emergency.

Intradialytic Body Weight Reduction and Outcome of Vascular Access: Analysis of Data from the Japan Dialysis Outcomes and Practice Patterns Study (J-DOPPS)  
Manabu Asano,1 Kenichi Oguchi,2 Akira Saito,3 Yoshihiro Onishi,1 Yosuke Yamamoto,4 Shunichi Fukuhara,5 Takashi Akiba,6 Tadao Akizawa,7 Busei Hospital, Saitama, Japan; J-DOPPS Research Group, Japan; 1Hope International, Kyoto, Japan; 2Inst for Advancement of Clinical and Translational Science, Kyoto Univ Hospital, Kyoto, Japan.

Background: There is no doubt that large-volume ultrafiltration is one of the important risk factors for vascular access (VA) thrombosis in hemodialysis patients. However, the relationships between intradialytic body weight reduction and VA patency are still in the middle of being discussed. We tried to determine whether large-volume ultrafiltration was practically associated with VA failure by means of the results obtained from the phase 3 and 4 J-DOPPS.

Methods: Referring data from the phase 3 and 4 J-DOPPS, the current analyses were limited to 2736 patients who were evaluable for VA patency and body weight change during dialysis. They were assigned to one of the following three groups according to the tertiles (T1-T3) of intradialytic fluid removal per body weight: T1, -9.5% to 3.8%; T2, 3.8% to 5.1%; and T3, 5.1% to 13.7%. The hazard ratio of VA failure was compared across these tertile groups using Cox regression models. The models were adjusted for the following risk factors: age, gender, BMI, diabetes, phosphorus, potassium, ESA use, and antplatelets use. Primary VA survival was defined as the days until the first VA intervention. Secondary VA survival was defined as the days until new VA creation.

Results: The incidence rates (events/100 person-years) of primary and secondary VA events were 4.7 ± 1.3 for T1, 6.4 ± 3.7 for T2, and 7.9 ± 4.3 for T3, respectively. The adjusted hazard ratios versus T1 for primary VA patency were 1.16 (95% confidence interval [CI], 0.88 to 1.52) for T2 and 1.41 (95% CI, 1.07 to 1.87) for T3. The hazard ratios versus T1 for secondary VA patency were 1.29 (95% CI, 0.78 to 2.13) for T2 and 1.45 (95% CI, 0.86 to 2.45) for T3.

Conclusions: This study shows that large-volume ultrafiltration during dialysis tends to increase VA failure in hemodialysis patients.

FR-PO695

Post-Endovascular Intervention Venous Access Pressure Ratio (VAPR) Predicts Access Survival  
Lahalathaksha Kumbar,1 Gerald Zusawa,2 Anatole Besarab,3 Kim Hirshman,3 Jerry Yee,3 1Henry Ford Hospital, Detroit, MI; 2Stanford, Palo Alto, CA; 3Vasc-Alert, LLC, Evanston, IL.

Background: The vascular access pressure ratio test identifies vascular access (VA) dysfunction in hemodialysis patients when 3 consecutive VA pressure (VAPR)MAP measurements are >0.55. We hypothesized that a post-interventional VAPR decline predicts VA outcomes in patients with VA dysfunction.

Methods: Retrospective analysis of all VA procedures from 09/2013 to 04/2015. Data collection included demographics, comorbidities, VA features, mean VAPR <30 days pre- and post-procedure, time-to-next-procedure, and access type. Kaplan-Meier arteriovenous graft (AVG) and fistula (AVF) survival curves were compared by the log-rank test. A Cox-proportional hazard model was used to determine the association of VAPR Δ% (Pre-Post)/Pre>100% with access survival.

Results: Analysis of 92 subjects [females 57% (n=53); black 88%; and diabetes mellitus 61% (n=56)] included 46 AVG with 94 procedures and 46 AVF with 86 procedures. Mean VAPR Δ% was 26 ± 61% (SD) and 16 ± 54% for AVG and AVF, respectively. VAPR decline was absent in 13 AVG. AVG with no VAPR decline (<0%) post-intervention when compared to AVG with any decline (>0%) required more subsequent procedures (64% vs 47%), with fewer days to next procedure (75 vs 149 d), and lower survival (p = 0.002). For AVG, a post-intervention VAPR decline >10% (p = 0.04) projected AVG survival. 34% of AVG procedures had <10% decline (n=30) and required more subsequent procedures than AVG with >10% decline (64% vs 39%). AVG without VAPR decline had a 3-fold greater risk of failure (p = 0.003). The risk of failure was 2.0-fold greater (p = 0.04) for AVG with <10% decline.

Conclusions: A 10% post-intervention reduction of VAPR in AVG and any VAPR reduction in AVF predicts greater VA survival.

FR-PO696

Abnormalities in Mineral Metabolism and Dialysis Arteriovenous Fistula Thrombosis in the HEMO Study  
Anna Jeanette Jovanovich,1 Eugene J. Nuccio,2 Alfred K. Cheung,3 Tom Greene,4 Michel Chonchol,2 1Denver VA Medical Center; University of Colorado Denver; VA Salt Lake City; 2Univ of Utah.

Background: Vitamin D deficiency and fibroblast growth factor 23 (FGF23) excess are highly prevalent among patients requiring chronic hemodialysis. This study aims to determine the association of 25-hydroxyvitamin D (25(OH)D), 1,25-dihydroxyvitamin D (1,25(OH)2D), and FGF23 serum levels with arteriovenous fistula (AVF) thrombosis in hemodialysis patients.

Methods: The HEMO Study was a randomized multicenter study evaluating the effects of high-dose versus standard-dose and high-flux versus low-flux hemodialysis. Serum 25(OH)D, 1,25(OH)2D, and intact FGF23 levels were measured in stored serum samples obtained at baseline in 881 patients in this cohort. Cox proportional-hazards models were used to examine the association of 25(OH)D, 1,25(OH)2D, and FGF23 serum levels with time to first AVF clotting event after controlling for important clinical covariates in the HEMO Study.

Results: Patients had a mean age of 57 ± 14 years, 55% were females, and 46% were white. During a median follow-up of 3.0 years, 111 AVF clotted. Median (IQR) serum 25(OH)D, 1,25(OH)2D, and FGF23 levels were 19.1 (14.2, 26.6) ng/mL, 6.3 (2.9, 14.5) pg/mL, and 3118 [726, 12928] pg/mL. Among patients with levels in the highest tertile compared to the lowest tertile, both 1,25(OH)2D and FGF23 were significantly associated with an increased risk of clotting in adjusted analyses, hazard ratio (HR) 2.79 (95% CI, 1.21-6.46) and HR 1.35 (95% CI, 1.02-1.83), respectively. No statistically significant associations were observed between 25(OH)D serum levels and AVF thrombosis.

Conclusions: Calcitriol and FGF23 excess were associated with an increased risk of AVF thrombosis among chronic hemodialysis patients.

Ultrasound-Guided Evaluation of New AV Fistulas Safely Decreases Time to First Cannulation  
Farzin Farpour,2 Roshan A. Patel,1 George N. Coridis,1 1Nephrology, Elmhurst Hospital, Icahn School of Medicine at Mount Sinai, Elmhurst, NY; 2Nephrology, Broadway Atlantic Dialysis Center, Elmhurst, NY.

Background: The use of bedside ultrasonography (USG) in various medical specialties has exploded over the last decade. For the past year, we have been using bedside USG for earlier AV fistula utilization and for diagnosing potential problems. Prior to the use of USG, cannulation was based on physical exam. We were interested to see whether use of bedside USG helps in early cannulation of AVF.

Methods: USG procedures from February 2014 to February 2015 were reviewed. Time to cannulation in the year prior to the introduction of USG (2013 - 2014) was calculated and compared to similar data with USG use. By week 4 all new fistulas underwent the first USG exam. Examinations were performed by the renal attendings and fellows each exam lasting about 5 minutes. Sonosite M-Turbo ultrasound machine was used.

Results: Total of 44 USG examinations were performed on 14 patients while monitoring new AVF maturation. In 10 patients USG-guided cannulation occurred at an average of 6.2 ± 0.9 weeks compared to 10.2 ± 0.9 weeks prior to USG use (P = 0.006). There were no complications seen with using the earlier USG-guided cannulations. Subsequent cannulations by the nursing staff were successful without USG. In 4 patients failure of maturation was diagnosed by USG at an average of 3.8 ± 0.9 weeks vs 9.6 ± 1.2 weeks prior to USG (P = 0.08). Antibiotic dosing occurred 21 times prior to USG compared to 11 times with USG, despite the similar cannulator rates for both years.

Conclusions: USG use facilitates early AVF cannulation with decreased time to first use. Identification of potential AVF issues and their referral are accomplished earlier. This may translate to earlier catheter removal and fewer infections.

FR-PO698

Arteriovenous Grafts Reduce Cather Dependence in the Elderly  
Thomas M. Loh, Matthew E. Bennett, Francis E. Loh, Eric K. Peden.  
Vascular Surgery, Houston Methodist, Houston, TX.

Background: Arteriovenous fistulas (AVF) are the permanent access of choice. The benefits of AVF, durability and longevity, are minimized in the elderly where more than 40% of patients will die within their first year of initiating hemodialysis. We investigate an expanded role for primary arteriovenous grafts (AVG) in this population.
Methods: We retrospectively review consecutive patients over the age of 70 who underwent upper extremity access creation from January 2008 to July 2014. Data collection included demographics, past medical histories, subsequent interventions, volume flows, access usage, and patient survival.

Results: We performed 366 AVF and 124 AVG creations in 442 patients over the age of 70 (197 women, 245 men). There were no significant differences in the comorbidities between the two access types. The AVG group was significantly older and more likely to be female, 79.2 yo vs. 77.2 yo (p<0.001) and 60% vs. 41% (p<0.001) respectively. Patients with AVF were significantly more likely to never use their permanent access, 25% vs. 11% (odds ratio 3.6, p=0.002) and if utilized, cumulated significantly later, 3.6 ± 0.2 months vs. 1.3 ± 0.1 months (p<0.001). Catheter dependence at 6 months was 40% for AVG and 28% for AVF. (Figure 1) Secondary patency at 18 months was 64% for AVF and 63% for AVG.

Conclusions: Prosthetic grafts should be considered as the preferred permanent access type in the elderly. Better predictors of mortality, including frailty scores, should be investigated for determining the best choice of permanent access in elderly patients.

FR-PO699
Anticoagulation-Free Dialysis Is Not Associated with Failure to Meet Ultrafiltration Target: A Single-Center Inpatient Dialysis Study
Rozina B. Ali, Akshatha Rao, Sandeep Aggarwal. Div of Nephrology and Hypertension, Drexel Univ College of Medicine, Philadelphia, PA.

Background: Conventional outpatient hemodialysis utilizes various forms of anticoagulation to prevent access and extracorporeal circuit clotting. In contrast, to reduce the risk of bleeding events, inpatient dialysis units do not frequently use anticoagulation. We aimed to investigate the consequences of anticoagulation-free dialysis and the factors associated with failure to achieve ultrafiltration target (UFT) in our inpatient unit.

Methods: We performed a retrospective analysis of 250 consecutive hemodialysis treatments in 125 chronic patients. Patients were excluded if they were admitted for initiation of dialysis or required systemic anticoagulation. We looked at both instances of successful achievement and failure of UFT. We looked at the following factors: type of access, episode of intradialytic hypotension (IDH), episode of access clotting, and episode of extracorporeal circuit clotting. No anticoagulation was used in the HD treatments. Correlation analyses were performed and categorical data was analyzed using chi-square test. STATA, version 11, was used for statistical analyses.

Results: Overall the incidence of failure to meet UFT was 35%. Association of failure to meet UFT and IDH was noted (p=0.002). Access clotting and IDH were associated with failure of UFT. We looked at the following factors: type of access, episode of intradialytic hypotension (IDH), episode of access clotting, and episode of extracorporeal circuit clotting. No anticoagulation was used in the HD treatments. Correlation analyses were performed and categorical data was analyzed using chi-square test. STATA, version 11, was used for statistical analyses.

Conclusions: Our study of 250 anticoagulation-free hemodialysis treatments suggests that access and extracorporeal circulation were not associated with failure to meet ultrafiltration target. However, the failure to achieve ultrafiltration target was significantly associated with intradialytic hypotension. Larger cohort, multi-center prospective trials should be performed to look at causality of failure to meet ultrafiltration targets in the hospitalized patient.

FR-PO700
Evaluation of the Ability of Transonic Monitoring to Predict Dialysis Access Stenoses
Jerald Zaki Knefati-Hayek,1 Gaurav Ghosh,2, Stephen Kruger,1 Jeffrey I. Silberzweig.2,3 1Dept of Medicine, New York-Presbyterian Hospital, New York, NY; 2Weill Cornell Medical College, New York, NY; 3The Rogosin Inst, New York, NY.

Background: Patency of vascular access is critical to successful maintenance hemodialysis. It is well established that lesions are easier to treat if they can be identified prior to thrombosis. Non-invasive evaluation of access blood flow with the Transonic device is established for this purpose. We previously analyzed its performance after two years and demonstrated >99% sensitivity and specificity. We now seek to extend that work by looking at performance over a fifteen-year period.

Methods: Transonic studies are performed on approximately 1500 maintenance dialysis patients with AV grafts or fistulae in our 7 clinics in New York City. Transonic flow rates <600 cc/min or decreases by >10% from prior readings prompt referral to Interventional Radiology or Vascular Surgery. We report on the sensitivity, specificity and predictive values for patients treated between 1998 and 2012.

Results: Sensitivity was 42%; specificity 72%. Positive predictive value (PPV) was 20%; negative predictive value (NPV) was 85%.

We evaluated our ability to predict stenosis based on decreased dialysis clearance: for Kt/V, PPV was less than 10% and NPV less than 80% for different cutoff points; for URR, NPV was less than 10% and PPV less than 80%.

Conclusions: We hypothesize that the large numbers of false positive and false negative results were caused by scheduled referrals to Interventional Radiology, which have become routine. This study suggests that routine Transonic studies may no longer be as important as they were in 2000; however, Transonic studies provide better predictive ability than reductions in urea-based dialysis clearance.
FR-PO702
Association of Bacteremia with Arteriovenous Access Failure in Hemodialysis Patients
Syed Mustafa Ahmed, Laura Plantinga, Rachel E. Patzer, Jason Cobb, William M. McClellan.
Emory Univ, Atlanta, GA.

Background: Obesity, female sex, diabetes, peripheral vascular disease, and pacemakers are known risk factors for arteriovenous fistula (AVF) and arteriovenous graft (AVG) failure. We examined whether bacteremia in hemodialysis (HD) patients with AVF/AVG represents an additional, independent risk factor for subsequent AVF and AVG failure.

Methods: We conducted a retrospective observational study among 29,571 U.S. patients from the United States Renal Data System who started HD with AVF and AVG between 1/1/2009 and 9/30/2010. We used inpatient ICD-9 codes after dialysis start to define bacteremia and AVF/AVG failure. We then used a multivariable Cox proportional hazards model to assess relationship between exposure to bacteremia and time to access failure.

Results: Overall, 12.2% of patients with bacteremia experienced an access failure, compared to 4.0% of patients without bacteremia (P<0.001). This difference persisted over a median follow-up of 582 days. With adjustment for known confounders, patients who had bacteremia after dialysis start were at ~3-fold greater risk of subsequent access failure, relative to those who did not (HR=3.18, 95% CI: 1.71 – 5.95).

Conclusions: This observational study indicates that decreased AVF and AVG survival may be associated with exposure to bacteremia among HD patients.

FR-PO703
Comparison of Loss of Vascular Access Patency in Hemodialysis Patients with End-Stage Renal Disease due to Systemic Lupus Erythematosus versus Other Causes
Laura Plantinga, Sung S. Lim, Rachel E. Patzer, Stephen O. Pastan, Cristina Drenkard.
Emory Univ, Atlanta, GA.

Background: Previously we found that U.S. patients with systemic lupus erythematosus (SLE) and end-stage renal disease (ESRD) were 40% less likely than other ESRD patients to have a permanent vascular access in place at the start of dialysis. Here, we examine whether subsequent loss of patency differs in SLE vs. other ESRD patients who have a permanent vascular access.

Methods: A cohort of 106,993 U.S. patients starting hemodialysis with an arteriovenous fistula (AVF) or graft (7/05-9/11) was identified from a national registry of treated ESRD (United States Renal Data System). Kaplan-Meier analyses and multivariable Cox proportional hazards models were used to estimate the association between SLE vs. other ESRD (by provider-reported attributed cause at start of dialysis) and the time to first inpatient ICD-9 codes after dialysis start to define bacteremia and AVF/AVG failure. We then used a multivariable Cox proportional hazards model to assess relationship between exposure to bacteremia and time to access failure.

Results: Overall, 12.2% of patients with bacteremia experienced an access failure, compared to 4.0% of patients without bacteremia (P<0.001). This difference persisted over a median follow-up of 582 days. With adjustment for known confounders, patients who had bacteremia after dialysis start were at ~3-fold greater risk of subsequent access failure, relative to those who did not (HR=3.18, 95% CI: 1.71 – 5.95).

Conclusions: This observational study indicates that decreased AVF and AVG survival may be associated with exposure to bacteremia among HD patients.

FR-PO704
The Placement of Tunneled Central Venous Catheters Through Percutaneous Puncture of Superior Vena Cava in Hemodialysis Patients
Tianlei Cui, Xiaoxi Zeng, Yuhuan Feng, Ping Fu. Nephrology Dept, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China.

Background: After the exhaustion of traditional insertion sites of tunneled central venous catheters (IVCVCs), it can be challenging to place the IVCVCs in exotic locations. A retrospective case series in West China Hospital was studied to assess the placement of IVCVCs through percutaneous puncture of superior vena cava (SVC) in patients with inimate veins occlusion.

Methods: Sixteen patients (male: 62.5%; mean age: 64.7 years; mean duration of HD: 5 years) who underwent placement of IVCVCs through percutaneous puncture of SVC were retrospectively analyzed. They had either exhausted IV access sites or chosen not to undergo other vascular access placement. All of the patients had occlusion in innominate veins on both sides. The outcomes were function measurements of IVCVCs, and safety parameters. The technique: With patients supine, following the guidance of fluoroscopy, a S-F catheter was placed at the distal end of SVC through the femoral vein, iliac vein or hepatic vein, serving as a fluoroscopic target. Later, guided by fluoroscopy vertically and horizontally, the puncture needle and sheath were placed into SVC through a percutaneous route with the insertion site at 0.5-1.0 cm lateral-inferior to the clavicle head of sternocleidomastoid, allowing the access of the guidewire and the placement of a IV catheter.

Results: The procedure succeeded in all of the patients. During the follow-up (mean: 12 months, range: 3-36 months), access failure due to thrombosis was observed in one patient, and the failure was treated by aspirin and Clopidogrel. The remaining continued to function well until the end of the follow-up or until the death of the patients (n=3). The procedure was generally safe. No pneumothorax occurred. The most common complication was mediastinal hematoma after the failure of SVC puncture. The fluoroscopy could reveal the hematoma during the procedure. The largest hematoma was 2cm in diameter in the current series and it resolved spontaneously.

Conclusions: In patients with inominate veins occlusion and exhaustion of the conventional insertion sites, the IVCVCs can be safely placed through SVC puncture using percutaneous route.

FR-PO705
Analysis of Survival of Cardiac Function in Maintained Hemodialysis Patients with Arteriovenous Fistula and Tunneled Cuffed Catheter
Li Hua Wang, Fang Wei, Ai Li Jiang. Dept of Kidney Disease and Blood Purification Centre, Inst of Urology & Key Laboratory of Tianjin, 2nd Hospital of Tianjin Medical Univ, Tianjin, China.

Background: Until now, there is little data of cardiofunction regarding to different type of vascular access. This study was to investigate survival of patients with arteriogenous fistula and tunneled cather group. The baseline anthropometric and laboratory parameters were measured. The time and cause of mortality were documented. The survival of patients with arteriogenous fistula and tunneled cather group in terms of cardiac function was compared to the survival of patients with arteriogenous fistula and tunneled cather group.

Methods: Total of 219 patients who received maintained hemodialysis were included in this study. Patients were divided into two groups: arteriogenous fistula group and tunneled catheter group. The baseline anthropometric and laboratory parameters were measured. The time and cause of mortality were documented.

Results: There were significant difference of left ventricular hypertrophy [x^2=6.645, P=0.001], left ventricular diastolic dysfunction [x^2=4.007, P=0.045], between two groups. But there was no significant difference of left ventricular diastolic dysfunction between two groups. Kaplan-Meier survival curves showed that the mortality was enhanced among tunneled cather group.
Patients with left ventricular hypertrophy, left ventricular systolic dysfunction, left ventricular diastolic dysfunction in arteriovenous fistula group have a high survival rate compared with tunneled catheter group. Furthermore, iPTH, calcium, systolic blood pressure and diastolic blood pressure were the independent risk factors of mortality for patients on maintained hemodialysis by Cox regression model.

Conclusions: Development of vascular access may have influence on mortality in patients on maintained hemodialysis. Those with tunneled catheters have lower survival rate when left ventricular dysfunction occurred.

FR-PO706
A Retrospective Study of Preferable Alternative Sites to Right Internal Jugular Vein for Tunneled Hemodialysis Catheters Insertion: Right External Jugular Vein versus Left Internal Jugular Vein
Yuefei Wang, Pei Wang, Xianhui Liang, Xiaoqing Lu, Zhangsuo Liu, Yingjin Qiao, Sijie Zhou, Blood Purification Center, The First Affiliated Hospital of Zhengzhou Univ, Zhengzhou, Henan, China.

Background: It has been recommended by the KDOQI guidelines that right internal jugular vein (RIJV) is a preferred insertion site for hemodialysis (HD) catheters, and both right external jugular vein (REJV) and left internal jugular vein (LIJV) are alternative sites for those who have encountered severe thrombosis and/or occlusion of RIJV. The retrospective study aimed to determine if superiority exists in the two alternative sites by comparing the outcomes of tunneled (cuffed) dialysis catheters (TDCs) through REJVs versus LIJVs in HD patients who had failed RIJV.

Methods: From January 1, 2013 to December 31, 2014, 28 LIJ-TDCs and 21 REJ-TDCs were inserted in our hospital. All events were recorded from patient charts until May 31, 2015. Using SPSS 22.0 software, data were analyzed by the Fisher exact test or chi-square test. Event-free catheter survival was estimated by the Kaplan-Meier method. Multivariable Cox hazards analysis was fitted to detect the independent risk factors of events. A P-value of <0.05 was considered statistically significant.

Results: A total of 20924 (LIs, 11782; REJs, 9141) catheter-days were evaluated and the mean was 427.02 days. Most of the patients (53.1%) were older than 65 years with an average dialysis time of 25.3 months. The event-free catheter survival time was (516.20±55.60)±1 in REJ-TDCs and (343.91±40.63)±1 in LIJ-TDCs (P=0.038). Mean effective blood flow was higher in REJ-TDCs than in LIJ-TDCs (270.95±24.93 vs 244.82±30.35 ml/min, P=0.02). A substantial positive trend toward statistical significance was found between two groups in incidence of all events, including death, death related to catheter complication and catheter removal. The total historic catheters indwelling time was identified as an independent risk factor for severe TDC events by Cox regression hazards test (P=0.01).

Conclusions: REJ might be superior to LIJ as an alternative insertion site for TDC placement in HD patients who had failed RIJV.

FR-PO707
Haemodialysis Recirculation in Patients with Catheter Access: Damien Ashby, Imperial College Renal and Transplant Centre, Hammersmith Hospital, London, United Kingdom.

Background: Recirculation is a well described impairment of the haemodialysis circuit which reduces dialysis dose and electrolyte clearance. Catheter tips are designed to minimise recirculation based on in vitro experiment, with most designs having a tip separation of 25 mm, but clinical studies of catheter-related recirculation have not been published.

Methods: In a group of stable adult patients receiving haemodialysis by tunneled catheters, recirculation was calculated by 3-sample urea measurement, and analysed in 25 mm, but clinical studies of catheter-related recirculation have not been published. Defining thresholds to avoid high recirculation (>5%) with tip separation over 25 mm high recirculation was seen in 6 patients. Increasing threshold tip separation to 30mm reduced the number of patients with high recirculation to 2. The same was achieved using a weight-based tip separation threshold of 0.5 mm/kg. High recirculation was associated with high erythropoietin requirement (R=0.29, p=0.030) but not with low Kt/V (p=0.26).

Conclusions: Significant recirculation affects a significant minority of patients dialysing on tunneled catheters, and is closely related to tip separation. A tip separation threshold of 25 mm may be inadequate to avoid high recirculation, and 30mm or perhaps a weight-based threshold may be superior. Erythropoietin resistance is a possible consequence of this type of haemodialysis recirculation.

Funding: Clinical Revenue Support

FR-PO708
Risk Factors for Fatal Dialysis Access Haemorrhage
Nicole M. Lioufas, Jonathan E.H. Ling, Gail Theresa Read, Matthew D. Jose, Royal Hobart Hospital, Hobart, Tasmania, Australia; School of Medicine, The Univ of Tasmania, Australia.

Background: Haemodialysis requires access to the circulation via an arteriovenous fistula or graft, or a synthetic vascular catheter. Annually there are deaths associated with catastrophic bleeding from dialysis vascular access.

Methods: A systematic search strategy including data from the National Coronial Information System (NCIS, containing coroner’s reports from all Australian states and New Zealand), the Australian and New Zealand Dialysis and Transplant registry (ANZDATA), published cases from Australia and New Zealand, individual renal units and State Renal Network reports. Data was analysed for all deaths where cause of death was reported as being due to dialysis access haemorrhage from 1st January 2000.

Results: A total of 83 patients (mean age 67 years (range 30 – 89), 55% female) receiving renal replacement therapy died due to dialysis vascular access haemorrhage. These were identified through NCIS 54, ANZDATA 64, State networks 3, Publications 2, and individual unit units. Most deaths occurred within the access itself (66%) with complications including infection (22%), dialysis catheter problems (17%), recent access intervention (15%) or use of a thig arteriovenous fistula (11%). Bleeds commonly occurred at home in people treated with satellite haemodialysis. Modality at the time of death was home haemodialysis in 12 people. Use of Warfarin or cognitive impairment was identified in only 1 death each. Coronial inquests and Root Cause Analyses were identified in only 7 deaths with recommendations involving communication, staffing, clinical policy, practice changes and equipment modifications.

Conclusions: Death due to dialysis access haemorrhage is an uncommon, catastrophic, but potentially preventable event. A number are preceded by vascular access infection, vascular access complications or recent intervention. Only a minority of deaths have been investigated, but where they have, critical recommendations for optimising future care are presented.

FR-PO709
Subcutaneous Implantable Electronic Devices in Chronic Kidney Disease and Hemodialysis Patients

Background: While epicardial leads have been reported to bypass central venous stenosis, their placement is much more invasive and requires the services of a cardiac thoracic surgeon. Recent data have demonstrated successful defibrillation using a subcutaneous ICD (SICD). While the use of these devices is expanding, their insertion in advanced renal failure and hemodialysis patients is somewhat limited. In this analysis, we present 9 cases of SICD implantation in haemodialysis patients treated successfully with an SICD. Demographic characteristics revealed; male–8, diabetes–8, hypertension–13, coronary artery disease–10, peripheral vascular disease–8. Two of the four hemodialysis patients had an AVF while two were dialyzing with a tunneled dialysis catheter. Mean GFR for the CKD patients was 40.3 ± 6.6 ml/min. Patients received the SICD device for primary prevention of sudden cardiac death (cardiomyopathy with low ejection fraction). 3/13 patients had non-ischemic cardiomyopathy (CMP) with an ejection fraction of <25%, while 10/13 suffered from ischemic CMP with an EF of <30%. There were no procedure-related complications in 20 patients. Death due to dialysis access haemorrhage is an uncommon, catastrophic, but potentially preventable event. A number are preceded by vascular access infection, vascular access complications or recent intervention. Only a minority of deaths have been investigated, but where they have, critical recommendations for optimising future care are presented.

Methods: Retrospective evaluation of SICD in patients with CKD and ESRD.

Results: Thirteen patients with CKD and ESRD on dialysis received successful SICD. A total of 83 patients (mean age 67 years (range 30 – 89), 55% female) receiving renal replacement therapy died due to dialysis vascular access haemorrhage. These were identified through NCIS 54, ANZDATA 64, State networks 3, Publications 2, and individual unit units. Most deaths occurred within the access itself (66%) with complications including infection (22%), dialysis catheter problems (17%), recent access intervention (15%) or use of a thig arteriovenous fistula (11%). Bleeds commonly occurred at home in people treated with satellite haemodialysis. Modality at the time of death was home haemodialysis in 12 people. Use of Warfarin or cognitive impairment was identified in only 1 death each. Coronial inquests and Root Cause Analyses were identified in only 7 deaths with recommendations involving communication, staffing, clinical policy, practice changes and equipment modifications.

Conclusions: Death due to dialysis access haemorrhage is an uncommon, catastrophic, but potentially preventable event. A number are preceded by vascular access infection, vascular access complications or recent intervention. Only a minority of deaths have been investigated, but where they have, critical recommendations for optimising future care are presented.

Modified Non-Transposed Brachio basilic Arteriovenous Fistula for Hemodialysis: A Randomized Controlled Study
Yanrong Hu, Chunyu Zhou, Chandra Mohan, Changbin Li, Jie Tang, Ai Peng, Shanghai Tenth People’s Hospital, Tongji Univ School of Medicine, Shanghai, China; Univ of Houston, Houston, TX; DHHA-Univ of Colorado School of Medicine, Aurora, CO.

Background: Transposed brachiobasilic arteriovenous fistula (BBAVF) is technically challenging. It not only associates with severe arm swelling and pain, but also takes longer to be ready for use. Here we introduce a novel modified non-transposed BBAVF (mNT-BBAVF), and compare its outcomes those of the standard brachiobasilic arteriovenous fistula (BCAVF).

Methods: From January 2010 to December 2012, 74 incident hemodialysis patients with suitable basilic and cephalic veins were randomized equally into mNT-BBAVF and
Management of Catheter Related Bacteraemias: New Insights into an Old Problem

Methods: We retrospectively reviewed all blood cultures taken from our institution’s dialysis patients for 1 year (October 2013 and September 2014). The records of patients with positive cultures were reviewed to ascertain if the infection was related to their access. Data was then collected on the type of organism grown, management of the episode, recurrence rate, and any long term complications.

Results: 1014 cultures were taken from approximately 930 haemodialysis patients. 45% of these were dialysing via a catheter. There were 52 instances of CRB giving a CRB rate of 0.34 per 1000 catheter days. 65% were due to gram-positive organisms, 29% were due to gram-negative organisms and 6% were fungal related. The overall recurrence rate of 0.34 per 1000 catheter days. 65% were due to gram-positive organisms, 29% were due to gram-negative organisms and 6% were fungal related. The overall recurrence rate was 26%.

Conclusions: We observed significantly more infective complications with gram-negative organisms compared with gram-positive. This probably reflects the underlying characteristics of these patients rather than the pathogenicity of the organisms per se (19% of patients with gram-negative infections were intravenous drug users). Never the less our data suggests that gram negative infections are a risk factor for complications and clinicians should consider further investigations in these cases. Our CRB rate was low compared to quoted rates in the literature; this may reflect routine the use of citrate lock in our catheters.

Assessment of Arteriovenous Fistula Access Flow Using Video Image Processing Technology

Background: Vascular stenotic lesions are the main cause of failure in arteriovenous fistula (AVF). Routine measurement of access flow (AF) is important in the timely detection of changes and planning interventions. The aim of this pilot study was to investigate whether video image processing (VIP) techniques can be used to detect AVF motion and explore the relationship between motion patterns and AF.

Methods: Skin above the AVF was imaged for 1 minute using a digital single lens reflex camera prior to HD. The video was processed using Eulerian video magnification (Wu et al. ACM Trans. Graph. 31(4), 2012) to amplify AVF motions. Thereafter the motion-amplified video was converted to quantitative waveform data using an algorithm based on change in color of each image (Matlab Image Processing Toolbox). Monthly AF measurements were recorded and correlated with the post-processed AVF waveform pattern.

Results: We studied 12 hemodialysis patients (51.5±11.3 years, 50% male) with a mean:SD AF 150±392ml/min (N=9; AF was unavailable in 1 subject). Amplitude of skin displacement was 0.069±0.04mm (N=9; technical issues occurred in 2 subjects). While amplitudes of that size are hardly visible to the naked eye, they were clearly discernible in post-processed amplified videos. Amplitude was notably smaller in subjects with lower AF (Fig. 1). Amplitude analysis of the amplified video indicates a relationship with AF (R=0.73, p<0.01; N=9).

Conclusions: Our proof-of-concept study demonstrates this video imaging and analysis technique has potential to provide a quick, noninvasive, low cost way to obtain quantitative information related to AF. Research is underway to assess the impact of clinical interventions on the amplitude pattern.
In the control profile, real-time Kt/V (Fig 1a, solid line) closely followed the target line (Fig 1a, dashed line) and was associated with normal \( P_t \) and \( P_r \). In patients with high access recirculation, real-time Kt/V tracking line deviated widely from the target line (High Recirc Kt/V Profile; Fig 1b, c, d) and remained deviant throughout the treatment session. Fig 1d demonstrates a case wherein the initial low Q (High Recirc Kt/V Profile; Fig 1b, c, d) and remained deviant throughout the treatment session. It was noted that the initial low Q (High Recirc Kt/V Profile; Fig 1b, c, d) and remained deviant throughout the treatment session.

**Results:** 49 stents were inserted during 45 procedures in 39 patients. 12 had diabetes. Mean age was 64.5±25.5 yrs, median dialysis vintage was 1162±1504 days (range 5–5027). Median time from access creation (82% arteriovenous fistula) to stent insertion was 318±926 days (range 31–3752). 34 stents were inserted peripherally (cephalic arch and distally), the majority in the cephalic arch. Equal numbers of covered and bare-metal stents were inserted. 4 stents were placed in thrombosed access. 7 procedures were due to surveillance alone, a further 8 due to surveillance and pressure/flow problems. 12 stents were inserted for rupture or dissection (overall access procedure complication rate 1%). Median time from first stent to access failure/ceded HD was 333±653 days, assisted by median 2 (range 0-11) further procedures. Treatment for rupture was not associated with significantly shorter access longevity. Only 10 patients’ access failed following follow-up. Our overall HD definitive access prevalence rate was 86-90%.

**Conclusions:** Appropriate HD access is essential in minimising HD morbidity. We recommend stent insertion for fibre-requiring stenosis or rupture during endovascular procedures. Our data suggest that appropriate, judicious stent insertion in an appropriately structured pathway results in access durability and longevity.

**FR-PO715**

Recurrent Vascular Access Stenosis as a Novel Marker for Cardiovascular Outcome in Hemodialysis Patients

Hyo Jin Kim, Hajeong Lee, Dong Ki Kim, Kook-Hwan Oh, Yon Su Kim, Curie Ahn, Kwon Wook Joo. *Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea.*

**Background:** Vascular access (VA) is essential component and its stenosis is a major complication in hemodialysis (HD) patients. Nevertheless, there are few data for outcomes of patients who had recurrent VA stenosis. We have explored the influence of recurrent VA stenosis on cardiovascular (CV) event, patient death, and VA failure.

**Methods:** This is a single-center, retrospective study. Patients who had VA operation at Seoul National University Hospital between January 2009 and March 2014 were enrolled. Patients who had two or more instances of percutaneous angioplasty or revision operation within 180 days were categorized recurrent group. The primary outcome was CV event, as coronary artery or heart failure or cerebrovascular, and or peripheral vascular events. The secondary outcomes were all-cause mortality (ACM), composite of ACM or CV events, and VA failure. The two groups were compared before and after matching with propensity scores (PSM).

**Results:** A total of 766 patients (59.7% male, age 59.6 ± 14.3 years) were analyzed. Recurrent group patients (n = 77; 10.1%) were older and had higher underlying CV disease and dyslipidemia. A total 213 patients (14.2% in non-recurrent, 71 in recurrent group) were selected by PSM. During 28.7±13.5 months follow-up, 46 patients (21.6%) had CV outcomes, 30 patients (14.1%) died, and 14 patients (6.6%) experienced vascular access failure. After adjustment, recurrent group was an independent risk factor for CV events (adjusted hazard ratio [HR] 2.66; 95% confidence interval [CI] 1.46–4.86, \( p < 0.001 \)) and composite of ACM or CV events (adjusted HR 1.99; 95% CI 1.21–3.27, \( p = 0.007 \)). However, it was not associated with increased ACM and VA failure.

**Conclusions:** Recurrent VA stenosis was a novel independent risk factor for CV event in HD patients, rather than VA failure. For patients suffered from recurrent vascular stenosis, diligent monitoring should be warranted not only for VA patency but also for CV events.

Stent Insertion Is an Important Tool in Maintaining Arteriovenous Access Patency

Stephen G. John,1 Kumar Abayasekara,2 Peter M. Bangay,3 Mario De Nunzio,4 James E. Kirk,4 John Graham Pollock,5 Peter D. Tharley,6 Paul J. Owen,1 Richard J. Fluck,1 Lindsay J. Chesterton,1 1Nephrology, Royal Derby Hospital; 2Vascular Surgery, Royal Derby Hospital; 3Radiology, Royal Derby Hospital, Derby, United Kingdom.

**Background:** Definitive access for haemodialysis (HD) remains the cornerstone of optimal dialysis. However, HD patients are becoming older, access attempts more problematic and vein preservation remains critical. Clinical examination and access monitoring enable appropriate, timely, endovascular intervention. Stents may be inserted for recurrent stenosis or after endovascular rupture, but their role remains debatable. We report on our single-centre experience of access surveillance and endovascular intervention, highlighting the role of stent insertion.

**Methods:** Electronic hospital records were retrospectively analysed in all access-related stents inserted from 2006-2014 by 5 vascular radiologists.

**Results:** 49 stents were inserted during 45 procedures in 39 patients. 12 had diabetes. Mean age was 64.5±25.5 yrs, median dialysis vintage was 1162±1504 days (range 5–5027). Median time from access creation (82% arteriovenous fistula) to stent insertion was 318±926 days (range 31–3752). 34 stents were inserted peripherally (cephalic arch and distally), the majority in the cephalic arch. Equal numbers of covered and bare-metal stents were inserted. 4 stents were placed in thrombosed access. 7 procedures were due to surveillance alone, a further 8 due to surveillance and pressure/flow problems. 12 stents were inserted for rupture or dissection (overall access procedure complication rate 1%). Median time from first stent to access failure/ceded HD was 333±653 days, assisted by median 2 (range 0-11) further procedures. Treatment for rupture was not associated with significantly shorter access longevity. Only 10 patients’ access failed following follow-up. Our overall HD definitive access prevalence rate was 86-90%.

**Conclusions:** Appropriate HD access is essential in minimising HD morbidity. We recommend stent insertion for fibre-requiring stenosis or rupture during endovascular procedures. Our data suggest that appropriate, judicious stent insertion in an appropriately structured pathway results in access durability and longevity.

Association of Vascular Access Flow and Volume Status on Fistula Arm by Bio-impedance Analysis in Hemodialysis Patients

Hun Jeong,1 Hyung Jong Kim,2 Eun jung Ko,1 Younhee Lee.1 1Internal Medicine, CHA Bundang Medical Center, CHA Univ, Seongnam, Korea; 2Internal Medicine, Seoul Bukbu Hospital, Seoul, Korea.

**Background:** Multi-frequency bioimpedance is a tool of body composition measure and can monitor changes in extracellular volume during dialysis. Arterio-venous fistulae(AVF) could potentially affect fluid retention in the arm. We investigated whether multi-frequency bioimpedance could detect AVF stenosis or association of AVF with fluid retention in the AVF arm.

**Methods:** We measured the extracelluar (ECW) and total body water (TBW) in AVF arm following hemodialysis by multi-frequency bioimpedance(biohyd S10®) using an eight-electrode contact technique. We measured AVF flow by transonic ultrasonography using an ultrasound dilution technology (HD 03®) in hemodialysis.

**Results:** Total 28 patients (male 13 patients) were enrolled and the mean age of patients was 54.8± 13.21 years. ECW/TBW ratio of fistula arm was a significantly higher than ECW/TBW ratio of non-fistula arm(0.389 ± 0.01 vs 0.382 ± 0.001, \( p<0.05 \)). ECW/TBW ratio of fistula arm was a significantly negative correlation with access flow level (mL/min) on fistula(\( p=0.05 \)). The 5KHz reactance of fistula arm was a significantly positive correlation with access flow level (mL/min) on fistula(\( p<0.05 \)).

**Conclusions:** Absolute and relative extracellular fluid volumes are increased in the fistula arm of hemodialysis. We thought that extracellular fluid volumes in the fistula arm were associated with access flow level (mL/min) and/or relative fistula stenosis. We suggest that multi-frequency bioimpedance can be a useful assistant tool of vascular access flow measure.

Background: Complications of long-term use of tunneled catheters for hemodialysis involve a high risk of infection, thrombosis, hospitalization and expense. This study reviews a single center experience to identify factors that may contribute to the high rate of patients initiated with tunneled HD catheters.

Methods: We conducted a 13-question survey of 47 CKD patients who had been newly initiated on dialysis through a tunneled central vein dialysis catheter during their hospital admission in a university hospital from December 2013-May 2015.
