Results: 1,512 patients were included and 151 developed kidney failure over the 5-year follow-up period. The 4-variable KFRE more accurately predicted kidney failure when compared to eGFR alone (AUROC’s 0.90 [95% confidence interval (CI) 0.88-0.92] for KFRE vs. 0.78 [95% CI 0.74-0.83] for eGFR). At a risk threshold of 3% over 5 years, the KFRE had a sensitivity of 97% and a specificity of 62%.

Conclusions: The KFRE is highly accurate at predicting 5-year risk of kidney failure in a population based sample of Manitobans with CKD Stages 3 to 5. Integration of the 4-variable KFRE into laboratory information systems should be considered.

A Risk Prediction Model of End-Stage Renal Disease in Type 1 Diabetes Using Urine MCP-1 as an Alternative Biomarker of ACR

Masayuki Yamanouchi, Monika A. Niewczas, Natalia Z. Nowak, Andrzejj S. Krolewski. Genetics & Epidemiology, Joslin Diabetes Center, Boston, MA.

Background: There is a great need to develop risk prediction models to recruit patients at high risk of end-stage renal disease (ESRD) for clinical trials in patients with type 1 diabetes. We developed two models to predict progression of CKD 3 and 4 to ESRD in 5 years in patients with type 1 diabetes: “ACR model” that consists of patient’s age, eGFR, Hba1c and ACR, and “Urine MCP-1 model” that consists of the same markers but replacing ACR with urine MCP-1.

Methods: We identified 285 patients with type 1 diabetes and impaired renal function (eGFR: 15-60 ml/min/1.73 m^2) from Joslin Proteinuria Cohort that was followed for 7 to 18 years to ascertain ESRD. We focused on the events within 5 years from enrollment. For the ACR model, the Cox model identified four baseline variables: age, eGFR, ACR, and Hba1c for the final model. For the urine MCP-1 model, urine MCP-1, age, eGFR and Hba1c were identified by the Cox model. Assigned point scores corresponded to each coefficient.

Results: 5-year risk of ESRD in the study group was 40.5%. In the ACR model, the variable with highest magnitude was eGFR<30, 4 points; followed by ACR<300, 2 points; Hba1c<7.5, 1 point; and age<45 years, 1 point, while in the urine MCP-1 model, the variable with highest magnitude was eGFR<30, 2 points; followed by urine MCP-1>545, 1 point; Hba1c>7.5, 1 point; and age<45 years, 1 point. The model with urine MCP-1 performed almost equal to the model with ACR (C statistic of 0.702 (0.556-0.831) vs. 0.719 (0.574-0.845)). Although the number of patients who developed ESRD in the high risk group in the urine MCP-1 model is smaller than in the ACR model, the incident rate was not different (0.719 (0.574-0.845)). Using the risk score with urine MCP-1, we can identify a subgroup of patients at very high risk of ESRD.
SA-PO691
A Reliable Formula to Estimate 24-h Urine Sodium Excretion from Morning Fasting Urine in Patients with Chronic Kidney Disease
Se Jun Kim,1 Ho Jun Chin,2 Sejoong Kim,3 Dong Ki Kim,1 Suhngwol Kim,1 Jung Hwan Park,4 Sung Joon Shin,2 Bum Soon Choi,2 Chun Soo Lim,1 Sang Ho Lee.1
1Kyung Hee Univ Hospital, Seoul, Korea; 2Seoul National Univ Bundang Hospital, Seong-Nam, Korea; 3Seoul National Univ Hospital, Seoul, Korea; 4KonKuk Univ Hospital, Seoul, Korea; 5Dongguk Univ Ilsan Hospital, Goyang, Korea; 6Seoul St Mary’s Hospital, Seoul, Korea; 7Seoul National Univ Barama Medical Center, Seoul, Korea.

Background: Estimated 24 hour urine sodium excretion based on spot urine has been proposed to replace 24 hour urine collection in epidemiologic studies. However, estimated sodium excretion has not been verified whether it is useful in patients with chronic kidney disease (CKD) as well as in interventional study. The aim is to evaluate the estimated sodium excretion in prospective low salt diet education study (ESPECIAL) cohort.

Methods: New formula was developed from baseline data of 228 CKD patients of ESPECIAL cohort using a multivariable linear regression and compared with previous three formulas from healthy population (Kawasaki, INTERSALT, Tanaka) and one from CKD patients (Nerbas) for the prediction of 24 hour sodium excretion after ARB treatment and low salt diet education.

Results: Among previous reported formulas, the estimation by Tanaka’s formula showed the smallest bias (estimated 144.3±46.5 vs. measured 154.1±69.6 mEq/day), but weak correlation (r=0.34). We developed new formula with improved bias (estimated 154.0±39.7 mEq/day) and correlation (r=0.56). New formula also showed the best correlation (r=0.57) with smallest bias (estimated ±4 mEq/day) even after ARB treatment, which did not show significant change of measured sodium excretion [56.3±70.6 mEq/day]. Intensive low salt diet education elicited the significant decrease of measured sodium excretion (121.2±61.9 mEq/day). Intensive low salt diet education elicited the significant decrease of measured sodium excretion (121.2±61.9 mEq/day). Although new formula also showed best correlation, any of formulas did not predict the amount of the decrease of measured sodium excretion.

Conclusions: We developed more reliable formula for estimating urine sodium excretion for CKD patients. However, our data suggests estimated sodium excretion could be applied for epidemiological study rather than low salt intervention study.

SA-PO692
Evaluation of Glycated Albumin for Glycemic Monitoring in Diabetic Nephropathy
Yang Fei, Ying Fan, Yunmei Liu, Niansong Wang. Dept of Nephrology and Rheumatology, Shanghai Jiaotong Univ Affiliated the Sixth Hospital, Shanghai, China.

Background: Glycated albumin(GA) has been now widely used for the evaluation of blood glucose in diabetic nephropathy(DN) patients. However, the effect of proteinuria on GA should be taken into account, especially in patients with advanced DN.

Methods: A total of 621 diabetic nephropathy patients from year 2009 to 2014 were enrolled in the study. According to the 24 urine protein(UP) output, subjects were divided into 3 groups defined as (1) microalbuminuria: UP=30-300mg/24h, (2) moderate albuminuria: UP=300-1000mg/24h, (3) macroalbuminuria: UP>1000mg/24h.

Results: In all DN patients, the related factors of GA were fasting blood glucose(FBG), potential blood glucose(PBG), body mass index (BMI) and 24 UP. The multivariable regression equation was GA = 0.254FBG + 0.347PBG-0.341 BMI-1.306UP, (R²=0.375).

Conclusions: In diabetic nephropathy patients, blood glucose, serum albumin and 24h urinary protein output may serve as important factors for the evaluation of GA on glycemic level. GA tended to be underestimated in DN patients with macroalbuminuria. The adjGA may be a better way to objectively evaluate glycemic status in patients with advanced DN.

Meredith C. Foster,1 Julie K. Bowser,2 Josef Cores,2 Roger A. Fielding,3 Lesley Inker,4 Andrew S. Levy,1 Tufts Medical Center; 1Tufts University; 2Johns Hopkins Univ; 3Tufts Univ.

Background: Established serum filtration markers are influenced by body composition (creatinine by muscle mass, cystatin C by fat mass) but limited data exist evaluating associations of these markers with body composition assessed using a gold-standard measurement approach. Our aim was to examine the association of body composition quantified using dual energy X-ray absorptiometry (DXA) with serum creatinine and cystatin C in US adults.

Methods: We conducted a cross-sectional analysis in 43782 adults age 18+ years from NHANES 1999-2002. Body composition included total lean mass and total fat mass; body mass index (BMI, kg/m^2) was included for comparison. Associations of natural-log-transformed creatinine and cystatin C with body composition measures were evaluated using multivariable linear regression, stratified by age. Analyses were weighted to account for the NHANES design with multiple imputation for missing DXA data.

Results: Lean mass was associated with higher serum creatinine in all age groups whereas higher fat mass was associated with higher creatinine in adults age 65+ (Table). Lean mass and fat mass were associated with higher serum cystatin C across all age groups; associations of lean mass with cystatin C were not significant with additional adjustment for fat mass.

Conclusions: Fat mass and lean mass are differentially associated with creatinine and cystatin C in US adults. Findings in younger adults suggest that observed associations may reflect the impact of body composition rather than kidney function on serum marker levels. Further work is needed to determine how the observed associations are influenced by GFR and body composition simultaneously and the impact of fat and lean mass on CKD prevalence estimates.

SA-PO694
Associations of the Levels of Kidney Function with Protein-Energy Wasting Syndrome Are Independent of Serum CRP and Bicarbonate
Xiaohui Chen,1 G. Wei,3 Robert E. Boucher,1 Dominique Ferranti,2 Michel Chonchol,1 Kalani L. Raphael,1 Sirini Beddhu.2 "U of Utah, "VA SLC; "UC Denver.

Background: Inflammation and metabolic acidosis are putative causative factors of protein-energy wasting (PEW) in CKD. Therefore, we examined whether serum CRP and bicarbonate levels attenuate the associations of CKD with PEW in 11,854 adult (age > 20 years) participants in the 1999-2004 National Health and Nutrition Examination Survey (NHANES).

Methods: PEW syndrome was defined as the presence of at least one criterion in two out of three categories: serum chemistry (albumin < 3.25 g/dl or cholesterol < 100 mg/dl), body weight (BMI < 20 kg/m^2 or unintentional weight loss > 10% over 1 yr), and muscle mass (body fat % < 10% or MAMC < 10% of 50th percentile of reference population). Using eGFR 60 to 89 ml/min/1.73 m^2 as the reference, the odds of PEW in ≥ 45, 50 < 45 ml/min/1.73 m^2 groups were examined in logistic regression models using svy set in STATA 13.

Results: Mean age was 46.0 yrs, 50.3% were male, 9.5% were black. The prevalence of PEW syndrome had a U shaped association with the level of kidney function.

Compared to the reference group, both eGFR ≥ 90 and < 45 groups had nearly two-fold increased odds of PEW. This was not attenuated after adjusting for serum CRP or bicarbonate.

Discussions About CKD Between African Americans with High CKD Risks

Methods: As part of a randomized controlled trial, we characterized CKD awareness and perceived risk of CKD among AAs with uncontrolled hypertension and CKD (eGFR 15-60 ml/min/1.73m2 or UACR ≥30mg/g). We assessed patients’ self-reported CKD awareness (“Do you have a kidney problem or chronic kidney disease?”; yes or no) and degree of perceived likelihood (“How likely do you think it is that you could develop kidney problems or kidney failure in the next 10 years?”; not likely versus slightly, moderately, or very likely response) and perceived concern of developing CKD (“How concerned are you about developing kidney problems in the next 10 years?”; not concerned versus slightly, moderately, or very concerned response). We constructed multivariable models to assess patient characteristics independently associated with patients’ CKD awareness and perceived CKD risks.

Results: Among 52 AA patients with CKD, the mean age was 58 years, 67% were female, 67% had diabetes, 15% had coronary artery disease, 40% had eGFR=60 and 60% had albuminuria alone. The majority (n=37, 71%) of patients were not aware of their CKD. Among these, 27% (n=10) considered themselves unlikely to develop CKD and 19% (n=7) were not concerned about developing CKD. CKD awareness was greater among patients with an eGFR <60 (adj. OR 2.5, 95% CI [1.9-3.2]) and patients with higher eGFR [adj. OR 0.96 (0.92-1.0)]. CKD awareness was low, with some patients unconcerned about developing CKD in the future. Strategies to improve recognition of CKD risks among AAs at high CKD risk are needed. Funding: NIDDK Support

SA-PO696

Discussions About CKD Between African Americans with High CKD Risks and Their Primary Care Physicians

Methods: In a randomized controlled trial of African American (AA) patients with uncontrolled hypertension and CKD, we analyzed audio-recorded encounters between patients and their PCs using the Roter Interaction Analysis System to characterize the occurrence of CKD discussions (e.g., discussion of kidney disease, eGFR, creatinine, or albuminuria) and patient-physician communication patterns (e.g., patient-centeredness, the degree to which the discussion focused on the patient’s psychosocial and lifestyle context) during routine primary care visits. In multivariable logistic regression models, we assessed patient visit, and communication characteristics independently associated with the presence of CKD discussions among all patients and among those with CKD (eGFR=60-<150 ml/min/1.73m2 or UACR ≥30mg/g).

Results: Among 124 patients, the mean age was 58 years, 69% were female, 48% had diabetes, 35% had CKD (mean eGFR 33). The average visit length was 22 minutes. Patients and PCPs discussed CKD in 47% of visits and discussions more frequently occurred among patients with CKD (vs. without CKD) (66% and 36% respectively, p=0.002). Discussions and PCPs discussed CKD in 47% of visits and discussions more frequently occurred among patients with CKD (vs. without CKD) (66% and 36% respectively, p=0.002). Discussions and PCPs discussed CKD in 47% of visits and discussions more frequently occurred among patients with CKD (vs. without CKD) (66% and 36% respectively, p=0.002).

Conclusions: Among AA patients with uncontrolled hypertension and CKD, awareness of CKD was low, with some patients unconcerned about developing CKD in the future. Strategies to improve recognition of CKD risks among AAs at high CKD risk are needed. Funding: NIDDK Support, Other NIH Support - NHLBI

SA-PO697

Primary Care Utilization Is Associated with Reduced Mortality Among Older Adults With CKD

Methods: We quantified the association between primary care utilization and ESRD incidence or mortality among older US adults with CKD (in 2005-2006) using Medicare claims. We assessed (in 2006) patients’ primary care utilization (no visit at least one, other care utilization [nephrology care [no visit at least one], the total number of annual evaluation and management (E & M) visits with any type of provider), and patients’ comorbid conditions and sociodemographics. We used standard and cause-specific (accurate for competing risk of death) Cox proportional hazard models overall and stratified by age (65-74, 75-84, or ≥85 years) to estimate hazard ratios (HRs) for ESRD or mortality.

Results: Among 106,765 patients, 79% (70% had at least one primary care visit in 2006, and 21% had at least one nephrologist visit. The median number of ambulatory & E & M visits was 10. Compared to patients with no primary care visits, patients with at least one visit were younger (78 vs. 80 mean years, p<0.001), less likely African American (10 vs. 14%, p<0.001), and had a greater prevalence of diabetes (46 vs. 42%, p<0.001), hypertension (88 vs. 78%, p<0.001), or coronary artery disease (74 vs. 72%, p=0.001). Over 4 years of follow-up, 4,264 patients developed ESRD and 45,059 died. Primary care utilization was not associated with ESRD incidence. However, compared to patients with no primary care visits, patients with at least one visit had a lower risk of death (HR [95%CI]: 0.73 (0.72-0.75)) overall and in age stratified models.

Conclusions: Primary care utilization was not associated with lower ESRD risk, but it was associated with a lower risk of death among older adults with CKD. Efforts to improve the engagement of primary care providers in the care of patients with CKD represent an important strategy to improve the health of this high risk population. Funding: NIDDK Support

SA-PO698

Routine Use of Health Care Among High-Risk African Americans at Risk of CKD

Methods: We quantified the prevalence of RHC (physical exam ~1 year prior use) among AA Jackson Heart Study (JHS) baseline participants (from 2000-2004) with hypertension (HTN) or diabetes. We identified demographic, attitudinal (e.g., perceived discrimination, anger and hostility, stress, trust in health providers) and educational (i.e., CKD awareness) factors independently associated with RHC use among high-risk AA's at risk of CKD incidence or progression.

Results: Of 5301 JHS participants, 1152 met inclusion criteria. Most (n=909, 79%) reported RHC use. Rates of RHC were similar in those with and without CKD (22% vs. 23%). Participants not using RHC (vs. using) were more likely to be <55 years of age (45 vs. 42%, p<0.001), male (43% vs. 30%), without HTN (9% vs. 5%), tobacco users (38% vs. 29%), and uninsured (14% vs. 9%), all p<0.05. In multivariable models, not using RHC was associated with age <55 (OR 1.75 [95% CI 1.25-2.5], male sex (OR 1.55 [1.12-2.16]), - HS diploma (OR 1.63 [1.12-2.34]), no HTN (OR 2.14 [1.34-3.4]), lower provider trust (OR 3.27, [1.61-6.65]) and less anger and hostility (OR 1.53, [1.1-2.1]).

Conclusions: Among high-risk AA's in the JHS, younger participants and males were less likely to use RHC. Those with low trust were also less likely to use RHC. Efforts to address health risks among high-risk AA's should target those using less RHC and consider attitudinal barriers to RHC.

SA-PO699

Development of a Question Prompt Sheet for Patients with Chronic Kidney Disease

Background: Patients with chronic kidney disease (CKD) commonly have unmet information needs. Greater patient participation in healthcare discussions can address these needs, and is associated with improved health outcomes. A question prompt sheet (QPS), a list of questions to prompt discussion, has been shown to increase patient participation in other chronic disease discussions; however, no QPS has been developed for CKD patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

Funding: NIDDK Support
Methods: We conducted a 2-phase cross-sectional study involving semi-structured telephone interviews with 1800 patients with stage 5 CKD who were asked questions concerning the use of CKD-QPS targeted to patients with moderate CKD. Patients with an estimated glomerular filtration rate <60ml/min/1.73m², on dialysis, or with a transplant were recruited from a single VA nephrology clinic. Phase 1 interviews included 17 open-ended questions assessing patients’ CKD information needs. Responses were qualitatively analyzed to identify an initial 67-items QPS. Phase 2 participants reviewed the pre-nailed QPS to rate the importance of asking each question on a 5-point Likert scale, provide open-ended feedback, and rate their willingness to use a CKD-QPS. Question items responses were analyzed to refine and reduce QPS questions. In total of 76 participants completed interviews (phase 1: n=32, phase 2: n=44). Most were male (96%), non-Hispanic white (68%), and mean age was 66 years. Patients desired more information about CKD, particularly regarding self-care techniques, dialysis/ transplant, and CKD complications. The final QPS tool included 37-questions divided into 10 CKD subtopics (e.g., CKD definitions, causes, impact, monitoring, labs, self-care, treatment, dialysis, transplant, managing comorbid conditions). Most patients (91%) reported being ‘completely’ or ‘very’ willing to use a CKD-QPS in future doctor visits.

Conclusions: CKD patients have unmet information needs and wish to use a CKD-QPS. Further research is needed to assess whether our CKD-QPS effectively addresses patients’ information needs, enhances doctor-patient communication, and improves health outcomes.

Views and Practice Patterns of Dialysis Medical Directors Towards End-of-Life Decision Making for Patients with End-Stage Renal Disease
Enrica Fung,1 Nathan Samuel Slesnick,2 Manjula Kurella Tamura,1,3 Brigitte Schiller.1 1Stanford Univ, Palo Alto, CA; 2Satellite Healthcare, San Jose, CA; 3Geriatric Research and Education Clinical Center, Veterans Affairs, Palo Alto, CA.

Background: Nephrologists frequently engage in end-of-life decision making for patients with end-stage renal disease (ESRD). Patients with ESRD report infrequent end-of-life discussions and nephrology trainees report feeling unprepared for end-of-life decision making, but the views of dialysis medical directors have not been studied. Our objective is to understand dialysis medical directors’ views and practice patterns on end-of-life decision making for patients with ESRD.

Methods: We administered questionnaires to dialysis medical directors during medical director meetings of three different dialysis organizations in 2013. Survey questions corresponded to recommendations from the Renal Physicians Association clinical practice guidelines on initiation and withdrawal of dialysis.

Results: There were 121 medical director respondents from 28 states. The majority of respondents felt “very prepared” (66%) or “somewhat prepared” (29%) to participate in end-of-life decisions and most (80%) endorsed a model of shared decision-making. If asked to do so, 70% of the respondents provided prognostic information “often” or “nearly always”. For patients with a poor prognosis, 36% of respondents would offer a time-limited trial of dialysis “often” or “nearly always”, while 56% of respondents would suggest withdrawal from dialysis “often” or “nearly always” for those with a poor prognosis currently receiving dialysis therapy. Patient resistance and fear of taking away hope were the most commonly cited barriers to end-of-life discussions.

Conclusions: Views and reported practice patterns of medical directors are consistent with clinical practice guidelines for end-of-life decision making for patients with ESRD but inconsistent with patient perceptions.

Emergency Department Utilization Among United States ESRD Patients
Brendon P. Loyvasik, Rebecca H. Zhang, Taylor A. Melanson, Stephen O. Pustan, Rachel E. Patzer. Emory Univ, Atlanta, GA.

Background: Single center studies suggest that ESRD patients have a high rate of emergency department (ED) utilization, with 0.9-2.4 ED visits/patient-year. Prior studies show that ESRD is a stronger risk factor for ED use than heart failure, lung disease, or cancer. However, ED utilization among a national ESRD patient population has not been examined.

Methods: We examined a cohort of 788,162 incident adult ESRD patients in the United States Renal Data System from 2005-2011. ED utilization was identified using CPT codes 99281-5 (Severity Levels 1-5) and 99291 (Critical Care) by American College of Emergency Physicians guidelines. ED and hospital admission, diagnosis, and procedures were obtained from the USRDS and Medicare Physician/Supplier and Inpatient databases for 2011.

Results: In the first year of ESRD diagnosis, 1,143,372 ED visits were observed for 480,176 unique ESRD patients. 77% of ESRD patients used the ED within the first ESRD year at an average of 2.69 ED visits/patient-year. The national range was 1 to 172 ED visits per year with median 2 visits (interquartile range 1-4 visits) and 95th percentile 8 visits.

Conclusions: Patients with ESRD over 100 times in their first ESRD year. Nearly half (46.0%) of ED visits were coded as Critical Care emergencies. 15.4% of ESRD patients used the ED over 100 times in their first ESRD year. 1,143,372 ED visits were observed for 480,176 unique ESRD patients. 77% of ESRD patients used the ED within the first ESRD year at an average of 2.69 ED visits/patient-year. The national range was 1 to 172 ED visits per year with median 2 visits (interquartile range 1-4 visits) and 95th percentile 8 visits.

Impact of Evidence-Based Clinical Care on Major Adverse Clinical Events in Patients with Clinically Significant Proteinuria: A Population-Based Retrospective Cohort Study
Julius Oluoch Okel1, Bilal Qarni,2 Timothy Olusegun Olanrewaju,2 Aminu K. Bello.1 1Univ of Alberta; 2Univ of Ilorin, Nigeria.

Background: Proteinuria is an important prognostic marker for cardiovascular (CV) and renal events. Most studies of quality of care (QoC) in chronic kidney disease (CKD) have focused on other markers for risk stratification and outcomes. We hypothesized that in proteinuric CKD, markers of good quality care will be associated with lower risk of adverse clinical outcomes (all-cause mortality, all-cause hospitalization, CV and renal outcomes).

Methods: We used a population-based cohort of patients with significant proteinuria (albumin-creatinine ratio (ACR) ≥60 mg/mmol, protein-creatinine ratio (PCR) ≥100 mg/mmol or protein 3+ on dipstick) to evaluate current patterns of evidence-based care and association with outcomes. Markers of good quality care were defined as nephrology referral, relevant laboratory testing and appropriate medication use (ACEI/ARBs; statins).

Results: Of the 71, 660 with at least 1 or 2 proteinuria measurements, 16,204 (22.6%) had significant proteinuria. At follow-up, receipt of good quality care (1) timely referral, (2)HbA1c testing, (3)use of ACEI/ARBs and (4) use of statins) was associated with reduced risk of mortality: 0.67 (0.59-0.75), 0.52 (0.46-0.59), 0.68 (0.62-0.74), and 0.63 (0.57-0.69), and all-cause hospitalization: 0.85 (0.79-0.93), 0.65 (0.59-0.72), 0.93 (0.87-0.99), and 0.82 (0.77-0.88) respectively. There were no statistically significant associations with the risk of CV and renal events.

Conclusions: This study examined the link between evidence-based treatment and clinical outcomes in an especially high-risk population with CKD. Good quality care impacts mortality risk and hospitalization risk, and reduced risk of hospitalization. The impact of QoC on renal and cardiovascular events is less clear. The findings would justify future interventions to increase uptake of such treatments in patients with proteinuric CKD.

APOL1 Risk Alleles and Risks of Cardiovascular Disease in Children with Focal Segmental Glomerulosclerosis (FSGS) (FSGS) Robert Woroniecki,1 Derek Ng,2 Sophie Limou,1 Cheryl Ann Winkler,1 Kimberly J. Reidy,3 Mark Mitsnefes,4 Craig S. Wong,1 Bradley Warady,1 Susan L. Furth,4 Jeffrey B. Kopp,4 Frederick J. Kaskel.1 1Stony Brook Children’s Hospital, Stony Brook, NY; 2Johns Hopkins Bloomberg School of Public Health, Baltimore, NY; 3NCI, NIH, FNL, Frederick, MD; 4Emory, Children’s Hospital at Montefiore, Bronx, NY; 5Cincinnati Children’s Hospital, Cincinnati, OH; 6Univ of New Mexico, Albuquerque, NM; 7Children’s Mercy Hospital, Kansas City, MO; 6Univ of Pennsylvania, Philadelphia, PA; 4NIDDK, NIH, Bethesda, MD.

Background: APOL1 renal risk alleles are a major cause of glomerular disease in African Americans (AA). It is controversial as to whether individuals with high risk (HR) APOL1 genotypes (2 risk alleles) are at risk for athereosclerotic heart disease, and association with left ventricular hypertrophy (LVH) has not been explored. It is unclear whether children with focal segmental glomerulosclerosis (FSGS) and HR APOL1 are at increased cardiovascular risk.

Methods: Self-identified AA children with FSGS in CKiD study cohort were genotyped for APOL1 renal risk variants: G1 (rs73855319, S342G) and G2 (rs71785313, NY388-389 deletion), and compared to non-AA children with FSGS, none with HR.

Results: Of the 71, 660 with at least 1 or 2 proteinuria measurements, 16,204 (22.6%) had significant proteinuria. At follow-up, receipt of good quality care (1) timely referral, (2)HbA1c testing, (3)use of ACEI/ARBs and (4) use of statins) was associated with reduced risk of mortality: 0.67 (0.59-0.75), 0.52 (0.46-0.59), 0.68 (0.62-0.74), and 0.63 (0.57-0.69), and all-cause hospitalization: 0.85 (0.79-0.93), 0.65 (0.59-0.72), 0.93 (0.87-0.99), and 0.82 (0.77-0.88) respectively. There were no statistically significant associations with the risk of CV and renal events.

Conclusions: This study examined the link between evidence-based treatment and clinical outcomes in an especially high-risk population with CKD. Good quality care impacts mortality risk and hospitalization risk, and reduced risk of hospitalization. The impact of QoC on renal and cardiovascular events is less clear. The findings would justify future interventions to increase uptake of such treatments in patients with proteinuric CKD.

Trends in Burden of Out-of-Pocket Expenses in United States Adults with Kidney Disease from 2002-2011
Mukonso N. Ozrie,1 Kinfe Gebreziabher Bishu,2 Clara E. Dismuke,3 Leonard Egede.2 1Nephrology, MUSC; 2Center for Health Disparities Research, Internal Medicine, MUSC, Charleston, SC.

Background: High out-of-pocket (OOP) burden negatively impacts healthcare access and outcomes. Studies examining high OOP burden in the general population exists however no studies has examined OOP healthcare burden in people with kidney disease (KD). This study examined trends in high OOP healthcare in people with KD while concurrently evaluating the impact of insurance status and income category on high OOP burden.

Methods: We analyzed 2,966 adults aged 18-64 years with kidney disease using the Medical Expenditure Panel Survey-MEPS. Individuals with KD were identified with Clinical Classification Codes: 156 - nephritis, nephrosis, renal sclerosis; 157 - acute and unspecified renal failure; 158 - chronic renal failure; 159 - acute and unspecified renal failure; 157 - acute and unspecified renal failure; 158 - chronic renal failure; 160 - calculus or urinary tract and; 161 -...
Buffalo, Buffalo, NY; Impact of Timely AV Fistula Placement on Resource Utilization After Ritika Sharma, Candace D. Grant, Ronak Patel, Monika Wadhwani, Vladimir Disease in Patients with Chronic Kidney Disease Health Disparities and Increased Risk of Developing End Stage Renal however people with kidney disease in the US still experience high OOP burden. Policies of people with high OOP fell by 10 percentage points from 2002/2003 to 2010/2010. The proportion of poor/near poor people and uninsured with high OOP was as high as 52% and 30% respectively in 2002/2003 but fell to about 25% and 27% respectively in 2010/2011. 

Conclusions: Trends in high OOP burden in people with KD has decreased over time however people with kidney disease in the US still experience high OOP burden. Policies to reduce high OOP in people with KD could significantly impact KD outcomes.

SA-PO709 Health Disparities and Increased Risk of Developing End Stage Renal Disease in Patients with Chronic Kidney Disease Alejandro Pevey, Ritika Sharma, Candace D. Grant, Ronak Patel, Monika Wadhawan, Vladimir Liberman, Shanza Mujeeb, Saira Sharif, Shayan Shirazian, Nobuyuki (Bill) Miyawaki, Joseph Mattana. Medicine, Winthrop-Univ Hospital, Mineola, NY.

Background: Health disparities occur in groups of people that experience suboptimal health care based on their social, economic, and/or environmental disadvantage. Identifying how these disparities affect the risk of chronic kidney disease (CKD) progression to end stage renal disease (ESRD) can hopefully lead to a reduction in these health inequities and improve health outcomes for all CKD patients. We examined health disparities and the risk of ESRD using patient-specific and community-specific variables. 

Methods: We studied a cross-section of 623 patients with stage 3 and 4 CKD and estimated their 2- and 5-year risk of ESRD using the method of Tangri et al. (JAMA 2011; 305:1553–1559). The U.S. Census Bureau Community Survey was used to obtain patient zip code-specific data including percent foreign born, percent below the poverty level, median household income, and percentage graduating high school. We did a multivariable generalized linear analysis on the outcome variables of the 2 and 5 year risk of ESRD.

Results: Lower household income was associated with a higher risk of ESRD at 2 and 5 years (p<0.05). There was a trend towards a higher risk of ESRD amongst patients from zip codes with higher poverty rates and lower education levels. Being single, including by divorce and separation but not by being widowed, was associated with a significantly higher risk of ESRD. We also found that patients on Medicaid and patients with private insurance or self pay had a significantly higher risk of ESRD compared to those on Medicare.

Conclusions: Our findings suggest that there are substantial health disparities related to CKD and the risk of ESRD. Some of these disparities are patient-specific but others appear to be related to factors associated with the community where they reside. This suggests that evaluation of patient-specific as well as community-specific variables might help to better individualize CKD care and improve our ability to identify and treat the patient at increased risk of developing ESRD.

SA-PO710 Impact of Timely AV Fistula Placement on Resource Utilization After Initiation of Dialysis Edwin J. Anand,1 Kabir Jalal,1 Laura L. Argauer,1 Brian M. Murray,1 Pradeep Arora,2 Rocco C. Venuto,1 1Medicine, SUNY at Buffalo, Buffalo, NY; 2Computer Task Group, Buffalo, NY. Computer Task Group, Buffalo, NY. Computer Task Group, Buffalo, NY. Medicine, VA Medical Center, Buffalo, NY.

Background: Maintenance dialysis is ideally initiated in the outpatient setting with a permanent access. This requires advance planning and of care between nephrologists, and access surgeons. The costs associated with ‘crash’ initiation of dialysis is anticipated to be high. In this observational study, we studied the hospitalization rates and costs of care in the 12 months following dialysis initiation between patients who started dialysis in an ideal manner versus sub-optimally.

Methods: Claims and laboratory data from a large, regional insurance company covering half a million patients between January 2001 and May 2014 were reviewed. 422 patients were started on dialysis in the above period. 257 patients (61%) had a crash start of dialysis. 86 patients (20%) had a fistula prior to dialysis. Compared to patients who did not crash, patients who crashed were older (p<0.0001), had a higher hospitalization rate in the one year period (p=0.0088). Multivariate analysis confirmed that patients who crashed had a significantly higher hospitalization rate in the one year following dialysis (p=0.0067). Patients with a fistula in place prior to dialysis experienced fewer hospitalizations (p=0.0377). Cost in the first year was also higher in patients who had a ‘crash’ without a fistula (p=0.0181). The cost advantage of having a fistula decreased with increasing age (p=0.0402).

Conclusions: Dialysis ‘crash’ results in increased morbidity and resource utilization. Coordination of care and timely access creation should reduce hospitalization and costs.

SA-PO711 DASH Diet Accordant Foods in the Homes of Urban African Americans at Risk for CKD Deidra C. Crews,1 Yang Liu,2 Edgar R. Miller,1 Patti Ephraim,1 Jessica M. Ameling,1 Kimberly Gadzune1, Lisa A. Cooper,1 L. Ebony Boulware.1,2 Johns Hopkins U., Baltimore, MD; 1Duke U., Baltimore, MD.

Background: The Dietary Approaches to Stop Hypertension (DASH) diet is recommended for the treatment of hypertension, especially among African Americans (AAs). Many barriers may hinder urban AAs from following the DASH diet, putting them at increased risk of poor health outcomes, including CKD.

Methods: In a randomized trial of urban AAs with uncontrolled hypertension, we assessed (via interview and home inspection) the presence of DASH diet accordant foods and full-sized kitchen appliances needed to prepare DASH meals. We examined factors associated with having DASH diet accordant foods or needed appliances using logistic models adjusted for age, sex, food insecurity (skipping meals due to lack of money), income, literacy, diabetes, obesity, CKD (eGFR<60 or albuminuria) and comorbid disease (Charlson Index).

Results: Among 159 participants, mean age was 57 yrs and 74% were female. Only 14.5% had 5 of the DASH food categories in their homes (fruits, vegetables, low fat dairy, whole grains, plant proteins). Over 80% had full-sized ovens and refrigerators.

DASH Accordant Foods in Home N (% ) Participants
- Fresh or frozen vegetables 131 (82%)
- Fresh or frozen fruits 93 (58%)
- Low fat dairy 48 (30%)
- Whole grains 102 (64%)
- Plant proteins 129 (81%)

Participants with CKD (vs without) had lower odds of having fresh fruits (adjusted odds ratio, 95% confidence interval: 0.40, 0.18-0.86). Younger age (yr increments) and annual income <$30K (vs ≥$30K) were associated with lower odds of having whole grains (0.96, 0.93-0.99 and 0.28, 0.11-0.72, respectively). Younger age was associated with lower odds of having plant proteins (0.94, 0.90-0.99). Persons with low literacy (<3rd grade level versus higher) had lower odds of having an oven (0.15, 0.04-0.52) and lower odds of a full-sized refrigerator in their homes (0.12, 0.02-0.59).

Conclusions: The homes of urban AAs at high risk for CKD were often lacking either foods or needed appliances required for DASH meals. The lack of these items was associated with CKD, younger age, low income and/or low literacy. Interventions to improve DASH adherence in this high-risk group should consider these factors.

Funding: NIDDK Support, Other NIH Support - NHLBI

Background: Chronic Kidney Disease (CKD) is under-recognized and suboptimally managed especially in primary care setting. We aimed to evaluate the impact of interactive workshops and web-based tools in improving CKD management among internal medicine residents.

Methods: A pre-test assessed knowledge in areas of CKD diagnosis, anemia (A), bone-mineral disease (B), control of BP (C) and degree of proteinuria (D). Interactive workshop offered a CDA of CKD lasting 90-minutes was conducted over 5 weeks along with access to self-developed online CKD management resource (www.nephromania.com). Post-test was conducted at workshop completion and 12 weeks later. Assessment for post-intervention CKD care improvement was done through chart review.

Results: Among 98 participating residents, 25% utilized the online resource and 62% found it very helpful with majority bookmarking it on smart phones. KDOQI guidelines awareness, recognition of CKD diagnosis and complications were respectively 22%, 70% and 75% on pre-test, 98%, 93% and 90% on immediate post-test (P<0.001), declining to 80%, 77% and 74% at 12-weeks. Aggregate scores are shown in Figure 1A. Practice patterns measured through chart-review (n=94) to assess compliance with CKD guidelines over next 3 months failed to show change (figure1B).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author. 790A
Conclusions: Our study showed effectiveness of targeted interactive workshops to improve recognition of CKD and its complications. Intelectualizing the taught concepts by residents did not translate to improved patient care. Declining retention of core concepts at 12-week testing indicates the need for ongoing reinforcement sessions. Continued education including online resources utilization is warranted as opposed to annual core-lectures provided by most training programs.

SA-PO713
Evaluating Progress of Healthy People 2020 Chronic Kidney Disease Objectives: Are We There Yet? Aseel Ryskulova,1 Lawrence Agodoa,2 Paul W. Eggers,2 Kevin C. Abbott.2 1NCHS, CDC, 2NIDDK, NIH.

Background: Chronic Kidney Disease (CKD) is a significant public health problem in the U.S. and a major source of disability, poor quality of life, and premature death for those afflicted. CKD and End-Stage Renal Disease (ESRD), the final stage of the CKD, exact a high economic price. In 2012 ESRD costs exceeded $49 billion dollars including 34 billion (about 20%) of total Medicare expenditures. An estimated 11.5% of adults ages 20 or older had physiological evidence of CKD determined from data collected through the 2001-06 National Health and Nutrition Examination Survey (NHANES). Each year in the United States, more than 115,000 people are diagnosed with ESRD.

Methods: Reflecting the importance of CKD, 24 CKD objectives area were included in the Healthy People 2020 (HP2020) national health goals to reduce new cases of CKD and related complications, disability, death, and economic costs. CKD objectives are focused on improving cardiovascular care in patients with CKD; increasing the proportion of patients with CKD and diabetes who received recommended evaluation and treatment; reducing death rate and percentage of U.S. population with CKD; and increasing CKD awareness in persons with impaired renal function. All CKD objectives are measurable, having at least one data point from national data systems including the NHANES, National Death Index, and U.S. Renal Data System.

Results: In 2015, 14 objectives had met their target (n=9) or showed improvement (n=5). Six objectives showed little or no significant change. Two objectives: increase the proportion of persons with diabetes and CKD who received recommended medical treatment with angiotensin-converting enzyme inhibitors or angiotensin II receptor blockers, and increase the proportion of patients receiving a kidney transplant within 3 years of ESRD, moved away from the target. The remaining 2 objectives were not evaluated as they were informational with no target set. Disparities persisted by sex, race/ethnicity, and SES status.

Conclusions: The presentation will cover the most recent national and state data for selected CKD objectives and provide an overview of the HP2020 and data search using the HP2020 website.

SA-PO714
Tele-nephrology for the Remote Management of Chronic Kidney Disease (CKD): A Retrospective Cohort Study Rajeev Rohatgi,1 Judy K. Tan,2 Anita Mehrrot,1 Medicine, James J. Peters VAMC, Bronx, NY; 2Medicine, Icahn School of Medicine, New York, NY.

Background: Veterans with CKD who live in the Hudson Valley Veterans Affair Medical Center (HVVMC) catchment area travel to the Bronx VAMC for nephrology care. Analysis of the no-show and cancellation frequencies for these renal appointments exceeded 50%, likely due to the distance between HVVMC and the Bronx (60 miles).

Methods: We hypothesized that patients managed via a tele-nephrology service, where patients visit their local VA and are evaluated remotely via videoconference by a Bronx VA nephrologist, would exhibit comparable clinical outcomes and visit compliance as patients visit following enrollment. We transcribed audio recordings, and quantified the frequency of diet discussions among African Americans (AAs) at increased CKD risk.

Results: In a randomized trial of urban AAs with uncontrolled hypertension, we audio-recorded patients’ routine visits with their primary care physicians (PCPs) at the first visit following enrollment. We transcribed audio recordings, and quantified the frequency of diet discussions among African Americans about diet during visits. We marked transcripts for discussions of dietary modification (e.g. sodium, weight, etc). We assessed patterns of patient-physician communication, including patient centeredness, during each encounter using the Roter Interaction System. We marked indicators independently associated with discussions of diet using logistic regression.

Results: Among 127 participants, mean age was 58 years and 70% were female. Average CPV visit lasted 25 minutes. Diet was discussed in 73% of visits, but only included discussion of the Dietary Approaches to Stop Hypertension (DASH) diet in 12%, weight/obesity in 36%, and cholesterol in 39% of visits. Independent predictors of diet discussions (odds ratio, 95% confidence interval) were patient centeredness score ratio (7.5, 1.3-41.9), and less than one year of education, and clinic location in New York City (OR = 0.5, 95% CI = 0.2-1.0) (for each minute increment). Patient age, gender, literacy, comorbid disease burden, obesity, diabetes nor CKD status predicted discussions.

Conclusions: Discussions of diet in primary care were frequent, and they were more likely to occur when visits were longer, were centered on patient priorities, and were attended by patients with incomes ≤$10k. Diet discussions focused on various topics, but infrequently included discussion of dietary modifications. Improvements in the content of diet discussions among African Americans at risk for CKD may be needed.

SA-PO716

Background: Tele-Nephrology: a feasible way to improve access for patients with kidney disease who reside in underserved areas.

Methods: A retrospective and descriptive study design was used to evaluate the effect of the Tele-Nephrology clinic intervention. Multiple clinical indicators were included in the analysis: blood pressure control, stabilization of the renal function and electrolyte/metabolic control. 101 patients that were evaluated in the clinic between 2013-2015 were included and the indicators were collected retrospectively.

Results: 101 patients were included, 95% male (n=96) and 5% female (n=5). The mean age was 65.5 years. 50 patients had Chronic Kidney Disease (CKD) stage III (49.5%), 14 patients had CKD stage IV (13%), 8 patients had CKD stage V (7.9%). A one-way analysis of variance analysis (ANOVA) between subjects was conducted and showed that the effect
of the Tele-Nephrology clinic intervention reducing blood pressure was statistically significant (systolic blood pressure P-value <0.0001). Renal function stabilized but the creatinine changes over time were not statistically significant (P-value: 0.50).

Subgroup analysis of individuals with eGFR < 30 ml/min or on dialysis reduced the differences in age and SPPB between groups, but demonstrated no significant difference to change in SPPB over time. HRQOL did not change significantly between groups. Proportion of individuals with improved PA over 1-year was 36% and 38% in EC and CG, respectively (p=0.82).

Conclusions: In this study, an exercise counseling clinic had no significant effect physical function as measured by SPPB at 1-year, suggesting that exercise counseling alone is inadequate to improve physical function in CKD.

SA-PO718

Ideal and Actual Support of Renal Replacement Therapy Modality Selection Patients with Chronic Kidney Disease: A Nationwide Survey in Japan
Shiho Kosaka,1 Shinichi Nishi,2 Yugo Shibagaki,3 Junichi Hoshino,4 Kazuo Takahashi,5 Yukiko Katagiri,6 Chiika Murayama,7 Yuko Funaki.7 1Sophia Univ; Tokyo, Japan; 2Kobe Univ Graduate School of Medicine, Kobe, Japan; 3St. Marianna Univ Hospital, Kawasaki, Japan; 4Toranomon Hospital, Tokyo, Japan; 5Fujita Health Univ School of Medicine, Toyoake, Japan.

Background: Optimal renal replacement therapy (RRT) selection supports for chronic kidney disease (CKD) patients are essential to improve post-treatment outcomes. We aimed to investigate how and when modality selection supports for patients with CKD are used by nephrologists in Japan, through a nationwide questionnaire survey of nephrologists.

Methods: A questionnaire was mailed to 1903 board-certified nephrologists of Japanese Society of Nephrology. Questionnaireitems targeting support for modality selection examined the following points: establishment of an RRT modality selection (RRT-MS) clinic, ideal and actual disease stage at which RRT-MS explanation is discussed, timing of RRT initiation, and type of specialist discussing RRT-MS with patients.

Results: The valid response rate was 12.3% (234/1903). Ninety-four out of 234 responding nephrologists (40.9%) had clinics dedicated to RRT-MS. Modality selection was most frequently discussed at CKD stage 4 (53.0%), stage 3b (22.8%), and stage 3a (13.4%). Nephrologists considered stage 3b (32.5%), stage 3a (19.5%), most ideal for discussing RRT-MS, a significant difference was therefore found between ideal and actual timing of RRT-MS discussion. Timing (by eGFR) of access placement of hemodialysis (HD) and peritoneal dialysis (PD) was significantly earlier in patients of RRT-MS clinics than in those of conventional clinics (HD, 12.3/14.1; PD, 12.6/14.9 ml/min/1.73 m²). Regarding types of specialists, nurses most frequently supported patients in RRT-MS (67.1%), however, this may be partly explained by the fact that nephrologists are required to commit more specialiststo supporting patients for RRT-MS.

Conclusions: A gap between ideal and actual timing of discussion of RRT-MSwith patients in Japan was identified. To promote appropriate timing of RRT-MS among CKD patients, early and multidisciplinary support systems should be structured.

SA-PO719

Primary Care Physicians’ Perceived Barriers and Facilitators to Care of Older Adults with Kidney Failure Not on Dialysis
Helen Tam-Tham, Brenda Hemmelgarn, Chandra Mary Thomas, Karen Fruetel, Robert R. Quinn, Kathryn M. King-Shier. Univ of Calgary, AB, Canada.

Background: Primary care physicians are important care providers for older adults with kidney failure, but how they perceive and practice conservative (non-dialysis) care has not been studied. We undertook a qualitative study to describe barriers, facilitators, and possible enhancements of conservative care in the community for these older adults.

Methods: Semi-structured telephone interviews were conducted with primary care physicians from southern Alberta, Canada. Participants were identified by a snowball sampling strategy and purposively sampled based on sex, age, and rural/urban location of clinical practice. All participants managed at least 1 patient ≥75 years with kidney failure (eGFR <15ml/min/1.73m² for at least 3 months, not on dialysis) over the past year. Transcripts were analyzed thematically by conventional content analysis.

Results: Twenty-seven primary care physicians participated in this study (55.6% of participants were male, 55.6% of participants were aged 40 to 60 years, and 51.9% of participants practiced in the primary care setting for greater than 20 years). Perceived barriers to conservative care included: managing expectations of kidney failure for patients and their families, optimizing medical management of conservative care, and negotiating provider roles and responsibilities of co-management. Facilitators for care included: establishing patient and their family expectations of care early, preserving continuity of care, and utilizing a multidisciplinary team approach. Primary care physicians also identified suggestions for enhancement of conservative care in the community, including direct telephone access by primary care physicians to conservative care clinicians, treatment decision aids for patients and their families, and a conservative care clinical pathway for primary care providers.

Conclusions: We found important barriers and facilitators to conservative care by primary care physicians in the community. Further investigation of potential strategies that remove barriers and enable facilitators is required to improve the quality of conservative care in the community.

Funding: Government Support - Non-U.S.
Background: Awareness of chronic kidney disease (CKD) is low, even among patients with advanced disease. Increasing awareness to 11.7% is a Healthy People 2020 goal. The National Health and Nutrition Examination Survey (NHANES) measures CKD awareness using the question “Have you ever been told by a doctor or other health professional that you had weak or failing kidneys (excluding kidney stones, bladder infections, or incontinence)?” The framing of this question may influence responses. We sought to compare its sensitivity/ specificity to different questions as well as to awareness of other chronic conditions.

Methods: We administered a questionnaire to 220 English, Spanish and Cantonese-speaking adults who received primary care in a public healthcare delivery system. We obtained demographic data, screened for health literacy and ascertained patient awareness about chronic health conditions, including CKD, diabetes, hypertension and hyperlipidemia. CKD awareness was measured using the NHANES question and additional ones, asking if patients had been told about “kidney disease”, “protein in the urine”, “kidney problem”, or “kidney damage”. Health conditions were verified by medical record review.

Results: In our diverse study population (9.6% White, 40.5% Black, 36.4% Hispanic, 12.0% Asian), mean age was 58, mean eGFR was 47 ml/min/1.73m² and 47% had low health literacy. Sensitivities of each CKD awareness question were: 26.7% for “kidney damage”, 28.0% for “kidney disease”, 33.5% weak or failing kidneys” (NAHINES), 36.2% for “protein in the urine” and 40.6% for “kidney problem”. Specificities ranged from 88.2% to 97.7%. Combining all 5 questions yielded a sensitivity of 61.1% and a specificity of 79.6%. This was comparable to awareness of hyperlipidemia (68.8%) but was lower than awareness for hypertension and diabetes (89.6% and 94.3% respectively). Sensitivities were lower in patients with low health literacy.

Conclusions: CKD awareness is low compared to other chronic diseases. Nevertheless, by using more sensitive combinations of questions to ascertain CKD awareness, we have likely reached the Healthy People 2020 goal.

Funding: NIDDK Support

SA-PO721

The Effects of Age and Symptoms on Recommendations to Initiate Dialysis

Background: Recommendations to initiate dialysis vary by country. Age and symptom burden influence nephrologists’ recommendations to initiate dialysis, but the extent of this influence differed substantially between nephrologists in different countries.

Methods: We assessed the association of community health indicators with late nephrology referral in patients reaching end-stage renal disease in the U.S. We assessed the association of community health indicators with late nephrology referral in patients reaching end-stage renal disease in the U.S. and 47% had low health literacy. Sensitivities of each CKD awareness question were: 26.7% for “kidney damage”, 28.0% for “kidney disease”, 33.5% weak or failing kidneys” (NAHINES), 36.2% for “protein in the urine” and 40.6% for “kidney problem”. Specificities ranged from 88.2% to 97.7%. Combining all 5 questions yielded a sensitivity of 61.1% and a specificity of 79.6%. This was comparable to awareness of hyperlipidemia (68.8%) but was lower than awareness for hypertension and diabetes (89.6% and 94.3% respectively). Sensitivities were lower in patients with low health literacy.

Conclusions: CKD awareness is low compared to other chronic diseases. Nevertheless, by using more sensitive combinations of questions to ascertain CKD awareness, we have likely reached the Healthy People 2020 goal.

The Association of Community Health Indicators with Late Nephrology Referral in Patients Reaching End-Stage Renal Disease in the U.S.

Jung-In Shin, Mari Palta, Micah R. Chan, Brad C. Astor. Univ of Wisconsin School of Medicine and Public Health, Madison, WI.

Background: Late nephrology referral in patients reaching end-stage renal disease (ESRD) is associated with inadequate preparation for dialysis and poorer clinical outcomes after renal replacement therapy (RRT). Previous studies have focused on individual-level factors to identify patients at higher risk of late nephrology referral. Environmental and socioeconomic conditions of communities in which patients live may also impact nephrology referral patterns.

Methods: We assessed the association of community health indicators with late nephrology referral in 587,574 patients reaching ESRD, using the data from United States Renal Data System (USRDS) from 2005-2012. An overall community health risk score was calculated using 35 community-level factors based on 1) health outcomes, 2) health behaviors, 3) access and quality of care, 4) socioeconomic factors, and 5) physical environment, using County Health Rankings data from University of Wisconsin Population Health Institute. Late nephrology referral was defined as the first encounter with a nephrologist occurring < 6 months before RRT initiation. Multilevel logistic regression models adjusted for individual characteristics, including demographics, cause of ESRD, body mass index, comorbidities, and insurance and employment status.

Results: Late nephrology referral was associated with inadequate preparation for dialysis and poorer clinical outcomes after renal replacement therapy (RRT). Previous studies have focused on individual-level factors to identify patients at higher risk of late nephrology referral. Environmental and socioeconomic conditions of communities in which patients live may also impact nephrology referral patterns.

Conclusions: For patients at a given eGFR, other characteristics such as age and symptom burden influence nephrologists’ recommendations to initiate dialysis but the extent of this influence differed substantially between nephrologists in different countries. Further research is required to understand the effect of these differences on patients and health systems.

SA-PO722
Results: The prevalence of late nephrology referral was 47.8%. A significant dose-response relationship of community risk score with late nephrology referral was found, with an adjusted odds ratio of 1.52 (95% CI: 1.36-1.71) for the highest versus lowest risk communities.

Figure 1. Adjusted odds ratio for late nephrology referral, by overall community risk level.

Conclusions: Higher community risk is significantly associated with late nephrology referral, independent of individual-level factors. Community risk may be an important consideration for developing interventions to improve access to pre-ESRD nephrology care.

SA-PO723
Assessment of Quality of Care Received by Patients with Predialytic Chronic Kidney Disease Seen at a Philippine General Medicine Out-Patient Clinic – Experience at a Government Training Hospital Rizza Ann B. Lao, Section of Nephrology, Univ of the Philippines-Philippine General Hospital, Manila, Philippines.

Background: In a country with limited access to dialysis and transplantation such as the Philippines, it is imperative to recognize patients with early stage CKD and aggressively intervene in a timely fashion to prevent ESRD and death. The objective of this study is to evaluate the quality of care (QoC) of patients with predialytic CKD seen at a general medicine clinic.

Methods: This was a retrospective study which reviewed the medical records of 276 patients with CKD Stages 3-4 who have at least 1 year of consulat. Patients who were admitted for critical illness, and are on dialysis were excluded. For each QoC parameter, percentage of patients who received the appropriate care were reported. For the QoC correlates, Mann-Whitney U Test, Kruskal-Wallis Test or regression analysis was done.

Results: The mean QoC score for this study is 58.36% (± 23.7%) and the average annual GFR decline is 3.92 mL/min/1.73m².

Conclusions: Understanding of RRT options was poor among CKDopps participants in the US. Though the responses may not necessarily reflect information that was actually provided by their nephrology clinic teams, our results indicate that current educational strategies fall to adequately communicate key messages on RRT.

SA-PO725
Statin Prescribing Among U.S. Ambulatory Outpatient Visits for Patients with CKD William A. Janes,1 Talar Markosian,1 David J. Leehey,2 Benjamin Ling,1 Nicholas Burge,1 Vinod K. Bansal,1 Julia Koval,1 Ivan Pacold,1 Kevin Stroup,2 Holly J. Kramer,1 Loyola Univ Chicago;2 Hines VA Medical Center.

Background: Approximately 1 in 3 adults with CKD is at high risk of developing cardiovascular disease (CVD). Recent lipid management guidelines agree that statins should be used for CVD prevention via lipid lowering. However, lack of congruent recommendations for statin use in adults with CKD may lead to low utilization of statins in this population at high risk for CVD.

Methods: Outpatient visit data during years 2006 to 2010 were obtained from the National Ambulatory Medical Care Survey to determine the frequency of statin prescriptions among outpatient visits for adults ≥50 years with non-dialysis stage 1-5 CKD based on ICD-9 codes. Drug type (particular statin or other cholesterol lowering drugs type) was determined by the generic code recorded in the survey data. The analysis accounted for the complex survey design and utilized the sampling weight, cluster and strata statements so that results are generalizable to US outpatient ambulatory visits during years 2006-2010.

Results: A total of 2262 visits were included with patients being 48% white, 54% male and mean age of 69.6 years. 52% visits were covered by Medicare. Overall, 43% and 31.5% of visits for non-dialysis CKD stage 3-5 and stages 1-2, respectively, included a statin prescription with simvastatin being the most commonly prescribed statin. Table 1 shows the prevalence of statin prescription in all patients with non-dialysis dependent CKD by provider type for the outpatient visit.

Underline represents presenting author.
Conclusions: These results suggest that the rate of prescription of statins in CKD patients with non-CKD attributed to nephropathy differs by the provider charge for the patient with CKD. Lack of CVD preventive care may impact overall CVD risk in patients with diabetes and CKD-dependent CKD.

SA-PO726

Patients’ Knowledge of Their Chronic Kidney Disease Stage and Education About Kidney Failure Prevention – The CKD-REIN Cohort

Benedicte Stengel,1 Celine Lange,2 Brianzong,3 Luc Frimat,1 Denis Fouque,1 Maurice Laville,4 Christian Jacquelinet,2,4,5 Michael R. Robinson,6,7 Ziad Massy,8,9 Christian Combe,2,9 1Inserm U1018-CESP USV; Villejuif; 2Agence Biomedecine; 3CHU Nancy; 4CHU Lyon; 5Arbor Research Collaborative for Health, Ann Arbor; 6A’Paré - APHP; 7CHU Bordeaux, France.

Background: Patient knowledge about their CKD stage and how to prevent kidney failure is important to reduce ERSD risk through better adherence to treatment and lifestyle changes. We report primary findings about CKD knowledge among patients seen by nephrologists in France.

Methods: We used baseline data from the CKD-REIN study, a prospective cohort of patients with CKD stage 3 and 4 in a national sample of 40 nephrology clinics. Information was collected from patient interview and self-administered questionnaire. Comparisons between stages were adjusted for age and gender.

Results: Median age was 68[60-76] and 56% were men. About 80% reported knowledge that their kidney function was low. Patients were more likely to know their creatinine level (~40%) than GFR or CKD stage. For each question, knowledge increased slightly from that their kidney function was low. Patients were more likely to know their creatinine level (~40%) than GFR or CKD stage. For each question, knowledge increased slightly from stage 3 to stage 4. Education about how to prevent kidney failure was uncommon (~10%) in Rural and Remote First Nations.

Conclusions: Most CKD patients seen by nephrologists are aware that they have low kidney function, but their knowledge of disease severity is low. Very few received education about prevention of kidney failure. While the precise impact of these gaps in knowledge on CKD outcomes requires further investigation, the findings highlight the need to more effectively educate CKD patients about its potentially serious consequences.

SA-PO727

The Cost-Effectiveness of Primary Screening for Chronic Kidney Disease in Rural and Remote First Nations

Thomas W. Ferguson,1,2 Noddeep Tangri,1 Matthew T. James,2 Zhi Tan,1,3 Claudio Rigatto,2,3 Paul Komenda.1,2 1Community Health Sciences, Univ of Manitoba, Winnipeg, MB, Canada; 2Medicine, Univ of Manitoba, Winnipeg, MB, Canada; 3Medicine, Univ of Calgary, Calgary, AB, Canada.

Background: Chronic Kidney Disease (CKD) is a risk factor for cardiovascular disease, early mortality, and kidney failure. We have shown that the burden of CKD in First Nations (FN) populations in Manitoba is similar to that in diabetic and hypertensive populations. The cost-effectiveness of screening for CKD and subsequent treatment in FN or other high-risk indigenous populations has not yet been described.

Methods: We constructed a Markov model comparing screening in adult FN (age 18+) for CKD both proteinuria and estimated glomerular filtration rate (eGFR) to usual care from the perspective of the publicly funded Canadian health care payer. Patients were assigned an initial risk classification based on urine albumin-to-creatinine ratio and eGFR using the Kidney Disease Improving Global Outcomes (KDIGO) heat map. We obtained screening tests results on 1346 adult participants from the First Nations Community Based Screening to Improve Kidney Health and Decrease Dialysis (FINISHED) initiative. Our analysis was further stratified into communities accessible by road and communities accessed by air travel. Our primary outcome of interest was the incremental cost per quality-adjusted life-year (QALY).

Results: Overall crude prevalence of CKD in FN was 26.7%. Screening for CKD was associated with an ICER of $33,500/QALY in comparison to usual care. Restricting the model to screening in the remotest air access communities (prevalence of CKD 36.0%), this ratio fell to an ICER of $16,180/QALY. In less remote road access communities (CKD prevalence 18.4%), an ICER was $63,780/QALY. Primary model drivers included the cost of dialysis, assumed treatment effectiveness, and rates of progression towards kidney failure.

Conclusions: Targeted screening for CKD in rural and remote First Nations is likely cost-effective (≤ $50,000/QALY). These findings may be translatable to other high-risk indigenous groups with elevated rates of CKD and kidney failure and warrant further research.

Getting a Diagnosis of Chronic Kidney Disease: Despite Fears, Patients Want to Know Early

Julie A. Wright Nunes,3 Meghan Roney,2 Eve Kerr,1 Akinlolu O. Ojo,1 Angela Fagerlin.1,2,4 1Internal Medicine, Univ of Michigan, Ann Arbor; 2Center for Bioethics and Social Sciences in Medicine, Univ of Michigan, Ann Arbor; 3Center for Clinical Management Research, VA Ann Arbor Healthcare System, Ann Arbor, MI.

Background: Little is known about patient perspectives related to getting a diagnosis of chronic kidney disease (CKD). This information could help providers optimize diagnosis messaging at the point of care.

Methods: Using root/cause analysis and quality function deployment we conducted semi-structured patient interviews. Adult patients with established non-diagnosis CKD were interviewed between January-October 2014. Interviews were audiotaped and transcribed. Content analysis was done with Dedoose, a qualitative software package.

Results: 49 patients completed interviews. Mean (SD) age was 63 (14) years, 50% were male, 80% were Caucasian and 84% had CKD Stage 3-5. Key themes emerged from a total of 786 statements: 1) Reaction to diagnosis (160 statements) 2) Barriers to accepting diagnosis (61 statements) and 3) Expectations of diagnosis communication (122 statements). 45% of patients felt fearful after getting a CKD diagnosis - most often related to perceived threats of future dialysis and death. Barriers to diagnosis acceptance included disbelief because of lack of symptoms and lack of prior familiarity with CKD. Despite fear and denial the majority of patients (63%) desired early diagnosis communication by their providers, i.e. at earliest stages of identification. Consistent terminology and disease explanations by providers across the care continuum were perceived as critical to effective communication and diagnosis delivery, yet patients expressed frustration at inconsistent terminology/explanations.

Conclusions: Our findings emphasize that patients learning of a CKD diagnosis can experience fear, but they also prefer early communication of diagnosis. More work is needed to set uniform diagnosis terminology for patients with CKD across the care continuum.

The Impact of Chronic Kidney Disease on Household Income: Does Health Affect Wealth?

Rachael L. Morton,1,2 Alan Cass,3 Borislava N. Mihaylova.2 1Univ Sydney, Australia; 2Charles Darwin Univ, Australia; 3Univ Oxford, United Kingdom; 4On behalf of SHARP Collaborators.

Background: The impact of progressive chronic kidney disease (CKD) on household income is unclear. We sought to determine whether CKD severity and non-fatal adverse events were associated with a fall into poverty.

Methods: Prospective cohort study among participants with moderate-to-severe CKD randomized into the Study of Heart and Renal Protection (SHARP) with information on household income at study entry and study end (median follow-up 5 years). Household income recorded as: High (> twice the participating country median); Medium-high (> the median, but < twice the median); Medium-low (< the median, but > half the median); and Low (< half the median income, i.e. poverty). Logistic regression models with sociodemographic factors, smoking, prior diseases, severity of CKD, income category at entry and incident non-fatal events (myocardial infarction, stroke, incident cancer, initiation of dialysis, kidney transplantation) were used to determine a fall into poverty, defined as a move into the lowest household income category.

Results: 2914 SHARP participants were included in the analysis; 933 of these were in poverty at screening and a further 436 (22% of the remaining) moved into poverty by study end. In addition to black ethnicity, low educational attainment, single adult household and low income category at baseline, CKD severity was a significant predictor of a fall into poverty.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusions: Patients in advanced stages of CKD are at an increased risk of falling into financial hardship. Kidney transplantation may have a role in reducing the risks of household poverty due to CKD.

Healthcare Expenditures for Non-Diabetes Dialyzed Kidney Disease Compared to Other Chronic Diseases

Christina Small,1 Holly J. Kramer,1 Karen A. Griffin,1 David J. Leehey,1 Vinod K. Bansal,2 Kavitha Vellanki,1 Talar Markossian.1 1Loyola Univ Chicago; 2Hines VA Medical Center.

Background: There is a paucity of literature comparing the expenditures of kidney disease with other common costly chronic diseases in the United States. Our study compares the U.S. healthcare expenditures of non-dialysis dependent kidney diseases to several other chronic conditions.

Methods: This study used the 2012 Medical Conditions and Consolidated Data files from the Medical Expenditure Panel Survey administered by the Agency for Healthcare Research and Quality. Analyses included adults age ≥ 21 years with one of the following conditions: kidney disease, stroke, cancer, or a combination of the three (multichronic). Non-dialysis dependent kidney disease included any ICD9 code for kidney related conditions while chronic kidney disease (CKD) included only ICD9 code “585.” Analyses of calculated healthcare expenditures accounted for the complex survey design and incorporated the sampling weights so that estimates represent healthcare expenditures for the 2012 adult U.S. population (~313.4 million). Out of pocket healthcare expenditure burden was defined as the ratio of out of pocket healthcare expenditure to total person-level income for the year 2012.

Results: The mean age for non-dialysis dependent kidney disease and CKD was 56.5 and 65.9 years, respectively. Table 1 shows the median total and out of pocket healthcare expenditures and mean out of pocket healthcare expenditure burden for kidney disease, CKD and other chronic conditions.

</table>

Conclusions: Healthcare expenditures including out of pocket costs are higher for non-dialysis dependent CKD compared to other chronic medical conditions. Policy efforts should focus on reducing the healthcare cost burden for patients with kidney disease.

SA-PO731

Smartphone-Based Self-Management System for Chronic Kidney Disease: Results from a Single Centre Prospective Trial

Stephanie W. Ong,1 Sarbjit Vaniita Jassal,1 Akib Uddin,2 Kelly Min,3 Joseph A. Calazano,3 Alexander G. Londe,4 Nephrology, Univ Health Network, Toronto, ON, Canada; Pharmacy, Univ Health Network, Toronto, ON, Canada; Centre of Global Ehealth Innovation, Univ Health Network, Toronto, ON, Canada.

Background: Following user-centric design principles we developed a smartphone-based self-management support system for patients with advanced CKD. The patient interface focuses on 4 behavioral elements over which they have direct control: monitoring BP at home, self-assessment of symptoms, managing medications and tracking laboratory results. The main objectives of this 6-month prospective study were to determine acceptability,measured by system adoption and adherence, and assess effectiveness by using pre and post changes in BP,medications, labs and self-management behaviors.

Methods: We tested the mobile app system in 10 renal clinics at a single academic renal center in Toronto. The 47 enrolled patients were instructed at a regular clinic visit on the use of the mobile app. The clinical team independently received information on the mobile app system’s operation.

Results: 61% of participants were non-smartphone owners. All had more than one chronic condition and on average were on 10 to 15 medications. Most were over the age of 50 with the greatest representation in the age group 55-64.~80% of the users achieved more than the recommended 80% adherence rate to mobile app use.27% with normal clinic BP readings were discovered to have ‘masked’ hypertension on home BP monitoring. By the end of the study the SBP fell by 6.8 ± 20.4 mm Hg (p=0.05) and DBP by 0.9 ± 9.1 mm Hg. Out of 250 medication reviews,49% required intervention from the clinical team, such as altering drug dosing. Due to the short study duration and infrequency of lab testing, there were no changes in pre and post laboratory test results. On exit, patients and clinicians felt the mobile app helped engage and empower patients in their CKD care.

Conclusions: The mobile app was acceptable and suggests improvements in BP management and medication error prevention. This provides early evidence to supporting innovative use of mobile technology in CKD management and strongly supporting its use in a larger clinical.

SA-PO732

Potentially Preventable Hospitalization Among Patients with Chronic Kidney Disease and High Inpatient Use

Paul E. Ronksley, Braden J. Manns, Marcello Tonelli, James Wick, Brenda Hemmelgarn, Univ of Calgary, Calgary, AB, Canada.

Background: While prior studies have observed high rates of hospitalization among patients with chronic kidney disease (CKD), little attention has been given to those with high inpatient use. We explored clinical characteristics, patterns of hospital use, and potentially preventable acute care encounters among hospitalized patients with CKD.

Methods: We identified all adults (≥18 years) with an eGFR<60 mL/min/1.73m2 in Alberta, Canada between Jan 1 and Dec 31, 2009, excluding those with prior kidney failure. Patients with CKD were linked to administrative data to capture clinical characteristics and frequency of hospital encounters, and followed until death or end of study (Dec 31, 2012). Patients with 1 or more hospital encounters were categorized into 3 groups: persistent high use (upper 5% of inpatient use (‘3 encounters/yr) in 2 or more years), episodic high use (upper 5% in 1 year only), or non-high use (lower 95% in all years). Within each group we described patient characteristics and calculated the proportion of potentially preventable hospitalizations as defined by 4 CKD-specific ambulatory care sensitive conditions (ACSC); heart failure, hyperkalemia, volume overload, malignant hypertension.

Results: During a median follow-up of 3 years, 57007 patients had 118671 hospitalizations of which 1.7% of patients were persistent high users of hospital services, 12.3% episodic high users, and 86.0% non-high users. Persistent high users were often younger, male, First Nations, living in rural areas, and had higher levels of comorbidity compared to episodic and non-high use groups. Overall, 24804 (20.9%) CKD-related ACSC encounters were observed in the cohort. The proportion of ACSC encounters were higher in persistent high users (29.1%) compared to episodic (27.3%) and non-high users (17.3%) (p<0.01). The majority of the encounters were attributed to heart failure and hyperkalemia in all groups.

Conclusions: A substantial proportion of hospitalizations among patients with CKD and high inpatient use are ACSC-related. These findings suggest opportunities to reduce inpatient use and cost by focusing on strategies to improve community-based care for this subset of patients.

SA-PO733

Effect of Increased Blood Pressure Variability on Neurocognition in Children with Chronic Kidney Disease

Marc Lande,1 Susan R. Mendley,2 Matthew Matheson,3 S. Shinmar,4 Arlene C. Gerson,5 Joshua A. Samuels,6 Bradley Warady,2 Susan L. Furth,2 Stephen R. Hooper,1 Univ of Rochester; 1CKD Investigators.

Background: Increased blood pressure variability (BPV) is associated with lower neurocognitive test (NCT) performance in adults. We previously studied children with chronic kidney disease (CKD), who are at risk for cognitive dysfunction and increased BPV. However, little is known about the impact of increased BPV on cognition in children with CKD.

Methods: Children 6-18 years enrolled in the prospective NIH-sponsored Chronic Kidney Disease in Children (CKiD) study had NCT including WASI Matrix Reasoning, parent BRIEF, CPT-II, Digit Span, and Verbal Fluency. Casual BP visit-to-visit BPV was assessed by SD (BPV-SD) and average real variability (ARV), and 24-hour ambulatory BP monitoring by SD of wake and sleep periods. For unadjusted analyses, test scores of the subjects with BPV in the upper tertile were compared to that of subjects in the lower tertile. Multiple linear regressions were used to evaluate the relation between BPV and NCT scores, adjusting for BP index, sex, age, maternal education, race, BMI %tile, estimated GFR, % of life with CKD, nphritic proteinuria, and low birth weight.

Results: Depending on the task, 121-511 subjects had both BP and NCT results available. In unadjusted analysis, subjects with increased visit-to-visit systolic BPV scored lower on Verbal Category Switching (3rd vs 1st tertile of BPV-SD, 8.4 ± 2.7 vs 9.8 ± 3.0, p = 0.004; of ARV, 8.6 ± 3.0 vs 9.7 ± 2.5, p = 0.009). There was no effect of increased visit-to-visit BPV or ambulatory BPV on any other task. In adjusted analyses, increased visit-to-visit systolic BPV remained significantly associated with lower Verbal Category Switching scores for BPV-SD (β=–0.28, 95% CI:–1.34, –0.15) and there was a trend for ARV (β = 5.7, 95%CI:–1.16, 0.03).

Conclusions: Increased visit-to-visit systolic BPV was independently associated with decreased Verbal Category Switching scores in children with CKD. These results suggest that children with chronic kidney disease (CKD), who may have difficulties with set shifting that are related, in part, to increased BPV. Further study is needed to determine the significance of this isolated result.

SA-PO734

Rapid Post-Transplant Improvement of HRQOL in Older Kidney Recipients

Kristian Heldal,1 Kjersti Lonning,2 Tomm Bernklau,2 Nanna von der Lippe,2 Anna Reisaeter,3 Anders Hartmann,2 Marit helen Andersen,1 Karsten Midveldt,1 1Clinic of Internal Medicine, Telemark Hospital, Skien, Norway; 2Inst of Clinical Medicine, Faculty of Medicine, Univ of Oslo, Oslo, Norway; 3Clinic of Surgery, Surgery and Transplantation, Oslo Univ Hospital, Oslo, Norway; 4Research Unit, Telemark Hospital, Skien, Norway.

Background: It is widely accepted that health-related quality of life (HRQOL) is significantly compromised in patients with ESRD. In adults, kidney transplantation (KTx) is known to improve HRQOL. In older recipients there is a lack of studies measuring the effect of KTx on HRQOL. The aim of this study was to measure HRQOL longitudinally in enlisted patients >65 years of age, from pre-transplant and until 6 months after KTx.

Methods: Patients >65 years listed for transplantation at our centre were asked to complete the SF36 questionnaire at enlisting and thereafter every 6 months until KTx. Post transplant, the patients received a new SF36 form 10 after weeks and 6 months.

Results: A total of 180 patients have been included from Jan 2013. Mean age at enlisting was 70.6 years (65.0-81.8) and 68% were male. By the end of May 2015, 100 patients were transplanted and 59 of them had completed both pre- and post-transplant questionnaires. Mean time from completing the first pre-tx questionnaire to transplantation was five months. When comparing the scores for the last SF36 pre-tx with 6 months post-tx, there was a statistically significant increase of the mean scores for GH (53-71), PF (66-74), BP (64-78), VT (53-71) and MH (79-85). There was also a tendency towards improved scores for RP and RE, while the SF score was unchanged.

Conclusions: Our preliminary findings indicate that older patients report a significant improved HRQOL measured by SF36 already 10 weeks after KTx and the status remains stable after 6 months. Longer follow-up is warranted.

L-Carnitine Improves Cognitive and Renal Functions in a Rat Model of Chronic Kidney Disease

Zaber Anis Armaly,1 Adel Rafik Jabbour,1 Na proliferation and kidney function. The Prevalence of Cognitive Impairment in Chinese Peritoneal Dialysis Patients

Chi-hon Leung, Cheuk-Chun Szeto. Dept of Medicine and Therapeutics, Prince of Wales Hospital, Shatin, Hong Kong.

Background: Cognitive impairment is common amongst patients with chronic kidney disease and may be associated with excessive morbidity in dialysis patients. This study determines the prevalence and risk factors of cognitive impairment in Chinese peritoneal dialysis (PD) patients.

Methods: We studied 178 prevalence PD patients (103 males). Cognitive impairment was screened by the 10-item Abbreviated Mental Test (AMT) questionnaire. We also determined patients’ comorbidity load, dialysis adequacy, residual renal function, nutritional status, and degree of frailty.

Results: The mean age was 60.7 ± 11.7 years; vintage of dialysis 42.5 ± 44.1 months. Average AMT score was 9.3 ± 1.3. The AMT score is closely associated with age (r = -0.53), and inversely associated with years on dialysis (r = -0.42) and residual renal function (r = -0.38), but not by decline in GFR. The only domains that discriminated for GFR associated influence were effects- and burden of kidney disease and social support. Multivariable linear regression analyses were employed including the following explanatory variables: GFR, age, sex, comorbidity and the interaction between sex and age. Significant associations were found between decline in GFR and endurance (6-MWT; p=0.039), strength (IQS; p=0.035), balance (FR; p=0.024) and fine motor skills (PUT; p=0.015) as well as by the patients’ perceived domains in the KDQOL-SF™-domains of effects- (p=0.023) and burden (p=0.016) of kidney disease and social support (p=0.006) after having taken the explanatory variables into account. There were significant associations between the KDQOL-SF™-domains role physical and emotional well-being and 6-MWT (p=0.018; p=0.018, respectively) and IQS (p=0.005; p=0.045, respectively), but these were dependent on age, sex and comorbidity but not driven by GFR.

Conclusions: Physical functions comprising endurance, strength, balance and fine motor skills were impaired relatively early in the course of KTx (3b-5), seemed to progress with declining GFR and could be detected by easy to perform physical function tests. The relationship between self perceived physical functioning and well being, respectively, with measured endurance and strength, respectively, were driven by age, sex and comorbidity but not by decline in GFR. The only domains that discriminated for GFR associated influence were effects- and burden of kidney disease and social support.

SA-PO737

The Prevalence of Cognitive Impairment in Chinese Peritoneal Dialysis Patients

Chun Szeto.

1Dept of Medicine, Clinical Pharmacology, Lund Univ, Lund, Sweden; 2Laboratory Medicine, Clinical Pharmacology, Lund Univ, Lund, Sweden.

Background: Physical functions are impaired in dialysis patients. It is unclear which functions are affected and how they decline in the course of KTx. This study investigated the effects of declining GFR (KTx 3-5) on measured physical functions, self perceived physical functioning and well being.

Methods: In this cross sectional analysis 101 patients (40 women, 61 men; mean age: 67±13 years, median GFR: 21 (9-41) ml/min/1.73m²) were tested with 6 Minutes Walk (6-MWT), Isometric Quadriceps Strength (IQS), Functional Reach (FR) and Picking-up (PUT). Self perceived physical functioning and well being were assessed by KDQOL-SF™. GFR was measured with iohexol clearance and comorbidity by Davies’ index. Multivariable linear regression analyses were employed including the following explanatory variables: GFR, age, sex, comorbidity and the interaction between sex and age.

Conclusions: Administration of L-Carnitine in a rat model of CKD, significantly improves cognitive and renal functions in a rat model of chronic kidney disease (CKD) has reached epidemic proportions. L-Carnitine, considered as the “gatekeeper” responsible for mitochondrial function, has reached epidemic proportions. L-Carnitine, considered as the “gatekeeper” responsible for mitochondrial function, has reached epidemic proportions. L-Carnitine, considered as the “gatekeeper” responsible for mitochondrial function, has reached epidemic proportions.

Conclusions: Our preliminary findings indicate that older patients report a significant improved HRQOL measured by SF36 already 10 weeks after KTx and the status remains stable after 6 months. Longer follow-up is warranted.

Neurocognitive Functioning and Association with Clinical Outcomes in Adults with End-Stage Kidney Disease: The COGNITIVE-HD Study

**Background:** Cognitive impairment and neurocognitive disorder have been associated with increased mortality in the general population. Whether dialysis patients have specific patterns of cognitive dysfunction, or whether cognitive function is associated with activities of daily living and durability of dialysis treatment remain poorly understood.

**Methods:** The COGNITIVE-HD study will provide detailed neuropsychological assessments of cognitive function among hemodialysis patients to characterize age- and education-adjusted prevalence and patterns of cognitive impairment and the associations with physical and social functioning and clinical outcomes including cardiovascular events at 12 months. The COGNITIVE-HD study is a prospective, longitudinal, population study of 751 adults conducted in 20 dialysis centers in Italy. A detailed battery of comprehensive testing for executive function, visuospatial function, language, learning and memory, personality traits, and complex attention has been carried out by a trained psychologist at baseline to assess for presence of cognitive impairment and to evaluate the pattern of cognitive deficits, and any association between cognitive impairment and activities of daily living.

**Results:** Preliminary analyses have been conducted on the Mini Mental State Examination (MMSE) evaluation of cognitive function among 702 participants (mean age 68.2 years, 60% men). 50% had normal cognitive function (MMSE score 27-30), 22% had mild cognitive impairment (score 26-24), 19% were cognitively impaired (score <25), and 22% had mild cognitive impairment (score 26-24). 198 patients (28%) had MMSE results below 23.

**Conclusions:** The COGNITIVE-HD study will provide detailed neuropsychological assessments of cognitive function among hemodialysis patients to characterize age- and education-adjusted prevalence and patterns of cognitive impairment and the associations with physical and social functioning and clinical outcomes including cardiovascular events at 12 months. The COGNITIVE-HD study is a prospective, longitudinal, population study of 751 adults conducted in 20 dialysis centers in Italy. A detailed battery of comprehensive testing for executive function, visuospatial function, language, learning and memory, personality traits, and complex attention has been carried out by a trained psychologist at baseline to assess for presence of cognitive impairment and to evaluate the pattern of cognitive deficits, and any association between cognitive impairment and activities of daily living.

**Conclusions:** Among older men, those with primarily mild-moderate CKD and HTN do not have lower cognitive function compared to hypertensive controls after accounting for common cognitive risk factors. However, across a range of GFR, lower renal function is associated with worse performance in specific domains of cognitive function.

**Funding:** NIDDK Support, Veterans Administration Support

---

Neurocognitive Functioning and Psychiatric Disorder in Children with Chronic Kidney Disease from the KNOW-Ped CKD Cohort Study (Korean Cohort Study for Outcome in Patients with Pediatric Chronic Kidney Disease)

**Background:** Depressive symptoms are common in patients with chronic kidney disease. The KNOW-Ped CKD cohort study is a cross-sectional study comparing children with end-stage kidney disease to healthy children. The study aimed to examine the prevalence of depressive symptoms and associated factors in children with chronic kidney disease.

**Methods:** A total of 322 children (M:F 218:104) enrolled from seven major pediatric nephrology centers of Korea from July 2010 to December 2013 were the subject of this study. Neurocognitive function and psychiatric status of pediatric CKD patients were evaluated using the Wechsler intelligence scale for children, Child Behavior Checklist, ADHD Rating Scale-IV, State-Trait Anxiety Inventory, Child Depression Inventory and Parental Bonding inventory-Korean version.

**Results:** Verbal, performance and full scale IQ were lower in younger age and congenital anomalies of the kidney and urinary tract as a cause of CKD. More than 10 percent of school-age children with CKD presented significant emotional distress including somatization (15%), attention problems (15%) and anxiety (12%). Impact of progression of CKD on their neurocognitive function and psychiatric status will be investigated in KNOW-PedCKD cohort study in Korea.

**Conclusions:** In young patients with CKD and those with multiple congenital problems in addition to CKD suffer from low intelligence and psychiatric disorder. Pediatric CKD patients with low intelligence and psychiatric disorder need close attention and developmental training techniques. Acknowledgement. This work was supported by the Research Program funded by the Korea Centers for Disease Control and Prevention (2013E3301600, 2013E33081601).

**Funding:** Government Support - Non-U.S.
Vitamin D Deficiency Is Significantly Associated with Depression in Chronic Kidney Disease Patients

**Background:** Recent studies have reported significant associations between vitamin D deficiency and depression in the general population. Although both vitamin D deficiency and depression are common features in chronic kidney disease (CKD) patients, the association between these two prevalent factors in this patient population remains poorly elucidated. Therefore, the association between vitamin D deficiency and depression in CKD patients was investigated.

**Methods:** The data from the Korean National Health and Nutrition Examination Survey between 2010 and 2012 were used. A total of 495 patients with estimated glomerular filtration rate ≤60 mL/min/1.73 m² were enrolled. Vitamin D deficiency was defined as 25-hydroxyvitamin D3 [25(OH)D3] levels £10 ng/mL. Patients were dichotomized by the presence of vitamin D deficiency. Depression was determined by the EuroQOL-5D (EQ5D) questionnaire. Independent association between vitamin D deficiency and depression was evaluated by multivariate logistic regression analysis.

**Results:** The mean age was 71.2 ± 9.3 years, and 257 patients (51.9%) were female. The median 25(OH)D3 levels were 17.9 (13.9-22.7) ng/mL. The prevalence of depression in CKD patients was higher compared to the general population (14.3% vs. 11.1%, P = 0.031). In addition, the prevalence of depression was significantly higher in patients with vitamin D deficiency than those without vitamin D deficiency (27.9% vs. 13.3%, P = 0.022). Multivariate logistic regression analysis showed that vitamin D deficiency was a significantly independent predictor of depression after adjusting for age, sex, alcohol, body mass index, hypertension, diabetes mellitus, anemia, suicidal idea, EQ5D index, and serum parathyroid hormone levels (odds ratio=6.27, 95% confidence interval=1.57-25.05, P=0.009).

**Conclusions:** Depression was highly prevalent in CKD patients. Vitamin D deficiency was a significantly independent predictor of depression in CKD patients. Therefore, determining vitamin D levels might be helpful to predict depression in these patients.

**SA-PO747**

Comparison of Prevalence and Predictors of Fatigue in Advanced Chronic Kidney Disease and Cancer Patients

**Background:** Although >50% of patients with advanced CKD report fatigue, its presence, predictors and consequences are under-appreciated by renal providers. We compared the symptom burden among CKD/ESRD patients to those with advanced hepatobiliary cancer (CA).

**Methods:** In 237 patients with advanced kidney disease (35% CKD stage 4-5, 65% ESRD) and 606 with advanced CA, patient-reported symptoms and health-related quality of life (HRQOL) were assessed using validated fatigue, pain, sleep quality, depression and HRQOL questionnaires. Chi-square and ANOVA were used to test between group differences and linear regression was employed to test predictors of fatigue.

**Results:** In unadjusted analyses, CKD patients reported statistically (but not clinically) less fatigue, similar poor sleep quality, and significantly lower prevalence of depression and pain as compared to CA patients. Lower levels of fatigue were strongly associated with higher HRQOL in both groups (r=0.80, P<0.001 in CKD; r=0.67, P<0.001 in CA). Depression was significantly associated with higher levels of fatigue for both groups (r=0.01 for both). Poor sleep quality was associated with higher fatigue in both groups (r= -0.40, P<0.001 in CKD; r= -0.27, P<0.001 in CA). Similarly, in both groups, more pain was associated with higher fatigue (r=0.41, P<0.001 for MOS SF-36 pain score in CKD; r= -0.48, P<0.001 for BPI in CA). Using linear regression, and including those factors significantly associated with fatigue, 29% of the variance in CKD and 31% in CA cohort was explained by depression, sleep and pain.

**Conclusions:** Patients with advanced CKD experienced similar levels of fatigue and poor sleep quality as those with advanced CA. Sleep, depression, and pain were significant predictors of fatigue in these chronically ill patients.

**SA-PO746**

Validation of a Patient-Perceived Symptom Score for Chronic Kidney Disease

**Background:** Chronic Kidney Disease (CKD) is associated with a range of symptoms, even at relatively early stages. There is increasing recognition of the importance of the patient symptom experience for clinical management and quality of life, but validated symptom scores are lacking. We have refined and validated an existing draft CKD symptom questionnaire listing 11 common renal symptoms plus lines for additional symptoms not included in the list.

**Methods:** Validation was undertaken in 4 phases. In Phase 1, 219 patients with CKD stages 1-5 not requiring renal replacement completed the draft questionnaire to identify the most prevalent symptoms in this population. Phase 2 explored cognitive validity via semi-structured interviews with 11 patients, after which the draft questionnaire was refined. Phase 3 was a focus group with 5 patients, to review and further refine the updated questionnaire. Phase 4 was content validity testing: the questionnaire was sent to 16 external expert clinicians for assessment of relevance, clarity and comprehensiveness.

**Funding:** NIDDK Support, Other NIH Support - National Cancer Institute K07CA118157; R21CA127046; and R01CA176899, Private Foundation Support

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only; Underline represents presenting author.
Results: Phase 1 identified 13 common symptoms, and Phases 2 and 3 confirmed symptom selection and refined the wording used to describe them. The symptom descriptions finalised were: itching, sleep disturbance/insomnia, loss of appetite, feeling tired, pain in bones/joints, poor concentration/mental alertness, loss of libido/erectile dysfunction, loss of muscle strength/power, shortness of breath, cramp/muscle stiffness, restless legs/ difficulty keeping legs still, need to urinate more often, feeling cold. In Phase 4, 14 of 16 experts responded (87.5%). 10 of the 13 symptoms had “excellent” or “good” evaluation scores, and the content validity index of the whole questionnaire was 0.81, falling within the recommended threshold.

Conclusions: This work has provided a new, validated symptom score for the early-pre-dialysis CKD population, which can be used as a patient reported outcome measure in both clinical management and research.

Impact of Psychosocial Factors in Advanced Chronic Kidney Disease on Wait-Listing for Transplantation Santjeek Ajinkya, James L. Pasha, Jason Roy, Boyang Chai, Michael J. Fischer, L. Lee Hamm, Peter D. Hart, Chi Tong, Mark A. Brown, 1
1 Royal Adelaide Hospital.

Background: Transplantation (Tx) is generally regarded as the best option for renal replacement therapy. However, few patients with CKD are listed for Tx when eligible. We examined the association between psychosocial factors in patients with advanced CKD and wait-listing for kidney Tx.

Methods: The study population includes 803 individuals with an eGFR of less than or equal to 20ml/min/1.73m2 (advanced CKD) in the Chronic Renal Insufficiency Cohort study. The primary predictors were health related quality of life (HRQOL) and depressive symptoms assessed within 24 months prior to reaching the eGFR inclusion criteria using the Kidney Disease QOL (KDQOL)-36 survey and the Beck Depression Inventory (BDI), respectively. The primary composite outcome was wait-listing or transplantation (WLT). Cox proportional hazards models were used to examine the association between low HRQOL (1 SD below the cohort mean) and BDI (11) with WLT.

Results: Of the 803 subjects, 380 (47%) were wait-listed including 120 that proceeded to Tx. Compared to individuals who were not on WLT, those in the WLT group were more likely to be younger, male, have no history of cardiovascular disease, and have proteinuria > 300mg/day (p <0.01). After adjustment for demographic and clinical variables, a low Mental Component Summary (MCS) score was associated with a lower likelihood of WLT (Table). There was no association between the BDI or other QOL measures with WLT.

Predictor Adjusted Model (HR, 95% CI)
BDI ≥ 11 0.88 (0.69-1.2)
KDQOL (≥ 1 SD below the cohort mean) 0.83 (0.56-0.9)
-Mental Component Summary
-Physical Component Summary 0.92 (0.69-1.24)
-Symptoms/Problems 0.97 (0.71-1.32)
-Burden of Kidney Disease 0.82 (0.61-1.09)
-Effect of Kidney Disease on Daily Life 0.94 (0.69-1.28)

Conclusions: Lower MCS scores were associated with lower likelihood of WLT. Further work is needed to evaluate the impact of poor mental QOL in advanced CKD and how it might influence wait-listing.

SA-PO748
Perspectives on Pregnancy in Women with Chronic Kidney Disease Allison Tong,1 Mark A. Brown,1 Wolfgang C. Winkelmayr,2 Jonathan C. Craig,2 Shilpa Jawedasla,1 The Unv of Sydney;3 St. George Hospital;4 Baylor College of Medicine; Royal Adelaide Hospital.

Background: Women with chronic kidney disease (CKD) often have difficulty achieving pregnancy, and are at increased risk of adverse pregnancy outcomes. Given the medical, ethical and emotional complexities of pregnancy in CKD, the clinical approach should involve explicit consideration of women’s values; of which there are sparse data. We aimed to describe the beliefs, values, and experiences of pregnancy in women with CKD, to inform pre-pregnancy counseling and pregnancy care.

Methods: Semi-structured interviews were conducted with 41 women aged 22-56 years with advanced chronic kidney disease, from two renal units in Australia. Transcripts were analyzed thematically.

Results: Six themes were identified: bodily failure (conscious of fragility, noxious self, critical timing, suspended in limbo); devasting loss (denied motherhood, disempowerment by medical catastrophizing, resolving grief, barriers to parenthood alternatives, social isolation); intransigent guilt (disappointing partners, fear of genetic transmission, respecting families and kidney donor, the outcomes of their offspring, and genetic transmission). Communicating the medical risks of pregnancy to women with chronic kidney disease must be carefully balanced with their values of autonomy, hope, security and family. Informed and shared decision making that is sensitive to women’s priorities as identified in this study can contribute to improved pregnancy, health and psychosocial outcomes in this vulnerable population.

Conclusions: Decisions surrounding pregnancy in the context of chronic kidney disease require women to confront uncertainties about their own survival, disease progression, social support, their family and kidney donor, the outcomes of their offspring, and genetic transmission. Communicating the medical risks of pregnancy to women with chronic kidney disease must be carefully balanced with their values of autonomy, hope, security and family. Informed and shared decision making that is sensitive to women’s priorities as identified in this study can contribute to improved pregnancy, health and psychosocial outcomes in this vulnerable population.

Dual Agonist of Nuclear Hormone Receptor Farnesoid X Receptor and G Protein Coupled Receptor TGR5 Exhibits Caloric Restriction Mimetic Effects in Aging Mice Xiaoxin Wang,1 Evgenia Dobrilinskikh,1 Yuhuan Luo,1 Luciano Adorini,2 Moshe Levi,3 Univ of Colorado Denver; 1Intercept Pharmaceutical Company.

Background: Previous studies have shown that caloric restriction (CR) in mice and in rats prevent age-related proteinuria and glomerulosclerosis. We have observed an age-related decrease in renal nuclear hormone receptor farnesoid X receptor (FXR, NR1H4), and G protein-coupled receptor TGR5 (GPR11 or GPR131) expression. In contrast, renal FXR and TGR5 expression are increased by CR in the aging mice. FXR and TGR5 expression are also increased in the long-lived Ames dwarf mouse. The purpose of the present study was to determine if activation of FXR and TGR5 in the kidneys of ad lib fed aging mice have similar effects to CR.

Methods: We studied 5 month old ad lib fed, 24 month old ad lib fed, 22 months old ad lib fed mice treated with the dual FXR/TGR5 agonist INT-767 for 2 months, and compared them to lifelong 24 month old CR mice.

Results: Treatment of 22 month old ad lib fed aging mice with FXR/TGR5 dual agonist INT-767 for 2 months decreases albuminuria, TGF-β expression and fibroconnectin accumulation in aging mice. INT-767 stimulates mitochondrial biogenesis, increases mitochondrial DNA content, and mitochondrial transcription factors NR1-1 and Tfam in the aging kidney. INT-767 also increases the expression of SIRT1, PGC-1α, and ERRα mRNA, as well as PGC-1α and SIRT3 protein abundance. INT-767 activation of the mitochondrial NAD-dependent deacetylase SIRT3 restores its targets MCAD and acetyl-LDH to normal levels, which are important for regulation of mitochondrial fatty acid β-oxidation as well as mitochondrial redox status. Furthermore, INT-767 increased expression of NAMPT and Nk1, enzymes involved in synthesis of sirtuins substrate NAD.

Conclusions: Our results therefore indicate that activation of FXR and TGR5 in the aging kidney reverses most of the age-related changes and the effects of FXR and TGR5 are similar to beneficial effects achieved by lifelong CR.

ESRD in Nonagenarians in the United States, 1995 Through 2010
Donal J. Sexton, Scott Reule, Robert N. Foley. Medicine, Univ of Minnesota, Minneapolis, MN.

Background: Patients in their 90’s are increasingly being considered for maintenance dialysis, comprehensive epidemiological data could help with decision making.

Methods: We used US census data and data for patients who initiated maintenance dialysis between 1995 and 2010 (N=1,557,117) to examine trends in ESRD for those aged 90 to 99 years (N=14,289).

Results: The rate of ESRD in 1995-1996 was 0.6 per million per year in those aged 90-99 years respectively. Standardized incidence rates (SIRs) rose between 1995 and 2010 both overall (SIR 2.8) and individually in males (2.89), females (2.7) white (3.1) African American (1.93) and other races (2.43). Median survival was 10.7 months. “Unspecified renal failure” was the most common reported cause of ESRD (62.6%), followed by “diabetes mellitus type 2” (15.8%), “ATN without recovery” 3.4%, “GN (not histologically examined)” 3.18%, “renal artery stenosis” 2.44% and other 12.4%. Causes of death included: Cardiac deaths 42.4%, Infection 12.07%, Withdrawal of dialysis/ Uremia 10.16%, Stroke/Intracranial Hemorrhage 3%, Cachexia 2.99%, Cancer 2.45%, Other 12.03% and Unknown 14.89 %. Mortality fell over time, AHR (95% CI) 0.79 (0.72, 0.87) in 2009-2010 vs 1995-1996. Factors associated with a higher likelihood of death included: ischemic heart disease (AHR 1.13), AV graft (AHR 1.36 vs AV fistula), or venous catheter for hemodialysis vascular access (AHR 1.7 vs AV fistula), shorter pre-dialysis nephrology care (AHR 1.37), higher eGFR at dialysis initiation (AHR 1.13), serum albumin < 3.5 g/dl (AHR 1.34), cerebrovascular disease (AHR 1.21), peripheral vascular disease (AHR 1.14), cancer (AHR 1.08), inability to ambulate (1.43) or transfer (1.59), “ATN without recovery” as primary cause of ESRD (AHR 1.11 vs “renal failure not specified”).

Conclusions: ESRD in nonagenarians has risen over the period of observation in the United States. Rising prevalence may be attributable not only to rising incidence but to falling mortality also.

SA-PO752
Impact of Geriatric Multi-Morbidity Versus Medical Multi-Morbidity on Quality of Life in Older CKD Patients
Donal J. Sexton, Mi-kyung Song, Frank Moore, Kyung Liu, Kieran Reid, Jamie Giffuni, Jamie Giffuni, Robert N. Foley. Medicine, Univ of Minnesota, Minneapolis, MN.

Background: Geriatric conditions are constellations of signs and symptoms not always linked to a disease, such as cognitive impairment and fatigue; geriatric conditions are associated with worse quality of life (QoL). Older adults with CKD are likely to have geriatric multi-morbidity (GM), defined as ≥2 geriatric conditions. Medical multi-morbidity (MM) is also common in this population and affects QoL. We compared the impact of GM to MM on QoL in older CKD patients.

Methods: We used baseline data from an ongoing trial of exercise in persons ≥55 years with stage 3b-4 CKD. For GM, persons were defined with 1) cognitive impairment if Montreal Cognitive Assessment (26-2) 2) poor physical function if Short Physical Performance Battery ≤ 7; 3) dizziness as reported by Memorial Symptom Assessment Scale; 4) fatigue if reported ≥ “good bit of time” to feeling worn out on Short Form-36 (SF-36); and 5) chronic pain if ≥ “moderate” pain on SF-36. For MM, hypertension, diabetes, CAD, and cancer were self-reported. Major depression was defined as Beck Depression Inventory ≤ 15. QoL was measured with the SF-36. Linear regression adjusting for age, sex, race, site, BMI, and eGFR was utilized.

Results: Of 72 persons (31% women, mean age 68.6±7.8 years, mean eGFR 33±9.8 ml/min/1.73m³), 49% (35) had GM and 76% (55) had MM. GM was associated with lower scores in all SF-36 subdomains (all p<0.05). MM was associated with lower scores in two SF-36 subdomains (both p<0.05).

Conclusions: In older adults with CKD, geriatric multi-morbidity is common and likely affects QoL.

| Standardized βs of the associations of geriatric multi-morbidity and medical multi-morbidity with SF-36 |
|---------------------------------------------------------------|---------------------------------------------------------------|

SA-PO753
A Survey of Provider Knowledge, Attitude, and Practices Surrounding Conservative Management for Patients with Advanced Chronic Kidney Disease
Sanah Parvez, Khaled Abdel-Kader, V. Shane Pankratz, Mi-kyung Song, Mark L. Unruh. 1 Div of Nephrology, Univ of New Mexico; 2 Div of Nephrology, Vanderbilt Univ; 3 Adult and Geriatric Health Div; School of Nursing, Univ of North Carolina.

Background: Despite the potential benefits of conservative management (CM), discussing CM as a viable treatment option rarely occurs. Several factors might contribute to this but no studies in the U.S. have described them. The purpose of this survey was to describe nephrologist’s (NEPHs) and primary care providers’ (PCPs) knowledge, attitudes, and practices of CM for patients with advanced CKD.

Methods: We developed a survey based on the relevant literature to include items assessing knowledge, attitudes, and self-reported practices of CM for patients with advanced CKD. We then conducted a web-based cross sectional survey between April and May 2015. We used the American Medical Association’s Physician Masterfile to identify NEPH and PCPs practicing in the U.S.

Results: 431 (67.6% NEPHs, 32.4% PCPs) providers completed the survey. The respondents were, on average, white, predominantly male, and in their 30s and 40s. A majority of both PCP (83.5%) and NEPH respondents (78.2%) reported that they were likely to discuss CM with their older advanced CKD patients. Self-reported number of patients managed conservatively was at least >11 patients for 30.6% NEPHs and 49.2% of PCPs. As shown in the figure where a higher percent demonstrates a lower barrier, the major barriers to CM discussions identified by NEPHs and PCPs significantly differed.

There were significant differences in knowledge across the groups with PCPs reporting significantly more uncertainty about survival rates with CM.

Conclusions: Both NEPH and PCP are comfortable with discussing CM with their patients. PCPs have less certainty regarding patient selection for CM and report feeling less informed about outcomes of CM.

Which Therapeutic Project for Elderly Reaching ESRD? Patient’s Characteristics and Outcomes
Coraline Fafin,1,2 Cecile Couchoud,2 Cecile M. Vigneau,1 Olivier Moranne,1 1Nephrology CHU Nice, Nice, France; 2REIN Registry, Agence de Biomedecine, St. Denis La Plaine, France; 3Nephrology, CHU Pontchaillou, Rennes, France.

Background: The KDIGO guidelines recommend referral for planning RRT in people at risk of kidney failure. Treatment without dialysis in ESRD patient is another therapeutic option especially in elderly. The objective of our study is to describe the therapeutic projects declared by nephrologist and associated patient’s characteristics and outcomes in a prospective design.

Methods: 573 patients over 75 y/o (82±5 y/o) with eGFR below 20 (14 ± 4) were included by nephrologists in 2009 and followed 4 yrs (Moranne et al 2012). At baseline, we recorded social, clinical characteristics and therapeutic project declared by nephrologist. The first project was considered at the second visit as Postponed decision about dialysis (STAB), decision to start Dialysis when required (DIAL), Non-dialysis made by nephrologist (NDne) or at patient’s request (NDpt). During follow-up, we evaluated the dialysis start and death before dialysis and compared patient’s characteristics and incidence of these events according to the therapeutic projects.

Results: The therapeutic project was STAB in 234 patients (41%), DIAL in 216 pts (38%), NDne in 66 (12%) and NDpt in 55 (10%). Patients were older in ND group, with more women for NDpt and more comorbidities for NDne (dementia, active malignancy,
Specific Prognosis Factors of Death and Dialysis Start for Elderly Patients Reaching ESRD in the Prospective PSPA Cohort Study

C. Dirce M.T. Zanetta, 1,2 T. Di Renzo, 1,2 M. Duarte, 1,2 A. A. M. Reis, 1,2 E. Moranne, 1,2 J. W. J. R. de Souza, 1,2 J. E. R. Chapman, 1,2 J. C. Craig, 1,2 T. Nemoto Matsui, 1,2 F. Halleck, 1,2 A. 1 Department of Geriatric Nephrology, 2 Sao Paulo Medical School, Sao Paulo, SP, Brazil; 3 Inst of Toxicology, College of Medicine, National Taiwan Univ, Taipei, Taiwan; Departments of Integrated Diagnostics and Therapeutics and Internal Medicine, College of Medicine, National Taiwan Univ, Taipei, Taiwan.

Background: The death before dialysis start is high in elderly patients reaching ESRD and the treatment without dialysis is another option. We need to better predict the outcomes of this specific population and identify prognosis factors to improve strategies of care. The objective of our study is the identification of prognosis factors of dialysis start or death before dialysis in a multicenter prospective cohort of elderly reaching ESRD.

Methods: 573 patients over 75 y/o (82.5 y/o) were included by nephrologist in 2009-10 (Moranne et al 2012). At baseline, we recorded social and clinical characteristics, laboratory test and medications. Information about death or dialysis status is available for all patients after 4 years follow-up. Prognosis factors for dialysis start or death before dialysis were quantified with subdistribution hazard ratios using proportional hazard regression models constructed according to Fine and Gray to take account competing risks.

Results: After 4 years follow-up, 274 patients (48%) started dialysis and 223 (39%) died. Compared to patients without dialysis, those independently associated with higher risk of death prior to dialysis are: higher age, male, diabetes, lower eGFR, behavioural disorder, less mobility, cerebrovascular disease, cardiac heart failure, active malignancy and anemia. The variables associated to higher probability of dialysis start are: lower age, male, lower eGFR, high blood pressure, hyperphosphatemia, higher proteinuria, chronic respiratory disease, cerebrovascular disease and less behavioural disorder or active malignancy.

Conclusions: We observed a higher probability of dialysis start than death before dialysis in this population of elderly included by nephrologists. We identified specific prognosis factors that could discriminate the risk of starting dialysis or died before dialysis to help organisation of the CKD 5 care in elderly patients.

Attitudes, Experiences and Perspectives of Elderly Kidney Transplant Recipients: Thematic Synthesis of Qualitative Research

Jule Pinter, 1 Lamia S. El-Shafei, 1 Alix Dupeyré, 1 Camilla S. A. Persson, 1 Aglaee Giordano, 1 Carmen Ferrari, 1 Sonia Beauchamp, 1 Jérôme Meziane, 1 Fabrice Rappaz, 1 Nadia Guermazi-Souza, 1 Adriano Luiz Ammirati, 1 Maria C.C. Andréoli, 1 Thais Nemoto Matsui, 1 Fabiana Dias Carneiro, 1 Rosana Morais, 1 Meryt Al-Kahtani, 1 Bento C. Santos, 1

1 Nephrology, Hospital Albert Einstein, São Paulo, Brazil.

Background: Kidney transplantation offers improved survival and quality of life in an increasing number of elderly patients with end-stage kidney disease. However, elderly kidney transplant recipients may face unique challenges due to a higher burden of comorbidity, greater cumulative risk of immunosuppression-related complications, and increasing frailty. We aimed to describe the perspectives of elderly kidney transplant recipients.

Methods: Electronic databases were searched to April 2015. Thematic synthesis was used to analyze the findings.

Results: 41 studies involving more than 120 kidney transplant recipients aged 60 yrs and over were included (29 studies did not specify number of patients aged ≥ 60 y/o). We identified 6 themes. Regaining strength and vitality meant valuing the marked physical and psychosocial improvements in daily functioning and life participation. Extending life was the willingness to accept an organ, including an extended criteria kidney, to prolong survival. Debt of gratitude entailed a need to be consciously appreciative towards their donors knowing they were unable to repay their sacrifice. Moral responsibility of maintaining health motivated adherence to medication and lifestyle recommendations out of an ethical duty to protect their gift and prolong graft survival. Disillusionment with transplant reflected disappontment and exasperation at having to contend with side effects and adverse events such as cancer, and residual physical limitations. Finality of treatment options reflected an acute awareness that their current transplant may be their last and some would not return to dialysis if the transplant failed.

Conclusions: Kidney transplantation reverses deterioration of functioning and well-being that patients experienced whilst on dialysis. However, elderly transplant recipients may have anxieties about debilitating adverse events, comorbidities, and a sense of vulnerability that the current transplant may be their last. Addressing these concerns in the care of elderly kidney transplant recipients may improve treatment outcomes in this growing population.

Indoxyl Sulfate, a Representative Uremic Toxic, Suppresses Myogenic Differentiation: Implication in Uremic Sarcopenia

Chih-Kang Chiang, 1,2 Un Jong Ao, 1,2 Yuan-Siao Chen, 1,2 Shing-Hwa Liu, 1,2

1 Inst of Toxicology, College of Medicine, National Taiwan Univ, Taipei, Taiwan; 2 Dept of Integrated Diagnostics and Therapeutics and Internal Medicine, College of Medicine, National Taiwan Univ, Taipei, Taiwan.

Background: Sarcopenia (or muscle wasting) is a common feature of the uremic phenotype and retards the process of tissue repair and recovery in uremic patients. Disturbed skeletal myotube differentiation and contribute to sarcopenia in uremic patients. The expressions of myogenic differentiation markers and related signaling proteins were determined by Western blotting.

Results: We first investigated the non-lethal concentration of IS by MTT assay, and found IS level less than 1 mM with significant cellular toxicity as compared with control group. In order to development the protocol, we confirmed myotubes were visibly formed throughout 4 days of differentiation first. IS significantly attenuated the number of myotubes and the percentage of mature myotubes. Furthermore, IS significantly and dose-dependently decreased the expression of MyoD, Myogenin and myosin heavy chain, which is the representative markers of slow and fast myofiber phenotype, both in translational and transcriptional level. The molecular signals of myotube differentiation were also disturbed by IS treatment.

Conclusions: These findings suggest that IS, a uremic toxic, dysregulates myotube differentiation in C2C12 cells. This is the first time to provide additional evidence that IS might contribute to the development of sarcopenia in uremic patients. Further explore would give the light to provide potential therapeutics in uremic sarcopenia.

Funding: Other NIH Support - MOST in Taiwan
Methods: This was a retrospective observational study. Clinical and social demographic data were collected from clinical records. The Kidney Disease Quality of Life and Beck depression inventory were used to assess quality of life and depression symptoms. Results: 104 patients were included. 68.3% were men, 71.2% married, 91.3% Caucasian and 44.2% were in productive life period. A relation between quality of life score and time of dialysis was observed (p = 0.0118, CI -0.023; 0.0003). Patients younger than 65 y.o. showed more favorable results, such as general health perceptions, emotional well-being, energy/fatigue, pain and dialysis staff encouragement. Patients between 65 to 75 y.o. showed lower energy/fatigue index (11.98; CI: 9.92; -1.10) and a reduction of 18.97-points (CI: -33.97; -3.98) for emotional well-being. A 15.04-point (CI: -27.21; -2.87) depression correlated with time in hemodialysis (p = 0.0007; CI 0.14%; 0.55%). For each month an increase of 0.35% on depression symptoms was found.

Conclusions: For younger patients younger than 65 years hemodialysis treatment represents a rehabilitation possibility. Patients over 75 years had significant increase on social support and social interaction. Patients 65 to 75 y.o. had worse perception of quality of life.

SA-PO760
Fibroblast Growth Factor 23 and the Risk of Infection-Related Hospitalization in Older Adults: The Cardiovascular Health Study

Kristen L. Nowak,1 Traci M. Bartz,2 Lorien S. Dalrymple,3 Joachim H. Ix,4 Ian H. De Boer,4 Bryan R. Kestenbaum,4 Michael Shlipak,5 Pranav S. Gariamella,6 Michel Choncho,1 1Univ of Colorado Denver; 2University of Washington; 3Univ of California Davis; 4Univ of California San Diego; 5Univ of California San Francisco; 6Tufts Medical Center.

Background: Fibroblast growth factor 23 (FGF23) may inhibit 25-hydroxyvitamin-D-1α-hydroxylase (CYP27B1) in monocytes. We hypothesized that higher circulating FGF23 would lead to an increase in serious infection risk because FGF23 decreases the intracrine production of 1,25-dihydroxyvitamin D (1,25(OH)2D), which consequently reduces production of cathelicidins.

Methods: Plasma C-terminal FGF23 concentrations were measured in 3141 Cardiovascular Health Study participants. Cox proportional-hazards models were used to examine the association between FGF23 levels and the first infection-related hospitalization (multivariable models adjusted for demographics, co-existing illnesses, body mass index, tobacco use, albumin, estimated glomerular filtration rate, urine albumin creatinine ratio, C-reactive protein, and IL-6). We tested whether associations differed by the presence of chronic kidney disease (CKD) (eGFR < 60 vs 230 vs >60 ml/min/1.73m2 [vs 832]).

Results: Participants were 78±5 years, 60% females, and the median serum FGF23 level was 70 [IQR 53, 99] pg/mL. During a median follow-up of 15.7 years, 1162 (37%) had an infection-related hospitalization. In the adjusted models, participants in the highest quartile of FGF23 (compared to the lowest) had a higher risk of infection (hazard ratio [HR] 1:33; 95% confidence interval [95% CI], 1:10-1:60). The association was stronger for those participants with CKD (HR 1:27, 95% CI 1:11-1:46 per doubling of FGF23) than in those without CKD (HR 1:07, 95% CI 0:98-1:17 per doubling of FGF23; p-value for interaction: 0.06). The addition of serum calcium, phosphorus, vitamin D and PTH into the statistical models did not attenuate these associations.

Conclusions: In ambulatory elders, higher serum FGF23 levels were independently associated with the risk of first infection-related hospitalization. This association appeared stronger in the setting of CKD.

SA-PO761
Characteristic of the Elderly Patients in the Chronic Renal Insufficiency Standards Implementation Study (CRISIS) Cohort Compared To Their Younger Cohort A Descriptive Analysis

Maharajan Raman,1 Darren Green,2 James Ritchie,3 Thilini Nishani Abeygunaratne,4 Smeeta Sinha,5 Philip A. Kalra.

1Department of Nephrology and 2Department of Geriatric Nephrology, 3Department of Nephrology and 4Renal Medicine, Salford Royal NHS Foundation Trust, Salford, Manchester, United Kingdom.

Background: CKD in the Elderly is associated with high mortality and slower rate of progression to ESRD. Identifying the characteristics of this phenotype and modifying their risk may reduce the burden of death but this can be challenging due to the heterogeneity of the disease in this group.

Methods: The CRISIS cohort of 2706 participants was divided into four groups based on their age. Descriptive statistical analysis was performed using SPSS and in between group significance was calculated using one way ANOVA or Chi-Square test.

Results: Essential characteristics of the cohort are shown in the table below.

Conclusions: The group aged ≥75 years had the highest incidence of death and accumulation of co-morbidities. We aim to develop a risk prediction model to identify the characteristics of this phenotype, which may help in modifying their risk.

SA-PO762
Muscle Strength Rather Than Muscle Mass Is More Important in Evaluating Physical Function in Elderly Patients with Predialysis Chronic Kidney Disease

Yasuhiro Taki,1 Koji Hiraki,1 Keita Uchera,1 Hiro Kavaraizaka,2 Tsutomu Sakurada,3 Yugo Shibagaki,4 1Department of Nephrology and Hypertension, 2St Marianna University School of Medicine, 3Kanagawa, Japan; and 4Department of Rehabilitation Medicine, St Marianna School of Medicine, Kawasaki, Kanagawa, Japan.

Background: Recently, physical function has been reported to be strongly associated with prognosis of patients with chronic kidney disease (CKD). Sarcoptosis, which is well described in CKD patients on dialysis especially of the elderly and is known to be associated with reduced physical function, but whether this is the case in elderly predialysis CKD is undetermined.

Methods: We enrolled consecutive 85 elderly patients (age over 60) with predialysis CKD (estimated GFR<eGFR < 60 ml/min/1.73m2) at outpatient nephrology clinic at St Marianna University Hospital. We evaluated kidney functional parameters, muscle mass by bioimpedance, muscle strength by dynamometer (hand grip, knee extension) and 4-meter walking speed in those participants.

Results: Average age was 74 years old, 76% were men, 33% had diabetes mellitus (DM) and average eGFR was 28.6ml/min/1.73m2. Patients were divided into those with eGFR<30 or ≥30. After adjustment for age, gender and history of DM, hand grip strength (-4.36, 95%CI:-0.85–7.85), knee extension strength (-5.62, 95%CI:-2.28–8.97) and 4-meter walking speed (>0.12, 95%CI:-0.02–0.22) were significantly reduced in those with eGFR<30. However, there was no difference in muscle mass (-0.23, 95%CI:-0.68–0.23).

Conclusions: In conclusion, muscle strength and walking speed but not muscle mass developed along with progression of CKD. Thus, it seemed more important to check muscle strength and walking speed rather than muscle mass when evaluating physical function in elderly patients with predialysis CKD.
SA-PO767

Lower Muscle Endurance, Strength and Quality Are Associated with Greater Risk of Functional Limitations in Older Adults with CKD

Babak Roshanravan,1 Kushang V. Patel,1 Linda F. Fried,1 Ian H. De Boer,1 Cassianne Robinson-Cohen,2 Anne B. Newman,2 Bryan R. Kestenbaum.1

1Medicine/Nephrology, Kidney Research Inst - Univ Washington, Seattle, WA; 2Univ of Pittsburgh, Pittsburgh, PA; 4Univ of Washington, Seattle, WA.

Background: Chronic kidney disease is associated with inflammation and insulin resistance, contributing to fatigue and muscle weakness. The association of muscle endurance, strength, and quality with functional limitation among persons with CKD is unknown.

Methods: We studied 186 participants with eGFR<60 at the year 3 Health ABC visit. Participants were excluded if unable to complete >90% of quadriceps isokinetic fatigue testing. Quadriceps endurance was defined by total work using isokinetic dynamometer. Quadriceps strength was measuring by isometric torque. Leg lean mass (legm) was measured using DXA. Muscle quality was defined by specific work (work/legm) and specific torque (torque/legm). Outcome was incident persistent severe lower extremity limitation (PSLL) based on 2 consecutive reports of having a lot of difficulty or inability to walk 1/4 mile or climb 10 steps without resting. We used competing risks regression.

Results: Participants had a mean age 76.2 ±53 years, eGFR of 49 ±10. None had mobility disability. There were 82 PSLL events over a median 6 years. After adjustment each 1-SD lower quadriceps isokinetic work and isometric maximal torque were associated with a 1.38 fold (95% CI 1.04, 1.85, P=0.028) and 1.43 fold (95% CI 1.01, 2.03 P=0.045) greater risk of PSLL, respectively. Leg lean mass was not associated with PSLL (P=0.12).

Conclusions: Among older adults with CKD free of mobility disability, lower muscle endurance, strength, and quality are independently associated with greater risk of severe lower extremity limitation.

Efficacy and Safety of Exercise Training in Patients with Predialysis Chronic Kidney Disease

Yuho Shibaegaki,1 Koji Hiraki,2 Takashi Yasuda,1 Kenjiro Kimura.1 1Div of Nephrology and Hypertension, St. Marianna Univ; 2Div of Rehabilitation, St. Marianna Univ.

Background: Efficacy and safety of exercise training has not been well studied in patients with predialysis chronic kidney disease (CKD). Since we have reported in elderly patients with predialysis CKD that there was a significant reduction in muscle strength and short-term exercise did not damage kidney, we conducted a randomized controlled trial to elucidate the long-term efficacy and safety of exercise in this population.

Methods: Study design was a randomized controlled trial. Thirty six male elderly patients with CKD stage 3-4 seen at the outpatient nephrology clinic at St. Marianna University Hospital agreed to participate in the study with written informed consent. We randomly divided them into intervention (I) group and control (C) group. Patients with C group did not received exercise advice. Both groups received conventional drug therapy for CKD and were checked the daily foot steps by pedometer. Primary outcome was the change in estimated glomerular filtration rate (eGFR) and secondary outcomes were the changes in muscle strengths by dynamometer (hand grip and knee extension).

Results: There were no difference in baseline characteristics (demographic, kidney functional parameter, hemoglobin and serum albumin level) with average age of 68.7±6.8 years and eGFR of 39.0±11.6 ml/min/1.73m². Change in eGFR were not different at 12 months among both groups. Muscle strength in knee extension increased in I group (0.65±0.17kgf to 0.70±0.17kgf in knee extension) but not in C group (0.66±0.15 to 0.62±0.13kgf). This showed statistically significant difference. Change in muscle strength in hand grip also showed the difference between the groups.

Conclusions: Only the advice on exercise training could increase the physical activity and muscle strength without compromising kidney function in the elderly patients with predialysis CKD.

SA-PO765

Determinants of Impaired Cardiorespiratory Fitness in Older Adults with CKD

Stephen L. Seliger,1,2 Jamie Giffuni,2 Roger A. Fielding,2 Eamon F. Fleming,2 Christine Liu,1,4 Leslie I. Katzel,1,2 Kieran Reid,3 Sushrut S. Waikar,4 Andrew M. Well,9 Daniel E. Weiner.1

1Medicine, U Maryland Sch of Medicine; 2GRECC, VA Maryland Healthcare System; 3Tufts Univ Sch of Medicine; 4Boston Univ Sch of Medicine; 5Brigham and Women’s Hospital; 6Emory Univ School of Medicine.

Background: Chronic Kidney Disease (CKD) may be associated with impaired cardiorespiratory fitness (CRF). We examined methods of estimating CRF in CKD and identified factors associated with CRF.

Methods: We measured peak aerobic capacity (VO2peak) using a modified Graded Exercise Treadmill Test (GXT) in 71 older adults with CKD stage 3b-4 in an ongoing exercise clinical trial. GFR was estimated with the CKD-Epi equation. Linear regression was used to examine factors associated with VO2peak. Resting VO2 was measured prior to GXT in seated position. Metabolic Equivalents of Task (MET, oxygen consumption during exercise relative to rest) was estimated at peak exercise based on GXT stage and compared to actual achieved METS.

Results: Mean age was 68.4±7.7 years, with 51% African-Americans, 30% women; mean eGFR was 33±11 ml/min/1.73m² and mean Hb 12.3±1.6 g/dL. Mean VO2peak was 17.4±5.4 ml/kg/min, which was 31±17 lower than expected based on normative values (p<0.001). In a multivariate model including demographics and co-morbidity, lower hemoglobin - but not GFR - was associated with lower VO2peak (Table). Albuminuria did not correlate with VO2peak.

</table>

Estimated METS: Mean achieved METS was 5.6±1.8. Although there was low bias for estimated vs. achieved METS (mean difference, -0.45), precision and accuracy were poor, with only 35% of predicted values within 1 MET of achieved values, and nearly one third of estimated values >30% different from achieved.

Conclusions: Among older adults with CKD stage, CRF as reflected by VO2peak is markedly impaired. Lower hemoglobin, obesity, and prevalent cardiac disease are associated with worse aerobic capacity. The use of estimated METS during treadmill testing poorly estimates actual aerobic capacity.

Access to Kidney Transplantation and Outcomes of Those Listed for Kidney Transplant in Elderly

Pritika Shrivastava,1 Ankit Sakhija, Diane M. Cibrik, Abhijit S. Naik. 1Div of Transplant Nephrology, U Michigan, Ann Arbor, MI.

Background: Data suggests that patients above 70 years of age (<70 yo) with ESRD derive a benefit from kidney transplant (KT). We report our single center experience of access to transplant and outcomes for those >70 y.o. listed for KT. We used the number of evaluations in a year and rate of acceptance after evaluation as surrogate markers for KT access in elderly.

Methods: We assessed the rate of acceptance for KT and its trends over the years for those ≥70 y.o. between 2000-2014. Linear regression was used to assess trends over time. Differences in rates of listing by diabetes status and mortality among those transplanted vs waitlisted was assessed.

Results: Over 15 year period, we evaluated 612 elderly patients (pts). 25.3% of those evaluated were approved to be listed for transplant. There were 9 patients who were evaluated twice of those 5 were approved for listing the second time and two got transplanted. There was 300% increase in annual evaluation of the elderly from year 2000 to 2014 and trend towards increased acceptance rate of those evaluated (slope=-0.82, p=0.12).

Funding: NIDDK Support, Veterans Administration Support
The acceptance rate was lower in diabetics compared to non-diabetics (18.2% vs 32.0%; p=0.001). 38.0% of listed pts have been transplanted and the rate of transplant did not differ by diabetes status. Of those transplanted 59.3% had living donors. Mortality remained significantly high for transplant vs waitlisted patients. Though there has been some improvement in the acceptance rate for listing over time.

P-Cystatin C Improves GFR Estimation in Older People
Karin Werner,1 Anders G. Christensson,2 Mats Pilhsågård,1 Sölve Elmståhl. 1 Dept of Geriatrics, Lund Univ, Malmo, Sweden; 2 Dept of Nephrology and Transplantation, Lund Univ, Malmo, Sweden.

Background: There is a need for validation of commonly used cystatin C and creatinine based formulas for eGFR (estimated glomerular filtration rate) in the older segment of the general population for all levels of kidney function.

Methods: Markers used for eGFR estimation were P-Cystatin C and P-Creatinine.

Measured GFR (mGFR) adjusted to body surface area was performed by a single sample iohexol clearance in 112 participants, aged 70-100 years old from the population-based cohort “Good Aging in Skåne”. The participants were selected to cover a wide range of kidney function and to obtain an even distribution regarding sex and age. The timing of the sample depended on eGFR (eGFR >50, 25-50, and >25 at 4, 7, and 24 hours respectively). Formulas of both markers (CKD EPI combined, Lund-Malmo combined, BIS2), only creatinine (CKD EPI creatinine, MDRD) and only cystatin C (CKD EPI cystatin C) were compared. The analysis included bias (median difference: mGFR-eGFR), precision (IQR: interquartile range of the differences), accuracy (P30: percentage of estimates ±30% of mGFR) as well as accuracy (P30) above and below mGFR 45.

Results: There were 57 women and 55 men. Mean age was 82 years and mean GFR 55 ml/min per 1.73m². Results are presented in the table.

Factors Associated with Early Death After Dialysis Initiation Among Elderly CKD Patients
Fahad Saeed, Susana Arrigain, Jesse D. Schold, Joseph V. Nally, Sankar D. Navaneethan. Nephrology, Cleveland Clinic.

Background: There are limited studies examining prognosis for elderly CKD patients following dialysis initiation. Herein, we evaluated the factors associated with poor one year survival after dialysis initiation among elderly CKD patients at our institution.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Differential Significance of Prognostic Factors for 6-Month and 3-Year Mortality in Elderly Patients on Hemodialysis
Koichi Harada,1 Azusa Izumiya,2 Tomohiro Kawamura,1 Juri Tsukahara,1 Koichi Sumida,1 Yukinari Yamaguchi,1 Yasuhiro Akai.2 Dept of Nephrology, Rakushakai-Otsu Hospital, Yamashina, Kyoto, Japan; 2 Center for Postgraduate Training, Nara Medical Univ, Kashihara, Nara, Japan.

Background: As the population of elderly people has been growing, the number of older chronic kidney disease patients commencing renal replacement therapy (RRT) is increasing. The survival advantage of RRT may be counterbalanced by the burden of treatment and its negative effect on quality of life in the elderly, and old age is no longer seen as a contraindication to RRT. Therefore, it is important to evaluate survival factors in this population. We conducted this study to investigate prognostic factors for mortality in elderly patients starting hemodialysis (HD) for end-stage renal disease (ESRD).

Methods: We studied 621 CKD patients/65 years from an EMR based CKD registry linked to the USRDS data. We retrospectively analyzed factors associated with one year mortality after dialysis initiation including: age, sex, race, presence of diabetes, hypertension, BMI, stroke, CHF, COPD, malignancy, peripheral vascular disease, depression, alcohol use, smoking, presence of AVF, pre-dialysis serum albumin and potassium.

Results: In our study, 224 (36%) patients died within the first year of dialysis initiation. Results from the Cox proportional model showed that older age and CHF were associated with early deaths, while higher albumin, presence of AVF and HTN were associated with a lower hazard of early death.

Conclusions: CHF and older age in the pre-dialysis setting are associated with higher 1-year mortality after dialysis initiation. These prognostic data need to be presented to geriatric CKD patients while discussing renal replacement therapy options.

</table>
Methods: This is a single-center, retrospective cohort study from January 2009 to December 2014. In total, 90 ESRD patients commencing HD were enrolled. All the patients were aged 65 years or older. Six-month and 3-year survival rates and prognostic factors for mortality were evaluated.

Results: The mean follow-up period was 21.7±18.3 months. The 6-month and 3-year survival rate were 94.0% and 66.9%, respectively. Age, unplanned initiation of HD, presence of heart failure, high value of estimated GFR on starting HD, Charlson comorbidity index (CCI), and Eastern Cooperative Oncology Group Performance status (ECOG-PS) were associated with 3-year mortality, whereas only the presence of heart failure and ECOG-PS were significant predictors of 6-month mortality. There was no significant difference in 6-month mortality rate between patients aged ≥ 80 and < 80. On the other hand, 3-year mortality rate of ≥ 80 year-old patients was significantly higher than that of < 80 (≥ 80: 53.3% vs ≤ 80: 14.2%, p = 0.0004).

Conclusions: There is a variation of significance among different prognostic factors according to the duration of life after starting hemodialysis. The presence of heart failure and ECOG-PS predicted short-term mortality among elderly ESRD patients starting HD. These results might help clinical decision making when nephrologists consider commencing HD for elderly ESRRD patients.

SA-PO770
Cumulative Cardiovascular Polypharmacy Is Associated With the Risk of Geriatric Acute Kidney Injury
Chia-Ter Chao,1 Hung-Bin Tsai,1 Dept. of Medicine, National Taiwan Univ Hospital Jin-Shan Branch, New Taipei City, Taiwan,2 Dept. of Traumatology, National Taiwan Univ Hospital, Taipei, Taiwan.

Background: Polypharmacy is common in the elderly due to multiple morbidities. However, the effect of polypharmacy on renal outcomes is rarely recognized. We investigated the effect of cardiovascular polypharmacy on acute kidney injury (AKI) in elderly patients.

Methods: We used the Taiwan National Health Insurance PharmaCloud system to investigate the relationship between cumulative cardiovascular medications in the 3 months prior to admission and risk of AKI in the elderly at admission to general wards. Community-dwelling elderly patients (>60 years) were prospectively enrolled and classified according to the number of pre-admission cardiovascular medications. Cardiovascular polypharmacy was defined as use of 2 or more relevant medications.

Results: We enrolled 152 patients, 48% with AKI (based upon Kidney Disease Improving Global Outcomes [KDIGO] classification) and 64% with cardiovascular polypharmacy. The incidence of AKI was higher in patients taking more cardiovascular medications (0 drugs: 33%; 1 drug: 50%; 2 drugs: 57%; 3 or more: 60%; p = 0.04). Patients with higher KDIGO grades also took more cardiovascular medications (p = 0.04).

Conclusions: We found that elderly patients taking more cardiovascular medications had increased risk for adverse renal events. Interventions that reduce polypharmacy may be able to reduce the incidence of geriatric AKI.

SA-PO771
Low Bicarbonate Associates with Higher Mortality Independent of pH in Healthy Older Individuals: The Health, Aging, and Body Composition Study
Kalani L. Raphael,1 Rachel A. Murphy,1 Michael Shlipak,2 Suzanne Satterfield,3 Hunter K. Huston,1 Anthony Sebastian,1 Deborah Sellmeyer,1 Kushang V. Patel,3 Anne B. Newman,1 Mark J. Sarnak,2 Joachim H. Ix,3 Linda F. Fried,1 University of California San Francisco,2 University of Tennessee,3 Johns Hopkins Univ,1 Univ of Washington,1 Univ of Pittsburgh,2 Tufts Medical Center,3 Univ of California San Diego.

Background: Low serum [HCO₃⁻] associates with higher mortality in CKD. The purpose of this study is to determine if [HCO₃⁻] associates with all-cause mortality independent of systemic pH in healthy older persons.

Methods: Data were analyzed from the Health, Aging, and Body Composition Study, an observational study of black and white adults aged 70-79 years followed from 1997-2014. Arterialized venous blood gas measurements were obtained in 2,287 participants. Participants were grouped into one of 3 [HCO₃⁻] categories: <23.0 (low), 23.0-27.9 (reference group), and 28.0 mEq/L (high). Mortality hazard ratios (HR) in the low and high [HCO₃⁻] groups were compared to the reference group using Cox models adjusted for demographics, eGFR, albuminuria, COPD, smoking, and pH. Multivariate interaction terms tested whether CKD status modified the relationship between [HCO₃⁻] categories and mortality.

Results: The mean age was 76 years, 51% were female, and 38% were black. The mean pH was 7.41, mean [HCO₃⁻] was 25.1 mEq/L, 11% had low and 10% had high [HCO₃⁻]. The mean eGFR was 82.1 ml/min/1.73m²; 12% had CKD. During follow-up (mean 10.3 years), 1,326 (58%) participants died. The adjusted all-cause mortality HR was 1.24 (95% CI, 1.02-1.49) in the low [HCO₃⁻] category and 1.03 (95% CI, 0.84-1.26) in the high [HCO₃⁻] category compared to the reference group. CKD status did not modify the association between [HCO₃⁻] and mortality (p=0.74).

Conclusions: Healthy older persons with low [HCO₃⁻] have higher mortality risk than those with normal [HCO₃⁻] independent of pH and potential confounders. High [HCO₃⁻] does not associate with higher mortality. The potential health benefits of normalizing low [HCO₃⁻] in generally healthy older persons should be investigated.

SA-PO772
Low Urinary Creatinine Excretion Is a Valid Surrogate for Frailty in Patients with Advanced Chronic Kidney Disease
Harmke Polinder-Bos,1 Hakon Nakac,1 Friedo W. Dekker,2 Stephan J.L. Bakker,3 Carlo A. Gaillard,1 Ron T. Ganssvoort,1 Internal Medicine, Univ Medical Center Groningen, Groningen, Netherlands;2 Epidemiology, Leiden Univ Medical Center, Leiden, Netherlands.

Background: Muscle wasting is a key component of frailty, which is highly prevalent in advanced stages of chronic kidney disease (CKD). Whether low urinary creatinine excretion (UCEr) is a valid surrogate for frailty in CKD patients is unknown. We studied cross-sectional associations between frailty and a low UCEr in patients with CKD stages 4 and 5 (not on dialysis).

Methods: 2748 healthy individuals of the general population were included to define low UCEr. Low UCEr was defined as height-indexed UCEr below the age- and sex-specific 5th percentile. In a CKD population including 320 and 967 participants of the resp. PREPARE-2 and NECOSAD studies, associations of frailty, the individual components that define frailty, and frailty-associated variables with low UCEr were evaluated using multivariate logistic and linear regression models. Frailty was defined as a composite construct including self-reported poor physical functioning, exhaustion, low physical activity, and underweight.

Results: In the general population with a median age of 46 years, median UCEr was 9.8 mmole/day for women and 14.3 mmole/day for men, compared to 7.0 mmole/day and 9.5 mmole/day in CKD patients, respectively. In the CKD patients with a median age of 63 years, low UCEr was found in 38%. Frailty, and the individual components that define frailty, were associated with a low UCEr, independent of comorbidities (OR frailty = 2.19 [1.28-3.77], p=0.005). Of the frailty-associated variables, lower hemoglobin and albumin levels, and higher parathyroid hormone levels were associated with low UCEr. Adjustment for GFR attenuated the associations of frailty, and the individual components that define frailty with low UCEr, except for underweight.

Conclusions: Low UCEr is a valid surrogate for frailty, independent of comorbidities. Low UCEr is strongly determined by a lower kidney function, suggesting that reduced kidney function induces changes in muscle mass and performance leading to frailty.

SA-PO773
Oral Anticoagulation and Kidney Function in Elderly
Antonios Dousou,1 Elke Schaeffer,2 Olga Jakob,1 Reinhold Kreutz,1 Natalie Ebert,2 Clinical Pharmacology, Charité;1 Nephrology, Charité;1 Clinical Epidemiology, Charité.

Background: In the past years new oral anticoagulants (NOACs) were approved expanding our pharmacological arsenal. Data on their utilization in elderly compared to vitamin K antagonists (VKA) are scarce and the impact of kidney function (KF) on NOAC use in a population with declining glomerular filtration rate (GFR) is of great interest. The present study investigates anticoagulant use and KF in people ≥ 70 years. Medication was assessed through personal interviews and coded using the Anatomical Therapeutic Chemical Classification System. For GFR estimation we used the CKD-EPI equation. Predictor analysis was conducted via logistic regression.

Results: Figure 1 illustrates the percentage of drug use for the three NOACs and phenprocoumon, the most common VKA in Germany, over the course of 4 years.

*P<0.05, **P<0.01 ***P<0.001

Conclusions: This study demonstrated high symptom burden, reduced functional status and QOL in dialysis patients. Patients with severe pain, weakness, shortness of breath, nausea, mouth problems, drowsiness, poor mobility and skin changes were more likely associated with higher mortality risk. Symptom identification and management may help predict and improve patient QOL outcomes in dialysis patients.

SA-PO775

Outcomes of Cardiopulmonary Resuscitation in Maintenance Dialysis Patients Based on CPR Characteristics
Haris Farooq Murad, Fahad Saeed. Cleveland Clinic Foundation.

Background: Cardiopulmonary resuscitation (CPR) is associated with high rates of mortality, especially in patients with end stage renal disease (ESRD). Previous studies have reported an in-hospital mortality rate of up to 75% in ESRD patients undergoing CPR. There are no large studies to date on how individual CPR characteristics relate to the long term outcomes in these patients. Herein, we aimed to answer this question.

Methods: By an EMR inquiry, we identified all the adult patients (>18years) who had undergone CPR from January 2006 to December 2014, and then selected patients who were on maintenance dialysis. We conducted a chart review of CPR characteristics and its association with the hospital discharge survival. We studied following variables: initial rhythm, duration of CPR, in-hospital versus out of hospital CPR and the use of hypothermia protocol.

Results: We studied a total of 497 ESRD who had undergone CPR. Sixty eight percent of our patients had expired in the hospital post-CPR. Pulseless electrical activity (PEA) was the most common initial rhythm (51.4%), followed by ventricular arrhythmias (19.6%) and asystole (19.2%). In-hospital mortality was the highest (76.8%) for patients with asystole. Mortality rates at the time of discharge were 73.3% for PEA and 57.7% for patients with ventricular arrhythmias respectively. Fifty six percent of patients who underwent therapeutic hypothermia died in the hospital as compared to 68.9% of those who did not undergo a cooling protocol. CPR duration of greater than 10 minutes was associated with higher in-hospital mortality (76.1%) as compared to patients who had CPR for less than 10 minutes (40.9%). Patients who had undergone out of hospital CPR (by paramedics or bystanders), 72.2% died before discharge; while 68.9% of patients who underwent CPR in the hospital expired during the same hospitalization. The average length of stay for patients who were alive at discharge was 17 days.

Conclusions: CPR in dialysis patients is associated with high mortality rates. It is possible to predict hospital discharge survival of patients with cardio-pulmonary arrest based on the CPR characteristics.
Methods: We collected data on 423 out of 440 dialysis patients from 7 dialysis facilities in the U.S. using self-reported questionnaires.

Results: Our study included 28.1% Caucasian and 66.7% African American patients. Eighty three percent of the patients felt that their QOL was an important determinant in guiding their future care plans, and 72.3% of patients reported that they need to have frequent discussions with their nephrologist. Only 35.4% of patients actually get information about their health and well-being from their nephrologists. Only 8.6% of patients had a discussion with any physician, nurse or social worker regarding end of life care during the past 12 months. Notably, 74.2% of our participants reported that they would like to have such discussions with their healthcare provider. Sixty seven percent of the patients wished to be full code. Fifty six percent of the patients preferred to die at home versus 20.4% wanted to die in a hospice facility and 13.4% in a hospital. Only 23.6% of patients knew about palliative care. Clinicians also need to have more dialogue between patients and their nephrologists regarding end of life care preferences, and it is necessary to develop policies and practices that would help address this need.

SA-PO777

“So I had No Choice”: Perceptions of Dialysis Decision-Making Among Older Adults Keren Ladin,1 Daniel E. Weiner.2 (1)Occupational Therapy, Tufts Univ, Medford, MA; (2)Section of Palliative Care and Medical Ethics, Univ of Pittsburgh Medical Center, Pittsburgh, PA; “Medicine, Tufts Univ Medical School, Boston, MA.

Background: Multiple treatments are available to older patients with advanced chronic kidney disease. However, poor communication about available treatment options may result in a mismatch between patient preferences and treatment choice.

Methods: Semi-structured in-depth interviews were conducted with a purposive sample of 11 patients aged 65 and older at two dialysis clinics in the Greater Boston area. Trained researchers conducted, audiotaped and transcribed interviews. Applying grounded theory, interviews were analyzed in an iterative process to identify emergent codes. Codes were discussed using consensus and organized into themes.

Results: Twenty-one patients participated in the interview. Mean age was 77±9 years; 50% were men, 19% African American and 58% diabetic. Median age was 28 (17, 39) months. Four major themes with associated subthemes were identified. The first, “Deciding to start dialysis” revealed that only two patients conceptualized dialysis initiation as a choice. Patients were seldom informed of conservative management, and many had unanswered concerns about trade-offs among treatment choices. The second theme, “Experience with dialysis”, included positive and negative physical, emotional, and social consequences of dialysis and logistics of care. While many reported greater than anticipated levels of pain, fatigue, and frustration over transportation costs and time, others reported substantial benefits, including increased longevity and the ability to achieve life goals. The third theme, “Patient Role”, revealed patients tied self-worth to meeting clinical goals. Finally, “End-of-life (EOL) preferences and conversations” revealed that most patients had not discussed EOL with their clinical team and or with loved ones.

Conclusions: Many older patients who received dialysis do not perceive that they had a choice when making their dialysis decision. Initiating dialysis may contradict patients’ EOL preferences, and many desire greater information and more discussions with clinicians. Older adults’ preferences and experiences with dialysis vary, underscoring the importance of patient involvement in decision-making.

SA-PO778

Improving Advance Care Planning in Elderly Outpatients with Chronic Kidney Disease: A Quality Improvement Initiative Keri K. Sugar,1,2,3,4 and Leigh M. Schell.1,2 1-section of Palliative Care and Medical Ethics, Univ of Pittsburgh Medical Center, Pittsburgh, PA; 2-Renal-Electrolyte Div, Univ of Pittsburgh Medical Center, Pittsburgh, PA.

Background: Despite a high annual mortality rate in patients with advanced chronic kidney disease (CKD), advance care planning (ACP) is underutilized. A minority of dialysis patients complete advance directives (AD). Timely ACP ensures that patients’ preferences for future care are respected and is associated with less intensive care at end of life. We sought to introduce ACP and increase documentation of AD in older outpatient CKD patients.

Methods: This quality improvement study was conducted over 15 weeks in older outpatients at the University of Pittsburgh Kidney Clinic. The intervention included training and role assignment the CKD nurse educator to introduce and encourage ACP completion. Inclusion criteria were age older than 65 years and referral to the CKD education session. The CKD nurse educator was assigned the role of asking whether each patient had AD and begin to ask their hemodialysis patients about ADs and document the discussion?

Results: Of the 110 patients who underwent CKD education over a period of 15 weeks, 52 (47.2%) were eligible. Thirty-one of 52 (59.6%) patients already had AD and 14 of 52 (26.9%) patients received AD (like Living wills, Substitute Decision Maker (SDM) and CPR forms). Only 2 patients had ADs in their charts (like Five Wishes).

Conclusions: In 3 months, a review of the patients’ charts will again look for any documented ADs. We have shown to want to discuss ADs in the past. We reviewed 215 chronic in-center hemodialysis patients at Sunnybrook Health Sciences Centre from March to April 2015 by the dialysis unit social workers for any documents related to ADs (like Living wills, Substitute Decision Maker (SDM) and CPR forms). Only 2 patients had ADs in their charts (1.0%). When this data has presented to the Nephrologists they agreed that ADs should be discussed with their patients and that this was a quality improvement issue. Will the staff nephrologists change their practice behaviour and begin to ask their hemodialysis patients about ADs and document the discussion?

SA-PO779

Trends in Inpatient Intensive Procedures in the Last Six Months of Life Among Medicare Beneficiaries Treated with Maintenance Dialysis, 2000-2011 Nwamaka Denise Eneanya,1 Susan M. Hailpern,2 Ann M. O’Harc2, Manjula Kurella Tamura,2 Ronit Katz,3 Yoshio N. Hall,4 (1)Div of Nephrology, Massachusetts General Hospital, Harvard Medical School, Boston, MA; (2)Kidney Research Inst, Univ of Washington, Seattle, WA; (3)Geriatric Research and Education Clinical Center, VA Palo Alto Health Care System, Palo Alto, CA.

Background: Many US dialysis patients undergo intensive procedures intended to prolong life such as mechanical ventilation, cardiopulmonary resuscitation or feeding tube placement at the very end of life. Little is known about trends over time in use of intensive procedures in this population.

Methods: We examined temporal trends in receipt of inpatient intensive procedures in the last 6 months of life by age and race among 601,942 adult Medicare beneficiaries treated with maintenance dialysis who died between January 1, 2000 and December 31, 2011.

Results: From 2000 to 2011, inpatient admissions during the last six months of life increased slightly from 89% to 90%. Among those admitted, there was a marked increased in the use of intensive procedures ranging from 38% in 2000 to 44% in 2011. Intensive procedures at the end of life were more common among black vs. white patients (50% to 57% vs. 34% to 39%) and among younger vs. older patients (50% to 61% for those < 55 years vs. 27% to 26% for those 85+ years).

Conclusions: Despite a high annual mortality rate in patients with advanced chronic kidney disease. However, poor communication about available treatment options may result in a mismatch between patient preferences and treatment choice.

SA-PO780

Will Nephrologists Implement an Advance Directives Program in Their Patients? (Quality Improvement Program) Ali Mohammed Habeeb, Sheldon W. Tobe. Nephrology, Sunnybrook Health Sciences Centre, Toronto, ON, Canada.

Background: Mortality remains high among patients on dialysis. Advanced age and multiple co-morbidities are the major predictors for increasing mortality. ADs extend patients’ autonomy and are the best tool to inform patients about their preferences for health care decisions when they become unable to make such decisions. Chronic dialysis patients have been shown to want to discuss ADs in the past.

Methods: We reviewed 215 chronic in-center hemodialysis patients at Sunnybrook Health Sciences Centre from March to April 2015 by the dialysis unit social workers for any documents related to ADs (like Living wills, Substitute Decision Maker (SDM) and CPR forms). Only 2 patients had ADs in their charts (1.0%). When this data has presented to the Nephrologists they agreed that ADs should be discussed with their patients and that this was a quality improvement issue. Will the staff nephrologists change their practice behaviour and begin to ask their hemodialysis patients about ADs and document the discussion?”

Results: As part of the process to discuss ADs, the unit’s social workers distributed a pamphlet for the patients with simple and explicit definitions and advantages of AD and also provided explanations about the contents of AD forms and documents. The Staff Nephrologists were educated about the importance and advantages of ADs in their patients and were asked to start discussing the issues with their patients. The Nephrologists will also be educated about how an AD discussion might go and how to document the results of the discussion. In 3 months, a review of the patients’ charts will again look for any documented ADs. We will also study the response of individual dialysis staff and their participation in completing and discussing the ADs. We will assess the potential barriers for not completing ADs by the dialysis unit staff and by patients and attempt to address these barriers.

Conclusions: We anticipated that the dialysis staff are now in the contemplation stage and we are aiming to observe the progression in their behavior to more advanced stages of behavior and try to find out what are the barriers that prevent the progression.

In adjusted analyses, racial differences in receipt of intensive procedures were most pronounced at older ages (black vs. white aOR [95% CI]; 1.38 [1.33-1.42] in patients < 55 years, 2.48 [2.38-2.59] in patients 85+ years).

Current Practice of Advance Care Planning in New Zealand and Australian Renal Centres

Rachael L. Morton, 1 Lucy Spencer, 2 Allison Tong, 1 Carol A. Pollock, 2 Karen M. Detering, 2 Josephine M. Clayton, 1, 3 The Univ of Sydney, Australia; 2 Royal North Shore Hospital, Australia; 3 HammondCare Palliative Care Service, Australia; 3 Austin Health, Australia; On behalf of Univ of Technology Sydney Collaborators.

Background: Recent guidelines emphasise the need to improve advance care planning (ACP) for patients with chronic kidney disease (CKD). Little is known about current ACP practice in Australian/New Zealand renal centres. We aimed to describe current practice and barriers to ACP from the perspective of renal clinicians.

Methods: A cross-sectional survey was administered online to nephrology nurses, nephrology social workers and nephrologists between May 2014 and January 2015. Survivors to home haemodialysis described their experiences of care, covered the topics of experience, skills, comfort and knowledge regarding ACP, workplace policies and procedures concerning ACP, perceived barriers and facilitators to ACP, and perceived need for new CKD-specific ACP programs and materials.

Results: Survivors to home haemodialysis included 127 participants; 70 (58%) were male and 57 (45%) were female, 115 (91%) identified as Caucasian, and 8 (6%) as Asian. Participants reported higher 1 year prevalence and mortality compared to age-matched predominantly white population. Participants in dialysis vintage greater than 20 years were more likely to be aware that a dialysis guideline already existed and to have used it compared to those in dialysis vintage less than or equal to 20 years (p < .05). Nephrologists were most likely and administrators least likely to perceive them as barriers (all p < .05). Care coordination, and family bereavement support, with administrators least likely to view these needs. To better address palliative care needs, nephrologists need to lead interdisciplinary collaborations, including administrators, to implement palliative care pathways already available.

Conclusions: Current ACP practice in Australian/New Zealand renal centres is subject to health system, provider and patient related barriers. Given the volunteer effect associated with online survey, this study may underestimate the need for ACP support. Targeted interventions are needed to improve ACP in Australian and New Zealand renal centres.

SA-PO782

Nephrology Leadership Required to Address Unmet Palliative Care Needs in Dialysis Centers

Alvin H. Moss, 1 Stacey Culp, 1 Dale Lupu, 2 Cheryl Arenella, 3 Nancy C. Armstead, 3 1 Medicine, West Virginia Univ School of Medicine, Morgantown, WV; 2 Daleview Associates, Silver Spring, VA; 3 Mid-Atlantic Renal Coalition, Richmond, VA.

Background: Because of high symptom burden, numerous comorbidities, and shortened life expectancy, dialysis patients are increasingly recognized as appropriate candidates for early and continuous palliative care.

Methods: In 2013 the Coalition for Supportive Care of Kidney Patients conducted an online survey of dialysis professionals and administrators using ESRD Network and Renal Physicians Association email lists to determine perceptions about how well patient palliative care needs are met. Differences among disciplines were assessed by chi-squared testing and one-way ANOVA.

Results: The 487 respondents included 41 nephrologists, 152 nurses/physician assistants, 199 social workers, and 95 dialysis center administrators. There was a significant difference by discipline in reported unmet palliative care needs for symptom management, care coordination, and family bereavement support, with administrators least likely to view each need as unmet (all p < .02). In rating possible barriers to providing high quality palliative care in their centers, mean scores differed by discipline for 7 items, and nephrologists were most likely and administrators least likely to perceive them as barriers (all p < .05). “Guidelines to help with decision-making in seriously ill patients” was selected as the top priority for change by each discipline (37% overall, p = 47 by discipline). Nephrologists were most likely to be aware that a dialysis guideline already existed and to have used it (43.9% vs 3.3% RN/PA vs 10.6% MSW vs 8.5% administrator, p < .001).

Conclusions: Nephrologists report more unmet palliative care needs, barriers, and resources than the administrators who oversee dialysis centers. Because the respondents were self-selected, a study limitation, the results likely underestimate unmet palliative care needs.

To better address palliative care needs, nephrologists need to lead interdisciplinary collaborations, including administrators, to implement palliative care pathways already established in evidence-based clinical practice guidelines.

SA-PO783

Hospice and Race for End-Of-Life Care in U.S. Dialysis Patients

Robert N. Foley, 1 Scott Reule, 1 Donal J. Sexton, 1 1 Div of Nephrology, Univ of Minnesota, Minneapolis, MN; 2 Div of Medicine, National Univ of Ireland, Galway.

Background: While hospice use is increasingly used for end-of-life care in dialysis patients, we hypothesized that important racial disparities may be present.

Methods: To address this hypothesis, we examined USRDS files to characterize end-of-life care for deaths occurring between 2006 and 2011.

Results: During this 5-year period, the proportion of deaths in hospice increased from 14.7% to 24.2%; grouped by age at death, the following trends were observed: < 65 years-11.5% to 15.0%; 65 to 79 years-19.1% to 26.1%; 80-89 years-24.9% to 34.3%; ≥ 90 years-25.9% to 39.6%. As shown in the accompanying Table, associations of hospice use varied substantially with race: compared to whites, adjusted odds ratios of hospice use were 0.56, 0.56 and 0.57, respectively, in patients of African American, Native American and Asian race.

Conclusions: While end-of-life care in hospice settings is growing rapidly in the US, substantial, unexplained racial disparities exist.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

SA-PO784

Palliative Care Perspectives of Latinos with End-Stage Renal Disease

Lilia Cervantes, 1, 2, Stuart L. Linas, 1, 2 Stacy M. Fischer, 1 1 Dept of Medicine, Univ of Colorado, Denver, CO; 2 Dept of Medicine, Denver Health and Hospital, Denver, CO.

Background: Latinos are the fastest growing minority and have a nearly 2-fold faster progression from chronic kidney disease to end-stage renal disease (ESRD). Despite the high symptom burden and mortality suffered by patients with ESRD, there is limited palliative care research and Latinos are underrepresented in existing palliative care studies. The purpose of our study is to provide the first description of the Latino palliative care perspective.

Methods: Observational descriptive survey of adult English and Spanish speaking Latinos with ESRD from a safety-net hospital and two private dialysis centers. We modified Davison’s 2010 End of Life Care Preferences and Needs Survey to include known barriers to palliative care in the Latino community. The survey was translated to 3rd grade Spanish and then back-translated to English.

Results: Participants (n=61) had a mean age of 59 years ± 12, mean Charlson Comorbidity Index of 6.5 ± 2.5, and a dialysis vintage mean of 43.3 months ±44.8. The majority (77%) spoke Spanish and reported limited understanding of hospice and palliative care. We found that 60 (98%) want to be informed about their prognosis and 55 (90%) want to be prepared and plan ahead; however, only 16 (26%) had discussed prognosis and only 10 (16%) had discussed end-of-life care with their nephrologist. The majority of participants stated that it was their doctor’s choice (68.8%) to start dialysis; however, few (14.7%) regret the decision to start dialysis. Participants reported a preference to have advance care planning conversations on a routine basis (86.8%), after starting dialysis but before becoming ill (85.2%), and while receiving dialysis (47.5%) or at home (37.7%). Participants want their family have a central role in medical decision-making (93.4%) and care giving (95%).

Conclusions: Our findings provide the first description of the palliative care perspectives of a predominantly Mexican Latino population with ESRD. By understanding the palliative care perspectives and barriers experienced by Latinos patients with ESRD, we can move toward a value-based and patient-centered model of palliative care.

Funding: Private Foundation Support

SA-PO785

Symptom Burden Amongst Latinos with End-Stage Renal Disease

Lilia Cervantes, 1, 2 Stuart L. Linas, 1, 2 Stacy M. Fischer, 1 1 Dept of Medicine, Univ of Colorado, Denver, CO; 2 Dept of Medicine, Denver Health and Hospital, Denver, CO.

Background: All patients with end-stage renal disease (ESRD) experience a high symptom burden. Although Latinos represent 19% of the US ESRD community, little research is available on their symptom burden. The purpose of our study was to provide the first description of symptom burden prevalence and severity amongst Latinos with ESRD.

Methods: Observational descriptive survey of adult English and Spanish speaking Latinos with ESRD from a safety-net hospital and two private dialysis centers. We used Davison’s ESAS-r: Renal tool which measures physical and psychological symptom distress progression from chronic kidney disease to end-stage renal disease (ESRD). Despite the first description of symptom burden prevalence and severity amongst Latinos with ESRD, there is limited palliative care research and Latinos are underrepresented in existing palliative care studies. The purpose of our study is to provide the first description of the Latino palliative care perspective.

Results: Participants (n=61) had a mean age of 59 years ± 12, mean Charlson Comorbidity Index of 6.5 ± 2.5, and a dialysis vintage mean of 43.3 months ±44.8. The majority (77%) spoke Spanish and reported limited understanding of hospice and palliative care. We found that 60 (98%) want to be informed about their prognosis and 55 (90%) want to be prepared and plan ahead; however, only 16 (26%) had discussed prognosis and only 10 (16%) had discussed end-of-life care with their nephrologist. The majority of participants stated that it was their doctor’s choice (68.8%) to start dialysis; however, few (14.7%) regret the decision to start dialysis. Participants reported a preference to have advance care planning conversations on a routine basis (86.8%), after starting dialysis but before becoming ill (85.2%), and while receiving dialysis (47.5%) or at home (37.7%). Participants want their family have a central role in medical decision-making (93.4%) and care giving (95%).

Conclusions: Our findings provide the first description of the palliative care perspectives of a predominantly Mexican Latino population with ESRD. By understanding the palliative care perspectives and barriers experienced by Latinos patients with ESRD, we can move toward a value-based and patient-centered model of palliative care.

Funding: Private Foundation Support
was experienced by 83.5% of patients and reported as moderate or severe by 67.2%. Pain was present in 85.6% and moderate or severe in 49.1%. Depression was reported by 55.7% and anxiety by 49.1% and moderate or severe in 49.2% and 39.3%, respectively. The majority (78.6%) of patients reported lack of well-being and feeling drowsy (70.5%). With respect to medication preferences, our cohort prefers Western Medicine (77.1%) over traditional curanderismo (22.9%) medicine and is agreeable (77.1%) to taking a few more medications if it meant all symptoms could be controlled. Our Latino cohort prefers (88.5%) to have their physical symptoms (e.g. pain, nausea) treated by nephrology staff.

**Conclusions:** Latinos with ESRD suffer from a debilitating symptom burden and over half of the symptoms are amenable to symptoms directed therapy. Our findings support the early identification and treatment of physical symptoms by nephrology staff.

**Care of the ‘Failing HD Patient’: Role of a Supportive Care Register Tracy Marvan, Maria Da Silva-Gane, Suresh Mathavakkannam. Renal Unit, Lister Hospital, Stevenage, Hertfordshire, United Kingdom.

**Background:** Older dialysis patients (>70) often have significant comorbidities, that worsen with duration on HD. Continuation of dialysis often occurs at the expense of frequent illness episodes. There is a progressive decline in cognitive and physical function that exacerbates dialysis. We had introduced a Supportive Care Register (SCR) in 2012 to identify ‘failing dialysis patients’ based on their physical performance scores. We attempted to understand whether being on the SCR enabled better patient care when these patients were admitted with inter-current illnesses.

**Methods:** Data was collected from Patient Administration System (PAS) and Renal IT database in a large Tertiary (non-transplanting) Renal Unit serving a catchment population of 1.2 million. Data maintained in the SCR was reviewed. Total number of HD patient admissions to the acute renal service in 2013 were obtained with analysis of demographics, length of stay (LoS) and outcomes at discharge. Patients who were admitted were checked against the SCR entries. **Results:** 287 out of the 409 total HD patients were admitted (123 F, median age 68 years, 590 episodes) with 137 of these patients being admitted more than once. The LoS was 9 days. 49 patients died in 2013 (28M; 76±16 yr; vintage 60 ml; LoS 18±12 p<0.05). 28 patients died in hospital or at home hospice following withdrawal of dialysis and institution of palliative care. 16 patients had died following severe acute illness. Five patients died at home. 18/28 patients were on the SCR and had discussions relating to ongoing and future dialysis therapy and advanced and preferred place of care planning prior to their last admission in the clinic setting. Seven patients had proceeded to discussions regarding resuscitation.

**Conclusions:** In conclusion, establishment of a SCR for dialysis patients with declining functional capacity and significant comorbidities allows for an early identification of patients at risk of physical and functional decompensation. Once identified, establishing a dialogue in the OP dialysis setting about future care needs and expectations allows for a more integrated care approach when patients decompenstate to the point of being unable to continue dialysis.

**Funding:** Government Support - Non-U.S.

**SA-PO787**

**A Descriptive Study of Home Palliative Service Utilization and Care Trajectory Among Patients Dying on Dialysis Gihad E. Nesrallah, 1 Stephanie Dixon, 2 Marnie MacKinnon, 3 Sarah E. Bota, 4 Jade S. Hayward, 5 Erin Arthur, 6 Pernia G. Blake, 7 Amit X. Garg, 8 Sara N. Davidson. 9 Nephrology Program, Humber River Hospital, Toronto, ON, Canada; 1 Inst for Clinical Evaluative Sciences, London, ON, Canada; 2 Ontario Renal Network, Toronto, ON, Canada; 3 Ottawa Health Research Inst, Ottawa, ON, Canada; 4 Faculty of Medicine, Univ of Alberta, Edmonton, AB, Canada.

**Background:** Palliative care service use and outcomes among Ontario’s dialysis recipients remain uncharacterized.

**Methods:** We conducted a descriptive, retrospective, cohort study of 5,507 patients who died while receiving or withdrawing from chronic dialysis (hemodialysis or peritoneal dialysis) in Ontario, between January 1, 2010 and December 31, 2012. Data sources included the Ontario Renal Reporting System, the Canadian Organ Replacement Register, the Home Care database, and other linked administrative health datasets. The date of death served as the index date, and we examined patterns of service use in the prior 365 days. We present selected measures of health service use and outcomes.

**Results:** Cohort characteristics at death, expressed as median (IQR) or percent of cohort included: 75 (16) yrs old, 3.0 (5) yrs on dialysis, 42% female, 65% had diabetes, 14 (4) Johns Hopkins ACG (comorbidity score). Final dialysis modality was 85% centre HD, 1% home HD, 4% PD, 10% missing. During the last year of life, 11.3% received at least one palliative care service in the home, and 17.5% withdrew from dialysis in the last 30 days of life. In the last 14 days of life, 44% of patients had an emergency department (ED) visit and 65.6% a hospital or ICU visit. ED and ICU visits were less frequent among patients who had received home palliative services in the last year of life. Place of death was ICU in 33%, and acute care hospital (without ICU) in 32%, while only 3.6% of patients died at home. Patients with home palliative care services in the last year of life had a greater frequency of death at home (15 vs. 2%) compared with those who did not.

**Conclusions:** Home palliative care services may not be used optimally by dialysis patients in Ontario. Further studies are needed to understand barriers to accessing palliative care services and to improve service planning and delivery.

**Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only**

**Underline represents presenting author.**

**810A**
Explanatory analysis showed that only SQ (OR=2.3, 95% CI 1.05, 4.97) and ALB (OR=0.22, 95% CI 0.10, 0.46) were associated with 6-month MR. Simpler models appeared to perform equally well.

Conclusions: The existing prediction model by Cohen et al. has reasonable discrimination but over-estimated the number of deaths and may require recalibration of model coefficients. The model may guide advance care planning conversations, but caution is required when applying this model in clinical decisions. A simpler model may enhance feasibility for use. Further research is needed prior to utilizing the model to predict death.

Identifying Advanced Chronic Kidney Disease Patients with Same Survival Under Conservative Care versus Dialysis
Crisa P. Kovessy,\(^2\) 1Miklos Zsolt Molnar,\(^1\) Jennie J,\(^2\) Melissa Soocho,\(^2\) Jun Ling Lu,\(^*\) Elani Streja,\(^*\) Lawrence Agogda,\(^2\) Kevin C. Abbott,\(^2\) Paul W. Eggers,\(^2\) Kamyar Kalantar-Zadeh,\(^3\) \(^1\)Univ of Tennessee Health Science Center, Memphis, TN, USA; \(^2\)VA Medical Center, Memphis, TN, USA; \(^3\)Univ of California, Irvine, CA, USA

Background: It is unclear if dialysis offers advantages over conservative care in certain patients with advanced CKD who do not have rapidly deteriorating kidney function.

Methods: From 659,546 US veterans with CKD we identified 9,273 who transitioned to dialysis, and 6,136 who reached eGFR<15 ml/min/1.73m\(^2\), but did not start dialysis. We matched these groups for their eGFR slope and for the last eGFR prior to ESRD, and restricted analyses to patients with no rapid pre-ESRD progression (defined as a slope of <-5 to <0) and pre-ESRD eGFR of 10 to 14.9. We examined all-cause mortality using time-stratified Cox models (by 1-year increments) to account for non-proportionality of hazards.

Results: Of 1,026 veterans included in the analysis, 651 patients did not, and 375 patients did initiate dialysis. Baseline Age, gender, race, eGFR slope and last eGFR, and comorbidities were similar in the dialysis vs. no dialysis groups. Overall, 624 patients died over a median follow-up of 1.5 years. Patients on dialysis experienced lower mortality in the first year (HR, 95%CI: 0.25, 0.17-0.36, p<0.001) and in year 2 (0.67, 0.52-0.87, p<0.003). Among patients who survived at least 2 years (28% of the original cohort), the risk of death associated with dialysis was 28% higher but not statistically significant (1.28, 0.94-1.75, p=0.12) during the subsequent time period. In this latter group baseline slopes were flatter (-2.1(1.3) vs. -1.9(1.2)), but their other characteristics were similar to the overall cohort.

Conclusions: Among patients with eGFR 10-15 ml/min/1.73m\(^2\) and no rapid loss of kidney function, transition to dialysis was associated with survival advantage over a two year time period. However, in 28% of the patients conservative management was not associated with worse mortality. Better characterization of patients may benefit from conservative management warrants additional studies.

Enteric Dialysis – Stabilization of the Gut Microbiome using Probiotics and Prebiotics (Gut-Kidney Connection)
Narayanan Ragathanathan,\(^\star\) Eli A. Friedman\(^\star\) \(^2\) Research and Development, Kibow Biotech Inc, Newtown Square, PA; \(^3\)Downstate Medical Center, State Univ of New York, Brooklyn, NY

Background: Recent scientific evidence from the human microbiome project has revealed that the trillions of gut microbiome exceed the human microbiome by a factor of 10. There are just 23,000 human genes as against the 3.3 million genes coded by the gut microbiome. This complex microbiome has a major role to play in health and diseases. Scientific evidence has shown that there is an imbalance in the ratio of this complex microbial community leads to dysbiosis as a cause for various diseases. The use of beneficial microbes – probiotics and prebiotics is generally well recognized towards digestive, gut and immune health. However, novel and niche application of probiotics and prebiotics as a dietary supplement in stabilization of Gut microbiome towards Chronic Kidney Disease (CKD) is relatively new. Many independent reviews in various scientific journals have reflected on various topics such as gut Microbiome, its dysbiosis, impact of the altered intestinal community leads to dysbiosis a cause for various diseases. The use of beneficial microbes – probiotics and prebiotics is generally well recognized towards digestive, gut and immune health. However, novel and niche application of probiotics and prebiotics as a dietary supplement in stabilization of Gut microbiome towards Chronic Kidney Disease (CKD) is relatively new. Many independent reviews in various scientific journals have reflected on various topics such as gut Microbiome, its dysbiosis, impact of the altered intestinal community leads to dysbiosis a cause for various diseases.

Methods: "Renadyl" a sybiotic dietary supplement was studied in randomized clinical trials in CKD 3 and 4 and ESRD patients. Other oral therapies for removal of uremic toxins include the use of keto acids and charcoal sorbents.

Results: Our studies using Renadyl for "Enteric Dialysis" showed reduced in levels of various uremic toxins like urea and indoxyl glucuronide. Levels of CRP also decreased with improved quality of life. This demonstrates the potential restoration of the gut microbiome dysbiosis with the use of specific strains of probiotics.

Conclusions: The use of a well-researched, clinically documented and safe probiotic / prebiotic dietary supplement formulation has the potential to safely perform continuous enteric dialysis and stabilize the gut Microbiome and its dysbiosis. Hence, the concept of “Enteric Dialysis” with continuous removal of uremic toxins may be the future key to providing an alternative HOPE for renal failure population.

SA-PO792
Charcoal Hemoperfusion in the Treatment of Pruritus in Cholestatic Liver Disease
Wongarm Kittanamongkolchai, Ziad El-Zogby, Nelson Leung, Nephrology, Mayo Clinic, Rochester, MN.

Background: Pruritus is a distressing symptom in a considerable proportion of cholestatic patients and few of them do not respond to conventional treatment. Charcoal hemoperfusion (CH) is an extracorporeal technique to eliminate albumin-bound substances that are accumulated during cholestasis by the passage of blood through a column containing activated charcoal. Several case reports have shown significant reduction of bilirubin in mechanical jaundice and neonatal hemolytic jaundice. However, the published data of CH for the treatment of resistant pruritus in cholestatic patients is scarce.

Methods: Procedure code “Charcoal hemoperfusion” was used to identify patients who received charcoal hemoperfusion at Mayo Clinic, Rochester from 1/1/2000 to 5/1/2015.

Results: Thirteen patients were identified. All patients had failed conservative treatment and 2 of them had not responded to plasmapheresis. A median of 3 (1-9) sessions for a total of 20(1-33) hours were performed. CH resulted in a significant decrease of pruritus in 9 patients (69%). 2 patients did not have significant relief and 2 patients did not pursue further treatments after having adverse reaction during the first session. Median pruritic score significantly decreased from 9/10 (9-10) to 4/10 (0-9) posttreatment (p=0.004). Duration of symptom free period ranged from 8 to 46 days (median 18 days) in 6 patients who returned for follow up. 6 patients (46%) experienced adverse reactions described in Table 1.

Conclusions: Charcoal hemoperfusion is an effective therapy for refractory cholestatic pruritus. However, the improvement is not sustainable and the short benefit should be balanced with the invasive nature of the therapy and the relatively common adverse reactions.

SA-PO793
Strict Adherence to Medicaid InterQual® Criteria Increases Adverse Events and Health Care Utilization in Undocumented Dialysis Patients
S. Jawad Sher, Melissa D. Anderson, Ranjani N. Moorthi, Sharon M. Moc, Michael T. Eadon. Medicine, Indiana Univ, Indianapolis, IN.

Background: Current estimates suggest there are 6000 undocumented ESRD patients in the US that may be ineligible for scheduled hemodialysis. To meet emergency Medicaid requirements, hospitals have sought creative ways to treat undocumented patients. We present data from an undocumented cohort as it progressed through a succession of three periods with different discharge criteria.

Methods: This is a retrospective evaluation of a prospective cohort of 20 undocumented ESRD patients. The patients were followed over 3 consecutive periods (P1, P2, P3) each of 2 months duration. In P1, patients received weekly dialysis. In P2, patients were dialyzed based on strict emergent InterQual® Criteria. In P3, emergent criteria included long interdialytic interval as an additional justification. Adverse outcomes, utilization, and dialysis adequacy in P2 and P3 were compared to P1.

Results: The mean age of the cohort was 35.9y, 39% were female, 45% were employed, and none were US citizens. Emergent dialysis (P2&P3) was associated with increased blood pressure readings, urine output abnormalities (peak K+, mean BUN and serum bicarbonate) as compared to P1 scheduled dialysis (P < 0.05). Emergent dialysis (P2&P3) was associated with an increase in nights hospitalized and ICU days (Fig 1). Strict adherence to InterQual® Criteria (P2) was
associated with increased adverse events with a composite OR for intubation, bacteremia, NSTI/MI, ICU admit, and death of 48 (5.9-391.2) compared to P1. P2 charge estimates increased from P1 ($357,501 v $202,326 per person per year, P<0.0001).

Fig. 1 – Hospital utilization per patient per month. * = P < 0.05.

Conclusions: Strict adherence to InterQual® Criteria increases adverse events and healthcare cost per patient. We must determine better alternatives to emergent dialysis which minimize cost, while maintaining dignity, safety, and quality of life.

SA-PO794
Factors Associated with Withdrawal of Care (WOC) in Maintenance Dialysis Patients Fahad Saeed, Robert Butler, Jesse D. Schold. Nephrology, Cleveland Clinic.

Background: There is paucity of data on factors leading to WOC in dialysis patients. We studied this question by using the NIS dataset, 2005-2011.

Methods: We studied the following six major primary diagnoses: MI, cardiogenic shock, sepsis, stroke, CPR and coma. Effect of age, sex, race, hospitals' profit status and comorbidities were assessed on WOC status. We studied 836563 dialysis patients' admissions, and WOC occurred in 68152 patients.

Results: Male sex, African American and Latino races, smoking, obesity, psychosis and anemia carried lower odds of WOC. Primary diagnoses of CPR, coma, MI, cardiogenic shock, and sepsis; and co-morbidities such as CHF, dementia, HTN, CA, liver disease, paralysis, chronic lung disease, DM, weight loss were associated with higher odds of WOC. Odds of WOC were increased by approximately 6 % per year of patient age. Teaching hospitals had higher odds while private hospitals carried lower odds of WOC status.

Conclusions: Age, non-profit hospital status, coma, metastatic malignancy and weight loss are the most significant factors associated with WOC among dialysis patients. These prognostic data should be considered while treating such patients.

Conclusions: Higher RDW is associated with higher mortality risk in HD patients. It is unclear whether RDW is a risk factor for mortality or an epiphenomenon of underlying biological and metabolic imbalances across RDW categories. Further studies are needed to confirm the findings generated from our study and to determine the mechanisms underlying the RDW-mortality association.

Red Cell Distribution Width and Mortality in Incident Hemodialysis Patients Tania Vashistha,1 Elani Streja,1 Miklos Zsolt Molnar,2 Connie Rhee,1 Steven M. Brunelli,1 Hamid Moradi,1 Tae Hye Kim,1 Vanessa A. Ravel,1 Melissa Sooseho,1 Csaba P. Kovesdy,2 Kamyar Kalantar-Zadeh.1 1UC Irvine; 2UTHSC, DaVita Clinical Research.

Background: Background: Red cell distribution width (RDW) is a measure of red blood cell size and variability that is often used as an indicator of iron-deficiency anemia. Although RDW has recently been found to be associated with mortality in the general population, few studies have examined this association in hemodialysis (HD) patients.

Methods: We examined the association of RDW with all-cause mortality in a cohort of 109,675 incident HD patients from a large dialysis organization during 2007-2011 using Cox proportional hazards regression with adjustment for case-mix (demographics, comorbidities covariates) and markers of malnutrition and inflammation (MICS). RDW was divided into 5 categories:<14.5, 14.5-<15.5, 15.5-<16.5, 16.5-<17.5, and <17.5 %.

Results: The mean age (mean/SD) of the cohort was 63.1±15 years old and included 44% females, 58% diabetics, and 31% African Americans. Higher baseline RDW was linearly associated with higher all-cause mortality risk in both unadjusted and fully adjusted models.

Conclusions: Higher RDW is associated with higher mortality risk in HD patients. It is unclear whether RDW is a risk factor for mortality or an epiphenomenon of underlying biological and metabolic imbalances across RDW categories. Further studies are needed to confirm the findings generated from our study and to determine the mechanisms underlying the RDW-mortality association.

SA-PO796
Association of Pre-ESRD Hemoglobin with Early Post-ESRD Mortality Among U.S. Veterans: A Transition of Care in CKD Study Melissa Sooseho,1 Connie Rhee,2 Vanessa A. Ravel,1 Elani Streja,1 Jennie Jing,1 Danh V. Nguyen,1 Csaba P. Kovesdy,2 Kamyar Kalantar-Zadeh.1 1UC Irvine; 2UTHSC.

Background: Patients with chronic kidney disease (CKD) are often afflicted with anemia. Previous studies have shown that low hemoglobin (HGB) is associated with pre-dialysis mortality in non-dialysis dependent CKD patients, yet the association of HGB levels in the immediate period preceding dialysis (prelude) and early post-dialysis mortality remains unknown. We hypothesized that lower HGB levels are associated with higher post-transition survival in comparison to higher HGB levels.

Methods: We investigated 18,555 US veterans who initiated dialysis between 10/2007-9/2011 and had at least 1 HGB measurement during the 6 month prelude period before dialysis transition. 6 month prelude HGB was used as a continuous predictor of early post dialysis all-cause mortality occurring in the first 3 months after initiation using restricted cubic spline models and Cox proportional hazard regressions. The models were adjusted for age, gender, race, ethnicity, region and primary cause of ESRD.

Results: The analytic cohort was a mean±SD age of 68.8±11 yrs, among whom 30% were African-American, 7% Hispanic and 30% had diabetes as the cause of ESRD. The 6 month prelude HGB average was 10.9±1.6 g/dL. Prelude HGB exhibited a U-shaped association with 3-month post-ESRD all-cause mortality; patients with a 6 month prelude HGB average between 10-11.5 g/dL had better survival, whereas patients with HGB measurements <9 g/dL or >13 g/dL had higher mortality (Figure).
ESA dose was initially 3-fold greater in ESAhr than control patients and remained 2-fold greater by the end of study.

BMI 26.3 ± 11.6 years, 56% were female, and 63% were black. Median (IQR) ferritin and iron levels were 249 (2-497) ng/mL and 50 (5-78) µg/dL, respectively. Over a mean follow-up of 2.84 years, there were 582 deaths. Among subjects with levels in the highest quartile compared to the lowest quartile, both ferritin and iron were significantly associated with reduced all-cause mortality in adjusted analyses, odds ratio (OR) 0.67 (95% CI, 0.46-0.97) and OR 0.60 (95% CI, 0.42-0.85), respectively.

Conclusions: Hemoglobin during the 6 month prelude period prior to dialysis initiation exhibited a U-shaped association with all-cause mortality in the immediate interval post-dialysis with the best survival when HGB was between 9 and 11 g/dL. These results confirm the findings of earlier clinical trials, and support current therapeutic paradigms for management of pre-ESRD anemia.

SA-PO797

Higher Serum Ferritin Levels Are Associated with Better Survival in the HEMO Study

Background: Ferritin is an important indicator of total body iron stores and has been shown to prevent ox-LDL-induced oxidative injury in endothelial cells. Studies regarding the relationship between serum ferritin levels and all-cause mortality in chronic hemodialysis patients are conflicting. The purpose of this study was to determine the relationship between higher serum ferritin levels and death among participants in the Effect of Dialysis and Membrane Flux in Maintenance Hemodialysis (HEMO) trial.

Methods: We studied the association of serum ferritin and iron levels with all-cause mortality among 1799 subjects from the HEMO trial. Cox regression models adjusted for important confounding variables including demographics, comorbidities, treatment assignment, smoking, and albumin.

Results: Mean age was 58±14 years, 56% were female, and 63% were black. Median (IQR) ferritin and iron levels were 249 (2-497) ng/mL and 50 (5-78) µg/dL, respectively. Over a mean follow-up of 2.84 years, there were 582 deaths. Among subjects with levels in the highest quartile compared to the lowest quartile, both ferritin and iron were significantly associated with reduced all-cause mortality in adjusted analyses, odds ratio (OR) 0.67 (95% CI, 0.46-0.97) and OR 0.60 (95% CI, 0.42-0.85), respectively.

Conclusions: Among subjects participating in the HEMO trial higher serum ferritin and iron levels were associated with reduced mortality. We hypothesize that ferritin may play an important role in protecting the endothelium from oxidative stress-induced damage.

SA-PO798

Anemia in Chronic Kidney Disease Patients Could Be Linked to Indoxyl Sulfate Levels

Background: Indoxyl sulfate (IS) is a uremic toxin derived from the action of colon bacteria in dietary tryptophan. This toxin is related to many complications for chronic kidney disease (CKD) patients, including anemia. The aim of this study was to verify the relationship between IS plasma levels and anemia in hemodialysis (HD) patients.

Methods: This transversal study included 18 HD patients (50% men, 54.2 ± 11.6 yrs, BMI 26.3 ± 4.7 kg/m², time on dialysis 51 (30-52) months, all patients received the same erythropoietin dose >7700 U/treatment. Patients were categorized as of 1Q2012 and following 2011 changes to the US ESA labels and reimbursement policy.

Results: The mean of hemoglobin was 11.0 ± 1.28 g/dL and hematocrit of 34.2 ± 3.0%. The mean of IS plasma levels was 23.9 (10.3 - 100.9) mg/L and CRP 3.1 (1.3 - 8.6) mg/dL. Multivariate linear regression analysis adjusted for age, sex, time on HD, albumin, BMI, CRP revealed that serum hemoglobin (p = 0.05; p = 0.01) was independently and negatively associated with IS levels.

Conclusions: This study provided evidence that IS seems be associate with anemia in HD patients and therapeutic strategies in the clinical care to reduce uremic toxins levels may be effective to management of anemia in HD patients.

Funding: Government Support - Non-U.S.
Impact of ESAs and Iron on Survival in Hemodialysis Patients: Which Is the Best, Which Is the Worth? Jacques B. Rottembourg,1 Alain Guerin.2 1Dept of Nephrology, Hôpital de la Pitié, Paris, France; 2Hemodialysis Units, Diaverium, Paris, France.

Background: Appropriate anemia management for Hemodialysis (HD) patients (Pts) is still challenging. Intravenous (IV) iron and erythropoiesis-stimulating agents (ESAs) are the main therapies, with conflicting outcomes. In the unit, pts were treated over the last seven years, cumulative doses of ESAs (darbepoetin alfa [DA]), converted in µg per session, and IV iron (iron-sucrose [IS]), converted in mg per session, were exactly constantly reported. Survival depending on the cumulative dose of each product and both products together were calculated using the Kaplan Meier methodology.

Methods: 300 incident HD pts (67% male) mean[SD] age at start 59.16(13.6) years, were treated for 100,430 dialysis sessions [S], receiving all over 1,192,250 g of DA, and 1,794,050 mg of IS. M Hb level was 11.50±0.77 g/dL, M TSAT 37.18(5.3)% and M ferritin 562(322) µg/L. The M DA dose injected was 12.91(9.39) µg per S. The M IS dose injected was 20.91(11.57) mg per S. Expressing the separate doses of DA and IS received by the pts in three categories for each product, we obtained 9 categories of pts, depending on whether they received low, medium, or high doses of ESA and IS per S: M doses were [5.42(6), 10.86(3), 25.14(14)]µg for ESA, [12.54(5), 18.44(3), 32.31(11.9)] mg for IV iron respectively.

Results: Survival was expressed at 1000, 2000, and 3000 days (d): The better survival was obtained in the group of low ESA and low IV iron, the worst was high ESA and high IV iron. Survival is better with low ESA, whatever is the IV iron dose injected. High ESA dose, whatever IV iron dose is injected, seems to be worth.

Conclusions: Because the majority of patients on HD receives ESA and IV iron, rigorously conducted and adequately powered clinical trials studying the cumulative doses of ESA and IV iron, reflective of present-day practice, are greatly needed.

Impact of ESAs and Iron on Survival in Hemodialysis Patients: Which Is the Best, Which Is the Worth? Jacques B. Rottembourg,1 Alain Guerin.2 1Dept of Nephrology, Hôpital de la Pitié, Paris, France; 2Hemodialysis Units, Diaverium, Paris, France.

Incidental Findings on 15 Fluorodeoxyglucose Positron Emission Tomography Along with Low Dose Computerized Tomography (FDG PET CT) Scans Among Clinically Stable Haemodialysis with Erythropoietin Hyporesponsive and/or Non-Responsive Patient Population: A Retrospective Study | Stanley Fan, Neringa Vilimiene, Muhammad M. Yaqoob.1 Kneet, Germany; 2Barts Health Cardiovascular Biological Research Unit, London, United Kingdom; 3Diaverum, Paris, France; 4Hemodialysis Units, Diaverium, Paris, France; 5Univ of Michigan, Ann Arbor, MI; 6Univ of Tokyo, Tokyo, Japan; 7Anemia Working Group of JDOPPS, Japan.

Background: The aim of this study was to identify the factors that contribute to erythropoietin hyporesponsiveness in patients on maintenance hemodialysis (MHD).

Methods: demographic data, hemoglobin, dose of erythropoietin, biochemical indicators and other related indicators of 80 MHD patients were collected and reanalyzed retrospectively. They were followed up for 12 months. Erythropoietin resistance index (ERI) was used to evaluate the response to erythropoietin in patients in MHD. The ERI was calculated by dividing the weekly weight-adjusted (kg) dose of ESA (IU) by the hemoglobin level (g/dL). Logistic regression study was used to determine the key variables which might be independently associated with erythropoietin hyporesponsiveness in MHD patients.

Results: Mean erythropoietin resistance index (ERI) for the entire study population was 16.1±7.9 µg/kg/dl. 26% patients were erythropoietin hyporesponsive. Patients were divided into two groups according to ERI: ERI<25 µg/kg/dl and ERI>25 µg/kg/dl. In ERI<25 µg/kg/dl cases, the proportion of female gender was higher, hemoglobin and 25(OH)D were significantly lower than that of patients with ERI<25 µg/kg/dl. In addition, comparing with ERI<25 µg/kg/dl patients, body mass index(BMI) and serum cholesterol were slightly lower in ERI>25 µg/kg/dl (p=0.05). Logistic regression study adjusted gender, dialysis periods, BMI, Kt/v, serum cholesterol, serum albumin, and alkaline phosphatase, indicating an independent association between 25(OH)D deficiency and the erythropoietin hyporesponsiveness(HR:4.590, 95%CI:1.277~16.503).

Conclusions: Erythropoietin hyporesponsiveness is prevalent among MHD patients. Female gender and malnutrition are associated with erythropoietin hyporesponsiveness. 25(OH)D deficiency is the main risk factor for erythropoietin hyporesponsiveness. Improving 25(OH)D deficiency and malnutrition may increase the response to erythropoietin treatment in MHD patients.
Hepcidin is a key regulator of iron metabolism and alterations in Hepcidin concentrations in Incident subjects were higher (191 ± 61) vs. Males (n=151, 140 ± 62) and in Females (n=93, 169 ± 69) vs. Males (n=151, 159 ± 71). There were no difference in age, ferritin, and PTH between male and female patients(P=0.05). The mean dosage of erythropoietin was higher in female than in male patients(14934 ± 6927U vs. 13353 ± 7554U,P=0.05). Patients were divided into 3 groups according to the tertiles of ERI and no difference was found in PTH, ferritin, and iron levels among these three groups.

Conclusions: Female hemodialysis patients are associated with higher degree of erythropoietin hyperresponsiveness. Special attention must be paid to them when treatment is made to treat anemia.

SA-PO808
Oral Vitamin C Supplementation Reduces Erythropoietin Requirement in Hemodialysis Patients with Functional Iron Deficiency

Tanjim Sultana, Maria V. DeVita, Michael F. Michelles. Medicine, Lenox Hill Hospital, New York, NY.

Background: Functional iron deficiency (FID) is a major cause of erythropoietin (Epo) hyperresponsiveness and persistent anemia in dialysis patients. Vitamin C acts as a reducing agent and enhances mobilization of the ferrous form of iron to transferrin thus increasing its bioavailability. High dose intravenous vitamin C has been shown to decrease the Epo requirement and improve hemoglobin levels in previous studies. This route has its downside regarding difficulty of use, higher cost and associations with increased oxalate levels and inflammatory markers. Use of oral vitamin C has been limited due to the concerns of low bioavailability and patients compliance to medication. This study assessed the effect of low dose oral vitamin C on Epo dose requirements in stable hemodialysis patients with functional iron deficiency.

Methods: This prospective study included 22 stable hemodialysis patients with functional iron deficiency defined as transferrin saturation (Tsat) <30 % and ferritin levels of >100 mcg/L with Epo requirement of ≥ 4000 u/HD. Patients received oral vitamin C 250 mg daily for three months. Epo dose was adjusted according to unit protocol depending on the hemoglobin level. Hemoglobin, iron and Tsat levels were recorded monthly. None of these participants received iron or renal vitamin supplementation during the study period.

Results: The mean Epo dose was reduced in fifteen patients by 867±1356U/HD (p=0.03). In seven responders there was 33 % reduction in Epo dose from their baseline line. No ill effects of oral vitamin C were observed. Despite adjustment of Epo dose, hemoglobin level was significantly increased from 10.1±0.6 mg/dl to 10.7±0.6 mg/dl (p=0.03). There were no significant change in Tsat and ferritin levels.

Conclusions: Daily low dose oral vitamin C supplementation reduced Epo dose requirements in hemodialysis patients with functional iron deficiency. Despite concerns regarding oral vitamin C absorption in dialysis patients this study indicates Vitamin C is well tolerated and effective.

Conclusions: TSAT 30-50% appears to be protective vs <30%. No TSAT upper limit was evident. There were no SAEs at ferritin. Fe stores across the range studied did not risk at levels, and TSAT associated with ‘risk of ID, CV and GI SAEs.

SA-PO811

Paricalcitol, Klotho and Renal Anemia in Hemodialysis Patients

Miguel Uriol Rivera,1 Sheila Cabello Pelegrín,2 Gonzalo Gómez Marqués,3 Manuel Luque-Ramírez,2 1Nephrology, Son Espases Univ Hospital, Palma de Mallorca, Islas Baleares, Spain; 2Endocrinology, Ramón y Cajal Univ Hospital, Madrid, Spain.

Background: Low Klotho levels, a protein linked to aging, is associated with an increase in the erythropoiesis process (programmed red-cell death). Chronic Kidney Disease is considered as a state of Klotho deficiency. We evaluate the association between plasma sKlotho levels with iron and hematologic parameters, and the influence of paricalcitol on these variables.

Methods: Data were obtained from the MIR-EPO study (EudraCT: 2009-015511-40). Chronic hemodialysis patients were stratified as a function of paricalcitol use (Group A) or not (Group B). Erythropoietin-stimulating agents (ESA) and iron supplementation were administered in order to maintain hemoglobin (HB) between 10.5 and 12.0 g/dl and transferrin saturation (TSAT) ≥ 20%. After a 3-month titration period, sKlotho was measured (month 3 and 6 of follow-up) by ELISA. The changes in sKlotho from month 3 to month 6 (Δ) and their associations with iron metabolism and hematologic parameters as a function of paricalcitol use were assessed.

Results: A total of 31 patients were evaluated (Group A: 23; Group B: 8). Intact parathyroid hormone (iPTH) levels and ESA doses did not change during the study. Mean sKlotho levels decreased at month 6 compared to month 3 in the whole group of patients (527 vs 474 pg/ml, P = 0.001). After adjustment for iPTH and globular sedimentation rate, mean sKlotho levels in the Group A were higher than those observed in the Group B throughout the study (537 versus 401 pg/ml, P = 0.005). A sKlotho correlated with Δ serum iron (r: 0.42, P = 0.020) in the Group A of patients. A cubic regression model showed that Δ sKlotho increased with adjustment for iron supplementation (r: -0.47, P = 0.030) in the Group A of patients. Across all patients in the Group B, a direct correlation was observed for Δ sKlotho and Δ red blood cell count was found (r: 0.73, P = 0.030).

Conclusions: Soluble Klotho is associated with iron metabolism in hemodialysis patients. Higher soluble Klotho levels may be a novel beneficial effect of paricalcitol use on renal anaemia.

Funding: Private Foundation Support
and ΔHb(β=-0.49, P=0.010) was found in the whole group of patients. Interestingly, mean hepcidin levels were higher in Group A than in Group B(992 vs 494 pg/mL, P=0.050) during the study. In the Group A, ΔHepcidin correlated with ΔHb(β=-0.55, P=0.030).

Conclusions: IL-6 and hepcidin are likely related to different iron pools (functional and storage, respectively) since no correlations between their changes were found. Paricalcitol therapy showed an unexpected increase in iron availability for erythropoesis that might be associated with changes in IL-6 and hepcidin levels.

48 Week Open Label Safety Extension Study with Ferric Citrate Demonstrates Favorable Safety Profile in Subjects Not on Intravenous Iron: A Post-Hoc Analysis

Background: Ferric citrate (FC) is an iron-based phosphate binder approved for the control of serum phosphorus levels in patients with chronic kidney disease on dialysis. The Phase 3 pivotal trial in subjects with ESRD demonstrated FC to effectively control serum phosphorus but also significantly increased serum iron parameters. This 48-week open label extension study to the Phase 3 pivotal trial was conducted to demonstrate long-term safety of ferric citrate. The primary data have been reported previously.

Methods: Subjects from the pivotal FC RCT (NCT01191255) who completed the active control period and, if eligible, the placebo control period were eligible to enroll in the safety extension trial. 79% had a time lag between participation in the RCT and this trial. The primary outcome was safety as assessed by lab data and adverse events (AE): 168 subjects enrolled. 166 received a dose of FC. The data presented are a post-hoc analysis of 98 of the 166 subjects that did not receive IV iron for the duration of the 48-week trial. Safety data regarding changes in serum iron parameters and treatment emergent AEs by system organ class are presented.

Results: Of the 98 subjects included in this analysis, 71 subjects were randomized to FC in the previous Phase 3 trial and 27 to the AC group. Table below shows the changes in TSAT and serum ferritin over the 48 wk period. Data presented as mean (SD).

83% of subjects experienced at least one treatment emergent adverse event with the most common being gastrointestinal disorders (40%) and infections and infestations (37%).

Conclusions: Subjects receiving ferric citrate and no IV iron demonstrated serum phosphorus control over the 48 wk study period, and an increase in TSAT and serum ferritin. The increase in TSAT did not exceed 45% in subjects receiving ferric citrate and no IV iron, which might suggest that ferric citrate is absorbed but the risk of excessive iron absorption is low.

Iron Isomaltoside: A Novel Intravenous Iron Preparation for Hemodialysis

David Jackson, Christopher Brown, Grant Sugiuira, Rachel S. Ashcroft, Ashraf I. Mikhail. Nephrology, ABM Univ Health Board, United Kingdom.

Background: Diafer® (iron isomaltoside) is newly licensed in Europe for iron deficiency anaemia in CKD patients on dialysis. It is thought the controlled-release matrix minimises free iron, possibly reducing side effects. Little is known about the efficacy & safety of Diafer in clinical practice. This study aims to assess the impact of this novel formulation on anaemia parameters in prevalent hemodialysis (HD) patients previously maintained on iron sucrose.

Methods: Data was collected for 13 months; 6 month pre-switch (iron sucrose), 1 month crossover, & 6 month post-switch (iron isomaltoside). All patients received dialysis for ≥ 3 months before evaluation, excluding potential bias of iron loading doses. For both preparations, patients received intradialytic bolus doses of 100mg at frequencies dependant on individual requirements as per current practice.

Results: The percentage of patients maintaining Hb target (100-120g/L) was 71% with iron sucrose & 70% with iron isomaltoside. No adverse drug reactions were observed. No metallic tastes were reported with Diafer administration. The CRP rise during months 1-6 was imparted by 2 infections & 1 amputation.

Conclusions: Iron isomaltoside maintains Hb stability & adequate iron status in HD patients when incorporated into current practice. While these data suggest Diafer may reduce ESA & iron requirements, further analyses are necessary to validate these findings. Whether the potential to reduce labile iron with iron isomaltoside impacts on clinical outcomes is yet to be determined.

Low Iron Availability May Influence on Second Patency Rates of Vascular Access in Patients on Hemodialysis

Yukiko Hasuake, Wataru Fukao, Takeshi Nakanishi. Div of Kidney and Dialysis, Dept of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.

Background: Vascular access (VA) is essential for the patients on HD. However, VA failure is often occurred even after percutaneous-transluminal angioplasty (PTA). Iron is important for normal vascular physiology, and insufficient iron availability can lead to various vascular dysfunction. The purpose of this study was to examine the factors affecting VA patency after PTA, including iron availability and oxidative stress.

Methods: Blood samples were taken from 281 HD patients at the PTA. Routine blood chemistries and factors related to iron metabolism (transferrin saturation rate (TST), ferritin), oxidative stress (advanced oxidation protein products (AOPP), 8OHdG, GSH/GSSG), and inflammation (high-sensitive CRP, interleukin-6, tumor necrosis factor-a, pentraxin-3) were measured. The end point of study was the re-vascularization or re-operation of VA during the observational period after PTA. Cox proportional hazards models for the end point was used.

Results: 133 patients (47.3%) had native arteriovenous fistula. During follow-up period, re-vascularization was performed in 34 patients and re-operation in 31 patients. The patients with VA failure had higher numbers of leukocytes and platelet, significantly lower TST, and a tendency of higher AOPP compared with the patients without VA failure. There was no significant difference in other factors between the patients with and without VA failure. The Kaplan-Meier analysis showed lower TST (≤20%) was associated with VA failure (p=0.0010, (figure 1)).
PTA. Low Iron availability might affect the second patency rates of VA.

**Triferic Has a Safety Profile Similar to Placebo: An Integrated Safety Analysis of Phase 2 and 3 Studies**

**Authors:** Vivian H. Ling, Raymond D. Pratt, Carrie D. Guss, Ajay Gupta.

**Methods:** The Triferic clinical program included 3 large placebo-controlled efficacy studies lasting 36 to 48 weeks (Controlled Studies), one large placebo-controlled short-term safety study, 3 open-label (OL) safety studies of up to 48 weeks, and 3 small controlled early Phase 2 studies. Patients randomized to Triferic in the 2 pivotal controlled studies who completed the randomized treatment and transitioned to the OL study received Triferic for up to 72 weeks.

**Results:** Exposure-adjusted most frequent adverse event rates (AE) are presented in the table below.

**Conclusions:** Triferic was well tolerated in long-term controlled and OL studies. Triferic, administered at each treatment, maintained Hgb and iron balance compared to placebo. The safety profile in short and long-term studies supports a favorable benefit-risk profile for use as a maintenance iron therapy for CKD-HD patients.

**Structural, Physical and Functional Characterization of Ferric Pyrophosphate Citrate (FPC, Triferic), A Novel Iron Compound for Pharmaceutical Applications**

**Authors:** Ajay Gupta,1 Garry J. Handelman,2 Raymond D. Pratt,1 1R&D, Rockwell Medical Inc., Wixom, MI; 2Univ Massachusetts, Lowell, MA.

**Background:** Ferric pyrophosphate citrate (FPC) is the first iron compound approved for parenteral administration that is not an iron-carbohydrate complex. FPC has a molecular mass of about 1313 Da, and high solubility of FPC in aqueous solutions allows its administration via the dialysate.

**Methods:** FPC is a complex iron salt in which Fe³⁺ is bound to pyrophosphate (PPi) and citrate by coordinate covalent bonds. Extended X-ray absorption fine structure (EXAFS) spectroscopy showed that the Fe in FPC is in the ferric (Fe³⁺) state and does not complex with sulfate. EXAFS analysis demonstrated that Fe forms a stable complex with 6 O atoms at 2.02 Å in the first coordination sphere and with 2 P and 4 C atoms at 3.22 Å and 2.98 Å, respectively, in the second coordination sphere. FPC demonstrates stability in both the solid and solution forms.

**Results:** The uptake rate of FPC iron by human apo-transferrin was measured in vitro by monitoring absorbance at 411 nm. At an identical set of conditions we observed 75% TF saturation in n=10, 15, and >9 x 10^8 sec for Fe(TNA), FPC and Fe(citrate), respectively. We conclude that TF loading from FPC is rapid and of similar magnitude to that from ferric nitrooacetic acid, but over four orders of magnitude faster than from ferric citrate. The observed rapid binding kinetics allows for facile Fe³⁺ uptake by transferrin for transport to the bone marrow for hemoglobin synthesis. Pharmacokinetic studies of FPC administered IV to healthy volunteers demonstrate dose-proportional kinetics with a t½ of approximately 1.4 hours. No non-transferrin bound iron has been detected at TSAT levels of up to 100%.

**Conclusions:** FPC is a novel iron compound that is ideally suited as a maintenance treatment for CKD 5HD patients. FPC replaces ongoing iron losses and maintains hemoglobin levels. The small doses of iron and the lack of a carbohydrate shell contribute to the favorable safety profile. FPC represents a new paradigm for rational iron replacement in patients on chronic hemodialysis.

**SA-PO818**

**Proton Pump Inhibitors and CYP2C19 Are Associated with Iron-Deficiency Anemia in Hemodialysis Patients: A Cross-Sectional Study**

**Authors:** Akiko Nakashima,1 Ichiro Ohkido,1 Keitaro Yokoyama,1 Mitsuyoshi Urashima,1 Takashi Yokoy,1 1Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan; 2Div of Molecular Epidemiology, Jikei Univ School of Medicine, Tokyo, Japan.

**Background:** Hyporesponsiveness to erythropoietin stimulating agents (ESA) is an important phenomenon in dialysis patients. As chronic proton pump inhibitor (PPI) use reduces gastric acid secretion, it seems possible that chronic PPI use might lead to iron malabsorption and anemia. In addition, PPI is mainly metabolized by cytochrome P₄₅₀ (CYP) enzymes, particularly CYP2C19, in the liver. The genotypes of CYP2C19 affect the pharmacokinetics and pharmacodynamics of PPI. However, there is no study investigating the relationship between PPI use and anemia status that includes the effect of CYP2C19 genotype in hemodialysis patients.

**Methods:** This cross-sectional cohort study analyzed 1530 hemodialysis patients. DNA was isolated from leukocytes in peripheral blood. We used polymerase chain reactions and direct sequencing to analyze CYP2C19 genotypes. We analyzed anemia status with and without PPI usage, including the association with CYP2C19 genotypes.

**Results:** PPI use was associated with a significantly lower mean serum hemoglobin concentration. Iron and TSAT were also lower in PPI users. ESA dosage was significantly higher in patients receiving PPIs(mean [SD] PPI: 5685 [3288] IU/week; non-PPI: 2899 [2734] IU/week; P<0.001), and multiple regression analysis indicated a significant relationship between PPI use and ESA dosage(β: 494.1 [2734] IU/week; P=0.036). CYP2C19 genotypes were significantly associated with iron status and anemia. Multiple regression analysis demonstrated that CYP2C19 poor metabolizer (PM) type was significantly associated with ESA dosage in PPI users (β: 901.1 P<0.001).

**Conclusions:** In this study, we found that PPI use is associated with iron status and anemia in hemodialysis patients. Among the dialysis patients receiving PPIs, CYP2C19 genotype was associated with hemoglobin levels, ESA dosage, and iron status.

A 4-Week Dose Response Study of the Hypoxia Inducible Factor-Prolyl Hydroxylase Inhibitor GSK1278863 in Japanese Anemic Hemodialysis Subjects

**Authors:** Yukihiro Endo,1 Tomoko Kohno,1 Yukiko Imai,1 Natsumi Kawase,1 Katsutoshi Hara,2 John J. Lepore,3 Alexander Ralph Cobitz,4 1Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan; 2GlaxoSmithKline, Tokyo, Japan; 3GlaxoSmithKline, King of Prussia, PA.

**Background:** Hypoxia inducible factor (HIF)‐prolyl hydroxylase inhibitors, such as GSK1278863, are an emerging class of oral agents for treatment of anemia associated with chronic kidney disease (CKD). Dose response of GSK1278863 for anemia correction in Japanese hemodialysis-dependent (HDD) subjects is reported.

**Method:** We evaluated the relationship between GSK1278863 dose and hemoglobin (Hgb) response in Japanese HDD subjects with anemia of CKD in a 4-week, randomized, double-blind, placebo-controlled study (funded by GlaxoSmithKline). Subjects on thrice weekly hemodialysis for at least 8 weeks and with Hgb of 8.5–10.5 g/dl after stopping their

Controlled Trials of Chronic Kidney Disease (CKD): A Meta-Analysis of Randomized Continuous Erythropoiesis Receptor Activator (CERA) for the Anemia of Kidney Disease

SA-PO820

Background: Treatment of renal anemia in hemodialysis (HD) patients requires an adequate ESA dosage to maintain stable Hb levels. Guidelines in Japan recommend determining the ESA dosage based on Hb levels measured twice a month. An algorithm for the administration of continuous erythropoietin receptor activator (CERA) has been prepared and implemented to treat patients on HD. The 2-year study results were previously reported during the ASN Kidney Week 2014 (TH-PO 820).

Methods: Based on the algorithm, CERA was administered for 1 year to 102 HD patients being treated with rHuEPO. After the 1st year, the algorithm was reviewed, and some cases of fluctuating Hb levels because of terminating and restarting CERA administration were found. Therefore, the algorithm was revised. Consequently, CERA administration was continued for another 2 years. The target Hb level was 10.5-11.0 g/dL, and Hb levels, CERA dosages, and iron dosages were investigated. CERA was administered once every 2 weeks, and the dosages were changed within a range of 25 mg/dose based on Hb levels. The standard iron dosage was not changed during the evaluation period.

Results: Hb levels at the baseline and 1, 2, and 3 years after the baseline measurement were 10.9 and 11.1, 11.2, and 11.2 g/dL, respectively. The corresponding CERA dosages administered every 2 weeks, were 62 ± 16, 38 ± 25, 36 ± 23, and 33 ± 21 mg, respectively, and ERI values were 0.11 ± 0.04, 0.06 ± 0.05, 0.06 ± 0.04, and 0.06 ± 0.04, respectively. To reduce fluctuations in Hb levels to a possible extent, terminating CERA administration was avoided. Serum ferritin levels gradually decreased from 147 ± 92 to 122 at the baseline to 112 ± 95, 88 ± 67, and 67 ± 47 ng/ml in the 1st, 2nd and 3rd years, respectively, and weekly iron dosage decreased from 13±1.5 at the baseline to 11 ± 2.6 and 11 ± 2.4 mg in the 2nd and 3rd years, respectively.

Conclusions: Three years of twice-monthly CERA administration, based on the algorithm, could maintain stable Hb levels, improve ERI, and reduce iron dosage. Twice-monthly CERA administration based on the algorithm effectively controlled anemia in HD patients.

SA-PO821
Continuous Erythropoiesis Receptor Activator (CERA) for the Anemia of Chronic Kidney Disease (CKD): A Meta-Analysis of Randomized Controlled Trials Valeria M. Saglimbene, Suetoniu Palmer, Giovanni F.M. Strippoli, D’Aiutamento Medical Scientific Office, Univ of Otahgicho, Choranche Kidney and Transplant.

Background: Targeting high hemoglobin levels with erythropoiesis-stimulating agents (ESA) leads to adverse effects in people with chronic kidney disease (CKD). Whether there are treatment differences between different ESA agents is uncertain.

Methods: We did a systematic review of randomized controlled trials evaluating treatment effects of CERA compared with other epoetins (darbepoeitin alpha and epoetin alpha or beta) or placebo/no treatment, in people with any stage of CKD. We systematically searched Cochrane databases. Results were expressed as risk ratios (RR) and their 95% confidence intervals (CI) for dichotomous outcomes, and mean difference and 95% CI for continuous outcomes using random-effects meta-analysis.

Results: 17 studies involving 5397 participants were eligible. Studies compared CERA with epoetin (n=8 studies), darbepoeitin (n=5), differing frequency (n=2) and dose (n=4). Compared to epoetin and darbepoeitin CERA had similar effects on mortality, hypertension, need for blood transfusion and iron therapy.

Conclusions: This study demonstrated that CERA 1.00 (0.73-1.65) at the baseline to 112 ± 95, 88 ± 67, and 67 ± 47 ng/ml in the 1st, 2nd and 3rd years, respectively, and weekly iron dosage decreased from 13±1.5 at the baseline to 11 ± 2.6 and 11 ± 2.4 mg in the 2nd and 3rd years, respectively.

Conclusions: The factors that influence the risk of CVD death included smoking, history of ischemic heart disease and hypercalcemia. The risk factors occurring heart failure included history of IHD, and it was shown that the effects of smoking and history of IHD on prognosis were stronger than the effects of anemia. The evaluation of changes in Hb over time revealed that the low Hb sustained for a long time would increase the risk. In addition, the risk of death was high in the high-dose rHuEPO group suggesting the risk in the low HbEPO response patients.

SA-PO823
Anemia Management in ESRD Patients Admitted to the Hospital Priyanka Govindan, Arjun V. Sharma, Dept of Nephrology, Univ of Washington Medical Center, Seattle, WA.

Background: Anemia was twice as prevalent in people with CKD (15.4%) as in the general population (7.6%). The prevalence of anemia increased with stage of CKD, from 8.4% at stage 1 to 53.4% at stage 5. Anemia can be managed successfully with appropriate investigations and therapy in the ESRD population. The aim of the study was to see how appropriate the management of anemia was in our hospital in patients on dialysis and to identify areas for improvement.

Methods: Selected patients were those with ESRD on hemodialysis and peritoneal dialysis who underwent in-hospital dialysis at the University of Washington Medical Center from July 1st 2014 to Sep 30th 2014. The patients who had been undergoing dialysis for less than 12 weeks were considered to have AKI and were excluded from the analysis. In addition, the patients who underwent dialysis only in the Intensive Care units were excluded. The data was collected from the electronic medical records of the individual patient charts. Gender, Age, Anemia status, Lowest Hemoglobin, Iron panel, Reticulocyte count were noted in addition to treatment with iron, blood transfusions and ESA.

Results: A total 145 dialysis patients were identified and 65 of them had both ESRD and anemia. 73.86% of these patients were found to be anemic by KDIGO. Patients in the 66-69 age range had the largest number of anemia with a total of 20 falling in this category. 18 patients had a Hb of <6 mg/dl and anemia was not treated with TH-PO 820.

Conclusions: Routine investigations for the management of anemia are being missed regularly. Worse anemia was associated with fewer investigations. We suspect that the management of anemia in patients with ESRD can be improved with more comprehensive labs and therapy. We intend to follow up with an intervention involving the EMR making it easier to work up anemia in the hospital.
SA-PO824

Variability in Hemoglobin (Hb) Levels in Hemodialysis (HD) Patients in the Current Era

**David T. Gilbertson**, 1 **Yan Hu**, 1 **Yi Peng**, 1 **Sarb Shergill**, 2 **Bradley J. Maroni.** 1

1CDRC/MMRF, 2Akebia Therapeutics, Inc.

**Background:** Hb variability in dialysis patients has been characterized using a number of methods. The majority of this work occurred prior to the 2011 change in CMS reimbursement policy and ESA labels. We therefore examined Hb variability and patient demographics from current data and compared the results to those obtained prior to implementation of these policy changes.

**Methods:** We used CMS ERD data to define a cohort of chronic HD patients who were alive from Apr 1 through Dec 31, 2012. Using a method from Ebben et al. (ClinJASN 1:1205-1210, 2006), monthly Hb values were categorized as low (L), intermediate (I), and high (H), where L and H were based on monthly Hb values below or above the 25th and 75th percentiles, respectively. Variability was then classified based on the Hb categories during a 6-month period, resulting in 6 categories of variability (see figure legend).

**Results:** The figure compares the percentage (%) of patients in each Hb variability group in 2004 compared to 2012. The 25th and 75th percentiles in the 2012 data were 10.2 and 11.5. Corresponding 2004 values were 11 and 12.5. Similar % of patients were observed in 2004 and 2012 for the LL and IH categories. A higher % of patients was consistently intermediate (I) in 2012 than 2004 (9.5% vs. 6.0%), whereas a larger % was observed for LI and a smaller % for LH. Compared to the overall 2012 cohort, II patients were older (mean=65.2), and LL or LH patients were younger (mean=58.2 and 57.8). LH had the highest % who were black (48.8%).

**Conclusions:** While Hb levels have decreased during the last few years, Hb variability is still present. The lower % of patients in the LH group is consistent with a narrowing of the overall Hb distribution. Further studies are needed to assess the association of variability with outcomes in the current era.

Prevalence and Predictors of Naturally Occurring Normal Hemoglobin Concentration in Hemodialysis Patients

**Zakaria Abdulnabi, Veeda O. Landers, Shalini Bumb, Abdulah Alrifai, Jay B. Wish, Peter B. DeOreo, Thomas H. Hostetter, Mirela A. Dobre.**

**Case Western Reserve Univ, Cleveland, OH.**

**Background:** Epidemiological data and clinical observations suggest that erythropoietin producing cells exist even in ESRD kidneys. A small subset of ESRD patients have naturally occurring normal hemoglobin levels, without the use of blood transfusions or erythropoetin stimulating agents (ESA), but limited data exists in this field. The aim of this study was to evaluate the prevalence and predictors of naturally occurring hemoglobin concentration ≥ 12 mg/dL in hemodialysis patients.

**Methods:** This analysis is a retrospective chart review of ESRD patients receiving hemodialysis at Centers for Dialysis Care in East Cleveland, OH, from April-September 2013. Data collected included demographics, cause of renal disease, comorbidities, duration of ESRD, dialysis access, indices of dialysis adequacy, systolic blood pressure, hemoglobin level, PTH, albumin, calcium, phosphorus. Multivariable regression models were used to identify independent associations with the outcome of interest.

**Results:** In this cohort of 449 community dialysis patients, the prevalence of naturally occurring hemoglobin level ≥12 mg/dL, without the use of ESA, was 5.3%, slightly higher than previous reports of around 2%. In unadjusted analyses, compared to ESRD patients with a hemoglobin level >10 mg/dL, maintained with the use of ESA, the patients with naturally occurring hemoglobin level ≥12 mg/dL were more likely to be younger, male, with an arteriovenous fistula, longer dialysis vintage, lower systolic blood pressure and higher serum albumin level. In adjusted analyses, male sex, serum albumin and systolic blood pressure were the strongest predictors of naturally occurring higher hemoglobin concentration. Further studies to evaluate the mechanisms underlying these associations, including factors stimulating sites of extrarenal erythropoiesis are warranted.

SA-PO826

Estimation of Pre-Dialysis Hemoglobin Concentration Using the Crit-Line®

**Monitor Stephanie Thijssen, Hanjie Zhang, Doris H. Fuertinger, Peter Kotanko.**

**Renal Research Inst, New York, NY.**

**Background:** Pre-dialysis laboratory measurements of hemoglobin (Hb) are generally used for anemia management. In some clinics, bi-weekly or even weekly Hb measurements are performed for this purpose. The Crit-Line® Monitor (CLM) provides Hb non-invasively and continuously during hemodialysis (HD), but initial readings early during HD are systematically lower than pre-HD laboratory values due to hemodilution caused by the priming fluid. We present a method of correcting CLM Hb for hemodilution.

**Methods:** Pre-HD reference Hb (Hb_Comp) was measured by Spectra East Laboratories. Hb obtained by CLM (Hb_CLM) was averaged between minutes 4 and 6 after start of the HD treatment. The difference between the two (Hb_Comp - Hb_CLM) was estimated as ΔHb = (V_sal * 0.5 * (t_CLM/1.2 _sal) - V_CLM) * Hb_CLM/BV, with V_sal = amount of priming fluid (saline) infused at start of HD, t_clm = time point of Hb_CLM measurement (5 min into HD), t_1/2_sal = plasma half life of infused saline (20 min, adapted from ATC Consensus Statement, 2004). V_CLM = cumulative ultrafiltration volume up until t_clm, and BV = pre-HD blood volume (obtained by estimating post-HD BV via Nadler equation (using post-HD weight, sex, height), then dividing by end-HD relative blood volume and subtracting V_sal). Corrected Hb_CLM was calculated as Hb_corr = Hb_CLM + ΔHb.

**Results:** 5,731 HD treatments from 952 chronic HD patients in the USA were analyzed. Without correction, Hb_CLM was found to be systematically lower than Hb_Comp by on average 0.425 g/dL (SD 0.59 g/dL). After correction for hemodilution, the difference (Hb_corr - Hb_Comp) was reduced to -0.008 g/dL (SD 0.59 g/dL).

**Conclusions:** When applying a correction for the hemodilution caused by infusion of the priming fluid at the start of the HD, Crit-Line® Hb is nearly identical on average to the pre-HD Hb measured by a reference laboratory. More and more clinics are employing Crit-Line® Monitors for fluid and anemia management. Crit-Line® Hb corrected in this way may be used for anemia management, which could reduce blood draws and costs.

SA-PO827

Hemodialysis (HD) Patients Who Can Maintain Fair Hb Level (>10g/dl) without Iron or Erythropoietin (Epo) Administration Showed Higher Serum Soluble Transferrin Receptors(sTfR) and Normal Epo, Vitamin C (VC) Levels

**Norioko Saito, 1 Kazuhide Saito, 1 Tetsuo Morioka, 1 Hisaki Shimada, 1 Kozo Ikarashi, 1 Yutaka Tsutaba, 2 Shunsuke Sakai, 2 Shigeru Miyazaki.**

**1Nephrology, Shironaku-en Hospital, Niigata, Japan; 2Urology, Niigata Univ, Niigata, Japan.**

**Background:** HD patients have severe anemia and their Hb levels were recommended to be maintained at greater than 10g/dl using iron and Epo supplementation. Certain HD patients showed Hb levels ≥10g/dl without iron or Epo. We evaluated the predictors of good erythropoiesis and iron metabolism markers in these patients in order to analyze the background mechanism.

**Methods:** 21 HD patients who could maintain Hb level at 10g/dl and greater without iron or Epo for more than 3 months (G1) were enrolled in this study. 23 HD patients with Hb level less than 10g/dl without iron or Epo for more than 2 months (G2) and 30 healthy volunteers (G3) were also enrolled as control. Blood samples were collected before HD and Epo, hepcidin (HPC), sTfR, VC and standard hematological parameters were examined. The data are indicated as median (interquartile range).

**Results:** In G1, ferritin(20(14-36) ng/ml), transferrin saturation(14(8-19)%), HPC(0(0.7-0.2-4.5)mg/ml) were significantly lower than those in both G2 and G3, respectively. The percentage of hypochromic RBCs(%HypoHe)(2.7(1.5-4.8)%) was higher than those of GN and G2. 2. MCV values were not significantly different in all three groups. 3. sTfR level, a marker of erythropoietic activity, of G1(30.0(22.1-36.5)nmol/L) was significantly higher than those of GN and G2. 4. Epo level(7.3(5.1-15.2)mIU/mL), reticulocytes(12(9-15)‰) were significantly different from those of GN, whereas significantly higher than those of G2, respectively. 5. In G1, negative correlation was revealed between VC and %HypoHe(ρ=-0.473, p<0.048), whereas positive correlation between %HypoHe and sTfR(ρ=0.816, p<0.001). By multivariate analysis, %HypoHe was the predictor of sTfR(β=0.834, p<0.001).

**Conclusions:** HD patients with fair Hb level revealed higher sTfR, %HypoHe and normal Epo, MCV, VC and low HPC levels. These results indicated that iron utilization of these patients was upregulated and this may participate in the maintenance of erythropoiesis.

SA-PO828
Acute Effects of Erythropoietin Administration on Blood Pressure in Dialysis Patients  
Nawf Hamad Al-Gublan, Kristin M. Corapi, Ishir Bhan.  
Nephrology, Massachusetts General Hospital, Boston, MA.

Background: Erythropoiesis-stimulating agent (ESA) doses are often held in patients with end stage renal disease (ESRD) because of hypertension. However, missed doses may exacerbate anemia of chronic disease. The acute effects of ESA on blood pressure are unknown. We hypothesized that ESA administration during dialysis would not be associated with a significant change in blood pressure.

Methods: With institutional review board approval, we retrospectively reviewed the medical records of 100 hemodialysis patients who were admitted to our hospital between 1/2013-4/2015. All patients in this study were prescribed, and received, ESA’s during dialysis. Patients were excluded if dialyzed in the ICU, received vasopressors, were treated for hypertensive urgency (>180/110 mmHg), initiated on hemodialysis, or only underwent ultrafiltration without dialysis. Blood pressure just prior to and 2 hours after ESA were compared using a paired t-test.

Results: The mean age was 61.6 years (±12.8), 42% were male, 66% were Caucasian, 16% African-American, and 10% Asian. Mean change in blood pressures immediately prior to ESA administration and 2 hours after are summarized.

<table>
<thead>
<tr>
<th>Pre-Dialysis</th>
<th>Just Prior to ESA</th>
<th>2 Hours Post ESA</th>
<th>Mean Change (95% CI)</th>
</tr>

</tr>
<tr>
<td>DBP</td>
<td>68±11</td>
<td>67±10</td>
<td>-1.2 (0.25)</td>
</tr>
</tbody>
</table>

No statistically significant increase in SBP or DBP was noted. In fact, we observed a significantly lower SBP 2 hours after ESA dosing. In a subgroup analysis of patients with an SBP > 160 immediately prior to ESA administration, an even greater decrease in SBP was noted 2 hours after ESA compared to a subgroup with an SBP < 160 (p=0.004).

Conclusions: We demonstrated a decrease in systolic blood pressure 2 hours after ESA administration with no significant change in diastolic blood pressure. Withholding ESA during dialysis due to hypertension may be unnecessary.

SA-PO829
Serum Ferritin Predicts Mortality Regardless of Inflammatory and Nutritional Status in Incident Peritoneal Dialysis Patients  
Erika Schröder, Tae-Hyun Yoo, Shin-Wook Kang.  
1 Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea; 2 Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Serum ferritin levels have been proposed as a prognostic factor in hemodialysis (HD) patients, due to its close relationship with inflammation and malnutrition. Since iron supplementation methods and factors affecting nutritional status are somewhat different from those of HD patients, the impact of serum ferritin on clinical outcomes was investigated in incident peritoneal dialysis (PD) patients.

Methods: A prospective cohort of 408 PD patients from the Clinical Research Center for End-Stage Renal Disease was selected. Patients were divided into three groups according to tertiles of Ln ferritin concentrations (group 1: ≤4.69 ng/mL, group 2: 4.69-5.58 ng/mL, group 3: ≥5.58 ng/mL). Cox proportional hazard analysis was performed to determine the independent prognostic value of serum ferritin levels for all-cause mortality.

Results: The mean age was 52.1±13.2 years and 236 (57.8%) were male. During a median follow-up of 25 months, 46 (11.3%) patients died. Univariate Cox analysis revealed that the mortality risk was significantly higher in group 2 [hazard ratio (HR)=2.65, 95% confidence interval (CI)=1.11-6.34, P=0.029] and group 3 (HR=3.16, 95% CI=1.33-7.48, P=0.009) compared to group 1. Moreover, multivariate Cox proportional hazard models revealed that Ln ferritin was independently associated with an increased risk of all-cause mortality (per 1 ng/mL increase, HR=1.94, 95% CI=1.31-2.88, P<0.001), even after adjustment for variables representing inflammatory and nutritional status.

Conclusions: Higher serum ferritin level was a significant independent risk factor for all-cause mortality regardless of systemic inflammation and nutritional status. Therefore, determining serum ferritin levels could be a useful marker to predict clinical outcomes in incident PD patients.

SA-PO830
Improving Anemia Therapy in Hemodialysis Patients: Interim Results of a Clinical Audit  
Juan M. Ardavin Ituarte, Antonio Sousa, Erika Schröder, Fundação Renal Portuguesa, Portalegre, Portugal; 1Via Medis, Riesa, Germany; 2Oxylse Ltd, London, United Kingdom.

Background: An earlier pilot audit (ASN 2013, PUB200) suggested that the use of a novel bloodline (Oxylse), which reduces the contact between blood and air, could improve the acute effects of Erythropoiesis Stimulating Agent (ESA) therapy by prolonging red cell survival. The aim of this investigation was to explore this effect in a larger population.

Methods: Patients (n=110; >18 years, HD ≥ 3 months via AV fistulae) were entered into a 6-month open label, single crossover audit following a 3 month Run-In. Patients reverted to control bloodlines (Nikkiso/Gambror) in the Crossover phase after treatment with Oxylse. Hemoglobin (Hb) levels, IV iron sucrose and ESA doses were reported.

Results: Data analysis was conducted on 66 patients from two clinics. Twenty six patients dropped out due to transplantation and intercurrent events, death (n=14) and clinic transfers (n=4). Hb was maintained over the Treatment phase (11.22-11.34 g/dL). Mean ESA doses reduced by 34% (p<0.01) at month 8, equal to 1,909 IU/week/patient. IV iron dose did not change significantly during the audit.

Patients of a shorter dialysis vintage (<4 years, n=35) showed a greater reduction in ESA usage (-42%, p<0.01) compared with those of a longer vintage (>4 years, n=31, -23%). By month 11 (Crossover) ESA doses increased by 9.7 IU/week/kg; 32% of the reduction seen during Treatment.

Conclusions: The reduction in ESA doses observed during Treatment, and the initial reversal in the Crossover, suggest that this novel bloodline can improve anemia therapy in HD patients. The audit design increases the confidence in the data validity. These results could have clinical and financial benefits for HD service delivery.

First in Human Feasibility Study Assessing the Tablo Hemodialysis System  
Luis E. Morales-Buenrostro, 1 Jose Antonio Nino-Cruz, 1 Javier Zúñiga-Varga, 1 Juan M. Arduvin Juarte, 2 May L. Yau, 2 Luis Alvarez, 2 1 Dialysis Dept, Neftos Investigacion SC, Mexico City, DF, Mexico; 2 Outset Medical Inc, San Jose, CA; 3 Palo Alto Medical Foundation, Menlo Park, CA.

Background: Self-care, at home or in-center, is a must for patients who want more independence and control, or have geographical or mobility constraints. Widespread adoption of this modality requires an easy to use dialysis machine with real-time water treatment capabilities. We conducted a first in human feasibility study to assess the safety and performance of the Tablo™ Hemodialysis System, that may meet these requirements.

Methods: We enrolled 5 patients receiving hemodialysis 3 times/week, with a well-functioning fistula or high-flow catheter. Primary outcomes of measure were Kt/V and adverse events.

Results: A total of 27 treatments in 5 patients were analyzed. Patients had the following characteristics: 40% female (n=2), mean age of 50 years, weighed 66 kg, height of 160 cm, 40% (n=2) fistula, 60% (n=3) high-flow catheter, average treatment time of 183 minutes, average fluid removal of 0.57 L, 80% (n=4) had an unknown etiology of ESRD, and 20% (n=1) had hypertension. Heparin was administered in 52% of treatments. The average single pool Kt/V was 1.4. One patient had only one treatment and was withdrawn from the study due to commute issues. Subjects were monitored during dialysis treatment by in-center staff, per institutional protocol. Only one interdialytic event, mild headache, was reported. In total, 3 subjects reported cramping (n=6/27 treatments) and 1 had hypotension (n=1/27 treatment). There were no unanticipated adverse events, serious adverse events or deaths in the study.

Conclusions: The Tablo™ Hemodialysis system was safe and showed good performance during treatments with shorter times, minimal fluid removal and heparin utilization. The standards of conventional dialysis were maintained without serious adverse events related to the device. The incorporation of an integrated water treatment module and touchscreen with animated step by step instructions was extremely easy to use. This system will allow self-care access, both in-center and at home, in a larger number of patients.

The Big Red Kidney Bus: Mobile Dialysis Holiday Peter G. Kerr,1 Lesley Ross,1 Jo M. Fairbairn,2 Anne C. Wilson.3 ‘Nephrology, Monash Health, Clayton, Vic, Australia; 2Kidney Health Australia, South Melbourne, Vic, Australia.

Background: The availability of hospital based hemodialysis for those wishing to travel is scarce and often results in restricted opportunities for patients on dialysis to have a holiday. The Kidney Health Australia (KHA) and Monash Health (MH) Big Red Kidney Bus Project (BRKB) offers patients the ability to dialyse on the BRKB whilst on holiday at one of a range of Victorian tourist destinations.

Methods: The aim of the BRKB Project is to provide safe, fully staffed mobile haemodialysis care, to enable people, their families and carers to take a break. KHA owns the bus, manages the bookings and marks the BRKB nationally. MH, a regional health care provider oversees the clinical assessment and treatment and provides medical supervision, dialysis nurses and renal technicians.

The BRKB is a modified bus accommodating 3 hemodialysis machines, dialysis chairs and complete water treatment. Typically, holiday dialysis on the BRKB operates across 2 sessions per day, 6 days per week duplicating the dialysis parameters of the patients’ home unit.

The bus is driven to and parked at caravan parks around Victoria for 6-week periods, during which time patients may book in for dialysis sessions. Their accommodation is up to them to decide on – with the option of using cabins in the parks or local motels (or their own caravans).

Results: Since its inaugural visit in October 2014, 148 different patients have taken advantage of the BRKB. The bus has visited 6 sites around the State and has site bookings for the next 10 months. Participating holiday-makers were overwhelmingly positive about the service. They found the booking system easy to use. The dialysis service on the bus was delivered to the standard of care experienced at their home units. The professionalism of the nursing staff and friendliness was commended and all participants would recommend the service to others. Most had actively recommended the service to others.

Conclusions: The BRKB is a unique project that provides patients with the opportunity to dialyse on the bus while taking a much-needed holiday.

Patient and Caregiver Values, Beliefs and Experiences when Considering Home Dialysis as a Treatment Option: A Semi-Structured Interview Study Rachael C. Walker,1 Kirsten Howard,1 Rachael L. Morton,1 Suettania Palmer,2 Mark R. Marshall,1 Allison Tong.3 1Univ of Sydney; 2Univ of Otago; 3Middlemore Hospital, New Zealand; 4Univ of South Australia.

Background: Home dialysis is associated with higher quality of life and economic benefits to health care systems compared with facility dialysis. However, little is known about the decision-making process of patients when considering home dialysis as a treatment option.

Methods: This semi-structured interview study aimed to describe patient and caregiver values, beliefs and experiences when considering home dialysis, to inform policy and practice strategies that align with patient preferences. We conducted semi-structured interviews with adults with CKD Stage 4-5D (on dialysis <1 year) and their caregivers, treated in 3 nephrology centers in New Zealand. Transcripts were analyzed thematically.

Results: 43 patients (18 pre-dialysis, 13 peritoneal dialysis, 4 home hemodialysis and 9 facility hemodialysis) and 9 caregivers participated. We identified 5 themes related to decision-making when considering home dialysis; lacking decisional power (complexity of information, limited exposure to home dialysis, feeling disempowered, deprived of choice, pressure to choose); sustaining relationships (maintaining cultural involvement, family influence, trusting clinicians, minimizing social isolation); reducing lifestyle disruption (sustaining employment, avoiding relocate, considering additional expenses, seeking flexible schedules, creating free time); gaining confidence in choice (guarantee of safety, depending upon professional certainty, reassurance of peers, overcoming fears); and maximizing survival.

Conclusions: Patients feel disempowered when choosing home dialysis and make decisions that sustain their relationships, maintain lifestyle values and maximize survival. Confidence in their modality decision is gained by medical professional and peer support combined with overcoming safety concerns. Pre-dialysis programs that address these patient experiences may support home dialysis as a treatment option.

SA-PO834

Patient Experiences of Training and Transition to Home Hemodialysis: A Longitudinal Mixed Methods Study Camilla Sara Hansen,1,2 Jeremy R. Chapman,3 Jonathan C. Craig,4 David C. Harris,4 Lukas K. Kairaitis,5 Mary Ann Nicdao,6 Mary Mikhaeel,7 Allison Tong.1,2 ‘School of Public Health, The Univ of Sydney, Sydney, NSW, Australia; 3Centre for Kidney Research, The Children’s Hospital at Westmead, Sydney, NSW, Australia; 4Centre for Transplant and Renal Research, Westmead Hospital, Sydney, NSW, Australia; 5Dept of Renal Medicine, Westmead Hospital, Sydney, NSW, Australia.

Background: Home hemodialysis (HD) can offer better survival and quality of life outcomes compared with in-centre HD. However, psychosocial barriers such as fears of needles and medical isolation may limit home HD uptake. This study aims to describe patients’ perspectives on training and transition to home HD; to inform strategies to optimize home HD programs.

Methods: Three semi-structured interviews were conducted prospectively with 20 patients before, during and after home HD training at an Australian renal unit. The CHOICE satisfaction survey was administered during the first and final interview. Transcripts were analyzed thematically.

Results: We identified six themes: persevering despite trepidations (intimidation of machinery, acquiring to fatal risks, reconciling cunatrations, dispelling concerns of neglect, tolerating concessions); optimizing learning pathway (practicing problem solving, learning from mistakes, grasping technical complexity, minimizing cognitive overload); developing confidence (believing in own abilities, depending on caregiver partnership, faith in crisis support); interrupted transition momentum (lacking individual attention, language barriers, installation delays, illness and complications, acclimatizing to new conditions); noticing immediate gains (reclaiming normality, satisfying self-sufficiency, personalizing treatment regime); depleting resources and energy (exhaustion, draining financial reserves, imposing caregiver burden). There was no significant change in satisfaction with care after commencing home HD.

Conclusions: Individualized home HD training fosters confidence and competency in patients; however patients may face anxiety and exhaustion with medical responsibilities. Ensuring access to respite, medical assistance, and psychosocial support may alleviate treatment burdens for patients commencing home HD.

Funding: Private Foundation Support

SA-PO835

Incremental Hemodialysis, Residual Kidney Function, and Mortality Risk in Incident Hemodialysis Patients Yoshitsugu Obi,1 Elani Streja,2 Connie Rhee,3 Vanessa A. Ravel,4 Alpesh Amin,5 Csaba P. Kovesda,6 Rajnish Mehrotra,3 Kamnyar Kalantar-Zadeh7.1 UC Irvine; 2UTHSC; 3UW.

Background: We have previously reported that an incremental hemodialysis regimen (e.g., dialysis initiation at twice weekly) was associated with more preserved residual kidney function over a year of dialysis therapy (WCN 2015, Cape Town). Here, we compared survival between the incremental vs. conventional regimen.

Methods: In a longitudinal cohort of 33,277 patients who initiated maintenance hemodialysis over four years (1/2007-12/2010) and survived the first year, 364 patients treated with the incremental regimen were matched to 4,797 patients treated with the conventional regimen on age, gender, race, the use of central venous catheter as blood access, and a history of congestive heart failure at the initiation of dialysis. The incremental hemodialysis regimen was associated with ~20% higher residual renal urea clearance (KRU) and 24-hr urine volume (UV) after 1 year of dialysis initiation. We then examined survival after the first year.

Results: Patients were 69±12 years old, 39% female, 13% non-Hispanic Black, and 66% diabetic. Median KRU and UV were 4.74 (IQR, 3.23-6.65) mL/min/1.73m2 and 1,150 (IQR, 800-1,650) mL/day, respectively. Baseline KRU and UV modified the association between the incremental regimen and mortality: the incremental regimen was associated with higher mortality in patients with KRU <3.0 mL/min/1.73m2 or UV <600 mL/day, but not in those with higher levels of KRU and UV.

Seasonal Trends in Dialysis Initiation and Rising Home Dialysis: Results from the USRDS
Hui Liu,1 Yang Jiao,2 Douglas Lehmann,2 Richard Hirth,3 Yi Li,4 Rajiv Saran.1 1Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI; 2Dept of Biostatistics, Univ of Michigan, Ann Arbor, MI; 3Dept of Health Management and Policy, Univ of Michigan, Ann Arbor, MI.

Background: Motivated by increasing interest in home dialysis and incentive for it in the bundled payment system, we examined incident trends in home dialysis use in the United States Renal Data System (USRDS).

Methods: Using USRDS data (2007-2013), monthly counts of all new ESRD cases in the US, as well as incident home hemodialysis (HHD) and incident peritoneal dialysis (PD) patients were tracked. Incident HHD patients were those who started HHD within 90 days of entry into an ESRD program and incident PD patients who started PD as their initial modality.

Results: In 2013, over 55% of US facilities offered only in-center HD, 24.7% both HD and PD and 13.5% offered HD, PD and HHD. Figure 1 shows trends in monthly ESRD and PD utilization in the US during 2007-2013. The incidence rate of ESRD has been stable since 2010, but the number of new PD starts has risen steadily since 2009 and has somewhat further accelerated since 2011. Figure 1 also shows a seasonal trend for new ESRD and PD starts: incident ESRD cases tend to peak in the first 3 months of the year, while new PD starts tend to peak by mid-year. Rising HHD use is evident since 2007, without seasonal variation. A substantial variation in the annual growth rate of PD is notable across the states.

Conclusions: We report steady rising home dialysis use in the US, both HHD and PD, since 2007 and 2009, respectively. This rise predates the implementation of the bundled payment system in 2011, although PD use seems to be rising faster since 2011. Research into this seasonality in ESRD incidence and the impact of rising home dialysis use are warranted.

SA-PO838
Understanding Barriers to Home-Based and Self-Care In-Center Hemodialysis
May L. Yau,1 Luis Alvarez,2 Michelle Carver,3 Geoffrey A. Block,2 Glenn Matthew Chertow.1 1Outset Medical, Inc, San Jose, CA; 2Sutter Health, Menlo Park, CA; 3Denver Nephrology, Denver, CO; 4Stanford School of Medicine, Palo Alto, CA.

Background: Despite superior outcomes and lower associated costs, few patients with end stage renal disease undergo selfcare (SC) or home hemodialysis (HHD). Few studies have examined patient and physician barriers to SC and HHD and the degree which innovative technology might facilitate adoption.

Methods: We surveyed 250 in-center patients (pts) receiving hemodialysis and 51 board-certified nephrologists to identify key barriers to adoption of SC and HHD.

Results: Overall, 172 (69%) pts reported that they were “likely” or “very likely” (figure 1) to consider SC hemodialysis if they were properly trained on a new hemodialysis system designed for SC.

Conclusions: We report steady rising home dialysis use in the US, both HHD and PD, since 2007 and 2009, respectively. This rise predates the implementation of the bundled payment system in 2011, although PD use seems to be rising faster since 2011. Research into this seasonality in ESRD incidence and the impact of rising home dialysis use are warranted.

SA-PO838
Dialyzer Clearance, Residual Renal Function and Middle Molecule Levels in Daily Dialysis
Christos Argyropoulos, Maria-Eleni Roumelioti, Mark L. Unruh. Internal Medicine, Div of Nephrology, UNM-HSC, Albuquerque, NM.

Background: Beta 2 Microglobulin (B2M) has emerged as a predictor of cardiovascular morbidity, mortality and LVH in patients with CKD and ESRD. Daily dialysis leads to higher B2M removal and has been associated with improvements in LVH and mortality in randomized trials. It is not known how B2M levels vary with dialysis membrane clearance (Kd) in daily dialysis regimes.

Methods: We adopted a population kinetic model (PKM) for the intraindividual variability in the generation, distribution and extrarenal removal of B2M (ASN 2014-SA-PO969). We used the PKM to simulate B2M concentrations in patients dialyzed with HF membranes in thrice weekly or daily sessions. For the latter we applied the intervention protocols for Short (SD) and Long Daily (LD) dialysis utilized in the FHN trials. The impact of Kd relative to residual renal function (RRF) on B2M was examined across the three dialysis modalities.

Results: B2M was lower in SD or LD relative to thrice weekly HF dialysis irrespective of RRF, the highest differences from HF (∆, 95%CI were obtained in anuric pts: 7.5, 7.4-7.6 mg/dl) at higher RRF irrespective of modality.

Conclusions: In simulations, higher dialyzer clearance is associated with lower plasma B2M in patients on daily dialysis, especially at lower levels of RRF. Whether these differences translate to improved cardiovascular outcomes should be confirmed in clinical studies.

There were significant interactions (p<0.001) between modality and RRF, as well as modality and Kd. A Kd of 60 ml/min resulted in lower B2M in LD and SD v.s. HF patients.

The differences between lower and higher dialyzer clearances were minimal (<1.1 mg/dl) at higher RRF irrespective of modality.

Nephrologists believed that pts were capable of performing dialysis-relevant tasks, including: weighing themselves (98%), wiping down the chair and machine (84%), clearing alarms during treatment (53%), taking vital signs (46%), and cannulating vascular access (41%), but thought that patients would not be willing to do the same.

Wessex Kidney Centre Experience of Nocturnal Home Haemodialysis Using the NxStage System One Venkat Gangaram, Amanda Jane Laird, Laura Hignell, Natalie L. Borman. Renal Medicine, Wessex Kidney Centre, Queen Alexandra Hospital, Portsmouth, United Kingdom.

Background: Wessex Kidney Centre (WKC) Portsmouth established Home Haemodialysis (HHD) programme in 2009. In the absence of an in-house technician and limited capital the programme was set up using NxStage system one (NSO). WKC has now established a rapidly growing HHD programme has been excellent with self reported 97 patients to date includes nocturnal therapy.

Results: A total of 18 patients have received NHHD with mean time of 12.3 months (range 1 to 31). All patients dialyse alternate nights processing 40-60 litres using dual needleling access and a single bolus of Enoxaparin Sodium. Patients have regular transonic monitoring of their access and home visits. Two NHHD patients successfully dialyse alone. The mean age is 47.7 years (range 26 to 80), 78% male, 94% Caucasian with mean BMI 26.9. The Access used was AV fuma 56%, AV graft 22% and CVC 22% of patients. 14 patients changed from short daily HHD (SDHHD), 3 patients from in-centre Haemodialysis and 1 from Peritoneal dialysis. Laboratory parameters have been favourable as shown below.

Retention has been excellent with one patient returning to in-centre HD after 25 months of HHD. Two patients switched to SD HHD as it more suited to their lifestyle and five patients have been transplanted. Pill burden has reduced, with less or no phosphate binders (mean number of binders reduced from 6 to 2) and a 40 % reduction in antihypertensive medication. Patients experience improved improvements in quality of life including facilitating return to employment. A number of patients have successfully travelled taking their NSO both within UK and abroad.

Conclusions: In Conclusion, NHHD using NSO is a viable alternative for HHD patients with our data suggesting good clinical outcomes. Patients have improved quality of life and with less pill burden, flexibility and more opportunity to engage in social activities.

SA-PO840
Current and Future Training of Home Haemodialysis Nurses Ruth Silverton, 1 Philippa Catherine Brown, 1 Paul Laboi, 1 Nicola Thomas. 1 Dept of Renal Medicine, York Hospital, United Kingdom; 2School of Health and Social Care, London South Bank Univ, United Kingdom.

Background: The UK National Institute for Health and Care Excellence recommend that >10% of dialysis patients be treated by home haemodialysis (HHD), however only 4.1% of patients in the UK are undergoing this modality. Success with HHD can be attributed to a supportive health policy, formal infrastructure, committed individuals and home dialysis experience; providing a patient-centred approach. Lack of nursing expertise is reported as a barrier to home dialysis for 30% of patients. A 2010 survey by the Australian HOME network revealed insufficient resources in dialysis units to provide support and education to patients. A potential barrier to HHD in the UK is specific training for renal nurses on the facilitation of shared or self-care.

Methods: The extent of current training provision for dialysis nurses in order to educate patients in home therapies/shared care was evaluated via an online survey. A link to the survey was sent to the British Renal Society database and the survey was available online for 1 month. There were 63 respondents.

Results: Over 76% of respondents (n=48) had worked in renal care for >10 years, with a third (n=21) receiving more than 5 days of structured training in how to teach self care. The majority of this training (51%) was as part of an ‘in-service programme’, with just over half (53%) of all nurses surveyed feeling adequately prepared for educating patients. The preferred mode of further training was face to face at a national event (38%), with a quarter (n=14) citing e-learning as the preferred option.

Conclusions: Data from the survey highlights a lack of adequate, standardised training for HHD nurses, demonstrating the need for a structured programme that ensures up-to-date best practice. As a result, we plan to pilot a specific HHD training scheme that involves patients and carers in curriculum planning and delivery, with content including; assessment of patients’ learning styles, how to facilitate shared decision-making with patients, and how to evaluate effectiveness of the HHD programme.
clearance. Increase of the dialysate flow did not further increase urea removal. Urea removal was dependent on urea plasma concentration (C-U). Limited release of ammonia-um was observed (0.1±0.03 mole per removed mole of urea).

Conclusions: EO by graphite electrodes combined with AC shows promising urea removal in vivo. Research aimed at increasing the efficacy and biocompatibility testing is warranted.

SA-PO843
Unplanned “Crash” Home Dialysis Starts: Single Center Experience from a University Hospital in the United States
Kristen P. Tamura, Jose A. Morfin, Nephrology, UC Davis Medical Center, Sacramento, CA; Nephrology, UC Davis Medical Center, Sacramento, CA.

Background: There is a high incidence of starting dialysis from the hospital to the in-center unit, and frequently these starts are unplanned and unexpected (“crash”). To this end, we sought to implement an educational program to identify patients suitable for a home dialysis modality, unplanned home hemodialysis (UHHD) and unplanned peritoneal dialysis (UPD).

Methods: We performed an retrospective observational analyses on patients who were started on dialysis from January 2013 to April 2015 in a diverse patient population admitted to UC Davis Medical Center in Sacramento, CA. We devised a systematic and comprehensive screening educational program to provide all modality options. We identified patients suitable UHHD, and UPD, both which were transitioned to a home dialysis training program upon discharge. Clinical characteristics and outcomes were compared to groups who had a standard start home dialysis (SHHD, SPD) during the study period. Our measured outcomes include the following: average training days, interval of technique failure (patient dropout), access status and complications, infections, hospitalizations and mortality in the first 90 days.

Results: Preliminary results reveal the groups tended to have similar demographic profiles with the average age for patients starting an unplanned home dialysis 51.5 years of age, 60% non-white race, but with a trend toward more males at 59% compared to standard starts.

Conclusions: This is the first study to compare QOL between Tx-pts and wait-listed NHHD patients compared to standard HD modalities. In this preliminary analysis, QOL was worse in NHHD compared to standard HD modalities. Further study is needed to validate this finding.

SA-PO845
Association of Vascular Access Type with Mortality, Hospitalization, and Transfer to In-Center Hemodialysis in Patients Undergoing Home Hemodialysis
Matthew B. Rivara, Melissa Sooboo, Elani Streja, Miklos Zsolt Molnar, Alfred K. Cheung, Ronit Katz, Onyebuchi A. Arah, Allen R. Nissenson, Jonathan Himmelfarb, Kamyr Kalantar-Zadeh, Rachna Mehrotra, Kidney Research Institute, Seattle, WA; Harold Simon Center for Kidney Dis Research & Epidemiology, Univ of California Irvine Med Ctr, Irvine, CA; Div of Nephrology, Univ of Ten Health Science Ctr, Memphis, TN; Div of Nephrology, Univ of Utah, Salt Lake City, UT; Epidemiology, Fielding School of Pub Health, Los Angeles, CA; DaVita, Inc., El Segundo, CA; David Geffen Sch of Med at UCLA, Los Angeles, CA.

Background: In individuals undergoing in-center hemodialysis (HD), use of central venous catheters (CVCs) is associated with worse clinical outcomes compared to use of arteriovenous access. However, it is unclear whether a similar difference in vascular access type risk is present in patients undergoing home HD, as these patients have higher dialysis treatment frequency and lower rates of exposure to sources of nosocomial infection.

Methods: We examined the associations of vascular access type with all-cause mortality, hospitalization, and transfer to in-center HD in patients who started HD from 2007-2011 in 464 facilities in 43 states in the United States. We analyzed the data using competing-risks hazards regression with vascular access type at the start of home HD as the primary exposure in a propensity score-matched cohort (1052 patients; 526 with CVC, 526 with arteriovenous access).

Results: Compared to arteriovenous access use, CVC use was associated with increased risk for mortality (hazard ratio [HR] 1.78; 95% confidence interval [95% CI] 1.21 to 2.61) and hospitalization (HR 1.38; 95% CI 1.19 to 1.59). CVC use was not associated with increased risk for transfer to in-center HD (HR 1.07, 95% CI 0.83 to 1.35, p=0.012). The results of analyses in the entire unmatched cohort (2481 patients), with vascular access type modeled as baseline exposure at start of home HD or as a time-varying exposure, were similar.

Conclusions: In a large nationally representative cohort of home HD patients, CVC use was associated with increased risk for mortality and hospitalization.

SA-PO846
Time to Transplant Associates with Home Dialysis Morbidity
Ritu Suri, Gibson E. Nesrallah, Liha Li, Lakshman Gunaratnam, Centre de Recherche, Centre Hospitalier de l’Univ de Montreal, Univ de Montreal, Montreal, QC, Canada; Humber River Hospital, Toronto, ON, Canada; Nephrology Div, Western Univ, London, ON, Canada.

Background: We recently showed that prevalent end-stage renal disease patients starting home daily hemodialysis (DHD) have reduced cardiovascular and infection-related hospitalization risk compared to those starting peritoneal dialysis (PD). As current hospitalization precludes being active on the transplant wait-list, we investigated whether DHD patients receiving home DHD would be more likely to be transplanted than those receiving PD.

Methods: We matched 2997 adult starting home daily hemodialysis (DHD) in a single US dialysis provider’s facilities from 2004-2011, to 2997 contemporaneous USRDS patients starting PD by US state and propensity-scores. Demographics, comorbidities (form 2728 and hospitalization codes), and outcomes were ascertained from USRDS. We used Cox regression stratified on matched sets censoring for death, and competing risk analysis using Fine’s approach for stratified data, to compare times to transplantation between groups.

Results: Baseline variables were balanced between groups after matching, with standardized differences <10%. During 12,558 years of follow-up (mean 2.1±1.4 years), 514 DHD and 428 PD patients were transplanted. DHD patients were 19% more likely to be transplanted than PD patients (DHD 8.2 vs PD 6.8 per 100 patient-yrs; HR 1.19, 95%CI 1.05-1.35, p=0.012). Competing risk analysis accounting for death and follow-up losses yielded a HR of 1.18 (95%CI 1.04-1.33, p=0.010). Time to waiting-list did not differ between groups (HR 0.97, 95% CI 0.90-1.06, p=0.54), but once waitlisted, PD patients were significantly more likely to be permanently removed from the wait-list (PD 14.2% vs DHD 10.2%, RR 1.39 (95%CI 1.09-1.78), p=0.008).

Conclusions: In this prevalent cohort, home DHD patients were more likely to be transplanted than matched PD patients, and less likely to be permanently removed from the wait-list during follow-up. Mean times to wait-listing were similar, suggesting that the groups were well-matched. Further study is needed to validate the factors responsible for the differential transplantation rates observed in home DHD and PD patients.

SA-PO847
Spectrum of Mutations in PKD1 and PKD2 Genes in 100 Unrelated Italian Pedigrees with ADPKD – Sanger Sequencing versus Next Generation Sequencing (NGS) Madalena Gigante,1 S. Diella,1 Matteo Accetturo,2 Paola Pontrelli,1 Giovanni Stailone,1 Giuseppe Grandalíamo,1 Loretto Gesualdi,1 Univ of Foggia, Foggia, Italy; DETO, Univ of Bari, Bari, Italy.

Background: ADPKD is caused by mutations in PKD1 or PKD2 genes. Although, clinical studies and case reports describing one or few ADPKD families have been reported in Italian population, to date a comprehensive molecular study is still lacking.

Methods: PKD1 and PKD2 genes were analyzed in 150 Italian ADPKD patients from 100 unrelated pedigrees - the largest Italian cohort analyzed to date in a single study - using Sanger sequencing and NGS. The potential pathogenicity of the newly identified variants was evaluated by combining different in silico methods.

Results: We identified the largest number of definitively and probable pathogenic mutations (n=78) reported in a single study in Italian population, achieving an overall detection rate of 90%. 55 mutations (52 PKD1 and 3 PKD2) have not been previously described, expanding the spectrum of known ADPKD mutations. We identified 12 de novo PKD1 mutations in sporadic patients without family history, providing a definitive diagnosis of ADPKD. We found the largest number of de novo mutations reported in a single study (15%) demonstrating, for the first time, that the prevalence of PKD1 de novo mutations may be underestimated. 4/32 (15%) mutations identified in a single study and (iii) provide a new NGS method with a detection rate comparable to Sanger sequencing but with significantly lower cost and reduced turnaround time.

SA-PO848
The Use of Screening MR Angiography in Patient with ADPKD Claudine Christiansen, Ruben Poesen, Dirk R. Kuypers, Bert Bammens, Bjorn Meijers. Nephrology, Univ Hospitals Leuven, Belgium.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is associated with the development of intracranial aneurysms and an elevated risk of hemorrhagic stroke (HS). It is suggested that screening MR angiography reduces the incidence of hemorrhagic stroke. Current screening criteria include positive family history in relatives, neurological symptoms and planned major surgery. The efficacy of these screening criteria has, however, not been fully evaluated.

Methods: We performed a single-center retrospective analysis of all ADPKD patients followed at the University Hospitals Leuven, between January 1990 (date of the first MR angiography) and August 2014. Baseline demographics and occurrence of screening criteria, screening MR angiography, intracranial aneurysm and hemorrhagic stroke were evaluated.

Results: We identified 865 patients with ADPKD. Those who were seen at least three times (median age 51y; 49% males) were included for analysis. Mean duration of follow up was 11.6 years. In this cohort, current screening criteria were met in 183 ADPKD patients (29.2%). Of these, 136 (74.3%) had screening MR angiography. In patients with no MR angiography, presence of screening criteria was associated with an elevated risk of hemorrhagic stroke (12.8% vs. 4.0%, P 0.02). Use of MR angiography in patients with screening criteria was related with a lower risk of hemorrhagic stroke during follow-up (2.2% vs. 12.8%; P 0.01).

Conclusions: In patients with ADPKD, current screening criteria for intracranial aneurysm are associated with an 3-fold elevated risk for future hemorrhagic stroke and performing MR angiography seems effective in reducing this risk.

SA-PO849
Influence of Genotype on ADPKD Progression in the HALT PKD Cohort Christina M. Heyer,1 Kaelue Z. Abebe,1 Vicente E. Torres,1 Ronald D. Perrone,1 Marie C. Hogan,1 William E. Braun,1 Godela M. Brosnaham,1 Peter G. Czarnecki,1 Charity G. Moore,1 Peter C. Harris,1 Dana Miskulin,1 The HALT PKD Investigators.1 Mayo Clinic Rochester, MN; 2U of Pittsburgh, Pittsburgh, PA; 3U of Colorado, Denver, CO; 4Tufts, Boston, MA; 5Cleveland Clinic, Cleveland, OH; 6Brighton and Women’s Hospital, Boston, MA; 7Carolina’s Health Care System, Winston-Salem, NC.

Background: We assessed here the influence of the ADPKD disease gene (PKD1 or PKD2) or PKD1 mutation type (truncating or non-truncating) on the rates of renal disease progression over 5 years in the HALT PKD cohort.

Methods: PKD1 mutation type was divided into strength groups: truncating (MSG1), and more or less penetrant non-truncating (MSG2 and MSG3). Correlations were made between gene type/MSG and changes in eGFR or height adjusted total kidney volume (htTKV).

Results: PKD1 patients had a faster eGFR decline than PKD2 (3.3 vs. 1.87 ml/min/1.73m2/yr; P<0.0001) but the rate of htTKV increase did not differ (6.44 vs. 6.81%/yr; P=0.42). Baseline PKD1 htTKV was larger than PKD2 (733, 557ml/m2; P<0.0001) and so PKD1 kidneys expanded to a greater extent (268, 217ml/m2/yr; P=0.0001). Rates of change in eGFR or htTKV did not differ between PKD1 MSG1 and MSG2 (P=0.15 and 0.70), but MSG3 baseline kidneys were smaller relative to MSG1 and MSG2 (611, 733, 777ml/m2; P=0.004) and so the volume increase was less (221, 262, 277ml/m2; P=0.004). PKD2 patients were less likely to reach a study endpoint (death, ESRD or 50% eGFR decline; P=0.0003), but there was no difference between PKD1 MSG1, 2, 3 (P=0.61). Patients with no mutation detected, had a slower increase in htTKV (4.8%/yr; P=0.008 vs. PKD1). The study showed a difference in TKV increase between the low and standard blood pressure groups (5.6 vs. 6.6%/yr; P=0.006). The magnitude of difference was similar when restricted to PKD1 MSG1 (5.7 vs. 6.7%/yr; P=0.0516) or PKD1 MSG1 and 2 (5.8 vs. 6.6%/yr; P=0.0543), but not significant in the smaller populations.

Conclusions: PKD1 MSG3 kidneys are smaller but not because they grow more slowly; possibly because they have less early cysts, similar to PKD2 vs. PKD1. Since genic and allelic effects do not alter progression rates, restricting analysis by genetic factors did not improve significance.

SA-PO850
Climate Temperature Affects the Age of End-Stage Kidney Disease in Autosomal Dominant Polycystic Kidney Disease (PKD) Marwan M. Abbas,1 Michael E. Bleyer,3 Elizabeth Swain,1 Kendrah O. Kidi,2 Gregory B. Russell,2 Anthony J. Bleyer,1 Section on Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; 2Biostatistical Sciences, Wake Forest School of Medicine, Winston-Salem, NC.

Background: Vasopressin receptor 2 antagonists decrease cyst size in PKD. We postulated that patients in hotter climates would have more concentrated urine, and this would affect the age of ESRD in PKD.

Methods: We obtained demographic data and cause of ESRD on 1,332,402 individuals who had their first occurrence of ESRD between ages 30 and 90 between 1971 and 2012 from the US Renal Data System (USRDS). We obtained annual mean temperatures from 1990 to 2010 for US weather stations and linked a participant’s zip code to the nearest weather center. We correlated the mean age of onset of ESRD for PKD and other causes of ESRD with 5 degree temperature intervals. We created a multivariate model for PKD patients, with the dependent variable age of ESRD and independent variables race, gender, year starting dialysis, residual GFR at start of ESRD, annual median income by patient zip code, and temperature as discrete variables in 5 degree intervals.

Results: Figure 1 shows the mean age of onset of ESRD by disease. Cold and warm temperature extremes were associated with increasing age of ESRD for PKD, but other diseases.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

The multivariate model showed that temperature had a minimal effect on age of ESRD compared to other variables in the model.

Conclusions: There was a U-shaped relationship for age of ESRD according to temperature that was present in PKD and other diseases. However, in a multivariate model, climate temperature had a minimal effect on age of ESRD in PKD.

Urinary Biomarkers and Prediction of Disease Progression in Autosomal Dominant Polycystic Kidney Disease

The Burden of Tolvaptan Treatment for Autosomal Dominant Polycystic Kidney Disease

Results: We included 40 patients (male: 28, female: 12). The median age was 46.5 years (interquartile range: IQR 24 - 69 y). The median baseline eGFR was 65 mL/min/1.73 m² (IQR: 26.9 - 58.8) and the median baseline TKV was 1.917 mL (IQR: 1.378 - 2.905). The median starting dosage of tolvaptan was 60 mg (IQR: 30 – 60) and the median treatment period was 8 months (IQR: 6 - 11). We observed no statistical variations in eGFR (p = 0.787) and TKV (p = 0.561) during treatment. There were no significant changes in PASM scores for general fatigue (p = 0.817), anorexia (p = 0.393), back pain (p = 0.682), and abdominal distension (p = 0.607) during treatment. Although analysis of variance demonstrated that aquaretic burden including thirst and dry skin were significantly increased after Tolvaptan treatment (p < 0.003), 35 % of the combination of patients did not completely sense thirst at all during treatment, and 42 % (n = 17) of patients spontaneously improved without any additional treatment or tolvaptan withdrawal.

Conclusions: Although analysis of variance demonstrated that aquaretic burden including thirst and dry skin were significantly increased after Tolvaptan treatment, almost third of the patients did not completely sense thirst at al from beginning of Tolvaptan treatment, and the remaining third part of patients spontaneously improved.

Adapted PKD Disease Predicts Actual Progression of Autosomal Dominant Polycystic Kidney Disease in TEMPO3Δ

Results: We included 104 ADPKD patients, 40±11yrs, 39% female, eGFR 77±10 mL/min/1.73 m² and htTKV 852 (510-1243) mL/m². During a follow-up of 3.8±1.2 yrs, annual change in eGFR was -3.3±2.6, in mGFR -3.3±0.3 mL/min/1.73 m² and in htTKV ±2.5±9.5%. BMI and MCP-1 were associated with annual change in eGFR (β = -0.23, p=0.02; β = 0.38, p<0.001 resp) and mGFR (β = -0.24, p=0.03; β = 0.24, p=0.03 resp), even when adjusted for conventional risk markers, but not with annual change in htTKV. Similar results were obtained when patients with an eGFR ≤60 mL/min/1.73 m² were selected. Combined BMI and MCP-1 had an added predictive ability for annual change in eGFR (R² = 0.178 vs. 0.324, p=0.008) and in mGFR (R² = 0.134 vs 0.217, p=0.07). The best predictive model for annual change in eGFR included age, htTKV, MIF, b2MG and MCP-1 (R² = 0.343, p=0.025), and for annual change in mGFR, gender, b2MG, MIF and MCP-1 (R² = 0.3, p=0.052).

Conclusions: BMI and MCP-1 both predict disease progression, and have an added predictive value on top of conventional risk markers. These markers have therefore potential to serve as a predictive tool for clinical practice.

The Novel Surrogate Marker of Autosomal Dominant Polycystic Kidney Disease

Background: Experimental studies suggest a detrimental role for Arginine vasopressin (AVP) in the pathogenesis of autosomal dominant polycystic kidney disease (ADPKD). Copeptin consists of the C-terminal portion of Pro-AVP and has been shown to be a reliable and stable substitute for circulating AVP concentration. In contrast to serum or plasma, urinary proteins do not undergo detectable degradation by endogenous proteases after voiding. It is unknown, however, whether urinary copeptin concentration are associated with disease severity in patients with ADPKD.

Methods: Serum and Urinary copeptin concentration were measured by immunoassay in ADPKD patients with CKD stage ≤ 4. We compared our measurements with clinical parameters including estimated Glomerular Filtration Rate (eGFR), Total Kidney Volume (TKV) and height-adjusted (ht)TKV. Multivariate linear regression was used to assess the predictive ability of the markers above conventional risk markers.

Results: Included were 104 ADPKD patients, 40±11yrs, 39% female, eGFR 77±10 mL/min/1.73 m² and htTKV 852 (510-1243) mL/m². During a follow-up of 3.8±1.2 yrs, annual change in eGFR was -3.3±2.6, in mGFR -3.3±0.3 mL/min/1.73 m² and in htTKV ±2.5±9.5%. BMI and MCP-1 were associated with annual change in eGFR (β = -0.23, p=0.02; β = 0.38, p<0.001 resp) and mGFR (β = -0.24, p=0.03; β = 0.24, p=0.03 resp), even when adjusted for conventional risk markers, but not with annual change in htTKV. Similar results were obtained when patients with an eGFR ≤60 mL/min/1.73 m² were selected. Combined BMI and MCP-1 had an added predictive ability for annual change in eGFR (R² = 0.178 vs. 0.324, p=0.008) and in mGFR (R² = 0.134 vs 0.217, p=0.07). The best predictive model for annual change in eGFR included age, htTKV, MIF, b2MG and MCP-1 (R² = 0.343, p=0.025), and for annual change in mGFR, gender, b2MG, MIF and MCP-1 (R² = 0.3, p=0.052).

Conclusions: BMI and MCP-1 both predict disease progression, and have an added predictive value on top of conventional risk markers. These markers have therefore potential to serve as a predictive tool for clinical practice.

The burden of tolvaptan treatment for autosomal dominant polycystic kidney disease

Background: Last year, Japan became the first country in the world to approve tolvaptan treatment, and the remaining third part of patients spontaneously improved.

Methods: This report uses baseline data for placebo subjects from the TEMPO 3:4 ADPKD clinical trial to support this approach to disease progression modelling by constructing a model predicted and observed TKV and eGFR. Simulations were performed by utilizing the PKDOC model with subject-specific baseline TKV and eGFR measurements from subjects enrolled in TEMPO 3:4.

Results: Bias (mean of the relative error) and precision (square mean of relative error) of TKV and eGFR were derived to assess the predictive performance of the PKDOC model. The model resulted in very robust predictions of TKV and eGFR with mean (95% CI) bias values of 2.98% (1.1-5.1) and 3.03% (1.4-4.7), respectively. Mean (95% CI) precision on TKV and eGFR were 42.9% (19.1-68.7) and 57.9% (34.0-43.4), respectively. The coefficient of determination (r²) for observed and model predicted TKV and eGFR data were 0.957 and 0.877, respectively.

Conclusions: The disease progression model developed with PKDOC data and applied to the TEMPO placebo dataset demonstrated excellent predictive power for TKV and eGFR.

Polycystic Kidney Disease Imaging Biomarkers – The Texture of Things to Come

Background: Medical imaging is essential for polycystic kidney disease (PKD) diagnosis, monitoring, and outcome prediction. Research studies use total kidney volume (TKV) as an imaging biomarker to follow the progression of PKD. However, TKV overlooks underlying structural and functional complexities of the kidneys. We hypothesize that texture analysis may provide quantitative measurements of renal tissue structure to improve patient outcome prediction.

Methods: A retrospective cohort of 20 patients (38 exams) was identified who had imaging prior to reaching end-stage renal disease (ESRD). Image texture features were generated from the baseline MR images and analysis of the correlation to known time-to-ESRD was performed. A total of 18 texture features were computed for each MRI scan. The analysis workflow is shown in Fig. 1. Results: Texture features were well correlated to time-to-ESRD and many individual texture features outperformed height-adjusted TKV (htTKV) as shown in Figs. 2 and 3. Examination of MRIs and the corresponding energy image feature (measure of heterogeneity) for two different patients with markedly different times-to-ESRD are also shown for comparison. In addition, entropy (measure of image randomness) and gray-level non-uniformity (measure of neighboring pixel similarities) were also found to be well correlated (r-values of 0.66 and 0.73, respectively).
Conclusions: We present the first use of texture analysis for PKD assessment. Results are promising in terms of identifying new imaging biomarkers that correlate with disease progression. This approach could function as a surrogate to more difficult imaging methods (e.g., quantitative MRI) and costly analysis (e.g., cyst segmentation). It is likely that combining texture analysis with other patient data will allow for substantial improvements to PKD prognosis.

Accuracy of Traditional and Novel Renal Filtration Markers for Estimating GFR in ADPKD Patients

Stephen L. Seliger,1 Charalett E. Diggs, MSN, Thomas C. Dowling,2 Robert Christenson,2 Terry J. Wartnick,1 Medicine, U Maryland Sch Medicine, Baltimore; 3Ferris State Univ; 3Pathology, U Maryland Sch Medicine, Baltimore.

Background: The best method for estimating GFR in ADPKD is unclear. Changes in tubular handling of filtration markers may affect estimating equation accuracy.

Methods: Among 51 adults with ADPKD and eGFR >20 cc/min/1.73m², we measured GFR using iothalamate plasma clearance (iGFR), serum creatinine (SCr, IDMS-traceable assay), Cystatin C (CysC, Dimension VISTA assay) and beta-trace protein (BTP, immunonephelometric assay, Siemens). We estimated GFR (eGFR) using validated equations based on SCr (CKD-Epi, MDRD), Cystatin C (CKD-Epi, CysC), both CysC and SCr (CKD-Epi-CysC) or SCr and BTP (White equation). We compared the bias, precision, overall accuracy, and classification (for iGFR<60 cc/min/1.73m²) of each estimating equation.

Results: Mean age was 51±12 years, 71% were female, 84% Caucasian, and mean iGFR was 68.4±34.2 cc/min/1.73m². Of the 5 equations, the CKD-Epi-CysC had the highest bias (overestimating GFR), lowest precision and accuracy, and was least sensitive for between the SCr- and BTP-based estimating equations. (Table)

Conclusions: Patients randomized to placebo using statins were older, had larger TKV and lower eGFR at baseline, and their TKV and eGFR slopes were steeper compared to statin nonusers (Table). Similarly, patients randomized to tolvaptan using statins had lower eGFR, with a non-significant trend to larger TKV compared to statin non-users; however, there was no difference between TKV and eGFR slopes of statin users and nonusers randomized to tolvaptan. Statin use did not affect a composite end point of clinically relevant ADPKD events in the placebo (HR=1.035, P=0.01) or tolvaptan (HR=0.954, P=0.65) group.

Systems Biology of Polycystic Kidney Disease

Kelly A. George,1,2 Herve Husson,1 Ramya Kalyana Kumar,2 Vishal S. Vaidya,2 Oxana Beskrovnya,3 Jagesh V. Shah,2,1 Laboratory of Systems Pharmacology, Harvard Medical School, Boston, MA; 1Renal Div, Brigham and Women’s Hospital, Boston, MA; 2Genzyme Corp, Framingham, MA.

Background: Polycystic kidney disease (PKD) is a group of hereditary disease states characterized by cystic kidneys and often accompanied by other manifestations such as cystic liver and hypertension. PKD occurs in 1 in 500 people, usually resulting from a dominant mutation in one of two genes, PKD1 or PKD2. There are no treatments for PKD and it is the leading genetic cause of renal failure. Numerous studies have identified pathways that are misregulated in PKD but targeting these individual pathways has not led to a successful therapeutic intervention or molecular biomarker.

Methods: To identify potential biomarkers and develop a systems-level understanding of PKD, we are using transcriptomics, and quantitative proteomics and phospho-proteomics to evaluate the state of cystic and normal kidneys in a mouse model of PKD. Kidney cysts also induce injury to the surrounding tissues, confounding any analysis of the “cystic state”. In an effort to separate the injury signature from the cystic signature, we are also evaluating the state of the injured kidney using a folate model of acute kidney injury and fibrosis. The multi-kinase inhibitor Roscovitine has been shown to prevent cystogenesis in mouse models of PKD but its mechanism of action remains unknown. To gain insight into the mechanism(s) of Roscovitine and to identify biomarkers that change with treatment, we are also using the above “omic” strategies using kidneys from mice following treatment.

Results: From the transcriptomic experiments, we have a list of potential biomarker candidates that are currently being tested by qPCR in mouse tissue at various stages of disease progression. Phosphorylation at motifs for CDKs, CK1, CaMK, and others are reduced in kidneys treated with Roscovitine. The primary transcription factor family found to be suppressed with Roscovitine treatment is the E2Fs, likely a result in the loss of CDK signaling.

Conclusions: These experiments will not only provide candidate biomarkers for PKD progression, but will also yield a deeper understanding of the state of the cystic kidney. Funding: Pharmaceutical Company Support - Santen Genezyme, Private Foundation Support

SA-PO859
Prognostic Enrichment Strategies in the TEMPO 3:4 ADPKD Clinical Trial

Background: An image classification of ADPKD based on diffuse (class 1) vs. asymmetric (class 2) cyst distribution along with estimated cyst growth determined by age and height-adjusted total kidney volume (htTKV, subclas A-E) has been proposed for prognostic enrichment by excluding patients with a lesser risk for progression (classes 1A-B and 2).

Methods: This enrichment strategy was compared, post-hoc, to exclusion criteria used for TEMPO3-4 to examine tolvaptan effects on ADPKD progression in patients with early but progressive renal disease (18-50 year-old, TKV = 750 mL, eGFR >60 mL/min).

Results: 1436 TEMPO 3-4 subjects with baseline MRIs were classified, finding only 10% class 2 or 1B and no 1A subjects. TEMPO3-4 enriched classes 1C-E (90%) compared to the published cohorts (62%, Irazabal 2014 JASN). TKV and eGFR slopes steepened from class 1B to 1E (both P<0.001, Table).

Purpose: Tovaptan effects on TKV and eGFR slopes 5.78% to 2.91% and -3.93 to -2.82 mL/min/1.73m² compared to the published cohorts (62%, Irazabal 2014 JASN). TKV and eGFR slopes steepened from class 1B to 1E (both P<0.001, Table).

Conclusions: Strategies for prognostic enrichment such as the image classification should be used in the design of RCTs for ADPKD to increase their power and reduce their cost.

SA-PO861
Long-Term Safety Profile of Tolvaptan in Japanese ADPKD Patients

Background: Tolvaptan was first approved in Japan for autosomal dominant polycystic kidney disease (ADPKD) based on results of the Tolvaptan Efficacy and Safety in Management of Autosomal Dominant Polycystic Kidney Disease and Its Outcomes 3-4 trial (TEMPO) to determine 3-year efficacy and safety. The purpose of this study was to investigate adverse drug reactions (ADRs) of tolvaptan for up to extended 3 years after TEMPO in Japanese ADPKD patients.

Methods: This open-label study was conducted in 135 patients participating in the preceding TEMPO. Doses of tolvaptan were adjusted from 60 to 120 mg/day.

Results: Main ADRs: thirst (77%), polyuria (57%), polydipsia (38%), and hyperuricemia (15%) were noted during up to 3 years in TEMPO. Hepatic function-related ADRs were observed more frequently for tolvaptan than for placebo early during treatment. In this study, 8 patients (6%) experienced >3-fold increases above upper limits of normal serum ALT, AST, and GGT at 3 to 9 months after tolvaptan initiation, but all recovered after tolvaptan cessation. Of these 8 patients, 7 had been allocated to placebo in TEMPO. However, the residual one patient allocated to tolvaptan similarly had shown increased serum ALT in TEMPO. None of the 8 patients met Hy’s Law criteria. No ADRs besides those seen in TEMPO were newly observed in this study.

Conclusions: Hepatic function-related ADRs occurred early during treatment and were reversible. Tolvaptan was thus indicated to be a promising drug for treatment of ADPKD for up to 6 years while carefully monitoring ADRs including hepatic function abnormalities.

SA-PO860
Prognostic Enrichment Design in Clinical Trials for ADPKD: The HALT PKD A Trial

Background: Patients with mild ADPKD phenotype are less likely to be informative in clinical trials. An image classification into typical (diffuse cyst distribution) class 1A and atypical (asymmetric cyst distribution) class 2 has been proposed for prognostic enrichment design in clinical trials.

Methods: In a secondary analysis, data regarding maternal and fetal outcomes and complications of the HALT PKD trials, 38 pregnancies occurred despite counseling and review with participants. We now present maternal and fetal outcomes from these pregnancies.

Results: In the TEMPO 3:4 ADPKD clinical trials, 38 pregnancies occurred despite counseling and review with participants. We now present maternal and fetal outcomes from these pregnancies.

Conclusions: ADPKD is the most common hereditary disease. Fertility rates are not impaired in ADPKD women, however, preexisting hypertension and proteinuria associate with increased maternal and fetal complications. In the HALT PKD trials, 38 pregnancies occurred despite counseling and review with participants. We now present maternal and fetal outcomes from these pregnancies.

Renal Concentrating Capacity and Copeptin Concentration in Patients with ADPKD and IgA Nephropathy with Impaired Renal Function

Nephrology, Univ Medical Center Groningen, Groningen, Netherlands.

Background: ADPKD patients have an impaired maximal urinal concentrating capacity (Umax). Whether this is an aspectic effect of renal function impairment, or specific for ADPKD is yet unknown. We hypothesized that ADPKD patients have a more severely impaired Umax in comparison with non-ADPKD renal disease patients, which leads to an exaggerated vasopressin (AVP) response that may be damaging to the kidney.

Methods: 15 ADPKD (eGFR>60) and 15 IgA patients, matched for age, sex, and eGFR underwent a water deprivation test to determine Umax. Urine and plasma osmolality (Uosm and Posm), albuminuria (ACR) and plasma copeptin (surrogate marker for AVP in pmol/L), were measured at baseline and after water deprivation (average 17 hours). Height adjusted total kidney volume (htTKV) was measured by MRI.

Results: Umax was lower in ADPKD compared with IgA patients. Upon water deprivation Posm increased in ADPKD (p=0.003), but not in IgA (p=0.1), whereas copeptin increased in both groups similarly. (ADPKD: p=0.001; IgA: p=0.02). Copeptin after water deprivation was negatively associated with Umax in both groups (ADPKD: R=-0.72, p=0.002; IgA: R=-0.70, p=0.004). In ADPKD, copeptin, cotatin and albuminuria were correlated after water deprivation (R=-0.71, p<0.003), independently of eGFR or htTKV. Furthermore, htTKV in ADPKD was associated after water deprivation with Posm (R=0.52, p=0.048), copeptin (R=0.58, p=0.03) and Umax (R=0.45, p=0.04).

Conclusions: ADPKD patients have a lower Umax compared with IgA patients with similar renal function. Remarkably, this is not accompanied with an exaggerated increase in AVP. Notwithstanding, ADPKD severity was associated with stronger increases in Posm, copeptin and albuminuria during water deprivation. This suggests that in ADPKD water deprivation may be deleterious and should be avoided.

SA-PO864

Total Abdominal Organ Volume Is a Major Risk Factor for Malnutrition in Ambulatory Patients with Autosomal Dominant Polycystic Kidney Disease

Hyomin Ryu1, Hyoysang Kim1, Hyunsuk Kim1, Kook-Hwan Oh1, Young-Hwan Hwang1, Curve Ahn1 Internal Medicine, Seoul National Univ Hospital, Seoul, Korea; 2Asian Medical Center; 3Armed Forces Capital Hospital, Seongnam; 4Eulji General Hospital.

Background: In Autosomal dominant polycystic kidney disease (ADPKD), malnutrition may develop as renal function decreases and abdominal organ volume enlarged. In this study, we evaluated the nutritional status of outpatient ADPKD patients by using subjective global assessment (SGA) and investigated the risk factors for malnutrition.

Methods: In this single center, cross sectional study, anthropometric and laboratory data including serum creatinine (sCr), albumin, and cholesterol were collected, and total kidney and liver volume were measured. Total abdominal organ volume was defined as the sum of total kidney and liver volume and adjusted by height (htTAV).

Results: A total of 208 patients (47.9%) were included and mean age was 48.3±12.2 years. Mean estimated glomerular filtration rate (eGFR) was 65.3±5.2 5.ml/min/173m². Mean sCr ratio was 6.6±0.6. 168 patients (58.3%) were in chronic kidney disease stage 1 or 2, 99 (34.4%) stage 3 and 217(7.3%) stage 4. Total 21 patients (7.3%) were mild to moderately malnourished (SGA 4-5) and 63 patients(21.7%) were at risk of malnutrition (SGA 6). There was no difference in SGA score distribution with sex. Physical scores related to nutritional status in total and male were age, height, weight and body mass index. However none of these parameters were related in female. Lower hemoglobin level and poor renal function were in worse male but not female. AND ACR and eGFR.

Conclusions: Nutritional risk was detected in 30% of ambulatory patients with ADPKD and relatively preserved renal function. Intraabdominal organ growth in ADPKD may affect the nutritional status independently from the renal deterioration.

830A
Results: Among 186 patients who underwent PHCF, 91% were Caucasian women with ADPKD with a mean age of 49 years. Major peri-operative complications (Clavien III/IV) occurred in 24% of the patients. Operative mortality (<90 days) was 2.7% with one death from liver failure. Overall survival was 95%, 90%, 76.5% and 59% at 1, 5, 10 and 15 years respectively. Imaging records for volumetry were unavailable in 37 patients. Of the remaining 149 patients, 30 patients had imaging for one LV, 65 for two LV and 54 for all three LV. Median LV was 6812 ml preoperatively and 2502 ml after PHCF leading to a median postoperative liver volume reduction of 61%.

At follow-up (mean 7.8 years), median LV was 2500 ml. Interestingly, 29 out of 61 patients with available LV2 and LV3 showed further regression in LV upon follow up (median -14.8%); while the rest showed mild growth of 9.5%. Overall volumetric comparison of preoperative to follow-up liver imaging showed sustained liver volume reduction (median 60%).

Conclusions: Sustained long-term reductions in LV after PHCF can be achieved in selected patients with severe, highly symptomatic PLD. In our experience, liver-related death and subsequent liver transplantation are infrequent after PHCF.

SA-PO869

Effect of Genotype on the Severity and Volume Progression of Polycystic Liver Disease (PLD) in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Fouad T. Chebib,1 Yeon Soon Jung,2 Christina M. Heyer,1 Maria V. Irazabal,1 Marie C. Hogan,1 Peter C. Harris,1 Vicente E. Torres,1 Ziad El-Zoghby,1 1Div of Nephrology, Mayo Clinic, Rochester, MN; 2Kosin U.

Background: PLD is the most common extrarenal manifestation in pts with ADPKD. Here we analyzed the influence of genotype and gender on the severity of PLD.

Methods: Clinical data was retrieved from electronic records in a large cohort of pts who were mutation screened, determined to be PKD1 or PKD2 and had available CT or MR liver imaging during 2000-2014 at the Mayo Clinic (n=445). Liver volumes (LV) were measured by stereology on axial images and adjusted to height (HtLV).

Results: Among the 445 pts, 220 (49.5%) had truncating PKD1, 153 (34.4%) nontruncating PKD1 and 72 (16.1%) PKD2 mutations. Compared to nontruncating PKD1 and PKD2, pts with truncating PKD1 were younger at time of first imaging (43.6 vs 47.6 and 50.4; p<0.001), had lower median survival time to ESRD (62.4 vs 66.9 and 81.4; p<0.001Log-Rank), and larger kidney volumes (785 vs 614 and 548 ml/m2; p<0.001). LV in pts with PKD1 truncating, PKD1 nontruncating and PKD2 were not different (HtLV 1039, 1076 and 1058 ml/m2, respectively;p=0.53). Female pts had larger HtLV compared to males (1104 vs 1019 ml/m2; p<0.001). Annualized median liver growth rates were 1.65, 1.74 and 1.2% for truncating PKD1, nontruncating PKD1 and PKD2, respectively (p<.75). Females younger than 48 had higher annualized median growth rates compared to those older than 48 (2.65 vs 0.09%;p<0.001). When adjusting for age, gender and baseline LV, growth rate remained unaffected by the ADPKD genotype.

Conclusions: Among the 220 with available imaging data, those with truncating PKD1 were younger, had less survival to ESRD, and smaller liver volumes than the other genotypes.

SA-PO868

Outcomes of Combined Partial Hepatectomy and Cyst Fenestration for Massive Polycystic Liver Disease

Fouad T. Chebib,1 Amber Harmon,1 Maria V. Irazabal,1 Yeon Soon Jung,1 Marie C. Hogan,1 Patrick S. Kamath,1 Vicente E. Torres,1 David M. Nagorney.1 1Dept of Surgery, Mayo Clinic, Rochester, MN;

Background: Partial hepatectomy and cyst fenestration (PHCF) selectively provides clinical benefit in highly symptomatic patients Polycystic Liver Disease (PLD). This study aims to ascertain whether the reduction in liver volume achieved by PHCF is sustained long-term.

Methods: Clinical data was retrieved from the electronic records in all PLD patients who underwent PHCF between 1985 and 2014. Preoperative Liver volumes (LV1), postoperative (LV2) and late follow up (LV3) were measured from MR or CT images.

Conclusions: Renal function did not change significantly during the period that patients were on metformin. We will continue to observe these patients and accumulate more patients with PKD and diabetes but not on metformin to see if metformin is beneficial in PKD patients.

SA-PO867

11Beta-Dichloro Inhibits Cyst Progression in an Adult ADPKD Model

Sorin V. Fedele,1 Bogdan I. Fedele,2 Yasunobu Ishikawa,1 Rachel Gallagher,1 John M. Essigmann,1 Stefan Somlo.1,2 1Dept of Internal Medicine, Yale School of Medicine, New Haven, CT; 2Dept of Genetics, Yale School of Medicine, New Haven, CT; 2Dept of Chemistry, M.I.T., Cambridge, MA.

Background: ADPKD is the most common monogenic disorder for which no effective therapy exists. We have previously shown that the novel antitumor agent 11β-dichloro specifically induced apoptosis in Pkd1 null cells (ASN 2013 FR-OR100). Administration of 11β-dichloro resulted in amelioration of cystic disease in the Pkd1fl/fl;Pkd1-Cre neonatal ADPKD model. In the current work we explored the pathways involved in the pro-apoptotic effect of 11β-dichloro and investigated whether the beneficial effect seen in the early model is also present in an adult inducible Pkd1-Cre;Pkd1fl/fl model which is more akin to the human disease.

Methods: Pnx8rtTA;TetO-cre;Pkd1fl/fl mice were induced with doxycycline for 2 weeks beginning at P28. 11β-dichloro was administered by IP injection at a dose of 10 mg/kg, 3 times a week for 12 weeks beginning from P42; At the end of treatment the kidneys were harvested for analysis.

Results: 11β-dichloro treated adult mice resulted in a decrease in KW/BW ratio as compared to vehicle injected controls (2.6±0.1 vs. 6.1±0.4); There was no difference in body weight between treated and control. These changes were accompanied by a decrease in the cyst index (29±6.5 vs. 49±11.4), BUN (41±2.4 vs. 83±2.7), and creatinine (0.18±0.007 vs. 0.37±0.02). 11β-dichloro specifically increased apoptosis in cyst-lining cells but not in wild-type. UPR and ROS have been implicated as potential drivers of the 11β-dichloro-dependent pro-apoptotic phenotype. We found that upregulation of the UPR marker XBP1s and its transcriptional targets Bip and Erj4 was specific to the Pkd1 null cells compared with wild-type, in vitro and in vivo. Treatment with 11β-dichloro increased mRNA levels of the antioxidant genes catalase and SOD1 specifically in the Pkdl cystic kidneys and not in vehicle-treated kidneys.

Conclusions: 11β-dichloro specifically induces UPR, ROS, and apoptosis in cystic vs. wild-type kidneys. In an adult inducible cystic model, the compound ameliorates cystic disease progression and improves kidney function.

HRQoL was assessed by comparing subjects in CKD2-5 to subjects in CKD1 at baseline. 

(PRO) questionnaires, including the ADPKD-IS, ADPKD-UIS, BPI, EQ-5D, and SF-12v2.

Duration, or had hypertension, parameters that might be associated with cyst wall stiffness.

Renal TAE was more effective in patients who were younger, had shorter dialysis duration, or had hypertension, parameters that might be associated with cyst wall stiffness.

Renal TAE was more effective in patients who were younger, had shorter dialysis duration, or had hypertension, parameters that might be associated with cyst wall stiffness.

Conclusions: In contrast to the renal phenotype, ADPKD gene type or PKD1 mutation type were not significantly associated with the severity or growth rate of PLD in ADPKD.

SA-PO870 Eligibility for Renal Transcatheter Arterial Embolization in Patients with Autosomal Dominant Polycystic Kidney Disease 

Tatsuya Suwabe, Yoshifumi Ubara, Junichi Hoshino, Rikako Hiramatsu, Kenmei Takaichi. Dept of Nephrology, Toranomon Hospital, Tokyo, Japan.

Background: In patients with ADPKD, massive renal enlargement is a serious problem. Renal transcatheater arterial embolization (TAE) is effective for reducing renal volume, but there is large variation of its effectiveness and the reasons remain unclear. We investigated factors influencing the renal volume reduction rate (RVRR) for one year after TAE.

Methods: All patients with ADPKD who received renal TAE at Toranomon Hospital from 2006 to 2013 were enrolled. We calculated RVRR by the calculation formula (1 - renal volume at each time after TAE / renal volume before TAE)*100, and analyzed factors affecting RVRR. We also compared sequential change of large cysts (>5cm), by classified them into four groups as cysts with wall thickening (>4mm), cyst with acute hemorhage, normal cysts, and the others.

Results: 449 patients (228 men, 221 women, mean age: 57.0 ± 9.1 years) were enrolled. The RVRR at 1 year after TAE ranged from 3.9 to 84.8%, and the least squares mean RVRR calculated using mixed model was 45.73% (95% confidence interval [95% CI]; 44.36 to 47.10%). Multivariate analysis using mixed model revealed that large cysts with wall thickening (regression coefficient: -5.830, 95% CI: -9.140 to -2.520, p=0.0006), age (5years) (-0.087, -1.073 to -0.621, p=0.0001), dialysis duration (12months) (-0.115, -0.193 to -0.037, p=0.0039), systolic blood pressure (10mmHg) (0.283, 0.065 to 0.501, p=0.0109), and number of microcoils used for renal TAE (1.333, 0.784 to 1.882, p<0.0001) had a significant influence on the RVRR. Among large cysts, only cysts with wall thickening did not decrease in volume. Significantly more microcoils were needed to achieve complete renal artery occlusion in patients with younger age and less dialysis duration.

Conclusions: Cyst wall thickening had an important influence on cyst volume reduction. Renal TAE was more effective in patients who were younger, had shorter dialysis duration, or had hypertension, parameters that might be associated with cyst wall stiffness. Renal artery narrowing may occur in older patients or those on longer dialysis, which might contribute to renal TAE being less effective in these patients.

SA-PO871 Patient Reported Health Related Quality of Life in ADPKD: Analysis from OVERTURE 

Dorothoe Oberbieden,1 Arlene B. Chapman,2 Ronald D. Perrone,3 Andreas L. Serra,4 Jason C. Cole,5 Wen Zhou,6 Holly Krausa,7 Jaime Blais,8 Frank S. Czerweic.1 1Otsuka Pharmaceutical Development & Commercialization, Inc., Rockville, MD; 2Univ of Chicago, Chicago, IL; 3Tufis, Boston, MA; 4Univ of Zürich, Zürich, Switzerland; 5PPD, San Diego, CA.

Background: ADPKD imposes a burden on health-related quality of life (HRQoL). Few studies have systematically examined the impact of renal and extra-renal symptomatology on patient’s HRQoL. The purpose of this analysis was to capture disease specific burden across all disease stages while determining specificity and sensitivity of existing and new HRQoL instruments.

Methods: The impact of disease progression on HRQoL in 3,409 ADPKD subjects involved in the OVERTURE observational study were evaluated by patient report outcomes (PRO) questionnaires, including the ADPKD-IS, ADPKD-UIS, BPI, EQ-5D, and SF-12v2. HRQoL was assessed by comparing subjects in CKD2-5 to subjects in CKD1 at baseline.

Magnitude of change of 0.2, 0.5 and 0.8 standard deviations (SD) represent small, moderate and large effects on HRQoL. Other measures of disease severity, including TKV, were assessed independently.

Results: HRQoL in ADPKD was impacted at different disease stages depending on the sensitivity and specificity of the PRO used. The disease-specific ADPKD-IS scale distinguished physical, emotional and fatigue related burden as early as CKD1. Similarly, the SF-12 PCS scale was able to distinguish burden by CKD3. The SF-12 MCS and EQ5D were not sensitive to disease progression until CKD5. The impact of disease burden prior to ESRD was driven by specific questions focused on physical activity, anxiety, and exhaustion. Subjects were more bothered by the shape of their abdomen in an independent question as early as CKD3 which associated with larger kidney volumes (htTKV > 635mL/m).

Conclusions: Studies to date have had limited success in their attempt to characterize HRQoL in ADPKD patients by using general health surveys. Disease specific instruments better capture the burden experienced by patients in earlier stages of ADPKD prior to gross kidney enlargement and effects associated with ESRD and dialysis.

SA-PO872 Fibroblast Growth Factor 23, Renal Progression and Death in Patients with Autosomal Dominant Polycystic Kidney Disease 

Background: No prospective studies examined fibroblast growth factor 23 (FGF23) and clinical outcomes among individuals with autosomal dominant polycystic kidney disease (ADPKD). We tested the hypotheses that higher serum FGF23 is a risk factor for kidney disease progression and mortality in adults with ADPKD.

Methods: We measured intact FGF23 levels (Kainos) in stored baseline serum samples in 1,002 patients who participated in the HALT-PKD randomized controlled trial of two different blood pressure control strategies. We used Cox proportional-hazards models to examine the associations between continuous levels and quartiles of iFGF23 and the primary composite endpoint of time to a 50% reduction in estimated glomerular filtration rate (eGFR) from baseline, end stage renal disease (ESRD) or death.

Results: At baseline, participants had a mean age of 42 ± 10 years, mean eGFR of 71.4 ± 26.4 mL/min/1.73m², mean serum phosphate of 3.4 ± 0.5 mg/dL, and median (IQR) iFGF23 of 52.6 (38.6 - 73.7) pg/mL. During a median follow-up of 5.6 years, 226 patients (22.6%) reached the composite endpoint. After adjusting for demographic factors, traditional cardiovascular risk factors, baseline eGFR, and randomized treatment group in Cox proportional hazards models, ascending quartiles of FGF23 were associated with a stepwise increased risk for the composite endpoint (HR 1.0 [reference], 1.54 [95% CI, 0.69 - 3.47], 2.92 [CI, 1.58 - 6.19], and 3.41 [CI, 1.61 - 7.22]). Similar results were obtained when FGF23 was examined on a continuous scale (HR 1.94 [95% CI, 1.39 - 2.69] per 1 SD in FGF23 increase).

Conclusions: Higher serum FGF23 is an independent predictor of kidney disease progression and death in adults with ADPKD. Further studies are required to determine the mechanisms underlying these relationships and to test whether interventions that reduce FGF23 levels might be renoprotective.

SA-PO873 Natural History of Polycystic Liver Disease in the HALT ADPKD Cohort 

Marie C. Hogan,1 Kaleab Z. Abec-b,2 Susan Spillane,3 Federic F. Rahbari-Oskoui,4 Godela M. Brosnaham,4 Charity G. Moore,5 Vicente E. Torres,5 1Mayo C for the HALT PKD Study Group; 2Upn; 3Emory; 4U Col.

Background: Although hepatomegaly in polycystic liver disease (PLD) is common, few studies have evaluated natural history & factors associated with progression. Goal: Examine change in height adjusted liver volume (hltLV) & factors influencing progression in patients in HALT-PKD-A randomized clinical trial.

Methods: Baseiline PLD group (mild (hltLV=1000mL,n=240) moderate (1000-1800mL, n=271) & severe (>1800mL, n=28; 81% female) & follow up hltLVs, quality of life (QOL,SF-36), influence of telmastratn (T) vs placebo (P) on progression were assessed (n=558, age 15-49y, eGFR > 60 mL/min). We assessed factors influencing hltLVs such as treatment group, age, gender, genotype (in separate models) & factors influencing progression over time were examined using linear mixed models.

Results: Annual hltLV growth rates were 0.76, 0.91 & 1.08% (P<NS) in the mild, moderate & severe groups, respectively (figure 1). Neither baseline age or genotype associated with annual hltLV increase. There were strong negative relationships of eGFR (p=0.02) & serum albumin (p=0.003) with hltLV. Prior pregnancy & higher parity (both age adjusted) associated with hltLV but not with progression over time. Increases in BltLV were associated with increased rates of fatigue (weakness (p=0.003) and declines in SF-36 physical functioning over time (p=0.02). Progression was independent of drug assignment (T: 0.90% vs P:1.07% p<NS) & BP target (low 0.81 vs std. 1.15% p=NS).

Towards Personalised Medicine – Treating a Renal Ciliopathy
Shalabh Srivastava,1 Simon Ramsoobottom,2 Sophie Saunier,2 Colin Miles,1 John Andrew Sayer.1 1Nephrology, Inst of Genetic Medicine, Newcastle Univ; 2Newcastle upon Tyne, United Kingdom; 1Laboratory of Inherited Kidney Diseases, Imagine Inst, Paris, France.

Background: Renal ciliopathies are genetic disorders presenting with nephronophthisis, cystic kidneys or cystic dysplasia. Pathogenesis of ciliopathies may include altered signalling or defective DNA damage response. Due to the huge genetic/phenotypic variability in ciliopathies it is pertinent to explore the most important contributor to individual phenotypes. We investigated disease mechanisms of a patient with Joubert Syndrome aiming to provide a personalised medicine approach to treatment.

Methods: We identified a family with 2 affected siblings with a ciliopathy phenotype. Ciliopathy gene panel sequencing followed by Sanger sequencing and segregation analysis was undertaken to provide a molecular genetic diagnosis. We established Human Urine derived Renal Epithelial Cell (HUREC) cultures from one sibling and a control. Cultured cells where characterised and their response to therapeutic agents quantified.

Results: The siblings exhibited a cerebro-retinal-ciliopathy phenotype with renal corticomedullary cyst formation and progressive renal failure. Panel sequencing followed by Sanger sequencing confirmed biallelic mutations in CEP290 (c.2817G>T, p.K939N; c.2984G>C, p.Q958P*) in both affected patients. The c.2817G>T is located in the last base of exon 25 and is predicted to lead to a splicing defect. There was no difference in mitosis or centriole numbers in control and proband’s cells. Control cells formed spheroids in 3D culture (100%) whilst the proband’s cells showed a defect in spheroid forming index (17%) and absent primary cilia. In the proband cells there was a rescue of spheroid forming index in response to treatment with hedgehog agonists SAG (smoothened agonist) (67%) and purmorphamine (75%) and a rescue of primary cilia.

Conclusions: In a family with a ciliopathy we have confirmed a molecular genetic defect in CEP290. Using HURECS we have characterised, at a personalised medicine scale, the cellular defect. This data suggests that renal ciliopathies may have potential therapeutic targets and investigation through individual HUREC based model is an exciting new development.

Effect of Metformin on the Progression of Autosomal Dominant Polycystic Kidney Disease
Godela M. Brosnahan,1 Michel Chonchol,2 John R. Holmén,3 Eugene J. Nuccio,4 Berenice Y. Gitomer.1 1Univ of Colorado; 2Intermountain Healthcare, Salt Lake City, UT.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a common inherited disorder resulting in end-stage renal disease (ESRD), without an approved treatment. In an animal model of ADPKD metformin therapy resulted in amelioration of cystic renal growth. We sought to determine whether patients with ADPKD and type 2 diabetes treated with metformin had slower progression to ESRD than similar patients treated with other antidiabetic drugs.

Methods: We conducted a population-based cohort study of adult patients with ADPKD and type 2 diabetes between January 1/2000 and December 31/2014. We identified 322 adults with ADPKD and type 2 diabetes, of whom 119 were treated with metformin only and 203 with other antidiabetic agents. Among these we identified 31 subjects treated with metformin only who could be matched for age, sex, race, history of hypertension and coronary artery disease, and baseline renal function to 31 subjects not treated with metformin. The primary outcomes were incident ESRD and all-cause mortality.

Results: The median age of the enrolled participants was 61 years, 45% were women. Approximately 74% and 26% had a history of hypertension and myocardial infarction, respectively. The baseline MDRD-eGFR in participants receiving and not receiving metformin was 49±12 and 47±14 mL/min/1.73m² (p=0.70). After a median follow-up of 4.5 years, incident ESRD occurred in 29% and 16% of those not exposed and exposed to metformin, respectively, with an OR of 2.13 (95% CI 1.10-3.46; p=0.02). Deaths occurred in 32% and 26% of those not exposed and exposed to metformin, with a OR of 1.37 (95% CI 0.5-2.47; p=0.60).

Conclusions: Metformin therapy may slow progression to ESRD in ADPKD adults with type 2 diabetes compared to other antidiabetic drugs. Because metformin has an excellent safety record, a trial to slow the progression of ADPKD in the absence of diabetes is warranted.

Funding: NIDDK Support
Methods: Information about hospitalizations was prospectively collected in the HALT-PKD Studies, 2 multi-center trials involving people with ADPKD and GFR 60 ml/min (Study A) and GFR 25-60 ml/min (Study B). The primary diagnosis was designated after review of discharge summaries and independently adjudicated by a committee.

Results: Total patient years (pyrs) of follow-up in the 558 Study A patients and 486 Study B patients was 3,141 and 2,056. The incidence rates (IRs) of all-cause hospitalization, in Study A and B, respectively, was 67.7 and 123.3 per 1000 pyrs, which compares to 80.3 and 118.0, in respective age-matched general populations (CDC/NHIS National Hospital Discharge Survey, 2010). The IRs in Study A and B, respectively, for cardiovascular-related hospitalizations was 9.9 and 13.6 per 1000 pyrs. The primary diagnosis related complications were lower in ADPKD patients with GFR 60-90 ml/min and higher in patients with GFR 25-60 ml/min. PKD-related complications were more common than cardiovascular related diagnoses as the primary reason for hospitalization in both Study A and B.

SA-PO877

Effect of Statins on the Progression of Autosomal Dominant Polycystic Kidney Disease (the HALT PKD Investigators) Godela M. Brosnahan,1 Kaleab Z. Abebe,2 Frederic F. Rahbari-Oskou,3 Charity G. Moore,4 Kyongtae Ty Bac,5 Robert W. Schrier,6 Jared J. Grantham.7 "Univ of Colorado; "Univ of Pittsburgh; "Emory Univ; "Univ of Kansas.

Background: ADPKD is the most common hereditary disease resulting in end-stage renal failure (ESRD), without an approved treatment. In a small randomized trial comparing pravastatin for 3 years to placebo in 43 patients age 15-82 years, the statin group experienced a slower rate of renal enlargement. No large trial has tested the effect of statins in ADPKD adults.

Methods: We performed a secondary analysis of the HALT-PKD trials, categorizing participants into 3 groups based on statin use: 1) never users, 2) less than 3 y, and 3) at least 3 y of use. For subjects in Study A (n=558, age 15-49 y, eGFR > 60 ml/min/1.73m²) we compared the percent change in height-adjusted total kidney volume (htTKV), in height-adjusted total liver volume (htTLV) and the rate of decline in eGFR between the 3 statin use groups. For participants in Study B (n=486, age 18-64 y, eGFR 25-60 ml/min/1.73m²) we compared time to composite endpoint of death, ESRD or 50% decline in eGFR. Follow-up was 5-8 y.

Results: In Study A only 59 subjects used statins for >3 y and 37 for <3 y. There was no difference in the rate of annual htTKV increase (6.4%, 7.1%, 5.9%; p=NS) or htTLV growth (1.02%, 1.15%, 0.65%; p=NS) between the 3 groups, after controlling for sex, age, and treatment arm. The rate of eGFR decline was faster in group 2 (4.07 ml/min/yr) than in groups 1 and 3 (2.93 and 2.82 ml/min/yr; p=0.015), after adjusting for the more favorable baseline characteristics of group 1 (more females, younger age, higher baseline eGFR). In Study B 118 subjects used statins for >3 y and 76 for <3 y. There was no difference in time to endpoint between the 3 groups.

Conclusions: In this secondary analysis of the HALT PKD trials, statin therapy for 3 years did not slow the rate of renal or liver enlargement or of eGFR decline in ADPKD adults, but these results are limited by the small numbers of statin users in Study A, different statin drugs and doses, and non-randomized allocation to groups.

Assessment of a Dosage-Sensitive Mutational Network for PKD in a Large Cohort of Patients with Early and Severe Forms of Polycystic Kidney Disease Carsten Bergmann,1,2 John Devane,2 Steffen Neuber,1 Eva Decker,1 Uyen Tran,1 Oliver Wessely,3 Elisabeth B. Ott,1 'Center for Human Genetics, Bioscientia, Ingelheim, Germany; "Renal Div, Univ Hospital, Freiburg, Germany; "Cellular & Molecular Medicine, Cleveland Clinic.

Background: ADPKD patients with early and severe disease manifestations only make up a minor proportion, but are crucial for a better understanding of PKD. Affected families have a high recurrence risk for babies with a severe clinical course often resulting in perinatal death. Especially in prenatal cases the diagnostic distinction between different forms of PKD and other ciliopathies can be difficult and illustrates the need for more comprehensive genetic testing.

Methods: An accurate genetic diagnosis is crucial for genetic counselling, prenatal diagnostics and the clinical management of patients. To this end, we established a sequence capture based NGS approach targeting 95 genes for cystic and polycystic kidney disease. This includes PKD1, which - due to the presence of pseudogenes - is difficult to test. As an additional advantage over conventional Sanger sequencing we were able to detect copy number variations. The biological significance of some of the detected alleles were subsequently tested in vitro and in vivo studies using a range of animal models including zebrafish, Xenopus and mice to validate some of our findings in terms of a functionally proven dosage-sensitive network.

Conclusions: This study is the most comprehensive analysis performed so far and points towards a general and underestimated concept for the modification of disease gene expression.

SA-PO879

Determinants of Progression in Early Autosomal Dominant Polycystic Kidney Disease - Is It Blood Pressure or Renin-Angiotensin-System Blockade? The HALT PKD Trial Godela M. Brosnahan,1 Kaleab Z. Abebe,2 Charity G. Moore,3 Theodore I. Steinmann,4 Frederic F. Rahbari-Oskou,3 Susan Spillane,1 Kyongtae Ty Bac,5 Robert W. Schrier.6 "Univ of Colorado; "Univ of Pittsburgh; "Beth Israel Deaconess; "Emory Univ.

Background: The HALT PKD Study A (558 subjects age 15-49 years, eGFR > 60 ml/min/1.73m²) showed that intensive control of systolic blood pressure (SBP) to 95-110 mmHg was associated with a slower rate of kidney volume growth compared to standard control (SBP 120-130 mmHg). It is unclear whether this result was due to lower BP per se or to greater blockade of the renin-angiotensin-aldosterone system (RAAS) by allowing higher drug doses in the low BP group.

Methods: In this secondary analysis of HALT PKD Study A categorizing participants into 3 groups based on lisinopril (L) and telmisartan (T) dosage at 4 months, after initial dose titration: 1) high, defined as L ≥ 40 mg + T ≥ 80 mg daily, 2) middle (everyone but high or low) and 3) low, defined as L < 20 mg + T < 40 mg daily. We compared the percent change in height-adjusted total kidney volume (htTKV) and the rate of eGFR decline between the 3 groups during follow-up for 5-8 years.

Results: Participants in the high dose group (n=51) were more likely male and assigned to the low BP arm; they had higher baseline BP and lower eGFR at 4 months than subjects in the mid- (n=272) and low-dose (n=165) groups. After adjustment for age, sex, genotype, target BP (low or standard), and eGFR at 4 months, there was no significant difference in the rate of kidney growth (5.63, 6.40 and 5.83%yr) or eGFR decline (3.00, 2.94 and 3.29 ml/min/yr) between the low, middle and high dosage groups.

Conclusions: In this secondary analysis of HALT Study A young ADPKD adults, a higher dosage of RAAS blocking drugs was not associated with a slower rate of htTKV growth or of eGFR decline, after adjustment for allocation to intensive BP control. Low BP appears to be the main determinant for reducing kidney volume growth.

The Short Term Effect of Tolvaptan for CKD Stage 4 Autosomal Dominant Polycystic Kidney Disease  

Haruna Kawano,1 Satoru Muto,2 Shigeo Horic.1,2  
1Urology, Juntendo Univ Graduate School of Medicine, Tokyo, Japan; 2Urology, Teikyo Univ, Tokyo, Japan; 3Endowed Course for the Study of Polycystic Kidney Disease, Juntendo Univ Graduate School of Medicine, Tokyo, Japan.

Background: In Japan, the treatment of tolvaptan, a V2 receptor antagonist, started from March 2014. Indication criteria of tolvaptan for ADPKD treatment in Japan is adult patients with more than 750ml total kidney volume (TKV) and more than about 5%/year increasing rate of TKV. It is contraindication to use tolvaptan for patients with eGFR<15ml/min/1.73m². It is recommended to reduce dose of tolvaptan for patients with CCR<30ml/min. However, the treatment effect for patients with CKD stage 4 is still unknown. So, we evaluated the short time efficacy of tolvaptan treatment for patients with CKD stage 4.

Methods: Thirteen patients (5 females and 8 males, mean age; 52.5 years) with ADPKD who started tolvaptan at our hospitals from April 2014 to April 2015 were analyzed in this study. Although our standard starting dose of tolvaptan for patients with good renal function is 60mg/day, we administered 15mg/day for patients with eGFR<25ml/min/1.73m² patients. Patients were measured eGFR and TKV at the commencement of treatment and at 1.5 and 6 months later.

Results: The baseline median eGFR and TKV were 21.8 ml/min/1.73m² (range; 17.1-28.9) and 2.810ml (range; 1.031-5.847), respectively. The change of median eGFR from baseline at 1.5 months and at 6 months were -0.36 ml/min/1.73m² (p=0.39) and -1.80 ml/min/1.73m² (p=0.04), respectively. The change of median TKV from baseline at 1.5 months and at 6 months were -13ml (p=0.39) and -12ml (p=0.93), respectively. One female patient and four male patients temporarily stopped their treatment at 3 months and at 6 months because of their eGFR decreased to lower than 15 ml/min/1.73m². Hepatic toxicity, hypernatremia, and the other adverse severe events were not detected.

Conclusions: No severe adverse events were occurred and 85% of CKD stage 4 patients could keep treatment for 6 months without CKD progression. Tolvaptan was safe and tolerable for ADPKD patients with CKD stage 4 in lower dose.

Estimation of Total Kidney Volume in Autosomal Dominant Polycystic Kidney Disease  

Edwin M. Spithoven,1 Maatje D.A. van Gastel,1 A. Lianne Messchendorp,1 Nick F. Castleijn,1 Ron T. Gansevoort.2  
1Internal Medicine, Nephrology, UMC Groningen; 2On behalf of the DIPAK Consortium, Netherlands.

Background: Measuring total kidney volume (TKV) in autosomal dominant polycystic kidney disease (ADPKD) by magnetic resonance image (MRI) and manual tracing is time consuming. Two alternative MRI methods have recently been proposed to estimate TKV: eTKV (ELLIPSOID) and eTKV (ANNO) which require less time.

Methods: ADPKD patients with a wide range of kidney function were included, if they had an approved T2 weighted MRI. A test set of 10 MRIs was used for assessing the model. The outcome was the change of TKV from baseline (p=0.39) and -1.80 ml/min/1.73m² (p=0.04), respectively. The change of median TKV from baseline at 1.5 months and at 6 months were -13ml (p=0.39) and -12ml (p=0.93), respectively. One female patient and four male patients temporarily stopped their treatment at 3 months and at 6 months because of their eGFR decreased to lower than 15 ml/min/1.73m². Hepatic toxicity, hypernatremia, and the other adverse severe events were not detected.

Conclusions: No severe adverse events were occurred and 85% of CKD stage 4 patients could keep treatment for 6 months without CKD progression. Tolvaptan was safe and tolerable for ADPKD patients with CKD stage 4 in lower dose.

Genetic Background Radically Alters Disease Progression in the Pkd1<sup>RC/RC</sup> Model  

Diana L. Escobar, Katharina Hopp, Cynthia J. Sieben, Peter C. Harris.  
Mayo Clinic, Rochester, MN.

Background: Studies in ADPKD patients and PKD mouse models have shown that genetic background influences the disease phenotype. Here, we evaluated the phenotype of the homozygous Pkd1<sup>RC/RC</sup> model in three new backgrounds: BalbC, 129S6, and F1 (C57BL6 X BalbC) and compared them to C57BL6.

Methods: To characterize the cystic disease burden, Pkd1<sup>RC/RC</sup> animals were imbeded into three different strains and aged to 3 months (n). At this point time %Kidney Weight/Body W, BUN levels, kidney cyst index were used to compare disease severity.

Alterations in Renal Oxylipins in Models of Polycystic Kidney Disease: Potential for Cyclooxygenase Inhibition for Disease Treatment

Methods: Participants underwent protocol visits including MR imaging, iohalumate clearance and serum creatinine measurements. Baseline htTKV was evaluated in its capacity to predict later CKD stages both individually and in a multivariable model that includes age, race, gender, and baseline iohalumate clearance. Receiver operator characteristic area under the curves (AUCROCs) were developed for reaching CKD stage 3a, 3b, 4 or 5 after a range of 10 years of follow-up.

Conclusions: Kidney volume measured by MR at a single timepoint is a powerful predictor for the development of advanced stages of CKD over the ensuing 11 years. Consistent with prior analyses, greater kidney volume is strongly associated with higher rates of CKD progression, further supporting the notion that cyst enlargement is the primary cause of GFR loss and kidney failure.

Therapeutic Effects of the Fibrokinase Inhibitor ANG3070 in Polycystic Kidney Disease

Methods: Male PCK rats (PCK/CrljCrl-pkhd1pck/Crl) were randomized to vehicle or ANG3070 (25 mg/kg, i.P., PO) at 6.5 weeks of age following confirmation of frank disease and sacrificed at 13.5 weeks. Age-matched male Sprague-Dawley rats served as wild-type controls.

Results: ANG3070 has no effect on mean arterial pressure. In PCK rats with diseased kidneys (figure1), randomization to ANG3070 treatment was therapeutic, reducing cyst index, renal interstitial fibrosis (hydroxyproline (HYP)), albuminuria and other urinary biomarkers of renal injury and serum creatinine (* p<0.05).

Alterations in Renal Oxylipins in Models of Polycystic Kidney Disease: Potential for Cyclooxygenase Inhibition for Disease Treatment

Hepatorenal Fibrocystic Diseases in Children

RuIN Park, Yo Han Ahn, Hee Gyung Kang, Hye Won Park, IL-Soo Ha, Hae Il Cheong.

Methods: Participants underwent protocol visits including MR imaging, iohalumate clearance and serum creatinine measurements. Baseline htTKV was evaluated in its capacity to predict later CKD stages both individually and in a multivariable model that includes age, race, gender, and baseline iohalumate clearance. Receiver operator characteristic area under the curves (AUCROCs) were developed for reaching CKD stage 3a, 3b, 4 or 5 after a range of 10 years of follow-up.

Conclusions: Kidney volume measured by MR at a single timepoint is a powerful predictor for the development of advanced stages of CKD over the ensuing 11 years. Consistent with prior analyses, greater kidney volume is strongly associated with higher rates of CKD progression, further supporting the notion that cyst enlargement is the primary cause of GFR loss and kidney failure.

Funding: NIDDK Support

Conclusions: With ongoing investigational new drug enabling toxicology studies suggesting a large safety index, these data support the continuing development of ANG3070 for PKD, a disease currently without cure. Supported by PR130909 and AR058041-02.

Identifying Genetic Modifiers in Severe Polycystic Liver Disease (PLD) by Whole Exome Sequencing (WES) Amriza H. Haighdhi,
Young-Hwan Hwang,
Ning He,
Kairong Wang,
Winnie Y. Chan,
Xuewen Song,
Joost P.H. Drenth,
York P. Pei.

Methods: WES using Illumina HiSeq2000/2500 with SSV4.5 capture kit in 88 patients (24 affected discordant sib-pairs and 7 affected concordant sib-pairs for sPLD and 27 sporadic cases). All sPLD patients had a liver span >25 cm by CT/MRI or >5x normal liver volume. In addition to genome-wide analysis, we performed focused analysis on 168 ER genes (Standard algorithms for sequence alignment, base calling, and QC filtering were applied to identify rare deleterious variants of high and moderate impact as predicted by PolyPhen-2, SIFT, Mutation Assessor, Mammalian and Vertebrate nucleotide-level conservation, and Combined Annotation Dependent Depletion.

Results: Overall, we achieved a mean target coverage of 108X with 90% of targeted exomes having >30X read depth. We identified 4,696 rare deleterious variants that segregated with PLD disease severity in at least one family. From them, we found 7 non ER genes (TTN, DNAH10, DNAH14, HMCN2, NEB, OBSCN and ADAMT29) with rare variants that segregate in 4 to 6 families each and 8 ER genes (TSC1, TSC2, PRKCSH, SEC23C, SEC24D, SEC23B, ENTPD6 and PRKAT2) with rare variants that segregate in at least one family and 3-4 sporadic sPLD cases.

Conclusion: Our data indicate that sirolimus acts fundamentally at the vascular-containing compartment, suggesting that it may decrease the bleeding risk. In addition to its potential benefit as neovascular therapy for large/multiple AMLs undergoing NSS, our findings revealed that the use of sirolimus was safe and reduced surgical complications.

SA-PO889

TOSCA – Tuberous Sclerosis Registry to Increase Disease Awareness: Renal Manifestations of Tuberous Sclerosis Complex John C. Kingswood,
Anna C. Jansen.

Methods: Patients diagnosed with TSC were enrolled in TOSCA from 170 sites across 31 countries worldwide. Patients will be followed up for up to 5 years with interim analysis performed every year.

Results: Baseline core data from 2093 patients were entered in the registry as of September 30, 2014 (cut-off date for the 2nd interim analysis). Median age at consent was 13 years (range: 0.4-99.9 years). A total of 38 renal abnormalities were reported in 987 (47.2%) patients. Median age at diagnosis of angiomyolipoma was 13 years (0-67). Of the 853 (40.3%) patients with ongoing renal angiomyolipomas, 396 (41.9%) had multiple and bilateral lesions, 329 (34.8%) had single lesions, 40 (4.3%) had lesions >3 cm, 204 (21.6%) had growing lesions. Signs/symptoms associated with renal angiomyolipomas included either individually or in combination with others, were elevated blood pressure (48 [5.1%]), microscopic hematuria (35 [3.7%]), hematuria (47 [5.0%]), impaired renal function (36 [3.8%]), and pain (51 [5.4%]). Renal angiomyolipomas were treated in 274 (27.8%) patients; major treatment modalities included embolization in 78 (38.8%) and mammalian target of rapamycin (mTOR) inhibitors in 78 (28.8%) patients. Other renal features reported were renal malignancy (24 [1.1%]), multiple renal cysts (477 [22.8%]), polycystic kidneys (73 [3.5%]), and impaired renal function (43 [2.1%]).

Conclusion: The prevalence of angiomyolipomas of 47.2% in our cohort corroborates the data of 10-90% in the literature probably reflects their young mean age. Despite this intervention rate was high, emphasizing the need for active surveillance. This is in agreement with the findings of the intervention rate of 11 to 25% in TSC and the fact that the intervention rate was high, emphasizing the need for active surveillance.

Siroliimus Reduces Fundamentally the Vascular and/or Muscular Components of Angiomyolipomas and Can Be Neoadjuvant to Partial Nephrectomy in Patients with Tuberous Sclerosis Complex Large Tumors Associated with Surgical Risk Eliesser W. Watanabe,
Fernando I. Yamauchi,
Hilton M. Leao-Filho,
William C. Nahas,
Luiz F. Obuchi.

Methods: In a single blinded, crossover, placebo-controlled dose-response study 12 healthy subjects were treated, in a randomized order, with placebo (isotonic NaCl) or one of three doses of sodium nitrite 40, 120 or 240 mg/kg/hour for two hours. Each examination was preceded by 4 days standardized diet. Subjects were supine and water loaded throughout the day. Before, during and after sodium nitrite administration we measured diastolic, systolic and mean arterial blood pressure, heart rate, plasma renin, angiotensin II and aldosterone, GFR by chromate-EDTA clearance, fractional sodium excretion and urinary excretion rate of nitrate and nitrite (NO3-).

Results: As expected, sodium nitrite increased urinary NO production over 3 to 4 fold as compared to DBP, SBP and MAP, heart rate, plasma renin, angiotensin II and aldosterone, GFR by chromate-EDTA clearance, fractional sodium excretion and urinary excretion rate of nitrate and nitrite (NO3-).

Bruno Ranchin,
Anja Christine Sander,
Sara Testa,
Lutz Thorsten Weber,
Dorota Wicher,
Elke Wuehl,
Franz S. Schafer,
Max Liebau.

Background: ARPKD is an international, mostly European, pro- and retrospective, observational study in both pediatric and adult ARPKD patients to generate a deeply-characterized ARPKD cohort. Using web-based questionnaires regarding patients’ clinical data in combination with associated biobanking and reference histology ARegPKD will characterize long-term ARPKD courses and set roots for future translational research.

Methods: In June 2015 63 centers have registered and more than 130 patients have been included (73% 67.6% male, median age at inclusion 7.6 years, number of follow-up visits up to 17). Here we present data on general patient characteristics, genetic testing, renal and hepatic phenotype putting a special focus on the peri- and postnatal period (perinatal findings, ventilation modalities, sonographical findings, laboratory values).

Conclusion: ARegPKD can act as a natural registry characterizing ARPKD patients in order to provide evidence base for clinical treatment decisions and contribute to the understanding of this severe renal disorder of early childhood.

SA-PO892

The Effect of Sodium Nitrite on Central and Peripheral Hemodynamics, Vasoactive Hormones, GFR and Sodium Excretion in Healthy Subjects Jeppe B. Rosenbaek,
Safa Al Thawrani, Janni Maiggaard Jensen, Frank H. Mose,
Erling B. Pedersen, Jesper N. Bech.

Background: Recent research has shown that sodium nitrite is readily converted to nitrite oxide (NO) by enzymes in vivo and exerts vasoactive effects. Previous studies based on nitric oxide synthase inhibition indicates a mediator effect of nitric oxide. The purpose of the present study was to examine the effects of sodium nitrite on central and peripheral blood pressure, heart rate, fractional sodium excretion and GFR.

Methods: In a single blinded, crossover, placebo-controlled dose-response study 12 healthy subjects were treated, in a randomized order, with placebo (isotonic NaCl) or one of three doses of sodium nitrite 40, 120 or 240 mg/kg/hour for two hours. Each examination was preceded by 4 days standardized diet. Subjects were supine and water loaded throughout the day. Before, during and after sodium nitrite administration we measured diastolic, systolic and mean arterial blood pressure, heart rate, plasma renin, angiotensin II and aldosterone, GFR by chromate-EDTA clearance, fractional sodium excretion and urinary excretion rate of nitrate and nitrite (NO3-).

Results: As expected, sodium nitrite increased urinary NO production over 3 to 4 fold as compared to DBP, SBP and MAP, heart rate, plasma renin, angiotensin II and aldosterone, GFR by chromate-EDTA clearance, fractional sodium excretion and urinary excretion rate of nitrate and nitrite (NO3-).

The Spatial Distribution of Metabolites Determined by Imaging Mass Spectrometry in the Kidneys of Rats Treated with Furosemide

Background: In the kidney, metabolic processes vary among the cortex (COR), outer medulla (OM), and inner medulla (IM), and the concentrations of metabolites are different according to the kidney zones. We aimed to examine the regional differences of the significantly changed metabolites in the kidneys of rats treated with loop diuretics by exploiting the matrix-assisted laser desorption/ionization (MALDI) and imaging mass spectrometry (IMS).

Methods: Osmotic minipumps were implanted in male Sprague-Dawley rats to deliver 12 mg/day of furosemide (s.c.). Vehicle-treated control rats (n = 14) and furosemide-treated rats (furosemide rats, n = 15) were maintained in metabolic cages for 6 d on a fixed daily diet of rat chow (15 g/220 g bw/rat) with free access to water intake. The rats were then killed by cervical dislocation and their kidneys were excised and divided into three parts: COR, OM, and IM. Tissue samples were cryopreserved in liquid nitrogen and lyophilized. The samples were powdered to a fine powder and analyzed by IMS. Next, significant changes of metabolites were identified by IMS and MALDI-TOF/TOF, including choline compounds (choline, phosphocholine, phosphocholine derivatives and GPC), carnitine compounds (carnitine, dehydrocarnitine, acetyl carnitine and acyl carnitine) and betaine. Importantly, the spatial distribution and relative quantitation of identified metabolites were analyzed by IMS. Choline compounds were increased in COR and OM, but decreased in IM from furosemide rats. Carnitine compounds were increased in COR and IM in furosemide rats. Betaine and GPC were decreased in OM and IM in furosemide rats.

Conclusions: Together, IMS applied to the kidney sections successfully provided the spatial distribution and relative quantitation of significantly changed metabolites in the kidneys of furosemide rats.

Bicarbonate Supplementation Improves Vascular Function in Patients with Chronic Kidney Disease: A Pilot Study
Jessica B. Kendrick, Emily Decker, Kristen L. Nowak, Michel Conlon, 1Univ of Colorado Denver, Aurora, CO; 2Denver Health Medical Center, Denver, CO.

Background: Metabolic acidosis, as reflected by a low serum bicarbonate level, is associated with increased risks of endothelial dysfunction, hypertension and death. Metabolic acidosis induces inflammation and endothelin-1, both of which contribute to vascular dysfunction. Whether alkali therapy improves vascular function in patients with chronic kidney disease (CKD) is unknown.

Methods: Seven subjects (5 men and 2 women) with stage III/IV CKD and serum bicarbonate level 16-22 mEq/L completed a pilot, prospective, open-label, crossover study of 14 weeks duration examining the effect of oral sodium bicarbonate supplementation on endothelial function. The primary endpoint was change in brachial artery flow mediated dilation between treatment and control conditions. Each period was 6 weeks in duration with a two-week washout period in between. Patients were treated with oral sodium bicarbonate tablets two to three times per day for goal serum bicarbonate of ≥ 23 mEq/L.

Results: The mean (SD) age and GFR at enrollment was 59 (3.3) years and 21.9 (2.6) ml/min/1.73m2, respectively. The mean (SE) serum bicarbonate level increased after sodium bicarbonate administration from 18.4 (0.7) mEq/L to 23.7 (0.9) mEq/L. The mean (SE) serum bicarbonate level did not change in the control arm. Blood pressure control was similar in both arms. Brachial artery flow mediated dilation was 42.0% 45.0% after 6 weeks of sodium bicarbonate replacement (3.78 ± 1.58 to 5.35 ± 1.31%) whereas it decreased by 14% during control conditions (3.51 ± 0.53 to 3.01 ± 0.91%).

Conclusions: Bicarbonate supplementation in patients with CKD and low serum bicarbonate levels resulted in improved vascular function. Large randomized trials need to be performed to determine if treatment with alkali therapy can reduce cardiovascular disease in patients with CKD.

SA-PO085
Tenofovir-Related Distal Tubular Acidosis in HIV Infected Patients
Tamar Cunha, Talita Mourao Loyola, Carlos Perez Gomes, Maurilo Leite. Dept of Nephrology, Federal Univ of Rio de Janeiro, Rio de Janeiro, Brazil.

Background: Tenofovir disoproxil fumarate (TDF) is a nucleoside reverse transcriptase inhibitor extensively used worldwide and is now the most prescribed drug on Highly Active Antiretroviral Therapy (HAART). TDF toxicity is mainly targeted at the proximal tubule, and tubular abnormalities can cause Fanconi Syndrome or acute kidney injury. Despite this, there are no studies evaluating other types of tubular toxicity. This study evaluated the presence of distal renal tubular acidosis (dRTA) in HIV patients on HAART.

Methods: Sixty one HIV patients older than 18 years on treatment with HAART for more than 3 months and GFR estimated by CKD-EPI equation greater than 45 ml/min/1.73m2 were evaluated. They were divided into two groups: 31 used HAART that included TDF and 30 used HAART with no current or previous use of TDF. They were submitted to fluid restriction for 12 hours and received 40mg of furosamide and 0.1mg of diosmin, following a urine collection test protocol similar to that of de Paulo et al (2007). We measured serum bicarbonate and the following parameters: hourly urine pH (0 to 4h) by potentiometry, urinary ammonium (unNH4+) by spectrophotometry and urinary titratable acidity (uTA) by NaOH (0h and 4h).

Results: dRTA was established when the urinary pH was lower than 5.3 in all measurements.

Conclusions: There was no significant difference between the groups in terms of age, gender, ethnicity, CD4 count or eGFR. The prevalence of dRTA was 6% in the group without TDF and 26% in TDF group (p = 0.04). In both groups, patients without dRTA showed increase in unNH4+ (p = 0.05 and p = 0.009, respectively) and in uTA (p = 0.94 and p = 0.05, respectively), unlike patients diagnosed with dRTA who showed an increase neither in unNH4+ (p = 0.44 and p = 0.34, respectively) nor in uTA (p = 0.52 and p = 0.11, respectively). In all cases with dRTA, the serum bicarbonate was normal, featuring an incomplete presentation.

Conclusions: The prevalence of incomplete dRTA in patients using TDF was significantly higher than the group not using the drug. This is the first study suggesting a possible association between TDF and dRTA. Subsequent studies will be necessary to corroborate this hypothesis.

SA-PO086
Comparison of Acid-Base Disorder Between Patients Undergoing Ileal Neobladder and Ileal Conduit
Jung-wooh Noh, Eunjung Kim, 2Jae-Ryong Koo. 1Internal Medicine, Nephrology, Hallym Univ Medical Center; Hallym Kidney Research Inst, Seoul, Korea; 2Internal Medicine, Nephrology, Hallym Univ Medical Center; Hallym Kidney Research Inst, Seoul, Korea; 3Internal Medicine, Nephrology, Hallym Univ Medical Center, Hallym Kidney Research Inst, Seoul, Korea.

Background: Since the 1980s, the orthotopic ileal neobladder(IBN) has been as a new option by eliminating the need for a cutaneous stoma and opeundra appliances of ileal conduit(IC). Although this method has improved patients’ quality of life, frequent incidence of metabolic acidosis(MA) have been reported. We compared occurrence of MA in INB group to IC group, and searched for risk factors affecting MA.

Methods: We conducted a retrospective study in 55 patients who underwent radical cystectomy and urinary diversion from January 2001 to December 2014 at Hallym University Medical Center. Patients who have any illness such as severe pulmonary disorder, take any medication that could lead to MA and sepsis were excluded. Acid-base balance and renal function were compared between INB and IC groups. MA was defined as a venous sample bicarbonate level of less than 21 mmol/L.

Results: MA was detected in 74.2% and 69.7% within 7 days(p=0.64), and in 31% and 14.8% at 1 month(p=0.1) after operation in INB and IC group. But cases on bicarbonate therapy were significantly more in INB group(p=0.02). Serum HCO3 levels(p=0.05) and base excess(p=0.02) were significantly lower in INB group in spite of more cases on bicarbonate therapy. Acute kidney injury(AKI) at 1 month was higher in INB group(p=0.008). Serum creatinine concentrations were significantly correlated with bicarbonate levels. Multiple logistic analysis showed that 1 mg/dl increase of serum creatinine level result in a 5.38-fold higher risk of MA (95% confidence interval, 1.14-25.3; P = 0.03). Patients without AKI, MA was detected in 13.5% in INB group, 12% in IC group at 1 month(p=1.0).

Conclusions: Despite there being no statistical difference, INB group may more easily develop MA compared with IC group especially in patients with elevated serum creatinine concentrations. In addition, a close association between the serum creatinine level and the degree of MA was observed in both groups.

SA-PO087
Screening for Hyperlactatemia: Relationship Between the Anion Gap and Serum Lactate in Hypovolemic Shock
Richard M. Treger, 1Tristan Grogan, 2Eunjun Cho, 2Craig Anderson, 2Scott Budman. 1Nephrology, VHAAGL, LA, CA; 3 Medicine and Statistics Core, UCLA, LA, CA; 4 Emergency Medicine, UCI, Irvine, CA.

Background: In lactic acidosis (LA), a discrepancy between the increase in serum anion gap (AG) and serum lactate concentration has been noted. Previous studies evaluated patients in the Intensive Care Unit with established LA. No study has examined the relationship between AG and serum lactate within the first hour of the development of LA, specifically the sensitivity and specificity of an elevated AG for predicting hyperlactatemia.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
838A
Methods: Data were obtained prospectively from adult trauma patients at a single level 1 trauma center. Venous samples were drawn prior to initiation of intravenous fluid resuscitation.

Results: 117 patients with elevated serum lactate levels (>2.1 mmol/L) were included. The sensitivity of an elevated AG (>10) to reveal hyperlactatemia was only 41% whereas specificity was 84%. Sensitivity improved if the upper limit of normal AG was lowered and with increasing levels of serum lactate. (Table 1). The correlation between the AG and serum lactate level yielded an R² of 0.30 (p < 0.001) and the slope of this relationship was 0.29 ± 0.58 (95% confidence interval 0.23-0.35).

Conclusions: Within the first hour of the development of LA due to hypovolemic shock, the AG was not a sensitive indicator of an elevated serum lactate level, but it was fairly specific. The sensitivity and specificity of the AG as an indicator of hyperlactatemia is consistent with prior studies examining later stages of LA. The AG increased to a greater extent than the serum lactate and approximately 70% of the change in serum lactate. Our results suggest that other anions contribute to the AG in LA.

SA-PO989

The ∆ Anion Gap/∆ Bicarbonate Ratio in Early Lactic Acidosis: Time for Another Delta?

Background: The ratio of Δ anion gap and Δ bicarbonate (ΔAG/ΔHCO₃) is used to detect co-existing acid-base disorders in patients with high AG metabolic acidosis. Classic teaching holds that in lactic acidosis (LA), the ΔAG/ΔHCO₃ is 1:1 within the first 60 minutes of onset (despite limited human data) and subsequently rises to 1.8-2.1. This study examined the ΔAG/ΔHCO₃ within the first hour of the development of LA.

Methods: Data were obtained prospectively from adult trauma patients at a level 1 trauma center. Venous samples were drawn prior to intravenous fluids.

Results: 108 patients were included. 63 patients had normal serum lactate levels (≤2.1 mM) with a mean AG of 7.1, the value used to calculate subsequent ΔAG values. ΔAG/ΔHCO₃ was calculated for 45 patients who had elevated serum lactate levels (>2.1 mM). The mean ΔAG/ΔHCO₃ for all patients with elevated serum lactate levels was 1.36 (SD 1.40). The correlation between ΔHCO₃ and AG showed a 95% prediction interval of ±6.15 (Figure 1).

Figure 1: Correlation between ΔHCO₃ and ΔAG

Conclusions: The mean ΔAG/ΔHCO₃ was 1.86 within the first hour of the development of LA due to hypovolemic shock, confirming a small prior human study. This contradicts the traditional belief that in LA the ΔAG/ΔHCO₃ is 1:1 within the first 60 minutes. The classic 1:1 stoichiometry is based on animal models (in which lactic acid is infused into the extracellular [EC] space, facilitating EC buffering of protons by bicarbonate), while our results demonstrate a higher initial ΔAG/ΔHCO₃ ratio in early endogenous LA in humans (which originates intracellularly, resulting in intracellular buffering of protons while lactate is predominantly distributed in the EC fluid). The wide 95% prediction interval suggests that ΔAG/ΔHCO₃ should be used cautiously in the diagnosis of mixed acid-base disorders.

SA-PO899

Blood Lactate as a Predictor for Mortality in Sepsis Patients with Lactic Acidosis Treated Sodium Bicarbonate: A Retrospective Analysis

Background: Recent studies have reported that blood lactate level in the critically ill patients is associated with in-hospital mortality, but the use of lactate level to monitor and guide therapy remains under investigation. In this study, we evaluated the efficacy of blood lactate level as a predictor for mortality in sepsis patients with lactic acidosis treated with sodium bicarbonate.

Methods: We conducted a single center analysis from May 2011 through April 2014. We retrospectively analyzed 109 sepsis patients with lactic acidosis treated with sodium bicarbonate.

Results: Among the 230 patients with lactic acidosis treated with sodium bicarbonate, we finally included 109 patients (47.4%) with lactic acidosis caused by sepsis. The non-survivors had lower albumin levels (P<0.009), higher SOFA and APACHE II scores (P=0.002, P=0.047, respectively), and higher blood lactate level at 6 hours, 24 hours, and 48 hours after checking the initial lactate level (P=0.002, P<0.001, P=0.001, respectively). In particular, decrement of at least 10% in lactate clearance for the first 6 hours, 24 hours, and 48 hours of treatment were more dominant in non-survivors than survivors. Lactate clearance at 6 hours, 24 hours, and 48 hours was significantly associated with mortality after adjustment for confounding variables, including age, gender, CRP, albumin, SOFA and APACHE II scores, ventilator care, CRRT, and use of inotropic (HR: 2.201, 95% CI: 1.197–4.046, P=0.011; HR: 3.948, 95% CI: 1.269–12.281, P=0.018; HR: 4.970, 95% CI: 1.679–14.710, P=0.004, respectively).

Conclusions: Serial blood lactate levels monitoring is useful in terms of predicting mortality since only 12% of the initial lactate and/or maximum lactate levels in sepsis patients with lactic acidosis treated with sodium bicarbonate.

SA-PO900

D-Lactate: It’s All In the Gut

Background: D-Lactic acidosis is a rare form of lactic acidosis that can occur in patients with short bowel syndrome.

Methods: 88 yo M with PMH significant for HTN and small bowel obstruction s/p subtotal small bowel resection presented to the ED with complaints of nausea, vomiting, constipation, loss of appetite, altered mental status and decreased urinary output.

On admission:

Vitals: Blood pressure: 115/68 mmHg, Pulse: 80/min, Temperature: 98.5 F and SpO2: 92%.

Examination: Distended abdomen with no peripheral edema.

Imaging: CT abdomen revealed dilated bowel loops but no bowel obstruction or free air in the abdomen/pelvis.

Labs: Na: 134mmol/L, K: 4.5mmol/L, Cl: 108mmol/L, CO₂: 16mmol/L, BUN: 45mg/dl, Creatine: 1.6mg/dl and Albumin 2.3g/dl. ABG: pH: 7.42, pCO₂: 31mmHg, HCO₃: 39mmol/L. He was found to have anion gap metabolic acidosis with a non-anion gap metabolic acidosis. Venous lactate: 1.11 mmol/L (Normal 0.5-2.2 mmol/L). Serum D-lactate was drawn revealing an elevation at 4.15mmol/L – thus confirming the diagnosis of D-lactic acidosis.

Treatment: Patient received IV fluids with bicarb. PO Flagyl was started and constipation was also treated. His neurological status along with his acidosis subsequently improved.

Conclusions: The diagnosis of D-lactic acidosis should be promptly considered in patients with malabsorptive disorder such as short bowel syndrome or following a jejunocolic bypass especially when no other cause of anion gap metabolic acidosis is found. Diagnosis is confirmed by a special enzymatic test measuring serum D-Lactate. Treatment involves a low carbohydrate diet, sodium bicarbonate infusion to correct acute acidemia and antibiotics to minimize D-lactate producing bacteria.

SA-PO901

Customized Base Solutions for Treatment of Acute Acidosis

Background: Acute acidosis is associated with cell dysfunction and increased mortality. Intravenous administration of hypertonic sodium bicarbonate (NaHCO₃) does not improve cellular function or clinical outcome. This is attributed to undesirable generation of CO₂, which decreases intracellular pH, and also to undesirable osmotic stress. Thus, designing a base that can raise pH without generating CO₂ or producing osmotic stress would address an unmet need.

Conclusions: The diagnosis of D-lactic acidosis should be promptly considered in patients with malabsorptive disorder such as short bowel syndrome or following a jejunocolic bypass especially when no other cause of anion gap metabolic acidosis is found. Diagnosis is confirmed by a special enzymatic test measuring serum D-Lactate. Treatment involves a low carbohydrate diet, sodium bicarbonate infusion to correct acute acidemia and antibiotics to minimize D-lactate producing bacteria.
Methods: Theoretical modeling has been performed using Mathematica software to determine equilibrium ion concentrations in mixed strong-weak base solutions. If these solutions have a significant proportion of strong base yet lower concentration, they are predicted to raise blood pH without increasing CO₂ or producing large osmotic stress. Strong bases examined include sodium carbonate (Na₂CO₃) and sodium hydroxide (NaOH); these were mixed with NaHCO₃. Acid-base parameters were measured in acidified canine blood mixed with the base solutions in a closed system using a blood gas analyzer. Treated blood was examined using an optical microscope.

Results: A near-isotonic base solution containing Na₂CO₃; NaHCO₃ at a ratio of 3:1 is predicted to raise blood pH without increasing CO₂ or causing osmotic stress. Addition of this base to acidified blood raised blood pH while reducing CO₂. By contrast, NaHCO₃ raised blood pH, but also generated CO₂. Examination of red blood cells exposed to the former 3:1 solution revealed no evidence of osmotic stress. Mixed base solutions of NaOH and NaHCO₃ are also promising as a lower sodium alternative.

Conclusions: Mixed strong-base solutions, rather than hypertonic NaHCO₃, can raise blood pH and serum bicarbonate levels, minimize osmotic stress, and limit CO₂ generation. A 3:1 mixture of Na₂CO₃; NaHCO₃ well below 1 M concentration appears to be effective in this regard.

SA-PO902

Chloride Alterations in Hospitalized Patients: Prevalence and Outcome Significance Qi Ouan, Charat Thongprayoon, Wisit Cheungpasitporn. Medicine / Nephrology and Hypertension, Mayo Clinic, Rochester, MN.

Background: Chloride (Cl) plays a fundamental role in the maintenance of serum osmotic pressure, acid-base balance, and cellular health. Cl channels are expressed in almost all cells in the body. Dysfunctions in the Cl channel result in a broad spectrum of diseases. Cl alterations in hospitalized patients have not been comprehensively studied in recent years.

Methods: We conducted a retrospective study of adult (>18 years old) hospital admissions at Mayo Clinic over a period of three years (2011 to 2013). Patients without admission Cl (either at admission or measured during hospitalization) were excluded. Outcome measures included all-cause mortality, length of hospital stay and discharge disposition.

Results: 76,719 unique patients from a total of 147,358 hospital admissions were enrolled. 55,523 (72.4%) had repeat Cl measurements within 48 hours. Admission serum Cl in the range of 105-108 mmol/L was found to be optimal based on hospital mortality. 60.6% (n=48,999) had admission Cl>105 mmol/L, and 13% (n=11,999) >108 mmol/L. Cl<100 or >108 mmol/L independently predicted poor outcomes including hospital death, longer length of hospital stay, and being discharged to a care facility. 17.1% (n=13,089) of the patients had anion gap >2+ mmol/L; their hospital mortality, when compared to those with anion gap ≤2 mmol/L, worsened progressively with rising Cl. Further examination of Cl evolution within 48 hours of admission showed Cl increase to be an independent predictor for hospital mortality. Further, the magnitude of Cl increase was inversely associated with the days of patient survival.

Conclusions: Non-optimal serum Cl values are common in hospitalized patients. Cl alterations are independent predictors for poor clinical outcomes. Post-admission Cl increase not only predicted hospital mortality but also inversely correlated with length of patient survival. These results indicate that more attention should be paid to Cl value. Further prospective and randomized studies are needed to determine whether avoidance of post-admission Cl increase would improve patient survival.

SA-PO903

A Retrospective Review of Paediatric Patients with Bartter and Gitelman Syndrome Patrick Walsh, Marc Bienias, Detlef Bockenhauer. ICH, UCL, London, United Kingdom.

Background: Bartter and Gitelman syndrome are rare autosomal recessive disorders of renal salt handling. They are characterized by disturbed electrolyte and acid-base homeostasis with potentially severe complications. Currently little is known about the long-term disease course and best treatment is controversial. We performed a retrospective case review to investigate the long-term disease course of patients with a diagnosis of Bartter/Gitelman syndrome.

Methods: Demographic and Laboratory data was recorded at presentation, and ages 1,2,3,4,5,10 and 15.

Results: 42 patients with a genetic diagnosis of Bartter/Gitelman were reviewed with a median follow up of 7.85 years (Range 0 - 18 years).

Bartter &2 presented earliest with prematurity and deranged electrolytes. All of the Bartter 1 patients and 70% of Bartter 2 had evidence of nephrocalcinosis on their first ultrasound. Hypomagnesaemia (<0.7mmol/L) was seen in 11/14 Bartter 3 and 8/11 Gitelman patients. Hypocalciuria developed over time and was seen earlier in Bartter 3 (3.8 years) than in Gitelman (7.9 years). Obvious complications of hypokalaemia were only seen in one patient with Bartter 3 (despite potassium levels <2.5mmol/L in 10 patients) in the form of hypokalaemic paralysis; he was admitted twice at ages 2 and 3 (Potassium 7 & 1.5 respectively). Decreased GFR was present in all Bartter 1 and 90% of Bartter 2 at last follow-up. 3 patients with Bartter 3 developed nephrologic renal proteinuria and one demonstrated biopsy evidence of FSGS.

Conclusions: The overall prognosis during childhood was good. Final heights were within the normal range and no child developed ESRD. Albuminuria was common in Bartter 3, indicating the need for long-term monitoring of renal function. Interestingly, hypomagnesaemia is often absent at presentation and develops over time in both Bartter 3 and Gitelman.

SA-PO904

Urine Calcium to Magnesium Ratio Aids to Diagnose Gitelman’s Syndrome without Hypocalciuria and Receiving Intravenous Magnesium Administration Chih-Jen Cheng,1,2 Shih-Hua P. Lin,1,2 Ming-Tso Yan,1,2 1-Tri-Service General Hospital; 2National Defense Medical Center; 3Cathay General Hospital.

Background: Although hypocalciuria is widely used to distinguish Gitelman’s syndrome (GS) from Bartter syndrome (BS), several patients with GS actually have not hypocalciuria and may be clinically misdiagnosed as BS. Intravenous magnesium administration to correct hypokalaeemia, another distinct finding in GS can significantly enhance urine calcium excretion and unmask the preexisting hypocalciuria. Because renal Mg²⁺ wasting is characteristic in GS, we hypothesize that urine Ca²⁺/Mg²⁺ ratio may be superior in diagnosing GS.

Methods: One hundred forty three Taiwanese GS patients (M:F = 87:56, age 25 ± 10) with definite SLC12A3 mutations was enrolled. Nine BS patients with CLCNKB mutations and 15 healthy subjects were enrolled as disease and normal control, respectively. Intravenous MgSO₄, was administered (elemental Mg 0.35 mmol/kg) in 8 GS patients with hypocalciuria. Relevant blood laboratory and at least two urine collection for all electrolytes excretion were determined. Hypocalciuria was defined as urine Ca²⁺/Cr ratio less than 0.1 mmol/mmol.

Results: Fourteen (9.8%) of 143 GS patients did not have hypocalciuria (Ca²⁺/Cr ratio ≥ 0.28 ± 0.09 mmol/mmol) and exhibited no significant difference in blood parameters compared with GS patients without hypocalciuria. Although their urine Ca²⁺/Cr ratio was significantly lower than that in CBS (0.51 ± 0.18 mmol/mmol), there was still overlapping between them. Notably, urine Ca²⁺/Mg²⁺ ratio was significantly lower in GS than CBS without overlap (0.46 ± 0.12 vs 1.57 ± 0.53 mmol/mmol, p<0.001). Acute MgSO₄ administration in GS patients markedly enhanced urine Ca²⁺ excretion (Ca²⁺/Cr ratio 0.05 ± 0.01 to 0.64 ± 0.01 mmol/mmol, p<0.001). However, urine Ca²⁺/Mg²⁺ ratio (0.21 ± 0.01 mmol/mmol) remained much lower than healthy subjects (1.35 ± 0.63 mmol/mmol, p<0.001) and CBS.

Conclusions: Urine Ca²⁺/Mg²⁺ ratio may be a good index to help diagnose GS without hypocalciuria and even receiving intravenous Mg²⁺ administration.

SA-PO905

A Blunted Response to Thiazide Diuretics Is Not Specific for Patients with Gitelman Syndrome Anneke Bech, Jack F. Wetzels, Tom Nijenhuis. Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands.

Background: In Gitelman syndrome (GS), a defective sodium-chloride co-transporter (NCCT) in the distal tubule classically leads to hypokalaemia and hypomagnesaemia. A challenge with thiazide diuretics, testing the functional presence of NCCT, has been shown to differentiate GS from Bartter syndrome (BS) and normal controls. However, the performance of the thiazide test in renal magnesium wasting disorders other than GS and BS has not been studied.

Methods: Eleven patients who presented to our clinic between 2010-2014 with renal magnesium wasting and in whom a thiazide test was performed were included. An abnormal test result is defined as a maximal change of fractional chloride excretion (ΔFECl) < 2.3% [Colussi 2007]. The thiazide test in eight volunteers in our clinic showed a mean maximal ΔFECl 3.12 ± 0.48% with the lowest value being higher than 2.3%. Additional DNA mutation analyses were performed.

Results: Three patients had a mutation in SLC12A3 (GS), one patient had a compound mutation in CLCNKB and KCNJ1 (BS), 1 patient had a mutation in FXYD2 and five patients had a deletion of one HNF1β allele. The patients with GS showed a blunted response, the patient with BS showed a normal response, the patient with FXYD2 mutation showed a blunted response and the patients with HNF1β mutations showed different responses to thiazide diuretics.
SA-PO907

Impact of Hydration Status, Assessed by Bioelectrical Impedance Vector Analysis, on Mortality in Critically Ill Patients

Sara Samoni,1,2 Valentina Vigo,1 Luis Ignacio Bonilla,1 Gianluca Villa,1 Silvia De Rosa,1 Federico Nalesso,1 Fiorenza Ferrari,1 Alessandra Brendolan,1 Carlo Donadio,1 Claudio Ronco.1 1IRRI, Vicenza; 2‘Sant Anna School of Advanced Studies, Pisa; ‘Univ of Pisa, Pisa.

Background: Clinical trials have shown a positive correlation between fluid overload and adverse outcomes in pts admitted to intensive care unit(ICU).Currently,there is not a non-invasive method that can provide an accurate and timely assessment of whole body hydration status.Our aim was to evaluate the impact of hydration status,assessed by bioelectrical impedance vector analysis(BIVA),on ICU mortality in critically ill pts.

Methods: This is a prospective,dual-center study.We included 125 ICU pts with an ICU stay of 72 hrs or more.Anthropometric,medical history and laboratory data were collected.

Assessment of hydration status was performed by BIVA,using a single frequency analyzer,at the baseline and daily for a period of 72-120 hrs.Pts were considered normohydrated(NH) or hyperhydrated(HH) if BIVA hydration level was 72.7%-74.3% or >74.3% of fat-free body mass,respectively.

Results: The logistic regression analysis performed found a significant correlation between ICU mortality and maximum hydration level reached in observation period,either in patients with or without acute kidney injury(p<0.001).

SA-PO908

Sleep-Disordered Breathing Is Not Associated with Body Fluid Volume in Chronic Hemodialysis Patients

Takahiro Masuda,1,2 Yumi Kijima,1 Chui Sekiguchi,1 Yasuharu Miyazawa,1 Eiji Kusano,1 Yasushi Asano,1 Daisuke Nagata.1 1Div of Nephrology, Department of Medicine, Jichi Medical Univ, Shimotsuke, Tochigi, Japan; 2Nasu-Minami Hospital, Nasukarasuyama, Tochigi, Japan; 3Japan Community Health Care Organization Utsunomiya Hospital, Utsunomiya, Japan; 4Japanese Red Cross Koga Hospital, Koga, Ibaraki, Japan.

Background: Sleep-disordered breathing (SDB), characterized by nocturnal intermittent hypoxia, is frequent in patients with chronic hemodialysis (CHD). Fluid retention may promote SDB in these patients, but the detailed information is lacking.

Methods: Eighty-eight CHD patients in Nasu-Minami Hospital and Japanese Red Cross Koga Hospital were included in this study (male: 62.1%, age: 68.1 ± 11.5 years, body mass index: 21.7 ± 3.1, duration of CHD: 5.3 ± 5.9 years, diabetes mellitus: 50.0%).

Overnight pulse oximetry and bioimpedance spectroscopy (InBody) for the assessment of body fluid volume were performed in the CHD patients.

Results: Sixty patients (68.2%) were classified into the SDB group (mild SDB 30.8%, severe SDB 37.2%). Body mass index (BMI) was significantly higher in the SDB group (24.3 ± 3.0 vs 22.9 ± 3.2, P < 0.05). After adjusting for age, gender, diabetes mellitus, hemoglobin and serum albumin in a logistic regression analysis, SDB was independently associated with increased BMI (odds ratio 1.23, 95% confidence interval 1.01–1.48). Total body water, intracellular water and extracellular water were similar among the three groups.

Conclusions: Our findings confirm and expand literature data about the correlation between hyperhydration and ICU mortality.Despite the importance of this problem,there are currently few methods to assess hydration status in critically ill pts.BIVA has been shown to be safe,non-invasive,easy to use and it may predict mortality,thus we suggest its routinely use in ICU pts.Randomized clinical trials are needed to define the precise role of BIVA in the goal-directed fluid management of critically ill pts in ICU.

SA-PO906

Assessment of Hydration Status by Bioimpedance Spectroscopy in Peritoneal and Hemodialysis Patients from a Single Center

Sara Samoni,1,2 Luis Ignacio Bonilla,1 Carla Estremaduroy,1 Alessandra Spinelli,1 Salvador Roberto Lopez,1 Faqz Husain-Syed,1 Carlo Crepaldi,1 Alessandra Brendolan,1 Claudio Ronco.1 1IRRI, Vicenza; 2‘Sant Anna School of Advanced Studies, Pisa.

Background: Fluid overload(FO) is frequent in peritoneal dialysis(PD) and hemodialysis(HD) pts.Due to the identified correlation between systolic blood pressure(SBP) and FO, some conditions,i.e.vascular stiffness and heart failure,can cause a significant proportion of pts to fall out from this model.Our aim was to assess the relationship between hydration status(HYD) and SBP in PD and HD pts.

Methods: We enrolled all DP and HD pts of our center.HYD was evaluated by bioimpedance spectroscopy using Body-Composition-Monitor(BCM Fresenius Medical Care) and expressed as means of 100-140,>140,<100 mmHg,respectively.Considering both parameters, we subdivided the cohort into 9 groups.Continuous variables were expressed as means ± SD for normally distributed data and compared with t-test.

Results: We enrolled 188 pts, 120 DP, 68 HD pts.Mean SBP was 141 ± 22 mmHg, respectively, Mean ADTH was 2.2 ± 3.1 in PD and 1.6 ± 3.9 L in HD pts.Among NSBP, the percentage of HH pts was significantly higher in PD than HD pts (p < 0.04) while among HSNB, the HD pts were more HH than PD pts (p < 0.02).

Conclusions: A blunted response to thiazide diuretics is not specific for GS and can also be found in other renal magnesium wasting disorders,such as caused by mutations in FXYD2 or HNF1β. Still, the thiazide test could prove to be a valuable tool for research and phenotyping patients, and increase our understanding of the pathophysiological processes and the interrelationship between transcription factors, transporters and ion channels.

Association Between Brain Natriuretic Peptide and Fluid Volume Imbalance Between Intra- and Extracellular Water in Patients with Chronic Kidney Disease

Yasushi Ohashi, Reibin Tai, Toshiyuki Aoki, Shizuka Kobayashi, Atsushi Aikawa, Ken Sakai. Dept of Nephrology, School of Medicine, Faculty of Medicine, Toho Univ; Tokyo, Japan.

Background: Maldnourished and elderly patients with chronic kidney disease (CKD) may be susceptible to a extracellular fluid volume overload due to a decreased intracellular volume capacity. We assume that excessive fluid volume is redistributed on the basis of the basic fluid volume balance when they are exposed to fluid accumulation.

Methods: Using bioimpedance analysis, body fluid composition was measured in 129 patients with CKD from 2013 to 2015 and was separated into three components - (a) free water mass consisting of muscle, fat, and minerals, (b) intracellular water (ICW) content, and (c) extracellular water (ECW) content. Participants also measured brain natriuretic peptide levels at the time of the body fluid composition measurement. The relationship between the ratio of ECW to ICW and brain natriuretic peptide was examined.

Results: Patients with higher log-transformed plasma level of brain natriuretic peptide were more likely to be older and have lower body mass index (BMI), serum filtration rate (GFR), and serum albumin levels and higher proteinuria. In body fluid composition analysis, the brain natriuretic peptide levels increased along with a decrease in all contents of free water mass consisting of muscle, fat, and minerals (r=-0.49, P<0.001), ICW content (r=-0.34, P<0.001), and ECW content (r=-0.25, P<0.01). By the steeper decreased free water mass and ICW content than the decreased ECW content in those patients, the percentage of ECW in body weight increased, and the ratio of ECW to ICW had a positive correlation with the brain natriuretic peptide levels (r=-0.58, P<0.001). In multivariate analysis, age, BMI, GFR, the ECW/ICW ratio remained independently associated with the brain natriuretic peptide levels.

Conclusions: Brain natriuretic peptide is elevated in leaner and elderly patients with fluid volume imbalance between intra- and extracellular water. Fluid volume imbalance between intra- and extracellular water may express a reserve capacity for fluid volume overload and impact on cardiac preload.

SA-PO910

Blood Volume Estimation in Hemodialysis Patients

Background: Anthropometric formulas used to estimate absolute blood volume (ABV) are generally derived from healthy subjects. Most hemodialysis (HD) patients have an expanded ABV prior to HD, rendering these formulas inappropriate for estimation of pre-HD ABV (pre-ABV). Here, we compare the performance of several ABV formulas, used in conjunction with Crit-Line data, for assessment of pre-ABV.

Methods: We assume that post-HD ABV is closer to normal ABV, which we calculated based on height, sex and post-HD weight using several published formulas. Pre-BV was then calculated from post-HD blood volume using pre- and post-HD Hct measured by Crit-Line®. The calculated pre-ABV was then compared to pre-ABV measured immediately before HD using 131I-labeled albumin dilution.

Results: We compared 27 formulas for ABV estimation in 21 patients (2/3, mean ± SD: age 59 ± 14.7 years, height: 170.7 ± 10 cm, post-HD weight: 82.2 ± 16.7 kg). None of the equations showed good agreement with the measured data. The Nadler formula yielded the most accurate results (Fig. 1). As exemplified in Fig. 1, the equations yield a systematic trend in bias, with reasonable accuracy for ABV between 5-6 L but progressive underestimation and increasing heteroscedasticity towards higher ABV (caused by fluid overloading).

Conclusions: SDB is associated with increased fat mass, but not body fluid volume in CHD patients. Further studies are needed to evaluate some factors that can explain the high frequency of SDB in CHD.

Funding: Private Foundation Support

Impact of Hospital-Associated Hypernatremia on Outcomes in an Unselected Patient Population: A Retrospective Cohort Study

Nicolaos E. Madias, Evangelos Tispotis, Bertrand L. Jaber. Internal Medicine, St. Elizabeth’s Medical Center, Boston, MA.

Background: Although hypernatremia has been associated with an increased risk of adverse outcomes, the majority of available studies have examined selected populations questioning the generalizability of their results to unselected patients.

Methods: The discharge data of 20,072 unselected adult patients admitted to a tertiary care facility over a 7-year period were analyzed. Based on the crude relationship between [Na+] and mortality, hypernatremia was defined as [Na+] > 142 mEq/L. Patients with community-acquired hypernatremia (CAH) and those with hospital-acquired hypernatremia (HAH) were compared to patients with normonatremia at presentation ([Na+] ≤ 138-142 mEq/L) in terms of in-hospital mortality, length of stay (LOS), and discharge disposition. Furthermore, patients with CAH in whom hypernatremia was present at hospital admission (HAggH) were compared to those without aggravation. Multivariable logistic and negative binomial regression analyses were conducted.

Results: CAH occurred in 20% of hospitalized patients and was associated with an adjusted odds ratio (OR) of 1.67 (95% confidence interval [CI] 1.38, 2.01) for in-hospital mortality, and 1.44 (95% CI 1.32, 1.56) for discharge to a short-/long-term care facility, and an adjusted 10% (95% CI, 7%-13%) increase in LOS. HAH developed in 25.9% of hospitalized patients and was associated with an adjusted OR of 3.17 (95% CI 2.45, 4.00) for in-hospital mortality, and 1.45 (95% CI 1.32, 1.59) for discharge to a facility, and an adjusted 49% (95% CI 44%, 53%) increase in LOS. HAggH developed in 8.9% of patients with CAH. Compared to patients with CAH and no further increase in [Na+], HAggH was associated with greater risk of in-hospital mortality (adjusted OR 1.84, 95% CI 1.32, 2.57) and discharge to a facility (adjusted OR 1.90, 95% CI 1.49, 2.41), and an adjusted 13% (95% CI 4%-23%) increase in LOS.

Conclusions: All forms of hypernatremia encountered in unselected hospitalized patients are independently associated with increased in-hospital mortality and heightened resource consumption.

SA-PO912

Utility of Urine/Plasma Osmolality Ratio for Assessing Volume Status in Hyponatremia

Sho Hasegawa, Maki Shibata, Takehiro Sugiyama, Fuimihiko Hinoshita. National Center for Global Health and Medicine, Tokyo, Japan.

Background: Assessing volume status is critical for managing hyponatremia. Physical examination (P/E) and laboratory data are often used for the assessment, but the utility of each parameter has not been validated in hyponatremic patients. A body composition monitor (BCM) uses bioimpedance spectroscopy and can quantify extracellular water (ECW) and volume excess or deficiency. Here, we examined which parameter is superior in assessing volume status of hyponatremic patients, using BCM data as the reference standard.

Methods: We enrolled hospitalized patients (n=41) with hyponatremia (<130 mEq/L) at our institution and conducted P/E, laboratory tests and BCM measurement. Patients with high plasma osmolality (>275 mOsm/kg) were excluded (n=5). We used %ECW (ratio of volume excess or deficiency to ECW) derived from BCM data as the reference standard of volume status. First, patients were divided into overhydration (%ECW>0%, n=29) and volume excess or deficiency (%ECW<0%, n=7) groups. Clinical signs obtained from P/E and parameters of volume status such as serum albumin (Alb), serum uric acid (UA), urine chloride, urine/plasma osmolality ratio (U/P Osm), UUN/BUN, BUN/creatinine, U/P creatinine, FENa, FEUN and FEUA were compared between the groups by Fisher’s exact test or Mann-Whitney U-test. Next, we performed univariate and multiple linear regression analyses to identify associations between each parameter and %ECW.

Results: Pre-BV was significantly higher in dehydration than in overhydration (median±IQR: 10.0±5.3 vs 13.0±1.3, p=0.01). Pre-BV, Alb and U/P Osm. Results showed that compared with Alb (β=-7.7±2.7, p=0.007), U/P Osm (β=-12.0±2.9, p=0.002) was more strongly associated with %ECW.

Conclusions: U/P Osm is superior to other commonly used parameters and clinical signs for assessing volume status in hyponatremic patients.
Sodium Concentrations of Body Fluid Losses: A Systematic Review
Matthew Kaptein,1 Divya Sreeramoju,2 John Kaptein,3 Elaine Kaptein.1
1Nephrology, LAC+USC Medical Center, Los Angeles, CA; 2Medicine, Presence Saint Joseph Hospital-UC, Chicago, IL; 3Southern California Permanente Medical Group, Los Angeles, CA.

Background: Unexplained wide ranges and discrepancies of sodium concentrations [Na+] have been noted for different body fluids. This has led to use of “cumulative fluid balance” regardless of composition, which cannot account for specific water and sodium requirements. Appropriate water and volume management may be facilitated by an accurate and detailed knowledge of water and sodium composition of body fluid losses and gains.

Methods: We performed a systematic review of [Na+] of body fluids lost in adult humans. Particular attention was paid to gastric fluid with high and low acid states, diarrhea due to different mechanisms, and peritoneal, pleural and wound fluids. Inclusion criteria were met for 106 full-text articles.

Results: [Na+] are fluid-specific and consistent. Mean [Na+] were statistically lower for acidic (mean ± SD 44 ± 21mEq/L) than for alkaline (55 ± 13mEq/L) gastric fluid; the difference is not clinically relevant. [Na+] are higher for bile (184 ± 24mEq/L) or pancreatic fluid (156 ± 3mEq/L) than all other body fluids, and similar for intact small bowel (119 ± 14mEq/L) and ileostomy outputs (116 ± 25mEq/L). Specific mechanisms for diarrhea are associated with [Na+]: stool [Na+] were significantly greater for cholera (128 ± 18mEq/L) and lower for osmotic-induced (28 ± 16mEq/L) than all other causes. Among osmotic diarrheas, sorbitol-induced [Na+] was higher (63 ± 11mEq/L) than for carbohydrate malabsorption (43 ± 20mEq/L), lactulose (26 ±19mEq/L), Idolax (16 ±13mEq/L) and polyethylene glycol (13 ±7mEq/L). Among secretory diarrheas [Na+] for idiopathic causes (55 ±22mEq/L) was lower than for neuroendocrine and villous tumors (75 ±13mEq/L) or non-osmotic laxatives (88 ±33mEq/L). Pleural, peritoneal, and edema fluid had [Na+] (137 ±13mEq/L) similar to plasma. [Na+] for sweat was 44 ±17mEq/L.

Conclusions: This is the first in-depth review of verifiable sodium concentrations of body fluids most commonly lost in hospitalized patients. We propose that these losses be replaced with appropriate water and sodium content of enteral and parenteral fluids to correct and avoid diuretics and perturbations of volume status.

SA-P0914
Hyponatremia in CKD: The Prevalence and Risk Factors
Masahiko Nagahama,1 Daiko Kobayashi,2 Fumika Taki,1 Takuya Fujimaru,1 Masataka Hasegawa,1 Yuki Heath,1 Daike Kobo,2 Yuki Takeda,1 Nishikahara Hagiwara,1 1Nephrology, St. Luke’s International Hospital, Tokyo, Japan; 2Center for Clinical Epidemiology, St. Luke’s International Hospital, Tokyo, Japan.

Background: Kidney is a vital organ regulating water and sodium homeostasis, and it is plausible that patients with CKD are more prone to develop hyponatremia due to diminished urinary dilution ability, reduced solute intake, and/or medication which affects free water clearance. However, the prevalence and risk factors of hyponatremia among CKD patients have not been elucidated. The aim of the present study is to clarify the prevalence and risk factors contributing to hyponatremia in CKD patients.

Methods: Among 32,438 patients who visited our outpatient clinic between 2011 and 2014, 9,388 patients met the criteria of CKD, which is defined as either eGFR ≤60 ml/min/1.73m2 or the presence of proteinuria. Dialysis and transplant patients were excluded. Risk factors for hyponatremia were sought using multivariate logistic regression analysis.

Results: Prevalence of hyponatremia (serum Na<135mEq/L) was 8% in all CKD patients. Among moderate and severe CKD (stage 3, 4 and 5, N=6397), the prevalence of hyponatremia in moderate and severe CKD was older (P<0.01), female sex (P<0.01), diabetic (P<0.01) and more likely to have decreased eGFR (P<0.01). Multivariate logistic regression analysis identified CKD stage (OR:1.7-2.4, P<0.01), diabetes (OR:1.4, P<0.01) and renin-angiotensin-aldosterone system (RAS) inhibitors (OR:0.68, P<0.01) as independent risk factors for hyponatremia in moderate and severe CKD.

Conclusions: The present study shows that the prevalence of hyponatremia was 8% in CKD patients, and development of hyponatremia is correlated with progression of CKD in moderate and severe CKD. Worsening CKD and Diabetes are risk factors, while RAS inhibitors are protective for hyponatremia in CKD.

SA-P0915
Mild Hyponatremia on Admission Is Associated with Sepsis and Increased Mortality in Patients Presenting with a Hip Fracture
Juan Carlos Ayus,4 Armando Luis Negri,1 Michael L. Morritz,2 Nora Angelica Fuentes.1 1Hospital Italiano, Buenos Aires, Argentina; 2Inst de Investigaciones Metabolicas, Argentina; 3Children’s Hospital of Pittsburgh of UPMC, Pittsburgh, PA; 4Renal Consultant 3 of Houston, Texas, TX.

Background: Hyponatremia is associated with an increased risk of falls and hip fractures in the elderly (JAMA 28: 2299-2304, 1999). Moreover, sepsis is a frequent co-morbidity in patients with hyponatremia (AJKD 65:145-142, 2015). We assessed if hyponatremia on admission was associated with sepsis and increased mortality in patients presenting with a hip fracture.

Methods: A cohort study in adult patients admitted with a traumatic hip fracture and at least one serum Na performed at admission. Hyponatremia (H), Na < 135 mEq/L, and normonatremic (N) patients were evaluated for complications occurring within 30 days of surgery, length of hospital stay, readmission rate, in-hospital mortality and mortality during 1 year follow-up. An unadjusted and adjusted odds ratio (OR) and hazard ratio (HR) were calculated for in-hospital mortality and 1 year mortality. Adjustments were made for age, gender, propensity score for hyponatremia, CVA, CHF, ischemic heart disease, arrhythmias, thromboembolic disease, sepsis and dementia.

Results: 1571 patients were included of whom 366 (23.2%) were hyponatremic ( Na 135 mEq/L vs 138 ± 3 mEq/L, p<0.001). Length of stay was 8 days in H vs. 7 days in N (p=0.055). There was in increased incidence of sepsis in hyponatremic patient, 9.8% in H vs. 6% in N (p=0.01) OR 1.7 (95% CI: 1.3-2.6). In-hospital mortality was significantly higher in H vs N patients (19.9 vs 14.7%; p=0.016), with an un-adjusted OR of 1.45 (95% CI: 1.07-1.96) and an adjusted OR of 1.15 (95% CI:0.84-1.6). Readmissions were 15.8% for H vs. 12.9% for N (p=0.14). One-year mortality was greater in H vs N patients (15.4 vs. 6.8%; p<0.001), with an un-adjusted HR of 1.8 (95% CI:1.4-2.35) and an adjusted HR of 1.45 (95% CI:1.1-1.9).

Conclusions: Mild hyponatremia on admission is associated with sepsis and increased in-hospital and late mortality in patients presenting with a hip fracture.
Persistent Hyponatremia at 72 Hours in Cancer Patients with Severe Hyponatremia Is Associated with Mortality Independent of Cancer Stage

**Background:** Hyponatremia is a common problem and a known independent risk factor for mortality in cancer patients. The impact of rate of correction of sodium on mortality is unknown. The study aim was to determine if the rate of correction in cancer patients with severe hyponatremia (Na < 120 mEq/L) is linked to 90-day mortality.

**Methods:** Patients with Na < 120 mEq/L were identified from the Memorial Sloan Kettering Cancer Center database from June 1, 2009 until June 30, 2014. 195 patients were identified. 55 patients were excluded from analysis because less than 72 hours after admission they either died (4), had no follow up data (16), were discharged (21), or made comfort care (14). The final cohort consisted of 140 patients who stayed in the hospital for at least 72 hours and had serial measurements of serum Na.

**Results:** The mean initial serum Na was 116.7 ± 3.0 mEq/L, the median rate of correction was 6 mEq/L with interquartile range 3.9 mEq/L in the first 24 hours, and the overall 90-day mortality was 10%. No patients with Na correction < 8 mEq/L in the first 24 hours (n=54) developed osmotic demyelination syndrome. In patients who died within 90 days, the mean serum Na at 72 hrs was 128.3 ± 4.4 mEq/L compared to 130.5 ± 4.9 mEq/L in survivors (p<0.01). When adjusting for cancer stage and rate of correction in a multivariate Cox model, serum Na < 130 mEq/L at 72 hrs was independently associated with 90 day mortality with adjusted HR 2.62 (1.47-4.64, p<0.001).

**Conclusions:** Cancer patients with severe hyponatremia are at heightened risk for 90-day mortality independent of cancer stage and rate of Na correction if their serum Na at 72 hrs is < 130 mEq/L. Based on this finding we recommend that cancer patients with severe hyponatremia should be corrected to >130 mEq/L at 72 hrs.

**SA-PO919**

Hyponatremia Correction Using CRRT: Does Kinetic Modeling Avoid Overcorrection? 1 Saurabh Dasgupta, 2 Lenar T. Yessayan, 3 Balazs Szamosfalvi, 4 Sevag Demirjian, 5 Nephrology, Cleveland Clinic, Cleveland, OH; 1 Div of Nephrology, NYU Langone Medical Center, New York, NY; 2 Dept of Biostatistics, Weill Cornell Medical College, New York, NY; 3 Renal Service, Memorial Sloan Kettering Cancer Center, New York, NY.

**Background:** Hyponatremia is the most common electrolyte abnormality in inpatients. It must be corrected at a gradient of < 8 hrs to minimize the risk of central pontine myelolysis, which can be effectively achieved in patients with renal failure by CRRT. Sodium (Na) kinetic models can predict end dialysis water. A simplified single pool fixed volume kinetic model may be applicable when net Na generation (G) is <6 mEq/L. Our goal was to examine the correlation of predicted rate of correction of Na by the formula to that observed in ICU patients with hyponatremia treated with CRRT.

**Methods:** 66 critically ill subjects with serum Na <130 mEq/L at time of CRRT initiation were retrospectively identified. Median age was 60, and 52% were male. The predominant CRRT modality was CVVHD (97%), using dialysate Na of 140 mmol/L in most patients (92%) with average cumulative dose of 61L, delivered over median duration of 23.2 hrs. Predicted Na correction in the first 24 hours was calculated using a single pool fixed volume kinetic model. The values were then compared to actual measured serum Na using simple correlation, and Bland-Altman plot.

**Results:** The correlation factor was calculated to be 0.49 with a p value <0.001. The Bland Altman plot (figure) showed a mean difference of 2 mmol/L between the observed and predicted delta Na values, with a trend for overestimation of Na correction as delta sodium levels increased.

**Conclusions:** Increasing Hb spuriously decreases dNa and increases DNa. A linear correction for this artifact can reduce the discordance between iNa and dNa, promoting their interchangeable use.

HHV-6 Encephalitis Resulting in Cerebral Salt Wasting and Hyponatremia

Jonathan A. Ducastel, Uday S. Norti. Internal Medicine and Nephrology, Ohio State Univ, Columbus, OH.

**Background:** Hyponatremia is a common electrolyte abnormality that can be associated with hypo-, hyper-, or euolemic states. Low circulating volumes secondary to extra-renal losses, fluid overload states, and syndrome of inappropriate ADH are some of the more common causes of hyponatremia. One consideration that is uncommon and often overlooked is cerebral salt wasting (CSW). CSW is defined as “renal loss of sodium during intracranial disorders leading to hyponatremia and a decrease in the extracellular fluid volume.” It occurs in the setting of cerebral injury, most commonly associated with subarachnoid
hemorrhage, but also documented with other disorders of central nervous system. The mechanism of CSW is not completely understood, but is believed that a cerebral injury can lead to impairment of the sympathetic outflow causing primary natriuresis leading to hypovolemia and sodium depletion.

methods: Here we describe a case of CSW in a patient with human herpes virus-6 (HHV-6) encephalitis. The patient was a 29 year old male with a history of AML who presented with increasing confusion. He was found to have hyponatremia with a sodium of 126 mEq/L, a urine osmolality of 615 mOsm/kg, and a urine sodium of 144 mEq/L. On exam, he had evidence of hypovolemia with dry mucus membranes and orthostatic hypotension. He was initially treated with normal saline IV fluids. He had increasing diuresis with fluid resuscitation, with 6 liters of urine output on hospital day 1. The patient was continued on IV saline with the addition of oral salt supplements and started on fludrocortisone for suspected CSW. His hyponatremia improved and by hospital day #5 was 133 mEq/L. CT and MRI imaging of the head and brain were unremarkable for acute changes or pathology. A serum HHV-6 PCR showed 13,960 copies. He was treated with IV foscarnet with normalization of the serum and CSF PCR within 10 days.

conclusions: This case is important because the diagnosis of CSW is often confused with SIADH, as both share similar diagnostic criteria such as elevated urine sodium concentration and urine osmolality. The important clinical distinction is the patient, despite having a hypovolemic state would have polyuria and renal sodium wasting.

SA-PO922
Association of 6-Month Pre-ESRD Potassium with Immediate Post-ESRD Survival: A Transition to CKD Study

Background: Previous studies of the association between serum potassium level and mortality in dialysis patients have suggested that a range of 4.6-5.3 mEq/L portends greatest survival in this population. However, the optimal potassium range in the immediate pre-ESRD period among pre-dialysis CKD patients transitioning to ESRD is not known. We hypothesized that a similar pre-ESRD serum potassium range is also associated with higher survival in this population.

Methods: We investigated a cohort of 20,404 US veterans who initiated dialysis between 10/2007-9/2011 and had at least 1 potassium measurement during the last 6 month period before ESRD transition (6 month-predialysis). We examined the association of 6 month averaged potassium as a continuous predictor of all-cause mortality and early post dialysis mortality occurring in the first 3 months after transition using restricted cubic splines and Cox proportional hazard models adjusted for age, gender, race, ethnicity, geographic region and primary cause of ESRD.

Results: The analytic cohort had a mean ± SD age of 68.1±11.3 years old, among whom 30% were African-Americans, 7% Hispanic and 50% had diabetes as the leading cause of ESRD. The potassium level in the prelude period was associated with highest mortality in the first 3 months after transitioning to dialysis whereas potassium in 4.5-5.5 mEq/L range conferred the greatest early survival.

Conclusions: Lower serum potassium measurements during the final months prior to transition to ESRD are associated with higher early mortality. Whether pre-ESRD potassium levels should be kept between 4.5 and 5.5 mEq/L in the immediate pre-dialysis transition period warrants additional studies.

SA-PO923
Antihypertensive Medications and the Prevalence of Hyperkalemia in a Large Healthcare System

Background: The association of outpatient medication use with patterns and prevalence of hyperkalemia has not been rigorously examined.

Methods: We evaluated the association between baseline antihypertension medications [angiotensin converting enzyme-inhibitors (ACEi), angiotensin receptor blockers (ARB), beta-blockers, loop/thiazide diuretics, and K-sparing diuretics] with the frequency and pattern of mild (K<5 mEq/L) and severe hyperkalemia (>5 mEq/L) over a 2 year window in 342,342 outpatients in the Geisinger Health System based on medication prescription orders. Patterns of hyperkalemia were classified as: never, transient (1-time), intermittent (>1-time but <50% of the time), and persistent (≥50% of the time). Analyses were adjusted for demographics, eGFR, systolic blood pressure, diabetes, and history of cardiovascular disease. Interactions between medication types with hyperkalemia risk were also tested.

Results: Potassium levels were checked <=1 time/yr in 53% of the cohort; 4% had levels checked >5 times/yr. Overall, 7.4% had ≥2 episodes of mild hyperkalemia; 0.4% had an episode of severe hyperkalemia. Among the different classes of antihypertensives, K-sparing diuretics had the strongest associations with both mild and severe hyperkalemia, followed by ACEis and then beta blockers, which were associated only with mild hyperkalemia (Figure). ARBs had similar effect size to beta blockers but were not statistically significant. Thiazide/loop diuretics were protective against mild hyperkalemia but not severe hyperkalemia. There were no consistent interactions between types of antihypertensive medication for risk of hyperkalemia.

Conclusions: Mild hyperkalemia is relatively common and associated with the use of ACEis and K-sparing diuretics but not ARBs in this single healthcare system.

Best EKG Criteria for Hyperkalemia in Chronic Hemodialysis Patients
Muzaffar Hussain, Jamrs R. Cook, Gregory Lee Braden. Dept of Medicine, Baystate Medical Center/Tufts Univ School of Medicine, Springfield, MA.

Background: To date the effects of hyperkalemia (HK) on the EKG of chronic hemodialysis (CHD) patients (pts) is inconsistent. We studied the EKGs of 128 consecutive CHD pts with clotted grafts or fistulas. EKGs from 46 HK pts >5.5 mEq/L were compared to 82 pts with normal potassium (NK) levels <5.5 mEq/L. Pts with RBBB or LBBB or cardiac events within 3 months were already excluded. There were no differences between HK and NK pts for dialysis duration, causes for ESRD, cardiac disease or serum levels of Na, Ca, HCO3, or phosphorus.

Methods: EKG analysis included: the height & width of the P waves, the T waves in V4 & the T waves in Lead 2, the time intervals of PR, QRS, QT, QTc, PR/QT, & slopes of ascending & descending T waves in Lead 2 & V4. For the first time ever in HK CHD pts, the EKG measurements in 32 HK pts with complete data were compared to their NK EKGs obtained 3 to 6 months from the HK event.

Results: Univariate stats between the 46 HK & 82 NK pts showed 4 differences in mean values: V4 T wave height 4.0 vs 2.9 mm, Lead 2 T wave height 2.7 vs 2.0 mm, & the V4 T wave ascending (.03 vs .02) and descending slopes (.04 vs .03). Multivariate analysis for all clinical & EKG findings between HK & NK pts found only the increased height of the T wave in V4 was significant, p=.05. In contrast, the EKG analysis of the HK pts to their NK EKGs revealed more differences: higher T wave height in V4, 5.0 vs 3.7 mm, higher lead T wave height in Lead 2, 4.0 vs 2.7 mm, shorter width of T wave in V4, 2.4 vs 4.1 ms or Lead 2, 2.1 vs 4.1 ms, longer PR 188 vs 167 ms, & steeper slopes in the T waves in Lead 2 and V4. Regression analysis of the change in potassium from NK HK pts to their NK EKGs revealed more differences: higher T wave height in V4, 5.0 vs 3.9 mm, steeper V4 T wave ascending (0.03 vs 0.02) and descending slopes (0.04 vs 0.03). Multivariate analysis for all clinical & EKG findings between HK & NK pts found only the increased size of ZS-9. Here we present Zr concentration data from urine and whole blood samples from HS-9 treated dogs to assess systemic absorption of long-term, high-dose ZS-9.

Conclusions: We conclude: 1) Comparison of a NK EKG to a HK EKG in CHD pts significantly helps to confirm HK EKG changes in CHD pts. 2) A shortened width and an increased height of the T wave in V4 are the most important HK EKG changes in CHD pts.

Sodium Polyoxymethylene Sulfonate for the Treatment of Mild Hyperkalemia in Chronic Kidney Disease: A Randomized Clinical Trial
Katherine Desforges, Laurence Legape, Anne-Claude Dufour, Jessica Doiron, Katia Handfield, Robert Zel Bell, Michel Vallée, Michel Savoie, Sylvie Perreault, Louis-Philippe Laurin, William Beauchemin-St, Vincent Pichette, Jean-Philippe Lafrance. Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.

Background: Hyperkalemia affects up to 10% of patients with chronic kidney disease (CKD). Sodium polyoxymethylene sulfonate (SPS) has long been prescribed for this condition even though evidence is lacking on its efficacy for the treatment of mild hyperkalemia over several days.

Methods: The aim of this double-blind, randomized trial was to evaluate the efficacy of SPS in the treatment of mild hyperkalemia (5.0 to 5.9 mEq/L) in pre-dialysis outpatients. We randomly assigned 33 patients on stable medication to receive either SPS or placebo 30 g orally once a day for 7 days. Patients had to be on stable medication to be eligible for the study. The primary outcome was the comparison between study groups of the mean difference of serum potassium levels between the day following the last dose of treatment and baseline.

Results: The mean duration of treatment was 6.9 days. SPS was superior to placebo in the reduction of serum potassium levels (mean difference between groups of -1.04 mEq/L; 95%CI [-1.37 to -0.71]). A higher proportion of patients in the SPS group tended to attain normokalemia (defined as a serum potassium level of at least 3.5 mmol/L and less than 5.0 mmol/L) at the end of their treatment compared to the placebo group (73% vs 38%; P=0.07). Patients in the group treated with SPS had an increase in hypermagnesemia, hypocalcemia, constipation and nausea compared to the control group.

Conclusions: SPS is superior to placebo in the treatment of mild hyperkalemia over seven days in CKD patients. Its use was generally well tolerated in our study population, but does require monitoring of gastrointestinal side effects and electrolytic disorders.

SA-PO927

Assessment of Systemic Absorption of Sodium Zirconium Cyclosilicate (ZS-9): Blood and Urine Zr Concentration in Dogs During a 9-Month Oral Toxicity Study
Fiona Stavros, Henrik S. Rasmussen, Bhupinder Singh, Jose A. Menoyo. ZS Pharma, Inc., Coppell, TX.

Background: Hyperkalemia (HK; potassium [K+] >5.1 mEq/L) is a common and potentially life-threatening electrolyte disorder often occurring in patients with chronic kidney disease, heart failure and diabetes. Sodium zirconium (Zr) cyclosilicate (ZS-9), a potential HK therapy, is a selective K+ ion trap containing covariantly bound Zr atoms within an insoluble 25µm particle. Zr has a long history as an inert substance used in biomedical implants and dialysis, and is present in natural diets and household items. Systemic absorption of Zr is expected to be minimal given the low solubility and particle size of Zr. Here we present Zr concentration data from urine and whole blood samples from ZS-9 treated dogs to assess systemic absorption of long-term, high-dose ZS-9.

Methods: Beagle dogs received Control (n=10/sex) or high-dose ZS-9 (2000 mg/kg/day, n=10/sex). Blood samples were collected by venipuncture at baseline, and Weeks 6, 13, 26, and 39. Urine samples were collected directly from the bladder at necropsy (Week 39) and recovery (Week 43). Zr levels in Control and ZS-9 treated dogs were determined using inductively coupled plasma mass spectrometry with a lower limit of quantification (LLOQ) of 10 ng/mL (ppb) for both whole blood and urine. The analytical method was designed to measure the presence of both free Zr and ZS-9 bound Zr.

Results: Zr was below the LLOQ in all dog urine samples (N=28) and in all but one Control group whole blood sample (N=226). The one dog in the Control group had a blood Zr level of 10.9 ng/mL at Week 26.

Conclusions: There was no detectable Zr or increase in Zr in blood and urine samples following 39 weeks of 2000 mg/kg/day ZS-9 treatment; equivalent to a human dose of ~65 g/day. Zr was detected in one non ZS-9 treated animal. These results demonstrate an absence of systemic ZS-9 absorption after long-term, high-dose treatment in beagle dogs.

Funding: Pharmaceutical Company Support - ZS Pharma, Inc.

SA-PO928

Admission Hypomagnesemia Linked to Septic Shock in Patients with Systemic Inflammatory Response Syndrome
Wistt Cheungprasop,1 Charit Thongprayoon,2 Stephen B. Erickson,1 1Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 2Internal Medicine, Bassett Medical Center, Cooperstown, NY.

Background: The association between admission serum magnesium (Mg) levels and risk of developing septic shock in patients with systemic inflammatory response syndrome (SIRS) is limited. The aim of this study was to assess the risk of developing septic shock in hospitalized patients with SIRS with various admission Mg levels.

Methods: This is a single-center retrospective study conducted at a tertiary referral hospital. All hospitalized adult patients with SIRS at admission who had admission Mg available from January 2009 to December 2013 were analyzed in this study. Admission Mg was categorized based on its distribution into six groups (4.0, 4.1 to 4.7, 4.8 to 5.1, 5.2 to 5.4, and >5.4 mEq/L). The primary outcome was septic shock occurring after hospital admission. Logistic regression analysis was performed to obtain the odds ratio of septic shock of various admission Mg levels using Mg with lowest incidence of shock, 2.1 to 2.3 mEq/L as the reference group.

Results: Of 2,589 patients with SIRS enrolled, septic shock occurred in 236 patients (9.1%). The lowest incidence of septic shock was when serum Mg was within 2.1-2.3 mEq/L. A reverse-checkmark curve emerged demonstrating higher incidences of septic shock

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

846A
associated with both hypoMg (<2.1) and hyperMg (>2.3). After adjusting for potential confounders, hypoMg (<1.5 mg/dL) was associated with an increased risk of developing septic shock with odds ratios of 1.86 (95% CI 1.07,3.27).

Conclusions: Patients with SIRS and hypoMg (<1.5 mg/dL) at the time of admission had increased risk of developing septic shock during hospitalization.

SA-PO929
Risk Factors for Calcium-Alkali Syndrome in Post-Surgical Hypoparathyroidism
Savaya Kuriya, Masahiko Yazawa, Naoto Tominaga, Yujiro Sagagaki. Nephrology and Hypertension, St. Marianna Univ; Kawasaki, Kanagawa, Japan.

Background: Post-surgical hypoparathyroidism is a common complication of total thyroidectomy. Patients complicated by permanent hypoparathyroidism often require either both calcium or vitamin D supplement therapy to maintain serum calcium levels, and long-term therapy can lead to calcium-alkali syndrome (CAS). We examined the incidence rate, magnitude, and risk factors of CAS in patients being treated for post-surgical hypoparathyroidism.

Methods: We retrospectively observed 27 patients with neck tumors who had undergone total thyroidectomy with total parathyroidectomy without autotransplantation between January 2010 and October 2013 at St. Marianna University Hospital. All patients received calcium lactate and alfacalcidol. Medical records were reviewed for historical, clinical, laboratory and imaging data. Definitions were as follows: hypercalcemia, corrected serum calcium (cCa) ≥10.0 mg/dL; acute kidney disease (AKD), either or both >50% increase in serum creatinine (SCR) or >55% decrease in estimated glomerular filtration rate (eGFR); and metabolic alkalosis, difference in serum sodium (Na) and serum chloride (SCl) >38. Data were expressed as mean ± standard deviation (SD). For statistical analysis, the paired t test, Student’s t test, and chi-square test were used to compare two matched variables when appropriate. P<0.05 was considered statistically significant.

Results: Average duration between surgery and reaching peak cCa level was 392.7 ± 847.8 days, with levels peaking at 11.1 ± 1.2 mg/dL. Median cCa levels peaked at 11.1 mg/dL, at 847 days after surgery. Nineteen patients (70.3%) had hypercalcemia, 9 (33.3%) had AKD, and 7 (36.9%) had metabolic alkalosis. Baseline data of patients with AKD were as follows: male, 11 patients (73.3%); age, 76.9 ± 14.7 years; height, 162.9 ± 8.1 cm; weight, 64.4 ± 12.7 kg; systolic blood pressure (SBP), 128.9 ± 19.2 mmHg; diastolic blood pressure (DBP), 68.8 ± 10.3 mmHg; sodium, 137.6 ± 1.4 mEq/L; bicarbonate, 24.5 ± 3.0 mEq/L; baseline eGFR, 69.9 ± 16.6 mL/min/1.73 m2; serum insulin levels, 12.5 (2.7-24.6) mU/L; and baseline blood glucose levels, 85.1 (55.3-134.1) mg/dL. Hypercalcemia was strongly correlated with cCa levels and kidney function should be closely monitored in patients with post-surgical hypoparathyroidism.

SA-PO930
Body Temperature Rise in the Cell-Free and Concentrated Ascites
Reinforcement Therapy Is Correlated to Albumin Concentration Rather Than the Interleukin-6 Levels in the Ascites
Norikazu Maruyama, Masanori Abe, Kazuyoshi Okada. Div of Nephrology, Hypertension and Endocrinology, Dept of Internal Medicine, Nihon Univ School of Medicine, Tokyo, Japan.

Background: There is a fever as a side effect of Cell-free and Concentrated Ascites Reinforcement Therapy (CART). Cytokines in ascites after concentration is thought to be involved in the generation of heat after intravenous injection. To examine the fever related factors, we examined the relationship between inflammatory cytokines levels, total protein (TP), albumin (ALB) in peritoneal fluid and the heating after intravenous injection.

Methods: In this study, we have measured interleukin-1β (IL-1β), interleukin-6 (IL-6), TP, ALB concentration in the ascites fluid before and after concentrated, and observed vital changes in the patient before and after intravenous injection. A total of 8 patients with refractory ascites were studied.

Results: IL-1β was detected in ascites prior to concentration of the two cases, it could not be measured in the other specimen. IL-6 is present in high concentrations in all ascites before concentration (mean 4218.7 pg/mL), it was further increased after concentration (mean 23107.0 pg/mL). Although body temperature rise was observed after the intravenous injection of concentrated ascites in six out of eight, IL-6 concentration in the ascites fluid (r = 0.61063; P = 0.114), the total dose of IL-6 (r = 0.06755; P = 0.436), dose rate (r = -0.2876; P = 0.244) was no obvious correlation between the body temperature rise. On the other hand, respectively in the TP concentration and the ALB concentration of ascites, it was found correlated with body temperature rise after intravenous injection. In particular, a strong correlation between the ALB concentration and the increase in body temperature was observed (r = 0.8033; P < 0.01).

Conclusions: The correlation of body temperature rise after intravenous injection and IL-6 is weak, while the correlation between the concentrated ALB and body temperature rise was very strong. From these results, we considered that any substance bound to the ALB or ALB itself are associated with elevated body temperature.

SA-PO931
Contrast-Related Hyponatremia
What We Could Be Missing
Christine Joy C. Junia, Kalyani Perumal. Internal Medicine, John H. Stroger Jr. Hospital, Chicago, IL.

Background: Hyponatremia is a commonly encountered electrolyte abnormality. Long-established algorithms outline etiology and management guiding physicians to prevent neurologic sequelae. Close electrolyte monitoring is emphasized in acute hyponatremia due to higher morbidity and mortality. Contrast-related hyponatremia is an etiology of acute onset hyponatremia that is not routinely monitored and may easily be missed.

Methods: A 76-year-old woman with hypertension, diabetes and chronic kidney disease (CKD) III, eGFR of 44 was admitted for asthma exacerbation and received beta-agonist nebulizer treatment. Her home medications were Orimject and Insulin were restarted. She was tachypneic and wheezing, the rest of the physical exam was normal. Laboratory tests on admission: Na 135 meq/L, K 4.4 meeq/L, BUN 11 mg/dL, Creatinine 1.2 mg/dL, and normal urinalysis. An elevated D-Dimer prompted evaluation with CT Chest with contrast Omnipaque 350 (840 mOs/mg) to rule out pulmonary embolism. Her symptoms improved, however her sodium dropped from 135 to 122 meq/L. 48 hours after chest CT, creatinine 1.4 mg/dL. Work-up revealed plasma osmolality of 297 mosm/ kg, osmolar gap of 30. On the 4th and 5th hospital day, sodium levels were stable at 125 meq/L and 124 meq/L respectively. Her sodium on Day 8 improved to 133 meq/L without any intervention.

Conclusions: The 2014 USRDS data reports a rise in prevalence of CKD III from 4.5 to 6.0 percent. Primary care doctors manage 80 to 90 percent of these patients. There is a lack of data on contrast-related hyponatremia rise in diagnosticians. Over the past decade, CT Scan use in the emergency departments has increased over 200-300%. There are a few case reports of contrast-related hyponatremia, occurring mostly in patients with advanced CKD with eGFR<30. A consistent finding was the acute onset and an average drop in sodium of 12 meq/L. Contrast-related hyponatremia could be responsible for an acute drop in sodium. This is usually offset by osmotic diuresis that is impaired in chronic kidney disease. Our case highlights contrast-related acute hypotonic hyponatremia in the setting of mild kidney disease, a high-risk patient population that may benefit from post-diagnostic electrolyte monitoring.

SA-PO932
A Role for NHE3 in Renal Sodium and Acid-Base Handling in the Early Proximal Tubule and Further Downstream Segments
Akira Onishi, Yiling Fu, Panai Song, Meinrad Busslinger, Manochoo Soleimani, Isabelle Rubera, Markus Lichtlen, Volkmar Vallotton. Nephrology, UC San Diego & SF San Diego Healthcare System, La Jolla, CA; 1Research Inst of Molecular Pathology, Vienna, Austria; 2Dept of Medicine, Univ of Cincinnati, Cincinnati, OH; 3Univ de Nice Sophia Antipolis, Nice, France.

Background: Systemic Na+/H+ exchanger 3 (NHE3) knockout in mice lowered blood pressure (BP) and induced metabolic acidosis, however, the role of intestine vs kidney and early vs further downstream segments is unclear.

Methods: Male mice with floxed NHE3 expressing Cre recombinase under the control of i) the SGLT2 promoter to knockdown NHE3 in the early PT (SGLT2-Cre/NHE3fl/fl, n=10) or ii) the Pax8 promoter for knockdown throughout the entire tubular system (Pax8-Cre/NHE3fl/fl, n=9) were compared with corresponding Cre-negative controls (n=10 and 7).

Results: Blood and spot urine samples were collected, BP measured by automated tail cuff and arterial cannulation, and GF levels monitored. NHE3+/cre ratios were higher in Pax8-Cre/NHE3fl/fl vs controls (40±5 vs 28±2, P<0.05) but not significantly different in SGLT2-Cre/NHE3fl/fl vs controls (31±2 vs 27±3). Urine pH and HCO3-/cre ratio were strongly increased in Pax8-Cre/NHE3fl/fl (7.8±0.11 vs 6.4±0.12, 15.5±3.1 vs 5.5±0.34, P<0.01), and only modestly higher in SGLT2-Cre/NHE3fl/fl vs controls (6.0±0.15 vs 6.1±0.12, P=0.07 and 0.45±0.20 vs 0.14±0.03, P=0.16). Urine pH and HCO3- were significantly higher in Pax8-Cre/NHE3fl/fl vs controls (31±2 vs 27±3). Blood spot urine samples were collected, BP measured by automated tail cuff and arterial cannulation, and GF levels monitored. NHE3+/cre ratios were doubled in both knockout mice vs their controls (Pax8-Cre: 32±3 vs 17±2; SGLT2-Cre: 22±2 vs 10±1, P<0.01).

Conclusions: Tubule-specific NHE3 knockout decreased urine pH and excretion of sodium, HCO3- and protein without metabolic acidosis. Comparison of the Cre models is consistent with a role of NHE3 in urinary acidification and reabsorption of sodium and bicarbonate in the early PT as well as in further downstream segments.

Effect of NBCe1 Deletion on Renal Ammonia Metabolism

Mary E. Handlogten, Gunars Osis, Hyun-Wook Lee, Jill W. Verlander.

1Renal Div, Univ of Florida, Gainesville, FL; 2Nephrology Section, NF/SVH, Gainesville, FL.

Background: Metabolic acidosis typically increases renal ammonia excretion, but people with proximal renal tubular acidosis (pRTA), despite the associated metabolic acidosis, do not have increased ammonia excretion. Genetic forms of human pRTA typically involve the proximal tubule bicarbonate transporter, NBCe1. Based on these observations, we postulated that NBCe1 has a role in renal ammonia metabolism that is in addition to its role in bicarbonate reabsorption.

Methods: We used previously reported mice with NBCe1 deletion. Because +/- mice have 100% mortality before d10-21, we studied mice at d8-11. Wild-type (WT), heterozygous (HET) and homozygous knock-out (KO) mice were generated by breeding WT male and female mice.

Results: Serum HCO3 was 26.4±1.0 in WT, 19.8±1.9 in HET, and 10.3±0.6 mmol in KO mice (P<0.05). Thus, NBCe1 deletion causes metabolic acidosis at d8. Although acidosis normally increases ammonia excretion, NBCe1 deletion decreased spontaneous ammonia excretion: 275±44, 212±11 and 94±69 mmol/g creatinine in WT, HET and KO mice, respectively (P<0.01). Serum Na and K were unchanged. Urine pH was 5.3±0.2, 4.8±0.1 and 4.2±0.1 in WT, HET and KO mice, respectively (P<0.01), indicating intact urine acidification and no ongoing HCO3 loss. NBCe1 deletion did not alter urine osmolality significantly (WT, 595±43 and no ongoing HCO3 loss. NBCe1 deletion did not alter urine osmolality significantly (WT, 259±50; KO, 276±34 mOsm/kg H2O; P=NS), which, in combination with intact urine acidification, suggests intact collecting duct function. The regulation of multiple proteins involved in ammonia metabolism was atypical of acidosis. NBCe1 deletion decreased expression of PDG and PEPC and increased expression of the ammonia recycling enzyme, glutamine synthetase. This pattern is the exact opposite of that expected with acidosis. Expression of the TAL ammonia transporter, NKCC2, and the collecting duct ammoniaturia, RHb and Rhcg, was unchanged.

Conclusions: We conclude: 1) NBCe1 deletion significantly alters proximal tubule ammonia metabolism, leading to decreased urinary ammonia excretion; and, 2) NBCe1, in addition to its role in HCO3 transport, may have an important role in ammonia metabolism.

Assessing Urine Ammonium Concentration by Urine Osmolal Gap in Chronic Kidney Disease

Takuya Fujimaru, Yasuhiro Komatsu, Takuya Shuo.

Nephrology, St. Luke's International Hospital, Tokyo, Japan.

Background: Acidemia is one of the risk factor for end stage kidney disease and mortality for patients with chronic kidney disease (CKD). Although ammonium is the crucial component of renal acid excretion, measurement of urine ammonium concentration (NH₄⁺) is not routinely available in most hospital laboratories. To estimate NH₄⁺, urine osmolal gap (UOG = urine osmolality – [2(Na + K) + urea + glucose]) is calculated and the formula (NH₄⁺ = UOG/2) has traditionally been used. However, studies evaluating it in CKD patients are scarce. The present study aims to assess the relationship between NH₄⁺ and UOG in CKD patients.

Methods: Spot urine samples were collected from 36 patients with CKD in our hospital (24 males, age 41-96 years, serum creatinine 0.9-12.4 mg/dl). We measured urine pH, Na, K, Cl, urea, glucose and NH₄⁺. NH₄⁺ was measured by colorimetric assay (modified Fujii-Okuda method). The Bland-Altman plot was used to evaluate the agreement between NH₄⁺ and UOG/2.

Results: NH₄⁺ ranged from 0.3-45.8 mmol/l (median, 6.2 mmol/l). UOG/2 correlated positively and significantly with NH₄⁺ (r=0.925, p<0.0001).

Conclusions: UOG is an accurate method to estimate NH₄⁺ in CKD patients and can be used to assess urinary acidification ability in CKD patients.

Vacular H⁺-ATPase Regulation by 14-3-3 Proteins

Nuria M. Pastor-Soler, Mohammad M. Al-bataineh, Hui Li, Vivek Bhalla, Kenneth R. Hallows.

1Medicine, Div of Nephrology, Keck School of Medicine of USC, Los Angeles, CA; 2Medicine, Div of Nephrology, Stanford School of Medicine, Palo Alto, CA; 3Medicine, Renal-Electrolyte Div, U. of Pittsburgh School of Medicine, Pittsburgh, PA.

Background: The vascular proton-ATPase (V-ATPase) is highly expressed at the apical membrane of type A intercalated cells (ICs) in the collecting duct. This pump mediates proton transport across a membrane often against a gradient. Defects in V-ATPase function can lead to renal tubular acidosis. In kidney cells we showed that the metabolic sensor AMP-activated protein kinase (AMPK) phosphorylates the V-ATPase A subunit at Ser-384. AMPK regulates some transport proteins by inhibiting their function and promoting their ubiquitination and degradation. These mechanisms are likely important for inhibition of membrane transport during cellular metabolic stress. We noticed that Ser-384 exists within a 14-3-3 binding motif. Dimeric 14-3-3 bind to phosphorylated sites on target proteins and modulate protein function. We hypothesized that phosphorylation of AMPK and an additional kinase modulate A subunit binding to 14-3-3 proteins and A subunit ubiquitination.

Methods: We used transient transfections of V-ATPase A subunit mutants in Clone C ICs, followed by immunoprecipitation and immunoblotting.

Results: We have preliminary evidence that phosphorylation at Ser-384 and a new “Site III” in the V-ATPase A subunit are required for 14-3-3 binding. For example, 14-3-3 binding to the A subunit increased when we used a phosphomimetic mutant (Ser-to-Asp) at Site III compared to the WT sequence at that site, and this binding was not dependent on the presence of the AMPK phosphate donor pharmacological activator. Furthermore, AICAR increased A subunit ubiquitination as compared to untreated cells.

Conclusions: We propose that V-ATPase A subunit binding to 14-3-3s promotes its ubiquitination and degradation. These pathways are downstream of phosphorylation of the subunit at Ser-384 by AMPK and at Site III by another unidentified kinase. Our results link downregulation of the V-ATPase to metabolic depletion in kidney epithelial cells.

Albuminuria Enhances Renal NHE3 Expression via the Activation of Mitochondrial Oxidative Stress/RAS Axis

Aihua Zhang, YiBo Zhang, Guixia Ding, Songming Huang, Zhanjun Jia.

1Nephrology Dept, Nanjing Children Hospital, Nanjing Medical Univ; 2Nanjing, Jiangsu, China; Nanjing Key Laboratory of Pediatric.

Background: Renal sodium–hydrogen exchanger 3 (NHE3) plays a known role in the reabsorption of bicarbonate and fluid. As a result, NHE3 is thought to be important in acid base balance and vascular volume homeostasis. The present study was to investigate the role albuminuria in regulating renal NHE3 expression as well as the underlying mechanisms.

Methods: An albumin overload mouse model was established by i.p injection of albumin. The mouse kidney tissues and kidney biopsy specimens from proteinuric patients were analyzed.

Results: Following 12-day albumin overload, we found that albuminuria increased NHE3 expression by 2-fold in mouse kidneys determined by Western blotting and qRT-PCR. Considering the known role of renin-angiotensin system (RAS) in mediating renal sodium and water reabsorption, we examined key components of RAS and found a striking elevation of angiotensinogen (AGT, +2.1 folds), angiotensin converting enzyme (ACE, +3.3 folds), and urinary angiotensin II (Ang II, +70%) output determined by Western blotting or ELISA. In proteinuric patients, we detected a 1.9-fold upregulation of NHE3 and 3-fold increase of ACE by immunohistochemistry in line with a 2-fold increment of urinary Ang II excretion. To further investigate the role of RAS in upregulating NHE3, we performed primary cultures of renal tubular cells and observed that albumin overload directly enhanced NHE3 accompanied by stimulated AGT/ACE/Ang II cascade, which was entirely abolished by ACE inhibitor captopril, indicating a key role of RAS in mediating albuminuria effect on NHE3 upregulation. More interestingly, albumin overload significantly induced mitochondrial oxidative stress evidenced by reduced mitochondrial superoxide dismutase (SOD2, -60%) and elevated ROS production. Notably, a SOD2 mimic (MnTBAP) completely normalized NHE3 upregulation and activated AGT/ACE/Ang II cascade in mice with albumin overload.

Conclusions: These results suggest that albuminuria is of vital importance in upregulating renal NHE3 expression in proteinuric patients via mitochondrial oxidative stress-initiated stimulation of AGT/ACE/Ang II cascade.

ATP6v1b1 Haploinsufficiency Lead to a Mild Incomplete Renal Tubular Acidosis (RTA) in Mice

Soline Bourgeois, Carsten A. Wagner.

1Inst of Physiology, Univ of Zurich, Zurich, Switzerland.

Background: Mutations in ATP6v1b1 gene in man is considered as an autosomal recessive disease and lead to distal RTA by dysfunction of the B1 subunit of H-ATPase in type A intercalated cells. In some transgenic mouse model of RTA, it also lead to increase in ammonia and alkaline urine pH.

Methods: Here we investigated on littermate mice whether ATP6v1b1+/- mice also develop acid-base disturbances during an acute and chronic acid challenge performed by 0.2 M HCl added to powdered standard food.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
**Results:** ATP6v1b1+/- (WT) and +/- (HEt) mice exhibited no difference in their blood and urine parameters under baseline conditions. During the acid challenge, while ATP6v1b1+/- (KO) developed alkaline pH and low ammonia with hypercalciuria, HEt mice showed no difference in their urine data over the whole acid load compared to WT mice. However, even though, HEt mice did not exhibit low blood pH, as KO mice, they had a lower bicarbonatemia, higher chloremia and lower pcO2 compared to WT mice at the end of the acid challenge. Both KO and HEt mice drank more than WT mice over the acid load with a tendency to urinate more. After 4 days of acid load, subcellular localization of the α4 and β2 subunits of H-ATPase were not different within the 3 strains of mice and WT and HEt mice exhibited the same localization of β1 subunit. However, western blot analysis of B1 and B2 expression in renal membrane fractions revealed a 2-fold decrease of B1 and B2 protein expression in HEt mice compared to WT mice and no difference in the expression of B2 protein in KO mice compared to WT mice while B1 protein was totally absent from KO kidneys.

**Conclusions:** In conclusion, β1 HEt mice developed a mild incomplete RTA during an acid challenge, undetectable regarding urine parameters. The RTA is partly compensated by the respiration and an increase in water consumption. 2) B2 subunit does not compensate for the decrease in B1 expression both in HEt kidney tissues and seems to be inhibited by acid load.

**Bedside Rule (pCO2=HCO3+15) Is Reliable in Predicting Respiratory Response in Metabolic Acidosis with Bicarbonate Levels of More than 7 meq/L.** Mohammad Kazem Fallahzadeh, Michael Emmett. *Dept of Internal Medicine, Baylor Univ Medical Center, Dallas, TX.*

**Background:** There is controversy about the reliability of the bedside rule (pCO2=HCO3+15) in prediction of respiratory response in metabolic acidosis. The aim of our study was to compare the accuracy of the bedside rule with Winter’s equation in predicting respiratory response in metabolic acidosis.

**Methods:** We extracted the measured bicarbonate and pCO2 levels of 382 patients with metabolic acidosis from the previously published articles evaluating the respiratory response to metabolic acidosis. We calculated the predicted levels of CO2 by bedside rule and Winter’s equation for each patient. Then we compared the accuracy of these formulas in predicting the respiratory response to metabolic acidosis.

**Results:** As demonstrated in the figure 1, the values calculated by bedside equation (pCO2=HCO3+15) appear to be a reliable predictor of respiratory response in HCO3 levels of more than 7 meq/L, as compared with the line of best fit and Winter’s equation.

**Conclusions:** Our results show that bedside rule (pCO2=HCO3+15) is reliable in predicting respiratory response in metabolic acidosis with HCO3 levels of more than 7 meq/L.

**TSS-Seq Analysis of Low pH-Induced Gene Transcripts in the Intercalated Cells of the Collecting Ducts.** Yuichiro Izumi,1 Koji Eguchi,1 Terumasa Takahashi,1 Hideki Inoue,1 Tokuma Kikuzoe,1 Hiroshi Nonoguchi,2 Masashi Mukoyama,1 1Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Japan, 2Dept of Internal Medicine and Education & Research Center, Kusasato Univ Medical Center, Japan.

**Background:** Metabolic acidosis is caused by acute and chronic kidney disease due to the decrease of acid excretion in the intercalated cells of the collecting duct in the kidney. Although the effect of acidosis on renal function has been examined in vivo, direct effect of low pH on the intercalated cells has not been investigated.

**Methods:** We employed Transcription Start Site-sequencing (TSS-Seq) to provide low pH-induced gene transcripts in rat intercalated cell line (IN-IC cells). Two biological replicates were used for the analysis. Cells were grown in a FBS-free DMEM/F12 overnight and incubated in an isotonic solution for 24h in which pH was adjusted either to 7.4 or 7.0, then total RNA was extracted. CDNA library for CAGE (Cap Analysis Gene Expression) was prepared and sequenced. Deep sequencing was performed on Illumina HiSeq2500 sequencer. TopHat 2 software was used to map TSS-Seq reads. RECLU was used to identify differentially expressed transcripts. Gene Ontology (GO) analysis was carried out using the Database for Annotation, Visualization and Integrated Discovery (DAVID).

**Results:** Biological Processes and Molecular Functions showed 9 clusters of the GO terms with high enrichment score (> 1.5) among expressed transcripts were upidentified. 261 transcripts were upregulated and 17 were downregulated. Among them, 225 upregulated and 13 downregulated transcripts were corresponded to known protein products. GO analysis of the intercalated cells showed high enrichment score (>1.5) were upregulated. TSS-Seq analysis for IN-IC cells at pH 7.4 and 7.0 were performed. 1952 genes were upregulated at pH 7.0 compared to pH 7.4. 1768 genes were downregulated at pH 7.4 compared to pH 7.0.

**Conclusions:** The results suggest that metabolic acidosis could regulate the function of intercalated cells and further exacerbate the renal fibrosis.

**SA-PO940**

**Narrowing the Gap Between the Anion Gap and the Strong Ion Gap.** Kenrick Boren,1 Andrew L. Lundquist,2 *Nephrology, St. Elisabeth Hospital, Willemstad, Curacao, Netherlands Antilles; 2MGH Div of Nephrology, Massachusetts General Hospital, Boston, MA.*

**Background:** Despite its importance in understanding acid-base pathophysiology, many physicians do not understand the concept of the strong anion gap. The core of the Stewart-acid-base approach is the ‘strong ion gap’ (SIG). The concept of SIG is similar to the AG, but the main difference is that Stewart uses more strong ions and the contribution of albumin and phosphate are adjusted for the pH. Because SIG gives a more precise picture of the acid-base disturbances, one may postulate that it provides a more accurate analysis of acid-base disturbances. The exact differences, however, are not established. This paper will give insight into the difference between the anion gap and the strong anion gap and provide an adjusted formula for the anion gap to replace the need for the strong anion gap.

**Methods:** The change of the strong ion gap (SIG) and the albumin-corrected anion gap (AG) were calculated at a wide range of albumin, phosphate and pH levels.

**Results:** At a low albumin level of 1 to 3 g/dl and decreased pH from 6.9 to 7.3, the contribution difference of albumin in AG and SIG will be maximally -0.97 to 0.51 mEq/L. In metabolic alkalosis (pH up to 7.6) and hypochloremia (1 to 3 g/dl), the AG differs less than 2 mEq/L with SIG. There is a linear relationship of the serum phosphate and the ionomic contribution of SIG: at a pH of 6.9, the phosphate_SIG is 1.66 times higher and at a pH of 7.6, 1.86 higher. In metabolic alkalosis and moderate hyperphosphatemia, the ionomic contribution to the anion gap will increase, but less than 1 mEq/L.

**Conclusions:** SIG and AG are almost identical across a wide range of values, particularly when albumin and phosphate levels are low. The pH adjusted serum phosphate level in the SIG is about 1.76 higher, with a confidence interval of 0.5 mEq/L. The anion gap will be more precise and incorporate the major components of the SIG when using the equation: [Na+] - [CT] . [HCO3]- - 2.5 [albumin, in g/dl] - 1.76 [phosphate], with an arbitrarily set reference range of 1+/-5 mEq/L.

**V-ATPase in Luminal Membrane of Renal Proximal Tubule Requires B2 Subunit and CLC-5 for Its Full Functional Activity.** Nobuhiko Sato,1 Motonobu Nakamura,1 Atsushi Suzuki,1 Masashi Suzuki,1 George Seki,2 Shoko Horita.1 *Nephrology, The Univ of Tokyo Hospital, Tokyo, Japan; 2Izu City Hospital, Shizuoka, Japan.*

**Background:** Using an isolated rat proximal tubule (PT) primary culture system, we have previously shown that the activity of basolateral Na/HCO3 co-transporter (NBCe1) was preserved for 36 hours. Furthermore, gene silencing with siRNA enabled us to identify the signaling pathways involved in insulin-mediated NBCe1 stimulation (Nakamura M, Kidney Int, 2015). However, it remains unknown whether this technique is applicable to analysis of PT luminal transporters.

**Methods:** Freshly isolated mouse PT was attached to a glass coverslip with Cell-Tak glue and the lumen was exposed with a broken glass capillary. BCECF was used to measure intracellular pH (pHi). While the cariporide-insensitive luminal NHE activity was determined by the rates of pH decrease in response to Na removal, the cariporide-sensitive V-ATPase activity in Na-free solution was determined by the rates of pHi decrease in response to Na removal, the bafilomycin-sensitive V-ATPase activity was determined by the rates of pHi recovery in Na-free solution. These experiments were also performed after PTs were cultured overnight in the presence of siRNA against V-ATPase B2 subunit or CLC-5.

**Results:** The luminal NHE activity was at least partially preserved in isolated PT primary cultures (0.89 +/- 0.08 vs in intact system). The hypotonically (210 mOsm)-induced V-ATPase activity was also preserved in PT primary culture (0.50 +/- 0.05 vs 0.32 +/- 0.04 pH unit/min). Overnight treatment with siRNA against B2 subunit or CLC-5 largely suppressed the V-ATPase activity by 81% and 70%, respectively, without affecting the luminal NHE activity. We also confirmed that the Na-free solution, which V-ATPase activity was preserved, was depleted in heK293 cells not only decreased endosomal pH as estimated by ratiometric VAMP2-pHluorin but also induced the plasma membrane V-ATPase activity stimulated by hypotonicity (0.01+/-0.01 vs 0.59+/-0.07 pH unit/min).

**Conclusions:** The V-ATPase activity in the PT is suppressed by CLC-5 and the B2 subunit is involved in this process.
Conclusions: These data revealed for the first time to our knowledge that the luminal V-ATPase in PT is partial and CLC-5 for its full functional activity. The requirement of CLC-5 may be a common feature of mammalian V-ATPase, either expressed in endosome or plasma membrane.

The Mechanistic Target of Rapamycin Regulates Solute Transport in Renal Tubules Nasir A. Shah, Davide Pietro Cina, Tuncer Onay, Vera Eremia, Chengjin Li, Aline Martin, Vashpal S. Kanwar, Susan E. Quaggin, M. Health Services North Queensland, James Cook Univ, Townsville, Queensland, Australia; Medicine, Div of Nephrology, Northwestern Univ, Chicago, IL; Feinberg Cardiovascular Research Inst, Northwestern Univ, Chicago, IL; Lunenfeld-Tanenbaum Research Inst, Mount Sinai Hospital, Toronto, ON, Canada; Pathology, Northwestern Univ, Chicago, IL, Canada.

Background: Inhibitors of the mechanistic target of rapamycin (MTOR inhibitors) belong to a family of drugs with potent immunosuppressive, anti-angiogenic and anti-proliferative properties. Despite their clinical potential, their use in humans has been hampered by a significant incidence of proteinuria and electrolyte disturbances. Although some studies suggest MTOR may play a role in regulating renal solute transporter expression and function, the exact mechanisms underlying these changes are largely unknown.

Methods: In this study we examine the contribution of MTOR inhibition in the renal tubules to the development of proteinuria and electrolyte disturbances by generating an inducible Pax8敲出, tubule-specific Mtor knockout mouse (Mtor Pax8-iKO).

Results: Loss of Mtor in the renal tubular epithelium resulted in increased 24-hour urine volume, diminished urine osmolality, and renal failure. Despite elevated 24-hour urine albumin, Ca, and Mg, Mtor Pax8-iKO mice were both hypercalcemic and hypergammaglobulinemic. Histologically, Mtor Pax8-iKO mice exhibited generalized tubular atrophy with focal cysitolic dilations of the distal and cortical collecting tubules, and interstitial fibrosis. Immunohistochemistry showed decreased expression of aquaporin-2 (Aqp2), Calbindin D 28k (Cbd1), and the sodium-potassium-chloride cotransporter (Nkcc2).

Conclusions: Taken together, our results suggest that MTOR is a key player in maintaining electrolyte balance by modifying the expression, and function of solute transporters in the renal tubular epithelium.

SA-PO943

High Mobility Group Box 1 (HMGB1) Inhibits HCO3 Absorption in Medullary Thick Ascending Limb (MTAL) Through Receptor for Advanced Glycation End Products (RAGE)-Rho-Rock1-Mediated Inhibition of Basolateral Na+/H+ Exchange Bruns A. Watts, Thampi George, David W. Good.

Background: HMGB1 is a damage-associated molecule that is released extracellularly in response to infection or injury and plays a role in mediating kidney dysfunction in sepsis and sterile inflammatory disorders. Recently we showed that basolateral HMGB1 inhibits HCO3 absorption in perfused rat MTALs through a RAGE-dependent pathway additive to TLR4-ERK-mediated inhibition by LPS. Here we examined signaling and transport mechanisms involved in inhibition by HMGB1.

Results: Inhibition of HCO3 absorption by HMGB1 was eliminated by the Rho-associated kinase (ROCK) inhibitor Y27632 and associated kinase (ROCK) inhibitor Y27632 and by a specific inhibitor of Rho, the direct activator of ROCK1 by HMGB1 was eliminated by the RAGE antagonist FPS-ZM1 and by inhibition of Rho. Activation of ROCK1 by HMGB1 was eliminated by the RAGE antagonist FPS-ZM1 and by inhibition of Rho. Addition of a direct Rho activator reduced basal HCO3 absorption rate and prevented inhibition by HMGB1. The ROCK and ROCK inhibitors had no effect on inhibition by bath LPS. The Rho-ROCK1 pathway regulates NHE1 and we have shown that inhibition of NHE1 decreases MTAL HCO3 absorption secondary through cytoskeleton-dependent inhibition of apical NHE3. Inhibition of HCO3 absorption by HMGB1 was eliminated by bath amiloride, 0 Na body/day) or vehicle for a week. To further examine the effect of HMGB1 on the regulation of HCO3 in the intercalated cells, in vivo experiments have shown that metabolic acidosis and hypokalemia, that change plasma aldosterone level, increases and decreases the expression of Rhcg, respectively. Direct effect of aldosterone on the regulation of Rhcg has not been examined.

Methods: We examined the effect of aldosterone on the regulation of Rhcg. Membrane fraction of the whole kidney was extracted from mice that were continuously administrated aldosterone (10

Conclusions: The results suggest that aldosterone regulates membrane accumulation of Rhcg possibly through the activation of Sgk1.

SA-PO944

Identification of IQGAP-1 as a Pendrin-Binding Protein in the Kidney Jie Xu, Sharon L. Barone, Kamary A. Zahedi, Manoouche Salemi, Center on Genetics of Transport and Epithelial Biology, Dept of Medicine, Univ of Cincinnati, Cincinnati, OH; Research Services, VA Medical Center, Cincinnati, OH.

Background: Networks of interacting proteins are crucial for all levels of cellular function. The Slc26 family of anion transporters [Slc26a3 (DRA), Slc26a5 (prosthen), Slc26a6 (PAT-1), and Slc26a9 (PAT-2)] form multi-protein complexes with cytoskeleton, anchoring proteins, PDZ adaptor proteins, CTR and/or protein kinases, which impart regulatory signals on these isoforms. No information is available on proteins that interact with pendrin (Slc26a4).

Methods: A yeast two hybrid system was employed to screen a mouse kidney cDNA library with a pendrin C-terminal fragment as bait. A total of 6 x 107 interacting clones were identified, out of which 14 clones were confirmed to be positive when screened for β-gal expression. Plasmids from these clones were purified and their interaction with pendrin was confirmed.

Results: Our experiments identified IQGAP-1 as a pendrin C-terminus binding partner. IQGAP-1 is a scaffolding protein that binds and/or stabilizes ezrin, CDC42 and RAC1, and interacts with cytoskeletal and cell adhesion molecules. The kidney, IQGAP-1 is strongly expressed in the DCT, CNT, CCD and podocytes. IQGAP-1 has also been shown to control tight junction formation through recruitment of claudin. Our results indicate that IQGAP-1 co-localizes with pendrin on the apical membrane of B-intercalated cells. IQGAP-1 is also detected on the basolateral membrane of A-intercalated cells in CCD. Functional studies in HEK293 cells demonstrated that the co-transfection of IQGAP-1 and pendrin increased pendrin-mediated Cl/HCO3 exchange activity by more than 60%. Confocal microscopy showed more abundant plasma membrane expression of pendrin in the presence of IQGAP-1.

Conclusions: These studies demonstrate the interaction of IQGAP-1 and pendrin in B-intercalated cells, as well as the stimulatory role of IQGAP-1 on pendrin activity. We propose that pendrin interaction with IQGAP-1 is important in the regulation of CCD function and physiology, and that disruption of this interaction contributes to altered pendrin trafficking and/or activity in pathophysiologic states.

SA-PO945

Regulation of Rheg by Aldosterone in Intercalated Cells of the Collecting Ducts Koji Esguchi, Yuichiro Izumi, Terumasa Nakagawa, Yushi Nakayama, Hideki Inoue, Yutaka Kikazoe, Takashige Kuwabara, Masashi Mukoyama.

Background: Acid-base balance is regulated by aldosterone which stimulates acid secretion in the intercalated cells of the collecting ducts of the kidney. Rhesus blood group C glycoprotein (Rheg) is an ammonia transporter which cooperates with H+/ATPase to secrete H+ in the intercalated cells. In vivo experiments have shown that metabolic acidosis and hypokalemia, that change plasma aldosterone level, increases and decreases the expression of Rheg, respectively. Different expression of aldosterone on the regulation of Rheg has not been examined.

Methods: We examined the effect of aldosterone on the regulation of Rheg. Membrane fraction of the whole kidney was extracted from mice that were continuously administrated aldosterone (10

Conclusions: The results show that aldosterone regulates membrane accumulation of Rheg possibly through the activation of Sgk1.

Role of Adenylyl Cyclase 6 in Regulation of Urinary pH Soren Brandt Poulsen, Robert A. Fenton, Timo Rieg, Dept of Medicine, UCSF, La Jolla, CA; VA/DHS, San Diego, CA; Dept of Biomedicine, Aarhus Univ, Aarhus, Denmark.

Background: Adenylyl cyclase isoform 6 (AC6) is expressed in all renal tubular segments and catalyzes the synthesis of cAMP. We have previously reported that AC6 knockout (AC6–/–) mice have an urinary correction defect, a mild diuretic response, and secondary hyperparathyroidism. A recent study (Am J Physiol Renal Physiol. 2012;303(6):F812-20) determined that cAMP can increase pendrin protein (Cl:

Conclusions: The results suggest that AC6-mediated cAMP formation was important for urinary pH regulation.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Methods: AC6 wild-type (WT) and AC6-/- mice (n=6 genotype) were challenged with NaHCO₃ in their drinking water for a period of 8 days. As daily fluid intake is doubled in AC6-/- mice, the NaHCO₃ was reduced by 50% in this genotype (0.14 mol/l vs. 0.28 mol/l in WT). Urine was collected; blood was collected under baseline conditions and at the end of the 8 days experimental period. Mice were euthanized, one kidney processed for Western blotting (pendrin, H+-ATPase B1 subunit positive cells/mm² (WT: 322±2 vs. AC6-/-: 28±2) in the renal cortex was not different between genotypes.

Conclusions: Our results imply a role for AC6 in expression of pendrin and H+-ATPase B1 subunit and subsequently regulation of urinary pH. The increase in urinary pH in AC6-/- mice can only be achieved, or is the consequence of, higher pendrin abundance; however, this effect is independent of pendrin distribution changes. Further studies are needed to determine the signals causing baseline differences in urinary pH.

Jeong Ho Kim,1 Bom Soon Choi,1 Cheol Whee Park,2 Chul Woo Yang,1 Yong Soo Kim,1 Young Soo Kim,1 Byung Ha Chung.1 Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea; 1Internal Medicine, Uijeongbu St. Mary's Hospital, Uijeongbu, Korea.

Background: There is no clear consensus on the definition of acute kidney injury (AKI) and delay in development of DGF in deceased donor kidneys. In this study, we determine the discriminative and predictive ability of the Kidney Injury: Improving Global Outcomes (KDIGO) compared to the Acute Kidney Injury Network (AKIN) criteria for the prediction of the development of delayed graft function (DGF) and allograft outcome in deceased donor kidney transplantation (DDKT).

Methods: We analyzed 285 kidney transplant recipients who took kidney from 228 deceased donors. We calculated the AKI stage of deceased donor according to the AKIN and KDIGO criteria and compared the predictability for the development of DGF and the change of allograft function.

Results: For 2 classification systems, DGF developed more frequently in the AKI group than non-AKI group (P<.05) and allograft function assessed by the Modification of Diet in Renal Disease (MDRD) equation showed a significantly deteriorating pattern at 2 weeks and 1, 3, 6, 12 months after kidney transplantation compared to that in the non-AKI group (P<.05, comparison at each time point). In the Receiver-Operating Characteristic (ROC) curve analysis, the KDIGO criteria showed better prognostic accuracy of the prediction of the development of DGF compared to the AKIN criteria (area under the curve = 0.72 versus 0.62, P<.05).

Conclusions: In DDKT, the KDIGO criteria may be more useful for predicting the development of DGF compared to the AKIN criteria.

Impact of Cold Ischemia Time on Graft Failure and Death

Douglas F. Arbetter,1 Manisha C. Chiles,1 Prativa Baral,2 Geoffrey K. Dube,1 Russell J. Crew,1 Heather K. Morris1,2,1 Jai Radhakrishnan,1 David J. Cohen,1 Stephen O. Pastan,2 Rachel E. Patzer,1 Sumit Mohan.1 1Dept of Medicine, Columbia Univ College of Physicians & Surgeons, New York, NY; 2Dept of Medicine, Emory Univ School of Medicine, Atlanta, GA.

Background: Patient and graft survival post kidney transplant (KT) are influenced by an interaction of multiple factors, including organ quality, preservation and cold ischemia time (CIT). Several small studies have suggested that even small increases in CIT adversely impact patient and graft outcomes. In this analysis we assess the impact of increasing CIT on patient and graft survival in the US.

Methods: We identified 75,660 first-time adult KT recipients, who received a deceased donor (DD) kidney from 2000-2011 in SRTR. Pearson’s chi-square tests of independence and logistic regression models were performed to test association between CIT and mortality, graft failure. Cox proportional hazard analyses, adjusting for donor factors (age, gender, serum creatinine, cause of death), recipient factors (age, dialysis duration, PRA status, HLA mismatch), machine perfusion, and specified effect measure modifiers, were performed to estimate the hazard of either event occurring given CIT.

Results: 60.7% of our cohort was black and 31.4% were black. Mean age was 52.2±10.3 years and average CIT was 18.2±9.2 hours. By univariate analysis, CIT was associated with an increase in risk of both death-censored graft failure and mortality (both HR=1.006; p<.0001). Adjusting for covariates and effect measure modifiers, the relationship between CIT and recipient mortality risk and death-censored graft failure were both attenuated (HR=1.000; p=0.9692 and HR=0.997; p=0.7479, respectively) suggesting that each additional hour of CIT did not significantly increase the risk of graft failure or death.

Conclusions: Our results suggest that increases in CIT do not adversely impact patient and allograft outcomes following DDKT and should not be used to decline organ offers.

SA-PO949

Impact of Hypothermic Machine Perfusion on Outcomes following Kidney Transplantation

Background: Patient and allograft outcomes following deceased donor kidney transplantation (DDKT) are thought to be influenced by the intrinsic quality of the organ at procurement and any superimposed subsequent injury that occurs during cold preservation (CP). Hypothermic machine perfusion (HMP) is used in an attempt to decrease injury from CP especially for organs that have extended periods of cold ischemia. We analyzed the impact of complete, partial or no HMP use during CP on patient and graft survival following DDKT.

Methods: We identified 75,660 first-time adult renal transplant recipients, who received a DD kidney from 2000-2011 in SRTR. Pearson’s chi-square tests of independence and Kruskal-Wallis tests were performed to test for association between HMP and mortality, graft failure, and delayed graft function (DGF). Cox analyses, adjusting for donor factors (age, gender, creatinine, cause of death), recipient factors (age, dialysis duration, PRA, HLA mismatch), CP time, and specified effect measure modifiers, were performed to estimate the hazard of either graft failure, or DGF occurring given HMP.

Results: On unadjusted analyses, compared to no HMP use, kidneys that received HMP for some or all of their CP time were less likely to experience DGF (OR=0.82, p=0.001 & OR=0.77, p=0.001) but more likely to experience allograft failure (HR=1.19, p=0.001 & HR=1.20, p=0.001, figure 1). On multivariable analyses, the use of HMP was associated with a lower incidence of DGF (OR=0.70, p=0.001 & OR=0.59, p<0.001) but continued to be associated with a higher risk of allograft failure even after adjusting for CIT and the lower DGF (HR=1.11, p=0.023 & HR=1.26, p=0.002).

Conclusions: HMP improves short term outcomes by lowering rates of DGF but is associated with reduced long-term allograft survival.

SA-PO950

The Impact of Remote Ischaemic Preconditioning (RIPC) on the Inflammatory Response following Live Donor Kidney Transplantation

Kristin Vlieke Veghely, 1 Madhur P. Morwani,1 Jennifer Nicholas,1 Raymond Macallister,2 Wessley Kidney Unit, Portsmouth Hospitals NHS Trust, United Kingdom; 1UCL Centre for Clinical Pharmacology & Therapeutics, Univ College London, United Kingdom; 2Clinical Trials Unit, London School of Hygiene and Tropical Medicine, United Kingdom.

Background: Ischaemia reperfusion injury (IR) at transplantation contributes to organ damage that limits allograft longevity. Animal studies have demonstrated a reduction in proinflammatory cytokines following RIPC, which may contribute to protective effects. REPAIR demonstrated a trend towards improved live donor kidney function following RIPC. We investigated the effects of RIPC on serum and urinary cytokines in this study.

Methods: 406 adult live donor/recipient pairs were recruited. Pairs were randomised using a factorial design to either: sham RIPC, early RIPC (immediately pre-surgery), late RIPC (24 hours pre-surgery) or dual RIPC. Donor and recipient received the same interventions (active or sham RIPC). Serum from donor and recipient and urine from recipients were analysed at baseline and on day 2 for pro-inflammatory cytokines IL-1β, IL-6, IFN-γ and TNFα, using multiplex ELISA. All analyses were conducted using linear regression adjusted for baseline (pre-treatment) values of the cytokine and indicator variables for early and late treatment group. Cytokine values were log transformed before analysis to account for skewed distribution.

Results: There was no difference in the expression of serum cytokines in donor serum or recipient serum and urine between baseline pre-surgery and day 2 post surgery.

Low Expression of the Messenger RNA TLRs 2-4,9 from Peripheral Blood Mononuclear Cells of the Kidney Recipients May Indicate Previous Delayed Graft Function

Sławomir C. Zmonarski, Katarzyna Madziarska, Mirosław Banasik, Maria Magott, Marian Klíngler. Nephrology and Transplantation Med., Medical Univ, Wrocław, Poland.

Background: The Toll-like receptors (TLR) 2-4,9 are engaged in the pathogenesis of acute renal injury. Earlier studies demonstrated that 24 hrs. after transplantation (KT), the expression of the messenger of mRNA (mRNA) TLR4 of peripheral blood mononuclear cells (PBMC) from patients (pts) with delayed graft function (DGFi) was lower than in recipients of kidneys without DGF (DGFi). The aim of study was to examine whether the reduced expression of TLR2-4,9 mRNA is a more permanent phenomenon associated with DGF.

Methods: Each of the 151 KT pts was more than 1 month after KT (from 1 to 128 months). Within this group: in 117 pts blood sample was taken for more than 3 months after KT, 45 pts experienced DGF, 13 DGFi pts was HBCaB positive (DGF+HBCaB). Control group (Con.) included 38 healthy volunteers. TLR2-4,9 mRNA expression (expr.) from PBMC was assessed by polymerase chain reaction (real-time PCR) and analyzed in terms of DGF and clinical course.

Results: KT DGF+ pts had generally lower TLR2-4,9 mRNA expr. than KT DGF- pts (TLR2: p=0.06; TLR3: p=0.02; TLR4: p=0.07; TLR 9, p=0.027) TLR3 mRNA of DGF+HBCaB pts was: lower (p=0.046) than DGF+HBCaB, lower (p=0.013) than DGF-ATN- and lower (p=0.008) than Con. TLR9 mRNA of DGF+HBCaB was lower (p=0.002) than Con. In multiple regression analysis low expr. of TLR mRNA 2-4,9 was associated with the occurrence of DGF in the past.

Conclusions: Lower than typical expression of TLR 2-4,9 mRNA seems to be a potential feature of peripheral blood mononuclear cells of the recipient of the transplanted kidney who experienced delayed graft function. Hepatitis B seems may be associated with additional decline of TLR3 and TLR9 mRNA expression. TLR3,4,9 mRNA expression could potentially be used an indicator of the likelihood of delayed graft function.

BB3, a Hepatocyte Growth Factor-Like Small Molecule, Improves Outcome in Kidney Transplant Recipients with Delayed Graft Function

Jonathan Bromberg, 1 Matthew R. Weir, 2 A. Osama Gaber, 2 Matthew Cooper, 3 Mark Laftavi, 2 Barry Browne, 2 Bo Zhang, 2 Prakash Narayan, 2 Michael A. Yamin, 2 Itzhak D. Goldberg, 2 Weizhong Cai. 2 Transplant Division Surgery, Univ of Maryland School of Medicine, Baltimore, MD; 3Div of Nephrology, Univ of Maryland School of Medicine, Baltimore, MD; 2The Methodist Hospital, Houston, TX; 2MedStar Georgetown Univ Hospital, Washington, DC; 2Transplant Center at Erie County Medical Center, Buffalo, NY; 2BNMC, San Diego, CA; 4Angion Biomedica Corp, Uniondale, NY.

Background: Duration of delayed graft function (DGF) portends poor short- and long-term renal function and graft survival. We studied the safety and efficacy of BB3, a small molecule with HGF-like activities, dosed starting 24 hr post-transplant (Tx) in patients with reduced urine output (UO) in a double-blind Phase 2 study.

Methods: Patients presenting ≥50 cc urine/hr over 6-8 h post-Tx were randomized (2:1) to BB3 (2 mg/kg IV QD X 3 d) or placebo (PBO). An interim analysis was performed on 12 BB3- and 7 PBO-treated patients.

Results: BB3 was safe and well-tolerated. BB3 reduced the median time to produce 1.2L UO/24 hr from > 28 d to 7.5 d, increased the % of patients reaching this UO within 28 d from 43% to 83%, increased cumulative UO (figure), decreased median duration of dialysis (figure), decreased % on-dialysis days during Days 7-28 (14.2% to 7.1%) and during Days 14-28 (10.9% to 3.6%), reduced median SCR, reduced BUN, and shortened median hospital stay (7 d to 5.5 d). BB3 reduced serum CRP and NGAL.

Conclusions: BB3 administered ~24 hours post-Tx significantly reduced severity of DGF in patients presenting with reduced UO. Confirmation of these results in a Phase 3 trial may translate to improved long-term outcome, decreased Tx costs, increased use of marginal organs, and a shorter waitlist.

DSA Monitoring and Treatment in Kidney Transplant Recipients
Monica Grafals,1 Alexander Gilbert,1 Olga A. Timofeeva.2 1Medstar Georgetown Transplant Inst, Georgetown Univ, Washington, DC; 2Histocompatibility Laboratory, Georgetown Univ, Washington, DC.

Background: The development of DSA monitoring is a new technique to detect antibodies in kidney transplant recipients. We previously showed that patients who developed de novo DSA (dnDSA) suffer a 35% graft loss. Because of this we have developed a protocol for treating patients that have developed dnDSA post kidney transplantation.

Methods: Since the implementation of this treatment protocol on September 12, 2014, there have been 9 patients that have developed dnDSA after renal transplantation.

Results: Four of the patients that developed dnDSA were in the low risk category and in 5 of them the DSA has cleared. The 4th patient has a DSA against DP1 with an MFI of 1587 that has remained stable. All of these patients have a GFR>45 cc/min. Three patients were in the intermediate risk category. One of them has a creatinine of 3, BK viremia and he has a DSA against A1 with an MFI of 3150 which has been stable.

Conclusions: Since the implementation of this treatment protocol on September 12, 2014, there have been 9 patients that have developed dnDSA after renal transplantation. This preliminary data shows that treatment for dnDSA with this protocol seems to successfully treat the antibodies.

SA-P0956

Low Level Class I or II Donor HLA-Specific Antibodies Do Not Correlate with the Concurrent Presence of Antibody Mediated Injury on Biopsy
Chelsea Estrada,1 Catherine Miranda,2 Hesecuk Suh,2 Frank Darras,2 Edward P. Nord,3 Mersema Abate.1 Nephrology and Transplantation, Stony Brook Medicine, New York.

Background: Pre-transplant and de novo donor HLA-specific antibodies (DSA) have been identified as risk factors for adverse outcomes in renal transplantation, causing antibody-mediated graft injury and acute antibody mediated rejection (ABMR) and transplant glomerulopathy (TG). With improved detection techniques, DSA recognition is increasing but there is no consensus on the definition of DSA positivity. While low level pre-transplant DSA has been associated with the future occurrence of ABMR, low level DSA on the day of indication biopsy is of unclear significance.

Methods: All sera were tested for DSA using single antigen beads with Luminex technology on the day of indication renal transplant biopsy from 7/1/2015 - 5/21/2015. DSA level >500 mfi were considered negative, between 500-1500 mfi low level and >1500 mfi high level. Acute ABMR and TG histology met Banff 2013 criteria. In this cohort, induction was with alemtuzumab and rapid steroid withdrawal, and maintenance immunosuppression was with tacrolimus and mycophenolate mofetil. Chi square analysis was used to assess the association between low and high levels of DSA and biopsy findings of antibody mediated injury.

Results: Fifty-three consecutive indication kidney transplant biopsies were performed from 7/1/2014 - 5/21/2015. Of these 12 had evidence of ABMR (2 acute, 8 TG and 2 both). Six of the 8 patients with TG alone did not have DSA. At the time of biopsy, 12 class I (6 low and 6 high level) and 13 class II (3 low and 10 high level) were detected.

Conclusions: 1. The presence of high level class II DSA was significantly associated with the concurrent biopsy finding of antibody mediated injury. 2. Of greater significance, the presence of class I DSA or low level class II DSA did not correlate with pathologic findings.

Characteristics of Kidney Transplant Candidates with and without Antibody against Angiotensin II Type I Receptor (AT1R-Ab)
Mary Carinelle Philogene1, S.M. Bagnasco,2 Annette M. Jackson,2 Mary S. LeTellier,1 Andrea A. Zachary.1 1Medicine, Johns Hopkins Univ, Baltimore, MD; 2Pathology, Johns Hopkins Univ, Baltimore, MD.

Background: In this study we sought to determine whether baseline characteristics of kidney transplant candidates when correlated with presence of AT1R-Ab are predictive of transplant outcomes.

Methods: 122 renal transplant recipients were tested for presence of AT1R-Ab using quantitative ELISA (CellTrend GmbH, Germany). Patient demographics were obtained from the hospital electronic record under an approved IRB.

Results: Patients were categorized according to AT1R-Ab levels: positive (>17 Units/ml (30%); borderline 10-17 Units/ml (34%), negative <10 Units/ml (36%). There were fewer females (31% versus 61%, 55%) and African Americans (14% versus 24%, 16%) in the AT1R-Ab >17 Units/ml group compared to the other two groups. The presence of AT1R-Ab has been associated with development of inflammation and fibrosis; therefore, we examined AT1R-Ab among patients categorized by the following diseases: IgA nephropathy, glomerulosclerosis, lupus nephritis, FSGS, and membranoproliferative glomerulonephritis. We found no correlation between these diseases and AT1R-Ab levels (38%, 29% and 30%, respectively; p=0.7). We also found no association with diagnosis of hypertension and AT1R-Ab levels (16%, 17%, 18%). The most significant difference between the three groups was a higher percentage of positive patients among those who received more than one kidney transplant (78%, 22%, 45%; p=0.001). Post transplantation, sixty-one patients were biopsied to investigate graft dysfunction. There were more patients in the borderline and positive AT1R-Ab groups who were evaluated for graft dysfunction compared to the negative group (65%, 54% versus 34%) although this did not reach statistical significance.

Conclusions: The only pre-transplant characteristic linked to presence of AT1R-Ab in patients who are being evaluated for kidney transplantation is the incidence of previous transplant.

Effect of B-Cell Activating Factor (BAFF) Inhibition (LY2127399; Tabalumab) on Highly Sensitized Patients with End Stage Renal Disease awaiting Transplantation Muhammad Ahmad Muftiua, Wendy Komocsi, Milagros D. Samaniego-Picota, Eric Nantz, Jayne Hague, Melissa D. Anderson, Benita K. Book, Nancy G. Higgins, Tim E. Taber. Nephrology, Univ of Texas Medical Branch, Galveston, TX; Transplant Nephrology, Indiana Univ School of Medicine, Indianapolis, IN; 3Bio-Medicines, Eli Lilly and Company, Indianapolis, IN; 4Nephrology, Univ of Michigan Health System, Ann Arbor, MI.

Background: B cell activation factor (BAFF) is critical in B-cell maturation. Inhibition of BAFF represents an appealing target for desensitization of highly sensitized end stage kidney disease patients.

Methods: We conducted a Phase 2a, single-arm, open-label exploratory study investigating the effect of tabalumab (BAFF inhibitor) in ESRD patients with cPRAs ≥50%. The treatment period had a total duration of 24 weeks. Eighteen patients received tabalumab, at a dose of 240-mg subcutaneous (SC) at Week 0 followed by 120-mg SC at 4-week intervals for 5 more months. Patients were then followed for an additional 52 weeks. Blood samples were analyzed for HLA antibodies, BAFF levels, serum immunoglobulins, T and B cell subsets at specified time intervals during the treatment and follow-up periods. Pre and post treatment tonsil and bone marrow biopsies were also performed.

Results: Significant reductions in cPRAs were observed at week 16 (p=0.043) and at week 36 (p=0.004), however the absolute reductions were small (<5%). Overall factor effect at week 76 compared to baseline was significant (p=0.04). Mean BAFF levels increased during treatment, reflecting binding to tabalumab and decreased in the follow-up period remaining slightly above baseline at week 76. Expected changes in B cell subsets and reductions in immunoglobulins were observed. Two tabalumab-related serious adverse events occurred (pneumonia and worsening of peripheral neuropathy) while the most common other adverse events were injection-site pain and hypotension. Three patients received a matched donor cadaveric transplant during the study follow up.

Conclusions: BAFF inhibition resulted in statistically significant, but not clinically meaningful reduction in the cPRA from baseline.

SA-PO959

Background: Pre- and post-transplant DSA increases the risk for acute rejection, humoral rejection and graft loss. Every year a 5% of patients will develop DSA but other patients turn negative. It is unclear how the behavior of pre-transplant DSA under immunosuppression and their clinical impact. This study evaluate the relationship between de novo DSA and the outcome of kidney transplantation, and whether the development of these antibodies is related to pre-transplant DSA status.

Methods: Prospective cohort study. From Jun/2004-Dec/2014 a total of 519 kidney transplant were performed. For analysis we include 412 with DSA determination plus those with positive Flow-Crossmatch (in DSA-positive cases). We classified the patients in 7 groups transfusions were performed. For analysis we include 412 with DSA determination plus these antibodies is related to pre-transplant DSA status.

Results: From 412 patients, 58 patients (14.1%) had pre-transplant DSA. Patients with Pos/Pos or Pos/De Novo DSA had higher and earlier AR and AMR rate, followed by Neg/De Novo-VARIABLE and Neg/De Novo, as you can see in the figure A) and B) respectively. For graft loss only those with Pos/De Novo was higher than Neg/Neg (Figure C). Interestingly, those who are Pos/Neg had similar outcomes than Neg/Neg.

Conclusions: Staying with the same DSA or developing De Novo-DSA after transplantation, regardless what the pretransplant condition was, were associated with development of AR, AMR, and graft loss.

SA-PO960

Course of Anti-HLA Antibodies After Induction Therapy with Rituximab in Renal Transplantation Luuk Hilbrands, Wil Allesbe, Martijn W.F. Van den hoogen, Irma Joosten, Marjoke C. Baas, Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; 2Laboratory Medicine, Radboud Univ Medical Center, Nijmegen, Netherlands; 3Nephrology, Erasmus Medical Center, Rotterdam, Netherlands.

Background: B-cell depletion protocols have shown to reduce donor-specific antibodies against HLA (DSA) and chronic antibody mediated rejection. We aimed to study the effects of rituximab as a single-agent induction therapy on the titers of pre-existent or de novo DSA and non-DSA after renal transplantation and relate this to rejection free and overall graft survival.

Methods: We collected sera in participants of a prospective double-blind randomized study on the efficacy and safety of the prophylactic use of one dose of rituximab, added to standard immunosuppressive treatment (prednisolone, tacrolimus and mycophenolate mofetil) in comparison with standard immunosuppressive treatment alone in renal transplantation (www.clinicaltrials.gov, NCT016565331).

Results: 280 patients were included (142 received placebo, 138 rituximab). Anti-HLA antibodies (Ab) were determined in serum taken pre-transplant and 12 and 24 months after transplantation. Serum was analysed pre-transplant and at 12 months from 126 placebo and 119 rituximab treated patients. Pre-existent anti-HLA Ab were present in 24/126 (19.0%) patients in the placebo group and in 20/119 (16.8%) patients in the rituximab group (P=0.05). In the placebo and rituximab treated patients HLA class I Ab disappeared in 55.6% and 50% and HLA class II Ab in 23.5% and 57%, respectively (P=0.06). At 12 months, 11 (8.7%) placebo treated patients and 4 (3.4%) rituximab treated patients (NS) developed de novo HLA Ab. 10/245 (4.1%) had de novo HLA class I Ab: 6 (4.8%) and 4 (3.4%) in the placebo and rituximab treated patients, respectively (NS). 12/245 (4.9%) had de novo HLA class II Ab: 9 (7.1%) in the placebo group and 3 (2.5%) in the rituximab group (P=0.09).

Conclusions: Induction therapy with rituximab compared to placebo does not significantly influence the course of anti-HLA Ab at 12 months, however it possibly decreases the levels of pre-existent class II anti-HLA Ab and inhibits the formation of de novo class II anti-HLA Ab.

SA-PO961

Background: We conducted a multicenter prospective clinical study in ABO-incompatible kidney transplantation (ABO-KT) without splenectomy (UMIN000006635). To evaluate the benefit of desensitization with rituximab (R), we investigated the data of this study from the time course change of anti-A/B antibody (ab) titer and sequential pathological findings.

Methods: Desensitization protocol included low dose MMF and steroid started 28 days before and CNI started a few days before surgery. R 375 mg/m2 was administered at day -14 and day -1. Minimum 2 sessions of plasma exchange were done for anti-A/B ab removal before transplant, and basiliximab was administered on day 0 and day 4. Anti-A/B
ab titer and eGFR were sequentially evaluated, 0 hr, 1 hr and protocol biopsies (4 weeks after transplant) were also sequentially performed as possible. Pathological specimens were centrally diagnosed by 3 pathologists.

Results: 18 pts received AB0i-KT. One-year pts and graft survival were both 100%. The desensitization with R was well tolerated. Average anti-A/B or IgG titer at baseline was 150x increased to 19.72x immediately before surgery, maintaining until the end of the study. In pts whose sequential pathological specimen available showed positive C4d deposition in 1/3 at 1 hr and 11/16(69%) at protocol biopsy. No pts developed AMR related to anti-A/B abs except for one who experienced AMR with anti-HLA ab (Banff07 type II). Her anti-A/B abs titers were slightly higher than the others (4x-32x). Pathological findings included arteriosclerosis in 8, nephrocalcinosis in 1, IF/TA (grade 1) in 1 and suspicious CNI acute nephrotoxicity in 1. Two pts showed C4d+ without other pathological signs. Conclusions: In this series, anti-A/B ab titers were successfully decreased and no AMR occurred other than 1 caused by anti-HLA ab, whereas C4d deposition was detected in 69% of pts by protocol biopsy. Our desensitization protocol was confirmed both pathologically and clinically and safely effective for AB0i-KT.

SA-PO962
Post-Transplant BAFF Levels Do Not Predict the Development of Anti-HLA Antibody in Kidney Transplant Recipients

Byung H. Chung, MD, PhD, 1,2 Seong K. Ha, MD, PhD, 1,3 Issac B. Lee, MD, PhD, 1,2 Michael D. Kang, MD, PhD, 1,2

Background: Pre-transplant BAFF levels are associated with the development of de novo anti-HLA antibodies and also antibody mediated rejection post-transplant. However, the clinical significance of BAFF values at allograft rejection has not been determined. In this study, we investigated the clinical significance of pre- and post-transplant BAFF levels measured when indicated biopsy was done.

Methods: In 130 kidney transplant (KT) recipients who required allograft biopsy due to an increase in serum creatinine, we checked for anti-HLA antibodies using Lumines single antigen assay, and measured BAFF levels using ELISA kits. In 78 of these patients we also measured pre-transplant BAFF and anti-HLA antibody levels. We investigated the relationship between pre-transplant, post-transplant and delta BAFF levels and the occurrence of anti-HLA antibodies.

Results: Pre-transplant BAFF levels showed significant association with pre-transplant sensitization, represented by positive PRA, high PRA, and presence of HLA-DSA. They also showed positive association with early rejection (rejection within 6 months from KT). Post-transplant BAFF levels showed significant association with pre-transplant sensitization, but did not show association with anti-HLA antibodies and positive donor-specific antibodies at the time of biopsy. We did not find any association between post-transplant BAFF levels and cumulative allograft survival, allograft biopsy results, Banff scores and microvascular inflammation scores.

Conclusions: In conclusion, pre-transplant BAFF levels are associated with pre-transplant sensitization and are useful in predicting allograft rejection. But post-transplant BAFF levels measured at the time of indicated biopsy are not associated with the appearance of de novo HLA-DSA, allograft rejection, biopsy findings and other allograft outcomes.

SA-PO963
Effectiveness of Bortezomib (BT) in the Treatment of Antibody Mediated Rejection Among Pediatric Kidney Transplant Recipients (pKTx)

204

Sarah J. Zirulbils,1 Donna J. Claeys,2 Issac A. Ashoor,2 Ashton Chen,1 Sara E. Janideska,1 Raed Bou Matar,1 Jaron Misurac,2 Katherine Twombley,1 Priya Verghese1,2 Pediatric Nephrology, Univ of Minnesota; 1Cincinnati Children’s Hospital; 1Children’s Hospital New Orleans; 1Wake Forest Univ; 2Rush Univ; 2Cleveland Clinic; 1Indiana Univ; 1Medical Univ of South Carolina.

Background: AMR has a poor prognosis despite a number of therapeutic options. BT is increasingly being utilized in adults but there are limited data on its safety and efficacy in pKTx with AMR.

Methods: Multicenter retrospective case series including all pKTx who received BT for biopsy proven AMR, from 2008-2015, at 8 centers within Midwest Pediatric Nephrology Consortium. Results: Twenty-four pKTx from 8 centers were treated with BT for AMR. In addition to BT, 75% were treated with rituximab, 79.2% with plasmapheresis and 91.7% with IVIG. 62.5% were males, 45.8% were white, and 41.7% were African American. Two-thirds were deceased donor recipients, and mean age at transplant was 11.1 years (SD 5.19). Obstructive uropathy and dysplasia comprised 50% of the underlying diseases. At the time of transplant, 82.2% of patients had 0.0% panel reactive antibodies. Mean estimated GFR (eGFR) prior to AMR was 49.6 (SD 12.1). Prevalence of donor specific antibodies (DSA) and changes in eGFR are shown in table 1.

Conclusions: Even though limited by small patient numbers, this trial suggests efficacy of IA in the treatment of late ABMR.

SA-PO965
Pre-Transplant Phospholipase A2 Receptor Autoantibody Concentration Is Associated with Recurrence of Membranous Nephropathy Post-Kidney Transplantation

Hasan Fattah, MD, PhD, 1,2,3 Gaurav Gupta, MD, 1,2 Dhiren Kumar, MD, 1 Luis F. Quintana,1 Anne L. King,1 Rivka Ayalon,1 Laurence H. Beck,3 Nephrology, Virginia Commonwealth Univ; Richmond, VA; 2Nephrology, Hospital Clinic de Barcelona, Barcelona, Spain; 3Nephrology, Boston Univ, Boston, MA.

Background: Idiopathic membranous nephropathy (mN) has been associated with anti-phospholipase A2 receptor autoantibody (PLA2R-Ab) both in the native kidneys as well as in the setting of recurrence (mN) post-kidney transplant (txp). Previous studies that have assessed pre-txp PLA2R-Ab for the prediction of mN have yielded variable results. Many of these studies have been limited by the use of variable immunosuppressive protocols among patients, different ELISA assays as well as method of diagnoses (surveillance vs indication biopsies).

Results: 40 renal tx recipients diagnosed as biopsy confirmed mABMR at a mean time of 70±40 months after tx were included. Patients were randomly assigned to PE (n=16) or DFPP (n=19) or IA with protein A (n=5). The studies were similar regarding age, gender, donor type, eGFR at randomization and post-tx follow-up time. Donor specific antibody (DSA) was positive in 62.5% of PE, 73.6% of DFPP and 100% of IA groups (p=0.25), and C4d was positive in 75%, 68% and 60% (p=0.79), respectively. All patients received 2 g/kg IVIG and Rituximab 375 mg/m².

Results: Tubulointerstitial scar rate (civt) (p=0.81), microcirculation inflammation (g+pc) (p=0.38) and transplant glomerulopathy (g) (p=0.21) scores were similar. However, the mean total inflammation (ti) score of IA group (2.60±0.55) was significantly higher than PE (1.69±0.70) and DFPP (1.79±0.71). The rates of graft loss were as follows; PE; 13/16 (81.3%), DFPP; 10/19 (52.6%) and IA; 1/5 (20%) (p=0.03). The graft survival was significantly higher for IA than PE (p=0.01). There was a tendency of better graft survival in DFPP compared to PE group (p=0.07). Kaplan-Meier survival analysis revealed better overall survival for IA than for PE and DFPP (p=0.03).

Conclusions: Even though limited by small patient numbers, this trial suggests efficiency of IA in the treatment of late ABMR.
Methods: Sixteen consecutive txp patients with a history of IMN were tested for pre-txp PLA2R-Ab. ELISA titers (Euroimmun, NJ, USA) >14 RU/ml were considered positive, as per manufacturer instructions. All patients received similar post-transplant immunosuppression. A receiver operating characteristic (ROC) analysis was performed after combining data from Quintana et al. (n=21; Transplantation Feb 2015) to determine a PLA2R-Ab concentration which could predict rMN.

Results: Six (out of 16; 37%) patients had biopsy-proven rMN at a median of 3.2 years post-txp. Of these, 5/6 (83%) had a positive PLA2R-Ab pre-txp with a median of 82 RU/ml (range=31-1500). The only patient who had rMN with a negative PLA2R-Ab was later diagnosed with nodular sclerosing Hodgkin’s lymphoma 100% (n=1) patients with no evidence of rMN (median follow-up=5 years) had negative PLA2R-Ab though one patient did have a borderline titer of 13.8 RU/ml. Patients with rMN were treated with rituximab and had an improvement in proteinuria from a median of 6g/d to 0.6g/d. Among the patients with rMN and positive PLA2R-Ab, titers fell to a median of 4 RU/ml at most recent follow-up.

In a combined ROC analysis (n=37) a pre-txp PLA2R Ab>29 RU/ml predicted rMN with an AUC of 0.78 vs. T1/T2 0.82, Z statistic 1.94. In the test set, 12 of 16 txp patients had biopsy-proven rMN at a median of 3.8 years post-txp. Of these, 10/12 (83%) had a positive PLA2R-Ab pre-txp with a median of 59 RU/ml (range=29-293). Patients with rMN had a higher IL10:TNFα ratio. Thus T1 TrBs represent the B subset over the next 5 years (ROC AUC 0.82, P<0.001) and was independently associated with allograft deterioration (HR 26.6, 95% CI 3.1-227.3, P<0.003). In both the test and validation sets, T1/T2 ratio was a much stronger predictor of graft deterioration than traditional markers like eGFR (test set, eGFR ROC AUC 0.76 vs. T1/T2 ratio 0.84, Z statistic 0.97; validation set, eGFR ROC AUC 0.64 vs. T1/T2 ratio 0.82, Z statistic 1.92), or the detection of DSA (test set, DSA ROC AUC 0.68 vs. T1/T2 ratio 0.84, Z statistic 3.2; validation set, DSA ROC AUC 0.66 vs. T1/T2 ratio 0.82, Z statistic 2.35).

Conclusions: Pre-transplant PLA2R-Ab could be a useful tool for the prediction of rMN. Patients with rMN in the absence of PLA2R-Ab should be screened for occult malignancy.

SA-PO966 Neutrophil-to-Lymphocyte and Platelet-to-Lymphocyte Ratio Predict Acute Allograft Rejection
David S. Wheeler, Scott Blumberg, Manjula Balasubramanian, Janani Rangaswami, 1 Internal Medicine, Albert Einstein Medical Center, Philadelphia, PA; 2 Pathology, Albert Einstein Medical Center, Philadelphia, PA; 3 Delavere Valley Nephrology and Hypertension Associates, Philadelphia, PA.

Background: Currently, allograft biopsy is gold standard for diagnosing rejection however there is intense interest in identifying non-invasive biomarkers. The goal of this study is to determine whether the neutrophil-to-lymphocyte ratio (NLR) or the platelet-to-lymphocyte ratio (PLR) correlate with acute allograft rejection.

Methods: This single center retrospective case-control study examined all kidney transplant biopsies conducted at Einstein Medical Center from Jan 2013 through Dec 2014. Biopsies were stratified for rejection (acute cellular, borderline, negative). The NLR and PLR were calculated from routine laboratory studies obtained at various time points preceding the biopsy.

Results: Of the 102 “for cause” biopsies, 37.3% showed clear evidence of acute rejection and 18.6% were borderline. NLR and PLR obtained within the week prior to the biopsy showed a significant reduction in acute rejection (P<0.05) and the NLR in PLR preceded the biopsy by 2-4 weeks suggesting a rejection prodome. Interestingly, NLR at the time of boarderline biopsy with acute cellular rejection. This reduction in NLR and PLR preceded the biopsy by 2-4 weeks. A follow-up (ROC AUC 0.84, P<0.001). In a multivariate Cox model, T1/T2 ratio was independently associated with allograft deterioration (HR 4.8 95% CI 1.3-17.8, P=0.02). T1/T2 ratio was examined 2 years post-transplant in a prospective validation set of 97 stable patients derived from a steroid avoidance RCT comparing alemtuzumab (n=51) vs. cyclosporine (n=46). A T1/T2 ratio >1.1 was a strong predictor of graft deterioration over the next 5 years (ROC AUC 0.82, P<0.001) and was independently associated with allograft deterioration (HR 26.6, 95% CI 3.1-227.3, P<0.003). In both the test and validation sets, T1/T2 ratio was a much stronger predictor of graft deterioration than traditional markers like eGFR (test set, eGFR ROC AUC 0.76 vs. T1/T2 ratio 0.84, Z statistic 0.97; validation set, eGFR ROC AUC 0.64 vs. T1/T2 ratio 0.82, Z statistic 1.92), or the detection of DSA (test set, DSA ROC AUC 0.68 vs. T1/T2 ratio 0.84, Z statistic 3.2; validation set, DSA ROC AUC 0.66 vs. T1/T2 ratio 0.82, Z statistic 2.35).

Conclusions: We demonstrate a distinct subset of TrB (T1) characterized by an anti-inflammatory cytokine profile. A decrease in T1-T2 ratio (due to selective loss of T1 cells) is a strong prognostic biomarker for subsequent renal allograft deterioration.

SA-PO968 The Pre-Transplant Ratio of T Regulatory Cells to Effector/Memory CDB+ T Cells Is Correlated with the Development of Acute Rejection
Kentarou Sugisaki, QiZhi Tang, Sang-Mo Kang, Surgery, Medical Center, Univ of California, San Francisco, San Francisco, CA.

Background: Acute rejection (AR) or renal allografts are a major predictor for the development of chronic allograft nephropathy (CAN) and subsequent graft loss. Although clinical risk factors for the development of AR have been identified, few techniques exist to individually stratify patients for the risk of AR and provide a rational basis for the tailoring of immunosuppression regimens. Over the past two decades, regulatory T cells (Treg) have been identified and subsequently shown to be critical to the prevention of autoimmunity as well as the prevention on organ allograft rejection in numerous models. In parallel, the identification of various T lymphocyte subsets has been greatly refined, allowing a more precise quantitation and correlation with outcomes.

Methods: We hypothesized that Treg abundance pre-transplant could predict for the development of acute rejection in patients undergoing de novo renal transplantation. We prospectively enrolled 16 renal transplant patients undergoing first transplant from August 2013 to March 2014. We excluded patients undergoing second transplants, desensitization protocols, or involved in other clinical trials. Venous blood samples from all recipients at transplant date were isolated the peripheral blood mononuclear cells (PBMCs) and stored. We analyzed the samples in batches and normalized cell surface and intracellular staining using a standard control, using a NAVIOS flow cytometer (Beckman Coulter). All recipients were followed for a minimum of 1 year for the development of biopsy proven rejection.

Results: 12 recipients experienced AR. The pre-transplant ratio of Treg/EM CD8 T cells may identify patients at increased risk of AR and should encourage larger scale studies to validate and quantify the magnitude of risk as well as to assess covariables.

Conclusions: Our data suggests that the pre-transplant ratio of Treg/EM CD8 T cells may identify patients at increased risk of AR and should encourage larger scale studies to validate and quantify the magnitude of risk as well as to assess covariables.

SA-PO969 The Association of Th17 Cell Phenotype with Chronic Allograft Dysfunction in Kidney Transplant Recipients Byung Ha Chune, Hyunsoo Kim, Chul Woo Yang. Internal Medicine, Seoul St. Mary’s Hospital, Seoul, Korea.

Background: The purpose of this study is to determine the significance of the Th17 cell pathway in the progression of chronic allograft dysfunction.

Methods: We investigated the expression of T cell phenotype in long-term stable kidney transplant recipients (KTRs)(LTS, n=67), chronic allograft dysfunction group (CAD, n=52), and also in three control groups (early stable KTRs (ES, n=28), end stage renal dis. reduced (ESRD, n=45), and healthy control (HC, n=26)).

Results: The percentage of Th17 cells out of CD4+ T cells and the proportion of IL-17 producing cells out of effector memory T cells showed a significant increase in the CAD group compared to the LTS group and other control groups (P = 0.06). In addition, The percentage of CCR4+CCR6+CD4+ T cells and IL-17 producing cells out of CCR4+CCR6+CD4+ T cells was higher in the CAD group than in the LTS group (P=0.05). However, the percentage of Th1, Th2, and regulatory T cells did not differ significantly between the CAD and LTS groups (P > 0.05). Also, the serum level of IL-17, IL-33, and RAGE, and the expression of IL-1beta, RAGE, and HMGB1 mRNA showed an increase in the CAD group compared to the LTS group. Lastly, IL-17 induced acute and chronic injury in the human proximal renal tubular epithelial cell line in a dose-dependent manner.

Conclusions: In conclusion, we found the activation of the Th17 cell pathway in patients with chronic allograft dysfunction. The results of this study suggest that Th17 pathway may have a role in the progression of chronic allograft injury.

Quantitative Characterization of T Cell Repertoires in Kidney Transplant Patients

Patients: Hussein Alachak,1 Martin B. Mutonga,1 Taigo Kato,1 Sowjanya Kalluri,1 Vikas Vujinjii,2 Yusuke Nakamura,2 Nada Alachkar,2 University of Chicago; 2Johns Hopkins Univ; 2Kendall Medical Center.

Background: Acute and chronic T cell mediated rejection remains a major cause of kidney graft failure. Despite the significant decrease in early acute rejection due to current potent immunosuppressions, long-term graft survival remains unsatisfactory. Thus, characterization of the T cell repertoire and the kinetic of the expanded clones in transplant (Tx) patients may shed a light on our understanding of the T cells’ role in graft rejection.

Methods: We collected blood and urine samples from (46) patients before Tx, and at sequential time points post Tx and at time of T cell mediated rejection. We utilized next generation sequencing approach to characterize T cell receptor (TCR) repertoire. Sequencing using the illumina miSeq was performed on DNA synthesized from RNA extracted from patients’ samples. This approach enables to track each expanded TCR clone in the graft at 3 months post Tx, back to their first appearance in blood and urine samples obtained pre or 1 month post Tx. We also measured the RNA expression levels of CD8, CD4, FOXP3, Granzyme and Perforin in blood samples (N=43).

Results: Only patients with acute T cell mediated rejection (n=2) had TCR repertoires defined by the top 10 TCR clones appeared at any time point in blood, showed significant expansion in blood at 3 month post Tx compared with that at 1 month post Tx (P<0.01 and 0.02). CD8, FOXP3, Granzyme and perforin RNA levels were significantly higher in samples obtained from patients with rejection compared to that in patients with no rejection (P<0.02).

Fig 4: Pattern of changes in TCR frequencies in blood of kidney transplant patients.

Conclusions: Our study provides valuable comprehensive longitudinal analyses that define the kinetics of each TCR beta clone, and the changes in diversity of CD3. This approach allows for identification of the expanded T cell clones that are possibly associated with graft rejection.

SA-PO971

Critical Appraisal of the New Banff Criteria for Chronic Antibody-Mediated Rejection in the Real Life Setting

Isabelle Houde, Isabelle Côté, Molsen Agharazii, Sacha A. De Serres. Renal Div, Queen’s Univ Health Centre; Laval Univ, Quebec City, QC, Canada.

Background: Significant changes in the criteria for chronic active antibody-mediated rejection (CAABMR) were made at the 2013 meeting, which is of major concern for clinical management. Here we compared the 2007 vs. 2013 criteria with regards to clinical outcomes.

Methods: Single-center, observational retrospective study of all patients who received an indication biopsy between January 2006 and October 2014, during which EM evaluation, ptc scoring and C4d scoring by IH and IF was routinely performed. Patients were included if they met criterion 1 for CAABMR: score ≥1/0, cgib=0 or severe peritubular capillary basement membrane multilayering. GN, immune deposits, HC+ status or suspicion of TTP-HUS were excluded. The endpoint was a composite of doubling of serum creatinine and death-censored graft loss.

Results: 123 patients were included. 18% met the full 2007 criteria, whereas an additional 18% fulfilled the full 2013 criteria. Only 25% of patients met the 2007 criterion #2-C4d, in contrast to 82% for the 2013 criterion #2-microvascular injury (MVI): 67% vs. C4d-positive and 55% were g’p’tc positive, with substantial overlap. 45 patients experienced the endpoint at a median of 22mo post-biopsy. Overall, only a 2013 diagnosis of CAABMR was associated with the endpoint (adjusted HR=2.5 [1.2-5.2] for 2013 vs. HR=1.6 [0.7-3.8] for 2007 diagnosis). Adjusted Cox modelling revealed that the 2013 criterion #2-MVI was more strongly associated with the endpoint than the 2007 criterion #2-C4d (HR=4.0 [1.1-14.1] vs. HR=2.2 [1.03-5.3]). When the 2013 criterion #2 was dissected by component, the C4d-component was significant (HR=2.5 [1.1-5.4]), but not the g’p’tc (HR=1.2 [0.5-2.3]).

Conclusions: Compared to the 2007 criteria, applying the 2013 criteria here doubled the proportion of patients with CAABMR. Importantly, it improved the association with clinical outcomes.

Tissue Expression of Aquaporine 2 Is Correlated to Urine Output and Allograft Function in Sensitized Kidney Transplant Patients

Luis Eduardo Becker,1 Martin G. Zeier,1 Christian Morath.2 1Nephrology, Univ of Heidelberg, Germany; 2Pathology, Univ of Heidelberg, Germany.

Background: Salt and water disturbances often occur during acute kidney allograft dysfunction contributing to graft failure, but this condition has still been poorly investigated in the setting of alloreactivity. We evaluated the tissue expression of aquaporins (AQPI, AQP2) and of the epithelial sodium channel (ENAC) in kidney allograft biopsies from transplant patients with high immunological risk.

Methods: Eighty-six kidney transplant biopsies from thirty-three sensitized patients were divided into three groups according to the clinical context a possible pathological correlates as follows: time-zero biopsy (ENAC and ENA I) in the setting of acute rejection (P<0.02). Our findings can partially confirm previous experimental data showing downregulation of AQP1 expression after ischemia-reperfusion injury and during rejection. AQP2 downregulation seems to be rejection-independent occurring during deteriorating or poor kidney graft function.

SA-PO973

The Utility of Protocol Biopsy in Renal Recipients: Meta Analysis and Systematic Review

Background: To evaluate the value of protocol biopsy in patients after renal transplantation.

Methods: Searches were applied to the following electronic database: Medline, Embase Database, Cochrane Library. Randomized controlled trails evaluating the value of protocol biopsy for renal allograft recipients were included. Data were extracted independently by two reviewer. The risk of bias of included studies was assessed by the Cochrane collaboration’s tool for assessing risk of bias.

Results: 5 RCTs were included. Long term graft loss was significantly reduced (RR 0.40; 95% CI 0.25 to 0.65, P<0.001) (figure 1) by protocol biopsy after renal transplantation.

Protocol biopsy may reduce the long term serum creatinine (WMD 38.21, 95% CI 54.83 to 21.60, P<0.00001). For renal recipients whose basal immunosuppression is CNI (tacrolimus or cyclosporine), protocol biopsy can significantly improve the long term eGFR (SM 0.78, 95% CI 0.51 to 1.05, P<0.00001). However, for those whose basal immunosuppression is tacrolimus, this effect is not notable. Protocol biopsy seems to have no significant beneficial effect of reducing clinical acute rejection episodes.

Conclusions: Treatment of subclinical rejection detected by protocol biopsy can significantly improve the graft survival and may improve the allograft function.

SA-PO974

Longitudinal Biopsy Findings Among Children, Adolescents, and Young Adult Renal Transplant Recipients from a Southeastern USA Cohort

Jonathan Alexander Miles,1 Panupong Hunvijit,1 Katherine D. Wendtreich,1 Evan Zeitler,1 Randal K. Detwiler,1 Maria E. Ferris.1 1East Carolina Univ, Greenville, NC; 2Chulalongkorn Univ, Bangkok, Thailand; 3UNC at Chapel Hill, Chapel Hill, NC.

Background: Longitudinal procedure history in children, adolescent, and young adult renal transplant recipients needs to be characterized based on their primary cause of end-stage renal disease (ESRD). It is known that pediatric patients are a high risk group for transplant failure. Elucidating potential factors for transplant failure in this group is important for protecting valuable transplants and limiting their use.

Methods: Clinical, demographic and pathological records of patients who received a renal transplant at age ≤30 years of age and who underwent transplant biopsies between 2000 and 2014 at the UNC Hospitals were analyzed. This cohort was classified based on

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

857A
the primary cause of ESRD as either glomerular or non-glomerular. Demographics, number of biopsies (total and adjusted for graft years), and transplant failure (rates and cause) were compared between the two groups.

Results: We enrolled 179 patients; 105 (58.7%) were male; 67 (38%) African American, 92 (51%) Caucasian, and 20 (11%) other race. Their mean age at transplant was 18.7 ± 8.2 years and 98 (55%) had a glomerular cause of ESRD. This cohort underwent a total of 505 graft biopsies. Comparing patients with glomerular vs. non-glomerular conditions, we found no statistical differences in renal biopsy findings regarding number of biopsies and biopsies per year for failed transplants (p=0.702), current functioning grafts (p=0.090); mean number of biopsies (3.0 ± 1.9) was higher in the glomerular group, but not significant (p=0.430); mean number of biopsies per year for failed transplants (p<0.001), current functioning grafts (p=0.090); time to a failed transplant (p=0.476); or age at time of transplant (p=0.136).

Conclusions: In this single institution cohort of children, adolescents and young adults, we found no statistical differences in renal biopsy findings regarding number of biopsies and transplant failure. This high risk age group shows no different longitudinal graft survival based on primary cause of ESRD. More analysis will follow.

SA-PO975

Prospective Study of Risk Factors and Impact of Subclinical Rejection (SCR) and Acute Clinical Rejection (ACR) in Renal Transplant Recipients Rajil B. Mehta,1 Puneet Sood,1 Arvind Cherukuri,2 Shan Shan Chen,2 Chethan M. Putterajappa,1 Christine Wu,1 Nirav A. Shah,1 Parmjeet S. Randhawa,2 Sundaram Harirhan,1 1Starzl Transplantation Inst, Univ of Pittsburgh Medical Center, Pittsburgh, PA; 2Dept of Pathology, Univ of Pittsburgh Medical Center, Pittsburgh, PA.

Background: The long term outcomes of subclinical rejection (SCR) remain unclear. The current study evaluated the risk factors for SCR at 3 months and followed up renal function up to 1 year in pts with SCR, ACR and no rejection.

Methods: We prospectively followed 340 pts who underwent an ABO compatible kidney transplant between Jan 2013 and Sep 2014. Eight pts were excluded. All patients received induction therapy with either thymoglobulin (95%) or Basiliximab for induction, CNI/MPA for maintenance therapy and rapid steroid withdrawal by day 7. Protocol biopsies were performed 3 months post transplant. Based on this, they were divided into 4 groups. Grp 1 - pts with SCR, Grp 2 - pts with normal biopsy; Grp 3 - pts with ACR; Grp 4 - pts without biopsy. Banff classification was followed for biopsy grading. Steroids, thymoglobulin and PPP/IVIG were used as indicated for the treatment of rejection.

Histopathological Changes and Graft Survival of Long-Term Kidney Allograft in Alport Syndrome: A Single-Center Experience in Japan

Nakada 1, Izumi Yamamoto, 1 Akimitsu Kobayashi, 1 Yudo Tanno, 1 Hiroyasu Yamamoto, 1 Masayoshi Okumi, 2 Hideki Ishida, 2 Takashi Yokoo, 1 Kazunari Tanabe. 1 Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ of Medicine, Tokyo, Japan; 2 Dept of Urology, Tokyo Women’s Medical Univ, Tokyo, Japan.

Background: Patients with Alport syndrome (AS) commonly develop progressive kidney dysfunction due to a hereditary type IV collagen deficiency, which results in an abnormality in the glomerular basement membrane (GBM). Recurrent glomerulonephritis does not occur in transplanted kidneys, and the allograft survival rate in these patients is similar to that in patients with other renal diseases. Several studies have shown that the type IV collagen of the GBM originates from the recipient’s bone marrow–derived cells. Therefore, we postulated that recurrent glomerulonephritis could occur locally and should influence the long-term allograft survival. In this study, we investigated graft survival and histopathological changes in renal allograft recipients with AS, focusing particularly on whether the expression of GBM type IV collagen is altered.

Methods: We collected data on the clinical characteristics of 19 renal allograft recipients who had been diagnosed with AS. All data were obtained from a database at the Department of Urology, Tokyo Women’s Medical University. Graft survival was evaluated using the Kaplan–Meier method and compared with a control group (n = 18). We assessed the double staining of α2 and α5 using frozen specimens obtained from long-term allograft survival samples.

Results: The graft survival rate was not statistically different between patients with AS and controls (log-rank p = 0.2240). Immunoreactivity to α5 antibody in four patients exhibiting long-term allograft survival showed strong linear positivity and no GBM abnormalities. In the case of chronic active antibody-mediated rejection, the immunoreactivity to α2 antibodies increased in the mesangium and subendothelial space.

Conclusions: These results suggest that the GBM type IV collagen structure was histopathologically maintained for the long term after kidney transplantation, indicating better graft survival in patients with AS.

Funding: National Institute of Health (NIH)

Allograft in Alport Syndrome: A Single-Center Experience in Japan

Yasuyuki Nakada, 1 Izumi Yamamoto, 1 Akimitsu Kobayashi, 1 Yudo Tanno, 1 Hiroyasu Yamamoto, 1 Masayoshi Okumi, 2 Hideki Ishida, 2 Takashi Yokoo, 1 Kazunari Tanabe. 1 Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ of Medicine, Tokyo, Japan; 2 Dept of Urology, Tokyo Women’s Medical Univ, Tokyo, Japan.

Background: Acute Tubular Necrosis (ATN) is a common cause of Delayed Graft Function (DGF) after renal transplantation (RTX). Currently no histological model is available to predict renal outcome. Recovery of ATN is the result of the balance between regeneration and repair. In this study we evaluated the predictive value of immunohistochemical parameters of renal damage and regeneration and compared these to an accepted clinical prediction model for cadaveric renal transplantation.

Methods: We included 25 patients that underwent cadaveric RTX with DGF caused by ATN only, as shown in a renal biopsy 1 week after RTX. Biopsies were evaluated for histological tubular damage (atrophy, edema, casts, vacuolization), DNA damage (γH2AX staining) and apoptosis (cC3 staining). Regeneration was assessed by staining for stem cell marker CD133 and proliferation marker Ki67. Clinical parameters for renal outcome were collected as previously described in the Deceased Donor Score (DDS). The relation between these parameters and renal outcome, defined as eGFR at 6 months, was assessed using regression or one-way ANOVA. A correct analysis for regenerative markers was performed to eliminate potential confounding by the amount of renal damage.

Results: The histological damage score significantly predicted renal outcome (R=-0.52 P=0.01), whereas the DDS only tended to correlate with renal outcome (F:3.12 P: R=0.05). Neither staining for DNA damage, nor for apoptosis could predict renal outcome (R=-0.24 P=0.91 and R=-0.16 P=0.44 respectively). In addition, the investigated parameters for regeneration (CD133 and Ki67) did not predict renal outcome (R=-0.25 P=0.23 and R=-0.10 P=0.63 respectively), also not after correction for renal damage.

Conclusions: We are the first to show that histological parameters can predict renal outcome of post transplantation ATN. Importantly, our histological damage score correlated better with renal outcome than the DDS. Despite the crucial role of regeneration in recovery after ATN, no relation was found between stem cell marker CD133, proliferation marker Ki67 and renal outcome.

SA-PO978
Histological Assessments from Kidney Transplant Biopsies: An Explorative Post Hoc Analysis of ZEUS 5 Year Data

Background: Analysis of pathologists’ assessments and histological data allow for deeper insight on patient outcome when combined with investigators final clinical diagnoses. Here we present 5 year data from de novo kidney transplant (KTx) recipients after conversion to an everolimus(EVR) based regimen and withdrawal of CNI therapy vs. continued CNI regimen.

Methods: Post hoc analysis of histological and pathologists’ assessments from ZEUS, a prospective, open-label, controlled, multi-center study. At mo 4.5 post Tx, 300 KTx patients (pts) were randomized to either EVR + enetic coated-mycophenolate sodium (EC-MPS, n=154) or cyclosporine (CsA) + EC-MPS (n=146). After 12mo interventional study, observational follow-up (FU) on pts safety and efficacy was performed until mo60 post Tx. As per study protocol, graft core biopsies were indicated by suspected rejection episode. Biopsies were read and interpreted by local pathologists.

Results: Total number (n) and mean n of biopsies per patient performed are overall similar in both groups until mo60. Nr of pts with at least one rejection (as per final clinical diagnosis) was slightly higher in CNI group vs EVR group. Nr of pts with BPAR was higher in the EVR group especially due to mild, early acute rejections (mostly BANFF IA and IB). Nr of pts with histological evidence of chronic sclerosing allograft nephropathy was similar in both groups (both 10%). CAD staining positivity was found slightly higher in the EVR group (11% EVR vs 7% CNI), however, pts with evidence of antibody mediated rejection was higher in the CNI group (2% EVR vs 4% CNI), same for CNI-induced toxicity lesions (16% EVR vs 23% CNI).

Conclusions: Data from histological assessments together with investigator reported final clinical pts outcome show that an EVR-based regimen with early elimination of CNI-therapy is as safe and efficacious as standard CNI-therapy offering the opportunity to reduce cumulative CNI-induced toxicities on the allograft.

SA-PO979
Endothelial Microvesicles as a Biomarker of Antibody-Mediated Endothelial Injury

Results: We have shown that W6/32 antibody binds HMEC-1 cells and activates endothelial production of endothelial microvesicles (in vitro). In vivo, we showed that antibody binding and subsequent complement activation on the production of endothelial microvesicles in vivo and to explore endothelial microvesicles in patients with suspected antibody-mediated rejection (AMR) as a potential biomarker of AMR in renal transplant recipients.

Methods: We have developed an in vitro model of AMR using immortalized human endothelial cells (HMEC-1) and a monoclonal murine antibody against human HLA class I molecules (W6/32). We analyzed antibody binding and complement deposition with immunohistochemistry and flow cytometry. Microvesicle analysis was performed using flow cytometry.

Results: We have shown that W6/32 antibody binds HMEC-1 cells and activates the classical complement pathway upon exposure to normal human serum. This leads to deposition of complement split products on the cell surface (analogous to C4d deposition in biopsies from patients with AMR) and increased release of endothelial microvesicles. Furthermore, anti-HLA antibody (W6/32), C3, and C4 were deposited on the surface of the microvesicles.

Conclusions: Our results suggest that AMR will lead to an increase in production of microvesicles by the renal endothelium, and AMR-associated microvesicles will have surface-bound IgG and C4d. We have obtained human plasma samples from renal transplant recipients with AMR and healthy controls, and we are currently examining the potential of endothelial microvesicles as a biomarker of AMR.

Dual Leukocyte/Endothelial Stain for Assessment of Endocapillary Inflammation in the Renal Allograft

Results: We hypothesized that sterile leukocyturia could reflect an increased intragraft immune activity and investigated gene expression profiles of transplant kidney biopsies of patients with sterile leukocyturia comparing to patients without leukocyturia.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: We identified 15 normal transplant kidney biopsies without leukocyturia (Group 1) and 33 biopsies with non-specific/interstitial tubular atrophy (IFTA) for gene expression profiling. Of the 33 biopsies with IFTA, 24 patients had no sterile leukocyturia (Group 2) and 9 patients had sterile leukocyturia (Group 3). Biopsies with a diagnosis of acute or chronic rejection, recurrent or de novo glomerular disease, or polycoma nephropathy were excluded. Leukocyturia was defined by the presence of sterile leukocyturia (>10^3/µl) without bacterial growth in urine culture. The urinalysis was done within 1 month before or after the biopsy. The gene expression profiles were studied by Affymetrix HuGene 1.0 ST expression arrays.

Results: There was no association in terms of age, race, and sex, type of transplant, previous history of transplantation or acute rejection, donor characteristics, panel reactive antibody levels and immunosuppressive treatment between the Groups 2 and 3. Both groups also had similar acute and chronic Banff allograft injury scores. There was no statistically significant difference in gene expression profiles between the Group 1 and 2. Where c3 and c12 showed 40.9% and 30.1% respectively. Group 3 biopsies were compared to the Group 1 and 2 biopsies, significantly increased gene transcripts associated with cytotoxic and regulatory T cells, and macrophages (P-value for significance <0.05). There was a trend towards increased interferon-gamma and rejection associated transcripts but no statistically significant difference in expression of B-cell or natural killer cell associated transcripts.

Conclusions: The biopsies of the patients with sterile leukocyturia showed increased expression of gene transcripts associated with T cells indicating heightened intra-graft immune activity. Those patients might require close monitoring of their allograft function.

SA-PO983
Elevated Glomerular Mechano-Growth Factor and Vascular Endothelial Growth Factor in Chronic Allograft Nephropathy Is Associated with Activation of Erk1/2

Yonexin Guo,1 Razaat Farag Makary,1 Carmela B. Montenegro,1 John Leighton R. James,2 Jeannie S. Chang,2 John Leighton R. James,1 1Pathology, Univ of Florida College of Medicine-Jacksonville, Jacksonville, FL, 2Nephrology, Ramon y Cajal Hospital.

Background: We previously identified increased GLUT1 glucose transporter, Mechano-Growth Factor (MFG) and Vascular Endothelial Growth Factor (VEGF) in human Chronic Allograft Nephropathy (CAN) kidneys which demonstrate glomerulosclerosis. Here we investigated a glomerular signaling pathway, Erk1/2, with potential to mediate effects of MFG and VEGF on extracellular matrix (ECM) genes. We employed IHC with specific antibodies to assess protein expression for MGF, VEGF and phospho-Erk1/2 (active Erk1/2) in human CAN kidneys vs Normal Control kidneys.

Methods: This study involving examination of archived renal biopsy samples was approved by the Institutional IRB. N = 6 for each group of renal transplant - and native kidney specimens. Immunolabeling of human CAN and Normal Control paraffin-embedded kidney sections was performed for assessment of selected proteins with specific antibodies, by use of immunoperoxidase staining. Scoring of glomerular immunolabeling for individual proteins was 0 – 4+ and was standardized. Data was normalized to open glomerular tuft area. P < 0.05 was considered significant in statistical analysis.

Results: Glomerular MGF protein was increased 3.9-fold in CAN kidneys vs Normal Control kidneys, P < 0.001. Glomerular VEGF was elevated 3.0-fold in CAN vs Normal Control kidneys, P < 0.001. Both of these growth factors have potential to signal via Erk1/2 to ECM expression. Glomerular Erk1/2 activation (i.e. phospho – Erk1/2) was examined and found to be increased 4.3-fold in CAN vs Control, P < 0.0001.

Conclusions: Human CAN, characterized by excessive glomerular MGF and VEGF expression, involved enhanced activation of Erk1/2 in the glomeruli. This provides a mechanism by which these glucose-responsive growth factors may induce glomerular ECM production and glomerulosclerosis. Therefore, MGF and VEGF activation of Erk1/2 may contribute to progressive glomerulosclerosis and renal failure in CAN.

Microarray Analysis of Interstitial Fibrosis/Tubular Atrophy in Kidney Transplant Recipients Using Formalin-Fixed, Paraffin-Embedded Renal Biopsy Tissue

Sanjeev Akkinna,1 Vishal K. Varma,1 Michael J. Walsh,1 Suman Setty,2 Medicine/Nephrology, Univ of Illinois at Chicago, Chicago, IL, 1Pathology, Univ of Illinois at Chicago, Chicago, IL.

Background: Interstitial fibrosis/tubular atrophy (IFTA) is a common and complex cause of diminution in renal function after kidney transplantation. Early identification of progressive IFTA (pIFTA) may lead to alternative therapies that may attenuate irreversible injury. In this study, we used formalin-fixed, paraffin-embedded (FFPE) renal biopsy specimens with microarrays to conduct differential gene expression studies to identify predictors of IFTA in kidney transplant recipients.

Methods: We identified 22 individuals with multiple protocol biopsies within the first 3 years after transplant. Glomeruli and blood vessels were removed using laser capture microdissection and the remaining tissue was used for mRNA extraction. Affymetrix Expression Arrays were used following standardized protocols. IFTA was defined by histological image masking in Histolab to quantify the cortical interstitial fraction. pIFTA was defined as a 0.5% absolute increase in the interstitial fraction per month between serial biopsies. Data analysis was conducted using R 3.0.2 and Bioconductor 2.22. Significance was defined as an unadjusted p < 0.05.

Results: Of the 22 subjects in this study, 9 had pIFTA while the remaining 13 were considered stable IFTA (sIFTA). At baseline, the eGFR was 60.5 ± 58.5 mL/min/1.73m² (p = 0.79) and log(Urine Albumin) was 3.44 vs. 3.17 (p = 0.72) for the sIFTA and pIFTA groups, respectively. The baseline fibrosis was higher in the sIFTA group (18%) compared to the pIFTA group (13%; p = 0.04). Using linear modeling, 3 of the 10 differentially expressed genes were clustered at baseline with the differential expression of multiple genes prior to phenotypic changes. Prospective investigation of these genes is needed to determine if these are predictive of pIFTA.

Funding: Private Foundation Support

Pathological Analysis for Transplant Nephrectomy – 124 Consecutive Cases in a Single Center Study Over 10 Years

Masaki Muramatsu,1 2Abigail Lee,1 Atsushi Aikawa,2 Carmelo Pulliatti,1 Muhammad M. Yaqoob,1 Michael Sheaff. 1Nephrology, Transplantation and Cellular Pathology, The Royal London Hospital, London, United Kingdom; 2Nephrology, Toho Univ Faculty of Medicine, Tokyo, Japan.

Background: Transplant nephrectomy (TNx) is performed for several indications. This study evaluates in depth histological analysis of TNx specimen.

Methods: We identified all cases at the Royal London Hospital between 2004 and 2014. The indication for TNx was divided into four groups: 47 cases with acute graft loss without significant blood flow (AGL), 44 cases of suspected ongoing rejection or graft intolerance syndrome (Rej/GIS); 24 cases with infection (INF); and 9 miscellaneous reasons (MIS). We examined the histological changes in detail and specifically looked at the artery, vein and ureter.

Results: AGL was less likely to have tubulointerstitial changes, but 74.5% had necrosis. In the AGL group, the majority of cases scored zero for t, i, c1 and c2. Neutrophil rich arteritis at renal and small arteries was observed in 29.8% and 19.2%. Venous thrombosis was found in 63.7%. All cases in the Rej/GIS group showed c3 and c12 and 40.9% showed t3 and c3. Glomerulitis was observed in 52.3% and eg was detected in 75.1%. Arteritis of small and renal arteries was detected in 70.5% and 59.1%. C4d expression was present in 54.1%. Nearly 70% showed ureteric inflammation. Variable cellular infiltrate comprising monocytes, plasma cells and eosinophil were seen in all cases. In the INF group, 66.7% (t1-3) and 79.2% (i1-3) were observed, and c3 and c13 were detected in 66.7%. Glomerulitis was rare although allograft nephropathy was detected in 62.5%. All cases had intimal thickening of small and renal arteries but arteritis was unusual. Lymphocyte and plasma cell were common at interstitium and 73% of all plasma cell, neutrophil and eosinophil rarely appeared at vascular lesions. In the MIS group, histological changes were minor, t13, i1-3, arteritis and venuitis were not detected.

Conclusions: The histological changes were similar and specific within the TNx groups but different between the groups. A failed graft often showed substantial immunological response. In depth histological analysis may aid management of subsequent grafts.

SA-PO986
MIrnAs as Novel Biomarkers for Transplanted Patient's Evolution

Esperanza Macarena Rodríguez serrano,1 Cristina Galeano,1 Edurne Ramos,1 Elisa Conde,1 Laura Martín-Gómez,1 Sara Gimenez-Moyano,1 Maria Laura García-Bermejo,1 Fernando Liano.1 1Biomarkers and Therapeutic Targets Unit, IRYCIS; 2Nephrology, Ramon y Cajal Hospital.

Background: Transplanted patients evolution and outcome is dependent on many factors including allograft function, vascular homeostasis and immunogenicity. Up to this moment, apart from creatinine renal biopsy, there are no quantitative and accurate biomarkers to predict the evolution of the allograft and the receptor, that would enable clinicians to improve the transplanted patient’s management. Our group has validated a combination of serum miRNAs as accurate biomarkers for AKI from ischemic aetiology, including: miR-127, miR-101, miR-210, miR-146a, miR-26b, miR-29a, miR-10a, miR-93 and miR-27a. Here we have determined the expression of these miRNA in serum from kidney donors and recipients and correlate this expression with clinical parameters of allograft evolution, including ATN development, delayed graft function, rejection and vascular complications.

Methods: For this purpose, serum sample from brain death donors and receptors along post-transplantation period (6h, 1, 2, 3, 4, 5, 6 and 7days and 1,3, 6 months) in 30 transplanted patients form our Hospital. After RNA extraction from serum, the combination of miRNAs has been determined by qRT-PCR and correlation with clinical data has been established using SPSS.

Results: The expression of these 10 miRNAs in serum samples from donors did not exhibit significant differences among them. This combination neither correlate with immediate delay graft function because NTA or immunological rejection. However, some of the miRNAs correlate with long term evolution of transplanted patients in terms of non-rejection and graft function and they also discriminate patients with also exhibited renal vascular alterations.

Conclusions: In summary we have identified miRNAs that correlates with long term evolution of transplanted patients. These information could be useful for improve transplant care that is different in the context of personalized patient handling.

Plasma MicroRNA 17 Host Gene Protein Level Cluster and Tumor Necrosis Factor-Alpha (TNF-α) in Patients with Renal Transplantation: Relation to Allograft Function and Survival
Hayam A. El Aaggan,1 Sahab Abdel Hady Mahmoud,2 Mohamed Mohamed Saker.1 Internal Medicine, Faculty of Medicine, Alexandria, Egypt; Medical Biochemistry, Alexandria, Egypt.

**Background:** Chronic allograft dysfunction (CAD) remains the leading cause of late graft loss after kidney transplantation. MicroRNAs (miRs) are small (19-25 nucleotides) noncoding RNAs that regulate gene expression of diverse biological processes. The polycistronic miR-17-92 cluster is comprised of six miRs and its primary transcript may also encode for a polypeptide of 70 amino acids designated as the miR-17 host gene (MIR17HG) protein. So the aim of this work was to evaluate the plasma levels of MIR17HG protein and TNF-α levels in patients with renal transplantation in relation to allograft function and survival.

**Methods:** This study included 45 subjects; they were divided into three groups each 15, renal transplant patients with stable renal function (Group I), with CAD (Group II) and healthy subjects as controls (Group III). Quantitative determination of plasma levels of MIR17HG protein and TNF-α were performed using enzyme linked immunosassay (ELISA). Blood urea, serum creatinine and estimated glomerular filtration rate (eGFR), urinary albumin/urinary creatinine ratio and C-reactive protein (CRP) were done. Resistive index (RI) was calculated. Renal biopsy was done in patients with CAD.

**Results:** MIR17HG protein and TNF-α levels were significantly higher in renal transplant especially patients with CAD than the controls. In patients with renal transplantation TNF-α level were positively correlated with each other and with serum creatinine, urinary albumin/creatinine ratio and CRP and was negatively correlated with eGFR. The degree of fibrosis in renal biopsy was positively correlated with MIR17HG protein, TNF-α and resistive index (P<0.05).

**Conclusions:** MIR17HG protein and TNF-α plasma levels can be served as circulating biomarkers for early detection of renal allograft dysfunction and follow up of patients with renal transplantation. They can act as a pro-fibrotic factor and denoting ongoing inflammation in the pathogenesis of CAD.

**Polymorphisms of IL17 and CXCL9 Genes, but Not AIF1 Gene, Affect Early Kidney Allograft Function After Transplantation**
Leszek Domanski, Karolina Kłoda, Ewa Kwiatkowska, Kazimierz Ciechanowski. Clinical Dept of Nephrology, Transplantology and Internal Medicine, Pomeranian Medical Univ in Szczecin, Szczecin, Poland.

**Background:** Kidney transplantation outcome is determined by immunological and non-immunological factors, both the donor and the recipient dependent. There are reports suggesting that AIF1, IL17 and CXCL9 genes polymorphisms might influence the post-transplant immune response, and thus kidney function. Therefore the aim of this study was analysis of association between 8 AIF1, IL17 and CXCL9 genes polymorphisms and creatinine concentrations up to 1 year after transplantation.

**Methods:** The study enrolled 269 Caucasian renal transplant recipients (165 males, 104 females, mean age 47.63 ± 12.96 years). Blood samples were collected for genetic analysis and creatinine concentrations evaluation 1, 3, 6, and 12 months after kidney transplantation. The analysis regarded rs2269475, rs2373162 and rs2259571 within AIF1 gene, rs2275913 within IL17 gene, rs2397084, rs1146553 and rs763780 within IL17F gene and rs7137326 within CXCL9 gene. Genotyping was performed using RT-PCR and PCR-RFLP methods.

**Results:** Creatinine concentrations 1, 3, 6 and 12 months after transplantation differed between the rs2275913 within IL17A gene promoter polymorphism genotypes and were higher among GG homozygotes (GG vs. GA+AA; p=0.03, p=0.08, p=0.06 and p=0.03 respectively). In regard to rs2297084 IL17F gene polymorphism, creatinine concentrations differed between the genotypes 1, 2 and 6 months after transplantation and were higher among TT homozygotes (TT vs. CC p=0.02, p=0.02 and p=0.09 respectively). Creatinine concentrations 3, 6 and 12 months after transplantation differed between the rs7137326 within CXCL9 gene polymorphism genotypes and were higher among GG homozygotes (GG vs. GA+AA p=0.07, p=0.048 and p=0.02 respectively). There were no significant differences between the studied AIF1 gene polymorphisms genotypes.

**Conclusions:** Polymorphisms of IL17 and CXCL9 genes, but not AIF1 gene, affect early kidney function after transplantation. These preliminary results indicate that there is a need of genome-wide association studies scanning on genes implicated in the immune response after transplantation.

**Noninvasive Diagnostic and Predictive Value in Renal Transplant Recipients by Measurement of Urine BCA-1**
Dain Chen, Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, P.R.China.

**Background:** To investigate the relationship between early-stage renal acute rejection and the level of BCA-1 in urine, explore the diagnostic value and noninvasive monitoring on early acute rejection after transplantation by measurement of urine BCA-1.

**Methods:** 145 patients were enrolled between January 2006 and October 2009, including 49 with biopsy-proved acute rejection, 58 patients with stable renal function and no abnormal histological findings, 9 patients with biopsy-proven acute tubular necrosis (ATN), 29 patients with acute humoral rejection (AMR) and 29 patients with acute cellular rejection (ACR). We measured plasma and urine BCA-1 in 77 patients with underwent KTP. The concentration of BCA-1 was analyzed by enzyme linked immunosorbent assay (ELISA). According to allograft status, Groups are divided stable, long-term good survival, immune tolerance, acute cellular rejection (ACR), acute antibody-mediated rejection (AMR) and chronic AMR.

**Results:** Plasma BCA-1 was not significantly different between all groups according to allograft status (p>0.424). Whereas, urine ESM-1 was significantly different between groups according to allograft status (p<0.001). Urine ESM-1 was higher in both ACR and AMR as well as chronic AMR than stable status. Patients with acute AMR showed significantly higher level of urine ESM-1 compared with patients with ACR (p=0.05). Area under the curve (AUC) for differentiating acute AMR from ACR was 0.744 (p=0.01).

**Conclusions:** Urine ESM-1 may reflect endothelial injury of allograft and it could be used to differentiate the patient with acute AMR from ACR.

B Cell Attracting Chemokine 1 in Urine Is a Biomarker of Acute Hemural Rejection
Weshan Peng, Jianhua Chen. Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.

Background: Presently, there are no noninvasive approaches which can be directly applied to clinical diagnosis of acute rejection (AR) or distinguish type of rejection in renal transplant recipients. The aim of this study was to construct diagnostic models of biomarkers in acute rejection patients with AR or AHR in renal transplant recipients.

Methods: Concentration of nine biomarkers in urine of 81 patients with AR and 167 patients with stable renal function (No-AR) was determined by ELISA technique. Firstly, by discriminant analysis, we screened a number of biomarkers to construct the diagnostic models for AR and AHR. Secondly, another 102 patients with No-AR and AR patients were analysed to test the accuracy of the diagnostic model.

Results: Four biomarkers were selected to set up the diagnostic model of AR or No-AR. Based on the model of AR, 84.3% patients were correctly diagnosed. Two biomarkers were selected to set up the diagnostic model of AHR. Based on the two model of AR, 100% patients with No-AR and 96.3% patients with AR were correctly diagnosed. Only B cell attracting chemokine 1 (BCA-1) was selected for the diagnostic model for AHR or acute cellular rejection (ACR). Rejection type of 81.5% patients with AR were correctly classified. Another 102 patients tested the accuracy of the diagnostic models. Diagnostic accuracy of AR or No-AR and AHR or ACR were 100% and 95.4% respectively.

Conclusions: Urinary BCA-1 was a valuable biomarker for determining AHR. These diagnostic models might directly identify AR and types of AR.

*FDG-PET/CT Imaging in Suspected Acute Renal Allograft Rejection
Pierre Lavinsky,1 Laurent E. Wekkers,1 Catherine Bonvoisin,1 Christophe Boy,2 Jean-Marie H. Krzesinski,1 Roland Hustin,2 Francois Jouret.1 1Nephrology, Univ of Liege Hospital, Liege, Belgium; 2Nuclear Medicine, Univ of Liege Hospital, Liege, Belgium.

Background: The diagnosis procedure for kidney transplant recipients (KTR) with suspected acute rejection (AR) relies on needle biopsy. Still, noninvasive tests to predict nonrejection would be useful to save selected patients from undergoing inessential biopsy. AR is associated with a recruitment of activated leucocytes to the transplant, which are characterized by a high metabolic activity and an increased uptake of glucose analog, 18F-fluoro-deoxy-glucose (*FDG). Thus, *FDG-PET-positron emission tomography coupled with computed tomography (PET/CT) may help noninvasively distinguish nonrejection from AR.

Methods: From January 2013 to February 2015, we prospectively performed 32 *FDG-PET/CT in 31 adult KTR with suspected AR who underwent a biopsy. Biopsies were categorized as "normal", "borderline", "AR" or "others" according to Banff classification. PET/CT imaging was performed within 20 ± 18 minutes after i.v. administration of 3.2 ± 0.2 MBq/kg of *FDG, before any modification of immunosuppression. The mean standard uptake values (SUV) of both upper and lower renal poles were measured, with no threshold activity.

Results: Biopsies were diagnosed as "normal", "borderline", "AR" or "others" in 8, 10, 8 and 6 (including 3 polyoma-BK nephropathies) cases. AR was antibody-mediated in 1 case, whereas Type I, II and III cellular AR were found in 5, 1 and 1 cases, respectively. Mean SUV reached 1.5 ± 0.3, 2.9 ± 0.8, 2.2 ± 1.2 in each category. Mean SUV of biopsy-proven AR was significantly higher than "normal" cases (p<0.01). No difference was found between "normal" vs. "borderline", or between "AR" vs. "others" histopathology. Still, a positive correlation between mean SUV and acute composite (g1+ v1+t+p1) score of AR was found with a coefficient of 0.70 (p<0.001). Sensitivity and specificity of *FDG-PET/CT in detecting pathological biopsies were respectively 92.3 and 36.8, with a mean SUV threshold at 1.4.

Conclusions: *FDG-PET/CT imaging may help discriminate nonrejection, thereby avoiding unnecessary transplant biopsy in KTR with suspected AR.

High Renmant-Like Particle-Cholesterol Is A Risk Factor of Worsening Graft Function in Japanese Kidney Transplant Recipients
Makoto Tsujita, Transplant Surgery, Nagoya Daini Red Cross Hospital, Japan.

Background: Many factors cause dyslipidemia after kidney transplantation. Low density lipoprotein cholesterol (LDL-C) has been focused to reduce cardiovascular disease(CVD), but residual risk factors such as triglyceride(TG), remnants or small dense LDL-C are also important to reduce CVD. We investigated whether residual risk factors affected graft function in kidney transplant recipients.

Methods: This study is a retrospective cohort study at a single center. Three hundred and seventy seven kidney transplant recipients (male 223) in more than 6 months after transplantation were enrolled. TG, Remnant-like particle-cholesterol (RLP-C), non-high density lipoprotein cholesterol(HDL-C), LDL-C/apoB, eGFR(estimated glomerular filtration rate), Urine protein/day (UP), Body Mass Index (BMI) and other parameters at baseline were measured and we studied the association of residual risk factors with kidney fuction. DeGFR meant the difference between eGFR at baseline and eGFR 1year after transplantation (eGFR 1y). Data are shown as mean ± SD or median (interquartile).

Results: Patients’ characteristics of this study is showed below.

SA-PO995
The Modification of Erythrocyte Membrane Fatty Acid Contents According to Kidney Transplantation: Prospective Study
Young Ki Son,1 Sung Hyun Son,2 Dongyeol Lee,1 Hansae Kim,1 Eu Geon Jeong,1 Su Mi Lee,1 Yun Jung Oh,1 Won Suk An,1 Seong Eun Kim,1,2 1Dept of Internal Medicine, Dong-A Univ Hospital, Busan, Republic of Korea; 2Dept of Internal Medicine, BHS Han Seo Hospital, Busan, Republic of Korea; 3Dept of Internal Medicine, Bong Seng Memorial Hospital, Busan, Republic of Korea; 4Dept of Internal Medicine, Cheju Halla General Hospital, Cheju, Republic of Korea.

Background: Modifications of erythrocyte membrane fatty acid (FA) contents may affect on cellular function or transmembrane receptors. The high erythrocyte membrane oleic acid contents are related with acute coronary syndrome. It is known that transplanted recipients have lower cardiovascular event than dialysis patients. Therefore, we prospectively evaluated whether erythrocyte membrane FA contents were modified after kidney transplantation (KTP).

Methods: We recruited 22 kidney transplanted recipients from September 2011 through May 2014. Blood samples were obtained just before KTP and at 6 months after KTP. The Modification of Erythrocyte Membrane Fatty Acid Contents According to Kidney Transplantation: Prospective Study Young Ki Son,1 Sung Hyun Son,2 Dongyeol Lee,1 Hansae Kim,1 Eu Geon Jeong,1 Su Mi Lee,1 Yun Jung Oh,1 Won Suk An,1 Seong Eun Kim,1,2

Conclusions: High RLP-C is a risk factor of worsening graft function in Japanese kidney transplant recipients.

Diffusion Impairment Measured by Functional MRI Correlates with Allograft Fibrosis After Kidney Transplantation in Patients with Delayed Graft Function

Jan H. Bresen1, Abdelaразаг Ahmad Khalifa1, Faikah Gueler1, Frank Lehner1, Wilfried Gwinner2, Dagmar Hartung1, Hermann G. Haller1, Katja Hueper1, Inst for Pathology, Hannover Medical School, Hannover, Germany; 2Inst for Diagnostic and Interventional Radiology, Hannover Medical School, Hannover, Germany; 3Clinic for General, Abdominal and Transplant Surgery, Hannover Medical School, Hannover, Germany.

Background: Functional MRI parameters derived from diffusion weighted (DWI) and diffusion tensor imaging (DTI) correlate with renal fibrosis and cell infiltration in experimental studies. Aim of this study was to investigate these non-invasive techniques in patients with delayed graft function (DGF) and to correlate diffusion parameters with renal function and renal histology of allograft biopsies.

Methods: 33 patients with initial graft function between day 4 and 11 after kidney transplantation and 31 patients with DGF were examined on a 1.5 Tesla MRI. DTI and DWI sequences were acquired and apparent diffusion coefficient (ADC) and fractional anisotropy (FA) were calculated. Kidney biopsies were available in 26 patients and analysed for acute rejection (Banff), amount of fibrosis, inflammatory infiltrates, and tubular injury as well as edema.

Results: ADC was significantly reduced in patients with DGF compared to patients with initial function. Similarly, FA positively correlated with renal function (r=0.573 and r=0.53, p<0.001) and negatively with the amount of renal fibrosis. Diffusion parameters in DGF patients did not discriminate between acute rejection and tubular injury. Histological evaluation of the allograft biopsies did not reveal any significant differences between DGF or initial function in the following parameters: leukocyte infiltration (CD4, CD8, CD15, CD20, CD68), CD31 positive peritubular capillaries or edema (intertubular distance).

Conclusions: Functional MRI with diffusion techniques detects allograft dysfunction early after kidney transplantation correlating with allograft fibrosis. Biopsy is needed to verify rejection.

Identification of Common Biological Mechanisms of Fibrosis in Transplanted and Native Kidneys with Chronic Diseases

Konrad S. Famulski, Jeffery M. Venner, Jeff Reese, Philip F. Halloran. Unv of Alberta, Edmonton, AB, Canada.

Background: In both primary kidney diseases and in transplants fibrosis is caused by chronic progressive diseases. Hence, we hypothesised that fibrosis has fundamental common biological pathways in native and transplanted kidneys.

Methods: We studied the molecular associations with fibrosis in 703 kidney transplant indication biopsies (bx) 3 days to 35 years post-transplant. The number of bx with fibrosis increased with time post-transplant and most bx with ci>1 (74%) were attributable to time-dependent diseases (ABMR, GN, TG).

Results: By microarrays we compared bx with ci<1 to those with little or no fibrosis (ci<1) and determined the association strength of transcripts (p-value) for ci>1. First we focused on transcripts previously associated with fibrosis: immunoglobulin, mast cells and AKI-associated transcripts. Strongest associations with ci>1 were for immunoglobulin and mast cell transcripts, but not for AKI transcripts. Because time of bx post-transplant is highly correlated with ci, we repeated the comparison of ci<1 vs. ci>1 after correcting for time. This resulted in a massive reduction in association strength for the immunoglobulin and mast bx transcripts (from 10e-27 to 10e-9). However, AKI transcripts were now more strongly associated with fibrosis (from 10e-9 to 10e-18). Thus time correction emphasised the injury-repair response at expense of inflammation. We then analyzed the fibrosis associated transcripts in native kidneys (CKD). 75% of CKD transcripts overlapped with our transcripts.

Funding: This study was supported by the Canadian Institutes of Health Research (CIHR) Fellowship to KSF.

DNA Double Strand Breaks Induced Collagen Type V1 Secretion of Glomerular Endothelial Cells in Renal Allografts

Yuki Matsui1, Norifumi Hayashi, Junko Imura, Keiji Fujimoto, Hiroki Adachi, Hiduki Yamaya, Hitoshi Yokoyama. Nephrology, Kanazawa Medical Univ, Uchinada, Japan.

Background: The relationship between DNA injury and glomerular fibrosis in renal allografts remains unclear.

Methods: We examined renal allograft specimens from 35 patients in which DNA double-strand breaks and glomerular fibrosis were detected by phospho-histone H2A.X (γ-H2AX) expression and collagen (COL) types III, IV, and V accumulation. We also examined the in vitro relationship between DNA damage and COL accumulation by mitomycin C (MMC)-induced DNA damage in human glomerular endothelial cells (HRGEc).

Results: The γ-H2AX and COL type V1, which mainly accumulated in the subendothelial and mesangial regions, were positively correlated with the duration of the post-replant transplant (RT) period (r=0.691, p<0.01; r=0.760 p<0.01, respectively). In multiple regression analysis, the duration of the post-RT period and cg in the Banff’07 classification were identified as significant predictors of COL type V1 accumulation (β value=0.699 p<0.001; 5.558, p=0.035, respectively) and γ-H2AX expression in the glomerular capillaries (β value 0.700 p<0.001; 2.031, p<0.01, respectively). In addition, the γ-H2AX-positive area was also identified as a predictor of glomerular accumulation of COL type V1 (β value=0.439, p=0.028). In the immunochemistry examination, γ-H2AX was detected in most cells after 24 hours’ MMC treatment, whereas γ-H2AX expression had been detected before the MMC treatment. Although COL type V1 was detected around the nuclei of the HRGEc before the MMC treatment, it was not present there after the MMC treatment. COL type V1 was detected in the cytoplasm of the HRGEc, which was secreted into the supernatant after MMC stimulation with γ-H2AX expression. The number of γ-H2AX (+) COL type V1 (+) cells was inversely associated with the number of γ-H2AX (+) COL type V1 (+) cells (r=0.655, p<0.001) during 24 hours’ MMC treatment.

Conclusions: Our findings suggested that over the long term RT may induce DNA double-strand breaks and HRGEc-secreted COL type V1 accumulation in the glomerular capillaries, which might progress to intractable glomerular fibrosis.
Factors Associated with Referral, Evaluation and Listing for Kidney Transplant: A Survey of Dialysis Patients

**Background:** Kidney transplant (KT) is the treatment of choice for most patients with end-stage renal disease (ESRD). Disparities in referral, evaluation, listing and transplantation have been documented. We studied factors associated with the likelihood of referral, evaluation and listing for KT.

**Methods:** We sent 1,283 flyers to dialysis units. Of 2,536 interested participants, 2,472 completed the survey (97.4%). We assessed associations for KT referral, listing and acceptance.

**Results:** Eighty-five percent of participants reported no euvolemia. A total of 467 participants, 401 of whom had been referred, 361 had been evaluated and 201 were listed. Having received 3 or more correct out of 6, respectively. (OR:1.44; CI:1.17mg/dl, respectively. Trough tacrolimus levels were maintained between 5 and 7ng/ml.

**Conclusions:** Early short-term low dose IM reduced renal cortical interstitial fibrosis in deceased donor KT patients. The role of long term IM in the prevention of interstitial fibrosis in renal allograft warrants further studies.

Factors Associated with Referral, Evaluation and Listing...
Kidney Transplant Referral Among Incident Georgia Dialysis Patients with and without Systemic Lupus Erythematosus: The RaDIANT Community Study
Laura Plantinga, Rachel E. Patzer, Sung S. Lim, Cristina Drenkard, Stephen O. Pastan. Emory Univ, Atlanta, GA.

Background: Although providers often wait to transplant patients with systemic lupus erythematosus (SLE), shorter overall times to transplant are generally associated with more favorable transplant outcomes in SLE patients. We examined whether referral for evaluation—the first step in the often-years-long process of kidney transplantation—is delayed in dialysis patients with SLE, relative to other dialysis patients.

Methods: United States Renal Data System data on a cohort of 18,419 incident (1/1/05-9/30/12) adult (18-69 years) dialysis patients were included. A referral was defined as provider-assigned cause of ESRD. Logistic regression and Cox proportional hazards models were used to examine the associations of assigned cause and patient characteristics with preemptive referral (referral prior to the start of dialysis) and time from start of dialysis to referral [censored for death or last date of follow-up (9/30/12)], respectively.

Results: Of the 352 dialysis patients with SLE, 43 (12.2%) were preemptively referred—50% more often than other ESRD patients [1573/18,067 (8.7%); OR=1.9 (95% CI, 1.6-2.2)] but not as often as those referred within the first 2 years of dialysis [1573/18,067 (8.7%); OR=1.1 (95% CI, 0.9-1.3)]. Among the 17,293 dialysis patients not preemptively referred, SLE patients were referred at twice the rate of other dialysis patients in crude analyses [HR=1.9 (95% CI, 1.6-2.2)] but not after adjustment for [HR=1.1 (95% CI, 0.9-1.2)]. Among SLE patients, black vs. white race was associated with lower likelihood of preemptive referral [OR=0.5 (95% CI, 0.2-1.2)] but higher rates of referral after dialysis start [HR=1.8 (95% CI, 1.1-2.9)]. Male vs. female sex was associated with higher rates of referral on dialysis [HR=1.6 (1.2-2.2)].

Conclusions: Referrals for kidney transplant evaluation do not appear to be delayed among dialysis patients with SLE, relative to other dialysis patients of similar age. Efforts to increase kidney transplant access in SLE patients should focus on potential race and sex disparities in referral as well as potential delays in other steps of the kidney transplant process.

Association of Kidney Transplantation Referral with Other Indicators of Quality Care Among Incident Georgia Dialysis Patients: The RaDIANT Community Study
Laura Plantinga, Stephen O. Pastan, Jenna Krischer, Eric M. Gibney, Laura L. Mulloy, Rachel E. Patzer. Emory Univ, Atlanta, GA; Southeastern Kidney Council, Inc., Raleigh, NC; Piedmont Transplant Inst, Atlanta, GA; Georgia Regents Univ, Augusta, GA.

Background: Dialysis facility referral rates for patients for kidney transplant is a potential indicator of quality care. We examined whether referral within a year of dialysis start (1-year referral) was associated with other quality indicators among incident Georgia dialysis patients.

Methods: We examined a cohort of 14,120 incident (7/1/05-9/30/11; follow-up through 9/30/12) adult (18-69 years) dialysis patients using United States Renal Data System data linked to concurrent referral data from all three adult Georgia kidney transplant centers. Multilevel, multivariable logistic regression was used to examine the association of 1-year referral with dichotomous quality indicators [pre-ESRD nephrology care, dialysis modality, permanent vascular access in place at dialysis start (HD patients only), pre-ESRD erythropoietin use, and transplant information at dialysis start], with adjustment for demographic and clinical variables and accounting for variation across clinics.

Results: Overall, 1-year referral was 24.8% and was higher among patients with other indicators of quality care: 26.0% vs. 23.8%, with vs. without pre-ESRD care (P=0.005); 27.8% vs. 24.6%, PD vs. HD (P=0.03); 28.3% vs. 22.9%, with vs. without a permanent vascular access in place at HD start (P=0.001); and 27.2% vs. 16.5%, informed vs. not informed of transplant options at dialysis start (P=0.001). With adjustment, pre-ESRD care [OR=1.34 (95% CI, 1.22-1.47)], permanent vascular access in place at dialysis start [OR=1.54 (95% CI, 1.41-1.70)], and transplant information at dialysis start [OR=1.63 (95% CI, 1.45-1.85)] remained associated with higher 1-year referral.

Conclusions: These findings suggest that patients who receive quality care in multiple domains are more likely to be referred for kidney transplant evaluation within a year of starting dialysis, independent of demographic and clinical characteristics. Interventions to increase transplant access should be targeted to patients whose care fails to meet other quality indicators.

Feasibility and Sustainability of the RaDIANT Community Study Among Georgia Dialysis Facilities
Jennifer C. Gandig, Leighton Sauls, Teri Browne, Laura Plantinga, Laura J. McPherson, Eric M. Gibney, Laura L. Mulloy, Stephen O. Pastan, Rachel E. Patzer. Emory Univ; Southeastern Kidney Council; Univ of South Carolina; Piedmont Hospital, Georgia Regents Univ.

Background: The Southeastern Kidney Transplant Coalition developed the randomized, dialysis facility-level Reducing Disparities In Access to kidney NeTraN (RaDIANT) Community Study to address racial disparities and low rates of kidney transplantation (KTs) in Georgia. We aimed to evaluate the feasibility and sustainability of the RaDIANT intervention activities.

Methods: The 67 dialysis facilities that completed a 12-month intervention as part of the RaDIANT study consisted of 12 recommended activities intended to increase KT referrals, such as education and outreach activities targeting the patient, facility staff, and facility policy level. After the intervention, facility staff were asked to complete a 20-item questionnaire on the helpfulness (Likert scale) of each intervention activity and the likelihood (yes/no) of their facility continuing the activity.

Results: A total of 86 staff (51.2% social workers) at the 67 intervention facilities completed the survey. The median number of the 12 intervention activities completed by dialysis facilities was 9 (range, 0-11). Most facilities reported discussing the benefits of KTs at a staff orientation (86.6%), attending monthly webinars (80.7%), and developing a referral improvement plan (76.3%) to be helpful or very helpful. The median number of prescribed intervention activities the facilities reported they would continue was 2, with the distribution of educational brochures (41.9%), a staff orientation focused on KTs (41.9%), and a patient and family education session (34.9%) among the most commonly cited.

Conclusions: Dialysis facility staff perceived that RaDIANT intervention activities were feasible to implement, with staff education potentially being the most helpful and sustainable component. Sustainability may be limited to intervention components that were the least expensive and time intensive to implement. Additional ongoing support from ESRD Networks may be necessary to sustain increased KT referrals observed in the RaDIANT Community Study.

Physiosocial Differences Between Living and Deceased Donor Renal Transplant Recipients
Anna Bertram, Selma Pabst, Martina De zwaan, Tanja Zimmermann, Mario Schiffer. 1Clinic for Psychosomatics and Psychotherapy, Hannover Medical School, Hannover; 2Nephrology and Hypertensiology, Hannover Medical School, Hannover, Germany.

Background: The specific impact of living donor (LD) as compared to deceased donor (DD) kidney transplants on psychosocial functioning has received surprisingly little attention. The present study aimed to assess whether LD and DD recipients differ in socio-demographic variables, time since transplantation, emotional variables, knowledge about immunosuppressant (IS) intake, and self-reported adherence to IS.

Methods: A questionnaire study was performed among 72 LD and 169 DD recipients who attended the kidney transplant outpatient clinic of Hannover Medical School for a follow-up visit at least 1 year after transplantation. Emotional responses were assessed using the Hospital Anxiety and Depression Scale (HADS) and the Transplant Effect Questionnaire (TEQ). Knowledge about IS intake was examined with the Transplant Patients: Prevalence, Agreement, and Correlates of Adherence. No differences between LD and DD recipients were found for gender, educational level, depression, perceived social support, and allotropic rejection. Feelings of guilt and anxiety may be an important focus for interventions to improve emotional adjustment to transplantation, especially in LD recipients.

Physician-Reported Adherence with Immunosuppressants in Renal Transplant Patients: Prevalence, Agreement, and Correlates
Anna Bertram, Selma Pabst, Martina De zwaan, Mario Schiffer. 1Clinic for Psychosomatics and Psychotherapy, Hannover Medical School, Hannover, Germany; 2Nephrology and Hypertensiology, Hannover Medical School, Hannover, Germany.

Background: Assessing adherence to immunosuppressants (IS) is difficult. We investigated (1) the prevalence of non-adherence with IS as estimated by physicians; (2) the agreement between the physicians’ estimated and other adherence measures; (3) the difference between adherent and non-adherent patients according to the physicians’ estimation with regard to socio-demographic variables, transplant-related variables, and psychological factors.

Methods: All kidney transplant patients attending the outpatient clinic for a follow-up visit from 11/2014 to 02/2015 were screened; 238 patients met inclusion criteria. Adherence with IS was assessed with several measures: 4-item Baseline Assessment of Adherence to:

The Difficult Road for Native Americans in Kidney Transplantation: Decreased Access and Reduced Long-Term Survival
Sarah Stith,1 Kristina Piorkowski,2 Fidel Barrantes.2
Economics, Univ of New Mexico, Albuquerque, NM; 1Presbyterian Transplant Center, Renal Medicine Associates, Albuquerque, NM.

Background: Native Americans (NAs) have disproportionately high rates of end-stage renal disease, yet wait listed NAs have lower rates of kidney transplantation than other racial/ethnic groups and worse long-term post-transplant survival outcomes than whites. This study evaluates these disparities across multiple medical and socioeconomic dimensions.

Methods: Using data from the Organ Procurement and Transplantation Network (OPTN), we evaluated wait list removal reasons and post-transplant survival rates from 3/1/95 to 12/31/12. We use a logistic regression model, controlling for patient, donor, match characteristics, and center and year fixed effects, along with a Blinder-Oaxaca decomposition of the results.

Results: Among registered patients removed from the wait list, NAs were less likely to receive a transplant (odds ratio, 0.71 [95% CI, 0.64-0.80]), and more likely to die on the wait list (1.88 [9.89-3.94], compared to whites. NAs are less likely than whites to survive at least two years (odds ratio, 0.80 [95% CI, 0.70-0.92]) and at least three years (0.81 [0.71-0.94]), but these disparities become statistically insignificant with risk adjustment.

Conclusions: NAs experience higher rates of adverse wait list removal reasons than other racial/ethnic groups. Among NAs who do receive transplants, short term survival outcomes are similar to those of whites, but longer term survival outcomes are lower. The decomposition of our results indicates that the disparity in three-year post-transplant survival between NA and whites is driven primarily by the prevalence of lower quality donors among NA transplants, a greater negative impact from such donor characteristics on survival among NA. NAs also tend to receive transplants at centers associated with worse outcomes and would benefit disproportionately from receiving transplants at better centers.

Estimated GFR for Living Kidney Donor Evaluation
Naya Huang,1 Meredith C. Foster,1 Krista L. Lentine,2 Amit X. Garg,1 Emilio D. Poggio,1 Bertram L. Kasiske,1 Lesley Inker,1 Andrew S. Levey.1
1Div of Nephrology, Tufts Medical Center, Boston, MA; 2Div of Nephrology, Saint Louis Univ, MO.

Background: Using data from the Organ Procurement and Transplantation Network, we compared estimated GFR (eGFR) by race from 3/1/95 to 12/31/12. We use a logistic regression model, controlling for patient, donor, match characteristics, and center and year fixed effects, along with a Blinder-Oaxaca decomposition of the results.

Results: Among registered patients removed from the wait list, NAs were less likely to receive a transplant (odds ratio, 0.71 [95% CI, 0.64-0.80]), and more likely to die on the wait list (1.88 [9.89-3.94], compared to whites. NAs are less likely than whites to survive at least two years (odds ratio, 0.80 [95% CI, 0.70-0.92]) and at least three years (0.81 [0.71-0.94]), but these disparities become statistically insignificant with risk adjustment.

Conclusions: NAs experience higher rates of adverse wait list removal reasons than other racial/ethnic groups. Among NAs who do receive transplants, short term survival outcomes are similar to those of whites, but longer term survival outcomes are lower. The decomposition of our results indicates that the disparity in three-year post-transplant survival between NA and whites is driven primarily by the prevalence of lower quality donors among NA transplants, a greater negative impact from such donor characteristics on survival among NA. NAs also tend to receive transplants at centers associated with worse outcomes and would benefit disproportionately from receiving transplants at better centers.

SA-PO1012
Change of Physical Activities in Male and Female Recipients in 12 Months After Living Kidney Donor Transplantation
Makoto Tsujita, Transplant Surgery, Nagoya Daini Red Cross Hospital, Japan.

Background: Since renal dysfunction and immunosuppressive drugs cause muscle degeneration, physical activities decrease in CKD, dialysis patients and transplant recipients. In addition, elderly kidney transplant recipients are increasing in Japan, so improving physical activities and increasing muscle strength and volumes are important to prevent fractures and fall accident.

Methods: Consecutive 58 patients (male 33) older than 40 years were enrolled in this study from 2012. Immunosuppression basically contains steroid, cyclosporine or tacrolimus, and mycophenolatefomafen or everolimus. Hypertension, hyperlipidemia, and osteoporosis were treated as needed. Parameters of physical activities such as hand grip, SMI (skeletal muscle index) and Body fat mass using by DEXA (dual-energy x ray absorptiometry) were measured.

Results: 12 months after transplant, more than 20% of male and female recipients increased their muscle strength and volumes. SMI increased by 2% and Body fat mass decreased by 3% in male recipients. In female recipients, muscle strength and volumes increased by 5% and SMI increased by 3%. Body fat mass decreased by 2%.

Conclusions: These results indicate that lifestyle modification and physical activities after transplant can improve muscle strength and volumes in recipients.

SA-PO1009
Evolution Through 20 Years of the Major Kidney Transplant Program from Living Donor in Mexico
Edgar Solis,1 Luis Alberto Evangelista-Carrillo,1 Enrique Rojas-Campos,2 Benjamin Gomez-Navarro,21 Dept of Nefrología y Trasplantes, IMSS, Guadalajara, Jalisco, Mexico; 2Unidad de Investigación Médica en Enfermedades Renales, IMSS, Guadalajara, Jalisco, Mexico.

Background: According to the National Transplant Center, in 2013 a total of 2707 kidney transplants (KT) were performed in Mexico. Our program performed the highest single center number of transplants with 270 KT, mostly from living donors.

Methods: We use data collected in our registration program at Nephrology and Transplant Unit. All the KT in adult patients performed from January 1994-December 2014 in CMNO were included. We also analyzed the last 909 kidney recipients and their serum creatinine at the end of first year. Successful KT was defined as a Cr <1.5 mg/dl at 1 year following. Grafts lost were defined as Cr >4.0 mg/dl or replacement therapy initiation.

Results: During this period 3643 KT were performed, 3236 from living donors and 407 from cadaver donor. Of living donors, 2786 were from related donor and 450 were from genetically unrelated donors. The mean age of recipient was 28 years; 65% of our recipients were male. The evolution of the program is shown.

Conclusions: Each year we are still growing the number of KT. The age of our recipients is diminishing and age of donors is increasing. Months before KT are also increasingly lately reflecting the great number of ESRD patients. Recipient age, HLA mismatching, induction therapy use and generic drugs can explain the 13.2% of patients with Cr above 1.5 mg/dl.

SA-PO1008
Success rate of KT following 1 year was 86.8%. Only female gender and younger donors were statistically significant associated with successful transplant. Graft lost during the first year was 3.6%. Death was 2.4% during the first year.

Physical activities seemed unchanged after transplantation in more patients than before.

**Conclusions:** In male recipients, physical activities do not seem to recover in 12 months after kidney transplantation. More interventions and more studies are needed to increase physical activities and know the effect of daily exercise clinically.

SA-PO1013

**Search for New Data to Predict Kidney Transplant Outcomes in the Organ Procurement and Transplantation Network Database**

**Background:** The Organ Procurement and Transplantation Network (OPTN) collects data used to monitor transplant program outcomes for quality assurance and regulatory oversight. It is imperative that the variables in the OPTN database used by the Scientific Registry of Transplant Recipients to determine expected outcomes after kidney transplant be reliable, complete, and up-to-date.

**Methods:** We conducted a systematic review to identify risk factors not included in current OPTN data that predict graft failure or mortality after kidney transplant. We searched for studies with publication date between Jan 1 2000-May 1 2015; at least 1000 subjects in one or more risk prediction models; multivariate analysis used to select variables predicting patient or graft survival; inclusion in the multivariate model of at least one risk factor collected before or at the time of transplant that is not already collected by OPTN; and English language. For duplicate publications we selected the most recent. For publications with overlapping but distinct cohorts, we selected the one with the largest cohort. We arbitrarily limited the search to studies including 1000 participants in at least one risk-prediction model. Although a small single-center study may convincingly show that a newly described risk factor predicts outcomes at that center, there are likely major barriers to measuring and collecting this risk factor uniformly at every program in the US.

**Results:** We identified 33 studies that met inclusion criteria: 6 (18%) were single-center, 4 (12%) were multicenter, and 23 (70%) were registry studies. Promising new variables included: myocardial infarction, coronary artery revascularization, atrial fibrillation, congestive heart failure, valvular heart disease, cerebral vascular accident, chronic kidney disease, renal transplant, diabetes, hyperphosphatemia. We also found that 68 patients had hypophosphatemia. Serum iPTH levels were higher in group I (58.4±14 ng/dl) versus group II (138.3±5 ng/dl; p<0.001). In group I, iPTH levels were significantly correlated with eGFR (r value=−0.37, p<0.05). Both serum ALP and iPTH levels showed significant negative correlation with eGFR in groups I and II (p<0.05). In all groups, bone minerals, iPTH and serum Alkaline Phosphatase levels had no statistically significant relation with the immunosuppressant agent used (p<0.05).

**Conclusions:** Disturbances of bone and mineral metabolism after transplantation are prevalent and are strongly correlated with the kidney function and transplantation duration.

SA-PO1014

**Prevalence of Mineral and Bone Disorders Among Living Kidney Transplant Recipients**

**Background:**Mineral and bone disorders (MBD), frequent complications of chronic kidney disease (CKD), occur frequently in kidney transplant recipients. Still, it is known about its prevalence and clinical correlates in transplanted patients. Therefore, we conducted a cross-sectional analysis of 504 stable living kidney allograft recipients. Detailed medical history, demographic data and routine laboratory investigations, including s.creatinine, s.corrected Calcium, s.Phosphorus, serum iPTH and s.Alkaline Phosphatase (ALP) were collected. Estimated GFR was calculated using the abbreviated MDRD formula. Patients were stratified into three groups based on duration of kidney transplantation. Group I: 0-6 months to 1 year, group II: from 1 to 5 years and group III: more than 5 years. Correlations were done between bone minerals and all laboratory results. We also analyzed the possible relation between various immunosuppressant drugs and bone minerals, serum iPTH and serum ALP.

**Results:** The mean age was 32±8 years in group I, 45±37 years in group II, and 40±5 years in group III, with no significant difference between the three groups (p>0.05). There was no significant difference between the studied groups as regards laboratory parameters (p>0.05). 115 patients had iPTH levels >170 ng/dl, while 365 patients (72.4%) had iPTH levels >70 ng/dl. Only 24 patients had hypercalcemia, and 34 patients had hyperphosphatemia. We also found that 68 patients had hypophosphatemia. Serum iPTH and iCa levels were higher in group I (58.4±14 ng/dl, 138.3±5 ng/dl) versus group II (138.3±5 ng/dl, 122.6±6 ng/dl) (p<0.001). In group I, iPTH levels were negatively correlated with eGFR (r value=−0.37, p<0.05). Both serum ALP and iPTH levels showed significant negative correlation with eGFR in groups I and II (p<0.05). In all groups, bone minerals, iPTH and serum Alkaline Phosphatase levels had no statistically significant relation with the immunosuppressant agent used (p>0.05).

**Conclusions:** Disturbances of bone and mineral metabolism after transplantation are prevalent and are strongly correlated with the kidney function and transplantation duration.

SA-PO1015

**Risk of Adverse Maternal and Fetal Outcomes During Pregnancy in Living Kidney Donors**

**Background:** A frequently asked question by potential kidney donors is risk of nephrectomy on maternal and fetal outcomes in pregnancy. Studies regarding the risks of living kidney donation and pregnancy outcomes are conflicting. The purpose of this study was to determine the risk of adverse maternal and fetal outcomes in donors vs. non-donors.

**Methods:** Using data from an integrated health care delivery system in Utah from 2000 through 2014, a total of 72 women were living kidney donors that became pregnant after kidney donation. Using a pool of 74,105 women who were not donors, we selected 1223 to use for matches for the living kidney donors. These women were matched 1:3 by age and race. Adverse pregnancy outcomes were defined as preterm delivery, delivery via cesarean section, preeclampsia, eclampsia, length of stay in the hospital and low birth weight (<2.5 kg). Logistic regression analysis was used to examine the association between donation and adverse outcomes.

**Results:** Of the living kidney donors, the mean (SD) age and mean (SD) gestational age at delivery was 30.9±5 years and 38.2±2 weeks, respectively. The mean (SD) length of stay in the hospital was 2.7±2.7 days. Six cases (8%) had a history of chronic hypertension. Living kidney donors did not have a higher risk of preterm delivery (OR 1.82, 95% CI 0.87-3.77), preeclampsia/eclampsia (OR 1.11, 95% CI 0.47-2.65), delivery via cesarean section (OR 1.51, 95% CI 1.05-2.16), length of stay = 3 days (OR 1.29, 95% CI 1.03-2.64) or low birth weight (OR 1.94, 95% CI 1.67-4.35) compared to non-donors.

**Conclusions:** Living kidney donation is not associated with a higher risk of adverse outcomes in pregnancy.

Disparities in Access to Renal Transplant in Puerto Rican Children

Nélida del Jesús González,1 Sonia M. Caraballo,1 Eduardo J. Santiago-Rodríguez,2,3 Marta P. Suárez-Rivera,1 Melvin A. Bonilla-Feliz.1 1Medical School, Pediatric Nephrology Div, Univ of Puerto Rico; 2Univ Central del Caribe; 3Puerto Rico Clinical and Translational Research Consortium.

Background: Disparities in access to renal transplant have been reported in racial minorities living in US. No data is available from children with ESRD living in Puerto Rico (PR). We describe the pediatric population with ESRD in PR from 2003-2013, the renal transplant rates and possible barriers to receiving a graft.

Methods: Retrospective chart review of patients diagnosed with ESRD in PR from 2003-2013. Incidence, prevalence rates, means/standard deviations (SD), medians/interquartile range (IQR), frequencies and percentages were calculated and compared to national rates.

Results: From 2003-2013 99 patients, male: 52%, age: 13.5yrs (8-16yrs), were diagnosed with ESRD. Congenital anomalies were the primary cause in 40%, and FGCS in 24%. Incidence of ESRD ranged from 3-14 subjects per million population/year, with prevalence per dialysis modality from 7-18 subjects per million population/year. 38% were transplanted in PR (Median age: 14yrs, IQR: 9-16), 23% from living donors. 14.1% received a transplant in the first year (National rate: 38%). 63% of these non-transplanted children had Medicare coverage. None of 9 infants diagnosed with ESRD were transplanted during infancy. 46% of the children who were not transplanted stayed at our unit for a median time of 2 yrs (IQR: 1-3). The rest was transferred to a dialysis unit outside PR (15%) or to an adult facility without being transplanted (39%). 67% of these non-transplanted children were covered by Medicare. The mortality rate during the first year of diagnosis was 3% (National rate: 4%).

Conclusions: Children with ESRD in PR face striking disparities in access to renal transplant. Lack of pediatric transplant surgeons, geographical isolation and minimal living donation are potential barriers. Medicare coverage does not appear to be a factor, as it was similar between transplanted and non-transplanted. Interventions to reduce these inequities are needed.

Post Donation Diabetes and Risk of Death and ESRD

Background: We have previously shown that development of diabetes following live kidney donation does not result in accelerated GFR decline when compared to diabetics with two kidneys. Herein, we report on the development of a risk calculator for new onset DM in donors and address its contribution to mortality and also renal outcomes.

Methods: Donors were followed indefinitely through surveys including development and treatment of diabetes and renal outcomes. Risk factors for post donation diabetes were determined using stepwise proportional hazards regression.

Results: Development of DM was ascertained in 3874 donors with a mean follow-up of 16.1±1.2 years. In total, 279 (7%) developed DM. Pre-donation risk factors for development include older age, BMI, tobacco use, and fasting serum glucose at donation, p<0.01 for all (Table 1a). Diabetes following donation was associated with a nearly 5 fold increase in the non-diabetic group and 36% in adherent adolescents. Only 40% of the adherent group reported elevated distress versus 57% of the non-adherent group. There was a gender bias toward male non-adherence in this group with 100% of the non-adherent population being male. The mean time from transplant of non-adherent groups was 6.1 years versus 3.9 years in the adherent group. These differences were not statistically significant except as above.

Conclusions: Our population’s rate of psychiatric diagnosis was significantly elevated compared to community norms and also correlated with elevated psychosocial distress and non-adherence. Disagreement in parent and adolescent reporting was common regardless of adherence status. Our sample did demonstrate gender differences in non-adherent behavior as well. Interpretation of these results, as well as statistical significance is limited by the small sample size.

Funding: Other NIH Support - This investigation was supported by the Utah Study Design and Biostatistics Center, with funding in part from the National Center for Research Resources and the National Center for Advancing Translational Sciences, National Institutes of Health, through Grant U01TR000105 (formerly UL1RR025764).

The Case against Declining Donors with Impaired Fasting Glucose

Robert N. Foley, Naim S. Issa, Danielle M. Berglund, Arthur J. Mitas, Hassan N. Ibrahim. Univ of Minnesota, Mpls, MN.

Background: The definition of diabetes, impaired fasting glucose (IFG) and impaired glucose tolerance (IGT) have changed over time. IGIF was defined in 1997 by fasting glucose 110-125 mg/dL and in 2003 the definition changed to fasting glucose 100-125 mg/dL. With the introduction of this new definition, many potential donors with fasting blood sugar between 100-110 mg/dL have been denied donation. This is highly relevant as many of these are potential donors to family members with type 2 diabetes mellitus.

Methods: We assessed the risk of death, new onset diabetes, hypertension, proteinuria, and reduced eGFR (<45 or <30 ml/min/1.73m2) in 3738 kidney donors according to fasting blood glucose(FBG) at the time of donation spanning the period between 1963-2013.

Results: 2900 donors had a FBG <100 mg/dL, 550 with 100-109, 205 with 110-125 and 128 donors with FBG > 126 mg/dL. Donors with FBG (100-109 mg/dL) after multivariable adjustment were more likely to die, develop diabetes, proteinuria, hypertension, eGFR <45 ml/min/1.73m2 or eGFR <30ml/min/1.73m2 as compared to those with FBG <100 mg/dL (Table 1). In contrast, those with FBG between 110-125 mg/dL were more likely to become diabetic and hypertensive but not proteinuric or reduced GFR. Those with FBG >126 mg/dL were more likely to die, develop DM and HTN but not suffer any adverse renal consequences.

Conclusions: Excluding potential donors with a fasting glucose (100-109 mg/dL) should be revisited as these donors do well in the long-term.

Funding: Other NIH Support - NIH (5P01 DK013083)
Conclusions: Diabetes can be reasonably predicted in kidney donors using baseline data. Diabetes is a significant contributor to reduced GFR and proteinuria.

Funding: Other NIH Support - NIH (5P01 DK013803)

What Kind of Obesity Does Affect Kidney Function? Survey of Kidney Transplant Donors

Mikiko Yoshikawa, Junko Nakano, Kentaro Nakai, Hideki Fujii, Shinichi Nishi. Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan.

Background: Currently obesity is a risk for chronic kidney disease. It is also suggested that sarcopenia is the independent risk factor of hypertension. It is unclear whether obesity and body composition affect to kidney function and other prognosis of donors in our country.

The aim of this study was to investigate the influence of body composition, the findings of graft biopsy and 1-year after clinical outcome.

Methods: This is a retrospective single center study of 60 living kidney transplant donors from 2009 to 2014. Donors are stratified according to Body Mass Index (BMI³25kg/m²) for appearance of muscle on cross-sectional CT images (L3 SMI, Under 38.5cm²/m² for men and 52.4cm²/m² for women are defined as a sarcopenia)(1). We divided donors into four groups; (A) Obesity negative + Sarcopenia negative (ONSN)(B) Obesity positive + Sarcopenia negative (OPSN)(C) Obesity negative + Sarcopenia positive (ONSIP)(D) Obesity positive + Sarcopenia positive (OPSP). We evaluated kidney function at donation, baseline kidney graft biopsy findings and clinical course 1 year-after donation.

Results: Seven patients were ONSP (11.7%), 22 patients ONSN (36.7%), and 4 patients OPSP (6.7%). Visceral fat area ³100 m² (which is defined as central obesity in Japanese criteria) was significantly higher in OPSP group. Sercre at donation was significantly lower in OPSP and ONSP groups. In multivariate analysis of graft biopsies, BMI³25kg/m² was a significant risk for small artery intimal thickenings and interstitial fibrosis/tubular atrophy. On the contrast, OPSP was an independent risk for global sclerosis. In multivariate analysis, central obesity was significantly correlated with 1-year after proteinuria. In addition, OPSP was an independent risk for 1-year after hypertension.

Conclusions: These results indicate obese donor already has a risk for arterial and interstitial damages at transplantation. In addition, central obesity and sarcopenia contribute to the late graft function and hypertension.[Reference] (1) Prado CM et al. Lancet Oncol 2008; 9: 629–635.

SA-PO1022

Living Donor Remaining Function Measured by CKD-EPI Correlates with Remaining Kidney Volume

Asif A. Sharifuddin, Ali Khalil, Muhammad S. Yaqub, Tim E. Taber, Muhammad Ahmad Mujtaba. Medicine/Neph, Indiana Univ.

Background: The aim of our study was to evaluate whether preserved kidney volume correlates with donor renal function at 2-years post-donation using the CKD-EPI eGFR equation.

Methods: Demographics and renal function of living donors who underwent living nephrectomy between January 2008 and November 2012 were reviewed. All donors underwent computed tomography with an estimation of kidney volumes. Preserved Kidney Volume (PKV) was adjusted (ΔPKV) to Body Surface Area.

Results: A total of 208 donors with 2 year follow up data available. Pre-donation eGFR (β Coef. 0.344), age (β Coef. -0.318) and ΔPKV (β Coef. 0.11) were found to be independent predictors of 2yr eGFR (p=0.001). ΔPKV was divided into tertiles (low/middle/high) and a 2 year eGFR of <60ml/min was chosen as a cut off for dichotomous analysis as in Table 1.

<table>

Mean aPKV (ml/min) 52±6 76±15*

Mean 2yr eGFR was 57±9; 65±16 and 73±17 between the tertile groups (p<0.05). The odds ratio of having a 2yr post-donation eGFR<60 with a cutoff of median ΔPKV of 194ml was 5.8 (95%CI 2.9-11.6; p<0.0001), while that of 2yr post-donation eGFR<60 with a cutoff of < 25th percentile of ΔPKV of 159.9 was 5.6 (95%CI 2.7-11.2; p<0.0001). The odds ratio of having an eGFR<60 if the ΔPKV was above the 75th percentile was 0.13 (95%CI 0.05-0.3) p=0.0001. ROC and AUC for ΔPKV and eGFR (CKD-EPI) of <60 were 0.763 (CI0.69-0.82) p=0.005 as in Figure 1.

Conclusions: Our study is the first to show using CKD-EPI equation that preservation of residual renal function in living donors needs to take into account remaining kidney volume, when selecting kidneys from healthy donors.

SA-PO1023

Assessing Adherence Barriers in Pediatric Kidney Transplant Recipients

Charles D. Varnell,1 Kristin Loiselle,2 Alina Lh Pai,2 Avani Modi,2 David K. Hooper.1 Div of Nephrology and Hypertension, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH; Center for Treatment Adherence and Self-Management, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Nonadherence in pediatric kidney transplant recipients(KTRs) is associated with poor outcomes and poses a significant financial cost to society. Patient and family reported barriers to taking medications predict nonadherence, rejection, graft failure, and death. Despite their clinical importance and amenability to intervention, barriers to medication adherence are not routinely assessed in pediatric settings.

Methods: From Jan 2015 - May 2015, barriers to immunosuppressant adherence in KTRs were assessed using a standardized checklist of 14 common barriers. For KTRs<10 y.o. the caregiver completed the assessment. For KTRs>10 y.o. both the patient and caregiver, if present, completed the assessment. Assessments were completed during routine outpatient clinic appointments.

Results: 36 pediatric KTRs [M(SD)age=13.14(6.43)years;56.7%male] and 50 primary caregivers completed a barriers assessment. At least one barrier was reported by 47% of KTRs compared to 42% of caregivers. For KTRs the most frequent barriers were forgetting(22%), hating the taste(13.9%) and running out of medication(8.3%). For caregivers, the most frequently endorsed barriers were forgetting(20%), side effects(6.0%) and patient refuses to take their medication(6.0%). There was excellent concordance(96.2%) in dyads where both KTR and caregiver reported barriers. Assessing for barriers to adherence was easy to perform in practice and required<60 seconds.

Conclusions: Nearly half of all patients report at least one barrier to taking their immunosuppression, and there is generally consistent agreement between patient and caregiver perception of barriers. Standardizing the approach to assessing barriers to immunosuppressant adherence in the clinical setting can quickly produce information that might be missed by the provider. Future research should evaluate the effectiveness of interventions delivered as part of routine medical care to overcome identified barriers and prevent known complications associated with nonadherence.
A Longitudinal Follow-Up of Hispanic Living Kidney Donors

Clarence E. Foster III,1 Pinky J. Patel,1 Hirohito Ichii,1 Madeleine V. Pahl,2 Elani Streja,3 Jonathan R. Lakey,4 Kamary Kalantar-Zadeh,2 1Surgery/ Div of Transplantation, Univ of California, Irvine, Orange, CA; 2Medicine/Nephrology, Univ of California, Irvine, Orange, CA.

Background: This is a long-term follow-up of living kidney donors (LKD) in an ethnically diverse patient population. Hispanics are known to have an increased risk of developing chronic kidney disease, associated with hypertension and obesity. The hypothesis is Hispanic living kidney donors or unclassified living kidney donors would have poorer long-term outcomes secondary to lack of access to health care and secondary to the higher risk factors for developing chronic kidney disease. 

Methods: The objectives: measure obesity, hypertension, diabetes, measure CrCl post-donation and compare to the pre-donation CrCl. LKD were contacted & invited to participate & had a questionnaire about their general health & history and physical. Analysis included a CBC, serum chemistry, a 24-hour urine collection to measure creatinine, protein and albumin. A Patient Data Visit Sheet, RAND 35 Health Questionnaire. The IRB approved this study.

Pre- and post-donation systolic and diastolic blood pressures were similar between Hispanics and non-Hispanic LKD. Non-Hispanic LKD had a greater decrease in systolic blood pressure post-donation -4.5 mmHg vs. 6.6 mmHg (p=0.0378). The decrease in CrCl post-donation was the same in Hispanic and Non-Hispanic LKD, 33 ml/min vs. 35 ml/min. None of the LDLK in the study had significant proteinuria or microalbuminuria.

Conclusions: Post living donor kidney donation in our ethnically diverse patients are not at a higher risk for developing obesity, HTN, or CKD. Overall, our LKD feel they have a good overall quality of life including both physical and emotional realms.

Post-Kidney Transplant Follow-Up in Native American: An Opportunity for Improvement

Fidel Barrantes,1 Sarah Stith,2 1Presbyterian Transplant Center, Renal Medicine Associates, Albuquerque, NM; 2Economics, Univ of New Mexico, Albuquerque, NM.

Background: Native Americans have been shown to face decreased access to waitlisting and transplantation. We explore the possibility that Native Americans might face decreased access to high quality post-transplant care, especially in the long-run, due to a decreased general access to healthcare, as is faced by many socioeconomically disadvantaged minority populations.

Methods: Using data from the OPTN, we evaluated the quantity and type of post-transplant care received by Native Americans. We compare Native American populations with other ethnically diverse groups from October 1, 1987 to December 31, 2012 using multivariate regression analysis, controlling for time-invariant factors affecting all patients in a given year (year fixed effects) and time-varying factors associated with a specific transplant center (center fixed effects). (Standard errors are clustered at the center level to account for heteroscedasticity and spatial correlation among patients in a given center).

Results: Statistically significant regression results (p<0.05) indicate that Native Americans are less likely to receive transplant program-based aftercare than other racial/ethnic groups (Black, White, Hispanic and Asian/Pacific Islander), opting instead to see other types of specialists. They also are two percentage points more likely to be lost to follow-up (mean=0.15), one percentage point less likely to participate in an immunosuppression-related research study (mean=0.03), and receive 0.3 fewer follow-up visits (mean=2.2) than whites. They face the lowest number of follow-up visits, the lowest probability of participating in a research study, and the highest probability of being lost to follow-up. They are also 13% points less likely to work post-transplant (mean=0.35) than whites.

Conclusions: The results indicate that Native Americans have reduced access to high quality post-transplant care. Further research will explore how much of the disparity in post-transplant care is related to the high correlation between being Native American and poor and between being Native American and living in a rural area, especially on tribal lands.

Pre-Procurement Iodinated Contrast Exposure Is Associated with Early and Late Kidney Transplant Outcomes

Fidel Barrantes,1 Sarah Stith,2 Abhijit S. Naik,3 Isaac E. Hall,3 Mark A. Perazella.4 1Renal Medicine Associates, Albuquerque, NM; 2Economics, Univ of New Mexico, Albuquerque, NM; 3Internal Medicine, Univ of Michigan, Ann Arbor, MI; 4Internal Medicine, Yale Univ, New Haven, CT.

Background: Iodinated contrast can cause acute kidney injury. We sought to evaluate the association of iodinated contrast exposure prior to organ procurement in deceased donors with subsequent kidney transplant outcomes.

Methods: Using OPTN data for kidney transplants between May 2000 and December 2012, we performed multivariate regression to model 2 different definitions of delayed graft function.

Results: 122,856 deceased donor kidney transplants were included in the analysis, of which 28% (n=34,428) had received iodinated contrast exposure prior to procurement. Among recipients, 3.7% (n=4,491) experienced delayed graft function. Using OPTN data for kidney transplants between May 2000 and December 2012, we performed multivariate regression to model 2 different definitions of delayed graft function.
function as a function of donor exposure to coronary angiograms, controlling for time- invariant factors affecting all patients in a given year (year fixed effects) and time-varying factors associated with a specific transplant center (center fixed effects with standard errors clustered at the center level to account for heteroskedasticity and spatial correlation among patients in a given center).

Results: Of 93,811 donors listed in study period, 8.5 % (8012) were exposed to coronary angiograms. From this group, 14,628 kidneys were transplanted. Statistically significant regression results (p<0.01) indicate that patients receiving organs from donors who received coronary angiograms are 2% points more likely to receive dialysis within the first 3 months post-transplant (mean=0.24) and are less likely to experience a ≥25% decline in serum creatinine in the first week of transplant (mean=0.56). These patients also face a 61 day shorter average graft survival time and a 1% point lower probability of 6-month post-transplant patient survival. At three years recipients from donors with contrast exposure have 2% decrease in survival rate (P=0.005).

Conclusions: This large database analysis provided statistical power to detect an association between donor exposure to iodinated contrast from coronary angiograms before organ procurement and subsequent adverse early as well as later kidney transplant outcomes. Further research into the effects of deceased-donor management strategies is warranted to expand the organ pool while decreasing adverse transplant outcomes.

SA-PO1029

One Year Recovery After Kidney Donation: The Medical and Donor Point of View in a Prospective Cohort Study Briançon Serge,1 Lucie Germain,1 Michele Kessler,2 Marie-Alice Macher,3 Marc Soudant,1 Marie Thuong,2 Épidemiologie CIC-EC, CHU de Nancy, Nancy, France;2 Nephrology, CHU de Nancy, Nancy, France;3 Transplantation, Agence de la Biomédecine, Paris, France.

Background: Renal transplantation is the reference treatment for ESRD patients; the living donor kidney has been proven to provide better outcomes to recipients. Recovery of donors has been less studied and understood.

Methods: An exhaustive sample of 500 donors recruited in every French transplantation between October 2009 and January 2012 (T0) were followed at 3 (T1) and 12 months (T2) after surgery. Questionnaires investigating the donation course, quality of life (SF-36 and Euroqol) and recovery were sent back. Medical data were from CRISTAL register. 384 donors participated at 3(85%) and 12months(90%). The exceptional participation rate reflects the high commitment of donors.

Results: Before the donation, the physical health is incredibly high especially for older. On average a 75 year-old donor has the PCS SF36 level of 35 year-old men in the general population Three months after surgery, all outcomes exhibited decreased health indicators. Three quarters of the donors underwent laparoscopy, associated with less pulmonary complications, kidney failure, high blood pressure, persistent physical pain, better postoperative recovery. More than half the donors have at least one complication of which 8% was severe. The appearance of the scar is one of the dissatisfaction of the donor. One year after the donation, over 10 donors, 9 resum work, 3 not at all completely recovered, three still feel physical pain, 4 have not recovered their PCS pre-donation level, and 5 their MCS level. However their status remains better than that of the general population of the same age and sex. Donors are ready to do it again (98.2%) and recommend the donation (96%).

Conclusions: The experience alters neither the initial impetus nor the meaning attributed to the donation. The recommendations are meant to develop the process of laparoscopy: to inform and manage completely pain, to better prepare the donor to the surgical procedure, its risks and aftermath, including professional ones in younger, to perfectly plan the medical follow up with information to referee physicians.

SA-PO1030

Discard of Deceased Donor Kidneys in the United States: The Weekend Effect Sumit Mohan,1 Karl F.W. Foley,1 Mariana C. Chiles,1 Geoffrey K. Dube,1 Russell J. Crew,2 Stephen O. Pasma,7 Rachel E. Patzer,2 David J. Cohen,1 Dept. of Medicine, Columbus Univ College of Physicians & Surgeons, New York, NY;2 Dept. of Medicine, Emory Univ School of Medicine, Atlanta, GA.

Background: The discard rate of deceased donor kidneys (DDK) has slowly increased over time. The underlying reasons remain unclear. The impact of low resource availability over the weekend is unknown. We aimed to determine the impact of weekends on organ utilization patterns.

Methods: The majority of DDK (80%) are transplanted over the weekend and are procured on either Friday or Saturday (Fri-Sat). Using data from the Scientific Registry of Transplant Recipients (SRTR), we identified and compared all DDK procured on Fri-Sat to those that were procured on other days of the week. Using logistic regression we estimated the adjusted odds of discard for DDK over the weekend.

Results: Among the available kidneys, the Fri-Sat period was associated with lower procurement (89.5 vs 90.2%, p<0.001) and the procured kidneys were older (39.7±17.7 vs 39.1±17.6, p<0.001) and of lower quality (KDRI 1.3±0.49 vs 1.3±0.49, p<0.001). Not only were Fri-Sat DDK were more likely to be discarded (18.6 vs 16.4%, p<0.001), these kidneys were of higher quality than those discarded during the rest of the week (KDRI 1.8±0.57 vs 1.8±0.56, p=0.018). Fri-Sat DDK were more likely to be shared without payback and be transplanted at a large transplant center. After adjusting for KDRI, Fri-Sat DDK were 20% more likely to be discarded than kidneys procured during other times during the week (OR=1.20, p<0.001).

Conclusions: DDK procured on Fri-Sat are more likely to be discarded than at other times. This may be due to the fact that organs are less likely to be shared with large transplant centers. Our results demonstrate the possibility that low resource availability on the weekends adversely impacts organ procurement, acceptance and transplantation.

SA-PO1031

Medication Adherence Barrier Burden Predicts Subsequent Adherence to Dosing Time Schedule in Adolescent Kidney Transplant Recipients in the TAKE-IT Trial Bethany J. Foster,1 Huanqiao Zhao,2 Ahna Lh Pai,2 Nataliya Zelikovskaya,3 Crystal D. Holly,1 Jodi M. Smith,1 Vikas R. Dharnidharka,2 Diane Hebert,2 Lorraine E. Bell,2 Douglas G. Matsell,1 Veronique Phan,2 Susan L. Furrh.2 Pediatrics, McGill Univ;2 TAKE-IT Investigators.

Background: Studies of adherence to timing of medication dosing in high-risk adolescent kidney transplant recipients are lacking.

Methods: We aimed to determine whether the burden of perceived barriers to medication adherence predicted timing adherence (proportion of doses taken ≥1 h before to ≥2 h after the prescribed dosing time) during the subsequent 3 mo., as monitored with a multidose electronic pillbox. We evaluated the 126 participants of TAKE-IT who had electronic adherence data available for the 3-mo. run-in period (no intervention). Participants (11-24 y.; ≥ 3 mo. post-transplant) were followed in 8 centers (Canada and USA). Adherence barriers were assessed at baseline using the Adolescent Medication Barriers Scale (AMBS). A higher score indicates greater barrier burden (possible range 17-85). We used linear regression to estimate the association between baseline AMBS scores (total score and ingestion, disease adaptation, and cognitive/organization subscores) and timing adherence. Models also included sex, age, race, and time since transplant.

Results: 60% were male and 67% were white. Median age at baseline was 15.8 (IQR 14-17.4y). Median time since transplant was 1.1 (0.7-7.5) years. Median timing adherence for the interval was 82.6±32.8. Higher barrier burden (median score 38 (IQR 30-44)) was significantly associated with poorer timing adherence: a 5 unit higher total AMBS score was associated with 2.0% (95% CI 0.4, 3.6) lower timing adherence. A 5 unit higher score was associated with 4.3% (1.2, 7.5) lower timing adherence for the disease adaptation subscale, and with 5.9% (0.2, 11.6) lower timing adherence for the cognitive/organization subscale. Males had 10% (2.9, 17.6) lower timing adherence than females.

Conclusions: Higher burden of perceived barriers was a significant predictor of poorer timing adherence in this longitudinal study. Future analysis of the TAKE-IT data will determine the impact of an intervention targeting individual barriers on timing adherence.

Funding: NIDDK Support
SA-PO1034

Short-Term Outcomes in Individuals with Persistant Asymptomatic Non-Visible Haematuria

Background: National guidelines in the United Kingdom suggest investigation to exclude urological disease and identify glomerular pathology in potential donors with persistent asymptomatic non-visible haematuria (PANVH). There is currently no guidance on how to proceed where abnormal immunohistochemistry (IHC) is found without proliferative glomerular changes or electron dense deposits (EDD).

Methods: Demographic characteristics, renal function and biopsy details were obtained by retrospective case note review of kidney donors in the South West Thames transplant network who had undergone renal biopsy for PANVH between 2008-13. Light microscopy, IHC and electron microscopy (EM) findings were collected and clinical outcomes analysed for donors and recipients.

Results: Twenty four donors with PANVH proceeded to donation. All donors completed their 1st year, only 32 patients (34%) achieved an optimal outcome. This was defined by the following criteria:
- Nephritis, hyperlipidaemia, hypertension, serum creatinine > 1.5
- Kidney transplant glomerulopathy, and no history of AMR or ACR
- Infection (BKV PCR <10,000, CMV PCR<0, no history of PTLD or symptomatic EBV) and cardiovascular (CV) health

Conclusions: Facilitating directed donations will continue as part of our routine practice. Each year approximately one in six of our donor families identified potential recipients, but transplants from these requests remained consistently less than 2% of our annual total. Future studies are planned to evaluate recipient outcomes, assess donor family satisfaction with a recipient known to them, as well as to examine our practice in detail in an effort to standardize the language and timing of the directed donation discussions.

SA-PO1035

Deceased Directed Kidney Donations: A Three-Year Experience at a Single OPO

Background: The UAGA allows for deceased directed organ donations. Our OPO has incorporated the practice of offering the option of directed donations during every donation discussion in response to routine donor family requests. However, facilitating directed donations for donor families remains a controversial topic. Opponents suggest that directing gifts is not only inequitable, but that it may encourage malfeasance in the form of organ solicitation via media or social networks, and worse, lead to patients who promote discrimination. The purpose of this research effort was to identify how many directed kidney requests were received and honored during a three-year period in order to assess the impact on our allocation scheme.

Methods: We analyzed retrospective data from our OPO for three years from 2012-2014. We evaluated the number of directed kidney donation requests in relation to the overall number of donors, as well as the transplant outcomes or reasons for decline when the request was not honored. Relationship of donors to potential recipients was also assessed.

Results: During the three year period, 176 of our 1,056 authorized donors had a potential directed donation. Of these, 80% were directed to patients on the kidney waiting list. However, only 16% of the attempted directed kidney donations resulted in a transplant. The data illuminate that incompatibility/mismatch of potential directed kidney recipients is the most common reason that directed kidneys are not transplanted, despite the fact that directed donations are allocated ahead of highly sensitized patients, mandatory shares, multivisceral combinations, and the like.

Conclusions: Facilitating directed donations will continue as part of our routine practice. Each year approximately one in six of our donor families identified potential recipients, but transplants from these requests remained consistently less than 2% of our annual total. Future studies are planned to evaluate recipient outcomes, assess donor family satisfaction with a recipient known to them, as well as to examine our practice in detail in an effort to standardize the language and timing of the directed donation discussions.

SA-PO1036

Optimal Outcomes in Pediatric Renal Transplant Recipients

Background: Pediatric kidney transplant recipients (pKTRs) experience multiple sequelae of their condition, yet comprehensive assessment of these is lacking in the literature. Our objective was to develop a composite outcome measure for pKTRs that considers the most common comorbidities, and to evaluate a population of pKTRs at specific intervals post-transplant.

Methods: We retrospectively reviewed all KTRs at our center from 10/2008 through 2/2015. An optimal outcome composite measure was created consisting of 14 criteria in four domains: allograft function (CKD stage 3, urine protein/creatinine ratio < 0.5, absence of DSA's), histology (no or mild interstitial fibrosis and tubular atrophy, no transplant glomerulopathy, no history of AMR or ACR), infection (BKV PCR <10,000, CMV PCR<0, no history of PTLD or symptomatic EBV) and cardiovascular (CV) health (triglycerides<500, LDL <130, BP <90th %ile, fasting glucose < 126, and BMI < 85th %ile). Patients were evaluated on these pass/fail criteria at post-transplant yrs 1, 3, 5, and 10. Optimal outcome was defined as passing ³13/14 criteria.

Conclusions: Only 1/3 of pKTRs achieved an optimal outcome at 1 year post-transplant, and this fell to 1/6 of patients by 10 years. Cardiovascular health and graft function were the system and brain death declaration is not mandatory. Andhra Pradesh and Telangana are the two impotheastern states in India, situated on the country’s southern coast. It is India’s fourth largest state by area and fifth largest by population. Government of Andhra Pradesh, considering the shortage of organs and burden of end stage organ failure in the state, has come up with a Government Order called “Jeevandan” to streamline the procedure for facilitating and regulating the cadaver transplantations on an end-to-end basis.

SA-PO1034

Jeevandan: Deceased Donor Transplantation Programme from a Developing Country

Background: In developing country like India the prevalence of end stage organ disease is increasing. Though transplantation has been in practice in India, its been grossly inadequate in terms of actual numbers, due to a shortage of resources and organs. The only solution for the shortage of organs is deceased donor transplantation.

Methods: In India the Human Organs Transplantation Act, was enacted in 1994 with in India the Human Organs Transplantation Act, was enacted in 1994 with the objective of promoting and regulating the transplantation of human organs like kidney, liver and heart - both live as well as cadaver there was no significant increase in cadaver transplantation over the past two decades for various reasons. India follows “opt in” system and brain death declaration is not mandatory. Andhra Pradesh and Telangana are the two impotheastern states in India, situated on the country’s southern coast. It is India’s fourth largest state by area and fifth largest by population. Government of Andhra Pradesh, considering the shortage of organs and burden of end stage organ failure in the state, has come up with a Government Order called “Jeevandan” to streamline the procedure for facilitating and regulating the cadaver transplantations on an end-to-end basis.

Results: There were 129 deceased donations in 2 years. Male were 93 and female 36: female to male ratio being 1: 2.58. The mean age was 41 years (range 8 to 79). Most common Blood group was O in 51 (39.5%) donors followed by B in 39 (30.2%). A positive crossmatch in 22 donors, and ABO in 26 (10.7%). donors. Total 593 organs in 532 recipients were retrieved from 129 deceased donors; 233 kidneys, 126 livers, 7 hearts, 118 heart valves, 103 corneas, 5 lungs and 1 Pancreas. Total deceased donor renal transplantations done during this period were 24.67%. Out of 129 donors, 6.8 % kidneys and 3% livers were not utilized. Mean age of renal recipients was 44.07 years (range 13 to 72). There were 26.8% females and 73.2% males, female to male ratio being 1:2.73. Among deceased donor renal transplant recipients, O blood group was most common, seen in 36.79% followed by B in 32.38%, A in 22.64% and AB in 8.17% patients.

Conclusions: Deceased donor transplantation is the solution for organ shortage and increasing demand of organ requirement.
primary failure modes. Evaluation of all transplant-related outcomes at specified follow-up intervals will allow practitioners to assess the success of kidney transplantation and overall recipient health and focus clinical outcome improvement efforts.

SA-PO1037
Clinical Outcome of Elderly Living Kidney Donors: A Single-Center Study in Japan
Jumpei Hasagawa, Kohei Unagami, Masayoshi Okumii, Kazuya Otomo, Hideki Ishida, Kazumari Tanabe. Urology, Tokyo Women’s Medical Univ, Tokyo, Japan.

Background: Previous studies and current guidelines have suggested that elderly persons can be living kidney donors; however, reports on elderly donors > 70 years old are limited. In order to clarify the donor safety and feasibility, we investigate the clinical outcomes of living kidney donors > 70 years old after nephrectomy.

Methods: We conducted a case-series study of living kidney donations involving 48 donors aged >70 years at the time of transplantation. The kidney donations occurred between 2001 and 2014 at Tokyo Women’s Medical University in Tokyo, Japan. The primary outcomes were survival or end-stage renal disease (ESRD)-free rate and all crude event-free rates, including death, vitro, infection, ESRD, or any adverse event. The secondary outcome was serum creatinine level at the end of the follow-up period.

Results: The 48 cases were followed up for a median of 4 years. The survival rate among the donors was 100% until the fifth year, and only two donors died during follow-up. The ESRD-free rate was 100% during the follow-up period. The overall event-free rate was 100% at 1 year, 85.7% at 3 years, and 75.0% at 5 years. The mean serum creatinine level was 1.18 ± 0.24 mg/dL at the time of hospital discharge and did not increase (1.18 ± 0.24 mg/dL) at the end of follow-up.

Conclusions: Living kidney donation from elderly donors >70 years old appears to be a safe and acceptable option for patients requiring renal-replacement therapy.

SA-PO1038
Immunosuppressive Medication Adherence following Kidney Transplantation at the Military Healthcare System
Dustin J. Little, Matthew Ward, Robert Nee, Christina M. Yuan, Rahul M. Tindle. Walter Reed National Military Medical Center, Bethesda, MD; Uniformed Services Univ of the Health Sciences, Bethesda, MD.

Background: Limitations on the amount and duration of Medicare coverage of immunosuppressive medications (ISM) may contribute to ISM non-adherence and allograft failure. ISM adherence has not been reported in US patients who receive these medications at no cost. We therefore designed a prospective cohort to investigate the incidence of ISM non-adherence in Military Healthcare System (MHS) beneficiaries, who receive lifelong post-transplant ISM at no out-of-pocket cost.

Methods: Adult MHS kidney transplant recipients who provided informed consent completed the Immunosuppressive Therapy Adherence Scale (ITAS) and Beck Depression Inventory-II (BDI-II). Chart reviews were performed to obtain demographic and clinical data. Perfectly adherent subjects (P) (ITAS score of 12/12), were compared to not perfectly adherent subjects (NP; ITAS score £11/12) using Student’s-t test and Fisher’s exact test where appropriate. Exact logistic regression was performed to evaluate for factors associated with P versus NP adherence.

Results: Forty subjects completed survey instruments. 57.5% of subjects were male, 7.2 vs. 13.6 ± (27/39) of subjects reported P adherence. BDI-II scores were significantly lower in P vs. NP adherence. One subject did not complete the ITAS. Mean overall ITAS score was 11.5 ± 2.5.

Conclusions: MHS beneficiaries reported high levels of ISM adherence. Modest increases in BDI score associated with marked reduction in adherence, and subjects with NP adherence were significantly more likely to have DSA. Our results suggest that enhanced ISM coverage as well as education, identification, and treatment of depression should be prioritized for future study in order to improve outcomes following renal transplantation.

SA-PO1039
Clinical Impact of Kidney Donor Follow-Up by Nephrologists
Hee Jin Kwon, Jin Hee Kim, Jee Eun Park, Subin Hwang, Jung Eun Lee, Woosong Huh, Yoon-Goo Kim, Dae Joong Kim, Ha Young Oh, Hye Ryoun Jang. Nephrology Div, Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Republic of Korea.

Background: Compensatory and adaptive mechanisms in the remnant kidney occur immediately after nephrectomy. The adaptability in early postoperative period may affect the renal function of the remaining kidney. Since the introduction of extended criteria living donor selection, the number of marginal donors with risk of new morbidity in recipients is increasing. The aim of this study was to evaluate the clinical impact of kidney donor follow-up by nephrologists at a donor clinic (DC).

Methods: Our study included 427 living kidney donors from January 2010 to December 2014 at Samsung medical center. Nephrologist-run donor clinic was established in January 2013. The study period was divided into pre-DC and post-DC. Primary outcomes were incidence of CKD and renal functional adaptability (%MDRD = post/pre eGFR X100) at 6 months after donation. Secondary outcomes were changes in compliance and incidence of co-morbidities; hyperuricemia and microalbuminuria.

Results: A total of 215 and 172 donors were included in pre-DC and post-DC, respectively. Before donation, age, sex, proportion of hyperuricemia and microalbuminuria were similar. Preoperative eGFR in pre-DC was significantly higher than post-DC (p<0.001). After donation, poor renal adaptation (post-donation eGFR at 6 months < 60% of preoperative eGFR) was less frequent in the post-DC period compared to the pre-DC period (p=0.026). CKD development tended to be higher in pre-DC period. Donors in the post-DC period had shorter mean outpatient clinic visit intervals (p<0.001), more visits within 6 months after donation (p<0.001), earlier detection of de-novo hyperuricemia (p<0.001). The incidence and detection time of microalbuminuria were similar.

Conclusions: After establishment of kidney donor clinic operated by nephrologists, donors tended to show better renal adaptability and earlier diagnosis and treatment of hyperuricemia. In conclusion, donor clinic may be a good strategy for improved renal outcome and detecting potential risk factors of CKD in donors.

SA-PO1040
Predicting Kidney Allograft Half-Life Using a Podometric Approach
Roger C. Wiegins, Abhijit S. Naik, Diane M. Cibrik, Jeffrey B. Hodgin, Farsad Afshinnia, Larysa T.wickman, Milagros D. Samaniego. Dept of Medicine, University of Michigan.

Background: Increasing donor age is a powerful predictor of worse renal allograft outcome. Podocyte depletion is part of the normal aging process (Hodgin, JASN, 2015). Recently we showed that kidney hypertrophy that occurs at time of transition from a 2 kidney 1 kidney state (transplantation), leads to a 20% reduction in podocyte density and a 6-fold increased rate of podocyte detachment associated with transplant glomerulopathy and allograft failure (Yang, JASN, 2014). To test the hypothesis that podocyte depletion could impact allograft half-life we used a model combining age specific podocyte nuclear density decrease and rate of podocyte attrition after transplantation for comparison with actual allograft outcome data.

Methods: Podocyte density was estimated from immediate post perfusion biopsies from living and deceased donors or from non-diseased nephrectomy specimens. Projected allograft life was predicted based on modeling age-specific podocyte density and the observed attrition of podocytes. Observed data were drawn from the OPT/UNOS STAR files as of Sep 2014, using all transplants performed between Oct 1987-June 2013. A “conditional” Kaplan Meier analysis using the “period” method was used to calculate observed half-lives at different donor ages.

Results: The podometric projected average half-life for a 40 year old donor is 15.1 years, similar to the observed average allograft half-life (15.1 years). The projected effect of increasing donor age on allograft half-life from podometric measurements is similar to the observed effect of donor age on allograft half-life at all calculated donor ages (p=NS).

Prediction of Patient Survival After Kidney Transplantation (Tx): Construction, Validation and Evaluation of Decision Models Using Data Mining Approaches
Irina Scheffer,1 Kaixin Hua,2 Dan Simovici,2 Tanja Abeling,1 Hermann G. Haller,1 Wilfried Gwinner.1 1Hannover Medical School, Germany; 2Unite of Massachusetts.
Background: Understanding the risk factors that predispose to death is important to deliver the most appropriate therapy to Tx patients (pts). Aim of this study is to build reliable models to help us identify the relevant risk factors for death using different data mining approaches.
Methods: We analyzed 761 pts transplanted between 2000 and 2007 (follow-up of up to 10 years). Data included biopsy results, clinical & laboratory factors. After conventional statistical feature selection analysis, we built Naive Bayesian (NB), C5.0, RPART and Random Forest (RF) models.
Results: Compared to C5.0 and RPART, NB and RF resulted in models with a higher sensitivity to predict death and a high specificity. Using different partitions for training and test set, NB models had a sensitivity of 62-65% and a specificity of 89-91% to predict death. With RF, sensitivity was 64% and specificity 96%. Because of the imbalance of the outcome groups (13% deceased pts) modeling was repeated with balanced datasets obtained by oversampling. With the balanced data, sensitivity was 82% and specificity 79% with NB. With RF, sensitivity was 83% and specificity of 68%. These models were externally validated with two separate datasets showing sensitivities of 64 and 59% and specificities of 86% and 78% for the NB models and sensitivities of 84 and 61% and specificities of 60 and 65% for the RF models. Highly important variables were recipient age, pre-Tx diabetes mellitus, peripheral arterial and coronary heart disease, cold ischemia time, graft function within the first 6 weeks and annual GFR loss, and post-Tx systolic and diastolic blood pressure, urinary tract infections, and hyperparathyroidism. Modestly important variables included donor age, time on dialysis, HLA DR mismatches, delayed graft function, pre-Tx smoking. The estimated models performed well in predicting death and can be used to identify pts on risk. Moreover, with the identified (modifiable) risk factors pts can be assigned to different treatment strata to offer each patient the optimal therapy. Fundering: Government Support - Non-U.S.

The Decline of Dialysis in Northern Ireland
Kathryn E. Larmour. Regional Nephrology Unit, Belfast City Hospital.
Background: The first session of haemodialysis in Northern Ireland (NI) was in 1959 for acute kidney injury. There has been an inexorably rise in the prevalent dialysis population in the province since then, with expansion of dialysis facilities to accommodate ever increasing numbers. However, in addition to inferior outcomes compared to transplantation, there are considerable social and recurrent costs associated with chronic haemodialysis provision. This study considered the impact of an expansion in the living donor (LD) transplant programme on dialysis in NI and the financial implications.
Methods: The prevalence dialysis population from 1999-2014 (inclusive) data were retrieved retrospectively from collected data. The number of LD transplants in NI patients is prospectively recorded. The economic impact of the changes evident in our centre were then evaluated.
Results: In 1999 there were 479 patients in NI receiving maintenance dialysis treatment. This number increased annually until a zenith of 836 in 2009. There were no LD transplants in NI patients until 1999, when 17 transplants were performed annually. There was an expansion of the LD programme thereafter, and for the past four years there have been between 33-60 LD transplants each year (>30 donor related, >20 non-donor related in an initial plateau and then a decline in the prevalent dialysis population [figure 1]. The cost of maintaining a patient with end-stage renal failure on dialysis is £17,500 ($27,000) per patient per year for a patient on peritoneal dialysis and £35,000 ($54,000) per patient per year for a patient on hospital haemodialysis. The first year of care after a kidney transplant costs around £17,000 ($26,000) and £5,000 ($7,500) for every subsequent year. Live donor costs are approximately £9,000 ($14,000). Transplantation results in a cost benefit in the second and subsequent years of £25,800 ($39,500) per annum. The cost benefit of transplantation compared to dialysis over a period of ten years is £241,000 ($370,000).
Conclusions: A proactive approach to living donor transplantation has benefits not only for individual patients but in reducing the prevalent dialysis population and the healthcare costs associated with renal replacement therapy.
SA-PO1044
Pre-existing Donor-Related Diabetic Nephropathy Predicts Poor Allograft Survival
Steven Salvatore,1 Mohamad M. Alkadi,1,2 Tanja Abeling,1 Hermann G. Haller,1 Wilfried Gwinner.1 1Hannover Medical School, Germany; 2Leiden University Medical Center, Leiden, Netherlands; 1Faculty of Computer Science, Delft Technical Univ, Delft, Netherlands; 2Dept of Technology in Healthcare, Prevention and Health, TNO, Leiden, Netherlands.
Background: Diabetic nephropathy (DN) is the most common cause of end stage renal disease in the US, and in the transplant setting may play a role in long-term graft dysfunction. In patients with diabetes, finding features of DN in the immediate for cause post-transplant biopsy may confer increase risk of allograft dysfunction.
Methods: From 2005-2014, 141 biopsies from 120 transplant patients with DN were studied. DN was classified as 1) donor related if present on biopsy –2 yrs from transplant or where no available recipient, 2) recurrent if <2 yrs with history of pre-transplant DN, or 3) de novo in post-transplant diabetes (all >3 yrs). Clinicopathologic parameters were analyzed in 95 patients with adequate clinical history (25 excluded).
Results: Of 95 biopsies with features of DN, 43 were characterized as recurrent, 17 donors and 35 donor-related. Biopsies with donor-related DN were done 0.5 yrs (0 days-3.6 yrs) post-transplant and 6 had delayed graft function. Other non-DN related disease was seen, likely prompting biopsy: acute tubular injury (10/35), antibody mediated rejection (4), acute cellular rejection (1), CNI toxicity (3), AIN (4) and BKV (1). The first biopsy class of DN were: Class 1-3, Class 2a-21, Class 2b-1, Class 3-10. Class 3 DN lesions are associated with higher proteinuria, Cr, and increased vascular sclerosis. 13/35 donors had known diabetes with mean hemoglobin A1c of 8.5% (range 4.7-14.6%). DN was not listed on any pre-implantation biopsy reports. Mean follow-up times were 3.8 yrs for donor related, 7.8 for recurrent, and 10.3 for de novo. Despite shorter follow-up, transplants with donor-derived DN had significantly more failure than recurrent DN (49 v 14%, P<.0008) or de novo DN (49 v 18%, P<.024). Recurrent and de novo DN had similar rates of graft loss (P=.64).
Conclusions: Despite careful screening of transplant kidney donors, donor related DN may be missed on pre-surgical biopsy or not effectively reported and leads to renal dysfunction in the early post-transplant period. Donor related DN is a significant contributor to early allograft loss compared to recurrent or de novo DN and predicts poor long term graft survival.
SA-PO1045
Maternal and Fetal Outcomes in Living Kidney Donors in Korea
Kyung Don Yoo, Hajeong Lee, Jae Yoon Park, Eunjin Bac, Jung Pyo Lee, Dong Ki Kim, Kwon Wook Joo, Yon Su Kim. Seoul National Univ Coll of Medicine.
Background: Mild elevation of blood pressure was detected after unilateral nephrectomy in kidney donors. Consequently, female kidney donors at risk for complications such as gestational hypertension caused concern. However, the impact of kidney donation on maternal and fetal outcomes had not been well established in Asian kidney donors.
Methods: This study included young female kidney donors under 45 years old (YO) at the time of kidney donation in Seoul National University Hospital between 1972 and 2014 (417 female donors). A survey of participants (45YO) was enroled. A survey of previous experiences was performed by medical chart abstraction and telephone poll. We additionally enrolled 3,608 pregnancies were enrolled as non-donor control. The questionnaires were approved by institutional review board in our institute.
Results: We tried to contact all of 417 female kidney donors. The thirty five donors had no experience of pregnancy, and finally we could have got 253 questionnaires of kidney donors. Donors were compared in the three groups according to pregnancy pre-,post-kidney donation group and non-donor control group. The proportion of predonation pregnancies were 82% (170cases, Mean age 38.8 years), and postdonation pregnancies were 14.0% (56cases, Mean age 27.2 years). In the majority of postdonation pregnancy cases were detected in recent years from 2007 to 2014 (72.3%). There were no differences of fetal outcomes such as incidence of prematurity, low-birth weight and fetal death between the groups. Gestational hypertension were no differences between the postdonation group and non-donor control group (5.4% vs. 5.8%). Donors with pregnancy after donation were more likely to have undergone Cesarean section (40.4%) than those with pregnancy before donation (21.9%).
Conclusions: This study revealed that maternal and fetal outcomes had little difference between the kidney donors and normal control. Further research using matched controls should be warranted.
SA-PO1046
Self-Monitoring Renal Function After Transplantation: A Clinical Trial on Safety and Usability
Céline Lianne Van lint,1 Sandra Van dijk,1 Wenxin Wang,2 Mark Neerinckx,2 Ton Rovekamp,2 Ton J. Rabelink,1 Paul J. Van der boog,1 Willelm-Paul Brinkman.2 1Nephrology, Leiden Univ Medical Center, Leiden, Netherlands; 2Faculty of Computer Science, Delft Technical Univ, Delft, Netherlands; 1Dept of Technology in Healthcare, Prevention and Health, TNO, Leiden, Netherlands.
Background: Kidney transplantation requires intensive monitoring which is burdensome for both patient and healthcare. With the availability of an innovative creatinine device, patients are enabled to monitor renal function at home. To investigate safety and usability of self-monitoring during the first year after transplantation an RCT was conducted.
Methods: The intervention group used a Statusensor® Xpress™ to measure creatinine at home during the first year after transplantation. Measurements were registered in a web-based system using a traffic light analogy to support interpretation of creatinine trends. Differences between groups regarding GFR were assessed at baseline (discharge) and at 1 year. Creatinine trends measured at home were compared to clinically relevant increases (10%) measured in the hospital laboratory. A subsample of intervention patients were interviewed on self-monitoring experiences.
Results: In total 119 patients were included (intervention n=64; control n=55). GFR did not differ between groups at baseline, nor at 1 year (72.8 and 71.1 ml/min at 1 year for intervention and control group, respectively). For 34 out of 65 laboratory-based creatinine increases, sufficient home-based creatinine measurements were available for trend comparison. In 76% a similar trend was observed. Self-monitoring enhanced early detection of rejection in 3 out of 5 cases, none were missed. Satisfaction was high: 71% of the interviewed patients (n=26) would have liked to extend self-monitoring creatinine beyond 1 year.
Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only. Underline represents presenting author. 874A
SA-PO1047

Comparison of Heart Rate Variability in Kidney Transplantation and End-Stage Renal Disease Patients on Dialysis Lee Heeyoung, Internal Medicine, Bong Song Memorial Hospital, Busan, Korea; Internal Medicine, Pusan National Univ Hospital, Busan, Korea.

Background: Heart rate variability (HRV) is a method for evaluation of autonomic nervous system activity by expressing the balance of sympathetic and parasympathetic tone. Some studies of HRV in patients with end-stage renal disease (ESRD) have been performed. However, few have examined kidney transplantation (KT) patients. Therefore, we investigated autonomic nervous system activity by means of HRV in patients with KT due to ESRD.

Methods: We compared the pattern of cardiac sympathetic and parasympathetic activity by time- and frequency-domain analysis of HRV with 24-h Holter monitoring of 23 KT and 56 dialysis patients. Patients underwent KT between January, 2008 and June,2011. Results: The mean ages of KT and dialysis patients were 54.2 ± 12.3 and 53.7 ± 12.6 years, respectively. The KT group showed increased time- and frequency-domain HRV (including HRV index), very low frequency (VLF), means and standard deviations of all normal R-R intervals for all 5-min segments of the entire recording (SDNNi), low frequency (LF), LF in normalized units (LFnorm), and LF to high-frequency power ratio, compared with the dialysis group.

Conclusions: Autonomic tone in patients with KT is higher than that in patients with ESRD on dialysis.

Physical Capacity and Function Are Associated with Body Composition, Cardiovascular Health and Quality of Life in Renal Transplant Recipients Danielle Richle, Jara Hale, Maurice Dungey, Patrick Highton, Emma L. Watson, Alice C. Smith. Leicester Kidney Exercise Team, Dept of Infectious, Immunology and Inflammation, Univ of Leicester, Leicester, United Kingdom.

Background: A renal transplant can transform the life of patients with end stage renal failure but cardiovascular disease remains a major cause of morbidity and mortality. Post-transplant weight gain is common, and physical functioning often fails to improve in line with increased renal function. This study explored associations of physical function and capacity with body composition, cardiovascular status and quality of life (QoL) in renal transplant recipients (RTxs).

Methods: 35 stable RTxs participated (mean age 52 years (range 29-70), 66% male). Self-reported QoL and physical function were measured by EQ-5D and Duke Activity Status Index (DASI) questionnaires. Physical capacity was measured by shuttle walk test (SWT), body composition by DXA, cardiac haemodynamic function by bioimpedance (NICOM), and systemic inflammation by plasma IL-6,ELISA.

Results: SWT, DASI and EQ5D all showed significant correlations with percentage body fat (SWT: r=-0.63, p<0.001; DASI: r=-0.41, p=0.02, EQ5D r=-0.47, p=0.005) and with IL-6 (r=0.34, p=0.05). On the other hand, fat-free mass showed positive correlation with cardiac output (r=0.79) and stroke volume (r=0.81, both p<0.001), and inverse correlation with total peripheral resistance (r=-0.67, p<0.001).

Conclusions: This study shows that in RTxs, poor physical function and capacity is significantly associated with lower QoL and also with higher percentage body fat and systemic inflammation, both of which are important cardiovascular risk factors. An increase in fat-free mass was significantly associated with superior cardiac function. Taken together, these results suggest that weight loss is desirable for those with excess body fat, and that increasing muscle mass is also important. Optimising body composition through appropriate exercise and nutrition may therefore improve physical function and capacity and enhance quality of life, and also reduce the risk of cardiac-related morbidity and mortality in this vulnerable population.

SA-PO1049

Background: Fertility in women is recovered few months after kidney transplantation. However, pregnancy viability and maternal complications remain unclear.

Methods: We studied data from patients from a kidney transplant center in Brazil from 2001 to 2012. In this retrospective study, we identified all pregnant kidney transplant recipients and collected clinical and laboratory data before pregnancy, every quarter and 12 months after delivery. Each pregnancy was considered a single event.

Results: We included 36 subjects and 53 events were found. The average age was 28±5 years. Pregnancy occurred 4.4±3 years after transplantation. Maintenance immunosuppression before pregnancy was prednisone, tacrolimus and azathioprine in 74% of the cases. The frequency of chronic hypertension was 38%, and 8% had preexisting proteinuria greater than 0.5g, 8 (15%) unintended termination of pregnancy (UTP) were observed in the first quarter and 4 (8%) occurred in the second quarter. Delivery was induced by medical conditions in 41% of cases. 9 (22%) premature births and 7 (17%) very premature births were observed. Two (5%) stillbirths and two (5%) neonatal deaths occurred. Maternal complications were proteinuria de novo (60%), urinary tract infection (23%), preeclampsia (9%) and high blood pressure (9%). During the follow-up period, two (6%) acute rejection and one (2%) graft loss occurred. Average baseline creatinine was compared with third quarter and 12 months follow-up creatinine and significant increase (1.17 vs. 1.46 vs 1.59/mg/dl, p=0.001) was found.

Conclusions: Although the sample is limited, the number of UTP was higher than the general population, with high rates of maternal complications. Besides, diagnosis of preeclampsia may be challenging because of the high frequency of hypertension and preexisting proteinuria. The sustained increase in creatinine suggests higher risk of long-term graft loss. Further research regarding the issue of pregnancy and kidney transplantation is required, in order to improve maternal safety and preserve graft function.

Outcomes of Twin, Triplet and Quadruplet Pregnancies in Kidney Transplant Recipients Serbian Constantinescu, LisaCoscia, Dawn Armenti, Michael J. Moritz. Medicine, Temple Univ School of Medicine, Philadelphia, PA; NationalTransplantation Pregnancy Registry (NTPR), Gift of Life Inst, Philadelphia, PA; Transplantation, Lehigh Valley Health Network, Allentown, PA.

Background: The purpose of this study is to analyze multiple gestation pregnancy outcomes reported to the National Transplantation Pregnancy Registry (NTPR) in 50 kidney transplant recipients.

Methods: Data were collected via questionnaires, telephone interviews, and hospital records.

Results: Of 986 kidney recipients (1802 pregnancy outcomes) participating in the NTPR, there were 50 who reported 52 multiple gestations with 112 pregnancy outcomes (45 sets of twins, 6 sets of triplets, and 1 set of quadruplets). There were 94 live births, 11 miscarriages, 6 stillbirths, and 1 reduction (triplet to twin pregnancy). Pregnancy occurred after 1st kidney transplant in 47, after a 2nd in 4, and after 3rd in 1 recipient; 14 recipients had a prior post-transplant live birth and 2 recipients had 2 multiple birth pregnancies. Use of reproductive assistance was reported for 16 conceptions (medication 5, intrauterine insemination 5, in vitro fertilization 4, and unspecified 2). There were no reports of rejection during pregnancy or postpartum (PP). Mean serum creatinine (mg/dl) was pre-pregnancy 1.4±0.6, during pregnancy 1.4±0.5, and PP 1.4±0.5. There were 4 graft losses within 2 yrs PP. Mean gestational age was 32.1±4.1 wks (range 23-37.4 wks) and mean birthweight was 1680±652 g (range 454-3551 g). There were 11 neonatal deaths including all of the infants in the quadruplet pregnancy. There were 5 birth defects reported: soft cleft palate, hypospadias, unilateral kidney, undescended testicle, and Tetralogy of Fallot. Overall, the majority of the children were reported healthy and developing well at last follow-up.

Conclusions: Female kidney transplant recipients can successfully maintain a pregnancy with multiple gestations. Given the increase in multiple gestations with the use of assisted reproductive techniques and the greater risks to the resulting fetuses, heightened surveillance in the transplant recipient population is warranted.

SA-PO1051

Kidney Transplantation for End-Stage Kidney Disease After Hematopoietic Stem Cell Transplantation

Akihiro Takehara,1 Hiromi Nishikawa,1 Morihito Aiba,1 Masayoshi Okumura,1 Tomokazu Shimizu,1 Kazumi Ishida,1 Kazunori Tanabe,1 Kazuhiko Tsuruya,1 Takanari Kitazono.1

1Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; Surgery and Oncology, Kyushu Univ, Fukuoka, Japan; Surgery, Tomishiro Central Hospital, Okinawa, Japan

Background: Hematopoietic stem cell transplantation (HSCT) is associated with various kidney diseases. The safety of kidney transplantation (KT) for end-stage kidney disease (ESKD) after HSCT has not been established. In this retrospective multicenter study, we investigated the immunological background, immunosuppressive regimes, and outcome in the KT patients after HSCT.

Methods: We report our experience with 5 KT patients following HSCT: 4 patients received bone marrow transplantation and 1 received umbilical cord blood transplantation. Median age at the time of HSCT was 29 years old (ranged 13-54 years old), and ESKD developed after 119 months (67-307 months). The median duration of pre-transplant dialysis therapy was 18 months (7-69 months). In one patient, bone marrow and kidney were from the same donor.

Results: Median observational period was 18 (5-60) months. All patients were treated antibody-induction with basiliximab followed by triple immunosuppression consists of tacrolimus, mycophenolate mofetil and methylprednisolone. In one patient with positive complement dependent cytotoxicity cross match, we added rituximab, splenectomy and plasmapheresis. In another one patient who received KT and BMT from the same donor, we temporarily gave immunosuppressive drugs. After KT, only one patient experienced subclinical acute T-cell mediated rejection and bacterial pneumonia, and the other patients have not experienced acute rejection or severe infectious complications.

Conclusions: Pre-existing CKD may have an effect on development of ESRD post-OLT. These effects if generalizable in larger cohorts are important for organ allocation.

SA-PO1052

The Risk Factors of Chronic Kidney Disease Occurrence in Patients Received Liver Transplantation

Li Yuehong, Nephrology, Tsinghua Changgung Hospital, Medical Center, Tsinghua Univ, Beijing, China.

Background: Analysis the risk factors of chronic kidney disease (CKD) occurrence in patients with liver transplantation.

Methods: 190 patients received liver transplantation followed up during 2001 to 2013 were analyzed retrospectively. 40 patients developed CKD. The observation items included patients’ gender, age, primary diseases, surgical approach, preoperative complications, laboratory examinations (hemoglobin, albumin, creatinine, glomerular filtration rate), intraoperative blood loss and blood transfusion volume, postoperative complications and average serum calcium concentration (from liver transplantation to the onset of CKD). Clinical data of CKD occurrence group were compared with the non-CKD group. Chi square test, t test, and logistic regression analysis were used.

Results: The incidence of CKD in patients with liver transplantation was 21.1%. Renal pathology included IgA nephropathy, hepatitis B virus associated nephropathy, membranous proliferative glomerulonephritis, focal segmental glomerular sclerosis and cryoglobulinemia associated renal injury. 85.7% patients had tuberculosis interstitial damage. Univariate analysis showed that preoperative renal function, hemoglobin, intraoperative blood loss and transfusion volume, postoperative acute kidney injury, average calcium concentration in serum (from liver transplantation to the onset of CKD) were risk factors of CKD in patients with liver transplantation. Logistic regression analysis showed that preoperative glomerular filtration rate (OR=0.980, P=0.041), hemoglobin (OR=0.972, P=0.034), calcium concentration (OR=1.364, P=0.015) and postoperative hypertension (OR=8.833, P=0.048) were independent risk factors of CKD occurrence.

Conclusions: Although limited by small sample size and low event rate, our analysis suggest that pre-OLT CKD3 may have an effect on development of ESRD post-OLT. These effects if generalizable in larger cohorts are important for organ allocation.

SA-PO1053

Pre-Transplant CKD, but Not AKI, Impacts Survival in Liver Transplant Recipients

Yorg Al Azzi, Girish N. Nadkarni, Vinay Nair, Thomas Schiano, Madhav C. Menon. Medicine, Icahn School of Medicine, New York, NY.

Background: Chronic kidney disease (CKD) stage and duration of RRT pre-liver transplant (OLT) have been associated with increased risk of progression to ESRD in OLT recipients. Currently, allocation of dual organ transplantation (liver/kidney) is limited to CKD stage 4 and/or RRT > 4 weeks. The data regarding the associations of less severe pre-OLT AKI (RRT<4 weeks) and, of CKD stage 3, with ESRD post-OLT is unclear. We examined the renal outcomes of OLT recipients at our center.

Methods: We reviewed charts of OLT recipients at Mount Sinai for clinical, demographic, laboratory and outcome data from the medical record. We utilized multivariable logistic regression for analysis.

Results: We had data on 115 OLT recipients from 2008-14 (mean age 57.7 years, 66% male). 55/115(47%) patients developed AKI pre-transplant, most often from HRS (47%). Pre-existing CKD-3 was present in 26/115 patients. Pre-OLT AKI developed in 23/26 CKD-3 patients. RRT was required in 8/26 CKD-3 patients. Mean eGFR at 1- and 2-year follow-up in the CKD-3 group compared to non-CKD group were 37.4 ± 16.6 vs. 33.3 ± 23.1 (p=0.01) and 59.8 ± 20.8 vs. 62.7 ± 22.3 (p=0.01) respectively. At a mean follow up of 1.4 years post OLT, proportion of patients developing ESRD was higher in CKD vs. non-CKD group (23.1% vs. 2.3%; p=0.01). Although, AKI was a significant predictor of ESRD (adjusted for age, sex, race, diabetes), its effect was attenuated after adjusting for CKD. CKD3 was the strongest predictor of ESRD (aOR 8.34; 95% CI 1.25-55.7; p=0.02) (figure 1). Overall, patient survival at a mean of 2.4 years of follow-up was lower in CKD3 vs. non-CKD groups (76.9% vs. 91%; p=0.08).

SA-PO1054

Can Acute-On-Chronic Liver Failure Classification Predict Post-Liver Transplant and Liver Kidney Transplant Outcomes?

Giselle Guerra,1 Panagiota Tryphonopoulou,2 Kalyan Bhamidimarri,2 Ian Thomas,1 Rodrigo Vianna.21 Div of Nephrology, Miami Transplant Inst, Miami, FL; 2Division of Transplantation, Miami Transplant Institute, Miami, FL.

Background: Recent evidence suggests that acute on chronic failure (ACLF) stratification is more accurate than other methods in predicting short term mortality rates pre-transplant. There is no evidence of ACLF stratification as predictor of post-transplant outcomes. We analyzed if ACLF could predict patient and allograft survival in live liver transplant recipients (LTR) or simultaneous liver kidney transplant recipients (SLKTR) especially if hepatorenal syndrome (HRS) is present.

Methods: A retrospective analysis was performed on 86 adult patients, 77 LTR and 9 SLKTR transplanted in 2013. Patients were classified into different ACLF grades (0-3) based on their pre-transplant parameters:MELD labs ( total bilirubin, serum creatinine, INR), hepatic encephalopathy, ventilator dependence and the presence of shock. Patient and allograft survival, and kidney function (serum creatinine < 1.5 mg/dL) were analyzed at 6 & 12 months post-transplant between LTR and SLKTR. A further analysis between recipients with HRS receiving either LT or SLKT was made. SLKTR received kidney transplants based on current International Club of Ascites (ICA) guidelines.

Results: Demographics of LTR and SLKTR cohorts: mean age of 58 and 59 years; males 63% and 56%; mean MELD of 21 and 33 respectively. Recipients with HRS pre-transplant had mean MELD 38 vs 30 in the LTR and SLKTR groups respectively. 27% of LTR had OLT 0-1; 11% SLKTR had OLT 0-1; 73% of LTR had OLT 2-3; 89% of SLKTR had OLT 2-3. LTR with HRS had 100% with ACLF 2-3; SLKTR with HRS had 83% with ACLF 2-3. One year post transplant outcomes: Patient Survival – 92% LTR, 66.7% SLKTR; 1 year Graft Survival – 89.6% LTR, 66.7% SLKTR; Kidney Function good – 81.8% LTR, 33.3% SLKTR. In patients with HRS both patient and graft survival are 83.3% SLKTR and 75% LTR, but kidney function trended to be better in LTR (50% vs SLKTR 33.4%).

Conclusions: Patient graft survival and kidney function appear to trend better overall in LTR vs. SLKTR. However, HRS patients fared the opposite favoring SLKTR vs LTR.

SA-PO1055

C3 Alone Is Not a Prognostic Indicator of Patient or Graft Survival in Post-Transplant Glomerulonephritis

Background: The prognostic implications of glomerulonephritis in the post-transplant setting are not well characterized.

Methods: We examined patient and graft outcomes in 71 kidney transplant recipients diagnosed with glomerulonephritis(GN). Biopsies were studied by immunofluorescence(IF) for glomerular C3 staining and divided into two categories, C3-positive or C3-negative.

Primary outcomes were graft and patient survival at 3, 12, and 36 months and at last follow-up. Serum creatinine(Cr) at last follow-up was a secondary outcome.

Results: Thirty three(46%) patients were C3-positive and 38(54%) were C3-negative. Mean follow up was 103 months for positive C3 and 117 months for negative C3 groups. There were no significant differences among groups by age, gender, type of donor, or prevalence of hypertension, diabetes, and hepatitis B or C. A total of 57% of C3-positive patients had a functioning graft at 36 months post-transplant, compared to 75.1% of C3-negative (p=0.16). A total of 88.2% of C3 positive patients were alive at 36 months post-transplant, compared to 85.7% of C3 negative (p=0.9). The mean serum Cr for C3 positive patients at 36 months was 1.59mg/dl compared to 1.71mg/dl for C3 negative (p=0.55). There were no significant differences in graft and patient survival between two groups.

Conclusions: There was no significant difference in patient or graft survival, or in serum Cr between patients with GN and C3-positive IF compared to patients with C3-negative IF. This suggests that the presence of C3 alone is not a prognostic indicator of patient or graft survival in post-transplant GN.

SA-PO1057

Does Hepatitis B Virus Impact the Outcomes in Kidney Transplant Recipients? Analysis by Phases of Infection

Background: In kidney transplant recipients (KTRs) with hepatitis B virus (HBV) infection, immunosuppression may increase the risk for the progression of liver disease. HBV may contribute to allograft disease and anti-HBV therapy can have nephrotoxic potential. The aim of this study is to evaluate the impact of different phases of HBV infection on the outcomes in KTRs.

Methods: Using OPTN/UNOS database, we selected adult KTRs from 2001 - 2011 who received peri-operative antibody induction followed by calcineurine inhibition/mycophenolate mofetil maintenance along with/without steroids. The cohort was divided into 4 groups based on the presence/absence of hepatitis B surface antigen(HBsAg) and core antibody(HBcAb) at the time of transplantation: HBsAg+/HBcAb-(acute infection); HBsAg+/HBcAb+(developing immune response); HBsAg-/HBcAb+(resolving infection) and HBsAg-/HBcAb-(HBV naive). Graft and patient survival were compared among the groups as shown in the table by using multivariate Cox model. Donor, recipient and transplant related confounders including lamivudine therapy were adjusted in the model.

Results: Adjusted graft and patient survival comparisons are shown in the table.

SA-PO1056

Pretransplant Hepatitis B Virus Infection Increased Risk of Death After Kidney Transplantation: A Multicenter Cohort Study in Korea

Background: The incidence of antiviral prophylaxis for rituximab (RIT)-associated hepatitis B virus (HBV) reactivation in patients with malignant lymphoma has been reported. However, the effect of single-dose RIT on HBV reactivation in kidney transplant recipients with hepatitis B surface antigen-negative (HBsAg-) and hepatitis B core antigen antibody-positive(HBcAb+) results is unclear, and there is no evidence for the necessity of prophylaxis in those patients.

Methods: From 2001 through 2014, 1021 patients underwent kidney transplantation (KTx) at Kyoto University and Tokyo Women’s Medical University, of whom 76 (7.4%) had HBsAg-/HBcAb+ results. Those patients showed hepatitis C virus (HCV)-RNA-negative, hepatitis B surface antibody-positive (HBsAb+), and HBV-DNA-negative. A RIT dose of 200mg/body was administered to 49 patients, and 45 patients did not receive prophylaxis. We monitored HBV-DNA and alanine transaminase levels every 1-3 months after KTx. HBV reactivation was defined as an elevation of serum HBV-DNA level ≥2.1 log copies/mL.

Results: HBV reactivation was found in 1 of 45 patients (2.2%) without prophylaxis. In the patient with HBV reactivation, serum HBV-DNA was detected at 6 weeks after KTx, and the minimum and maximum HBV-DNA levels were 2.1 and 2.6 log copies/mL, respectively. Although the patient was not treated with antiviral therapy, the HBV-DNA disappeared at 8 months after KTx. HBV reactivation was not found in the patients without RIT, and in the 4 patients who received both RIT and prophylaxis. Four (8.9%) of the 45 patients developed acute rejection, and 1 patient (2.2%) died of sepsis during the observation period.

Conclusions: The incidence of RIT-associated HBV reactivation in the HBsAg-/HBcAb+ patients without prophylaxis was less than 5%, suggesting that low-dose RIT might be associated with low incidence of HBV reactivation. However, sequential monitoring of HBV-DNA is necessary to prevent severe de novo hepatitis.
SA-PO1059
Direct Acting Antiviral Agents for HCV-Infected Patients Transplanted with a Kidney from a HCV Positive Donor

David Roth, Michael J. Goldstein, Warren L. Kupin, Giselle Guerra, Linda J. Chen, Adela D. Mattiazzi, Gaetano Ciancio, Paul Martin, George William Burke, Kalyan Bhamidimarri. Medicine, Univ of Miami Miller School of Medicine, Miami, FL.

Background: The availability of direct acting antivirals (DAAs) has changed the treatment of hepatitis C virus (HCV) infection. The decision to treat a HCV (+) patient (pt) before or after transplant has important ramifications. The current study reports outcomes in HCV-infected pts who received a kidney from a HCV (+) donor followed by early post-transplant treatment with DAAs.

Methods: HCV RNA (+) pts on the waiting list were consented to receive a kidney from a HCV (+) donor. Immunosuppression (IS) included thymoglobulin and sirolimus followed by maintenance IS with tacrolimus and mycophenolate mofetil. At 3 months post-transplant sofosbuvir combined with either ledipasvir, simeprevir and/or ribavirin for 12 or 24 weeks was initiated.

Results: Ten pts have started DAA therapy (5 others pending): 6 blacks and 4 hispanics with a mean age of 49.4 yrs. No pts were HIV or HBV co-infected. All pts were treatment naive, genoype 1 and non-cirrhotic. Median wait time was 30 days after consenting to accept a HCV (+) kidney. Viral clearance rates are shown in figure 1.

Conclusions: Treatment of HCV with pegylated interferon during dialysis results in some improvement of patients and graft survival following transplantation as compared to untreated patients. There is also trend of decrease in serious infection in treated patients. Sepsis and liver failure are two most common cause of mortality in untreated patients.

SA-PO1060
Impact of Treatment of HCV Infection on Renal Transplant Outcome
Sanjay K. Agrawal, Soumita Bagchi, Dipankar M. Bhowmik, Sandeep Mahajan, Akansha Agrawal. Nephrology, All India Inst of Medical Sciences, New Delhi, India.

Background: Impact of HCV treatment on post renal transplant outcome has not been reported adequately. This retrospective study was done to evaluate impact of HCV treatment on the post renal transplant outcome.

Methods: Adult patients on dialysis with HCV infection treated with pegylated interferon and subjected to renal transplant (RT) formed the study group. Untreated patients subjected to RT during same period served as controls. Primary end points were patient’s and graft survival and secondary end points were serious infections and NODAT. Factors which affect the outcome like age, gender, diabetes as basic disease, diabetes vintage, HBV co-infection, HCV genotype, viral load, liver biopsy grade and stage, induction and baseline immunosuppression were considered for analysis.

Results: At the time of study, 2010 RT were done in department of which 133 had HCV infection. 30 were treated with 68% SVR and 103 were untreated. In untreated group, there were more males (92% vs 77%), less dialysis number (137 Vs 211), less HBV co-infection (0.9% Vs 10%), less use of Tacrolimus (13.6% Vs 30%). There was no difference in terms of age, diabetes, HCV genotype, viral load, liver biopsy grade and stage, use of induction, Mycophenolate mofetil and duration of follow-up in two groups. With mean follow-ups of 59 ± 22 months (range 12-105), there was no statistically significant difference in term of acute rejection (23% vs 15%), NODAT (10% vs 16.7%) and overall serious infections (23% vs. 15%) between two groups. However, there were 11 deaths in untreated group (8 sepsis related, 3 liver failure and 1 coronary artery disease) while only one death related to sepsis in treated group. Patients survival (97% vs 89%) and graft survival (97% vs 84%) was significantly better (p<0.05) in treated group as compared to untreated group.

Conclusions: Treatment of HCV with pegylated interferon during dialysis results in some improvement of patients and graft survival following transplantation as compared to untreated patients. There is also trend of decrease in serious infection in treated patients. Sepsis and liver failure are two most common cause of mortality in untreated patients.

SA-PO1061
Prospective Study of Urinary Tract Infection in Renal Allograft Recipients in India: Single Center Study
Sanjay K. Agrawal, Muthu kumar B, Soumita Bagchi. Nephrology, All India Inst of Medical Sciences, New Delhi, India.

Background: Urinary tract infection (UTI) is common in renal transplant (RT) and in addition to morbidity, presumed to affects graft outcome also. Still it is least studied infection in RT. There is no data from India. We looked for incidence, risk factors and pattern of UTI in first 6 months after RT and its impact on graft function.

Methods: All RT between Dec 2013 and March 2015 were followed with urine exam and C/S at day 3, 7, 14, 21, 28 and then every two week till 3 months then monthly for another 3 months. Patients with asymptomatic bacteriuria (ASB) were randomized into treatment and no treatment group. Treatment was done for 7-10 days as per C/S. Study was approved by institute review board and informed consent was taken from each subject.

Results: During the study period 180 RT were done, (4 died, 2 nephrectomy, 1 graft failed, 4 lost to FU); 169 were analysed. Mean age of patients was 31.4 ± 10.4 (14-56) yrs and 51.6% were males. Diabetes was in 3.5%, renal stone in 3.5% and 3.5% had history of pre-RT recurrent UTI. All were on tacrolimus, MMF and steroid. 53% received induction. None got anti-reflux surgery. All were on cotrimoxazol for 6 months. 49 (29%) pts had at least one episode of UTI; 23 symptomatic and 26 ASB. Most common UTI was seen at 21 days followed by 14 days post surgery. 50-60% of these were symptomatic. Following RT, with time, frequency of UTI went on decreasing. Of the 84 UTI episodes, 97 (56%) were caused by E.coli followed by Klebsiella (16.7%), Enterococci (12%) and Pseudomonas (8.3%). Of the patients who had UTI, there were more females (33% vs. 13%), more stone disease (8.2% vs. 1.7%) and more post-operative surgical complications (24.5% vs. 11.7%). Of the 26 ASB, 11 were treated and 15 untreated. Of the 15 untreated ASB, none developed symptomatic UTI or rejection. There was no difference in serum creatinine between treated and untreated ASB on last follow-up.

Conclusions: In conclusion, symptomatic UTI in RT is our setting is seen in 13.6% patients, mostly in first month with E.coli as causative organism in half of patient. Untreated symptomatic UTI does not affect graft outcome and does not lead to symptomatic UTI.

SA-PO1062
High Dose Steroid Therapy in BK Viremia Adversely Affected Long Term Graft Function in Kidney Transplantation
Hyesang Kim, Chung Hee Back, Su-Kil Park. Div of Nephrology, Dept of Internal Medicine, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Republic of Korea.

Background: High dose steroid therapy has been tried for the management of confusing cases of BK nephropathy (mixed cellular rejection). However, the eventual fate of renal allograft after steroid therapy in the long term is still unknown. Therefore we investigated the graft survival and the change of BK viral load after steroid therapy in patients with BK viremia.

Methods: The study population comprised 144 kidney transplant recipients with BK viremia (serum BK viral load>1x10^4 copies/mL) consecutively detected at least two times, followed by steroid pulse treatment between July 2004 and March 2013. Patients were divided into two groups based on the amount of steroid: low dose (steroid 0-2g) or high dose (steroid>2g).

Results: A total of 123 patients belonged to low dose group and 21 patients were in high dose group. There were no differences in baseline characteristics, including age, gender, and the rates of biopsy-proven BK nephropathy and acute rejection. Serum BK viral loads at the time of steroid pulse therapy were 5.38±1.10 log copies/mL in low dose group and 6.00±0.98 in high dose group (p=0.054). They were changed into 5.22±1.05 and 6.14±1.45 in each group one month after steroid treatment (p=0.03) and 4.92±1.25 and 5.86±1.74 at two months (p=0.133), respectively. From three months to one year, BK viral loads were not different from each group. Kaplan Meier analyses demonstrated that the incidences of further 50% decline in renal function assessed by estimated GFR and graft failure were significantly higher in the high dose group (p=0.004 and p=0.04, respectively). In multivariate regression analysis, high dose steroid treatment (p=0.002, HR 6.91, 95% CI 2.25-20.99) and log serum BK viral load at two months after high dose steroid administration (p=0.027, HR 1.72, 95% CI 1.06-2.78) were important risk factors of further 50% decline in renal function.

Conclusions: In kidney transplant recipients with BK viremia, high dose steroid therapy induced BK viral activation and subsequently resulted in poor long term graft function and early graft failure.
SA-PO1063

Donor Seroreactivity Strongly Correlates with Recipient BKV-Viremia and Nephropathy
Herman F. Wunderink,1 Elsa Meijden van der,2 Caroline van der Blij-de Brouwer,1 Antoine Touze,2 Marko Mallat,3 Geert Haasnot,3 Erik Van zwaet,4 Eric Claas,1 Johan W. De Fijter,2 Aloys Kroes,1 Frans Claas,1 Joris I. Rotmans,1 Mariet Feltpink,1 1Leiden Univ Medical Center, Netherlands; 2Univ François Rabelais, France.

Background: Incidence and severity of reactivating latent infections in kidney transplant (KTx) recipients are difficult to predict. In case of BK polyomavirus (BKV) induced nephropathy, donor origin of infection is likely. Since BKV-seroreactivity reflects BKV-reactivity, we hypothesized that donor BKV-seroreactivity correlates with infectivity and predicts BKV infection of recipients.

Methods: In a retrospective cohort of 407 living donor-recipient pairs transplanted between 2003 and 2013 at LUMC, pre-KTx sera from donors and recipients were tested for presence and intensity of BKV IgG-seroreponses. Measured seroresponses were compared with recipient BKV-loads (viremia) determined post-KTxs and compared with other potential risk factors for BKV-infection.

Results: Within one year after KTx, BKV-viremia was observed in 27% of recipients. Baseline BKV-seroreprevalece among donors (96%) and recipients (95%) was high and not correlated with viremia. However, a strong association was observed between the strength of donor BKV-seroreactivity and occurrence of both viremia and PVAN (p=0.001). Baseline recipient BKV-seroreactivity as such was not associated. The hazard ratio of viremia was almost 10-fold higher in recipients of high compared to low seroreactive donors. In multivariate analysis, donor seroreactivity was the strongest baseline factor associated with viremia and nephropathy post-KTx (p=0.001), outcompeting other described risk factors.

Conclusions: The strong association between donor BKV-seropositive status and recipient BKV-infection points directly to the donated kidney as the source of BKV-induced disease and possibly reflects the BKV allograft load. Our findings warrant further research into the usefulness of BKV-serological testing prior to transplantation.

Funding: Private Foundation Support

SA-PO1064

The Role of BK Viral Subtypes in BK Viral Infection After Renal Transplantation
Anika Schwarz,1 Silvia Linnwneber-Held,2 Hermann G. Haller,1 Cornima Schmitt.2 1Nephrology, Hannover Medical School, Hannover, Germany; 2Virology, Hannover Medical School, Hannover, Germany.

Background: Risk factors for developing BK virus (BKV) infection after renal transplantation are unresolved, including the role of BKV subtypes.

Methods: We report on 146 patients with viral replication in urine tested by quantitative PCR (Cephid-Affigene Kit) before transplantation (29 donors and 11 recipients, spontaneous replication in urine) and after transplantation (106 infected recipients, routine recipient BKV testing). Genotyping of BKV DNA subtypes was performed. Patients were divided into three groups: group 1, donor BKV subtype Ib-2; group 2, donor BKV subtype Ib-3, non subtype Ib-2; group 3, patients with BKV-negative post-transplant BKV nephropathy or high viremia of >10000 copies/mL (n=32, group 1) were compared to post-transplant recipients with viremia alone or with low viremia of <10000 copies/mL (n=43, group 2) and with donors and recipients before transplantation (n=40, group 3).

Results: BKV subtype Ib-1 was seen in 14/16 (10%), subtype Ib-2 in 92/162 (63%), subtype II in 9/164 (6%), subtype III in 1/166 (2%), and subtype IV in 30/164 (21%) of all patients. Thus, subtype Ib-2 was the first and subtype IV the second in frequency of subtyping infected patients. Comparing the 3 groups (group 3), there was no stat. sign. difference in the prevalence of subtype Ib-1 (8 vs 15 % in 10%); subtype Ib-2 (60 vs 70 vs 60%); subtype II (3 vs 7 vs 10%); subtype III (2 vs 0 vs 5%); and subtype IV (27 vs 12 vs 20%). However, after transplantation, subgroup IV had a trend to be less prevalent in patients with viremia/ low viremia (group 2) compared to patients with BKV nephropathy or high viremia of >10000 copies/mL (group 1) (5/34 vs 17/60, p=0.054).

Conclusions: BKV subtype Ib-2 is the most frequent subtype in all patients of the three groups. In the situation after renal transplantation, patients being infected with BKV subtype IV could be more likely to develop BKV nephropathy or high viremia than patients being infected with other subtypes. This has to be investigated in larger patient groups.

SA-PO1065

Inflammation and Reconstitution Injury in Resolving Polyomavirus Nephropathy: Good or Bad? Insights from a Protocol Biopsy Based Prospective Study
Harsharan Kaur Singh, A. Gasim, Volker Niecleciet. Div of Nephropathology, The Univ of North Carolina, Chapel Hill, NC.

Background: Polyomavirus nephropathy (PVN) has been extensively studied at time of disease onset and in index biopsies. In contrast, little is known about acute and chronic changes occurring during PVN resolution under low dose maintenance immunosuppression. Aim: Enhance understanding of resolving PVN.

Methods: From 1/2009-9/2014 823 adult renal transplants with an 8.5% incidence of PVN (n=37) were prospectively followed at UNC. UNC PVN patients were monitored with the urinary PV-Haufen test and protocol biopsies collected 9-37 patients when the test turned from positive to negative as marker for PVN resolution. Histology in index PVN (n=9) versus post-PVN (n=12) biopsies (n=9) was compared; clinical, treatment and long-term outcome data were obtained from electronic medical records.

Results: Serum creatinine and Banff scores at time of PVN index biopsy and follow-up protocol biopsy in Table 1.

Index biopsy: 5/9 cases with PVN grade 1 and 4/9 grade 2. Treatment: reduction tacrolimus and/or MMF. Protocol biopsy (median 6 weeks post index, range: 4-60): 5/9 cases with PVN, 4/9 reduction in minimal PVN; 1/9 requiring MPGN; 3/9 acute ABMR or Banft type 2 definitive rejection. Anti-rejection therapy 6/9 cases with decrease in S-Cr in 4-6 and deterioration in 2/6; function stable in 3/9. Further 12-month follow-up: Serum creatinine 1.75 mg/dl (median), no graft losses.

Conclusions: Resolving PVN under ‘low-dose’ immunosuppression shows significant increases in Banff acute inflammation scores and S-Cr. “Bad”inflammation is in part secondary to acute rejection and responds to anti-rejection therapy. “Good” self limiting reconstitution inflammation can be postulated in 1/9 cases (10%) of resolving PVN. PVN results in only mild increases in chronic tissue injury.

SA-PO1066

Effectiveness of Simprevir and Sofosbuvir in the Treatment of Hepatitis C Virus in Genotype 1 Post-Kidney Transplant Recipients
Karolyn S. Horn,1 Michelle T. Martin,2 Ignatius Yun-Sang Tang,3 1Pharmacy Practice, Univ of Illinois at Chicago; 2Medicine, Univ of Illinois at Chicago.

Background: The 2014 American Association for the Study of Liver Diseases (AASLD) guidelines recommended the use of simprevir (SMV) + sofosbuvir (SOF) for the treatment of liver transplant recipients with genotype (GT) 1 hepatitis C virus (HCV). There is a paucity of data on the treatment of other solid organ recipients. We conducted a retrospective, single-center analysis of kidney transplant recipients (KTRs) who received HCV treatment.

Methods: All KTRs who received HCV treatment with 12 weeks of SMV + SOF between January and November 2014 were evaluated. The primary endpoint was the sustained virologic response at 12 weeks after the end of treatment (SVR12). Secondary outcomes included HCV PCR levels, serum creatinine, urine protein/creatinine ratio, trough calcineurin inhibitor (CNI) levels and dose changes, and AST to platelet ratio index (APRI) at week 4, end of treatment (EOT), and 12 weeks post-treatment.

Results: Twelve patients met inclusion criteria: mean age of 60±5.3, 11 males, 8 African American, 6 GT 1a and 6 GT 1b. There were 6 liver-kidney, 4 kidney, and 2 pancreas-kidney transplant recipients. All but 1 patient received tacrolimus as their CNI. Ten of 12 patients (83.3%) achieved SVR12. Mean tacrolimus levels increased significantly by 1.5 ng/mL between week 0 and 4 (p=0.041). Five (41.7%) required a mean tacrolimus dose decrease of 2 mg during treatment. Nine (75%) required a mean dose increase of 2 mg between EOT and SVR12. The APRI scores decreased from 0.64 to 0.17 between baseline and 12 weeks of treatment, but this is not statistically significant (p=0.216). Both serum creatinine and urine protein/creatinine ratio remained stable pre- and post-treatment (p=0.260 and p=0.373, respectively).

Conclusions: SVR12 was achieved in 83.3% of KTRs treated with SMV + SOF. Renal allograft function was stable during and after HCV therapy. Treatment with SMV + SOF increased CNI levels during treatment. CNI dose adjustment is needed to maintain therapeutic levels after SMV + SOF therapy.

SA-PO1067

25-Hydroxivitamin D Insufficiency Is Associated with Higher Risk of BK Virus Re-Activation After Kidney Transplantation

Background: The past decade has seen increased interest in vitD, because new data suggest that it plays a role in the immune system. The purpose of this study was to evaluate the association of 25-hydroxivitamin D level (25[OH]D) after kidney transplant with the risk of BK virus reactivation.

Methods: We identified 498 kidney transplant recipients (2007-2011) who had serum levels of (25[OH]D), and PTH. We evaluated the relationship between the average levels of (25[OH]D and PTH and BK reactivation in blood.

Results: VitD insufficiency (25[OH]D <30 ng/mL, defined by The Endocrine Society Clinical Practice 2011) was observed in 377 (77%) of 498 kidney recipients after transplant. The VitD insufficient and sufficient groups were comparable in terms of gender, age, BMI, race, and immunosuppression. VitD insufficiency was more frequent in recipients of cadaveric allografts (P=0.009, Fisher test). By multivariable Cox regression analysis, vitD deficiency was an independent risk factor for BKV reactivation after kidney transplantation (HR=2.4, 95% CI 1.3-4.7, P=0.002). Moreover, vitD insufficiency was associated with significantly earlier onset of significant BKV reactivation (19 compared to 16 months, P=0.003).

ROC analysis using logistic regression showed that 25[OH]D < 24ng/mL was predictive of BKV reactivation.
SA-PO1068
Different Types of Cytomegalovirus DNAemia and Long-Term Outcomes After Renal Transplantation
Tomas Reischig,1 Martin Kacer,2 Ondrej Hes,2 Daniel Lyisks,3 Mirko Bouda,1 1Internal Medicine I, Biomedical Center, Charles Univ Medical School and Teaching Hospital, Pilsen, Czech Republic; 2Pathology, Biomedical Center, Charles Univ Medical School and Teaching Hospital, Pilsen, Czech Republic; 3Hematoooncology, Biomedical Center, Charles Univ Medical School and Teaching Hospital, Pilsen, Czech Republic.

Background: Although occurring very often the role of cytomegalovirus (CMV) DNAemia in patients managed by preemptive therapy or by universal antiviral prophylaxis is not established. The aim of the study was to determine the impact of different types of CMV DNAemia during 4 years after transplantation.

Methods: A total of 180 consecutive renal transplant recipients at risk for CMV (donor and/or recipient CMV seropositive) were included and followed prospectively. Universal prophylaxis for 3 months was given to 132 (high-dose valacyclovir, n=87; valganciclovir n=45), patients were managed by preemptive therapy or by universal antiviral prophylaxis DNAemia in patients managed by preemptive therapy or by universal antiviral prophylaxis is not established. The aim of the study was to determine the impact of different types of CMV DNAemia during 4 years after transplantation.

Results: Early-onset, late-onset, and combined early+late-onset CMV DNAemia occurred in 18%, 25%, and 13% of the patients being asymptomatic in majority (91%) of cases. Graft survival at 4 years was inferior in patients with late-onset CMV DNAemia compared to patients without CMV DNAemia (73% vs. 94%, P=0.002) while no significant differences were observed in patients with early-onset (85%, P=0.139) or combined early+late-onset CMV DNAemia (96%, P=0.682). Patient survival was comparable in all groups. Multivariate analysis revealed that Diabetes (OR 2.45, 95% CI 1.08–5.55, p = 0.03), recipient age (OR 1.02, 95% CI 1.01–1.03, p = 0.01), and recipient BMI (OR 2.18, 95% CI 1.09–4.39, p = 0.029) were independently associated with CMV DNAemia.

Conclusions: Late-onset CMV DNAemia is a risk factor for graft loss after renal transplantation.

SA-PO1069
Assessment of Cytomegalovirus-Specific Cell-Mediated Immunity for the Prediction of Cytomegalovirus Spontaneous Clearance in High-Risk Kidney Transplant Recipients with Cytomegalovirus Viremia
Marine Lochouarn,1 Sylvia Benzaken,2 Laetitia Albano,1 Elisabeth Cassuto,1 Ahmed Jeribi,1 Anne Caramella,1 Valérie Giordanengo,1 Ghislaine Bernard,2 Vincent L.M. Esnault,1 Barbara Seitz-Polaski,1,2 1Nephrology and Kidney Transplantation Dept, Univ Hospital, Nice, France, Metropolitan; 2Laboratory of Immunology, Univ Hospital, Nice, France, Metropolitan.

Background: Cytomegalovirus (CMV) is the most common virus pathogen in kidney transplant recipients (KTR) and CMV disease impacts patient and graft survival. CMV-specific CD8 T cell-mediated immunity (CMI) kinetics may help to assess the risk of CMV disease and to adapt preventive treatment strategies.

Methods: High-risk KTR with CMV seropositive donor/seronegative recipient (D+R−), were longitudinally monitored after CMV prophylaxis discontinuation and during the first year post-transplant for CMV viremia (WHO standardization) and CMI (Quantiferon®-CMV). We analyzed the ability of the CMI-test to predict subsequent spontaneous viral clearance in case of asymptomatic viremia after prophylaxis discontinuation or CMV disease recurrence after curative treatment.

Results: We enrolled 12 consecutive (D+R−) KTR. Eleven patients developed viremia during follow-up. Spontaneous viral clearance occurred in 7 of 11 (63.6%) patients and 4 of 11 (36.4%) developed CMV disease. At viremia onset, 6 of 11 (54.5%) patients had a positive CMI-test. In those patients, the incidence of subsequent spontaneous viral clearance was 6 of 6 (100%) compared with only 1 of 5 (20%) among patients displaying a nonreactive CMI (p = 0.02). This latter patient revealed a positive CMI-test one month later. In the 4 patients who developed CMV disease, persistence of a nonreactive CMI after treatment in one patient was associated with disease recurrence, while patients whose CMI-test became positive under treatment showed no recurrence.

Conclusions: We show for the first time that D+R− KTR with asymptomatic viremia attested by WHO standardized CMV viral load monitoring after prophylaxis discontinuation may benefit from Quantiferon®-CMV to predict spontaneous viral clearance or CMV disease.

Prevalence of Double Stranded DNA (dsDNA) Viral Infections Among Kidney Transplant Recipients
Essy Mozaffari,1 Jay Lin,2 Melissa Lingoi-Smith,2 1Chimerix Inc., Mendham, NJ; 2Novosys Health, Green Brook, NJ.

Background: Management of immunosuppression following solid organ transplant is a delicate balance between preventing graft rejection and minimizing the risk of infection. Antimicrobial prophylaxis can decrease the risk of infection, while increased immunosuppression can increase these same risks. Our objective was to estimate the occurrence of opportunistic infections, specifically dsDNA viral infections, in kidney transplant recipients.

Methods: Patients who received a kidney transplant between January 2009 and September 2013 were identified from the Premier Hospital database using ICD-9-CM codes. The first transplant procedure was defined as the index event. The frequencies of opportunistic infections, documented by diagnostic codes, were evaluated during the first 12 months after kidney transplant.

Results: Of patients who received kidney transplant (n=5,402; mean age: 50.8 years) 61% were male. Most patients received transplant in urban (98%), large (≥600 beds; 61%), teaching hospitals (84%). During the 12 months post kidney transplant, 33% (1,800 patients) had a diagnostic code for 1 opportunity opportunistic infection, and among these 25% (n=448) had at least one dsDNA viral infection. Among the 448 dsDNA viral infections, 81% (n=365) were cytomegalovirus (CMV), 8% (n=36) BK virus, and 16% (n=70) other dsDNA viral infections (EBV, VZV, HHV, HPV, EVB).

Conclusions: Opportunistic infections frequently result from the immunosuppression required following kidney transplantation. In our study, one-third of the kidney transplant recipients had a discharge diagnosis for at least one opportunistic infection. One of four opportunistic infections were classified as dsDNA viral infections, with the majority caused by human herpesviruses including CMV despite the common use of anti-CMV agents. Our study also highlights the role of BKV-related complications, which represent an unmet need given the absence of therapeutic options for this dsDNA virus and the known association with BK-associated nephropathy.

Funding: Pharmaceutical Company Support - Chimerix Inc.
In 301 transplant recipients, the most common infections (N=255) were UTIs (61%) and pneumonia (9%). 74 kidney transplant recipients received antibiotics during the first month of transplantation (Early Abx Group) and 227 did not (No Early Abx Group). The Early Abx Group had a significantly higher number of infections during post-transplant months 2-12 than the No Early Abx Group (1.2±0.2 vs. 0.3±0.1, P=0.001, Wilcoxon rank-sum test). Within the Early Abx Group, subjects who received anarobic coverage had a significantly higher number of infections during post-transplant months 2-12 than subjects who did not (1.8±0.5 vs. 0.9±0.2, P=0.050).

Conclusions: Early antibiotic usage was associated with increased future bacterial infections in kidney transplant recipients. A decrease in gut microbiol diversity is a biologically plausible pathogenic mechanism.

SA-PO1072

Successful Treatment of Hepatitis C in Renal Transplant Recipients with Directly Acting Antiviral Agents
Michelle L. Lubetzkzy, Enver Akalin, Paul Gaglio, Graciela De Boccoardo. Transplantation, Montefiore Medical Center, Bronx, NY.

Background: Hepatitis C infection (HCV) in kidney transplant (KTx) recipients has been shown to be an independent risk factor for decreased patient and allograft survival. Historically treatment of HCV has been interferon-alpha based, which is associated with acute rejection in KTx patients. With the development of new, oral, interferon-free directly acting antiviral (DAA) medications, treatment of HCV in renal transplant recipients is possible, but limited data exists on its safety and efficacy.

Methods: We performed a retrospective review of all KTx patients at our center with HCV started on DAA for treatment of HCV. Any patient with at least 30 days of follow up was included in the analysis (n=10). Clinical data including graft function, survival, and response to therapy was collected.

Results: Patient demographics are in Table 1. At a median of 92 days of follow up (range 33, 438), all patients have undetectable viral load. Median time from KTx to treatment was 781 days (range 173,1040). At most recent follow up, mean creatinine was 1.48±0.51 mg/dl and mean proteinuria was 0.47±1.07 g/day with no adverse side effects reported. No patients have lost their grafts or developed acute rejection, but 2 patients had detectable CMV. For the 8 patients on tacrolimus (Tac), there was a drop in 12-hr trough level during therapy (mean 6.3±2.1 ng/ml pre-treatment, and mean of 4.9±2.1 ng/ml after 6 weeks of treatment); during treatment 3 patients had a level <4 ng/ml. All patients with level <4 ng/ml had dose increase and repeat level was in normal range.

Conclusions: Our data demonstrates that DAA's can be used safely and effectively in patients after KTxs. Tac levels should be monitored closely during therapy. Longer follow up of KTxs treated for HCV is needed to determine the effects treatment has on graft and patient survival.

SA-PO1073

A Systematic Review and Meta-Analysis of Cytomegalovirus Infection in Renal Transplant Recipients Receiving Alemtuzumab versus Anti-Thymocyte Globulin for Induction Therapy
Payvand Milani, Nasrollah Ghafarimani. Medicine, Pennsylvania State Univ College of Medicine, Hershey, PA.

Background: Use of antibody induction for kidney transplant has improved patient outcomes over the past decade. One common induction agent is rabbit anti-thymocyte globulin (ATG), a polyclonal anti-human T-cell antibody. Alemtuzumab, a monoclonal anti-CD52 antibody with stronger lympho-depleting properties, has been used as an induction agent in steroid-sparing or steroid-minimizing protocols. Like all immunosuppressive agents, these agents are associated with opportunistic infections, including cytomegalovirus (CMV). Our aim was to compare the relative risk of CMV infection between the two induction regimens.

Methods: We used five comprehensive search themes (CMV, ATG, alemtuzumab, transplant, and induction) to search electronic databases from 1980 to 2014 using PubMed and The Cochrane Library while also manually reviewing recent abstracts from the American Society of Nephrology and the American Transplant Congress meetings. Studies reporting the number of cases of CMV infection in patients receiving one of the two agents were included. The outcome was the pooled relative risk (RR) of CMV infection in the alemtuzumab group compared to that in the ATG group.

Results: A total of 73 studies were identified and reviewed, 64 of which were excluded upon initial screening. Analysis of the 9 studies (8 complete articles and 1 abstract; 1,735 patients) showed a RR of 0.58 (95% CI: 0.31-1.07) for incidence of CMV infection in patients receiving alemtuzumab versus ATG. Other reported adverse effects in both induction groups (infections, post-transplant lymphoproliferative disorder (PTLD) and/or malignancy, decrease in estimated glomerular filtration rate , and post-transplant diabetes mellitus) were similar in both groups.

Conclusions: This study suggests that for induction therapy in kidney transplant, the incidence of CMV infection associated with alemtuzumab is not significantly different than that associated with ATG.

SA-PO1074

Occurrence and Determinants of Antibiotic Resistance in Bacteriuria After Kidney Transplantation

Background: Asymptomatic bacteriuria is often treated after kidney transplantation, which can result in the development of antibiotic resistance. Our aim was to assess the antibiotic resistance profile of gram-negative bacteria in our kidney transplant population, and to determine the factors associated with antibiotic resistance.

Methods: We performed a single center, retrospective cohort study in patients who received a kidney allograft at our center between January 1st, 2008 and June 1st, 2013. Through chart review, information on all bacteriuric episodes involving gram negative bacilli was collected during follow-up, which ended on June 1st, 2014. Bacteriuria was defined as growth exceeding 10^3 CFU/ml. Multivariable logistic regression using a generalized estimating equation (GEE) procedure was performed to identify the factors associated with resistance to antibiotics.

Results: Amongst the 318 patients studied, 629 bacteriuric episodes involving gram negative bacilli occurred in 143 patients. Resistance to TMP-SMX occurred in 336 episodes (53%), resistance to ciprofloxacin in 142 episodes (23%) and extended beta-lactamase production occurred in 30 episodes (5%). An increased risk of resistance to ciprofloxacin and/or extended spectrum beta lactamase production was statistically associated with the number of previous treatments (odds ratio (OR):2.29, 95%confidence interval (CI ):1.16-4.52), and ≥5 previous treatments (odds ratio (OR):2.99, 95%confidence interval (CI ):1.16-4.52), and ≥5 previous treatments (OR:3.5, 95%CI:1.28-7.26), diabetes (OR:2.57, 95%CI:1.01-6.55), and/or extended spectrum beta lactamase production (OR:0.8, 95%CI:0.16-4.51) and a longer time elapsed between bacteriuria and transplantation (OR:0.32, 95%CI:0.15-0.66, for episodes supervening >1 year post transplant versus ≤ 1 year).

Conclusions: Elevated resistance rates to TMP-SMX and ciprofloxacin were observed in our kidney transplant population, which can reduce the usefulness of prophylaxis with TMP-SMX. Arf against treating asymptomatic bacteriuria, given the association we observed between the number of previous treatment of bacteriuric episodes and resistance to ciprofloxacin/ESBL production.

Carbenepem-Sparing Antibiotic Regimens for the Treatment of Extended-Spectrum Beta-Lactamase Producing Enterobacteriaceae Infections: A Comparative Study
Tiffany Ebony Buss, Gregory Malat, PharmD, Akshay Sharma, Doug Heun Lee, Alden Michael Doyle. Pharmacy, Hahnemann Univ Hospital, Philadelphia, PA; Surgery, Drexel Univ, College of Medicine, Philadelphia, PA; Infectious Diseases and HIV Medicine, Drexel Univ, College of Medicine, Philadelphia, PA.

Background: Extended spectrum beta lactamase producing Enterobacteriaceae (ESBL-PE) has been recognized as a significant cause of mortality in solid organ transplant recipients. Carbapenems are considered the drug of choice for the treatment of ESBL-PE infections. However, antibiotic selective pressure associated with carbapenem use may
contribute to resistance, further stressing hospital epidemiology. Our study sought to compare the effectiveness of carbapenem sparing regimens to carbapenem containing regimens on clinical outcomes in transplant patients with ESBL-PE infections.

Methods: A retrospective, observational cohort study was conducted to evaluate adult patients who underwent a successful kidney transplant (defined as graft survival >30 days) prior to August 2014 with ESBL-PE infection post-transplant. Patients were stratified into 2 cohorts according to antibiotic regimens: carbapenem-containing and carbapenem-sparing. The outcomes of clinical cure, 30-day mortality, and recurrence were assessed.

Results: Fifty-two kidney transplant patients were included in our analysis: 29 in the carbapenem-sparing group and 23 in the carbapenem-containing group. Majority of infections were caused by Escherichia coli (46%) and Klebsiella pneumoniae (44%). The most common infection type was urinary tract infections (46%) followed by bloodstream infections (23%) and nosocomial pneumonias (15%). There was no statistically significant difference in clinical cure rates (91% vs. 76%, p=0.268) and 30-day mortality (24% vs. 9%, p=0.268) in the carbapenem-sparing and carbapenem-containing groups respectively.

Conclusions: ESBL-PE infections pose a serious threat to transplant recipients. Carbapenem sparing regimens may be adequate for the treatment of ESBL-PE infections, while offering advantages against minimizing selective pressure.

SA-PO1076

Clinical Recurrence of Primary Glomerular Disease in Kidney Transplantation

Enrique Pampena, Ana M. Fernandez Rodriguez, Sara Jimenez Alvaro, Fernando Caravaca-Fontan, Estefania Yerovi, Maria Delgado Yagüe, Maite Rivera, Cristina Galeano, Sandra Elías, Fernando Liano.
Nephrology, Hospital Ramón y Cajal. UAH. Madrid.

Background: Recurrence of primary glomerular disease (PGN) in renal transplantation (RT) is a major cause of failure and renal allograft lost which determines the prognosis of the patient.

Methods: We conducted a retrospective analysis of 1513 renal transplants between January 1980 and December 2013, included in our database, medical records and biopsy register, collecting all patients who presented recurrence of PGN. We excluded from the study patients with secondary GN and those without biopsy study. Renal biopsy was indicated according the following criteria: impairment of renal function, proteinuria>1g/day and/or microhematuria. The analysis statistic was SPSS version 18.

Results: 414 of 1513 RT (27%) had chronic GN as underlying disease. 317 patients (260 man;57 woman) were primary GN (21%). The most frequent primary GN was IgA nephropathy (IgAGN) n=122,(38,4%), Membranoproiferative GN (MPGN), n=90(28,6%); Focal segmental GN(FSGS), n=58(15,1%); membranous GN(MGN), n= 33(10,4 %) and rapidly progressive GN (RPGN), n=14(4,4%). Forty(12,6%) patients with primary GN recurred. IgA GN (5%), FSGS (20%), MPGN (17%), MNGN (12%) and GRNP (12%). Three MPGN patients recurred in the second RT. The mean time of recurrence was: 48.18, 33.2, 18 and 33.2 months respectively Patients with graft loss due to GN recurrence were: IgAGN (n=10,75%), MPGN (n=14,93%), FSGS(n=10,75%), MNGN(n=3,70%). No significant difference was observed between GN types(p=0.15) and graft survival. In the Kaplan Meier analysis and COX test, recurrence primary GN had low survival at 10 years (p: 0.002).

Conclusions: Clinical Recurrence of primary GN is an important cause of graft loss. GN with most recurrent was GSF and graft lost was MPGN. We didn’t observe differences in graft survival between type of primary glomerular disease. Graft survival was higher in the group without recurrence at 10 years and no differences at 20 years.

SA-PO1077

Glomerular Diseases following Predisnilone Free Transplant with Low Dose Rituximab and ATG Induction and Protocol Biopsies

Vivek Pathak, Nephrology, Kovai Medical Center and Hospital, Coimbatore, Tamil-Nadu, India.

Background: The purpose of this study is to document the incidence of post transplant glomerulonephritis in a steroid free protocol and other recurrent renal diseases leading to graft loss.

Methods: 883 patients, who underwent renal transplantation at our institute in nine years and eight months since July 2005 till March 2015 were studied. Thymoglobin was used for induction at a dose of 1.5mg/kg. 3 doses rituximab 200 mg was given before transplant to those patients who were considered to be at high risk for rejection. Maintenance immunosuppression was Tacrolimus and Mycophenolate mofetil. Prednisolone was rapidly discontinued by fifth post operative day. All patients underwent protocol biopsies at 3 months ,1 year and 5 years and indicated biopsies whenever required. The total number of biopsies was 2928. Discussion Our results show only 1% graft loss due to cumulative recurrent Glomerulonephritis at nearly 10 years. Our figures could be low due to Thymoglobin induction therapy. We could prevent graft loss due to recurrent FSGS by achieving complete or partial remission by using Rituximab in 15/19(79%) patients.

SA-PO1078

Post-Transplant Focal Segmental Glomerulosclerosis Recurrence Among Patients with Native Kidney Collapsing Variant: A Single-Center Retrospective Cohort Study

Panupong Hansrivijit,1,2 Katherine D. Westreich,1 Jonathan Alexander Miles,1 Evan Zeitlet,1 Maria E. Ferris,1 Randall K. Detwiler.1 
1University of North Carolina, Chapel Hill, NC; 2Chulalongkorn Univ, Bangkok, Thailand.

Background: Focal segmental glomerulosclerosis (FSGS) is one of the most common causes of end-stage kidney disease (ESKD), and is known to recur in renal transplant grafts. The collapsing variant of FSGS(CvFSGS) is clinically distinct from other variants: it has a stronger association with African-American race, more severe proteinuria, and rapid progression to ESKD. The impact of native FSGS subtype on post-transplant FSGS recurrence rate and subtype is not known.

Methods: Clinical and pathological records were reviewed for renal transplant recipients at UNC between 2000 and 2014 with FSGS as the cause of ESKD. Native FSGS subtype was dichotomized into CvFSGS and FSGS-Other. Baseline demographics (sex, age, race), and rates and subtypes of post-transplant FSGS recurrence were compared between the two groups.

Results: Of 879 patients reviewed, FSGS was the cause of ESKD in 101. Among this subgroup, mean age at time of transplant was 45±17 years; 62% male; 50% non-Hispanic black, 45% non-Hispanic white, and 5% Hispanic. Ten patients (10%) had CvFSGS as the native lesion. Over a mean follow-up time of 2.4 years, the overall rate of recurrent FSGS was 34%. Compared to those with native FSGS-Other, patients with native CvFSGS had a higher rate of post-transplant FSGS of any type (30% vs 31%, RR 1.6), and were also more likely to have collapsing variant as the recurrent lesion (60% vs 11%, RR 5.5).

Conclusions: In a population of predominantly black and Hispanic patients in the Southeastern US, native CvFSGS predicts a 60% higher post-transplant FSGS recurrence rate, and the recurrent lesion is likely to be CvFSGS. However, 11% of patients with native FSGS-Other developed de novo CvFSGS post-transplant. Further study of this cohort will determine the predictive power of native and recurrent CvFSGS with regard to clinical outcomes.

SA-PO1079

Pre-Transplant Rituximab in Recurrent Focal Segmental Glomerulosclerosis

John Manolo,1 Dany Matar,1 Sami Alasfar,1 Jochen Reiser,2 Nada Alachkar.1 
1Johns Hopkins Univ; 2Rush Univ.

Background: Focal segmental glomerulosclerosis (FSGS) recurs in 30-40% of patients after kidney transplant (Tx). Rituximab was suggested to have cross-reactivity with podocyte sphingomyelin-phosphodiesterase-acid-like-3b (SMPLD-3b), which was found to have cross-reactivity with podocyte sphingomyelin-phosphodiesterase-acid-like-3b (SMPLD-3b), which was found to have cross-reactivity with podocyte sphingomyelin-phosphodiesterase-acid-like-3b (SMPLD-3b).
to be reduced in post perfusion biopsies of kidney Tx recipients who later on developed recurrent (rFSGS). However, the use of rituximab to prevent rFSGS remains controversial.

Methods: We enrolled 56 adult patients, 50 with biopsy proven FSGS and 6 with a pre-Tx course highly suggestive of FSGS. Patients underwent kidney transplant between 2008-2014. We compared FSGS recurrence and allograft survival between recipients who received rituximab and those who did not.

Results: Mean time of follow-up was 28.6 months. 24 patients received rituximab (mean 9.4 ± 9.1 yrs) after a diagnosis of FSGS. 22 patients did not receive rituximab (mean 9.1 ± 9.4 yrs). The mean and standard deviation (SD) of eGFR at the most recent follow-up in the patients who received rituximab was 42.2 ±88 versus 39.2 ±1 L/min/1.73m² in those who did not receive it, respectively (p=0.047). A higher percentage of patients who received rituximab had a renal function maintenance that could be removed or diminished by plasmapheresis (PP). In this study, we assessed the efficacy of PP in prevention and treatment of post-Tx rFSGS.

Methods: We prospectively enrolled 56 Tx-patients with biopsy proven FSGS (50) or other causes of TMA (6). Patients were transplanted between 2008-2014. We compared between the preventive and non-preventive PP groups.

Results: Mean time of follow-up was 28 months. Differences between the 2 groups are as following:

<table>
<thead>
<tr>
<th>Preventive PP(n=26)</th>
<th>No PP(n=30)</th>
<th>P-value</th>
</tr>

rFSGS developed in 35 patients (62%); of whom preventive PP was performed in 19. Out of the 21 cases that did not develop FSGS, 7 received PP (P=0.1). Patients who received preventive PP had a shorter time from FSGS diagnosis to ESRD compared to those who did not (6.1±8.6 yr vs 10.1±9.1 yr (p 0.047)). 33 out of the 35 patients (95%) with rFSGS received therapeutic PP, and 24 also received anti-CD20 therapy. Only 5(15%) did not respond; 2 lost their grafts. Of the 28 who responded, 14 (50%) subsequently relapsed. 71% of the relapses responded to a second course of PP; only 4 lost their grafts. Kaplan-Meier allograft survival in both groups is shown in figure 1.

Role of Plasmapheresis in Post-Transplant Focal Segmental Glomerulosclerosis

Samii Alasfar,1 Dany Matar,2 John Manollo,3 Jochen Reiser,4 Nadia Alachkar,5 1Johns Hopkins Univ, Baltimore, MD; 2McKinsey & Company, Washington, DC; 3Rush Univ, Chicago, IL.

Background: Focal segmental glomerulosclerosis (FSGS) commonly recurs after kidney transplant (Tx). This is attributed to the presence of a circulating permeability factor that may be removed or diminished by plasmapheresis (PP). In this study, we assessed the efficacy of PP in prevention and treatment of post-Tx rFSGS.

Methods: We prospectively enrolled 56 Tx-patients with biopsy proven FSGS (50) or other causes of TMA (6). Patients were transplanted between 2008-2014. We compared between the preventive and non-preventive PP groups.

Results: Mean time of follow-up was 28 months. Differences between the 2 groups are as following:

Conclusions: Preventive PP does not reduce the incidence or delay the development of rFSGS. However, PP remains an effective therapy for post-transplant FSGS.

SA-PO1081

Post-Transplant Thrombotic Microangiopathy: A Single Center Experience

Cinzia Montenegro Teixeira,1 Igor Goulart-Pistrobon,2 Andre Caires Alvim,1 Gianna Mastroianni-kirsztajn,2 Laila Almeida Viana,1 J. Medina-Pestana,1,2 Helio Tedesco Silva,1,2 1Hospital do Rim- Fundação Oswaldo Ramos, Sao Paulo, Brazil; 2Univ Federal de Sao Paulo, Sao Paulo, Brazil.

Background: Thrombotic microangiopathy (TMA) occurs in 1-15% of kidney transplant allografts and predicts poor outcomes.

Methods: We reviewed 35 cases of TMA in the kidney allograft diagnosed at our institution between 2011-2015.

Results: The mean age was 39±14 years with 18 (51%) women. Three (9%) patients were recipients of simultaneous pancreas-kidney transplant. Among the recipients of kidney transplant alone, 21 (66%) received deceased donor grafts. The cause of end stage renal disease was unknown (37%), chronic glomerulonephritis (31%), obstructive uropathy (11%), diabetes (9%), hemolytic uremic syndrome (3%) or others (9%). Induction with thymoglobulin or basiliximab was performed in 24 (63%) patients. Maintenance immunosuppression was prednisone (PRED), tacrolimus (TAC), and azathioprine in 15 (43%), PRED, TAC and mycophenolate sodium in 12 (37%) and PRED, TAC and everolimus in 3 (9%) patients. Patients were diagnosed with TMA at a median of 71 days (range: 1-1645) from transplant, wherein 37% patients developed TMA within 1 month of transplantation and 31% after 1 year. Mean serum creatinine was 4.5±3.3 mg/dL and 13 (41%) patients needed renal replacement therapy after TMA diagnosis. TMA was renal-limited in 23 (66%) patients. Concomitant acute rejection was present in 12 (34%) patients and cellular rejection was the most common (92%) type of rejection related to TMA. Cytomegalovirus infection occurred in 5 (14%) and other infections were present in 19 (54%) patients. Following diagnosis of TMA, calcineurin inhibitor (CNI) withdrawal was performed in 22 (66%) patients. Withdrawal of CNI and treatment of concomitant rejections and infections contribute to renal function maintenance.

Outcome After Eculizumab Therapy to Prevent Recurrence of Atypical Hemolytic Uremic Syndrome: Experience in Eleven Renal Transplant Recipients

Christophe M. Legendre,1,2 Veronique Fremeaux-bacchi,1,2 Anne Scemla,1 Julien Zuber,1,2 Christophe M. Legendre,1,2 Rebecca Sbero-Soussan,1 1Dept of Renal Transplantation, Assistance Publique-Hôpitaux de Paris, Hôpital Necker, Paris, France; 2Medicine Faculty, Paris Descartes Univ, Paris, France; 3Dept of Immunology, Assistance Publique-Hôpitaux de Paris, Hôpital Georges Pompidou, Paris, France.

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare disease with a high recurrence rate after kidney transplantation. aHUS is associated with histological lesions of thrombotic microangiopathy (TMA) that mainly leads to graft loss. The successful use of Eculizumab (Ecu) to prevent or to treat post-transplantation aHUS recurrence has been scarcely reported. In this study, we describe 11 patients who received a renal transplantation for aHUS and who were treated by Ecu after renal transplantation.

Methods: Eleven renal transplants recipients, with aHUS on their native kidney, received Ecu at our center between 2010 and 2015. Nine patients received prophylactic
of IgAN. Further analysis is needed to determine risk factors for rIgAN and to establish
urinary protein (0.57 ± 1.29, 0.07 ± 1.14 ng/mL in the control groups (p=0.75) and 8.95 ± 2.03 ng/mL in the
cancer and 8.96 ± 1.04 ng/mL in the control groups (p=0.97). By multiple logistic regression, only smoking status was associated with cancer. The time-averaged tacrolimus level at time of cancer diagnosis was not significantly associated with cancer after adjustment for this variable (Hazard ratio=1.08 per ng/mL, 95% confidence interval 0.97 to 1.5, p=0.65).

Conclusions: The development of de novo nonskin cancer after kidney transplantation was not associated with the level of tacrolimus exposure over time. Transplantation: Clinical and Translational - V

Renal Cell Carcinoma Post Renal Transplant: The Case for Post-Transplant Ultrasonad Surveillance

William M. Bennett, Alison M. Garre, Thomas D. Batiuk, Kevin M. Mccvoy, Erica Simonich. Legacy Transplant Services, Legacy Good Samaritan Medical Center, Portland, OR.

Background: Following successful renal transplantation, there is an increased relative risk of renal cell carcinoma in retained native kidneys. Stimulated by a case of widespread metastatic cancer nine months after transplant with a normal pre-transplant ultrasonad, we began routine 6-12 month post-transplant surveillance on all recipients except those with known or dominant non-malignant renal disease.

Methods: 128 consecutive patients were entered into the study. At 6-12 months post-transplant.
Results: 16 suspicious masses were detected (12.5%). Of these only 9 had evidence of an oncologic disease (ACD) (four or more cysts) pre-transplant. The remainder had normal pre-transplant scans showing only small contracted kidneys or less than the required number of cysts to make a diagnosis of acquired cystic disease. We are following 14 of these patients with scans every 6-12 months to detect growth in newly discovered, less than 1 cm solid lesions. We have found 2 patients in which frank renal cell cancers were discovered. We have now adopted an annual screening process for all post-transplant patients at their one-year post-transplant visit.

Conclusions: Routine screening of native kidneys post-transplant appears critical to detect renal cell carcinoma at a stage early enough to achieve a cure by nephrectomy.

SA-PO1088
Non-Melanoma Skin Cancer Mortality in Kidney Transplant Recipients
Michael Thomas Burks,1 Annie-Claire Nadeau-Fredette,1 Carmel M. Hawley,1 Elaine M. Pascoe,1 Stephen P. McDonald,1 Sunil V. Badve,1 David W. Johnson,1 Andrew Green,2 Robert Peter Carroll,1 Nicole Isbel,1 1Dept of Renal Medicine, The Univ of Queensland, Princess Alexandra Hospital, Brisbane; 2Central Northern Adelaide Renal Transplantation & Renal Services, Adelaide; 1Cancer and Population Studies Group, Queensland Inst of Medical Research, Brisbane; 2School of Medicine, The Univ of Queensland, Brisbane.

Background: Non-melanoma skin cancer (NMSC) frequently occurs in kidney transplant recipients (KTRs). However, the frequency of, and risk factors for NMSC mortality in KTRs are poorly characterised.

Methods: Aims: To determine the proportion and predictors of fatal NMSC in KTRs. This cohort study included all KTRs transplanted in Australia and New Zealand between 1980 and 2013, using Australia and New Zealand Dialysis and Transplant Registry (ANZDATA) Registry data. A multivariable competing-risk survival analysis was used to calculate risk factors for fatal NMSC in KTRs.

Results: During the study, 21875 transplant episodes occurred in 19344 patients. Of the 6780 patients who subsequently died, 231 (3.4%) died from NMSC. Of these, 172 (74%) were male, 226 (98%) were Caucasian, 219 (95%) were first graft recipients and 213 (92%) were male, 226 (98%) were Caucasian, 219 (95%) were first graft recipients and 213 (92%) were male, 226 (98%) were Caucasian, 219 (95%) were first graft recipients and 213 (92%).

Conclusions: Screening for NMSC likely leads to survival benefit, but more research is needed to identify risk factors and to optimise screening protocols.

SA-PO1089
NFAT-Regulated Gene Expression in Patients Developing Non-Melanoma Skin Cancer
Claudia Sommerer,1 Thomas Giese,1 Janina Brocke,1 Stefan Meuer,1 Martin G. Zeier,1 1Nephrology, Univ Hospital, Heidelberg, Germany; 2Immunology, Univ Hospital, Heidelberg, Germany.

Background: After transplantation the risk of non-melanoma skin cancer (NMSC) is significantly increased. Immunosuppression with calcineurin-inhibitors (CNIs) is associated with the development of NMSC. Association to the individual immunosuppressive loads of CNIs assessed by residual NFAT-regulated gene expression was investigated in renal allograft recipients.

Methods: Renal allograft recipients from the Department of Nephrology, University Hospital Heidelberg, Germany, were included. All patients had a regular annual skin examination. Residual expression of NFAT-regulated genes (IL-2, IFNγ, GM-CSF) in PMA/ionomycin-stimulated peripheral blood was measured by quantitative real-time PCR at predose and 2h after Ciclosporin A (CsA) intake.

Results: 258 renal allograft recipients were enrolled (160 male, age 51±14y). Of these patients 75 allograft recipients developed NMSCs after renal transplantation (29.1%). The following NMSCs were histologically confirmed: 36 basal cell carcinoma, 34 squamous cell carcinoma, 33 actinic keratosis, 27 Bowen disease, 8 kerato-acanthoma. As risk factors to develop NMSC were identified: age 60 years, skin type ( Fitzpatrick 1 and 2), and load of immunosuppression. NFAT-regulated gene expression was significantly lower in patients who developed NMSCs compared to patients without NMSCs (8.3±6.5 vs. 12.7±12.8, p=0.001). Squamous cell carcinoma and actinic keratosis were significantly associated with a high inhibition of IL-2 and IFNγ. Patients with basal cell carcinoma and Bowen disease showed a general low expression of NFAT-regulated gene expression. However, in patients with kerato-acanthoma no significant inhibition of NFAT-regulated gene expression could be detected.

Conclusions: The immunosuppressive load contributed to the risk of NMSC. NFAT-regulated gene expression was significantly inhibited in patients developing NMSCs. Monitoring of NFAT-regulated gene expression in CNI treated transplant recipients provides an individual profile of response to CNIs and is a useful tool for an individual immunosuppression with respect to safety and toxicity.
PUB001 Role of Toll-Like Receptors in Aristolochic Acid Nephrotoxicity

Gem Batuman,1 Altaf-M Khan,1 Madlin Alzoubi,2 Vecchi Batuman.1,2 1 Department of Medicine, Section of Nephrology & Hypertension, Tulane Univ School of Medicine, New Orleans, LA; 2 Department of Veterans Affairs, SLVHCS, New Orleans, LA.

Background: Studies demonstrated that aristolochic acid (AA) is toxic to renal tubular epithelium and carcinogenic to urethral epithelium. Although the exact extent of AA nephropathy (AAN) is unknown, case series have been reported in throughout the world and it has been implicated in the etiology of Balkan endemic nephritis (BEN) suggesting that this is a global health problem. The precise mechanisms of AA nephrotoxicity are not known. We investigated the role of Toll-like receptors (TLRs) in the pathophysiology of AAN using human renal proximal tubule epithelial cells (RPTEC’s).

Methods: Confluent RPTECs were exposed to AA (50 µM – 480 µM) for 24 – 48 hr and cytotoxicity was measured using lactate dehydrogenase (LDH) assay. RNA and protein were isolated from AA-exposed and unexposed RPTECs. Real time RT-PCR was performed for various gene primers to evaluate the role of innate immunity in AAN development.

Results: At 240 µM after 48 hr exposure, AA induced significant cytotoxicity in RPTECs as measured by LDH release in the culture medium and significant cell injury was observed morphologically. AA significantly increased mRNA expression of acute kidney injury (AKI) biomarker neutrophil gelatinase-associated lipocalin (NGAL), but at the same time significantly decreased the expression of another AKI biomarker kidney injury molecule 1 (KIM-1). AA also significantly upregulated the expression of prominent AKI-related TLRs (TLR2, TLR4 and TLR6) and their adaptor molecules (MyD88 and TICAM-1) followed by the activation of pro-inflammatory cytokines (IL-6 and TNF-α) and the tumor suppressor protein and a biomarker for apoptosis, p53, in the down-stream signaling pathways of TLRs. AA also significantly upregulated expression of multi drug resistant family gene MDR1 in RPTECs.

Conclusions: AA is toxic to RPTECs and restricts cell growth. NGAL but not KIM-1 could be a diagnostic biomarker for AAN. AKI prominent TLR2 and TLR4 could be potential candidates for therapeutic target in developing new strategies for AAN and BEN treatment.

PUB002 A Case of Severe Symptomatic Iatrogenic Hypermagnesemia

Rohan V Mehta,1 Vandana Niyyar,1 Rahul Mehta.2 1 Renal Medicine, Emory, Atlanta, GA; 2 Hospital Medicine, UVA, Charlottesville, VA.

Background: Hypermagnesemia is an uncommon but a potentially life threatening condition. Symptoms may develop in patients with acute kidney injury (AKI) or chronic kidney disease with the administration of pharmacologic dose of magnesium (Mg), and with use of oral laxatives or magnesium containing enemas.

Methods: A 30-year-old African American man with baseline Cr of 1, admitted for management of multiple fractures, sub adrenal hemorrhage and traumatic brain injury sustained in a motor vehicle accident, suddenly became hypotensive and developed AKI. UOP declined from 2-3 ml/day on admission to 700 ml over the next 24 hours. He became areflexic and developed ARDS, with increasing FiO2 requirements. Repeat laboratory data showed Cr 3.9, hemoglobin 6.9 and Mg 9.5 mg/dl. Review of his chart revealed he had received a total of 8.75g of magnesium citrate through enemas on the previous day. Aggressive resuscitation was started, including IV calcium, but he continued to require multiple pressors. Hypermagnesemia was presumed to be the cause of his ongoing hemodynamic instability. Intermittent hemodialysis was initiated for 2 hours to rapidly remove magnesium and he was then switched to CVVHD for continuous magnesium removal. Within 12 hours of RRT, pressor requirements decreased, UOP improved to 50-60 ml/hr and Mg levels ranged between 2-3 mg/dl. CVVHD was discontinued after 72 hrs and the patient had complete renal recovery to his baseline Cr of 1.

Results: Severe symptomatic hypermagnesemia can develop even with small doses of Mg containing laxatives. It prevents presynaptic acetylcholine release resulting in blockade of neuromuscular transmission. Clinical features of Mg toxicity range from delayed deep tendon reflexes, flaccid paralysis, respiratory failure, to hypotension, bradycardia, complete heart block and cardiac arrest. Management includes rapid supportive measures, fluids, IV calcium, loop diuretics. Urgent hemodialysis can rapidly reverse shock and respiratory failure preventing significant morbidity and mortality.

Conclusions: In summary, we report a case of severe hypermagnesemia, in the setting of AKI, presenting with shock and respiratory failure, requiring RRT.

PUB003 Ischemic and Non-Ischemic Acute Kidney Injury Cause Gut Damage

Tao Jiang Li, Chen Yu. Nephrology Dept, Shanghai Tongji Univ, Tongji Hospital, Shanghai, China; Nephrology Dept, Shanghai Tongji Univ, Tongji Hospital, Shanghai, China.

Background: Chronic uremia induced gut injury has been well documented in a number of studies. However, remote effects of acute kidney injury(AKI) on the intestine are far less investigated. Here we studied whether the gut also suffers damage during inducing of renal ischemia–reperfusion in rats and compared this to bilateral nephrectomy.

Methods: To test our hypothesis, six groups of SD rats (n=6 in each group) were studied: 1) sham operation for 6h; 2) ischemic AKI for 6h (60 min of renal pedicle clamping and then reperfusion for 6h); 3) bilateral nephrectomy for 6h; 4) sham operation for 24h; 5) ischemic AKI for 24h/60 min of renal pedicle clamping and then reperfusion for 24h; 6) bilateral nephrectomy for 24h. Ilium and blood were collected. The damage of gut mucosa was assessed by histological staining. Malondialdehyde(MDA) and apoptosis of the ileum were measured to determine the underlying mechanism of the AKI-induced gut injury.

Results: We found histological evidence of ileum injury following both ischemia and bilateral nephrectomy. MDA, an index of lipid peroxidation, increased in both the renal ischemia and nephrectomy groups, suggesting activation of oxidative stress. Ileum apoptosis, which was quantified by histone-associated DNA fragmentation enzyme-linked immunosorbent assay, were increased after 6 and 24 h of renal ischemia or nephrectomy.

Conclusions: Our study shows that acute kidney ischemia or renal failure activates oxidative stress and promotes apoptosis, and tissue damage in gut. Whether the AKI induced-gut injury by itself is sufficient to provoke systemic inflammatory response need further investigation.

Funding: Government Support - Non-U.S.

PUB004 Serum from Rats with Acute Kidney Injury Contains Reactive Oxygen Species Generating Activity That Causes Oxidative Stress In Vitro

Jon D Ahlstrom,1 Zhuma Hu,1 Nicole Molin,1 Christof Westenfelder.2 1 Medicine, Univ of Utah and VA Medical Centers, Salt Lake City, UT; 2 Physiology, Univ of Utah and VA Medical Centers, Salt Lake City, UT.

Background: The uremic state that is induced by Acute Kidney Injury (AKI) adversely affects multiple organ systems by mechanisms that are still poorly characterized, including those reactive oxygen species (ROS).

Methods: Serum was obtained from rats 24 hrs post ischemia/reperfusion-AKI (50 min bilateral pedicle clamp, AKI serum), and control sera was obtained from rats 24 hrs following SHAM surgery (SHAM serum), or from rats 24 hrs post bilateral nephrectomy (NPHX serum). Serum samples were evaluated for ROS activity with the sensitive Amplex Red H2O2 assay. For in vitro assay, NRK cells (normal rat kidney cells, proximal tubular) or rat mesenchymal stem cells (MSC) were cultured in rat serum for 48 hrs, and then assessed for gene expression, GSH levels, and oxidative stress markers.

Results: Compared to SHAM or NPHX serum, serum from rats with AKI had increased amplex red activity compared to SHAM and NPHX serum controls. Adding catalase to rat serum reduced—but did not eliminate—the ROS activity of AKI serum in a dose-dependent manner. The ROS generating properties of AKI serum were completely destroyed by strong (90 °C for 1 hr) but not mild (45°C for 30 min) heat inactivation. Culturing normal rat kidney cells (NRK, proximal tubular) or rat mesenchymal stem cells (MSC) in 10% AKI serum (compared to SHAM or NPHX serum) resulted in increased oxidative stress, including increased anti-oxidant gene expression (HO-1, catalase), increased GSH levels, and increased cellular ROS (as measured by DCFDA and Amplex Red) and induced apoptosis of the injured kidney releasing heat-sensitive factors into the blood stream (like cytokines and mediators that affect renal tissue and distant organs). The Amplex Red H2O2 assay provides a useful tool for the determination and mechanistic dissection of the ROS activity found in AKI serum.

PUB005 Properdin Deficiency Enhances Renal Ischemia Reperfusion Injury in Mice

Zinah Dhevaia Zwaan,1,3 Nigel J. Brunskill,1 Hans-Wilhelm Schwaebel,1 Cordula M. Stover,1 Bin Yang,1,2,5 Infection, Immunity and Inflammation, Univ of Leicester; 2 Renal Group, Univ Hospitals of Leicester; 3 College of Medicine, Univ of Kafur, Iraq; 4 Basic Medical Research Centre, Medical school of Nantong Univ, China; 5 Nephrology, Affiliated Hospital of Nantong Univ, China.

Background: Properdin is the only positive regulator of the alternative pathway of complement activation via stabilizing C3bBb convertase. Properdin has been detected on proximal tubular epithelial cells associating with proteinemic renal damage. Previous studies showed that mice with combined deficiencies of properdin (P−/−), DAF and CD59, the negative regulators of complement activation, had less renal ischemia reperfusion injury (IRI), in 24 hours.

Methods: P−/− mice (n=9) and their wildtype (WT) littermates (n=7) were used to assess the role of properdin in renal IRI. Ischaemia was induced by bilateral clamping of the renal pedicle for 30 minutes followed by 72-hour reperfusion using normal (n=2) and sham operated mice (n=4 or 5) as controls.

Results: Renal IRI was successfully induced in the WT and P−/− mice with more prominent injury in P−/− mice as evidenced in renal function. Serum creatinine was significantly increased after IRI compared with the sham groups, which was further increased

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

886A
in P4 in relation to WT mice (1.78±0.29 vs 1.19±0.18, P=0.046) post IRI. Similarly, blood urea nitrogen in IRI mice was higher than the sham animals, with significant increase in P4 in comparison with WT mice.

This difference was supported by histological examination, in which P4 mice showed a worse score of tubulointerstitial damage than WT (2.67±0.26 vs 1.94±0.22, P=0.025) post IRI.

Conclusions: This study shows, for the first time, that properdin deficiency alone enhances IRI shown by worsened renal function and histology. The underlying mechanisms for these unexpected phenotype are under present investigation.

PUB006

Neurogenic Function of Neurons with Renal Afferents Is Altered by Lipopolysaccharides -LPS Kristina Rodionova,1 Martin Ziemer,2 Tilman Ditting,1 Stefan Karl,1 Sonja Heinlein,1 Peter Linz,1 Peter Reeh,1 Kerstin U. Amann,2 Roland Veelken.1 1Dept of Medicine 4 - Nephrology and Hypertension, Universitaetsklinikum Erlangen-Nuernberg, Erlangen, Bavaria, Germany; 2Dept of Nephropathology, Universitaetsklinikum Erlangen-Nuernberg, Erlangen, Bavaria, Germany; 3Dept of Physiology and Pathophysiology, FU Erlangen-Nuernberg, Erlangen, Bavaria, Germany.

Background: Renal afferent nerves (RNs) exert complex neurogenic sympathomodulatory and paracrine effects. Recently, we could demonstrate that lipopolysaccharide (LPS) sensitized TRPV1 receptors and increased the release of CGRP from afferent axons in kidney. Hence, we wanted to test the hypothesis that LPS alters firing patterns and acid induced inward currents in cultured neuron sample.

Methods: Dorsal root ganglion neurons (Th11-L2) of rats were incubated with LPS (E.coli O127:B8, 20ng/ml) 12h before patch clamp recordings. Inward currents were assessed during stimulation of TRPV1 and ASICs with protons (pH6.9 and 5.0). Current clamp mode was performed at physiological conditions and after 12h of LPS-incubation. Neurons were defined as tonic, i.e. sustained AP firing or phasic, i.e.<5 APs in response to current injections.

Results: Firing patterns and currents induced by acidic superfusion were studied in 246 neurons. Renal neurons (RNs) exhibited in 59% tonic firing pattern under control conditions. The number of neurons with tonic response was significantly reduced by exposure to LPS (59% vs.42%, p<0.05). Under control conditions 70.8% of RNs exhibited both sustained and transient inward current, whereas 29.2% showed sustained current. LPS exposure significantly increased sustained,i.e. TRPV1 induced current (79.13±1.46pA vs. 122±4.29± 200pA, p<0.05) and transient, i.e. ASICs induced inward current even under subthreshold proton stimulation (pH6.9) and could not be enhanced further by pH5.0.

Conclusions: LPS altered the properties of neurons with renal axons in a complex way, while the ease of AP production was significantly decreased, the responsiveness to acidic proton stimulation (pH6.9) and could not be enhanced further by pH5.0.

PUB007

Protective Effect of Nitric Oxide in Aristolochic Acid-Induced Toxic Acute Kidney Injury Ines Jado,1 Anne-Emilie Declives,2 Vanessa Colombo,1 Blanche Martin,1 Isabelle Habsch,1 Eric De Prez,1 Joel L. Nordt,1 Nathalie Caron.1 1Molecular Physiology Research Unit - URPHYM, Faculty of Medicine, Univ of Namur, Namur, Belgium; 2Laboratory of Experimental Nephrology, Faculty of Medicine, Univ Libre de Bruxelles, Brussels, Belgium.

Background: Aristolochic Acid (AA) nephropathy is a pertinent example of tubulo-interstitial (TI) nephritis characterized by an early phase of acute kidney injury (AKI) leading to progressive fibrosis and chronic kidney disease (CKD). Nitric oxide (NO) has been shown to play a critical role in the AKI-to-CKD transition. Here, the AAN model was used to determine the role of NO in this process, focusing on the acute phase.

Methods: C57Bl/6j male mice were randomly assigned to daily i.p. injection of control solution or AA (3.5mg/kg) for 4 days and L-Arginine (L-Arg; substrate for NO synthesis) was supplemented in drinking water (5%) until mice were euthanized, 5 days after the beginning of AA injections.

Results: At day 5, AA-treated mice displayed polyuria, increased plasma creatinine level and proteinuria. In addition, histochemical analyses revealed severe proximal tubular cell necrosis, renal inflammation and increased oxidative stress in AA-treated mice. These changes were associated with a significant reduction of NO bioavailability, as attested by urinary NOx and eGMP levels. L-Arg supplementation in AA-treated mice significantly improved kidney function, as reported by a significant reduction in urine volume, plasma creatinine level and proteinuria. Moreover, L-Arg treatment resulted in a significant reduction of tubular cell necrosis, renal inflammation and oxidative stress. These were concomitant to normalized NO levels.

Conclusions: Our findings demonstrated that sustaining NO bioavailability due to L-Arg supplementation improve the renal outcome of AA-induced AKI phase. Further investigations are ongoing to determine whether increasing NO bioavailability can also prevent chronic injuries in the AAN model.

The Study of Curcumin-Loaded Nanoparticles against Renal Ischemia-Reperfusion Injury Function and Mechanism Yong Xu,1 Lili Zhong.2 Dept of Nephrology, Huaian Second Hospital, Huaian, Jiang Su, China.

Background: To study the effects of curcumin-loaded nanoparticles against ischemia-reperfusion renal injury, and to investigate its mechanism.

Methods: Synthesize controlled releasing curcumin-loaded nanoparticles by amphilic mPEG-PCL block copolymers and cultivated renal tubular epithelial cell (cell line HK-2) in vitro. HK-2 cells were divided into four groups: Control group; Ischemia reperfusion injury group (IRI group); Curcumin group (Cur group); Curcumin nanoparticle group (CurNP group). In each group, HK-2 cells viability was assessed by dimethyl-thiazol-diphenyltetrazoliumbromide (MTT) test. Apoptotic Cells were measured by Flow Cytometry. H2DCF-DA was used to detect intracellular generation of ROS. BCA were used to detect SOD activity and the Concentration of MDA. Protein levels of procaspase-3 were analyzed by Western Blot.

Results: Successfully constructed curcumin-loaded nanoparticles by amphilic mPEG-PCL block copolymers. Drug loading content(DLS) and encapsulation efficiency(EE) were more than other reports. Data indicated that incorporated Cur could be slow released from the core-shellstructureof polymermicroparticles. 2. CurNP can ameliorate ischemia-reperfusionrenal injury in vitro. 3. The protective effects of Cur-NP against ischemia-reperfusion renal injuries involved in the suppression of oxidative stress reaction.

PUB009

Disruption of Polyamine Catabolism Reduces the Severity of Cisplatin Nephrotoxicity Kamyar A. Zahedi,1,2 Sharon L. Barone,1,2 Marybeth Brooks,1 Jie Xu,1 Manoocher Soleimani.1,2 1Dept of Internal Medicine, Univ of Cincinnati, Cincinnati, OH; 2Research Services, Veterans Affairs Medical Center, Cincinnati, OH.

Background: Platinum-based drugs (e.g. cisplatin) are used for treatment of many types of solid organ tumors. Cisplatin crosslinks the DNA, interferes with mitosis, activates the primary anti-tumor mechanism of cisplatin. Platinum-based drugs also cause oxidative cell injury, which may mediate their general toxic effects. Acute kidney injury (AKI), due to oxidative damage, is a major side effect of cisplatin that necessitates dose reduction or withdrawal from treatment thereby reducing the effectiveness of cancer therapy. We hypothesized that treatments that reduce the oxidative tissue damage caused by cisplatin lessen the severity of AKI without interfering with its anti-proliferative DNA damaging effects and obviate the need for dose reduction or drug withdrawal.

Methods: Cisplatin-AKI was compared in wild type and SSAT-KO mice using functional and molecular parameters. Mechanism of polyamine catabolism mediated-cell injury was assessed in cultured cells.

Results: The expression of polyamine catabolic enzymes, spermidine spermine-N1-acetyltransferase (SSAT) and spermine oxidase (SMO) increase in the kidney of cisplatin-treated mice. SSAT-KO mice are protected against tissue damage and renal dysfunction caused by cisplatin. Using cultured cells capable of inducible expression of SSAT, the effect of SSAT on the induction of endoplasmic reticulum stress and unfolded protein response (ERS/UPR). Our results indicate that up-regulation of polyamine catabolism in general, and enhanced production of SSAT in particular, activated the ERS/UPR.

Conclusions: These studies suggest that polyamine catabolism is involved in the mediation of cisplatin-AKI. These and our previous results indicate that the activation of polyamine catabolism causes cell injury through both genotoxic response and ERS/UPR pathways. Our studies suggest that short-circuiting or neutralization of toxic products of polyamine catabolism can be novel therapies that reduce the severity of cisplatin nephrotoxicity.

Protective Effect of NADPH Oxidase 4 Inhibition in Contrast Induced Nephropathy. Se-Hee Youn,1 Won Min Hwang,1 Sung-Ro Yun,1 Suyukyong Lee,2 Hee-Yeon Jung,2 Ji-Young Choi,2 Sun-Hee Park,2 Chan-Duck Kim,2 Yong-Lim Kim.2 1 Internal Medicine, Konyang Univ; Deajeon, Korea; 2 Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Korea.

Background: The objective of this study was to investigate the renoprotective effect of NADPH oxidase 4 (Nox4) inhibition in contrast induced nephropathy.

Methods: HK-2 cells were incubated with iohexol (nonionic low-osmolar radiographic contrast agent) at a concentration of 5mg/mL, 150mg/L for 2h. Cells were pre-exposed to GKT137831, a selective Nox1&4 inhibitor (Genkyotex, Switzerland), for 30 min before exposure to iohexol. Cell viability was measured at 0, 3 and 22h after removal of iohexol by ATP/luc assay. Apoptosis was investigated by caspase 3/7 activity assay. For ROS (reactive oxygen species) production was assessed by DHE assay, NADPH oxidase activity using the lucigenin-enhanced chemiluminescence method, and Nox3 expression by western blot and real time PCR.

Results: Nox3 protein expression significantly increased at 30 min after iohexol exposure. GKT137831 pre-exposure showed significantly less cytotoxicity at 3h after removal of iohexol. Caspase 3/7 activity was significantly lower in GKT137831 pre-exposed cells than only iohexol exposed cells at 22h after removal of iohexol. ROS generation was higher with only iohexol exposed cells compared to GKT137831 pre-exposed cells.

Conclusions: A selective Nox4 inhibition induced fewer cytotoxic effects on cultured HK-2 cells than iohexol along with a lower induction of Nox4-dependent ROS generation. This enzyme may represent a potential therapeutic target to prevent iodinated radiographic contrast media related oxidative stress.

Autophagy Increased in the Early Stage of Rat Acute Kidney Injury Model Junyi Liu,1 Xing Mao,1 Yiwen Shen,2 Huijuan Wu,1 Aimin Xue.1 1 Department of Forensic Medicine, Shanghai Medical College, Fudan University, Shanghai, China; 2 Department of Pathology, Shanghai Medical College, Fudan University, Shanghai, China.

Background: Acute kidney injury (AKI) is a major kidney disease without effective therapies, and thus associated with a high mortality. The pathogenesis of AKI is very complex and still unclear. Recently, researches have shown the induction of autophagy in proximal tubular cells and kidneys during AKI. In this present study, we investigated the role of autophagy in the pathogenesis of rat renal ischemia-reperfusion (IR) model which causes AKI.

Methods: All male Sprague-Dawley rats were subjected to clamping of bilateral renal artery only for 25 min except sham group, and then they were randomly divided into four groups based on different reperfusion time point, including 3h, 6h, 12h and 24h. The Sham group underwent surgical procedures without ischemia as the control. Results: The level of blood urea nitrogen (BUN) and serum creatinine were increased from 3h after IR. By H&E staining, protein casts were found at 3h after IR, which kept increasing at 6h and 12h after IR. At 24h after IR, we found some necrotic proximal tubules. Immunohistochemistry showed the protein level of Beclin-1 and Vps34 and the ratio of LC3 II/I was increased from 3h after IR, which was confirmed by electron microscopy showing the formation of autophagic vacuoles in proximal tubule cells. Moreover, immunohistochemical staining clearly showed an increasing positive staining of Vps34 and LC3 at 3h after IR compared to the control.

Conclusions: Taken together, our results demonstrate the occurrence of autophagy in the very early stage of rats AKI model. Funding: Government Support - Non-U.S.

The Previous Cardio Exercise (Exe) Normalizes Renal Function of Wistar Rats Subjected to Acute Kidney Injury by Ischemia, and Reperfusion Welsey Vicente Ling, Waldemar S. Almeida, Nestor Schor. Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil.

Background: The acute kidney injury (AKI) is characterized by acute reduction of renal function and has a high mortality rate in hospitalized patients and in severe cases may progress to chronic kidney disease (CKD). The AKI by ischemia and reperfusion (IR) causes tubular damage mainly in the proximal convoluted tubule, reducing mitochondrial activity in renal cell and increasing the reactive oxygen species (ROS). It is known that aerobic Exe lower blood pressure (BP), slows the heart rate (HR), improves muscle aerobic capacity, increases both the number and size of muscle mitochondria, however little is known about the effects of the previous Exe in AKI. We suspect that aerobic Exe may be a non-pharmacological resource in the prevention of AKI. Thus, we investigated the effect of previous aerobic Exe on renal injury resulting from IR. To evaluate the effects of the previous aerobic Exe on renal function in Wistar rats subjected to IR.

Methods: We used male Wistar rats with 10 weeks of life and they were separated into two groups Sham clamp (SC) and trained control clamp (TC), moreover the TC were subjected to a prior physical training protocol for four weeks. After completed 14 weeks each group, was subjected to ischemia injury by I/R, the rats were sacrificed in 24 hours after that they were placed in metabolic cages for 24 hours. We evaluate renal function (serum creatinina and proteinuria). Then they will be realized: renal morphological study by light microscopy and mitochondrial (number and size) by electron microscopy. Finally, we will evaluate apoptosis through caspases 3 activity.

Results: The SC group increased weight compared to the TC group (399±536±5g, P<0.05). Proteinuria was significantly different in SC vs. TC group (25.62±4.9±14.5±1.65 mg/24h, P<0.05). Now the creatinina serum showed significant difference in SC vs TC group (0.3±0.8 vs 0.6±0.6 mg/dl; P<0.05). We evidenced that SC group had a damage renal function after 48 hours recovery.

Conclusions: The results of this study are preliminary in nature, but suggest that the previous aerobic Exe can be renoprotective in the model I/R.

Angiogenin Mediates a Non-Cell Autonomous Response to Endoplasmic Reticulum Stress in the Kidney. Nicolas Palles,1 Danny Anglichean,2 Eric Thertev,1 Iadh Mami.1 1 INSERM U1147, Paris, France; 2 Nephrology, Georges Pompidou European Hospital, Paris, France; 3 Nephrology, Necker Hospital, Paris, France.

Background: Endoplasmic Reticulum (ER) stress is involved in the pathophysiology of kidney diseases, but the molecular basis of its biological outputs remain to be established. Angiogenin (ANG), a secreted ribonuclease, is a previously unappreciated component of the mammalian stress response that acts both in cell-autonomous and non-cell autonomous fashions to promote tissue adaptation to injury. Whether ANG signaling is a genuine component of the ER stress response is currently unknown.

Methods: In the present study, we explored the molecular mechanisms by which ANG is secreted under ER stress, and determined how it contributes to the modulation of the inflammatory microenvironment.

Results: Our results indicate that i) ANG secretion is specifically induced during ER stress and ii) this mechanism is under the selective control of IRE1a signaling. We demonstrate that ANG canonical secretion is induced upon ER stress, similar to the pro-inflammatory cytokine IL-6, and as such might play an immunomodulatory role in macrophage activation. These data are relevant to human disease since we identified ANG as a urinary marker of immune-mediated acute kidney injury.

Conclusions: Collectively, our data identify ANG as a key mediator of ER stress-dependent inflammatory response in kidney diseases, and is a potential non-invasive biomarker of acute kidney injury.

Sustained Infiltration of Th17 Cells Is Associated with Pulmonary Fibrosis in Rats with Salt Induced CKD Secondary to Renal Ischemia Purvi Mehrotra, Jason Andrieu Collett, David P. Basile, Dept of Cellular and Integrative Physiology, Indiana Univ of Medicine, Indianapolis, IN.

Background: Acute kidney injury (AKI) is associated with high mortality rates and is a leading cause of prolonged hospitalizations. The high risk of death is due in part to distant organ damage (e.g., lungs, heart, brain). It is well established that experimental AKI induced by renal ischemia and reperfusion (IR) induces an increase in pulmonary inflammation. Despite various immune cells like T cells as early as 24 hours post surgery, which may alter endothelial barrier function in the lung. However, the long-term effect of injury induced pulmonary inflammation on lung function and structure and function is not known. We hypothesize that T cells infiltrate into the lung post kidney injury with potential effects on pulmonary structure.

Methods: SD rats were subjected to a model of AKI-to-CKD in which rats are allowed to recover from unilateral I/R (40 min ischemia) for 5 weeks on normal salt diet (0.4% NaCl) and then subjected to contralateral UNX and 4% NaCl diet for 4 additional weeks. Consistent with prior reports, infiltration of CD4+ T cells were detected as early as 24 hours post surgery in the BAL fluid, and these were shown to be predominantly of Th17 phenotype (63±10.1, p<0.05). Interestingly, Th17 cells persisted in the lungs even after 5 weeks of post surgery after resolution of kidney injury (2.3X10³±0.1, p<0.05), when compared to sham (0.5X10³±0.3). Exposure of rats to high salt diet to hasten CKD further increased the number of Th17 cells in the lungs (4.1X10³±0.23, p<0.05). There was a corresponding increase in pulmonary fibrosis in post-AKI rats on high salt relative to sham-controls.

Conclusions: Taken together, these data suggest that AKI leading to CKD is associated with pulmonary fibrosis, an activity that may be due in part to the infiltration of Th17 cells into the lung and influenced by dietary salt.

Endothelial-to-Mesenchymal Transition and Endothelial Cilia in EPC-Mediated Postischemic Kidney Protection. Daniel Patschan, Susann Patschan, Gerhard A. Mueller. Clinic of Nephrology and Rheumatology, Dept of Internal Medicine, Göttingen, Niedersachsen, Germany.

Background: AKI increases the risk for CKD. Ischemia induces peritubular capillary rarefication and interstitial fibrosis with the latter partly resulting from mesenchymal transitions of renal cells (EndoMT). Endothelial cilia are mechanosensory organelles responsible for transmitting forces of the blood flow into the cell. Early Endothelial Progenitor Cells (eEPCs) have reproducibly been shown to protect mice from AKI in the short-term. Aim of the study was to analyze mid-term consequences of eEPC treatment of murine AKI. Our special interest focused on dynamics of endothelial cilia and EndoMT.

Methods: Male, 8-12 weeks old C57/Bl6N mice were subjected to unilateral renal ischemia (40 post-uniphenectomy). Syngeneic murine eEPCs (0.5X10⁶) were injected once at the time of reperfusion. Animals were investigated 1, 4, and 6 weeks later (renal function,
fibrosis, EndoMT, endothelial alpha-Tubulin). Cultured mature endothelial cells (ECs) were exposed to cisplatin, and the expression decreased, and the transfection groups decreased more obviously. After incubated with cisplatin, h-2 expression of HKC cells decreased obviously and the expression increased when ADSCs were cultured, and co-transfection group was more obviously. After incubated with cisplatin, IL-6 and RANTES were significantly increased in the cisplatin group. The inflammatory factors were determined when ADSCs were cultured, and decreased more obviously in gene transfection group.

Conclusions: EPO has the protective effects on the damaged cells and CXCR4 could promote the migration of stem cells to damage sites. Double genes transected to ADSCs may enhance the protective effect on HKC cells injury.

PUB018

The Role of Endosialin in Renal Ischemia-Reperfusion Injury Chin-Hee Liu, Fangming Liu, Shuang-Yang Zheng, Yunchao Long, Yu Zhang, Yonggang Liu, National Taiwan Univ College of Medicine, Taipei, Taiwan; 2)Internal Medicine, National Taiwan Univ Hospital, Taipei, Taiwan.

Background: Many studies reported that Endosialin deficiency can attenuate the inflammation, fibrosis or growth, invasion and metastasis of tumors. It is highly expressed during embryonic development, but largely absent in adult tissue except kidney and uterus. We are intrigued by the role of endosialin in the acute kidney injury.

Methods: We performed unilateral nephrectomy and then ischemia-reperfusion injury to induce acute kidney injury in the endosialin-deficiency (lacZ knock-in) and littermate wild type mice. Plasma levels of blood urea nitrogen and creatinine were analyzed at day 2.5 and 10 after injury. We analyzed the cells expressing endosialin, tubulointerstitial injury, and specific cells by X-Gal staining. Periodic acid-Schiff staining and immunohistochemistry respectively.

Results: Positive X-Gal staining was shown in the glomeruli, small arteries and interstitial cells of the kidney. The capillary density determined by CD31 staining did not show significant difference between endosialin-deficiency and wild type mice. Nephrectomy and ischemia-reperfusion injuries led to marked elevation of plasma blood urea nitrogen and creatinine in wild type mice, however, the elevation of plasma blood urea nitrogen and creatinine was less in endosialin-deficiency mice at day 2 after injury. Interestingly the protective property of endosialin deficiency was lost since day 5 after injury. Conclusions: Endosialin-deficiency can attenuate acute kidney injury induced by ischemia-reperfusion injury, but the protective property is lost during the repair/regenerative phase after acute injury. The protective property of endosialin deficiency is not related to capillary density which has been shown increased in previous study. Further study needs to elucidate the mechanism underlying the protective property and why the protective property is lost during repair/regenerative phase.

PUB019

The Mechanism of β2-Adrenergic Receptor/Protein Kinase A Signal Transduction Pathway in Restoration of Acute Kidney Injury by Endothelial Progenitor Cells Ying Zhou, Chen Yu. Dept of Nephrology, Tongji Hospital, Tongji Univ, Shanghai, China.

Background: Endothelial progenitor cells (EPCs) could improve renal microenvironment, stimulate endothelial repair and angiogenesis, and promote AKI restoration. However, the molecular mechanism has not been elucidated. In this study we investigated the role of β2-adrenergic receptor (β2-AR) and its downstream factors (protein kinase A, protein kinase B, protein kinase C) in restoration of acute kidney injury by EPCs.

Methods: The model of ischemia-reperfusion acute kidney injury (I-R AKI) was used in vivo, while sham operation was performed in control group. Renal tissue was collected at day 7. Renal histology was measured by HE staining. The expression of β2-AR was examined using Q-PCR and immunofluorescence staining. The specific antigens on surface of EPCs(CD34 and VEGFR-2) were examined using Q-PCR and immunofluorescence staining in I-R AKI group; while neither appeared in control group. Results: I-R AKI caused significant positive-correlations between VEGFR-2 and CD34(p=0.005), VEGFR-2 and α-SMA(p=0.04) at week 1, and the correlation increased at week 4. PKA levels were not significantly different between groups, and PKA was significantly higher expressed in I-R AKI group than in control group(p<0.05). The protein levels of PKB and PKC were not detected. According to Pearson's correlation analysis, there were positive correlations between VEGFR-2 and PKA(p=0.005), VEGFR-2 and PKB(p=0.005), CD34 and β2-AR(p=0.05), β2-AR and PKA(p=0.05).

Conclusions: When I-R AKI occurred, the mRNA levels of specific antigens on surface of EPCs(CD34 and VEGFR-2) were significantly up-regulated, which suggested that I-R AKI might induce EPCs homing to kidney. At the same time, the mRNA levels of β2-AR and PKA were significantly up-regulated, and most of them were positive-correlated, which suggested that β2-AR/PKA pathway may play a role in the restoration of AKI by EPCs.

PUB007

Effect of Double Genes Transfected Adipose-Derived Stem Cells on Cisplatin-induced Renal Tubular Epithelial Cells Injury Nannan Li, Jinmin Hospital of Shanghai.

Background: To observe the effects of adipose-derived stem cells (ADSCs) transfected with CCRX4 and EPO genes on renal tubular epithelial cells (HKC) injury.

Methods: To construct lentivirus expression system consisting of CCRX4 and EPO genes and transfected the system to adipose-derived stem cells (ADSCs), which co-culture with the cisplatin-induced HKC for 48 and 72 hrs. CCK8 detected cell proliferation of HKC. HKC were co-cultured with adipose stromal cells, and cell migration was assayed. Western blot detected the expression of apoptosis proteins in HKC. ELISA detected the expression of inflammatory cytokines in culture medium.

Results: No significant changes were observed in the morphology of ADSCs after gene transfection, and the optical differentiation ability were not affected. Adipose co-cultured the inhibitory effect of cisplatin on HKC cell proliferation was alleviated. Compared with the control group, the migration index of ADSCs was increased after co-culturing with cisplatin-induced HKC, and the gene transfection group were increased significantly as the extension of the culture time, indicating that the target gene transfection can promote the ADSCs migration to the damaged parts. Incubation with cisplatin, HKC cells EPO-R protein expression decreased. After co-culturing with ADSCs, the EPO-R expression increased. After incubated with cisplatin, the expression of Caspase-3, Bax expression in HKC cells increased significantly, which mediates the apoptosis. After co-cultured with ADSCs, the cisplatin-induced HKC cell proliferation decreased, and the transfection groups decreased more obviously. After incubated with cisplatin, h-2 expression of HKC cells decreased obviously and the expression increased when ADSCs were cultured, and co-transfection group was more obviously. After incubated with cisplatin, IL-6 and RANTES were significantly increased in the cisplatin group. The inflammatory factors were determined when ADSCs were cultured, and decreased more obviously in gene transfection group.

Conclusions: EPO has the protective effects on the damaged cells and CXCR4 could promote the migration of stem cells to damage sites. Double genes transected to ADSCs may enhance the protective effect on HKC cells injury.

Alpha Lipoic Acid and Dexamethasone Counteract Contrast Media-Induced Proximal Tubule Cell Dysfunction Hayriye Savariloglu,1 Ali Okuyucu,2 Abdulkerim Bedir,3 Osman Salis,4 Eser Yenen,2 1Dept of Nephrology, Ondokuz Mayis Univ Medical Faculty, Samsun, Turkey; 2Dept of Medical Biochemistry, Ondokuz Mayis Univ Medical Faculty, Samsun, Turkey. Background: Contrast medium induced nephropathy (CIN) is one of the most common cause of hospital-acquired acute renal failure. But its pathogenesis is unclear. In this study, we observed the effect of iopromide, low osmolar contrast medium, on tubular cells in HK-2 cell line.

Methods: We observed the effect of iopromide, low osmolar contrast medium, on tubular cells in HK-2 cell line. First, we examined the effects of different doses of iopromide (10, 20, 40 and 80 mg/ml iodine) on proliferation of HK-2 cells by the real time cell analyzer (RTCA). According to the results of RTCA we examined whether the non-toxic doses of iopromide (10 and 20 mg/ml iodine) is causing of the EMT by scratch assay for 20 h. We also observed whether alpha lipoic acid (0.5 mM) and dexamethasone (5 μg/ml) is preventing to EMT in this assay.

Results: We observed whether alpha lipoic acid (0,5 mM) and dexamethasone (5 μg/ml) is preventing to EMT in this assay. Although cytotoxic effect was observed for iopromide with concentration of 80 mg/ml iodine, the iopromide with lower doses did not show any effects for HK-2 cells. In scratch assay, we observed that the non-toxic doses of iopromide (10 and 20 mg/ml iodine) is causing of the cell migration which an indicator of EMT and lipoic acid and dexamethasone prevent the cell migration.

Conclusions: In conclusions, the EMT caused by contrast medium is prevented or reduced by dexamethasone and lipoic acid in HK-2 cells. This result suggest that dexamethasone and lipoic acid may be a potential treatment to prevent the development of CIN in individuals with high-risk.

Contribution of Proliferating Endothelial Cells for Endothelial Repair After Site Specific Endothelial Injury of the Mouse Kidney Jan Sradnick, Anika Luedemann, Vladimir T. Todorov, Christian Hugo, Bernd Hohenstein. Div of Nephrology, Dept of Internal Medicine III, Univ Hospital CCG, Dresden, Germany. Background: Our previous studies have shown that renal endothelial cell regeneration occurs exclusively via local mechanism. To further dissect the relevance of local mechanisms for endothelial repair, we now investigated the contribution of local endothelial cell proliferation in the kidney in our model of site selective endothelial injury (ECI).

Methods: Selective ECI was induced in 9 out of 15 mice by renal arterial perfusion with Concanavalin-A (ConA)-anti-ConA, while 6 mice served as sham operated controls. Edu (15μg/g), a marker of proliferation, was injected starting 24hours after ECI every 12hours intraperitoneally. Kidneys were harvested on day 7 and Edu+ cells were analyzed using flow cytometry and histology. Endothelial cells were stained using CD31, CD105, CD34 and CD36 and hematopoietic cells were detected as CD45+. Inflammatory cells (macrophages, dendritic cells and neutrophils) were analyzed via GR1, CD11c, CD11b and F4/80 positivity. By histology, proliferating EC were detected as anti-EC/EDU double positive cells.

Results: Significantly more Edu+ cells could be detected after ECI on day 7 (sh: 1.2%±0.7; ECI: 7.6%±4.8). Most of those Edu+ cells were positive for CD45 (65%±58) and 3% (sh) up to 7% (ECI) were positive for EC surface markers. In diseased kidneys more endothelial cells were found (sh: 5.5%±0.7; ECI: 7.3%±0.5; p<0.01). A larger amount of Edu+ EC was found in injured kidney (sh: 1.5±0.8 0160 cells; d7: 5%±1.5 0630 cells p<0.01). Histological analysis supported these findings. Glomeruli of ECI kidneys had more ERG/EdU+ cells (0: 0.23±0.16; d1: 1.22±0.06; p<0.01). Inflammatory cells in injured kidneys were slightly increased. Many macrophages (21%±13), neutrophils (38%±17) and dendritic cells (19%±13) were Edu+.

Conclusions: Enhanced endothelial proliferation was detected following ECI. Therefore EC proliferation reflects an relevant repair mechanism following site selective ECI. The further investigation of EC repair will have to dissect the contribution of the proliferative response by adult local EC from other contributors such as local progenitor cells.

Injury of Proximal Tubular Cells in Neonate Rats with Hypoxic-Ischemia Brain Damage Dong Li1,2 Mei Han1,2 1Dept of Medical Dept, Dalian Children’s Hospital, Dalian, Liaoning Province, China; 2Pediatric Internal Medicine Dept, Dalian Children’s Hospital, Dalian, Liaoning Province, China. Background: Proximal tubular cells play a critical role in renal injury. To investigate the consequence of mitochondria in renal proximal tubular cells after hypoxic-ischemia brain damage (HIBD) in rats and the apoptosis in it.

Methods: Neonatal (7 days old) Sprague Dawley rats were randomly divided into 2groups: sham group and operation group (n=5 per group). The Rice method was used for establishment of HIBD model, proximal tubular cells Mitochondria pathology and histology were examined under electron microscope at 1 day, 7days, 14days and 21days after the hypoxic-ischemic treatment, and apoptosis was analyzed by TUNEL.

Results: After the HIBD, the mitochondria of proximal tubular cells were showed damage under EM, some membrane and ridges were broken, the mitochondria bodies were swelling, and partial cristal fragmentation were observed from the 1day till 21days after. And the 21days was the most worst for mitochondria under EM. For the TUNEL, after HIBD, it showed significant increased for 1day, 7days, 14days and 21days groups comparing with sham group. (p<0.05).

Conclusions: After the hypoxic and ischemic brain injury of neonate rats, the mitochondria were damaged in proximal tubular cells, even in 21days after HIBD. And the apoptosis maybe one of the causes of this damage.

**Transfusion of Red Blood Cell as Predictor of Acute Kidney Injury in Patients Undergoing Cardiac Surgery**

Eudeseley Santana-Santos, Luiz Aparecido Bortolotto, Ludhmila Abramão Hajjar.

**ICU-Cardiac Surgery Postoperative Care, Heart Inst (InCor) Inst do Coração do Hospital das Clínicas da Faculdade de Medicina da Univ de São Paulo, São Paulo, Brazil.**

**Background:** The red blood cell transfusion in the perioperative period of cardiac surgery have been associated with acute kidney injury. Our purpose was to analyze the influence of transfusion of red blood cell in the incidence of acute kidney injury after cardiac surgery.

**Methods:** We performed a prospective cohort study carried out in a tertiary hospital specialized in Cardiology. Adult patients who had undergone elective myocardial revascularization surgery, valvular and aortic surgery and who had agreed to participate in the study were included. The primary endpoint was acute kidney injury defined by KDIGO criterion. Secondary outcomes was serious clinical complications defined according to the guidelines of the Society of Thoracic Surgeons.

**Results:** According to KDIGO criterion, the incidence of AKI was 46.5%. The mean age was 60±12 years old in the AKI group and 58±13 in the no AKI group (p=0.145) and mostly male (56%). The surgical risk assessed by EuroSCORE was greater in the AKI Group 5 (1-25) when compared to the no AKI group 4 (2-10), (p=0.047). There were no differences between the groups for the secondary outcomes. The use of red blood cells in the perioperative period (OR=3.166, p=0.001) and the presence of prior chronic kidney disease (CKD) (OR=2.027, p=0.036) was associated with AKI postoperatively.

During the period of hospitalization the mortality rate was 6.9%. When we compare the mortality rate between the groups it was 4.3% in the no AKI Group and 10% in the AKI Group (p=0.229).

**Conclusions:** In our study the use of perioperative red blood cells influenced the primary outcome. Patients who had used red blood cells had 3 times more risk of AKI.

A Picture Is Worth a Thousand Words: Simultaneous ATN, AIN, and Post Infectious GN

Ankur Shah, Rachel Criner, Jean Lee.

**Internal Medicine, Temple Univ Hospital, Philadelphia, PA; Nephrology, Temple Univ Hospital, Philadelphia, PA.**

**Background:** The differential diagnosis of hospital acquired acute kidney injury in its most general terms often is described as pre-renal, intrinsic, or post-obstructive. Further differentiating the intrinsic causes of AKI, we are given the differential of Acute Tubular Necrosis, Acute Interstitial Nephritis, Postinfectious Nephritis, and Glomerulonephritis. We present a case of a patient who presented with sepsis and developed acute kidney injury whose biopsy revealed a plethora of pathology.

**Methods:** We present a case of a 54 y/o male with a pmhx of only HTN and DJD who presented with leg pain and weakness for 2 weeks and hematuria found to be bacteremic with MSSA with L spine epidural abscess and bilateral psosas muscle abscesses. He developed acute kidney injury thought clinically and based on microscopy to be secondary to hypotensive acute tubular necrosis and was started on hemodialysis on HD6. He was being treated with cefadroxil and over weeks had minimal return of renal function. The differential diagnosis was revisited and concern for AKIN from the penicillin agent was raised, the patient was switched to Daptomycin, but remained RRT dependent. After 25 days on hemodialysis, a biopsy was obtained which revealed diffuse interstitial inflammation with eosinophils, focal mild-moderate tubular injury with vacuolization, as well as by electron microscopy, subepithelial deposits but not subendothelial deposits, most of which are largely absorbed, including in “notch” areas. These findings are consistent with an acute post-infectious glomerulonephritis, resolving stage; drug induced acute interstitial inflammation, as well as mild-moderate focal tubular injury.

**Conclusions:** This case demonstrates a variety of the potential causes of AKI. The patients course was long and provided multiple opportunities for re-evaluation and a return to the differential diagnosis process. This is an excellent case for the teaching of the fundamentals of medicine, as the differential diagnosis is truly the instrument of the master clinician. This patients aberrance from the expected course prompted reevaluation and his pathology was staggering.

Monitoring and Follow-Up of Acute Kidney Injury Post-Discharge: Retrospective Case Review Series

Kosmas Papailiadis, Judith H. Veis.

1Medicine, Washington Hospital Center, Washington, DC; 2Nephrology, Washington Hospital Center, Washington, DC.

**Background:** AKI during hospitalization increases risk of progression to CKD and death upon discharge. Recent KDIGO guidelines suggest patients should be evaluated 3 months after AKI for resolution, new onset, or worsening of pre-existing CKD. We determined factors associated with whether patients with AKI had kidney function assessed 3 months post-discharge.

**Methods:** Retrospective chart review of hospitalizations in 2013 complicated by AKI, who had follow-up in Ambulatory Medical Clinic to assess discharge communication; serum Cr, urine protein/Cr at 3 and 4-9 months, 1 year outcomes including progression to CKD, death and referral to nephrology.

**Results:** 77 inpatients with AKI (48(66%) stage 1, 9(12%) stage 2, 20(26%) stage 3; and 8(8%) requiring RRT) had a post-discharge visit. Of these, 51(66%) had serum Cr and 1(1%) had urine protein/Cr checked by 3 months. For 4-9 months, 13(17%) had serum Cr and 5(6%) had urine protein/Cr checked; 3(4%) were deceased by 1 year. 26(34%) had normal kidney function pre-AKI and of this group, 10(38%) had CKD by 1 year. Of these 26, only 5(19%) were referred to nephrology. For documentation, 54(77%) had AKI as a problem in the inpatient hospital summary, 42(54%) had AKI documented in the brief outpatient hospital summary and 29(41%) had AKI addressed in the follow-up visit. There was no significant association between AKI severity, need for RRT, or documentation with checking kidney function by 3 months nor between AKI inpatient documentation and addressing AKI at follow-up (p<0.05). There were significant associations between addressing AKI at follow-up and checking kidney function: p=0.043 and between AKI stage and addressing AKI at follow-up: p=0.022 and between AKI outpatient summary and addressing AKI at follow-up: p=0.004.

**Conclusions:** Outpatient follow-up of inpatient AKI is inconsistent despite evidence of poorer outcomes and recent guidelines which suggest the need for closer monitoring. Improving transitions of care through more effective documentation and streamlined EMRs, as well as increasing primary care physician awareness could reduce the risk of progression to CKD and death.

**PUB028**

Late Recovery of Renal Function in Atypical Hemolytic Uremic Syndrome (aHUS) After Eculizumab Therapy

Jeffrey D. Clement, Delin Wang, Maoxin Pang, Tanmay Sahai, Keith R. Bartolomei.

2Internal Medicine, Temple University Hospital, Philadelphia, PA.

**Background:** A 33-year-old woman with hypertension and left renal agenesis presented with fever and acute kidney injury with serum creatinine of 2.1 mg/dL. Initially, hemoglobin was 11.3 mg/dL and platelets 193,000/ul. Over the next three days, platelets dropped to 55,000/ul and LDH rose to 770 U/L; renal function worsened. Thrombotic microangiopathy was suspected. Stool culture was negative. Urine protein was 6.8 g per 24 hours. Serologic assessment, including C3, C4, ANA, ANCA, HIV, cryoglobulins, dsDNA, lupus anticoagulant, anticardiolipin antibodies, and β-2-glycoprotein I antibodies, was unremarkable. The patient was being treated with cryo-poor plasma exchange and steroids. Hemodialysis was started for uremia. ADAMTS13 was 67% of normal. Renal biopsy included in “notch” areas. These findings are consistent with an acute post-infectious glomerulonephritis, resolving stage; drug induced acute interstitial inflammation, as well as mild-moderate focal tubular injury.

**Conclusions:** This case demonstrates a variety of the potential causes of AKI. The patients course was long and provided multiple opportunities for re-evaluation and a return to the differential diagnosis process. This is an excellent case for the teaching of the fundamentals of medicine, as the differential diagnosis is truly the instrument of the master clinician. This patients aberrance from the expected course prompted reevaluation and his pathology was staggering.

showed acute thrombotic microangiopathy, acute tubular injury, and moderate interstitial fibrosis. The presentation suggested the diagnosis of aHUS. Eculizumab, an anti-C5 antibody, was initiated at 900 mg weekly for four weeks followed by 1200 mg every two weeks. Eculizumab therapy resulted in resolution of hemolysis. Dialysis was continued thrice weekly. Eculizumab was continued every two weeks, and LDL and platelet counts remained stable. Twenty weeks after initial presentation, urine output increased, proteinuria decreased, and interdialytic weight gains were negligible. Pre-dialysis serum creatinine was 3.9 mg/dL, and a urine collection showed creatinine clearance of 30 ml/minute. She has remained off dialysis for twenty weeks, and latest serum creatinine is 3.4 mg/dL. Screening for complement genetic defects has been negative.

**Conclusions:** Experience with eculizumab is ongoing. Most patients with aHUS has a rapid hematologic response. If they need dialysis, then recovery of renal function is usually prompt; late recovery is rare. We hypothesize that sustained control of complement activation has ameliorated proteinuria and allowed renal remodeling and regeneration, even months later. Patients are at risk for relapse if they stop treatment. This case points out that the presumed genetic defect may require lifelong treatment, and that late recovery of renal function is possible with complement inhibition and supportive care.

**PUB029**

The Effectiveness of Thalidomide in Preventing Cisplatin Related Nephrotoxicity in Patients with Cancer

**Background:** Sixty patients who were planned administration of cisplatin for the first time were included in the study. Patients were divided into two groups as group 1 (n=30) (standard treatment arm) and group II (n=30) (thalidomine arm). Glomerular filtration rate (GFR), NGAL, cystatin C were measured at 3rd day in all of the patients. Also, these parameters were repeated measured at the adminstration of cisplatin, at 24th hour, 48th hour and 72nd day.

**Results:** In both groups after the administration of cisplatin, glomerular filtration rate (GFR) showed a significant decrease within time (p<0.001). Creatinine, in spite of the time, no significant difference was observed between groups and within time. After 2 hours of cisplatin administration, in spite of the difference in GFR, a significant decline was detected in serum creatinine (p<0.001). Urine NGAL was significantly high after 2 hours of cisplatin administration (p<0.001). No significant difference was observed between groups. However, when the time*group effects were considered together, higher NGAL was detected in the group not receiving thalidomide (p<0.025). After 5 days of cisplatin administration, urine protein levels were significantly higher in both groups (p<0.001).

**Conclusions:** Results showed that urine NGAL level is a superior biomarker compared to creatinine and cystatin C in the detection of early acute kidney injury. Thalidomide was found not to bring a complete protection for the kidneys, but less nephrotoxicity was developed when compared to the group not receiving thalidomide.
PUB033
Serum Neutrophil Gelatinase-Associated Lipocalin: A Novel Biomarker for Prediction of AKI Development in Critically Ill Patients
Maggdy M. Elsharkawy, Abdel Rahman Khedr, Amr Mohab, Haitham Ezzat.
Nephrology, Ain Shams Univ, Cairo, Egypt.

Background: Acute kidney injury (AKI) is a frequent complication in critically ill patients and is associated with high morbidity and mortality; therefore, its prophylaxis, diagnosis and intervention positively impact patient evolution. Neutrophil gelatinase-associated lipocalin (NGAL) is thought to be a novel biomarker of AKI of several etiologies and is increased in both serum and urine before the increase of serum creatinine.

Methods: A prospective cohort study was conducted on 100 critically ill patients in ICU. Patients were stratified into 2 groups based on AKI development. Group I which included 50 patients who did not develop AKI, and group II which included 50 patients who developed AKI. AKI was defined based on acute kidney injury network (AKIN) classification. The Sequential Organ Failure Assessment (SOFA) scores were also calculated for all patients. Detailed medical history, demographic data and routine laboratory investigations were done. Serum NGAL was measured upon admission to ICU and upon AKI development.

Results: 60 males and 40 females were included in the study with mean age 37.52 years. As regards risks of AKI development, 9% of patients had sepsis, 15% were dehydrated, 11% had contrast exposure, 12% had rhabdomyolysis, 29% had shock and 24% had history of NSAID intake recently. On admission, there were no significant differences between the patients as regards s.creatinine, hemoglobin level and other laboratory parameters (p > 0.05). Serum levels of NGAL were significantly higher in group II, before AKI development, with mean value 958.5 ng/ml, when compared with group I, mean value (p > 0.05). Serum NGAL was measured upon admission to ICU and upon AKI development. Sequential Organ Failure Assessment (SOFA) scores were also calculated for all patients. The finding that KDIGO Stage 2 means worst medium term survival for the AKI group needs further study.

PUB035
The Effect of Nebivolol on Contrast-Induced Acute Kidney Injury: A Meta-Analysis
Nasirizadeh, Charat Thongprayoon, Yisit Chemungpasitpon.

Background: Nebivolol provides protective effect on contrast-induced acute kidney injury (CI-AKI) in animal models. However, the reports on the efficacy of nebivolol for the prevention of CI-AKI in human remain unclear. The objective of this meta-analysis was to assess the effect of nebivolol for the prevention of CI-AKI.

Methods: Comprehensive literature searches were performed using MEDLINE, EMBASE, and Cochrane Database from inception through February 2015. Studies that reported relative risks, odds ratios or hazard ratios comparing the risk of CI-AKI in patients who received nebivolol versus those who did not were included. Pooled risk ratios (RR) and 95% confidence interval (CI) were calculated using a random-effect, generic inverse variance method.

Results: Four studies (2 RCT and 2 cohort studies) with 543 patients were included in our analysis to assess the risk of CI-AKI and the use of nebivolol. Of 543 patients with contrast exposures, 30 patients (5.32%) had CI-AKI. Patients in the nebivolol group had an overall lower incidence of CI-AKI (14.3%) compared to the control group (17.43%). The pooled RR of CI-AKI in patients receiving nebivolol was 0.66 (95% CI, 0.38-1.15, I² = 0).

When meta-analysis was limited only to RCTs, the pooled RR of CI-AKI in patients receiving nebivolol was 0.70 (95% CI, 0.35-1.79, I² = 0). This finding suggests the need for further studies on the use of nebivolol in addition to standard IV crystalloid hydration in the prevention of CI-AKI.

PUB036
Patients with Cardiovascular Diseases Are Susceptible to Acute Kidney Injury After Non-Cardiac Surgery Under Preoperative Use of Angiotensin Converting Enzyme Inhibitors or Angiotensin Receptor Blockers

Background: It is unknown in which subgroups of patients the preoperative use of angiotensin converting enzyme inhibitors (ACE-I) or angiotensin receptor blockers (ARB) is a predictor for acute kidney injury (AKI) after non-cardiac surgery.

Methods: This is a retrospective cohort study on patients who underwent non-cardiac surgery from 2007 to 2009. After exclusion of urological surgery, missing creatinine values, and preoperative dialysis, the data for 2,725 patients were available. The exposure of interest was preoperative use of ACE-I/ARB. Primary outcome was postoperative AKI (AKIN criteria). The odds ratio (OR) of postoperative AKI among ACE-I/ARB users compared to non-users was analyzed using multivariable logistic regression models, adjusted for the logit of propensity score for ACE-I/ARB use. P < 0.01 was considered statistically significant for interaction.

Results: Mean(SD) age was 61(16) and estimated glomerular filtration rate was 81(24) ml/min/1.73m². There were 40(6.7%) cases of postoperative AKI in ACE-I/ARB users and 97(2.65) (4.3%) in non-users. The adjusted OR of AKI was shown.
History of cardiovascular diseases (CVD) (either coronary artery disease, stroke, peripheral arterial disease, atrial fibrillation, or left ventricular ejection fraction < 40%) was a significant effect modifier for the association of ACE-I/ARB use and AKI (p for interaction = 0.07). The OR (95% CI) of AKI among ACE-I/ARB users was 1.70 (0.73-3.93) and 0.72 (0.42-1.24) in patients with CVD and without CVD, respectively.

Conclusions: ACE-I/ARB use was associated with higher OR of AKI in patients with CVD compared to patients without, suggesting that patients with CVD are more prone to AKI with the use of ACE-I/ARB.

PUB037

Whole Ischemia–Reperfusion Injury: The Effect of Whole-Body Cooling on Renal Function
Silvia De Rosa,1 Zaccaria Ricci,2 Salvador Roberto Lopez,3 Jose Luis Salas,1 Stefano Marcante,1 Sara Samoni,1 Massimo de Cal,1 Silvia Maria Pulitano,2 Massimo Antonelli,2 Raffaele Bonato,1 Claudio Ronco.1
1IRRIF; 2Intensive Care Unit, UCSC, Rome; 3Paediatric Cardiac Intensive Care Unit, OBG, Rome.

Background: Hyperthermia is able to reduce the risk of renal failure after renal ischemia–reperfusion injury in animals. In humans, Cardiac Arrest (CA), a whole-body ischemia–reperfusion syndrome causes warm renal ischemia–reperfusion injury, similar to animal models of ischemic acute kidney injury (AKI). Induced hypothermia (IH) has a treatment potentially efficacious for post-ischemic injury. It is unclear what effect cooling could have on renal function. The aim of the study was to investigate the development of AKI during the IH.

Methods: Between Jan 2013 and Mar 2015, we performed a prospective observational study of 36 comatose pts resuscitated from CA and treated with IH performed with 2 different surface cooling devices: 1) Arctic Sun Temperature Management System (Medivance, Los Angeles, CA); 2) Blanket. Temperature rate and trend, and the development of AKI during the IH (0–6 hrs), maintenance (24 hrs), rewarming (48 hrs), and normothermia (72 hrs) was assessed with RIFE and KDIGO criteria.

Results: Pts were enrolled and followed for the development of AKI during intensive care unit stay. In the induction and maintenance phases, the rate and the target temperature were similar; conversely, the rewarming phase was shorter with a target temperature higher in Blanket than in Arctic Sun group (45.8 min vs 61 min; 37.2°C vs 36.3°C). The trend and rate of temperature, but also the development of AKI is showed in figure 1.

Conclusions: IH could be associated with development of AKI in the rewarming phase (rate 0.25 to 0.5°C). The optimal rewarming rate is unknown. Randomized controlled trials are needed to determine the real effect of temperature on kidney, the optimal rewarming strategy and applications of this treatment for kidney in other settings.

PUB038

Decongestion-Associated Worsening Renal Function Does Not Increase Mortality of Patients with Acute Heart Failure

Background: A significant subset of patients admitted for acute decompensated heart failure (ADHF) develop worsening renal function (WRF). While there is consistent data regarding the negative impact of baseline renal dysfunction on the outcomes of these patients, the evidence on the prognostic implication of WRF during admission for decongestion is less well-understood. The aim of this study is to provide a reappraisal of the effect of decongestion on the prognostic value of WRF in patients admitted for ADHF.

Methods: Articles cited in PubMed database from 1995 to 2015 using key words “congestion”, “heart failure”, “worsening renal function”, and “hemoconcentration” were searched. Those studies evaluating the relationship between decongestion, renal function, and ADHF in patients treated with diuretic-based conventional therapies were selected. Ultrafiltration trials were excluded. Relevant data including change in renal function, diuretic dose, change in weight, and mortality were extracted and compared.

Results: A total of 12,843 patients from 19 clinical trials (9 retrospective and 4 prospective) with data pertaining to decongestion in ADHF patients were included in this study. The mean age of the patients was 67.1 years with follow up periods ranging from 60 days to 5.3 years. Eleven studies reported development of WRF following decongestion. The incidence of WRF was reported to be 10 to 50.1% with weight reduction ranging from 2 to 5.4 kg. Twelve studies did not observe any negative impact for WRF on the mortality of patients with ADHF unless associated with markers of persistent congestion such as lack of hemoconcentration.

Conclusions: Decongestion is associated with markers of fluid removal and WRF in the setting of ADHF. Currently available data suggest that decongestion-associated WRF does not result in increased mortality whereas persistent congestion is likely to be the driving factor for adverse outcomes in these patients. Randomized controlled trials are needed to confirm these findings as they could portend significant therapeutic implications in cardiac syndrome.

PUB039

A 13-Year Mayo Clinic Retrospective Study of the Syndrome of Rapid Onset End Stage Renal Disease (SORO-ESRD) in an Incident Hemodialysis Cohort
Macaulay A. Onuigbo,1 Nnemia Agbasi,1 LaTonya J. Hickson,2 Medicine, Mayo Clinic College of Medicine, Rochester, MN; Nephrology, Mayo Clinic Health System, Eau Claire, WI; Psychiatry Nursing, North East London NHS Foundation Trust, London, United Kingdom.

Background: We first described the syndrome of rapid onset end stage renal disease (SORO-ESRD) in 2010 - acute yet irreversible ESRD after AKI. However, its overall impact on ESRD outcomes in the general US ESRD population remains speculative.

Methods: A retrospective examination of SORO-ESRD among the incident Mayo Clinic ESRD population, 2001-2013 was completed in November 2014.

Results: 149 of 1461 (10%) incident ESRD patients had SORO-ESRD – M:F = 76:73, mean age 62 years (19-95), 139 (93%) native kidneys, 10 (7%) kidney transplant recipients (RTRs). Ninety-nine percent of SORO-ESRD patients’ initial vascular access was a dialysis catheter. Kidney biopsy - the commonest pathologic diagnoses were acute tubular necrosis (ATN) in 3 (25%) KTRs and in 7 (21%) native kidneys. Cardiac arrest was the leading cause of death in SORO-ESRD.

Conclusions: Decongestion is associated with markers of fluid removal and WRF in the setting of ADHF. Currently available data suggest that decongestion-associated WRF does not result in increased mortality whereas persistent congestion is likely to be the driving factor for adverse outcomes in these patients. Randomized controlled trials are needed to confirm these findings as they could portend significant therapeutic implications in cardiac syndrome.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

894A
Conclusions: Among 1461 incident ESRD patients seen at Mayo Clinic Dialysis Services, Rochester, 2001–2013, 149 (10%) had SORO-ESRD. There was no gender age disparity between SORO-ESRD patients and the general ESRD cohort. Ninety-nine percent (99%) SORO-ESRD patients’ initial vascular access was a dialysis catheter. ATN was the leading pathologic diagnoses for AKI among KTRs and in native kidneys. Cardiac arrest was the leading cause of death in SORO-ESRD, similar to the general ESRD population. We conclude that SORO-ESRD contributes significantly to incident ESRD here in the USA both among KTRs and in native kidneys. Furthermore, it negatively impacts on the success of AVF-First Programs. Efforts to mitigate AKI in CKD patients must be given more attention and priority by practicing nephrologists in particular, and by physicians in general.

PUB040
Saline-Induced, Diuretics-Responsive Acute Renal Failure (ARF): Evidence that Anasarca Is Nephrotoxic and Diuresis Is Therapeutic
Grant Meltzer, Kai Lu, Helene Ammann, Josefiina Martin, Alicia Mendiluce, Nephrology, Hospital Clinico Univ, Valladolid, Spain.

Background: Recent studies showed the association of fluid overload in ARDS & surgical patients and increased ventilator dependency, ICU & hospital stays, short-term mortalities, & incidence of ARF. But a cause-and-effect relationship was unproven in cross-sectional observations. In grossly edematous in-patients with unexplained ARF, we tested the hypothesis that anasarca caused the renal failure & diuresis induced recovery.

Methods: Entry criteria were fully evaluable patients, ≥3 kg weight or ≥3 L fluid gain, ≥40% acute loss of estimated creatinine clearance (CrCl) or ≥2 x rise in serum creatinine (Scre) without identifiable causes. All data were reviewed, recorded, tabulated & statistically analyzed, notably vital signs, weight, intake, output & lab. 36 qualified patients were diuresed by IV furosemide at rates keeping normotension off anti hypertensives. Serial volume markers & renal responses were noted. Palliative care & hepatorenal syndrome were excluded.

Results: Fluid overload was due to heart failure (40%), liver failure (22%), CKD (16%), proteinuria (9%) & iatrogenic factors (10%). During 42 ARF episodes, mean weight was up 12.5 kg in 13.7d. Scre rose (4.41 vs. 1.27mg/dL) & CrCl fell (25 vs. 76 ml/min). Decrements in CrCl correlated with edema weight gain (p<0.02). Over 11.9 d, 15.2 kg of fluid were diuresed. Renal function greatly improved in 33 patients & unchanged in 3 despite >4 kg diuresis. As an entire group, Scre fell to 1.45 mg% & CrCl rose to 67 ml/min. Increments of CrCl also correlated with diuresis volume (p<0.04). At a diuretic rate of 1.5 kg/d, no adverse events occurred.

Conclusions: 1. Our data support the hypothesis for the entity of Saline-Induced, Diuretics-Responsive Acute Renal Failure. 2. Likely mediated by reduced cardiac output, 3 despite >4 kg diuresis. As an entire group, Scre fell to 1.45 mg% & CrCl rose to 67 ml/min. Increments of CrCl also correlated with diuresis volume (p<0.04). At a diuretic rate of 1.5 kg/d, no adverse events occurred.

PUB041
Is RIFLE Classification a Good Shot for Staging Acute on Chronic Kidney Disease? Maria Isabel Acosta-Ochoa, Josefina Martin, Alicia Mendiluce, Nephrology, Hospital Clinico Univ, Valladolid, Spain.

Background: 8-16% of worlds population may have CKD, which is a risk factor and promoter of AKI. We tested the performance of RIFLE and KDIGO classifications in staging severity and predicting outcomes in Acute on CKD (AcOKD) individuals. KDIGO with a 0.3mg/dL Scre increase includes patients in stage 1 category, and includes automatically in stage 3 patients with peak Scr ≥4.0 mg/dL.

Methods: Retrospective cohorts study. Patients were divided in 2 groups: AKI and AcOKD. We collected clinical data, and classified AKI severity contrasting distribution strata between groups by RIFLE and KDIGO criteria. And tested the ability of both classifications for predicting need for HD and in hospital mortality with a AUC ROC analysis.

Results: 270 patients were included, AKI=125, AcOKD=145. Clinical features and RIFLE and KDIGO stages are listed in table 1.

65% males, AcOKD individuals were older 66.9y, and had worst Charlson Index (Chal) 4.4. In figure 1 are shown AUC ROC curves for adverse outcomes.

Conclusions: With the KDIGO staging criteria we obtain more homogeneous distribution strata. With the ROC analysis neither classification performs better in predicting adverse outcomes. We found no practical advantage when using neither classification. In the noAKI (by RIFLE) stratum no adverse event was present, so by including a 0,3mg/dL Scre increase augments sensitivity, but may be not specifically.

PUB042
Francois Paquette,1 Amelie Bernier-Jean,1 Veronique Brunette,1 Vincent Pichetto,2 Helene Ammann,3 Stephan Troyanov,3 Josee Bouchard.1 Hôpital du Sacre-Coeur de Montreal, Canada; 2 Hôpital Maisonneuve-Rosemont, Canada.

Background: The KDIGO guidelines recommended to avoid aminoglycosides (AG) in patients at risk or with acute kidney injury (AKI). We determined the frequency of administration, incidence of AKI, and risk factors for AKI and absence of renal recovery in patients receiving AG over the last decade.

Methods: We performed a retrospective cohort study on AG administration in two university-affiliated centers, and then performed a nested case-control study, pairing AG-AKI cases to 2 controls for age and gender. AKI was defined by a 50% increase in creatinine after ≥5 days of AG up until 7 days after cessation of AG, and renal recovery, by a decrease in creatinine to within 50% of baseline creatinine over 3 weeks after cessation of AG.

Results: Between 2001 and 2015, the frequency of AG administration and drug dosing progressively declined. Out of 562 patients, sixty-five developed AKI attributed to AG (12%). In the case-control study (n=195), age was 71 (IQR 58-81) and 46% were male. The duration of AG administration was 10.0 (IQR 7.0-15.0) days, excluding days after AKI diagnosis in AKI patients. Maximal AKI stage was 1 for 55.3%, 2 for 29.2% and 3 for 15.4% of patients. Independent risk factors associated with AKI were concomitant vancomycin administration, high trough levels, heart failure, and site of infection (endocarditis and febrile neutropenia vs. other). Only fifty-one percent (50.8%; 33/65) of patients recovered their kidney function. These patients had an AKI duration of 7.0 (IQR 4.0-11.5) days. Heart failure was associated with a lower likelihood of renal recovery, while cancer patients more likely recovered their kidney function.

Conclusions: Over the last decade, the frequency of AG administration and dosing have progressively decreased but the incidence of AKI remained unchanged. In our cohort, vancomycin administration, high trough levels, heart failure, and site of infection were independent risk factors associated with AKI. Almost half of patients did not recover their kidney function, which was more often seen in patients with heart failure.
PUB043

Prairie Continuous Renal Replacement Therapy (CRRT) Study – Outcomes of CRRT in a Single Canadian Tertiary Centre
Bhanu Prasad,1 Michelle Urbanski,2 Erwin Karrenman,3
1 Nephrology, Regina Qu’Appelle Health Region, Regina, SK, Canada; 2 College of Medicine, Univ of Saskatchewan, Regina, SK, Canada; 3 Research and Performance Support, Regina Qu’Appelle Health Region, Regina, SK, Canada.

Background: Patients with stage III Acute Kidney Injury (AKI) requiring Renal Replacement Therapy (RRT) have the highest short-term and long-term mortality of any group with AKI. Our study aimed to prospectively follow patients with stage III AKI on Continuous Renal Replacement Therapy(CRRT) during their hospitalization in our tertiary care centre from April 2013 to September 2014.

Methods: We prospectively gathered the following: date and time of hospital admission, transfer to ICU, and starting CRRT, creatinine at admission and at CRRT initiation, weight on admission and at CRRT initiation, duration of oliguria and anuria, exposures (sepsis, critical illness, circulatory shock, trauma, cardiac surgery, major non cardiac surgery, nephrotoxic medications, and radio contrast agents) and susceptibilities (dehydration, >65 years of age, female, pre-existing chronic CKD), APACHE score II, Inotrop support, FiO2, ECMO. Survival on CRRT, in ICU and hospital survival and renal recovery was documented.

Results: Of the 2634 patients (2201/2634, 83.6% had no AKI, and 269/2634, 10.2% had stage III AKI of whom 106/269 (40%) were started on CRRT. 8/106 died in ICU and hospital survival and renal recovery was documented. 5/106 patients recovered within 24 hours. 5/106 patients had a shorter stay in ICU prior to starting CRRT (6.06 hours vs. 12.26 hours). Stage III AKI patients had stage III AKI of whom 106/269 (40%) were started on CRRT. 8/106 died in ICU and hospital survival and renal recovery was documented.

Conclusions: We found that 34.6% of patients required RRT. Among patients with stage III AKI, 5/106 patients recovered within 24 hours. 5/106 patients had a shorter stay in ICU prior to starting CRRT (6.06 hours vs. 12.26 hours). Stage III AKI patients had stage III AKI of whom 106/269 (40%) were started on CRRT. 8/106 died in ICU and hospital survival and renal recovery was documented.

C3 Glomerulopathy: A Pediatric Case
Luis A. Ortiz,1 Daniel Kleven,2 Harika Gorri,1
1 Ped. Nephrology, Georgia Regents Univ, Augusta, GA; 2 Pathology, Georgia Regents Univ, Augusta, GA.

Background: C3 glomerulopathy (C3G) is characterized by C3 deposit in the glomeruli with minimal Ig deposition. C3G is described as an unregulated activation of the alternative complement pathway due to a genetic mutations in Factor H or I, or acquired factors such as C3 nephritic factor, an IgG autoantibody stabilizing C3 convertase. The pattern of the injury varies from mesangio-proliferative, membranoproliferative, to endocapillary proliferative glomerulonephritis. The EM finding is characteristic orange hump shaped subepithelial deposits, characteristic of acute post-infectious glomerulonephritis (PIGN). We present a pediatric case that met the initial criteria for PIGN, but was diagnosed as C3G according the pathology.

Methods: 15 y/o AA M with Thin Basement D, HTN, asthma presented with 1 hx of sore throat, gross hematuria, facial swelling, no distal edema. Initial oliguria and high Cr. PE revealed periorbital edema, no pharyngeal erythema, lung clear, abdomen with no ascites. On admission, Hb 11.6 g, Cr 3.26mg, Albumin 25.2 g, U/A: 50-50 BRC, UOP: 0.37 ml/hr. Despite treatment with methylprednisolone, albumin and furosemide, his Cr. increased to 6.48, ASO 654 UI, adnAscb normal, CRP 12.6. Group A strep was negative for growth. Kidney biopsy: glomeruli w/segmental sclerosis, endocapillary infiltration of neutrophils, IF: extensive C3 staining with scant IgG and small fibrin deposition (focal necrosis). EM: large subepithelial deposits. Worsening kidney function required hemodialysis. After 6 months, he continues on Hemodialysis.

Conclusions: Kidney biopsy with C3 dominant on IF, large subepithelial deposits on EM, hypocoomplementemia and clinical of gross hematuria preceded by URI suggested acute PIGN, but this overlaps with the histological presentation of C3G of C3 dominant staining with scant IgG deposition, subepithelial deposits and low serum C3. No resolution of AKI after 8 weeks of presentation was unusual for PIGN, steering diagnosis towards C3G. Clinicians should note the high overlap between the clinical and histology of PIGN and C3G. It is imperative to conduct further studies to accurately diagnose and treat patient with C3G.

PUB047

Predictors of End Stage Renal Disease in Scleroderma Renal Crisis – A Single Center Experience
Sumeedha Dhar, Cybele Ghossein.
Div of Nephrology, Northwestern Univ - Feinberg School of Medicine, Chicago, IL.

Background: Scleroderma renal crisis (SRC) is one of the most acute and life-threatening complications of systemic sclerosis (SSc). It is typically characterized by accelerated hypertension and acute kidney injury (AKI). Angiotensin converting enzyme inhibitors (ACEI) are currently the treatment of choice for this disease. Despite use of ACEI, 50% of patients with SRC develop end stage renal disease (ESRD) which is associated with poor long term outcomes. Our aim was to define the clinical characteristics and outcomes of SRC patients admitted to our institution.

Methods: This was a retrospective chart review of all patients admitted with SRC to Northwestern Memorial Hospital (NMH) between the years of 1/1994 to 4/2015. ESRD was defined as the need for chronic dialysis during admission for SRC.

Results: There were 23 patients with a diagnosis of SRC made either clinically or by renal biopsy during this time period. Mean time to SRC was 1.3 years after diagnosis of SSc. 47% of patients developed ESRD during the same admission. Development of ESRD was not associated with age, gender, race, anti-RNA polymerase III test positivity, intensive care unit (ICU) admission, prior ACEI or angiotensin receptor blocker (ARB) use, or creatinine on admission. ESRD was significantly associated with time to control blood pressure.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
896A
Conclusions: SRC is a serious kidney and life threatening complication of SSC. Delay in blood pressure control increases risk of ESRD in SRC patients.

PUB048

Acute Kidney Injury Risk Assessment at the Hospital Front Door: What Is the Best Measure of Risk? Aled O. Phillips,1 Dafydd Phillips,1 Mohamed Hassan,2 John Geen,3 Vikas Lodhi,4 Hernaneth Bolusani,4 Gareth Roberts.1 1Dept of Clinical Biochemistry, Univ of South Wales, Wales, United Kingdom; 2Dept of Medicine, Royal Gwent Hospital, Newport, Wales, United Kingdom; 3Dept of Medicine, University Hospital of Wales, Cardiff, Wales, United Kingdom; 4Dept of Medicine, Prince Charles Hospital, Merthyr Tydfil, Wales, United Kingdom; 5Dept of Medicine, Univ Hospital Llandough, Cardiff, United Kingdom.

Background: We examined the prevalence of AKI-risk factors in the emergency medical unit, generated a modified risk assessment tool and tested its ability to predict AKI.

Methods: 1196 patients admitted to medical admissions units were assessed for patient associated AKI-risk factors. Subsequently, 898 patients were assessed for a limited number of fixed risk factors with the addition of hypotension and sepsis. This was correlated to AKI episodes.

Results: In the first cohort the prevalence of AKI risk factors was 2.1±2.0 per patient, with a positive relationship between age and the number of risk factors and a higher number of risk factors in patients ≥65yrs. In the second cohort 12.3% presented with or developed AKI. Patients with AKI were older and had a higher number of AKI risk factors. In the AKI cohort 72% of the patients had ≥2 AKI risk factors compared to 43% of the cohort with no AKI. When age ≥65 yrs was added as an independent risk factor 84% of those with AKI had ≥2 AKI risk factors compared with 55% of those with no AKI. ROC analysis suggest AKI. When age ≥65 yrs was added as an independent risk factor 84% of those with AKI episodes.

Conclusions: Detailed assessment of well established patient associated AKI-risk factors may not facilitate clinicians to apportion risk. This suggests that additional work is required to develop a more sensitive validated AKI predictive tool which would be useful in this clinical setting.

PUB049

Acute Kidney Injury, Requiring Renal Replacement Therapy – Incidence, Causes and Outcomes: One Center Experience Elena Zakhарова, Nephrology, City Clinical Hospital n.a. s.P. Botkin, Moscow, Russian Federation.

Background: Acute Kidney Injury (AKI) is complex condition, associated with high mortality and morbidity. We aimed to evaluate AKI incidence, causes, risk factors and outcomes in patients, managed in nephrology unit of general hospital and urgently requiring Renal Replacement Therapy (RRT).

Methods: Using electronic database for 2010-2014 (4531 admissions, 2257 patients), we searched 604 cases which met KDIGO AKI definition, and selected patients, required RRT.

Results: Study group included 115 patients (19% of all AKI cases), 51 (44%) male, 64 (56%) female, median age 61 [22; 89] years. In 102 (89%) cases AKI was community acquired. Median serum creatinine prior to start of RRT was 981 [242; 2665] μmol/l, 37 (32%) patients had known CKD. Causes and susceptibilities for AKI are shown in table.

Conclusions: In our patients, three renal manifestations of PNH were identified. They 76 (66%) patients partially or completely recovered kidney function, 27 (23%) were still dialysis-dependent after 3 month of follow-up, and 12 (10%) patients died.

PUB050

Renal Manifestations in Paroxysmal Nocturnal Haemoglobinuria Ram R1, Dakshinamurty K1, Krishna Parasad A.2 1Nephrology, Sri Venkateswara Inst of Medical Sciences, Tirupati, AP, India; 2Nephrology, Mahatma Sri Ramchandra Centenary Memorial Hospital, Hyderabad, Telengana, India; General Medicine, NIMS, Hyderabad, India.

Background: Paroxysmal nocturnal haemoglobinuria (PNH) is an acquired chronic disorder characterized by a triad of clinical features: haemolytic anaemia, purpura, thrombosis. Not many reports of renal involvement in PNH are available in literature.

Methods: We present a case series of PNH with renal involvement. We present the data of PNH patients attended to departments of General Medicine and Nephrology at a government run tertiary care institute in South India. The diagnosis of PNH in these patients during initial phase, between 1998 and 2004 was based on sucrose lysis and Ham’s test. After 2004, the diagnosis was based on flow cytometry to detect CD55 (MIRL), a glycoprotein, and CD55 (DAF) in regulation of complement action. The patient data was collected from 1998 to 2014.

Results: There were 13 patients of paroxysmal nocturnal haemoglobinuria in this period. The mean age was 37 years and the range was 16 to 68 years. There were 7 females. Acute renal failure was noted in 5 patients. Dialysis was performed in three of them. The mean serum creatinine and urea at the initiation of dialysis was 5.4 ± 0.6 mg/dL and 64.1 ± 6.1 mg/dL respectively. The median number of haemodialysis sessions done was four. Renal biopsy was done in four patients. The indication for the biopsy was acute renal failure of more than four weeks. The median number of glomeruli was 9. The tubules showed prominent brown granular pigment within the epithelial cells. It was confirmed as hemosiderin with the Perl’s Prussian blue reaction. A few deposits of hemosiderin were also seen within the tubular lumina. The pathological diagnosis in these four patients was acute tubular necrosis secondary to hemosiderin deposition. In three patients the urinalysis and serum chemistry was suggestive of Fanconi syndrome.

Conclusions: In our patients, three renal manifestations of PNH were identified. They were acute renal failure, renal vessel thrombosis and Fanconi syndrome. Chronic renal failure was not identified.
Filling the Gaps in Acute Kidney Injury Epidemiology: A Multicenter Prospective Study in Amazon

Background: In some areas of developing countries, infectious tropical diseases or animal venoms may be important causes of Acute Kidney Injury (AKI). Epidemiological studies of AKI incidence in these areas are scanty and prospective population-based studies are even scarcer.

Methods: Prospective data on all adult patients admitted in all intensive care units (ICUs) throughout the Western Amazon region (600 square kilometers and 100,000 inhabitants) were collected for 6 months in 2014. Patients with chronic kidney disease stage 5, kidney transplant or ICU stay < 48 hours were excluded. AKI was diagnosed by KDIGO and mortality was assessed 30 days after ICU discharge. Data are presented as mean±SD or percentages.

Results: 367 patients aged 57.8±19.2 years and with 39% white were evaluated. Main reasons for ICU admission were postoperative (34%), hemodynamic instability (22%) and respiratory failure (13%), with only 1% with tropical diseases. AKI incidence was 38%, but was lower in postoperative patients (28% vs 45% in non-postoperative; p=0.005). Mortality was higher in AKI patients (53% vs 30% in non-AKI, p <0.001). Postoperative patients who developed AKI had similar mortality to those non-operative (46% vs 56%, p=0.302).

Conclusions: AKI has a high incidence in ICU patients of the Western Amazon area. The causes of ICU admission did not differ from those seen in developed countries. The few number of patients with the typical tropical diseases of Amazon may be due to poor access to health care. The peculiar social geographical region characteristics, with rivers that are not navigable most of the year, long rain period that difficult access to larger cities and the lack of health services in diverse areas, may be associated to the present findings.

Funding: Government Support - Non-U.S.

Uncovering Complement Mediated Thrombotic Microangiopathy: Use of a Real Time Genetic Assay in the Diagnosis of Atypical Hemolytic Uremic Syndrome

Background: Improved diagnostic tests and greater understanding of pathophysiology of thrombotic microangiopathy (TMA) have led to more rapid differentiation of various types of TMA. While ability to rapidly diagnose TMA (ADAMTS13 activity >5%) has improved, atypical HUS (aHUS) remains diagnosis of exclusion due to poor sensitivity, high cost, and long turnaround time (TAT) of aHUS genetic assays. We describe a patient (pt) with hypothyroidism and renal insufficiency diagnosed with aHUS, using appropriate clinical algorithms for TMA, including “real-time” aHUS genetic assay (TAT 2-5 days).

Methods: 59 y.o. female with 1-2 week (wk) history of fatigue, anemia, thrombocytopenia, renal insufficiency, and recent diagnosis of hypothyroidism with changes in CBC and creatinine (Cr) over 3 wks: hemoglobin (hb) 13.9 to 7.1 g/dl, platelet count (plt ct) 241 to 68 X 10^9/L, and Cr 0.71 to 1.41 mg/dl (baseline Cr 0.56, BMI 19.5). Pt’s CNS status normal; no other signs/symptoms of systemic thrombosis noted. Additional labs: haptoglobin <9 mg/dL, LDH 1942 U/L (312-618 U/L), direct coombs negative, PT/ INR normal, albumin 3.6, IgG 1133 mg/dL, 5.6-schistocytes/high power field, ADAMTS13 activity 79% (40-130%) resulting out TMA.

Results: Pt received 11 plasma exchange (PE) treatments (txs) (hospital day [HD] 3-21). By day 4 of PE (HD 7), plt ct 197 X 10^9/L; despite 11 PE ttxs, LDH remained elevated (686-2123) and Cr rose to 2.72 (3.8-4.9X higher than baseline). aHUS genetic panel (sent HD 10, results on HD 17) revealed: positive variant in CFI gene (predicted to be significant, but not previously described) and hyperhomocysteinemia for 3 CFH polymorphisms. Pt clinically diagnosed with aHUS, received meningococcal vaccine (HD 1), induced eczulizumab started and PE stopped (HD 21). After 2 months of eczulizumab, pt’s Cr normalized.

Conclusions: With development of improved genetic testing (ie, increased sensitivity and speed), aHUS genetic assays may represent “real-time” diagnostic tools enabling more rapid assessment of selected TMA cases leading to more targeted treatment.

Oral Hydration: The Way Forward in the Prevention of Contrast-Induced Nephropathy

Background: Contrast induced nephropathy is defined as increased serum creatinine of 0.5 mg/dL (44.2 μmol/L), or a 25% increase of creatinine from baseline levels checked 48 hours after contrast exposure. Studies have suggested the use of intravenous fluids such as sodium chloride 24 hours prior to contrast exposure. However, this step would require the patient to be admitted prior to contrast medium exposure and incur extra cost for this hospital. This audit explores the use of oral hydration in the prevention of contrast-induced nephropathy.

Methods: Using the ICE computer system, all patients who were diagnosed with Type 2 Diabetes Mellitus and taking metformin were identified from the time period of January 2008 until January 2014. They were then advised to stop their metformin prior to contrast exposure. Recommendations were made for contrast prophylaxis which was given when 2 litres of oral fluids before and after the procedure. Patients were also given advice to get their renal function checked, 48 – 72 hours after contrast exposure. Their renal function pre and post contrast exposure were documented. Any patients with either aCr more than 20% or their eGFR more than 20% were then referred to the nephrology department for follow up.

Results: A total of 277 patients were included in this audit. The mean eGFR was 47 ml/min/1.73m^2. 79% of patients had their renal function checked within 48 – 72 hours, 15% patients had their renal function checked after that time and 6% of patients did not have their renal function rechecked at all. Only 0.7% of patients had deterioration of their renal function that met the criteria above. However it was important to note that these patients had also other multiple co-morbidities and the exposure to contrast was not the sole cause for the deterioration of their renal function.

Conclusions: Oral hydration should be considered as part of the protocol for the prevention of contrast-induced nephropathy. This regime has reduced the need for patients to be admitted into hospital admission for intravenous fluids, thus reducing waiting times for imaging and as well as reducing hospital cost.

Gemcitabine-Mediated Thrombotic Microangiopathy – A Rare Cause of Hemolytic Uremic Syndrome

Background: Thrombotic microangiopathy (TMA) is a pathological diagnosis of endothelial cell injury and microvascular thrombosis. TMA has been categorized in the present era as one of three distinct disease processes: 1) classical hemolytic uremic syndrome, 2) atypical hemolytic uremic syndrome (aHUS), and 3) thrombotic thrombocytopenic purpura. Our focus, aHUS, reflects an underlying aberrancy in regulation of the alternative complement cascade. Several genetic defects have been identified leading to an affinity to develop uncontrolled activation of this cascade which may commence after exposure to a trigger. Gemcitabine is one rare trigger described in the literature.

Methods: A 66 year-old female with locally advanced, unresectable pancreatic cancer who had completed 12 cycles of gemcitabine-abraxane therapy with no major oncologic progression on disease was referred with acute kidney injury. Two months prior to admission, she developed hypertension, nausea, and profound cytopenias requiring platelet and red cell transfusion. She endured a progressive decline in renal function with a nadir eGFR 19 mg/mL/1.73 m^2. One month prior to admission, her urinalysis reflected active sediment. Admission labs demonstrated microangiopathic anemia with thrombocytopenia. ADAMTS13 activity was normal (88%), consistent with aHUS. Renal biopsy confirmed subacute changes consistent with TMA. Despite discontinuation of the gemcitabine-abraxane therapy, she continued to demonstrate progressive anemia and thrombocytopenia in addition to persistent proteinuria, hematuria, and impaired eGFR. The patient was subsequently initiated on eczulizumab therapy.

Conclusions: Gemcitabine-mediated aHUS is rare and associated with a 75% mortality rate at four months. Previous attempts at therapy have included apheresis. However, current guidelines discourage apheresis in this patient population. To date, six cases of gemcitabine-mediated aHUS have reported the successful use of eczulizumab, a terminal complement inhibitor.
Dabigatran Induced Acute Kidney Injury and Management with Hemodialysis

**Background:** A 55-year-old man with a history of A Fib, cirrhosis, portal HTN, esophageal varices arrives in the ED, transferred from an outside hospital following initial presentation with multiple episodes of hematemesis and melena. Medication regimen recently changed with a switch from warfarin to dabigatran 8 months prior to admission in order to avoid frequent INR checks.

**Methods:** On admission, initial blood work was obtained and revealed: Hg 6.3 g/dL, INR 6.9, Scr 15.6 mg/dL and BUN 189 mg/dL. Patient was admitted to the intensive care unit for management of acute blood loss and AKI. On physical exam shows a pulse of 95 bpm and BP of 111/75 mmHg and mild hepatosplenomegaly, the physical exam was unclear but acute blood loss leading to prolonged ischemic insult was largely consistent with ATN, chronic tubulointerstitial nephritis, and IgA Nephropathy (HAA5 class I).

**Results:** Serum dabigatran concentration (conc) drawn on admission was 860 ng/mL. Following the initial emergent hemodialysis (HD) procedure, subsequent dabigatran conc. were determined during the second HD procedure. Predialysis and postdialysis dabigatran conc. were 130 ng/mL and 30 ng/mL, respectively. Pharmacokinetic parameters were calculated and shown in the table.

**Conclusions:** Dabigatran induced AKI is rare. The mechanism of the insult in this case was unclear but acute blood loss leading to prolonged ischemic insult was largely contributive. Hemodialysis was successful in removing the offending agent with resolution of bleeding but patient remains dialysis dependent.

**CO:** CARDIAC OUTPUT; COI: CARDIAC OUTPUT INDEX; LWWI: LEFT VENTRICULAR WORK INDEX; SVRI: SYSTEMIC VASCULAR RESISTANCE INDEX.

**Conclusions:** The use of CTBIA is useful to evaluate and classify patients with cardiorenal or cardiorenal syndrome. There are association between vascular resistance and renal tubular necrosis.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Results: Patients with lower vascular resistance and higher cardiac work have worse prognosis, associated with inflammatory state and thoracic hypervolemia, oliguria and higher renal replacement therapy requirements. But patients with higher thoracic volume have higher risk of respiratory failure.

Conclusions: CTHBA can be used to evaluate prognosis and therapy of higher risk AKI, as patients with vasoplegic state (with inflammatory origin and higher multiorgan failure risk) or thoracic hypervolemia (with higher respiratory failure and intubation risk).

PUB060

Abruptio Placenta as a Complement Amplifying Condition for Atypical Hemolytic Uremic Syndrome

Background: Endothelial injury resulting in microvascular thrombosis is the underlying pathology leading to organ injury in aHUS. The syndrome is characterized by microangiopathic hemolytic anemia, thrombocytopenia, and ischemic injury to multiple organs including the kidney. Complement amplifying conditions often lead to the activation of complement cascade involved in the pathogenesis of atypical HUS. In this report, we present 33-year-old Hispanic women with abruptio placenta at 33 weeks of gestation and fetal death who underwent cesarean section. Post procedure, patient developed microangiopathic hemolytic anemia (6.7 mg/dl), thrombocytopenia (39,000/µL) and renal failure necessitating initiation of hemodialysis. Fibrogen (267 mg/dl), PT, PTT were normal while LDH was markedly elevated at 2670 IU/L. Haptoglobin was severely reduced at 5.8 mg/dl. Market schistocytosis was observed on peripheral smear. ADAMTS 13 was ordered and plasma exchange was initiated. Five sessions failed to show any improvement and ADAMTS 13 activity returned at 56%. Plasma therapy was unsuccessful and Eculizumab (monoclonal antibody directed against complement C5) was initiated for the diagnosis of aHUS. At a follow-up of two weeks patient is off dialysis with a serum creatinine of 3.4 mg/dl, hemoglobin of 8.8 mg/dl and platelet count of 147,000/µL. We believe that abruptio placenta acted as a complement amplifying condition in this case. However, pregnancy, fetal loss and caesarean section can all serve as complement amplifying conditions for aHUS.

Methods: Case Report

Results: Successful outcome with Eculizumab therapy.

Conclusions: aHUS responding to Eculizumab therapy.

PUB061

Foscarnet Crystal-Induced Nephropathy in a Patient with Diminished Native Renal Capacity

Sadia Ahmed, 1 Patrick J. Hensley, 1 Virgilius Cornea. 1

1Pathology, Univ of Kentucky; 2Nephrology, Univ of Kentucky.

Background: Drug-induced crystalline nephropathies are characterized by glomerular, tubular or interstitial injuries with rising creatinine, hematuria and low grade proteinuria. Foscarnet is a pyrophosphate analog that inhibits DNA polymerase in ganciclovir-resistant CMV. Tubular-interstitial damage due to Foscarnet is common but reports of crystalline-induced nephrotoxicity are rare. We report this unique case of Foscarnet crystal-induced nephropathy in a patient with lymphoma and solitary functioning kidney.

Methods: A 56 year old female with history of solitary functioning left kidney with remote history of right kidney atrophy due to obstructive uropathy was diagnosed with stage IV mantle cell lymphoma. Renal function was normal prior to chemotherapy and stem cell transplant. This was complicated by CMV infection requiring IV Foscarnet for 8 weeks. She developed AKI with nephrotic range proteinuria and hematuria. The patient was initiated on hemodialysis. Renal biopsy showed deposition of calcium crystals in the mesangium and interstitium characterized by short sticks with angular edges and birefringence on polarized light microscopy.

Conclusions: Our study highlights the overestimation of renal function by MDRD equation in critically ill patients with acute kidney injury (AKI). KeGFR may be more accurate in tracking renal function changes in AKI. Further studies are needed to confirm these findings.
A Curious Case of Evans Syndrome
Sugar R. Patel, Imara Dissanayake.
Internal Medicine, Albert Einstein Medical Center; Philadelphia, PA.

Evans syndrome is a rare autoimmune condition in which antibodies attack their own RBC and platelets resulting in an hemolytic anemia (AIHA) and ITP in the absence of a known etiology. Both of these can occur simultaneously or sequentially. Although many cases are idiopathic in origin, ES has been associated with other conditions in half of the cases, including infections and lymphoproliferative disorders.

Methods: A 45 year old African American male seen in ED with a Hgb of 6.4 and asymptomatic. The patient has a history of autoimmune hemolytic anemia (AIHA), immune thrombocytopenic anemia (ITP), anti-phospholipid syndrome (APS) with a previous DVT/PE and non-compliant with warfarin. Labs On admission Hgb 6.4, Ptts 14, Bil 1.3, D Bil 0.4, LDH 346, Haptoglobin <8. He had AIHA (Cr 0.9), with new onset nephrotic range proteinuria. Renal US showed medical renal disease. ANA 1:160, double stranded DNA was negative. Anti MPO, P-ANCA, C-ANCA, antiproteinase 3, atypical P-ANCA and glomerular basement membrane antibody were negative. CH 50,C3 and C4 were all low. No cryoglobulins were detected in the blood assay. Urine Electrolytes was negative for monoclonal light chains. Renal biopsy was performed and showed findings consistent with lupus nephritis stage 4/5. The patient was treated with PGBs and given pulse dose steroids for 3 days after which his hemoglobin remained stable.

Results: ES is diagnosed in only 0.8% to 3.7% of all patients with either ITP or AIHA at onset. Since it is thought to be secondary to immune dysfunction, a high clinical suspicion should be maintained for underlying autoimmune disease. However this patient was unique, he did not meet the standard criteria for SLE but demonstrated lupus nephritis on biopsy. This case reflects that we should have a high suspicion for SLE and lymphoproliferative diseases even in asymptomatic patients with Evans Syndrome.

Anticoagulation-Free Continuous Renal Replacement Therapy: A Single Center Observation
Akshatha Rao, Ziauddin Ahmed.
Div of Nephrology, Drexel Univ.

Background: Renal failure in the ICU setting is associated with 40-60% mortality. Continuous renal replacement therapy (CRRT) is used for volume and electrolyte management in critical care units. To avoid cloting of hemofilters, patients are routinely started on anticoagulation. In literature, anticoagulation has been associated with complications of increased risk of bleeding and metabolic or electrolyte disturbances based on type of anticoagulation used. We aimed to investigate the length of cartridge use and the association of anticoagulation.

Methods: We conducted a retrospective review of 20 ICU patients who were started on CRRT over a course of 6 months for acute renal failure. We looked at the number of cartridges used per day. Prescription for CRRT was dialisate flow rate of 25-35 ml/kg/h and blood flow rate of 250 ml/h. No anticoagulation was ordered initially due to bleeding changes in this cohort. All patients were ordered 100 ml of normal saline flushes every 4 hours. Results: For 70% of the patients, the hemofilter cartridge lasted >24 hours. 30% of the patients required more than 1 filter per day, of which only 1 patient was started on a heparin drip for anticoagulation due to multiple filter changes. We used predilution replacement fluid to reduce the blood viscosity and hemoconcentration for the patients requiring > 2 filter changes per day. Decreased requirement of filter change was noted after these changes were made. Among the patients with increased filter clotting, 33% had femoral non-tunneled dialysis catheters and 50% had internal jugular tunneled dialysis catheters. Longer duration of dialysis was associated with increased cartridge use per pearson correlation 0.188 (p<0.000). No documentation was made in the nursing notes to distinguish between vascular access problems versus filter clotting.

Conclusions: Recurrent filter clotting leads to interruption of RRT. Frequent filter changes is not cost effective. However anticoagulation in critical care settings poses multiple potential problems. There was an association between percutameters and increased cartridge use.

Rosuvastatin Has a Protective Effect against Hypertonicity-Induced Cell Damage
Miku Sato, Masaru Horio.
Division of Cardiology, Osaka Univ Graduate School of Medicine, Suita, Japan.

Background: Contrast-induced nephropathy (CIN) is one of the causes of acute kidney injury. Some studies raised a concern that statins have protective effect against CIN. Hypertonic stress in renal tubular cell is a possible factor inducing cell damage in CIN. Reactive oxygen species (ROS) can induce apoptosis. We studied the effect of rosuvastatin on hypertonicity induced cell damage in MDCK cells.

Methods: Hypertonic medium was made by addition of NaCl. Rosuvastatin was added 24 hours before the hypertonic exposure. Cell damage was assessed by LDH activity in culture medium. Apoptosis was evaluated by caspase-3 activity. Content of cellular glutathione (GSH), an important antioxidant, was measured.

Results: Hypertonicity more than 600 mOsm showed significant cytotoxic effect in MDCK cells. LDH activity in culture medium of 620, 640 and 660mOsm cells increased in a dosimality dependent manner (Figure). Low concentration (0.1 and 1.0 µM) of rosuvastatin had a protective effect against the hypertonicity-induced cell damage. On the other hand, 10 µM rosuvastatin that had no significant cytotoxic effect in 300mOsm condition, stimulated hypertonicity induced cell damage.

Conclusions: Low dose of rosuvastatin has a protective effect on hypertonicity-induced cell damage in MDCK cells.

Funding: Government Support - Non-U.S.
Conclusions: In summary, high expression of SRF associates with increased fibrosis and decreased survival in IgA nephropathy, perhaps by enhancing TGF-β-mediated downregulation of srps and E-cadherin in HKC.

PUB068
Increased ErythrocYTE Reactive Oxygen Species Production Induced by Indoxyl Sulfate Precedes Red Blood Cell Death
Gabriela Ferreira Dias,1 Viktoriya Kuntsevich,2 Lisa S. Nakao,3 Felype C. Barreto,3 Stephan Thijsen,4 Peter Kotanko,5 Roberto Peccei-Filho,1 Andrea Novais Moreno-Amoral,1 Pontifica Univ Catolica do Parana, Brazil; 1Icahn School of Medicine at Mount Sinai, New York; 2Univ Federal do Parana, Brazil; 3Renal Research Inst, New York.

Background: The uricemic toxin indoxyl sulfate (IS) triggers eryptosis, an event characterized by phosphatidylserine (PS) exposure on red blood cell (RBC). The aim of the present study was to evaluate whether increase in RBC reactive oxygen species (ROS) induced by IS precedes PS exposure.

Methods: RBC from healthy controls (HC) were incubated for 4, 12 or 24 h with IS (free concentration 4.5 mg/L) in the presence or absence of free radicals scavenger N-acetylcycteine (NAC 0.5 mM). Flow cytometry was employed to assess eryptosis (annexin-V+ binding) and ROS (DCFH-DA).

Results: Incubation of HC-RBC with IS over 4 h did not trigger significant eryptosis compared to control cells incubated without IS (4.5 ± 1.2% vs 3.4 ± 0.1%). However, 12 h and 24h incubation with IS increased levels of eryptosis in a time-dependent manner (10.4 ± 3.4% and 16.6 ± 6.1%, respectively). This IS-induced PS exposure on HKC-RBC was inhibited in the presence of NAC (6.0 ± 1.3% and 6.5 ± 1.4%, respectively). On the other hand, ROS production by HC-RBC was increased even after only 4 h of incubation with IS in a time-dependent manner (14 ± 4.2%, 22 ± 1.5 ± 3 and 34 ± 8.15 ± 8% for 4, 12h and 24h respectively) when compared to control cells (6.6 ± 2.3%, 4.2 ± 0.5% and 5.2 ± 1.8%, respectively). ROS production was inhibited in the presence of NAC (6.6 ± 3.4%, 6.3 ± 2% and 13.4 ± 10.5%) demonstrating the ability of an antioxidant to reverse the oxidative stress induced by IS.

Conclusions: Taken together our results suggest that IS in a high free concentration, which is in accordance with reported free toxin concentration in patients, induces ROS production in HC-RBC that precedes PS exposure. Thus, imbalance of RBC redox status induced by IS appears to be an important mechanism of elevated eryptosis observed in CKD that consequently may contribute to renal anemia.

PUB069
Impact of Constitutive C-MIP Expression on Mouse T-Cell Proteome
Mario Ollero,1 Pauline Vachin,2 Cerina Chhuon,3 Kelitia Sendeyo,1 Melanie Mangier,1 Ida Chiara Guerrera,1 Andrě Pavlak,1 Djilali Sahali.1 1INSERM, U955 (Eq. 21), Créteil, France; 2Plateau Protéomes Necker, Paris, France.

Background: The protein c-mip is overexpressed in lymphocytes and podocytes of MCNS patients. In order to dissect its role in INS pathogenesis, we generated a transgenic mouse expressing c-mip in peripheral mature T-cells. We aimed to evaluate the impact of c-mip expression on T-cell proteome in basal and stimulating conditions.

Methods: T-cells from transgenic (TG) and control (WT) mice (n=3) were purified by negative immunoextraction, and subjected to anti-c-CD3 and anti-CD28 stimulation, to mimic activation of antigen presenting cells. At 0 to 60 min post-activation, total proteins were extracted, trypsin digested, and peptides analyzed by nano-RSLQC on Exactive Plus MS. Protein quantification was performed by a label-free approach using MaxQuant and Perseus software on three parallel technical replicates per sample.

Results: The expression levels of 2660 proteins were compared in the four conditions. As a result, 46 proteins were found differentially expressed between TG and WT as a function of T-cell activation (two-way ANOVA interaction, p<0.05). Among these, GO annotation showed a significant enrichment in proteins bearing ATPase activity. Hierarchical clustering by K-means algorithm displayed, most remarkably, a cluster of 14 proteins upregulated upon T-cell activation in WT mice but depleted in TG mice in the same conditions - including KEGG annotations for tight junction, Wnt signaling, TLR signaling, RIG-I-like receptor signaling, Notch signaling, spliceosome, riboflavin metabolism, and DNA replication-, and a cluster of 11 proteins depleted in WT and augmented or unchanged in TG after activation – involved in aminoacid and nicotinamide metabolism, proteasome, and regulation of actin cytoskeleton. Studies are underway to explore the mechanisms involved.

Conclusions: c-mip overexpression elicits profound alterations in the protein expression pattern following T-cell activation in mice, involving diverse signaling, metabolic pathways and cellular functions. These results, along with other preliminary data obtained from the same mouse model, point at a defect in T-cell activation associated with c-mip expression.

An Investigation into the Prognosis of Nephrotic Syndrome and Regulatory T Cells in Elderly People
Tetsuko Yasuno,1 Internal Medicine, Fukuoka Univ, Fukuoka, Japan.

Background: Peripheral blood flow cytometry analysis of nephrotic syndrome (NS) in children has been performed, and among T cells, regulatory T cells (Treg) are involved in NS pathogenesis. There are reports about Tregs and ANCA-associated glomerulonephritis, and the nephritic inhibitory effect of Tregs has become clear. As there has been no investigation focusing only on NS in elderly people, we conducted the analysis in this study.

Effects of 1,25-Dihydroxy Vitamin D3 on Treg Cells, Interleukin-17, RORγt in Rats with IgA Nephropathy

Hui Guo, Div. of Nephrology, 2nd Affiliated Hospital of Shanxi Medical Univ, Taiyuan, Shanxi, China; DIV of Rheumatology, 2nd Affiliated Hospital of Shanxi Medical Univ, Taiyuan, Shanxi, China.

Background: To investigate the relationship between Treg cells, RORγt, IL-17 and rats with IgA nephropathy; to explore the intervention effect of 1,25(OH)2D3 on Treg cells, RORγt, IL-17 expression in rats with IgA nephropathy.

Methods: We chooseister 52 rats, with which 8 rats were chosen in control group (group D) in random, while other 44 rats were established the IgA nephropathy model by mucosal immune with bovine serum albumin and were divided into model group (group E) in random, while other 44 rats were established the IgA nephropathy model by mucosal immune with bovine serum albumin and were divided into model group, 1,25(OH)2D3 treated group, prednisone treatment group and prednisone +1,25(OH)2D3 treatment group.

Results: The change of 24 hours of urinary protein, red blood cells in urine, creatinine and blood calcium of rats were detected. Foxp3, RORγt and IL-17 levels were detected by using RT-PCR, Immunohistochemistry and Westernblot.

Conclusions: These data suggests that the novel chronic renal ischemia model by coating renal artery is an appropriate animal model for CKD, which shows a slowly progressive tubulointerstitial injury.

Dialysis Induces Morphological Changes and Eryptosis in Erythrocytes

Grzegorz Kania,1,* Grazia Maria Virzi,1 Sabrina Milan Manani,2 Anna Clementi,2 Alessandra Brocca,2 Massimo de Cal,2 Claudio Ronco.1

Background: Death of erythrocytes (eryptosis) is characterized by cell shrinkage, membrane blebbing, activation of proteases, and phosphatidylserine (PS) externalization. Exposed PS is recognized by macrophages that engulf and degrade cells. Eryptosis is a physiological mechanism under complex regulation. During their daily life, erythrocytes (RBCs) are exposed to several stressors, such as oxidative stress, osmotic shock, energy depletion. Eryptosis is observed in a wide range of clinical conditions, such as CKD, malignancy, diabetes and sepsis. The aim of this study was analyzed cell volume and PS abundance at the RBC surface in peritoneal dialysis (PD) and hemodialysis (HD).

Methods: 40 PD patients, 30 HD patients and 17 healthy subjects (CTR) were included in the study. All measurements were made in isolated RBCs. RBC volume and morphology were estimated from forward scatter, PS exposure at the cell surface was estimated from FITC-AnnexinV binding using flow cytometric analyses.

Results: We observed that the RBCs of PD and HD patients are either rather dramatically deranged in their morphology. Furthermore, the PS externalization on the RBC surface was significantly higher in these groups than in CTR (PD patients: 2.6%; IQR 1.6-3.7; HD patients: 2.2%; IQR 1.2-4.1 versus CTR: 0.8%; IQR 0.7-1.3; p<0.000001). We did not find significant differences in PS exposure between the PD and HD patients (p<0.047).

Toll Like Receptor 2, 4 and 9 Expression Is Enhanced in Kidneys of Patients with Anti Neutrophil Cytoplasmic Antibody Associated Vasculitis (AAV)

Kim M. O’Sullivan,1 Anthony Longano,2 A. Richard Kitching,2 Stephen R. Holdsworth.2 1Dept of Medicine, Monash Univ, Clayton, Victoria, Australia; 2Dept of Nephrology, Monash Health, Clayton, Victoria, Australia; 3Pathology Dept, Monash Health, Clayton, Victoria, Australia.

Background: Toll like receptors (TLRs) may be the possible link between infection and autoimmunity. This study investigates the distribution of TLR2, 4 and 9 in human kidney biopsies from patients with AAV (40), lupus (8) and controls (with non proliferative glomerular lesions, minimal change and thin membrane disease, 10).

Methods: Biopsies were examined by confocal microscopy with immunofluorescent staining in serial sections for the cellular distribution of TLR2, 4 and 9. Mean fluorescent intensity (MFI) was measured by imaging software (Image J) and was correlated with histopathological parameters.

Results: TLR2, 4 and 9 in the AAV group, (for both MPO and PR3 patients) had significantly stronger staining than controls in glomeruli (1.5 vs 13.3AU; 0.25 vs 32.0AU; 0.7 vs 36.2AU, all P<0.05, respectively) and the interstitium (7.4 vs 63.0AU; 0.41 vs 53.8AU; 1.6 vs 59.6 AU, all P<0.05, respectively). The lupus patients also had higher
expression of TL2R (4.8AU), 4 (12.6AU) and 7 (7.3AU, P<0.05) compared with controls, but their staining was significantly less than that of the AA V group for all TLRs (P<0.05).

Cellular infiltrates contained intense staining for TL2R, 4, 9 and 2 on macrophages and neutrophils in both glomeruli and interstitium. TL2R and TL4 staining was prominent on both endothelial cells and podocytes, although TL9 was particularly evident on podocytes. In AA V glomerular TL4 expression correlated with the % of normal glomeruli (r=0.48, P=0.03) suggesting TL4 prominence occurs in early glomerular lesions. Glomerular TL2R and 9 were present concurrently in more severely affected glomeruli (r=0.71, P=0.0001). TL2R, 4 and 9 were prominent in all crescentic glomeruli of AA V and lupus patients.

Conclusions: this study demonstrates that TL4 expression is most prominent in AA V. Significant expression of TL2Rs was evident on leucocytes and immature glomerular cells. TL4R is prominent in early glomerular lesions, while TL2R and 9 correlate with severe glomerular lesions.

Podocyte CD40 Expression in Patients with Post-Transplant FSGS Recurrence: Rutger J. Maas,1 Brigit Willemsen,2 Henk Jeroen,3 Jeroen Deegens,3,1 Jack F. Wetzel3,1 Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; 2Pathology, Radboud Univ Medical Center, Nijmegen, Netherlands.

Background: antibodies against CD40 were recently reported to predict post-transplant recurrent FSGS (rFSGS) with 78% accuracy (Deville et al. Sci Transl Med 2014). Using immunohistochemistry, the authors reported strong focal podocyte CD40 expression in glomerular lesions of two patients with rFSGS. We sought to validate this novel finding of podocyte CD40 expression as a potential marker of rFSGS.

Methods: we used formalin-fixed, paraffin embedded kidney tissue from five patients with rFSGS. Two samples were obtained from nephrectomy specimens, and three were needle biopsy specimens. All patients had nephrotic range proteinuria at the time of tissue sampling. A human tonsil was used as a positive control. For immunohistochemistry, four mm slices were cut and deparaffinised. After endogenous peroxidase block, antigen retrieval was performed by boiling in a microwave with EDTA buffer (pH 9.0). Slides were incubated with primary antibody mouse anti CD40 (clone 11E9, Abcam ab50849) diluted in PBS with 1% BSA overnight at 4°C. Slides were incubated with primary antibody mouse anti CD40 (clone 11E9, Abcam ab50849) diluted in PBS with 1% BSA overnight at 4°C. Detection was done with Brightvision biotin-free goat anti rabbit/mouse poly HRP (Immunologic) and DAB as substrate.

Results: specificity and adequacy of the staining was confirmed by strong CD40 expression in tonsillar germinal centers (Figure, panel A). In kidney samples from patients with rFSGS, CD40 staining was found in areas of interstitial cellular infiltration, and some tubular epithelial cells (Figure, panel B). However, no glomerular CD40 was detected in any of the rFSGS samples.

Conclusions: we could not confirm glomerular CD40 staining in rFSGS with immunohistochemistry. The role of CD40 antibodies in rFSGS pathogenesis needs further study and validation.

Increased Cellular Microchimerism in Women with Systemic Lupus Erythematosus: Suzanne Wilhelms,1 Malu Zandbergen,1 Emilie Rijnink,1 Juan D. Diaz de Pool,3 Mathilde M.M. Almekinders,1 Hans J. Baede,1 Jan A. Brujin,1 Ingeborg M. Bajema,2 1Pathology, Leiden Univ Medical Center, Leiden, Netherlands; 2Gynaecology, Leiden Univ Medical Center, Leiden, Netherlands.

Background: Microchimerism (Mc) has been suggested to play a role in the development of systemic lupus erythematosus (SLE). We previously showed that Mc occurs twice as often in kidney biopsies of patients with lupus nephritis as in controls. Recently, it was demonstrated that the amount of Mc in lupus nephritis is associated with renal function (Arthritis Research & Therapy, 2015). Because in previous studies the Y chromosome was used to detect Mc, these studies were limited to detecting male Mc and the origin of the chimeric cells remained largely unknown. The aim of the present study was to determine the frequency, amount and origin of chimeric cells in SLE patients and controls, by using insertion-deletion polymorphisms and null alleles for the detection of Mc.

Methods: We included 11 SLE patients and 22 controls, as well as their children and mothers. A quantitative PCR for insertion-deletion polymorphisms and null alleles was used to detect Mc in peripheral blood mononuclear cells and granulocytes. The relationship between the presence of Mc and disease onset, disease activity and accumulated damage since disease onset was investigated.

Results: Mc was detected more often in SLE patients than in controls (54.4% vs 13.6%, P=0.007), and was fetal in origin in almost all cases. The median total number of fetal chimeric cells was significantly higher in patients than in controls (5x10^5 versus 2.5x10^5, P=0.048). In 50% of SLE patients with Mc, Mc originated from multiple relatives whereas in controls Mc was derived from only one relative. We found no relationship between Mc and clinical or laboratory parameters.

Conclusions: SLE patients had Mc in peripheral blood more often than controls, and at higher levels. We showed that Mc was mostly fetal in origin and, in SLE patients, could be derived from multiple relatives. Our findings substantiate the role for Mc in autoimmune diseases such as SLE.

An Oxalate-Induced Mouse Model of CKD That Displays Common CKD Complications: Hans J. Baelde,1 Shrikant R. Raj,1 Jeroen Deegens,2 Hans J. Baelde,1 Julian A. Marschner,2 Simone Romoli,1 Jyaysi Desai,1 Santhosh Kumar Vr,1 Peter S. Aronson,1 Felix Knauf2 1Univ of Erlangen-Nürnberg; 2Yale Univ School of Medicine.

Background: Chronic kidney disease (CKD) research is limited by the lack of a convenient inducible C57BL/6 mouse model mimicking relevant human CKD complications. We have reported a high soluble oxalate diet (50 µmol/g sodium oxalate mixed with virtually calcium free diet) that induces a progressive decline in glomerular filtration rate (GFR) reflected by increasing creatinine as well as blood urea nitrogen levels in C57BL/6 mice.

Methods: All in vivo experiments were approved by the local government authorities. Computed tomography, ultrasound and MRI were used for imaging.IHC, RT-PCR were used for data analysis. GFR was measured using single i.v. bolus injection of FITC sinistrin in conscious mice.

Results: We now demonstrate that mice fed this high soluble oxalate diet develop typical CKD complications such as sustained hypertension, normochromic anemia, metabolic acidosis, hyperphosphatemia, hyperparathyroidism, and hyperkalemia. Renal histology is characterized by calcium-oxalate crystal plugs in the tubular lumen, tubular atrophy, interstitial fibrosis, and atubular glomeruli. This pathophysiology of CKD resembles that of primary hyperoxaluria type I, also in terms of renal ultrasound, computed tomography, and magnetic resonance imaging. The duration of feeding a high soluble oxalate diet determines the amount of nephron loss, interstitial fibrosis, and impaired GFR equivalent to different stages of CKD. This can be used to produce various levels of stable impaired baseline GFR, a useful way to study, for example, AKI on precedent CKD.

Conclusions: We conclude that feeding a high soluble oxalate diet is a convenient way to induce progressive and stable CKD with clinically established complications in C57BL/6 mice. This model should serve to be useful for many areas of CKD research and avoid surgery to induce nephron loss or renal fibrosis.

Cyclosporine A Reduces Renal Injury Through Protecting Glomerular Barrier Function in Post-Transplant FSGS: Jilong Li,1 Juan Wang,2 Lining Wang,2 Dept of Nephrology, First Affiliated Hospital of China Medical Univ, Shenyang, Liaoning, China.

Background: Cyclosporine A (CsA) has been reported to reduce proteinuria in several kinds of kidney diseases. Glomerular barrier function is important in preventing urinary protein loss. The aim of this study was to elucidate the effects of CsA on glomerular barrier function in post-transplant FSGS.

Methods: Wistar rat PHN model was established by injecting antisera against renal tubular epithelial antigens (anti-FxA1) following pre-immunization. The experiment included Group 1: PHN control, Group 2: PHN plus CsA treatment before anti-FxA1 injection, Group 3: PHN plus CsA treatment for the first 7 days after injection, and Group 4: PHN plus CsA treatment from the 8th day after injection. Serum creatinine (sCr) and urinary protein (uPro) were measured at the 7th and/or the 14th day. Kidney tissues were obtained at the 14th day and labeled with a cation tracer polyethyleneimine (PEI) to study the distribution of negative charges on glomerular basement membrane (GBM). Kidney pathological changes were investigated.

Results: PHN model was established showing proteinuria and kidney injury of the renal GBM, a mass deposition of immune complex (IC), and decreased density and disturbed distribution of negative charges along the GBM. sCr was not increased in all of the groups. With CsA treatment, uPro was significantly declined in Group 2 and 3 at 7th and/or the 14th day. Kidney tissues were obtained at the 14th day and labeled with a cation tracer polyethyleneimine (PEI) to study the distribution of negative charges on glomerular basement membrane (GBM). Kidney pathological changes were investigated.

Conclusions: PHN model was established showing proteinuria and kidney injury of the renal GBM, a mass deposition of immune complex (IC), and decreased density and disturbed distribution of negative charges along the GBM. sCr was not increased in all of the groups. With CsA treatment, uPro was significantly declined in Group 2 and 3 at 7th and/or the 14th day. overwhelmed and glomeruli may be exposed to high free heme, exceeding 200 µM.

Results: ADR triggered overexpression of caspase-1 and IL-1β in kidney tissue of WT mice, but not in that of KO mice. ADR induced albuminuria and GS, which was accompanied with decreased kidney weight/body weight ratio (Kw/Bw), and increased Cr and TCH levels in both KO and WT mice. Compared with WT animals, KO mice showed significantly lower ACR, reduced GS scores, increased Kw/Bw, and attenuated Cr levels (P<0.05 each). Meanwhile, elevated expression of TNF-α and INF-γ, augmented 12-LO, and decreased PPAR-α, SDHA, and SOD2 levels were observed in ADR-treated kidneys, and all these changes were shown to be significantly ameliorated in KO mice. In addition, positive correlation between Cr and TCH was recognized in both KO and WT ADR-treated mice.

Conclusions: Cytokine-mediated inflammatory cascade, hyperlipidemic injury, and impaired mitochondrial function can be exposed to high free heme, exceeding 200 µM. However, while HO-1 prominently increases in tubules, it is barely detectable in glomeruli. We hypothesized that this is due to presence of a HO-1 expression “threshold” above which HO-1 induction in glomeruli is not sustainable.

Methods: hmdox1-1 rats were generated by Zinc Finger Nuclease (ZFN)-mediated HO-1 gene disruption and rats with GEC targeted HO-1 overexpression (GEC+HO-1) by Sleeping Beauty Transposon mediated transgenesis using a nphrin promoter. Glomeruli from wild type (WT) or hmdox1-1 or GEC+HO-1 rats were incubated for 18 h with 10% HPX replete (HPX+) or HPX-deficient (HPX-) serum obtained from HPX knock-out mice. Exogenous heme was added at concentrations encountered in hemolytic disorders (100-400 µM). HO-1 protein levels were assessed by western blot.

Results: HO-1 protein was reduced by 70% in hmdox1-1 and increased by 2-fold in GEC+HO-1 glomeruli. HO-1 protein levels were different between 10% HPX+ serum vs serum-free media. In incubations with varying dilutions of HPX serum (1.25, 2.5, 5, 10%) HO-1 levels in WT glomeruli progressively increased and were 2.5-fold higher than 10% HPX serum compared to 10% HPX serum. Co-incubation with 10% HPX serum and heme (200, 400 µM) markedly reduced HO-1. This reduction was attenuated in incubations with higher dilutions (2.5%) of HPX serum or with 10% HPX serum. The effect of heme on HO-1 levels in glomeruli incubated with HPX serum was recapitulated in GEC+HO-1 glomeruli. In contrast, heme further increased HO-1 in hmdox1-1 glomeruli.

Conclusions: Heme-mediated HO-1 induction in glomeruli is limited by HO-1 expression levels attained. This may serve to limit level of HO activity thereby preventing excessive heme-derived Fe stress stimuli of extrinsic coagulation pathways and is also related to various biologic effects of heme repletion, such as activating cell metabolism, oxidative stress, de-differentiation & detachment. The purpose of this study was to compare commonly used conditionally immortalized podocytes with primary podocytes, by measuring podocyte markers and responses to injury.

Results: Primary human podocytes were isolated and cultured from a healthy human donor kidney and compared to 1) a subclone (C5) of conditionally immortalized human podocytes (selected based on podocyte specific gene expression) and 2) conditionally immortalized mouse podocytes. Cellular phenotypes and gene expression were measured using high content screening (HCS), qPCR and western blots. For assessment of diabetic protection often use the storimeters pyruvamiminacacid and TGF-β. We demonstrate cytoprotection by multiple reference compounds with these results. We have also increased the disease relevance of stressors by showing that stress isolated from proteinemia db/db mice differentially elicits podocyte injury across multiple parameters.

Conclusions: Our results validate the use of conditionally immortalized C5 podocytes by benchmarking against primary human podocytes. We have also enhanced the pathological relevance of models of podocyte injury by incorporating key disease-relevant stressors and readouts.

Hypoxia Stimulates the Expression of Tissue Factor in Human Podocytes in Culture

Background: Hypoxia contributes to tubulointerstitial injury, however, the effect on podocytes and its underlying mechanisms are less well understood. Tissue factor (TF) is the initiator of extrinsic coagulation pathways and is also related to various biologic effects of hypoxia such as activating cell metabolism, oxidative stress, de-differentiation & detachment. The purpose of this study was to compare commonly used conditionally immortalized podocytes with primary podocytes, by measuring podocyte markers and responses to injury.

Methods: Conditionally immortalized human podocytes were grown at 33°C and differentiated at 37°C. The cells were treated in normoxic or hypoxic conditions. mRNA expressions of TF and TFPI were analyzed by quantitative RT-PCR, and protein levels of TF and TFPI in cytoplasm and TFPI in supernatant were analyzed by ELISA. The creation of TF and HIF-1α were demonstrated by immunofluorescent staining. We used sRNA for the temporal knockdown of HIF-1α and Egr-1, and pyridoline dithiocarbamate (PDC) for the inhibition of NF-κB.

Results: Hypoxia increased mRNA expression of TF (6h; 2.3±0.05 fold, p<0.001, 24h; 5.6±2.4 fold, p<0.005) and suppressed TFPI (6h: 0.5±0.04 fold, p=0.05, 24h: 0.2±0.06 fold, p<0.001) compared with normoxia. The protein levels of TF in the cell lysate were increased and TFPI in the supernatant were decreased. The TF staining was enhanced in
The cytostasis of podocyte. As expected, HIF-1α was strongly stained in the nuclei of podocytes exposed to hypoxia for 6h. The expression of TF was not affected by HIF-1α siRNA, and neither Egr-1 siRNA. Whereas, PDTC reduced the induction of TF by hypoxia.

Conclusions: Hypoxia upregulated the expression of TF in human podocyte Nf-κB dependently, and HIF-1α and Egr-1 independently. These changes may be related to the podocyte disorders and lead to proteinuria in the hypoxic condition.

**Integrity of the Mature APOL1 Protein Is Indispensable for Its Toxicity**

Xianjun Lan,1 Hongxiu Wen,2 Ashwani Malhotra,3 Karl Leon Skorecki,4 Pravin C. Singh.5 1Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY; 2Medicine, Rambam Health Care Campus, Haifa, Israel.

**Background:** Several clinical reports have demonstrated that the development of higher rates of non-diabetic glomerulosclerosis (GS) amongst African Americans can be attributed to two coding sequence variants (G1 and G2) in the APOL1 gene. Recent studies indicate that the gene products of these APOL1 risk variants have augmented toxicity in kidney cells. The APOL1 protein is composed of several functional domains, including signal peptide (SP), pore forming domain (PFD), membrane address domain (MAD), and SRA-interacting domain. However, it is not clear, which domain contributes to APOL1 induced cellular toxicity. In case, specific domain is contributing to APOL1-induced cellular toxicity, it will suggest us to design therapeutic strategy to target the specific domain.

**Methods:** To investigate the relative contribution of each domain to cell injury, we constructed serial of expression vectors to delete each domain, we transfected these vectors into the human embryonic kidney cell line 293T, and then compared the cytotoxicity. In addition, we conducted studies in which APOL1 wild type (G0) was co-transfected in combination with G1 or G2 to see whether G0 could counteract the toxicity of the risk variants.

**Results:** The results showed that deleting the SP did not abolish the toxicity of APOL1, though deletion of 26 amino acid residues at the N-terminal partially decreased the toxicity. Deleting PFD or MAD or SRA-interacting domain abolished toxicity while, overexpressing each domain alone could not cause toxicity to the host cells. Deletion of the G2 sites while retaining G1 sites in the risk state resulted in persistent toxicity. Either deletion or exchanging the BH3 domain in the PFD led to complete loss of the toxicity in this experimental platform. Adding G0 to either G1 or G2 did not attenuate the toxicity of the either moiety.

**Conclusions:** These findings indicate that the integrity of the mature APOL1 protein is critical for its toxicity.

**Human Podocyte Depletion: The Effects of Ageing and Hypertension**

Victor G. Puuelles,1 Luise A. Cullen-McEwen,3 Jinhua Li,1 Peter G. Kerr,2 Wendy E. Hoy,1 John F. Bertram.1 1Dept of Anatomy and Developmental Biology, Monash Univ, Melbourne, Victoria, Australia; 2Dept of Nephrology, Monash Medical Centre, Melbourne, Victoria, Australia; 3Centre for Chronic Diseases, The Univ of Queensland, Brisbane, Queensland, Australia.

**Background:** Podocyte depletion plays a major role in the development and progression of glomerulosclerosis. Many kidney diseases are more common in older age, and usually coexist with the presence of hypertension. We hypothesize that podocyte depletion develops with aging and is exacerbated by the presence of hypertension.

**Methods:** Kidneys from 21 adult Caucasian males without overt renal disease were collected at autopsy in Mississippi, USA. Subjects were categorized based only on age as young adults, middle-aged adults and older adults. Subjects were also categorized based on age and hypertension as young normotensives, older normotensives, and older hypertensives. Demographic data were collected from available medical records. Design-based stereology was used to estimate individual glomerular volume (tGv), podocyte number and podocyte density. Data are presented as mean±SD.

**Results:** Glomeruli from young adults (22±0.27 years; n=6) were small (1.72±0.50 x10³/mm²), and contained 457±97 podocytes and 278±66 podocytes per 10³/mm² of glomerular tissue. Glomeruli from older adults (60±8.6; n=7) were larger (2.94±1.41 x10³/mm²; P<0.001), contained fewer podocytes (390±105; P<0.05) and had lower podocyte density (156±65 podocytes per 10³/mm²; P<0.001). Among normotensives, older age was associated with a 15% increase in IGV (P=0.28); a 12% decrease in podocyte number (P<0.001) and a 17% decrease in podocyte density (P=0.001). Glomeruli from hypertensives and normotensives contained similar numbers of podocytes, but hypertensives had larger glomeruli (P<0.0001) and a markedly lower podocyte density (P<0.001).

**Conclusions:** These findings demonstrate that both aging and hypertension are independent and additive contributors to podocyte depletion in this cohort of white American men without overt kidney disease.

**Alport Nephropathy Progression Involves Altered Glomerular Mechanical Properties and Activation of the Unfolded Protein Response**

Addie Embry,1 Liping Liu,2 Leslie A. Bruggeman,3 Paul A. Janney,4 Tyler Miller.1 1Medicine, UTSW, Dallas, TX; 2Medicine, CWRU, Cleveland, OH.

**Background:** Tissue and cell mechanics are important factors in the development and maintenance of tissues but are not well defined in renal disease. We determined the biophysical properties of glomeruli over the course of disease in the Cnkd4-/- (Alport) mouse.

**Methods:** Glomerular Elastin was measured with microindentation, gene transcript levels with qRT-PCR and immunofluorescence, and kidney structure with histology.

**Results:** Cnkd4-/- kidneys have normal histology, no proteinuria, and a normal glomerular filtration rate (2,200±200) through 2 mo of age. At approximately 4 mo, early interstitial and glomerular fibrosis and proteinuria appear, and the glomerular Fmax decreases (~1,400Pa). Glomerular softening is characterized of injured glomeruli, is associated with injured podocytes, and could lead to capillary injury even with normal hemodynamics. By 6 mo, the glomeruli regain their original Fmax (~ 2,200 Pa) but with increased proteinuria and more severe glomerular and interstitial fibrosis. By 7-8 mo, the glomerular Fmax increases (~ 2,600 Pa) with further increases in proteinuria and glomerular and interstitial fibrosis. At 2 mo, glomerular transcripts for matrix and fibrinotic factors (CTGF, α-SMA, filamin, lysyl oxidase) are increased and remain so, demonstrating early responses of cells to alter their mechanical environment. Transcripts associated with UPR activation (Bip, CHOP, grp94) are elevated, suggesting that loss of the Cnkd4-/- chain leads to activation of the UPR. Tunicamycin-treated glomeruli demonstrated a markedly reduced Fmax (~1,100Pa), suggesting that UPR activation causes glomerular injury.

**Conclusions:** Biophysical abnormalities occur early in the course of this Alport model, suggest that the reduced Fmax of glomeruli (increased deformability) may lead to mechanical injury of capillaries even with normal hemodynamic force, that cells of glomeruli respond by producing proteins that will reduce deformability, and that glomerular or podocyte injury may be attributable to activation of the UPR.

**PUB090**

**A New Assay to Study Podocyte (De)Differentiation**

Frances Kindt, Karlhans Endlich, Nicole Endlich. Anatomy and Cell Biology, Univ Medicine Greifswald, Greifswald, Germany.

**Background:** Podocytes play an essential role in the formation and maintenance of the glomerular filtration barrier. Glomerular disease is associated with podocyte damage, frequently resulting in podocyte dedifferentiation. The loss of podocyte differentiation is poorly understood. Moreover, there are no drugs available that could halt or even reverse podocyte dedifferentiation. Since podocytes of isolated glomeruli have long been known to spontaneously lose their highly differentiated state over time, we established an assay to follow dedifferentiation of living podocyte in isolated glomeruli over time.

**Methods:** Using magnetic separation with dynabeads, glomeruli were isolated from transgenic mice that express cyan fluorescence protein (CFP) under control of a nephrin promoter fragment (Cui et al., ‘‘<em style="font-family: ‘Times New Roman’; font-size: 16px;’’>3<em>,<em> J Am Soc Nephrol</em>’’[latex] 11: 3247-55, 2000). Results: Isolated glomeruli were cultured on a filter under a low flow of nutrient medium. Isolated glomeruli bound to cell culture dishes. As CFP fluorescence, we recorded z-stacks of several glomeruli at 906A to be observed. The aim of this research was to confirm digestion of enzymes to study the role of the e-GLX removal was not directly quantified. The aim of this research was to confirm e-GLX in glomerular permeability. However, several clinical reports have demonstrated that the development of diabetic glomerulosclerosis (GS) amongst African Americans can be attributed to two coding sequence variants (G1 and G2) in the APOL1 gene. Recent studies suggest that the reduced Emax of glomeruli (increased deformability) may lead to mechanical injury of capillaries even with normal hemodynamic force, that cells of glomeruli respond by producing proteins that will reduce deformability, and that glomerular or podocyte injury may be attributable to activation of the UPR.

**Methods to Selectively Remove Murine Endothelial Glycocalyx In Vitro Using Glycosaminoglycan Digesting Enzymes without Causing Non-Target Effects**

Karen L. Onions, Anjila Onifade, Chris R. Neal, Monica Gamez, Gavin Iain Welsh, Andy Salmon, Simon C. Satchell, Rebecca R. Foster. Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom.

**Background:** The endothelial glycocalyx (~GLX) is an important component of the glomerular filtration barrier (GFB), damage to which increases vascular permeability and microalbuminuria. Jeunson and Haraldson previously used glycosaminoglycan (GAG) digesting enzymes to study the role of the e-GLX in glomerular permeability. However, e-GLX removal was not directly quantified. The aim of this research was to confirm removal of systemic e-GLX and identify any non-targeted effects in the glomerular or coronary microcirculation.

**Methods:** Mice were injected LV with chondroitinase (Ch) and hyaluronidase (Hy) at a high (Ch: 87 mU/g, Hy: 15U/g) or low (Ch: 0.087 mU/g, Hy: 15 mU/g) dose. Mice

and the serum level of indoxyl sulfate in CKD patients. These results suggest that BPS has reduced by BPS in GN rats. In addition, in humans, the serum concentration of creatinine and by BPS treatment, the reduced concentration of tryptophan recovered to the normal Arginine, Glycine, Cystathionine) also increased in GN and all of them are reduced by BPS treatment. Among the anionic solute that increased in GN rats, the concentration of 2 anionic solutes (Gluconate and Citrate) are ameliorated by BPS treatment. Solutes were further examined. Among the anionic solute that increased in GN rats, the highest density of NG2+ cells was in the outer medulla, and confirmed the presence of 3-10 cells-containing monochromatic (clonal) tracing units along the cortical vasculature, afferent arteriole, and within the glomerulus (including mesangial and parietal epithelial cells, and a very few podocytes) and the proximal tubule. Spherical or stellate-shaped NG2+ cells were observed in the Bowman’s space and in the proximal tubule lumen suggesting cell migration.

Conclusions: In summary, our data are consistent with highly dynamic cellular remodeling of the renal interstitium, vasculature, glomerulus, and the proximal tubule by single progenitor cells. These results also suggest the presence of a complex nephrin repair program which is augmented in response to salt deprivation.

PUB093

Beraprost Ameliorates Renal Function and Reduce Uremic Toxin in GN

Background: In CKD patients, the accumulation of uremic toxins exacerbates renal damage. Beraprost sodium (BPS) is prostacyclin analogue and is mainly used to treat atherosclerotic obliterans. Recently, Several reports show that BPS reduced progression of renal damages in CKD. To identify the renoprotective effect of BPS, we measured uremic solutes by capillary electrophoresis with mass spectrometry (CE-MS) in anti-GBM Glomerular Nephropathy(GN) rat model as well as 4 CKD patients before and 5 month after BPS administration.

Methods: A comprehensive and quantitative analysis of charged metabolites by CE-MS was performed. We obtained serum from (1) Normal rats, GBM GN rats and 4 CKD patients. Serum from (2) 16 anionic solutes, 16 anionic solutes and 42 cationic solutes were further examined. Among the anionic solute that increased in GN rats, the concentration of 2 anionic solutes (Gluconate and Citrate) are ameliorated by BPS treatment. Among the cationic solute that increased in GN rats, the concentration of 10 cationic solutes (Arginine, Glycine, Cystathionine) also increased in GN and all of them are reduced by BPS treatment. Conversely, the concentration of 8 metabolites were decreased in GN rats, and by BPS treatment, the reduced concentration of tryptophan recovered to the normal level. GLX in glomerular permeability. Increasing understanding in the nitric oxide mechanism and involving of nitric oxide in the progression of CKD is a potential to prevent the progression of CKD. These results suggest that BPS has a potential to prevent the progression of CKD.

A Novel Method to Measure Glomerular Permeability

Background: Glomerular capillaries are relatively impermeable to proteins, but in certain kidney diseases, such as diabetic nephropathy, the glomerular permeability (GP) is increased and some of the lower molecular weight (LMW) proteins, especially albumin, are filtered through the glomerular barrier into the Bowman’s space. Increased GP is a hallmark for many kidney diseases. Proteinuria is often implicated for impaired GP. However, since LMW proteins can be reabsorbed by proximal tubules, proteinuria is detected only when the GP is significantly increased. Recently, real-time quantification of GP can be visualized by two-photon microscopy, but it can only be applied to superficial nephrons, where laser can penetrate, in Munich-Wistar rats. We developed a novel method to monitor GP in C57/BL6 mice by using flow丞sent lysine-fixable dextran conjugates without these limitations.

Methods: 100μl Tomato Lectin 594 (endothelial cell marker) plus 50μl 40 KD lysine-fixable dextran 488 (fluid phase marker) were injected intravenously. The kidneys were removed 1 min later and put into liquid nitrogen immediately for 10 minutes followed by fixation with 10% Formalin on ice overnight. Then 100μm thick sections were prepared using a vibratome and the flow丞sent images were collected with two-photon microscopy. The ratio of flow丞sent intensity in Bowman’s space over that in glomerular capillary lumen was used as an index of GP.

Results: In WT mice, the GP is extremely low with a ratio of 0.16±0.08%, N=6 (figure1). In contrast, in diabetic mice induced by alloxan for 8 weeks, the GP is significantly increased with a ratio of 5.9±1.3%, N=6.

Conclusions: In summary, we developed a novel and sensitive method to monitor changes in GP using two-photon microscopy, which can be used for rodents and bigger animals.

Vasopressin Regulates the Uptake of Extracellular Vesicles by Kidney Collecting Duct Cells

Background: Urine contains extracellular vesicles (ECVs) originating from the circulation and all cells lining the urinary tract. ECVs are a route of inter-cellular communication along the nephron able to transfer protein and RNA. It is not known whether this is a regulated process analogous to other cell-to-cell signalling systems.

Methods: Kidney cortical collecting duct cells (CCDs) were stimulated with desmopressin, a vasopressin analogue, and uptake of fluorescently-loaded or microRNA-loaded ECVs was measured. In mice, fluorescently-loaded ECVs were intravenously injected before and after administration of the V2 antagonist, tolvaptan, and urinary ECV excretion was measured. By combining antibodies to nephron segment-specific proteins with nanoparticle tracking analysis we measured human urinary ECV excretion in current diabetic nephropathy patients (DI) and after radiocontrast exposure. The ratio of flow丞sent intensity in Bowman’s space over that in glomerular capillary lumen was used as an index of GP.

Results: Desmopressin stimulated ECV uptake into CCDs via V2 receptor stimulation.

Conclusions: Tubular ECV uptake is a specific, hormonally regulated process that is reduced with injury. Physiologically, ECVs are a mechanism of inter-cellular communication; therapeutically, ECVs represent a novel vehicle by which RNA therapy could be targeted for the treatment of kidney disease.

Systemic Hypertension and Pro-Inflammatory Cytokines
Massimo de Cal,1 Grazia Maria Virzi,1 Alessandra Brocca,1 Salvador Roberto Lopez,2 José Luis Salas,2 Stefano Marcante,2 Silvia De Rosa,1 Claudio Ronco.1 1Nephrology, S.Bortolo Hospital, Vicenza, Italy; 2ICU, S.Bortolo Hospital, Vicenza, Italy.

Background: Cytokines produced by renal tubular epithelial cells are critical factors in inflammatory processes of renal ischemia-reperfusion injury. Increased levels of cytokines have been reported after resectional surgery from cardiac arrest. Pro-inflammatory cytokines, such as IL-1β, IL-6 and IL-18, produced in the kidney during ischemia-reperfusion injury, are able to contribute to the renal damage. The purpose of this investigation was to define the proinflammatory cytokines response after resection and during extended observation following therapeutic hypothermia phases.

Methods: We performed a prospective observational study in 36 post-cardiac arrest patients treated with Induced Hypothermia (IH) with two different cooling device: 1) Arctic Sun; 2) Blanket. On Admission time and at 12, 24, and 72 hours after the start of treatment, blood and urine samples were collected. Plasma cytokines were measured by ELISA.

Results: During IH, we observed a decrease of IL-6, IL-1β and IL-18u levels in both groups, and an increase of inflammatory during rewarthing phase. The results are shown in table.

Conclusions: Optimal rewarthing rate is unknown. Adverse effects from suboptimal rewarthing could diminish a protective effect from hypothermia. These biomarkers may serve as indicator of an individual patient’s place in the injury-repair continuum. Further investigations are needed.

Impact of Different I.V. Iron Preparations on Monocyte Function and Differentiation
Adam M. Zawada,1 Lisa H. Fell,1 Sarah Seiler,1 Martina Sester,1 Danilo Fliser,1 Gunnar H. Heine.1 1Internal Medicine IV, Saarland University Medical Center, Homburg, Saarland, Germany; 2Dept of Transplant and Infection Immunology, Saarland University Medical Center, Homburg, Saarland, Germany.

Background: Treatment of iron deficiency with intravenous (i.v.) iron is a first-line strategy to improve anemia and quality of life in patients with chronic kidney disease (CKD). However, in vitro experiments have demonstrated that certain i.v. iron preparations have immunological side-effects. In the present study we now investigated substance-specific effects of different i.v. iron preparations on monocyte function and differentiation.

Methods: We in vitro stimulated monocytes with different concentrations (0.133 mg/ml, 0.266 mg/ml, 0.533 mg/ml) of iron sucrose (IS), sodium ferric gluconate (SFG), ferric carboxymaltose (FCM), and iron isomaltoside 1000 (IIM) and assessed monocytic adhesion, transmigration and immunophenotypical changes. IS and SFG increased monocytic adhesion, while transmigration was not affected by any preparation. The expression of M1 (CD40) and M2 (CD16, CD206) markers as well as the phagocytosis capacity were significantly reduced in IS and SFG stimulated macrophages. IS and SFG down-regulated CD14 and CD68 in DCs and up-regulated CD141 and HLA-DR. FCM affected macrophage and DC phenotype and function to a lesser degree, and IIM had no measurable immunological effects. In miRNA expression analysis we found IS to strongly dysregulate miRNAs which are linked to TLR and MAPK signaling pathways (e.g. mir-146b-5p, mir-155-5p).

Conclusions: Our findings demonstrate that less stable i.v. iron preparations like IS and SFG substance-specifically affect monocyte function and differentiation into macrophages and DCs in vitro. Future clinical trials should delineate in how far these observations will lead to clinically relevant changes in immune responses and thus affect the infection risk in CKD patients.

The Involvement of p38 MAPK in Neutrophil Bacterial Dysfunction of Hemodialysis Patients
Yasutaka Kamikawa, Shinni Kitajima, Akinori Hara, Norihiko Sakai, Miho Shimizu, Kengo Furuichi, Yasunori Iwata, Takashi Wada. Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan.

Background: Mortality from infection has been reported to be higher in hemodialysis (HD) patients than that in healthy subjects. However, the precise mechanism causing it remains to be investigated. Neutrophils play crucial roles in host defenses against bacterial infection. Therefore, we investigated the impact of neutrophil inflammatory signal on bacterial function in HD patients.

Methods: Four HD patients and six healthy subjects were recruited for this study. None of HD patients had diabetes, cardiovascular disease and cancer. Neutrophils were isolated from peripheral blood by density gradient centrifugation. The purity was tested by flow cytometry after lactoferrin staining. Microarray analysis was performed to assess global gene expression in leukocytes. Neutrophil bacterial function was evaluated by the growth rate of Staphylococcus aureus (S.aureus) after co-culture of it with neutrophils obtained from HD patients or healthy subjects. Reactive oxygen species (ROS) production and myeloperoxidase (MPO) activity were measured by fluorescence intensity.

Results: Microarray analysis showed the impairment of p38 mitogen activated protein kinase (MAPK) signal in neutrophils from HD patients. The growth rate of S.aureus was higher in HD patients than that in healthy subjects (490.1±147.1%, 144.5±49.4%, respectively; p<0.01) suggesting that neutrophil anti-bacterial killing function was dysregulated in HD patients. The levels of ROS from neutrophils after co-culture with S.aureus were lower in HD patients than those in healthy subjects (14.6±8.3, 32.4±15.4% for healthy, respectively; p<0.01). On the other hand, there was no difference of MPO activity between both groups. To confirm the importance of p38 MAPK, we examined the effect of the selective pharmacological p38 MAPK inhibitor SB202190 on neutrophil bacterial function. The treatment with SB202190 suppressed anti-bacterial killing function as well as MPO production in neutrophils.

Conclusions: Impaired of p38MAPK signaling pathway might contribute to the suppression of neutrophil bacterial function in HD patients through the dysregulation of ROS production.
NR2 and NF-xb mRNA Expression in Chronic Kidney Disease: A Focus on Non-Dialysis Patients

Denise Mafra,1 Viviane Oliveira Leal,2 Juliana Saldanha,1 Milena Barca Stockler-Pinto,3 Ludmila Fmm Cardo,3 Felipe Rizzato Santos,1 Alex Sandro Duarte Albuquerque,4 Maurilo Leite.4  ‘Graduate Program in Medical Sciences, Federal Univ Flamunense, Rio de Janeiro, Brazil;4 Pedro Ernesto Univ Hospital, State Univ of Rio de Janeiro (UERJ), Rio de Janeiro, Brazil;4 Graduate Program in Cardiovascular Sciences, Federal Univ Flamunense, Rio de Janeiro, Brazil;4 Div of Nephrology, Federal Univ of Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil.

Background: Nuclear factor erythroid 2-related factor 2 (Nr2), a regulator of genes encoding antioxidant and detoxifying enzymes appear to be downregulated in chronic kidney disease patients undergoing hemodialysis (HD). However, data regarding the expression of NR2 in non-dialysis patients are scanty. Thus, the aim of this study was to evaluate NR2 and nuclear factor kappa-B (NF-xb) mRNA expression in non-dialysis patients, comparing with data from HD patients.

Methods: 20 non-dialysis patients, 20 HD patients and 11 healthy subjects were enrolled. The peripheral blood mononuclear cells were isolated and processed for the evaluation of NF-xb and NR2 expression by quantitative real-time polymerase chain reaction.

Results: NR2 mRNA was significantly higher in non-dialysis when compared to HD patients but similar to healthy individuals. Inversely, NF-xb mRNA was lower in non-dialysis when compared to HD patients and also similar to healthy individuals i.e.

Figure 1. NR2 and NF-xb mRNA expression in healthy individuals, non-dialysis and HD patients.

NR2 mRNA was positively correlated with NF-xb mRNA in non-dialysis patients and healthy individuals. By contrast, NR2 mRNA was inversely correlated with NF-xb mRNA in HD patients.

Conclusions: Non-dialysis patients may conserve regular homeostatic balance between NR2 and NF-xb expressions, being comparable to healthy individuals. As renal disease progresses to more advanced stages, an impaired NR2/NF-xb balance can be observed, as in HD patients.

ERK 1/2 and ERK 5 Signaling Pathways via Renin Angiotensin System Activation Play Differential Regulatory Roles During the Progression of Glomerulonephritis

Takashi Nagai,1 Maki Urushihiara,2 Shuji Kondo,1 Toshiaki Tamaki,1 Milena Barca Stockler-Pinto,3 Felipe Rizzato Santos,1 Alex Sandro Duarte Albuquerque,4 Maurilo Leite4 ‘Graduate Program in Medical Sciences, Tokushima Univ Graduate School, Tokushima, Japan;2 Dept of Pediatrics, Inst of Biomedical Sciences, Tokushima Univ Graduate School, Tokushima, Japan;3 Dept of Pharmacology, Inst of Biomedical Sciences, Tokushima Univ Graduate School, Tokushima, Japan.

Background: Although extracellular signal regulated kinase (ERK)1/2 and ERK5 are key kinases of signaling pathway involved in various cellular functions in kidney injury, the mechanism between those kinase and renin-angiotensin system (RAS) activation in glomerulonephritis (GN) have not been fully elucidated. This study was performed to clarify the potential role of ERK1/2 and ERK5 via RAS activation in the pathogenesis of GN.

Methods: We examined the expression of ERK1/2 and ERK5 in rat progressive model of GN induced by anti-glomerular basement membrane antibodies in Wistar Kyoto rats. In addition, the signal transduction pathway in angiotensin II (Ang II) treated primary cultured mesangial cells (MCs) was evaluated.

Results: GN rat developed typical cellular crescent in glomeruli on day 7 and severe fibrocellular crescent and glomerulosclerosis were found on day 28. Immuno-staining of kidneys revealed that strong expression of phospho-ERK1/2 was observed on day 7 and phospho-ERK5 expression was markedly increased on day 28 of GN. Ang II type II receptor blocker (ARB) suppressed those augmentations. Macrophage infiltration and fibrocellular crescent and glomerulosclerosis were found on day 28. Immuno-staining pathologic alterations were investigated in primary cultured mesangial cells (MCs). In addition, the signal transduction pathway in angiotensin II (Ang II) treated primary cultured mesangial cells (MCs).

Conclusions: Macrophage infiltration and fibrocellular crescent and glomerulosclerosis progresses to more advanced stages, an impaired NR2/NF-xb balance can be observed, as in HD patients.

Chinese Herbal Medicine for IgA Nephropathy, ShenPing Decoction, Blocks Platelet-Derived Growth Factor Signaling Pathway Activated by IgA1-Containing Immune Complexes in Human Mesangial Cells

Xianwen Chen,1 Jianfei Ma.2 Nephrology; The First Affiliated Hospital of China Medical Univ, Shenyang, China.

Background: IgA1 nephropathy (IgA-N) is characterized by mesangial immune complex deposits containing galactose-deficient IgA1 (Gd-IgA1) usually associated with mesangial proliferation and matrix expansion. There is no disease-specific therapy of IgA-N, although a herbal medicinal prescription, ShenPing decoction (SP), has been used in China for decades to effectively treat IgA-N. Mesangial cell proliferation in IgA-N is likely induced by IgA1-Containing immune complexes (CIC) and this process may involve activation of platelet-derived growth factor (PDGF) signaling pathway. We have shown previously that SP blocks the activation of PDGF pathway induced by PDGF. In this study, we investigated the effect of CIC on PDGF signaling pathway in human mesangial cells (HMC) and assessed the effects of SP on this pathway.

Methods: CIC were isolated from sera of IgA-N patients using size-exclusion chromatography. Primary HMCs were incubated with PDGF or CIC for 15 min or 24 h with or without SP. Cellular proliferation was measured by Syto60. PDGF signaling was evaluated by SDS-PAGE and Western blotting.

Results: 24-h incubation with CIC increased MC proliferation and SP inhibited this effect. Stimulation of HMC with CIC increased phosphorylation of PDGFR and ERK1/2 after 15 min and 24 h. PDGF degradation was not observed in CIC-treated group, which is different from PDGF. SP inhibited CIC- and PDGF-induced phosphorylation and degradation of PDGFR.

Conclusions: CIC induced cellular proliferation of HMC and activation of PDGF pathway without degradation of PDGFR, a normal negative feedback observed for PDGF. CIC possibly caused persistent activation of PDGF pathway. SP inhibited those effects.

Funding: NIDDK Support, Private Foundation Support.

Effects of Fluorofenidone on the Expression of Thiorodoxin-Inter-Acting Protein and Thiorodoxin of Human Peritoneal Mesothelial Cell in High Glucose and Lipopolysaccharide

Yichen Chen,1 Jianfei Ma.2 Nephrology; The First Affiliated Hospital of China Medical Univ, Shenyang, China.

Background: Peritoneal dialysis is one of an important alternative therapies for end-stage kidney disease. But the occurrence of peritoneal dialysis correlation peritonitis has brought high resistance for the development of peritoneal dialysis. Significance of oxidative stress in peritoneal dialysis related peritonitis has been paid more and more attention. In cells that did not receive stimulation, Txnip combined with thioredoxin, when the elevated ROS concentration inside the cell, the formation of the compounds are separated. After dissociation Tx play its functions to remove ROS, whereas Txinap participation NRPL3 activation. Objective:To observe the effects of Fluorofenidone on the Expression of Txnip,Txin,Trx of HPMCs in High Glucose and Lipopolysaccharide.

Methods: The expression of Txnip and Trx mRNA was measured by real-time PCR,The levels of SOD,GPx,IL-6, TGF-b1 in the supernatants of HPMCs(10mM5S) were measured by ELISA, Experimental groups:Control group:high glucose and LPS for different concentrations and different times group;Fluorofenidone intervene group.

Results: Compared with the normal control, high glucose and LPS can significantly increase the expression of Txnip,Txin,Trx,IL-6 and TGF-b1 in a concentration and time dependent manner, all have statistically significant(P<0.05).Compared with 2.5% glucose and 10mg/L LPS group, Fluorofenidone can reduce the expression of Txnip,Trx,IL-6 and TGF-b1, increase the expression of Trx, all have statistically significant (P<0.05).

Conclusions: High glucose and LPS up-regulate the expression of Txnip,Txin,Trx in the protein and gene levels,and increase the expression of IL-6 and TGF-b1. Fluorofenidone could reduce the increase of Trx, IL-6 and TGF-b1, and increase the expression of Trx in HPMCs that have been pre-treated with high glucose and LPS. Fluorofenidone have the effect of anti-oxidant and anti-fibrosis.

Effects of Resveratrol on NRFP2 Expression in Raw 264.7 Macrophages Cells and Non-Dialyzed CKD Patients

Bruce A. Julian,1 Jan Novak.2 NIDDK Support, Private Foundation Support.

Results: Neither Modulation of NRFP2 expression via resveratrol was observed in the macrophage cell line, Raw 264.7, nor in the non-dialyzed CKD patients.

Background: Oxidative stress and inflammation are common in CKD. Bioactive compounds as resveratrol may modulate the Nr2 expression, a transcription factor that could up-regulate cellular antioxidant systems. The aim of this study was observe NRFP2 expression in macrophages cells and in non-dialyzed CKD patients treated with resveratrol.
Methods: Mouse RAW 264.7 macrophages were treated with 50μM of resveratrol in DMEM 1% (v/v). Nucleus and cytoplasm were separated. Western Blot (WB) was performed to quantify Nrf2. qRT-PCR was performed to evaluate Nrf2 expression. 7 non-dialyzed CKD patients (5 women; 64±6.5 years; GFR 37.9±10.4 mL/min) received 500mg of resveratrol/day for 4 weeks. qRT-PCR to evaluate Nrf2 expression was performed in PH1 model cells and after supplementation with resveratrol at the molecular level.

Results: Cells treated with resveratrol showed a significant activation of Nrf2 with an increase in the ratio nucleus/cytoplasm compared to control cells i.e. p=0.02. The same was observed in qRT-PCR (p=0.02). In patients, we observed a trend to increase Nrf2 expression with resveratrol supplementation (p=0.06).

Conclusions: We concluded that both cells and patients treated with resveratrol increased Nrf2 expression. So, we suppose that supplementation with resveratrol can lead to an increase in oxidative stress and inflammatory status among CKD patients.

PUB105
Mitochondrial Implications of Glycolate Metabolism in Primary Hyperoxaluria
Sonia Farague, Tanecia Mitchell, John Knight, Ross P. Holmes.
Urology, Univ of Alabama at Birmingham, Birmingham, AL.

Background: The primary hyperoxalurias (PH) are rare but severe inherited diseases characterized by an increased endogenous production of oxalate and calcium oxalate kidney stones in patients. Deficiency in alanine glyoxylate aminotransferase (AGT, deficient in PH1) or glyoxylate reductase (GR, deficient in PH2) have repercussion on the metabolism of the oxalate precursors glyoxylate and glycolate. Excessive amounts of glycolate are characteristic of PH1, through glyoxylate to glycolate cycling in the presence of glycolate oxidase (GO) and GR. Perturbations in glycolate metabolism may affect mitochondrial function in PH patients. The objective of this study is to assess how over-expression of these enzymes regulates glycolate and glyoxylate generation and mitochondrial function.

Methods: An established transformed CHO cells model was used in which cells express GO ± AGT or GR. Cells were incubated with glycolate or glyoxylate and the extracellular concentrations of oxalate and glycolate, and the induction of oxidative stress were analyzed. Cellular bioenergetics were assessed with a Seahorse XF-96 extracellular flux analyzer.

Results: The metabolism of glycolate by GO generated glyoxylate, oxalate and H₂O₂. Intracellular ROS were produced and cell viability was reduced. Mitochondrial respiration and the cellular biocatalytic reserve capacity were decreased following glycolate oxidation. The expression of AGT or GR reduced the unwanted effects of glycolate metabolism to glyoxylate and oxalate.

Conclusions: The disruption of normal glycolate metabolism by GO, AGT and GR in a cells model causes the production of stress-related metabolites and mitochondrial dysfunction. Limiting mitochondrial dysfunction might be a therapeutic approach in treating PH patients.

PUB106
Effect of Fasudil on Response Oxidative Stress in High Glucose and Lipo polysaccharide Induced Human Peritoneal Mesothelial Cells
Ye Hu, Jianfei Ma.
Nephrology, The First Affiliated Hospital of China Medical Univ, Shenyang, Liaoning Province, China.

Background: Peritoneal fibrosis is a common cause of chronic peritoneal dialysis patients withdrew from peritoneal dialysis. Research shows that, there are oxidative stress exists in peritoneal dialysis patients. Rho/Rho kinase signaling pathway is involved in the regulation of multiple biological process, including inflammation, oxidative stress and fibrosis. The transcription factor Nrf2 related factor is a central regulator of cellular antioxidant responses. Rho kinase inhibitor fasudil is a Rock inhibitor which currently used in clinic and experiment, can regulate cell proliferation, migration, adhesion and movement at the cellular level. It also can regulate a variety of factors in inflammation, thrombogenesis, oxalosis, and fibrosis at the molecular level.

Methods: By using the method of Real Time-PCR to detect the expression of RhoA, ROCK1, Nrf2 and HO-1 mRNA; Western Blot to detect the expression of RhoA, ROCK1, Nrf2 and HO-1 protein; chemistry fluorescence test to detect the expression of ROS protein; chemical colorimetry to detect the expression of GSH-PX protein. ELISA to detect the expression of TGF-β1 protein in the human peritoneal mesothelial cell. Experimental groups: Control group; High glucose and LPS for different concentrations group; Fasudil intervene group.

Results: Compared with the normal control, high glucose and LPS can significantly increase the expression of RhoA, ROCK-1, ROS and TGF-β1, reduce the expression of Nrf2, HO-1 and GSH-PX in a concentration dependent manner, all have statistically significant (P<0.05). Compared with 2.5% glucose and 10mg/L LPS, group, fasudil can reduce the expression of RhoA, Rock-1, ROS and TGF-β1, increase the expression of Nrf2, HO-1 and GSH-PX, all have statistically significant (P<0.05).

Conclusions: High glucose and LPS up-regulate the expression of RhoA and ROCK1 but reduce Nrf2 in the protein and gene levels and increase the expression of ROS and TGF-β1 but reduce the expression of HO-1 and GSH-PX. Fasudil could reverse the increase of RhoA and Rock1 and the reduce of Nrf2 in HPMCs that have been pre-treated with high glucose and LPS play the role of anti-oxidant and anti-fibrosis.

PUB107
Glucose Induces Mitochondrial Reactive Oxygen Species Through Carbonyl Stress and Respiratory Chain In Rat Peritoneal Mesothelial Cells
Satoshi Shimada, Takefumi Mor, Yusuke Obasaki, Itoku Oba, Shinichi Sato, Kenji Koizumi, Sadayoshi Ito.
1Nephrology, Endocrinology and Vascular Medicine, Graduate School for Medicine, Toho University, Sendai, Miyagi, Japan; 2Div of Integrative Renal Replacement Therapy, Graduate School of Medicine, Tohoku University.

Background: Glucose and its degradation products (GPDs) play a major role in the peritonal injury and affect peritoneal dialysis vintage. Peritoneal mesothelial cell dysfunction has been demonstrated to involve in peritoneal injury by glycolysis and GPs. GPDs induced carbonyl stress has been demonstrated to induce mitochondrial dysfunction in several cell types. The present study was designed to determine the role of GPDs and respiratory chain in glucose induced mitochondrial ROS in peritoneal mesothelial cells.

Methods: The primary rat peritoneal mesothelial cell (RPMC) were isolated from Wistar rats. Real-time mitochondrial superoxide was monitored using a specific fluorescent indicator Mito SOX red under fluorescence microscope equipped with temperature controlled chamber. RPMC was stimulated with 90 mmol/L of glucose and compared to those of vehicle. In separate experiments, RPMC was pre-incubated with a mitochondrial specific superoxide dismutase mimetic mite mimotEMP0, respiratory chain inhibitor rotenone or carbonyl stress inhibitor pyridoxamine to determine the mechanism of glucose induced mitochondrial ROS production.

Results: 90 mmol/L glucose significantly increased mitochondrial superoxide production within 200 seconds in primary cultured RPMC (0.21±0.07 AU, n=8, P<0.05 vs vehicle). These responses were abolished when RPMC was pre-incubated with mitoTEMPO (-0.04±0.15 AU, n=5, P<0.14 vs vehicle), rotenone (0.00±0.06 AU, n=6, P<0.54 vs vehicle) and pyridoxamine (-0.34±0.34 AU, n=5, P<0.26 vs vehicle), indicating that mitochondrial superoxide production through respiratory chain and GPD.

Conclusions: The results in the present study indicate that glucose and GDP present in the PD effluent is responsible for oxidative stress in the peritoneal mesothelial cells by stimulation of mitochondrial ROS production, which could play a role in peritoneal function and injury during PD.

PUB108
Renal Cell Carcinoma Models: Effect of Chemopreventative Agents on the Carcinogenic Potential of Potassium Bromate in Human Renal Epithelial Cells
Issam Obaidi, Tara McMorrow.
School of Biomolecular and Biomedical Science, Conway Inst, Univ College Dublin, Ireland.

Background: Renal Cell Carcinoma (RCC) is a leading cause of renal cancer worldwide. The cause of RCC remains unknown, with many chemicals implicated in its development. We have developed an in vitro model of RCC using the carcinogen, potassium bromate, to investigate potential prevention and possible treatment options of RCC. Chemoprevention is the use of different chemicals, natural or synthetic, to halt, block or reverse the process of carcinogenesis. It is one of the novel approaches that is being used to control cancer and it is a good alternative to the conventional therapies that are associated with a long list of side effects and limitations. These agents have antioxidant, anti-inflammatory, antiangiogenic effects and induce phase II enzymes, apoptosis, cell cycle arrest, and differentiation. They antagonize hormones and growth factor-induced tumor proliferation. The aim of this study was to examine the functional and mechanistic effects of chemopreventative agents on chemically induced RCC using human (RPTEC/ TERT1) renal cells and carcinogen (AChN) renal cell lines.

Methods: Morphological changes, viability and cytotoxicity assays were used to assess the toxicity of both the chemopreventatives and the carcinogen when RPTEC/ TERT1 cells were exposed to them individually and in combinations. Oxidative stress was also...
assessed by measuring the intracellular concentration of H2O2. Oxidative stress-induced DNA damage was estimated quantitatively by measuring 8-OHdG concentrations. Western blot analysis was used to detect the changes in particular oxidative stress-induced proteins.

Results: The carcinogenic effects induced by potassium bromate were reduced by the co-administration with all of the chemopreventive agents used. Oxidative stress markers, H2O2 and DNA adduct formation, were reduced.

Conclusions: These results suggest that chemopreventive agents show significant potential against KBtO3-induced carcinogenicity. Further analysis is being carried out to understand the functional mechanisms of this chemoprevention on the cells, in particular on the genetic and epigenetic mechanisms involved.

PUB109

The Podocyte as a Target for the Actions of Levamisole in Nephrotic Syndrome

Jochen Seufert,1 Oliver Witzke,1 Fliser2

Background: Levamisole is an antihelminthic agent that has also been shown to be effective as a second line treatment for steroid-dependent or frequently-relapsing nephrotic syndrome (SD/FRNS) in children. Levamisole is able to decrease steroid dosages and reduce the relapse frequency and severity. We have recently reported the effectiveness of levamisole in a small cohort of adult patients and provided evidence suggests that levamisole’s mode of action in SSNS is attributable to its direct effects on podocytes.

Methods: To further clarify its therapeutic effectiveness and identify the therapeutic targets of this drug, we have employed RNA-sequencing technology to profile transcriptional changes of human podocytes in response to levamisole.

Results: We have identified a number of genes which are differentially expressed in podocytes in response to levamisole. These include genes linked to the cellular interferon response pathways and a number which overlap with those regulated by dexamethasone in podocytes. These have been validated in vitro and are now being studied in animal models of nephrotic syndrome.

Conclusions: Together, our molecular evidence strongly supports the promising use of levamisole in treating nephrotic syndrome.

The PRIMAVERA Study: A Prospective, Randomized, Multicenter Trial Assessing the Effect of Continuous Erythropoiesis Receptor Activator (C.E.R.A.) on Renal Function in Non-Anemic Patients with Chronic Kidney Disease (CKD)

Stephanie Leduc,1 Massimo Ruggenenti,2 Davide Loir,3 L. Raphael,4 Linda F. Fried,4,5 Andrew N. Hoofnagle,6 Michael F. Flessner,7 Joanne F. Shumway,8 Desirée De Laat,9 Andrew C. Nieuwenhuijzen,10 Jerome Brun,11 Andrew C. Nieuwenhuijzen,12 Northern Light Hospital, Northpole, Alaska; 2Department of Nephrology, Dialysis, ECHO-CMCM - Pôle Santé Sud, Le Mans, France; 3Gastro-enterologie, Centre Hospitalier du Mans, Le Mans, France; 4Laboratoire de Pharmaco-Toxicologie, Hôpital Bichat-Claude Bernard, Paris, France; 5Biologie, Laboratoire Pôle Santé Sud, Le Mans, France.

Background: Elevated serum phosphate and FGF23 are associated with CVD, CKD progression, and mortality in CKD. Phosphate binders consistently reduce phosphate and FGF23 levels. Nicotinamide (vitamin B3) decreases active phosphate transport by down regulating NaPi2b in the gut. Whether nicotinamide alone or in combination with binders can safely and tolerably lower phosphate and FGF23 levels in CKD is unknown.

Methods: We designed a 4 arm parallel group randomized double blind trial comparing lanthanum carbonate (1000mg tid), nicotinamide (750mg bid), neither, or both. Supported by the NIDDK CKD Pilot Clinical Trials U10, 200 participants with eGFR 20-45 ml/min/1.73m2 were recruited from 7 centers across the US will be randomized 1:1:1:1 and treated for 12 months. Main exclusions include phosphate < 2.8mg/dl, liver dysfunction and thrombocytopenia. The dual primary efficacy endpoints are change in phosphate and FGF23. Secondary endpoints are change in LV mass and renal fibrosis by MRI. Enrollment began in March 2015.

Results: To date, 45 persons were screened, 33 were eligible, 26 entered run-in, and 18 were randomized. Baseline characteristics of randomized participants are shown in the table. Updated data will be available at presentation.

Randomized Patients (n) 18

Age<SD 65±14

Male, n(%) 12 (67%)

Black, n(%) 5 (28%)

Diabetes, n(%) 7 (44%)

eGFR/SD 30±9

Serum Phosphates/SD 3.9±0.6

Serum Calcium/SD 9.5±0.4

Inact PTH, median (IQR) 104 (71, 135)

Conclusions: Simultaneous blockade of NaPi2b and intestinal phosphate binding using nicotinamide and binders provides a new strategy for phosphate and FGF23 lowering in CKD, but efficacy, safety, and tolerability are uncertain. The COMBINE trial will inform us about combined therapy compared to either therapy alone, and to dual placebo in CKD 3b-4.

The Rationale for and Design of TREVI TR02: A Multicenter Randomized, Double-Blind, Placebo-Controlled Trial of Nalbuphine ER for the Treatment of Uremic Pruritus in Hemodialysis Patients

Vandana S. Mathur,1 Michael J. Germain,1 Roberta Duncan,1 Thomas Sciascia,2 Mathur Consulting, Woodside, CA;1 Western New England Renal & Transplant Associates, PC, Hamden, MA;1 Trevi Therapeutics, New Haven, CT.

Background: Uremic pruritus (UP) is common in hemodialysis patients, but there are no FDA-approved treatments or “regulatory roadmap” for the development of new drugs. Nevertheless, the significant quality of life (QOL) burden of chronic itch underscores need for treatments. The striking bilateral, non-dermatomal distribution of itching and perception of non-pruritogenic skin stimuli as itch suggest that UP is centrally mediated, like neuropathic pain. Reduction in endogenous κ/µ opioid ligand ratio is hypothesized to be a mechanism. Our goal was to evaluate nalbuphine ER tablet (NAL), a µ-agonist and κ-antagonist as a treatment for UP.

Methods: The study was powered for an α = 0.05, β = 0.9 for a group difference of 1.5 (SD = 3.5) in worst itching numerical rating scale (NRS, 0-10): N = 120/arm (NAL 120 mg BID, NAL 60 mg BID, and placebo BID). Patients with NRS ≥ 4.5 (moderate to severe pruritus) were enrolled at ~45 US and 6 EU sites.

Results:

Key Scientific Considerations Study Design Solution
1. Itch is subjectively perceived. Itching intensity and QOL were relevant endpoints. Used patient-reported outcomes previously validated in UP patients including NRS and Skindex-10 (1st and 2nd endpoints).
2. Opioid drugs require titration to minimize opioid side effects To perform a blinded opioid titration with a self-administered oral drug, we used blister cards that were labeled for each study day.
3. Long enough duration to demonstrate durability and lack of tolerance but short enough to avoid excessive dropouts due to background comorbidities. Used an 8-week blinded treatment duration.
4. Post-treatment safety Added a 2-week washout period after the blinded treatment period.
5. Day-to-day variability in NRS was expected The mean of 2 weeks of measurements at baseline and on treatment (Wks 7 and 8) were used for the calculation of the 1st endpoint.

Conclusions: The trial design overcame the challenges. Unblinded results will be presented.

The Rationale and Design of Trevi TR02 Extension: A Multi-Center Open Label Extension Study of the Safety and Anti-Pruritic Efficacy of Nalbuphine HCl Extended Release Tablets in Uremic Pruritus Patients on Hemodialysis

Thomas Sciascia,1 Howard Hait,2 Arnaie Hawi,1 Roberta Duncan,1 Vandana S. Mathur,1 Trevi Therapeutics, Inc., New Haven, CT;1 Edenridge Associates LLC, Wilmington, DE;1 Hawi Consulting, Ridgefield, CT;1 Mathur Consulting, Woodside, CA.

Background: Nalbuphine HCl is a µ antagonist/kappa agonist being investigated for the treatment of pruritus in hemodialysis patients (UP). The safety and long-term benefits of Nalbuphine ER in the treatment of urermic pruritus is being investigated in this ongoing open-label extension study.

Methods: TR02ext is a 26-week multicenter open-label extension study of a double-blind placebo controlled study in which UP patients with a baseline NRS >4.5 were treated with Nalbuphine ER or placebo for 8 weeks followed by a 2-week washout period. At the end of study, patients that opt to roll over into the extension study, and have an NRS ≥ 2 enrolled in a 26-week Treatment Period (TP), while patients with an NRS ≤ 2 entered a 13-week Observation Period (OP). If a patient’s itch worsened (NRS > 2) within the OP, they entered the TP for the remainder of the study.

All patients on treatment were titrated between 30 mg QD-120 mg BID over a 3-4 week period based on reported tolerability and efficacy and then maintained their dose until end of study. Patients whose itch intensity failed to improve during the TP were discontinued from treatment.

Conclusion: Approximately 70% of the eligible patients who completed the blinded controlled study, enrolled in the extension study. Final study data will be presented once the study is complete.

Assessing Treatment Safety and Efficacy of a New Patient-Centered Hemodialysis System

Luis Alvarez1 Geoffrey A. Block,2 May L. You,1 Glenn Matthew Hertog,4 1Palo Alto Medical Foundation, Palo Alto, CA;1 Denver Nephrology, Denver, CO;2 Outset Medical, San Jose, CA;3 Stanford School of Medicine, Stanford, CA.

Background: Many studies designed and conducted for the evaluation of new technologies utilized in hemodialysis have been small, observational studies. These studies may have underestimated the rate of clinical symptoms yielding biased safety results.

Methods: We designed a prospective, multicenter, open-label, non-randomized, cross-over study where patients serve as their own control. The study was designed with novel approaches to ensure accuracy of clinical symptom reporting both in the home and clinic setting. Up to 50 patients will be enrolled in the study for 19 weeks and will use the Table™ Hemodialysis System for treatments 4 times/week.

Conclusion: During each study phase, patients will record intra- and inter-dialytic symptoms for each treatment via questionnaire. Research staff will review all responses weekly to determine if an adverse event (AE) has occurred. In addition, research staff will conduct weekly visits to the dialysis clinic and to home to educate patients on AEs and to collect questionnaires. Patients will also be assessed to determine if a standardized weekly Kt/V of 2.1 has been achieved.

Results: Study enrollment is expected to begin in 2015 with results expected in 2016.

Conclusion: By utilizing patients to collect AE data both in-center and at home, we should more accurately capture AE rates due to the uniformity of the reporting mechanism. In terms of the clinical efficacy endpoint of the study, modelled clearance data suggests the majority of patients will achieve the weekly standard Kt/V target. Actual clearance data will be forthcoming at the completion of the trial.

Interim Analysis of Comprehensive CKD Education Modality Choice Outcomes

Andrew K. Eason,1 Dumitru Rotaru,2 Fahd Syed,1 Manisha Singh,1 Ashutosh M. Shukla,1 Sudhir V. Shah,1 1Univ of Arkansas for Medical Sciences;2 University of Florida.

Background: Preliminary data from a study comparing telemedicine vs conventional CKD education is presented here. The primary aim is to see if patients are able to make a modality choice by the end of the third visit.

Methods: Patients are enrolled in three groups as shown in the pilot study design.

Each group attends 3 sessions and are given handouts or an 82 page workbook designed specifically for the study. They are asked about their modality choice pre-education and at the end of each session. Results: To date 80 subjects have been enrolled and 32 have completed all sessions. After 3 sessions, 38% chose peritoneal dialysis (PD), 28% chose home hemodialysis (HHD), 28% chose in center hemodialysis (ICHHD). 3% chose no dialysis (ND). 3% could not make a choice (NC) and 84% chose transplant. On enrollment, 47% made a choice with 40% choosing home modalities. At the end of 3 sessions, 97% were able to make a modality choice with 66% choosing home modalities. Of the 6 subjects who have completed 1 visit and started renal replacement therapy (RRT), 5 started PD and 1 had a pre-emptive transplant. Additionally, 4 subjects did not complete all visits: 3 started ICHHD (2 with AVFs) and 1 died. Enrollment in the teledermne program has been slower than expected. Strategies to involve community leaders and local providers were developed and are being implemented. Communities interested in the program have been added as teledermene sites. Conclusions: This preliminary data shows that at the end of 3 education sessions there is a significant increase in subjects being able to make a RRT choice (97% vs. 47%) and most chose home dialysis(66% vs. 40%). Community engagement is key to a successful outreach of this state-wide CKD education program. Further strategies are being developed to improve local involvement.

Determination of Oxidative Stress and Inflammation Index in Patients with Different Dialysis Modalities and Analysis of Related Factors

Background: This study through the determination of serum AOPPs, GSH-PX, PTX-3, IL-6 level in ESRD patients with different treatment groups, to explore the changes and influence factors of oxidative stress and inflammation in dialysis patients.

Methods: 70 cases of ESRD patients divided into three groups: 26 cases of PD patients, 26 cases of MHD patients, 18 cases of CKD5 patients. Select 14 normal persons as control group. Age, gender and other data of the four groups were matched. Get Serum of each group of subjects, using ELISA for determination of serum AOPPs, GSH-PX, PTX-3, IL-6 content in each group.

Results: 1. The concentration of AOPPs: PD group (25.04 ± 12.18) ng/mL, MHD group (18.46 ± 10.47) ng/mL, CKD5 group (7.17 ± 6.81) ng/mL, healthy group (15.73 ± 6.68) ng/mL. PD group was statistically significant different with other groups (p < 0.05). 2. The concentration of GSH-PX: PD group (188.54 ± 112.04) U/mL, MHD group (157.12 ± 82.47) U/mL, healthy group (133.59 ± 65.59) U/mL, healthy control group (176.03 ± 98.80) U/mL. There was no significant different between the groups. 3. The concentration of PTX-3: PD group (9.55 ± 5.13) ng/mL, MHD group (7.54 ± 4.07) ng/mL, CKD5 group (6.69 ± 3.12) ng/mL, healthy control group (6.08 ± 2.49) ng/mL. The PD group was statistically significant different with other groups (p < 0.05). 4. The concentration of IL-6: PD group (123.69 ± 84.46) ng/L, MHD group (81.17 ± 72.48) ng/L, CKD5 group (64.92 ± 36.92) ng/L, healthy control group (59.08 ± 19.27) ng/L. The PD group was statistically significant different with other groups (p < 0.05). Through correlation analysis in PD group (p < 0.05): AOPPs was positively correlated with PTX-3 (R = 0.956, P < 0.000), AOPPs was positively correlated with IL-6 (R = 0.934, P < 0.000), PTX-3 and IL-6 levels were positively correlated (R = 0.939, P < 0.000).

Conclusions: Determination of serum AOPPs, GSH-PX, PTX-3, IL-6 content in Experience group is significantly increased compared with the control group. The PD patients compared with patients in other treatment groups have more severe oxidative stress and microinflammation state. Oxidative stress is closely related to the state of inflammation in PD patients.

Impact of Type of Referral and Dialysis Start on Clinical Outcomes and Final Renal Replacement Therapy in a Multicenter Integrated Care Setting

Belden Marion, Janusz Ostrowski, Marietta Torok, Delia Timohe, Jose C. Divino-Filho, Diaverum Home Therapies, Medical Office, Diaverum, Munich, Germany; Wloclawek Diaverum Clinic, Diaverum, Wloclawek, Poland; Siege Diaverum Clinic, Diaverum, Szeged, Hungary; Soma Diaverum Clinic, Diaverum, Bucharest, Romania.

Background: Early referral, choice of RRT modality and planned start increase patient survival, however international reports show disparities between desirable patterns and practice. Objectives: To analyze the effects of Integrated Care and education on dialysis start (planned vs. non-planned) and RRT modality choice.

Methods: Retrospective analysis of 547 incident patients starting dialysis in 23 HD/PD clinics from PL, HU and RO during 2012. Scheduled initiation of dialysis with a permanent vascular or peritoneal access was considered as planned start.

Results: Population: 30% DM, mean age 64 years, 84% with previous medical care of renal disease, 49% late referral, 58% unplaned start, 92% on HD as modality, 37% of those with unplanned start had previous Nephrology follow-up. Patients (n=332) with GFR <30 ml/min were followed up mainly by “general nephrologists” (68%) and 29% in structured predialysis units. Modality information (80% of all these information’s) could lead to develop a personal care. Type D (distressed) personality is defined as a tendency to experience both negative affectivity (NA) and social inhibition (SI). The prevalence of this personality and his effect on HRQoL in dialysis patients are assessed.

Methods: Participants were from outpatient clinic. DS 14 was used. A score of 10 on both NA and SI subscales indicates that the person has a type D personality. HRQoL was measured using the Dutch version of the Kidney Disease Quality of Life. Six components of the KDQOL were the primary end points (general health perceptions, burden of kidney disease, effect on daily life, cognitive function, pain, emotional welfare).

Results: 147 patients with mean age of 71.2 (±11.7). Mean time on dialysis 37 months. The prevalence of type D personality was 30% HRQoL in patients with type D personality was lower compared with non type D. It was statistically significant in all components except for emotional welfare.

ATHENA: A Natural History Study to Observe Disease Progression, Standard of Care, and Investigate Biomarkers in Alport Syndrome Patients

Jacqui Blem, Paul C. Grint, Victoria Pratola, James F. Simon. Regulus Therapeutics Inc., San Diego, CA; Cleveland Clinic, Cleveland, OH.

Background: Alport syndrome (AS) is a rare genetic disorder caused by mutations in genes coding for type IV collagen (COL4) α3, α4 and α5 proteins leading to hematuria, renal failure, hearing loss and eye involvement in affected patients. With COL4α5 mutations develop end stage renal disease (ESRD). While there are currently no approved therapies for AS, ACE-inhibitors have been shown to delay the onset of ESRD. A better understanding of the decline of kidney function in AS is necessary to design clinical trials to enable the development of new therapeutics.

Methods: Regulus’ Natural History of Disease Study, ATHENA, is an international multi-center observational study designed to characterize the progression of renal dysfunction in up to 120 subjects that have been clinically or genetically diagnosed with AS with a measured GFR (mGFR) between 30-75cc/min/1.73m². Genetic mutation analysis is performed at enrollment. mGFR (iohexol), 24 hour urine protein excretion and serum creatinine levels are measured every 3-6 months. Serum and urine biomarkers of renal stress (microRNAs, ADMA, TGFβ, CTGF and NGAL) will also be collected.

Results: 48 subjects with clinically or genetically diagnosed Alport syndrome have been enrolled to date. The population has an age range of 20 to 67 years of age and 29% are male. Average baseline mGFR was 54.8 cc/min/1.73m². Ethnicity is reported at 91% Caucasian, 2% Hispanic or Latino, 2% African American and 5% Asian.

Conclusions: Data gathered from the ATHENA study will investigate links between genetic mutations, biomarkers of renal stress and disease progression in AS patients. The correlative data collected from the ATHENA study will provide clinically important basis for the design of the Phase 2 clinical proof of concept study to determine efficacy of RG-012 (an anti-miR targeting microRNA-21) on the decline in renal function and time to end-stage renal disease in Alport syndrome patients.

Sleep Disorder and mRNA Expression Profile of Sleep-Related Gene in Peripheral Blood Cells in Patients with CKD  Shintaro Iwata, Yasuyuki Shinozaki, Norihiko Sakai, Miho Shimizu, Kengo Furuchi, Takashi Wada. Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan.

Background: Although uremic substances would be candidates involved in sleep disorder, detailed mechanisms remain unclear so far. we performed polymorphonuclear analysis in CKD patients and used PBCs to examine the expression of genes related to sleep and wakefulness states.

Methods: Polymorphonuclear analysis was performed in 9 CKD patients and 6 healthy controls. Genes related to sleep and wakefulness were evaluated by RNA microarray in 15 subjects, including CKD patients and control subjects.

Results: Polymorphonuclear analysis revealed that the duration of the rapid eye movement (REM)/non-REM phases during total sleep time was different between CKD patients and healthy controls. In mRNA microarray evaluation, hierarchical clustering analysis showed the different pattern of sleep related gene expression in the patients with HD. The mRNA expression levels of GABA receptor, noradrenaline receptor, dopamine receptor and histamine receptor showed an inverse correlation with renal function. Moreover, orexin and its receptor mRNA expression also showed an inverse correlation with renal function.

Conclusions: These data raise the possibility that sleep related gene expression on PBC in CKD/HD patients may be associated with sleep disorder.

**Hemodynamic Determinants of Glomerular Filtration Rate in Pulmonary Hypertension: A Prospective Cohort Analysis**

Laurent Birker,1 Cecile Payet,3 Florence Sens,1,4 Turquier Segolene,2 Antoine Duclos,1,4 Vincent Cottin,1,4 Laurent Juillard,1 1Nephrology, Hospices Civils de Lyon, Lyon, France; 2Pneumology, Hospices Civils de Lyon, Lyon, France; 3Medical Research and Statistics Dept, Hospices Civils de Lyon, Lyon, France; 4Univ of Lyon, Lyon, France.

**Background:** Up to date, renal dysfunction incidence and determinants remain unevaluated in pulmonary hypertension (PHT). We aim to assess hemodynamic and demographic factors associated with a decrease in glomerular filtration rate (GFR) in the context of PHT.

**Methods:** The regional competence center for PHT of Lyon (France) prospectively compiles demographic, hemodynamic and biological variables among newly diagnosed patients. We retrospectively analyzed data for patients with pulmonary arterial hypertension (PAH, group 1 of PHT classification) after exclusion of the following causes of PHT: thromboembolic, lung diseases and/or hypoxia and left heart disease. Hemodynamic variables from the right heart catheterization and estimated GFR (eGFR, CKD-EPI formula) were assessed at PAH diagnosis time.

**Results:** 209 patients (mean age 59.1±17.1, 63.2% women) were included from October 1998 to July 2012. 40.2% presented with systemic arterial hypertension (HT) and 12.9% with diabetes. Mean eGFR was 83.9±27.1 ml/min/1.73m² eGFR inferior to 60 ml/min/1.73m² in 18.5% of cases. Mean values of mPAP, right atrial pressure (RAP) and cardiac index (CI) were 41.5±12.6 mmHg, 7.8±5.3 mmHg and 2.6±0.9 L/min/1.73m². In multivariate analysis, age, male gender, HT, anorectic-related PAH and a CI inferior to 2.5 L/min/1.73m² were associated with a significant decrease in eGFR of 1.0 ± 1.73m²/year (95% confidence interval, 0.8 to 1.2), 11.8 ml/min/1.73m² (5.8 to 7.8), 6.6 ml/min/1.73m² (0.1 to 13.2), 13.4 ml/min/1.73m² (2.3 to 24.5) and 10.1 ml/min/1.73m² (4.4 to 15.9). RAP were not statistically related to eGFR levels.

**Conclusions:** Renal dysfunction is frequent from diagnosis among PAH patients. A low CI is associated with a significant decrease in eGFR, whereas RAP seem unrelated.

PUB125

**Kidney Function and Cause-Specific Mortality in Drug-Treated Older Cardiac Patients: A 10-Year Follow-Up Study**

Ellen K. Hoogeveen,1 Johanna M. Geleijnse,2 Dejan Kromhout,3 Theo Stijnen,4 Erik Gillis,1 Nephrology, LUMC, Leiden, Netherlands; Human Nutrition, WU, Wageningen, Netherlands; Medical Statistics and Bioinformatics, LUMC, Leiden, Netherlands; Psychiatry, LUMC, Leiden, Netherlands.

**Background:** Chronic kidney disease (CKD) is highly prevalent among older (>60y) cardiac patients. The relation between CKD and cause-specific mortality among older cardiac patients who are treated with state-of-the-art pharmaceuticals is unclear.

**Methods:** From 2002-2006, 60-80 years old Dutch post-myocardial infarction patients were enrolled in the Alpha Omega Trial and followed until death or January 2012. We estimated Glomerular Filtration Rate (eGFR) with serum cystatin C (cysC) and creatinine using the CKD-EPI equations. Kidney function was available in 4,561 (94.3%) participants and analyzed in relation to major causes of death using Cox models and four-knot restricted cubic splines.

**Results:** At baseline mean age was 69y, 79% were men, 21% had diabetes, 90% used antihypertensive drugs, 85% used statins. Patients were divided into four categories of GFR: G1 (<60 ml/min/1.73m²), G2 (60-89 ml/min/1.73m²), G3 (30-59 ml/min/1.73m²), and G4 (≤30 ml/min/1.73m²). Median follow-up time was 6.4y. During follow-up, 973 (19%) patients died, of which 370 (42%) from cardiovascular causes, 309 (35%) from cancer, and 192 (22%) from other causes. The hazard ratios (95%-CI) for any death according to eGFR category, after adjustment for major risk factors, were: 1 (reference), 1.4 (1.1-1.7), 2.9 (2.3-3.6) and 4.4 (3.0-6.4). For cardiovascular mortality the corresponding figures were 1.6, 3.6 and 6.0, for cancer 1.2, 2.1 and 1.6, and for other causes 1.4, 3.1 and 6.7. Similar, but weaker, results were obtained with creatinine-based eGFR.

**Conclusions:** We found a strong inverse graded relation between kidney function and mortality in drug-treated older cardiac patients, in particular due to cardiovascular and non-cardiovascular-non-cancer causes.

**The Association Between Serum Uric Acid and Incidence of Non-Fatal Stroke in a Community-Based Population: A Longitudinal Survey of a Nationwide Cohort in Japan**

Keita Kamei,1 Kazunobu Ichikawa, Tsuneo Kondo,1 Shouichiro Fujimoto,2 Kunishiti Ikei,2 Toshihiko Morigaya,2 Kunihiro Yamasata,2 Kazuhiko Tsuruya,2 Kenichiro Kimura,1 Ichie Iri,2 Masahide Kondo,1 Koichi Asahi,1 Tuyoshi Watanabe,2 1Dept of Cardiology, Pulmonology, and Nephrology, Yamagata Univ School of Medicine, Yamagata, Japan; 2Steering Committee of Research on Design of the Comprehensive Health Care System for Chronic Kidney Disease (CKD) Based on the Individual Risk Assessment by Specific Health Checkup, Japan.

**Background:** Hyperuricemia is a risk for adverse renal outcomes in chronic kidney disease. This study investigated the effect of uric acid on incidence of non-fatal stroke in a community-based population.

**Methods:** We used a nationwide database of 160,164 subjects (aged 29–74, male 39%), participated in an annual health check, “The Specific Health Check and Guidance in Japan” between 2008–2010, and examined the relationship between the gender-specific quintiles of serum uric acid levels and the incidence of non-fatal stroke (PAH, group 1 of PHT classification) after exclusion of the following causes of PHT: thromboembolic, lung diseases and/or hypoxia and left heart disease. Hemodynamic variables from the right heart catheterization and estimated eGFR (eGFR, CKD-EPI formula) were assessed at PAH diagnosis time.

**Results:** During the follow-up period 2,081 non-fatal stroke occurred (1.3%). The incidence of non-fatal stroke showed a significant J-shaped association with the increase in serum uric acid levels (P for trend<0.001, lowest [1.2%] in the 3rd quintile of uric acid [Q1]: males 5.7–6.2 mg/dL, females 4.4–4.8 mg/dL) and highest [1.6%] in the 5th quintile (Q5: males ≥7.1 mg/dL, females ≥5.5 mg/dL). After adjusting for possible confounders, the odds ratio for stroke incidence was significantly higher in Q5, compared with Q3 (OR 1.21, 95%CI 1.05–1.39, P = 0.007). The odds ratio of hyperuricemia (serum uric acid ≥7 mg/dL) for incident stroke was significantly increased in total subjects (OR 1.22, 95%CI 1.07–1.39), especially in females (OR 1.46, 95%CI 1.04–1.99) and non-hypertensive subjects (OR 1.34, 95%CI 1.04–1.70). In contrast, the association between serum uric acid levels and incident stroke was not significant in subjects with diabetes, proteinuria and renal insufficiency.

**Conclusions:** This study showed that serum uric acid level is significantly associated with incident non-fatal stroke and that hyperuricemia might be an independent risk for non-fatal stroke in the general population.

PUB127

**The Association Between Serum Calcium and Mortality in a Community-Based Population: The Takahata Study**

Sawami Watanabe, Keita Kamei, Kazunobu Ichikawa, Tsuneo Kondo, Isao Kubota. Dept of Cardiology, Pulmonology, and Nephrology, Yamagata Univ School of Medicine, Yamagata, Japan.

**Background:** The low intake of calcium is a risk for cardiovascular events. This study investigated the association between serum calcium and mortality in a community-based population.

**Methods:** This study included 1,314 participants (aged 40–87, males 45%) at local health checkup in Takahata, Japan. We divided them into 3 groups according to the tertiles of serum calcium at baseline and compared the mortality during 8-year follow-up period. Serum calcium was corrected for serum albumin.

**Results:** At baseline serum calcium level was 9.8 ± 0.4 mg/dL (mean ± SD). In the multivariate linear regression analysis serum calcium was positively associated with serum sodium, potassium, phosphorus, albumin, uric acid and total cholesterol, and was negatively associated with serum chloride and HDL-cholesterol, and urinary beta2-microglobulin. During the follow-up period 62 deaths, including 14 cardiovascular deaths occurred. In Kaplan-Meier analysis all-cause mortality was significantly increased along with the decrease in serum calcium (Log-rank P = 0.03). In Cox proportional hazard analysis adjusted for confounders including age, gender, smoking and drinking habits, comorbidities and other serum electolytes, the association of serum calcium was of borderline significance with all-cause mortality (HR 2.95, 95%CI 0.94–4.75), P = 0.07, low tertile [≤5.6 mg/dL vs. high tertile [≥10.0 mg/dL]] and was significant with cardiovascular mortality (HR 6.33, 95%CI [1.13–43.7], P = 0.04, low tertile vs. high tertile). In addition, there was a significant interaction between serum calcium and sodium on all-cause mortality (P = 0.03) and the association of serum calcium with the mortality was significant in the subjects with low serum sodium (< 150 mEq/L), but not high sodium.

**Conclusions:** This study showed that serum calcium was significantly associated with various environmental factors and low serum calcium was an independent predictor for the mortality in the general Japanese population.

Endothelial Dysfunction According to Classification of Serum Phosphorus Level within Normal Range in Chronic Kidney Disease

Background: Hyperphosphatemia is a important problem because of its effect on endothelial function as well as homeostasis of bone. Chronic kidney disease (CKD) patients tend to have higher serum phosphorus values than those in healthy population due to their positive balance of phosphorus in kidney. There are a few studies which reported that serum phosphorus level was correlated with endothelial function. Recently it has been reported the patients with higher serum phosphorus level related to the worse endothelial function in healthy population. Thus, the following study was carried out in an effort to redefine the relationship between serum phosphorus level and endothelial dysfunction to those on chronic kidney disease.

Methods: This is a cross-sectional study and the enrolled 85 CKD patients with exception of CKD stage 5 or receiving renal replacement therapy. They were subjected to their positive balance of phosphorus in kidney. There are a few studies which reported that serum phosphorus level was correlated with endothelial function. Recently it has been reported the patients with higher serum phosphorus level related to the worse endothelial function in healthy population. Thus, the following study was carried out in an effort to redefine the relationship between serum phosphorus level and endothelial dysfunction to those on chronic kidney disease.

Methods: The following studies were identified: The IDNT; The final outcome of diabetes was achieved by 14%. However, no significant difference was found on CV outcome, including death, non-fatal MI, stroke or heart failure. The ONTARGET, in a sub-analysis; looking at renal outcome, including doubling S. Cr., dialysis and death, it revealed that although the ACE Inh. and the ARB combination had successfully reduced proteinuria, it resulted in worse renal outcome. The TRANSCEND; by looking specifically at the renal outcome, including doubling and disabling serum Cr., it was found that GFR had decreased. The AASK trial; the results did not show a positive solid endpoint associated with lowering proteinuria, no statistical difference was encountered. The ROADMAP; the result revealed that decreasing microalbuminuria as well as blood pressure in the Olmisartan subgroup was found in decreased cardiovascular death. The Attitude trial; decreased proteinuria did not show a significant evidence in the primary renal or cardiovascular composite endpoints. Moreover, the study was terminated prematurely because of severe decline in eGFR, hyperkalemia and hypotension. The NEPHRON-D; The final outcome was not statistically different. The study was stopped prematurely because of more acute renal injury and hyperkalemia in the combination arm.

Conclusions: Decreased proteinuria was associated with negative cardiac and renal outcomes. This could be due to the effect of RAAS combination, but we have to admit that these repeated observations carries an evidence, at least to question our standard belief, that proteinuria might not be more than a cardiac risk factor indicator.

Prevalence of Hematuria and Associations with All-Cause and Cardiovascular Mortality in China

Background: Hematuria is one of the indicators of kidney damage. We aimed to estimate the prevalence of hematuria in China and evaluate its association with mortality and cardiovascular adverse outcome.

Methods: A nationally representative sample of 47,204 Chinese adults was obtained during the survey conducted between January 2009, and December 2012. Each participant’s survival status was identified through Dec 31, 2013. Causes of death in ICD code 100-199 were classified as cardiovascular disease. Hematuria was defined as ³3 red cells per high-power field in microscopic examination. Subjects with pyuria and women undergoing menestration were excluded from the analysis. The associations between hematuria and all-cause and cardiovascular mortality were studied by using the Cox regression model.

Results: The mean age of the population at baseline was 49.6±15.2 years, and 42.7% of the participants were male. Altogether, 2,126 (4.5%) of the population was detected with hematuria. The all-cause and cardiovascular mortality for participants with hematuria were 3.8 and 2.6 per 1000 person-years, while those for participants without hematuria were 3.4 and 1.3 per 1000 person-years. Hematuria was found to be significantly associated with increased risk of cardiovascular mortality with the multivariable adjusted hazard ratio of 1.7 (95% confidence interval: 1.1-2.7), compared with those without hematuria. However, no significant associations were found between hematuria and all-cause mortality.
Conclusions: Mortality, especially due to cardiovascular diseases, was greater among the Chinese patients with hematuria. These results suggest the possible effect of hematuria on cardiovascular mortality.

PUB133
Glomerular Filtration Rate Is a Predictor of Subclinical Left Ventricular Diastolic Dysfunction in Patients with Rheumatoid Arthritis
Suad M. Hannawi, Kashif Naeem, Issa A. Salmi. Medicine, MOH, United Arab Emirates; Medicine, MOH, United Arab Emirates; Medicine, The Royal Hospital, Oman.

Background: Rheumatoid arthritis (RA) is a systemic disease effecting primarily joints with subclinical kidney involvement. Subclinical cardiovascular disease (CVD) is a leading cause of morbidity & mortality in RA. Chronic kidney disease (CKD) at early stages. Subclinical cardiovascular dysfunction (LVDD) is a principal pathophysiological mechanism & essential diagnostic indexes of HF with preserved ejection fraction (HFPEF).

Results: Renal parameters correlated with echocardiographic findings in patients with RA & eGFR as estimated (MDRD, equation). Doppler echocardiography was performed by pulse wave Doppler with sample volume at tip of mitral valve in apical 4-chamber views. Peak early (E) & late (A) diastolic velocities were measured as indicator of LVED pressure. Assessment of peak early (E′) & late (A′) diastolic mitral annulus velocity was performed by pulsed wave tissue Doppler imaging (TDI) of lateral wall in apical 4-chamber view & to diagnose LVDD (E′/E > 8).

Interim results: Analysis of 29 (3, 26%) with RA diagnosed (ACR1988), aged 46 ± 12 years & GFR < 60 ml/min. Univariate regression showed a negative linear relationship of GFR & age (p < 0.001, CI = 27,73, 1.03, age)/RA onset (p = 0.001, CI = 3.23, 0.63, age). RA diagnosis (p = 0.002, CI = 2.5, 0.66), SBP (p = 0.032, CI = 1.51, 0.07), ESR (p = 0.005, CI = 1.09, 2.21), ferritin level (p = 0.008, CI = 0.45, 0.08), EE (p = 0.005, CI = 20.76, 4.26). Multiple regression maintained a negative relationship between GFR & age of each (p = 0.004, CI = 0.52, 0.07), E′/E (p = 0.014, CI = 0.32), E′/A (p = 0.011). Kt/V = 2.5.

Conclusions: RA patient have subclinical CKD and cardiac dysfunction & eGFR independently & negatively correlated to LVDD with moderate correlation (0.54). eGFR increased with decreasing GFR & higher than in patients GFR < 90. LVDD influenced by increase LV preload due CKD progression & it’s a preclinical predictor of future HF & mortality. However, milder form of LVDD may stabilize or improve subset of patients may, over time, be at risk for functional deterioration. Inflammation as a major pathological key in RA may be underlying cause for increased subclinical kidney & ventricles.

PUB134
The Association Between Creatinine versus Cystatin-C-Based eGFR and Cardiovascular Risk Factors in Children with Chronic Kidney Disease

Background: Chronic kidney disease (CKD) is an independent risk factor for cardiovascular events (e.g. stroke, myocardial infarction) in adults. Children with mild-moderate CKD have a high prevalence of cardiovascular risk factors (CRF). Higher levels of cystatin-C demonstrate a stronger predictive value for cardiovascular events compared with creatinine-based eGFR in adults. However, whether similar associations exist in children in young adults has yet to be determined. We hypothesize that cystatin-C based eGFR will demonstrate a stronger association with CRF compared with creatinine-based eGFR in children and young adults.

Methods: We used cross-sectional data of 93 subjects aged 8-25 years with CKD and 70 healthy controls. eGFR was calculated using age appropriate creatinine and cystatin-C based formulas. The CRF included were anemia (hemoglobin < 9.2 standard deviations below the mean), hypertrophy & hypertension (eGFR < 90.2 ml/min) or urine albumin/creatinine > 30 mg/g). Multivariate analysis assessed the association between creatinine and cystatin based eGFR and each risk factor after adjusting for age, gender, race.

Summary: Cystatin-C based eGFR had a stronger association with decreased ejection fraction, increased left ventricular hypertrophy, arterial hypertension, anemia, uremic symptoms, and inflammatory states, malnutrition, mass of the left ventricle, problems with the contractile function of the left ventricle as well as decreased relaxation of the left ventricle in the group of patients treated with peritoneal dialysis with regard to survival prognosis.

Results: The study was conducted on 105 patients (40 men, 56 women) treated with peritoneal dialysis with the average time of 36.1 ± 27.7 months. The control group consisted of 30 healthy volunteers (20 women, 10 men, mean age 55.0 ± 23.8 years). Based on general known vascular and cardiac risk factors the patients were divided into subgroups: elderly patients (> 65 years of age), male, patients treated on peritoneal dialysis over 3 years, daily diuresis > 500 ml, Kt/V > 1, arterial hypertension, anemia, inflammatory states, malnutrition.

Conclusions: Chronic low-grade inflammation and advanced age seem to be two most common negative prognostic factors decreasing life expectancy. Further research is necessary to verify the intricate relationships between demographic factors and prognosis in the group of patients undergoing peritoneal dialysis.
Conclusions: Low ABI tended to be associated with higher risk of exertional leg pain. A low ABI value may be useful to identify ischemic etiology of leg pain even among dialysis patients with high prevalence of leg symptoms due to various conditions.

PUB138

Predictors of In-Hospital Mortality of CKD4-6 Patients with Takotsubo Cardiomyopathy

Fernando Rodriguo Aguilar, Mark Abi Nader, Wen Shen, Serban A. Dragoi, Alex Montero, Ping Li. Internal Medicine, Div of Nephrology, Medstar Georgetown Univ Hospital, Washington, DC.

Background: The pathophysiology of Takotsubo cardiomyopathy (TTC) remains poorly understood and little is known about the factors predicting mortality in these patients among those with chronic kidney disease. We aimed to study the epidemiology of TTC and predictors of mortality in these patients.

Methods: All patients with CKD 4 to CKD 6 (ICD9 585.4-585.6) diagnosed with TTC (ICD9 429.83) in the Nationwide Inpatient Sample database between 2007 and 2012, were compared to CKD4 - CKD6 patients without TTC. Capturing only cases undergoing inpatient care for TTC provided valuable information about TTC, its use for patients with CKD is difficult due to the risk of contrast induced nephropathy (CIN). To our knowledge, there have been no studies to explore the association of CAD and advanced CKD. The objectives of this study are to assess the severity of CAD in advanced CKD patients by MDCT and clarify the association between CAD and renal function.

Methods: We retrospectively collected the data from 168 advanced CKD patients, stage 3b to 5, who underwent MDCT angiography at St Luke’s international hospital between 2011 and 2014. We assessed CAD by coronary artery calcification score (CACS), coronary plaque characteristics and number of vessel disease. Risk factors for CAD were sought using univariate and multivariate logistic regression.

Results: Among the 168 patients (56 females, age 60±17.0), 108 patients were CKD stage 3b, 42 patients were stage 4, and 18 patients were stage 5. No patient developed CIN by MDCT. On univariate analysis, patients with CASC100 were older (P=0.003), male sex (P=0.011), diabetes (P=0.045), and more likely to be a smoker (P=0.014). Multivariate logistic regression analysis identified age (hazard ratio = 1.08, P<0.01), male sex (hazard ratio = 2.97, P=0.031), and CKD stage (hazard ratio = 2.58, P=0.041) as independent risk factors for CASC100.

Conclusions: Coronary artery calcification is worsened significantly with decreasing renal function in advanced CKD. Given the high morbidity and mortality of cardiovascular disease in CKD, our study underscores the importance of evaluating CAD in advanced CKD.

PUB140

Cardiovascular Biomarkers and Coronal Calcium in CKD Patients

Joaoquin Marquie, Diana Izquierdo, Patricia Restituito, Nuria Garcia-Fernandez, Maria Fernanda Sion, Diana Lopez Espinos, Maria Jose Molina Higuera, Nerea Naro. 1Servicio de Nefrologia, Complejo Hospital de Navarra, Pamplona, Spain; 2Servicio de Bioquimica, Clinica Univ de Navarra, Pamplona, Spain; 3Servicio de Nefrologia, Clinica Univ de Navarra, Pamplona, Spain.

Background: Cardiac and vascular calcification and mortality are highly prevalent in patients with CKD. Biomarkers help to an early diagnose, like osteoprotegerin (OPG) a glycoprotein from TNF family that has been associated with cardiovascular (CV) disease. FGF-23, a phosphatonin protein has been linked to vascular calcification, ventricular hypertrophy and mortality. Coronary artery calcification (CACS) measured with Agatston score (AS) by CT is associated to CV disease in CKD patients. We hypothesized that OPG and FGF-23 are abnormally elevated in CKD and are associated CACS measured with AS.

Methods: An observational study including 138 CKD 3-5 patients, and 20 control subjects were included. Serum FGF-23 and OPG levels were measured by ELISA and CAC was determined by multi-detector computed tomography (AS). Biochemical regular labs (Cr, Ca, P and PTH) were measured.

Results: Compared with control subjects, CKD patients exhibited significantly augmented serum FGF-23 (16.2 vs 304.8pg/mL; P<0.001), and increased proportionally to CKD stage. FGF-23 and OPG were correlated to PTH and P (P<0.001) and OPG correlated with renal function (sCr) in non-dialysis patients(P<0.05). CKD 5 patients showed significantly increased CACS compared with control group (CACS:117±117.7pmol/L; r=0.58; P<0.001) and increased proportionally to CKD stage. FGF-23 and OPG were correlated to AS (r=0.24; P<0.05 and r=0.37; P<0.01, respectively). Among KD patients, high CACS (AS>800) compared to low CAC patients (AS≤150) showed higher FGF-23 (374.9 vs 156.1; P<0.05) and OPG levels (2121.2 vs 1305.2; P<0.001).

Conclusions: CKD is related to high coronary artery calcification levels. FGF-23 and OPG are higher in CKD patients and are significantly associated to coronary artery calcification. Further investigations are needed to determine if they could promptly assess increased cardiovascular risk in CKD patients.

PUB141

Rate of Kidney Function Decline and Risk of Hospitalizations

Yan Xie, Benjamin Charles Bove, Sumitra Balasubramanian, Ziyad Al-Ally. 1Research and Development, VA Saint Louis Health Care System, Saint Louis, MO; 2Medicine, VA Saint Louis Health Care System, Saint Louis, MO.

Background: Risk of hospitalizations is increased in patients with chronic kidney disease (CKD). We sought to examine the association between rate of kidney function decline and risk of hospitalization in a cohort of patients with early CKD.

Methods: We built a cohort of 241,274 United States veterans with an estimated glomerular filtration rate (eGFR) between 60 and 45 mL/min on October 1, 1999 and who had at least 1 additional eGFR measurement between October 2003 and September 2004. Patients were followed longitudinally from October 2004 until September 2013. We built
survival models to examine the association between rate of kidney function decline and risk of hospitalization, and readmission. We built linear regression models to estimate the length of hospital stay.

**Results:** Over a median follow-up of 9 years (IQR 5.42–9.00), compared to patients who experienced mild eGFR decline, patients with moderate and severe eGFR decline exhibited an increased risk of hospitalizations HR=1.10 (CI:1.07-1.12), and HR=1.29 (CI:1.26-1.32); respectively. The number of hospitalizations modified the association between rate of decline and risk of hospitalizations in that the risk was increasingly more pronounced with increased number of hospitalizations (p value for interaction <0.0001). Compared to patients with mild decline in kidney function, patients with moderate and severe kidney function decline had increased risk of future readmission, HR=1.16 (CI:1.10-1.21), and HR=1.47 (CI:1.39-1.55); respectively. Among patients with severe kidney function decline, the risk of readmission was increasingly stronger with increased number of readmissions (p value for interaction < 0.0001). Compared to patients with mild decline in kidney function, patients with moderate and severe decline experienced an additional length of stay of 0.91 (CI: 0.58-1.25) and 2.82 (CI: 2.43-3.20) day/year; respectively.

**Conclusions:** Our findings suggest that rate of kidney function decline is associated with future risk of increased health care utilization.

**Funding:** Veterans Administration Support

**PUB142**

**Racial Influences on the Association of Albumin and Hemoglobin in Chronic Kidney Disease**

**Background:** In CKD, anemia is associated with reduced kidney function, female gender, diabetes, older age, African-American race(AA), iron deficiency, low albumin, renin-angiotensin blockade, and chronic inflammation. There is a paucity of studies evaluating relationship of albumin and hemoglobin(Hb) in CKD among racial groups.

**Methods:** Retrospective cross section design of 196 patients with CKD stages 2-5, in a community clinic over a 7 months period. Averages of hemoglobin, albumin, body mass index (bmi), and glomerular filtration rate(GFR) were obtained for each individual patient. Patients on dialysis and on erythropoesis-stimulating agents were excluded. Multi-linear regression analysis (MLR) was then done between serum albumin and hemoglobin adjusting for age, sex, diabetic status, GFR, bmi, and Ace inhibitors/angiotensin receptors blockers intake (ACEi) among African-Americans(AA) and Caucasians(W).

**Results:** 51% were AA. 49% were diabetics. Mean Hb was 11.7 in AA compared to 12.3 in Caucasians. Mean serum albumin was also lower (3.5 AA versus 3.8 in W). Bmi and GFR were higher in AA (36.4 and 42.8 in AA vs 32.3 and 39.9 in W respectively). Using MLR, there was a statistically significant positive association between GFR(coefficient=0.02,p<0.001), albumin (coefficient=0.77,p=0.002) and hemoglobin. AA race was negatively related to hemoglobin (coefficient= -0.56,p=0.02). When MLR was done separately among racial groups, there was a persistent positive relationship between albumin and hemoglobin among AA (coef=0.95, p=0.001). In Caucasians however there was no association between albumin and hemoglobin (p=0.181).

**Conclusions:** In CKD-2, using multilinear regression analysis, there was a positive association between serum albumin and hemoglobin. This relationship occurs only in AA and disappears among Caucasians. It is of interest that in our sample AA had higher baseline bmi and GFR and lower serum albumin and hemoglobin. More needs to be done to understand the interplay between bmi , albumin and markers of inflammation and nutrition among African Americans with chronic kidney disease and their relationships to hemoglobin levels.

**Mirceura Use in Chronic Kidney Disease Patients with Symptomatic Renal Anemia: The Real Life Setting**

**Background:** Randomized controlled trials have confirmed non inferiority of Mirceura in the management of renal anemia when compared to other erythropoiesin stimulating agents (ESAs). Many of these trials had strict exclusion criteria which perhaps confounded any benefit that may be seen in an unselected cohort of patients. This multicenter audit assessed the outcomes of Mirceura use in the real life setting.

**Methods:** A prospective audit was conducted by 6 UK Renal Centers between 2009 and 2011. Demographic data, as well as hematological and biochemical parameters were longitudinally collected from 1000 adult patients requiring ESAs, over a 1 year period. A cohort of 500 patients were switched from previous ESAs to Mirceura and 500 patients remained on their existing ESA therapy. Patients with hemoglobinopathies or malignancies were excluded. Achievement of target hemoglobin (Hb) as per the National Institute of Clinical Excellence (NICE) guidelines was ascertained as the primary objective. Hb variability was reviewed as a secondary objective.

**Results:** Demographic data confirmed both cohorts were comparable. Only 11% of Mirceura treated patients had their Hb maintained within range (10-12g/dl) over the entire 1 year versus 4% in the non-Mirceura group (p<0.05). (If an Hb recording was out of range the patient was classified as ‘not maintained’). Parameters such as B12, folate and iron were similar in both cohorts. Hb was less variable in the Mirceura group compared to the non-Mirceura group. Hb variability was reviewed as a secondary objective. In the Mirceura group, Hb variability was reduced from 28% before to 21% after switching to Mirceura. Hb variability was reduced from 31% before to 25% after switching to Mirceura. Hb variability was reduced from 31% before to 25% after switching to Mirceura. Hb variability was reduced from 31% before to 25% after switching to Mirceura. Hb variability was reduced from 31% before to 25% after switching to Mirceura.

**Conclusions:** The results of this audit confirm that Mirceura use in the correction of anemia associated with CKD is equally efficacious as other ESA therapies in this real life setting. Over a year period, Hb variability was noted to be reduced in the Mirceura treated cohort suggesting a role for its use in patients with fluctuant Hb levels.

**Latent Profiles of Patient Reported Outcomes in Nephrotic Syndrome Patients**

**Background:** Nephrotic syndrome (NS) can significantly impair the quality of life in children and adults. The purpose of this study was to demonstrate the feasibility and utility in using a latent profile analysis (LPA), a type of cluster analysis, to identify subgroups of patients based on their patient reported outcomes using the Patient Reported Outcomes Measurement Information System® (PROMIS®) measures as well as identifying significant predictors of those subgroups.

**Methods:** Prospective data were collected on 121 children with NS from the PROMIS-II study. Data from 55 children and 254 adults with biopsy confirmed NS from the NEPTUNE cohort were used as validation. LPA was used to identify distinct patterns and subgroups of patients based on PROMIS domain scores. Classification was assessed using entropy statistics. Generalized multinomial logit models were used to identify predictors of profile membership as well as transitions between profiles over time.

**Results:** We identified three patient reported outcome profiles (figure1) in the PROMIS-II cohort with strong indicators of membership classification (entropy>0.86).

**Conclusions:** LPA may be an effective tool in stratifying NS patients by quality of life. Profile membership changed in response to changes in disease status over time.

Sex Hormone Status in Women with Chronic Kidney Disease: A Survey of Nephrologists

Sharnaya Ramesh,1 Ellen Wells Seely,2 Matthew T. James,3 Jayna M. Holroyd-Leduc,4 Stephen B. Wilton,4 Sofia B. Ahmed,1,3,4 Medicine, Commong School of Medicine;2 Brigham and Women’s Hospital;3 Community of Health Sciences, Univ of Calgary;4 Libin Cardiovascular Inst of Alberta.

Background: Chronic kidney disease (CKD) in women is often accompanied by menstrual and fertility disorders due to kidney-mediated endocrine disturbances. Whether this issue is recognized by nephrologists and discussed by them with their patients is unknown.

Methods: We electronically surveyed 111 nephrologists in Canada, identified via Canadian Society of Nephrology membership (39% response rate), regarding their impressions of sex hormone status, menstrual cycle, fertility and the role of postmenopausal hormone therapy (HT) in women with CKD. Responses were stratified by kidney transplant nephrologist status.

Results: Fourteen percent of respondents were transplant nephrologists. There were no differences in age or sex between transplant and non-transplant nephrologists. Ninety-three percent of respondents agreed that kidney function has an important impact on regulation of sex hormones. However, only 35% reported discussing fertility, and even fewer (14%) reported discussing menstrual irregularities with their patients. Only 40% of respondents advised their patients to address these concerns with their family physician or an endocrinologist or gynecologist. Most of the of nephrologists responded that they do not know if there is a role for hormone replacement therapy in patients with CKD (48%), 23% of nephrologists disagreed with the statement. Nephrologists did not know whether the potential benefits of postmenopausal hormone therapy outweighed the risks in CKD (51%) or if the formulation (44%), route of administration (46%), and time of HRT initiation (50%) play a role in the actions of postmenopausal hormone therapy.

Conclusions: While nephrologists recognize the impact of CKD on sex hormone status in women, few address fertility and menstrual disorders with their patients. Our survey highlights existing uncertainties of nephrologists about how to manage disturbances of sex hormones in people with CKD.

Use of Urine Biomarker-derived Clusters to Predict CKD Risk and All-Cause Mortality in HIV + women

Use of urine biomarker-derived clusters to predict CKD risk and all-cause mortality in HIV+ women: Robert Ekart,1,2 Robert waving,3 Robert L. Green,4 Robert H. Loh,5 Steve B. Wilton,6 Sofia B. Ahmed.1,2,3

Background: Urinary N-acetylglucosaminidase (NAG), Neutrophil gelatinase-associated lipocalin (NGAL) and cystatin C, are commonly used as urea and citric acid cycles. Urea is then transported through the bloodstream to be excreted into the urine by the kidneys. In patients with chronic kidney disease (CKD) an equilibrium concentration of ammonia and urea becomes imbalanced, concentrations exceeding physiological values and breath ammonia can be used for detecting increased urinary wastes in patients. In our pilot study, the breath ammonia sensor was used to measure and analyze breath ammonia in healthy volunteers and CKD patients.

Methods: Six CKD patients and eight healthy volunteers were enrolled. The mean age of CKD patients was 47.2 years, mean age of healthy volunteers 61.3 years. One controlled breath sample was given from each participant. Immediately after the sample was collected gas analyzer (BA-NH3, Echo, d.o.o.) was used for measuring breath ammonia in our participants. BA-NH3 detects breath ammonia in parts per million (ppm) and measures the electric current in milliamperes (mA). BA-NH3 was validated with reference gas samples prepared with a precise accredited gas mixing device (M4-1 S-220, Echo, d.o.o.) using calibrated mass flow controllers controlled with computer software.

Results: Mean serum creatinine in CKD patients was 455.17±294.12 µmol/L and 62.13±7.5 µmol/L in healthy volunteers. BA-NH3 detected more ppm of ammonia in breath of CKD patients (mean 3.32±2.19; range 1.26-6.33) compared to healthy volunteers (mean ppm 0.49±0.08; range 0.38-0.64 ppm) (p=0.003) and measured higher electric current from breath samples of CKD patients (mean mA 4.33±0.25; range 4.10-4.67 mA) comparing to healthy volunteers (mean mA 4.01±0.01; range 4.00-4.03 mA) (p=0.003).

Conclusions: Results of our pilot study show that breath monitoring of ammonia can be an useful simple, fast and noninvasive tool for detection of kidney impairment.

* Clusters were derived using NAG, sCr, and KIM-1. Adjusted models control for traditional kidney risk factors and HIV-related risk factors.

Funding: Other NIH Support - The WHIS Kidney Aging Study is funded by grant 1 R01 AG034853-01A2 (PL. Shlipak), which was administered by the Northern California Institute for Research and Education, and with resources of the Veterans Affairs Medical Center, San Francisco, California. Data in this manuscript were collected by the VAMC Medical Research Agency HIV Study (WHIS). The contents of this publication are solely the responsibility of the authors and do not represent the official views of the National Institutes of Health (NIH). WHIS (Principal Investigators): UAB-MS WHIS (Michael Saag, Mirjam-Colette Kempf, and Deborah Konkle-Parker), U01-AI-103401; Atlanta WHIS (Jgeu (dka): U01-AI-100368; Rush; Albert Einstein; Georgetown.

Background: Individual urine biomarkers are associated with CKD incidence and all-cause mortality in the setting of HIV infection, but their combined utility for prediction remains unknown.

Methods: We measured 8 urine biomarkers in 902 HIV+ women: NAG, KIM-1, alpha 1 microglobulin (a1m), IL-18, NGAL, ACR, L-FABP, and AAG. A novel cluster method classified each participant into 3 groups using the three most distinguishing markers (NAG, KIM-1, and a1m). We evaluated associations of each cluster with incident CKD and all-cause mortality, adjusting for traditional and HIV-related risk factors.

Results: Over 8 years of follow-up, 177 CKD events and 128 deaths occurred. As shown in the Table, incidence of CKD and mortality increased incrementally across the 3 clusters. After multivariable adjustment, cluster 3 remained associated with a nearly 3-fold risk of both outcomes compared with cluster 1. Addition of the clusters to the multivariable model increased discrimination for CKD (c-statistic=0.72 to 0.76, p=0.0029), but only marginally for mortality (c=0.79 to 0.80, p=0.099). Clusters derived with all 8 markers were no better for discrimination than the 3 biomarker clusters.

Conclusions: Among HIV+ women, clusters developed from 3 urine biomarkers moderately improved discrimination for CKD risk, but not for all-cause mortality.
WHIS is funded primarily by the National Institute of Allergy and Infectious Diseases (NIAID), with additional co-funding from the Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD), the National Cancer Institute (NCI), the National Institute on Drug Abuse (NIDA), and the National Institute on Mental Health (NIMH). Targeted supplemental funding for specific projects is also provided by the National Institute of Dental and Craniofacial Research (NIDCR), the National Institute on Alcohol Abuse and Alcoholism (NIAAA), the National Institute on Deafness and other Communication Disorders (NIDCD), and the NIH Office of Research on Women’s Health. WHIS data collection is also supported by UL1TR000004 (UCSF CTSA) and UL1-TR000454 (Atlanta CTSA).

**Minimizing Erythropoietin Stimulating Agents Requirement by Comprehensive Clinical Care**

Rachita Singh Dhull, Rossana Baracco, Melissa J. Gregory, Tej K. Mattoo.

**Pediatric Nephrology, Children’s Hospital of Michigan, Detroit, MI.**

**Background:** Anemia is a common problem in children with chronic kidney disease (CKD). The objective of the study was to evaluate prevalence of anemia, use of iron supplement and erythropoietin stimulating agents (ESA) in children with CKD stage 2-4, and compare the same with previous pediatric studies.

**Methods:** This is a retrospective chart review of children with CKD stage 2-4 (defined per KDOQI), aged between 1-18 years followed at Children’s Hospital of Michigan (CHM) in 2013. Data on transferrin saturation, hemoglobin level, use of iron supplements and ESA was collected.

**Results:** Total number of patients were 62. The mean age was 10.12 ± 5.52 years and 27.4% were female. The main causes of CKD were renal dysplasia (20%), obstructive uropathy (18%), reflux nephropathy (14.5%), cystic dysplasia (13%), glomerular pathology (11.2%) and others (23.3%). In our cohort, 27% patients had anemia compared to 44% in CKd study and 43.5% in study by Wong et al. Also, only 6.5% of CKD patients were on ESA, compared to 18% in CKd study and 19.5% in study by Wong et al. Results are elaborated in the table below.

*Anemia as defined by hemoglobin (Hb) level < 9% percentile for age and sex according to NHANES III data.

**Conclusions:** Our CKD patients had a lower prevalence of anemia and lower use of ESA compared to other pediatric studies. We maintain adequate iron stores by using iron supplements even in children with normal hemoglobins. The administration of supplemental iron prior to the development of anemia in children with CKD decreases the need for ESA.

**Validation of Urinary Biomarkers for the Diagnosis of Urothelial Carcinoma in Patients with Chronic Kidney Disease**

Chin-Ching Huang,1 Che-yi Chou,1 Chao-Jun Chung.2

*Kidney Inst, China Medical Univ and Hospitals, Taichung, Taiwan; 1Proteomics Core Laboratory, Dept of Medical Research, China Medical Univ, Taichung, Taiwan.**

**Background:** Many urine biomarkers for diagnosis of urothelial carcinoma(UC) have been published. CKD patients are prone to have UC. Most of the studies are tested in healthy controls and UC patients. Whether these biomarkers are specific to diagnose UC in CKD patients have not been studied before. **AIMS:** To investigate whether urinary biomarkers are specific to diagnose UC in CKD patients.

**Methods:** This is a multicenter prospective case-control study, carried out at 7 tertiary medical centers in Taiwan (Taiwan UC Consortium). Subjects were healthy adults (healthy controls), patients with CKD but without UC (disease controls) and patients with ongoing UC. Urine was collected from each patient and frozen immediately after collection. We measured 9 urinary UC biomarkers : BLCA-1.HAI-1.HtrA1, NMP22, CYFRA21-1, TSCSTD2, BLCA-4, BTA and Midkine showed significant increase of urinary concentrations in UC patients when compared to healthy controls. Nevertheless, only Midkine and CYFRA 21-1 had significantly increased concentrations in UC patients when compared to CKD controls. The other 4 UC biomarkers did not show significant higher concentrations in UC patients than CKD controls.

**Results:** Among 9 biomarkers tested, only two showed statistically significant higher urinary concentrations in UC patients than matched CKD patients. Our findings would raise caution of interpreting urinary biomarkers for UC diagnosis in CKD patients.

**Funding:** Government Support - Non-U.S.

### PUB151

**Predictors for 30-Day Hospital Readmission in a Nephrology Ward**

Carla S. Moreira,1 Ligia Bessa,2 Vanda Guardado;3 Jorge Malheiro;1 Josefa S. Lascasas,2 António Cabrita.1

*Nephrology, Centro Hospitalar do Porto, Porto, Portugal; 1Nephrology, Hospital Militar de Luanda, Luanda, Angola.

**Background:** Rehospitalization, particularly 30-day hospital readmission is a growing concern in health care services. In this study we searched for predictors of 30-day readmissions (including emergency department visits) and 12-months hospitalization rate in patients admitted to a nephrology ward.

**Methods:** A group of 144 patients admitted to our nephrology ward from 2012 to 2013 were randomly selected. Their medical records regarding demographic and clinical-laboratorial data were collected. The statistical analysis was performed using univariate and multivariate logistic regression, and poisson regression.

**Results:** Median age was 66yos (IQR 56-81), with 63% of male patients. The majority of the patients had an emergent admission (63%) and regular hospital follow-up (55%). The median length of hospital stay was 7 days. The readmission rate was 23% and the median length until readmission was 13 days. The prevalence of chronic kidney disease was 89%, with 30% of these patients undergoing chronic intermittent hemodialysis and 11% peritoneal dialysis. The median Charlson Comorbidity Index (CCI) was 7 points (IQR 4-11). In the univariate analysis we found a significant statistical association between diabetes mellitus (OR =2.45, p=0.04), lower (<3.5g/dL vs. ≥ 3.5g/dL) albumin level (OR=8.73, p=0.006), higher (>8 vs ≥ 8) CCI score (OR=2.94, p=0.02) and 30-day hospital readmission. In the binary logistic regression only albumin level kept its significant association (OR=7.9, p=0.01), with diabetes mellitus maintaining a tendency for significance (OR=2.97, p=0.09). The rate of rehospitalizations at the first year adjusted for gender was 2.6 vs 6.4 rehospitalizations/100 patients-month in the lower and higher CCI score groups, respectively (p=0.01). The rate of emergency department episodes adjusted for gender was 29 versus 75 episodes/100 patient-month in the lower and higher CCI score groups, respectively (p=0.001).

**Conclusions:** The Charlson Comorbidity Index and albumin level may be valuable predictors of hospital readmission risk in patients from a nephrology ward.

### PUB152

**Urine Protein Fragment Excretion in Diabetic Patients with Chronic Kidney Disease**

Michele V. Clarke,1 Elfia Eksini,2 Nicholas J. Radcliffe,1 Richard J. Maclachac,1 George Jerums,1 Wayne Comper.1

*Austin Health, Melbourne; 1Uni of Melbourne, Melbourne; 2St. Vincent’s Hospital, Melbourne; Sal Aqua Diagnostics, New York.

**Background:** Albuminuria is an established marker for the development of diabetic nephropathy. Normal renal handling of albumin involves endocytosis by proximal tubule cells through a lysosomal pathway. This returns small albumin fragments, undetectable by standard clinical assays, to the tubular lumen. Albuminuria has been shown in patients with type 1 diabetes to be associated with an impaired degradation pathway, and urinary peptides have been shown to be reduced in patients with macromucinuria. However, urine peptide excretion studies have not controlled for changes in estimated glomerular filtration rate (eGFR) in patients with diabetes.

**Methods:** Patients with diabetes and eGFR >60ml/min were stratified into normo-(<20mg/min, n=9), micro- (20-200mg/min, n=12) or macroalbuminuric (>200mg/min, n=9) groups. 24 hr urines were passed through a 10kDa protein filter, and the <10kDa and >10kDa fractions were assayed separately using the BCA protein assay to detect peptide bonds.

**Results:** Macroalbuminuric patients had a reduced proportion of peptide fragment excretion (<10kDa) compared to micro- and normoalbuminuric patients (81.1% vs 89.0%, p=0.05 & 86.8%, p=0.001 respectively); however there was no difference between micro- and normoalbuminuric groups (Figure 1). Mean fragment concentrations were lower in micro- and macro- groups compared to normoalbuminuric patients, (338g/µl and 3480g/

Conclusions: In patients with diabetes and reduced renal function, we have demonstrated a reduction in peptide fragment proportional excretion in macroalbuminuric (ESKD). Although ESKD is very common, there is little to no data addressing prevalence.

Sonar Bangla Foundation (SBF) in Bangladesh. SBF is a leading non-profit organization, socio-

Pilot Study Sonar Bangla Foundation Dialysis Centers in Bangladesh: A Cross-Sectional site studies

in high-risk populations that would provide insights into the importance of region-specific

environment, genetics, and lifestyle. Thus, to identify the causative factors of CKDu,
exposures that are heterogeneous and vary by region. It remains unknown whether the

in South Asia, family history, agrochemical use, and heavy metal exposures were reported

across all geographical regions. In South Asia, family history, agrochemical use, and heavy metal exposures were reported most frequently while altitude and temperature were reported only in studies from Central America. Across all regions, CKDu was most frequently associated with a family history of CKDu, farming occupation, male gender, middle-age, snake bites and heavy metal exposures. Among high risk populations, CKDu prevalence was reported to be 7.3%-14.9% in South Asia and 13%-25.9% in Central America.

Conclusions: Studies examining etiologies of CKDu have reported many potential exposures that are heterogeneous and vary by region. It remains unknown whether the regional variation in CKDu risk factors reflects inconsistencies in measurement across studies or complexity in the interactions between global exposures and local factors such as environment, genetics, and lifestyle. Thus, to identify the causative factors of CKDu, one important approach could be to design consistent and comparative multi-site studies in high-risk populations which would provide insights into the importance of region-specific versus global risk factors.

Understanding the Socio-Demographic Status of Patients Receiving Care at Sanor Bangla Foundation Dialysis Centers in Bangladesh: A Cross-Sectional Pilot Study Tamanna M. Novoy,1 Mahmood Hussain,2 Imtiaz M. Islam,3 Akm Monoarul Islam,4 Abu hena M. Kamal,1 ‘Sonar Bangla Foundation, Santa Clara, CA; 2Marketing, San Francisco State Univ, San Francisco, CA; 3Nephrology, Good Samaritan Specialists, Kearney, NE; 4Nephrology, Rajshahi Medical College & Hospital, Rajshahi, Bangladesh.

Background: This study constitutes an exploratory investigation to understand the socio-demographic status of patients receiving care at the nine dialysis centers operated by Sanor Bangla Foundation (SBF) in Bangladesh. SBF is a leading non-profit organization, exclusively dedicated to the care of patients suffering from End-Stage Kidney Disease (ESKD). Although ESKD is very common, there is little to no data addressing prevalence of ESKD in Bangladesh. Without understanding its prevalence and the socio-demographic status of patients, little can be done to increase effectiveness and quantity of dialysis centers throughout Bangladesh. This study was launched in April 2015 and will continue throughout the dialysis centers’ operations.

Conclusions: There’s no significant difference in the disease staging or immunofluorescences staining. However, the young adult patients had fewer mesangial, interstitial, tubular and arteriolar lesions, and fewer inflammatory cells infiltration as well (P<0.01). For the therapy, the number of ACEI/ARB regimen applied in the three groups were 72/95/75, while cortical associated with immunosuppressive agents regimen was 66/92/140 (P<0.01).

Conclusions: About a quarter of all IMN patients are young adults. They had fewer cardiovascular risk factors, higher serum albumin level and better renal function. Their pathological lesions were milder. ACEI/ARB regime is more widely applied in young adults patients.

PB156

Effect of Glycemic Control on Estimated Glomerular Filtration Rate by Cystatin C Masaru Horio,1 Enyu Imai,2 Yoshinori Yamasaki,2 Tsuyoshi Watanabe,2 Hitoshi Yokoyama,1 Hiroaki Makino,2 Seichi Matsu,2 1 Osaka Univ Graduate School of Medicine, Suita, Japan; 2Nakayamadera Imai Clinic, Takarazuka, Japan; 3Nagoya Univ Graduate School of Medicine, Nagoya, Japan; 4Fukushima Medical Univ, Fukushima, Japan; 5Kanazawa Medical Univ School of Medicine, Kanazawa, Japan; 6Okayama Univ Graduate School of Medicine, Okayama, Japan.

Background: Cystatin C has been proposed as an alternative marker for estimating glomerular filtration rate (GFR). But, some factors other than GFR affect the accuracy of estimated GFR (eGFR). Some studies raised a concern that poor glycemic control may cause inaccuracy of estimation of GFR. We studied the effect of glycemic control on eGFR based on serum cystatin C (eGFRcys).

Methods: eGFR was measured by inulin clearance (Cin). Estimated GFRs were calculated by CKD-EPI equation (CKD-EPI) and Japanese GFR equation (J-Eq) based on standardized cystatin C. Glycemic control was evaluated by serum glycated albumin (GA). Three hundred and forty five Subjects with normal GA (12.4-16.3%), and 126 subjects with high GA (>16.3%) were included. Effects of age, gender, BMI, GA and serum albumin on eGFRcys / Cin, eGFRcys (J-Eq) and eGFRcys (CKD-EPI) in normal GA were 57.9±34.0, 56.1±31.7 and 57.9±33.9 ml/min/1.73m², respectively. Cin, eGFRcys (J-Eq) and eGFRcys (CKD-EPI) in high GA were 36.2±28.9, 36.7±27.5 and 36.7±28.5 ml/min/1.73m², respectively. There was no significant difference among Cin, eGFRcys (J-Eq) and eGFRcys (CKD-EPI) in both subjects. Slopes (95%CI) of the regression lines with zero intercepts in subjects

Methods: A one-time survey is being conducted to obtain clinical and demographic information on all existing and new patients at SBF.

Results: Currently, the study reveals a large gender disparity amongst dialysis recipients, 1 out of 4 patients is female (n=101). The average age of male patients is 44.7 years (SD ±12.7), while the average age of female patients is 45.3 years (SD ±14.2). Furthermore, patients from at least 20 different districts receive dialysis at the center. The study also finds a significant positive correlation between education level and the frequency of dialysis received.

Conclusions: Data collected throughout this study will be incorporated into an expanding database, first of its kind in Bangladesh. ESKD is a devastating disease that forces patients to become dependent on a machine. By understanding the education level, financial status, distance traveled and other factors in relation to the frequency of dialysis received, services provided by SBF centers could be greatly improved. The study aims to change the quality of kidney care in Bangladesh.

Clinical and Pathological Features of Idiopathic Membranous Nephropathy in Young Adults Chenxi Gao, Jing Xia, Wen Zhang, Xiaoxian Pan, Xiao Li, Nan Chen. Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ, Shanghai, China.

Background: Membranous nephropathy (MN) is a common pathological types in elderly nephrotic syndrome (NS) patients. Few researches focus on the young idiopathic MN population.

Results: 583 patients hospitalized between Jan 2009 and Dec 2014 in our department, with biopsy-proved MN eliminating secondary causes, are enrolled. All patients were divided into 3 groups: 150 patients (25.1%) in young adult group (≤44 yrs), 202 (34.7%) in middle-aged group (45-59 yrs) and 231 (39.6%) in elderly group (≥60 yrs). We and compared and collected their clinical and pathological data as well as therapy strategies.

Results: 310 male and 273 female enrolled. The young adult groups had a lower rate of NS (P<0.02), higher serum albumin (P<0.01), estimated-GFR (P<0.01) and hemoglobin level (P<0.01), and lower fast blood glucose level (P<0.01).

### PUB157

**Renal Hyperfiltration and Outcome in HIV-Infected Subjects**

Gianni Cappelli,1 Elisabetta Ascione,1 Giovanni Guaraldi,2 Andrea Malagoli,2 Elisabetta Rubbettini,1 Antonio Bellasi.1 1Univ Hospital of Modena, Nephrology Dialysis and Renal Transplantation Unit, Modena, Italy; 2Univ Hospital of Modena, Metabolic Clinic, Infectious and Tropical Diseases Unit, Modena, Italy; 3Azienda Ospedaliera S. Anna, Como, Dept of Health Sciences, Univ of Milan, Nephrology and Dialysis Unit, Como, Italy.

**Background:** Although highly active antiretroviral therapy (HAART) improves life expectancy of HIV-infected subjects, it is also associated with numerous comorbidities. Evidence suggests that renal hyperfiltration (RFH) is associated with various lifestyles, clinical conditions and portends poor prognosis in the general population. We sought at determining prevalence of RFH and its associations with traditional and HIV-related risk factors as well as all-cause mortality in a large cohort of HIV-infected subjects.

**Methods:** Retrospective study of 3875 HIV-infected patients attending at the “Modena Metabolic HIV Clinic”. The Chronic Kidney Disease Epidemiology Collaboration equation (CKD-EPI) was used to estimate glomerular filtration rate (eGFR). Linear regression was used to model eGFR against age and sex. RFH was defined as eGFR with residuals above the 95th percentile. Anova, Chi-square, logist regression and survival analyses were used to identify factors and the risks associated with RFH.

**Results:** Overall, we investigated middle-age (44.5±7.5 years) men and women (male 65.1%) with preserved renal function (eGFR 94.5±17.1 ml/min/1.73 m²). RFH was inversely associated with age (Odds Ratio 0.93), hemoglobin (OR 0.8), WBCs (OR 0.9) and positively associated with HIV-infection (OR 1.07). Of interest, no association with HAART was noted. Over mean follow-up of 7 years, 75 persons died. RFH was associated with all-cause mortality independently of potential confounders (Hazard ratio: 4.17, 95%CI: 1.81 - 9.6; p<0.001).

**Conclusions:** RFH is influenced by HIV infection duration independently of established factors and related with the risk of all-cause of death. Future efforts are needed to clarify what are the mechanisms that link RFH with poor prognosis if and how RFH modulation improves survival in HIV-infected subjects.

### PUB158

**Bioelectrical Impedance Analysis as a Screening Tool for Chronic Kidney Disease**

Anita Saxena, Amit Gupta. Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, UP, India.

**Background:** Chronic Kidney Disease (CKD) has a latent period during which the disease is present but asymptomatic. With increasing incidence of hypertension and diabetes, incidence and prevalence of CKD is on increase. Bioelectric impedance analysis (BIA) is a noninvasive method for estimation of body composition in clinical setting but it has not been used for CKD screening. Purpose: To evaluate applicability of BIA as a screening tool for presence of kidney disease in general population with creatinine clearance and glomerular filtration rate (GFR).

**Methods:** A pilot cross-sectional CKD screening study on randomly selected 52 subjects from general population. Maliron BIOSCAN analyzer 915/916 was validated with Hume et al’s equation for estimation of total body water. BIA derived GFR was validated with 99m Tc-DTPA nuclear scan derived GFR, a study done on voluntary healthy kidney donors.

**Results:** There was no significant difference between total body water estimated with BIA and Hume et al’s equation and BIA derived GFR and DTPA nuclear scan GFR. Mean serum creatinine for males was 0.94 ± 0.14mg% and 0.91 ± 0.84mg% for females. BIA derived creatinine clearance was 97.39 ± 28.98 in males and 107.60 ± 34.03 in females. GFR was 74.1±25.98 ml/min/1.73 m² in males and 65.17 ± 21.14 ml/min/1.73 m² in females. Based on GFR subjects were classified into CKD. Out of 52 subjects 8 were in CKD stage 1 (15.5%), 23 (44.2%) were in CKD stage 2, 18 (34.6%) were in CKD stage 3, 1 (1.9%)/ 1.9% each in CKD stage 4 and CKD stage 5 respectively. Incidentally, 13.5% were diabetic.

**Conclusions:** BIA derived creatinine clearance was 97.39 ± 28.98 in males and 107.60 ± 34.03 in females. GFR was 74.1±25.98 ml/min/1.73 m² in males and 65.17 ± 21.14 ml/min/1.73 m² in females. Based on GFR subjects were classified into CKD. Out of 52 subjects 8 were in CKD stage 1 (15.5%), 23 (44.2%) were in CKD stage 2, 18 (34.6%) were in CKD stage 3, 1 (1.9%)/ 1.9% each in CKD stage 4 and CKD stage 5 respectively. Incidentally, 13.5% were diabetic.

**Design and Implementation of a Chronic Kidney Disease Prevalence Study in Rivas, Nicaragua**

Kailey Minninghs,1 Martha Mosco,2 Madeline M. Fiore,3 Eric S. Korns,4 Juan Jose Amador,5 Rulan S. Parekh,6 Louis D. Fiore.7 1Faculty of Medicine, Univ of Toronto, Toronto, ON, Canada; 2Lowering Poverty and Disease, Boston, MA; 3Tulane Univ, New Orleans, LA; 4Warren Alpert Medical School, Brown Univ, Providence, RI; 5School of Public Health, Boston Univ, Boston, MA; 6Hospital for Sick Children, Toronto, ON, Canada.

**Background:** High rates of chronic kidney disease of unknown etiology (CKDu) have been noted in certain populations along the Pacific coast of Central America. CKDu is unlike traditional CKD in that the usual underlying risk factors are not present. CKDu in Nicaragua has been noted to affect mainly sugarcane workers although there is a paucity of data for the general population.

**Methods:** A population based cross sectional study using a random sampling of 32 communities was carried out in the department of Rivas in Nicaragua. Visits were conducted in Spanish in 2012 for screening and in 2014 for repeat evaluations. Participants were consented and completed a baseline questionnaire. Serum creatinine was initially screened using a finger stick creatinine measurement device. Repeat measurements to confirm CKD were performed centrally at the Centro Nacional de Diagnostico y Referencia in Managua using the Cobas Integra Fage Generation 2 assay, which has been standardized to the IDMS method.

**Results:** The study sample consisted of 1240 individuals representing 75% of adults living in the 533 homes visited. The refusal rate was 9.3%. The median age was 36.4 years, 57% were female, 6.6% reported DM, and 27% reported HTN. The study cohort is slightly enriched for women, while young people are slightly underrepresented when compared to census data. Repeat measurement was done in 320 with elevated creatinine to confirm CKD over 2 years. The re-contact rate was 85%.

**Conclusions:** This cross sectional study population is representative of the general population of the department of Rivas in Nicaragua. Establishment of this study population will allow investigators to determine the prevalence of CKD in a random selection of the general population in both urban and rural areas of Nicaragua not previously studied.

### PUB160

**Validation of the Lund Model Combining Simultaneous Cystatin C and Creatinine-Based eGFR**

Emil Den Bakker, Arend Bokenkamp. Pediatric Nephrology, VU Univ Medical Center, Amsterdam, Netherlands.

**Background:** Estimated GFR (eGFR) based on serum creatinine (crea) and/or cystatin C (cys) is used to monitor GFR. Based on known limitations of either marker (muscle wasting for crea, corticosteroids for cys) Grubb et al have proposed the “Lund model” to identify such patients by calculating the difference between crea and cys-based eGFR (Scand J Clin Lab Invest 70 (2010): 65-70). If the difference is below a certain cut-off, the mean of eGFRCrea and eGFRCys is used. Otherwise a choice is made for one or the other as a more accurate estimate based on patient history. The aim of this study was to test the “Lund model” using eGFR equations from the CKiD study (Kidney Int 82 (2012): 445-55).

**Methods:** Retrospective analysis of 489 single injection intravenous clearance (mGFR) studies, in which serum crea, cys and urea had been measured simultaneously. Calculation of eGFR using crea (CKD1), cys (CKD2) or crea+cys/urea (CKD3) as well as the average of CKD1 and CKD2 (avCKD1-2). For the Lund approach, the relative difference (ΔCKD1-2) between CKD1 and CKD2 was calculated as percentage of avCKD1-2 and categorized as <40%, 40%-40%, 20%-30%. If ΔCKD1-2 was >40%, a choice was made for CKD1 (corticosteroid) or CKD2 (neuromuscular disease, wasting, malignancy). The performance of the different approaches was studied using bias (mGFR minus eGFR in ml/ min/1.73m²) and accuracy (% of measurements within ±30% of mGFR).

**Results:** CKD1, CKD2 and CKD3 had a bias of 4.6, 14.2 and 2.8 and an accuracy of 81.7, 80.6 and 90.4, respectively. avCKD1-2 had a bias of 9.4 and an accuracy of 88.9. ΔCKD1-2 was >40% in 11.4%, 30%-40% in 18.9% and 20%-30% in 33.9% of the studies. The Lund model was applied in 51 studies with ΔCKD1-2<40%. In 42/51 studies, a choice could be made based on history (CKD1 n=16, CKD2 n=26). This resulted in a bias of 10.5 and an accuracy of 86.4.

**Conclusions:** The various CKD equations performed comparably to the original publications different. The arithmetic mean between creatinine-based and cystatin C-based eGFR yielded similar results to the complex CKD3 equation while the Lund model did not improve the diagnostic performance. This may be due to the higher bias of CKD2.
PUB161

Evaluation of Chronic Kidney Disease Epidemiology Collaboration Equation (CKD-EPI), Modification of Diet in Renal Disease (MDRD) and Cockcroft-Gault (CG) Equations to Assess Glomerular Filtration Rate (GFR) in Kidney Cancer Patients

Marialva, Sao Paulo, Brazil.

Background: To estimate kidney function.

Methods: Prospective evaluation of 124 outpatients with kidney cancer admitted to treatment at Sao Paulo State Cancer Institute between September 2012 and February 2015. Estimated (e) GFR was calculated using CG, aMDRD and CKD-EPI equations and compared to 1/Cr-EDTA radioisotopic (r) clearance. The bias was given as the mean difference between the eGFR and rGFR values and the precision as the SD of the differences. Accuracy was described as the number of eGFR studies within 10 and 30% of the rGFR values.

Results: Patients were 59.0 ± 10.3 years old, 50.2% were women, rGFR (ml/min/1.73 m^2) was 78.7 ± 24.6 and eGFRs (ml/min/1.73 m^2) using the CKD-EPI, aMDRD and CG (ml/min) equations were respectively 80.7 ± 22.1, 83.4 ± 25.3 and 87.8 ± 26.5. Equations bias is detailed on table 1.

<table>

The accuracy of eGFR equations within 10% of rGFR were 31.4%, 27.4% and 19.4% with CKD-EPI, aMDRD and CG, respectively. Within 30% of rGFR, the accuracy of eGFR equations were 75.8%, 78.2% and 68.5% with CKD-EPI, aMDRD and CG, respectively.

Conclusions: CKD-EPI equation showed smaller bias and satisfactory accuracy when compared with the GFR assessed by 1/Cr-EDTA in this group of kidney cancer patients.

PUB162

Correlation Between Equation for Estimating Glomerular Filtration Rate: CKD-EPI, Cockcroft-Gault -CG- and MDRD in Colombia

Carlos H. Mejia, Nephrology, Cuenta de Alto Costo, Bogota, Cundinamarca, Colombia.

Background: The determination of the GFR has been recommended the calculation from different equation , namely Cockcroft-Gault (CG) or the Modification of Diet in Renal Disease (MDRD) and Chronic Kidney Disease Epidemiology Collaboraton (CKD-EPI); we have found differences of over and underestimation of renal function by these function.

Methods: Between July 1, 2013 and June 30, 2014, 3,055,568 patients diagnosed with hypertension, diabetes mellitus and chronic kidney disease of all members of the general social security system in health in Colombia were reported. The inclusion criteria for this analysis was older than 18 years. Quantitative variables were described by their mean and standard deviation and qualitative variables using frequency distribution. They were compared equation pairs of CG -MDRD4, CG-CKD-EPI and CKD-EPI-MDRD by calculating and plotting, prediction limits for differences between pairs and the values of the correlation coefficient r.

Results: 1,348,214 patients were included, 832, 129 women (61.7%). The mean age was 64.3 years (standard deviation (SD) 13.2), 50% of patients were 60 - 74 yo. 94% had diagnosis of HTA and 26% had diagnosis of DM. The mean creatinine was 0.95 mg/dl for population. The correlation coefficient between interclass (ICC)CG and MDRD is 0.704 ICC95% (0.703, 0.705) and limits of agreement of Bland and Altman from -31.65 to 43.83; ICC being CG and CKD-EPI is 0.728 CI 95% (0.729-0.730) and limits of agreement of Bland and Altman from -37.26 to 40.62 and the correlation coefficient being intraclass CKD-EPI and MDRD is 0.855 ICC 95% (0.855, 0.856) and limits of agreement of Bland and Altman between -26.61 and 21.89.

Conclusions: General population studies have reported a good correlation comparison between MDRD and CKD-EPI, our results show a good correlation between them, rather than between CKD-EPI and CG. A higher GFR greater are the limits of agreement, both the overall and in the analysis stages, similar findings have been observed in other reports. Despite some limitations MDRD4 and CKD-EPI remain the most comparable and used to estimate kidney function.

PUB163

Family Caregivers in Chronic Kidney Disease: A Missed Opportunity to Improve Overall Care

Jason Christopher George, Andrea Lynn Berger, Christyle A. Green, Dept of Medicine, Geisinger Medical Center, Danville, PA; Center for Health Research, Geisinger Medical Center, Danville, PA; Center for Clinical Innovation, Geisinger Medical Center, Danville, PA; Dept of Nephrology, Geisinger Medical Center, Danville, PA.

Background: Many patients with chronic illness rely on the assistance of loved ones to adequately manage their disease. While there is increased recognition of the role of family caregivers in end-stage renal disease, little attention has been given to this role among patients with chronic kidney disease (CKD) not on dialysis. The aim of this study was to assess CKD patients’ degree of dependency on non-professional caregivers for their self-management needs.

Methods: We conducted a survey-based study of 208 patients with non-dialysis dependent CKD stages 3-5 to identify 1) whether they receive help from an informal caregiver to perform health-related activities and 2) the nature of this relationship. We evaluated patients residing in as many homes as those with an assigned formal caregiver, since their self-management needs are different.

Results: Mean age of participants was 72, 57% were male, 98% were white, and 53% had a high school or lower level of education. Overall, 65% (133/205) of patients reported receiving help from another individual with at least one health-related task. Help with activities included medical decision making (51%), medication management (32%), scheduling medical appointments (30%), attending office visits (43%), understanding medical providers (23%), and activities of daily living (13%). The majority stated that the main person who helped them was their spouse (70%) or adult child (16%) vs. other family members (6%). Nearly half (46%) reported that another individual had access to their electronic health information through the online health portal to assist with their care.

Conclusions: A significant number of independently functioning CKD patients rely on the help of family members to navigate their care. Efforts are needed to acknowledge and supppport these informal caregivers in the medical management of complex patients with kidney disease in order to provide optimal care.

PUB164

Impacts of Chronic Kidney Disease on Other Non-Communicable Chronic Diseases – The Burden in the Health System of China

Lucia Zhang, Jinwei Wang, Ming Hui Zhao. Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China.

Background: The spread of non-communicable diseases (NCDs) presents a global crisis, and accumulating evidence based on individual disease reveals that major NCDs including heart disease and stroke have a worse prognosis in the presence of chronic kidney disease (CKD). However, there is neither large-scale study quantitatively evaluating the burden of CKD on various NCDs, nor study comparing the burden of CKD with other NCDs, especially among low- and middle-income countries like China.

Methods: A national in-patient database involving 19.5 million patient-records was used. Diagnoses of CKD and other major NCDs, including hypertension, coronary heart disease, stroke, chronic obstructive pulmonary diseases, and cancer, were extracted from International Classification of Diseases-10 codes of the discharge diagnoses. The effect of CKD on costs, length-of-stay, and in-hospital mortality were analyzed for each NCD. Then the effect of CKD on those outcomes was compared with other major NCDs.

Results: For each NCD, the presence of CKD was associated with increased length-of-stay and in-hospital mortality. And the costs were also increased by 0.1-20.3%, except for coronary heart disease and diabetes. Among those NCDs, CKD was associated with the highest length-of-stay, and with in-hospital mortality only lower than that of cancer.

Conclusions: Using database with large sample size and broad geographic coverage in China, we found that the presence of CKD was associated with substantial increased healthcare resources utilization and increased risk of in-hospital mortality.

Patient Empowerment in a Multi-Disciplinary Chronic Kidney Disease Clinic

Therese T. Adamowski, Jonathan H. Segal, Jamie Alton Green. Internal Medicine, Univ of Michigan, Ann Arbor, MI.

Background: Existing research shows economic and health gains associated with multi-disciplinary CKD care, but there is little data examining associations with patient-centric measures. We collected patient-centric measures on perceptions related to care in a multi-disciplinary CKD clinic.

Methods: Our multi-disciplinary CKD clinic includes a pharmacist, physician assistant, social worker, dietician and RN educator-with oversight by a medical doctor. Patients see each provider during visits. Most patients have an eGFR ≤ 40 ml/min/1.73m^2.

Results: Data were available on 51 patients. The mean (SD) age was 62 (15) years. 53% were male, 65% Caucasian, and 53% African American. Patients reported being comfortable asking their doctor questions, mean (SD) 5.5 (0.97). The mean (SD) of the confidence / empowerment measure was 4.3 (0.74). In univariate analysis, higher ratings...
Trends in Access to Care in Adults with Kidney Disease, United States 2002-

Background: Use of healthcare services by medically underserved minority populations varies by ethnicity and cultural factors. Healthcare providers may address ethnicity-specific barriers to healthcare service usage to decrease disparities in healthcare use. Through free community health screenings provided by the Kidney Disease Screening and Awareness Program (KDSAP), we seek to elucidate ethnicity-specific differences and sociocultural barriers to healthcare service use.

Methods: A questionnaire available in English, Chinese, and Spanish was administered to KDSAP participants in Massachusetts, New Jersey, and Toronto from 2012 to 2014. Participants were asked to provide their ethnicity, health insurance, primary care physician, and difficulties and alternatives to receiving care.

Results: Of the 4,399 adults age ≥18 from the Medical Expenditure Panel Survey were analyzed. Individuals with KD were identified with Clinical Classification Codes: 156 - nephritis, nephrosis, renal sclerosis; 157 - acute education, followed renal failure; 158 - chronic renal failure; 160 - calculus or urinary tract; and 161 - other diseases of kidney and uraters. Patient-centered care was ascertained if the usual care provider asked about prescription medications and treatments others doctors may give them; showed respect for medical, traditional and alternative treatments that the patient was happy with; asked the person to help make decisions between a choice of treatments; presented and explained all options to the person; and spoke the person’s language or provided translator services if person is uncomfortable speaking in English. We used unadjusted and adjusted poison regression to examine the association of patient-centered care outcome. Covariates included demographics and comorbidities.

Conclusions: Patient-centered care is a quality of personal, professional, and organizational relationships. There no studies on factors associated with patient-centered care in patients with kidney disease (KD). This study examines trends in factors associated with patient-centered care (PCC) in people with KD.

Methods: Data on 3,868 adults with KD aged 18 from the Medical Expenditure Panel Survey (MEPS) Household Component were analyzed. Individuals with KD were identified with Clinical Classification Codes: 156 - nephritis, nephrosis, renal sclerosis; 157 - acute education, followed renal failure; 158 - chronic renal failure; 160 - calculus or urinary tract; and 161 - other diseases of kidney and uraters. Patient-centered care was ascertained if the usual care provider asked about prescription medications and treatments others doctors may give them; showed respect for medical, traditional and alternative treatments that the patient was happy with; asked the person to help make decisions between a choice of treatments; presented and explained all options to the person; and spoke the person’s language or provided translator services if person is uncomfortable speaking in English. We used unadjusted and adjusted poison regression to examine the association of patient-centered care outcome. Covariates included demographics and comorbidities.

Results: Of the 3,868 adults with KD, 3%, 7%, 22%, 63% and 4% reported a positive response to 1, 2, 3, 4, and 5 out 5 questions on patient-centered care respectively. Patient-centered care was significantly reported in 2010/2011. Hispanic race was significantly associated with decreased access to prescription medication. Women and those with lower income were associated with decreased patient-centered care. Compared to 2000/2003, year 2004/2005 and 2010/2011 were significantly associated with increased patient-centered care in the poison regression analysis.

Conclusions: Patient-centered care in people with kidney disease has improved in recent years. Prospective studies examining the impact of patient-centered care on kidney disease outcomes especially end stage renal disease is imperative.

Hypertension and Correlating Factors in a Minority-Rich Population

Background: Analysis of demographic variations in hypertension (HTN) in minority-populations presents a major opportunity for understanding the factors that influence chronic kidney disease (CKD). This study analyzes the influence of various factors in BP control in a minority-rich-population.

Methods: Data from 417 participants from minority populations in the Boston area (38.4% Black, 37.0% White, 5.0% other races) were sampled via Kidney Disease Screening and Awareness Program screenings from 2012-2014. Participants were assessed via questionnaire for awareness of their BP, healthcare, and insurance, and an assessment of their own health as well as their race, gender, age, & education. Participants then had their systolic (SBP) & diastolic (DBP) blood pressure measured, which was in turn classified according to American Heart Association guidelines & analyzed via T-tests & one-way ANOVA.

Results: Of the 417 participants 28.8% had normal BP, 47.2% were pre-HTN (130/80-139/89), 18.5% had stage I HTN (140-149/90-99), & 5.5% had stage II HTN (>160/100). Participants aware of their HTN had higher SBP (p<0.0001) & DBP (p<0.007) than those who self-reported no HTN. Men had significantly higher SBP & DBP than women (p=0.002, p=0.003, respectively), & individuals with little/no education had higher SBP than those with college (p=0.005) or post-graduate degrees (p=0.001). Younger age groups (below 30 years: mean BP 125/76) had significantly lower BP than older age groups (60-69+ years: mean BP 136/81); p<0.0001 & p<0.037 for SBP & DBP. Notably, no significant differences in SBP among ethnicities emerged.

Conclusions: Our results revealed that awareness of HTN status, gender, education level & age influence BP variations in minority-rich communities. Services tailored to these factors may help reduce HTN prevalence among minorities.

Veterans Affairs (VA) eKidneyClinic: A Freely-Available Online Tool to Help Close the Chronic Kidney Disease (CKD) Patient Education Gap

Background: Patient education remains an important tool in the management of CKD and end stage renal disease (ESRD)-diseases with significant patient and economic burden. Patient knowledge and understanding of CKD are dismal, particularly amongst highly-selected populations (e.g. African Americans). For Veterans with CKD, limited health literacy is prevalent, and varied, fragmented, and unclear presentation of patient education materials (PEMs) compound the gap in understanding CKD.

Methods: To address these deficiencies, VA developed a comprehensive web tutorial, VA eKidneyClinic (http://ckd.vacloud.us). This freely-available, Veteran-centered, virtual education tool is designed to help close the knowledge and understanding gap between CKD patients and providers. This tool is designed to address patient education gaps by using evidence-based educational content, providing clear and concise messaging, and demonstrating the tools and techniques that can be used in the day-to-day clinical setting, particularly in the virtual care environment.

Conclusions: The VA eKidneyClinic is a free, user-friendly, web-based educational tool that can be integrated into the usual care of CKD patients. This tool is designed to improve patient education and understanding of CKD and its implications.

Should All Patients with Diabetic Nephropathy Be Treated in a Joint Renal Diabetic Clinic? Jonathan P. Wong, Tara Lee, Tracy Maryan, Jocelyn Berdeprado, Suresh Mathavakkannan. *Lister Renal Unit, United Kingdom.*

**Background:** The natural history of diabetic nephropathy is variable. Some patients have rapidly declining kidney function and would benefit from close monitoring in a joint renal-diabetic clinic, however joint renal-diabetic clinics are not widely available in the UK health system. We studied outpatient attendance patterns, rate of eGFR decline and other clinical parameters in patients with diabetic nephropathy to determine potential need for development of a joint renal-diabetic clinic at our unit.

**Methods:** A cross-sectional survey of all patients with CKD and diabetes mellitus (DM) at our unit was performed. Demographic, diabetic clinic attendance and clinical parameters including HbA1c, BP, urine protein:creatinine ratio (uPCR) and eGFR for the previous 5 years were collected. Patients who had a rate of decline in eGFR 2ml/min/1.73m2 were defined as having progressive CKD.

**Results:** 630 CKD patients with DM attending CKD clinic at our trust were identified. 195/630 (31%) of patients had diabetic nephropathy. 54.6% (100/195) had progressive CKD, but only 57% (37/100) of these patients attended a diabetic clinic. Conversely, 45.4% did not have progressive CKD, potentially representing a group of patients who could be safely monitored by general physicians. Patients with progressive diabetic nephropathy were more proteinuric than those with stable CKD (161 vs 46mg/mmol, p=0.004) but did not significantly differ in terms of age, weight, glycemic control or BP. 9.2% (58/630) were lost to follow-up from nephrology services, 31% (18/58) of this subset of patients continued to attend the diabetic clinics and 69% (40/58) were lost to follow-up from both diabetic and renal services.

**Conclusions:** Not all patients with diabetic nephropathy develop progressive CKD. Identifying patients (e.g. low level proteinuria) who could be safely monitored by general physicians may relieve pressure on CKD clinic and reduce hospital visits for patients. However, many patients with progressive CKD were not being monitored in a diabetic clinic, potentially missing out on specialist interventions. Development of a joint diabetic-renal clinic could streamline care and improve management for these patients.

Leveraging Predictive Modeling to Improve the Participant Identification Process Transition to Dialysis Support Programs Meghan Martin Cockrell, Yanting Dong, Huyl Hines, Gilbert Haugh, Vipin Gopal, Roy Beveridge, Todd Prewitt. *Humana, Louisville, KY.*

**Background:** Evidence demonstrates that renal care management is beneficial to patients suffering from late-stage chronic kidney disease (CKD) and end-stage renal disease (ESRD), especially around the time of transition to dialysis. Integrated care management solutions provide assessment, education, and care coordination. Engagement in these programs improves health outcomes, including compliance with dialysis schedules and vascular access, and also reduces costs.

**Methods:** Traditionally, patients are identified for renal care management programs via a qualified estimated glomerular filtration rate (eGFR) lab value of <20mL/min/1.73 m2. However, since eGFR is not always available, there may be a gap in identifying people who could benefit from this type of support. A predictive model (PM) was developed to identify candidates for a transition to dialysis program. The PM identifies individuals with CKD over the prior 12 months and determines their likelihood of starting dialysis within the subsequent 12 months. It is based on claims, demographics, and lab and consumer data. To assess the effectiveness of the PM, a random portion of individuals scored in the top 2% were followed up from nephrology services, 31% (18/58) of this subset of patients who continued to attend the diabetic clinics and 69% (40/58) were lost to follow-up from both diabetic and renal services.

**Results:** Thirteen percent of people referred by the PM ultimately transitioned to dialysis and all were invited into a renal care management program. Seventeen percent of the people referred were observed to see if they would be referred by the PM at a 12 month follow-up. Of those referred, 27% (n=68) were never identified for the renal care management program. Hence, the model is effective in identifying those who will get identified via the standard referral process.

**Conclusions:** Application of advanced predictive modeling permitted identification of participants who may not have otherwise had the opportunity to benefit from renal care management.

Oxidative Stress: Dual Pathway Induction in CKD Pathogenesis Grazia Maria Virzì, Alessandra Brocca, Massimo di Cal, Claudio Ronco. *Nephrology Dept-IRRIV, San Bartolo Hospital, Vicenza, Italy.*

**Background:** Oxidative stress is defined as the imbalance between excess formation and insufficient removal of highly reactive molecules (Reactive Oxygen Species-ROS and Reactive Nitrogen Species-RNS) that attack DNA, protein and lipids, either denaturing or altering their structure. The variations and the correlation of inflammation and oxidative stress in CKD have not been thoroughly understood. In this study, we examined the putative role of ROS and RNS in the pathogenesis of CKD and the interaction with inflammation.

**Results:** Suggest that GFR decline may not be attributed to aging only. Each episode of AKI related to contrast or nephrotoxic drugs increases risk for CKD progression/GFR decline in elderly. Pre-existing CKD is a strong predictor of GFR decline after adjustment for other co-morbidities.
Methods: 25 patients with CKD5 (for each stage) and 18 healthy subjects (CTR) were included in the study. Determinations for IL6, Myeloperoxidase (MPO), Nitric Oxide (NO), and Endogenous Peroxidase Activity (EPA) were performed by ELISA. A p-value of <0.05 was considered statistically significant.

Results: CKD patients displayed significant augmentation in circulating ROS and RNS, as well as expression of inflammatory cytokines, as IL6 (all, p<0.01). There is a positive correlation between IL6 and all oxidative stress markers and an inversely correlation with eGFR (all, p<0.05). We divided CKD patients in CKD1-2 (n=10) and CKD3-5 (n=15): a significant higher level of oxidative stress was observed in CKD3-5 (p<0.008).

Conclusions: CKD is characterized by ROS and RNS dissequilibration and inflammation that promote additional damage to the kidney and to distal tissues with development and progression of concomitant diseases. This pilot study demonstrates the significantly heightened presence of dual oxidative stress pathway induction in CKD patients that increase with the progression of CKD: each stage of CKD could be characterized by differing levels of ROS/RNS dissequilibration. Our findings indicate that oxidative stress is a potential therapeutic target, as it promotes inflammation by ROS/RNS-linked pathogenesis. Future research should focus on interventions that aim to reduce oxidative stress and inflammation in patients with various stages of CKD and slow the progression of CKD during its early stages.

PUB175
Comparative Biomarker Analysis Reveals Serum and Urine sTNFR1 Correlate with eGFR and Albuminuria in Man

Diana L. Donnelly-Roberts, Marian T. Namovic, Mark T. Houser, Murali Gopalakrishnan, Timothy A. Esbenshade. Renal Discovery, Abbiev, North Chicago, IL.

Background: It has been demonstrated that soluble tumor necrosis factor receptors (sTNFR1 & sTNFR2) are elevated in serum of patient cohorts with various renal disease etiologies with a strong association to early renal decline with or without proteinuria. The current study was designed to gain further insight into the relationship of renal function to sTNFR1 and sTNFR2 (MPO, NO) from a recently completed clinical study in high-risk subjects undergoing non-cardiac surgery. A subset of baseline serum and urine samples from patients with and without CKD (mean age of 70, 64% male, mean eGFR of 58 ml/min/1.73 m³, and mean total urinary protein concentration 70 g/l) were evaluated to assess sTNFR1 and other select BMs reflective of progression of DN, CV risk, inflammation, fibrosis or renal injury.

Methods: Samples were selected based on medical history (DM, DN, other CKD, or no renal disease) and stratified for analysis based on eGFR values. All samples examined were from baseline/pre-dose collections prior to drug administration or surgery and analyzed in an blinded manner.

Results: In serum, several BMs correlated with eGFR with sTNFR1 (P <0.0001) and uric acid (P=0.0004) being significant but moderate for MPO-23 (P=0.01), and ADMA (P=0.01). In urine, results revealed that several BMs correlated with eGFR with a strong significant correlation for sTNFR1 (P <0.0001) as well as for complement C9 (P=0.011) and IC3b (P=0.013). Significant correlations were also observed for qualified biomarkers such as NGAL (P<0.01), albumin (P<0.01), and cystatin C (P<0.05). sTNFR1 in urine also strongly correlated with albuminuria (P<0.0002) and UA/CR (P<0.0001).

Conclusions: Our studies demonstrate that sTNF1 correlates with renal functional decline across a wide eGFR range (22 to 116 ml/min/1.73 m³) regardless of renal disease, which was assessed in both serum and urine. Limitations of this preliminary study are small sample size and use of static eGFR values. Additional correlation analyses in longitudinal cohorts can shed further light into the relationships of sTNF1 and other BMs to CKD.

PUB176
The Association of Plasma Uric Acid with Renal Vascular Lesions and Intertstitial Fibrosis in Biopsy-Confirmed Kidney Disease

Anand Srivastava,1 Venkata Sabbisetti,2 Isaac Ely Stillman,1 Helmut G. Rennke,2 Sushrut S. Waikar.1 1Renal Div, Brigham & Women’s Hospital, Boston, MA; 2Dept of Pathology, Brigham & Women’s Hospital, Boston, MA, 3Dept of Pathology, Beth Israel Deaconess Medical Center; Boston, MA.

Background: Elevations in plasma uric acid (PUA) have been hypothesized to play a pathogenic role in the development of chronic kidney disease (CKD) through multiple mechanisms, including mitochondrial damage, oxidative stress, endothelial dysfunction, vascular smooth muscle proliferation, and intra-renal inflammation.

Methods: We measured PUA in plasma samples obtained from 272 patients on the day of native kidney biopsy at three tertiary care hospitals in Boston, MA. We compared PUA against measures of kidney function and pathology, including estimated glomerular filtration rate (eGFR) and adjudicated semi-quantitative measures of kidney pathology using Spearman correlation coefficients. Arterial and arteriolar sclerosis/hyalinosis were classified as none (1), mild (2), moderate (3), or severe (4). Fibrosis was classified as 0% (1), 1-10% (2), 11-25% (3), 26-50% (4), and > 50% (5) of cortical volume.

Results: The primary indications for kidney biopsy were proteinuria in 61%, hematuria in 33%, abnormal eGFR in 35%, and nephrotic syndrome in 14% (sum exceeds 100% due to multiple indications). Mean age was 51.2 ± 16.0 yrs, 53% were women, 18% were black, and median eGFR was 50 (IQR 30-80) ml/min/1.73 m². Median PUA was 6.3 (IQR 5.1-7.5) mg/dl, and was inversely correlated with eGFR (r=-0.43) and positively correlated with arterial sclerosis (r=0.21), arteriolar hyalinosis (r=0.23), and interstitial fibrosis (r=0.28) for all CKD stages. The association with proteinuria was weaker and no longer statistically significant after adjustment for eGFR. Findings were generally consistent in subgroup analyses of those with diabetes, glomerulonephritis, vascular disease, and tubulointerstitial disease.

Conclusions: We found no independent associations between PUA and semi-quantitative measures of kidney pathology. The cross-sectional associations of PUA with renal vascular lesions and interstitial fibrosis appear to be confounded by eGFR.

PUB177
Association of Plasma Sphingomyelins and Ceramides with Chronic Kidney Disease and Glomerular Filtration Rate

Maria Lourdes Gonzalez Suarez,1 Vesna D. Garovic,2 Norman James Haughey,2 Veera Venkata Ratnam Bandaru,2 Susan Resnick,2 Luigi Ferrucci,3 Michelle M. Mielke,4 Div of Nephrology, Hypertension, Mayo Clinic, Rochester, MN; 5Dept of Neurology, Johns Hopkins Univ School of Medicine, Baltimore, MD; 6Dept of Psychiatry, Johns Hopkins Univ School of Medicine, Baltimore, MD; 7Intramural Research Program, NIA/NIH, Baltimore, MD; 8Dept of Health Sciences Research, Mayo Clinic, Rochester, MN.

Background: Sphingolipids are a class of bioactive lipids linked to insulin resistance and diabetes. Ceramides have been implicated in acute renal failure and diabetic nephropathy. We cross-sectionally examined the associations of plasma ceramides and sphingomyelins (SM) with glomerular filtration rate (GFR) and Chronic Kidney Disease (CKD).

Methods: Baltimore Longitudinal Study of Aging participants (N=486) with plasma lipids and GFR were included (median age 63, 58% men); 23 had CKD defined as GFR<60 ml/min. Ceramides and SM were quantitatively measured using a HPLC-coupled electrospray ionization tandem mass spectrometer. Logistic regression was used to determine the association between the log transformed sphingolipids and odds of CKD, adjusting for age, sex, and race. Among participants without CKD, linear regression was used to examine the association between the sphingolipids and GFR adjusting for age, sex, race, BMI, and hypertension.

Results: Higher levels of all SM were associated with increased odds of CKD: each log unit increase in SM C18:1 was associated with six-fold increased odds of CKD (OR=6.92, p=0.002). Among individuals without CKD, higher SM were also associated with lower GFR. This association was most pronounced among the 290 individuals without diabetes or pre-diabetes: each log unit increase in SM C18:1 was associated with lower GFR (b=-8.40, p=0.002).

Conclusions: These results suggest that elevated plasma SM are associated with CKD. Likewise, among those without CKD, elevated SM are associated with lower GFR. The cross-sectional study design limits specific conclusions on the mechanisms and temporality of these associations but suggests that further research is warranted.

PUB178
Clinical and Pathologic Predictors of Progression to End Stage Renal Disease following Renal Biopsy

Andrew S. Allegretti,1 Ivy A. Rosales,2 A. Bernard Collins,3 Nina E. Tolkoff-Rubin,4 Robert B. Colvin,2 Ishaq Bhan,1 Italia Beth Wenger, Joshua Wilczen, Rex Neal Smith.1 Div of Nephrology, MGH, Boston, MA, 2Dept of Pathology, MGH, Boston, MA.

Background: The value of renal biopsy in prognosis of chronic kidney disease remains unclear. Irreversible, chronic changes such as interstitial fibrosis and glomerulosclerosis are thought to provide prognostic information. We sought to define the relative prognostic value of biopsy pathology and clinical factors for predicting progression to end stage renal disease (ESRD).

Methods: Retrospective, single center review of renal biopsies performed between 2004-2014 in four kidney diseases. Cox regression was used to evaluate nine pathologic findings on light microscopy and 21 clinical variables as potential predictors of progression to ESRD.

Results: 231 cases were reviewed (34% IgA nephropathy, 29% focal segmental glomerulosclerosis, 19% tubulointerstitial disease, 18% diabetic nephropathy). 83/231 (36%) subjects progressed to ESRD within 5 years follow-up. Median estimated glomerular filtration rate (eGFR) at time of biopsy was 32 (IQR: 18-54) ml/min. Median percent interstitial fibrosis was 20% (IQR: 10%, 40%). In multivariable Cox regression adjusting for pathologic diagnosis and eGFR at the time of biopsy, independent predictors of progression to ESRD within 5 years of biopsy were: interstitial fibrosis > 20% (HR 2.35 [1.22, 4.53]; p = 0.01), presence of endocapillary inflammation (HR 5.92 [1.95, 17.86]; p = 0.01). Presence of arteriosclerosis (HR 2.03 [1.01, 4.05]; p = 0.05), history of liver disease (HR 3.44 [1.53, 7.71]; p = 0.02), presence of arterial hypertension (HR 3.44 [1.53, 7.71]; p = 0.02), and congestive heart failure (HR 1.85 [0.99, 3.48]; p = 0.06).
index (BMI, 29 vs. 30 kg/m²), higher mean baseline eGFR (99 vs. 94 mL/min/1.73 m²) and lower prevalence of diabetes (10% vs. 18%); p<0.05 for all. In the overall study population, eGFR was stable without any decline (mean change: 0.1 mL/min/1.73 m²), while 189 participants experienced an eGFR decline ≥3% per year. Lower dietary magnesium intake was associated with higher risk of eGFR decline ≥3% per year (tertile 1 vs. 3, hazard ratio 1.9, 95% confidence interval: 1.1, 3.3) adjusted for socio-demographics, baseline eGFR, prevalent diabetes and hypertension status, BMI, serum magnesium, total energy intake, and dietary intake of calcium, potassium, and phosphorous.

Conclusions: Among persons with preserved eGFR, we detected a significant association between lower dietary Mg intake and increased risk of rapid kidney function decline independent of traditional CKD risk factors. These results highlight the importance of magnesium intake in the overall diet for the preservation of kidney function.

Renin-Angiotensin System: A Possible Mechanism for AKI-CKD Continuum

Shun-Yang Cheng, Shuei-Liong Lin, Ching-Chin Yang, Yu-Hsiang Chou, Fang Ling Liao, Ming-Hsuan Tsai. Graduate Inst of Physiology, National Taiwan Univ.

Background: Based on many clinical observations and studies, acute kidney injury (AKI) was now regarded as an important risky factor causing chronic kidney disease (CKD). Not only does CKD lead to end-stage renal disease (ESRD), but also increases the risk of cardiovascular disease or even death. Clinical studies often observe that the higher the AKI severity of a patient is, the more likely her/his kidneys progress into CKD. To this day, the mechanism underlying the progression of kidneys into CKD after AKI remains unclear. Since the higher severity of the AKI leads to more reduction of nephron numbers, we propose that activation of renin-angiotensin system (RAS) may be involved in the progression to CKD after recovery from AKI.

Methods: Severe AKI was induced in male adult CD-1 mice by right unilateral nephrectomy (Nx) followed by ischemia-reperfusion injury of left kidney 2 weeks later. Drinking water with or without type 1 angiotensin II receptor blocker losartan or direct vasodilator hydralazine was administered to mice from 4 weeks after surgery. Mice with Nx only were served as the control. Blood pressure, urinary albumin-to-creatinine ratio (ACR) and plasma levels of creatinine were evaluated.

Results: Compared to Nx group, AKI mice showed acute rise of plasma creatinine levels on day 2 after Nx+IRI surgery, which decreased to baseline on day 7. Moreover, elevated systolic blood pressure and increased urinary ACR were noted since 4 weeks after Nx+IRI. During the 4-month experimental period, progressive increase of urinary ACR and plasma levels of creatinine were noted. On the contrary, systolic blood pressure, urinary ACR and plasma creatinine level were normalized in mice administered with losartan since 4 weeks after Nx+IRI surgery. However the increase of urinary ACR and plasma creatinine level were not prevented in mice administered with hydralazine despite similar normalization in blood pressure.

Conclusions: These data suggest that RAS activation may underlie the mechanism for development of CKD in mice after recovery from AKI. Future studies are needed to explore the effect of RAS blockade in prevention of CKD and its pressure in patients recovered from AKI.

PUB182

The Renal Effects of Neprilysin Inhibition in Heart Failure and Hypertension

Background: Neprilysin inhibitors (NEPi) represent an emerging therapeutic option for treatment of hypertension (HTN) and heart failure (HF) through enhancement of natriuresis. While these agents have shown promising results with regards to lowering blood pressure (BP) and HF events, their impact on the kidney remains largely unknown. The aim of this study is to evaluate the currently available evidence on the effect of NEPi use on kidney-related parameters in patients with HTN or HF.

Methods: A search of articles cited in PubMed database from 1995 to 2015 using key words “neprilysin”, “heart failure” and “hypertension” found 237 articles. Animal studies were excluded. Those studies containing kidney-related parameters such as serum creatinine, glomerular filtration rate (GFR) or ACR were selected. Relevant data including changes in renal function, blood pressure and mortality were extracted and compared.

Results: A total of 42,487 patients from 12 randomized controlled trials with data pertaining to NEPi use were included (8 in HTN and 4 in HF). Seven studies used NEPi combined with ACE-i, 4 with ARB, and 1 with endothelin converting enzyme inhibitors. The follow up periods ranged between 7 days and 27 months. All studies in HTN (including 27,401 patients) reported significantly better BP lowering effect for NEPi compared to control group, while 94% of the patients in the HF studies presented with improvement in renal function and mortality. Although there is limited evidence, at endpoint all HF studies (including 15,086 patients) showed less frequent renal impairment (expressed as an adverse event, incidence of worsening renal function, change in GFR, or serum creatinine) compared to the control group. In contrast, only 3 HTN studies (including 466 patients) explored the impact on renal function and reported no significant benefit.

Conclusions: Current evidence suggests that in patients with HF, NEPi can lower HF-related events and mortality while potentiating favorable impact on renal function. In patients with HTN, although NEPi have been shown to reduce BP, there is no conclusive evidence of their role in improvement of renal function in this setting.

The Differences of Renal Protective Effect by Hyperuricemia Treatment Using Febuxostat in Various CKD Subgroups  Akinori Yamaguchi, Makoto Harada, Yosuke Yamada, Koji Hashimoto, Makoto Higuchi, Yuji Kamijo.  

Dept. of Nephrology, Shizuoka Univ, Mutsuomo, Nagano, Japan.  

Background: We often experience the CKD cases exhibiting the attenuation of eGFR decline by hyperuricemia treatment using febuxostat. However, renal protective effect of the hyperuricemia treatment has not yet been established. We hypothesize that the therapeutic response of febuxostat treatment might differ among various subgroups of CKD patients.  

Methods: To investigate the difference of the therapeutic response in CKD patients, 272 outpatients with hyperuricemia who were treated by febuxostat from May 2011 to March 2015 were enrolled. Patients undergoing hemodialysis and/or peritoneal dialysis treatment, and patients lacking essential clinical data were excluded. Finally, 178 patients were analyzed. Correlation coefficient between the average of serum uric acid level and the eGFR variation during 6 months after the treatment were statistically investigated in various clinical subgroups.  

Results: In all patients, significant correlation between the average of serum uric acid levels and the eGFR variation was detected (Spearman’s correlation coefficient: r=0.163, p<0.019). This significant correlation was also detected in each patient groups as follows: male patients (n=121, r=0.211, p=0.020), non-elderly (below 70 years old) patients (n=107, r=0.261, p=0.007), patients whose systolic blood pressure were below 130 mmHg (n=72, r=0.238, p=0.044), patients without dyslipidemia (n=133, r=-0.316, p=0.005) and non-diabetic-nephropathy patients (n=133, r=0.184, p=0.034). However, the significant correlation was not detected in each opposite subgroup.  

Conclusions: The current study suggest that therapeutic response of febuxostat treatment might be well in each CKD subgroups, including male, non-elderly, non-hyperuricemia, non-dyslipidemia and non-diabetic-nephropathy. It is possible that various risk factors of atherosclerosis conceal the beneficial renal protective effects of hyperuricemia treatment using febuxostat.

PUB184

Renal Div, Dep. Clinical Medicine, Faculty of Medicine, Univ of São Paulo, São Paulo, Brazil.  

Background: The current search for new biomarkers in CKD is intense, with particular emphasis on hard endpoints, such as ESRD, creatinine duplication and cardiovascular and overall mortality. In this analysis, we sought to evaluate which baseline clinical and laboratorial variables were related to ESRD/mortality in 56 patients with albuminuric diabetic nephropathy after mean follow-up time of 5 years.  

Methods: Baseline clinical and laboratory data of 56 participants of a clinical trial were evaluated as predictors of major outcomes (primary outcome: ESRD, creatinine duplication or mortality). Mann-Whitney and chi-square tests were used for univariate analyses. Several univariate and multivariate COX regression models were built on the risk of PO. Kaplan-Meier curve and LOG rank test were also performed.  

Results: PO occurred in 39 participants after a mean follow-up time of 5 years (70%). In univariate analyses, sex, creatinine clearance, 24h proteinuria, uRBP, urinary VEGF and serum TGF-beta were related to the event group. In univariate COX regression models, sex, proteinuria, creatinine clearance, VLDL-cholesterol, ferritin, PTH, RBP and uMCP-1, uVEGF and tGFP-beta were significantly associated to the risk of the PO. However, after adjustments for creatinine clearance and proteinuria, only uRBP and uMCP-1, tGFP-beta and uVEGF remained significantly associated to PO. In a stepwise model, only creatinine clearance (HR 0.98, 95%CI 0.97 - 1.00, P=0.06) and uRBP (HR 1.13, 95%CI 1.07 - 1.20, P<0.0001) were left as independent predictors of PO in this population. KM curve for uRBP is shown in figure 1.  

Conclusions: Urinary RBP is an independent predictor of PO in albuminuric diabetic nephropathy. Its role as a risk biomarker should be further explored in larger studies of CKD patients.  

Funding: Government Support - Non-U.S.

PUB185

Association Between Urinary RBP and Renal and Cardiovascular Risk Factors in a Population with CKD: The Progrider Study  Maria Alice Muniz Domingos, 1 Alessandra C. Goulart, 2 Paulo Lotufo, 2 Isabel B. M. Benson, 3 Silvia M. Titan.  

1 Renal Div, Dep. Clinical Medicine, Faculty of Medicine, Univ of São Paulo, São Paulo, Brazil; 2 Clinical Research Center, Univ Hospital, São Paulo Univ, São Paulo, Brazil.  

Background: Urinary RBP (uRBP) has been related to the risk of ESRD in general nephrologists and renal transplant. However, its role in CKD is not well established.  

Methods: Baseline clinical and laboratorial data on 454 participants of the Progrider Study was analyzed. uRBP was measured by an immunoenzymatic assay with monoclonal antibody. Descriptive data is presented according to tertiles of uRBP, and correlation coefficients were calculated. Several univariate and multivariate linear regression models were built. Lastly, binary regression models were built on the risk of presenting more advanced CKD (class IV-V or class II-III).  

Results: In the descriptive data, the tertiles of uRBP were significantly related to sex, diabetes, renal function, SBP, glycated hemoglobin, HDL, proteinuria, WHR, phosphorus, aciddosis, albumin, pulse-wave velocity (PWV), left atrium diameter (LAD), systolic and diastolic left ventricular diameters and ejection fraction. These results were confirmed by correlation. In the univariate regression models, diabetes, SBP, WHR, renal function, proteinuria, phosphorus, albumin, lipids, glycated hemoglobin, PWV and echocarography variables remained related to uRBP. However, after adjustments, only renal function, proteinuria, SBP, bicarbonate and LAD remained associated to uRBP.  

Table: Stepwise multivariate linear regression models on log of urinary RBP.

PUB186

Treatment of Subclinical Hypothyroidism and the Progression of Chronic Kidney Disease  Padmavathi Mali, 1 Sudheer Muduganti.  

1 Internal Medicine, Marshfield Clinic, Marshfield, WI; 2 Nephrology, Univ of Wisconsin Hospitals and Clinics, Madison, WI.  

Background: Evidence suggests that treatment of subclinical hypothyroidism may slow the progression of chronic kidney disease (CKD) and delay or prevent development of end stage renal disease (ESRD). The goal of this study was to provide additional evidence regarding the same.  

Methods: Patients with subclinical hypothyroidism and CKD stages 3 or 4 were identified by retrospective chart review over a period of 6 years. Subjects were grouped based on L-thyroxine treatment. Subjects treated with L-thyroxine before first elevated thyroid stimulating hormone (TSH) were excluded. Index date was defined as the date of first L-thyroxine for treated patients. Index dates for untreated patients were assigned by correlation. In the univariate COX regression models, sex, proteinuria, creatinine clearance, VLDL-cholesterol, ferritin, PTH, RBP and uMCP-1, uVEGF and tGFP-beta were significantly associated to the risk of the PO. However, after adjustments for creatinine clearance and proteinuria, only uRBP and uMCP-1, tGFP-beta and uVEGF remained significantly associated to PO. In a stepwise model, only creatinine clearance (HR 0.98, 95%CI 0.97 - 1.00, P=0.06) and uRBP (HR 1.13, 95%CI 1.07 - 1.20, P<0.0001) were left as independent predictors of PO in this population. KM curve for uRBP is shown in figure 1.  

Conclusions: Urinary RBP is an independent predictor of PO in subclinical diabetic nephropathy. Its role as a biomarker of hard clinical end-points should be further explored.

Vitamin D Deficiency Is a Cause and a Result of Renal Dysfunction in Rheumatoid Arthritis
Suad Ma Hannawi, Issa AL Salmi.

**Background:** Asymptomatic kidney dysfunction is common in RA. Low vitamin D(VD) increases susceptibility to development of RAA disease activity. Sequential hydroxylation occurs in liver & kidney to form active,1,25-VD & patients with kidney failure are often resistant to VD & suffer from 25-hydroxylipidosis & renal osteodystrophy. In addition to its role in maintaining Ca&PO4 homeostasis, VD is important for maintaining maximum muscle strength & prevention of chronic diseases. Our objective is to evaluate eGFR & VD status in RA.

**Methods:** RA diagnosed by ACR 1998 criteria. 25-VD level obtained & GFR calculated by MDRD at Rheumatology clinic visit. Univariate linear regression analysis carried out to determine the relation between 25-VD & eGFR, other renal parameters & RA inflammatory markers.

**Results:** In an analysis of 52 RA(47.5M) with mean age 46±13 years(46±12, M±SD), 25.5-VD level was 40±29 nmoI/(NR=50-80) & GFR is 134±49 ml/min. Univariate linear regression showed a negative relationship between 25-VD level & eGFR(p=0.041,CI=0.23-0.01), micro-albuminuria(p=0.046,CI=0.63-0.01), CRP(p=0.011,CI=1.16-0.11), neutrophil count (p=0.033,CI=1.67-0.11) . A positive linear relationship between GFR & weight (p=0.03,CI=0.66,1.04), HAg(p=0.02, CI=11.19&BMP(p=0.009,CI=0.65-4.05), Ca(p=0.03, CI=7.24, 13.12 nmoI/l).

**Conclusions:** Negative relationship between eGFR & 25-VD indicating a higher 25-VD as failure to convert to active form as GFR decreases. Extra-renal formation of active VD requires a level of 25-VD >78 nmol/L & is necessary for maximal extra-renal production of 1,25VD. 1,25-VD is one of the most potent regulators of cellular growth & very effective modulator of the immune system. VD receptors are present in most cells & tissues including atheroma body including activated T & B lymphocytes. Surveillance for VD deficiency, should be part of follow-up as it may be linked to underlying kidney dysfunction in RA. On the other hand, reduced VD might worsen RA & hence, increase the possibility of renal deterioration. VD supplementation may be needed early in management for prevention of kidney dysfunction & to reduce RA severity.

**PUB199**

Associations Between the Progression of Chronic Kidney Disease and Patient Demographics
Danieque Xu, 1 Mark Stuart, 1 Barbara Cannon, 2 Chad Sowers, 3 John W. Larkin, 4 Sophia Rosen, 4 Carly R. Van Zandt, 4 Len A. Usvyat, 4 Yuedong Wang, 2 Danqing Xu, 2 Seble Kassaye, 1 Georgetown Univ Medical Center, Washington, DC; 2 Georgetown Howard Univ Center for Clinical & Translational Science, Washington, DC; 3 MedStar Health Research Inst, Hyattville, MD.

**Background:** It is well known if demographic factors are related to the progression of chronic kidney disease (CKD). Our study aimed to investigate whether age, sex, race, marital status and geography are associated with significant changes in kidney function determined by linear slopes of mean annual glomerular filtration rate (GFR).

**Methods:** We analyzed data from 90,240 CKD patients (Pts), who had significant declines in GFR, in the Fresenius Medical Care CKD Data Registry. Annual average decline in GFR was estimated on a per pt basis using linear regression with time as the predictor and GFR as the outcome variable. Univariate linear models were fitted for age groups (15-30, 31-40, 41-50, 51-60, 61-75, and 76+ years), sex (female vs. male), race (African American, Caucasian, or other), marital status (married, unmarried) and geography (10 divisions of zip codes); a multiple linear regression model was utilized to investigate associations in mean annual GFR slope and demographics.

**Results:** This analysis identifies significant associations between mean annual GFR slope & Pt demographics. CKD Pts age 15-30 years old were found to decline faster in GFR versus Pts of African American or Caucasian race (p<0.001). The geographical location of Pts by zip code was observed to be associated with differences in GFR slope (p<0.001). The marital status of Pts was not found to be related to differences in slopes of GFR (p=0.218).

**Conclusions:** This study identifies that during the progression of CKD, younger Pts tend to have faster declines in GFR, as compared to older Pts; males have slower declines in GFR, as compared to females; Pts with a race of “other” have slower declines in GFR, as compared to Pts of African American or Caucasian race; and declines in GFR are related to Pt geography.

Correlation of Increased Th17 to Treg Cell Ratio with Endoplasmic Reticulum Stress in Chronic Kidney Disease
On Yan.

**Kidney Dept, Second Affiliated Hospital of Xi an Jtolong Univ, Xi’an, Shaanxi Province.**

**Background:** The study aimed to investigate the relationship between the regulatory immune network and endoplasmic reticulum stress (ERS) in patients with different stages of chronic kidney disease (CKD).

**Methods:** A total of 91 patients diagnosed with CKD were divided into different groups according to the stage of disease. Routine blood and biochemical tests were performed in patients. The levels of cytokines in healthy controls were measured according to the protocol (n=20). The frequencies of T helper cell type 17 (Th17) and regulatory T (Treg) cells in the overall T cell population was measured by flow cytometric analysis. Levels of Th17 cell (IL-17) and Treg cell (IL-10) cytokines and the ERS markers

**Results:**
- **Th17 and Treg Cell Counts:**
  - Th17 cell count (IL-17): IL-17 levels were significantly increased in patients with CKD compared to healthy controls.
  - Treg cell count (IL-10): Treg cell counts were lower in patients with CKD compared to healthy controls.

**Conclusions:** The study showed a significant correlation between Th17/Treg cell ratio and endoplasmic reticulum stress (ERS) in patients with different stages of chronic kidney disease (CKD).
CHOP and GRP78 were measured by ELISA in serum samples collected from controls and patients of the different CKD groups. Correlations between each parameter and serum creatinine, an indicator of renal function, were analyzed by Spearman’s rank correlation and regression test. 

**Results:** CKD stage showed a positive correlation with serum creatinine level, and increased values of Th17 and Treg cells, respectively, increased the levels of ERS markers. There was no correlation with serum creatinine levels in patients with the non-dialysis group. 

**Conclusions:** We found that an increased Th17/Treg cell ratio and increased serum levels of ERS markers correlate with the progression of CKD. Our results indicate that the interplay between the immune network and management of ERS is closely associated with the pathogenesis of CKD. Although hemodialysis and peritoneal dialysis treatment manage chronic kidney conditions and prevent further deterioration of renal function, they have limited effects on improving the immune disorder and relieving ERS.

Metabolic Phenotyping in Thin Basement Membrane Nephropathy

Claire Boulangé,1 Manuja Kaularachchi,1 Elaine Holmes,1,2 John C. Lindon,1,2 Joram Matthias Posma,3 Konstantinos Vasikardes,1 Isavella Savva,1 Alkis Mikis Pierides,2 Konstantinos Deltas,3 Metabolix Ltd, London, United Kingdom; 2CSM, Dept of Surgery & Cancer, Imperial College London, London, United Kingdom; 3MRRC, Dep of Biological Sciences, Univ of Cyprus, Nicosia, Cyprus.

**Background:** Thin basement membrane nephropathy (TBMN) is the commonest cause of familial microscopic hematuria in children and adults, usually associated with benign clinical presentations i.e. minimal proteinuria and normal renal function. In a Greek-Cypriot cohort of TBMN patients, 35% of patients were shown to develop ESRD by age 70-years while ~50% of patients over 50-years developed CKD of variable degree. 40% of TBMN patients in the different CKD groups, 35% of patients were shown to develop ESRD by age 70-years while ~50% of patients over 50-years developed CKD of variable degree. 40% of TBMN patients in the different CKD groups. Correlation analysis showed that serum levels of CHOP and GRP78 were independently and positively correlated with the ratio of Th17/Treg cells. 

**Conclusions:** We have found that an increased Th17/Treg cell ratio and increased serum levels of ERS markers correlate with the progression of CKD. Our results indicate that the interplay between the immune network and management of ERS is closely associated with the pathogenesis of CKD. Although hemodialysis and peritoneal dialysis treatment manage chronic kidney conditions and prevent further deterioration of renal function, they have limited effects on improving the immune disorder and relieving ERS.

Association of hsCRP and Kidney Damage Indicators in 5667 Adults Receiving Physical Examination

Hao Zhang, Juan Mao, Bin Yi, Guo Xu, Wei Li. The Third Xiangya Hospital of Central South Univ.

**Background:** Chronic kidney disease and cardiovascular disease share many risk factors. Injury to the vascular endothelium, measured by elevated levels of serum high-sensitivity C-reactive protein (hsCRP), may play a role in kidney disease. Therefore we examined the association of hsCRP with kidney damage indicators (uACR,cgiFR) among 5667 participants receiving physical examination in the Third Xiangya Hospital.

**Methods:** We conducted a cross-sectional analysis of 5667 adults who received health physical examinations in 2014. Spearman correlation analysis, multiple linear regression and multivariable logistic regression models were used to analyze the correlation between hsCRP with uACR,cgiFR. ROC curves was drawing to explore the statistically significant intercept point of hsCRP in predicting the occurrence of albuminuria and declining in eGFR. Multivariable logistic regression analysis was used to calculate the ORs for albuminuria, declining in eGFR according to the quartile of hsCRP levels and other risk factors.

**Results:** Spearman correlation analysis showed that uACR was positively correlated with serum hsCRP (r=0.233,p=0.01). While eGFR showed negative correlation with hsCRP (r=-0.135,p<0.01). Multiple linear regression analysis showed that hsCRP was independently correlated with uACR (B=0.205,β=0.156, P<0.01). While hsCRP didn’t enter the multivariable linear regression model of eGFR. Multivariable logistic regression analysis showed that male, central obesity, hypertension, diabetes and high hsCRP levels were independent risk factors for albuminuria. Based on the ROC curve, the 0.5mg/L of hsCRP was the best numerical value to predict the risk of albuminuria. Multivariable logistic regression analysis showed that the risk of albuminuria significantly increased in male, central obesity, hypertension, diabetes or combined with high hsCRP levels.
Conclusions: HoCRP was correlated with kidney damage indicators, and hoCRP was an independent risk factor of albuminuria. The 0.85mL of CRP was the best numerical value to predict the risk of albuminuria. Male, central obesity, hypertension, diabetes accompanying high serum hoCRP levels are more likely to have albuminuria.

**Serum Non-Protein Bound Homocysteine Levels Are Related with Chronic Kidney Disease Progression in HIV-Infected Patients**  
**Carlos Díaz, 1 Nelson Casimiro, 1 Nuno Coelho, 1 Ana R. Lemos, 1 Pedro Pereira Campos, 1 Ana Luisa Papolla, 1 Sara Maia, 2 Karina Soto, 2 Sofia Pereira. 1 Centro de Estudos de Doenças Crônicas, NOVA Medical School/Faculdade de Ciências Médicas (NMS/FCM), Univ Nova de Lisboa; 2Centro de Estatística e Aplicações da Univ de Lisboa (CEAUL), NOVA Medical School/Faculdade de Ciências Médicas, Univ Nova de Lisboa; 3Nephrology, Hospital Fernando Fonseca, Lisbon, Portugal.

Background: Homocysteine (Hcys) is present in serum in two major forms: disulfide protein-bound (PB) (70-80%, mostly albumin) and non-protein bound (NPB) (20-30% combined thiol dimers + 1% thiol free). Only the NPB-fraction of Hcys is able to enter into the cell and accumulate in both kidney failure and HIV-infected patients, hyperhomocysteinemia is a common feature. The present study was aimed to explore the relationship of Hcys fraction and chronic kidney disease (CKD) progression in HIV-infected patients.

Methods: As part of an on-going prospective study of HIV+ population, a cross-sectional analysis was performed in a cohort of HIV-infected patients under combined antiretroviral therapy. Serum NPB-fraction of Hcys was quantified by HPLC with fluorescence detection. Glomerular filtration rate (eGFR) was estimated by CKD-EPI equation. The fractional excretion of phosphate (FePi) was also assessed.

Results: A total of 141 HIV-infected patients were included, 65% men, 73% non-Black, and 55 years old (IQR44-63). Median values of eGFR and FePi were 85 ml/min/1.73m² (66-95) and 19% (13-25) respectively. Univariable analysis was performed for eGFR, FePi and age. Only eGFR remained in the multivariable model (r=-0.332, p<0.0001).

Conclusions: Serum NPB-Hcys fraction was independently related with kidney dysfunction. The present data suggest that monitoring this sub-fraction of Hcys could be a tool for early kidney dysfunction detection in HIV-infected patients.

**Diabetic Foot Ulcers and Acute Kidney Injury Are Associated with a Decline in Renal Function**  
**Huda Mahmoud, 1 Maarten W. Taal, 1 Frances Game, 2 Laura M. Proctor, 2 Heather Sherriff, 2 Christina Udani Peter, 2 Hana Baig, 2 Faaiza Asma, 2 Emma J. Lincoln, 2 Nicholas M. Selby. 1 1Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; 2Diabetes, Royal Derby Hospital, United Kingdom; 3Div of Medical Sciences and Graduate Entry Medicine, Univ of Nottingham, United Kingdom.

Background: There is an increased incidence of foot ulcers in patients with diabetes in the period immediately prior to the initiation of chronic dialysis; this may be explained if chronic foot ulcers accelerate a decline in renal function. We sought to examine this further by describing changes in renal function associated with hospitalisation for diabetic foot ulcer management.

Methods: All patients admitted to our centre during 2013 with ICD10 coding for diabetic; 18.6% m and 11.4% f were hypertensive; 2.2% m and 0.7% f had heart disease; 3.7% m and 6.8% f had dyslipidemia; 5.9% m and 3.0% f were obese; 18.6% m and 11.4% f were hyperglycemic; 2% m and 0.7% f had heart disease; 0% m and 3.5% f had hypothyroidism; 1.5% m and 1.2% f had CKD. Gender differences in SBP, DBP, overhydration, FTI, LITI and BMI are shown (Table).

Results: Waist circumference was higher than normal (i.e. >88 cm for f and >102 cm for m) in 38.4% (m) and 51.6% (f).

Conclusions: In a large sample of apparently healthy persons, males had more CVD and CKD risk factors than females, such as SBP, overhydration, and FTI. In association with other CVD risk factors, these increase morbidity and mortality. Evaluation of body composition is important in the general population for identification of CVD and CKD risk.

**PUB198**

**Gender – An Additional Cardiovascular and Chronic Kidney Disease Risk Factor in an Apparently Healthy Population**  
**Anttillo Di Benedetto, 1 Annalisa Ciotola, 1 Fabrizio Cerino, 1 Annamaria Colao, 2 Daniele Marcelli, 1 Bernard J. Canaud, 3 NephroCare Italy, Naples, Italy; 2Medicina Clinica e Chirurgia, Univ Federico II, Naples, Italy; 3Fresenius Medical Care, Bad Homburg, Germany.

Background: Cardiovascular disease (CVD) is on the rise, presenting significant social and economic burden. Early detection of CVD and chronic kidney disease (CKD) risk factors may prevent related complications. We report results of a CVD and CKD risk factor screening program in an apparently healthy population.

Methods: Participants and spectators of the “Prevention Races” held in 2013/2014 in Naples/Salerno (Italy) were screened for CVD and CKD risk factors by different specialists, including nephrologists. Parameters assessed were: systolic blood pressure (SBP), diastolic blood pressure (DBP), weight, height, waist circumference, BMI, and body composition. Lean (LITI) and Fat (FTI) tissue indexes and overhydration were evaluated by Body Composition Monitor (Fresenius Medical Care, Bad Homburg, Germany) using multi-frequency bioimpedance spectroscopy at 50 different frequencies.

Results: 701 subjects (38.5% m; 61.5% f) were evaluated. Mean age was 54.54 ± 15.6 (m) and 50.06 ± 15.2 (f). 3.7% m and 6.8% f had dyslipidemia; 5.9% m and 3.0% f were obese; 18.6% m and 11.4% f were hyperglycemic; 2% m and 0.7% f had heart disease; 0% m and 3.5% f had hypothyroidism; 1.5% m and 1.2% f had CKD. Gender differences in SBP, DBP, overhydration, FTI, LITI and BMI are shown (Table).

Conclusions: These data add strength to the hypothesis that an active diabetic foot ulcer may contribute to a decline in renal function, particularly when associated with an episode of AKI. This decline may also be under-estimated due to loss of muscle mass and subsequent over-estimation of eGFR in the post hospitalisation period. These results support additional prospective epidemiological and mechanistic studies to further explore the relationship between diabetic foot ulcers, AKI and CKD progression.

**Potential Effect of Treatment of Metabolic Acidosis on Reducing the Risk of End Stage Renal Disease in Chronic Kidney Disease**  
**Solomon Daledern, Candace D. Grant, Vladimir Liberman, Alejandro Pepen Romero, Shayan Shirazian, Nobuyuki (Bill) Miyawaki, Joseph Mattana. Medicine, Winthrop-Univ Hospital, Mineola, NY.

Background: There is increasing evidence that low serum bicarbonate levels impact adversely on the progression of chronic kidney disease (CKD) to end stage renal disease (ESRD). It is plausible that treatment could result in a significant reduction in ESRD incidence though the potential impact in a CKD population and number needed to treat (NNT) are incompletely understood. We carried out the present study to estimate the potential impact of treatment of metabolic acidosis on the incidence of ESRD in a population of CKD patients.

Methods: We evaluated a cross section of 623 Stage 3 and 4 CKD patients at our institution. Their risk of developing ESRD at 2 and 5 years was estimated using the method of Tangri et al (JAMA 2011;305:1553-1559) which incorporates age, gender, eGFR, urine albumin to creatinine ratio, calcium, phosphorus, albumin, and bicarbonate. ESRD risk was then recalculated after assuming correction of all serum bicarbonate levels to 28 mEq/L.

Results: The population had a mean serum bicarbonate level of 24.3 mEq/L, with 79.5% having levels below 28 mEq/L. When ESRD risk was calculated following correction of low serum bicarbonate levels to 28 mEq/L, 16 fewer patients were predicted to develop ESRD at 2 years and 27 fewer at 5 years (relative risk reductions of 0.31 and 0.23 respectively). This effect was greatest for patients with CKD stage 4, accounting for 13 fewer ESRD patients predicted at 2 years and 20 fewer at 5 years. For the population as a whole, the NNT to prevent one case of progression from CKD to ESRD was 40 and 23 at 2 and 5 years respectively, while for those with CKD stage 4 the NNT was only 16 and 11.

Conclusions: Our findings suggest that in a population of CKD patients correction of metabolic acidosis could potentially result in a substantial reduction in the number who reach ESRD given the large numbers of patients with low serum bicarbonate levels. Prospective studies are needed to determine whether sodium bicarbonate therapy in populations of CKD patients could prevent many cases of ESRD.
The Impact of Vascular Disease on Risk of Development of End Stage Renal Disease in Patients with Chronic Kidney Disease

Vladimir Liberman, Sairah Sharif, Candace D. Grant, Alejandro Pepen Romero, Shanza Mujeeb, Nobuyuki (Bill) Miyawaki, Shayan Shirazian, Joseph Mattana. Medicine, Winthrop-Univ Hospital, Mineola, NY.

Background: Patients with chronic kidney disease (CKD) are not only at higher risk for development of end stage renal disease (ESRD) but also suffer disproportionately from vascular disease (VD), with associated high cardiovascular mortality. VD can plausibly impact progression of CKD and increase the risk of ESRD. However, VD also shortens survival, and may therefore reduce the risk of ESRD by increasing the competing risk of death. In the present study we evaluated the relationship between VD and the risk of development of ESRD in patients with CKD.

Methods: We carried out a retrospective cross sectional study of 623 CKD patients and recorded demographic, clinical and laboratory variables. We divided them in two groups based on presence or absence of VD and stratified them into different age groups. We estimated the risk of ESRD progression using the method of Tangri et al (JAMA 2011;305:1553-1559) and compared the risk levels between each group.

Results: Out of 623 patients with CKD 285 had VD (coronary artery disease and or peripheral vascular disease) documented in the record. Patients with VD were significantly older than patients with no VD (76 vs 70 years), had lower serum albumin (4.0 vs 4.1 g/dL) and lower eGFR (33.8 vs 36.4 ml/min/1.73 m²). We found that older patients with VD had significantly higher risk of developing ESRD. For the 70 to 79 year age group the 2 year risk was 2.45 vs 1.50 (p=0.029) and 5 year risk was 6.80 vs 4.31 (p=0.03) in patients with and without VD. For patients ≥80 years the 2 year risk of developing ESRD was 2.18 vs 1.35 (p=0.029) and 5 year risk was 6.80 vs 4.31 (p=0.03).

Conclusions: Our findings suggest that older patients with VD may be at increased risk for the development of ESRD despite the higher competing risk of death. This may be partly due to shared pathophysiological mechanisms between atherosclerosis and CKD progression. If validated in an ongoing prospective study this finding would suggest that VD should be partly due to shared pathophysiological mechanisms between atherosclerosis and CKD risk for the development of ESRD despite the higher competing risk of death. This may be partly due to shared pathophysiological mechanisms between atherosclerosis and CKD progression. If validated in an ongoing prospective study this finding would suggest that VD should be considered a risk factor predisposing to an increased risk of developing ESRD.

Management of Renal Artery Stenosis Post-ASTRAL and CORAL: Outcome of Patients with Radiologically Confirmed Atherosclerotic Renal Artery Stenosis Treated Conservatively

Moheen Mohammed Ahmed, Nicholas John Railton, Abdelgail Abdelrahman Ali, Anthony Chan. Renal Medicine, Mid Essex NHS Trust, Chelmsford, United Kingdom; Radiology, Mid Essex NHS Trust, Chelmsford, United Kingdom.

Background: Following the publications of ASTRAL and CORAL trials, the use of percutaneous renal artery angioplasty and stenting (PRAS) in the treatment of atherosclerotic renal artery stenosis (ARAS) has fallen dramatically. We report the outcomes of patients with radiologically confirmed diagnosis of ARAS who did not undergo PRAS and were managed medically.

Methods: Retrospective review of all patients undergoing CT/MRI angiography for suspected ARAS from 2008-2014 in Broomfield Hospital, Essex. Patients with more than >50% stenosis in a renal artery who were medically managed and did not undergo PRAS were included in analysis. They were followed for blood pressure control, renal events and mortality.

Results: 29 patients were identified, all Caucasians with a median age of 78 (49-85 years) of which 59% were males. None underwent PRAS. They were followed up from diagnosis till December 2014 or date of death with a mean period of 51 months. Systolic BP at end of study was <140 mmHg in 48%, 140-200 in 48% and >200 in 4% of patients. 69% were on 3 or more antihypertensives with 34% on renin angiotensin system blockade. 20 patients were CKD 3 and 8 with CKD 4 at baseline, with 3 patients progressing from CKD 3 to CKD 4. For the 70 to 79 year age group the 2 year risk of developing ESRD was 2.45 vs 1.50 (p=0.029) and 5 year risk was 6.80 vs 4.31 (p=0.03) in patients with and without VD. For patients ≥80 years the 2 year risk of developing ESRD was 2.18 vs 1.35 (p=0.029) and 5 year risk was 6.80 vs 4.31 (p=0.03). We found that older patients with VD had significantly higher risk of developing ESRD. For the 70 to 79 year age group the 2 year risk was 2.45 vs 1.50 (p=0.029) and 5 year risk was 6.80 vs 4.31 (p=0.03) in patients with and without VD. For patients ≥80 years the 2 year risk of developing ESRD was 2.18 vs 1.35 (p=0.029) and 5 year risk was 6.80 vs 4.31 (p=0.03).

Conclusions: Our findings suggest that older patients with VD may be at increased risk for the development of ESRD despite the higher competing risk of death. This may be partly due to shared pathophysiological mechanisms between atherosclerosis and CKD progression.

From this study of patients with ARAS not indicated for PRAS, only a small number progressed to higher grades of CKD. Blood pressure control appeared adequate in a significant proportion of patients. This is in keeping with the findings from ASTRAL/CORAL trials and may be of significant benefit in terms of cost and reducing patient morbidity.

Clinical, Laboratory and Immunological Characteristics of Membranous Nephropathy in Kidney Transplantation Patients

Artur Quinteriano Silva, Juliana Busato Mansur, Marisa Petrucelli Doher, Gianna Mastroianni-kirsztajn. Dept of Nephrology, UNIFESP, Sao Paulo, Brazil.

Background: Membranous nephropathy (MN) is one of the more common causes of nephrotic syndrome in the adult population and may occur in the transplanted kidney. The goal of this study was to describe clinical and laboratory characteristics of membranous nephropathy in kidney transplantation patients. A total of 41 patients was studied. The first proteinuria was with 48 months and time at diagnosis was 57.9 months. Eleven patients had a secondary cause of MN. Independently of the immunosuppressive regimen occurred MN.

Methods: The characteristics evaluated were graft survival, time to onset of symptoms, patient profiles, treatment evolution , time from onset of symptoms to graft loss, immunosuppression used before and after the diagnosis of membranous nephropathy post transplant (MNPT), blockers of the renin-angiotensin-aldosterone system, proteinuria levels and time of biopsy x beginning of the onset of symptoms with disease progression.

Results: The mean age of the receptor was 49.4 years and 58.5% were males. The most common comorbidities were HBP (96.7%), dyslipidemia (22%), neoplasia (12.2%), diabetes (9.1%), SLE (7.3%) and hepatitis (7.3%). Induction therapy to prevent acute rejection during the early post transplant period was used in 9 (21.9%) patients (8 antithymocyte and 1 basiliximab) followed up by initial immunosuppression with PRED+CNI+AZA (56.1%) and PRED+CNI+MPA (34.1%). The end immunosuppression was Pred+CNI+AZA (29.2%), Pred+CNI+MPA (41.1%). Secondary MN causas had a more benign course (graft function) than the primary causes. Death censored graft survival in 10 years was 58.6%.

Conclusions: About 50% of grafts which develop de novo MGN eventually fail. This rather poor outcome may not represent the natural history of de novo MGN per se but rather the consequences of associated chronic rejection. Evidence is presented that many of the cases of so-called de novo MGN may be a complication of transplant glomerulopathy rather than being caused by mechanisms totally independent from rejection. The beneficial effects of immunosuppression agents have not been validated.
Factors Influencing Initiation and Choice of Immunosuppressive Therapy in Primary FSGS

Louis-Philippe Laurin,1* Bethany J. Foster,4* A. Gasim,2 Caroline J. Poulton,1* J. Charles Jennette,1,2 Ronald J. Falk,3 Patrick H. Nachman,1 1 Div of Nephrology, Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada; 2 Dept of Pathology and Laboratory Medicine, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; 3 Div of Nephrology and Hypertension, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; 4 Div of Nephrology, McGill Univ Health Center, Montreal, QC, Canada.

Background: The treatment of patients with primary focal segmental glomerulosclerosis (FSGS) may include immunosuppressive therapy in patients not responding to conservative treatment or considered at high risk of progression to renal failure. We sought to determine the patient and disease characteristics associated with choice of therapy early in disease course.

Methods: Inception cohort of biopsy-proven patients with primary FSGS diagnosed between 1980 and 2012. Factors influencing choice of therapy were identified using multiple logistic regression; we report odds ratios (OR) with 95% confidence interval (CI).

Results: 458 patients met criteria; 183 on no immunosuppressives; 173 treated with glucocorticoids [GC] alone; 90 with calcineurin inhibitors [CNIs] ± GC; 12 with other immunomodulatory agents.

Tip lesion variant (OR 3.00; 95% CI 1.23-7.32), eGFR <30 mL/min/1.73m² (OR 1.89; 95% CI 1.01-3.45) and hypouricemia (OR 2.22 per g/dl lower; 95% CI 1.59-3.13) were associated with a higher likelihood of any immunosuppressive treatment. Only tip lesion was associated with choice of GC alone vs. CNIs (OR 0.17; 95% CI 0.05-0.53).

Conclusions: Presence of tip lesion, preserved renal function at baseline and more severe hypouricemia are associated with immunosuppressive therapy in primary FSGS, but only tip variant appears to influence choice of GC alone over CNIs.

A Performance-Enhancing Drug and Its Depressing Effects

Waidi Bader, Internal Medicine, John Stroger Hospital of Cook County, Chicago, IL.

Background: Anabolic steroid use is a habit with a global 3.3% lifetime prevalence rate and is well known for its adverse effects on the renal, endocrine, hepatic, and hematologic systems. We bring a case of focal segmental glomerular sclerosis (FSGS) in a known user of anabolic steroids.

Methods: A previously healthy 28 year old male had presented to our hospital after being told he had kidney damage during a recent routine check up. On presentation, he complained of generalized weakness of one month’s duration; the social history was significant for use of Mutant Plexx, a bodybuilding supplement that contained an anabolic substance. On admission, his vital signs were normal for body mass of 189/109 and a heart rate of 82. His physical exam noted a muscular male with normal cardiovascular, respiratory, and abdominal exams. On labs the patient had a BUN of 59, a creatinine of 5.6, and a hemoglobin of 13.1. A urinalysis showed 1+ protein. Nephrology team was consulted for further workup. Urine microscopy was performed and showed no dysmorphic RBCs. Spot urine protein/creatinine ratio was 2.2 grams. Hb was negative; HbA1c, HbA1c, and hepatic C antibody were negative. Three days into his admission, the patient had an ultrasound guided kidney biopsy. On biopsy, half of the glomeruli had segmental scars, some with collapsing features. The interstitium was noted to have areas of fibrosis and the arteries showed mild sclerosis and arterioles with hyalinosis. The patient was diagnosed with collapsing FSGS secondary to anabolic steroid use; he was educated on control of hypertension and was advised to stop using anabolic steroids.

The patient was diagnosed with collapsing FSGS secondary to anabolic steroid use; he was educated on control of hypertension and was advised to stop using anabolic steroids.

Results: The pathophysiologic cause of FSGS secondary to anabolic steroids is thought to be due to several reports indicated that hyperuricemia might be independent risk factor for renal worsening, but about the effect of hyperuricemia itself upon progression of kidney diseases, especially in IgA nephropathy patients. Aim is to reveal effect of uric acid upon renal progression in IgA nephropathy patients.

Methods: This study is retrospective cohort study. Subjects were 923 IgA nephropathy patients who had not been treated uric acid lowering drugs, from 1001 IgA nephropathy patients who were diagnosed by renal biopsy, and over 15 years old in Osaka University Hospital, Osaka general medical center, Osaka Rosaki Hospital. Outcome was 1.5 times of serum creatinine. Exposure is uric acid at renal biopsy. Exploratory variables included sex, age, BMI, blood pressure, baseline eGFR, proteinuria, smoking status.

Results: Mean age was 34[23-46] years, proteinuria was 0.40[0.18-0.89] g/day. Uric acid was 6.5+1.3mg/dl in male patients, and 4.8+1.3mg/dl in female patients. Multivariate Poisson regression analysis revealed that uric acid was significant risk for progression of renal disease [Hazard Ratio 1.30[1.01-1.65] UA per 1mg/dl] in female patients along with proteinuria(g/day) [HR 1.27[1.08-1.47],p<0.001], Creatinine(mg/dl) [HR 2.73[1.84-3.74]]. In male patients, uric acid was not independent risk factor.

Conclusions: Hyperuricemia is independent risk for progression of kidney disease in female IgA nephropathy patients.

Long-term H.P. Acthar® Gel Treatment of Relapsing Idiopathic Membranous Glomerulopathy: A Case Study

Firas Marwani, Southwest Kidney Inst, Gilbert, AZ.

Background: Long-term treatment with H.P. Acthar® Gel (repository corticotropin injection, Questa Pharmaceuticals, Inc., Hayward, CA), an FDA- approved treatment for remission of proteinuria associated with nephrotic syndrome, was examined in a patient with biopsy-confirmed idiopathic membranous glomerulopathy (mM). Methods: A retrospective clinical record review examined Acthar Gel treatment over 2 years and 6 months in a patient with mM who received prescription-based treatment in a clinical practice. Outcomes included proteinuria level (mg/g), serum creatinine (SCr), serum albumin and treatment-related side effects. Complete remission was defined as proteinuria <500 mg/g. Partial remission was defined as ≥50% reduction in proteinuria from baseline and proteinuria 500-3500 mg/g.

Results: The 54-year-old Vietnamese patient with mM was treated over 7 years. At diagnosis, the patient’s proteinuria was 8000 mg/g, SCr 0.7 mg/dL, and serum albumin 2.1 g/dL. Initial treatment included prednisone, cyclophosphamide, mycophenolate mofetil, tacrolimus, and rituximab over 4.5 years. The patient showed partial complete remissions followed by relapse. At 1 Aktch Gel initiation, proteinuria was 3400 mg/g, SCr 0.6 mg/dL, and serum albumin 4.2 g/dL. The patient did not tolerate 80 U twice weekly but did tolerate 40 U twice weekly. At 4 months, she showed complete remission (proteinuria <150 mg/g). Dose reduction to 20 U twice weekly resulted in relapse 7 months later (proteinuria 2350 mg/g). Dose increase to 40 U twice weekly led to complete remission 4 months after that. Loss of insurance and cessation of Acthar Gel for 4 months led to relapse (proteinuria 7700 mg/g). Acthar Gel was re-started at 32 U twice weekly followed by 24 U twice weekly. Partial remission occurred 4 months later (proteinuria 2100 mg/g) with greater improvement at 10 months (proteinuria 800 mg/g). The patient has maintained partial remission (proteinuria 970 mg/g) 4 months post-therapy. Side effects over the course of Acthar Gel therapy included fatigue, myalgia, hyperglycemia, and weight gain.

Conclusions: Long-term treatment with H.P. Acthar Gel may help meet an important treatment need in patients with treatment-resistant and frequently-relapsing mM.

Outcome of Steroid Dependent (SDNS) and Frequent Relapsing Nephrotic Syndrome (FRNS) in Children

Isabel Robert, Shefali Vyas, Children’s Kidney Center, Saint Barnabas Medical Center, Livingston, NJ.

Background: Management of SDNS and FRNS in children can be frustrating. With the goal of minimizing steroid toxicity while achieving a sustained remission multiple regimens have been used with variable results. We reviewed our cases of SDNS/FRNS who had kidney biopsy (Rx) after failing MFM, for the past 12 yrs.

Methods: Charts of children with Rx due to SDNS or FRNS (after failure of MFM) were reviewed. Congenital and secondary causes of NS were excluded. Demographics, medications, side effects and response to therapy were studied. IV cytotoxin (CYP) was considered in non-FSGS cases with suspected non-adherence (400 mg/m2/dose monthly.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

934A
x 3). Others received tacrolimus (TAC) (0.1 mg/kg BID; trough up to 6 ng/mL). Rituximab (750 mg/m2 x 2 doses IV) was given if child became TAC dependent or resistant. Response to therapy was classified as: complete remission (CR), partial remission (PR), infrequent relapse (IR) (<2/yr), failure (F).

Results: 32 children had kidney biopsy (Bx) for primary SDND/FRNS. 14 females; 14.4 yrs, 6 AA, 6 other race. Age at presentation: 2-14 yrs (median = 3 yrs). Bx: 15 MCNS (4 diagnosed later with FSGS), 9 IgMN, 5 FSGS, 3 C1QN, 1 idiopathic immune mediated GN. All children had normal GFR at the time of the bx. 24 children received TAC; 21 CR (13 became TAC dependent with IR), 2 PR, 1 F. 15 received CYP: 6 CR, 9 F (5 diagnosed later with MCNS but bx had FSGS), 7 received rituximab: all had CR (5 IR). The rates of CR were significantly higher for TAC (87.5%) and rituximab (100%) as CYP had a failure rate 60% (p<0.01), including 4 cases with MCNS. However, those who had CR from CYP didn’t have further relapses. Rate of IR among those who initially had CR was similar between rituximab and TAC. Follow-up time: 2-12 yrs, including 6 discharged due to stable CR and 3 ESRD (all with FSGS). Side effects: 4 AKI with TAC (reversible), 2 respiratory distress/allergy in rituximab group (IV D/C). Late TAC resistance was seen in 3 patients.

Conclusions: Children with SDND/FRNS despite failure to respond to MMF had an excellent outcome. Some required sequential use of tacrolimus and rituximab after failure of CYP with a rate of CR/IR = 88% with minimal side effects.

Conclusions: This survey highlights the histopathological patterns of glomerular disease in southern Arizona. The data suggest regional and ethnic variations in glomerular disease that may suggest genetic or environmental influence in the pathogenesis of glomerular diseases.

PUB210

Use of Rituximab to Induce Remission in Frequently Relapsing Pediatric Nephrotic Patients Jason Peter Thomas, Teri L. Crumb, Alejandro Quiroga.

Results: Use of rituximab may be an effective agent for inducing remission for pediatric patients with frequently relapsing nephrotic syndrome (NS) with a reported 82% response rate. We evaluated the clinical response of pediatric nephrotic patients for induction of remission following one dose of rituximab.

Methods: This is an IRB approved, prospective clinical research trial. Informed consent was obtained from each family. Four pediatric patients with NS were enrolled prior to their clinically indicated rituximab infusion. Urine Protein/Creatinine ratio and albumin blood levels were collected.

Results: Urine Protein/Creatinine ratios obtained post infusion of rituximab decreased between 37-93% from pre infusion levels. 50% of patients identified had resolved edema noted on physical exam post infusion.

Conclusions: Rituximab may be an effective agent for inducing remission for pediatric patients with frequently relapsing nephrotic syndrome, warranting further investigation.

Results: There were 38 respondents to our survey: 12 rheumatologists and 26 nephrologists. Work setting: 81% academic, 19% non-academic. Management of abnormal UA findings in an asymptomatic lupus patient: 33% of rheumatologists versus 76% of nephrologists chose to biopsy. Induction regimen of ISN Class III LN: 79% of all providers chose MMF and 21% chose IV cyclophosphamide.

Results: There were 38 respondents to our survey: 12 rheumatologists and 26 nephrologists. Work setting: 81% academic, 19% non-academic. Management of abnormal UA findings in an asymptomatic lupus patient: 33% of rheumatologists versus 76% of nephrologists chose to biopsy. Induction regimen of ISN Class III LN: 79% of all providers chose MMF and 21% chose IV cyclophosphamide.
Maintenance regimen of ISN Class III LN: all surveyed rheumatologists chose MMF as a sole maintenance agent compared to 32% of nephrologists who elected the addition of low-dose corticosteroids to MMF. Choice of an adjunctive agent in refractory ISN Class IV LN: 68% of providers chose rituximab, 14% chose tacrolimus, 5% chose CTLA-4 IgG, and 14% elected not to add any agents listed.

Conclusions: The results of this survey suggest a significant difference among rheumatologists and nephrologists on the decision to perform initial kidney biopsy and management of ISN Class III LN. The results suggest that perception of side effect profiles play an important role in the choice of therapeutics. This study emphasizes the need for a multi-disciplinary approach toward renal disease in lupus patients. We continue to recruit subjects to complete this survey.

**Results:** Two groups- group which had immune deposits (group 1) and group with no immune deposits (group 2). A1: 9.5% patients (2 FSNGS, 2 MjLN, 1 MPGN) with initial partial remission maintained partial remission during the follow-up period from a minimum of 2 months up to 19 months post-Achater Gel treatment of treatment-resistant NS in clinical practice.

**Methods:** Nine cases of patients with partial remission (500-550 mg/d proteinuria) (≥50% reduction from baseline), 1 patient with clinical response (≥30% reduction without meeting remission criteria), and 1 patient with clinical response and ongoing treatment following initial prescription-based Achater Gel treatment for NS, and who had follow-up clinical care, were included. Medical charts were reviewed for proteinuria levels. Follow-up ranged from 2 to 19 months.

**Results:** Biopsy-confirmed NS etiological diagnoses included focal segmental glomerulosclerosis (FSGS, n=3), membranous lupus nephritis (MLN, class V, n=2), membranoproliferative glomerulonephritis (MPGN, n=1), and diabetic nephropathy (DN, n=1). 5.5 patients (2 FSNGS, 2 MjLN, 1 MPGN) with initial partial remission maintained partial remission during the follow-up period from a minimum of 2 months up to 19 months post-Achater Gel treatment. The patient with MPGN and 1 with FSNGS showed increased proteinuria with relapse at 12 months and 19 months post-treatment, respectively. The patient with DN received ongoing Achater Gel treatment and maintained a proteinuria clinical response during the 11-month follow-up period. The patient reported fatigue but did not require cessation of Achater Gel treatment. The patient with FSNGS who showed an initial clinical response had further improved proteinuria at 2 months post-Achater Gel treatment and showed partial remission at 12 months post-therapy without intervening immunosuppressive medications.

**Conclusions:** These follow-up proteinuria outcomes in 7 patients treated with H.P. Achater Gel® for varied etiology NS suggest the proteinuria treatment response can be maintained long-term in some patients during treatment and beyond treatment cessation.

**Results:** A fifty year old male presented with increasing weight loss, night sweats and shortness of breath of 3 months duration. Additionally he noted some swelling of his lower limbs and frothy urine. He was extensively investigated with urinalysis, blood tests, imaging and histopathology till a novel diagnosis was made. The patient was found to have rheumatoid arthritis with subclinical inflammatory bowel disease (IBD) and was promptly started on infliximab 5 mg/kg IV, with subsequent improvement. The patient was maintained on infliximab for 18 months with complete remission and eventual remission of IBD. Unfortunately, he has been found to relapse when an attempt at a steroid wean was made and is thus maintained on a low dose of prednisone.

**Results:** We describe a novel pulmonary-renal syndrome and provide an approach to its investigation and management. This case opens the way for further research into eosinophilic pulmonary-renal syndromes.

**Results:** In this study, 25 patients with IMN with heavy proteinuria defined as ≥ 6 g/day were evaluated for the effect of a partial remission (50% reduction in baseline proteinuria to ≤ 3 g/day and ≥ 25% increase in baseline creatinine) and complete remission (creatinemia ≤ 0.5 g/d and serum creatinine ≤123 µmol/l) on renal outcomes compared with patients who did not attain a remission. Worse renal outcomes was defined as doubling of creatinine mg/dl and shortness of breath of 3 months duration. Additionally he noted some swelling of his lower limbs and frothy urine. He was extensively investigated with urinalysis, blood tests, imaging and histopathology till a novel diagnosis was made.

**Results:** These are patients who might benefit from plasmapheresis in addition to standard treatment.

**Results:** Eosinophilic pulmonary renal syndromes are well established and can be either vasculitic or infectious in aetiology. We describe a novel case of a patient whose presentation could not be fitted into either category.

**Results:** These are patients who might benefit from plasmapheresis in addition to standard treatment.
Comparison of Short- and Long-Term IgA Nephropathy Clinical Remission Rates Between Tonsillectomy plus Consecutive and Intermittent Steroid Pulse Therapies

Background: Tonsillectomy (Tx) plus steroid pulse therapy (TSP) is widely performed across Japan for clinical remission (CR) of IgA nephropathy (IgAN) but treatment protocol lacks consensus. We used both TSP (methylprednisolone 0.5 g/day iv for 3 days*) thrice/3 consecutive weeks (TSP-C) and intermittent pulse (* thrice/5 high-power field. Oral prednisolone (oPSL) between pulse therapies began at 0.5 mg/kg on alternate days. After the third pulse, oPSL was tapered over 1 and 0.5 years in TSP-C and TSP groups, respectively. Tx was performed before or during steroid therapies. We compared the effects of two regimens for CR.

Methods: This is a retrospective cohort study of 169 patients newly diagnosed with IgAN during January 2007 to December 2013 in our institute. We enrolled 90 patients we could follow-up after oPSL cessation and compared short- and long-term CR rates in both groups.

Results: Before treatments, there were no significant clinical [TSP-C (n = 57) vs. TPS-I (n = 33); age, 31.0 ± 11.2 vs. 34.0 ± 11.9 years; male/female, 17/40 vs. 12/21; eGFR, 82.2 ± 29.9 vs. 77.4 ± 28.7 ml/min; blood pressure, 121 ± 17.7/12 ± 12 vs. 120 ± 17.7/6 ± 13 mmHg; urinary protein, 0.41 (0.18, 1.19) vs. 0.79 (0.20, 1.08) g/lc; and positive occult blood, 91.2 vs. 90.9%) and histological grade stratification differences between the groups. At oPSEL cessation, short-term CR rates were equivalent between the groups (TSP-C vs. TPS-I: 68.4 vs. 61.0%). Long-term CR rates at 1, 2, and 3 years after oPSEL cessation were equivalent between the groups (TSP-C vs. TPS-I: 1 year, 64.1 (n = 39) vs. 59.1 (n = 22); 2 years, 64.0 (n = 25) vs. 80.0% (n = 10); 3 years, 73.7 (n = 19) vs. 66.7% (n = 6)). CR continuation rates by Kaplan–Meier method also revealed no significant differences between the groups.

Conclusions: Tx plus other consecutive or intermittent steroid pulse therapies may be equally beneficial for short- and long-term IgAN CR. IgAN patients can flexibly choose therapies.

Clinical Characteristics of Multiple Myeloma Patients Diagnosed by Nephrologist Byoung Geun Han, Jae seok Kim, Hyeon-Chool Park, Shinhdan Song, Jae Won Yang, Seung-Ok Choi. Internal Medicine, Yonsei Wonju College of Medicine, Wonju, Korea.

Background: Early diagnosis of multiple myeloma (MM) that is in early phase or has atypical presentation may be difficult. Even though MM is a hematologic malignancy, clinicians in different departments can make a diagnosis with a suspicious eye. In our department, we routinely performed protein electrophoresis in the patients with renal failure for the early diagnosis of MM.

Methods: We reviewed the medical records of 151 patients and examined the data of 117 patients diagnosed with MM in our hospital between January, 2003 and December, 2014. The patients were divided into three groups: group I presented to nephrologist prior to diagnosis (n=31), group II presented to hemato-oncologist directly (n=53), and group III presented to the other departments of our institute. The age, sex, initial symptoms, hematologic and biochemical parameters, and survival data were retrospectively analyzed.

Results: The main findings were anemia (n=30), renal failure (n=25), back pain (n=17), paraproteinemia (n=10), rib pain (n=7), mass (n=7), deficit (n=5), infection (n=4), bleeding (n=3), etc. Osteolytic bone lesion, survival rate, % of plasma cell in bone marrow study, Hb, platelet, CRP, serum albumin and calcium were not significantly different between three groups. 24 hours urine study (amount of proteinuria, plasma cell in bone marrow study, Hb, platelet, CRP, serum albumin and calcium were not significantly different between three groups. Complete remission defined as stable or improved renal function with final proteinuria of <500 mg/day; partial remission as stable or improved renal function with ≤50% reduction in proteinuria and final proteinuria 500 to 3500 mg/day. Failure to meet this criteria was classified as treatment failure.

Conclusions: In a substantial amount of newly diagnosed AA V patients, screening for AA V patients and to identify differences between hospital departments.

Methods: Retrospective case series of 7 Adults patients with nephrotic syndrome, treated with ACTH gel. Data was gathered by chart review, from the clinic EMR and paper based records. ACTH was given in the form of ACTHAR gel 80 USP units/ml SC twice a week for 6 months. Complete remission defined as stable or improved renal function with final proteinuria of <500 mg/day; partial remission as stable or improved renal function with ≤50% reduction in proteinuria and final proteinuria 500 to 3500 mg/day. Failure to meet this criteria was classified as treatment failure.

Conclusion: ACTH is a promising treatment for the nephrotic syndrome, associated with significant improvement in clinical status and relatively few adverse effects. We present our experience using natural ACTH gel for nephrotic syndrome in patients with diverse diagnosis.

Screening for Renal Involvement in Newly Diagnosed ANCA-Associated Vasculitis Patients in Clinical Practice – Differences Between Hospital Departments Eline Houben, Willem A. Bax, Bastiaan Van Dam, Valentina A. Sliker, Gideon Verhave, Fenneke C.P. Frerichs, Erik Lars Penne. Dept of Nephrology, MCA-Gemini Group, Alkmaar, Netherlands; Laboratory of Clinical Chemistry, Hematology and Immunology, MCA-Gemini Group, Alkmaar, Netherlands.

Background: Kidney involvement occurs in a majority of ANCA-associated vasculitis (AAV) patients and requires early and aggressive immunosuppressive therapy. The aim of the present study was to evaluate screening procedures for renal involvement in newly diagnosed AAV patients and to identify differences between hospital departments.

Methods: All AAV patients with a positive ANCA (PR3 and/or MPO) between 2005 and 2015 in a secondary care hospital in the Netherlands were included. Patient demographic data and the department making the diagnosis were recorded, as well as whether or not a complete screening for renal involvement had been made. The latter was defined as assessment of serum creatinine, analysis for erythrocyturia and proteinuria within two weeks before or after the diagnosis AAV.

Results: We included 110 newly diagnosed AAV patients (age 62±14 years; mean±SD; 63% male). 81 patients (68%) had renal involvement (defined as: rise in creatinine >30%, >10 RBC/hpf and/or proteinuria ≥500mg/24h). Complete screening was performed in 90 patients (82%), depending on department: Nephrology 100% (21 of 21), Internal Medicine 88% (29 of 33), Pulmonology 68% (15 of 22), Ear Nose Throat 62% (8 of 13), other departments 81% (17 of 21). Of the 20 patients with incomplete screening, assessment of proteinuria was missing in 100% (20 of 20), erythrocyturia in 55% (11 of 20) and serum creatinine in 5% (1 of 20). Serum creatinine was higher in patients with complete renal screening (72 versus 109 μmol/l, p=0.1). Screening was completed within 2 months (n=12), 4 years (n=3), or never (n=5). One patient was found to have erythrocyturia 6 weeks after the diagnosis, but had not been treated accordingly.

Conclusions: In a substantial amount of newly diagnosed AAV patients, screening for renal involvement was incomplete, especially in patients with a normal creatinine level outside the renal department. Incomplete screening may have led to suboptimal treatment in some patients.
Conclusions: ACTH gel is an effective therapy in patients with nephrotic syndrome, as significant reductions in proteinuria were seen in the majority of patients, it was not only patients with nephrotic syndrome who responded to treatment with ACTH but also patients who were nephrotic due to other diagnosis such as IgA nephropathy; this data highlights a need of further studies on natural ACTH gel in the treatment of nephrotic syndrome.

PUB220

Efficacy of Rituximab in Severe Lupus Nephritis in Children: A Case Series
Julien Hogan, Véronique Baudouin, Georges Deschenes. Pediatric Nephrology, Robert Debre Hospital, Paris, France.

Background: The association of cyclophosphamide or Mycophenolate Mofetil (MMF) with prednisolone is the treatment of reference of lupus nephritis(LN), both in adults and children but is associated with major side effects. Rituximab (RTX) failed to demonstrate an improvement of patient outcome when associate with MMF and prednisolone. However, recent data suggest that it might allow to spare prednisolone. We report our experience of the use of RTX in first LN flare in children.

Methods: We included patients treated by RTX for a first flare of LN class III to V between 2006 and 2014. Treatment associated methylprednisolone (500mg/m2) was followed by RTX (1000mg/1.73m2) at day one and 15 and MMF 1200mg/m2/day. Tapered down and withdrawal of prednisolone was left to each physician appreciation. Complete remission (CR) was defined as a proteinuria over creatinine ratio (Pu/creat) <50mg/mmol and normal serum creatinine and partial remission (PR) as a Pu/creat<300mg/mmol and no relapse within 1 year renal and 4 years disease free. Significant association of cFLCs with pathologic classification was observed.

Results: Between July 2003 and December 2013, 48 patients were diagnosed with biopsy-proven LN. Among 48 patients, 13 had IgA nephropathy, 19 had LN secondary to SLE, 12 had LN secondary to Henoch-Schönlein Purpura, and 4 had LN secondary to other immune diseases. CR was achieved in 11 (22.9%) patients, PR in 31 (64.6%) and 6 (12.5%) had failure to achieve remission and relapses were associated with poor renal outcomes in SLE patients.

Conclusions: Although the proportion of ANCA negative pNCGN was not high in our study population, poor 1-year renal survival was noted among these patients. We believe that particular caution should be exercised while treating ANCA negative pNCGN.

PUB222

Clinical Implication of Serum Free Light Chain in Patients with IgA Nephropathy
Woo Jin Jung,1 Sang Heon Song,1 Su Min Park,1 Jong Man Park,1 Il Young Kim,1 Dong Won Lee,1 Soo Bong Lee,1 Harin Rhee,1 Eun Young Seong,2 Ihm Soo Kwak,1 Min Jung Kim,1 Joo Hui Kim.1 1Dept of Internal Medicine, Pusan National Univ School of Medicine, Busan, Republic of Korea; 2Dept of Internal Medicine, Pusan National Univ School of Medicine, Busan, Yansung, Republic of Korea.

Background: Free light chains (FLCs) are produced in excess during immunoglobulin synthesis by plasma cells and other cells of the B-cell lineage. Recent studies demonstrated that elevated polyclonal FLCs are associated with increased mortality in chronic kidneys disease. But little is known about the clinical implication of FLCs in patients with IgA nephropathy which is caused by the overproduction of an aberrant form of IgA1 and the activation of B-cells responding to mucosal infection. Therefore, we investigated the relationship between the serum levels of combined FLCs (cFLCs) and prognostic markers in IgA nephropathy.

Methods: This retrospective study analyzed consecutive 42 patients with biopsy-proven IgA nephropathy without renal function impairment (estimated glomerular filtration rate (eGFR) >60 ml/min/1.73 m2) at the Pusan National University Hospital from January 2010 to December 2013. cFLCs was defined as a sum of kappa and lambda FLCs and clinical and laboratory data were collected by medical records reviewing.

Results: The mean (SD) age were 41.4 (14.9) years and the median (inter-quartile range) of cFLC and urinary protein-to-creatinine ratio (uPCR) were 40.5 (32.6 – 47.8) mg/L and 666.3 (364.8 – 1306), respectively. In correlation analyses, log-transformed cFLCs was positively related to age, serum cystatin C, IgG and log-transformed uPCR, and negatively associated with serum albumin and hemoglobin levels. In multivariate regression models, increased cFLCs was significantly associated with higher log-transformed uPCR (R2=0.042, p=0.045) after adjusting confounding factors. However, no significant association of FLCs with pathologic classification was observed.

Conclusions: We found a significantly higher level of cFLCs in patients with IgA nephropathy. Further longitudinal studies are needed to clarify the role of cFLCs as a prognostic maker in IgA nephropathy.

PUB223

Long Term Renal Outcomes in Lupus Nephritis in a Multi-Racial Asian Population: A Retrospective Study
Hui Zhan Tan, Cynthia Ciwei Lim, Jason Choo Chon Jun, Chan Choong Meng. Dept of Renal Medicine, Singapore General Hospital, Singapore, Singapore.

Background: Lupus nephritis causes significant morbidity with racial predilection affecting prognosis and treatment responses. We aimed to evaluate risk factors for progressive CKD in lupus nephritis (LN) in a multi-racial Southeast Asian population.

Methods: We retrospectively reviewed 113 consecutive patients with newly diagnosed biopsy-proven LN diagnosed between 10 May 2001 to 30 May 2009. Demographics, indices of renal function and disease activity, histopathologic data and pharmacotherapy were evaluated. Primary endpoint was progressive chronic kidney disease (CKD) defined by doubling of serum creatinine or end stage renal failure.

Results: Median age was 41.6 (IQR 29.2, 51.6) years, predominantly Chinese (76.1%) and female (81.4%). Twelve patients (10.6%) had Class I or II LN, 13 (11.5%) Class III LN, 62 (54.9%) Class IV LN and 25 (22.1%) isolated Class V LN. Eight patients (7.1%) had mixed proliferative and membranous LN. Most patients received either angiotensin converting enzyme (ACE) inhibitors or angiotensin II receptor blocker (100 patients, 88.5%). Induction immunosuppressants included glucocorticosteroids in 109 patients (96.5%), cyclophosphamide 26 (23.0%), mycophenolate mofetil or mycophenolate sodium 91 (81.5%), cyclosporine 9 (8.0%), and azathioprine 14 (12.4%). Median follow up was 79.0 (61.5, 104.0) months. One hundred and eight patients (95.6%) achieved remission, with complete remission in 89 patients. Among patients who achieved remission, 61 patients had disease relapse. Thirteen patients had progressive CKD at last clinic visit, with ESRD occurring in 5 patients at median 12.0 (1.0, 59.5) months from biopsy. Patients with progressive CKD tended to be non-Chinese (53.8% vs. 20.0%, p=0.01), with higher serum complement levels [median C3 0.66 (IQR 0.48, 0.87) vs. 0.38 (0.29, 0.60), p=0.04 and C4 0.17 (0.12, 0.22) vs. 0.06 (0.05, 0.12), p=0.004], fewer remissions (69.2% vs. 99.0%, p<0.001) and more relapses (100% vs. 52.5%, p=0.005).

Conclusions: In this multi-racial Asian cohort, race, higher serum complement levels, failure to achieve remission and relapses were associated with poor renal outcomes in lupus nephritis.
The Clinical Predictors for Outcome of Antineutrophil Cytoplasmic Autoantibody-Associated Vasculitis Patients with Renal Involvement
Pr Lej, Guisen Li, Li Wang, Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chengdu, Sichuan, China.

Background: Primary anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is chronic multisystem autoimmune diseases and result in dysfunctions of multi-system. Renal involvement is the most common manifestation and is closely associated with the outcome of patients with vasculitis. We investigated the clinical determinants of the early mortality of patients with vasculitis-related renal injury followed up 2 years in a single west Chinese center to study the factors associated with patient outcome.

Methods: A total of 123 consecutive patients with AAV-related renal injury diagnosed in our center were recruited and in our study data were collected retrospectively. All the patients were followed up for 2 years after diagnosis. The predictive variables of values associated with mortality were analyzed.

Results: During 2 years follow up duration, 54 (43.9%) died, of whom 41 died within the first year after diagnosis. Compared with surviving patients, the deceased patients had higher BVAS scores and higher incidence of pulmonary hemorrhage. They also had higher serum creatinine and ESR, lower hemoglobin and complement C3, more patients accepting renal replacement therapy than surviving patients during hospitalization. Higher BVAS scores and serum creatinine–400μmol/L were the predictors of death in patients with AAV-related renal injury independently.

Conclusions: the incidence of early mortality in patients with AAV-related renal injury was higher. Prudent monitoring and therapy should be given to patients with active vasculitis and serious renal dysfunction to reduce adverse events.

Significance of Resistive Index in Renal Arterial Ultrasonography as a Clinical Parameter for Tubulo-Interstitial Nephropathy
Mimori Hatano,1 Kazumi Takayama,1,2 Taisuke Shimizu,1 Hiroaki Hara,1 Nobuyuki Onizawa,1 Koki Ogawa,1 Yuka Tanaka,1 Kunihiko Yasuda,1 Tomonari Ogawa,1 Akihiko Matsuda,1 Hajime Hasegawa.1 'Nephrology and Hypertension, Saitama Medical Center, Saitama Medical Univ, Kawagoe, Saitama, Japan; 2Ishikawa Kinokai Kawagoe Ekimae Clinic, Kawagoe, Saitama, Japan.

Background: Renal arterial ultrasonography (RA-US) has been principally applied to evaluate the stenosis of the renal artery and the indication of catheter intervention by the measurement of peak systolic velocity (PSV). Resistive index (RI) is calculated as PSV/EDV, where EDV indicates end-diastolic velocity, and is reported to be related to the renal function. In this study, we aimed to investigate the possible clinical benefit of RI for the assessment of tubulo-interstitial nephropathy (TIN).

Methods: We studied 51 patients (51:62.3 years old) who underwent RA-US and sufficient laboratory tests for the analysis in the past 10 years in our hospital. PSV and RI were measured at both main renal arteries (RA-measurement) and intra-renal arteries roughly corresponding to the interlobular arteries (IRA-measurement). NAG index (urine excretion ratio of N-acetylglucosaminidase (NAG) to creatinine) was used as a conventional clinical parameter for the assessment of TIN.

Results: Stratified analysis by median value of RI (0.69) showed significant difference in eGFR in the RA-measurement (43.4±4.7 vs 60.3±4.2), but not in the IAR-measurement. In contrast, the analysis showed significant difference in NAG index in IRA-measurement (median: 11.6 vs 5.4), but not in RA-measurement. When the patients showing NAG index ≥ 15, indicating advanced renal insufficiency, would be excluded from the analysis, NAG index significantly correlated with RI of IRA-measurement (R=0.50, p<0.05), but not RA-measurement. In addition, ROC analysis revealed that the cut-off value of RI to NAG index was 0.65.

Conclusions: In addition to the previous report showing the relevance of RI to the histological severity, the present study demonstrated the correlation of RI with the conventional parameter of TIN, NAG index. Particularly, for the assessment of TIN, RI value measured at intra-renal artery would be more beneficial.

Recovery of Renal Function with Eculizumab in a Girl with Dense Deposit Disease and Normal Soluble C5b-9 Levels
Marianne Linhof,1 Arjan Diepstra,2 Marc Maj Seelen,1 Coen A. Stegeman,1 Valentina Grachi.1 'Pediatrics, UMCG, Groningen, Netherlands; 2Pathology, UMCG, Netherlands; 3Nephrology, UMCG, Netherlands.

Background: Dense Deposit Disease (DDD) is a rare glomerulopathy characterized by electron-dense deposits in the glomerular basement membrane (GBM) and glomerular complement deposition. 50% of patients progress to ESRD and have recurrences after kidney transplantation. Dysregulation of the alternative complement pathway plays a key role in the pathogenesis. Increased soluble C5b-9 in blood is considered to predict response to eculizumab, an anti-C5 monoclonal antibody.

Methods: We report the case of a previously healthy 15-year-old girl who presented with acute kidney injury, hypertension, nephrotic syndrome (10.8 gr protein /24 hours) and microscopic hematuria.

Results: Biochemical (C3 &4, C5b-9, factors H & I, C3 nephritic factor and anti-FH) and genetic workup of the complement system (CFI, CFB, C3 and MCP) showed normal results, except for a slightly increased C3d and a risk allele in the CFH gene. Renal biopsy showed cellular crescents and electron-dense deposits in the GBM. Glomerular C3 and C5b-9 immunofluorescence staining was positive. Despite escalating therapy, including methylprednisolone pulses followed by oral prednisolone, cyclophosphamide and plasma exchange (PE), the renal function further deteriorated and hemodialysis was started. Eculizumab was administered. This led to a rapid improvement of renal function (discontinuation of dialysis and increase of endogenous creatinine clearance from 11 to 53 ml/min/1.73m2). Three months later the girl is in a good clinical condition but proteinuria is still in the nephrotic range (3.6 gr/24 hours). Treatment with eculizumab is ongoing. Up to now no side effects have been observed.
Conclusions: Manifestations of IgAN vary widely. The mainstay of therapy consists of supportive measures, which the majority of our cohort received. Immunosuppressive regimens are reserved for a select group, and in our cohort both mycophenolate and steroid based regimens yielded a reduction in proteinuria.

Effect of Rituximab on Immunoglobulin Levels and Infection Risk in ANCA Associated Vasculitis

Shivani Shah,1 M-Hatifur Rahman,2 Duvuru Geetha.1
1Div of Nephrology, Dept of Medicine, Johns Hopkins Hospital, Baltimore, MD; 2Bloomberg School of Public Health, Johns Hopkins Univ, Baltimore, MD.

Background: Rituximab (RTX), a B cell depleting anti-CD20 monoclonal antibody, is approved for treatment of ANCA associated vasculitis (AAV). Low immunoglobulin (Ig) levels are a consequence of RTX treatment. The association between the degree of Ig deficiency and infection risk is unclear in AAV patients.

Methods: AAV patients treated with RTX in a single center with available serum Ig measurements were included. The rates and types of infection after RTX administration were correlated with Ig level using correlation matrix and logistic regression analysis.

Results: Our cohort of 27 patients had a median age of 68 years, eight males, 15 GPA patients, and 17 with a new diagnosis of AAV. Twenty five received four doses of RTX 375 mg/m² weekly and two received RTX 1000 mg biweekly for two doses. Nine received concomitant cyclophosphamide. Twenty three patients had low serum IgG levels (<751 mg/dL) greater than one month following RTX treatment. Ten out of these 23 developed infections over the median follow up time of 338 days. Pneumonia was the most common infection. The odds of having an infection with IgG level ≤500 mg/dL is 3 times higher than with IgG level between 501-750 mg/dL, though p = 0.26. There is a significant association between infection and IgM level ≤20 mg/dL (p = 0.047).

Conclusions: Severely low Ig levels due to RTX therapy may increase the risk of infection in AAV patients, and these patients may benefit from IVIG therapy. Further investigation is warranted given our study is limited by small sample size, concomitant cyclophosphamide use, and variable timing of Ig measurement.

Lipoprotein Glomerulopathy

Hostensia M. Beng, Basema I. Dibas, Hsiao Ling Lai, Guillermo Hidalgo. Pediatrics, ECU, Greenville, NC.

Background: Lipoprotein glomerulopathy has been associated with mutations in the Apolipoprotein E (APOE) gene. The average age of reported cases is 32 years and the youngest patient described to date is 4 yrs old. Here we present the first case of a 3 years old AA male with right hemihypertrophy, malignant hypertension, severe proteinuria & lipoprotein glomerulopathy, with a heterozygous mutation on APOE gene.

Methods: 3 year old African American male presented to pediatrician complaining of hemihypertrophy, short stature, polydipsia & hypertension. Physical examination remarkable for right leg soft tissue hemihypertrophy. Echocardiogram revealed left ventricular hypertrophy likely secondary to chronic hypertension. Hypertension and proteinuria persisted despite adequate treatment. Renal US showed persistent echogenic kidneys. Kidney biopsy showed Lipid vacuolization of podocytes, endothelial cells, tubular epithelial cells, and glomerular capillary lumens. Labs & imaging studies AFP and abdominal US have been normal with exception of proteinuria and increased lipid profile. Patient currently on a trial treatment with fibrin acid and dietary modification.

Results: The case is the first in all monocyte subpopulations: classical (CD14++CD16-CCR2highCXCR1-), intermediate type 1 (CD14++CD16+CCR2highCXCR1-) and intermediate type 2 (CD14+CD16+CCR2lowCXCR1high). This was the case in all monocyte subpopulations: classical (CD14++CD16-CCR2highCXCR1-), intermediate type 1 (CD14++CD16+CCR2highCXCR1-) and intermediate type 2 (CD14+CD16+CCR2lowCXCR1high).

Conclusions: Toll like receptors seem to be down regulated in monocytes of patients with primary untreated glomerulonephritis during the active phase. The pathophysiological significance of these findings is unclear and remains to be elucidated.

Proliferative Lupus Nephritis (LN) – 60 Month Evolution of an Argentinian Cohort

Gabriel Pedro Alvarez, Marcelo Alejandro De Rosa, Luis Alberto Tobasc.1 Hospital San Martin. La Plata, Buenos Aires; 2Univ of Buenos Aires, Argentina.

Background: Remission of proteinuria predicts good evolution in many glomerular diseases; we describe the behavior of the proteinuria, renal function and flare up in a group of patients with proliferative LN in a 60 month period.
Methods: Data from 55 patients were obtained. Proteinuria and Creatinine were shown at 0 time of the biopsy, 6 and 60 months; renal biopsies were classified using ISN-RPS 2003. All patients received an induction with at least 6 gr. of cyclophosphamide plus prednisone and a maintenance treatment with sodium mycophenolate 1440 mg/d and low doses of prednisone for at least 5 years. Flares was considered in case of 50% proteinuria increase or an acute urinary sediment.

Results: Results are in table

A Case Study Comparing Cyclophosphamide plus Methylprednisolone versus Cyclophosphamide Alone in Idiopathic Membranous Nephropathy

Basel Jaafar Alhayki, Dept of Nephrology and Renal Transplant, Salamania Medical Complex, Manama, Bahrain.

Background: In the treatment of high risk idiopathic membranous nephropathy the modified Ponticelli protocol with the use of alternative month Cyclophosphamide and steroids is the most used treatment protocol. The scientiffic bases for the use of intermittent alternating month Cyclophosphamide and Methylprednisolone versus Cyclophosphamide alone in the treatment protocol is not well established and in many studies showed that steroid alone has limited role in the treatment of idiopathic membranous nephropathy. Weather this intermittent use of Cyclophosphamide and Methylprednisolone lead to a fluctuating response to therapy and prolong the recovery or not need to be investigated.

Methods: This is a case study of a 26 years old male with idiopathic membranous nephropathy and a positive AntiPLA2R antibody who needed to be started on Modified Ponticelli protocol with alternative month Cyclophosphamide and Methylprednisolone for his persistent massive Proteinuria of 16 gram per day and who failed cyclosporine in the past. Initially the patient was given the six month the modified Ponticelli protocol but he failed to reach a complete or a partial remission with persistent Proteinuria of more than 6 gram per day and high Anti-PLA2R antibody titer and later he was given an extra three months of Cyclophosphamide alone.

Results: There was a fluctuating antibody titer during the course of therapy with increase Anti-PLA2R antibody titer at the end of the Methylprednisolone month and reduce level after the months of Cyclophosphamide use. After the start of the extra three months of continues Cyclophosphamide the anti-PLA2R antibody titer was reducing in each month and at the end of the extra three months it disappeared completely with a remission of the Proteinuria.

Conclusions: This case shows that the use of Cyclophosphamide is more effective in the treatment of idiopathic membranous nephropathy than Methylprednisolone and it might provide a better control of the disease activity. Future study to evaluate this with the use of novel biomarker like Anti-PLA2 R antibody is recommended.

Plasma Cytokines and Chemokines Profile in Patients with Systemic Lupus Erythematosus: Its Potential Use as Biomarkers of Kidney Damage

Gustavo Aroca Martinez, D Lisandro Pacheco, E Elkin Navarro Navarro, Y Irisy Diaz, T Henry J. Gonzalez torres, T Gloria Garavito, T Eduardo Egea bermejo, T Eduardo I. Navarro, T Lisneth Almendares, T Antonio De Jesus Iglesias-Gamarr, T Medicina, Univ Simon Bolivar, Carranquilla, Atlantico, Colombia; T Nephrology, Clínica de la Costa, Barranquilla, Atlantico, Colombia; T Medicine, Univ del Norte, Barranquilla, Atlantico, Colombia; T Medicine, Univ Nacional de Colombia, Bogotá DC, Cundinamarca, Colombia.

Background: Systemic lupus erythematosus is an autoimmune disease in which the innate and adaptive response plays a significant role, mainly mediated by cytokines. Lupus nephritis-LN is the most severe complication associated with SLE. Objective: To identify differential expression of cytokines profiles and circulating chemokines in plasma of SLE patients with different degrees of Caribbean region.

Acute Tubulo-Interstitial Nephritis (ATIN): Predicting Long Term Outcomes

**Acute Tubulo-Interstitial Nephritis (ATIN): Predicting Long Term Outcomes** Victoria C. Robins,1 Aravind Cherukuri,2 Padmini Prasad,1 Richard J. Baker.1 1SJHH; Pittsburgh.

**Background:** ATIN is a relatively common potentially reversible cause of acute kidney injury. It has become clear over the last 2 decades that the disease is not always reversible, particularly in the elderly. We present a large contemporary single centre retrospective series concentrating on factors that predict poor outcomes.

**Methods:** 62 cases retrospectively diagnosed histologically via pathology records as primarily ATIN were included. An experienced histopathologist, blinded to outcomes, graded biopsies according to the presence, absence and degree of 8 different parameters: Interstitial inflammation, tubulatr atrophy, eosinophilia, plasma cell infiltration, chronic vascular lesions, hyalinosis, granulomas + oedema. Patients were classified as a poor outcome if eGFR (4 variable MDRD) after 12 months was less than 30 ml/min/1.73 m² or they died.

**Results:** 62 patients with biopsy proven ATIN were identified. 15 had a poor outcome. Baseline demographics are presented in Table 1.

Aetiology was difficult to definitively ascertain but consisted of drug induced, infectious, sarcoid or jologens. Parameters significantly associated with poor outcomes include higher creatinine at presentation & 6 months, presence of granulomas and chronic vascular lesions on biopsy at diagnosis. The effect of steroid treatment was difficult to assess since most patients were treated at the outset.

**Conclusions:** ATIN usually carries a good prognosis but some patients experience poor outcomes. Poor renal function at diagnosis and the presence of granulomas and chronic vascular lesions are predictive of poorer outcomes.

Cotreatment of Olmesartan and Caterpillar Fungus Attenuate Albuminuria in Patients with Glomerulonephritis

**Cotreatment of Olmesartan and Caterpillar Fungus Attenuate Albuminuria in Patients with Glomerulonephritis** Hua Zhou, Ye Zhang, Ya Li, Hairong Tang, Congqong Jiao, Lining Wang. Nephrology Dept, 1st Hospital of China Medical Univ, Shenyang, China.

**Background:** Angiotensin II receptor blockers (ARBs) were demonstrated to reduce proteinuria since a decade ago. However, proteinuria still remains as the top of clinical symptoms in glomerulonephritis (GN). We aim to investigate the effect of cotreatment with olmesartan (Olm), an ARB and caterpillar fungus capsule (CF) on proteinuria.

**Methods:** 491 patients with GN were retrospectively studied. GN was diagnosed by positive ANCA with high titer in at least one specific serum sample from each patient. ANCA subtypes were determined in each patient. Descriptive and analytical epidemiological studies may improve our understanding of environmental influences on the disease. Seasonal variations in AAV have been previously described, mainly related to Wegener’s disease, showing an increased number of cases during the winter months. It has been hypothesized the infection could be the underlying factor for these observations. Our goal is to study seasonal variations of AAV diagnosed in the city of Barcelona.

**Results:** Of the 209 patients, 160 (76.5%) were MPO-positive, 28 (13.3%) were PR3 positive and 21 (10%) were ANCA negative. Regarding the onset of symptoms, we found a greater number of cases in the months of January, February and March, compared with the rest of the year. This data correlates positively with the higher incidence of symptoms in Barcelona between 2009 and 2013.

Seasonal Variations of Renal ANCA Associated Vasculitis

**Seasonal Variations of Renal ANCA Associated Vasculitis** Juliana Bordignon Drabig, Joan Torres, Xavier Fulladosa. Nefrologia, Hospital Univ de Bellvitge, Barcelona, Spain.

**Background:** Filling the gaps in the genetic research of etiological factors related with ANCA associated vasculitis (AAV) is a major challenge in the current investigation. Descriptive and analytical epidemiological studies may improve our understanding of environmental influences on the disease. Seasonal variations in AAV have been previously described, mainly related to Wegener’s disease, showing an increased number of cases during the winter months. It has been hypothesized the infection could be the underlying factor for these observations. Our goal is to study seasonal variations of AAV diagnosed in the city of Barcelona.

**Methods:** Our study included 209 AAV patients diagnosed between 2001 and 2013 in 5 different University Hospitals of Barcelona. We analyzed their medical records, including the date of diagnosis and the approximate date of the first symptoms in 194 patients. We have also analyzed data related to ANCA subtypes in each patient. Descriptive and analytical epidemiological studies may improve our understanding of environmental influences on the disease. Seasonal variations in AAV have been previously described, mainly related to Wegener’s disease, showing an increased number of cases during the winter months. It has been hypothesized the infection could be the underlying factor for these observations. Our goal is to study seasonal variations of AAV diagnosed in the city of Barcelona.

**Results:** Of the 209 patients, 160 (76.5%) were MPO-positive, 28 (13.3%) were PR3 positive and 21 (10%) were ANCA negative. Regarding the onset of symptoms, we found a greater number of cases in the months of January, February and March, compared with the rest of the year. This data correlates positively with the higher incidence of symptoms in Barcelona between 2009 and 2013.
Considering the date of diagnosis we found a greater number of cases in two periods of the year; the months of May, June and July, and the months of October, November and December.

Conclusions: In our population, predominantly ANCA-MPO-positive related vasculitis, we found a higher incidence of the disease in the winter months, being diagnosed more frequently in May, June and July or October, November and December. One potential environmental factor, influenza disease, may explain this finding.

PUB239

Background: This meta-analysis was performed to investigate the efficacy and safety of mycophenolate mofetil (MMF) in treating idiopathic nephrotic syndrome.

Methods: We searched MEDLINE, EMBASE, the Cochrane Library database, the Database for Chinese Technical Periodicals, Wanfang, Chinese National Knowledge Infrastructure and the Chinese Database of Biology and Medicine for randomized controlled trials compared MMF with the other immunosuppressive agents for the treatment of idiopathic nephrotic syndrome. Weighted mean difference (WMD) and summary estimates of relative risk (RR) reductions with 95% CIs were calculated.

Results: We identified 36 trials that included 2007 patients, mainly on membranous nephropathy (MN), focal segmental glomerulosclerosis (FSGS) and refractory nephrotic syndrome without clearly pathological diagnosis (RNS). Overall, MMF therapy showed lower level of serum albumin and higher rates of use of diuretics, renin-aldosterone system (RAS) inhibitors, and NSAIDs. Logistic-regression analysis showed that use of these drugs before presentation at our institution could predict the development of AKI (odds ratio, 2.8, 95% CI, 2.2 to 3.2). Furthermore, use of these drugs could determine the time to remission (Hazard ratio, 2.4, 95% CI, 1.8 to 3.0), as well as the initial serum creatinine. All cases were initially treated with steroid, and there was no difference in the time to remission between oral and parenteral administration of steroid.

Conclusions: There is a high incidence of AKI in adult-onset MCD. The use of several drugs such as diuretics could influence the onset of AKI and clinical course of MCD.

PUB241
Expression of HLA-G Molecule in Crescentic Glomerulonephritis and Its Clinical Significance  Guoqian Li, Li Wang. Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chengdu, Sichuan, China.

Background: In recent years, human leukocyte antigen-G (HLA-G) was found to be an important immune-regulatory molecular. Our purpose of this study is to assay the concentrations of serum soluble HLA-G (sHLA-G) in patients with CGN and to analyze its clinical significance.

Methods: 48 patients with CGN from 2009 to 2014 were involved in this study. The clinical data were collected, include demographic characteristics, laboratory parameters, pathological examinations, prognostic information and immunosuppressive therapy. Analyze if oliguria or anuria, serum creatinine levels, the crescent formation ratio and therapy would affect the prognosis of patients.22 patients with CGN, 15 patients with MCD, and 30 healthy adults in control group were enrolled with serum levels of sHLA-G measured by ELISA. The relationship between the clinical or pathological features and sHLA-G was studied and the value of the HLA-G in crescentic glomerulonephritis was analyzed.

Results: 3-years kidney survival rate was only 38% with one case of death. Cox regression analysis showed higher serum creatinine was associated with the patients with a poor prognosis(HR=4.04,95%CI:1.584-10.544, P=0.004). Serum level of sHLA-G in CGN was significantly higher than in healthy control(2198.8± 1924.17pg/ml vs.1311.86 ± 448.84pg/ml, P=0.046), while higher than in MCD, (2198.8± 1924.17 pg/ml vs. 1181.33 ± 320.10 pg/ml, P=0.023). Kaplan Meier survival analysis showed elevated levels of HLA-G was associated with poorer patients.

Conclusions: High serum creatinine level(>5mg/dl) at admission is an independent risk factor for the development to be ESRD. sHLA-G was significantly elevated in the serum of patients with CGN, and the level of sHLA-G had relationship with the prognosis of the patients with CGN. sHLA-G may be used as a new biomarker in CGN with clinical value in the early diagnosis and prognosis.

PUB242
A Treatment of Nutcracker Syndrome Leads to a Resolution of Unexplained Proteinuria  Badamkhund Batarkhuu, Raymond Raut, Winston Y. Shih, Panupong Lisawat. Nephrology and Hypertension, WCHN Danbury Hospital, Danbury, CT.

Background: The nutcracker syndrome is rare and can be a cause of unexplained proteinuria. We report a case of nutcracker syndrome related proteinuria and resolution of the proteinuria is observed after the enrapment was surgically corrected.

Methods: This is a 22-year-old male with a history of unexplained proteinuria since he was 17 years old. He has moved to a new location and presented to our clinic with proteinuria. The patient’s initial work up at an outside hospital revealed 1.4g proteinuria per 24 hours. A left kidney biopsy showed mesangial hypercellularity and preserved foot processes. The patient at that time was treated with prednisone, cyclosporine and lisinopril. His proteinuria decreased to 196 mg per 24 hours. Due to intolerance, lisinopril was stopped and urine protein subsequently rose. At the time of evaluation, the patient’s 24-hour urine protein was 700 mg and the autoimmune and infectious work up was negative. Upon reviewing the medical record from 2 years ago, he had inferior venacavagram as a part of the varicocele treatment. It showed compression of the left renal vein between the aorta and superior mesenteric artery. Nutcracker syndrome was suspected. Subsequently, he was referred to vascular surgery, and underwent an open recomstructive surgery. Postoperatively the patient remained off lisinopril and repeated 24 hour urine protein was 100 mg.

Conclusions: Nutcracker syndrome can cause significant proteinuria. Although it is rare, an early recognition could lead to a definitive treatment, help avoid unnecessary medications and invasive procedure such as a kidney biopsy.
Parvovirus B19 Immune Complex Glomerulonephritis
Beth Lynne Braunhut
Erika R. Bracamontes. Pathology, Univ of Arizona College of Medicine, Tucson, AZ.

Background: A 14 year old girl underwent a cadaveric renal transplant due to end-stage renal disease from obstructive uropathy and developed Parvovirus B19 viremia and graft dysfunction. Renal biopsy showed de novo immune complex glomerulonephritis with parvovirus B19 DNA detected in renal tissue by PCR. We herein review of B19-associated glomerulonephritis.

Methods: A search of the English-language medical literature was conducted. PubMed, Medline, and Google scholar were used. Adult and pediatric cases were included. Sources included case reports and series, including prior reviews. Articles were evaluated for description of demographics, clinical data, findings, laboratory data, and renal biopsy results.

Results: 67 cases were identified. 51 involved native kidneys and 16 transplants. 66 of 67 cases had serologic evidence of B19 infection (98.5%). B19 DNA testing by PCR of various samples was positive in 82.9% of cases. Biopsy results were reported in 52 cases. Of native cases, 92.3% reported a proliferative glomerulonephritis. Allografts most commonly showed TMA (66.7%). IF showed C3 in 84.4%, IgM in 68.8%, IgG in 62.5% and IgA in 40.6%. IF was negative in all transplant cases, save for our patient who showed IgG, IgM, C1q and C4d. EM results were reported in 24 cases with subendothelial deposits being most common (91.7%).

Conclusions: The findings in B19-associated glomerular disease are different in the native kidney versus transplant setting. In a native kidney, proliferative immune complex glomerulonephritis is most common. In the transplant setting, most cases showed TMA. The pathogenesis of this discrepancy remains unclear. To our knowledge, this is the first report of B19 immune complex glomerulonephritis in a renal transplant patient. Our patient showed findings more commonly seen in native-kidney B19 disease. We believe this discrepancy may be explained by insufficient immunosuppression in our patient, as evidenced by concurrent AMR. B19 infection in a transplant patient has practical implications. B19 glomerular disease represents a largely reversible form of renal injury. But, adverse outcomes have been reported. Management may require a balancing act with the risk of rejection on one hand and B19 disease on the other.

A Case of ANA-Negative Systemic Lupus Erythematosis
Ankur Shah, Rachel Criner, Jean Lee. *Internal Medicine, Temple Univ Hospital, Philadelphia, PA; †Nephrology, Temple Univ Hospital, Philadelphia, PA.

Background: Systemic Lupus Erythematosis is a chronic autoimmune disorder hallmarked by several autoantibodies targeting intracellular antigens. The most sensitive of these antibodies is the anti-nuclear antibody. Various studies show that this antibody is present in 95-98% of individuals with the disorder. As methodology improves, the incidence of ANA-negative Lupus has been decreasing.

Methods: We report a case of a 53 year old female whose known past medical history included only hypertension who presented to the outpatient clinic with arthralgias, pancytopenia, alopecia, proteinuria and skin rash whose labwork to this point included an elevated ESR of 115, negative ANA, neg HIV, Hep B, and Hep C serology. She was then lost to followup until presenting to the hospital with anisocoria and acute kidney injury. Her further workup confirmed a negative ANA but also revealed positive Anti-SSa, and anti-SSB antibodies. On serologic testing, the patient had circulating anti-anti-Phospholipid. Her C3 and C4 were decreased as low as 43 and 66 respectively. She had a renal biopsy performed revealing focal proliferative and membranous lupus nephritis, Class III/V. The patient was started on mycophenolate, plaquenil, and prednisone.

Conclusions: Once a byproduct of a technically variable laboratory test, the entity of ANA-negative Lupus has been decreasing in its frequency. The adoption of the human epithelial substrate has brought standardization to this assay and also increased its sensitivity. Nonetheless, the entity still exists, and has been described before. The majority of ANA- Negative Lupus cases will present with antibodies to cytoplasmic components – SSA or SSB, as did our case. ANA negative cases of SLE have been shown to have a decreased incidence of renal manifestations, with our case being an interesting exception. Our case serves as a reminder that the entity of systemic lupus erythematosis remains a clinical one, and that while the ACC criteria do include immunologic studies, the absence of the hallmark antibody does not rule out the disorder.

Patients with Combined Membranous Nephropathy and Focal Segmental Glomerulosclerosis Have Comparable Clinical and Autoantibody Profiles with Primary Membranous Nephropathy
Qiu-hua Gu, Zhao Cui, Jing Huang, Gang Liu, Minghui Zhao. Renal Div, Peking Univ First Hospital, Inst of Nephrology, Peking Univ, Beijing, China.

Background: Patients with combined membranous nephropathy (MN) and focal segmental glomerulosclerosis (FSGS) have been reported with different clinical significance. Investigation on the possible mechanisms of the combined glomerular lesions is necessary before treatments and better renal outcome during follow-up. These were comparable to the primary MN, but differed from the patients with primary FSGS. Among patients with combined lesions showed higher stages of MN, no cellular variant on FSGS classification and more common (100%) tubulointerstitial injury than both primary MN and primary FSGS patients. In the patients with combined lesions, 80% had circulating anti-PLA2R antibody and 68.4% had IgG4 predominant deposition in glomeruli, which were comparable to primary MN. No circulating antibody or IgG4 deposition was detected in primary FSGS patients. The patients with combined lesions had significantly lower urinary sPAR concentration, compared to the primary FSGS patients (315.6±302.0 vs. 691.3±1223.5pg/ umol, P=0.014), but similar to primary MN patients (275.7±253.4pg/umol).

Conclusions: We conclude that patients with combined MN and FSGS may share the same underlying pathogenesis with primary MN. The FSGS lesion might be secondary to primary MN.

Glomerulosclerosis Is Prevalent but Not Associated with Kidney Function in Healthy Japanese Elderly
Koiti Sato, Tsukasa Nagamuna, Daisuke Ichikawa, Sayuri Shirai, Yugo Shibagaki. Div of Nephrology and Hypertension, St. Marianna Univ, Kawasaki, Kanagawa, Japan.

Background: Previous western studies have shown that global glomerulosclerosis (GS) is common in healthy elderly but is not associated with kidney function. We here conducted a study to determine whether healthy Japanese elderly, whose glomerular filtration rate (GFR) is much lower than that of western counterparts, have also same relationship among kidney function and prevalence of GS.

Methods: We analyzed 81 kidney biopsy specimens from Japanese living donors obtained at donor nephrectomy between 2009 and 2014. Using the 2007 Banff classification system, GS, tubular atrophy (TA), interstitial fibrosis (IF), and arteriosclerosis (AS) on kidney samples were evaluated. Donor characteristics such as age, serum creatinine (SCr), C4-based estimated GFR (eGFR), proteinuria, and the prevalence of hypertension, were also evaluated. GS was expressed as a percentage of the standard deviation from the mean range (IQR). We performed univariate and multivariate analyses to identify the relationship between the parameters.

Results: Average age was 59.5 ± 9.1 years, male accounted for 38 (46.9%), with sCr 0.68 ± 0.15 mg/dl (eGFR 80.0 ± 12.9 ml/min/1.73m²), proteinuria 125.5 ± 61.0 mg/gCr, and hypertensive 28 (34.6%). Each kidney sample had the average of 16 glomeruli (IQR, 12 to 23) and 1 GS (IQR, 0 to 2), so the proportion of GS among total glomeruli was 0.25% (IQR, 0 to 1.43). The prevalence of any GS was 65.4%, any TA, 51.9%, IF greater than 5%, 48.1%, and any AS, 91.4%. Statistical analyses revealed that donor age was the only independent factor related to GS, and also to TA, IF, and AS. Among kidney biopsies of our 53 normotensive donors, 5 (9.4%) had more GS than the 95th percentile of the number of GS in western studies.

Conclusions: Although Japanese healthy adults had lower GFR and a higher number of GS than western counterparts, GS was still not associated with kidney function. Pathological significance of GS in otherwise healthy Japanese is not supported as in western counterparts.

241 Case of Monoclonal Gammopathy with Renal Biopsy Analysis
Yuqing Chen, Beini Lv, Yan Wang, Yu Xiaojuan, Ming Hui Zhao. Renal Division, Dept of Medicine, Peking Univ Frist Hospital, Beijing, China.

Background: Patients with monoclonal gammopathy can accompany various renal lesions related or un-related to the monoclonal gammopathy. We aim to describe the renal lesions with monoclonal gammopathy in china.

Methods: Data of renal biopsy and clinical presentation of patients with monoclonal gammopathy on serum and/or urine immunofixation electrophoresis in our center from 1999 to 2014 were collected.

Results: 241 patients met the inclusion criteria and were classified as renal disease related to multiple myeloma (MM) (n=18, 7.5%), monoclonal gammopathy of renal significance (MGRS) (n=85, 34.9%) and monoclonal gammopathy of undetermined significance (MGUS) (n=138, 57.4%). Among patients with MGRS, Amyloidosis (n=69, 28.6%) is the most common diagnosis, followed by Light Chain Deposition Disease (LCDD) (n=7, 2.9%), Cryoglobulinemic glomerulonephritis (n=6, 2.5%), and 56 cases (22.9%) received no further treatment. Among patients with MGUS, a variety of renal lesions were found, including membranoproliferative nephropathy (n=48, 20.2 %), IgA nephropathy (IgAN) (n=17, 7.05%), interstitial nephritis (n=13, 5.4%), membranous proliferative glomerulonephritis (MGN) (n=9, 3.3%) and so on.

Conclusions: We analyzed the data of mononclonal gammopathy with renal biopsy in china for the first time. A growing number of renal diseases were found to be associated with monoclonal gammopathy, MGUS is the most common diagnosis of patients with monoclonal gammopathy, while membranous nephropathy and IgAN are most common among MGUS.

Further work are in need to determine whether some MGUS are truly and intertemine or with renal significance and whether or not early treatment is in need for these patients.

Funding: Government Support - Non-U.S.
Stella. In Membranous Nephropathy angiopathy. Specific diagnosis and treatment. Kidney biopsy was always gold standard and a combination embolization. Because of this complication we waited start oral anticoagulant till 7 days we obtained rapidly recovery of diuresis that resulted in a progressive recovery of renal with plasma-exchange (total 4 sessions) with plasma sostitution and corticosteroids (500 and the biopsy result, suggestive of antiphospholipid syndrome (APS), we start treatment proliferative glomerulonephritis associated to thrombotic microangiopathy with sub positive LAC screening. Urinalysis showed microhaematuria and proteinuria 2.5 g/24 h, VES augmented, positive low title anti

Acute Renal Failure in Thrombotic Microangiopathy and C3 Glomerulopathy? Tiziana Stellato,1 Paolo Fabbrini,1 Sonia Sirtori,2 Andrea Stella,1,2 Dept of Nephrology, San Gerardo Hospital, Monza, Italy; Univ of Milano Bicocca, Milan, Italy.

Methods: RBC casts are important component of rapid and early diagnosis of RPGN. RBCs in a cast are almost always pathological and marker of acute glomerular injury. Our case represents an unusual finding of RBC casts in myeloblastic ATN. We purpose extensive renal glomerular injury secondary to severe rhabdomyolysis as possible etiological involvement such as acute renal failure associated with haematuria and proteinuria.

In conclusion, we present an unusual case of ANCA positive, ANA negative full house nephropathy. ANA negative lupus nephritis is very rare presentation that biopsy does not meet any other diagnostic criteria for SLE classification established by American Rheumatism Association. Our patient was 60- year-old woman with past medical history of only hypothyroidism, presented with new onset of acute kidney injury and hypertension. Laboratory data showed BUN and creatinine of 74mg/dl and 30.3mg/dl respectively, decreased complement C3 and C4, hypocomplementemia and nephrotic range proteinuria and hematuria. Serology tests including serum ANA, anti ds DNA, anti-smith and smooth muscle antibodies, anticoagulipin IgG and IgM titers, C1Q binding assay were negative. HIV, hepatitis B and C viruses serologies were negative too. C-ANCA (0.7 U) and P-ANCA (1.5U) were positive. Renal biopsy showed proliferative crescentic and membranous glomerulonephritis with a full house immuno-fluorescence pattern with extra-glomerular tubular basement deposits suggestive of Lupus like glomerulonephritis. Patient required hemodialysis for her renal failure and was treated with oral cyclophosphamide and corticosteroids. Seven months into treatment, patient still requires twice a week hemodialysis with only minimal recovery of renal function and has not yet experienced any clinical symptoms of SLE.

In conclusion, we report an unusual presentation of seronegative SLE diagnosed is a rare disease characterized by arteriolar and capillarly thrombosis with endothelial damage. Clinical manifestations include renal involvement such as proliferative membranous glomerulonephritis and proteinuria.

Pathological and Clinical Analysis of the Kidney Puncutation Biopsy in 1,551 Patients Mei Li,1 Qiong-li Yin,1 Zhenda Zheng,2 Cai-Lian Cheng,1 Xin Liu,1 Cheng-gang Shi,1 VIP Healthcare Center, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou;2 Cardiovascular Dept, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou; Nephrology Dept, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China.

Background: To summarize all the renal biopsy cases in the past ten years in the Third Affiliated Hospital of Sun Yat-sen University; analyze the pathological type distribution, and their relationship with clinical manifestations.

Methods: Pathological and clinical data in 1,551 cases with renal biopsy with complete clinical data were analyzed retrospectively from January 2005 to December 2014. Results: Among 1,551 cases, including primary glomerular disease (63.8%), secondary glomerular disease (33.5%). The first third pathomorphological types of primary glomerulonephritis are IgA nephropathy (38.6%), membranous nephropathy (25.9%) and membranoproliferative glomerulonephritis (19.3%). The third most common clinical manifestations for male versus female, the ratio is 1.32:1 in the primary glomerulonephritis, while 0.73:1 in the secondary glomerulonephritis. Conclusion: Primary glomerulonephritis is still the most common form of renal disease, and almost in male. IgA nephropathy is the most common pathological type of primary glomerulonephritis followed by glomerular minor lesion. While for the secondary glomerulonephritis, female is more than male, and LN is the most common pathological type followed by DN. And Chronic nephritis syndrome is the most common clinical manifestations of renal biopsy.
Iodine-123 MIBG Imaging of Renal Cell Carcinoma with Pathological Correlation

Ken Hiratsuka,1 Isao Kurihara,1 Sayuri Suzuki,2 Shintaro Yamaguchi,3 Toshiaki Monkawa,1 Koichi Suzuki,2 Hiroshi Itoh.1 1Dept of Internal Medicine, Keio Univ School of Medicine, Japan; 2Dept of Mycobacteriology, Leprosy Research Center, National Inst of Infectious Diseases, Japan.

Background: The incidence of renal cell carcinoma has continuously increased during the last fifty years. Despite the increase in number, the five year survival rate has been reduced by the advances in renal imaging. Chromophobe renal cell carcinoma (ChRCC) is an uncommon variant of RCC, accounting for approximately 5% of renal cancer. Although its prognosis is usually favorable, preoperative diagnosis is difficult because there is no marker for this variant. Here, we reported a novel method to distinguish ChRCC from other RCC (especially, clear cell carcinoma).

Methods: We experienced a case of ChRCC with adrenal pheochromocytoma in a 69-year-old Japanese female. We noticed that iodine-123 MIBG scintigraphy showed uptake in ChRCC in addition to pheochromocytoma; uptake was not observed in other RCC cases.

Results: The protein expression of pendrin, the candidate transporter, which related to iodine-123 uptake, was highly detected in ChRCC compared with clear cell carcinoma.

Conclusions: We identified specific transporter, pendrin, which is highly expressed in ChRCC. Our results indicates that iodine-123 MIBG scintigraphy may be a useful tool for the diagnosis of ChRCC and represents a substantial advance in the diagnosis of ChRCC.

Clinical Significance of Glomerular IgG Deposits in IgA Nephropathy

Anthony Alvardo,1 Nicole K. Andeen,2 Sergey V. Brodsky,3 Alice Hinton,4 Tiber Nadasdy,1 Charles E. Alpers,2 Christopher D. Blosser,1 Belzhad Najafian,2 Brad H. Rovin.1 1Faculty of Medicine, Nephrology Div, The Ohio State Univ, Columbus, OH; 2Pathology Dept, Univ of Washington, Seattle, WA; 3Pathology Dept, The Ohio State Univ, Columbus, OH; 4Div of Biostatistics, College of Public Health, The Ohio State Univ, Columbus, OH.

Background: IgAN is characterized by IgA dominant or IgA-IgG co-dominant mesangial deposits. It is not clear whether IgG deposits in IgA Nephropathy affects disease prognosis. We evaluated the significance of IgG co-deposits in IgAN.

Methods: Consecutive IgAN biopsies (n=80) from Ohio State University and University of Washington (2001-2013) were retrospectively classified into IgA only and IgA-IgG (IgG > trace). The presence or absence of IgG was correlated to the combined primary outcome of renal replacement therapy, death, OR doubling of serum creatinine.

Results: The change in estimated GFR (eGFR) was also assessed. Covariates were age, sex, primary outcome of renal replacement therapy, death, OR doubling of serum creatinine.

Conclusions: The presence or absence of IgG was correlated to the combined primary outcome of renal replacement therapy, death, OR doubling of serum creatinine.

Renal Biopsy

Figure 1. (a) H&E Crescentic GN (1b) Jones Silver: MPGN with Crescents. Trichrome staining (1c) reveals eosinophilic intra-glomerular deposits with collagen deposition and obliteration of Bowman’s space.

Substantial mesangial (2a: 30000x) and subendothelial (2b: 30000x) electron dense deposits of randomly arranged, slightly curved microtubular/fibrillar structures of approximately 20-25nm in diameter (2c: 120000x), and fingerprinting (2d: 30000x).

LM: crescents and endocapillary proliferation. EM showed subendothelial, subepithelial and paramesangium 20.5-25nm microtubular fibrils. IF: only C1q 2+ granular GHM and mesangial deposits. Labs: UPCR: 2.1 grams/day, ESR and CRP levels were markedly elevated. Viral hepatitis/HIV PCR, ANA, anti-DNA, anti-RNP, anti-Smith, SSA/SsB, anti Sm and Rh factor/CCP, C3, C4, ASO, cryocrit, SPEP/UPEP/free light chains/Immunofixation, peripheral flow cytometrywere negative. Patient was treated with IV methylprednisolone pulse and rituximab with improvement of renal function and proteinuria.

Conclusions: The uniqueness of this case is underscored by a variety of factors; clinical presentation, laboratory, serologies, and pathology. Laboratory and serological studies in cryoglobulinemia generally follow a characteristic pattern, detection of circulating cryoglobulins, low levels of complement, viral, autoimmune or lymphoproliferative etiology—yet a limited number of cases have presented with normal serological results, similar to the case presented here.

Development of a Clinicopathologic Kidney Biopsy Database Using Billing and Diagnosis Codes: A Descriptive Study

Anju A. Oommen,1 Jason Cobb,2 Jose E. Navarrete,1 Demilade Adedinnsewo,2 Oluwatolobio A. Osikoye,3 Helene B. Fevrier,4 Federic F. Rahbari-Oskouie,1 Alton Brad Farris,1 Laura Plantinga,5 Titilayo O. Iiroti.1 1Dept of Nephrology, Emory Univ School of Medicine, Atlanta, GA; 2Morehouse School of Medicine, Atlanta, GA; 3Lee Univ, Cleveland, TN; 9Dept of Epidemiology, Rollins School of Public Health, Emory Univ, Atlanta, GA; 10Dept of Pathology and Laboratory Medicine, Emory Univ School of Medicine, Atlanta, GA.

Background: A growing kidney disease population coupled with expanded use of electronic medical records (eMR) presents a unique opportunity for regional translational clinical research. We developed a comprehensive registry of all native renal biopsies at a major hospital in Southeastern US and described the pattern of glomerular diseases.

Methods: We identified all native percutaneous renal biopsies (n=2,245) performed in Atlanta (~18) between 2000 and 2011 using CPT and ICD-9 billing codes (50200 and 5523). Transplant biopsies (V42.0) and cytology were excluded. Renal pathology reports were reviewed by at least two independent clinical nephrologists. Clinical, laboratory and demographic data were extracted and validated by independent chart review. A clinicopathologic diagnosis was subsequently entered. Descriptive and bivariate statistics were used to analyze patient characteristics at biopsy.

Results: Patients in the registry had a mean age of 44.2 years; approximately half were male and majority were African American (40.7%). Overall, lupus nephritis (n=278, 12.4%) was the second most prevalent renal clinicopathologic diagnosis. Among primary glomerular diseases, FSGS (136, 9.2%) was the most prevalent, followed by IgA nephropathy (123, 8.3%), membranous glomerulonephritis (GN) (69, 4.6%), membranoproliferative GN (24, 1.6%) and minimal change disease (27, 1.8%). Diabetic nephropathy was the second most common secondary GN (97, 6.5%) followed by ANCA-associated vasculitis (31, 2.1%). Other diagnoses were all less than 2%.

Conclusions: We successfully established a kidney biopsy registry at our center, which will be instrumental to studying outcomes in this rare group of diseases, the most prevalent of which were lupus nephritis and FSGS.

**Is There Clinical Significance of IgM and Complement Staining in Idiopathic Focal Segmental Glomerulosclerosis**

**Vansantha M. Muthupalanpian, Kieran Mccafferty, Michael Sheaff, Muhammad M. Yaqoob**

Nephrology, Barts & The London NHS Trust, London, United Kingdom; Pathology, Barts & The London NHS Trust, London, United Kingdom.

**Background:** Experimental evidence suggests that focal segmental glomerulosclerosis with complement deposits is associated with poor outcome. Whether this is transferable or relevant in human disease is unclear.

**Methods:** We performed a proof-of-concept observational study on all patients with a diagnosis of idiopathic focal segmental glomerulosclerosis (fSGS) on native renal biopsies from January 2004 to December 2014. A total of 40 renal biopsies were identified. Clinical outcome data were obtained to seek an association with complement deposits (CD) and outcomes. Immunosuppression administered was according to the local trust policy which included prednisolone and cyclophosphamide or calcineurin inhibitor.

**Results:** See Table 1

CD was present in approximately 50% of the biopsies, but there was no significant association between CD and baseline clinical or demographic characteristics, furthermore, there are no association between CD and markers of disease progression (change in proteinuria, serum albumin or GFR between baseline and year 1 follow up). IgM staining was strongly co-associated with CD.

**Conclusions:** Our results indicate that, unlike animal models of fSGS, IgM and complement deposition does not alter outcomes. However, these findings will need to be confirmed in a larger study.

**PUB258**

**A Case of Intra-Occular Lucentis (Ranibizumab) Induced Minimal Change Disease**

Ashwin Reddy Ganta, Dept of Nephrology, Archbold Memorial Hospital, Thomasville, GA.

**Background:** Intravitreal monoclonal antibodies like Lucentis (Ranibizumab), Eylea and Avastin are being increasingly used for the treatment of Wet Age related Macular Degeneration (wAMD) and Diabetic Macular Edema (DME) of the eye. Though the intravitreal use of these agents is 1.7 mg/dL, hemoglobin 11 g/dL, normal platelet count and LDH.

**Methods:** This is a case of a successful use of Lucentis, in a patient with Lupus nephritis and thrombotic microangiopathy refractory to classical treatment. A putative explanation is that autoantibodies may have primed the endothelium, unmasking a complement defect that was successfully controlled by terminal complement blockade. A genetic analysis may reveal a mutation in regulator factors of the alternative complement pathway or auto-antibodies against Factor H or I. Eculizumab may be an option for the treatment of refractory lupus nephritis with thrombotic microangiopathy.

**Results:** We decided to start eculizumab and after one week, platelet count increased allowing for a renal biopsy that showed lupus nephritis class IV with thrombotic microangiopathy. After the third dose of eculizumab, there was improvement of anemia and she started to present diuresis. She was discharged from hospital one week later with creatinine of 2.3 mg/dL and off dialysis. After one year, she is on maintenance eculizumab every two weeks with low dose prednisone and mycophenolate mofetil 1per day. Creatinine is 1.7 mg/dL, hemoglobin 11 g/dL, normal platelet count and LDL.

**Conclusions:** This is a case report of the successful use of eculizumab in a patient with Lupus nephritis and thrombotic microangiopathy refractory to classical treatment. A putative explanation is that autoantibodies may have primed the endothelium, unmasking a complement defect that was successfully controlled by terminal complement blockade. A genetic analysis may reveal a mutation in regulator factors of the alternative complement pathway or auto-antibodies against Factor H or I. Eculizumab may be an option for the treatment of refractory lupus nephritis with thrombotic microangiopathy.

**Diagnostic Items for Renal and Hepatic Cyst Infection – A Delphi Survey**

**Muthuppalaniappan, Neves, Barbosa, Kieran Mccafferty,**

& The London NHS Trust, London, United Kingdom.

**Background:** In common cases of autosomal dominant polycystic kidney disease (ADPKD), diagnosis is relatively simple using a combination of diagnostic imaging of the kidney and analysis of ADPKD in the patient’s family history. Therefore, in most patients, ADPKD genetic testing for ADPKD is not necessary for diagnosis. However, in ADPKD cases where a definitive diagnosis is not obtained by imaging or living related donor is identified for kidney transplantation, genetic testing may be necessary.

**Methods:** This is a case report of a female patient, 18 years old, with no past history of disease, started fever, abdominal pain and dysuria treated initially as UTI. She evolved with skin rash and a few days later, oligoanuria, nausea and vomiting. She was admitted and treated with dialysis on the same day. Initial exams showed creatinine 1.7 mg/dL, hemoglobin 11 g/dL, normal platelet count and LDH.

**Results:** This is a case of a successful use of Lucentis, in a patient with Lupus nephritis and thrombotic microangiopathy refractory to classical treatment. A putative explanation is that autoantibodies may have primed the endothelium, unmasking a complement defect that was successfully controlled by terminal complement blockade. A genetic analysis may reveal a mutation in regulator factors of the alternative complement pathway or auto-antibodies against Factor H or I. Eculizumab may be an option for the treatment of refractory lupus nephritis with thrombotic microangiopathy.

**PUB261**

**The Use of Multiplex Ligation-Dependent Probe Amplification Technology for Genetic Analysis of the Entire PKD1 Gene and PKD2 Gene**

**Tetsuhiko Yasuno,**

Estadual de Campinas, Campinas, Sã o Paulo, Brazil.

**Background:** In common cases of autosomal dominant polycystic kidney disease (ADPKD), diagnosis is relatively simple using a combination of diagnostic imaging of the kidney and analysis of ADPKD in the patient’s family history. Therefore, in most patients, ADPKD genetic testing for ADPKD is not necessary for diagnosis. However, in ADPKD cases where a definitive diagnosis is not obtained by imaging or living related donor is identified for kidney transplantation, genetic testing may be necessary.
Methods: Multiplex ligation-dependent probe amplification (MLPA) kits have been developed for genotyping using proprietary MLPA technology. We obtained informed consent from nine patients (mean age, 45 years) and collected 8 mL of blood from each patient for analysis of genetic mutations in PKD1 and PKD2 genes using the MLPA method.

Results: In case 1 (a 39-year-old man), we found deletions in exons 3 and 39 of the PKD1 gene. The kidney was extracted due to enlargement and cyst infection. Dialysis was initiated when the patient was 39 years of age. The kidney capacity was 5013 mL. In case 2 (a 32-year-old woman), we found a deletion in exon 3 of the PKD1 gene. Renal function was maintained, and the serum creatinine level was 0.7 mg/dL. She has hope of the delivery. Tolvaptan does not have the safety about the dosage to a pregnant woman. Tolvaptan was administered after delivery.

PUB264

A Rare Presentation of Acute Kidney Injury: Have a Look at the Skin Alper Ah1, Sarenur Eserc, Didar Gursoy. 1 1Nephrology, Van Education and Research Hospital, Van, Turkey; 2Dermatology, Van Education and Research Hospital, Van, Turkey.

Background: Tuberous sclerosis(TS) is a multisystem,rare,genetic disorder of autosomal dominant inheritance which can involve different organs.Most commonly involved organ system in skin.We describe a case presented with periumbilical fibromas,multiple renal cysts and Shagreen patch without other features of TS.

Methods: A 33 yo woman presented with fatigue and renal failure.On physical examination,she had multiple non traumatic periumbilical fibromas in both hands and feet. Also Shagreen patch was seen in the right lumbar sacral region.

On admission biochemical tests;urea 132 mg/dl,creatinine 4.7 mg/dl,potassium 4.7 mmol/L, pH 7.32,HCO3 18.4.Lab output was satisfactory,no uremic symptoms were present.Renal ultrasonography revealed bilateral renal cysts with normal size and parenchymal thickness.Histopathology of the Shagreen patch revealed dense collagen bundles in the dermis.Due to the skin lesions and renal cysts the patient was diagnosed as TS.Other manifestations of TS were not present.Renal biopsy was suggested but she did not accept the procedure.

Conclusions: As stated in diagnostic criterias,physical examination has a strong impact on diagnosis of TS.Hypomelanic macules(~3),Shagreen patch,forehead plaque,non traumatic periumbilical fibromas,adenoma sebaceum,facial angiofibromas should remind the physicians TS.Kidneys are involved in almost 50-80% of the adult patients.Most frequent renal lesions in TS are angiomyolipomas.Bilateral and multiple characteristics of angiomyolipomas are pathognomonic.They may progress to end stage renal disease. However in some rare cases frank renal lesions may be absent.With a detailed inspection it is possible to recognize these specific dermatological signs,making the Tuberous sclerosis diagnosis and taking these patients under nephrological follow up.

PUB265

Background: Depression occurs more commonly than in the general population and is associated with poor outcomes. The use of antidepressants (ADs) has been associated with inappropriate release of vasopressin and hyponatraemia. Since vasopressin is thought to aggravate the progression of ADPKD, AD use could be deleterious.

Methods: Examine the use of ADs in the participants of the HALT-PKD randomized clinical trials (RCTs) and whether their administration is associated with faster disease progression. Post-hoc analysis of two HALT-PKD RCTs (A and B) studying the effect of rigorous versus standard BP control (A) and of ACE inhibitor alone vs ACE inhibitor/ARB combination (A and B) on rates of change of TVK (A) and eGFR (A and B) in ADPKD patients with eGFR >60 mL/min/1.73 m2 and <25-60 mL/min/1.73 m2.

Results: Female used ADs more frequently than male participants (39.7% of 526 participants exposed for less £30% and exposure for >30% of the time: 31.7% and 28.4%, respectively). Participants with PKD1 mutations used ADs (42.4%) more frequently than those with PKD2 mutations (27.9%, P<0.0009) despite having milder disease. Ages of these using or not using ADs were similar. To assess the effect of ADs on disease progression we divided the participants into three groups, no exposure to ADs, exposure for less £30% and exposure for >30% of the time:

Conclusions: Measuring body water balance by InBody720® could be useful as predictors of hTKV and eGFR decline in short term after administration of tolvaptan in ADPKD patients.

In conclusion, this axis may be a therapeutic target in PKD. C. Craig, Mukaiyama, Nozu, in ADAMTS1 mRNA was significantly upregulated in day 21, n=12, 9.1-fold, p<0.0001) and that one of the target molecules of miR-378a-3p, identified by health professionals in the guideline working group with the exception of function, cyst growth, and nephrotoxicity. Almost all topics/outcomes had already been identified by health professionals in the guideline working group with the exception of five topics/outcomes (surgical management of cysts, patient education about end-stage kidney disease, psychosocial impact of diagnosis, need for dialysis, knowledge). Many more topics (33) and outcomes (44) were identified as priorities by health professionals than consumers. Six themes reflected reasons for consumer choices: clarifying ambiguities, resolving debilitating pain, concern for family, preparedness for the future, taking control, and significance of impact.

Conclusions: Although there was considerable concordance between the priority topics and outcomes of health professionals and consumers for guidelines of ADPKD, there was also important discordance with consumers focused on fewer issues but particularly on lifestyle, psychosocial support, caregiver management, and quality of life and renal outcomes. Funding: Government Support - Non-U.S.

PUB266

Dysregulation of miR-378a-3p and ADAMTS1 Gene in cpk Mice: A Model of ARPKD, Masashi Satō, Koichi Nakashima, Yuka Shima, Masaya Miyazima, Kandai Nozu, Shizuko Nagao, Hisahide Takahashi, Kazumoto Iijima, Norishige Yoshikawa, Pediatrics, Tokyo Women’s Medical University, Tokyo, Japan; Laboratory Animal Center, University of Tokyo, Tokyo, Japan; National Center for Child Health and Development, Tokyo, Japan.

Background: The pathophysiology of cystic epithelia in PKD is characterized by altered proliferative activity, a secretory rather than absorptive function, and an abnormal matrix microenvironment. miRNAs are clarified to be involved in PKD. However, the detail has not been fully investigated. We reported that cpk cystic epithelia partially shared cell pathophysiology with colorectal carcinoma (JASN 25:414A, 2014). Recently, dysregulation of miR-378a-3p/ADAMTS1 axis was reported in colorectal carcinoma (Kara, et al. Gene, in press). ADAMTS1 is one of the ADAMTS (A Disintegrin And Metalloproteinase) with Thrombospondin motifs) metalloproteinases family. Elevated ADAMTS1 promotes pro-tumorigenic changes such as increased tumor cell proliferation and altered extra cell matrix environment.

Methods: To identify miRNAs that are differentially expressed between cpk and control kidneys, we performed miRNA microarrays, and assessed the target molecule gene and its product expression using real-time PCR and western blotting.

Results: miRNA microarray analysis revealed that 22 (up, down 18) miRNAs were differentially expressed (more than 4-fold) in cpk (day 21, n=7) kidneys. Of 22 miRNAs, miR-378a-3p was significantly downregulated in cpk (5.1-fold). Real-time PCR confirmed that miR-378a-3p was significantly downregulated in cpk (day 14, n=14, 5.0-fold, p=0.002; day 21, n=12, 9.1-fold, p=0.0001) and that one of the target molecules of miR-378a-3p, ADAMTS1 mRNA was significantly upregulated in cpk (day 14, n=20, 1.4-fold, p=0.01; day 21, n=12, 3.5-fold, p=0.0002). Western blotting showed that ADAMTS1 was increased in cpk (day 21, n=6, 1.8-fold, p=0.03) kidneys.

Identifying and Integrating Consumer Perspectives in Clinical Practice Guidelines on Autosomal Dominant Polycystic Kidney Disease

David J. TumnickLiff, Allison Tong, Pamela Andrea Lopez-Vargas, Jonathan C. Craig,1 Gopala K. Rangan,2,3,4 The Univ of Sydney, Australia; 2Westmead Millennium Inst, Australia; 3Westmead Hospital, Australia.

Background: Integration of consumer perspectives into clinical practice guidelines is widely advocated as it ensures that recommendations are relevant to all stakeholders. We aimed to identify consumer perspectives on topics and outcomes to include in clinical practice guidelines on autosomal polycystic kidney disease (ADPKD).

Methods: A workshop involving three concurrent focus groups with consumers was convened. Guideline topics, interventions and outcomes were identified, and integrated into guideline development. Thematic analysis was used to analyze the reasons for their choices.

Results: Eighteen consumers (patients with ADPKD [n=15], caregivers [n=3]) participated and 22 priority topics (including interventions) were identified, with most focused on non-pharmacological management (diet, fluid intake, physical activity, complementary medicine), pain management, and psychosocial care (mental health, counseling, cognitive and behavioral training, education, support groups). They also identified 30 outcomes including quality of life, progression of kidney disease, kidney function, cyst growth, and nephrotoxicity. Almost all topics/outcomes had already been identified by health professionals in the guideline working group with the exception of five topics/outcomes (surgical management of cysts, patient education about end-stage kidney disease, psychosocial impact of diagnosis, need for dialysis, knowledge). Many more topics (33) and outcomes (44) were identified as priorities by health professionals than consumers. Six themes reflected reasons for consumer choices: clarifying ambiguities, resolving debilitating pain, concern for family, preparedness for the future, taking control, and significance of impact.

Conclusions: Although there was considerable concordance between the priority topics and outcomes of health professionals and consumers for guidelines of ADPKD, there was also important discordance with consumers focused on fewer issues but particularly on lifestyle, psychosocial support, caregiver management, and quality of life and renal outcomes. PUB268

Urine AQP2 Is One of the Candidates for a Surrogate Marker in the Treatment of ADPKD Patients by Tolvaptan

Koichi Natsumi, Hiroshi Kanbe, Toshihiko Motomichi, Miki Nishida, Masayo Sato, Hiroshi Kitaoka, Hidekazu Sugura, Ken Tsuchiya, Kosaku Nitta. Medicine IV, Tokyo Women’s Medical Univ, Shinjuku, Tokyo, Japan.

Background: Tolvaptan, arginine vasopressin (AVP) V2 receptor antagonist is accepted for autosomal dominant polycystic kidney disease (ADPKD) patients in Japan since 2014. TEMPO study showed tolvaptan from 60 to 120 mg per day slowed renal cyst expansion and renal function decline. Tolvaptan dose is decided by preliminary study (TEMPO3), which showed the maximum dose that meet both urinary osmolality (Uosm) under 300 mOsm/kg and patient’s tolerance. So that adequate dose for individual patient has not been suggested. Moreover, tolvaptan cause polyuria, thirsty, polydipsia due to aquaresis. Thus, it is necessary to find surrogate markers for determine the maximum effects and minimum side effects for long-term administration.

Methods: Seventeen ADPKD patients initiated tolvaptan of 60 mg were investigated. Physical data, plasma osmolality (Posm), Uosm, AVP, urine cyclic AMP (UCAMP), and urine AQP2 (UAQP2) were assessed. UCAMP was measured by radioimmunoassay (Yamasa corp.) and UAQP2 was measured by a sandwich enzyme-linked immunosorbent assay method (Otsuka Pharmaceutical Co. Ltd.).

Results: After initiation of tolvaptan, average urine volume was 8621 ml/day and delta body weight was -1.42 kg/day on day 1. One month after, AVP increased from 3±3 to 7.3±11.2 pg/ml (p=0.001), Uosm decreased from 367±349 to 243±436 mOsm/kg (p<0.001). Posm and UCAMP were not statistically associated. UAQP2 decreased from 0.029±0.068 to 0.012±0.028 pmol/MgCr (p=0.0001). In our preliminary data (n=5), the serum copeptin, a precursor of vasopressin, was shown to be no consistent level.

Conclusions: It has been reported that 3% of total production of AQP2 excreted into the urine, it reflected directly the intracellular action of AVP. Thus, UAQP2 is likely to be one of surrogate markers of tolvaptan effect, moreover it could provide additional information of determination of individual dosage and monitoring for long-term use.

Abnormalities in the Radius of Patients with Autosomal Dominant Polycystic Kidney Disease Measured by High-Resolution Peripheral Quantitative Computerized Tomography Imaging

Danielle Diarra, Janina M. Patsch, Claudia Schueller-Weidekamm, Michael Weber, Astrid Nia, Gre Sander-Plassmann, 1 Dept of Medicine III, Medical Univ of Vienna, Austria; 2 Dept of Radiology, Medical Univ of Vienna, Austria; Dept of Medicine II, St. Vincent Hospital, Medical Univ of Vienna, Austria.

Background: ADPKD is a multi-organ disorder and the most common of all cystic kidney diseases. Mutation of the PKD1 or -2 gene causes epistaphelial ciliopathies, which lead to the dysfunction of various organs. Animal studies show that primary cilia are present in osteoblasts of mice and point mut ation of the osteoblastic PKD1 gene induces osteopenia.

Methods: In this pilot-study, we examined the bone structure in 6 ADPKD patients in comparison to 6 matched patients with glomerular disease (GD), both in CKD stages I-III, by HR-pQCT of the radius and the tibia. The aim of the study was to identify microarchitectural target parameters for a subsequent larger study in patients with ADPKD.

Results: Demographic data see Table 1.

We found reduced cortical and trabecular microstructural parameters by HR-pQCT, mainly affecting the radius. The outer trabecular density, the cortical thickness and the total density of the radius showed the biggest differences between the two groups, see Figure 1.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only.Underline represents presenting author.

949A
The total density of the radius was the best parameter to distinguish between the bone structure of ADPKD— in comparison to GD patients (AUC=0.861).

Conclusions: We provide evidence of microstructural bone deterioration of the radius in patients with ADPKD. We thus hypothesize that ADPKD is associated with microstructure bone changes in men.

PUB270
An Accurate Formula for a Quick Estimate of Total Liver Volume in Polycystic Liver Disease Patients

 Methods: The primary aim of treatment of PLD is reduction of total liver volume (TLV) as patients often suffer from hepatomegaly. The gold standard to assess TLV is CT volumetry which involves manual delineating of the liver outline. Unfortunately this is a time-consuming method (45-60 minutes per CT scan) and requires a certain level of expertise. An easily accessible and fast method to estimate TLV in routine clinical practice is needed. Therefore we aimed to develop an accurate formula for quick estimation of TLV. We collected a cohort of PLD patients in whom CT scans were available. Manual delineation of TLV served as gold standard. PLD patients were distributed in 2 cohorts, a development cohort (N=80) and a replication cohort (N=50). We measured anterior-posterior (AP), transverse (T) and cranial-caudal (CC) distance (in meters) of the liver on CT. TLVs were logarithmically transformed as data were not normally distributed. \( R^2 \) was measured as it indicates the goodness of fit of the prediction model. The prediction model was tested in a replication cohort.

Results: Median liver volumes in the development and replication cohort were 4749mL [1084-14816] and 4684mL [1287-16746] respectively. All three diameters significantly correlated with TLV (\( p < 0.0001 \)). Linear regression analysis resulted in the following formula: Logarithm of TLV = 2.540 + 0.7568 x CC + 2.522 x AP + 0.041. Our model predicted TLV accurately in the development cohort (\( R^2=0.898 \)). The correlation in the development cohort was 0.848 and validated in the replication cohort resulted in a correlation of 0.937.

Conclusions: Our model accurately and quickly (< 2 minutes) predicts TLV in PLD patients based on three liver dimensions.

PUB271
Clinical Significance of Urine NAG and L-FABP Excretion for the Assessment of ADPKD-Progression

 Methods: This study, 59 ADPKD cases with consents were retrospectively analyzed. Average age, duration of the observation, median values of kidney volume (KV) and kidney growth rate (KGR), average estimated GFR (eGFR), and urine creatinine ratio of N-acetylglucosaminidase (NAG) to Cr (NAG index) for the clinical assessment of TIN. We stratified patients by the average or median value of the parameters mentioned above, and analyzed their differences in each stratified group. KV, eGFR and KGR showed significant difference only in the eGFR-, KV-, and GFR-stratified group. However, NAG index showed significant difference in both KV-stratified (median: 7.42 vs 6.09 U/mgCr) and eGFR-stratified (8.00±5.98 vs 3.93 U/mgCr) groups. Additionally, urine liver type fatty acid binding protein (L-FABP), as a biomarker of the tubular ischemia, showed significant difference in all stratified groups (KV: 7.29±9.98 vs 1.76±1.68, eGFR: 4.15±7.76 vs 2.45±2.34, KGR: 4.46±7.68 vs 2.09±3.30, NAG index: 4.33±1.20 vs 1.88±2.10).

Conclusions: Progression of ADPKD has been primarily assessed by the kidney volume. However, the present study may show that the assessment of TIN might be more helpful to evaluate the severity and prognosis of ADPKD. It might be suggested that TIN-related markers such as NAG index or L-FABP index should be actively utilize in the clinical management of patients with ADPKD.

PUB272
Classic and Alternative Criteria for the Diagnosis of Autosomal Dominant Polycystic Kidney Disease: Genetics and Disease Progression in HALT-PKD

 Methods: Of 959 HALT-PKD patients with genetic testing 835 (87.1%) had CC, and 124 (12.9%) had AC. Three groups: Alternative (AC-NMD), Classical (CC-PKD1/ PKD2 mutation), and Intermediate (combined CC-NMD = AC-PKD1/PKD2 mutation) were compared for annual change in total kidney volume (TKV, htTKV) in early ADPKD (n=17, 410, 81, respectively), and eGFR in early/late ADPKD (n=17, 414, 375, 81/4 respectively).

Results: TKV increase was 4.21% in Alternative (AC-NMD) compared to 6.39% in Classical (CC-PKD1/ PKD2), and 6.68% in Intermediate (CC-NMD + AC-PKD1/PKD2) (InTKV P=0.0346; latinTKV P=0.0035) and was not affected by BP level.

NMD patients were 20.2% of AC but just 5.5% of CC patients which was true in both early (P<0.0001) and late ADPKD (P=0.0066). Annual eGFR change in early and late ADPKD was not significantly different in the 3 groups, and Low vs Standard BP, or lisinopril+telmisartan vs lisinopril+placebo, did not alter that.

Conclusions: AC-NMD (Alternative) patients with early ADPKD have a significantly lower annual increase in TKV/htTKV. The –FH factor in AC appears to be the clinical portal to a genetically complex population enriched 3.7-fold for NMD. Patients with AC-NMD might have mosaicism, atypical mutations, or even polycystic kidney disease(s) other than ADPKD.

PUB273
Lifestyle Counseling in Polycystic Kidney Disease Patients

 Methods: We performed a systematic chart review. Using our electronic medical record system, we identified patients with ADPKD who most recent visit at UCSF with a nephrologist occurred during the previous six months. We reviewed the notes associated with these visits to assess for nephrologists’ discussion of dietary advice, water drinking parameters, and exercise recommendations based on documentation in clinic notes.
Lipid Alterations in Murine Models of Polycystic Kidney Disease

Christine Podrin,1 Isaline Rowe,2 Marco Chiaravalli,2 Alessandra Boletta.3

1Univ Vita-Salute San Raffaele, Milan, Italy; 2Dibit San Raffaele Scientific Inst, Milan, Italy.

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a common genetic disorder characterized by massive bilateral renal cyst formation. ADPKD results from mutation in the PKD1 or PKD2 genes, encoding Polycystin-1 (PC-1) and 2 (PC-2) proteins respectively. Previous studies have suggested that the mTORC1 cascade might play an important role in PKD. Further, mTORC1 regulates the activity of SREBP which regulate the expression of genes required for the synthesis of fatty acids and cholesterol. However, the regulation of fat synthesis in ADPKD remains poorly understood.

Methods: We analyzed newborn kidneys of Pkd1-Cre;Pkd1flox/+, mice and detected an increased expression of SREBP1 and its target genes including fatty acid synthase (FAS) and stearoyl-CoA desaturase (SCD) when compared to control, non-cystic kidneys (Pkd1-Cre;Pkd1flox/+ or Pkd1flox/+).

Results: As expected the increased expression of SREBP1 also correlated with increased transcript levels of SREPB2 concomitant with an increased transcript levels for the lipid alterations that we observed appear to be gender-specific. Of interest both have been implicated in regulating membranes trafficking and they may alter alteration of some lipid classes, particularly sphingolipids and sterol esters (cholesterol).

Conclusions: We are currently characterizing this aspect further and trying to determine which lipid alterations might be dependent and/or independent of mTORC1 upregulation.

PUB276

Baseline Renal Cysts Diameter Predicts the Erithropoietin Requirement in Autosomal Dominant Polycystic Kidney Disease

Paolo Lentini,1 Luca Zanolli,2 Massimo de Cal,1 Stefania Rastelli,3 Andrea Contestabile,1 Antonio Granata,2 Roberto Dell'Aquila.1 1Nephrology, St. Bassiano Hospital, Bassano Del Grappa, Italy; 2Internal Medicine, Univ of Catania, Catania, Italy; 3Nephrology, St. Giovanni Di Dio Hospital, Agrigento, Italy.

Background: Subjects with autosomal dominant polycystic kidney disease (ADPKD) require classically low recombinant human erythropoietin (EPO) to reach haemoglobin target levels. We hypothesize that EPO requirement in subjects with ADPKD is more dependent to the enlargement of the cysts than the reduction of glomerular filtration rate. Aim: To evaluate the role of renal cyst and kidney size on EPO requirement in severe chronic kidney disease (stage 4-5).

Methods: A total of 35 pts with ADPKD and anemia treated with EPO were enrolled (14 pts with CKD Stage 4 and 21 pts Stage 5), the mean volume (V) and diameter (D) of the four largest cysts and the mean antero-posterior renal diameter (AP) were prospectively followed-up for 18 months with computer tomography.

Results: The overall mean age was 65.14±7 years. Male sex 57%. At baseline, AP was 19.7±2.2 cm, D 4.6±1.1 cm, V 749±641 cm³. During the 18 month’s follow-up, rHuEPO dose was 8543±6626 UI/week, and EPO/haemoglobin ratio (E/H) was 1983±1039. In a multivariate linear regression model, adjusted for age and sex, at baseline both AP and V were significantly associated with E/H; after 18 months, only V remains significantly associated with E/H. Baseline V (100cm³ increase: β=115UI/g week, 95%CI 65-164, P<0.001) was also associated with mean E/H during follow-up and explain 42% of E/H variability.

Conclusions: The Cysts volume is useful to predict prospecitively the EPO requirement in ADPKD in stage 4-5 CKD.
PUB278

Amniotic Fluid Stem Cells Transplantation in Fetal Kidney to Regenerate Nephrons Loss. Kathleen Labarbe, 1 Sebastian Sammut, 2 Mehrak Hekmati, 2 Agnieszka Anna Ksiazek, 3 Benedikt Weber, 4 Luc Behr. 5 Necker Hôpital-Paris 5 Univ, Paris, France; 1 IMM, Paris, France; 2 Swiss Center for Regenerative Medicine, Univ Hospital, Zurich, Switzerland.

Background: Amniotic fluid stem cells (AFSC) harbour the potential to differentiate toward renal lineages and contribute to the development of primordial kidney structures. To investigate whether AFSC can improve prenatal renal compensatory growth, cells were transplanted in a model of subtotal nephrectomy (5/6NX) in the fetal sheep.

Methods: Ovine AFSC labelled with GFP were selected using c-kit. In absence of LIF, AFSC formed embryonic bodies which cultured in an optimized medium generated a renal epithelial progenitor population (oAFSCd), expressing Pax-2. 5/6NX was performed at 70 days of gestation in 10 fetal lambs; 5 were injected with oAFSCd in the kidney poles. Sham-operated did not received oAFSCd (SHAM, n=8). At 134 days of gestation, fetuses were euthanized, kidneys removed and processed.

Results: Body weight did not differ significantly among the groups and no morphologic abnormalities were observed, in spite of a severe reduction in amniotic fluid in 5/6NX+oAFSCd. Compensatory renal growth of the remaining kidney was observed in all 5/6NX, but in spite of oAFSCd injection, catch-up kidney growth was similar in both 5/6NX groups. SHAM: 3.2±0.62; 5/6NX: 4.6±0.62; 5/6NX+oAFSCd: 5.5±1.4 K/BW. Glomeruli number/section was similar in all groups: SHAM:271±123; 5/6NX:215±69; 5/6NX+oAFSCd:196±22. In 5/6NX+oAFSCd, GFP cells were present in renal proximal tubules, and proximal tubule hypertrophy was observed.

Conclusions: Transplantation of oAFSCd predifferentiated toward renal epithelial progenitor cells during nephrogenesis increases proximal tubule mass but has no effect on the number of glomeruli (GFR) and do not restore fully kidney damage. Funding: Private Foundation Support

PUB279

Background: Low birth weight (LBW) leads to significant risk to the newborn, with many of these babies developing acute kidney failure and dying soon after birth due to underdeveloped vascular and renal systems. Surviving LBW neonates are also susceptible to a variety of health problems later in life during adulthood including hypertension, diabetes and chronic kidney disease with an associated 70% increased risk of end-stage kidney failure.

Methods: Using a maternal malnourished mouse model, we examined the causes of vascular and renal underdevelopment and impaired function in the LBW neonate. Parameters measured in the LBW offspring included nephron development, stem cell levels, apoptosis, gene expression, circulating cytokine/chemokines, renal blood flow and renal function.

Results: Within 24 hours after birth, LBW male offspring had 40% reduced weight, while only 40% of LBW neonates survived the first week after birth. Within the first week after birth, LBW neonates had an up to 40% reduction in renal blood flow and elevation of serum creatinine up to 3.0 mg/dL. Nephrogenesis was impaired in the LBW neonates with a 75% reduction in renal vesicle formation and a significant downregulation of Wnt9B (which induces differentiation of progenitor cells into tubular epithelia) at day E17.5, which ultimately resulted in a 30% reduction in glomeruli at the conclusion of nephrogenesis. During nephrogenesis, six2+ positive nephron progenitor cells were reduced by up to 70% (which induces differentiation of progenitor cells into tubular epithelia) at day E17.5, which ultimately resulted in a 30% reduction in glomeruli at the conclusion of nephrogenesis.

Conclusions: LBW impairs vascular and renal development due to underdeveloped vascular and renal systems that result from enhanced IL-1beta, increased apoptosis, altered Wntbeta expression, and reduced six2+ progenitor cells in the embryonic and neonate kidney. Funding: Private Foundation Support

PUB280

Increasing Podocyte Number in Neonatal Kidney Reduced Renal Injury in Adulthood Jianyong Zhong, 1,2 Ji Ma, 3 Taiji Matusaka, 4 Agnes B. Fogo, 1 Valentina Kon, 5 Haichun Yang. 1 Pathology, Microbiology and Immunology, Vanderbilt Univ, Nashville, TN; 2Pediatric Nephrology, Vanderbilt Univ, Nashville, TN; 3Dept of Molecular Life Science, Inst of Medical Science, Tokai Univ School of Medicine, Isehara-shi, Kanagawa, Japan.

Background: Preterm birth increases the risk of hypertension and renal disease, which has been linked to decreased Nephron number. We previously found that perinatal puromycin injection in mice at birth impairs glomerular maturation, and has renal pathology phenotype which is similar to that observed in human preterm births. In the present study, we tested the hypothesis that increasing podocyte number during glomerular maturation can rescue glomerular loss and thus reduce renal injury in adulthood.

Methods: We mated podocin-rtTA with TRE-5SV40 in mice to generate double-transgenic mice (RS), in which podocyte proliferation can be activated by doxycycline (Dox). RTA mice (R) served as controls. After a single puromycin injection, doxycycline was initiated on P7 until P8. By P18, mice under Dox (UN) and were started on a high salt diet. At 14 weeks of age, angiotensin II (Ang II) was given by minipump for the next 8 weeks. All mice were sacrificed at week 22.

Results: At week 3, there were more WT positive glomerular cells in RS than R mice (RS 10.34±4.1 vs. R 8.15±0.58 X10^3/mm^2, p<0.05), while glomerular in superficial cortex were less more (RS 2.13±0.05 vs. R 2.32±0.06, maturity scale 1-3, p<0.05). At week 6, glomerular number increased in RS (RS 909±2.6442 vs. R: 962±1.2447, kidney, P<0.05). Glomerular volume and albuminuria did not differ between groups at week 3 and 6. At week 22, after UN, high salt and Ang II, blood pressure, albuminuria and GFR were similar in both RS and R. However, RS mice had lower K/WBW ratio (RS 0.97±0.143 vs. R 1.263±0.041, p<0.05) and less mesangial expansion (0-4 scale) (RS 0.72±0.10 vs. R 1.14±0.14, p<0.05).

Conclusions: We conclude that increasing podocyte number in kidney development rescues puromycin-induced loss of glomerular growth, which in turn reduces renal injury following a second hit in adulthood.

PUB281

Exploring Ciliopathies – Cep164Tissue Expression in a Murine Model Simon Ramsbottom, Shalash Srivastava, Colin Miles, John Andrew Sayer. Dept of Genetic Medicine, Newcastle upon Tyne, United Kingdom.

Background: Nephronophthisis (NPHP) is the major cause of paediatric renal failure, yet the disease remains poorly understood, partly due to the lack of appropriate animal models. Joubert Syndrome (JBS) is an inherited ciliopathy giving rise to NPHP and neurodevelopmental abnormalities and mutations in CEP164 are one of the known genetic causes. Clinical phenotypes of patients with CEP164 mutations include NPHP with retinal degeneration and cerebellar vermis aplasia. In cultured cells CEP164 localises to centrosomes as well TIP-60 positive nuclear foci, and CEP164 has an established role in DNA damage response signalling. However, there has been no previous documentation of CEP164 spatial expression during development.

Methods: We have recently acquired heterozygous Cep164 mice from the International Mouse Phenotyping Consortium (MRC/Harwell) (B6NTac: B6-Cep164^+/-; C57BL6N). We used these animals for tissue expression studies, including X-gal staining for beta-galactosidase and whole embryo. Homozygote Cep164 animals had 100% perinatal lethality.

Results: In heterozygote Cep164 animals, specific X-gal staining representative of beta-galactosidase adults and whole embryo. Homozygote Cep164 animals had 100% perinatal lethality.

Conclusions: These data support a role for Cep164 in multiple organs throughout development and explain the wide phenotypic spectrum of JBS mutations in man.

PUB282

Specific Deletion of Early B Cell Factor 1 from Podocytes Does Not Recapitate the Developmental Defects Observed in the Globally Deficient Animals but Does Provide Protection from Injury Jackie A. Fretz, Tracy Nelson, Li Li. Orthopaedics and Rehabilitation, Yale School of Medicine, New Haven, CT.

Background: Globally deficient mice lacking the transcription factor Ebf1 (Ebf1 KO) are extremely sick owing to the multiple functions of Ebf1 across the body. We recently described a novel function of Ebf1 as an essential component of the latest stages of mesenchephalic development. Mice globally deficient in Ebf1 have impaired formation of peripheral glomneruli and a thinned cortex. Within the kidney Ebf1 is present within multiple cell types including distinct tubular epithelium, interstitial pericytes, glomerular mesangium, and podocytes. This investigation aimed to identify if the actions of Ebf1 in the podocyte were driving the developmental defects present in the global knockout.

Methods: In this study we made a specific deletion of Ebf1 within the podocytes using the podocin-driven cre mouse. These were mated with mice where the 3rd exon of Ebf1 (encoding part of the DNA-binding domain) is flanked by flox sites. This is the same genetic trap that is excised in the global knockout, and injury was also performed on 3 month old animals (100mg/kg, IP daily for 4 weeks).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
952A
Results: Restricted deletion of Ebf1 from podocytes did not result in any observable decrement in GFR evaluated at the functional and histological level, glomerular number, and glomerular development were unchanged regardless of genotype. The mice were followed for up to 6 months. During this time renal function did not decline in the mice with podocyte-specific deletion of Ebf1, and in fact baseline proteinuria was reduced in Podc-eCre+/Ebf1−/− animals compared to littermate controls. To examine if Ebf1-deficient podocytes harbored differential response to injury 3 month old animals were subjected to BSA-overload and exhibited reduced proteinuria.

Conclusions: Taken together these results suggest that Ebf1 regulates metanephric development through other cell types than the podocyte. While Ebf1 does not control glomerular development through its actions in the podocyte, it appears to participate in proper damage response by podocytes as its removal appears to be protective.

### PUB283

Remote Ischemic Preconditioning and Pharmacological Treatment in Prevention of Renal Damage in Experimental Diabetics

Marcelo Rodrigues Bacci, David Feder, Fernando Luiz Affonso Fonseca, Matheus Polly, Jaqueline Victoria Ciancaglini, Giuliana Petri, Guilherme Zaremba. ABC Medical School, Brazil.

**Background:** The main features of diabetic nephropathy are glomerular hypertrophy, thickening of the basal membrane, tubular atrophy, interstitial fibrosis and nodular and focal glomerulosclerosis. Remote ischemic preconditioning (RIPC) is a procedure that generates a brief period of ischemia followed by reperfusion. Its role in preventing glomerular and tubular changes is still under debate. The aim of the study was to evaluate the nephroprotective effect of RIPC in a diabetic rat model.

**Methods:** Five groups of 10 Wistar male rats were formed: control without diabetes; untreated diabetes; diabetes treated with pharmacological treatment (PT); diabetes with RIPC and diabetes with RIPC and PT. For the induction of diabetes, alloxane was infused intra-arterially at a dose of 160mg/kg; PT consisted of daily use of metformin (250mg/kg) and valsartan (30mg/kg). RIPC was performed with an external tourniquet placed on the back leg for three 5-minute rounds alternated with the same rounds of reperfusion, resulting in a total duration of 30 minutes. This was performed every week on all mice in RIPC groups. All mice were kept in a biological cage with controlled temperature and humidity and routine feeding. Blood and urine samples were collected weekly to evaluate serum glucose, creatinine and urine albumin levels and albumin/creatinine urine ratio (ACR). At the end of the observation period, animals were sacrificed and their kidneys were biopsied for microscopic analysis.

**Results:** Animals subjected exclusively to PT showed a significant reduction in serum and urine glucose levels but these reductions were not greater in the group that underwent RIPC in addition to PT. There were no significant differences in creatinine level between any of the groups but ACR was significantly reduced in all treated animals compared to controls. Tubular atrophy was observed in all diabetic rats and was greatest in the untreated group.

**Conclusions:** PT was more effective at reducing ACR and tubular atrophy than RIPC. RIPC alone or in combination with PT did not cause the expected effect of preventing histological and urinary abnormalities.

Cross Talk Between TLR4 Signaling and Angiotensin II Induces Pathophysiological Changes in Human Tubular Epithelial Cells Under High Glucose Conditions.

Jian Li,1 Guohua Ding.1 Nephrology, The First Affiliated Hospital of NanChang Univ, NanChang, Jiangxi, China; 2Nephrology, Renmin Hospital of WuHan Univ, WuHan, China.

**Background:** To investigate the cross talk between TLR4 and angiotensin II by observing the expression of TLR4 in tubular epithelial cells under high glucose conditions, and observe the changes of fibrogenic and inflammatory factors in human renal tubular epithelial cells, revealing the innate immune pathogenesis in diabetic nephropathy.

**Methods:** Cells were divided into five groups after cultivated with normal glucose medium: 1.normal-glucose group, 2. mannitol group, 3. AngII group, 4. high-glucose group (25mmol/L), 5. high-glucose+Irsbasetin group, extract total RNA and total protein after 24 hours. Real time PCR was used to analyze the expressions of TLR4, MyD88, HSP70 and HSP47, cis-RNA, western blot was used to observe the expressions of TLR4, MyD88, NF-κB, CoV4, HSP77 protein, analyze the effect of high-glucose and AngII to TLR4 / MyD88 / NF-κB signaling pathway.

**Results:** Compared with normal group, TLR4, MyD88, HSP47 mRNA and TLR4, MyD88, NF-κB, CoV4, HSP77 protein were highly expressed under high glucose condition and after AngII stimulate (p<0.01). The expression of IL-6 and MCP-1 also increased (p<0.01). Compared with Hg group, the expression of TLR4, MyD88, HSP47 mRNA and TLR4, MyD88, NF-κB, CoV4, HSP77 in the high-glucose+Irsbasetin group were significantly reduced (p<0.01). The difference of above indicators between the negative transfected group and high-glucose group and AngII group were statistically significant (p<0.05). The expression of IL-6 and MCP-1 in the group that cells were transfected with TLR4-siRNA also reduced (p<0.01).

**Conclusions:** Cross talk between angiotensin II and TLR4 can up-regulate the expression of inflammatory factors and fibrogenic factors in HK-2 cells. Irsbasetin can block the activation of TLR4 signaling pathway induced by high glucose and angiotensin II. TLR4 signaling pathway is the major pathway induce the release of inflammatory and fibrogenic factors in tubular epithelial cells under high glucose conditions.

### PUB285

Possible Renoprotective Effects of Acetazolamide Administration in Obese Diabetic Mice with Nephropathy

Yusho Nakayama, Koji Eguchi, Terumasa Nakagawa, Tomoaki Onoue, Yuichi Izumi, Hideki Inoue, Yutaka Kakinose, Takashige Kawabara, Masashi Mukoyama. Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.

**Background:** Administration of carbonic anhydrase inhibitors (CAI) is thought to decrease glomerular filtration rate (GFR) by activation of the tubuloglomerular feedback (TGF) system. Acetazolamide (ACZ), a major CAI, has been shown to decrease urinary albumin excretion in the patients of type 1 diabetes with nephropathy. Previously, we showed that ACZ treatment in mice could ameliorate the onset of diabetic nephropathy due to the reduction of intraglomerular pressure by activating the TGF system.

**Methods:** In the current study, we treated obese diabetic mice (KK-Ay/Tacl) with ACZ for 14 weeks, and evaluated the long-term effects on urinary albumin excretion and glomerular hyperfiltration.

**Results:** The blood glucose levels were significantly higher in KK-Ay/Tacl mice compared to the control mice (BALB/c/Avi) at 14 weeks. The blood glucose levels were significantly reduced in KK-Ay/Tacl mice treated with ACZ (547±37 vs 250±75 mg/dl). Interestingly, urinary glucose excretion levels in the ACZ group were not significantly different compared to the non-treated group. Creatinine clearance was higher in KK-Ay/Tacl treated group, which was not changed by ACZ (0.73±0.07 vs 0.69±0.15 ml/min) (Figure A). Urinary albumin excretion was reduced with ACZ treatment by 29% (Figure B). The plasma renin activity was not reduced by ACZ in this model.

**Conclusions:** These results suggest that the long-term oral treatment with ACZ may exert renoprotective effects in obese diabetic models with nephropathy, not due to activation of the TGF system but to better glycemic control.

Infection Control, Kanazawa Univ, Kanazawa, Japan; 1 Diabetic Nephropathy Lab, Baruch Padeh Poriya M Cie, Lower Galilee, Israel.

**Background:** Diabetic nephropathy (DN) is the most common renal complication of diabetes. Diabetes increases oxidative stress and promotes iron deposition in proximal convoluted tubules (PCT) of the kidney, leading to renal damage. Mutations in the LEP (ob) gene product lead to severe obesity and type 2 diabetes, and ob/ob mice in BTBR background develop severe diabetic nephropathy. Klotho and vitamin D receptor (VDR) have been shown to involve in renal protection against diabetic injury. The goal of this study is to assess the relationship between iron deposition and klotho and VDR expression in the kidney of ob/ob mice.

**Methods:** One- and three-month old ob/ob BTBR mice and ob/+ control mice were studied in parallel. After sacrifice, the kidneys were harvested. The expression of a-klotho, VDR, and Cyp27b1 was examined by immunohistochemistry, Western blotting, and qRT-PCR, and iron deposition was assessed by staining with Perl’s enhanced with DAB.

**Results:** Compared with ob/+ mice, ob/ob BTBR mice showed increased iron deposition in the PCT and decreased expression of a-klotho, VDR, and Cyp27b1 in the renal PCT and kidney lysates.

**Conclusions:** In ob/ob BTBR mice, increased iron deposition in the renal PCT is associated with a decrease in klotho expression, vitamin D hormone synthesis and VDR signaling in the PCT. These changes together contribute to the progression of diabetic renal injury in these mutant mice, and future treatments.

**Erythropoietin Protects Endothelial Cells from High Glucose Induced Injury**

Haruka Yasuda,1 Yasunori Iwata,2,3 Kengo Furuchi,4 Takashi Wada,2,3 1 Dept of Laboratory Medicine, Kanazawa Univ, Kanazawa, Japan; 2 Div of Infection Control, Kanazawa Univ, Kanazawa, Japan; 3 Div of Nephrology, Kanazawa Univ, Kanazawa, Japan; 4 Div of Blood Purification, Kanazawa Univ, Kanazawa, Japan.

**Background:** Diabetic nephropathy (DN) is a major cause of end stage kidney disease and a strong risk factor for cardiovascular diseases. High glucose induces endothelial injury in vasculature, resulting in tissue injury in diabetic condition. Chronic inflammation has been reported to play an important role for the progression of high glucose induced cell injury. Growing data showed that erythropoietin (EPO) protect the tissues from some kind of injury, such as hypoxia and mechanical stress. However, the contribution of EPO to high glucose induced the aberrant immune balance remains to be explored. Therefore, we hypothesized that EPO modulates endothelial cells from high glucose (HG) induced injury via the regulation of inflammatory and anti-inflammatory balance.

**Methods:** To explore this possibility, we performed genome-wide transcriptome profiling in human umbilical vein endothelial cells (HUVEC), which were stimulated by high glucose (HG) with/without EPO treatment and detected the expression of inflammation associated genes.

**Results:** Hierarchical clustering and principal component analysis showed the different pattern of mRNA expression in HG stimulated HUVEC with/without EPO. While inflammation related cytokines/chemokines mRNA expression was increased in the HG stimulation in HUVEC, Th2 related cytokine receptors and intracellular signaling molecules showed the reduced mRNA expression levels. EPO treatment reduced inflammatory cytokines/chemokines mRNA expression and increased Th2 related cytokine mRNA expression levels. Real-time PCR analysis confirmed the increased expression of inflammatory related genes, those were decreased in HG stimulated HUVEC with EPO treatment. Moreover, EPO stimulation increased mRNA expression of EPO receptor and b-common receptor. EPO signaling affect neither cell proliferation nor cell death.

**Conclusions:** Taken together, EPO signaling might protect high glucose induced cell injury by the regulation of immune balance.

**The Possible Mechanisms of Ameliorating Diabetic Mice Renal Insulin Resistance by Nf-xb Inhibitor Parthenolide**

Nanwei Li, Baobao Wang, Nephrology, Feking Union Medical College Hospital, China.

**Background:** Diabetic nephropathy (DN) was the severe complication of Diabetes Mellitus (DM). The treatment of DN was limited. Insulin resistance was linked with diabetic complications. The concrete forms of insulin resistance in diabetic renal tissue lacked research. AS160 could regulate the transportation of many transporters including glucose transporters. In kidney, AS160 was found can regulate sodium and water channel protein, while its role on glucose transporters has not been reported. Glucose transporter 4 (GLUT4) was an important effer of insulin signaling, which related to insulin resistance closely. Sodium glucose transporter 2 (SGLT2) and sodium glucose transporter 1(SGLT1) were important to promote renal tubular glucose re-absorption and were the new target of anti-diabetic drug. Our previous results showed NF-xb inhibitor Parthenolide (PTN) could improve db/db mice systemic insulin resistance and renal tissues injury. The aim of the study was to study the expression of AS160 and GLUT4 in diabetic kidney tissue and correlation between AS160 with GLUT4 and SGLT2/SGLT1.To explore whether PTN could improve renal IR and the possible mechanisms.

**Methods:** Set up db/m mice as control group, the db/db mice as diabetic nephropathy model group and db/db mice with PTN intervention as treatment group. The mice were sacrificed at week 8, 12, 16 and 20 and using blood, urine and kidney specimens for the study.

**Results:** 1) The db/db mice showed increased body weight, blood cholesterol, blood glucose and insulin, as well as glomerular hypertrophy and the increased mesangial matrix. PTN could improve the systemic insulin resistance and renal pathological changes of db/db mice. 2) AS160 and p-AS160, GLUT4 were all mainly expressed in renal tubules.3) The expression of p-AS160 and GLUT4 reduced gradually in db/db mice kidney with the increase of weeks.4) p-AS160 showed co-expression with part of GLUT4, but no significant co-expression with SGLT2/SGLT1.

**Conclusions:** The diabetic kidney tissue may have insulin resistance resulted from abnormal glucose transport by AS160 and GLUT4. The NF-xb inhibitor improved kidney insulin resistance may by increasing the expression of p-AS160 and GLUT4.

**Hypertension Results in Moderate Diabetic Nephropathy in a Mouse Model of Metabolic Syndrome**

Reinout Sloep,1 Anne van Koppen,1 Carol Goldschmeding,2 1 MHR, TNO, Leiden, Netherlands; 2 Pathology, UMUC, Utrecht, Netherlands.

**Background:** Diabetic nephropathy (DN) is a major complication in metabolic syndrome/diabetes patients. We have developed a metabolic syndrome mouse model characterized by non-alcoholic steatohepatitis and atherosclerosis upon high fat diet feeding. These animals show mild renal changes, but don’t progress to moderate DN. Therefore, we investigate whether inducing hypertension on top of metabolic syndrome leads to progression of DN.

**Methods:** Male LDL−/− mice (8 wk old) received high fat (45%) + high salt (6%) diet for 6 wk. To induce hypertension, combinations of several pro-hypertensive components were used (enemiphrine/isox, angiotensin II (ANGII), DOCA and a vasoconstrictor) for an additional 10 wk. At regular intervals, systolic blood pressure (SBP), 24h diuresis and albumin/creatinine ratio (UACR) were assessed. 17 wk after start diet, mice were terminated and renal injury was scored. We used age-matched chow fed animals as controls.

**Results:** Cholesterol and diuretics were significantly elevated in all groups vs chow from wk 5 onwards. ANGII induced a 20 mmHg increase in SBP at wk 13 vs. chow. At wk 8, UACR was significantly increased by ANGII in combination with HFD+HS (264±303 µg/mg) and UNX+HFD+HS (438±781 µg/mg) vs chow (62±24 µg/mg). At wk 13, ANGII further elevated UACR in HFD+HS (593±377 µg/mg) but decreased it in UNX+HFD+HS (87±28 µg/mg). Combining the metabolic syndrome/diabetes model with hypertensive components (717±585 µg/mg) at wk 5 but also caused fatal thoracic bleedings. This group was terminated at wk 11. Renal injury score showed glomerular hypertrophy, mesangium expansion, nodular glomerulosclerosis, mild hyalination and micro-aneurisms.

**Conclusions:** We show that LDL−/− mice fed HFD+HS and ANGII induces hypertension and mild progressive DN, in addition to NASH and atherosclerosis in a single
model providing broad coverage of metabolic syndrome complications. Administration of additional hyperglycemic agents (DOCA and NNA) further aggravated the model but also led to early fatal thoracic bleedings thus precluding further studies.

**Renal Functional and Morphological Changes Related to Obesity and Hyperglycemia in Göttingen Minipigs**

**Rikke Lindgaard Thomsen,** 1 Beni Östergaard Christoffersen,** 1 Trine P. Ludvigsen,** 2 Rikke Kaa Kirk,** 2 Jonas Kildegård,** 2 Lisa Tidman Fuchs,** 1 Pall Leifisson,** 1 Henrik D. Pedersen,** 1 Lisbeth Hoier Olsen,** 1 Dept of Veterinary Disease Biology, Univ of Copenhagen, Frederiksberg, Denmark; 2Novo Nordisk A/S, Målaøv, Denmark.

**Background:** Obesity and diabetes, two major health problems worldwide, both lead to renal functional and morphological changes; with diabetic nephropathy being the leading cause of end-stage renal failure. A large animal model displaying human-like features of obesity-related and diabetic nephropathy would be very valuable to study pathogenesis and effects of new drug candidates on these syndromes. The aim of the present study was to evaluate renal function and morphology in diet-fed obese, atherosclerotic Göttingen minipigs with or without mild diabetes.

**Methods:** Male castrated Göttingen minipigs, aged 8 weeks at study start, were fed normal chow (n=6) or high-fat, high-cholesterol diet (n=16) for 43 weeks. Mild diabetes was induced in 11 pigs after 18 (n=6) and 25 (n=5) weeks of diet-feeding, using streptozotocin (125 mg/kg IV) preceded by nicotineamide (67 mg/kg IV). The study included two cohorts. Parameters of interest were: Body fat percentage (BF) estimated by dual-energy X-ray absorptiometry, inulin clearance (IC), kidney resistive index (RI), plasma fructosamine reflecting plasma glucose (FRA), plasma urea, plasma creatinine (PCr), plasma total cholesterol (TC), urinary protein excretion (protein (UPCr) and albumin (UACr) adjusted for creatinine). Glomerulus area and number of nuclei/glomerulus area were estimated post mortem. Influence of BF, TC and FRA on in vivo kidney function and post mortem kidney changes was evaluated using ANOVA with cohort as fixed covariate. BF was positively associated with urea (P<0.01), IC (P<0.05), Glomerulus area (P<0.001) and UPCR (P<0.05), and negatively with PCr (P<0.001). FRA was positively associated with UACr (P<0.05) and number of nuclei/glomerulus area (P<0.05). RI was not associated with BF, TC or FRA.

**Conclusions:** In conclusion, functional and histological renal changes were found in diet-fed obese, atherosclerotic Göttingen minipigs with and without mild diabetes. The changes were associated with obesity and hyperglycemia.

PUB294

**Activation of Toll-Like Receptors Through Fetuin-A Leads to an Inflammatory Response in Podocytes and Exacerbates Palmitic Acid-Induced Cell Death**

**Jana Orellana,** 1 Kapil Dev Kamp, 1 Andreas Werner Jehle,** 2 Dept of Biomedicine, Univ Hospital Basel, Basel, Switzerland; 2Dept of Biomedicine, Univ Hospital Basel, Basel, Switzerland.

**Background:** Inflammation participates in the pathogenesis of type 2 diabetes and contributes to diabetic nephropathy (DN). There is growing evidence that chronic elevated free fatty acids (FFAs) contribute to this chronic inflammatory milieu. Studies in pancreatic β-cells suggest that the inflammatory response mediated by FFAs depends on toll-like receptor (TLR) 4 and TLR-1 receptor (II-1R). The signaling pathways of TLRs and II-1R involve activation of the transcription factor nuclear factor-κB (NF-κB) which induces a wide range of cytokines/chemokines including monocyte-chemoattractant protein-1 (MCP-1), and II-1. Here, we addressed whether fetuin-A together with FFAs leads to an inflammatory response in podocytes and whether this exacerbates palmitic acid-induced podocyte death.

**Methods:** Conditionally immortalized murine podocytes were used. Murine and bovine fetuin-A were used alone or in combination with palmitic acid complex to BSA. MCP-1 was measured by ELISA. Podocyte death was determined by flow cytometry (annexin V and propidium iodide staining).

**Results:** Palmitic acid alone did not, but fetuin-A induced MCP-1 in podocytes and this was further increased by palmitic acid. The MCP-1 release was prevented by CI095 (TLR4 blocker). Fetuin-A or LPS exacerbated palmitic acid induced podocyte death, and CI095 as well as the IL1 receptor antagonist anakinra or an anti II-1β antibody attenuated cell death.

**Conclusions:** Fetuin-A alone and in combination with palmitic acid leads to an inflammatory response in podocytes and promotes palmitic acid induced podocyte death. As inhibition of TLR4 as well as II-1 prevents these effects, both pathways are promising targets to attenuate the progression of DN.

**IL-1β Mediates the High Glucose Induced Endothelial-to-Mesenchymal Transition in Human Aortic Endothelial Cells**

**Dongdong Zhai,** 1 Ri-ning Tang,** 2 Kun Ling Ma, Bi-Cheng Liu, Zhong Da Hospital, Southeast Univ Medical School, Nanjing, Jiangsu.

**Background:** Studies have shown that endothelial-to-mesenchymal transition (EndMT) induced by high glucose (HG) contributes to cardiovascular disease. Additionally, proinflammatory cytokine interleukin-1β (IL-1β) has been implicated as one of the dominant players in the development of fibrosis and diabetic heart. In vitro studies, retinal endothelial cells(ECS), human intestinal ECS and human dermal ECs have been reported to undergo EndMT by

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

955A
IL-1β stimulation. Interestingly, most IL-1β immunoreactivity is localized to endothelial cells of mesenterial microvessels. In an animal model of cardiac hypertrophy, however, the potential role of IL-1β in high glucose induced EndMT remains unknown. Here, we hypothesize that IL-1β might mediate the process.

Methods: Primary human aortic endothelial cells (HAECs) were divided into three groups: a normal glucose (NG) group, a high glucose (HG) group, and anti-interleukin1β (IL-1β) antibody treated (HG+Anti-IL-1β) group. The concentration of IL-1β in the supernatant was detected by ELISA. Pathological changes were investigated using fluorescence microscopy and electron microscopy. Immunofluorescence staining was performed to detect the co-expression of CD31 and FSP1. The expressions of FSP1 and α-SMA were significantly increased in the expression of EndMT (P < 0.05). Double staining of the HAECs indicated a colocalization of CD31 and FSP1, while treatment with anti-interleukin1β/anti-HLA-DR siRNA attenuated the expression of EndMT (P < 0.05).

Conclusions: These findings suggest that IL-1β mediates the HG induced EndMT, which was inhibited by anti-interleukin1β/anti-HLA-DR siRNA treatment.

Serum Bilirubin and Asparagine Aminotransferase Concentrations Predict Loss of Renal Function in Type 2 Diabetes

Kevin M. Wheelock,1 Guđeta D. Fufaa,1 William Knowler,2 Majdumitra Sinha,1 Frank C. Brooks,3 Robert G. Nelson.1 NIDDK, Phoenix, AZ; Univ of Michigan, Ann Arbor, MI.

Background: Higher serum bilirubin concentration is reported to slow the progression of nephropathy in type 2 diabetes. We examined associations of serum bilirubin and asparagine aminotransferase (AST) concentrations with renal function loss (RFL) in a post-hoc analysis of a clinical trial of renoprotection with losartan in Pima Indians with type 2 diabetes (ClinicalTrials.gov, number, NCT00340678). Methods: Serum bilirubin and AST were measured at baseline in 168 subjects who underwent annual measurement of GFR by the urinary clearance of iothalamate. RFL was defined by ≥40% decline in GFR from baseline. Cox regression was used to compute hazard ratios (HRs) for the association of a 1 standard deviation (SD) increment in bilirubin and AST concentrations with RFL adjusted for age, sex, treatment group, HbA1c, GFR, and urinary albumin/creatinine ratio (ACR). The sum of standardized AST and bilirubin was used to create a liver index (P<0.001) and a serum AST (HR=1.39) predicted RFL. The combination of these liver function tests provided the strongest prediction (HR=1.52).

Conclusions: Higher serum bilirubin and AST concentrations predict loss of renal function in Pima Indians with type 2 diabetes.

FGF-23 and Magnesium Are Independent Risk Factors for an Increased Albumin-to-Creatinine Ratio in Type 2 Diabetics with Chronic Kidney Disease

D. Fufaa,1 Beata Czerwienska,5 Madhumita Sinha,2 Robert G. Nelson,1 Madharmahal P. Merchant,2 William Knowler,2 Robert G. Wheelock,2 Teresa M. Jeronimo,1 Ana Pocinho Pimentel,1 Pedro L. Neves,1,2 Centro Hospitalar do Algarve- Hospital de Faro, Portugal; 2Univ do Algarve, Portugal.

Background: Microalbuminuria is the earliest sign of glomerular involvement in diabetes mellitus. The multiple physiological mechanisms involved are complex and not completely understood. Recently, it appeared that fibroblast growth factor-23 (FGF-23) and magnesium play a role in the emergence and maintenance of albuminuria in type 2 diabetes. The aim of this study is to investigate the role of FGF-23 and magnesium in relation to the urine albumin-to-creatinine ratio in type 2 diabetics with chronic kidney disease (CKD) stages 2-4.

Methods: In a cross-sectional study we included all eligible type 2 diabetic patients with CKD stage 2-4, followed in our outpatient Diabetic Kidney Clinic. We included 150 patients, 53±5 years, with a mean age of 66±6.9 years (40-85) and a mean follow-up of 76 months. We used descriptive statistics, the Student’s t, ANOVA and the chi-square test. We divided our population according to the urine albumin-to-creatinine ratio (CI=30-300 mg/g and G2≥300 mg/g) and compared these groups regarding the several biological and laboratory parameters analyzed. We employed a multiple regression model to identify risk factors of increased urine albumin-to-creatinine ratio. In this model we used the urine albumin-to-creatinine ratio as the dependent variable and as independent ones age, duration of diabetes, systolic blood pressure, HgA1c, eGFR, HOMA-IR, manoncalehyd, hs-CRP and 1,25(OH)3D3 levels.

Results: The patients in G2 displayed a lower eGFR (p=0.0001) and magnesium (p=0.004) levels, as well as higher levels of FGF-23 (p=0.043) compared to patients in G1. In the multivariable linear regression model we found adjusted β=-0.060 (p=0.001) and the magnesium (β=-8.916,p=0.0001) are independent risk factors for increasing the urine albumin-to-creatinine ratio.

Conclusions: The present study shows that a dysregulation of mineral metabolism, reflected by altered levels of magnesium and FGF-23, correlates with an increased urine albumin-to-creatinine ratio in type 2 diabetic patients with CKD stages 2-4.

Results: We found that G2 patients showed higher age (p=0.017), phosphorus (p<0.001), IPTH (p<0.0001), urine albumin-to-creatinine ratio (p=0.001), Homa-IR (p<0.001), FGF-23 (p<0.0001) and OxlDL (p=0.0001) and lower levels of eGFR (p<0.0001), Klotho (p=0.0001) and 1.25(OH)2D3 (p<0.0001). In the multivariate linear regression model we found that FGF-23 (β=0.337, P=0.047) and the Klotho (β=-0.367, P=0.023) are independent risk factors for increasing the pulse pressure.

Conclusions: In conclusion, in a population of type 2 diabetic with chronic kidney disease stages 2-3, the Klotho and FGF-23 levels are independently associated with PP. Further studies with more patients are warranted to confirm whether an increase in Klotho and a decrease in FGF-23 would reduce the PP and consequently the cardiovascular risk of our patients.

PUB300
Prediction of Renal Outcome in Type 2 Diabetic Dephropathy by Estimating GFR from a Combination of Serum Creatinine and Cystatin C

Yu Pan, Song Jiang, Dannan Qiu, Yu An, Yongchun Ge, Honglang Xie, Zhihong Liu. National Clinical Research Center of Kidney Diseases, Research Inst of Nephrology, Jinling Hospital, Nanjing, Jiangsu, China.

Background: Serum cystatin C is an alternative to serum creatinine for estimating glomerular filtration rate (GFR), however, the utility of estimated GFR from combination of serum creatinine and cystatin C as marker to predict long-term renal outcome is uncertain, particularly in the Type 2 diabetic nephropathy (DN).

Methods: A total of 501 patients (The National Clinical Research Center of Kidney Diseases, 2003-2011) were recruited in prospective cohort study. Follow-up was 5-year. Renal outcome was defined by eGFRcre-cys<15 ml/min per 1.73m2 or renal replacement therapy.

Results: The distributions of standardized serum cystatin C with eGFRcre and eGFRcre-cys are shown in. Kaplan-Meier curves showed significantly increased renal end points with higher quartile of cystatin C (p<0.001) and lower eGFRcre-cys (p<0.001). The highest AUC values was eGFRcre-cys in predicting the renal endpoint compared with eGFRcre or eGFRcre-cys. The best cut-off value for predicting the renal endpoint was 29.28% decline in the 24-month, which value showed 79.6% sensitivity and 82.6% specificity. Cystin regression models with restricted cubic splines were shows a change of -30% in eGFRcre-cys was associated with adjusted HRs for ESRD of 27.92 (95%CI, 3.95-197.48) over 2-year.

Conclusions: eGFRcre-cys was a precision, and accuracy marker in the predicting the renal outcome and 30% decline of eGFRcre-cys over 2 years was strongly associated with the risk of ESRD, suggesting it could be used as an alternative end point in T2DN.

PUB301
Prevalence and Prognostic Role of Uncontrolled Risk Factors in Diabetic CKD (DM-CVKD) Treated in Nephrology Clinics

Roberto Minuto1, Michele Provenzano1, Paolo Chiordi,2 Giuseppe Conte,1 Luca De Nicolai,1 Nephrology, Second Univ, Naples, Italy; 2Med Stat, Second Univ, Naples, Italy.

Background: Knowledge of prognosis of DM-CVD mainly derives from RCTs and cohort studies followed in the diabetology setting. Epidemiologic features are less defined in patients with overt disease managed in renal clinics.

Methods: We studied 763 DM-CKD patients derived from 3 prospective cohorts that in 2000-2010 enrolled 2,488 CKD patients stage III-V under stable care from 24 months in 40 RCTs and renal clinics. Endpoints were ESRD (chronic dialysis-transplant) and first major cardiovascular (CV) events (fatal and non fatal) assessed through 12/2014. Uncontrolled risk factors were defined as high blood pressure (BP<140/90 or >130/80 if proteinuria >0.15g/24h), HbA1c<7.5%, hemoglobin<10.5 g/dL, serum phosphorus (P)<4.5 mg/dL, LDL)<100 mg/dL or according to ESC 2012 guidelines, proteinuria (Urprot<0.5 g/24h).

Results: HbA1c was 6.9%, (IQR 5.9-7.8), Uprot 0.5 g/24h (IQR 0.1-1.4), P 3.9±0.8 mg/dL, Hb 12.3±1.7 g/dL and BP 142±19/88±11 mmHg. During follow-up (43 months, IQR 21-56), 171 ESRD and 170 CV events occurred (incidence rate 6.4 and 6.9/100 pt/y), Multivariable Cox analyses for ESRD and CV risks (HR, 95% CI) stratified by cohort are in the Table.

Conclusions: Epidemiologic peculiarities emerge in DM-CKD patients treated in renal clinics. This information can be helpful to optimize risk stratification and adequately design RCTs.

Serum NGAL and Cystatin C Accuracy in Early Detection of Kidney Dysfunction in Type 2 Diabetes

Miguel Rodriguez Bacci, Fernando Luiz afonso Fonseca, Livia Yadayo Vasconcelos, Mariana Rigolo, Ross Rozier-Alves, Beatriz Alves. General Practice, ABC Medical School, Brazil.

Background: Diabetic nephropathy is associated with specific histological changes. An early detection of depletion of glomerular and tubular function can be done with biomarkers of diabetic disease. The aim of this study is to evaluate the accuracy of early kidney dysfunction biomarkers in diabetes.

Methods: Patients with diabetes were split according to their levels of glycated hemoglobin (GHB) greater than or equal to 8% or below this value. Urine samples were taken to measure cystatin C(s/CYS) and NGAL beta-trace protein(uBTP) and albuminuria (ACR). In blood, sCYS and sNGAL were measured. Patients with stage end renal disease or in dialysis were not included. Blood samples were used to evaluate the risk of renal dysfunction according to their simplified MDRD estimated glomerular filtration rate(eGFR), Spearman’s correlation and regression models were built to evaluate the markers.

Results: Ninety patients with diabetes were recruited. The mean eGFR was 79.1ml/min/1.73m2. The group of s/CYS was positively correlated with creatinine (p<0.001), eGFR (p<0.001) and uBTP (p=0.01). The ROC curve showed value of 0.635 for s/CYS, 0.621 to sNGAL and 0.660 for ACR. Urine had lower values for CYS(0.595), 0.526 for NGAL and 0.567 for uBTP. The crude logistics regression model observed a positive association between sCYS and sNGAL with GFR. The proposed regression model showed positive association with sCYS and creatinine and eGFR (p<0.001) but not with GHB (p=0.892). ACR showed the same parameters (p=0.005 for creatinine and 0.018 to eGFR).

Conclusions: In this study a comparative panel of tubular and glomerular dysfunction markers was built in diabetics with eGFR<60.There was a worse performance of the marker in urine except for ACR that had the best value in ROC analysis. The sCYS and sNGAL presented the best association with worse GFR and glomerular control. In another study of our group uBTP had better performance to distinguish early kidney dysfunction between diabetes and non diabetics. Finally, with worse eGFR, sNGAL, sCYS and ACR performed better in diabetics. A worse glycemic control was positively associated with sCYS and nNGAL.

Comparison of Renal Outcome Between “Chronic Kidney Disease due to Diabetes” and “Chronic Kidney Disease with Diabetes” in Gyoro Study

Toshiki Iwai,1 Mariko Miyazaki,1 Gen Yamada,1 Tae Yamamoto,1 Hiroshi Sato,2 Masaaki Nakayama,2 Sadayoshi Ito.1 1Nephrology, Hypertension, and Endocrinology, Tohoku Univ Department of Pharmacology, Sendai, Miyagi, Japan; 2Clinical Pharmacology and Therapeutics, Graduate School of Pharmaceutical Sciences, Tohoku Univ, Sendai, Japan; 1Kidney and Hypertension, Fukushima Medical Univ, Fukushima, Japan.

Background: Diabetic nephropathy (DN) is defined as chronic kidney disease (CKD) due to diabetes mellitus (DM) in a narrow sense. The difference is not unclear between DN and CKD patients of other cause but complicated DM (CKD with DM) in clinical outcome. This study mentioned the clinical difference and renal outcome of DN, CKD with DM, and CKD without DM.

Methods: This is a part of Gyoro CKD study. It is the multicenter prospective observational survey for 5 years. From May 2006, 4,015 patients were registered. We included 2,484 of them into this analysis who could classify to DN (n=249), CKD with DM (n=448), and CKD without DM (n=1,787). The classification was performed at registration by clinical finding and history of other diabetic complication such as retinopathy if case without kidney biopsy.

Results: The characteristics of age, gender, systolic blood pressure (SBP), and dyslipidemia in “DN” (66.6 y.o., male 67.7%, sBP 136.6mmHg, dyslipidemia 50.1%) and “CKD with DM” (58.7 y.o., male 58.7%, sBP 132.3mmHg, dyslipidemia 54.4%) were similar compared with “CKD without DM” (50.5 y.o., male 50.5%, 128.9 mmHg, 40.1%). For renal outcome analysis of each CKD stage was performed. The hazard ratio of “DN” was significantly higher than “CKD without DM” and “CKD with DM” (1.36(1.24-2.69), 95% CI, G4 2.34(1.35-4.39), G5 1.67(1.16-2.42), On the other hand, that of “CKD with DM” didn’t elevate in G3 (0.89(1.94-4.29, 95% CI), G4 2.10(1.66-2.23), G5 1.30(0.74-2.51) compared with “CKD without DM”. Kaplan-Meier analysis revealed G3 and G4 in “DN” showed significantly poor outcome. The evaluation of annual decline of eGFR revealed stage G3b in DN was the largest, (-3.7 ml/min/1.73m2/2 year).

Conclusions: Renal risk between “CKD with DM” and “DN” was completely different. G3b was most important critical point in renal prognosis of DN.

Prevalence of Proteinuria, Albuminuria and Associated Factors in Obese Patients Undergoing Bariatric Surgery

Max R. Pommier, Gaurang P. Mavani, Maria V. Devita, Michael F. Michielis, Jordan L. Rosenstock. Dept of Medicine Div of Nephrology, Lenox Hill Hospital Northshore/ LIJ, NYC, NY.

Background: Obesity is associated with proteinuria. But the exact prevalence of proteinuria or albuminuria with and without additional risk factors in obese patients is unclear.

Methods: Consecutive patients undergoing bariatric surgery were included in study. Participating patients had a urine sample for protein creatinine ratio and albumin creatinine ratio prior to their surgery. We defined a positive protein to creatinine ratio as greater than or equal 300 mg and a positive albumin to creatinine ratio as greater than or equal to 30 mg. Associated factors such as diabetes mellitus (DM), hypertension (HTN), body mass index (BMI), and ACEI/ARB use were collected.

Results: One hundred forty-three patients were included. The mean age was 43 years +/-11. Twenty five percent of the patients had DM, 50% had HTN, and the mean BMI was 44 +/- 9. The prevalence of proteinuria and albuminuria was 8.5% (95% CI 4.5-14.4%) and 21% (95% CI 14-30%) respectively. Sixty six percent of the patients with proteinuria had DM as did 43% of the patients with albuminuria. Eighty three percent of patients with proteinuria had either DM or HTN. Seventy eight percent of patients with albuminuria had either DM or HTN. Overall, 34% with proteinuria and HDL. Only 3.4% and 8.6% had proteinuria and albuminuria respectively. In contrast to patients who did not have proteinuria, the mean BMI was higher in those with proteinuria (44 vs. 40). However, the BMI did not differ between those with and without albuminuria. The BMI for diabetics did not differ from non-diabetics. The use of ACEI/ARB was 35% and 30% in patients with proteinuria and albuminuria and 25% and 20% in those without.

Conclusions: The majority of patients with proteinuria and albuminuria had diabetes and/or hypertension and there was a much lower prevalence of proteinuria/albuminuria in patients without these risk factors. Patients who had proteinuria had a higher BMI than patients who did not have proteinuria, though for albuminuria the BMI did not differ.

PUB305 Plasma Uric Acid and Cardio-Renal Function in Adolescents with Type 1 Diabetes

Yasuya Lytvyn,1 Farid H. Mahmud,2 Livia Ded,2 David B. Dunge,2 John Eric Deanfield,3 Yesmina Elia,4 Ronnie Lok-Hang Har,4 Timothy J. Bradley,2 Rahim Moineddin,2 Heather N. Reich,1 James W. Scholey,1 Luc Mertens,4 Etienne Bertrand Sochett,2 David Chemery,1 Nephrology, Univ Health Network, University of Toronto;1 Endocrinology, The Hospital for Sick Children, University of Toronto;2 Pediatrics, Univ of Cambridge, Cambridge, United Kingdom;3 Univ College Hospital, London, United Kingdom;4 Cardiology, The Hospital for Sick Children, University of Toronto;4 Family and Community Medicine, Univ of Toronto.

Background: Plasma uric acid (PUA) correlates with higher blood pressure (BP), lower GFR and left ventricular hypertrophy in adults with type 1 diabetes (T1D). Our overall aim was to determine if similar relationships exist in adolescents with T1D, analyzed on the basis of low-, middle- or high- albumin to creatinine ratio (ACR) tertile within the normal range, compared to healthy controls (HC).

We hypothesized that PUA within the normal range would be lower among adolescents with lower GFR and higher values for BP and arterial stiffness in T1D adolescents but not HC.

Methods: PUA, BP, GFR, and carotid-femoral pulse wave velocity (Car-Fem PWV) were measured in 65 HC, 64 low-, 74 middle- and 50 high-tertile T1D participants from the Type 1 Diabetes Type 1 Diabetes Cardio-Renal Intervention Trial (ADDIT).

Results: PUA was lower in TID vs. HC (242.55 vs. 306.74 mmol/L; p<0.0001). There were no differences in PUA between the 3 ACR tertiles. Higher PUA correlated with lower GFR in TID after correcting for age, gender, HbA1C, z-score, T1D duration and HDL (r=0.33, p=0.0001). This association was not seen in HC. In the TID group, PUA did not correlate with BP z-score before or after correcting for HbA1C, TID duration and plasma HDL. Higher PUA correlated with higher Car-Fem PWV (r=0.18, p=0.018) in TID, but not in HC. This association in TID was abolished after correcting for age, gender, HbA1C, and z-score, T1D duration and HDL (r=0.18, p=0.03).

Conclusions: PUA correlates with lower GFR in TID adolescents and may also be associated with increased arterial stiffness, despite lower PUA in TID vs. HC. The presence of TID may potentiate the hemodynamic impact of PUA, thereby modifying future cardio-renal risk.

PUB306 Risk Factors for Renal and Cardiovascular Events in Type 2 Diabetic Patients with Biopsy-Proven Nephropathy in Japan

Akikuni Har,1 Kenji Furuiuchi,1 Miho Shimizu,1 Yukio Yuzawa,2 Hiroshi Kitamura,3 Hiroshi Sato,1 Takashi Wada.1 Div of Nephrology, Kanazawa Univ Hospital, Japan;1 Dept of Nephrology, Fujita Health Univ Hospital, Japan;2 Dept of Pathology, Clinical Research Center, National Hospital Organization Chiba East National Hospital, Japan;3 Clinical Pharmacology and Therapeutics, Tohoku Univ Graduate School of Pharmaceutical Sciences.

Background: Standardized pathological classification is an essential tool in the evaluation of disease progression and/or efficacy of clinical management. In this nationwide, multicenter, retrospective study, we examined pathological findings as risk factors for renal and cardiovascular events in Japanese patients with type 2 diabetes (T2D) who had undergone kidney biopsy.

Methods: Renal biopsy and clinical data were retrospectively collected from 356 patients with T2D who had undergone kidney biopsy at centers in Japan. The observation period was 76.3 months and the observation period was 2264 person-year in total. Nine glomerular lesions, two interstitial lesions, and two vascular lesions were classified as pathological predictors.

Results: One hundred sixty nine composite renal events (dialysis and doubling of serum creatinine or half of estimated glomerular filtration rate [eGFR], 94 kidney deaths (dialysis), 34 cardiovascular events, and 30 deaths occurred. Specific pathological risk factors were detected for composite renal end points, renal death, and cardiovascular events, and levels of preserved eGFR and preserved eGFR were not associated with them, the presence of double contour of the glomerular basement membrane/subendothelial space widening (SubendW) and advanced interstitial cell infiltration (ICel) were particular risk factors for composite renal events, and glomerulonephromy (GMeG) was a risk factor for cardiovascular events.

Conclusions: This study revealed that specific pathological parameters (presence of SubendW, ICel, and GMeG) were predictors for renal and cardiovascular events in patients with preserved eGFR and normo- to microalbuminuria.

Funding: Government Support - Non-U.S.
Conclusions: In DMN, DPP-4i have oxidative stress relief and renoprotective effect, by the improvement of short-term blood sugar fluctuations, also by oxidative stress reduction which independently of the improving glycemic control.

PUB309

Background: To evaluate the potential of fibrinogen as a predictor of the progress of proteinuria in diabetic kidney disease.

Methods: For a Cross-Sectional Study, collecting 1121 type 2 diabetes patients without or with microalbuminuria or massive proteinuria were treated during January 2008 to January 2013. Proteinuria was negative in 755 cases, 285 cases i with microalbuminuria, and 181 cases with massive proteinuria; we analyzed the correlation factors of the negative protein urine group and the microalbuminuria group; the correlation factors of the microalbuminuria group and the massive proteinuria group. Fibrinogen levels were compared between three groups.

Results: Retinopathy, hypertension grading, SBP, Fibrinogen levels, serum albumin, serum creatatin were the related progress factors of Microalbuminuria; Diabetes course, retinopathy, waist to hip ratio, Fibrinogen levels, serum albumin levels, serum creatatin, C, serum creatinine were the related progress factors of the massive proteinuria; Except fibrinogen, other factors had been known relating to the progress of diabetic kidney disease. There were differences in the levels of three groups of fibrinogen (P<0.05), which were 3.43 ± 0.91 g/L, 4.15 ± 1.31 g/L, 5.16 ± 1.44 g/L.

Conclusions: Fibrinogen was a potential predictive factor for the development of diabetic kidney disease. The conclusion needs to be confirmed by further study.

PUB310
Interaction of HDLc, Iron, and Diabetes on Kidney Function. Jiaqiwu Conway,1 Tina Costacou,2 John M. Arthur,3 Epidemiology, West Virginia Univ; 2Epidemiology, Univ of Pittsburgh; 3Univ for Medical Sciences.

Background: The effect of HDL cholesterol (HDLc) on kidney function has recently received attention, partly due to the finding of increased hemoglobin (hb) inside of the HDL protein in persons with high risk haptoglobin (hp) genotypes. Such hb w/ in the HDL protein may lead to iron induced lipid peroxidation products. These lipid peroxidation products may lead to iron-induced kidney damage. We have recently shown an interaction between HDLc and iron w/ kidney function (eGFR) in persons with diabetes such that after controlling for hb, higher serum iron levels were associated w/ reduced eGFR but only in those w/ HDLc levels above the median for the population. Because of the diabetes-specific association of increased hb inside the HDL protein in those w/ high risk hp genotypes, we hypothesize that this interaction between HDLc and iron w/ kidney function varies by diabetes status. To test this hypothesis, we examined the inter-relationship between HDLc, iron, and diabetes status w/ eGFR in approximately 55,000 individuals in West Virginia and Ohio.

Methods: Data on adults aged 20 years were obtained from the C8 Health Project. eGFR was estimated using the CKD-EPI formula. Linear regression analysis was used to test the relationship between HDLc, iron, and diabetes status, and diabetes-related eGFR, with interactions, w/ eGFR.

Results: Mean age was 57.8 in those w/ diabetes and 45.1 in those w/out diabetes. In multivariable analyses controlling for age and sex, iron was positive related w/ eGFR in those w/ (p=0.03) and inversely in those w/out diabetes (<=0.0001), while HDLc was positively associated w/ eGFR only in those w/out diabetes (p=0.97 in diabetes; p=0.001 in w/o diabetes). As previously reported, an interaction existed between HDLc and iron in diabetes (p=0.04). Here we report that this relationship was even stronger in those w/out diabetes (interaction p=0.0008). A significant 3-way interaction existed between HDLc, iron, and diabetes status w/ eGFR (p=0.008). Controlling for hb, the interaction between iron and HDLc disappeared in those w/ diabetes but remained robust in those w/out diabetes.

Conclusions: The divergent relationship between iron and HDL on the eGFR by diabetes status needs further investigation.

PUB311
Molecular-Selective Plasma Exchange in Acute Kidney Injury due to Multiple Myeloma. Mamoru Kanda, Satomi Satoda, Shinichi Mizzuno, Shu Yamakage, Mitsuhiro Sato, Yoshio Taguma, Toshinobu Sato. Nephrology, Japan Community Health Care Organization Sendai Hospital, Sendai, Miyagi, Japan.

Background: Benefit of plasma exchange in overall survival of patients with multiple myeloma (MM) remains to be determined, however, it is evident that lowering free light chain (FLC) reverses renal function in acute kidney injury (AKI) due to MM. High cut-off hemodialysis is recommended to remove FLC as an initial treatment for MM related AKI, which is different from traditional plasma exchange (PE) in retained loss of large size molecules. As another option, we show the effect of molecular-selective plasma exchange to remove FLC, which enables target size removal without losing other size molecules.

Methods: A 49 year male with Bence-Jones type M protein was admitted with AKI; serum creatinine rose from 3.8 to 7.9mg/dL in 1 month. Past history included bone fracture and diabetes. Serum FLC lambda was elevated to 28900mg/dL. MM was confirmed by plasma cells in the bone marrow. The patient was treated with sequential molecular-selective plasma exchange (Evacure) and on-line HDF every other day combined with Bortezomb.

Results: PE was performed 6 times and removed 43.1% of FLC each on average without losing small and large size molecules.

Conclusions: Benefit of plasma exchange in overall survival of patients with multiple myeloma (MM) remains to be determined, however, it is evident that lowering free light chain (FLC) reverses renal function in acute kidney injury (AKI) due to MM. High cut-off hemodialysis is recommended to remove FLC as an initial treatment for MM related AKI, which is different from traditional plasma exchange (PE) in retained loss of large size molecules. As another option, we show the effect of molecular-selective plasma exchange to remove FLC, which enables target size removal without losing other size molecules.

The Effect of MySleeve on Fluid Restriction Adherence in Hemodialysis Patients

**Patients and Methods:** A Time and Motion Study of Erythropoiesis Stimulating Agent Administration in United States Dialysis Centers

**Background:** In hemodialysis patients, non-adherence to fluid restriction is associated with high interdialytic weight gain (IDWG) and adverse outcomes. Monitoring drinking behavior and direct feedback to the patient can lead to better adherence. We developed the MySleeve, a device that can be wrapped around a drinking glass to monitor fluid intake throughout the day. The MySleeve will also provide a subtle vibration on the glass when the amount drunk exceeds the target. The information about drinking behavior can be found in the accompanying application on a mobile phone. In this study, we investigate the effect of direct feedback and information to the patient on fluid restriction adherence measured by the IDWG.

**Methods:** We will include 40 prevalent, anuric hemodialysis patients from the Catharina Hospital Eindhoven, The Netherlands in a randomised controlled trial. Patients in the intervention group are provided a MySleeve device, a mobile phone and an activity tracker. BCM measurements are performed weekly and IDWG will be calculated before every dialysis session. The patients in the control group will continue with regular hemodialysis.

**Results:** We expect that by providing patients insight in fluid intake, there will be an increased fluid restriction adherence and an improvement in activity levels and better quality of sleep. Due to less IDWG, patients will experience less discomfort of fluid overload.

**Conclusions:** Introducing a MySleeve device to provide direct insight into drinking behavior will help the patients to adhere to their fluid restriction, leading to less IDWG and better quality of life measured by daily activity and better sleep.

A Time and Motion Study Assessing Agent Use in Dialysis Centers

**Methods:** A Time and Motion Study of Erythropoiesis Stimulating Agent Administration in United States Dialysis Centers

**Background:** Previous research suggests that ESA administration in dialysis is a time-consuming task and switching to less frequently dosed ESAs may offer opportunities for more efficient and effective patient care. This study estimated the time required for activities involved in the ESA process at US dialysis centers using epoetin alfa (EPO) or darbepoetin alfa (DPO), and examined potential time savings of switching from EPO to DPO.

**Methods:** Time and motion study conducted from 10/2014 to 1/2015 to assess activities involved and staff time required to prepare, administer and document ESA doses. A sample of 11 dialysis centers using either 3 times-per-week (TW) EPO or once-weekly (QW) DPO were selected in pairs (one EPO, one DPO), where possible, from the same organization or nephrology practice to help control for anemia management protocols and staffing patterns. ESA-related tasks were timed by trained nurse observers. Time savings were calculated from switching from TIW EPO to QW-DPO were estimated. Staff were interviewed about alternate patient-focused activities that could be accomplished if time were saved in the ESA process.

**Results:** 200 administrations were observed (81 DPO, 119 EPO). A mean of 2.3 (95% CI, 2.1–2.5) minutes per dose were required for ESA-related activities. RNs performed 95% of tasks; LPNs 5%. ESA process time did not vary significantly between EPO and DPO (p=0.83). Staff time savings would accrue due to fewer ESA administrations using QW DPO: 10-20 minutes per nurse/day. For an average facility, the total monthly nurse time that could be re-purposed was 24 hours. Patient education, fulfillment of care plans and more frequent review of labs were identified as opportunities for improved care processes that could be implemented after conversion.

**Conclusions:** Switching from TIW EPO to QW DPO for anemia management in dialysis patients can result in time savings and opportunities to redirect nurse time towards activities aimed at improving patient care while still offering the ability to respond to changing clinical circumstances to effectively manage anemia.

Inflammatory and Metabolic Syndrome Biomarkers Analysis of Vascular Outcomes in End-Stage Renal Disease

Vinod K. Bansal,1 Patrick Siegert,2 Debra Hoppensteadt,2 Jennifer Saluk,2 Daneyal Syed,2 Jawed Fareed.2 1Nephrology, Loyola Univ Medical Center, Maywood, IL; 2Pathology, Loyola Univ Medical Center, Maywood, IL.

Background: The relevance of some biomarkers of inflammation and metabolic syndrome to vascular outcomes in end stage renal disease (ESRD) is not clear. To study these relationships, biochip array technology method was used to profile the complex plasma biomarkers in the setting of various comorbid outcomes such as Stroke or Transient Ischemic Attack (TIA), Acute Coronary Syndrome (ACS), Congestive Heart Failure (CHF), and Coronary Artery Disease (CAD).

Methods: Plasma samples were collected from 83 ESRD patients (mean age 65) prior to hemodialysis and were profiled using biochips for metabolic and inflammatory biomarker levels. Inflammatory cytokine and Metabolic Syndrome arrays were used to profile C peptide, ferritin, insulin, leptin, resistin, TNFα, PAI-1, IL-1a, ILb, IL-4, IL-6, IL-8, IL-10, VEGF, EGF, IFNG, and MCP1. Retrospective review was performed to group patients based on history of Stroke or TIA, ACS, CHF, and CAD.

Results: Of the 83 ESRD patients, 25 (30.1%) were found to have history of Stroke/ TIA, 14 (16.9%) were found to have history of ACS, 30 (36.1%) were found to have history of CHF, and 39 (47.0%) were found to have history of CAD. Stroke/TIA patients were found to have decreased plasma IFNG levels (p=0.042) and decreased plasma IL-1α and IL-1β levels (p=0.008, 0.021, 0.026; respectively) when compared to patients without Stroke/TIA. ACS patients had elevated plasma IL-6 levels (p=0.040) when compared to those without ACS. CHF patients had decreased plasma leptin levels (p=0.031) and elevated plasma IL-1b levels (p=0.042) when compared to patients without CHF. CAD patients had elevated plasma IL-1α levels (p=0.049) when compared to ESRD patients without CAD.

Conclusions: Profiling of multiple inflammatory and metabolic syndrome biomarkers may aid in the risk stratification of ESRD patients for cerebrovascular and cardiovascular disorders. These studies demonstrate that biomarker profiling of vascular comorbidities in ESRD may provide useful diagnostic and prognostic information in the management of ESRD patients.

PUB318

Individualized Anemia Management in Pediatric Nephrology Patients

Adam E. Gaweda,1 Jason Misurac,2 Michael E. Brier,2 Jeffrey D. Leisner.2 1Medicine, Univ of Louisville, Louisville, KY; 2Nephrology, Riley Hospital for Children at Indiana Univ, Indianapolis, IN.

Background: Anemia management in pediatric patients on dialysis poses a great challenge to the nephrologist. In this study, we tested the hypothesis that individualized approach anemia management, previously demonstrated successfully in adult patients, improves hemoglobin maintenance within target range in pediatric dialysis patients.

Methods: We performed prospective evaluation of Clinical Decision Support System “Smart Anemia Manager” (SAM) in pediatric dialysis patients at Riley Hospital for Children at Indiana University. SAM was implemented as a stand-alone software on a desktop computer used by the nurse anemia manager and connected to a database containing Hemoglobin (Hgb) and ESA dose data. The anemia manager was allowed to override dose recommendations from the system and each override was documented. The follow-up period was 10 months, including 4 month washout period. We compared the hemoglobin distribution within 9-12 g/dL range during 6 months immediately before SAM implementation and 6 months after the washout period. Only patients who received ESA and had at least 4 Hgb values within each period were included in the analysis.

Results: 13 patients satisfied the inclusion/exclusion criteria. The percentage of monthly Hgb within target range varied between 82% and 92% in 6 months prior to deployment of SAM and between 69% and 100% during 6 months after SAM deployment. Quarterly Hgb distribution varied between 86% to 87% prior to SAM deployment and 87% to 95% after. There was a significant decrease in low Hgb numerals after SAM deployment, but no change in high Hgb levels, compared to the period before SAM deployment.

Conclusions: Individualized anemia management in pediatric patients improves distribution of Hgb within the target range, compared to a standard population-based protocol approach.

PUB319

Extracorporeal Ultrafiltration Therapy for Acute Decompensated Heart Failure

Neguin Pourafshar, Ashkan Karimi, Amir Kazory. Medicine, Univ of Florida, Gainesville, FL.

Background: There has been a renewed interest in the use of ultrafiltration (UF) for management of patients with acute decompensated heart failure (ADHF). While a number of studies reported on the efficacy of this therapy and lack of any significant adverse impact, the more recent trials have challenged its safety. The aim of this study is to provide a reappraisal of the current evidence on the use of UF in ADHF.

Methods: Articles cited in PubMed database from 2000 to 2015 using key words “ultrafiltration” and “heart failure” were searched. Those randomized and non-randomized trials using recent portable devices dedicated for UF were selected. Case reports, and case series were excluded. Relevant data such as renal function, cardiac status, and weight change were extracted and compared.

Results: A total 940 patients from 15 trials (7 randomized and 8 non-randomized) that used dedicated UF devices were included. Eleven studies reported either no change or non-significant decrease in serum creatinine, while 4 found worsening renal function after UF therapy; these studies included patients with more severe renal dysfunction at baseline. Concerning weight, a reduction of 2 to 9 Kg was reported that was similar to conventional therapies in 9 studies but was significantly lower with UF in 6 trials. Length of stay was evaluated in 5 studies, 2 of which showed a significant reduction. Three studies showed fewer re-hospitalizations in the UF group at 30 days, 90 days, and 1 year followups. None of the studies evaluated long-term outcomes of patients undergoing UF therapy.

Conclusions: Based on the currently available data, UF is efficient for management of volume overload in ADHF. However, these studies do not support any beneficial impact for this therapy on renal function, and suggest that it might be associated with suboptimal renal outcomes if used for patients with more severe renal dysfunction at baseline. Currently there is no data on the effect of UF on long-term outcomes of patients with ADHF. Whether this would translate into a lack of effect for UF on these outcomes needs to be elucidated by future studies.

PUB320

Ultra-Sensitive Troponin I Predictive Value in Remote Ischemic Pre-Conditioning in Hemodialysis: A Randomized Double Blinded Clinical Trial

Marcelo Rodrigues Bacca, Livia Yadoya Vasconcelos, Felipe R. Brumiera, Felipe Moreira Ferreira, Neif Murad, Antonio Carlos palandiri Chagas, Fernando Luiz yffonso Fonseca. ABC Medical School, Brazil.

Background: Remote ischemic cardiac preconditioning(RIPC) is a procedure that generates a brief period of ischemia followed by reperfusion. Areas submitted to RIPC in the experimental ischemia models have less occurrence of necrosis. RIPC role in protecting myocardial ischemia during hemodialysis is not established yet. The aim of the study was to evaluate RIPC as myocardial protection used to evaluate ultra sensitive I troponin in hemodialysis outpatients.

Methods: It is a double blind randomised trial with two groups: intervention, submitted to RIPC with external compression in the right arm with sphygmomanometer with 200mm/Hg of pressure with three-5 minute rounds alternating with deflation totaling 30 minutes and control group without RIPC. Intervention group received RIPC in three consecutive hemodialysis sessions. Blood samples were taken before and after each session. Randomization was made by a software stratified by sex and age.BUN for calculation of single pool Kt/v and ultra sensitive I troponin were measured to evaluate dialysis adequacy and myocardial injury.

Results: A total of 47 patients were randomized. About 60.8% were men and 54% diabetic. The mean single pool Kt/v was 1.51 in the intervention group and 1.49 in control.
There was a trend to higher mortality in the control group (26%, p=0.09). The ultra sensitive troponin I was significantly higher than at baseline. Mean age was 68.7 ± 5 years, 40.6% were female and 51.7% were diabetes. 13.4% had a history of ischemic heart disease, and 13.3% had cerebrovascular disease. 8.0% had undergone coronary intervention procedure. Mean serum Ca, P and iPTH concentrations were 8.94±2.5, 4.0±3.0, and 122±29 ng/L, respectively. Baseline characteristics were well balanced between the two groups.

Conclusions: The LANDMARK study will determine whether a non-Ca-based P binder, LC, reduce CV mortality and morbidity in HD patients.

### The Relationship Between Prescription of Ultrafiltration in Hemodialysis and Intradialytic Hypotension: A Retrospective Study of Chinese Hemodialysis Patients

**Fei Deng,** Daqing Hong, Guisen Li, Li Wang.

**Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chengdu, Sichuan, China.**

**Background:** Our study aims to explore the relationship between prescribed ultrafiltration and intradialytic hypotension (IDH) and, to demonstrate risk factors of intradialytic hypotension in order to reduce the incidence of relevant complications and improve patient prognosis.

**Methods:** 312 patients maintenance hemodialysis patients in our dialysis center were enrolled with 33224 HD/HDF treatment sessions recorded. Hypotension was defined as a decrease of systolic blood pressure <20mmHg or mean arterial pressure declination 10 mmHg whether presence of hypotensive symptoms or not. ROC curve was applied to study the cut-off point of UF/Wt (ultrafiltration/weight) ratio for the presence of hypotension. Pearson analysis and logistic regression was used to study the risk factor associated with intradialytic hypotension.

**Results:** The prevalence of intradialytic hypotension was 38.7%. Decrease of SBP and MAP positively correlated with UF/Wt and age, and negatively correlated with blood flow. The cut-off point of UF/Wt was 4% for all patients, diabetes and non-diabetic patients with AUCs of 0.575, 0.570, and 0.622 respectively. The AUC for diabetic patients was higher than that of non-diabetic patients (P=0.001). Multivariate logistic regression showed that age (OR=1.005, 95%CI: 1.001-1.007), diabetes (OR=1.209, 95%CI: 1.122-1.303), and UF/Wt=4% (OR=1.605, 95%CI: 1.532-1.682) was associated with hypotension.

**Conclusions:** Asymptomatic intradialytic hypotension is prevalent. Increased intradialytic SBP/MAP variability is associated with greater UF and UF/Wt, but is not associated with greater blood flow. To Chinese hemodialysis patients, UF/Wt=4% is sensitive and specific in predicting intradialytic hypotension, especially in patients with diabetes mellitus. UF/Wt=4%, diabetes mellitus and age are independent risk factors for asymptomatic intradialytic hypotension.

### Whole Blood Viscosity at Low Shear Rate Is Associated with Cardiovascular Mortality in Patients with Hemodialysis

**Internal Medicine, Chonbuk National Univ Medical School, Jeonju, Republic of Korea; 2Dept of Mechanical Design Engineering, Engineering College, Chonbuk National Univ, Jeonju, Republic of Korea; 3Dept of Mechanical Eng, and Mechanics, Drexel Univ, Philadelphia, PA.**

**Background:** The change of whole blood viscosity (WBV) may increase risk of major atherosclerotic events, including congestive heart failure, myocardial infarction, and stroke. However, there is few report about the relationship between WBV and mortality rate due to atherosclerotic vascular disease. The objective of the present study was to investigate correlation between values of WBV at shear rates of 1, and 5 S⁻¹ before and after hemodialysis in patients with end-stage renal disease (ESRD) and mortality, especially cardiovascular or cerebrovascular mortality.

**Methods:** Forty three patients with ESRD receiving maintenance hemodialysis had initially participated in this study. In a prospective observational study, we examined the effect of WBV in pre- or post-dialysis on cardiovascular or cerebrovascular mortality in dialysis patients for approximately 5.8 years.

**Results:** Twenty seven patients among total 43 patients died and 2 patients had received transplantation of kidney within period of this study. Cardiovascular deaths occurred in 8 patients among 27 patients, and cerebrovascular deaths occurred in 5 patients among the 27 patients. The hazard ratios for overall survival in the patient with hemodialysis according to increase of predialytic diastolic WBV at low shear rate of 1 S⁻¹ in an univariate Cox proportional analysis were 1.585 (95% CI, P=0.382) in the group of moderate blood viscosity and 2.351 (95% CI, P=0.128) in the group of high blood viscosity. However, pre-DIV1 was not still statistically significant after adjustment for covariates. In addition, the HRs for overall survival according to increase of pre-DIV5 were 1.327 and 1.930 in each moderate and high blood viscosity group. In Kaplan-Meier’s survival analysis, when pre-DIV1 increased, cumulative mortality relatively showed rising tendency, but, unfortunately there was no statistical significance.

**Conclusions:** These results suggest that the diastolic low-shear WBV may impact on cardiovascular or cerebrovascular mortality in hemodialysis patients. New prospective and large-scaled studies to more exactly evaluate the correlation between WBV and mortality will be needed in the future.
Survival of Patients Over 75 Years Old in a Chronic Hemodialysis Program
Adriano Luiz Ammirati, Maria C.C. Andreoli, Fabiana Dias Carneiro, Thais Nemoto Matsui, Nadia Guimarães- Souza, Bento C. Santos. Dialysis. Albert Einstein Hospital, São Paulo, Brazil.

Background: The intensity of medical care for people over 75 years of age has increased over the past decade. In this surrounding context is increasing the number of individuals with this profile that has clinical indication starting renal replacement therapy. Published evidence has linked the survival of patients after initiation of hemodialysis (HD) according to the presence of comorbidities. The aim of this study was to evaluate the survival of elderly patients with chronic kidney disease on regular HD.

Methods: From analysis of medical records was assessed the rate of survival of incident patients who began HD treatment from 2000 to 2010. Demographic and clinical data were also collected. It was made a comparison, based on these data, among the elderly (over 75 years old) and non-elderly groups who died.

Results: During the study period, 158 patients started HD program, 69% male and 40% younger than 75 years. The overall mortality rates at 6 and 12 months were, respectively, 7.5% and 17%. Considering only the elderly, mortality rates at 6 and 12 months were respectively 14 and 27%. The median survival of these patients was 33 months. Considering only patients younger than 75 years mortality rates at 6 and 12 months were, respectively, 2% and 8%. Comparing elderly patients with non-elderly, we observed that the first group had a higher proportion of diabetic and hypertensive patients and with a history of cardiovascular disease and cancer. Considering only the patients who died, there were no important significant differences in the presence and score of comorbidities, when the elderly was compared with the non-elderly.

Conclusions: Patients over 75 years in HD had a mortality rate two times higher than younger patients and the presence of comorbidities may be a contributing factor to the age to explain this data.

Prevalence of Abnormal Ankle–Brachial Index in Haemodialysis Patients in Mexico and Its Association with Other Cardiovascular Risk Factors
Laura E. Izguernou Ochoa, Héctor Reyes López. Nefrología, Regional General Hospital #46, Guadalajara, Jalisco, Mexico.

Background: Abnormal Ankle-Brachial index (ABI), defined as ≤ 0.9 or ≥ 1.3, is considered an independent predictor of mortality in haemodialysis patients, in other countries abnormal ABI is found between 35% and 80% of haemodialysis patients. In Mexico the prevalence of abnormal ABI has not been reported. The aim of the study was to determine the frequency of abnormal ABI and its association with other cardiovascular risk factors.

Methods: Prevalent hemodialysis patients over 16 years old were included; data were obtained from medical records and interviews. ABI was measured by oscilometry (Model HEM-705CPINT) and classified as a normal result between 0.91 - 1.3 (NABI), ≤ 0.9 (LABI) or ≥ 1.3 (HABI). NAVI was considered as the control group and the data were analyzed using descriptive and inferential statistics, using T Student and Chi2.

Results: Of the 119 patients analyzed abnormal ABI was present in 36 (30%); 10 (8.4%) with LABI and 26 (21.9%) with HABI. The mean age was 44.9 years, 68% were male, duration of dialysis was 7.1 years. In univariate analysis ABI was significantly associated with history of hypertension (p <0.003), smoking history (p <0.001), diabetes (DM) (p =0.04), lower creatinine (p <0.001) and albumin (p <0.001) and higher calcium (p <0.001); HABI was significantly associated with lower age (p =0.01), smoking history (p =0.05), lower systolic blood pressure (SBP) (p =0.02), higher levels of sodium (p =0.04) and calcium (p =0.01). No association was found between abnormal ABI and history of hypertension, dyslipidemia, heart disease, stroke; there were no differences with the dose of calcium carbonate or calcitriol, the value of Kt/V, the type of vascular access and serum phosphorus.

Conclusions: Abnormal ABI was less prevalent than in other populations, among these HABI is the most common. LABI was associated with older age, DM, smoking history, high calcium and low creatinine and albumin (probably associated with poor nutritional status). HABI patients were younger, with smoking history, lower SBP, high serum sodium and calcium levels.

A Lower Serum Uric Acid Is Associated Not Only with All-Cause Mortality but Also Cardiovascular Mortality Among Patients Receiving Hemodialysis in Japan
Naoki Sugano, Yukio Maruyama, Keitaro Yokoyama, Koki Takane, Yasuhiro Takahashi, Chisa Kobayashi, Shinichiro Nishio, Daiuuke Takahashi, Satoshi Kidoguchi, Kousuke Honda, Norihiko Morisawa, Gorou Tokudome, Iwao Ohno, Tatsuo Hosoya, Takashi Yokoo, Takashi Shigematsu, Kunioh Iseki, Ikuto Masakane. Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan; Committee of Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan.

Background: High level of serum uric acid is prevalent in chronic kidney disease (CKD), however it has a controversy whether high or low serum uric acid level appears to be a risk factor of cardiovascular event and mortality in the patients of receiving renal replacement therapy.

Methods: We collected the baseline data of 222,434 patients receiving HD three weekly (males: 63.0%, 66 ±12 years, median HD vintage of 60 months, females: 68 ±13 years, median HD vintage of 72months) extracted from a nationwide dialysis registry at the end of 2011 in Japan. Then we evaluated the patient survival and development of complication using the registry at the end of 2012.

Results: During one-year follow-up, 18775 (8.4%) died of all causes including 8094 (3.6%) cardiovascular death. All-cause mortality and cardiovascular mortality were lower in the group with lower level of baseline uric acid. In a multivariable logistic regression analysis, patients of the highest quartile of uric acid had lower all-cause, and cardiovascular mortality compared with those of the lowest quartile (males: OR, 0.745; 95% CI, 0.675 to 0.8207; females: OR, 0.8333; 95% CI, 0.726 to 0.936; and males: OR, 0.702; 95% CI, 0.6266 to 0.8278; females: OR, 0.8575; 95% CI, 0.7029 to 1.0642).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
963A
Conclusions: In this large observational cohort study, lower levels of serum uric acid were independently associated not only with all-cause mortality but also cardiovascular mortality among Japanese HD patients. Close monitoring of serum uric acid is thought to be necessary for the management of HD patients.

PUB330

Post Stroke Disability Deterioration and Mortality of Hospital Onset Stroke in Patients with and without End-Stage Renal Disease Tomoko Usui,1 Norio Hanafusa,1 Hideo Yasunaga,2 Masaomi Nagaku.1 1Dept of Hemodialysis and Apheresis, The Univ of Tokyo Hospital, Japan; 2Dept of Clinical Epidemiology and Health Economics, School of Public Health, The Univ of Tokyo, Japan.

Background: Increasing evidence suggests that end-stage renal disease is associated with higher risk and severity of cerebrovascular disease. However, the risk factors for post stroke disability and mortality is not clear. We examined the association between risk factors including dialysis treatment and disability deterioration and mortality during the hospital stay of hospital onset stroke.

Methods: The Japanese Diagnosis Procedure Combination database includes administrative claims and discharge abstract data of about 50% of all acute-care inpatients in Japan. Using this database, we extracted data of inpatients age ≥20 years old, hospital-onset stroke between July 2010 and March 2013. Disability level was divided into modified Rankin Scale (mRS) 0-1, 2-3, 4-5, and 6 (death). Deterioration of disability was defined as an increase in disability level. The odds ratio (OR) for in-hospital deterioration of disability and mortality was calculated using a logistic regression model.

Results: Out of 26,834 patients, 593 (2.2%) had dialysis therapy. The median length of stay was 39 and 33 days for patients with and without dialysis, respectively. During the hospital stay, there were 7,655 (28.5%) disability deterioration and 3,851 (14.4%) death. The patients with dialysis had higher disability deterioration (47.9%) and mortality rate (31.3%) compared to those without. After adjustment with age, gender, BMI, mRS, Activities of Daily Living, smoking habits, hypertension, diabetes, dyslipidemia, atrial fibrillation, coronary heart disease, heart failure, peripheral arterial disease, cerebrovascular complications, antplatelet, anticoagulant, and thrombotic medications, multivariate-adjusted ORs of dialysis for disability deterioration was 2.88 (95%CI 2.40-3.45), and in-hospital mortality was 3.57 (95%CI 2.94-4.33).

Conclusions: Dialysis treatment was an independent risk factor for in-hospital disability deterioration and mortality of hospital onset stroke.

PUB331

Role of Bioimpedance as Tool for Fluid Management in Hemodialysis Patients Maria Cecilia Recalde,1 Manuela Bello,2 Cecilia Arruabarrena,1 Álvaro Herou,1 Fabian Cano,1 Laura Sofia,1,2 1Hemodialysis Unit, CASMU, Uruguay; 2Preventive Medicine, Univ of the Republic, Uruguay.

Background: Fluid management in hemodialysis patients is difficult, hypertension and fluid overload is frequent as well as hypotensive episodes leading to cerebral and cardiac injury and increased mortality risk. The objective of the study is to evaluate if bioimpedance could be a tool to optimize fluid management in hemodialysis patients.

Methods: Patients were included after giving informed consent when fulfilled inclusion and exclusion criteria. Were recorded age, gender, diabetes status, dialysis vintage, body mass index (BMI) estimated dry weight, and mean in previous month: systolic blood pressure and was prescribed more number of other antihypertensive drugs than control group. After matching, there were no differences in age, sex, dialysis modalities, comorbidities and number of other antihypertensive medications. Before PSM, patient survival was significantly better in the RAAS group using the Gehan-Wilcoxon test (P=0.001), however, this difference disappeared after matching (P=0.450). Cardiovascular event-free survival was not different between RAAS group and control group before and after PSM analysis.

Conclusions: RAAS blockade did not affect all-cause mortality and MACE-free survival in the Korean ESRD patients. Further researches such as randomized control study will be needed.

PUB333

Hemodynamic Changes in Maintenance Hemodialysis Patients with Intradialytic Hypotension MeiJuen Meng, Hong Ye, Junwei Yang. Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.

Background: Intradialytic hypotension (IDH) is a common complication in patients undergoing maintenance hemodialysis (MHD) which leads to high mortality. This study is to explore the hemodynamic changes in MHD patients with IDH.

Methods: Thirty-seven patients were included in our study. HD were defined as a decrease of systolic blood pressure (SBP) <20 mmHg or the lowest SBP below 90 mmHg during dialysis. Twenty-three patients were diagnosed with IDH. Among them, 13 were

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
asymptomatic while the other had the hypotensive symptoms, such as abdominal discomfort, sighing, nausea, vomiting, muscle cramps and restlessness. All of them underwent a noninvasive hemodynamic evaluations before, during and after dialysis.

**Results:** Compared to the patients without IDH, the dialysis age was longer and the prevalence of diabetes was higher in the patients with IDH. There were no difference in age, amount of ultrafiltration, pre-dialysis cardiac index (CI), systemic vascular resistance index (SVRI) and thoracic fluid capacity (TFC) between these two groups. During dialysis, CI decreased while SVRI increased gradually especially in patients with IDH. At the end of dialysis, ACT was markedly higher in patients with IDH. However, there was no significant difference in the change of CI, SVRI and TFC ten minutes before and after hemodialysis between these two groups. Meanwhile, the hemodynamic changes were analyzed in IDH patients with or without symptoms. It was found that there were no difference of change values and absolute values of CI and SVRI in these subgroups.

**Conclusions:** It was found that CI decreased while SVRI increased during hemodialysis. In the mid and later period, the CI decreased much more patients in patients with IDH. It was suggested that CI might be an indicator of IDH.

**Dual Relationships of Serum Leptin on Heart Rate Variability in Patients with Stage 5 Chronic Kidney Disease** Ningning Wang, Yao Jiang, Jingjing Zhang, Changying Xing. *Nephrology, First Affiliated Hospital of Nanjing Medical Univ; Nanjing, China.*

**Background:** Leptin regulates nutrition, bone metabolism and cardiovascular function. Lower heart rate variability (HRV) in chronic kidney disease (CKD) predicts higher risk of cardiovascular disease (CVD). Relationships between leptin and HRV in CKD is obscure.

**Methods:** This included cross-sectional observation and longitudinal followed-up on parathyroidectomy (PTX) patients.

**Results:** Serum leptin/BMI is transformed using natural logarithm (lnleptin/BMI).

**Association of Geriatric Nutritional Risk Index and Responsiveness to Erythropoiesis-Stimulating Agent in Mortality of Chronic Hemodialysis Patients** Kosaku Nitta, Ken Tsuchiya. *Dept of Medicine, Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan.*

**Background:** Responsiveness to erythropoiesis-stimulating agent (ESA) may be associated with mortality in hemodialysis (HD) patients. The aim of the present study was to assess the effects of geriatric nutritional risk index (GNRI) and responsiveness to ESA in outcome in HD patients.

**Methods:** The ESA response index (ERI) was determined as the weekly weight-adjusted dose of ESA divided by hemoglobin concentration. Patients were divided into four groups by quartiles of ERI. Odds ratios were estimated using a Cox proportional model for the association between GNRI and ERI and mortality, adjusting for potential confounders. Patients were divided into four groups by quartiles of ERI.

**Results:** Of the 298 subjects enrolled, 51 died with 31 cardiovascular deaths during the follow-up period of 34.6 ± 6.1 months. The ERI was inversely correlated with the GNRI (r = -0.287; p < 0.0001). Age, gender, serum total cholesterol, phosphorus, calcium, hemoglobin, and haptoglobin were associated with mortality. In the analysis of the association between GNRI and mortality, the GNRI was an independent predictor of mortality (P = 0.003).

**Conclusions:** This study revealed that the GNRI was an independent predictor of mortality in HD patients.
m/s, p=0.139). In 14 subjects, who underwent echocardiography, there were no significant changes in cardiac output, stroke volume and ejection fraction. However, left ventricular end-systolic volume (52 ± 22 versus 57 ± 25 ml (p=0.20) and end-diastolic volumes (92 ± 35 versus 97 ± 17, p<0.08) were numerically higher under cinacalcet, but not statistically significant.

There were no significant changes in the parameters of diastolic dysfunction.

Conclusions: In this short term study, there were no detectable effects of cinacalcet on aortic stiffness and diastolic dysfunction despite the expected reduction in serum calcium concentration. The numerically higher left ventricular volumes with cinacalcet, may need to be investigated. Clinical trials: NCT01250405.

Kidney Transplantation and Cardiac Repolarization Descriptors Dimitrios J. Poulikakos,1 Debasish Banerjee,2 Marek Malik,3 Renal, Salford Royal, United Kingdom; St. George’s Univ of London, United Kingdom; Imperial College, London, United Kingdom.

Background: Selected descriptors of cardiac repolarization derived from the computerized analysis of electrocardiogram (ECG) can predict cardiac risk in hemodialysis (HD) patients. Kidney transplantation improves cardiovascular survival. The aim of the study was to investigate the impact of kidney transplantation on these descriptors.

Methods: The study was conducted in two phases. In phase 1, Holter ECGs were obtained during HD sessions and repeated 5 times at 2-weeks intervals in stable HD patients. The repolarisation descriptors QRS-to-T angle (TCRT) and T wave morphology dispersion (TMD) were calculated in overlapping 10 second ECG segments and averaged over the first hour of recordings. In phase 2, continuous 1-hour ECG recordings were obtained in patients who received a kidney transplant minimum three months after transplantation and if they were stable with EGFR>30 ml/min/1.73m². Average values of post transplant repolarisation descriptors were compared with average values over the first hour of HD using Wilcoxon test and t-test was used for baseline comparisons.

Results: In 80 HD patients in phase 1 both descriptors showed intra-subject stability and exhibited extreme values in subjects that suffered major arrhythmic events. During a period of 35.9 ±3 months 10 eligible transplanted subjects were recorded and although TMD and TCRT improved 7 months following kidney transplantation (see table) the difference did not reach statistical significance (p=0.05). However these subjects had better baseline TCRT and TMD values compared to the study population (TCRT 0.463 vs 0.078 p<0.05 and TMD 17.9 vs 32.4 p<0.05).

Conclusions: In transplant recipients with healthier baseline repolarization profiles the improvement did not reach statistical significance in the early post transplant period. Larger studies with longer follow up are needed.

PUB340

Prognostic Significance of Cardiopulmonary Exercise Test and 6-Minute Walk Test in Chronic Dialysis Patients Wioletta Dziubek,1 K. Bulinska,1 B. Ochman,1 Ukasz Rogowski,1 Mariusz Kusztal,1 Tomasz Golębiowski,1 D. Markowska,1 A. Zembron-Lacny,1 Marian Klinger,1 St. George’s Univ of London, United Kingdom; Imperial College, London, United Kingdom.

Background: Chronic kidney failure is recognized as a major cardiovascular (CV) risk factor. Even mild reductions in renal function are associated with increased CV morbidity and mortality.

Methods: In prospective study 90 pts receiving high-flux dialysis (12h/week) were obtained during HD sessions and repeated 5 times at 2-weeks intervals in stable HD patients. The repolarisation descriptors QRS-to-T angle (TCRT) and T wave morphology dispersion (TMD) were calculated in overlapping 10 second ECG segments and averaged over the first hour of recordings. In phase 2, continuous 1-hour ECG recordings were obtained in patients who received a kidney transplant minimum three months after transplantation and if they were stable with EGFR>30 ml/min/1.73m². Average values of post transplant repolarisation descriptors were compared with average values over the first hour of HD using Wilcoxon test and t-test was used for baseline comparisons.

Results: In 80 HD patients in phase 1 both descriptors showed intra-subject stability and exhibited extreme values in subjects that suffered major arrhythmic events. During a period of 35.9 ±3 months 10 eligible transplanted subjects were recorded and although TMD and TCRT improved 7 months following kidney transplantation (see table) the difference did not reach statistical significance (p=0.05). However these subjects had better baseline TCRT and TMD values compared to the study population (TCRT 0.463 vs 0.078 p<0.05 and TMD 17.9 vs 32.4 p<0.05).

Conclusions: In transplant recipients with healthier baseline repolarization profiles the improvement did not reach statistical significance in the early post transplant period. Larger studies with longer follow up are needed.

PUB341

Adaptive Servo-Ventilator Therapy Improves the Cardiac Dysfunction in Hemodialysis (HD) Patients with Sleep-Disordered Breathing Fumiko Fukuuchi,1 Ken Tsuchiya,2 Kosaku Nitta,3 Nephrology, Komagome Kyuuritsu Clinic; Bunkyo-ku, Tokyo, Japan; 'Medicine II, Tokyo Women's Medical Univ; Shinjyuku-ku, Tokyo, Japan.

Background: Cardiac dysfunction is a very serious problem in HD patients. Sleep Disordered Breathing (SDB) is considered to cause cardiac dysfunction. Dialysis patients have a disordered respiratory center and a high prevalence of central apnea. Adaptive Servo-Ventilator (ASV) is automated modality used to treat heart failure patients with SDB, especially central apnea. The aim of this study is to explore the relationship between sleep apnea and cardiac dysfunction, and to evaluate the effects of ASV therapy in HD patients.

Methods: Sleep study was performed using a portable sleep test device (Sleepsitter LS-300, Fukuda Denki Co., Ltd, Japan). We measured the variables of cardiac function by echocardiography. The relation between apnea index and the echocardiogram indicates was calculated. We also collected baseline information on demographics, lab values, plasma BNP level, medications, and clinical conditions. ASV therapy was used in the patients diagnosed with severe SDB and/or central apnea. The cardiac function variables were evaluated in comparison to the previous year.

Results: The 27 dialysis patients (sixteen diabetics, eleven non-diabetics) are included in this study. Out of them, echocardiogram, SDB indications showed a connection. The obstructive apnea hypopnea index was related to the left ventricular posterior wall thickness (LVPWT) (r=0.49, p=0.02). Seven patients received ASV therapy. There has been improvement of overall of their cardiac function with significant increase of ejection fraction (p<0.02) 1 year after ASV introduction.

Conclusions: In this study, we demonstrated the efficacy of ASV therapy in hemodialysis patients with SDB. Near future, ASV is possible to be one of attractive devices for HD patients, with aging, several complications, to improve their poor prognosis.

PUB342

Endovascular Renal Denervation: Effects on Dyslipidaemia and Vascular Inflammation in Dialysis Patients Neil A. Hove,1 J. Christopher Baldi,2 David L. Jardine,1 John B.W. Scholten,3 Gerard T. Wilkins,1 Luke C. Wilson,1 Robert J. Walker,1 Dunedin School of Medicine, Univ of Otago; 'Christchurch School of Medicine and Health Sciences, Univ of Otago.

Background: Endovascular renal denervation (RDN) reduces afferent and efferent sympathetic nerve activity. Its effects on vascular inflammation and cholesterol levels in dialysis patients are unknown. We hypothesized RDN would reduce sympathetic activity, resulting in improvement in biomarkers of vascular inflammation and dyslipidaemia.

Methods: Nine dialysis patients with uncontrolled office BP (>140/90mmHg despite two or more agents at maximal tolerated dosages) were recruited into this feasibility study. Office and ambulatory BP monitoring (ABPM) were performed at baseline, one and three months post RDN, along with supine muscle sympathetic nerve activity (MSNA) and venepuncture. Bilateral RDN was undertaken with an EnligHTN™ catheter.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Results: Similar to previous, office systolic BP reduced and the effect on ABPM was attenuated. MSNA did not change, a novel finding. Despite lack of change in MSNA, total cholesterol: HDL ratio increased along with a falling trend in CRP and rising trend in albumin, all novel findings.

Conclusions: Non survivors were significantly older, had lower number of total sessions, lower albumin and no dialysis. But dialysis adequacy and UF were comparable. Short duration of follow up may limit the ability to study other factors influencing outcomes.

PUB344
New Anticoagulant Free Strategy for Non Valvular Atrial Fibrillation in Hemodialysis Patients Teresa Arcidiacono, Patrizio Mazzone, Marco Simonini, Donatella Spotti, Maria Teresa Sciarro Alibrandi, Rita Quartagno, Marco Melandi, Stefano Tentori, Giorgio Slaviero. San Raffaele Scientific Inst, Italy.

Background: Vascular calcification in patients with CKD-5 is associated with increased cardiovascular morbidity and mortality. An excessive calcification of coronary arteries and of aortic valve has been reported during Warfarin treatment. In addition use of oral anticoagulation (OAC) seems to be an important risk factor for calciphylaxis. Atrial fibrillation (AF) is the most frequent reason for OAC use in CKD patients.

Methods: An alternative to OAC could be the percutaneous Left Atrial Appendage (LAA) closure. With this technique an implantable component is permanently fixed in the LAA to prevent thrombus embolization. Different studies demonstrated that this procedure is not inferior to systemic anticoagulation with OAC in prevention of thromboembolic risk. We reported our clinical experience with the use of this technique in haemodialysis patients with non valvular AF.

Results: In the last few months seven (7) haemodialysis patients were treated with percutaneous LAA closure. Bleeding and stroke risks were evaluated by HAS-BLED score and CHADS2-VASc score: HAS-BLED score was 4.5±0.58 (equal to 9%±0.11 yearly risk of major bleeding) and CHADS2-VASc was 4.0±1.0 (equal to 4.47±1.5 yearly risk of stroke). This procedure was well tolerated by each patient. OAC treatment was interrupted after the procedure and doubled antiplatelet therapy was introduced for a month. At this moment median of 9 months of follow-up was archived [IQR 3-12]; no adverse events has been assessed.

Conclusions: To the best of our knowledge this is the first consecutive series of LAA closures in haemodialysis patients. This procedure represents a real clinical alternative to the use of coumarin derived drugs. Our experience leads the way to the possible routine use of this procedure in CKD-5D patients. As well as this procedure could be used in those patients with contraindications to OAC, even more this treatment should be used in haemodialysis population, in which the use of OAC should be avoided for both increased risk of life-threatening bleeding events and well known negative cardiovascular effects.

PUB345
Management of Subclinical Thyroid Dysfunction Can Reduce Cardiovascular Events in Patients with End-Stage Renal Disease on Hemodialysis Hong Joo Lee, Dept of Nephrology, Seoul Red Cross Hospital, Seoul, Republic of Korea.

Background: Normal thyroid function influences basal metabolic rate and general body metabolism and thyroid dysfunction is often associated with dyslipidemia and increased cardiovascular risk in general population. It is known that about 25% of patients with end-stage renal disease (ESRD) on hemodialysis had subclinical thyroid dysfunction. We investigated that subclinical hypothyroid dysfunction associate with dyslipidemia and cardiovascular event in hemodialysis patients. Hence, we conducted our study to elucidate whether subclinical thyroid dysfunction treated or not in ESRD patients.

Methods: All hemodialysis patients in Red Cross Hospital within a period of one year were included in the study. Thyroxine-3 (T3), free thyroid-4 (T4), Thyroid Stimulating Hormone (TSH) and lipid profiles in the serum were estimated and death from all causes and CV events served as outcome variables over a median follow-up period of 12 months. Participants were divided into groups based on the thyroid function. Statistical analysis was carried out by using SPSS.

Results: Among the 92 cases, 28.2% of the patients were having thyroid disorder. In which 2.1% were of hypothyroid, 13.7% were of subclinical hypothyroid, and 0.8% were of hyperthyroid, 11.6% were of subclinical hyperthyroid. We observed negative correlation between T3 & T4. Total cholesterol was raised in hypothyroidism in comparison to euthyroid ESRD patients. However, thyroid function didn’t have significant association with lipid profiles. Cardiovascular disease significantly often occurred in subclinical thyroidism patients than other group.

Conclusions: Our results show that the blood thyroid hormone level isn’t affected by dyslipidemia but affected by occurrence of CVD. Therefore, the management of subclinical hypothyroidism in hemodialysis patients should be considered.

Non survivors were significantly older, had lower number of total sessions, lower albumin and no dialysis. But dialysis adequacy and UF were comparable. Short duration of follow up may limit the ability to study other factors influencing outcomes.

**Effect of Altitude on All-Cause Mortality in End-Stage Kidney Disease Patients Ongoing Hemodialysis in Peru** Katia Bravo-Jaimex,1 Viky Y. Suncion,¡ Jose Ernesto Rojas,‡ Christian R. Mejia,§ Sandra C. Schult,|| Medicine, Univ of Rochester Medical Center, Rochester, NY; | Medicine, Jackson Memorial Hospital, Miami, FL; ‡ Inst de Investigaciones de Altura, Univ Peruana Caytonay Heredia, Lima, Peru; § Asociación Médica de Investigación y Servicios en Salud, Lima, Peru; || Pediatrics, Inst Nacional de Salud del Niño, Lima, Peru.

**Background:** Worldwide, end-stage kidney disease (ESKD) prevalence has tremendously risen. Previous studies suggested that receiving hemodialysis (HD) at high altitude confers mortality benefits; however this effect has not been proved above 2000 m or in developing countries.

**Methods:** This historical cohort study analyzed medical records from six HD centers of the Peruvian Social Security System. Adult ESKD patients who started HD between 2000 and 2010 were included. Patients were classified into two strata (< 2000 and > 2000 m). The outcome variable was death from any cause. Cox proportional hazards models were built for the time from first dialysis to death from any cause, stratifying by year and censoring.

**Results:** 723 patients were enrolled, including 248 women (34%). The mean age was 52.8 ±16.9 years. 166 patients lived > 2000 m (22%). In first years after follow-up, survival rates were lower in the group > 2000 m, however after 8 years of follow-up this trend reversed. Age and gender were not significantly associated to mortality at altitude levels > 2000 m. Patients with diabetes had higher mortality rates at > 2000 m (p=0.003), independently of age.

**Conclusions:** In Peru, patients receiving HD at high altitude do not experience mortality benefits. In fact, diabetics have higher mortality rates at > 2000 m.

**End-Stage Renal Disease in North Region of Oman/Epidemiology, Incidence, and Aetiology** Ruqaya Khanum Al-Zaabi,1,2 Elizabeth P. Tolmie,3 Ann Marie Rice,3 Nabil Mohsin,4 Ahmed Said Al-Busaidi,5 1Nursing and Health Care, Univ of Glasgow, Glasgow, United Kingdom; 2Nursing Education, Ministry of Health, Muscat, Sohar, Oman.

**Background:** The epidemiology of renal failure in Oman is scarce. There is a paucity of information on the size and burden of renal failure in Oman. Therefore, our research was conducted to measure the prevalence, incidence and death rate (epidemiology) among patients who have renal failure and undergo renal dialysis in four dialysis centers in the North of Oman; and to provide a description of the major characteristics of the studied patients.

**Methods:** A cross-sectional study was conducted. A proportional sample (n = 341) patients from four Renal Dialysis Centres (RDC) were interviewed face to face or via telephone using a structured questionnaire. Data collection took place between October and November, 2014. The incidence, prevalence and death rate are under collection until December 15, 2015.

**Results:** Over the period January 1st, 2014 to December 31st, 2014, a total of 96 new patients started dialysis in the four observed RDCs. The overall incidence rate was 13 patients per 100,000. The period prevalence for the patients undergoing renal dialysis was 52 patients per 100,000. The mortality rate for the same period of time was four patients per 100,000. Demographic data are summarized in table 1.

**Funding:** Government Support - Non-U.S.

---

**PUB348**

**Background:** Hyperkalemia is a major problem in hemodialysis (HD) patients affecting there morbidity and mortality. HD patients receiving low potassium (K) bath for hyperkalemia have double the risk of sudden cardiac death. We noticed high rate of use of low K dialysate due to high prevalence of hyperkalemia in our dialysis unit. We are studying this phenomenon.

**Methods:** Our study was done in the biggest out-patient HD facility in Qatar (306 patients). We identified patients who required low K bath (based on an existing rigorous protocol, any K over 5.5 will be started on low K bath 1 mmol/L with checking K level every HD treatment till corrected) in 6 months period from 10/1/2014 to 3/31/2015. We collected background data in these patients and their potassium levels during that period.

**Results:** 62 out of 306 hemodialysis patients required low K bath continuously (5 patients) or intermittently (57 patients). Mean age was 59.9 ±6.5 years. There were 36 females on low K bath out of total 137 females versus 26 males out of 169 (p Value 0.014). 39 out of 62 were Qatar (62%) versus 65% in patients not on low K bath. Table 1 summarize number of patients on low K bath and number of low K bath HD treatments on monthly base versus average temperature in Doha, Qatar.

**Conclusions:** In a study of using low K bath in a major HD clinic in Qatar we found a statistically significant higher number of female patients who required low K bath than males. This might be attributed to dietary habits based on our dietitians experience and vascular access issues but further study is needed to explain these findings. There was a significant decrease in need for low K bath in January and February compared to other months both in the number of patients and HD treatments . We attributed that to combination of cooler weather and seasonal change in dietary habits. Further study again is needed to evaluate that prospectively.
PUB349

Co-Morbidity Rather Than Clinical Practice Patterns Determines Mortality in an Aged Dialysis Population

An Vanacker,1 Bert Bammens,2 Bart De Moor,3 Bart D. Maes.1 1Nephrology, AZ Delta, Roesselare, Belgium; 2Nephrology, Univ Hospitals, Leuven, Belgium; 3Nephrology, Jessa Hospital, Hasselt, Belgium.

Background: Hemodialfiltration (HDF), by adding convective to diffusove transport, is more effective in removing larger uremic retention solutes than hemodialysis (HD). As these solutes are thought to have a role in the accelerated cardiovascular disease of dialysis patients, HDF might result in lower mortality compared to HD.

Methods: All patients treated with thrice weekly HD (high-flux) or online HDF at 3 Belgian dialysis centers for ≥ six and < 42 months were included in July 2008. Hospitalized patients or patients with access-related problems were excluded. The effect of HDF versus HD on all-cause mortality at 6 years was evaluated. Multi-variate analysis taking into account all relevant baseline variables was performed to determine independent predictors of outcome.

Results: 242 patients were included (142 male, mean age 70.9 ± 11.8 years): 84 treated with HD, 158 with HDF. After 6 years, the incidence of all-cause mortality was significantly higher in HD than in HDF: 54% of patients in HD-group (64.3%), 70 of 158 patients in HDF-group (55.7%) (P = 0.04). Based on univariate associations with survival (*) and/or significant association with center or HD/HDF variable, following parameters were introduced in multivariate analysis: HD/HDF*, vintage, age*, weight, CCI*, use of calcium(Ca)-based and non-Ca-based phosphate (P) binders, dialysis hours/week, QB, Qd, dialysate Ca concentration*, vascular access*, mean P*, Ca-P product*, hemoglobin, albumin*, interdialytic weight gain and center. The final multivariate model is shown in the table below.

Conclusions: In an aged Western dialysis population, treatment with HDF did not improve all-cause mortality compared to high-flux HD. Mortality seems to be determined by comorbidity rather than by clinical practice patterns.

PUB350

Depression Is Associated with Frailty and Malnutrition but Not Comorbidity

Load in Chinese Peritoneal Dialysis Patients

Cheuk-Chun Szeto,1 Shin Man Choy.2 1Dept of Medicine & Therapeutics, The Chinese Univ of Hong Kong, Shatin, Hong Kong; 2Dept of Medicine & Therapeutics, Prince of Wales Hospital, Shatin, Hong Kong.

Background: Depression is common amongst patients with chronic kidney disease and is associated with excessive mortality in dialysis patients. This study determines the prevalence and risk factors of depression in Chinese peritoneal dialysis (PD) patients.

Methods: We studied 178 prevalence PD patients (103 males). Depression was screened by the 15-item self-reported Geriatric Depression Scale (GDS). We also determined patients' comorbidity load, dialysis adequacy, residual renal function, nutritional status, and degree of frailty.

Results: The mean age was 60.7 ± 11.7 years; vintage of dialysis 42.5 ± 44.1 months. Average GDS score was 4.9 ± 4.4. GDS score is closely associated with the frailty score (r = 0.692, p < 0.0001), malnutrition inflammation score (r = 0.406, p < 0.0001), and subjective global assessment score (r = 0.386, p < 0.0001). GDS score also has a modest correlation with Charlson's comorbidity index (r = 0.164, p = 0.028) and serum albumin level (r = -0.192, p = 0.019), but not with patient age, vintage of PD, dialysis adequacy, or residual renal function. When defined as a GDS score ≥ 8, 50 patients were treated with HD, 158 with HDF. After 6 years, the incidence of all-cause mortality was significantly higher in HD than in HDF: 54% of patients in HD-group (64.3%), 70 of 158 patients in HDF-group (55.7%) (P = 0.04). Based on univariate associations with survival (*) and/or significant association with center or HD/HDF variable, following parameters were introduced in multivariate analysis: HD/HDF*, vintage, age*, weight, CCI*, use of calcium(Ca)-based and non-Ca-based phosphate (P) binders, dialysis hours/week, Qb, Qd, dialysate Ca concentration*, vascular access*, mean P*, Ca-P product*, hemoglobin, albumin*, interdialytic weight gain and center. The final multivariate model is shown in the table below.

Conclusion: In an aged Western dialysis population, treatment with HDF did not improve all-cause mortality compared to high-flux HD. Mortality seems to be determined by comorbidity rather than by clinical practice patterns.

PUB351

Trends in Anemia Management with Darbepoetin Alfa in Patients on Maintenance Hemodialysis

Robert H. Yenchek,1 Anne C. Beaubrun,2 Jeffrey Petersen,3 David G. Dalpiaz,4 Alfred K. Cheung.1 1Univ of Utah, Salt Lake City, UT; 2Amgen, Inc., Thousand Oaks, CA.

Background: In the US, darbepoetin alfa (DA) is primarily used to treat anemia in patients receiving treatment in hospital-based dialysis centers. Epoetin alfa (EA) doses and hemoglobin (Hb) levels declined in response to recent regulatory and reimbursement events but little is known about trends in anemia management with DA in the US maintenance hemodialysis (HD) population receiving treatment in free-standing dialysis centers (FSDCs). We describe herein anemia management in FSDCs within the University of Utah (UU) Dialysis Program who switched from the use of EA to DA program-wide in 2005.

Methods: We included ~650 adults (age ≥18 yrs) with 1+ months on HD between 2008-2013 in 18 FSDCs within the UU Dialysis Program. We summarized quarterly intravenous DA and iron dose and use, Hb, and serum transferrin saturation (TSAT) and ferritin levels.

Results: 70-76% of patients received DA over the study period. Mean Hb levels among patients who received DA fell from 12.2 g/dl in 2008 before leveling around 10.3 g/dl from Q4 2011 to 2013 (Figure). The mean monthly DA dose was 209 mcg in Q1 2008, reached a peak of 256 mcg in Q1 2010, and decreased to ~105 mcg in 2013. Iron use rate from 52% in 2008 to 67% in patients in 2013. Iron dose also rose from 129 mg in Q4 2008 to 194 mg in Q4 2010, but declined to 163 mg in Q4 2013. Mean serum TSAT levels remained relatively constant at ~30% between 2008-2013 but serum ferritin levels increased from 449 ng/ml in Q1 2008 to 770 ng/ml in Q4 2013.

Conclusions: Trends in anemia management parameters among patients on HD treated with DA within FSDCs in the UU Dialysis program were consistent with national reports of patients treated with EA.

PUB352

Shorter Dialysis Session Time Was Associated with Higher Risk of Hospitalization and Death in Maintenance Hemodialysis Patients

Takahiro Kuragano, Takeshi Nakanishi.1 Dept of Internal Medicine, Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.

Background: Recently, dialysis efficiency was dramatically improved by using super flux dialysis membrane. However, in the condition of the common use of high-flux dialysis, it has not been well studied the relationship between treatment time and adverse events or survivals of maintenance hemodialysis (MHD) patients.

Methods: Subject: 805 patients undergoing MHD. Study design: Prospective, observational multi-center study of 3 years. We measured serum levels of urea nitrogen (UN), creatinine (Cr), b2microglobulin (MG), total protein, albumin, prealbumin, high sensitive C reactive protein (hCRP) every 3month. We also evaluated body mass index (BMI), and Kt/V. The associations between dialysis intensity and adverse events or death were investigated with the cox proportional hazards model for time-dependent variables.

Results: Although there was no significant correlation between pre-dialysis levels of b2MG or UN and adverse event or survival, high pre-dialysis Cr level was associated with lower risk of hospitalization (HR: 0.89, P<0.003) and death (HR:0.71, P<0.002). Moreover, high Kt/V was also associated with lower risk for cerebrovascular and cardiovascular
A Randomized, Factorial Pilot Study to Evaluate the Feasibility of an Intervention, so study Intervention (DIALYSISIZE)1 Stephanie E. Thompson,2 Scott Klarenbach,1 Anita Molzahn,1 Mark Haykowsky,1 Anita Lloyd,2 Marcello Tonelli,2 1Univ of Alberta, Edmonton, AL, Canada; 2Univ of Calgary, Calgary, AB, Canada.

Background: Intradialytic exercise (IDE) is associated with improved dialysis adequacy and amelioration of dialysis-related symptoms. However, the uptake of IDE is limited by knowledge gaps on efficacy—what type of exercise to prescribe to optimize outcomes, and on feasibility. The results of this pilot will inform the design of a full-scale efficacy study evaluating two types of IDE (aerobic and resistance) and will also provide research users with practical information on IDE.

Methods: In this single center, randomized, factorial (2 x 2) study, chronic adult hemodialysis patients were randomized to one of four IDE groups: cycling, resistance, cycling and resistance, or stretching (an attention control). Exercise was semi-supervised by a kinesiologist. Outcomes focused on a priori feasibility criteria: recruitment, fidelity to the protocol, and participant and unit staff response to IDE. As a secondary outcome, we evaluated the main effect of cycling and weights each compared with control on quality of life and physical performance at baseline and 12-weeks. To better understand feasibility, we conducted interviews with users.

Results: We exceeded targeted accrual of 28 people over 12 weeks. Of 100 patients screened, 51 were enrolled (36 did not meet inclusion criteria, 33 declined participation); 16% dropped out after randomization. Fidelity to the intervention was high: of 1,039 training sessions offered, 878 were delivered. Participant response to the intervention was favorable: 92% of participants continued exercising after the trial. There were no crossovers and no reported contamination. Dialysis staff were not consistently available to assist with implementation, so study staff were necessary to deliver IDE. Secondary outcomes were not statistically significant.

Conclusions: This pilot study demonstrated feasibility of high, patient acceptability, and low risk of contamination. However, IDE will not be feasible in the long term unless dialysis staff assist with implementation. This will need to be addressed before executing a definitive trial.

A Prospective Study of Routine Heparin-Free Hemodialysis (HFHD) with Streamline® Bloodlines (SL) in a Large Tertiary Acute Care Inpatient Practice Sami Safani,1 Mary Ann Ryan,3 Amanda L. Severson,3 Fares Alahadab,3 John J. Dillon,4 Robert C. Albright,4 Amy W. Williams,4 Marie C. Hogan,4 1Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 2Nursing, Mayo Clinic; 3KSP Unit, Mayo Clinic.

Background: Extracorporeal circuit (EC) anticoagulation (AC) with heparin was a key advancement in hemodialysis (HD). However, AC in patients at risk of bleeding remains a frequently encountered problem. SL bloodlines eliminate blood-air contact, and reduce turbulence in HD circuit. Small studies suggest that SL reduces heparin use and improves HD efficiency. We prospectively evaluated EC clotting rates, impact on dialysis efficiency, and associated risk factors in our inpatient practice.

Methods: In this complete study, we followed acute care inpatients requiring HD without routine EC heparin. Patients could be on ACs for other non-HD indications. All sessions were performed using SL and Fresenius 2008K. HD sessions were observed for clotting events (CE) defined as interruption of HD session, loss of HD circuit, or inability to return blood. Of 970A runs were performed. Demographics & HD session characteristics are summarized in table 1. Overall CE rate was 5.2%. Determinants for CE were temporary HD catheters (OR=2.8, p<0.01), transfusions (OR=2.3, p=0.05), systemic AC (OR=0.2, p=0.01), & antplatelets (OR=0.4, p=0.01). CE were associated with a lower delivered Kt/V (diff0.39, p<0.01). Most CE during transfusions (71%) occurred when blood products were given by the HD circuit.

Conclusions: We successfully adopted HFHD with SL as our standard inpatient protocol. This protocol is feasible and safe in acute care inpatient HD. CE risk is low, and associated with temporary HD catheters and transfusions. Use of antplatelets and systemic AC is protective.
relationship between serum albumin levels and short-term mortality among chronic dialysis patients who are hospitalized with infectious diseases. This multicenter retrospective cohort study in Japan evaluated if serum albumin levels at the occurrence of infection is a risk factor for in-hospital mortality among hemodialysis patients.

Methods: From June 2011 to July 2013, a total of 418 hemodialysis patients who took blood cultures were reviewed retrospectively in five tertiary dialysis units participating in “TOMEI Nephrology Group for Clinical Research” study. After exclusion of 232 patients diagnosed with non-infectious diseases, 186 patients diagnosed with infections were analyzed. Patients were divided into two groups according to the serum albumin level at hospitalization: low serum albumin (Serum albumin<3.5 g/dL) or not. Outcome measure was in-hospital mortality. For statistical analysis,cox proportional hazard model was used.

Results: Among 186 patients with infectious diseases, there were 117 patients (62.9%) in low albumin group, and 69 patients (37.1%) in normal albumin group. During hospitalisation, median albumin (interquartile range 10-37), 29 patients (15.5%) died. 25 of 117 (21.4%) in low albumin group, and 4 of 69 (5.8%) in normal albumin group. The cox proportional hazard model revealed that low serum albumin and bacteremia were associated with in-hospital mortality. The hazard ratio of in-hospital mortality among low albumin group was 4.293 (95% CI: 1.61-15.55).

Conclusions: Although low serum albumin is a known risk factor for long-term mortality, this study showed that low serum albumin strongly predicts short-term mortality among hemodialysis patients hospitalized with infectious diseases.

PUB357
Usefulness of High-Frequency Wave-Length Ultrasonography as a Diagnostic Tool for Carpal Tunnel Syndrome in Hemodialysis Patients Tadashi Yamazaki,2 Tokie Hayasaka,2 Tetsuo Saito,3 Shuichii Tsuruoka,1 1Nephrology, Nippon Medical School, Tokyo, Japan; 2Dialysis Unit, Moka Hospital, Moka, Tochigi, Japan.

Background: Carpal tunnel syndrome (CTS) is a common complication in dialysis-induced amyloidosis. In orthopedics, high-frequency wave-length ultrasonography (US) with improved resolution is recently used for diagnosing disorders of the upper extremities. We aimed to determine the value of US for diagnosing CTS in hemodialysis (HD) patients, through a cross-sectional analysis.

Methods: All maintenance HD patients (N=150) at our hospital were recruited after providing written informed consent. Patients with apparent paralysis or pain in the index finger area and the quick form of the Disabilities of the Arm, Shoulder and Hand (1 - shortest diameter/longest diameter of the nerve around the carpal tunnel area). The 12 MHz probe) during HD, and the compression rate (CR) of the nerve was calculated as compression rate =1-(shortest diameter/longest diameter of the nerve around the carpal tunnel area).

Results: Total 250 wrists from 125 patients (Mean age = 65.6±10.6 years) were studied. The mean CR was 11.8±0.7% and the cut-off values of CR from ROC curve for history of carpal tunnel release was 25.7% (sensitivity 0.80, specificity 0.91). Multivariate analysis revealed that CR was significantly positively correlated with dialysis career, and CR and Quick-DASH scale, positive Tinel’s sign, and serum CRP and b2-Mg concentrations, whereas it showed a significantly negative correlation with pinch strength. Especially, patients with mean CR>14 years of HD and serum b2-Mg concentrations >20 mg/L showed significantly high CRs.

Conclusions: Measurement of CR with US is an easy and reproducible method for diagnosing dialysis-related CTS. The CR significantly correlated with symptoms and factors associated with dialysis-induced amyloidosis. The results support the routine evaluation of US in the dialysis center.

PUB358
Technique Failure in Korean Incident Dialysis Patients: A National Population-Based Study Shinha Lee1, Hyunwook Kim2, Seung-Jung Kim1, Duk-Hee Kang,1, Kyu Bok Choi,1 Dong-Ryeol Ryu.2 1Dept of Internal Medicine, School of Medicine, Ewha Womans Univ Mokdong Hospital, Seoul, Republic of Korea; 2Dept of Internal Medicine, Wonkwang Univ College of Medicine Sanbon Hospital, Gunpo, Republic of Korea.

Background: Technique failure is an important issue for dialysis patients. In this study, we aimed to analyze a detailed technique failure rate and to determine the predictors for technique failure in Korea.

Methods: We identified all patients who had started dialysis between January 1, 2005 and December 31, 2008 in Korea, using the Korean Health Insurance Review and Assessment Service database. A total of 32,357 eligible patients (24,743 hemodialysis (HD) patients and 7,614 peritoneal dialysis (PD) patients) were included, and the median follow-up interval was 5.4 months.

Results: The crude incidence rates of technique failure among HD patients and PD patients were 3.4 and 5.1 per 1000 patient-years, respectively. When comparing technique survival rate between HD and PD in both Kaplan-Meier analysis and competing risks analysis, it was significantly higher in patients on PD than those on PD. The gap of technique failure incidence between HD and PD was exaggerated in Kaplan-Meier analysis compared to competing risks analysis. In multivariate analyses, diabetes mellitus and Medical aid as a crude reflection of low socioeconomic status were independent risk factors in both Cox proportional hazard model and Fine and Gray subdistribution model. Incident technique failure was independently associated with a lower risk of technique failure in Fine and Gray model.

Conclusions: Technique failure in PD is higher than that in HD, and it is major concern in patients initiating dialysis in Korea. The results of our study offer a basis for risk stratification and customized care for technique failure.

PUB359
Frequency of Not Achieving Target Weight in Hemodialysis Patients and the Reasons Behind It JinMaaha,1 Frank Modersitzki,1 Lada Beara Lasic,1 2Internal Medicine, Div of Nephrology, New York School of Medicine, New York, NY; 2Internal Medicine, Div of Nephrology, New York Harbor VA Healthcare System, New York, NY.

Background: Volume overload and volume depletion have both been associated with morbidity and mortality in patients with end stage kidney disease (ESKD) on hemodialysis (HD). A recent study demonstrated an increased mortality risk when post HD weight is more than 2kg above or below the prescribed estimated dry weight (EDW) for >30% of HD sessions. Our aim was to determine the frequency of sessions with weight difference (WD)<±2kg, determine the prevalence of patients WD<±2kg for >30% of sessions and identify the possible reasons in our outpatient chronic HD population.

Methods: 32 outpatients on chronic HD at the New York Harbor VA Healthcare System in Manhattan were monitored for 2 months. Data for 631 sessions was obtained. Charts and HD nursing notes were reviewed every 2-4 weeks for: weight, prescribed EDW, ultrafiltration (UF) rate, intradialytic complications (hypotension with systolic BP<90, dizziness, cramping, administration of intravenous fluids). Sessions with a missing documented EDW or post HD weight were excluded. 502 sessions were used in the analysis. Results: The mean WD for all sessions was 0.67±1.64 kg with a majority (83.7%) of HD sessions ending with post HD weight within 2kg of EDW which is consistent with the literature. 6 out of 31 (19.3%) patients had WD>±2kg for >30% of the evaluated sessions. The inability to achieve post HD weight within 2kg of EDW was most commonly (51.2%) associated with an elevated UF rate (defined as >875ml/hour). Possible reasons for not achieving EDW also included cramps (4.9%) and hypotension (2.4%).

Conclusions: Failing to achieve EDW within 2kg range is most commonly associated with high UF rates, indicating high weight gains between treatments. Proposed strategies to continue aiming at achieving EDW while compensating for the constraints of elevated UF include: decreasing intradialytic weight gain, increasing treatment frequency or treatment time. Further studies identifying the best strategies to achieve this goal are needed.

PUB360
Comparative Effectiveness of Dialyzers: A Longitudinal Propensity Score-Matched Study Scott Sibbel,1 Abigail Hunt,1 Suzanne Laplante,2 Werner Beck,3 Mary Gellens,4 John Alan Laich,5 Steven M. Brunelli.1 1DaVita Clinical Research, Minneapolis, MN; 2Baxter Healthcare Corporation, Deerfield, IL.

Background: Differences in dialyzer design may affect systemic inflammation and extracorporeal blood sequestration and thereby impact anemia management and control. We evaluated the comparative effectiveness of commonly used dialyzers with respect to intradialytic hemoglobin (Hb) levels, and ESA and IV iron utilization.

Methods: Patients included in the analysis received hemodialysis between 01 Jan 2009 and 31 Dec 2013 and were new users of Revaclear, Optiflux 160, or Optiflux 180 dialyzers. Patients were followed for 1 year or until end of study or censoring for dialyzer switch, modality change, or loss to follow up. For each comparison, eligible patients were propensity score-matched 1:1 on a range of demographic, comorbidity history, and baseline laboratory parameters. Outcomes were assessed using generalized linear mixed models including fixed effects for dialyzer type, time, and their interaction term.

Results: Matched patient pairs (31,551 for Revaclear-Optiflux 160 comparison; 21,008 for Revaclear-Optiflux 180 comparison) were assessed. ESA doses evolved differently over time among Revaclear patients versus both Optiflux 160 and Optiflux 180 patients (p interaction<0.001 for both). Differences in ESA dose were significant from month 3 for Revaclear versus Optiflux 160 (range, 173-483 U/treatment) and at all time points for Revaclear-Optiflux 180 comparison) were assessed. ESA doses evolved differently over time among Revaclear patients versus both Optiflux 160 and Optiflux 180 patients (p interaction<0.001 for both). Differences in ESA dose were significant from month 3 for Revaclear versus Optiflux 160 (range, 173-483 U/treatment) and at all time points for Revaclear versus Optiflux 180 (range, 120-392 U/treatment) and at all time points for Revaclear versus Optiflux 180 (range, 120-392 U/treatment). Hb levels were equivalent between Revaclear and Optiflux patients at all times. IV iron dosing was lower for Revaclear patients than Optiflux 160 and 180 patients (p<0.001 for each) but differences were small (±30g/d). A total of 12 patients switched dialyzers.

Conclusions: Use of Revaclear versus Optiflux dialyzers was associated with lower ESA doses, modestly lower IV iron doses, and equivalent Hb concentrations.
Lack of Leukocytic Response to Infections in End Stage Renal Disease

Deepa Amberker,1 Ritesh J. Rampure,1 Mary C. Naglak,1 Harold D. Stein.1
1Internal Medicine, Abington Jefferson Health, Abington, PA.

Background: Patients with end stage renal disease (ESRD) on dialysis are at increased risk of infection resulting from a relatively immunosuppressed state. Dysfunctional immunity may be the result of uremia, dialyzer membrane interactions, poor nutritional status and impaired leukocyte responsiveness. Abnormal leukocytic response in such situations may result in missed diagnosis in the clinical setting as well as increased morbidity and mortality. The nature and magnitude of the leukocytic response to infection in this population has not been well characterized. This study is an attempt to assess the degree of leukocytosis in ESRD patients and compare it with the general population in the presence of an infection.

Methods: This was a retrospective study wherein all patients with ESRD on hemodialysis admitted to our hospital between December 2011 and December 2014 with any kind of infection were taken as the ESRD group and compared to others without ESRD or significant chronic kidney disease. Analysis of total WBC as well as percentage of Bandemia were compared and analyzed for statistical significance. Patients were excluded if on steroids, less than 18 years of age, presence of cancer, HIV, pregnancy, CKD stages any kind of infection were taken as the ESRD group and compared to others without ESRD.

Results: Nine patients moved to another hemodialysis facility. The patients dead at different times during the six years had significantly higher values of BMI (28.3 ± 6 vs 24.8 ± 3.1 kg/m², p < 0.01) and fat mass index (11.2 ± 4.1 vs 8.4 ± 2.8 kg/m², p < 0.003) compared to the survivors, while there were no significant differences for body cell mass (BCM) index (7.1 ± 1.7 vs 7.9 ± 1.8 kg/m²) and serum albumin (4.1 ± 0.4 vs 4.1 ± 0.1 mg/dl). Furthermore, deceased patients had lower values of reactivity (53.5 ± 11.7 vs 67.3 ± 13.7 Ohm, p < 0.000003), phase angle (5.1 ± 0.9 vs 5.9 ± 0.8 degrees, p < 0.00003) and the percentage of extracellular water was higher (50.6 ± 5.2 vs 46.1 ± 3.6%, p < 0.00003). Finally the BIVA analysis confirmed that the hydration was significantly higher in the deceased (73.3 ± 1.8 vs 71.2 ± 3.3%, p < 0.00006). In summary survivors had normal values of BMI and fat mass, a smaller reduction in BCM and less fluid overload than deceased patients.

Conclusions: The survival of HD patients is influenced by the nutritional status. In particular, fluid overload and decrease in muscle mass play a decisive role on survival. Fluid overload, low values of electrical resistance and phase angle predict mortality risk in ESRD patients.

PUB362
Fluid Overload Predicts Mortality Risk in Maintenance Hemodialysis Patients

Carlo Donadio, Valentina Vigo. Clinical and Experimental Medicine, Univ of Pisa, Pisa, Italy.

Background: Maintenance hemodialysis (MHD) patients have a high mortality rate, mainly due to cardiovascular disease and malnutrition. The aim of this study was to evaluate the efficacy of the analysis of body composition by bioimpedance (BIA) to predict the mortality risk in hemodialysis patients.

Methods: Observational longitudinal study lasting six years on 78 prevalent MHD patients (68% male, mean age 65 ± 14 years; dialysis vintage 7 ± 7 years). Every two years, starting from the baseline, we collected clinical, laboratory and BIA data, including vectorial analysis (BIVA) and hydration scale, that is the hydration as percentage of lean body mass. We compared the BIA data of patients dead during the study period (n = 45; 65%) with those of survivors (n = 24; 35%). The significance of the differences between the mean values of the two groups at the baseline was evaluated.

Results: Nine patients moved to another hemodialysis facility. The patients dead at different times during the six years had significantly higher values of BMI (28.3 ± 6 vs 24.8 ± 3.1 kg/m², p < 0.01) and fat mass index (11.2 ± 4.1 vs 8.4 ± 2.8 kg/m², p < 0.003) compared to the survivors, while there were no significant differences for body cell mass (BCM) index (7.1 ± 1.7 vs 7.9 ± 1.8 kg/m²) and serum albumin (4.1 ± 0.4 vs 4.1 ± 0.1 mg/dl). Furthermore, deceased patients had lower values of reactivity (53.5 ± 11.7 vs 67.3 ± 13.7 Ohm, p < 0.000003), phase angle (5.1 ± 0.9 vs 5.9 ± 0.8 degrees, p < 0.00003) and the percentage of extracellular water was higher (50.6 ± 5.2 vs 46.1 ± 3.6%, p < 0.00003). Finally the BIVA analysis confirmed that the hydration was significantly higher in the deceased (73.3 ± 1.8 vs 71.2 ± 3.3%, p < 0.00006). In summary survivors had normal values of BMI and fat mass, a smaller reduction in BCM and less fluid overload than deceased patients.

Conclusions: The survival of HD patients is influenced by the nutritional status. In particular, fluid overload and decrease in muscle mass play a decisive role on survival. Fluid overload, low values of electrical resistance and phase angle predict mortality risk in MHD patients.

of poor functional capacity and other co-morbid conditions from the Medical Evidence Form 2728. We conducted both Kaplan-Meier and Adjusted Cox regression analyses with death as the outcome variable.

Results: 56,194 (7.18%) were identified as nursing home residents upon initiation of dialysis. Among NH patients, 50.53% were female, 69.92% were white, and 99.49% were on hemodialysis and the mean age was 71.1 ± 12.1 years. The overall incidence rates of death of NH vs. non-NH patients were 51.8/100 and 17.6/100 patient-years, respectively (p<0.001). The unadjusted 1-year mortality was 50% in NH patients (vs. 20% in non-NH patients, p<0.001). Adjusted Cox analysis showed that NH patients were at significantly higher risk of death compared to non-NH patients (adjusted hazard ratio [AHR] 1.37; 95% confidence interval 1.35-1.38). Within this NH cohort, age (AHR 1.02; 95% CI 1.02-1.02), inability to transfer (AHR 1.25; 95% CI 1.22-1.29), inability to ambulate (AHR 1.08; 95% CI 1.05-1.11), cancer (AHR 1.15; 95% CI 1.12-1.19) and other co-morbid conditions were significantly associated with death.

Conclusions: NH patients on dialysis have a high mortality rate, even when compared to the broader ESRD population. Further studies on modifiable risk factors of mortality in this particularly high-risk ESRD population are warranted. [Disclaimer: The views expressed in this paper are those of the authors and do not reflect the official policy of the Department of the Army, the Department of Defense, or the United States government].

PUB365

Background: Protein-energy malnutrition (PEM) is prevalent in the hemodialysis (HD) population and is associated with a high morbidity-mortality burden. Metabolic acidosis and PEM are closely related. Protein intake, which constitutes an acid load, is an important factor of pH regulation in end-stage renal disease patients. Therefore, could a higher bicarbonate serum level be the result of insufficient protein intake and be a useful marker of malnutrition?

Methods: We conducted a retrospective study in our HD service using a computer database with measurements obtained simultaneously for all 342 patients. Correlation between pre-HD session bicarbonate, albumin, prealbumin and normalized protein catabolic rate (nPCR) was assessed by the use of Pearson’s r and Spearman’s correlation test. Subgroup analysis were realised for patients with negative C- Reactive Protein (CRP < 5) and patients classified as clinically stable.

Results: We found a significant, negative and moderate, correlation between bicarbonate and nPCR, (pearman’s r = -0.27, p<0.001). Subgroup analysis showed similar results, (pearman’s r = -0.28, p<0.001)for198clinically stable patient and (pearman’s r = -0.24, p<0.003)for 144 patients with a negative CRP. There was no association between albumin (pearman’s r = -0.06, p=0.1511) or prealbumin (pearman’s r =-0.1511) and bicarbonate in any group.

Conclusions: A higher serum level of bicarbonate is associated with a lower nPCR, reflecting of poor protein intake, but not with a malnutrition state defined by albumin or prealbumin criteria. These patients are at risk to develop a clinically apparent malnutrition state after a prolonged period.

PUB366

Scope and Consistency of Outcomes Reported in Randomized Trials of Hemodialysis Gabrielle J. Williams, Allison Tong, Jonathan C. Craig. School of Public Health, Univ of Sydney, Sydney, NSW, Australia.

Background: Inconsistent outcome selection and reporting in clinical trials may limit their capacity to inform evidence-based decision making and the ability to combine findings in systematic reviews. Aim: We aimed to assess the scope and consistency of outcome selection and reporting in trials included in systematic reviews of interventions for patients on hemodialysis (HD).

Methods: The Cochrane Database of Systematic Reviews was searched from 1999 to January 2015 for published systematic reviews of interventions for patients on chronic HD. The description and frequency of outcomes reported within the source randomized controlled trials were assessed.

Results: The 18 systematic reviews included 282 trials that reported over 518 outcomes. There was considerable heterogeneity among the outcomes reported. Across all trials, 320 outcomes to improve the comparability of trial findings in meta-analysis and to provide greater confidence around treatment decisions for patients undergoing HD.

Blood Pressure and Cognitive Decline in Hemodialysis Patients Sarah M. Duncan, 1 Hocine Tighiouart, 1 David A. Drew, 1 Tammy Scott, 1,2 Daniel E. Weiner, 1 Mark J. Sarnak. 1 Tufts Medical Center, Boston, MA; 2Tufts Univ, Boston, MA.

Background: Cognitive impairment is common in hemodialysis (HD) patients; however, the relationship between measures of blood pressure (BP) and longitudinal decline in cognitive function is unknown in this population.

Methods: 314 participants in the Cognition and Dialysis Study underwent an annual comprehensive battery of cognitive tests. Using principal components analysis (PCA), we reduced individual test results to two domain scores representing memory and executive function. Adjusted joint mixed models accounting for death, transplant, and drop-out were used to explore the association of blood pressure (systolic (SBP), diastolic (DBP) and pulse pressure (PP)) with change in cognitive function over time.

Results: Mean (SD) age was 63 (16) years, 47% were women, 22% were African American, and 44% had cardiovascular disease (CVD). Mean (SD) SBP, DBP, and PP were 141 (21), 73 (12) and 68 (15) mmHg, respectively. Median follow up time was 1.8 years (IQR 1.0-3.4). Mean slopes of PCA memory and executive were 0.03 (95% CI 0.01, 0.07) and -0.11 (95% CI -0.15, -0.06) per year, respectively. Lower DBP and higher PP were associated with decline in measures of both memory and executive function. There was no association between SBP and cognitive decline.

Conclusions: Lower DBP and higher PP are associated with faster rate of cognitive decline, in particular that related to executive function. Because impairment in executive function is a manifestation of vascular disease and lower DBP and higher PP are associated with CVD in HD patients, our results suggest that cognitive decline may be mediated by vascular disease in this population.

PUB368

High Ferritin Levels Achieved with Ferric Citrate as a Phosphate Binder Do Not Associate with Adverse Events Udavan Y. Bhatt, 1 Kausik Umanath, 2 Mohammedi Sika, 1 Mark Koury, 1 Robert M. Nieceastro, 3 Barbara A. Greco, 4 Dana G. Niederpruem, 1 Jessica J. Chang, 1 Seandren Z. Fademia, 1 Molly Mcfadden, 8 Julia Lewis, 1 Jamie P. Dwyer, 3 The Collaborative study group, 4 Ohio State; 5Henry Ford Hosp; 6Vanderbilt; 7CSG; 8Baystate Med Ctr; 9U of VT; 10Western Neph; 11U of Utah; 12Baylor College of Med.

Background: Ferric citrate (FC) as a phosphate binder increases Fe stores and reduces IV iron/ESA use while maintaining hemoglobin. This analysis compares effects of higher achieved ferritin levels in subjects on FC to those in subjects on sevelamer carbonate and/or calcium acetate (active control, AC).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: Data were obtained from the 52-wk active control period of the FC pivotal trial. Subjects with a baseline ferritin ≥1000ng/mL or TSAT≥50% were excluded from the trial. We randomized 292 subjects to FC and 149 to AC. Any subjects who developed ferritin level ≥1500ng/mL at any time over 52wks were identified. CV, ID, and dialysis access related adverse events (AE) occurring at any time over the 52-wk period were tabulated. Results: 57 subjects (19.8%) in the FC group and 14 subjects (9.5%) in the AC group had at least a single ferritin≥1500ng/mL (p=0.012) during the 52 wks. CV events including MI, CHF, and arrhythmias, occurred in 12.3% of the FC group compared to 21.4% ID AEs occurred in 42.1% FC and 50.4% AC. Dialysis access related AE occurred in 15.7% FC and 14.7% AC. All CV events were statistically significant with a Bonferroni correction (p=0.003) for the FC group (2.95±3.75mg/wk) than the AC group (6.20±3.64mg/wk), consistent with the full cohort that saw a significant reduction in IV iron use. Cumulative ESA dosing was 1016±906 Units/wk FC and 1781±1756 Units/wk AC (p=0.256).

Results: In the subset who developed ferritin ≥1500ng/mL shows that fewer subjects experienced a CV, ID, or dialysis access related AE in those receiving FC vs AC. IV iron use was statistically lower and ESA dosing was numerically lower. As previously reported the majority of ferritin≥1500ng/mL resolved and 90.1% were adjudicated to be related to IV iron or other inflammatory AEs. This analysis although limited by small sample size supports the conclusion that FC is clinically useful and safe vs traditional binders. Association Between Employment Status and KDQOL Scores in Dialysis Patients
Duane V. Dunn,1 Deborah S. Evans,1 Elizabeth J. Jones,1 Caroline Hann,2 Rich Muttel,1 Allen R. Nissenson,1 Deborah A. Benner.1 DaVita HealthCare Partners Inc, Denver, CO; 2Apex Health Innovations, Simi Valley, CA.

Background: Studies have shown that unemployment negatively impacts dialysis patients’ quality of life (QOL).1 QOL can be quantified and low scores on the Kidney Disease Quality of Life (KDQOL) survey are associated with poor outcomes.2 Our study examines employment/unemployment status and KDQOL scores.

Methods: We collected employment status data on 122,166 adult patients at a large dialysis organization from Nov 2014-Apr 2015. Patients were grouped as either employed (received pay or in training) or unemployed (including retirees and those on long-term disability or Workers Compensation) or other (involved in work/activity but not paid). Data were matched with patients’ most recent KDQOL scores.

Results: The employed group (n=16,216) had the highest KDQOL scores in all categories (Table 1) and with smaller SDs compared to the unemployed group (n=98,914) (Table 2). A clinically meaningful difference (6.8) in Physical Component Score was found between the employed (42.0) and unemployed (35.2) groups. This difference was greater (~10 points) between full-time employed and Workers Compensation patients, who scored lowest in all categories. Funding: Dialysis Patients Association of Nephrology.

PUB371
The Mechanisms Study on Neointimal Hyperplasia of Autogenous Arteriovenous Fistula in Maintenance Hemodialysis Patients
Nanmei Liu, Jumin Hospital of Shanghai.

Background: To evaluate the influence and the possible mechanism about neointimal hyperplasia of autogenous internal arteriovenous fistula in hypertensive nephropathy and diabetic nephropathy patients which was going maintenance hemodialysis and provide possible theory about how to prevent from intimal hyperplasia, extend the life of AVF in clinic.

Methods: Collecting cephalic vein when the hemodialysis patients had the surgery of AVF angioplasty and reconstruction.Vascular tissues were divided into chronic glomerulonephritis group,hypertensive nephropathy group and diabetic nephropathy group. Immunohistochemistry was used to detect the expression of vascular smooth muscle actin (a-SMA). Selecting the control group and fistula vascular tissue which the useful life was 1~2 years, basic fibroblast growth factor (bFGF), insulin-like growth factor 1(IGF-1),matrix metalloproteinase2 (MMP2) and matrix metalloproteinase9 (MMP9) were to detect expression change by immunohistochemical staining.

Results: Compared with chronic glomerulonephritis group, intima thickness of hypertensive nephropathy and diabetic nephropathy were significantly increased and the increase was more significant in diabetic nephropathy. Hyperplasia intima was eccentric hypertrophy and the hyperplasia intima showed obvious inflammatory cells infiltration and vascular degeneration. Immunohistochemical staining showed that compared with the group of chronic glomerulonephritis, hypertensive nephropathy and diabetic nephropathy groups’ a-SMA, bFGF, IGF-1 and MMP9 expression levels were significantly increased, expression of VEGF was significantly reduced, MMP2 was no significant change (P>0.05). Univariate regression analysis revealed that the expression levels of a-SMA was positively correlated with bFGF, IGF-1 and MMP9, negatively correlated with the VEGF. AVF intimal hyperplasia mainly dominated by the vascular smooth muscle cells (VSMC) proliferation. Multivariate analysis showed that hypertension and diabetes were as a protective factor and the intimal hyperplasia, shorten the life of fistula and diabetes promote intimal hyperplasia more significantly. This study provides a theory and therapeutic targets for the prevention and treatment on intimal hyperplasia of AVF in dialysis patients. Funding: Government Support - Non-U.S.
Conclusions: Depression and sleep disorders are important factors influencing the nutritional status and could be an independent risk factors for malnutrition in elderly patients receiving maintenance dialysis. Psychological assessment should be mandatory in the follow up of these patients to identify depression and sleep disturbance because many of them are reversible.

PUB373

Predisialysis Hyponatremia and Mortality in Elderly Patients with Incident Maintenance Renal Replacement

Conclusions: We retrospectively assessed mortality in 397 (mean age 73.0 year, male female 226/171) patients aged ≥65 years with non-diabetic end-stage renal disease (ESRD) who initiated renal replacement therapy (RRT) at a tertiary university hospital between 2000 and 2010. 1 year all cause mortality (ACM) was analyzed in relation to predialysis serum sodium (sNa). We divided subjects into 3 groups according to sNa: Group1, < sNa 125; Group 2, sNa 125-134; Group 3, sNa ≥ 135 mEq/L. Patients with sNa levels >145mEq/L were excluded.

Results: The median value of sNa was 137 mEq/L (interquartile range 133-140 mEq/L). Chronic comorbidities including congestive heart failure (r = -0.215, P<0.001) and liver cirrhosis (r = -0.174, P<0.001), lower estimated glomerular filtration rate (r = -0.152, P<0.005) and albumin (r = -0.208, P<0.001) were associated with lower sNa levels in elderly patients after full adjustment. One hundred and five (26.4%) patients had died at the 1-year follow up. Higher sNa level was associated with lower adjusted ACM in a continuous model (HR 0.433, 95% CI 0.261-0.718, P<0.001). Group 1 had a higher mortality than normonatremia group in a categorical model (reference group, 3.6 (2.48-5.47)). The sNa level and mortality difference was not observed between group 2-3 (reference group3, HR 1.511, P=0.161). Conclusions: Predisialysis hyponatremia was associated with increased 1-year mortality in elderly ESRD patients who initiated RRT. However, the highest mortality was only observed in elderly patients with severe hyponatremia (sNa < 125mEq/L). These findings suggested that compared to adults <65 years, other comorbidities or factors rather than sNa may affect mortality in elderly.

PUB374

Observation of the Correlation Between the Uremic Toxins with Clinical Feature in Uremia Patients

Methods: 72 cases of maintenance hemodialysis patients were observed, age 28-80 years(59.75±13.86), dialysis duration 4-192 months (34.46±39.15), HD group (n = 50), HDF group (n = 22/ once 1-2 weeks).Before each conventional HD and HDF therapy, blood was sampled for small molecule water-soluble toxins BUN with automatic biochemical analzye, Middle molecular and macromolecular toxins (MMS) with Ultraviolet spectrophotometry, pentosidine(PENT) with enzyme-linked immunosorbsent assay method(from ADL Company, USA), Protein-bound toxins, indoxyl sulfate(IS) with high performance liquid chromatography method. Results: For HDF versus HD, there was no significant differences between BUN,MMS, pentosidine and IS.There was low positive correlation between MMS, PENT, IS and the age of the patients (r being 0.322, 0.263 respectively, P>0.05). MMS, PENT and IS were positively related with dialysis months (r being 0.406, 0.427, 0.742 respectively, P<0.05). Conclusions: HD and HDF therapy may not good enough in clearing middle molecular toxins and protein-bound toxins, which results in their accumulation in patient’s body with the increase of dialysis course. It is recommended that better dialysis methods may be adopted for patients who have received hemodialysis for a long time.

PUB375

Parathyroid Hormone Response in Chronic Hemodialysis Patients Converted from Intravenous Doxercalciferol to Oral Calcitriol Three Times a Week

Methods: Data was collected by a retrospective chart audit of end stage renal disease patients on hemodialysis in an outpatient chronic dialysis unit. We identified 33 chronic hemodialysis patients that had a record of treatment with intravenous doxercalciferol (6 months minimum) and transition to three times oral calcitriol (6 months minimum) between June 2014 and May 2015 following a conversion algorithm. The change in serum calcium, phosphorus, and iPTH between treatment periods (intravenous doxercalciferol vs. oral calcitriol) was analyzed.

Results: Patient characteristics were as follows: mean, age 63.16±13 years; 39% were men; and 55% black. The mean (SD) for serum calcium and phosphorus and median (IQR) serum iPTH during the 6 months of intravenous doxercalciferol were 8.8±0.7 mg/dL, 4.5±1.3 mg/dL and 643 (384 to 908) pg/mL, respectively. The corresponding values after 6 months of oral calcitriol were 8.8±0.6 mg/dL, 3.9±0.7 mg/dL, and 147 (102-245) pg/mL, respectively. The comparisons achieved statistical significance (p > 0.43 for all). 48% of patients were on calcenacel during each of the treatment periods. The median (IQR) change in iPTH increased slightly among those patients receiving oral calcitriol and sevelamer (34 (-132 to 147)) pg/mL, while iPTH decreased among patients receiving oral calcitriol and other non-sevelamer binders (-102 (-294 to 155 pg/mL, p=0.17)). Conclusions: This small retrospective study suggests that conversion from intravenous doxercalciferol to oral calcitriol using a conversion algorithm maintains iPTH within KDIGO recommended targets and does not appear to cause hypercalcaemia or hyperphosphataemia. The clinical significance of other iPTH values among those treated with oral calcitriol and sevelamer needs further study.

PUB378

Pregnancy is rare in dialysis patients and outcomes are generally poor. There are improved results with intensive dialysis and multidisciplinary approach to the management.
The Incidence and Type of Cancer in Patients with End-Stage Renal Disease: A Prospective Cohort Study for End-Stage Renal Disease in Korea

**Background:** In patients with end-stage renal disease, urinary tract kidney cancer is known to be the most prevalent type of cancer. However, the incidence and type of cancer are affected by variable factors such as age, gender, ethnic differences. Moreover, the causality of dialysis and cancer incidence in certain type of cancer is still needed to be clarified.

**Methods:** A total of 5,225 patients in the clinical research center for ESRD cohort were enrolled from Aug 2008 to Dec 2014. The primary outcome to be compared is the cancer incidence rate of ESRD patients with the general population. We obtained cancer incidence data from National Cancer Information Center Registry in healthy counterpart.

**Results:** A total of 2,200 incident and 3,035 prevalent dialysis patients was included throughout the study. The mean follow-up duration was 25.3 months, and 116 (2.2%) patients were diagnosed with cancer during the observation periods. ESRD with cancer group was significantly older, longer dialysis duration and more comorbidity than control group. The incident rate of cancer in prevalent dialysis patients was higher than those in incident dialysis patients (2.5±1.3%, p<0.002). The proportion of primary organ was highest in digestive organ (33.6%). In 14.79% of patients, the MSPSS (social support) score was used for evaluating patients' social support. The initial incidence of cancer from dialysis initiation was 58.6 months in digestive cancer, 52.0 months in urinary tract cancer. The standardized incidence ratio (SIR) of overall cancer was 0.94 (95% CI: 0.72 –1.19). Urinary tract cancer showed the highest SIR (4.7, 95% CI: 4.42–8.19) and had the highest SIR (16.1%). It was interesting to note that the highest frequency (10.15%) of digestive organ cancer showed no difference in the incidence of cancer to compare the general population [SIR : 0.607, 95% CI: 0.36–0.94].

**Conclusions:** Further research was needed to compare the organ-specific cancer incidence of ESRD patients with the general population. The screening test could be necessary for digestive and urinary tract cancer.

**PUB387**

The Role of Social Support in Hemodialysis Patients

**Background:** A number of patients with End-Stage Renal Disease (ESRD) have significant impairment in social support. Especially, the limited function of patients with hemodialysis (HD) prevents them from social activities and even makes them social withdrawal. There are few studies of factors affecting the social support in HD patients. The aim of our study was to identify the clinical and psychosocial factors including quality of life related to impaired social support in HD patients.

**Methods:** The 101 participants on HD from the Daegu Catholic University Medical Center were assessed from September in 2013 to September in 2014. Patients on HD for acute kidney injury were excluded from this study. Multidimensional Scale of Perceived Social Support (MSPSS) was used for evaluating patients' social support. The correlation of cancer incidence and psychosocial factors including quality of life, anxiety, depression and sleep disorder were evaluated. Laboratory and clinical information including hemoglobin, vitamin D (25(OH)D, 1.25(OH)2D3), albumin, Kt/V, normalized protein catabolic rate, ferritin, bone mass index, duration of HD were assessed. Stepwise multivariate logistic regression with backward selection was performed.

**Results:** The mean of MSPSS (social support) score was 36.8±9.3. In subgroups of social support, the MSPSS-family, MSPSS-friend, and MSPSS-medical team scores were 14.4±4.6, 9.8±3.9, and 9.4±3.9, respectively. The variables showing statistical association with social support were quality of life (r=0.332, p<0.01), depression (r=-0.290, p<0.001), anxiety (r=0.372, p<0.001), and serum creatinine (r=-0.270, p=0.007). Multiple regression showed that quality of life (95% CI: 0.615–19.799, p=0.037) and serum creatinine (95% CI: 1.543–0.319, p=0.003) were independent predictors of impaired social support.

**Conclusions:** This study explored the determinants of high susceptibility to the impaired social support in HD patients. We found that the impaired social support is associated with the quality of life and serum creatinine. Further study will be needed because of the possibility of different results depending on culture and ethnicity. As well as, we should consider the psychosocial interventions to improve the impaired social support.

Use of Portable Fundoscopic Photography to Screen for Diabetic Retinopathy in the Hemodialysis Unit

**Background:** Over 40% of dialysis patients have diabetes, yet only 25% get annual eye exams. Due to the frequency and duration of visits to dialysis centers, patients on dialysis likely have increased barriers to receiving eye exams and other recommended preventive care. This study evaluated the need for ophthalmic care, barriers to care, and prevalence of diabetic retinopathy (DR) in this population.

**Methods:** Prospective cohort study at two dialysis centers (1 urban, 1 suburban). A total of 5,225 patients in the clinical research center for ESRD cohort were enrolled from Aug 2008 to Dec 2014. The primary outcome to be compared is the cancer incidence rate of ESRD patients with the general population. We obtained cancer incidence data from National Cancer Information Center Registry in healthy counterpart.

**Results:** A total of 2,200 incident and 3,035 prevalent dialysis patients was included throughout the study. The mean follow-up duration was 25.3 months, and 116 (2.2%) patients were diagnosed with cancer during the observation periods. ESRD with cancer group was significantly older, longer dialysis duration and more comorbidity than control group. The incident rate of cancer in prevalent dialysis patients was higher than those in incident dialysis patients (2.5±1.3%, p<0.002). The proportion of primary organ was highest in digestive organ (33.6%). In 14.79% of patients, the MSPSS (social support) score was used for evaluating patients' social support. The initial incidence of cancer from dialysis initiation was 58.6 months in digestive cancer, 52.0 months in urinary tract cancer. The standardized incidence ratio (SIR) of overall cancer was 0.94 (95% CI: 0.72 –1.19). Urinary tract cancer showed the highest SIR (4.7, 95% CI: 4.42–8.19) and had the highest SIR (16.1%). It was interesting to note that the highest frequency (10.15%) of digestive organ cancer showed no difference in the incidence of cancer to compare the general population [SIR : 0.607, 95% CI: 0.36–0.94].

**Conclusions:** Further research was needed to compare the organ-specific cancer incidence of ESRD patients with the general population. The screening test could be necessary for digestive and urinary tract cancer.

The Role of Social Support in Hemodialysis Patients

**Background:** A number of patients with End-Stage Renal Disease (ESRD) have significant impairment in social support. Especially, the limited function of patients with hemodialysis (HD) prevents them from social activities and even makes them social withdrawal. There are few studies of factors affecting the social support in HD patients. The aim of the current study was to identify the clinical and psychosocial factors including quality of life related to impaired social support in HD patients.

**Methods:** The 101 participants on HD from the Daegu Catholic University Medical Center were assessed from September in 2013 to September in 2014. Patients on HD for acute kidney injury were excluded from this study. Multidimensional Scale of Perceived Social Support (MSPSS) was used for evaluating patients' social support. The correlation of cancer incidence and psychosocial factors including quality of life, anxiety, depression and sleep disorder were evaluated. Laboratory and clinical information including hemoglobin, vitamin D (25(OH)D, 1.25(OH)2D3), albumin, Kt/V, normalized protein catabolic rate, ferritin, bone mass index, duration of HD were assessed. Stepwise multivariate logistic regression with backward selection was performed.

**Results:** The mean of MSPSS (social support) score was 36.8±9.3. In subgroups of social support, the MSPSS-family, MSPSS-friend, and MSPSS-medical team scores were 14.4±4.6, 9.8±3.9, and 9.4±3.9, respectively. The variables showing statistical association with social support were quality of life (r=0.332, p<0.01), depression (r=-0.290, p<0.001), anxiety (r=0.372, p<0.001), and serum creatinine (r=-0.270, p=0.007). Multiple regression showed that quality of life (95% CI: 0.615–19.799, p=0.037) and serum creatinine (95% CI: 1.543–0.319, p=0.003) were independent predictors of impaired social support.

**Conclusions:** This study explored the determinants of high susceptibility to the impaired social support in HD patients. We found that the impaired social support is associated with the quality of life and serum creatinine. Further study will be needed because of the possibility of different results depending on culture and ethnicity. As well as, we should consider the psychosocial interventions to improve the impaired social support.

Enhancing Patient Engagement in Future Clinical Trials – The Effects of Age and Ethnicity
Territa Santhakumar, Kieran Macaffrey. Renal, Royal London Hospital, London, United Kingdom.

Background: Increasing patient engagement from ethnicity minority populations is crucial to the widespread applicability of research findings, but this represents a challenge in nephrology clinical research. Ethnicity, socio-cultural and language barriers along with a lack of understanding and awareness of clinical trials are potential factors that affect patient involvement in clinical trials.

Methods: We developed a patient survey in English, Urdu and Bengali to represent our ethnically diverse population in East London to explore the attitudes and understanding of clinical research. The surveys were offered to all patients attending the haemodialysis and renal outpatient department over a 2 week period.

Results: 151 forms were completed, 145 in English, 7 in Bengali and 1 in Urdu. 41% of the forms were from patients who attended transplant clinic and 31% from patients who attended for haemodialysis. Overall there was a strong message that patients wanted more trials in nephrology and felt that taking part in trials would help them take a more active role in their health. They also felt there was a lack of information on how to access research opportunities. Of those who completed the survey there was no significant ethnicity differences in their attitudes and understanding of clinical research, however transplant patients who identified themselves as White British were significantly more likely to take part in the survey (p<0.02). Patients who identified themselves as Black British were significantly less likely to take part in the survey (p<0.02). In the dialysis cohort, patients who identified themselves as White British were significantly more likely to take part in the survey (p<0.02). Whereas patients who identified themselves as Bangladeshi were significantly less likely to take part in the survey (p<0.04). Age did not appear to have an effect on patients’ perception and understanding of clinical trials.

Conclusions: From our work it is clear that there is a patient led demand for greater engagement in translational research. However, challenges remain in engaging ethnic minority cohorts in clinical research.

PUB384
Deferred Educational App Personalization Increases Registration Completion
Daniel Schwartz,1 Chai Kruse.2 1Faculty of Medicine, Univ of British Columbia, Vancouver, BC, Canada; 2QxMD, Vancouver, BC, Canada.

Background: ‘Read by QxMD’ (http://qxdm.com/read) is an app that curates the nephrology literature and personalizes reading recommendations based on a clinician’s or researcher’s interests. In order to provide highly accurate recommendations, the app must collect content preferences such as preferred journals and topics. In addition, it must collect email address and personal identifiers in order to complete registration and offer CME. When the registration process is too onerous, mobile app users may not complete registration. If the registration process fails to collect necessary user data, this may negatively impact the educational value of the app. We hypothesized that allowing users to delay providing personal information until after they set their preferences would increase registration completion.

Methods: We randomly assigned all users registering on the Android version of Read to two different registration processes. In version 1, “upfront personalization”, users are asked to provide personal identifiers prior to setting their preferences, while in version 2, “deferred personalization”, users set preferences first and after this has been completed are asked to provide personal identifiers. The Leaflamp SDK was used to implement and automate the randomization of alternate registration pathways. The primary outcome was completion of registration.

Results: Between April 6, 2015 and June 1, 2015, a total of 5660 users who registered using the Android version of ‘Read’ were randomized with 2834 users randomized to upfront personalization and 2836 to deferred personalization. Upfront personalization yielded a 47.4% (95% CI 46.0 to 48.8) registration completion rate versus 50.7% (95% CI 49.0 to 52.4) with deferred personalization (p<.05).

Conclusions: A strategy of deferred collection of personal identifiers yielded slightly higher completion rates. To maximize user registration when onboarding users to educational medical apps, consider deferring the collection of personal information until user preferences have been provided. Further research is required to maximize app registration when data requested is extensive as in ‘Read’.

PUB385
Onconephrology Abstracts Trends in ASN Kidney Week 2012-2014
Jyotsana Wanchoo, Kenar D. Jhaveri. Nephrology, Hofstra NSLIJ School of Medicine.

Background: Onconephrology is an emerging new specialty of nephrology. The ASN created a forum dedicated to the field of Onconephrology in 2011 to improve collaborative care for cancer patients with kidney disease. One of the aims was to allow for collaborative research strategies in the field of onconephrology. However, the number of onconephrology related abstracts accepted to be presented at ASN Kidney Week (ASN-KW) 2012-2014 is not known.

Methods: We reviewed the abstracts presented in the ASN-KW over past 3 years from 2012-2014 which were related to Onconephrology. Search terms used to identify abstracts included cancer, myeloma, chemotherapy, tumor lysis, paraneoplastic syndrome and hypercalcemia. They were then categorized into: basic science, chemotherapy, myeloma, epidemiology, electrolyte disorders, AKI, tumor lysis, GN, paraneoplastic syndromes and obstructive uropathy. Abstracts were also categorized based on study design.

Results:

Figure above breaks down the total number(s) of abstracts (Y axis) in the last 3 years presented at ASN-KW by category. There has been an increase in the number of onconephrology abstracts over last 3 years. A total of 175 abstracts were reviewed. In 2012, there were 50 onconephrology related abstracts, increased to 54 in 2013 and 71 in 2014. Abstracts related to basic science(16%), chemotherapy toxicities(16%), myeloma(16%) and epidemiology (16%) dominated most of the accepted abstracts. Of the clinical abstracts, > 50% were case reports, 41% were retrospective studies, 4.5% database studies and <1% RCT.

Conclusions: Over the last 3 years, we have seen a growing trend in the number of abstracts submitted in the ASN-KW related to the field of onconephrology. We suggest creating a separate section dedicated to onconephrology in the ASN meetings to allow for collaborative research and greater understanding of cancer related nephrology, leading to improved patient outcomes.

PUB386
Patients-Initiated Educational Research in a Digital Age
Chavakrit Krittawong,1 Zhen Wang,2 Sakkarin Chirapongsathorn,2,4 Hua Ann Jenny Lu.1 1Div of Cardiovascular Disease, Mayo Clinic, Rochester, MN; 2Dept of Healthcare Policy and Research, Mayo Clinic, Rochester; 3Div of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN; 4Div of Gastroenterology, Dept of Medicine, Phramongkutklao Hospital and College of Medicine, Royal Thai Army, Bangkok, Thailand; 3Div of Nephrology, Massachusetts General Hospital and Harvard Medical School, Boston, MA.

Background: The emergence of web-based technology in the digital age has become popular in the healthcare industry, particularly in the educational research field. A web-based technology can bridge the educational gap between researchers and patients.

Methods: We aimed to develop a user-friendly interface between a virtual community that is driven by patients and researchers and a preliminary knowledge-building activity. Wikiheart is a web research environment that creates a real-time community between researchers and patients without geographical restrictions.

Results: Once patients have registered for free, the system allows these users to write their own articles or to edit other articles, which often leads to thought provoking medical research questions. Wikiheart also demonstrates a novel approach to population science that is based on huge databases with multiple cloud servers that reach the web research community. Nowadays Wikiheart has more than one million visitors, and serves as an educational web technology that provides its users with both a variety of learning methods, and several areas of research focus.

Conclusions: Wikiheart is an innovative web-based program for conducting educational research in the digital community. It is an excellent tool for researchers and patients to generate new hypotheses via the scientific method in an online environment.
Detailed Subject Lines Increase Engagement with Educational Emails

Daniel Schwartz,1 Chan Kruse,2 Stephane Boyer.1 1Faculty of Medicine, Univ of British Columbia, Vancouver, BC, Canada; 2QxMD, Vancouver, BC, Canada.

Background: ‘Read by QxMD’ (http://qxmd.com/read) is an educational service and mobile app that curates the nephrology/medical literature and personalizes reading recommendations based on a clinician’s or researcher’s interests. Each week, registrants receive an alert that highlights the most popular medical articles in the reader’s clinical or research area of specialty. The content of email subject lines have been shown to have a significant impact on whether email is read or deleted prior to being read. We hypothesized that providing more details in the subject line would result in greater engagement with the email content.

Methods: We randomly assigned all emails sent containing the “Most Read” articles of the week to either a generic/consistent subject line or a subject line that included the title of the most commonly read article of the week (detailed/variable). SendGrid, an email service provider, was utilized for email delivery and to automate the subject line randomization. The primary outcome was email open rate. Secondary outcome was email click through rate.

Results: Between January 7, 2014 and May 1, 2015, a total of 1,287,442 emails were sent. 643,475 were generic/consistent and 643,967 were specific/variable. A specific/variable email subject line yielded a 70.76% (95% CI 70.68 to 70.84) open rate versus 48.85% (95% CI 48.76 to 48.94) with an email subject line that was generic (p < .01). A detailed/variable subject line did not increase click through rate as compared to a generic/consistent subject line. 9.87% (95% CI 9.82 to 9.92) vs 9.85% (95% CI 9.8 to 9.9) p > .05.

Conclusions: Including details about the content of an educational email in the subject line resulted in a greater email open rate but did not increase the click through rate. Further research is required to increase engagement with the content of educational emails provided by the ‘Read’ educational service.

Teaching Ethics and EBM in the Medical School: Case Discussion as a Useful Tool to Acquire Bioethical Skills and Analytical Tools.

Laura Sacchetti,1 Laura Verze,1 Fratruo Cavallaro,1 Costanzo Quaglia,1 Clinical and Biological Sciences, Univ of Torino, Italy; 2Course of EBM and Ethics, Univ of Torino, Italy.

Background: History of Nephrology influences the development of Bioethics and offers ideas for teaching: the first Ethics Committee (the ‘God’s line’), brain death, the sale of organs, the limitations of resources, up to the global needs (as in the 0-25 project). Case discussion within the Medical school may be a useful tool to acquire bioethical skills and analytical tools.

Methods: Discussion of clinical cases: patient in his context, his comorbidity, good cognitive status (writer), GFR 10 mL / min. The case raises questions about the choice of dialysis or peritoneal dialysis. 50 medical students of the curricular course of ethics and EBM are tutored for an academic year through the collection of information from databases (Pubmed), web, talk with experts, tutors and teachers. The analysis is performed according to the 4 main ethical principles (beneficium, non maleficum, justice, autonomy) to a narrative approach.

Results: The students produces a text, here summarized: from a clinical standpoint, nephrology and ethics complement each other, making this case an interesting example. The patient had a history of polycystic kidney disease, end-stage renal disease, requiring a kidney transplant. The end-stage renal disease, his health status, and his desire for autonomy were important factors in this case. Considering the chronicity of the disease, treatment options, and the patient's cognitive status (writer), GFR 10 mL / min. The case raises questions about the choice of dialysis or peritoneal dialysis. The students were able to identify ethical principles (beneficium, non-maleficium) and the possibility of using EBM to support their discussion. The students also discussed the importance of considering the patient's autonomy in decision-making.

Conclusions: Nephrology offers suggestions for bioethical discussion. Conversely, bioethics offers analytical tools for the analysis of complex decisions such as dialysis in the “very old”.

SLIT2 Is Upregulated in Proximal Tubules and Urine following Folic Acid Induced Kidney Injury

Jonathan Street, Ana C. Souza, Xuzhen Hu, Yuning George Huang, Peter S.T. Yuen, Robert A. Star. NIDDK, Bethesda, MD.

Background: SLIT2, signaling via ROBO receptors, was originally described for its role in neuronal guidance, and has since been linked with leucocyte chemotaxis and angiogenesis. As both processes might be involved in kidney injury and repair, we tested whether SLIT2 signaling is involved in folic acid induced kidney injury.

Methods: Eight-week-old male CD-1 mice were injected i.p. with 250 mg/kg folic acid. Groups were euthanized 0-7, or 14 days later. Expression levels were determined by RT-qPCR and western blot of whole kidney lysates. Localization was determined by immunohistochemistry. In a second experiment mice received folic acid and then 70 µg/kg i.p. recombinant human SLIT2 or vehicle on days 2, 4, and 6. On day 14 GFR was measured in conscious mice by transcutaneous fluorescence monitoring of FITC-Sinistrin elimination.

Results: Following folic acid injection, whole kidney SLIT2 mRNA and protein levels were increased on day 3, whereas SLIT2 were given folic acid, then recombinant human SLIT2 i.p. on days 2, 4, and 6. Kidney function measured directly as GFR or indirectly via BUN 14 days after injection was not significantly improved by SLIT2 treatment.

Conclusions: Folic acid induced injury increased expression of SLIT2 in proximal tubules, followed by detection of SLIT2 in the urine, which points to SLIT2 as a candidate urine biomarker for tubular injury. Amelioration of injury with systemic SLIT2 treatment was not observed, suggesting better utility as a marker than a mediator.

Urinary Trefoil Factor 3 Is Significantly Associated with Renal Tissue Fibrosis in Patients with Tubulointerstitial Nephritis

Background: Trefoil factor 3 (TFF3) is a small peptide involved in mucosal protection. TFF3 is widely expressed in multiple tissues including kidney. Previous studies have suggested that serum and urinary TFF3 significantly increases in patients with chronic kidney disease and that urinary TFF3 level decreases in rats with acute kidney injury. However, it is unclear whether serum or urinary TFF3 is associated with human renal tissue injury. The aim of this study is to elucidate the relationship between serum and urinary TFF3 levels and the degree of renal tubulointerstitial injury.

Methods: The total study population included 52 patients (tubulointerstitial nephritis: 31, minor glomerular abnormalities and thin basement membrane disease as controls; 21) who underwent renal biopsy. The serum and urinary TFF3 concentrations were determined by a specific ELISA. The degrees of tubulointerstitial cell infiltration and fibrosis were semiquantitatively graded in biopsy specimens and defined by the inflammation score and the fibrosis score, respectively. An immunohistochemical analysis was performed to reveal the localization of the TFF3 protein.

Results: The median serum and urinary TFF3 levels of the disease group were significantly higher than those of the controls (p<0.002 and p<0.008, respectively). A statistically significant positive correlation was observed between the urinary TFF3 levels and the fibrosis score in the disease group. However, there was no correlation between the serum or urinary TFF3 level and the renal inflammation score in disease group. TFF3-positive cells were observed in the renal tubular epithelium.

Conclusions: The data indicate that serum and urinary TFF3 levels are significantly increased and, in particular, that urinary TFF3 could reflect renal tissue fibrosis in patients with tubulointerstitial nephritis. Further studies are required to elucidate the precise distribution of renal TFF3 protein and mRNA, and the mechanism underlying the contribution of TFF3 to renal fibrosis.

Induction of Epithelial-to-Mesenchymal Transition and Fibrosis Signals via AKT and Peroxisome Proliporator-Activated Receptor Pathway in Renal Tubular Cells Induced by a Plasticizer Di(2-ethylhexyl) Phthalate

Shing-Hwa Liu,1 Li-Chen Huang,2 Bo-Lin Chen,1 Chih-Kang Chang.1 1Inst of Toxicology, College of Medicine, National Taiwan Univ, Taipei, Taiwan; 2DIDT, NTUH, Taipei, Taiwan.

Background: Di(2-ethylhexyl)phthalate (DEHP) is a plasticizer and a probable endocrine disruptor. More than two million tons of DEHP were used each year worldwide. Recent studies have suggested that DEHP has potential adverse effects on the liver, kidney, and reproductive system. It could also cause carcinogenicity and developmental toxicity. DEHP exposure might exacerbate kidney progression. Tubular epithelial-to-mesenchymal transition (EMT) is recognized to play pivotal role in the process of renal fibrosis. However, the mechanisms of nephrotoxicity induced by DEHP remain unclear. Here, we investigated whether DEHP could induce renal fibrosis via EMT process.

Methods: A rat renal proximal tubular cell model (NRK-52E cells) was used to evaluate EMT and fibrosis signaling. Cell morphology was observed by microscope. Cell viability evaluated by MTT assay. The molecular signals of EMT and fibrosis were analyzed by flow cytometry, confocal laser scanning microscopy, immunocytochemistry, and Western blotting. Treatment with DEHP (5-25 µM) for 72h caused the change in renal tubular cell morphology shifting to spindle-like shape. DEHP did not induce cell apoptosis, but significantly induced G2/M cell cycle arrest. Moreover, the expressions of vimentin, α-SMA, and CTGF, which are the markers of the mesenchymal phenotype, were significantly increased. The expressions of E-cadherin, a maker of epithelial cells, was significantly decreased by DEHP. DEHP could also inhibit the expression of peroxisome proliferator-activated receptor (PPARα) and α. The phosphorylation of Akt and Smad 2/3 was also significantly increased by DEHP. Notably, treatment with MK2206 (an Akt inhibitor) significantly inhibited DEHP-induced phosphorylation of Akt and EMT. Further investigation revealed that MK2206 suppressed the expression of Akt downstream proteins (NF-kB and GSK3).

Conclusions: These findings suggest that DEHP is capable of inducing the EMT process through AKT and PPAR signaling pathway, which may lead to renal fibrosis.

Funding: Government Support - Non-U.S.
Case Report: A 61-year-old man was admitted for orthostatic hypotension with syncopal episodes and proteinuria. He was well until six months prior to admission, when he began experiencing frequent unexplained dizziness. His past medical history included hypertension, hypercholesterolemia, and obesity. On initial evaluation, his blood pressure was 90/60 mmHg while lying supine and 70/40 mmHg when standing. Cardiac and neurological examinations were unremarkable.

Methods: This case report highlights the need for further research in the field of orthostatic hypotension and showcases the importance of early diagnosis and management.

Results: Our findings emphasize the importance of a multidisciplinary approach to the management of orthostatic hypotension, including the use of pharmacological and non-pharmacological interventions.

Discussion: The case presented here underscores the need for increased awareness and education among healthcare providers to improve patient outcomes.

Conclusion: Early recognition and appropriate treatment of orthostatic hypotension can significantly improve quality of life and prevent morbidity in affected individuals.
Discussion: The B Thalassemia is a hereditary disorder of hemoglobin synthesis in the B-globin gene that present clinically with microcytic hypochromic anemia, erythropoiesis ineffective, normal reticulocyte counts or slightly elevated and high levels of A2 hemoglobin. In the kidneys can cause tubular injury and GFR decline. Developing glomerulosclerosis and fibrosis. We can not rule out that CKD is secondary to B-thalassemia, a genetic study would be necessary. It is an uncommon diagnosis in Latin America, but should be considered in patients with CKD and microcytic hypochromic anemia refractory to convecional treatment.

PUB397

Introduction: Intestinal obstruction, even without perforation or ischemia, predisposes patients on peritoneal dialysis (PD) to peritonitis by gut commensals including fungi. Fungal peritonitis (FP), with (Secondary) or without (Primary) prior antibiotic use, is associated with increased mortality and technique failure. This raises the question of empirical antifungal use in PD patients with bowel obstruction. We present our experience with such a patient.

Case Description: A 74 year old male who had been on Continuous Cycling Peritoneal Dialysis for the past four years with his prescription being 5 exchanges of 2 liters of 1.5% and 2.5% dianeal with a last fill of 2 liters of icodextrin, presented with worsening abdominal pain. His dialysate was clear and had just 3 leucocytes. His CT abdomen showed small bowel obstruction (SBO) with conservative management pursued. Over the next few days, the SBO resolved and dialysate cell counts remained unremarkable. On day 5, he became hypotensive. Examination was notable for increased abdominal tenderness and a cloudy dialysate. Repeat dialysate studies were sent and intraperitoneal vancomycin and cefepime were started. Imaging suggested SBO. He responded appropriately to the antibiotics over the next three days with no growth on any cultures thus far. However, the dialysate grew yeast the next day. Fluconazole was started, later being switched to micafungin with the next three days with no growth on any cultures thus far. However, the dialysate grew Candida glabrata on day 1.2. His Tenckhoff catheter was removed and hemodialysis (HD) was initiated. He completed 4 weeks of micafungin and opted to continue on HD.

Discussion: Evidence on antifungal prophylaxis while treating PD related bacterial peritonitis has been mixed, with the decision being individualized on a per-center basis. Additionally, no clear role has been defined for prophylactic antimicrobials in PD patients with bowel obstruction. With a high risk for both primary and secondary FP, these patients may also develop IgA antibodies against specific HIV antigens. Renal lesions may result from HIV antigen-specific immune complexes that are derived from the circulation and from in-situ complex formation.

Case Description: We present a case of a patient with HIV/AIDS, on highly active antiretroviral therapy (HAART), who was evaluated for microscopic hematuria and worsening renal function. The patient’s only complaint was early morning peri-orbital edema. On examination, BP was 103/72 mm Hg with a BMI 23 kg/m². Labs showed normal electrolytes, serum creatinine 1.7 mg/dL (baseline 0.7 mg/dL), urine protein/creatinine ratio of 2.5 grams/dL. Other serologies were negative. HIV VL was undetectable, and CD4 count was 183. Renal US showed bilateral enlarged, echogenic kidneys. Renal biopsy revealed sclerosing glomerulopathy with IgA immune type deposits on immunofluorescence. The patient was initiated on an ACE inhibitor and a low salt and protein diet, with resolution of his proteinuria to 0.7 Grams/dl. His renal function stabilized, with a creatinine of 1.6 mg/dL.

Discussion: In conclusion, IgA glomerular disease arising in HIV positive patients has clinical and pathologic aspects similar to idiopathic IgA nephropathy. IgA nephropathy should be suspected in patients with HIV presenting with unexplained hematuria, and renal biopsy should be performed as soon as possible for early diagnosis and therapy. Current management recommendations are similar to those with idiopathic IgA, including ACE inhibitors orARB for control of proteinuria (>1 g / day) or hypertension.

PUB398

Introduction: Leukocytosis and peripheral blood eosinophilia were well described in acute rejection of transplanted livers and pancreas rejection This laboratory abnormality was not well evaluated in kidney allograft rejection. In this case report, we explore leukocytosis and peripheral blood eosinophilia as possible laboratory abnormalities preceding ACR.

Case Description: We are presenting a 65 years old woman with a history of ESRD due to ADPKD, who had a DDKT in 2012. Her medications included Prednisone, Tacrolimus, and Mycophenolate Mofetil. She maintained a stable allograft function, with a creatinine of 1.2. She was found to have leukocytosis and peripheral blood eosinophilia. Evaluation for infections and malignancy was negative. 6 weeks later she was noted to have AKI. She complained of mild lower extremities swelling. Physical examination was unremarkable. Labs evaluation revealed a creatinine of 2 mg/dL, WBCs count of 15.9 k/µL, and eosinophilia. Renal biopsy however, showed ACR (figure1). There were abundant infiltrates with neutrophils and eosinophils. She was treated for ACR with return of creatinine to baseline.

Discussion: Several reports have evaluated the predictive value of peripheral blood eosinophilia as a simple noninvasive diagnostic marker for ACR of transplanted livers and of acute pancreatic rejection. However, peripheral blood eosinophilia was not evaluated as a possible test predicting renal ACR. In a case report, Baradhin et al, described the etiology of AKI following treatment with armodafinil for narcolepsy. They indicated that both (AIN and ACR) has similar biopsy characteristics. However, our patient had no clinical features to suggest AIN, including no new medications. We conclude that leukocytosis and peripheral blood eosinophilia could represent signs of impending acute cellular rejection of transplanted kidneys.

PUB399

A Case of IgA Nephropathy in an HIV-Positive Patient Hermes Garcia-Sanchez, Vandana Niyyar, Thomas E. Rogers. Nephrology, Emory Univ, Atlanta, GA.

Introduction: IgA nephropathy has been described in patients infected with HIV. Though IgA levels are commonly elevated in HIV, these patients may also develop IgA antibodies against specific HIV antigens. Renal lesions may result from HIV antigen-specific immune complexes that are derived from the circulation and from in-situ complex formation.

Case Description: We present a case of a patient with HIV/AIDS, on highly active antiretroviral therapy (HAART), who was evaluated for microscopic hematuria and worsening renal function. The patient’s only complaint was early morning peri-orbital edema. On examination, BP was 103/72 mm Hg with a BMI 23 kg/m². Labs showed normal electrolytes, serum creatinine 1.7 mg/dL (baseline 0.7 mg/dL), urine protein/creatinine ratio of 2.5 grams/dL. Other serologies were negative. HIV VL was undetectable, and CD4 count was 183. Renal US showed bilateral enlarged, echogenic kidneys. Renal biopsy revealed sclerosing glomerulopathy with IgA immune type deposits on immunofluorescence. The patient was initiated on an ACE inhibitor and a low salt and protein diet, with resolution of his proteinuria to 0.7 Grams/dl. His renal function stabilized, with a creatinine of 1.6 mg/dL.

Discussion: In conclusion, IgA glomerular disease arising in HIV positive patients has clinical and pathologic aspects similar to idiopathic IgA nephropathy. IgA nephropathy should be suspected in patients with HIV presenting with unexplained hematuria, and renal biopsy should be performed as soon as possible for early diagnosis and therapy. Current management recommendations are similar to those with idiopathic IgA, including ACE inhibitors or ARB for control of proteinuria (>1 g / day) or hypertension.

PUB400

Introduction: Calcium channel blocker overdose is rare but carries a high mortality due to cardiovascular complications. Generally the management is supportive with use of vasopressors, IV fluids, cardiac pacing, and insulin therapy. There are reports of CVVHDF, hemodialysis or hemofiltration alone and charcoal hemoperfusion for the treatment of CCBB overdose. Effective management strategies are needed to improve outcomes.

Case Description: Here we describe a patient who presented to the ER after a suicide attempt with ingestion of Norvasc. On arrival to the ER he was awake but later he was intubated. The patient developed acute kidney injury and became anuric. Patient was started on CVVHDF that lasted 48 hours. Unfortunately after two days the patient continued to decompensate and expired.

Discussion: Amlodipine is a CCB of the dihydropyridine group acting primarily on vessel walls whereas the non-dihydropyridines act more on cardiac muscle and pacer cells. In our case it was clear Norvasc selectively took its effect on the vasculature with profound hypotension with preserved systolic function and no arrhythmia. The case was complicated with ARDS related to diffuse pulmonary edema, a well known complication with CCB overdose. In our case renal failure was likely related to severe hypoperfusion leading to ischemia. There was development combined respiratory and metabolic acidosis. The metabolic acidosis was attributed to renal failure but it is possible that CCB induced inhibition of insulin secretion leading to ketoacidosis may also have contributed. In terms of management of CCB overdose, if recent ingestion then GI decontamination is reasonable with activated charcoal or whole bowel irrigation. The use of high dose insulin therapy has been tried and its role may include increasing ionized calcium levels, improvement of hyperglycemic acidosis, and improved myocardial function. Most case reports, though
few, have shown little benefit from hemofiltration or hemodialysis therapy due to high protein catabolism, increases in protein catabolism and rapid metabolism of the drug. One case report did show some promise when multiple therapies were used including IV lipid emulsion, CVVHDF and charcoal hemoperfusion.

Introduction: Heavy chain disease (HCCD) is rare, especially without light chain deposition and when causing non-amyloid tissue deposits.

Case Description: A 75-year-old male with chronic kidney disease (CKD) stage 3 (baseline creatinine 2.3mg/dL) and right single lung transplant for idiopathic pulmonary fibrosis. In 2008 presented with extremity edema and decreased urine output. He has no history of diabetes or uncontrolled hypertension. Admission labs showed BUN 77 mg/dL, creatinine 4.37 mg/dL, and subtherapeutic tacrolimus levels at 3.9 mg/mL. Urine protein/creatinine ratio was 6.6. A 24-hr urine protein collection revealed 5822 mg/24hr. Serum protein electrophoresis showed hyperalbuminemia, but no monoclonal proteins were identified. Urine protein electrophoresis was negative for Bence Jones proteins or monoclonal proteins. Urine protein concentration was 713 mg/dL, consisting of 57.8% albumin and 42.2% globulins. C3 and C4 complement levels were low at 46.5 mg/mL and 8.92 mg/mL respectively. Antinuclear antibodies (ANA), anti-streptolysin O (ASO), anti-neutrophil cytoplasmic antibodies (C-ANCA and P-ANCA), and cryoglobulins were negative. Renal ultrasound showed multiple renal cysts without hydropsynthesis. Renal biopsy revealed nodular sclerosing glomerulonephritis with crescents involving 10% of glomeruli and interstitial fibrosis and microscopic dysmorphic RBCs. Skin biopsy showed thrombotic vasculopathy with no plasma cell dyscrasia. To our knowledge, no cases have been described with no plasma cell dyscrasia. To our knowledge, no cases have been described with no plasma cell dyscrasia. To our knowledge, no cases have been described with no plasma cell dyscrasia.

Discussion: With more than 2 million Americans using cocaine, diagnoses of cocaine-induced vasculitis are being made with increasing frequency. A case report described in this study is crucial in providing insight into the clinical presentation and treatment of such a rare disease. It is estimated that about 70% of the cocaine used here in the US is contaminated with levamisole – a substance used as a biocide in animal feed and agriculture. This contamination can increase Levamisole exposure should be included in guidelines for treatment make HCDD challenging to treat. We describe a rare case of IgG1 HCDD with no plasma cell dyscrasia. To our knowledge, no cases have been described using oral prednisone and therapeutic plasmapheresis to treat HCCD renal dysfunction.

Introduction: An increasing number of cases of cocaine-induced vasculitis are being found among cocaine users in the United States which is due to the use of Levamisole laced cocaine. It is estimated that about 70% of the cocaine used here in the US is contaminated with Levamisole.

Case Description: We describe a 65 year old male, with a 20 year history of cocaine abuse, who presented with a 1 month history of a progressively worsening, non-healing and painful rash on his trunk and extremities. He denied fever, weight loss and myalgias but admitted to itchiness. Examination revealed multiple tender, erythematous and indurated plaques with central necrosis on the trunk and extremities. These plaques were found to be in different stages of healing with their size ranging from 1cm-7 cms. Lab investigations revealed an elevated creatinine of 2.9 mg/dL, an elevated ESR, an elevated WBC, neutrophilic granulocytosis, and a negative ANA. Renal ultrasound showed multiple renal cysts without hydropsynthesis. Renal biopsy revealed nodular sclerosing glomerulonephritis with crescents involving 10% of glomeruli and interstitial fibrosis and microscopic dysmorphic RBCs. Skin biopsy showed thrombotic vasculopathy with no plasma cell dyscrasia. To our knowledge, no cases have been described using oral prednisone and therapeutic plasmapheresis to treat HCCD renal dysfunction.

Discussion: The Emergency room visits and hospital admissions are more in emergent dialysis patients with the complication of uremic ascites. The serum albumin, a marker for volume status especially in vascular-occlusive events and death is lower in these patients. We conclude that uremic ascites increase the morbidity and mortality in emergent dialysis population with ESRD. The modalities such as Continuous ambulatory peritoneal dialysis, scheduled outpatient dialysis and kidney transplant may prove beneficial.

Case Description: A 12-year-old boy was referred to our hospital for treatment of nephritic syndrome with massive proteinuria and generalized edema. He was treated with the standard corticosteroid regimen stipulated by the International Study of Kidney Disease in Children (ISKDC). Although he achieved complete remission, he suffered two relapses of nephrotic syndrome during administration of prednisolone in alternative days. In the second relapse, the disease became resistant to the steroid therapy, and therefore he received two courses of steroid pulse therapy followed by steroid tapering concomitant with cyclosporine administration. Two months after the diagnosis of steroid-resistant nephrotic syndrome, the patient underwent renal biopsy. Magnetic resonance imaging demonstrated compression fractures from the sixth thoracic vertebra to the first lumbar vertebra. Therefore, the steroid dosage was rapidly reduced and then withdrawn because he was able to maintain remission under cyclosporine therapy.

Discussion: It is necessary to evaluate the state of bone particularly the bone mineral density of the lumbar spine, at an early stage of treatment for nephrotic syndrome in children, even though the incidence of glucocorticoid-related vertebral fracture is low in this patient population.

Introduction: Dialysis related amyloidosis (DRA) is a debilitating complication of long-term hemodialysis characterized by excess accumulation of Beta 2-microglobulin, which deposits as amyloid fibrils in the bones, joints, and organs of affected patients. The Lixelle Beta 2-microglobulin apheresis column (Lixelle Column) in the United States Vesh Srivastava1, Anjali Masand, Jeffrey I. Silberzweig. 2Dept of Nephrology and Hypertension, NYP. Weill Cornell Medical Center, New York, NY; 2Dept of Nephrology, The Rogosin Inst, New York, NY.

Introduction: Lixelle Beta 2-Microglobulin Apheresis Column (Lixelle Column) for Dialysis Related Amyloidosis in the United States

Discussion: The patient is a 65 year-old man diagnosed with end-stage renal disease of unknown etiology in 1968. A deceased donor renal transplant in 1969 failed within 6 months, and a second transplant in 1970 functioned for 3 years. He has been diagnosed after excluding liver, cardiac, infectious and malignant causes. The incidence of uremic ascites in standard dialysis population was described as 0.7-20%. We believe that emergent dialysis patients with uremic ascites have higher morbidity and mortality.

Case Description: Total of 463 emergent dialysis patients, who were initiated on dialysis between July 2010 and April 2015 were analyzed. Among 36 patients with Ascites or of any cause, 12 patients were included in the study group of uremic ascites. A cohort of 36 patients without ascites was randomly selected for comparison. Two groups were compared based on demographics and morbidity indicators.

The mean age was 50 years with predominance of Hispanic male in both groups. The serum albumin in the uremic ascites group and the cohort group was 2.6±0.4 and 3.29±0.2 respectively. Volume overload and abdomen pain were the major reasons for admissions in the study group. They underwent paracentesis and frequent dialysis during the hospital course.

Introduction: Light chain deposition disease (HCDD) is rare, especially without light chain deposition and when causing non-amyloid tissue deposits. To our knowledge, no cases have been described using oral prednisone and therapeutic plasmapheresis to treat HCCD renal dysfunction.

Introduction: Glucocorticoid therapy has a number of adverse effects, among which osteoporosis and bone fracture are major complications. However, there are few reports of this condition in pediatric patients. Here we describe a pediatric case of multiple vertebral compression fractures due to glucocorticoid-induced osteoporosis in a Pediatric Patient with Nephrotic Syndrome Akihiko Shirasu,1 Akira Ashida,2 Yuko Fuji,3 Hideki Matsumura,4 Hiroyo Nakamura,5 Motoshi Hattori,2 Hiroshi Tamai,1,2 Dept of Pediatrics, Osaka Medical College, Takatsuki, Osaka, Japan; 1Dept of Pediatric Nephrology, Tokyo Women's Medical Univ, Tokyo, Japan.

Introduction: Glucocorticoid-induced osteoporosis (GIO) is one of the adverse effects of glucocorticoid therapy, especially in children and young adults. GIO is diagnosed after excluding liver, cardiac, infectious and malignant causes. The incidence of uremic ascites in standard dialysis population was described as 0.7-20%. We believe that emergent dialysis patients with uremic ascites have higher morbidity and mortality.

Case Description: Total of 463 emergent dialysis patients, who were initiated on dialysis between July 2010 and April 2015 were analyzed. Among 36 patients with Ascites or of any cause, 12 patients were included in the study group of uremic ascites. A cohort of 36 patients without ascites was randomly selected for comparison. Two groups were compared based on demographics and morbidity indicators.

The mean age was 50 years with predominance of Hispanic male in both groups. The serum albumin in the uremic ascites group and the cohort group was 2.6±0.4 and 3.29±0.2 respectively. Volume overload and abdomen pain were the major reasons for admissions in the study group. They underwent paracentesis and frequent dialysis during the hospital course.
An Unusual Case of Anticoagulant-Like Nephropathy in a Non-Anticoagulated Patient

Elvah Safar, Apurv Khanna.

**Introduction:** Anticoagulant-related nephropathy is a well-known cause for Acute Kidney Injury (AKI), which was first described in Coumadin anti-coagulated patients, usually with excessive anticoagulation (INR >4). It was also reported to be associated with other Anticoagulants such as direct thrombin inhibitor Dabigatran. We report a case of Anticoagulant-related Like Nephropathy in a Non-anticoagulated patient.

**Case Description:** A 71-year-old male was admitted to the VA medical center for shortness of breath and hemoptysis. Past medical history was significant for Non Small cell Lung Cancer, Cryptogenic Liver cirrhosis and COPD. CT chest, showed no pulmonary emboli. He was treated with Vancomycin and Zosyn for Pneumonia. The patient reported gross hematuria initially, which resolved spontaneously. His admission creatinine was 1.1 mg/dl, (baseline 0.6 mg/dl), and went up to 2.4 mg/dl. The patient had another episode of gross hematuria and his creatinine went up to 3.5 mg/dl. The patient remained non-oliguric throughout the course of his AKI. Kidney biopsy showed Tubular epithelial cells injury with red cell casts, but no inflammatory changes and no Immune complexes by Immunofluorescence. The histopathologic pattern shown by the kidney biopsy was consistent with Anticoagulant-related nephropathy. However, the patient was not anticoagulated with Coumadin, Heparin, or any other anticoagulants. His Prothrombin time (PT) was 13.1 seconds (normal 9-12 seconds) and INR 1.2. His PTT was 20.1 seconds (normal 25-34 seconds). He had a low platelets count between 55-100K/mm3, due to liver cirrhosis.

The findings in this case, suggest a role for Thrombocytopenia in liver cirrhosis, in causing anticoagulant like intra-glomerular hemorrhage, which may result in an AKI.

**Discussion:** Thrombocytopenia and likely Platelets dysfunction in Liver cirrhosis can cause intra-glomerular Hemorrhage and results in Anticoagulant-like Nephropathy, even in the absence of excessive coagulopathy as evidenced by a normal PTT & near normal INR. To our knowledge, there has not been a reported case of Anticoagulant-like Nephropathy in Non-Anticoagulated patients.

**Smoking Related Idiopathic Nodular Glomerulosclerosis with Crescents**

Tahir Zaman,1 Frederic Clayton,2 Josephine Abraham.1 1 Nephrology, Univ of Utah, Salt Lake City, UT; 2 Pathology, Univ of Utah, Salt Lake City, UT.

**Introduction:** Idiopathic nodular glomerulosclerosis (ING) is a rare but important cause of nephrotic syndrome. There have been case series reported in the literature regarding the association of ING and smoking.

**Case Description:** A 37-year-old female with a history of rheumatoid arthritis (RA) presented to the hospital with cough and hemoptysis. Her RA treatment consisted of leflunomide, prednisone and folic acid. Her social history is pertinent for a history of smoking (20 pack-years). Urine analysis was with dysmorphic hematuria and proteinuria associated with ING.

**Discussion:** Smoking cessation was encouraged. Over time, it has progressed to involve his shoulders bilaterally, his hips, knees, wrists and most recently his colon. He has undergone bilateral total hip replacements and carpal tunnel release procedures. Given his extensive disease burden as a result of DRA despite adequate dialysis, we intend to enroll him in a post-approval study using the Lixelle column. Measures of disease burden will include pre- and post-treatment Beta 2-microglobulin levels, presence of bone cysts, and quality of life (QOL) scores.

**Discussion:** The Lixelle Beta 2-microglobulin apheresis column appears to increase the Beta 2-microglobulin reduction rate in a single dialysis session, and therefore may be an effective treatment option to improve symptoms and quality of life for patients with dialysis related amyloidosis.

Thrombotic Microangiopathy Secondary to Hepatocellular Carcinoma

Tahir Zaman,1 Frederic Clayton,2 Josephine Abraham.1 1 Nephrology, Univ of Utah, Salt Lake City, UT; 2 Pathology, Univ of Utah, Salt Lake City, UT.

**Introduction:** Thrombotic microangiopathy (TMA) is a microvascular occlusive disorder characterized by microangiopathic hemolytic anemia, thrombocytopenia and end organ damage. We report a case of malignancy associated TMA.

**Case Description:** 65-year-old female presented with diarrhea and was noted to be in acute renal failure with microangiopathic hemolytic anemia and thrombocytopenia. Therapeutic plasma exchange was discontinued after ADAMST 13 activity was normal. Patient underwent colonoscopy and EGD with evidence of microthrombi in bowel wall concerning for TMA.

**Discussion:** TMA occurring in older patients who fail to respond to TPE should increase suspicion of malignancy-associated TMA. 1 HCC is a rare but known cause of malignancy-associated TMA as noted in the literature. RCC-associated TMA is quite severe leading to rapid progression to a fatal outcome. 2 1. George, J. N. Systemic malignancies as a cause of unexpected microangiopathic hemolytic anemia and thrombocytopenia. Oncology 25, 908–14 (2011). 2. Seo, D. W. et al. Charcot Foot Syndrome in a Nondiabetic Hemodialysis Patient

Werner Kiezophas,1 2 Sebahat Sat,1 Barbara Klein,1 Andreas Westhoff,1 2 Frank Dellanna,1 2 Gerard Hetzel.1 2 1 Kitz-Devita Karlstrasse, Düsseldorf, Germany; 2 Heinrich-Heine Univ, Düsseldorf, Germany.

**Introduction:** The prognosis is very poor for diabetic hemodialysis (HD) patients with foot lesions. Foot lesions are associated with risk of systemic inflammation and cardiovascular (CV) morbidity. Severe cases of diabetic foot with neuropathic arthropathy, microvascular changes from medialclerosis, and alteration of foot architecture are known as Charcot Foot Syndrome (CFS). Since diabetic and nondiabetic HD patients may experience changes in calcium and phosphate metabolism and secondary hyperparathyroidism, the question arises whether CFS can occur in HD patients in the absence of diabetes.

**Case Description:** Presented is a decade-long case study of a male HD patient (DOB 1961) who was treated since Dec 1999 for biopsy-proven nephrotic syndrome due to glomerulosclerosis. The patient began thrice weekly HD in Sept 2005 without prior treatment for diabetes mellitus (A1C 4.9%). In Apr 2012 he presented with a painless inflammatory acute foot syndrome, then presented in Apr 2013 with a planar ulceration. After conservative wound management, prophylactic shoes were prescribed. In clinical examination he showed signs of chronic CFS and arthropathic changes in osa metatarsals 2 and 3 with ostolysis and luxation of tarsometatarsal joints. Lab results indicate secondary hyperparathyroidism: parathyroid hormone 465 pg/mL, phosphate 6 mg/dL, and calcium 2.2 mg/dL.

**Discussion:** ING with crescents has not been described in the literature. In a case series reported by Markowitz et al, patients with ING had renal failure with a mean sCr of 2.4 mg/dl and proteinuria. The main clinical predictors of progression included lack of angiotensin II blockade and continued smoking. 1 In retrospect, it is likely the severity of her intra-glomerular pressures which lead to proteinuria was exacerbated with steroid treatment and resolved with discontinuation.

Charcot Foot Syndrome in a Nondiabetic Hemodialysis Patient

**PUB409**

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

982A
Discussion: We believe this is the first description of chronic CFS in a non-diabetic HD patient. Acute CFS diagnosis is important because its symptoms (red warm skin, foot edema) are similar to those of phlegmon and osteomyelitis, and thus may be considered a differential diagnosis. Further investigations are necessary to determine whether this is an authentic entity of a foot syndrome, and if it’s associated with CV morbidity.

PUB410

Introduction: Crescentic GN is usually manifested by features of active glomerular disease in the urine and by progressive rapid loss of significant renal function. SLE can present as predominantly crescentic GN often as Class III or IV lupus nephritis (LN) usually resulting in rapid deterioration of renal function requiring RRT.

Case: 18 y/o female recently diagnosed with SLE, on SLA, Plaquenil presented to ER with nausea, vomiting and epigastric pain after consuming “tiny tea” and was found to have serum creatinine (SCr) 4.5 mg/dL, which further increased to 4.74 with 3+ protein (2.5g/day), 3+ blood and RBC casts on urinalysis. Other relevant lab data: ANA 1:600, negative dsDNA, positive RNP, anti-SM Ab and normal complements. She was initiated on IV fluids and SCr normalized within 2 days. Renal biopsy showed Pauci immune Crescentic GN, class IV-S (A/C) with minimal IF staining. The clinical course was complicated by seizures; the diagnostic considerations included lupus cerebritis vs. PRESS. She was put on valproate to be started on immunosuppression as outpatient. She was admitted a week later with acute liver failure due to valproate and Tyleenol at which time she was pulsed with IV Solu-Medrol and discharged on oral steroids with a plan to start MMF after normalization of LFTs.

Discussion: Crescentic and focally necrotizing GN can be infrequently present in the spectrum of diffuse proliferative LN. Such cases are generally ANCA negative. Normalization of SCr after hydration in this case suggest pre renal as the likely etiology which poses a treatment dilemma for biopsy proven crescentic GN. While there is not much literature available regarding the treatment of lupus with crescentic GN and normal SCr, a retrospective case series reported that even <50% crescents portend a significant renal risk despite clinically evident preserved renal function. We believe that intense immunosuppression should be used in patients with crescentic GN and preserved renal function, despite the absence of any controlled studies. Our patient was started on MMF and prednisone with improvement in proteinuria from 2.6 gm to 150 mg with normal SCr.

PUB411

Anti-Thymocyte Globulin Induced Non Cardiogenic Pulmonary Edema Jaya Kaia, Amit Lahoti. Nephrology, Univ of Texas MD Anderson Cancer Center, Houston, TX.

Introduction: Anti-Thymocyte globulin (ATG) is used in treatment of hematologic malignancies and solid organ transplantation. Immediate local and systemic reactions are known. There has been only one reported case of non cardiogenic pulmonary edema (NCPE) caused by ATG.

Case Description: Our patient was a 59-year-old man with Marginal Zone Lymphoma which had progressed to diffuse large B cell lymphoma. Despite Hyper CVAD and Rituximab his disease continued to progress. He received Matched Unrelated Bone marrow transplantation after conditioning with ATG and rituximab. The next day he was admitted to the ICU with respiratory distress and bilateral lung infiltrates initially thought to be pulmonary edema. He was started on Lasix drip but did not improve. His CVP was 5, and his echocardio gram showed normal ejection fraction. Based on these findings he was diagnosed to have NCPE. Bronchoscopy revealed pulmonary hemorrhage. His condition worsened and he was intubated and started on Continuous Renal replacement therapy. He was given additional doses of steroids but without improvement. His died due to respiratory failure after two days of ICU stay.

Discussion: Non cardiogenic pulmonary edema is a clinical syndrome characterized by presence of severe hypoxemia, bilateral alveolar infiltrates on chest radiograph without evidence of left atrial hypertension, fluid overload or congestive heart failure. Drug related NCPE is usually diagnosed after other causes of pulmonary infiltrates such as gastric aspiration, sepsis and pneumonia are excluded. The presence of normal echocardiogram and pulmonary hemorrhage within a day of administration of ATG, pulmonary infiltrates which did not resolve after intense attempts of volume removal indicated that the patient had NCPE. ATG is known to cause acute respiratory distress syndrome, alveolar hemorrhage and rapidly progressive interstitial fibrosis likely secondary to Cytokine release syndrome. Providers need to be aware of such complications as even though rare these cause increased morbidity and mortality. It is beneficial to give ATG infusions slowly and accompanied by high dose systemic steroids.

PUB412

Hypomagnesemia After Treatment with Pertuzumab Lilian Saro-Nunez,1 Tiffany A. Traina,2 Karen A. Cadoo,3 Teresa Gilewski,1 Ilya Gleizerman.4 1Nephrology, NYP-Well Cornell Medical Center, New York, NY; 2Breast Medicine Service, Memorial Sloan Kettering Cancer Center, New York, NY; 3Gynecologic Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY; 4Renal Service, Memorial Sloan Kettering Cancer Center, New York, NY.

Introduction: Hypomagnesemia is a known side effect of epidermal growth factor receptor (EGFR) inhibitors such as cetuximab and panitumumab. Pertuzumab blocks HER (human epidermal growth factor receptor) 2 dimerization with HER3 and EGFR, and is used in HER2+ breast cancer. We present two cases of hypomagnesemia with pertuzumab use.

Case Description: Case 1 58 year-old woman with history of breast cancer treated with trastuzumab (T), docetaxel, pertuzumab (two doses of 840mg and one dose of 420mg) and carboplatin (AUC6). Patient developed hypomagnesemia with serum magnesium (Mg²⁺) 0.7 (1.7-2.6)mg/dl and symptomatic hypomagnesemia of 5.9 (8.5-10.5)mg/dl. Since initiation of chemotherapy she experienced diarrhea controlled with loperamide. Fractional excretion of magnesium (FeMg) was 2%. Parathyroid hormone (PTH) was 309.2 (12-88)pg/ml. Pertuzumab and carboplatin were stopped. Mild hypomagnesemia persisted 6 months later.

Case 2 56 year-old woman with history of breast cancer on treatment with T, paclitaxel and pertuzumab (one dose of 840mg and 2 doses of 420mg) was admitted with Mg²⁺ of 0.3 (1.4-2.2) mEq/L and corrected calcium of 6.1mg/dl. She complained of chronic diarrhea which improved with loperamide and was receiving proton pump inhibitor (PPI). FeMg was 3%, PTH was 161 (12-88)pg/ml. PPI was stopped but patient received another dose of pertuzumab (840mg). She remained hypomagnesemic and required IV supplementation until her death from progression of disease 22 months later.

Discussion: Although there were other confounding factors that could have caused hypomagnesemia including diarrhea, PPI and carboplatin, hypocalcemia (a manifestation of hypomagnesemia) did not develop until patients were started on pertuzumab. Carboplatin has been associated with hypomagnesemia but not with the degree of hypomagnesemia seen in these two patients. We postulate that pertuzumab may interfere with reabsorption of Mg²⁺ similar to EGFR inhibitors.

PUB413

Acute Renal Infarction: Case Series Yelda Deligoz bildaci1, Rumeyza Kazancioglu.2 1Nephrology, Bezismalek Vakif Univ, Istanbul, Turkey; 2Nephrology, Bezismalek Vakif Univ, Istanbul, Turkey.

Introduction: Acute renal infarction (ARI) occurs from interruption of kidney’s blood supply either partially or totally. Causes of renal infarction include: thromboembolism (usually from injured or replaced heart valves, congenital heart defects etc.) vasculitic disorders, trauma to the kidneys or hypercoagulable state. We present five cases of ARI with different etiologies.

Case Description: Description of Cases: Two female, three male, mean age 52 (range 26-72) patients presented to the emergency department between 2013 and 2015 in a university based hospital setting. Presenting complaint was severe flank pain lasting between 2 to 5 days for all of them. At initial examination all patients had costo-vertebral angle tenderness at the affected side. Contrast enhanced abdominal tomography was useful for showing renal artery occlusion and also renal infarction. Trans thoracic echocardiography were all normal and were not adequate in identifying patients having had heart defects, trans esophageal echocardiography was obviously superior in finding cases with possible paradoxical embolism. All patients were treated with enoxaparin therapy. During follow-up there was neither further complication nor kidney damage.

Discussion: ARI usually is a hidden disease, which can easily be missed without any specific suspicion for patients presenting with flank pain. It should be kept in mind that there is no specific biochemical test for ARI and diagnosis process must involve evaluation of cardiac pathologies preferably with trans esophageal echocardiography.

PUB414

Disseminated Cryptococcal Infection in a 24-Year-Old Man with Primary Focal Segmental Glomerulosclerosis

Introduction: Focal segmental glomerulosclerosis (FSGS) is commonly treated with high doses of corticosteroids and calcineurin inhibitors to induce remission of proteinuria, however immunosuppression carries with it the risk of infection. We present here the case of a 24-year-old African American man following seven months of intermittent treatment for biopsy-proven FSGS with high-dose prednisone and cyclosporine.

Case Description: Our patient initially responded to prednisone 80 mg daily with proteinuria reduced to 37 mg/g from 3.5 g/g, but then suffered frequent hospitalizations for infection necessitating interruption of immunosuppression, now with decreased responsiveness to prednisone. Cyclosporine was added but interrupted after he developed skin findings concerning for necrotizing fasciitis. A surgical wound became infected, and he developed Clostridium difficile diarrhea. He was placed on ethacrynic acid and stavudine because of a sulfa allergy. His albumin remained < 1.5 mg/dL. Renal function worsened, now with ascites requiring paracentesis and subsequently developed E coli peritonitis. He was admitted to our medical ICU with hypoxia seven months after initial presentation. Chest xray at this time demonstrated pulmonary edema versus multilobar pneumonia. White blood cell count was 18.5, and increased to 30.0 after beginning prednisone taper. Broad-spectrum antibiotics and hemodialysis were initiated with no improvement. Head CT after seizure demonstrated diffuse hemorrhaging. Fungal cultures were sent, and patient was started on empiric voriconazole. Cultures returned after he expired positive for Cryptococcus. Autopsy showed disseminated Cryptococcus with cause of death attributed to cryptococcal pneumonia.

Discussion: This case demonstrates the infectious risk of high dose immunosuppression in treating resistant focal segmental glomerulosclerosis and the need to balance efficacy of treatment against these risks.

PUB415

A Rare Case of Kidney Amyloidosis Caused by Heroin Abuse

Introduction: Secondary(AA)Amyloidosis nephropathy is a rare manifestation of IVDA, as a condition characterized by deposition of insoluble fibrils in various organs; most commonly the liver and kidneys. Occurs as a result of chronic inflammatory states such as RA, IBD, chronic osteomyelitis, or familial Mediterranean fever. Kidney involvement in amyloidosis is a significant source of morbidity as it can progress to CKD.

Case Description: A 40 y/o AA man with no past medical history just 20 years of IV heroin abuse presented to the ED with the CC: Worsening lower extremity edema and a weight gain of 20 lbs. in the past few months. Patient denied any other medical problems or complaints. On PE, afebrile, normotensive, with clear lungs, normal heart at auscultation and benign abdominal findings, but with 3+ lower extremity edema. Multiple skin popping in upper and lower extremities with aching, and no evidence of active inflammation. Creatinine 0.8 mg/dL on arrival. The UA showed >600mg/dL of protein and no hematuria. A 24 hour urine collection showed 55 gm of proteinuria and serum albumin 2.1 g/dL. Cholesterol 232mg/dL, LDL 192 mg/dL, and Trig 189mg/dL. JPT’s were normal and the rest of serologic workup including HIV, Hep B and C were negative. A biopsy showed a nodular increase in mesangial matrix material that was congophilic and stained positive with both amyloid A and P, consistent with AA amyloidosis. The EM showed the presence of nonbranching fibrils that measure 7 and 12 nm in size. The mainstay treatment for secondary renal amyloidosis consists of targeting the underlying cause. In this case of heroin induced amyloidosis, the patient was counseled extensively about heroin cessation. Per the literature, not many other treatment options exist. We started him on colchicine as there are studies indicating its efficacy on disrupting the amyloid fibrils and decreasing progression of disease. He was also started on anti-coagulants and diuretics, but we were unable to start him on ACEI’s/ARB’s due to low blood pressure.

Discussion: AA kidney amyloidosis is a rare manifestation of IVDA, especially after a prolonged exposure. We should always consider this diagnosis in chronic heroin users presenting with proteinuria.

PUB416

Addressing Fertility and Management of a Patient with PCOS and C1q Nephropathy

Introduction: C1q nephropathy is a rare disease that can present in a variety of ways. We present the case of a 26 year-old female with PCOS and borderline diabetes who developed non-nephrotic-range proteinuria with preserved renal function who wished to become pregnant.

Case Description: Her serologic workup was unrevealing. She did not have any classical symptoms of SLE and her ANA was only mildly positive at 1:40. Biopsy of the kidney revealed predominant immunofluorescent staining for IgG and C1q with mesangial deposits of IgG. There was no clear evidence of focal segmental glomerulosclerosis to portend a worse prognosis. Her decision to pursue pregnancy prompted further inquiry into the effects of pregnancy on her renal disease.

Review of existing literature, limited as it may be, suggested that C1q autoimmunogenicity may be associated with normal placental growth and development in the context of hormonal changes.

Discussion: Therefore, interpretation of typical parameters, including urinary protein excretion alone, may not be sufficient in determining disease status. This case demonstrates the importance of renal biopsy in defining the underlying pathology in young women with evidence of glomerular disease who wish to become pregnant as it can help guide prognosis.

Outcomes of Calcific Uremic Arteriolopathy (CUA) Management: An Inner City Tertiary Center Experience

Introduction: CUA is a rare, necrotizing skin condition caused by medial calcification of subcutaneous arteries leading to tissue ischemia and eventual necrosis. It predominantly occurs in patients with chronic kidney disease, associated with high morbidity, mortality and variable outcomes– posing a difficulty in management.

Case Description: We conducted a retrospective chart review from 2010-15. 17 patients were diagnosed and treated for CUA in a tertiary university center. Diagnostic methods and multi-disciplinary treatment included parathyroidectomy, medical management of bone mineral disease, standard wound care, and sodium thiosulfate. We classified outcomes as No Improvement, Stable, and Improvement of Lesions related to the mean Calcium-Phosphate product (CaXPhos). Table 1 shows patient characteristics.

A Case of Adult-Onset Segmental Membranous Glomerulonephritis
Mao Watanabe, Toshiyuki Iimasawa, Takahiko Kawaguchi, Takafumi Yanakawa, Maiko Nagata, Moritoshi Kadomura, Hiroshi Kitamura. Internal Medicine, National Hospital Organization Chiba East Hospital, Chiba, Japan.

Introduction: Generally, adult-onset membranous glomerulonephritis (MN) has diffuse and global glomerular changes. We experienced a rare case of segmental MN (SMN).

Case Description: A 66 years old Japanese male was firstly noted proteinuria in an annual health check-up. Serum creatinine was 0.76 mg/dl, urine protein excretion was 2.1 g/gCr, and 10-19 red blood cells/high-power field were observed in the urine sediment. A percutaneous renal biopsy revealed segmental spike formation on the glomerular basement membrane (GBM) and segmental subepithelial deposits in all glomeruli. Granular deposits of IgG, IgM, IgA, C3, C1q were segmentally positive with granular patterns at the same regions. In electron microscopy, electron dense deposits were also found segmentally. The glomerular tufts with deposits included inflammatory cells (mainly macrophages). Any autoimmune disease, malignancies, and infections were detected by further examinations. Because urine protein decreased less than 1 g/gCr during the hospitalization, only temocapril hydrochloride has been prescribed from 67 years old. He has never taken immunosuppressive drugs. In 68 years old, because urine protein increased to 3g/gCr, the second renal biopsy was performed. Similarly to the first biopsy, segmental spike formation on GBM and segmental staining of immunoglobulins and complements were observed. The percentage of glomeruli with subepithelial deposits decreased to 60% (6/10) compared with 100% (20/20) at the first biopsy.

Discussion: Adult-onset SMN was rarely reported in spite of 30% of MN cases in childhood. Here, we firstly reported the sequential pathological changes of adult-onset SMN without any immunosuppressive therapy. We will also discuss about the pathogenesis about SMN.

PUB419
Hyporeninemic Hypoaldosteronism with Hypokalemia: A Rare Association
Julia Brown, Shankho Shuvro Ganguli, David J. Leehey, Kavitha Vellanki. Dept of Nephrology, Loyola Univ Medical Center, Maywood, IL.

Introduction: Hyporeninemic hypoaldosteronism is characterized by diminished renin and aldosterone secretion, with hyperkalemia and mild hyperchloremic metabolic acidosis being the hallmark clinical manifestations. It is often seen in diabetic patients with mild to moderate renal insufficiency or in patients taking calcineurin inhibitors. Here, we describe a rare case of hyporeninemic hypoaldosteronism in the setting of severe hypokalemia.

Case Description: A 19 year old male with a liver transplant due to cryptogenic hepatic encephalopathy, bipolar disorder, and autism. He was admitted to our institute with nausea, emesis, and poor oral intake. He was started on fludrocortisone 0.1 mg daily, which was subsequently increased to 0.1 mg twice daily. His serum potassium levels improved and remained stable without potassium supplementation. The etiology of his hyporeninemic hypoaldosteronism was thought to be calcineurin inhibitor use, with hypokalemia caused by persistent nausea, emesis, and poor oral intake.

Discussion: In conclusion, hypokalemia should not exclude work up for hyporeninemic hypoaldosteronism in the appropriate clinical setting.

PUB420
A Case of Hydrenephrosis due to Bilateral Retroperitoneal Fibrosis
Zachary Freesong, Abram M. Shaaban, Josephine Abraham. Nephrology, Univ of Utah, Salt Lake City, UT.

Introduction: Retroperitoneal fibrosis is characterized by inflammatory and fibrous retroperitoneal tissue. It is believed to be due to an exaggerated inflammatory reaction to aortic atherosclerosis resulting from an immunologic trigger. Retroperitoneal fibrosis can be classified as primary or secondary. Secondary causes include medications, malignancy, infection, radiotherapy, and trauma. Patients diagnosed with retroperitoneal fibrosis should undergo thorough evaluation for infectious causes and malignancy.

Case Description: A 55 year old male presented to the clinic with a chief complaint of left side flank and groin pain. He had additional symptoms of night sweats, left leg edema, and weight loss. He was referred to our clinic after initially presenting to the emergency department and receiving a CT scan of the abdomen identifying left side hydrenephrosis and a retroperitoneal mass. His past medical history included melanoma 4 years prior and cutaneous follicular lymphoma of the right mandible one year prior. Repeat ultrasound prior to initiation of therapy showed new right sided hydrenephrosis. The patient was started on monotherapy with prednisone 1 mg/kg/day. Imaging after initiation of therapy showed improvement in fibrosis with resolution of ureteral obstruction. The patient’s serum creatinine improved from 1.93 to 1.2 after initiation of therapy. No secondary causes of retroperitoneal fibrosis was identified.

Discussion: Retroperitoneal fibrosis can present as obstruction of the ureters. It is often idiopathic, but secondary causes should be ruled out. Secondary causes include malignancy, infection, and medications. Recommended therapy includes decompression of obstruction if renal function is compromised. If the cause of the disease is idiopathic, then immunosuppressive therapy is recommended. If the disease is due to secondary causes, the underlying cause should be immediately addressed.

PUB421
BK Virus-Associated Uropathy: A Culprit Mimicking Mechanical Post-Renal Obstruction in Early Post-Kidney Transplantation
Ekamol Tantisattamo, Aneshia S. Shetty, Bing Ho, Mohammed Javeed Ansari. Nephrology and Hypertension, Northwestern Univ.

Introduction: BK virus has a predilection towards infecting the uroepithelial cells and is a known but rare cause of ureteral obstruction of kidney allografts.

Case Description: A 26-year-old woman with ESRD underwent renal transplantation. Maintenance immunosuppression included tacrolimus(FK) and mycophenolic acid(MPA). FK and MPA levels were 8-16ng/mL and 2-5mg/L, respectively. Three months posttransplant,
Acute interstitial nephritis associated with probiotic use

Introduction: Acute interstitial nephritis (AIN) is associated with a variety of etiologies, including infections, autoimmune conditions, and medications. Probiotics are frequently prescribed over-the-counter microorganisms used for their potential to influence gut flora and treat minor gastrointestinal conditions. However, data on the incidence and clinical outcomes of AIN associated with probiotic use are limited. Reports indicating probiotics may have immunostimulatory and immunomodulatory effects. We report the first potential case of AIN associated with the use of probiotics.

Case Description: A healthy 44-year-old man was found to have a stable baseline Cr of 1.0 mg/dL with a measured CsCr in the normal range. 42 d later, to treat infrequent loose bowel movements (2x/wk), he consumed a probiotic regimen of 10 billion cells of Lactobacillus GG bid for 14 d. There was no diarrhea, fever, rash, blood in the stool, or exposure to NSAIDs, antibiotics, herbs, or other medications. 11 d after probiotics use, during routine physical, he was found to have an increase in his Cr to 1.66 mg/dL (an increase of .5 mg/dL in 52 d). There was no proteinuria or hematuria, and an ANA was negative. A renal sonogram revealed echogenic, normal-sized kidneys. His Cr remained 1.4-1.6 mg/dL and did not return to baseline. 135 d after exposure to probiotics, a renal biopsy was performed. The biopsy revealed patchy tubular atrophy and interstitial fibrosis affecting 10% of the cortical area with a few mononuclear inflammatory cells and focal mild lymphocytic tubulitis, consistent with resolving AIN.

Discussion: In this case, the temporal association between the use of probiotics with kidney injury and the absence of other causes of AIN implicates the probiotic Lactobacillus GG as the etiologic agent. The mechanisms by which probiotics could potentially cause AIN include manipulation of intestinal microbial communities, immunomodulation, alteration of
responsiveness of intestinal epithelial and immune cells, and altering the immunogenicity of degraded enteric antigens. Given the frequent over-the-counter use of probiotics, multiple potential coexisting etiologies for AUIN, the often indolent nature of this disease, the rarity of this association, and the need for a renal biopsy to establish the diagnosis, the association between probiotics and AUIN may be under-recognized.

PUB426

Decision-Making for the Critically Ill Un-Befriended Patient

Aparajita Mattoo, Jennifer S. Scherer. Nephrology, NYU School of Medicine, New York, NY.

Introduction: The “un-befriended” patient is one that lacks decision-making capacity & a surrogate decision-maker (SDM). Nephrologists encounter un-befriended patients often, yet limited literature exists to guide decision-making for these vulnerable patients. This case describes an organized approach to caring for a critically ill un-befriended patient.

Case Description: Mr. S was a 74 year old wheelchair bound nursing home (NH) resident who underwent an urgent right hemicolectomy for a perforated colon. His post-operative course was complicated by septic shock & multi-organ failure including AKI due to ATN. During this time his serum Cr increased from 0.8 to 3.6 mg/dl, with a urine output of <50cc/day. Mr. S was obtunded & had diffuse anasarca. He lacked advance directives & any SDM. The primary service believed that dialysis (HD) should be withheld given his overall poor prognosis. The consulting renal service utilized the four-topic approach to ethical decision-making to guide their recommendations. An estranged sister was asked to partake in an inter-disciplinary team (IDT) family meeting with renal, palliative care, bioethics, & the primary service to explore Mr. S’s values. It was established that Mr. S cherished his life in the NH & would have appreciated time there even if on HD. Given this information, the IDT decided that a time limited trial of HD would be reasonable. Before HD was needed however, Mr. S decompensated due to fungemia. The IDT agreed that death was imminent, even with HD. Under provisions of the NY State Family Health Care Decisions Act (FHCDA), it was determined to be ethically appropriate to withhold HD & transition Mr. S to comfort care.

Discussion: Utilizing the four-topic approach to decision-making, established legal policies, & an IDT, nephrologists can manage un-befriended patients within an organized, legally sound, & ethically sensitive framework.

PUB427

Persistent Kidney and Alveolar Damage in Patients with Goodpasture’s Disease and Negative Anti-GBM Antibodies

Giovanna Y. Arteaga Muller,1 Lilia Maria Rizo Topete,1 Elisa Maria Guerrero Gonzalez,2 Concepción Sanchez Martinez,1 Jesus Valdez Cruz,1 Gabriela Alarcón-Galván,1 Nephrology, Univ Hospital José E. Cruz González UANL, Monterrey, Mexico; 2Anatomic Pathology, Univ Hospital José E. González UANL, Monterrey, Mexico.

Introduction: Goodpasture’s disease is characterized by the presence of basement membrane antibodies which act against type IV collagen in the glomerular basement membrane (GBM) and alveoli, it represents 20% of all crescentic glomerulonephritis. Despite prompt initiation of therapy with plasmapheresis, negative control anti-GBM antibodies renal involvement may occur alone or associated with pulmonary hemorrhage. Our patient despite having negative anti-GBM antibodies presented pulmonary hemorrhage. The literature recommends confirming the effective addition of a second potassium sparing agent such as amiloride in ameliorating hypocalciuria, and normotensive aldosteronism. The existence of 2 unique recessive alleles presents as chronic, sometimes severe and symptomatic hypokalemia, hypomagnesemia, hypocalciuria, and normotensive aldosteronism. The existence of 2 unique recessive alleles inherited by two siblings makes this case even more of a rarity. Our case also demonstrates the effective addition of a second potassium-sparing agent such as amiloride in ameliorating the need for more supplementation.

Discussion: Gitelman syndrome occurs in only ~1% of the Caucasian population which presents as chronic, sometimes severe and symptomatic hypokalemia, hypomagnesemia, hypocalciuria, and normotensive aldosteronism. The existence of 2 unique recessive alleles inherited by two siblings makes this case even more of a rarity. Our case also demonstrates the effective addition of a second potassium-sparing agent such as amiloride in ameliorating the need for more supplementation.

Cerebral Ethylene Glycol Toxicity Despite Prompt Renal Replacement Therapy

Maria Bernadette Yballe, Sandeep Aggarwal. Div of Nephrology, Drexel Univ, Philadelphia, PA.

Introduction: Acute cerebral edema is a rare consequence of ethylene glycol toxicity. Despite prompt initiation of therapy with fomepizole and renal replacement therapy, rare case reports of central hypodensities on CT imaging with neurologic abnormalities have been reported.

Case Description: We present a case of a 38 year-old female with PMH of HTN and anxiety who was brought in for agitation. One hour later, the patient became obtunded with significant respiratory distress requiring intubation. Home medications included hypropion. It was unclear if she ingested any toxins but the patient did have a history of marijuana use. On physical examination, the patient was hypertensive 210/114 mm Hg with reactive pupils. She was found to have high anion gap metabolic acidosis with a pH of 6.808, a serum bicarbonate of 4, an osmolal gap of 68, and a lactic acid of 5.6. Levels of ethanol, acetaminophen, phenobarbital, salicylate, and valproic acid levels were undetectable while urine drug screen was only positive for THC. Head CT did not reveal any acute Direct immunofluorescence technique (400X). Linear glomerular basement membrane staining for IgG.

Immunosuppressive therapy begins with methylprednisolone and CYCLOPS protocol. Later hemoptysis which improves with plasmapheresis, negative control anti-GBM antibodies. After presented sudden hypoxemia, bronchoscopy with abundant hemosiderin-laden macrophages, whereby plasmapheresis is performed again together with methylprednisolone, cyclophosphamide and rituximab. Currently the patient is in chronic hemodialysis, with negative anti-GBM antibodies.

Discussion: In patients with positive anti-GBM antibodies renal involvement may occur alone or associated with pulmonary hemorrhage, our patient despite having negative anti-GBM antibodies presented pulmonary hemorrhage. The literature recommends confirm the sustained absence of anti-GBM antibodies and signs of recurrence every 6 months.
Encapsulating Peritoneal Sclerosis – Case Reports

Introduction: Encapsulating Peritoneal Sclerosis (EPS) is a rare but serious and potentially lethal complication in peritoneal dialysis (PD), first described in 1980. Intestinal obstruction, serious malnutrition and sepsis are the causes of death. This uncommon condition is the result of chronic abdominal inflammation of multifactorial origin. High risk patients include PD for more than 8 years and with frequent peritonitis (two-hits theory). The exact incidence is unknown.

Case Description: We described outcomes of 6 cases followed in a referral service of PD between 2010 and 2015.

Case | Gender/ Age (years) | CKD related infection | Time on PD (years) | Prevalent Peritonitis (number) | Clinical Features | Radio- logical Find | Peritoneal biopsy | Outcome |

SAH: Sistemic Arterial Hypertension; SLE: Sistemic Lupus Eritematosus; TZDM: Type 2 Diabetes Mellitus; PIGN: Post Infectious Glomerulonephritis/CKD. Chronic Kidney Disease.

Discussion: EPS is a severe event related a long term on peritoneal dialysis or severe cases of peritonitis.

AM Tolvaptan to Avert Hypoancretic Seizures in a Patient with Primary Polydipsia and New Mildly Impaired Free Water Excretion

Introduction: A former pilot with a history of primary polydipsia PP (past urines >6 l/day) complained of confusion. Plasma (P₅₀) and urine sodium were 123 and 37 mEq/l, and plasma (P₅₀) and urine osmolalities, 251 and 207 mOsmol/kg H₂O. With cessation of Prozac and advised fluid restriction (FR) P₅₀ corrected. Plasma P₅₀ was 286 mOsmol/kg and urine SG 1.005. Following multiple surgeries (decompressive laparotomy, subtotal colectomy, ileostomy, feeding gastrostomy, for compartment syndrome/pancreatitis), he was found to have a first hyponatremic seizure (HS). No cause for impaired free water excretion (iFWE) was found. Her PP made FR difficult, as she was thirsty at P₅₀ <125 mEq/l, and caused repeat HSs.

Case Description: After her 4th seizure, we replaced FR and salt tablets with AM tolvaptan. This normalized P₅₀, abolished her recurrent HSs, and was tailored to her new dreadful PP-SIADH combination.

Indeed, since sepsis is constant in DI but only diurnal in PP, the AM tolvaptan-induced daytime DI allowed her to quench her thirst without fear of HSs, since if we were recurred by hs, when the drug effect were off, and her PP abided. She was reluctant giving up this diurnal/nocturnal PP/DESIADH, for fear of seizures.

Discussion: Given the high capacity for FWE, a syndrome of inappropriate antidiuresis (SIAD) or impaired diuresis-aquarexia (SIDA), due or not to ADH (SIAD/H or SIDA/H) must coexist in PP, for HS to occur; conversely some PP or other source of free H₂O must exist in the SIDA/H – SIDA/H spectrum of iFWE to cause HS, since FR alone increases the low P₅₀, and prevents HS during depot ADH in man, or chronic dAVP infusion in rats. This is the first report of successful compassionate off label use of AM tolvaptan, instead of FR, to prevent HS in a patient where PP is the culprit. However FR instead of vaptans is the first line treatment of low P₅₀ in SIAD/H, yet here ADH is the culprit. Thus in that PP and SIAD/H (or iFWE state) must coexist to cause HS, and that ADH, as assessed by sensitive assays is rarely totally suppressed, resolves this paradox.

Acute Kidney Injury Associated with Brucella Infection

Introduction: Ethylene glycol ingestion can cause multi-organ dysfunction including acute kidney injury (AKI) and death. The diagnosis can be made based on history, a high anion gap metabolic acidosis with an elevated osmolar gap, oxalate crystalluria and an elevated ethylene glycol level. The diagnosis may be challenging with the concurrent use of other substances such as cocaine as it causes vasomotor AKI or ANCA vasculitis. To elucidate the diagnosis, a renal biopsy may be required. Herein, we present a patient with biopsy proven calcium oxalate nephropathy who presented with unexplained AKI likely related to unintentional low dose regular ethylene glycol use. She did not have any symptoms or classic biochemical features of ethylene glycol intoxication.

Case Description: A 57-year-old homeless woman with a history of rheumatoid arthritis, COPD presented with a productive cough and dysgeusia and was found to have a Cr of 3.9 mg/dl, elevated from a recent baseline of 0.9 mg/dl. Her anion gap was 17, with no other electrolyte abnormalities. Toxicology was negative for ethanol or salicylates. Her BP was 157/77 mm Hg and physical exam was unremarkable. Her last use of cocaine was 3 days prior to admission. She was initially given normal saline and maintained an adequate urine output, but her Cr continued to rise to 13.0 mg/dl. Urine sediment showed a few isomorphic RBCs only. A renal ultrasound revealed normal sized kidneys. Serological tests for autoimmune, post-infectious and dysproteinemic causes of AKI were normal or negative. Renal biopsy revealed acute tubular injury with calcium oxalate deposition. An in depth history did not reveal a high oxalate diet nor a medical history predisposing her to hyperoxaluria, however she admitted to the regular ingestion of “juiced” street alcohol. She did not require dialysis. Her follow-up Cr was 1.8 mg/dl two months later.

Discussion: In conclusion, a thorough history is required when encountering unknown AKI in patients with a history of drug abuse or homelessness, while keeping a high index of suspicion for drug intoxications including ethylene glycol.

Thrombotic Microangiopathy (Hemolytic-Uremic Syndrome) Induced Acute Kidney Injury Associated with Brucella Infection

Introduction: Thrombotic microangiopathies (HUS, TTP and DIC) have been associated with a host of infectious agents. Its association with Brucellosis is uncommon. We present a case of a patient who developed TMA associated with a case of Brucellosis.

Case Description: A 52-year-old woman with minimal past medical history presented to the hospital with abdominal pain, fever/chills and general body aches. History was significant for intermittent bloody diarrhea approximately 2 weeks prior to ED presentation. Physical examination revealed epigastric and right upper quadrant tenderness to palpation and patient was started on broad-spectrum, empiric IV antibiotic therapy with
Vancomycin, Piperacillin-Tazobactam, and Ciprofloxacin. Shortly thereafter, her clinical status deteriorated resulting in acute respiratory failure requiring intubation and mechanical ventilation. CBC was notable for a white blood cell count of 27,000, hemoglobin of 7.3 g/dL and a platelet count 80,000. Other labs were notable for total bilirubin 2.3 mg/dL, LDH 509 U/L, lactate dehydrogenase less than 10, albumin 5.7 mmol/L and elevated transaminases. Peripheric Smear was notable to be positive for pensive schistocytes. Patient was anuria and Nephrology consulted to begin CRRT in setting of sepsis requiring three vaspessors. Patient had a rapid improvement in symptoms after initiation of sepsis protocol and was weaned off all vaspessors by 72 hours. Initial workup including abdominal imaging and blood cultures were negative for a source of infection. Patient had remarkable spontaneous clinical recovery and was later found to be positive for Brucellosis by immunoglobulin assay.

Discussion: Brucella infection has uncommonly been associated with the development of Hemolytic Uremic Syndrome. In addition, clinical course is widely variable, ranging from spontaneous recovery, as occurred with this patient, to disease requiring long-term renal replacement therapy.

**Case Description:**

**Case 1:** A 69 year-old male started chemotherapy including bevacizumab (monoclonal antibody of VEGF) with a diagnosis of advanced lung adenocarcinoma of left upper lobe. The completion of four-course chemotherapy resulted in reduction of tumor volume, and then converted to bevacizumab monotherapy. At one year after the start of therapy, proteinuria with renal insufficiency developed. He was referred to our service for further evaluation and management. Renal biopsy demonstrated microthrombi in the loop wall with duplication of GBM, which was consistent with thrombotic microangiopathy (TMA). Thereafter, with cessation of anti-VEGF agent, proteinuria was gradually ameliorated to less than 1.0 g/day and renal function returned to normal range. **Case 2:** A 56 year-old male with renal cell carcinoma, who had undergone nephrectomy and diabetes. After the introduction of therapy, he exhibited progression of kidney disease with nephrotic-range proteinuria in a short time. In addition to the cessation of sintunin, hemodialysis was initiated because of fluid overload. After several times of dialysis, urine output was gradually increased and renal function returned to the baseline level.

Discussion: The renal adverse effects of anti-VEGF agents are supposed to arise from inhibition of podocyte-endothelial VEGF signaling pathway. VEGF signaling pathway plays an essential part in glomerular development and endothelial maintenance. We need to pay attention to renal adverse effects with anti-VEGF therapy.

**Case Description:**

**Case 1**:

A 29-year-old previously healthy man initially presented with cough, fever and AKI and was diagnosed with rheumatologic disease presented with cough, fever and AKI and was diagnosed with acute post-infectious glomerulonephritis. Group A Complement C3: 19 Ch50: <10, C4:34 Antistreptolysin O:400 [<200 IU/ml]. Urine sediment revealed many WBCs with no casts and some non-dysmorphic RBCs. A decision was made to proceed with kidney biopsy to identify the cause of her renal disease since the sediment was not supportive of Scleroderma associated renal disease. Kidney pathology showed acute interstitial nephritis with mild chronic changes which, when combined with the serologic tests, was highly suggestive of Sjögrens syndrome-associated renal disease. She was commenced on corticosteroid therapy and two months post-initiation, her renal function has stabilized.

Discussion: This case demonstrated the importance of kidney biopsy in elucidating a diagnosis in a challenging case of overlap syndrome. The rapid diagnosis of interstitial nephritis was particularly important in this patient since most cases of renal associated Sjögrens’ go unrecognized until significant renal dysfunction has occurred. It has been proposed to consider kidney biopsy findings of tubulointerstitial disease as additional supportive criteria in the classification of Primary Sjögren’s syndrome, which is a sentiment we also support.

A Case of Hyponatremia from Adrenal Insufficiency Mimicking Siadh
Pradeep Reddy Thodina, Rasith Raja, Siddhesh R. Lotlikar, Imara Dissmasyake, Eric J. Bloom. Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA.

Introduction: A 40 yr old male with a diagnosis of nasopharyngeal carcinoma was admitted for dysphagia and decreased oral intake. He had severe hyponatremia with serum Na 126 meq/l and Uosm of 932 osm/l. He was deemed to have euvolemic hyponatremia from SIADH and started on fluid restriction. There was no improvement in hyponatremia and Una increased to 235 meq/l. He was diagnosed with adrenal insufficiency with a co-syntropin test. Imaging studies did not demonstrate pituitary invasion by nasopharyngeal carcinoma. He was started on high doses of hydrocortisone with rapid improvement of hyponatremia and Una dropped to 355 meq/l. Hyponatremia with Una (280 meq/l) recurred during diuresis taper. He required prolonged high doses of diuretics to maintain normal serum sodium level. Although there have been many case reports of hyponatremia with adrenal insufficiency, to the best of our knowledge there has been no reports of hyponatremia with very high Urine sodium (> 200 meq/l).

This case highlights that euvolemic hyponatremia can occur with adrenal insufficiency with clinical and biochemical manifestations mimicking SIADH. Adrenal insufficiency should be considered in all cases of hyponatremia especially with very high urine sodium.

Hemodialysis: An Atypical Presentation of ESRD-Related Sleep Disorders
Desiree Garcia Anton, Franco H. Cabeza Rivera, Alexandre Abreu, Marco A. Ladino/Avellaneda. Nephrology, Univ of Miami, Miami, FL.

Introduction: Sleep disorders including obstructive sleep apnea (OSA), restless leg syndrome (RLS) and insomnia are highly prevalent in ESRD patients undergoing dialysis, however, these remain stable or tend to improve after initiation of dialysis. There is scarce evidence of new-onset sleep complaints or disorders after initiation of dialysis.

Case Description: We present a case of a 64 year-old male with HTN, DM, ESRD and no previous sleep problems who developed insomnia, RLS, sleepwalking and other sleep disturbances within a month after initiation of continuous hemodialysis. He presented to the nephrology clinic with secondary complications from uncontrolled diabetes (neuropathy, retinopathy and nephropathy); he had been followed by the nephrology service for 4 years before requiring dialysis for uremia and volume overload. Intermittent HD was well tolerated during first month of treatment, achieving good metabolic clearance and volume control; his KTV was 1.16, phosphorus was controlled at 4.6 mg/dl and his anemia improved to a hemoglobin of 9.6 mg/dl; iron was 36 mcg/ml, ferritin 135 ng/ml and transferrin saturation 15%. Despite clinical and laboratory improvement, disabling sleep symptoms were reported and he was referred to the Sleep clinic for further evaluation. On his initial actigraphy, a bedtime or rise time pattern was unable to be determined as it showed continuous movements 24 hours per day for the 14 days monitored. Overnight Polysomnography (PSG) revealed severe OSA and periodic limb movements (PLM); there was also evidence of insomnia with severely reduced sleep efficiency.

Discussion: New-onset sleep problems after initiation of dialysis in patients who previously had no sleep complaints are an atypical presentation. The role of RRT on sleep disturbances in the ESRD population is unknown. We propose PSG pre and post dialysis initiation on advanced CKD patients to assess for differences and identify how RRT may be a cause of sleep disturbances.

Case Description: A 32-year-old man with a history of bipolar disorder came to the hospital with severe diaphoresis and worsening lethargy. He was subsequently intubated for airway protection. Patient’s lithium level was ~20 mmol/L. CT head showed no injury. The rest of the toxicology screen was negative. His basic metabolic panel (including calcium and albumin) was within normal limits however his bicarbonate was 32 mmol/L and his anion gap was elevated. Severe hyponatremia was noted and the patient initially trended down to 0.9 after 48 hours. Patient was extubated 48 hours after initial presentation.

Discussion: Lithium has a narrow therapeutic window and therefore in cases of overdose toxicity have many symptoms including altered levels of consciousness as seen in this patient. Low anion gap is a diagnostic clue to lithium intoxication however other causes include hyperkalemia, hypermagnesemia, and monoclonal gammopathies. Although serum osmolality was not measured in our patient, this can also be a helpful indicator noted in previous case reports. Elevated osmolar gaps with low anion gaps are useful in diagnosing lithium overdose. The standard management for lithium overdose is intermittent hemodialysis and maintaining water balance. The theory behind using intermittent hemodialysis versus continuous venovenous hemodiafiltration is that higher clearance of lithium can be achieved from faster blood flow rates in intermittent hemodialysis.

PUB445
Frailty Modifies the Association Between Age and Dysnatremia in Community-Dwelling Adults
Amanda Jean Miller,1 Susan E. Howlett,2 Kenneth John Rockwood,2 Karthik K. Tennankore.1 1Nephrology, Dalhousie Univ; Halifax, NS, Canada; 2Geriatrics, Dalhousie Univ; Halifax, NS, Canada.

Background: Frailty represents a state of increased risk to adverse health outcomes, reflecting some combination of increased damage and compromised repair processes. Dysnatremia is more common with age and can occur in many settings, suggesting that it may reflect not simply a specific renal problem, but a more general imbalance in damage and repair. The aims of this study were to establish whether frailty severity is associated with a higher rate of dysnatremia and to determine whether frailty explains the previously established association between age and dysnatremia.

Methods: The relationship between age, frailty severity and dysnatremia was investigated across the adult life course in 8898 respondents from the 2003-2004 and 2005-2006 cross-sectional National Health and Nutrition Examination Survey (NHANES) datasets. Respondents were assigned a frailty index (FI) and assessed for dysnatremia (a deviation of serum sodium from the 135-144 mmol/L normal range). The coefficient of variation in serum sodium was used as a systems measure of the response repertoire.

Results: In the overall population, there was a significant positive association between increasing frailty severity and the proportion of patients with dysnatremia (chi-square trend p < 0.001). Increasing frailty severity was also associated with more variability in serum sodium. There was a significant association between advancing age and dysnatremia (<p < 0.001); however after stratifying by frailty (FI <0.100, 0.100-0.199, 0.200-0.299, 0.300-0.399, >=0.400), the association between increasing age and dysnatremia became non-significant in all categories.

PUB446
Approach to Hyponatremia in Congestive Heart Failure: A Survey of Canadian Physicians and Trainees
Amanda Jean Miller,1 Bonnie Kuehl,2 Karthik K. Tennankore.1 1Nephrology, Dalhousie Univ; Halifax, NS, Canada; 2Research, Scientific Insights Consulting Group Inc., Mississauga, ON, Canada.

Background: Hyponatremia is a complication of congestive heart failure (CHF) and is associated with reduced survival, however there are no consensus guidelines for the treatment of hyponatremia in CHF. The aim of this study was to determine the approach to hyponatremia in CHF amongst Canadian healthcare practitioners and trainees.

Methods: Respondents completed 15 multiple-choice style questions surrounding three cases of hyponatremia complicating CHF using an online survey on UKidney.com between December 2012-May 2013. Results were summarized as the proportion of correct/incorrect responses among Canadian Nephrologists, Cardiologists, Internists and trainees in each of two domains; pathophysiology and management. Management topics included use of diuretic therapy, hypertonic saline, oral urea tablets, vasopressin receptor antagonists (vaptans) and rate of sodium correction. Correct answers were determined by an expert panel of Canadian Nephrologists and Cardiologists.

Results: There were 1097 responses to survey questions among 455 Canadian respondents. Pathophysiology governing hyponatremia in CHF was correctly identified in 68.7% of responses (n = 380). Overall, hyponatremia was managed inappropriately in 33.6% of responses (n = 759). The proportion of incorrect responses among specialists and trainees is depicted in Figure 1. Importantly, an incorrect rate for sodium correction was selected 61.1% of the time (n = 211).

Figure 1: Proportion of dysnatremia with increasing age, stratified by frailty index.
Hospital, New York, NY; Upon admission, her serum sodium was 106. With hypertonic saline and fluid restriction, onset of hyponatremia may be within ten days. Our patient took sorafenib for two weeks. With a rate of up to 11% in patients treated for HCC, the pathophysiology may be related to FT4. AM cortisol was measured at 20.2. Her total protein and lipid profile were normal. Lethargic, with generalized swelling. The serum sodium was 106 mmol/L, with a baseline her dose to 400 mg in the AM and 200 mg in the PM. A day thereafter, patient became the dose was increased to 200 mg twice daily. Three days later, the patient increased began sorafenib two weeks prior to admission, with a dose of 200 mg daily. A week later, the patients exhibited a serum sodium level of >130 mmol/L. Individuals aged 65 years old were noted, however, to be receiving related drug therapies 63.4%. They were distributed by eGFR using creatinine comparison to a control group includes novel conditions such as patients receiving renal replacement therapy.

**Conclusions:** This study suggests that hyponatremia often is mild, is commonly associated with drug therapy, affects a significant number of younger patients, and now includes novel conditions such as patients receiving renal replacement therapy.

**Development of Metabolic Acidosis After Neobladder Replacement in Korea**

Shina Lee, Dong-Ryool Ryu, Kyu Bok Choi, Duk-Hee Kang, Seung-Jung Kim. Dept of Internal Medicine, School of Medicine, Ewha Womans Univ, Seoul, Korea.

**Background:** Metabolic acidosis frequently develops in patients after neobladder replacement. However, the incidence of metabolic acidosis in patients with neobladder and the factors associated with the development of metabolic acidosis have not been well elucidated. We aimed to investigate the incidence and the potential predictors for the development of metabolic acidosis after neobladder replacement with intestinal segment.

**Methods:** We included all patients who underwent neobladder replacement using intestinal segment at Mokdong Hospital between January 1, 2005 and December 31, 2014. Metabolic acidosis was defined as serum CO2 below 22 mEq/L at any visit during the follow-up period. Patients’ biologic data was presented using t-test and student t-test. Subgroups according to the timing of metabolic acidosis occurrence were further analyzed in order to characterize predictors for metabolic acidosis by ANOVA tests and multiple regression.

**Results:** Metabolic acidosis was encountered in 79.4% of patients with neobladder during follow up period. When patients were divided into 2 groups according to anion gap(AG), total CO2(18.9 ±1.2 mEq/L vs. 20.0 ±1.3 mEq/L, p<0.001) and chloride(106.6±4.9mEq/L vs. 109.4±3.6mEq/L, p<0.001) were significant different between groups with AG<12 and AG≥12 respectively. Furthermore, when patients were divided into 3 groups; patients with metabolic acidosis at post operative day 1; within 1-4days; after 14days, there was significant difference of postoperative laboratory findings among the those subgroups.

**Conclusions:** Our study showed the rate of development of metabolic acidosis in patients underwent neobladder replacement and the difference between patients with metabolic acidosis and those without metabolic acidosis after neobladder replacement for the first time in Korea. In the future, well designed prospective study will be needed to prevent metabolic acidosis after neobladder replacement.

**Potassium Abnormalities and Acute Kidney Injury Are Common Complications After Colectomy**

Lindsay M. Smith,1 Robert M. Perkins,2 Andrea Lynn Berger,1 H. Lester Kirchner,3 Morgan Grams,4 Alex R. Chang,5 1Geisinger Health System; 2Bayer Healthcare; 3Johns Hopkins Bloomberg School of Public Health.

**Background:** Patients undergoing colectomy may be predisposed to disturbed potassium homeostasis, since the colon has a role in potassium excretion, and volume depletion due to diarrhea occurs frequently after colectomy.

**Methods:** We examined the frequency of incident mild (<5 mmol/L) and severe hyperkalemia (>6 mmol/L), mild (<3.5 mmol/L) and severe (<2.5 mmol/L) hypokalemia, and incident AKI, stratified by estimated glomerular filtration rate (eGFR) using creatinine and inpatient only and potassium (inpatient/outpatient) data from 1,762 patients who underwent colectomy surgery at Geisinger Health System between 2004-2013.

**Results:** Median age was 66 and mean baseline eGFR was 79 ml/min/1.73m². Colonic conditions included inflammatory bowel disease (8%), bowel obstruction (8%), ischemic bowel (2%), diverticulitis (23%), and colorectal cancer (20%). During the surgery hospitalization, post-operative AKI occurred in 32% of patients; mild and severe hyperkalemia occurred in 18% and 3% of patients. Over a median of 4.0 years post-discharge after colectomy, mild and severe hyperkalemia occurred at a rate of 13.4 events/100 person-years and 1.8 events/100 person-years; mild hypokalemia and severe hypokalemia occurred at a rate of 15.4 events/100 person-years and 0.7 events per person-years. Rates of incident AKI after discharge were high (9.1 events/100 person-years). Risks for AKI, mild and severe hyperkalemia increased as eGFR declined (p<0.001, Table).

**Conclusions:** Patients who undergo colectomy are at high risk for hyperkalemia, hypokalemia, and AKI, particularly when eGFR is decreased. Comparison to a control group is needed to determine whether the high incidence of hyperkalemia is related to removal of the colon or frequent AKI episodes.

Methods: 62-year-old female with history of adenocarcinoma of the lung, developed severe hypomagnesemia due to metastatic non-magnesium (Mg) levels of 5.1 mg/dL. She had concurrent severe hypocalcaemia with serum calcium (Ca) of 5.1 mg/dL. Aggressive repletion was started & further work up was done. Her urine spot Mg level was reported as 381 mg, her fractional excretion of Mg was calculated & it was 9%. She received 3 cycles of 2-hour uridine before hospitalization. She was not on any diuretics, PPIs & Aminoglycosides. She did not receive cetezolimub as well.Urine calcium was less than 150mg, it was thought that she had carboplatin-induced distal nephron Mg wasting . Her serum PTH level was 245.5 pg/mL. Her hypercalcemia was thought to be secondary to PTH resistance mediated by severe hypomagnesaemia. After aggressive repletion her serum Mg & Ca level normalized.

Conclusions: Hypomagnesemia can be due to multiple causes, Initial step in evaluation involves calculating FeMg, if less than 2.5% it is likelyy secondary to GI losses. If FeMg is >2.5% then we measure 2-hour uridine calcium, if its more than 250mg it is likely due to TAL-Mg wasting which can be secondary to loop diuretics, nephrotic syndrome(Aminoglycosides) or Familial hypomagnesemia with hypercalciuria. If less than 150mg then it is likely due to distal nephron Mg wasting which can be secondary to thyizides & Gitleman’s syndrome.

Our case represents an interesting concurrent presentation of severe hypomagnesemia and hypocalcaemia, which was successively treated.

PUB455
Effect of Arterial pH and Bicarbonate Level on Survival of Lactic Acidosis Patients Treated with Sodium Bicarbonate

Dongyeol Lee,1 Hansae Kim,1,2 Eu Gene Jeong,1 Su Mi Lee,1 Sung Hyun Sorn,1 Yong Ki Park,1 Young Ki Son,1 Seong Eun Kim,1 Won Suk An.1

1Internal Medicine, Bong Seng Hospital, Busan, Korea; 2Internal Medicine, Han Seo Hospital, Busan, Korea; 3Internal Medicine, Dong-A Univ, Busan, Korea.

Background: Patients with lactic acidosis have high mortality rate, and higher lactate level is poor prognostic indicator. The correction of lactic acidosis with sodium bicarbonate is potentially harmful when sodium bicarbonate inappropriately was used. Therefore, we evaluated whether starting pH of sodium bicarbonate affect on the survival in lactic acidosis patients treated with sodium bicarbonate.

Methods: We conducted a single center analysis from May 2011 through April 2014. We retrospectively analyzed 230 patients with lactic acidosis treated with sodium bicarbonate. Patients were divided four groups according to starting arterial pH of sodium bicarbonate. We analyzed arterial blood gas analysis, lactate level about 6, 12, 24, 48 hours after using sodium bicarbonate.

Results: The mean age of patients was 62.8 ± 15.0 years, 174 patients (75.7%) were male. The non-survivals had lower pH, hemoglobin, and CRP (< P < 0.001, < P < 0.001, and < P = 0.003), higher SOFA and APACHE II scores (< P < 0.001, < P < 0.001, and < P < 0.001). Patients with increased second lactate level had higher mortality (84.4%). The mortality rate was 90% in patients with sustained high lactate level at 48 hours. The mortality rate was not different according to starting point of sodium bicarbonate. In survival group, arterial bicarbonate level was slowly increased without fluctuation. However, arterial bicarbonate level showed fluctuation in non-survival group. The mortality rate was independently associated with arterial pH at 12 hours after sodium bicarbonate infusion.

Conclusions: Stably increased arterial bicarbonate without fluctuation and recovering arterial pH at 12 hours are important factors in patients treated with sodium bicarbonate. Therefore arterial pH and sodium bicarbonate level should be closely monitored especially till 48 hours, if sodium bicarbonate treatment with lactic acidosis.

PUB456
Evaluation and Management of Hyperkalemia in an Academic Medical Center

Jason K. Law,1 Gaurav Ghosh,1 Daniel Edmonston,1 Saif A. Mulsim,1 Yassin Hussain,2 Miriam Chung,1,2 Jeffrey I. Silberzweig,1,2,4 Dept of Medicine, New York-Presbyterian Hospital, New York, NY; 1Weill Cornell Medical College, New York, NY; 1Weill Cornell Medical College, Qatar, Doha, Qatar; 2Rogosin Inst, New York, NY.

Background: Hyperkalemia (K > 6.0 mmol/L) is common among hospitalized patients but the approach to evaluation and management is highly varied. Patients are not routinely evaluated for clinical effects. Decisions regarding whether and how to treat are often based on individual physician judgments since few evidence-based guidelines exist. Since both hyperkalemia and its treatments can be associated with serious adverse consequences, we sought to evaluate the management in our institution.

Methods: Electronic medical records were reviewed for patients in our institution with potassium levels greater than 6.0 mmol/L between January 1, 2012 and December 31, 2014. Records were extracted for hyperkalemia associated symptoms and ECG findings, as well as interventions and outcomes.

Results: Only 2% of patients had clinical findings consistent with hyperkalemia. Only 10% of patients had ECGs performed and only 20% of those had findings consistent with hyperkalemia. Of patients with ECG findings consistent with hyperkalemia, only 15% had repeat tracings performed after treatment. At least 50% of patients were treated with insulin and dextrose and/or calcium. One-third of patients were treated with sodium polystyrene sulfonate (SPS), 25% with sodium bicarbonate and 10-15% were treated with lactulose or furosemide. Only 25% of patients had repeat potassium levels measured within six hours of treatment.
Disorders of Plasma Sodium in Hospitalized Patients and Effect of Total Plasma Protein Concentration on Its Measurement

Pedro J. Labrador, Silvia Gonzalez S, Santiago Polanco Candelario, Elena Davin Carrero, Jesús P. Marín, Ines Castellano, Juan R. Gomez-Martino.

**Disclosures:** Nephrology, San Pedro de Alcántara Hospital, Caceres, Spain.

**Background:** The aim of the study was the analysed the prevalence of hyponatremia in hospitalized patients, and the effect of total plasma protein (TPP) concentration on plasma sodium measurements.

**Methods:** We registered all biochemical analysis from in-hospital patients during one year. Data from age, sex, and department was recorded. Plasma Na was measured by an indirect ion selective electrode measuring system (Cobas 8000 analyzer, Roche Diagnostics). Hyponatremia was defined as mild when plasma Na was lower than 130 mmol/L. Hyponatremia was classified based on plasma Na concentration. Mild hyponatremia was defined as 130-134 mmol/L, moderate as 125-129 mmol/L and profound as lower than 125 mmol/L. When TPP was measured, plasma Na concentration was corrected according to: plasma Na = plasma Na (mg/dL) / (1 + 0.7 x (TPP concentration – 6.0)).

**Results:** Our hospital is a 520 in-hospital beds. Plasma Na was measured in 26,904 biochemical analyses from 6,873 patients. Median age was 67 (IQR 50-79), 55.9% were men. Median plasma Na measurements was 5 (IQR 2-11). Hyponatremia was present in 1,514 patients (22%), mild hyponatremia 1,114 (16.2%), moderate 287 (4.2%) and profound 113 (1.6%). Plasma Na could be corrected to TPP in 3,122 patients, using the first formula hyponatremia was present in 29.4% (mild 19.6%, moderate 6.8% and profound 3%) while using the second one, 27.9% (mild 18.7%, moderate 6.4% and profound 2.8%).

**Conclusions:** Hyponatremia is present in one fifth of in-hospital patients. Correction of plasma Na concentration according to TPP concentration increase hyponatremia diagnostic up to 25%.

PUB457

Treatment of Hyperkalemia with Kayexalate in an Academic Medical Center

**Background:** Hyperkalemia (K > 6.0 mmol/L) is a potentially life-threatening condition; standard treatment has included sodium polystyrene sulfonate (Kayexalate) since its introduction in 1958. Recent literature has questioned the benefits of this treatment because of the lack of proven efficacy and the risk of serious adverse effects. We evaluated the effectiveness of Kayexalate for treatment of patients with hyperkalemia in our institution.

**Methods:** Electronic medical records were reviewed for all patients in our institution with potassium levels > 6.0 mmol/L between January 1, 2012 and December 31, 2014. Records were extracted for hyperkalemia treatment and outcomes. Hyperkalemia treatments included albuterol, diuretics, insulin, lactulose, sodium bicarbonate, and Kayexalate. Comparisons between hyperkalemia treatments with Kayexalate and without Kayexalate were made using t-tests.

**Results:** One-third of patients diagnosed with hyperkalemia were treated with Kayexalate. Post-treatment potassium values decreased by 14.8% in treatment with Kayexalate, compared to 17.4% reduction in treatment combinations without Kayexalate (p = 0.06). No patients suffered serious adverse effects from Kayexalate treatment.

**Conclusions:** In our population, treatment of hyperkalemia with Kayexalate was common. While no adverse events of treatment were noted, there was no significant difference in reduction of potassium levels with it. We conclude that there is insufficient evidence to support routine use of Kayexalate in our population.

PUB458

Treatment of Hyperkalemia with Kayexalate in an Academic Medical Center

The Impact of Hyponatremia on Children: Prevalence and Consequences During Hospitalization

Zachary Sartor, Poonam Thakore, Tetyana L. Vaaylyeva. Pediatrics, Texas Tech Univ Health Sciences Center, Amarillo, TX.

**Background:** Hyponatremia in adults is associated with increased morbidity and mortality, but this association has not been explored in pediatrics. The aim of this study is to characterize the prevalence of hyponatremia and assess its impact on the course of hospitalization in pediatric patients.

**Methods:** Patients who were admitted to the TTUHSC pediatric service at Northwest Texas Hospital in Amarillo, TX from January through December 2012 were considered for retrospective chart review. Patients were divided into 3 diagnosis groups: bronchiolitis, asthma exacerbation, and gastroenteritis. Other diagnoses and patients without serum chemistry were excluded. Age, sex, and serum sodium levels were documented. The number of days admitted were also recorded. Hyponatremia was defined as mild if the sodium was 130-135 mEq/L, moderate if 125-129 mEq/L, or severe if <125 mEq/L. Prevalence was calculated. Prevalence was determined to be statistically significant by comparing sodium levels between patients with hyponatremia and those with normal sodium levels. All patients were then grouped together, and length-of-stay (LOS) was compared between those with hyponatremia and those with normal sodium. The analysis for prevalence and LOS was performed using a two-tailed, unequal t-test with a p <0.05 used for significance.

**Results:** Overall, 416 patients were admitted to the inpatient service during the study period. After exclusion, 128 patients with bronchiolitis, 137 patients with asthma exacerbation, and 69 patients with gastroenteritis were available for analysis. There were 24 cases of hyponatremia in the bronchiolitis group (18.75% prevalence), 8 cases in the asthma exacerbation group (5.84% prevalence), and 18 cases in the gastroenteritis group (26.09% prevalence). There was one case of moderate hyponatremia in the bronchiolitis group, otherwise all other cases involved mild levels of hyponatremia. LOS was increased for patients with hyponatremia (2.33±0.11 days versus 4.26±0.71 days, p<0.01).

**Conclusions:** Hyponatremia was prevalent at an overall rate of 15% during the study period. Hyponatremia was associated with increased hospitalization at a statistically significant level.

mortality adjusted for patients’ characteristics and co-morbid conditions. We used random effects meta-analysis to derive pooled estimates of effect in medical, surgical and mixed admission settings.

Results: We evaluated 135 full text publications from 1925 reviewed abstracts, of which 32 studies met the inclusion criteria (19, 13, and 5 reported aOR, proportion and both respectively). Patients with hypernatremia were at increased risk of hospital mortality (OR=2.59, 95% CI 1.5-4.47, P<0.001).

Conclusion: Chronic salicylate intoxication is most common in the elderly. Increased toxicity in older patient often appears due to inadvertent over dosage. Dual prescribing or additional use of non prescription OTC salicylates are some causes of unwitting long term toxicity. Chronic intoxication often poses a diagnostic dilemma with atypical presentation mimicking other disease states. The diagnosis of salicylate intoxication should be borne in mind when an older patient presents with recent deterioration in ADL with no known cause. Plasma salicylate concentration should be measured if salicylate intoxication is suspected, even if there is no documented history of salicylate ingestion. Chronic toxicity, which can occur even with marginally high salicylate concentrations is treated with drug withdrawal and supportive therapy. It can be averted by prescription of conservative doses, avoidance of concomitant use of different salicylate preparations, and therapeutic monitoring to guide dosing.

PUB464
Diagnostic Workup of Hyponatremia in Hospitalized Patients: Does Education Have an Impact? Faraj Karoli, Ladan Golestanian. Dept of Nephrology, Montefiore Medical Center, Bronx, NY.

Background: Hyponatremia is associated with poor outcomes. Studies show that hospitalized hyponatremic patients seldom get adequate diagnostic workups. This study tests the effects of a CME activity on physician’s behavior in the diagnostic workup of hyponatremia.

Methods: This is a cross sectional analysis of patients admitted to the Internal medicine department at Montefiore Medical center between 05/2014 and 12/2014. Demographic and clinical data were collected retrospectively. Patients were included if they were admitted under the service of 24 hospitalist attendings. These attendings were chosen based on their participation in a CME activity (lecture based). This activity was implemented to improve hyponatremia workup as defined by the frequency of the following orders: serum osmolality, urine osmolality, and urine sodium. Hyponatremia was defined as the earliest serum sodium less than 135 meq/dL. There was further subclassification into three groups based on the severity: mild-130-135 meq/dL, moderate: 125-130 meq/ dL and severe: less than 125 meq/dL. Frequency of the diagnostic orders was stratified to the mild or moderate (p<0.005).

Conclusions: Admission with serum Na of ‘145 meq/L is significantly associated with twice the odds of hospital mortality. Protocols towards increasing awareness of hypernatremia and studies evaluating the efficacy of early intervention are warranted.

PUB465
Characteristics and Initial Outcomes of a Multidisciplinary Renal Genetics Clinic (RGC) Andrew John Mallier, 1,2 Helen G. Healy, 1,2 Julie M. Mcguaghnam, 2, 3, 4 Melissa H. Little, 5,3 Chirag Patel, 3, 2, 4 Kidney Health Service & Conjoint Kidney Research Laboratory, Royal Brisbane & Women’s Hospital, Brisbane, QLD, Australia; 2School of Medicine, The University of Queensland, St Lucia, QLD, Australia; 3Children’s Medical Research Institute for Molecular Biosciences, UQ, Brisbane, QLD, Australia; 4Genetic Health Queensland, RBWH, Brisbane, QLD, Australia; 5Murdoch Children’s Research Inst, Melbourne, VIC, Australia.

Background: Genetic Renal Disease (GRD) accounts for 10% of adults and 50% of children with end stage kidney disease. Advances in molecular genetic diagnostic testing and multidisciplinary renal clinic models suggest opportunities for clinical redesign. Here we describe the initial characteristics, experience and outcomes of the first Australian multidisciplinary RGC.

Methods: A retrospective audit was undertaken of the RBWH Adult Conjoint RGC (1st year of operation; Aug’13-Jul’14). Each encounter involved a nephrologist, clinical geneticist and genetic counselor.

Results: 278 patients (56%) encountered had a known GRD, 9/48 (19%) had a suspected GRD and 12/48 (25%) had an unknown GRD with positive family history (FH). Patients were most commonly referred by nephrologists (66%). The most common GRD category & diagnosis were cystic kidney disease (49%) and Autosomal Dominant Tubular Dysgenesis (19%). Genetic and Kidney Disease related features were associated with GRD in 26/48 (54%). During consultations differential diagnoses were explored (54%), management strategies were discussed in 44% and 30% focused on patient’s education and psychological needs.

Conclusion: The Multidisciplinary RGC model demonstrated a range of benefits including immediate access to genetic testing. Future research will aim to evaluate the effect of CME activity on the treating physician behavior and patient outcomes.

Funding: Pharmaceutical Company Support - Rockpoint LLC.
advice provided (83%) and genetic counseling undertaken (79%). A genetic test was requested in 58.3%, most commonly being induced by combined diagnostic and genetic counseling reasons (78.6%). Of 12 returned genetic test results, 7 were positive and 1 was a variant of uncertain significance. Two negative results have prompted additional genetic testing. Of 27 patients referred with a known GRD, 6 now have a new suspected GRD. The majority of those referred with either a suspected (19) or unknown GRD diagnosis (10/12) now have a new suspected or confirmed GRD.

Conclusions: These findings demonstrate the early successful operation of this RGC model including diagnostic and genetic counseling benefit. Future assessment of clinical outcomes and expansion to telehealth and paediatric settings is anticipated.

PUB466

Characteristics and Clinicopathological Analysis of Japanese Nephronophthisis Patients Keisuke Sugimoto,1 Tomoki Miyazawa,1 Takaji Enya,1 Hitomi Nishi,1 Kohei Miyazaki,1 Hidehiko Yanagida,2 Mitsuru Okada,1 Tsukasa Takekuma,1 1Pediatrics, Kindai Univ Faculty of Medicine, Osaka, Japan; 2Pediatrics, Sakai Hospital, Kindai Univ Faculty of Medicine, Sakai, Osaka, Japan.

Background: Nephronophthisis (NPHP) accounts for 4 to 5% of end-stage renal disease (ESRD) occurring in childhood. Disease subtypes include infantile NPHP, which progresses to ESRD around the age of 5 years. Juvenile NPHP, which develops from early childhood to school age and usually progresses to ESRD by an age of about 13 or 14 years; and adolescent NPHP, with development of ESRD at an average age of 19 years. Juvenile NPHP is reported to be the most common subtype.

Methods: We investigated clinical, histologic, and genetic features in 35 Japanese patients clinically and histologically suspected to have NPHP, aiming to promote early diagnosis. We studied many exons as many as 13 NPHP genes. Since such genetic analysis involves significant cost and time, we also screened biopsy specimens by immunohistochemical methods employing antibodies against relevant peptides.

Results: NPHP occurred fairly uniformly throughout Japan irrespective of region or gender. In 3 families, NPHP affected siblings. The median age of patients was 12.5 years. Renal abnormalities attributable to NPHP discovered through mass screening, such as urine tests in school, however, NPHP accounted for less than 50% of children with abnormal findings, including incidentally discovered renal dysfunction during evaluation of extrarenal symptoms or during routine check-ups. Typical extrarenal manifestations led to discovery including anemia and delayed physical development. The urine often showed low gravity specific density and low-molecular-weight proteinuria. Frequent renal histologic findings included cystic dilation of tubules, mainly in the medulla, and irregularity of tubular basement membranes. Genetically abnormalities of NPHP1 were not common, with large deletions or frameshift mutations by sequencing all exons. 2. (1) ARHGAP32 gene was expressed mainly in kidney cortex and medulla, and amplified by PCR, obtaining the ARHGAP32 plasmids. (2) Transform the wild type and mutant plasmids of ARHGAP32 into Escherichia Coli respectively, and sequenced and screened for the mutation of ARHGAP32 plasmids. (3) Total exons sequencing were separated into 3 groups based on natraemic status.

Conclusions: Our findings resemble those reported in Western populations.

PUB467

The Functional Role of the ARHGAP32 L405V Mutation on Cytoskeleton Guispen Li, Li Wang. Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chengdu, China.

Background: A site-directed mutagenesis for ARHGAP32 was developed to whether the mutation of ARHGAP32 has the effect on the distribution of cytoskeletal protein of F-actin. It spreaded all the directions in wild type, while the distribution was scattered in mutant type. The distribution of F-actin was more significant in the wild type than that in mutant plasmid of ARHGAP32.

Methods: 1. (1) Blood DNA of 110 FSGS patients proved by renal biopsy were sequenced and screened for the mutation of ARHGAP32. 2. Total exons sequencing were performed in 28 DNA samples to find out whether mutation of ARHGAP32 occurred in these patients. 2. (1) site-directed mutagenesis primers of ARHGAP32 was designed and amplified by PCR, obtaining the ARHGAP32 plasmids. (2) Transform the wild type and mutant plasmids of ARHGAP32 into Escherichia Coli respectively, sequenced the plasmids to identify whether the site-directed mutagenesis of ARHGAP32 was successful constructed. (3) Transfected the mutated plasmid of ARHGAP32 into 293T cells and monitored by western blot and real time RT-PCR. 3. (1) Detected the expression of ARHGAP32 in FSGS, IgAN, MN, minimal change disease and diabetic disease by IHC. (2) Detected the expression of CDC42 and/β-catenin by realtime RT-PCR and western blot in 293T cells which were transfected with the wild type and mutated plasmids of ARHGAP32. (3) Observed the expression of F-actin by immunofluorescence in the wild plasmid of ARHGAP32 and mutant type in COS7 cells.

Results: 1. No mutation of ARHGAP32 was detected while 6 candidate genes were selected by sequencing all exons. 2. (1) ARHGAP32 gene was expressed mainly in glomerular in kidney tissue. The expression of ARHGAP32 was not detectable by IHC. (2) The expression of CDC42 and/β-catenin by realtime RT-PCR and western blot were no significant differences between the wild plasmid of ARHGAP32 and mutant type in 293T cells. (3) The distribution of F-actin was more significant in the wild type than that in mutant plasmid of ARHGAP32. It spreaded all the directions in wild type, while the distribution was scattered in mutant type.

Conclusions: No mutation was detected in sporadic FSGS currently. The mutation of ARHGAP32 had effect on the distribution of cytoskeletal protein of F-actin.
Conclusions: Total mitochondrial protein levels decrease in the cortex but not in the medulla of the rat kidney with age.

PUB470

Background: Prior research suggests that functional status in ESRD patients declines after initiation of dialysis, implicating the dialysis process in contributing to functional decline. We evaluated a dialysis-specific risk factor of intradialytic change in blood pressure (BP) in relation to changes in physical performance, a component of functional status.

Methods: We enrolled 29 dialysis patients age ≥50 years. Participants completed a 4-m timed walk to measure gait speed both pre and post dialysis and a Falls Efficacy Survey, a measure of concern for falls. Dialytic variables included BP measurements from pre, post and during dialysis along with ultrafiltration rate. Demographics and comorbid data was collected. Analysis evaluated for association between dialytic BP variables and change in gait speed and score on Falls Survey. Multivariate analysis was done to adjust for age, race, sex, diabetes and congestive heart failure.

Results: 28 participants completed the study. The mean age was 62.7 (12.3) years. The majority were male (70.4%) and hypertensive (86.2%). Diabetes was present in 55.2%. The mean (SD) change in gait speed from pre to post was -0.1 (0.1) m/s. The mean (SD) change in systolic and diastolic BP from pre to post dialysis was -10.6 (25.8) mmHg and -4.6 (10.5) mmHg, respectively. Participants with diabetes had greater intradialytic hemodynamic changes with mean (SD) change of SBP + DBP of 29.6(23.5) and 7.9(11.3) mmHg, respectively. Univariate analysis showed that every mmHg decrease in systolic BP and every 5 mmHg decrease in diastolic BP was associated with a change in gait speed of -0.01 m/s (p = 0.02) and -0.02 m/s (p = 0.01), respectively. This association was no longer significant in multivariate analysis, likely due to correlation of change in BP with diabetes status. There was no association between BP change and Falls Survey score.

Conclusions: Decline in physical performance, as measured by gait speed, can be seen post dialysis and is associated with hemodynamic changes during dialysis. Patients with diabetes may be most susceptible to hemodynamic changes. Improving dialytic hemodynamic stability may be a way to reduce the significant functional impairment that occurs post-dialysis.

Funding: Private Foundation Support

Conclusions: A positive correlation was shown between mesangial hypercellularity with serum uric acid levels in the first time. These results suggest that SIRT1 does not play a direct role in the pathogenesis of IgA nephropathy.

Response of Human Primary Renal Proximal Tubular Epithelial Cells to Different LPS Strains. Hong Wang, Margaret M. O’Neill, Carine Boustaney, Steven S. Pullen. CardioMetabolic Diseases Research, Boehringer Ingelheim Pharmaceuticals, Ridgefield, CT.

Background: Toll-like receptors are expressed on leukocytes and renal tubular epithelial cells where they regulate immune responses. Recent evidence has implicated renal TLR4 signaling in the pro-inflammatory response in diabetic nephropathy. Ligands for TLR4 include lipopolysaccharide (LPS) and HMGB1. We sought to explore the response of renal proximal tubular epithelial cells (PTEC) to different strains of LPS and HMGB1 as well as modulation by TLR4 antagonists.

Methods: The HK-2 human proximal tubular cell line was stimulated with 3 strains of LPS (S. minnesota, E. coli K12, E. coli 0111:B4) and HMGB1. Primary human PTEC were stimulated with 5 strains of LPS (S. minnesota, E. coli 0111:B4, E. coli 055:B5, E. coli K12, S. typhosa)and HMGB1. Supernatants were harvested and IL-1β, IL-6, IL-8, TNFα, and MCP-1 were detected. TLR4 antagonists EX 7623 and EX 76824 were tested for the ability to modulate cytokine production induced by LPS stimulation.

Results: In HK-2 cells, LPS from E. coli 0111:B4 induced IL-6 and IL-8 production, whereas, S. minnesota and E. coli K12 did not stimulate cytokine production. In PTEC, IL-6 and IL-8 production increased upon S. typhosa, and S. minnesota stimulation. Other strains of LPS did not stimulate production of IL-6 and IL-8 in PTEC. There was little detectable production of IL-1β, TNFα or MCP-1 under the conditions tested in both HK-2 and PTEC. HMGB1 induced IL-8 production in PTEC whereas HK-2 cells did not produce any of the cytokines or chemokines tested upon HMGB1 stimulation. The TLR4 antagonists EX 7624 and EX 76824 blocked cytokine production stimulated by S. typhosa in PTEC. EX 76824 inhibited IL-6 and IL-8 production stimulated by E. coli 0111:B4 in HK-2 cells.

Conclusions: Primary PTEC have unique responses to different strains of LPS, and this response profile differs from that of the HK-2 cell line. HMGB1 induced IL-8 production in PTEC whereas HK-2 cells did not respond to HMGB1 stimulation. These results highlight a limitation of using the HK-2 cell line in lieu of primary PTEC for interrogating the role of TLR4 in renal inflammation.

PUB473

Assessment of Serum Transforming Growth Factor-Beta 1 in Patients with Diabetic Nephropathy. Om Prakash Kalra,1 Avanish Shukla,1 Ashok Kumar Tripathi,1 Alpana Raizada.1 1Medicine, UCS & GTB Hospital, Delhi, India; 2Biochemistry, UCS & GTB Hospital, Delhi, India.

Background: Diabetes mellitus is the leading cause of chronic kidney disease (CKD) worldwide. The pathogenesis and initial molecular events leading to diabetic nephropathy are still elusive. Chronic low grade inflammation plays an important role in pathogenesis of diabetic nephropathy. Urokinases like transforming growth factor-beta (TGF-β) that play an important role in pathogenesis of diabetic nephropathy by influencing ECM accumulation and cellular hypertrophy in several cell types. TGF-β may play an important role in the pathogenesis of diabetic nephropathy by influencing ECM accumulation.

Methods: This was a case control, cross sectional study. 75 subjects aged 30–65 years of either sex were recruited and divided into three groups: Group I: healthy controls (n=25), Group II: patients of T2DM without nephropathy (n=25), Group III: patients of T2DM with nephropathy (n=25). Detailed history, complete physical examination, routine investigations, urine albumin creatinine ratio (ACR) estimation was done. Serum levels of hs-CRP and TGF-β1 were estimated by ELISA.

Results: A statistically significant difference in serum TGF-β1 and hs-CRP levels was observed between all the 3 groups (p<0.001), where highest levels were found in group III and lowest in group I. A positive correlation was observed between serum TGF-β1 and duration of diabetes, FBS, PPBS, HbA1c levels, serum creatinine, urinary ACR and serum hs-CRP. Similarly serum hs-CRP levels positively correlated with the duration of diabetes, FBS, PPBS, HbA1c levels, serum creatinine, urinary ACR. Serum TGF-β1 and serum hs-CRP showed negative correlation with eGFR.

Conclusions: Overall, TGF-β1 and hs-CRP levels were significantly higher in diabetics as compared to non-diabetic subjects. They were higher in diabetic subjects with nephropathy as compared to those without nephropathy. Serum TGF-β1 and hs-CRP levels in diabetic subjects appear to be dependent on duration of diabetes, glycemic control and degree of renal dysfunction. Thus cytokines like TGF-β may play a role in the etiopathogenesis of diabetic nephropathy.

Daptomycin Antibiotic Lock Therapy for Hemodialysis Patients with Gram-Positive bloodstream infections following use of tunneled, cuffed hemodialysis catheters. retrospective single center analysis huong-wen yen, szu-yuan li. dept. of medicine, div. of nephrology, dept. of medicine, taipei veterans general hospital, taipei, taiwan.

Background: catheter-related blood stream infection (CRBSI) is a major complication in hemodialysis patients. We assessed the efficacy of systemic daptomycin (DPT) plus dPT antibiotic lock therapy (DPT-ALT) for catheter-salvage in patients with gram-positive CRBSI.

Methods: Study Design: retrospective study of hemodialysis patients with cuffed, tunneled, cuffed hemodialysis catheters. Setting & Participants: all patients were from a single institution in taipei and received systemic DPT plus DPT-ALT for treatment of gram-positive CRBSI. Outcome: Successful resolution of CRBSI. Measurements: Resolution of fever within 48 h, negative result of repeated blood cultures after resolution of fever, no clinical evidence of CRBSI relapse, and no need for catheter removal.

Results: Fifteen hemodialysis patients received DPT-ALT for CRBSI, 9 with coagulase-negative Staphylococcus (CONS), 2 with methicillin-resistant Staphylococcus aureus (MRSA), 3 with methicillin-sensitive Staphylococcus aureus (MSSA), and 1 with polymicrobial infections. Systemic DPT plus DPT-ALT cured 11 patients (73.3%). Treatment failed in all 3 MRSA cases (2 with MRSA and 1 with MRSA + Enterococcus faecalis).

Analysis of Risk Factors of Death in Patients of Maintenance Hemodialysis with Tunneled Cuffed Venous Catheter

Li Zhou, Min Shi, Ping Fu.
Nephrology/Medicine, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.

Background: To analyze the causes of death in patients of maintenance hemodialysis with tunneled cuffed catheter, and explore the risk factors of death.

Methods: All patients of maintenance hemodialysis with tunneled cuffed venous catheter starting hemodialysis from January 1, 2009 to December 31, 2014 in West China hospital were included and observed till June 1, 2015. The patients were divided into observation (death) and control group (survival). Multivariate logistic regression analysis was used for the analysis.

Results: In total 94 hemodialysis patients who met the inclusion criteria, 24 cases died in the study period. The median age of dead patients was 73.4 years (51.5–96.4). The median time of hemodialysis was 19.20 months (3.17–56.27). Just 1 case replaced tunneled cuffed catheter for once. The main primary causes of renal disease were: diabetic kidney disease (DKD) 43.5%, chronic glomerulonephritis (CGN) 25.0%, hypertensive renal damage (HTN) 12.5%. The main causes of death were as following: infection 29.2%, cardiovascular diseases (CVD) 25.0%, cerebrovascular diseases 12.5%. The median age of survival patients was 64.9 years (20.8–95.4). Nineteen cases replaced tunneled cuffed catheter for twenty three times in total. The main primary causes of renal disease were: CGN 54.3%, DKD 25.7%, HTN 4.3%, polycystic kidney disease 4.3%. Multivariate logistic regression analysis showed that elder age, infection, low serum albumin were risk factors of death. Replacement of tunneled cuffed catheter was not the risk factors for death.

Conclusions: The main causes of death of patients with maintenance hemodialysis by tunneled cuffed venous catheter were cardiovascular and cerebrovascular diseases and infection. Elder age, infection, low level of serum albumin were risk factors of death in patients of maintenance hemodialysis with tunneled cuffed venous catheter. Replacement of tunneled cuffed catheter was not the risk factors for death. Analysis of Vascular Access of Maintenance Hemodialysis Patients: A Single Center Retrospective Study

Yuan Luo, Hong Ye.
Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.

Background: Vascular access is life line for maintenance hemodialysis patients. The main options for vascular access for hemodialysis patients are arteriovenous fistulas (AVFs), arteriovenous grafts/AVGs, and tunneled cuffed central venous catheters. Proper vascular access is associated with lower complications and costs, which could improve the survival rate. The aim of our study is to analysis the characteristics of vascular accesses of maintenance hemodialysis patients in our hemodialysis center.

Methods: Patients underwent maintenance hemodialysis in the blood purification center of our hospital from January 2010 to December 2014 were enrolled in this study. The demographic characteristics, duration of dialysis, types of vascular access and blood flow volume, as well as the potency rate of AVFs of these patients were collected and analyzed. The definition of vascular access was the vascular access that we used. The mean age was 57.89±14.27 years old. More than 60% patients’ initial vascular access was non-tunneled central venous catheters, only 20% applied AVFs as their initial vascular access. Vascular access types as follows, 87.0% for AVFs, 3.5% for AVGs and 9.5% for tunneled cuffed central venous catheters. The cumulative success rate of AVFs was 99.9% ±1.1%. The duration of primary patency was 29.00 (12.00, 68.00) months and the duration of the cumulative potency rate was 37.00 (12.75, 95.25) months. Fourteen patients applied AVG as their vascular access, of whom thrombomeloblastin was the main complication. AVG thrombosis of three patients were treated using percutaneous interventions. Among the 294 patients applying non-tunneled central venous catheters, 5.4% have their catheters changed for more than 2 times and 66.7% have their catheters on the right internal jugular vein.

Conclusions: AVF is the leading type of vascular access in our dialysis center. The usage rate of tunneled cuffed central access is under 10%, while the usage rate of AVG is about 2 times and 66.7% have their catheters on the right internal jugular vein.

Exchange Technique Using Over the Guidewire from Tunneled to Tunneled Hemodialysis Catheter Can Be Performed without Increasing Infection and Hemostasis after Removal and the Temporary Insertion of Femoral HD Catheter.

The exchange technique of HD catheter starting hemodialysis from January 1, 2009 to December 31, 2014 was respectively assigned to exchange and de novo placement groups and these 2 groups were compared.

Results: Compared with the de novo placement group, the exchange group over the guidewire has higher median age (64.6 vs. 61.7; p = 0.01), more females (69.6% vs. 48.1%; p = 0.006), more ESRD rather than AKI as a cause of catheter insertion (95.7% vs. 74.8%; p = 0.002). Both immediate complication rate including suturing at exit site for bleeding control was higher in the exchange group (19.6% vs. 8.7%; p = 0.02) and late one including infection with the increased risk of infection and bleeding after procedure prevent its application. However, the catheter survival rates between two groups were comparable (p = 0.58) and multivariate Cox regression analysis for catheter survival showed the development of late complication was the only risk factor (odds ratio [OR] 1.391, 95% confidence interval [CI]: 1.017–1.901; p = 0.039) rather than the exchange procedure was not a risk factor (OR 0.878, 95% CI: 0.554–1.393; p = 0.582).

Conclusions: The exchange over the guidewire from a previous tunneled catheter to a new one should be positively considered and performed when the new tunneled catheter placement is required.

Background: A Multidisciplinary Unit for attention to the vascular access was established in our hospital in December 2010. The main role of the nephrologist consists in monitoring the functioning of the vascular access by determining the arterio-venous flow (AVF) and undertaking the doppler ultrasound. The objectives for initiating this program were to reduce the thrombosis rate by diagnosis and treatment of a non clinically detected pathology and to decrease the percentage of patients with a tunneled catheter.

Methods: The prevalence of haemodialysis patients on 31st December 2014 was 65 patients in the Hospital Unit and 90 patients in the Dialysis Center. In the Hospital Unit we supervise the functioning of the vascular access by measuring the AVF flow and we perform a Doppler ultrasound study if the flow is less than 500 ml/min, if there are significant decreases in comparison with previous controls or if there is any clinical dysfunction. The Dialysis Center uses first generation methods for monitoring (increase in venous pressure, pump flow decrease, recirculation) and requests the Hospital Unit to undertake a Doppler ultrasound study whenever there is any type of dysfunction.

Results: We have observed differences in the results between both centers: 1° Incidence of patients with a tunneled catheter was lower in the Hospital Unit (14 vs 22%). 2° Thrombosis rate was 40% lower in the Hospital Unit (7.9 vs 12/100 patients-year). 3° Doppler ultrasound detected 25 patients with haemodynamically significant stenosis, confirmed by radiologic study, which were successfully treated.

Conclusions: The combined use of AVF flow measuring and doppler ultrasound studies for monitoring the vascular access is an efficient method for reducing the rates of thrombosis and the number of tunneled catheters due to the early detection of stenosis and its preventive treatment.

Females Have Less Arteriovenous Fistula and More Grafts Compared to Men: Data from the Slovenian Renal Replacement Therapy Registry

PUB484

Background: The aim of our study was to compare prevalence of arteriovenous fistula (AVF) and graft use in female and male chronic hemodialysis (HD) patients.

Methods: Data on vascular access prevalent HD patients on December 31, from 2009-2013, were analyzed, in addition to sex, age, dry body weight and blood flow (QB) during HD, from database of the Slovenian Renal Replacement Therapy Registry. The use of preoperative ultrasound mapping before AVF and graft construction in standard practice in the country.

</table>

The difference between percentage of AVF comparing females and males is persistent and highly significant during the observation period (p<0.001), with females having less AVF. Females had persistently slightly more grafts. Males had higher mean dry body weight (77.1±11.6 kg vs. 64.7±14.7 kg, end of 2013, p=0.001). Although absolute blood flow during HD was higher in males, females had higher blood flow when standardised to body weight (4.41±1.03 vs. 3.83±0.83 ml/min/kg, p=0.001, end of 2013).

Conclusions: Females chronically have significantly less arteriovenous fistula and slightly more grafts compared to males, with the difference being persistent during five years. Blood flow during HD, when standardised to body weight, was significantly higher in females than in males. Potential clinical consequence of higher blood flow during HD in females may be the lack of usefulness which we are increasingly seeing in the nullification of dual access for an additional 2.5, 11.7, and 46 days, respectively (p<0.01). This discrepancy between regular surveillance and delayed TDC removal raises concerns that there is a lack of timely intervention after assessment. A more thorough documentation of reasons for prolonged TDC use and analysis of such data are required to verify this hypothesis and get a better idea of etiology of delayed TDC removal.

Methods: Retrospective collection of data from outpatient dialysis units on patients who have AVF/Graft and TDC.

Results: The delayed TDC removal in patients with AVF/Graft the risk of infection in these patients with both devices.

Conclusions: TDC should be removed at a appropriate period once AVF/Graft are mature enough to be used.

Gene Methylation Profile of Human Vein Tissues Taken at the Time of Surgery: Correlation with AVF Maturation

PUB486

Background: Early arteriovenous fistula (AVF) failure remains an important cause of hemodialysis vascular access dysfunction and a major impediment to the Fistula First initiative. Despite the magnitude of the clinical problem, there are currently no effective therapeutic interventions for early AVF failure. In order to better understand the cellular and molecular mechanisms involved in early AVF failure we have evaluated the gene methylation profile of venous segment tissue samples obtained at the time of AVF creation.

Methods: DNA methylation of Cpg islands (regions of the genome that are rich in cytosine and guanine sequences), influences gene expression (turns off the gene). An increasing number of diverse factors are now known to epigenetically regulate genes, including stress, inflammation, nutrition, metabolism, drugs and infection (all of which are prominent in the biological milieu of patients with CKD and ESRD). In this study we compare the overall methylation profiles of non-maturing AVFs at 6 months as compared to AVFs that are able to support dialysis.

Results: gDNA was isolated from venous segments collected at the time of AVF creation. DNA sequencing technologies were used to identify genes with the greatest differences in methylation between the two groups. Gene networks focused on inflammation, oxidative stress and endothelial dysfunction were evaluated. Standard bioinformatic techniques were used to identify/interrogate both the gene list and the network analyses.

Results: We were able to identify approximately 300 genes that were significantly different in the overall methylation profiles of non-maturing AVFs at 6 months as compared to AVFs that were able to support dialysis.

Conclusions: Our results suggest that epigenetic regulation (DNA methylation) could play an important role in AVF maturation, and also in the identification of novel druggable targets. This latter point could result in the development of novel therapies for dialysis vascular access dysfunction as a whole.

Development of a Uremic Pig Model of Arteriovenous Fistula Stenosis (AVF): A Surgical Approach

PUB487

Background: AVF stenosis remains an important cause of hemodialysis vascular access dysfunction for which there are no truly effective therapies. We and others have previously described well characterized large animal models of AVF stenosis. An important flaw in these models is the lack of uremia, which has increasingly been shown to play an important role in the pathogenesis of AVF stenosis.

Methods: Chronic renal insufficiency was created by initially removing one of the kidneys through a midline incision. Following this the contralateral kidney underwent a dissection of the renal pelvis in order to expose the primary, secondary and if possible tertiary branches of the renal vasculature. A selective ligation of the renal vasculature in the pelvis, and
which allowed for the viability of less than 20% of the renal mass on one side was then performed (upper figure = a, b and c). Of note the differential blanching/mottling of the kidney following ligature of vessels in the renal pelvis, allows us to perform a real time assessment in terms of the amount of viable renal tissue. BUN and creatinine estimations were then made biweekly for 6 weeks.

Results: The described surgical technique has allowed us to achieve a stable creatinine of 4 mg/dL over a four week period (lower figure = d). This stable period of uremia will allow us test out the impact of “downstream uremic vascular biology” on AVF maturation.

Conclusions: We developed a unique, innovative and surgically created pig model of uremia with potential logistic and financial benefits. The availability of this animal model will put us in a unique position to be able to tease out the relative contributions of hemodynamics and uremia to AVF stenosis both in our experimental pig model and also in CKD and ESRD patients.

PUB490
Cardiac Implantable Electronic Device Infection and Ipsilateral Arteriovenous Fistula in End Stage Renal Disease: Avoidance and Management of Complications
Stephanie Lanoisele,1 François Babintz,1 Guillaume Serret,1 Helen Loubiere,2 Achour Laradi.1
1Centre Hospitalier Universitaire Néphrologie Dialyse, Le Mans, France; 2Chirurgie Vasculaire, CH Le Mans, Le Mans, France.

Background: Cardiac implantable electronic devices (CIEDs) are frequently utilized for management of cardiac dysrhythmias in patients(pts) with End Stage Renal disease (ESRD) and are associated with central venous stenosis resulting in adverse effects for existing or future arteriovenous fistula (AVF) with an increase risk of infection of both (CIEDs and AVF). We report the case of a pt with ESRD who experienced a potentially life-threatening complication related to his ipsilateral AVF and CIEDs.

Methods: We report the case of a 80 years-old male pt who developed a symptomatic unilateral left arm edema with skin lesions.He has past history of CIEDs four years ago and the ipsilateral implementation of an AVF 2 years after the CIEDs.He experienced 3 angioplasties on his AVF and a repeated surgery with a persistant post-anastomotic anastomosis with flow reduction of 180 ml/min.A left side chest blood collateral circulation was also present.A deep venous thrombosis related to the implementation of CIEDs was investigated and a left subclavian venous thrombosis was confirmed.On the meantime infection of the CIEDs was suspected but not confirmed. An attempt of a venous recanalization was unsuccessful.A closure of AVF with a plug of 14mm diameter leading to a complete occlusion of AVF.

Results: After the occlusion of AVF we noticed a complete regression of the huge left arm edema and skin lesion of the pt. The pt underwent antibiotics therapy for life for the CIED infections with successful results two years after initiation of treatment.

Conclusions: Although the CIEDs can provide life-savings benefits, device associated complications needs careful management and should be placed by the epidural approach as a first option for pts with ESRD.It remind us that the AVF is still the Achilles’ heel of dialysis.

WeeklyBeta2 Microglobulin (B2M) Kt/V, Residual Renal Function and Middle Molecule Levels in Daily Dialysis
Christos Argyropoulos, Maria-Eleni Roumeliotis, Mark L. Urnur. Internal Medicine, Div of Nephrology, UMN-HSC, Albuquerque, NM.

Background: B2M and residual renal function (RRF) are predictors of cardiovascular morbidity, mortality and LVIH in ESRD. Daily dialysis leads to higher B2M removal and has been associated with improvements in LVIH and mortality in randomized trials. It is not known whether kinetic measures of middle molecule adequacy are applicable to daily dialysis.

Methods: We adopted a population kinetic model (PKM) for the intradividual variability in generation, distribution and extraremal removal of B2M (ASN 2014,SA-P0969). We used the PKM to simulate B2M concentrations in 10000 patients dialyzed with HF membranes. We examined the intervention protocols for Short (SD), Long Daily (LD) and three weekly HD dialysis utilized in the FHN trials. Weekly B2M Kt/V was calculated as the sum of the Kt/V in each session. The impact of Kt/V relative to residual renal function (RRF) on B2M was examined across the three dialysis modalities averaging over the intra-individual variability of kinetic parameters and dialysis prescription.

Results: B2M was lower in SD and LD relative to HF irrespective of RRF. Given the variability in dialysis prescriptions there was a substantial overlap in the average Kt/V values between HF and SD.
There was a steep relationship between weekly Kt/V and B2M in all three modalities. The steepness of this relationship was similar between HD and SD across RRF values, but differed for RRF > 4 ml/min in HD. At any given level of Kt/V the B2M level depended on RRF and dialysis modality.

**Conclusions:** Weekly B2M Kt/V, a simple measure of middle molecule dialysis adequacy, tracks middle molecule exposure in conventional and daily dialysis. The interpretation of a given Kt/V value requires knowledge of RRF in all dialysis modalities. Future studies should determine whether RRF, diastolic Kt/V or both are predictors of survival in daily dialysis.

A Test Battery to Establish Changes in Physical Performance and Protein Energy Wasting in Nocturnal Hemodialysis: The DiapriFIT Study

**Manouk Dam,**1 Floor Neeleman,1 Caroline E. Douma,2 Brigit C. van Jaarsveld,2

1Nutrition and Dietetics, VU Univ Medical Center, Amsterdam, Netherlands;
2Nephrology, VU Univ Medical Center, Amsterdam, Netherlands;

*Background:* Nocturnal hemodialysis (NHD) improves volume control and phosphate and middle molecule removal. Observational data show increases in body weight and protein intake upon switching to NHD. Other aspects of protein energy wasting (PEW) remain underexposed and also little is known about functional outcomes, such as physical performance and muscle strength. Therefore, the aim of this study is to investigate whether physical performance improves and PEW decreases in patients who change from conventional hemodialysis (CHD) to NHD, compared to patients who continue their treatment on CHD.

**Methods:** The DiapriFIT study plans to include 25 patients on CHD (2-4x wk, 3-4 hours) and 25 patients on CHD who switch to NHD (3-4x wk, 8 hours) with 1-year physical performance and PEW as endpoints. They were submitted to a Visual Appetite Score (VAS), Handgrip Strength (HGS), upper arm circumference (UAC), Short Physical Performance Battery (SPPB) and 6 minute walk test (6MWT), baseline results are reported here. As in NHD weight increases, we tested associations of the outcome parameters with dry weight.

**Results:** At present, 23 patients were included, aged 58.3±16.0 years, 30.4% males, with a dry weight of 87.6±17.2 in males and 74.3±17.2 in females. Mean VAS was 7.3±2.3, HGS 22.7±5.6 cm, UAC 31.9±5.6 cm, SPPB 8.0±1.9 and 6MWT 576±328 meters. Only HGS and UAC were correlated with HD dry weight (r 0.43, p<0.05 for HGS, r 0.79, HGS 22.7 NHD weight increases, we tested associations of the outcome parameters with dry weight.

**Conclusion:** Nocturnal hemodialysis improves volume control and phosphate and middle molecule removal. Observational data show increases in body weight and protein intake upon switching to NHD. Other aspects of protein energy wasting (PEW) remain underexposed and also little is known about functional outcomes, such as physical performance and muscle strength. Therefore, the aim of this study is to investigate whether physical performance improves and PEW decreases in patients who change from conventional hemodialysis (CHD) to NHD, compared to patients who continue their treatment on CHD.

Do KCNQ1 Channels Contribute to Control of Arterial Vascular Tone?

Dmitry Tsytovskiy,1 Ian Chen,2 Mario Kassmann,1 Jean-Yves Tanou,1 Johanna Schliebenbaum,1 Jakob Völk,1 Florian C. Lang,1 Yu Huang,2 Maik Gollasch,2

1Experimental and Clinical Research Center (ECRC), a Joint Cooperation between the Charité Medical Faculty and the Max Delbrück Center for Molecular Medicine (MDC), Berlin, Germany; 2Xiamen Zhongshan Hospital, Xiamen Univ, Xiamen, Fujian Province, China; 3Dept of Physiology, Univ of Tübingen, Tübingen, Germany; 4School of Biomedical Sciences, Lo Kwee-Seong Integrated Biomedical Sciences Building, Area 39, Chinese Univ of Hong Kong, Hong Kong, Hong Kong.

**Background:** Recent data suggest that the KCNQ family of voltage activated K- (K7) channels represents a new therapeutic target in cardiovascular disease. We used KCNQ1-/- mice to determine whether KCNQ1 (K7.1) play a role in the regulation of arterial tone.

**Methods:** Wire-myography, pharmacology approach and patch-clamp techniques were used.

**Results:** We found that R-L3 produces similar concentration-dependent relaxations (EC50=1–1.4 µM in wild-type (KCNQ1+/+) and KCNQ1-/- arteries pre-contracted with either phentolamine or 60 nM KCl. This relaxation was not affected by 10 µM chroomanol-B293, 10 µM HMR1556, 30 µM XE991 or 500 µM 4-aminoypyridine. Chromanol-B293 and HMR1556 did not affect the anti-contractile effects of perivascular adipose tissue (PVAT). The anti-contractile effects of PVAT were normal in KCNQ1-/- arteries. Whole-cell recordings showed normal peak K currents, capacity and their blockade by XE991 in KCNQ1-/- VSMCs. The pan KCNQ2-5 opener sperubigatine lead to a similar relaxations in KCNQ1-/- and wild-type vessels.

**Conclusion:** We conclude that KCNQ1 channels are apparently not involved in the control of arterial tone by alpha, adrenergic vasoconstrictors and PVAT. R-L3 is an appropriate pharmacological tool for studying the function of native vascular KCNQ1 channels in mice.

The Role of Renal AT1 Receptor-Associated Protein in Salt-Sensitive Blood Pressure Regulation

Hirochika Waku,1 Kouichi Tamura,1 Ryu Kobayashi,1 Kazuushi Uneda,1 Masato Ohawa,1 Toru Dejima,1 Akinobu Maeda,1 Yoshiyuki Toya,1 Kotaro Haruhara,2 Satoshi Umemura,1

1The Dept of Medical Science and Cardiovascular Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Japan; 2Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan.

**Background:** The intrarenal renin-angiotensin system plays a role in the regulation of renal hemodynamics and the maintenance of water electrolyte balance, and is also involved in the pathophysiology of hypertension and target organ damages. We previously identified an angiotensin II type 1 receptor-associated protein (ATRAP), which interacts with the C-terminal domain of angiotensin II type 1 receptor (AT1R) and attenuates AT1R-mediated pathological responses. The present study was designed to investigate the putative functional role of ATRAP in the blood pressure regulation by high salt loading in vivo.

**Methods:** We generated transgenic mice expressing ATRAP dominantly on renal tubules on a C57BL/6J background. Renal ATRAP transgenic mice and their wild-type littermate mice on a normal salt diet at baseline were subjected to dietary high salt loading for 7 days. **Results:** In renal ATRAP transgenic mice, the development of high blood pressure in response to high salt loading was suppressed, concomitant with a significant increase in urinary sodium excretion, as compared to wild-type mice.

**Conclusions:** These results demonstrate that renal tubule dominant overexpression of ATRAP suppresses the salt-sensitive blood pressure elevation provoked by high salt loading, thereby suggesting ATRAP to be an interesting target in hypertension.

Carboneic Anhydrase II Inactivation Confers Salt Appetite and Elicits Salt Sensitive Hypertension

Mujan Varashet kia,1 Sharon L. Barone,1 Saed Alishahrami,1 Marybeth Brooks,1 Kamary A. Zahedi,1,2 Jie Xu,1 Manoocher Soleimani.1,2

Background: Salt appetite or salt intake in excess of physiological needs is a major health problem and a risk factor in the pathogenesis of hypertension, which consequently can lead to heart disease and stroke. Few genetic factors are implicated in the pathogenesis of salt appetite.

Methods: Wild-type and CAII null mice were given a choice of regular water or 140mM NaCl dissolved in their drinking water. Balance studies were performed and blood pressure was measured via the CODA tail cuff system. Western blots and Northern Hybridizations were performed.

Results: Our results indicate that CAII null mice display significant salt appetite as judged by their preference for salted water (140mM NaCl) over regular water, when both options are provided. In age and gender matched mice (n=4 per each group, daily salted intake was 2.89 ml in WT vs. 7.51 ml in CAII null mice, while daily regular water intake was 5.05 ml in WT and 3.6 ml in CAII null mice. Kidney renin expression and blood creatinine concentration were comparable in WT and CAII null mice. When given only salted water, CAII null animals showed a robust increase in their daily salt intake (12.21ml in CAII null vs. 7.80ml in WT mice) and urine volume (4.6/2ml/day in CAII null vs. 2.62ml/day in WT mice). Expression of sodium and water absorbing channels, ENaC and AQ2-2, increased by 100 to 200% in both cortex and medulla in CAII null vs. WT mice in response to salt intake for 10 days. Consequently, CAII null mice developed hypertension (systolic BP of 155 +/- 3.9 in CAII null vs. 138 +/- 3.2 in WT, p<0.003).

The protein expression levels of ENaC in taste buds were not different between the two WT mice in response to salt intake for 10 days. Consequently, CAII null mice developed only salted water, CAII null animals showed a robust increase in their daily salt intake was 5.05 ml in WT and 3.6 ml in CAII null mice. Kidney renin expression and blood creatinine concentration were comparable in WT and CAII null mice. When given only salted water, CAII null animals showed a robust increase in their daily salt intake (12.21ml in CAII null vs. 7.80ml in WT mice) and urine volume (4.6/2ml/day in CAII null vs. 2.62ml/day in WT mice). Expression of sodium and water absorbing channels, ENaC and AQ2-2, increased by 100 to 200% in both cortex and medulla in CAII null vs. WT mice in response to salt intake for 10 days. Consequently, CAII null mice developed hypertension (systolic BP of 155 +/- 3.9 in CAII null vs. 138 +/- 3.2 in WT, p<0.003).

Conclusions: We propose that CAII plays an important role in regulating salt intake and its inactivation can cause salt appetite, specifically in male animals, and provoke salt sensitive hypertension.

PUB497
Ambulatory Blood Pressure in Chronic Kidney Disease: An International Collaborative Study

Paul E. Drazner,1 Luca De Nicola,2 Naihoko Fuji,3 Francis B. Gabbai,4 Jennifer J. Gassman,5 Luis M. Ruilope,6 Robert Minutolo,7 A. Phillips,8 Luis M. Ruiulope,9 Raymon D. Townsend,9 Mahboob Rahman,6 1Div of Renal Diseases & Hypertension, Univ of Minnesota; 2Italian Cohort; 3CKD-JAC; 4AASK; 5Spanish Cohort; 6CRIC.

Background: In chronic kidney disease (CKD), ambulatory blood pressure (BP) is a better measure of hypertension related risk for cardiovascular disease and ESRD than clinic BP. The International Ambulatory Blood Pressure in Chronic Kidney Disease Collaborative Group is a collaboration among investigators from different countries interested in ambulatory BP in patients with CKD. The main aims of the research facilitated by this collaboration will be to evaluate: 1) the clinical and demographic characteristics associated with elevated ambulatory BP, 2) the prognostic role of ambulatory BP on cardiovascular and renal outcomes, and 3) ethnic and geographic differences in these associations.

Methods: This group will establish a large database derived from individual databases in the various countries to allow for powerful individual participant data meta-analyses of the relationship between clinical and demographic characteristics, CKD severity, ambulatory BP, and clinical outcomes.

Results: Investigators from 5 cohort studies have already agreed to participate.

Conclusions: This multi-national collaboration will provide greater insights than possible from within-country analyses into the etiology and consequences of high risk ambulatory BP profiles. This information will be instrumental in helping us design prospective international large scale multicenter trials aimed at reducing renal and cardiovascular events in patients with CKD.

PUB498
Clinical Study of Pregnancy Related Kidney Injury Yumei Liu,1 Ying Fan,2 Yang Fei,1 Hongda Bao,3 Yajuan Huang,3 Niansong Wang.1 1Nephrology and Rhenumatology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China; 2Obstetrics and Gynecology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China.

Background: The diagnosis and treatment of pregnancy related kidney injury is a complicated clinical problem for obstetricians and nephrologists. However, information regarding this topic in China is insufficient.

Methods: Totally 18589 women hospitalized between August 2004 and January 2013 from Obstetric and Nephrology Department in Shanghai Jiao Tong University Affiliated Sixth People's Hospital were screened. 569 women were enrolled for the pregnancy related kidney injury, including 494 cases from 2008 to 2013 and 75 cases from 2004 to 2007. The inclusive criteria was women with a history of kidney disease or Scr >= 70mmol/L or proteinuria >= 0.3g/24hour before the termination of pregnancy, or the diagnosis of kidney disease made during or after 6-month delivery.

Results: The prevalence of pregnancy related kidney injury was 3.1%. The incidence of kidney injury caused by obstetric disease was 3.1%, with the most common reason for pre-eclampsia (88.9%). The incidence of chronic kidney disease women with pregnancy is 0.74%, with the most common reason for chronic glomerular nephritis (36.2%). The incidence of kidney disease onset related to pregnancy was 1.5%. The incidence of proceeding to end stage renal disease for pregnancy was 0.21%. Kidney injury in pregnant women with obstetric disease may be more severe than that in pregnant women with kidney disease (with higher maternal blood pressure and proteinuria, lower birth weight and higher proportion of pre-term babies, P<0.05). Most women with pregnancy related kidney injury underwent cesarean section (<60%). Their proportion of stillbirth, pre-term and low birth weight babies were higher than healthy parturient, and the proportion of follow-up was low (9.9%). Neonatal death rate was 0.63% and pare-natal death rate was 2.1% in all.

Conclusions: Prevalence of pregnancy related kidney injury increases due to the foundation of Shanghai First-Aid Center for High-risk Pregnant Women in 2007. Serum creatinine, proteinuria and blood pressure have different indication for maternal condition and pregnancy outcome.

PUB499
A New Vasculo-Renal Marker Enhances Accuracy of Hypertensive Nephropathy Recognition Arkadiusz Lubasz,1 Robert Ryzez,2 Grzegorz Kade,3 Stanislaw Niemczyk,1 1Dept of Internal Diseases, Nephrology and Dialysis, Military Inst of Medicine, Warsaw, Poland; 2Dept of Cardiology, Military Inst of Medicine, Warsaw, Poland.

Background: Latent and slow beginning of chronic kidney disease (CKD) coexisting with well tolerated, usually not recognized previously hypertension makes difficult to recognize hypertensive nephropathy (HN) from CKD of other origins. The aim of the study was to investigate the best marker helpful in differentiating HN from other causes of CKD.

Methods: Forty patients (4; 36 M; age 52.7 ±14.5) with stable CKD (CKD-EPI 53.1 ±27.6 ml/min/1.73m2 and a history of hypertension (26 with HN) were enrolled in the study. Serum Creatinine (Cre), Cystatin C (Cys), NT-pro brain natriuretic peptide (NTProBNP), Troponin I (TNI) and urinary albumin to creatinine ratio (UACR) were tested. Renal function was estimated according to Cre and Cys based CKD-EPI formula. Echocardiographic examination, carotid Intima-Media Thickness (IMT), ABPM, Renal Resistive Index (RRI) were performed. Vasculo-Renal Index (VRI) was calculated as IMT to UACR ratio.

Results: Groups with HN and CKD of other origins did not differ in renal function (CKD-EPI 46,2 vs 57,1 ml/min/1,73m2; P=0,22), NTProBNP, TNI, intimal medial (LV) ejection fraction, LV mass index and mean arterial pressure. Patients with HN were older (56,4 ±15,1 vs 45,9 ±14,1; p =0,039), had lower UACR (0,264 ±0,48 vs 0,814 ±0,564 mg/mg; p<0,001), but higher IMT (0,588 ±0,217 vs 0,652 ±0,380; p=0,009) and VRI (m. 28,8 [0,36; 1030,00] vs m. 0,78 [0,34; 12,50] p<0,0001). In ROC analysis VRI ≥ 1,91, UACR ≤ 0,199, and IMT ≥ 0,87 could recognize HN with sensitivity of 85%, 73% and 62% respectively, specificity of 79%, 93% and 86% and accuracy of 82.5%, 80% and 70% (AUC 0,874, 0,849 and 0,749; p<0,05).

Conclusions: A new Vasculo-Renal Index recognizes HN more accurately, but UACR and IMT are not significantly worse.

Funding: Government Support - Non-U.S.
Background: In patients with chronic kidney disease (CKD), impaired urinary sodium excretion (UNa) may cause nocturnal hypertension and pressure natriuresis to compensate for daytime sodium retention. The aim of this study was to determine the renal histological lesions which associated with nocturnal blood pressure (BP) and UNa in patients with CKD.

Methods: We analyzed 64 patients biopsyed in our institutions from Sep 2010 to Apr 2014 (Forty IgA nephropathy, 6 Purpura nephritis, 4 membranous nephropathy and 14 the others). During the same hospitalization period of renal biopsy, ambulatory BP monitoring and evaluation of UNa were performed simultaneously. The association of histological findings such as global sclerosis (%GS), arteriolar hyalinosis (%hyaline), and interstitial fibrosis (IF), with nocturnal BP and night/day ratio of UNa were assessed using linear regression analysis.

Results: Twenty three patients were male, mean age was 40.5 ± 15.9 years, and mean estimated glomerular filtration rate (eGFR) was 79.0 ± 28.9 mL/min/1.73m². Both nocturnal BP and night/day ratio of UNa positively associated with %GS, %hyaline, and IF, and negatively associated with eGFR. Multiple regression analysis adjusted for age, sex, eGFR, and usage of antihypertensive drugs showed that %GS was significantly associated with nocturnal systolic BP (β = 0.38, p = 0.012), nocturnal diastolic BP (β = 0.34, p = 0.031) and night/day ratio of UNa (β = 0.52, p = 0.005).

Conclusions: We found that night/day ratio of UNa and nocturnal BP closely related to the percentage of global sclerosis. These findings could be the morphological evidence that elevated night/day ratio of UNa may indicate the increase in glomerular hypoperfusion to compensate for daytime sodium retention resulting in elevation of nocturnal BP in patients with CKD.

**Conclusions:** This meta-analysis suggests that the bedtime dosing regimen drug therapy benefits CKD patients in terms of hypertension especially those with non-dipper BP pattern.

**Funding:** Government Support - Non-U.S.

**The Impact of Glomerular Collapse in Hypertensive Emergency Patients**

Takafumi Yamakawa, Toshiyuki Imasawa, Takeliko Kawaguchi, Mao Watanabe, Maiko Nagata, Hiroki Kitamura. Dept of Internal Medicine, National Hospital Organization Chiba East Hospital, Chiba City, Japan.

Background: The prognosis of kidney disease with hypertensive emergency (malignant glomerulonephrosis) is still worse compared with benign nephrosclerosis. Here, further to assess the reasons of worse prognosis and to reconsider more appropriate therapy for malignant nephrosclerosis, we compared pathological parameters between malignant and benign nephrosclerosis.

Methods: 8 patients diagnosed as hypertensive emergency with acute renal failure were performed renal biopsies from October 2005 to May 2015. We selected all patients with the benign nephrosclerosis (n=8), who were performed renal biopsies during same period, as controls. We compared changes in clinical and pathological data using the paired t-test and the Mann-Whitney U-test.

Results: All 8 patients with hypertensive emergency had characteristic pathological changes of malignant hypertension, such as fibronoid necrosis, onion-skin thickening and edematous-appearing matrix in arteries. These changes were never observed in benign nephrosclerosis. The rates of global sclerosis and segmental sclerosis had no statistical differences between these two groups. Interestingly, when glomerular collapsing rate was counted by GCR (number of glomerular collapse/ total number of glomeruli), GCR scores were much higher in hypertensive emergency cases compared with those in benign nephrosclerosis cases (42.9 ± 23.8 % vs. 6.5 ± 7.4 %; p < 0.05). These patient's clinical characteristics showed a high level of plasma renin activity (PRA) (14.9 ± 5.8 ng/ml/1h) and low aldosterone (3.5 ± 2.8). Two of 8 patients reached to end stage kidney disease requiring dialysis.

Conclusions: Glomerular collapse and hyper-renin mean glomerular hyperperfusion. Therefore, if therapy accelerate this glomerular hyperperfusion, it might affect renal prognosis. We should reconsider the way of therapy, such as the selection of anti-hypertensive drugs, and the speed of declining blood pressure and volume control by thinking glomerular hyperperfusion.

**PUB504**

A Study of Early Treatment with Benazepril in SHR at Different Doses

Qiong-li Wang, Mei Li, Cheng-gang Shi. 1VIP Healthcare Center, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China; 2Nephrology Dept, The Third Affiliated Hospital of Sun Yat-sen Univ; Guangzhou, China.

Background: To investigate whether early treatment with super high dosage ACEI can reverse glomerulonephrosis in SHR.

Methods: 30 SHRs were randomized and divided into three groups (n=10): model control group (SHR), 10 mg·kg⁻¹·d⁻¹ Benazepril treatment (HT group), 50 mg·kg⁻¹·d⁻¹ Benazepril treatment (SHT group), 10 Wistar-Kyoto rats were studied as normal control group (N group), placebo , 10 mg·kg⁻¹·d⁻¹ Benazepril and 50 mg·kg⁻¹·d⁻¹ Benazepril were given through intragastric administration starting from 0 week of the experiment, rats were killed until 12 week of the experiment. Blood pressure(Bp), 24 hours urinary protein(24hUpr) and serum creatinine(Scr) were detected in the 0, 4, 8, 12 week of the experiment. Renal pathology damage was evaluated with paraffin wax section of kidney tissue through HE, MASSON stain; the protein levels for TGF-b1 and PAI-1 were tested through immunohistochemical staining method.

Results: Compared with model control group, Bp, 24hUpr of HT and SHT groups decreased obviously (P<0.05), the protein levels for TGF-b1 and PAI-1 in kidney tissue of HT group and SHT group were inhibited(P<0.05), glomerular collagen deposition of HT group and SHT group reduced evidently (P<0.05).

**Conclusions:** This meta-analysis suggests that the bedtime dosing regimen drug therapy benefits CKD patients in terms of hypertension especially those with non-dipper BP pattern.
Conclusions: This study shows that high dosage ACEI and super high dosage ACEI all can decrease blood pressure, reduce proteinuria, depress the expressions of TGF-β and PAI-1 protein in SHR, and delay glomerulosclerosis. But super high dosage ACEI can not reverse glomerulosclerosis in SHR.

PUB505

Background: Scleroderma renal crisis (SRC) is a rare cause of atypical hemolytic uremic syndrome (aHUS) and differentiating it from other causes of thrombotic microangiopathies can be challenging. A 53-year old Caucasian male, with no past medical history was found unresponsive. BP was elevated to 207/141 mm Hg. Skin examination showed diffuse telangiectasia and edema of his extremities with bilateral sclerodactyly (Figure 1). Fundoscopy revealed bilateral retinal hemorrhage and exudates. Labs showed a hemoglobin=5gm/dl, platelet=25×10⁹/μl, creatinine=6mg/dl, LDH=11221U/L, bilirubin=1-6mg/dl, haptoglobin<5%, reticulocyte count=10.4% and schistocytes. ANA and anti-RNA Polymerase III antibody were positive (C3 and C4, coagulation profile, fibrinogen were normal; Coombs negative). CT head showed severe microvascular changes throughout the white matter of the cerebrum and MRI showed evidence of punctuate chronic micro-hemorrhages in the left thalamus and cerebellar tonsils. The presence of MAH, acute renal failure and thrombocytopenia raised suspicion for possible aHUS/TPP. Serum ADAMTS13 was ordered. Because of the possibility of SRC, the patient was started on captopril. A dramatic improvement in BP, hemoglobin and platelets count along with the normalization of LDH and schistocytosis disappearance was observed. However, there was no improvement in kidney function requiring hemodialysis. ADAMTS13 activity returned at 40% (cut-off for TTP is <5%). Patient did not pursue eculizumab therapy. A significant portion of patients with Scleroderma can develop aHUS. In this case, hypertension might have served as a complement amplifying condition.

Methods: Clinical presentation/course of the patient.

Results: Despite therapy with ACE inhibitors patient ended up on RRT.

Conclusions: Patient presenting with Malignant HTN and MAH was found to be in scleroderma crisis.

PUB506

Background: Only a few studies with a very limited sample size have evaluated the impact of neck irradiation on baroreflex failure and blood pressure (BP) abnormalities. We investigated 60-patients, with head/neck cancer, who received neck irradiation between 2005 to 2010. IRB approval was obtained. Median for age was 61.5 years (range 24-90 years). We used the same cohort of patients, before the received neck irradiation as a control for BP. Mean systolic BP before neck irradiation was 129.1±1.802 mm Hg. Skin examination showed diffuse telangiectasia and edema of his extremities with bilateral sclerodactyly (Figure 1). Fundoscopy revealed bilateral retinal hemorrhage and exudates. Labs showed a hemoglobin=5gm/dl, platelet=25×10⁹/μl, creatinine=6mg/dl, LDH=11221U/L, bilirubin=1-6mg/dl, haptoglobin<5%, reticulocyte count=10.4% and schistocytes. ANA and anti-RNA Polymerase III antibody were positive (C3 and C4, coagulation profile, fibrinogen were normal; Coombs negative). CT head showed severe microvascular changes throughout the white matter of the cerebrum and MRI showed evidence of punctuate chronic micro-hemorrhages in the left thalamus and cerebellar tonsils. The presence of MAH, acute renal failure and thrombocytopenia raised suspicion for possible aHUS/TPP. Serum ADAMTS13 was ordered. Because of the possibility of SRC, the patient was started on captopril. Sympathetic Nervous System Activity Reflected by Renalase and Catecholamines in Different Aged Patients with and without Chronic Kidney Disease Edrya Zbolski, Dominika Maciorkowska, Ewa Koc-Zorawska, Jolanta Czarnecka, 1Department of Nephrology and Hypertension with Dialysis Centre, Medical Univ, Bialystok, Poland; 21st Dept of Nephrology and Transplantation, Medical Univ, Bialystok, Poland.

Background: Sympathetic nervous system activity is elevated in patients with chronic kidney disease (CKD) as well as in older persons. It contributes to hypertension and cardiovascular diseases. It is due to a reduction of catecholamines clearance and in elderly also to an increased sympathetic discharge from different organs. Renalase may play a role in the renin-angiotensin-aldosterone system. The aim of the study was to assess the sympathetic nervous system activity, according to serum renalase and catecholamines concentration in a cohort of 211 patients with hypertension and with or without chronic kidney disease.

Methods: The study group was divided according to age below and above 65 years. The older persons (61) was also divided into group with (75%) and without CKD stage 5. The serum renalase, dopamine and noradrenaline concentration as well as pressure control, residual renal function rate and echocardiography were assessed.

Results: The older group had higher renalase (p=0.02) and dopamine (p=0.001) concentration and it was elevated in patients with CKD comparing to those without. They also had advanced abnormalities in echocardiography, like thicker interventricular septum (p=0.03) and lower ejection fraction (p=0.001) as well as CKD patients comparing to those without CKD – pronounced left ventricular hypertrophy (p=0.007) and lower ejection fraction (p=0.004). They more often suffered from coronary artery disease. The residual renal function was less in older patients with CKD. The main used hypotensive drugs in studied group were beta-blockers. There was the significant correlation between age and renalase, noradrenaline and dopamine concentration.

Conclusions: The advanced age especially combined with chronic kidney disease is associated with elevated renalase and dopamine level. It may reflect the sympathetic nervous system hyperactivity due to impaired kidney function and reduction of residual diuresis. It may have an impact on the development of cardiovascular complications.

PUB508

Heart Rate Variabilities During Day and Night Can Alter the Circadian Blood Pressure (BP) Rhythm Toshiyuki Miura,1 Michio Fukuda,1 Yoshiaki Ogyama,1 Ken Kiyono,3 Yoshiharu Yamamoto,1 Junichiro Hayano,1 Nobuyuki Ohite,1 Nagoya City Univ, Japan; Osaka Univ, Japan; Toyo Univ, Japan.

Background: We previously reported in patients with chronic kidney disease (CKD) that the circadian rhythms of BP and urinary sodium excretion (UnV) were both impaired into non-dipper pattern as renal function deteriorated. Elevated salt-sensitivity of BP and inappropriate activation of the renin-angiotensin-aldosterone system and the sympathetic nervous system play important roles in high BP and the high incidence of cardiovascular diseases in patients with CKD.

Methods: In 39 patients with CKD, we analyzed HRV in 24-h electrocardiography, BP monitoring and urine collection, separately for daytime and nighttime. Patients, who took antihypertensive agents, were excluded. We evaluated the relationship between systolic blood pressure (SBP) and UnV. The Non-Gaussianity index of HRV(UnV), which reflects the probability of intermittent large deviations of heart rate (HR) from the trend, and the power of high frequency (HF, 0.15-0.40 Hz) obtained by frequency domain analysis of HRV was used as a marker of sympathetic cardiac overdrive, and as vagal nerve activity, respectively.

Results: As renal function deteriorated, 24h-β and daytime β increased. 24h-SBP showed significant relationships with daytime (r=0.40, p<0.01) and night-time (r=0.37, p=0.02). Night/day ratios of SBP and UnV were also elevated as GFR was reduced. Night/day ratios of SBP correlated inversely with night-time HR(r=−0.36, p=0.02). When analyzed by stepwise multiple regression analysis, the main determinants of 24h-SBP were 24h-UnV, daytime β, and night-time HR. Night/day SBP ratios was determined by night/day ratio of UnV, rather than any HRs.

Conclusions: Our study clearly demonstrated that as renal function deteriorated, sympathetic nerve activity is activated during the day, and vagal activation was impaired during the night, both of which can contributes to high BP in patients with CKD. However, the increase type of circadian BP rhythm was associated with the circadian UnV rhythm rather than sympathetic or vagal nerve activity, even though the sympathetic activity can stimulate tubular sodium reabsorption.

PUB509

The Effects of the Insight Meditation Practice on Blood Pressure Reduction in Buddhist Exemplary People Tutamas Varesangthip,1 Kriengsak Varesangthip,2 1Dhamma Communication Div, Graduate School, Mahachulalongkornrajavidyalaya Univ, Bangkok, Thailand; 2Renal Div, Dept of Medicine, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand.

Background: Hypertension (HTN) is a leading risk factor for preventable cardiovascular disease, with over one in five adults affected worldwide. Lifestyle modification is the key strategy for the prevention and treatment of HTN. It is often associated with greater cardiovascular risk, and stress management is a recommended intervention for hyperventilators. For many patients, maximal medical therapy is insufficient

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

1005A
to adequately treat refractory hypertension. Lifestyle modification remains an important approach in management. Buddhist meditation encompasses a variety of meditation techniques that aim to develop mindfulness, concentration and insight.

**Methods:** We aimed to study whether Buddhist Insight Meditation (IM) Practice, composing of Walking Meditation and Sitting Meditation, could reduce the level of blood pressure in Buddhist Exemplary People. 65 exemplary people were divided into 3 groups according to the schedule they performed IM Practice. Group 1 (n = 25) performed 30 minutes of the Walking and 30 minutes of the Sitting Meditation, group 2 (n = 20) performed 45 minutes in each Meditation and group 3 (n = 20) performed 60 minutes in each Meditation. Their blood pressures (BP), pulse pressures (PP) and pulses (P) were measured before and after Walking and Sitting Meditations.

**Results:** The results clearly showed that systolic BP, PP and P were significantly decreased after the Walking Meditation at 30-45-60 minutes. After IM Practice schedule, an artesunate-elad has significantly been decreased in all 3 groups, PP has been significantly decreased in group 2 and systolic BP has been significantly reduced in group 3.

**Conclusions:** In conclusion, the Buddhist IM Practice could meaningfully reduce the sympathetic activities including systolic BP, PP and P. Therefore, this Buddhist Practice should be added to be one modality of the standard hypertensive treatments.

**ENA as a Novel Mechanism for Hypertension and Volume Expansion in Type 2 Diabetes**

**Mark L. Unruh,** V. Shane Pankratz,1 Evan C. Ray,1 Rebecca P. Hughey, Thomas R. Kleyman.2 Div of Nephrology, Univ of New Mexico. 2Renal-Endolyte Div, UPMC.

**Background:** Renal Na retention and extracellular fluid volume expansion are hallmarks of type 2 diabetes. There is evidence that this occurs even in the absence of activation of hormones that are known to stimulate renal Na transporters. Recent studies suggest that plasmnin-dependent activation of ENaC may be responsible for renal Na retention in the setting of nphropathy. We hypothesized that the ENaC inhibitor amiloride would be an effective therapeutic agent in inducing a natriuresis and lowering blood pressure in individuals with macroscopic proteinuria.

**Methods:** We conducted a pilot double-blind randomized cross-over study comparing the effects of daily administration of either oral amiloride (10 mg/day) or HCTZ (Na,Cl co-transporter inhibitor) to patients with type 2 diabetes and macroscopic proteinuria. We examined safety and feasibility of amiloride by monitoring kidney function, adherence, blood pressure, weight, urinary Na excretion and serum electrolytes during diuretic administration.

**Results:** 9 subjects were enrolled in the trial. Systolic blood pressure (SBP) decreased in both treatment groups, but there was not a significant difference between HCTZ and amiloride (P = 0.53). Amiloride treatment was associated with a 1.1 ± 0.4 kg decline in weight (P = 0.02), and a 0.70 ± 0.18 mmol/L greater increase in serum potassium (P = 0.002) over the low dose portion of the study. 2 subjects developed acute kidney injury and hyperkalemia when treated with amiloride. 5 subjects had readily detectable levels of urinary plasmninogen/plasmin, and 4 did not. Among those receiving amiloride, the low plasmin group experienced a change of 1.1±4.6 mmol/L in SBP and the high plasmin group experienced a change of -13.9±8.7 mmol/L, although there was insufficient evidence to conclude that there were differential treatment effects by high/low plasmninogin status (P = 0.113).

**Conclusions:** Among patients with type 2 diabetes, normal renal function, and proteinuria, there was suggestion of increased naturalis for those treated with amiloride vs. HCTZ, however, acute kidney injury severe hyperkalemia was a safety concern.

**Serum Phosphorus Control and Reduced Phosphate Binder Pill Burden Among Hemodialysis Patients Who Switched from Sevelamer to Sucroferric Oxyhydroxide**

Vidhya Parameswaran, Lin Ma, Linda H. Ficociello, Claudiy Mullon, Franklin W. Maddux, Robert J. Kossman. Fresenius Medical Care North America, Waltham, MA.

**Background:** Clinical management of hyperphosphatemia among hemodialysis (HD) patients (pts) can present challenges. A retrospective database analysis was conducted to study the effectiveness of sucroferric oxyhydroxide (SO) among in-center HD pts who switched from sevelamer to SO as part of routine clinical care.

**Methods:** Pts who switched from sevelamer and had 1 serum phosphorus (sPhos) measured during SO treatment were included. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and pill burden were assessed at baseline (3-months prior to SO) and at follow-up (3-months during SO treatment).

**Results:** Pts (n = 1487) were, on average, 54 years old, with dialysis vintage of 4.4 years and hyperphosphatemia (baseline sPhos=6.94 mg/dl). Figure shows sPhos distribution at baseline and follow-up. Pts within-range sPhos (3.5-5.5 mg/dl) increased from 12% to 20.1% (68% increase). Mean sPhos decreased from 6.94 to 6.7 mg/dl (p = 0.001) and mean sCa decreased from 9.3 to 9.25 mg/dl (p = 0.001). There was a significant decrease (47 pills/day, p = 0.001) in pill burden (8.5 to 3.7 pills). No significant change in iPTH levels was observed in Baseline to follow-up in 461.3 to 637.6 pg/ml). TSAT and FER significantly increased (p = 0.001) from 33.7% to 35.3% and 983.5 to 1051.4 ng/ml, respectively. In pts not receiving IV iron (n=149), there were no significant changes in TSAT (36.3% to 35.9%) or FER (1221.5 to 1177.4 ng/ml).

**Conclusions:** Correlations of variables with sFe ultimately reflect correlations with ETr/Cr, TR/Cr or both (Clin Nephrol 83:167). As expected, sTr/Cr was closely associated with ETr/Cr. The other y-variables, which depicted comparisons of sTr/Cr, were inversely related to ETr/Cr as a specific indicator of P influx and a surrogate for [P], in the CDN. As [P] fell in the CDN, the difference rose between actual and maximal P reabsorption in the proximal nephron. We did not identify an endocrine mediator of this interaction.

**Funding:** Veterans Administration Support, Pharmaceutical Company Support - Genzyme Corporation
Observational Study at the Mexican Institute for Social Security and Services for State Worker’s National Medical Center 20 de Noviembre Nephrology Department Outpatient Clinic Using Cinacalcet as Renal Replacement Therapy for Secondary Hyperparathyroidism Caused by Chronic Kidney Disease

**Results:** We have found by western blot that there is an increase in intestinal NaPi-2b protein abundance and EvertedSac studies showed increased NaPi transport in the Alport Ileum compared to the WT littermate controls. Cardiac echo studies revealed that Alport mice have decreased ejection fraction (EF: 67±2% compared to 75±3% in the WT littermate) and diastolic dysfunction (mitral Doppler flow E/A ratio: 1.2±0.1 compared to 1.6±0.1 in the WT littermate, p<0.05), which could be corrected by treatment with Niacin (intestinal phosphate uptake inhibitor). In the treated Alport mice EF increased to 78±2% (p<0.05) and E/A ratio improved to 1.3±0.1 (p<0.05). In addition, there were significant decreases mRNA relative expression in β-MHC (0.08±0.02 in control vs. 2.19±0.34 in Alport, p<0.001, vs. 0.2±0.01 in Alport+Niacin, p<0.05). PAI-1 (0.12±0.01 in control vs. 1.05±0.15 in Alport, p<0.05, vs. 0.15±0.05 in Alport+Niacin, p<0.05), and TGF-β (0.03±0.01 in control vs. 0.77±0.23 in Alport, p<0.01, vs. 0.07±0.23 in Alport+Niacin, p<0.01), markers of heart failure and cardiac fibrosis.

**Conclusions:** Inhibition of intestinal phosphate transport with Niacin therefore improves systolic and diastolic cardiac dysfunction in CKD.

Establishing Regulatory Networks of Phosphorus Metabolism in HD Patients – A New Path of Treating Hyperphosphatemia

**Background:** The clinical efficiency of current treatment of hyperphosphatemia in HD varies widely on different patients. We assume that it is due to phosphorus regulation in vivo. In physiological conditions, phosphorus is regulated by a biological network consisting of interacting hormones and minerals. In HD, the networks change dramatically and affect serum phosphorus. This study aims to establish the regulatory networks of phosphorus in HD and identify the key factors that may have a causal effect on circulating concentrations of phosphorus.

**Methods:** 30 MHD patients were enrolled and divided into three groups (n=10, PTH<300 ng/ml; n=10, 300 ng/ml<PTH≤600 ng/ml; n=10, PTH>600 ng/ml). Predialysis blood samples were obtained on the mid-week dialysis day for detection of PTH, FGF23, 25(OH)D3, Klotho, and Ca every week for 12 weeks each patient. Causal inference, a widely used process of concluding a causal connection, was adopted to establish the regulatory networks of phosphorus metabolism within different PTH levels.

**Results:** The networks show that when PTH<600 ng/ml, FGF23 can stimulate the increase of serum Pi, Ca, and PTH, in turn, serum Ca and Pi can also stimulate the increase of FGF23. When PTH>600 ng/ml, FGF23 becomes the stimulator of only serum Ca, and serum Pi has a positive causal effect on PTH, besides, the rise of PTH increases serum Pi level, too. So, serum Pi is affect by FGF23 when PTH<600 ng/ml and by PTH when PTH>600 ng/ml. Since FGF23 promotes the increase of PTH when PTH>600 ng/ml, FGF23 becomes the key factor in disorders of phosphorus metabolism. The figures also shows that Klotho and 25(OH)D3 may be not important in the therapy of hyperphosphatemia.

**Conclusions:** Reducing FGF23 levels might contribute to the control of phosphorus.

**Funding:** Government Support - Non-U.S.
Results: Sample 0.3% CKD1, 4.8% CKD2, 28.6% CKD3, 38.1% CKD4 and 22.2% CKD5. Mean serum Ca 9.47 mg/dL, mean serum phosphate P 3.77 mg/dL, PTH level 174 ng/dL, VD3 27 mg/dL. Mean Ca excretion 126 mg/day. Mean P excretion 477 mg/dL. PTH level 174 mg/dL. Ca bound 22.2% on calcium, 12.7% on calcium and 26.8% on paricalcitol. 70% of the sample had Ca excretion > 100 mg/dL. When classifying by stages of the disease, increases the amount of patients with Ca excretion > 100 mg/dL: CKD1 25%, CKD2 50%, CKD3 50%, CKD4 80%, CKD5 83%. Decreasing the mean Ca excretion. The subgroup of patients with lower Ca excretion had a higher PTH level (155 vs 111 pg/mL, p < 0.05). 94% of patients treated with Ca based binders had a Ca excretion > 100 mg/dL with no difference in serum Ca. Patients on calcitriol, paricalcitol or calciotriol had lower Ca excretion than those without treatment.

Conclusions: According to our results, patients with CKD show a decrease in renal Ca excretion that become exacerbated as the renal disease progresses. Supplementation with hypercalciemic drugs is not balanced out with the expected increase of renal Ca excretion. Therefore, we think that CKD patients are exposed to a chronic Ca overload, sometimes underestimated, with the resulting negative impact in morbidity and mortality.

PUB518

effect of Parathyroid Hormone on Serum Magnesium Level: The Neglected Relationship in Hemodialysis Patients with Secondary Hyperparathyroidism

Bye Ting, Li Fang, Junwei Yang. Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.

Background: Chronic kidney disease-mineral and bone disorder (CKD-MBD) is an important complication in patients with end-stage kidney disease which is associated with cardiovascular morbidity and mortality. Since recent studies have shown that serum magnesium plays an important role in secondary hyperparathyroidism, vascular calcification and cardiovascular mortality, the interest on magnesium has grown.

Methods: This cross-sectional study was conducted on 111 patients with end-stage renal disease on maintenance hemodialysis who was hospitalized for secondary hyperparathyroidism. The interventional study was conducted on 23 patients underwent total parathyroidectomy.

Results: In our study, hypermagnesaemia (>2.5 mg/dL) occurs in up to 44% of cases and hypomagnesaemia did not present. No significant correlations were found between serum magnesium and parathyroid hormone (r = -0.143, p = 0.134). Correlation analysis and logistic regression analysis suggested that the derangement of magnesium between serum magnesium and parathyroid hormone (r = -0.143, p = 0.134). Correlation cases and hypomagnesemia did not present. No significant correlations were found

Conclusions: There is an increased prevalence of hypermagnesaemia in hemodialysis patients with secondary hyperparathyroidism. The derangement of magnesium between serum magnesium and parathyroid hormone was correlated with the derangement of calcium/phosphate homeostasis. Therefore, we think that CKD patients are exposed to a chronic Ca overload, sometimes underestimated, with the resulting negative impact in morbidity and mortality.

PUB519

Calciphylaxis in Patient with Chronic Renal Disease Not Dialytic and Multiple Myeloma

Patricia Junqueira Freitas, Aline Lourenço Baptista, Clóvis Antonio lopes Pinto, Joubert Araujo Alves, Pedro Caruso, Benedito Jorge Pereira, Fernanda Lemos Moura, Marina Harume Imanishi, Luis Andre Andrade, Germana Alves Brito. Nephrology, AC CAMARGO, Sao Paulo, Brazil.

Background: Calciphylaxis, also known as calcifying urerteral fibrosarcoma, is a rare medical condition, which is normally diagnosed in patients with terminal CKD who are already in renal replacement therapy (RRT). Objective report the presence of calciphylaxis in CKD, in patient with oncologic disease.

Methods: Female patient, 71 years old, caucasian, conducted to AC Camargo Hospital for etiological investigation of injuries in lower limbs associated with renal failure, hypercalcemia, anemia and astenia. Has history of hypertension and obesity. Physical examination: poor general state, dyspnea, respiratory and cardiovascular systems without changes, ulcerated lesions of necrotic center in lower limbs (FIGURE). Laboratory tests: Creatinine 8.8 mg/dL, Urea 169 mg/dL, K 4.1 mEq/L, HC03:16.3 mEq/L, pH 7.29, Ca: 1.58 mmol/L, PTH: 295 pg/ml, P: 3.6 mg/dL, total Ca 12.9 mg/dL, albumin 1.8 g/L, Renal US: regular, Parathyroid US: regular, Left biopsy(Bx) of skin, chronic inflammatory process, scar, thickened subcutaneous tissue, dermal necrosis, ulcerated lesions of lower limbs (FIGURE). Noninvasive hemodynamic evaluation was performed before, during and after dialysis. Results: Comparing with group 2, cardiac index (CI) was higher (P=0.252) while systemic vascular resistance index (SVRI) was lower (P=0.05) in group 1. The mean thoracic fluid capacity (TFC) of the two groups were similar (P=0.424) before dialysis. Before PTX, spheric blood pressures (SBP) of all the 12 patients were above 90 mmHg. Decreasing the mean Ca excretion. The subgroup of patients with lower Ca excretion had a higher PTH level (155 vs 111 pg/mL, p<0.05). The frequency of Ca > 2.60 mM and Ph > 1.5 mM are not modified at M6/M0. We compared M6’s biologic data with M0’s data.

Conclusions: At M6, Ca magnesium intake is reduced by 57% vs M0. Ph is similar vs M0. Mean serum calcium is not altered. The frequency of Ca > 2.60 mM and Ph > 1.5 mM are not modified at M6/M0. We compared M6’s biologic data with M0’s data. The only difference is related to a decrease of Calcium Intake (g/d) from M0 (1.51 +/- 1.13) to M6 (0.63 +/- 0.31, P<0.05).

Calcium Binders Are They All Equal? Comparison Calcium Acetate (CA) versus Carbonate Calcium (CC) in CKD 5D: Multicentric Study

Philippe Brouet, David Attia, Laurent Juillard. *Nephrology - Dialysis, Conception Hospital, Marseille, Bouches-du-Rhone, France; †Dialyse, Fresenius, Paris, IDF, France; ‡Nephrology - Dialysis, Edouard Herriot Hospital, Lyon, Rhone, France.

Background: CA’s phosphate binder is available since 2010 in France. A monocentric study indicates that CA is equivalent to CC based on phosphatemia reduction while reducing calcium intake by 60%. This study compare CA to CC in different dialysis centers i.e different CKD MBD protocols.

Methods: 28 hemodialysis centers are involved. CC is switched to CA at M6 with 6 months follow up (M1, M2). We compared M6’s, biologic data with M1’s, data.

Results: 293 patients (70+/-14 y) in 28 centers. At M1, CA dosage was 3.8 +/- 2 pills/day. Demographic characteristics are consistent with our National French registry. At M6, mineral values are similar to M0: Ph mM (1.54 +/- 0.55 vs 1.52 +/- 0.65, NS), Ca mM (2.23 +/- 0.17 vs 2.21 +/- 0.15, NS), PTH pg/ml (221 +/- 204 vs 262 +/- 217, NS), Vit. D mM (75 +/- 32 vs 79 +/- 24, NS), % pts with no calcium binder (43 vs 49, NS), % pts w. Ca > 2.6 mM (2 vs 1, NS), % pts w. Ph > 1.5 mM (39 vs 38, NS). The only difference is related to a decrease of Calcium Intake (g/d) from M0 (1.51 +/- 1.13) to M6 (0.63 +/- 0.31, P<0.05).

Conclusions: At M6, Ca intake is reduced by 57% vs M0, while Ph is similar vs M0. Mean serum calcium is not altered. The frequency of Ca > 2.60 mM and Ph > 1.5 mM are not modified at M6/M0. We compared M6’s biologic data with M0’s data. The only difference is related to a decrease of Calcium Intake (g/d) from M0 (1.51 +/- 1.13) to M6 (0.63 +/- 0.31, P<0.05).

Hemodynamic Changes in Maintenance Hemodialysis Patients with Hypotension After Parathyroidectomy

Meijuan Meng, Bing Tong, Hong Ye, Junwei Yang. Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.

Background: Parathyroidectomy (PTX) is applied to treat secondary hyperparathyroidism in hemodialysis patients. Some patients suffered from hypotension after PTX although hypocalcemia was corrected. The aim of this study was to demonstrate the hemodynamic changes in hemodialysis patients after PTX.

Methods: Twelve patients were included in this study. Among them 4 have hypotension after PTX (Group 1) and the other have their blood pressure remained after PTX (Group 2). Before PTX, systolic blood pressures (SBP) of all the 12 patients were above 90 mmHg. Noninvasive hemodynamic evaluation was performed before, during and after dialysis.

Results: Comparing with group 2, cardiac index (CI) was higher (P=0.252) while systemic vascular resistance index (SVRI) was lower (P=0.05) in group 1. The mean thoracic fluid capacity (TFC) of the two groups were similar (P=0.424) before dialysis. Serum Ca, PTH, ALP, ventricular ejection fraction and vascular calcification score of thoracic aorta, abdominal aorta and heart valve before PTX, as well as the weight of the removed parathyroid glands, serum Ca, ALP, hemoglobin after PTX of the patients were determined. No statistical differences were found. However, the phosphorus level was lower in group 1 both before and after PTX. CI, SVRI and TFC were similar in both groups during hemodialysis.

Conclusions: Patients with hypotension after PTX have a lower systemic vascular resistance index and a higher cardiac index, which might be associated with serum phosphorus level.

Cost of Medications Used in the Management of Secondary Hyperparathyroidism (SHPT) in Patients with End Stage Renal Disease (ESRD) Mark E. Bensink,1 Leigh Darryl Quarles,2 Vasily Bele佐off,1 Kerry Cooper,1 Jonathan D. Campbell,3 'Amgen Inc., Thousand Oaks, CA; 2Univ of Tennessee, Memphis, TN; 3Univ of Colorado, Aurora, CO.

Background: Management of SHPT associated with ESRD is complex, typically requiring combinations of medications. Eighty-five percent of the ESRD population is covered by Medicare with detailed drug expenditures reported annually by the US Renal Data System. For the remaining 18% covered by commercial health plans, drug expenditure information is unknown. The purpose of this study is to estimate the cost of medications used in the management of SHPT in ESRD patients from the US commercial health plan perspective.

Methods: Economic analysis with one-year time horizon to estimate per-member-per-month (PMPM) cost for SHPT related medications: calcium and non-calcium-based phosphate binders, calcitriol or active vitamin D analogs, and calcimimetics. Input parameters include: prevalence of ESRD in commercial health plans (MarketScan®); medication utilization and non-adherence (IMS Health for oral medications and Outcomes Plus for intravenous [IV] medications); and medication wholesale acquisition costs (WAC) (AnalysSource.com) with one-way sensitivity analysis.

Results: The total PMPM (2014 US Dollars) cost of SHPT-related medications is $0.34: cinacalcet $0.06, phosphate binders $0.16, oral vitamin D $0.02, and IV vitamin D $0.10.

Figure 1. Total PMPM Cost Breakdown

Calcimimetic 18.7%
Calcitriol 13.6%
Phosphate Binders 46.2%
Oral Vitamin D 6.6%
IV Vitamin D 2.9%

Results are most sensitive to variation in ESRD prevalence and cinacalcet WAC parameters.

Conclusions: Results indicate that the collective cost of medications for the management of SHPT in commercial health plans is substantial with the cost of cinacalcet being lower compared to phosphate binders and IV vitamin D, but higher compared to oral vitamin D.

Medullar Compression by Bone Tumor: Case Report Cinthia Sobral Vieira, Nicole D.T. Carvalho. Nephrology Unit- Cliniefo, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil.

Background: The presentation of vertebral tumors may have different kinds of manifestation. They can mimic nonploc, inflammatory and congenital diseases. The following report is about a patient with a lytic bone lesion in the thoracic spine causing medullar compression symptoms.

Methods: A 66 years old masculine patient, with chronic renal disease in hemodialysis for 5 years, non-adherent to treatment or diet, had his levels of phosphor, calcium/phosphor, alkaline phosphatase and parathyroid hormone (PTH) elevated in the last year. He did not take the medication prescription: Calcitriol and Sevelamer. The patient came to the ER of a general hospital referring constipation and abdominal distention. During the hospitalization he started to refer paresthesia in inferior members with progressive march dysfunction. The neurological exam showed ataxic/calcaneal gait and strength reduction (4+/5+) in the inferior members.

Results: After 5 years, non-adherent to treatment or diet, had his levels of phosphor, calcium/phosphor, alkaline phosphatase and parathyroid hormone (PTH) elevated in the last year. He did not take the medication prescription: Calcitriol and Sevelamer. The patient came to the ER of a general hospital referring constipation and abdominal distention. During the hospitalization he started to refer paresthesia in inferior members with progressive march dysfunction. The neurological exam showed ataxic/calcaneal gait and strength reduction (4+/5+) in the inferior members.

Conclusions: The presentation of vertebral tumors may have different kinds of manifestation. They can mimic nonploc, inflammatory and congenital diseases. The following report is about a patient with a lytic bone lesion in the thoracic spine causing medullar compression symptoms.

PUB524

Rescue-Therapy with Lanthanum-Carbonate (LC) in Uncontrolled Hyperphosphoremia in Dialysis Nicola Giotto, Angela maria Marino. Dept of Medicine, Nephrology and Dialysis Unit, Cardinal Massaia Hospital, Asti, AT, Italy.

Background: Control of hyperphosphatemia in hemodialysis provides an approach based on changes in diet, dialysis efficiency improvement, and use of phosphate binders. The latter, however, in some patients do not prove effective, conditioning the indirect increase of mortality and morbidity of the subject on dialysis. The objective of this study was to evaluate the difference in efficacy of a regimen of lanthanum carbonate plus standard therapy (LTS) compared to standard therapy alone (TS) in the treatment of patients with persistent hyperphosphatemia, as rescue-therapy.

Methods: We conducted an observational study of data on consecutive patients in hemodialysis who have presented more than four phosphorus values greater than 6 mg/dL in three months. Patients treated with TS, have varied therapeutic scheme introducing LC. Patients treated with sevelamer have outstanding this therapy and were treated with LC. The data analysis has been done considering a retrospective phase (FR) of three months and a prospective phase (FP) of six months, for each subject analyzing the effectiveness of therapy before and after enrollment.

Results: In a cohort of 163 patients on hemodialysis, we have selected for the study, 14 patients who had a mean age of about 65 years and length of dialysis than 6 years. The combination of LC plus TS produced a significant increase in the proportion of patients achieving the therapeutic targets as defined by the K/DOQI Guidelines. Reduction of 2.12 mg/dL (-32.7%) than the average of the P phase prospective (4.55 mg/dL) than the retrospective phase (6.77 mg/dL), was statistically significant (p <0.001), is associated with the reduction of 19:21 mg/dL (-32.9%) of the average value of CaXP in the prospective phase (39.07 mg2/dL2) compared to the retrospective phase (58.28 mg2/dL2), also statistically significant (p <0.001). The patients at the target of the FR accounted for 92.31% for P and 100% for the CaXP, respectively vs. the 7.14% and 50% of FR.

Conclusions: The introduction of the LC-as rescue therapy in the treatment of hemodialysis patients with uncontrolled hyperphosphatemia resulted very effective allowing more easily reach the therapeutic objectives.

PUB525

Glucocorticoid-Induced Osteoporosis in Renal Patients Gabrielle Goldet,1 George Greenhall,2 Alan D. Salama.3 'Basildon and Thurrock Univ Hospital; 2Royal Free Hospital, London; 3Royal Free Hospital, London.

Background: Glucocorticoid-induced osteoporosis (GIO) is associated with severe morbidity due to fragility fractures as well traumatic fractures and 50-90% of patients on long term steroids are affected by GIO. GIO is relevant in the renal context as steroids are widely used to treat renal disease and as part of immunosuppression in transplant. Also, renal patients are already at higher risk of fractures in association with renal bone disease.

Methods: We designed and undertook an audit to assess screening and management of GIO in nephrology outpatients in a university hospital in London, using national guidelines as a benchmark for our performance. We then presented the results at a local meeting, produced posters and leaflets on GIO to be placed in the outpatient waiting area for patients so as to raise awareness of this issue and provided a simple algorithm to be followed by clinicians in all the clinic rooms. We then re-audited after 6 months.

Results: 100 patients were audited in each audit cycle. Measures audited were a) whether all patients over 65 were treated with bone protection; b) whether all patients with documented fragility fracture were treated with BSA; c) whether all patients under 65 without fragility fracture underwent DXA scan; d) whether all patients with T-score under -2.5 were treated with BSA; e) whether all patients with T-score 0 to -1.5 underwent DXA scan; f) whether all patients under 65 without fragility fracture underwent DXA scan; g) whether all patients are managed according to national guideline (cycle 1: 29%; cycle 2: 41%). See table for breakdown of results.

Conclusions: Our intervention has improved performance as measured against national guidelines, though the rate of GIO screening remains low. Many patients could potentially benefit from bone protection, though larger studies would be needed to demonstrate an effect on fracture incidence.

The Kidney Stone and Increased Water Intake Trial in Steel Workers:

PUB526

**Results:** A total of 1443 workers were randomized to receive standard-dose (38.5 mg daily) or low-dose cinacalcet (25 mg alternate day) for 16 weeks. At 8 weeks, doses of cinacalcet could be increased to achieve a target of 30 mg daily for 12 weeks. The changes in serum iPTH, calcium, phosphorus, and alkaline phosphatase were compared between the two groups. The study found that low-dose cinacalcet was effective in reducing iPTH levels without significant changes in serum calcium or phosphorus. The study also found that low-dose cinacalcet was well tolerated and did not increase the risk of hypocalcemia.

**Conclusions:** Low-dose cinacalcet is effective in reducing iPTH levels in hemodialysis patients without increasing the risk of hypocalcemia. It is an alternative to standard-dose cinacalcet and may be a suitable option for patients who are at risk of hyperparathyroidism.

PUB527

**Methods:** The study was an open, randomized controlled trial (RCT) involving 1443 patients with secondary hyperparathyroidism. The patients were randomized to receive either standard-dose cinacalcet (38.5 mg daily) or low-dose cinacalcet (25 mg alternate day) for 16 weeks. The primary outcome was the percentage of patients achieving the KDIGO target at 16 weeks.

**Results:** The study found that low-dose cinacalcet was effective in reducing iPTH levels without significant changes in serum calcium or phosphorus. The study also found that low-dose cinacalcet was well tolerated and did not increase the risk of hypocalcemia.

**Conclusions:** Low-dose cinacalcet is effective in reducing iPTH levels in hemodialysis patients without increasing the risk of hypocalcemia. It is an alternative to standard-dose cinacalcet and may be a suitable option for patients who are at risk of hyperparathyroidism.

PUB528

**Methods:** The study was a randomized controlled trial involving 1443 patients with secondary hyperparathyroidism. The patients were randomized to receive either standard-dose cinacalcet (38.5 mg daily) or low-dose cinacalcet (25 mg alternate day) for 16 weeks. The primary outcome was the percentage of patients achieving the KDIGO target at 16 weeks.

**Results:** The study found that low-dose cinacalcet was effective in reducing iPTH levels without significant changes in serum calcium or phosphorus. The study also found that low-dose cinacalcet was well tolerated and did not increase the risk of hypocalcemia.

Parathormone Stability in Hemodialyzed Patients: Comparison on Non-Centrifuged EDTA and Serum Samples with 2nd and 3rd Generation Assays
Marie Dohet,1 Pierre Delanaye,2 Etienne Cavalier.1
1Clinical Chemistry, Univ of Liege, CHU Sart-Tilman, Liege, Belgium; 2Nephrology, Univ of Liege, CHU Sart-Tilman, Liege, Belgium.

Background: PTH stability is of importance. Many studies have shown divergent results between EDTA and serum, mainly linked to differences in protocols or cut-offs used to decipher whether PTH remained stable or not. No studies have yet compared PTH as measured by 2nd and 3rd generation assays on the same samples in hemodialyzed (HD) patients.

Methods: Five pairs of samples (EDTA and gel tubes) were obtained in 10 HD patients before session. One pair was centrifuged and run immediately to establish the “T0”. Two pairs were kept at 4°C and +25°C. They were centrifuged after 4 and 18 hours. Supernatant was kept at -80°C for one week. Then, all samples were measured in a single batch, on Roche Cobas and DiaSorin XL 2nd and 3rd generation PTH assays. Samples were considered as stable if 90% of subjects had a decrease lower than a total change limit (TCL) that takes both analytical and biological variability into consideration. All determinations were run in duplicates.

Results: At T0, no difference was observed between plasma and serum for any of the methods. PTH decreased in all samples and degradation was the same with 2nd or 3rd generation assays, whatever the method used. Percentages of decrease were systematically lower in EDTA plasma compared to serum and none of our subjects presented a decrease higher than the TCL with EDTA plasma. In serum, PTH was not considered as stable, but only when kept at 25°C for 18 hours.

Conclusions: PTH stability is of paramount importance for correct interpretation of the results. Many studies have tried to evaluate this stability but are not free from criticisms, mainly due to a poorly defined T0 and questionable acceptation limits. In this study, we used an unfrozen T0 and decision limits based on analytical and biological variations. Moreover, we tested 2nd and 3rd generation PTH on two automated platforms. Our results show that, if PTH is basically more stable in EDTA plasma than in serum, this advantage is only clinically significant when samples are stored for a long period (18h) at +25°C.

Vitamin D Metabolism Is Incompletely Restored After Kidney Transplantation
Thomas F. Hiemstra,2 Stephen M.S. Ting,1 Ragada El-Damanawi,1 Kenneth Lim,1 Martin Kaufmann,1 Glenville Jones,1 Daniel Zehnder.1
1Univ of Warwick, United Kingdom; 2Univ of Cambridge, United Kingdom; 1Massachusetts General Hospital, Boston; 2Queen’s Univ, Kingston, Canada.

Background: Vitamin D deficiency is widely reported in patients with renal impairment and is associated with adverse outcomes. The extent and rate of recovery of vitamin D metabolism after kidney transplantation is uncertain.

Methods: We enrolled 175 dialysis patients (HD) listed for kidney transplantation, and 85 hypertensive but otherwise healthy controls (HTN). We determined blood markers of mineral metabolism including intact FGF23 and vitamin D metabolites at entry (or immediately pre-transplantation), and 2 months. As a surrogate for vitamin D deficiency, we assessed the 25(OH)D3: 24.25(OH)2D3 ratio (D-ratio, normal 5:25).

Results: Of 175 dialysis patients, 76 were transplanted (TXR) during the study. TXR were transplanted with a lower BMI than controls. FGF23 was higher in HD patients than HTN at base-line, but normalised after 12 months (p<0.13). At baseline, vitamin D insufficiency (defined as 25(OH)D3 <30 ng/mL) was present in 82% of subjects and did not differ between groups. However, vitamin D deficiency (defined as 25(OH)D3 <10 ng/mL) was more common in dialysis (15% versus 4%, p=0.49). The baseline D-ratio was higher in HD (48, IQR 27-67) than in HTN (16, IQR 14-18, p<0.0001) patients. Transplantation resulted in significant reduction in D-ratio after 2 and 12 months compared to HD (p=0.0008 and p=0.005 respectively). The slope of D-ratio vs 25(OH)D3 increased after transplantation, but remained lower than for HTN controls, suggesting reduced expression or activity of the catalytic CYP24A1 (25-OH-D3-24-hydroxylase) in kidney failure.

Conclusions: Vitamin D insufficiency is highly prevalent in patients on dialysis and in hypertensive controls, and only partially resolves after kidney transplantation.

Low Time-Averaged Serum Intact Parathyroid Hormone Level Is an Independent Risk Factor for Overall Mortality and Major Adverse Cardiac and Cerebrovascular Events in Incident Dialysis Patients
Sul A Lee,1 Mi Jung Lee,1 Kyoung Sook Park,1 Jong Hyun Jee,1 Jae Eun Um,1 Meiyan Wu,2 Hyung Jung Oh,1 Jung Tak Park,1 Seung Hyoek Han,1 Shin-Wook Kang,1,2 Tae-Hyun Yoo.1
1Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea; 2Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Chronic kidney disease-mineral bone disorder (CKD-MBD) is known as a major risk factor for cardiovascular disease in end-stage renal disease (ESRD) patients. CKD-MBD is classified into low turnover and high turnover bone disease according to the bone dynamics, both of which are related with vascular calcification in ESRD. To evaluate the prognostic value of abnormal serum parathyroid hormone (PTH) levels on ESRD patients, we investigated the effects of time-averaged serum intact PTH (TA-iPTH) levels on overall mortality and major adverse cardiac and cerebrovascular events (MACCEs) in incident dialysis patients.

Methods: In this prospective observational study, 413 patients who started dialysis between January 2005 and September 2010 at Yonsei University Health System were enrolled. Patients were divided into three groups according to TA-iPTH levels during the 12 months after initiation of dialysis (group 1:<65pg/mL, group 2: 65 to 300 pg/mL, group 3: >300pg/mL). Cox regression analysis was performed to determine the prognostic value of TA-iPTH on overall mortality and MACCEs.

Results: The mean age was 56.5±14.5 years and 222 patients (53.8%) were male. During a median follow-up of 50.8 months, 49 patients (11.9%) were dead and MACCEs were occurred in 55 patients (13.3%). Multivariate Cox regression analysis demonstrated that low TA-iPTH level was an independent risk factor for both overall mortality [group 2 as reference; group 1, hazard ratio (HR)=2.08, 95% confidence interval (CI)=1.2-3.8, P=0.02] and MACCEs (HR=1.88, 95% CI=1.04-3.40, P=0.04) in incident dialysis patients after adjusting confounding factors.

Conclusions: This study demonstrates that low TA-iPTH is an independent risk factor for overall mortality and MACCEs in incident dialysis patients.

Combined Analysis of Hypercalcemia and PTH Levels as Clue to Unveil Persistent Transplant Hyperparathyroidism
Melani Custodio,1 Maria Julia C. L. N. Araujo,1,2 Wagner Dominguez,1 Rosa M. A. Moyaes,1 Elias David-Neto,1 Vanda Jorgetti.1
1Nephrology Div, Univ de Sao Paulo; 2Transplant Unit, Univ de Sao Paulo; 1UNINOVE, Sao Paulo, Brazil.

Background: Mineral and bone metabolism disorders in chronic kidney disease (CKD-MBD) are not always corrected after kidney transplantation (TxR). The persistence of hyperparathyroidism may have a negative impact on patient and graft outcome. Our objective was to evaluate the evolution off CKD-MBD and the incidence of hyperparathyroidism after 12 months of TxR.

Methods: In this study, we included all consecutive patients submitted to a TxR during the period between Jan 2010 and Dec 2014 in a University based center. We excluded patients with a PTH <300 pg/mL before TxR, multi-organ transplants, patients with an eGFR<30mL/min and those who underwent parathyroidectomy after TxR. Twelve-month eGFR, plasma levels of total calcium (Ca), phosphorus (P), alkaline phosphatase (AlkP), magnesium (Mg), parathormone (PTH), and 25-hydroxy vitamin D (25-OH vit D) were compared to baseline values. A PTH >100pg/mL and a total calcium >10.2mg/dL were considered abnormal. We defined high PTH, with or without hypercalcemia as the primary endpoints for the analysis.
Results: During the observation period, 408 patients were evaluated. There was a significant increase in eGFR and in calcium levels 12 months after the TxR. Compared to the baseline, PTH, AlkP, and P significantly decreased. 25-OH Vit D also did not change during the period. Fifteen percent of patients presented both PTH and Ca above the reference levels, while 37% presented isolated high PTH and 8% hypercalcemia only. Multivariate analysis disclosed that post-TxR hyperparathyroidism was dependent on pre-transplant PTH (OR 1.001; CI 95%: 1.001-1.002) and Ca (OR 1.233; CI 95%: 1.036-1.468).

Conclusions: Monitoring Ca and PTH before and after TxR may be important to detect patients at high risk of persistent hyperparathyroidism, and to identify patients in need of treatment to prevent its complications.

Predictors of FGF23 and Soluble Klotho in HIV Infection
Rubin Wang,1 Michael Shlippik,2 Joachim H. Ix,3 Michelle M. Estrella,1 Johns Hopkins Univ;1UCSF, UCSD.

Background: In the general population, FGF23 and its co-receptor, soluble klotho (sKlotho), have been implicated in the aging process. HIV+ individuals are at higher risk of age-related comorbidities compared with HIV- persons. We evaluated whether FGF23 and sKlotho levels differed by HIV status and determined clinical factors associated with each hormone in HIV+ men.

Methods: 384 HIV+ and 225 HIV- men in the Multicenter AIDS Cohort Study (MACS) were randomly selected for FGF23 and sKlotho measurements from samples stored in 2008-2010. We compared FGF23 and sKlotho levels by HIV status, adjusted for age and race. Multivariable linear regression models were used to determine predictors of FGF23 and sKlotho levels among HIV+ men.

Results: Mean age was 53y; 34% were black; and median eGFR was 90mL/min. 99% of HIV+ men were antiretroviral-treated. FGF23 and sKlotho were not significantly correlated (r=0.09). In adjusted analyses, HIV was associated with 11% (p=0.002) higher sKlotho but not FGF23 levels (-1%; p=0.84). Among HIV+ men, diabetes was associated with 3% (p=0.68) and HCV (34%); 95% CI: -14%, -49%); and cumulative tenofovir (TDF) exposure (-4%/year; 95% CI: -1%, -7%) were associated with 30% (95% CI: 3-65%) higher FGF23, whereas HCV (34%); 95% CI: 7%, 36%) [Figure] Neither CD4 count nor HIV RNA were associated with FGF23 or sKlotho concentrations.

Conclusions: HIV+ individuals had similar FGF23 but higher sKlotho levels compared to HIV- counterparts. Among HIV+ men, clinical predictors associated with FGF23 differed from those associated with sKlotho. Mechanisms by which HIV treatment and co-morbid conditions may impact these hormone levels need further study.

Response of Fibroblast Growth Factor 23 to Sodium Interventions in Diabetic Nephropathy and Arterial Hypertension
Selmer K. Humalda, Sarah Seiler, Marc G. Vervloet, Gunnar H. Heinic;2 Martin H. De Borst,1 Nephrology, The Royal Melbourne Hospital, Melbourne, Victoria, Australia;1Nephrology, The Univ of Melbourne, Melbourne, Victoria, Australia;2Nephrology, Saarland Univ Medical Center, Homburg, Germany;2Nephrology, VU Medical Center, for NGrAm, Amsterdam, Netherlands.

Background: Fibroblast growth factor 23 (FGF23) is known to regulate the sodium transporters thereby inhibiting tubular phosphate reabsorption. Chronic kidney disease (CKD) leads to FGF23 excess and deficiency of sKlotho but not FGF23 levels. The effect of excess sodium on volume status. FGF23 putatively induces sodium retention which significantly increases LOS. Further to consensus between renal and surgical teams we have increased the preloading dose of one-alfacalcidol to 5 mcg for 5 days pre operatively. A follow up study is planned in 12 months to observe the outcome of this change.

Hypocalcaemia Management Post Parathyroidectomy in Renal Patients – Our Experience and Change in Practice
Rajkumar Chinnadurai, Maharan Raman, Constantina Chrysoucho, Smeeta Sinha. Dept of Renal Medicine, Salford Royal NHS Foundation Trust, Salford, United Kingdom.

Background: Hypocalcaemia is common post parathyroidectomy in renal patients with secondary hyperparathyroidism due to hungry bone syndrome with an incidence as high as 51%. Hypocalcaemia can be prevented by effectively preloading patient with Vitamin D supplements and close monitoring of calcium levels post operatively. Currently there is no clear guidance on the preloading dose of one-alfacalcidol in literature. Our current practice is to preload all patients with 2 mcg one-alfacalcidol for 5 days pre operatively. Our aim was to study the management of hypocalcaemia post parathyroidectomy in renal patients and factors influencing length of hospital stay (LOS). To identify if any changes in current practice could improve outcome.

Methods: Retrospective observational study of all renal patients who underwent parathyroidectomy under a single surgeon over 6 years (April 2008 to September 2014). Data was collected from the Electronic Patient Record. Data were analysed using Stats direct and Fisher Exact test was used for testing statistical significance.

Results: 72% of our sample (n = 25) were male with a mean age of 54. Of the 25 there were 13 transplant, 9 haemodialysis and 3 CKD patients. The mean hospital stay was 5 days shorter than quoted in the literature (5.6 Days). 3 of 25 patients were not preload and 71% of our patients needed intravenous calcium replacements which was the main cause for increased LOS (p=0.0002). Haemodialysis patients had longer LOS than CKD and Transplant patients (p=0.0002), this group were more likely to not have received pre-loading. These undergoing total parathyroidectomy had increased LOS compared to subtotal parathyroidectomy (p=0.0009). There were no surgical complications contributing to a delay in discharge.

Conclusions: Insufficient preloading was identified as a major risk factor for hypocalcaemia, which significantly increased LOS. Further to consensus between renal and surgical teams we have increased the preloading dose of one-alfacalcidol to 5 mcg for 5 days pre operatively. A follow up study is planned in 12 months to observe the outcome of this change.

Fibroblast Growth Factor 23 Can Predict the Progress of Aortic Artery Calcification in Dialysis Patients
Zijin Chen, Xiaonong Chen, Xiaoobo Ma, Bei Ding, Huawei Ling, Nan Chen. 1 Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China; 2 Radiology, Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China.

Background: To investigate the factors associated with progress of aortic artery calcification in maintenance haemodialysis (MHD) patients and to determine whether plasma FGF23 level is related to progress of aortic artery calcification.

Methods: MHD patients from Ruijin Hospital from July 1st 2011 to July 31st 2011 were involved in our study. Follow up 36 months. Aortic artery calcification (AAC) was detected by a lateral lumbar X-ray plain and read by two radiologists.

Results: 120 MHD patients were enrolled and followed up for 36 months. To July 2014, a total of 67 MHD patients finished the study. Among 67 patients, 32 were male, mean age 53.9±13.1 years old, mean dialysis vintage 44.1±38.1 months, median FGF23 level 48052 (11372-35750.4)Ru/ml, LgFGF23 3.79±0.83. In July 2011, 53.7% of patients had visible calcification in the abdominal aorta and mean involved segment was 1.42 with mean AACS (ACAS). 3.96. In July 2014, 73.1% had AAC and mean involved segment was 2.34 with mean AACS 10.7. There are significant differences between two AAC involved segments and AACS (both P<0.001). Age, dialysis vintage and FGF23 level had significant difference between AAC progress group and no AAC progress group (P = 0.007, <0.001 and 0.020, separately). Logistic analysis showed that the independent parameters associated with AAC progress were age (OR=1.114, CI:1.045-1.186) and LgFGF23 level 48052 (11372-35750.4)Ru/ml, LgFGF23 3.79

Conclusions: The severity of vascular calcification progress yearly in maintain haemodialysis patients. Age and FGF23 are independently associated with the progress of AAC. FGF23 level could predict the progress of AAC in MHD patients.

Funding: Government Support - Non-U.S.

PUB539

Background: Hepcidin is a 25-amino-acid protein synthesized in hepatocytes and macrophages that acts as a post-translational inhibitor of ferroportin, the only receptor known to export iron from intracellular compartments to systemic circulation. Thus, higher hepcidin levels are associated with greater intracellular sequestration of iron, and increased risk of anemia. Vitamin D is an inhibitor of hepcidin expression; the working hypothesis is that FGF23 could be an ‘inverse’ regulator of iron metabolism in comparison to vitamin D, with a stimulation of hepcidin expression, an increase of intracellular ferritin and an inhibition of ferroportin expression in the cell membrane, leading to a further intracellular sequestration of iron.

Methods: Three different types of liver cells were used: HepG2, HepaRG and primary human hepatocytes (PHH). Cells were exposed to FGF23 (1, 10 or 100ng/mL) at different time points (6h, 24h, 48h). Cultures were performed in triplicates, and QRT-PCR in duplicates (StepOne Plus Real-Time PCR). Western Blots were also performed (Erk and Akt phosphorylation pathways, FGRF1, FGRF3, ferritin).

Results: In HepG2, even though FGF2R1 expression was found by Western blot analysis, FGF23 did not modify hepcidin expression by QRT-PCR, and Erk/Akt pathways were not activated by FGF23. In HepaRG cells, hepcidin expression was modified with FGF23 by QRT-PCR, i.e. increased at 6 hours and decreased at 24 hours.

PUB540

Prevalence of Hyperparathyroidism and Its Correlates in a Large Cohort of Hemodialysis Patients Pasquale Esposito,1 Fabio Malberti,2 Elena Caramella, Marta Calatroni,1 Edoardo La Porta,1 Marina Foramitt2, Rosanna Coppo,1 Antonio Dal Canton.1 Nephrology, Fondazione IRCCS, Pavia, Italy; 2 Nephrology, Istituti Ospitalieri di Cremona, Cremona, Italy; 3 Nephrology, Regina Margherita Children’s Hospital, Turin, Italy.

Background: Beyond experimental setting of randomized trials, little is known about the occurrence of mineral bone disorders (MBD) in the real-life clinical practice of hemodialysis (HD). This is the reason why we designed this observational study to define the prevalence of hyperparathyroidism (HPT) and its correlates in a large cohort of HD patients.

Methods: We enrolled HD prevalent patients from 38 Dialysis Units collecting data on: clinical information, dialysis parameters, biochemical and instrumental evaluations and pharmacological therapy. According to the KDIGO guidelines we divided the patients in: patients affected by HPT (i.e. PTH > 9 the upper reference limit of each laboratory) vs patients on target.

Results: Out of 495 patients, 34 (6.8%- 59.9% in 15.5 years, 53%M) presented HPT with mean PTH of 1064±536 pg/ml, while 461 patients resulted OHT (93.2%- 66.9;±13.7 years, 66%M), mean PTH 242±151 pg/ml (p<0.001). HPTs were younger than OHT (59.9±15 vs 69.9±13.7 years, p=0.008), with a longer HD history (126.2±125 vs 64.3±69 months, p=0.003). There were not significant differences in both clinical and dialysis parameters. Similarly, there were not differences in laboratory examination except from serum ALP that resulted higher in HPTs (194.8±142 vs 144.1±108 U/l OT, p<0.01). Moreover, there were not differences in the use of phosphate binders, whereas a significantly higher percentage of HPTs was taking paracalcitol and calcimetics and the prescribed vitamin D doses (both as calcitriol and paracalcitrol) were significantly higher in HPT patients.

Conclusions: The prevalence of HPT in our population was surprisingly lower, compared to that reported in previous studies. This finding could be due to the general application of KDIGO guidelines, which recommend more permissive PTH levels compared with the previous K/DOQI guidelines, thus to the availability of effective drugs, probably used more appropriately than in the past.

PUB541

Effect of Vitamin D Receptor Activators on Glomerular Filtration Rate: A Meta-Analysis and Systematic Review Qian Zhang, Jing Chen. Div of Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China.

Background: Vitamin D receptor activators (VDRAs) can protect against mineral bone disease, but they may also elevate serum creatinine and reduce glomerular filtration rate (GFR).

Methods: We conducted a systematic review and meta-analysis of randomized clinical trials (RCTs) to evaluate the effect of VDRAs on kidney function and adverse events. MEDLINE, EMBASE, the Cochrane Controlled Trials Register were searched for RCTs that evaluate vitamin D receptor activators (alfacalcidol, calcitriol, doxercalciferol, falcacidinol, maxalcalcitin and paracalcitrol) up to March 2015.

Results: We included 31 studies, all of which were performed between 1976 and 2015, which enrolled 2621 patients. Patients receiving VDRAs had lower eGFR (weighted mean difference WMD=-1.29 mL/min/1.73 m², 95% CI -2.42– -0.17) and elevated serum creatinine (WMD 7.03 µmol/L, 95% CI 0.61–13.46) in sensitivity analysis excluding studies with dropout rate more than 30%. The VDRAs and control groups had no significant differences in all-cause mortality (relative risk RR 1.41, 95% CI 0.58–3.80), cardiovascular disease (RR 0.84, 95% CI 0.42–1.71), and severe adverse events (RR 1.15, 95% CI 0.75–1.77). Episodes of hypercalcemia (RR 3.29, 95% CI 2.02–5.38) were more common in the VDRAs group than in the control group.

Conclusions: Although administration of VDRAs slightly reduced the eGFR, all-cause mortality and severe adverse events were comparable between the groups. Future RCTs with larger sample sizes are needed to assess whether the mild reduction of eGFR is of clinical significance.
Low Dose Cholecalciferol Supplementation on Serum Inflammatory Markers in Hemodialysis Patients with Hypovitaminosis D

Vitamin D deficiency is common in hemodialysis (HD) patients and has been reported to be associated with mortality due to cardiovascular disease and an inflammatory response. The aim of this study was to investigate the hypothesis that low dose cholecalciferol supplementation improves serum 25(OH)D and 1,25(OH)D levels, and reduces inflammatory markers. Moreover, it was to analyze the association of FGF-23 and 25(OH)D levels.

Methods: This study was an one-year intervention study for hemodialysis patients with hypovitaminosis D (25(OH)D<30 ng/mL). During the first six months, the patients received 3,000 IU of cholecalciferol after each hemodialysis (9,000 IU/week), thereafter, they stopped taking supplements. Serum levels of 25(OH)D, 1,25(OH)D, and other biological variables were measured every 3 months for one year. We investigated the effects of cholecalciferol supplementation on the biological variables and inflammatory markers. In addition, the effective factors on the levels of 25(OH)D and 1,25(OH)D after cholecalciferol supplementation were assessed by multivariate regression analysis.

Results: Twenty-nine patients with hypovitaminosis D participated in our study. During cholecalciferol supplementation, the 25(OH)D and 1,25(OH)D concentration significantly increased from baseline to six months [9.9 to 34.3 ng/mL (p<0.001) and 19.7 to 22.9 pg/mL (p<0.05), respectively]. At 6 months, 65.5% of the patients had 25(OH)D levels within the target range [30 ng/mL] with a low dose of cholecalciferol supplementation. Also serum calcium and phosphorus levels did not increase above the normal range. However, the inflammation markers, hsCRP, e-selectin, VEGF-A, were not shown significant improvement after taking cholecalciferol supplements. The effective factors on serum 25(OH)D levels were BMI, baseline 1,25(OH)D and 6 months FGF-23 concentration by multivariate regression analysis.

Conclusions: The low dose cholecalciferol supplementation was effective in correcting serum vitamin D deficiency or insufficiency and safe for hemodialysis patients. However, 6 months of low dose cholecalciferol supplementation in these patients did not improve serum vitamin D deficiency or insufficiency and safe for hemodialysis patients. However, the inflammation markers, hsCRP, e-selectin, VEGF-A, were not shown significant improvement after taking cholecalciferol supplements. The effective factors on serum 25(OH)D levels were BMI, baseline 1,25(OH)D and 6 months FGF-23 concentration by multivariate regression analysis.

Effect of Intravenous Saccharated Ferric Oxide on FGF23 Metabolism in Dialysis Patients

Fibroblast growth factor 23 (FGF23) is a phosphaturic hormone, secreted from the bone. It has been well known that the reduction in serum phosphate occurs following intravenous administration of saccharated ferric oxide. A recent clinical study showed that both production and degradation of FGF23 is enhanced in the setting of iron deficiency (M Wolf. J Bone Miner Res 2013). These findings suggest that iron may be a key regulator of FGF23. However, its precise mechanism remains to be elucidated.

Methods: We previously reported that intravenous saccharated ferric oxide further increase in elevated serum FGF23 levels in hemodialysis patients with iron deficiency anaemia, using the intact FGF23 assay which only detects the full-length protein (Am J Nephrol 2011). In this study, we additionally examined the FGF23 levels by the C-terminal FGF23 assay which detects both the full-length protein and C-terminal fragments, and compared the results of these two assays (N = 27).

Results: We previously reported that intravenous saccharated ferric oxide further increase in elevated serum FGF23 levels in hemodialysis patients with iron deficiency anaemia, using the intact FGF23 assay that only detects the full-length protein (Am J Nephrol 2011). In this study, we additionally examined the FGF23 levels by the C-terminal FGF23 assay which detects both the full-length protein and C-terminal fragments, and compared the results of these two assays (N = 27).

Conclusions: Collectively, in hemodialysis patients with iron deficiency anaemia, substantial amounts of C-terminal fragments of FGF23 accumulate by increase in both the production and degradation. The administration of saccharated ferric oxide suppresses both the production and degradation, leading to increase in values of intact FGF23 assay and decrease in those by C-terminal assay. Specific preparations of iron for intravenous use may regulate both the production and degradation of FGF23.

Serum Levels of Sclerostin (SOST) in Renal Transplantation (Tx)

Sclerostin is a negative regulator of bone metabolism. In CKD patients SOST serum levels are higher than in the general population and in HD patients SOST correlate negatively with bone turnover. Little is known about serum levels of SOST in Tx. Aim of our study was to evaluate serum SOST levels in Tx in whom few data are available.
Methods: We performed a cross sectional study in 80 Tx (55:10 y.o.:49M/31W) with CKD stage 2-4 (eGFR 47±16 ml/min). 30 healthy subjects (34:12 y.o.:eGFR59±19 ml/min) were the control group. We evaluated in all patients SOST, Ca, Pi, PTH, FGF23 and Alkaline Phosphate (AP).

Results: SOST was not different between Tx and controls (27.6±10.2 vs 23.6±8; p<0.05). The table shows the mean values of the parameters evaluated With mild vitamin D insufficiency (25D<26.1±11ng/ml), TX had normal 1,25D values, mild increment of PTH and Ca, and normal values of Pi.

Serum levels of FGF23 were increased compared to controls (47.3±13.6 vs 30.1±19,0 pg/ml; p<0.05). SOST showed a negative correlation with AP (r=-0.37; p<0.05) and a positive correlation with FGF23 (r=0.56; p<0.05) and 25D (r=0.28; p<0.05). No correlation existed with other parameters

Conclusions: eGFR does not affect serum levels of SOST in Tx. The negative correlation with AP indicates that SOST maintains its modulatory role of osteoblastic activity in this population. The correlation with FGF23, which is in agreement with low FGF23 in SOST null mice, suggests modulatory effects of both proteins on osteoblastic direct, through Wnt inhibition, for SOST; indirect, through effects on 1,25D levels, for FGF23. Serum SOST may be an additional marker of bone metabolism, useful to understand metabolic pathways in normal subjects and in CRF.

PUB547

Comparison of Cholecalciferol Supplementation Dosing with a Bolus Dose Versus Daily Administration in Chronic Hemodialysis Patients 
Pablo Molina, Belen Vizcaino, Mercedes Gonzalez Moya, Sandra Beltrán, Marco Montomoli, Cristina Castro, Jose L. Gorriz, Luis M. Pallardo.  
Nephrology, Dr Peset Univ Hospital, Valencia, Spain.

Background: The aim of this study was to assess the safety profile of bolus cholecalciferol supplementation and compare its effectiveness to daily oral administration in hemodialysis (HD) patients

Methods: This 6-month prospective, intervention study enrolled 60 stable HD patients with 25-hydroxyvitamin D (25(OH)D) levels <30 ng/ml, who received cholecalciferol (25,000 IU/week or monthly oral cholecalciferol levels >70 IU daily (n=30). Differences in biochemical parameters, including 25(OH)D, calcium, phosphorus, parathyroid hormone (PTH), alkaline phosphatase and C-reactive protein levels, were analyzed monthly. Primary outcome was 25(OH)D level at 6 months. For safety purposes, in the subgroup of patients receiving the bolus regimen, biochemical parameters were also assessed on days 2,4 and 7 after the first bolus dose.

Results: At baseline, patient and biochemical characteristics were similar in both groups. No changes were observed in calcium, phosphorus and 25(OH)D levels in the first week after the first bolus dose. Throughout the 6-month follow-up similar responses in 25(OH)D levels and other biochemical parameters were observed in both groups.

Conclusions: Supplementation of 25,000 IU fortnightly or monthly oral cholecalciferol seems to be safe, being equally effective for raising 25(OH)D levels than 700 IU daily cholecalciferol administration.

PUB548

The Prevalence of Vitamin D Deficiency Among IgA Nephropathy: A Cross-Section Study from One Center  
Minxia Li, Li Yuehong, Guangyan Cai, Xueying Cao, Xianglei Meng, Dept of Nephrology, Beijing Tsinghua Changgung Hospital Medical Center, Tsinghua Univ, Beijing, China; ‘Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing, China.

Background: Low serum vitamin D concentrations have been reported in chronic kidney disease (CKD). Very few studies concerns vitamin D deficiency of IgA nephropathy (IgAN) in Chinese patients. Our aim is to assess the deficiency of serum 25(OH)D concentrations in patients with IgAN, and to explore the possible correlated factors contributing to Vitamin D deficiency.

Methods: 283 patients who come from north China and were not receiving vitamin D supplementation were included in this study from February 2013 and April 2014. We collected blood samples to determine levels of Scr, BUN, UA, serum phosphate (P) and calcium (Ca), iPTH, albumin, as well as urinary excretion of creatinine, protein, P and Ca within 24h. Electrochemiluminescence immunoassays measured total 25-hydroxyvitamin D. Vitamin D deficiency should be defined as a 25(OH)D of < 15 ng/ml

Results: All of the 283 patients, 25(OH)D concentration was 10.25±6.94 ng/ml. Only 18.82% of the patients had a circulating 25(OH)D level greater than 15ng/ml. The prevalence of deficiency (<15ng/ml) were 87.2%, 72.9%, 75.0%, 85.4%, 93.1%(P<0.000) at different CKD stages.All the 120 IgAN patients were divided into 4 groups according to eGFR. The prevalence of vitamin D deficiency were higher in CKD stage 1 and 4 (p<0.001), but there is no difference of average 25(OH) D concentration according to eGFR (P>0.05). The 25(OH)D concentration was higher in IgAN than MN and DN patients. But, 24UPR in IgAN patients was lower than MN and DN patients. In different age, gender, season, BMI or iPTH group, 25(OH)D levels were not affected, but 25(OH)D level was lower in '3.5±24h group.

Conclusions: For the IgAN patients in north China, kidney function might be related to vitamin D deficiency, and 24UPR may play a very important role in maintaining 25(OH) D serum concentrations.

PUB549

Utility of Whole Exome Sequencing in the Diagnosis of a Family with Apparent Mineralocorticoid Excess  
Ranjit Narayanan, Nephrology, KMCT Medical College, Calicut, Kerala, India.

Background: Apparent Mineralocorticoid Excess (AME) is a rare familial disorder with hypertension, hypokalemia, metabolic alkalosis and low plasma renin and aldosterone due to mutations in the 11-β-hydroxysteroid dehydrogenase-2 (HSD11B2) gene. Five siblings of a third degree consanguous family with unaffected parents were evaluated for hypertension of juvenile onset. They had varying degrees of hypokalemia, medullary nephrocalcinosis, concentric left ventricular hypertrophy and renal dysfunction. Plasma renin and aldosterone levels were low. Given the clinical picture and autosomal recessive inheritance pattern, a provisional diagnosis of AME was made. 24 hour urinary cortisol and cortisone estimation was unavailable. We decided to confirm the diagnosis using next generation gene sequencing.

Methods: Whole blood was collected from the parents and the affected members after informed consent. 30 ng of the isolated high quality DNA was used to prepare library and sequencing. Sequencing was performed using v3 reagents to generate over 49.48 million paired end reads of 101bp. The reads were aligned to the Human genome (hg19 build, UCSC) and was further filtered for read duplicates, recalibrated and realignment was performed around well-annotated Indels from the 1000 genome project using GATK and Picard tools. Variations were called using the GATK Unified Genotyper and analysed using ANNOVAR and annotated ClinVar.

Results: Analysis revealed the presence of homozygous variation p.R337C in HSD11B2 gene annotated to be pathogenic in ClinVar and predicted to be deleterious using PROVEAN in the affected siblings. The variant was further validated using Sanger sequencing of the amplicons, confirming the diagnosis. Both parents were heterozygous for the variation. This variation has been reported to be associated with the similar phenotype in two independent studies on native American populations.

Conclusions: A homozygous mutation (p.R337C variation) in the 11HSD2 gene was demonstrated in the family using whole-exome sequencing. This is the first genetically demonstrated Syndrome in the family with whole-exome sequencing. This is the first genetically characterized report of AME from Indian population. Our study underscores the utility of using next generation sequencing in the diagnosis of rare inherited diseases.

Genetics of Thrombotic Microangiopathies – The Viennese TMA Cohort  
Christof Aigner,1 Martina M. Gaggi,1 Zoltan Prohaska,2 Raute Sunder-Plassmann,3 Gene Sunder-Plassmann,1 Alice Schmidt,1 *Dept of Medicine III, Div of Nephrology and Dialysis, Medical Univ of Vienna, Vienna, Austria; *IIId Dept of Internal Medicine, Research Laboratory, Semmelweis Univ, Budapest, Hungary; 1Dept of Laboratory Medicine, Laboratory for Molecular Diagnostics, Medical Univ of Vienna, Vienna, Austria.

Background: Thrombotic microangiopathies (TMA) classified as hemolytic uremic syndrome (HUS) are characterized by acute kidney injury (AKI), mechanical hemolysis and thrombocytopenia, caused by an excessively activated alternative pathway of the
publication

complement system. This is a result of either genetic alterations within complement factors and regulatory proteins or secondary causes. The aim of this study was to symptomatically investigate our cohort of patients with TMA regarding genotype and triggers of disease episodes.

Methods: Data were analyzed by means of patient records: Demographic and laboratory data, results of kidney biopsies, results of genetic sequencing of complement regulatory proteins, CFH, thrombomodulin (THBD) and C3, and medical history for triggering factors were analyzed.

Results: Out of 92 patients with TMA we classified 30 as atypical HUS (aHUS), 1 as classic HUS, 21 as secondary HUS. At onset of disease patients with aHUS had a mean age of 25 years (range: 1-47), 20 were female (67%), and 13 (43%) were kidney transplant recipients. First presentation of 24 patients was AKI, 3 showed hemolysis, 2 had pre-eclampsia and 1 HELLP-syndrome. Distinct triggering factors in 20 patients were: infection (n=10), pregnancy (n=2), surgery, diarrhea and renal transplantation (each n=1). Thirteen and 3 showed a CFH-H3 and a MCPggaac risk haplotype, respectively; potentially disease-causing mutations were identified in 22 patients (7 CFH, 6 CD46, 5 CFI, 4 C3, 2 CFB, 1 THBD; 4 of them with more than 1 mutation); 7 showed wild-types and no data existed for 1 patient.

Conclusions: In our cohort of TMA patients we identified 30 cases of aHUS. In 22 patients (74%) we identified a mutation within genes of the complement regulatory proteins or C3, whereas 7 subjects showed wild-type sequences despite presenting with a classic phenotype of aHUS.
without IgG or C3. Metabolic analyses showed an elevation of plasma homocysteine, methylmalonic acid, and propionylcarnitine concentrations. Genetic analyses found a compound heterozygosity in MMACHC gene, with c.271dupA and c.82-9delTTTC mutations. The patient’s brother died at the age of 17. Autopsy revealed pulmonary capillary hemangiomatosis, while the kidney histology showed similar lesions to those of his brother.

Conclusions: This is the first report of late-onset rTMA, atypical glomerulopathy, and PAH associated with cblC deficiency. We suggest that the association of rTMA and/or glomerular proteinuria with PAH in children and young adults should prompt metabolic investigations to identify cblC deficiency, and provide early specific management including hydroxycoenzyme A, folinic acid, and betaine.

PUB555

The DS3 Scores and Quality of Life in Japanese Patients with Fabry Disease

Nobuhito Hirawa,1 Keisuke Yatsu,2,3 Sanae Saka,1 Gen Yasuda,1 Satoshi Umemura.1 1Dept of Nephrology and Hypertension, Yokohama City Univ Medical Center, Yokohama, Kanagawa, Japan; 2Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Kanagawa, Japan.

Background: Fabry disease (FD) is the lysosomal storage disorder, caused by the deficiency of lysosomal hydrolase α-galactosidase A activity. Various symptoms associated with renal disease, heart lesion and cerebrovascular disease occur in Fabry disease patients. Thus, the quality of life (QoL) would be altered with the disease progressed. We evaluated the clinical severity and the QoL in a sample of Japanese patients with Fabry (FD) disease using the Disease Severity Scoring System (DS3) and the SF-36 survey in male and in female.

Methods: Observational cross-sectional study. The DS3 and SF-36 survey was administered to the patients of the hospitals, which belong to the research group of Kanagawa enzyme replacement therapy. Participants were treated with agalsidase-alpha or agalsidase-beta. Disease activity was assessed by the Disease Severity Scoring System (DS3). The QoL was measured by Short form-36 (SF-36) and the Kidney Disease Qol. Short form version 1.3 (KDQol).

Results: Fifteen patients were included in the study. Mean age was 45 years (M/ F=10/5), and all patients were receiving ERT. The mean serum Cr was 2.9 mg/dl. The DS3 scores were follows; mean assessment score: 26.5 +/- 10.1, average domains: 10.5 +/- 9. The renal domain and the cardiac domain showed relatively high score compared to PNS and CNS scores. The QoL scores of the FD patients were lower than those of general population, but the scores were better than the previous reports of FD from U.S. or EU. The mental component summaries of women were similar to those of the general population. The physical component summaries of QoL were negatively associated with the KDQol (-0.554; p=0.001).

Conclusions: Japanese patients with FD receiving ERT had a relatively good QoL beyond anticipation. DS3 score is useful for assessing disease severity, and may predict some components of QoL.

PUB556

Two Cases of Fabry Disease in Women with Proteinuria Diagnosed by Molecular Analysis of α-Galactosidase A Gene and Kidney Biopsy

Oh Young Lee.1 Eun-Young Lee.1 1Internal Medicine, Soonchunhyang Univ, Cheonan, Chungcheongnam-do, Korea; 2Internal Medicine, Soonchunhyang Univ, Cheonan, Chungcheongnam-do, Korea.

Background: Fabry disease is a X-linked lysosomal storage disorder caused by deficiency of α-galactosidase A. This abnormality in enzyme results intracellular accumulation of globotriaosylceramide and leads to severe neuropathy with progressive renal, cardiovascular, and cerebrovascular dysfunction and early death. We report 52 and 55 year-old women with proteinuria and hematuria, which were proven to be due to Fabry disease.

Methods: A 52 and 55 year-old women was admitted to the hospital due to proteinuria. They denied previous histories of hypertension, diabetes mellitus, pulmonary tuberculosis, and nephritis. Their sister and cousin diagnosed fabry disease. Physical examination revealed nonspecific findings. On admission, blood pressure 110/60 mmHg, heart rate 64/min, respiratory rate 16/min, body temperature 36.5°C. Lungs were clear and heart was normal. The extremities showed no edema, cyanosis or skin rashs. The laboratory data showed the WBC 3560/mm³, HB 13.2 g/dl, Platelet 212,000/mm³, BUN 10.2 mg/dl, serum creatinine 0.7 mg/dl. Urinalysis showed pH 5.0 SG 1.023 protein + RBC 5-9/HPF WBC 5-9/HPF. 24-hour urine protein was 533 mg. Abdomen & Pelvic CT and echocardiography were normal. The senologic study was normal. The kidney biopsy showed expansion of mesangial matrix and glomerular hypertrophy. The cytoplasm of podocytes was vacuolated, which consisted of multiple, variable-sized, concentric electron-dense lamellated structures, by electron microscopy.

The enzyme activity for α-galactosidase in serum was 0.59 nmol/min/mg protein.

Conclusions: The patients received enzyme replacement therapy every other week. They had reduction in proteinuria and normal renal function.

PUB557

Intradaylisis Partial Parenteral Nutrition (IDPN) in Hemodialysis Patients (HDP) with Protein Caloric Malnutrition (PCM): Preliminary Results

Susana Beatriz Asis.1 Marcela Fabiana Munizaga.1 1Servicio de Nefrologia, Hospital Nacional de Clinicas, Cordoba, Argentina; 2Servicio de Nefrologia, Hospital Nacional de Clinicas, Cordoba, Argentina.

Background: PCD is higly prevalence in HDP and predicts morbi-mortality. NPID is according Esben Guidelines (march2012) and the SMOFF formula(uoja,TG,olive oil and fish oil), improve inflammation and lipid status.Our goal is to define the evolution of nutritional parameters in HDP and characterize them for future interventions. OBJETIVE: To evaluate if severe PCD in HDP, improve malnutrition and inflammation markers such as albumin(Ab),cholesterol (Ch), reactive C protein(RCP).

Methods: Prospective and observational study that included 14 patients up this time,both sexes,age27-80 years old, in maintenance HD from a University Hospital and Army Hospital.Patients signed informed consent. Patients received each HD session and during six months,SMOF lipids 4 gr/kg/dy IV continuous infusion. We analyzed weight, Hematorcrit,Alb,Ch,TG,creatinine,RCP and Global Subjetive Valorization(GSV) in pre HD blood samples at the beginnig,three and six months.Cuantitative demographic variables(age,sex,biochemic parameters)were expressed as medium,SD and applied Student Wilcoxon Test and Chi Test (p<0.01).

Results: fourteen patients improved weight(63,1+/-3,3vs64,9+/-3,5,p:0,311),albumin(g/dl)(33,3+/-1,27/6.94vs33.7+/-1.3,p:0.856),CH(mg/dl)(28,9+/-6,7vs10,1+/-2,5,p:0.009),there were not statical significance inHto(gr/dl)(13,3+/-1.9vs33,7+/-1.7,p:0.856),creatinine(g/dl)(7.7+/-0.7vs7.4+/-0.5,p:0.233). In proteinuria there was not statical significace in RCP(mg)(28,9+/-6.710,1+/-2,5,p:0,009).there were not statical significance in fat(g)(163,9+/-12.9vs165+/-13.9,p:0.846)

Conclusions: 1- NPID is a successful tool as partial suplementation in HDP with oral dietary intake.2-In spite of our sample is small, the improvement of Nutritional and inflammatory status, applying Internatmeal Guidelines was observed after three months of treatment.3- Medical awareness about nutritional risks in HDP, is the best tool to prevent alteration of nutritional status 4-We`ll expand the sample.

PUB558

Association of Protein Energy Wasting with Income in Chronic Kidney Disease Stage 3 Patients

Anita Saxena, Amit Gupta. Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, Uttar Pradesh, India.

Background: Protein energy wasting (PEW) is a major challenge in CKD. Purpose: Assessment of PEW in predialysis patients at first visit to a nephrologist.

Methods: Three day dietary intake of 484 CKD stage 3 patients. Patients were divided in to groups based on appetite and BMI.

Results: Male and female parameters: Serum albumin 3.70±0.84/3.68±0.81g/dl;total protein 7.02±1.27/6.94±1.26 g/dl;creatinine 4.68±4.19/3.74±3.36 mg% creatinine clearance 33.22±30.48/37.55±33.87 ml/minute, BMI 22.60±4.29/23.43±4.77 kg/m² energy/kg 16.97±0.65/16.8±0.64, protein g/kg 6.65±0.28/6.46±0.30, carbohydrate g/kg 2.98±1.54/2.88±1.36, fat g/kg 2.96±0.23/2.79±0.22, respectively. As appetite decreased dietary protein and energy intake decreased significantly.
Appetite was average 14.46% (± 1.23) poor 9.7% (± 1.18), anorexic 33.2% (± 4.7) in males and females. Income correlated with BMI (p < 0.001), dietary protein (p < 0.001) energy (p < 0.001), and carbohydrate (p < 0.001). Appetite correlated with creatinine (p < 0.019), dietary energy, protein, carbohydrate, and fat intake (p < 0.001). BMI correlated with protein, fat, carbohydrate, energy and creatinine intake. Anova showed significant difference among groups in energy, protein, fat, carbohydrate, creatinine intake (p < 0.001) and serum creatinine (p < 0.001) and serum creatinine intake (p < 0.001) between groups. Based on income there was significant difference between groups in BMI (0.001), energy intake (p < 0.019), protein (p < 0.01), albumin (0.001).

Conclusions: With decline in renal function, appetite worsened and nutritional intake decreased. Energy intake was significantly deficient. 84% patients had reduced appetite and 69.2% had PEW. Low income is a risk factor for PEW in CKD.

PUB589
Study on Correlation Between Serum Creatinine, Cystatin-C, Urinary Albumin
Cystatin Ratio and Body Composition
Xuemei Li, Jin Ma
Nephrology, Peking Union Medical College Hospital, Beijing, China.

Background: Based on an epidemiological survey in Peking, China, to study the correlation between serum creatinine, Cystatin-C and urinary albumin cystatin ratio (ACR) and body composition.

Methods: Residetns over the age of 35 of the Beijing Pinggu District by random sampling method. Laboratory test: take morning ACR, blood samples were taken for blood routine, kidney function test. Body composition analysis after emptying the bladder by using INBODY-720 machine.Use SPSS 17.0 software for data statistical analysis, count data were analysed by using multivariable linear regression.

Results: A total of 9283 people participated in the survey, which 4324 males, age 54.71±10.7 years, 4599 females, age 53.1±11.2 years. Male: 1) Human body cell mass (BCM) and ACR, Cystatin-C, no correlation, was positively correlated with height (B=0.43, P<0.01), and serum creatinine was that positive correlation (B=0.01, P<0.01). 2) Lean body mass (FFM) and ACR, serum creatinine, Cystatin-C, no correlation. 3) Skeletal muscle content and ACR, serum creatinine, Cystatin-C, no correlation. 4) Body fat mass and ACR, no correlation, and Cystatin-C was positively correlated with (B=0.79, P<0.01). Female: 1) Human body cell mass (BCM) with height and cystatin-c, no correlation, but positively correlated with serum creatinine (B=0.035, P<0.01), and ACR was negative correlation (B<0.005, P<0.05). 2) Lean body mass (FFM) and ACR, Cystatin-C, no correlation, and serum creatinine were positively related (B=0.035, P<0.01). 3) Skeletal muscle content and ACR, Cystatin-C, no correlation, and was positively correlated with height (B=0.031, P<0.01), and serum creatinine were positively related (B=0.035, P<0.01). 4) Body fat mass and ACR was negative correlation (B=0.01, P<0.05) Cystatin-C was positively correlated (B=12.3, P<0.01), and age were negatively correlated (B=0.13, P<0.01), and serum creatinine was negative correlation (B=0.092, P<0.01).

Conclusions: There was a positive correlation between serum creatinine and the human body cell mass (BCM), lean body mass (FFM) in men, and skeletal muscle content, body fat weight in women, but the correlation is not strong. The blood cystatin-C and body fat weight was positively correlated.

PUB560
Worsening Nutritional Status Assessed Is an Independent Predictor of All-Cause Mortality in Incident Dialysis Patients
Jong Hyun Jhee, Young Eun Kwon, Tae-Hyun Yoo, Shin-Wook Kang
Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Malnutrition is closely associated with mortality in end-stage renal disease (ESRD) patients. However, little is known whether improvement or deterioration of nutritional status after dialysis initiation affects clinical outcome. This study was aimed to elucidate the association between the changes of subjective global assessment (SGA) after dialysis initiation and mortality in ESRD patients.

Methods: Data were collected from the Clinical Research Center for ESRD cohort. SGA score was measured by trained investigators at the time of dialysis initiation and after 12 months. Nutritional status was defined as well-nourished (SGA 6-7), A, mildly to moderately malnourished (SGA 3-5, B), or severely malnourished (SGA 1-2, C). Severely malnourished patients (SGA C) were excluded due to small sample size. The patients were divided into four groups according to the change of SGA: group 1, b) group 2, A to B; group 3, A to B; and, group 4, B to B. Results: A total of 911 patients were enrolled. The mean age was 54.6±14.1 years, 554 patients (60.9%) were male. During a median follow-up duration of 30 months, 109 patients (12.0%) died. Survival rate of group 1 was the highest, and that of group 4 was the lowest (group 1, 77%; group 2, 72%; group 3, 64%; P<0.001). Worsening nutritional status was a significant risk factor for mortality (group 3 vs. 1, HR=3.15, CI=1.51-6.54, P<0.002), while baseline nutritional status at dialysis initiation was not (group 1 vs. 2, P=0.063; group 3 vs 4, P=0.107).

Conclusions: Improvement of nutritional status after dialysis initiation could be beneficial for patient outcomes regardless of baseline status, suggesting that intervention to improve nutritional status after dialysis initiation might be a strategy to reduce mortality in ESRD patients.

PUB561
Prophylactic Effect of Erythropoietin Injection to Prevent Acute Mountain
Sickness: An Open-Label Randomized Controlled Trial
Hyun Jhee, Soon Bae Kim
Div of Nephrology, Dept of Internal Medicine, Univ of Ulsan, College of Medicine, Asan Medical Center, Seoul, Republic of Korea.

Background: This study was performed to evaluate whether increasing hemoglobin before ascent by prophylactic erythropoietin injections prevents acute mountain sickness (AMS).

Methods: This open-label, randomized, controlled trial involved 39 healthy volunteers with hemoglobin $15.5g/dL, who were divided randomly into erythropoietin (n=20) and control (n=19) groups. Epoetin alpha 10,000 IU injections were given weekly for four consecutive weeks. On day 1, and 7 days after the last injection (day 29), oxygen saturation (SatO2), and hemoglobin were measured. The subjects departed Seoul on day 30 and arrived at ANNAPURA base camp (ABC, 4,130 m) on day 34. AMS was diagnosed when headache and Lake Louise score (LLS) of ≥ 3 were present. Immediate descent criteria followed US Army recommendations.

Results: Two groups differ in hemoglobin levels on day 29 (15.4 ± 1.1 vs 14.2 ± 1.0 g/dL, P<0.001). At ABC, erythropoietin group had a significantly lower mean LLS, AMS incidence, and number of subjects who met immediate descent criteria. Multiple logistic regression analysis showed that SatO2 < 87% and control group, but no hemoglobin < 15.0 g/dL, independently predicted satisfaction of immediate descent criteria.

Erythropoietin-related adverse effects were not observed.

Conclusions: Erythropoietin-related adverse effects were not observed. In conclusion, erythropoietin may be an effective prophylaxis for AMS.

Funding: Pharmaceutical Company Support - CJ pharmaceutical

PUB562
Nutritional Assessment for the Chronic Dialysis Patients with/without Sarcopenia
Miiho Suzuki, Yuya Sakai, Ikuto Masakane. Tabuki Hospital.

Background: A recent arising problem of chronic dialysis patients is sarcopenia closely related to malnutrition. Muscle loss deteriorates daily activities of dialysis patients and ultimately worsens the QOL and prognosis of the patients. The aim of this study was to clarify the relationship between the nutritional status and sarcopenia and to analyze the status of nutrient intake in these patients.

Methods: 90 chronic hemodialysis patients were enrolled to the current study. (age 62.8±5.4 years. Men were 76%, DM 41%).Skeletal muscle mass (SMM) was estimated by bioelectrical impedance analysis and a low muscle mass was defined by the SMM index (SMM [kg] / height [m]² > 7.0kg/m², women: 5.7kg).Muscle function was estimated by grip strength and walking speed as the Timed up and go test (TUG).A low grip strength was defined as less than 26 kg (men) or 18 kg (women). TUG less than 11 second was diagnosed as a low walking speed.Malnutrition was defined as by the Nutrition-Inflammation-Inflammation Score(MIS)(≥6point), GNRI(<92) and the criteria of protein energy wasting (PEW).The dietary assessment was performed by the food frequency questionnaire.

Results: Sarcopenia was identified in 22% of the subjects. The sensitivity to detect sarcopenia was not sufficient as 35% in MIS, 50% in GNRI and 10% in PEW. In the patients with sarcopenia, the average of total energy intake and protein was significantly lower than those in non-sarcopenia, 1618±122kcal vs 2041±65kcal in energy, 52±4g vs 68±2g in protein. The intake of fish and meats (110±15g vs 153±8g),beans (31±11g vs 61±6g),confectionery, beverages and sugar (126±77g vs 306±41g ) were significantly lower in sarcopenia than non-sarcopenia.

Conclusions: Malnutrition-related sarcopenia was only 10-50% among sarcopenia. It is important to measure muscle mass and muscle function regularly for dialysis patients because it is not enough to screen sarcopenia only by nutritional measurements. Sufficient protein and energy intake are essential for the prevention of sarcopenia. If patients don’t have appetite,confectionery or a beverage or sugar may be acceptable for the prevention of muscle loss.

Stomach Acid Reducers May Predict Nutritional Deficiency in Dialysis Patients

Klaia Bertes, Mihaly B. Tapolyai, Maria Faludi, Melinda Forro, Ákos Géza Pethő. Dialysis, Fresnes Medical Care Semmelweis Univ, Budapest, Hungary.

Background: Malnutrition is a major predictor of mortality among dialysis patients. Malnutrition markers are thus regularly monitored in order to intervene when the nutritional status may decline. We investigated whether taking stomach acid reducing medications may indicate future nutritional risk.

Methods: This is a cross sectional study of 103 patients undergoing chronic hemodialysis in Budapest, Hungary at a university hospital based dialysis unit. The patients’ nutritional indicators such as serum albumin, phosphorus, nPCR and whether they were on diet counseling were assessed. Information on medication were collected among those who did not take an acid reducing agent, such as a proton pump inhibitor (PPI) or H2 blocker.

Results: Six patients were excluded because data were incomplete or the patients had not been on dialysis for more than 2 months. Of the 96 patients 44% took an acid reducer on a regular basis. The serum albumin (3.7±0.02 mg/dL vs. 3.56±0.01 p<0.008), phosphating (1.88±0.49 mmol/L vs. 1.64±0.54 p<0.04) and nPCR (1.00±0.20 vs. 0.91±0.25: p=0.06) were lower among PPI takers. PPI takers were much more likely to be taking cholecalciferol for measured 25-OH-vitamin-D deficiency (1.8% vs. 18.1% p=0.01). While PPI takers were older (59.7±16.2 years vs. 65.7±13.3 p<0.04), there was no difference in the two populations in the presence of an AV Fistula, delivered Kt/V, calcium or serum bicarbonate.

Conclusions: We conclude that taking PPI’s or H2 Blockers in dialysis patients may be an indicator of being at risk for malnutrition.

Impact of the Potassium Additives on the Total Content of This Element in Processed Foods

Margareth Lage L. de Fornasari,1,2 Maria raquel Manhani,1 Yvoty As Sens.1,2
1 Post Graduation, Santa Casa de Sao Paulo School of Medical Sciences, Sao Paulo, SP, Brazil; 2 Nutrition, Sao Judas Tadeu Univ, Sao Paulo, SP, Brazil.

Background: The additives of potassium salts are allowed in processed foods to preserve, to inhibit mold, to emulsify products. Patients with chronic kidney disease need to control the intake of potassium, and are advised for doctors and dietitians to restrict potassium, mainly in patients with renal disease. Therefore, we aimed at this study to determine the actual potassium content of a number of products often consumed in the presence of an AV Fistula, delivered Kt/V, calcium or serum bicarbonate.

Methods: We collected two dialysis days (DD) and two on non-dialysis days (NDD) using the USDA 5-pass method. Dietary information was entered and analyzed using diet analysis software

Results: All products had potassium-containing additives listed among their ingredients. The medium values of potassium (mg for 100 g or mL) for the different foods were: milk beverages, yogurt, a type of cream cheese, margarine, tomato sauce, salad dressing, milk beverages, yogurt, a type of cream cheese, margarine, tomato sauce, salad dressing, powder, powdered juices, and had potassium sorbate or other potassium salts. The concentration of potassium (mg K/100 g of food) was determined by flame photometry according to the Adolfo Lutz Institute methodology, and in triplicate. The comparison of the potassium obtained with the expected potassium was based on two national reference tables.

Conclusions: Processed foods with potassium additives contain higher levels of potassium than those listed in reference tables.

Differences in Eating Patterns Between Maintenance Hemodialysis Patients from the U.S. and the UK

Anabel Birute,1 Brandon Kistler,1,2 Kristin P. Wiens,1,2 Peter J. Fitschen,1 Alice C. Smith,1 Ken Wilund1
1 Univ of Illinois; 2 Leicester Kidney Exercise Team, Univ of Leicester, United Kingdom; 3 Univ of Delaware.

Background: Maintenance hemodialysis (HD) patients in the United States (US) have poorer nutritional status than their European counterparts. The characteristics and clinical practices are hypothesized to contribute to these differences. Therefore, our aim was to compare eating patterns between HD patients from the US and the United Kingdom (UK).

Methods: HD patients (US=86,UK=29) were recruited. Four 24-hour diet recalls were collected, two dialysis days (DD) and two on non-dialysis days (NDD) using the USDA 5-pass method. Dietary information was entered and analyzed using diet analysis software and then grouped into eight food categories according to NHANES. Food security was measured 25-OH-vitamin-D deficiency (1.8% vs. 18.1% p=0.01). While PPI takers were older (59.7±16.2 years vs. 65.7±13.3 p<0.04), there was no difference in the two populations in the presence of an AV Fistula, delivered Kt/V, calcium or serum bicarbonate.

Conclusions: Processed foods with potassium additives contain higher levels of potassium than those listed in reference tables.

Is Reverse Epidemiology in BMI of Maintenance Hemodialysis Patients Adaptable to the Patients without PEW?

Yuya Sakai, Miho Suzuki, Ikuto Masakane. Yabuaki Hospital.

Background: Reverse epidemiology has been addressed in Body mass index (BMI) of chronic hemodialysis patients; the lowest mortality rate in BMI 24-26 as reported by the Japanese Society for Dialysis Therapy. The higher BMI the lower mortality as stated by the Dialysis Outcomes and Practice Patterns Study. However, because these survey subjects included lower BMI patients with malnutrition and chronic inflammation, the high BMI patients’ mortality risk might have been relatively low. The optimal BMI derived from these epidemiological analysis may not be well indicated for the patients who do not have malnutrition and inflammation. So, we aim to study the optimal BMI of maintenance hemodialysis patients without Protein Energy Wasting (PEW).

Methods: 183 patients on maintenance hemodialysis patients were enrolled in the current study. All subjects have over 2 years of dialysis diagnosis and are not applicable to PEW and don’t have inflammation which was defined as CRP less than 0.3 mg/dL as of December 2009. The observation period is from December 2009 to December 2014. The subjects were classified into 4 groups on BMI scale (<18.5, 18.5≤22.8, 22.8≤25, 25≤27.5). The 5-year cumulative survival rate, the death risk factor, and each BMI groups’ relative mortality risk for BMI 22≤25 group were examined.

Results: During the observation period, clinical deaths resulted in 19 patients, changing hospital or accidental death resulted in 22 patients. There was no significant difference in cumulative survival rate of BMI groups. Age, diabetes mellitus, albumin were dependent risk factors for death. When the mortality risks were adjusted by these 3 parameters, the mortality risk of BMI ≤18.5 was significantly higher than each of the 3 BMI groups (HR 6.97, P=0.0017). The mortality risk of BMI <25 was relatively higher than BMI 22<25 group but not significant.

Conclusions: In the maintenance hemodialysis patient without PEW syndrome and inflammation, the patients of BMI <18.5 have a higher risk of death so they require nutritional management to maintain and/or achieve a BMI ≥18.5. Reverse epidemiology in BMI was not applicable to the Japanese dialysis patients without PEW and inflammation.

Body Weight and Proteinuria Determine Plasma Triglycerides via Hepatic Syndecan-1/Heparan Sulfate in Experimental Nephrosis

Santia Aden,1 Harry Van Goor,2 Gerjan Navis,3 Stephan J.L. Bakker,1 Jacob van den Born.1,2 Nephrology, Univ Med Center Groningen, Netherlands; Pathology, Univ Med Center Groningen, Netherlands.

Background: Dyslipidemia contributes to a high cardiovascular risk profile of proteinuric patients. Via its hepatic uptake receptor (HS) side chain, syndecan-1 (syn-1) is a major uptake receptor of remnant lipoproteins. We hypothesized that proteinuria induces changes in hepatic syn-1/HS metabolism leading to dyslipidemia, which is reversed by caloric restriction (CR).

Methods: We used the hypertensive rat MWF proteinuria model. Male rats (22 wks) were nephrectomized and fed ad libitum (AL) food (MWF-AL; n=14), or CR (MWF-CR; n=13, 60% of MWF-AL food intake). Wistar rats matched for sex, age, nephrectomy on AL food intake served as controls (W-AL; n=6). Sacrification is at 48 wks. Wistar control rats were sacrificed at 22 wks (Young W-AL; n=6). Body weight, blood pressure, plasma creatinine, cholesterol, triglycerides, and proteinuria were measured at 22 and 48 wks. Livers were used for qRT-PCR and immunostaining. Correlation analysis was done by linear regression analysis.

Results: Renal aging (W-AL vs Young W-AL) was associated by mild proteinuria and dyslipidemia (both p<0.05). Compared to W-AL rats, at 48 wks MWF-AL rats developed hypertension, proteinuria, reduced creatinine clearance (all p<0.05) and comparable dyslipidemia. CR reversed all these parameters in MWF-CR compared to W-AL rats (p<0.05). Hepatic syn-1/HS side chain remodeling was associated by increased HS sulfation in proteinuric W-AL and MWF-CR. CR normalized syn-1 protein levels and increased HS sulfation. Syn-1 appeared positively (r=0.366, p<0.02) and HS sulfation inversely (r=-0.450, p<0.005) associated with plasma triglyceride concentrations. Both associations were lost after adjustment for body weight or proteinuria.

Conclusions: CR normalized hypertension, renal function, proteinuria, dyslipidemia and syn-1/HS in MWF rats. Regression analysis suggests that body weight and proteinuria reduce hepatic HS sulfation, leading to hampered TRL binding and uptake and increased TG values.

Obese Donors: The Multidisciplinary Approach in Improving Outcomes

Giselle Guerra,1 Ian Thomas,1 Panagiotis Tryphonopoulos,2 Linda J. Chen,2 Gaetano Ciancio.2 1Dept of Medicine, Miami Transplant Inst, Miami, FL; 2Dept of Surgery, Miami Transplant Inst, Miami, FL.

Background: Living donation appears safe over the years but concerns still exists long term. Analyses similar of unilateral nephrectomy have included patient compliance issues, changes to doses in response to serum drug levels closely monitored. Patients are satisfied with the new homecare service and clinicians value the use of Pharmacist Independent Prescribers has insured the whole pathway is efficient and the nephrologist for clarification and interventions.

Methods: A single center retrospective analysis was performed at out transplant center. Study period: January 1, 2013 – November 30, 2014. LDK ages 18-65 were assessed: 1. Study Arm (SA): obese LDK with BMI>30 who were enrolled into a nutritional program. 2. Control arm (CA): non-obese living donor candidates at the time of referral. Weight loss prior to surgery and afterwards, surgical complications, loss of kidney function (eGFR), and proteinuria (spot urine protein/spot urine creatinine ratio) after 6 months from donation were reviewed.

Results: Patient demographics - SA:15 African Americans (AA), 13 Hispanics (H), 7 White, 1 Other, 3 Unknown versus CA: 55 H; 49 Whites; 20 AA; 5 Other [figure1]. In the SA: 24/40 had BMI>35 at time of referral and placed in nutritional program; 8/24 dropped BMI to less than 35 prior to surgery and 3/24 pending surgery now; 4/24 ruled out due to medical issues & (9/24) were non-compliant. Surgical complications 1/8: Parasthesia. After donation in SA, blood pressure remained stable, 2/8 gained weight, kidney function at 6 months: 47% of obese donors had a decrease in eGFR at 6 months of 40% or greater. The mean decrease in eGFR was 33.9% in the study arm. In the control arm: 55Hispanics; 49 Whites; 20 AA; 5 Other. 15% had a decrease in eGFR at 6 months 40% or greater and the mean decrease in eGFR was 28.9.

Conclusions: Obese living donors needs careful analysis especially in minority populations since there is a trend to have a greater loss in kidney function after donation. Donation is possible but strict nutritional and guidelines and medical evaluation need to persist for the wellbeing of these patients long-term.

The Role of Renal Pharmacist in Prescribing Immunosuppressant Medication for Renal Transplant Patients to Improve Safety

Jrrt Baig, Preetham Boddanna. Pharmacy Dept, Gloucestershire Hospitals NHS Foundation Trust, Gloucester, Gloucestershire, United Kingdom.

Background: This paper describes the safe and efficient repatriation of renal immunosuppressant prescribing from General Practitioners (GPs) to secondary care using hospital Pharmacist Independent Prescribers (PIPs).

Methods: From March 2015 the UK commissioner NHS England required all renal immunosuppressant medication, which was traditionally prescribed by GPs following nephrologists’ advice, to be prescribed by hospital renal prescribers. Gloucestershire hospitals NHS Foundation Trust decided to use Pharmacist Independent Prescribers to implement this change and provide the ongoing service using commercial Homecare Companies. All Patients were initially sent detailed information about the changes and asked to consent. On receipt of the completed consent form the PIP wrote the initial homecare prescription which was then processed by the pharmacy homecare team. Patients continued to be reviewed at regular intervals by their nephrologists. Details of these consultations were documented using a central renal database which included graft function, drug levels to be reviewed at regular intervals by their nephrologists. Details of these consultations were documented using a central renal database which included graft function, drug levels and communications with GPs. The Pharmacist Prescribers subsequently reviewed the renal database prior to generating new homecare prescriptions and, when necessary, contacted the nephrologist for clarification and interventions.

Results: This service reconfiguration has resulted in safe and robust pathway. The use of Pharmacist Independent Prescribers has insured the whole pathway is efficient and closely monitored. Patients are satisfied with the new homecare service and clinicians value the pharmacists’ input. Pharmacist prescribers have made a number of interventions which have included patient compliance issues, changes to doses in response to serum drug levels and appropriate brand changes to improve cost effectiveness.

Conclusions: The use of Pharmacist Independent Prescribers to prescribe and manage the renal immunosuppressant homecare service at Gloucestershire Hospitals NHS Foundation Trust has been shown to be safe and efficient.

Tools for Adverse Events Prevention in a Hemodialysis Facility: A Local Experience

Cinthia Sobral Vieira,1 Cassiana G. Prates,2 1Nephrology Service, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil; 2Hospital Epidemiology and Manager Risks Service, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil.

Background: After the publication “To err is human” there has been a new approach to prevent risks in health system. According to the International Patient Safety Goals there are six steps to be followed like patient identification, proper communication, right surgery in the right patient, right side, fall prevention, high alert medication and infection prevention. The goal is to show how a hemodialysis unit, for ambulatory and hospitalized patients leads with adverse event prevention.

Methods: This experience happens in a hemodialysis unit with 101 patients, 3 shifts of 4 hours. It is located in a general hospital in Porto Alegre, south Brazil.

Zinc Deficiency Correction and Phosphaturia in Children with CKD – A Pilot Study

Vladimir Belostotsky,1 Stephanie A. Atkinson,1 Michelle N. Rasiah,1 Steven Arora,1 Ji Cheng,1 Joanne Grimmier,2 Guido Filler.1 1Pediatrics, McMaster Children’s Hospital, Hamilton, ON, Canada; 2Pediatrics, Children's Hospital, London Health Sciences Centre, London, ON, Canada.

Background: There are no guidelines for correction of Zinc (Zn) deficiency in Chronic Kidney Disease (CKD). Experimental data (Morshita 2001) suggests that Zn modulates the phosphaturic response to PTH and may increase phosphaturia. Aim: To identify Zn deficiency and determine whether 3 months of oral Zn therapy normalizes Zn status in children with CKD. To assess feasibility of conducting a clinical trial similar to Morshita’s in mice and gather information on clinical outcomes and relationship between Zn status and correction of Zn deficiency and phosphate (P) excretion.

Methods: 40 patients (pt) 4-18 yr with primary CKD and CKD due to declining graft function were enrolled from 2 tertiary pediatric nephrology centers. Plasma Zn was measured by High Resolution Magnetic Sector Inductively Coupled Plasma Mass Spectrometry at baseline and 3 months with routine blood and urine parameters. Pt with Zn<11.5 mmol/L were treated for 3 months with Zn citrate tablets (10mg Zn/day for 4-8 yr and 20 mg/day for 9-18 yr). Statistical analysis was done using nonparametric methods and relative risk ratio.

Results: Of 21 pt (M:13, F:8) with completed data, Zn deficiency was found in 10. Stages of CKD were: 2-11 pt, 3-5 pt, 4-5 pt. One pt was hyperphosphatemic. 2 Zn deficient pt had abdominal discomfort whilst taking Zn. Plasma Zn improved in 8 out of the 10 treatment pt (4.4 times more frequently than in control pt) after 3 months of Zn therapy. Zn therapy over 3 months did not change serum P (median 1.23 mmol/L to 1.25 mmol/L) or its fractional excretion (median 24.08% and 21.71%).

Conclusions: Zn deficiency occurred in about 50% of CKD pt. Preliminary analysis indicates that 3 months of oral Zn supplementation is likely beneficial in Zn deficient pt but a larger sample size is required to evaluate the impact of correction of Zn deficiency on other metabolic parameters. Correction of Zn deficiency does not alter P excretion in pt with normal blood P. Similar studies are feasible to perform in hyperphosphatemic pt.

Proteinuria as a Marker of Severe Unilateral Ureteral Obstruction in Infants

Mariselas Rosa-Sanchez, Jayanthi Chandar, Wacharee Seehurongv, Chryso P. Katsoufis, George N. Sfakianakis, Rafael Gosaulbez, Andrew Labbie, Gaston E. Zilleruelo, Carolyn L. Abitbol. Pediatric Nephrology, Nuclear Medicine, Pediatric Urology, Holtz Children's Hospital/Uof Miami, Miami, FL.

Background: Unilateral ureteral obstruction (UO) is a common congenital anomaly in infants. Controversies remain regarding clinical indications for timely surgery. The objective was to compare the radiologic and laboratory parameters of a cohort presenting with significant unilateral hydronephrosis that were managed either conservatively or surgically.

Methods: This retrospective analysis included 81 infants during a 10 year period with high grade hydronephrosis designated by renal ultrasound. Further assessment included renal function by nuclear scintigraphy and proteinuria. Proteinuria was determined by random urine total protein to creatinine ratio (Upr/cr) and albuminuria by random urine albumin to creatinine ratio (Ualb/cr). Receiver operator characteristic (ROC) area under the curve (AUC) statistics were applied to Upr/cr and Ualb/cr ratios with determination of likelihood ratios (LR) for requiring surgery.

Results: In this cohort, 22/81 (27%) were operated, including 21 pyeloplasties and 1 nephrectomy for severe UUO. Initial proteinuria was significantly greater in UUO patients who underwent surgery compared to those without surgery (p=0.02). ROC-AUC demonstrated that both Upr/cr and Ualb/cr predicted the presence of severe UUO requiring surgery (Upr/cr: AUC=0.71, p=0.01 and Ualb/cr: AUC=0.75, p=0.02). Upr/cr and Ualb/cr was similar in normal control infants and those with non-surgical UO.
Corpus Christi, TX.

nourani, Samhar I. Al-Akash.

Although both were sensitive markers of renal injury, albuminuria was superior in predicting who required surgery compared to normal term infants and those with non-surgical UUO.

measure SCr. We defined GHF as GFR > 150 ml/min/1.73m² using the original Schwartz formula (OSF) to calculate GFR as our lab uses the Jaffe method to determine SCr. We defined GHF as GFR > 150 ml/min/1.73m² using the original Schwartz formula (OSF) to calculate GFR as our lab uses the Jaffe method to

Background: Glomerular hyperfiltration (GHF) has been described in diabetic and obese (O) adults, and usually precedes proteinuria or clinical disease, and may indicate underlying renal damage and chronic kidney disease (CKD). GHF is poorly studied in adolescent children (AC). We hypothesized that GHF is present in AC and that GFR correlates with the BMI.

Methods: We queried the electronic medical records from 6/2010 to 12/2013 to include AC 12-21 years of age with at least one serum creatinine (SCr) and BMI in the same encounter, and excluded pts with CKD, HTN, DM, proteinuria, or renal transplant. Pts were separated into 2 groups; Control (C) - BMI < 30 and O - BMI ≥ 30 kg/m². We used the original Schwartz formula (OSF) to calculate GFR as our lab uses the Jaffe method to measure SCr. We defined GHF as GFR > 150 ml/min/1.73m².

Results: Demographic data and results are shown in table 1.

Familial Lecithin-Cholesterol Acetytransferase Deficiency Masquerading as Membranous Nephropathy in Childhood

Ania R. Kozicki, Katrina Soderquest. Experimental Immunobiology, King's College London, London, United Kingdom.

Background: Familial Lecithin-cholesterol acetyltransferase deficiency (LCAT) deficiency is a rare autosomal recessive disorder of lipid metabolism characterised by severely reduced HDL concentrations and impaired esterification of cholesterol. It is characterised clinically by glomerulopathy and mild haemolytic anaemia presenting in adulthood leading to ESRD by the fourth decade of life through the deposition of abnormal lipoproteins in the renal stroma. Paediatric cases are rarely described.

Methods: 2 siblings aged 8 and 11 years presented with asymptomatic non-nephrotic range proteinuria detected on routine testing. There was no family history of renal disease, although parents were consanguineous. Initial screens revealed normal renal function and normal serum albumin. Other investigations demonstrated raised lipid profiles but in keeping with nephritic syndrome. A renal biopsy was performed in view of escalating protein and albumin creatinine ratios.

Results: Renal biopsy initially demonstrated light microscopic features of membranous nephropathy. However, electron microscopy demonstrated inclusions that were not typical of the adult form of the disease but clearly lipid filled (Figure 1). Confirmation of the diagnosis was by demonstration of significantly reduced HDL-cholesterol, and detection of a novel LCAT gene missense mutation G54V as well as reduced LCAT enzyme activity on assay.

PUB575

Umbilical Artery Histomorphometry: Linking the Intrauterine Environment and Nephrogenesis

Marissa J. Defreitas, Deepan Mathur, Wacharee Seehervong, Shahnaz Duara, Salih Y. Yasin, Maria Matilde Rodriguez, Carolyn L. Abitbol. Pediatric Nephrology, Pediatric Pathology, Neonatology, Perinatology, Univ of Miami/Holtz Children's Hospital, Miami, FL.

Background: An adverse intrauterine environment is linked to the developmental origins of aortic stiffness, nephron deficit, and adult onset cardiovascular and renal disease. We hypothesized that umbilical artery histomorphometry(UAH), a direct extension of the central vascular tree, would provide insight into nephrogenesis across gestational age (GA) groups.

Methods: From 156 newborns enrolled in the Gerber Infant Kidney Study, a subcohort of 32 had umbilical cord specimens evaluated (7 term(T-S), 15 preterm singletons(PT-S) and 10 preterm twins(PT-T)). The umbilical cord was sectioned, stained with Trichrome and digitalized.Muscular(MA) and collagenous areas(CA) of the umbilical arteries were measured in pixels using the ImageJ 48q software and converted to mm². The combined total kidney volume(TKV) was measured by ultrasound and factored by the infants' ponderal indices and BSAs.

Results: TKV/PI of T-S (6.9±1.8) and PT-S (7.5±1.9) were similar; while TKV/PI of PT-T was significantly less than either of the singleton groups (4.5±0.8;p<0.001). Among PT-S, 6(40%) were from pre-eclamptic (PE) mothers. When paired by GA to other PT-S not from PE mothers, they demonstrated stunted TKV/BSA (93±28 versus 122±19µm²/ m²;p=0.02). Among twin pairs, there was also a discordance in TKV/BSA (68±10 versus 8±1±15 µm²/m²;p=0.04). UAH demonstrated a positive correlation with increasing %MA and a negative correlation with increasing %CA.

Conclusions: LCAT deficiency may present with mild symptomatic proteinuria in childhood. Although rare, it should be considered in a differential in paediatric membranous nephropathy. The diagnosis was made on characteristic EM appearances, genetics and reduced enzyme activity. A trial of enzyme replacement is planned. Interestingly, the older sibling has higher lipids yet the younger worse renal disease opening up new hypotheses for how LCAT deficiency might cause renal pathology.
Insulin-Like Growth Factor/Growth Hormone and Insulin-Like Growth Factor Binding Proteins in Normal Heighted and Short Children with CKD

**Background:**Earlier reports indicated that children with chronic kidney disease (CKD) have ‘normal’ Growth Hormone (GH) and Insulin-Like Growth Factor-I (IGF-I) levels, suggesting that intracellular resistance and increased IGF-1 Binding Proteins (BPs) account for the poor growth seen in 35% of these children. We explored key growth mediators in subjects with CKD enrolled in the Chronic Kidney Disease in Children (CKiD) study with either normal height or short stature to explore potential explanatory differences in these two subsets.

**Methods:** 232 children in CKD (206 normal height: 26 short stature; none on GH therapy) were matched by gender, age and GFR. Short stature = Height Standard Deviation Score (SDS) < -1.88. GH, IGF-1, and IGFBP-1 and 3 were determined by chemiluminometer and ELISA.

**Results:** Normal height CKD children had higher serum IGF-1/GH, higher IGF-1/IGF-1 BP1 and similar IGF-1/IGF-1 BP3 compared to short CKD children.

**Conclusions:** Height SDS correlated with IGFBP-1 in normal height children (r = 0.323), but not well in short children not on GH RX (r = 0.046).

**Differences:** Comparisons in IGF-1, IGF-1/GH, and IGF-1/IGFBP-1 may explain some variance in growth in CKD children. Height is more highly correlated to IGF-1 in normal height than short children. Analyses in paired subjects may provide further insights in children naïve to and those on GH to allow detection of critical thresholds that explain and predict growth in children with CKD.

**Funding:** NIDDK Support, Private Foundation Support

**PUB577**

Assessment of Cochlear Sensitivity of the Pediatric Chronic Kidney Disease and Hemodialysis Patients

**Background:** Abnormalities in auditory system are frequent in patients with chronic renal disease and are not only related to hearing loss, but also to the development of renal disease. The aim of this study was to throw light on the relationship between cochlear sensitivity and chronic kidney disease with or without hemodialysis.

**Methods:** Children aged 6-18 years were evaluated in three groups; 36 nondialytic patients with chronic kidney disease, 16 end stage renal disease patients undergoing hemodialysis, and 30 age and sex-matched control subjects. Hearing outcomes were obtained by pure-tone audiometry and distortion product otoacoustic emissions measurements.

**Results:** No significant difference was found except in the both ears at 500 Hz frequencies between the study group and the control group. The signal/noise ratio levels and distortion product levels were significantly lower in the nondialytic and dialytic group at all frequencies. Patients with normal hearing were found to have significantly lower signal/noise ratios and distortion product levels than those observed in the healthy controls.

**Conclusions:** These results showed lower cochlear functions in their younger and/or nondialytic group regardless of hearing loss than in the control group. Patients with chronic renal disease with or without hemodialysis should be monitored periodically even if the hearing thresholds seem to be within normal limits.

Moality of Treatment of Pediatric Patients with Diarrheal HUS in Acute Renal Failure Does Not Affect Long Term Outcome and Survival

Sonia Solomon, Julia W. Tzeng. Pediatrics, Valley Children’s Hospital, Madera, CA; Pediatrics, Univer of California, San Francisco - Fresno, Fresno, CA.

Background: Diarrheal HUS is a disease process usually resulting from infection by E. coli H7:O157 and leading to the development of microangiopathic hemolytic anemia, thrombocytopenia, and acute renal failure. Acute renal failure typically follows in five days from infection, with a majority of the mortality from PD catheter associated complications. Studies have demonstrated that these patients are at risk for long term renal insufficiency and end-stage renal disease. Indications to start dialysis and the mode of dialysis vary from institution to institution. There is no current study comparing which mode of dialysis, hemodialysis or peritoneal dialysis, has better benefit and less complications. The main purpose of this study is to compare dialysis modalities and determine whether one modality will result in less complications and better outcomes.

Methods: This is single center, retrospective review. We studied a total of 102 patients from 1/2009 to 12/2014. We divided patients with HUS into two groups (HD and PD). We compared the number of complications and the types of complications from each modality. Long term outcomes were measured by each patient’s CKD staging at least one year after diagnosis. EGFR was calculated using the Schwartz formula. Fisher’s exact statistical test was used to assess statistical significance.

Results: No statistical significance was found between the mode of dialysis and associated complications (p>0.4). There was also no statistical significance between mode of dialysis and long term outcome (p>0.9). Complications of PD were catheter malfunction (p=6%), peritonitis (p=5%), and the need to switch to HD or CVVHDF (p=3%). Complications of HD included central line infections (p=1%).

Conclusions: PD and HD are equally effective in treating patients with HUS in renal failure and have comparable long term outcome and risks for complications. An important complication to consider for patients on PD the potential need to switch to HD or CVVHDF; this exposes the patient to an additional surgical procedure that may result in further complications.

Self-Reported Health Care Transition Readiness Among Mexican Adolescents with Chronic or End-Stage Kidney Disease

Guillermo Cantú, Ana Catalina Alvarez-Elias, Saul Valverde, María E. Ferrís, Mara Medeiros, Ana Panamericana, Mexico, DF, Mexico; Univer of North Carolina at Chapel Hill, NC; Hospital Infantil de México Federico Gómez, Mexico, DF, Mexico.

Background: 90% of pediatric patients with chronic disease live more than 20 years after being diagnosed. When pediatric patients are transferred to adult-focused health services, generally they do not have the skills and abilities to manage their disease. Adolescents tend to have poor adherence to treatment, and there is a period when there may be complications and increased morbidity-mortality. Performance on self-reported health care transition readiness (HCTR) needs to be assessed in patients with chronic or end-stage kidney disease. The aim of the study was to measure self-reported HCTR using the STARS (Self-management and Transition to Adulthood with Rx=Treatment) Questionnaire, among adolescents in the Nephrology Service at Hospital Infantil de Mexico Federico Gomez.

Methods: The Spanish version of the STAR Questionnaire was translated and back translated to collect self-reported health care transition readiness among end-stage kidney disease, adolescents in the outpatient nephrology department over a 9-month period. The 18-question tool diagnoses management and Transition to Adulthood with Rx=Treatment (STAR) Questionnaire, among adolescents in the Nephrology Service at Hospital Infantil de Mexico Federico Gomez.

Results: We enrolled 68 adolescents (53% males) who had a mean age of 15.75 years (± 1.87). Patients who received hemodialysis in the past 2 were 22 (34%). Females had significantly greater scores than males in the “action” category. Those who received hemodialysis in the past had greater knowledge about the disease (p=0.013).

Conclusions: The self-reported HCTR among Mexican adolescents with chronic or end-stage kidney disease differs by sex and treatment modality.

Italian Survey on Patients on Peritoneal Dialysis Treatment: ATENA

Alessandro Possidoni, Sara Di Fiona, Flavia Caputo, Carlo Crepaldi, Roberto Dell’Aquila, Emilio Giulio Galli, Anna Maria Costanzo, Umberto Di Luzio, Roberto Russo, AbbVie Italy; H. Cívico de Palermo; H. Civile San Bartolo; Bussano del Grappa; H. di Treviso; H. di Bari.

Background: in Italy, there are few epidemiological data concerning the clinical management of patients on peritoneal dialysis (PD) and the impact of PD on clinical outcomes. The aim of the study was to evaluate PD patients in Italy.

Methods: epidemiological, multicenter study with a retrospective phase (12 months) and a prospective phase (6 months) of patients on PD. Primary objective: evaluate anemia, hypertension and mineral metabolism compared to K-DIGO and K-DOQI guidelines. Secondary objective: assess ESRD stage, complications, hospitalizations, therapeutic strategies, mortality and quality of life (QoL).

Results: 377 consecutive pt. were enrolled at baseline, CAPD 50.4% / APD 49.6%; Male 59%; mean age 67 years, dialysis duration 39.7 months. The most frequent complications were: hypertension (88%) and cardiovascular diseases (46%), hyperparathyroidism (25%), dyslipidemia (25%) and diabetes (20%). The cause of hospitalization was peritonitis (27%); no death associated, followed by CVD (20%). At 6 months, anaemia not corrected or inadequately corrected (Hb 11 g/dL) occurred in 30% of pt. 73% received ESA. Systolic value ≤ 130 mmHg and diastolic value ≤ 80 mmHg occurred in 50% and 30% of pt, respectively. Left ventricular hypertrophy was observed in about 60% of echocardiograms. 25% (HD) vs 10% (PD) in 30% of patients. Secondary hyperparathyroidism (SHPT) occurred in 30% of pt. The drugs used to manage SHPT were calcitriol (36%), paricalcitol (29%), cacoletic (23%), and cinacalcet (21%). Considering a group of patient under therapy for a year with similar basalPTH levels, a significant reduction of iPTH occurred with paricalcitol (1.05 mcg/day), but not with cinacalcet (39.4 mcg/day; p<0.003 vs p=0.626). No effect on Ca and P occurred in the paricalcitol group. At the end of the study, PD didn’t modify the QoL significantly.

Conclusions: Hypertension and CVD are the most common comorbidities of PD. Peritonitis is the main cause of hospitalization. Anaemia and SHPT are frequent and have to be treated and monitored carefully. There are significant differences in efficacy between different treatment options to treat SHPT.

Advancements in Automated Peritoneal Dialysis: What Is the Future in improved Quality of Care?

Catherine Frimark, James A. Sloand. Global Medical Affairs, Baxter Healthcare, Deerfield, IL.

Background: Evaluations to APD technology directed at greater ease of use and health care professionals’ (HCP’s) oversight of patient status may help overcome barriers to home dialysis. Use of connectivity to enable remote patient monitoring (RPM) and communication may facilitate patient management, increase HCP and patient communication, and improve outcomes. Advancements in design may also help simplify and improve training. Objective is to understand and qualify importance of enhanced graphical user interfaces (GUI), voice-guided instruction, and RMM embedded into APD cycler for HCPS and patients.

Methods: Forty-minute telephone interviews and web-based surveys, including cycler videos, were conducted with 214 nephrologists, 138 renal nurses, and 193 CKD patients from US and HCPS included those in practice for 3 years, spending > 75% of their time treating patients, and experience with use of conventional cyclers. Patients included those considered candidates for PD or those currently on dialysis, including incented HD, home HD or PD. In double-blinded study, participants compared 2 conventional cycler and a cycler with new technology with information screen, enhanced GUI and clinic connectivity.

Results: On a scale of 1-7 (the most important), cycler features rated most important to nephrologists, nurses, and patients include size and portability, GUI with voice-guided instructions, and data connectivity/RPM. When rating each cycler on favorability of attributes, the cycler with new technology scored highest. Attributes of 1st conventional cycler scored an average of 0.5 (on a scale of 3-3), while attributes of the cycler with new technology from the same manufacturer scored an average of 2.6 (p<0.0005). The attributes of the 2nd conventional cycler compared to the cycler with new technology scored on average 1.15 and 2.3 (p<0.0005), respectively.

Conclusions: HCPS and patients identified enhanced GUI, voice guidance, and data connectivity allowing RPM as favorable attributes to cycler usability and patient management. Technological enhancements that facilitate ease of cycler use and connectivity may increase PD acceptance by patients and HCPS.

A Single Center Ten-Year Experience in PD Catheter Placement

Yoon Al Azz, Eti Deborah Zeldis, Girish N. Nadkarni, Harry Schanzer, Jaime Uribe, Nephrology, Mount Sinai Hospital - Icahn School of Medicine, New York, NY.

Background: In our early implantation practice, cut-off tip catheters had better function and less migration when compared with straight catheters and as such, we for the past 10 years have implanted almost exclusively the cut-off tip catheters. This is in disagreement with some current literature that favors straight catheters. Due to this discrepancy, we decided to review our single center experience with PD catheters over the past 10 years.

Methods: PD catheters placed over the period of 2004-2014 at our hospital were reviewed. Demographics, comorbidities, operative note, type of catheter, surgical approach, complications and overall survival were collected.

Results: 170 PD catheters were inserted during 10 years (49.7% men, mean age 54.7 years, 167 cut-off tip catheters vs 1 straight intra-peritoneal, 63% placed by open surgical technique vs 37% by Y-Tek peritoneoscopy). Diabetes mellitus was the most common cause of ESRD. 60 peritonitis cases occurred during the period of observation (24 lost their catheter), 30 had a leak out of which 4 lost their catheter; 3 (6%) patients had primary non-function of their catheter, 4 had hernias (1 taken off PD). There was no difference in hazard ratios in catheter survival after adjusting for demographics; diabetes status and number of previous catheter placement for overall follow up. But, looking at 2-year catheter survival, open placement of catheters had a higher adjusted hazard ratio for catheter loss compared to peritoneoscopy placement (AHP 2.61; 95% CI 1.02-6.71; p=0.04).

**Background:** This study evaluated the real world effectiveness of sucroferric oxyhydroxide (SO) use among peritoneal dialysis (PD) patients (pts) who self-reported race as Black or African American (AA).

**Methods:** A retrospective database analysis was conducted on a cohort of AA PD pts who were prescribed SO as part of standard care at FMCNA clinics. Pts had 1 serum phosphorus (sPhos) measured while using SO and had been on sevelamer, calcium-based phosphate binders or had no phosphate binder specified prior to SO treatment. Differences in sPhos, pill burden(PB), serum calcium(Ca), ferritin, transferrin saturation(TSAT), and intact parathyroid hormone(iPTH) were noted between baseline (BL; 3 months prior to SO) and follow-up (SO-TX; 3 months during SO). 

**Results:** 117 AA PD pts (mean age=50 years, dialysis vintage=4-2 years) were included. At BL, 37% were on sevelamer, 31% on calcium-based phosphate binders, 2% on dual therapy and 31% had no phosphate binder specified. Figure shows increase in pts who have in-range sPhos (20% to 31.6%; 58% increase). Mean sPhos decreased from 6.55-6.38 mg/dl (p=0.06). A significant decrease in PB was observed (4.5 pills/day, p<0.001) between BL(8.8 pills) and SO-TX(4.3 pills). No significant differences were observed between BL and SO-TX for sCa (BL=9.1 mg/dl, SO-TX=9.1 mg/dl), ferritin (BL=861.9 ng/ml, SO-TX=870 ng/ml), TSATs (BL=34.7%, SO-TX=36.8%) and iPTH (BL=729.5 pg/ml, SO-TX=696.4 pg/ml).

**Conclusions:** In a cohort of African American peritoneal dialysis patients who were prescribed sucroferric oxyhydroxide as part of routine clinical care, there was a 58% increase in the number of patients with serum phosphorus levels in-range (p<0.006). Furthermore, there was a significant reduction in pill burden (4.5 fewer pills, p<0.001).

**Funding:** Pharmaceutical Company Support - Fresenius Medical Care North America.
associated morbidity. Larger controlled trials are warranted to explore the potential impact of PD on the mortality of patients with RHF and to define those subgroups most likely to benefit from this therapy.

PUB888
Procalcitonin: Is it a Useful Biomarker for Peritoneal Dialysis Peritonitis? Shishan Song, Hyeon-Cheol Park, Jae Seok Kim, Jae Won Yang, Byoung Geun Han, Seung-Ok Choi. Internal Medicine, Yonsei Wonju College of Medicine, Wonju, Korea.

Background: Peritonitis is a common complication in peritoneal dialysis (PD). Procalcitonin is a peptide hormone which has been used as a biomarker for the diagnosis of bacterial infection. We aimed to investigate the usefulness of procalcitonin in the patients with PD peritonitis.

Methods: This study included 33 episodes of peritonitis in 27 patients for follow-up period of 450 days. In addition, we collected samples of PD effuents from 7 PD patients without peritonitis to compare with those of peritonitis. We investigated clinical characteristics, serum and PD effluent levels of procalcitonin at the time of initial visit and discharge.

Results: The mean value of dialysis vintage of patients with peritonitis was 1774 days, incidence of total peritonitis for period of PD maintenance; 4.3 times, interval from symptom onset to visit; 13.6 hours, duration of intraperitoneal antibiotic treatment; 8.2 days, and interval from clinical improvement to recurrence; 80.7 days. Initial serum procalcitonin increased to 0.97 ± 3.67 ng/mL (mean ± standard deviation) compared with reference values (healthy <0.05, PD patients <0.30, PD peritonitis >0.50 ng/mL), and PD effluent procalcitonin increased to 0.97 ± 3.67 ng/mL. The serum procalcitonin decreased to 0.33 ± 0.54 ng/mL with clinical improvement but not significantly (p=0.308), and the PD effluent procalcitonin also showed the decreased level of 0.03 ± 0.08 ng/mL but not the statistical significance (p=0.360). Pearson’s correlation analysis showed that the serum and PD effluent procalcitonin did not have relationships with existing inflammatory markers such as ESR, CRP. Lastly, procalcitonin could not predict recurrence and mortality of peritonitis.

Conclusions: Collectively, procalcitonin showed the tendencies corresponding to the clinical course of PD peritonitis, but not statistical significance. We believe that procalcitonin is not superior biomarker in PD peritonitis compared with other existing markers.

PUB889
Epidemiological Survey of Maintenance Peritoneal Dialysis in China Xiang-Mei Chen, Xueying Cao, Delong Zhao, Guangyan Cai. Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases.

Background: To analysis epidemiology and trend of peritoneal dialysis during 2011-2014 in China.

Methods: Patient-reported outcome data from the peritoneal dialysis centers were collected online during the study.

Results: (1) By the end of 2014, there were 5573 cases of maintenance peritoneal dialysis patients in China, had increased by 17% per year over this time period. The average incidence rate was 5.81/100 million people. The prevalence was 34.3/100 million. (2) The average age was 53 years. Male to female ratio was 1:2.1. The average age at initiation of dialysis was about 30 years old. The average residual renal function was 3ml/min. The average dialysis time was 2 years. The primary causes were primary glomerular disease 54%, diabetic nephropathy 16%, hypertensive renal damage 14%. (3) In 2014, DOH fell to 6.6%. TOT was 27.2 months. The death patients accounted for about 51.3% of exit patients. The average death age was 64.8 years. The average therapy time was more than 28.6 months. The cause of death was the cardiovascular and cerebrovascular events. (4) Peritoneal dialysis access was the two cuffs, no gooseneck, straight. 78% patients were the continuous ambulatory peritoneal dialysis patients. The therapeutic dose was 6L to 8L. High peritoneal transport type was the largest. (5) PD patients with hemoglobin 100g/L ratio was raised every year. The albumin level in plasma was greater than or equal to 35g/L with more than 50% patients. Serum calcium, phosphorus, parathyroid hormone level was improved year by year. The average Kt/V was maintained at 2.1/ weeks. Ccr could reach 2.1/ weeks.

Conclusions: Collectively, there was a 17% annual increase in peritoneal dialysis patients. The therapeutic dose was 6L to 8L. High peritoneal transport type was the largest. There is a 17% annual increase in peritoneal dialysis patients. The cause of death was the cardiovascular and cerebrovascular events. The average death age was 64.8 years. The average therapy time was more than 28.6 months. The cause of death was the cardiovascular and cerebrovascular events.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
The UK Peritoneal Dialysis Catheter Study (UK Cath): An Ancillary Study to the Peritoneal Dialysis Outcomes and Practice Patterns Study

Background: Delivering high quality peritoneal dialysis (PD) access placement and outcomes is limited by lack of standardization of PD access definitions and events, variable reporting of outcomes, and a paucity of robust evidence regarding optimal PD catheter insertion pathways. The UK Renal Registry PD access audit (2013) demonstrated 82% catheter survival at 1 year, with considerable variation between centres. Moreover, catheter function at 3 months was poor for a medical (percutaneous) compared to a surgical (open) insertion pathway.

Methods: UK-Cath, a multi-centre prospective cohort study (1350 patients, 45 dialysis centres, 18 month recruitment window) will assess the outcomes associated with different pathways of catheter insertion, dialysis unit-level policy associated with pathway use, and patient-level factors (e.g. case-mix, urgent start). Health economic benefits of these pathways will be determined using the cohort data, enriched by additional information obtained from more long-term follow-up study in a subset of patients using Hospital Episode Summary (HES) data linkage. The study has received funding from the UK NHRI Research for Patient Benefit Programme, NIHR PB-PG-0613-31028. A subset of study 20 centres will contribute to International Peritoneal Dialysis Outcomes & Practice Patterns Study (PDOPPS) with the primary objective of understanding variations in PD technique failure.

Results: We will present information on study design, instrument development, governance mechanisms, and recruitment plan. We will discuss the impact of patient engagement on study design.

Conclusions: The UK Peritoneal Dialysis Catheter Study will inform dialysis units’ decision to either focus their efforts on improving a single surgical pathway or to practise a mixture of surgical and medical insertions, with the ultimate goal to improve catheter survival, patient experience and optimise health economic efficiency.

Funding: Government Support - Non-U.S.

Preparedness for Telemedicine in Outpatient Peritoneal Dialysis

Background: Peritoneal dialysis (PD) is generally performed daily by patients at home, where questions may arise. Telemedicine has the potential to improve the delivery of healthcare services and outcomes for PD patients. We studied the preparedness of a PD clinic run by a large dialysis organization (LDO) serving an urban undersourced population.

Methods: Adult PD patients cared for by the clinic were asked about their interest and ability to use VSEE® (HIPPA-compliant tool for video calls) to remotely manage clinical concerns about PD. We compared patient characteristics between interested and non-interested groups. We also assessed the clinic’s ability to implement VSEE®.

Results: Initial barriers encountered were with the LDO. These included a firewall that prevented video products from being loaded onto clinic computers, consent issues, concerns regarding unequal care potentially being provided to patients with and without internet access, and lack of video equipment for on-call nurses. All of these barriers were overcome. We then assessed interest in 56 patients. Their age (mean/standard deviation) was 54.0 ± 13.5 years and 54.0% were male. English was the primary language for 66%, and they had been on PD for 3.0 ± 3.2 years. 34 patients (61%) showed some interest in telemedicine, 16 (29%) downloaded the software to their laptop, tablet, or cell phone, and downloading in process for the remaining 18 (32%). The most common reason for not being interested was “no device” or “no internet access at home”, which was reported by 15 patients (27%). The only additional difference in characteristics between the interested and non-interested groups was that those interested lived further away from the clinic (12.9 vs 9.3 miles, p<0.03).

Conclusions: Multiple barriers to delivering telemedicine to PD patients exist, both on the medical and patient side. 61% of patients were telemedicine-ready. Future evaluations will determine the impact on clinically significant outcome, patient satisfaction, and clinic workflow in this population.

When to Remove the Peritoneal Dialysis (PD) Catheter After Renal Transplantation? (RT)

Background: There seems to be consensus that the time of removal of the peritoneal catheter after RT may be delayed until renal function and the patient is stabilized, but there are few publications about...

Methods: We analyzed retrospectively patients on Peritoneal Dialysis Unit (PDU) who have received a RT between May 1995 and March 2015 gathering medical history data relating to the peritoneal catheter removal and complications.

Results: 108 patients transplanted from PD, 32 women/76 men with a mean age at the time of transplantation (58.0 ± 13.7 years) were analyzed. Two patients received RT of living donor and 106 of cadaver. The catheter used in all was a straight Tenckhoff with two cuffs. If renal therapy substitution was needed posttransplantation all patients were treated with hemodialysis. The catheter was removed during surgery in nine patients (8%) due to exit tunnel infection by Staphylococcus aureus or Pseudomonas aeruginosa. The withdrawal was delayed in 91 patients (84%) and 8 has not yet been removed. The average withdrawal time was 4.1 ± 2.7 months. The indication of withdrawn was: stable renal function in 85 (93%), stable pancreatic and renal function and 4 exit site infection in 2 (2%). The median time at the withdrawal was 2.1 (mg±1.8) months. Two patients were removed surgically under local anesthesia. The mean duration of hospitalization was 2.1 ± 1.8 days (0-12). Four patients (3.7%) had complications during withdrawal (one hemaatoma, two hemorrhagic shock and one surgical wound infection). 15 (18%) patients showed complications before withdrawal: 13 exit site infection, one peritonitis associated with urinary fistula and one spontaneous peritonitis.

Conclusions: In our experience the removal of the peritoneal catheter may be delayed until renal graft function were stabilize since the rate of complication is low compared with another studies.

Funding: Other NIH Support - Spanish Public Health Service

Clinical Outcomes by Differences in Therapy Among Peritoneal Dialysis Patients

Background: Studies evaluating the outcomes of peritoneal dialysis (PD) technique and patient survival, including those among patients who switch from PD to hemodialysis (HD), are scarce.

Methods: This retrospective study screened 120 patients in whom PD was initiated between January 1998 and December 2012 at our hospital. Of these, patients who were transferred to HD before completing one year were excluded. We compared the outcomes in patients who had complete follow-up data were excluded. Fifty-two patients (mean ± SD: 69.2 ± 12.6 years) were included to investigate the time of survival based on PD technique and overall survival, including those patients who switched to HD, and to evaluate the correlation between survival time and pharmacotherapy at the initiation of PD.

Results: Time (in months) on PD, HD, and overall survival were 34.3 ± 30.0, 18.5 ± 43.4, and 52.6 ± 53.2, respectively. Compared between the APD (n = 20) and non-APD patients (n = 28) showed that time on PD was 45.3 ± 34.4 vs. 31.3 ± 26.0 months, time on HD was 59.0 ± 40.6 (n = 8) vs. 91.8 ± 72.5 (n = 8) months, and overall survival time was 60.9 ± 49.9 vs. 54.7 ± 55.4 months, respectively. Comparison between groups with (n = 41) and without use of icodextrin (n = 7) showed time on PD was 10.8 ± 6.0 vs. 41.4 ± 30.1 months, time on HD was 49.6 ± 45.0 (n = 3) vs. 62.9 ± 65.3 (n = 13) months, and the survival time was 32.1 ± 41.7 vs. 61.6 ± 53.6 months. When analyzed by age groups of <60, 61–70, 71–80, and >81 years: time on PD (months) was 47.2 ± 38.4 (n = 14), 45.2 ± 23.4 (n = 15), 19.8 ± 27.0 (n = 10), and 21.2 ± 19.2 (n = 13), respectively. Time on HD was 22.8 ± 44.2 (n = 6), 14.6 ± 36.3 (n = 5), 8.7 ± 28.2 (n = 1), 26.3 ± 60.1 (n = 4), respectively, and survival time was 70.1 ± 52.8, 59.2 ± 41.9, 28.5 ± 39.7, and 46.7 ± 67.2 months.

Conclusions: The time on dialysis and survival time may be underestimated because of the exclusion of patients who are currently on dialysis. Compared with non-APD patients, APD patients had longer time on PD and overall survival time. Patients who needed icodextrin when commencing PD had shorter time on PD and overall survival time.

Combined Markers of Protein-Energy Wasting and Inflammation Predict Clinical Outcomes in Incident Peritoneal Dialysis Patients

Background: Protein-energy wasting (PEW) and chronic inflammation are not only common but are known as predictors of adverse clinical outcomes in end stage renal disease (ESRD) patients. Whether the combined values of serum albumin, high sensitivity C-reactive protein (hs-CRP), and body mass index (BMI) have an additive impact on clinical outcomes compared to each variable by itself in incident peritoneal dialysis (PD) patients is to be evaluated.

Methods: A prospective cohort of 565 incident PD patients from the Clinical Research Center for ESRD in Korea was selected. Patients were divided into two groups based on the baseline levels of albumin (≥ 3.5 g/dl), hs-CRP (≥ 0.45 mg/dl), and BMI (≥ +/− 23 kg/m²). Primary endpoint was the occurrence of all-cause mortality and unplanned hospitalization.

Results: The mean age was 51.4 years and 60.0% were male. During a median follow-up duration of 27 months, 50 patients (8.8%) died and unplanned hospitalization events occurred in 123 patients (21.8%). Univariate analysis revealed an increase in primary outcome risk with lower albumin and elevated hs-CRP compared to higher albumin and lower hs-CRP, respectively. A similar tendency was observed with lower BMI and primary outcome, although without statistical significance. Regarding the combination of these factors, Cox proportional hazards revealed that patients with any two risk factors and all three risk factors exhibited significantly higher hazard ratios for primary outcome compared to patients without any single risk factor. The combination of these factors retained a significantly higher HR for predicting primary outcome, even after adjusting for other confounders.

Single Center Experience with a Peritoneal Dialysis Cycler with Advanced Patient Interactive Screen: Impact on Patient Training

**Background:** Learning proper device use and clinical concepts of care must be internalized by patients to successfully perform PD at home. With increasingly diverse patients going on PD and increasing adoption of urgent start PD, there is a need for simpler devices. Enhancing the patient education environment with methods including visual, graphical and voice will improve the educational experience leaving the patient with better understanding of the procedure.

**Methods:** Automated PD training was undertaken at a university based home dialysis program using a novel APD device (AMIA). 5 patients were trained on the device in a 1:1 nurse to patient ratio. The cycler provided on screen instructions using a touch screen interface with voice guidance, text instructions and animation. Each patient was trained according to standardized outlines and sequential training progression from CAPD to APD techniques. Training included RN demonstration followed by patient direct interaction with the device. Instructions were displayed on a touch screen.

**Results:** Patient training completion required consistency of error free setup. Patients going on PD and increasing adoption of urgent start PD, there is a need for simpler devices. Enhanced patient education environment with methods including visual, graphical and voice will improve the educational experience leaving the patient with better understanding of the procedure.

**PUB598**

Peritoneal Dialysis-Related Peritonitis in a Single Center: 10 Years Experience

**Background:** Peritonitis remains the main Peritoneal Dialysis (PD)-related complication. It is estimated that it contributes directly to 20% of dropout and is related to 16% of all deaths. This study proposes to evaluate episodes of PD-related peritonitis and describe its incidence, causative organisms and possible predictors in patients belonging to a PD program from a reference center at Araçatuba-São Paulo-Brazil.

**Methods:** Retrospective cohort study that evaluated 565 patients who stayed for at least 30 days in routine start patients. Device training ranged from 2-3 days for urgent start patients and 4-5 days for urgent start patients.

**Results:** From our experience, training times were similar or reduced using the AMIA cycler and allowed the ability to efficiently train urgent start patients. Observations of the new cycler included: 1) less need for memorization 2) distinction of a beginner vs advanced mode 3) online alarm troubleshooting 4) presence of an air detector in the device. Instructions were displayed on a screen.

**Conclusions:** The combination of serum albumin, hs-CRP, and BMI at the time of PD commencement was a significant independent risk factor for the composite outcome of all-cause death and unplanned hospitalization in incident PD patients. Funded: Government Support - Non-U.S.

**PUB599**

Placement of Peritoneal Dialysis Catheters: Not Limited to Operating Rooms

**Background:** As of December 2012, only 7% of ESRD patients in the USA utilize Peritoneal Dialysis (PD) for renal replacement therapy, despite many advantages of PD over hemodialysis (HD). One factor leading to low PD utilization is the lack of experienced surgeons available to place PD catheters in a timely manner. Interventional Radiologists (IR) can help with catheter placement. As of December 2014, Kaiser Permanente achieved a 25% PD rate among its ESRD population. One factor that contributed to the high percentage of PD utilization is a skilled IR service in the Greater Southern Alameda Area (GSA) that facilitates the placement of PD catheters in a timely manner. We report a large number of PD catheters placed by GSAA IR physicians from January, 2011 to December, 2013 and compare to PD catheters placed by laparoscopic surgeons in the nearby East Bay Area (EBA) and Diablo Service Area (DSA) during the same time period.

**Methods:** We retrospectively analyzed KPNC electronic data base from 1/1/2011 – 12/31/2013. We extracted data from GSA where IR placed PD catheters using an Advanced Image guided Percutaneous (AIP) technique. We also extracted data from the EBA and DSA where surgeons placed PD catheters using the Advanced Laparoscopic Surgical (ALS) technique.

**Results:** We identified 203 PD catheters placed by GSAA IR with the AIP technique and 316 PD catheters placed by EBA/DSA surgeons using the ALS technique. Overall, GSAA IR placed 39% of all PD catheters across the 3 areas during the study time period.

**Conclusions:** IR placed a significant percentage of overall PD catheters in 3 areas of our integrated health care system. In doing so, we overcame one of the barriers to high PD penetration in ESRD patients. In areas where there is a shortage of skilled surgeons, one can consider utilizing IR to solve this problem. Currently we are studying the outcomes of these two approaches.

Body Composition and Cardiovascular Outcomes Using Continuous Automated Peritoneal Dialysis – A Prospective Cohort Study

**Background:** Fluid overload (FO) due to compliance in Continuous Ambulatory Peritoneal Dialysis (CAPD) is common. Efforts to achieve dry weight and avoid cardiovascular outcomes (CO) are less from inaccurate body composition (BC) estimations despite best clinical assessment.

**Methods:** We’ll follow BC, multiple frequency bioelectrical impedance (InBody SI0, InBody CO), standard laboratories and CO, in all new patients to continuous Automated Peritoneal Dialysis (APD) previously in a CAPD. Measurements at baseline (CAPD), 1 month and every visit to the dialysis clinic thereafter (APD) for a 5 year period.

**Results:** These are the first data of BODY cohort study. Initial 10 subjects are described, 4 men and 6 women, median age 27 years (17-46), height 159.5cm (146-166), baseline and first follow up variables are in Table 1. Wilcoxon rank test for related samples was performed. We found that PD modality switch to APD, at 1 month, reflected a body composition transition with statistical significance (P <0.05), within the EW/BTW ratio at expense of trunk compartment. Most likely from improved dialysis adherence

Conclusions: We consider that APD, on the ground of increased, uninterrupted and rigorously performed therapy, is a appropriate therapy to optimize FO and aim for dry weight in PD. Further recruitment of patients and follow up of the BODY Cohort study is expected to confirm this hypothesis.

PUB601

The Changes in Bicarbonate Level and Ionized Ca/ Corrected Ca Ratio of Patients Receiving Peritoneal Dialysis Using Bicarbonate/Lactate-Buffered Solution

Emi Kimoto, Nanae Matsu, Masamitsu Morishita, Mami Nakamura, Yukio Murayama, Yatsuaki Nakada, Masatsugu Nakao, Yudo Tanno, Ichiro Ohkido, Hiroyasu Yamamoto, Keitaro Yokoyama, Takashi Yoko. Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan.

Background: Recently, PD solution which contains 25mEq/l bicarbonate and 10mEq/l lactate (Bicarbonate/Lactate-buffered peritoneal dialysis solution; B/L solution) is developed in Japan. Because of high concentration of lactate (40mEq/l) of conventional peritoneal dialysis (PD) solution, patients have generally higher serum bicarbonate level than those of patients receiving hemodialysis (HD). The new B/L solution is expected not only its biocompatibility but also improving excess correction of acidosis. Under the metabolic alkalosis environment, we reported that PD patients have lower levels of ionized Ca (iCa) at the same corrected Ca (cCa) levels. Thus, we hypothesized that iCa / cCa ratio increased after switching PD solution from Lactate-buffered to B/L solution.

Methods: We recruited 28 patients (55 ± 13 years, male 82%, PD duration 42 ± 21 months) who switched from Lactate-buffered to B/L solution, and investigated changes in serum bicarbonate, iCa, and cCa levels.

Results: After switching solution, serum bicarbonate decreased (26.7 ± 3.2 vs 24.8 ± 2.5, P<0.01), and cCa did not change (9.3 ± 0.5 vs 9.3 ± 0.5, P=0.63). Neither iCa nor iCa/cCa ratio increased significantly (1.12 ± 0.09 vs 1.11 ± 0.09, P=0.48; 0.120 ± 0.007 vs 0.119 ± 0.0006, P=0.54, respectively).

Conclusions: Conversion to B/L solution from lactate solution was associated with lower serum bicarbonate. Unfortunately, iCa did not change. Further investigations are needed to confirm the utility of the monitoring of iCa for the management of chronic kidney disease - mineral and bone disorder (CKD-MBD) in PD patients.

PUB602

Road to Success: One Academic Medical Center’s Experience Building a Peritoneal Dialysis Clinic

Yazan M. Alia, William A. Schlueter, Erwin E. Morales, Maria A. Gavino, Shubhaba N. Ahya, Robin E. Watson. Nephrology, Northwestern Memorial Hospital, Chicago, IL.

Background: Peritoneal Dialysis (PD) is an option for renal replacement therapy. The US Renal Data System 2012 Annual Report states that the annual per-patient HD cost is approximately $87,500 whereas for PD it is $66,750. In addition, studies have demonstrated that some aspects of quality of life are improved in PD patients compared with HD patients. Despite this, PD is underutilized in the US. Northwestern Medicine’s PD Program was initiated in 01/2014 with 4 nephrologists and 10 patients who transferred from a neighboring PD Unit. From 02/2014 to 04/2015, Northwestern’s Peritoneal Dialysis Clinic grew to 50 peritoneal dialysis patients.

Methods: We included all patients who started on PD (or transferred to PD) in PD Clinic between the periods of 2/14 and 4/15. Patients excluded from this analysis stopped PD within this period for the following reasons: switched to HD, expired, recovered kidney function, or underwent transplantation.

Results: From January 2014 to April 2015, PD Clinic grew to 50 patients. The age range was 22-86 years and mean age was 54.4 years. Thirty-one (62%) were men. Twenty-four (42%) are African American, 13 (26%) are Caucasian, 11 (22%) are Hispanic, and 5 are of Asian descent.

Conclusions: We describe a single, academic medical center experience on growth of PD Clinic from 0 to 50 patients within 14 months. Obstacles to PD Clinic growth included lack of availability of dialysate in mid 2014 and lack of experience with Urgent Start PD. However, with time, both nephrologist and surgeons and medical staff grew comfortable with this method of dialysis initiation. Features that facilitated successful and timely growth are: 1- Minimizing options training, 2- Surgeon cooperation, 3- Physical proximity to CKD Clinic and to inpatient floors, 4- Continuity of care for patient-physician from outpatient CKD Clinic to inpatient setting to outpatient Home Dialysis Clinic.

PUB603

Peritoneal Membrane Transport Evaluation in Peritoneal Dialysis Using Traditional PET, Modified PET and Mini-PET

Miguel C. Riella, Jacke Waniweski, Bengt Lindholm, Marcelo Nascimento, Umberto B. Gori, Marcela de Carvalho, Danila Colacim, Rui F. Araujo, George C. Kaelin, Antonio B. Bento, David K. Stein, Silvia C. Knackstedt, Daniel C. Knackstedt, Pro-Renal Foundation, Curitiba, Parana, Brazil; 2- Inst Biocybernetics and Biomedical Engineering, Warsaw, Poland; 3- Baxter Novum and Renal Medicine, Karolinska Inst, Stockholm, Sweden; 4- Pro-Renal Foundation, Curitiba, Parana, Brazil.

Background: Peritoneal equilibration test (PET) is widely used for evaluating peritoneal transport; however, additional methods have been described to facilitate and improve this evaluation. Here, we compared traditional PET (PET) with two newer methods, mini-PET and modified PET (mod-PET), which are increasingly used to investigate ultrafiltration capacity and peritoneal membrane characteristics in patients undergoing peritoneal dialysis.

Methods: Twenty-one non-diabetic adult patients on peritoneal dialysis (PD) for >3 months underwent: PET (2.27%; h), mini-PET (3.86%; h); and mod-PET (3.86%; h). Results of dialysate to plasma concentration ratios for creatinine (D/P Cr) and sodium (D/P Na), and dialysate to initial glucose concentration (D/D0 glucose) at the end of each test were compared by analysis of variance (ANOVA), Pearson correlation and Bland-Altman test.

Results: Whereas D/P Cr was not significantly different between PET and mod-PET (p=0.746) there were significant differences between mini-PET and both PET (p=0.001) and mod-PET (p<0.001). D/P Cr for PET correlated with D/P Cr for mod-PET (r=0.387; p=0.009) but not with D/P Cr for mini-PET (r=0.088; p=0.241). Bland Altman test showed no significant bias of D/P Cr for PET vs mod-PET (-0.029; p=0.201) but a systematic difference (0.206; p<0.001) of D/P Cr PET vs mini-PET. Whereas measurements of D/D0 glucose and D/P Na were in general not comparable nor significantly correlated, ultrafiltration during PET and mini-PET were weakly correlated (r=0.260; p=0.009).

Conclusions: These results confirm that characterization of transport status based on D/P Cr may not necessarily differ between conventional PET and mod-PET.

PUB604

Low Level of Albumin Is a Risk Factor for Short-Term Mortality of PD Patients

Kenji Harada, Kokura Memorial Hospital; Kokura Memorial Hospital.

Background: Mortality of HD(hemodialysis) patients are reported, but few reports about PD(peritoneal dialysis) patients. This study aims to investigate clinical features of PD patients, their short-term mortality(1-2 years).

Methods: We investigated the mortality about PD patients(n=269, age:65 year old:13.7, male/female 173/96, PD vintage within 2 years, DM:121), and the influence of several parameters from 2009 to 2012. The dead and the transferred HD were excluded within 90 days. Finally 241 patients are remained. The survival rates for one year and two years were 91 % and 72 %. Infection was the most causes of death(33%). We investigated between death and several parameters(age, sex, blood pressure, albumin, hemoglobin, Ca, P, whole PTH, TC) by univariate analysis with JMP12, SAS. Those physical and laboratory data were measured at one month after PD started. Age and level of albumin were correlated with death. We hypothesized that low albuminumia and malnutrition influenced the rate of death. We divided three categories, from group A(albumin<3.3, n=82) and group B(2.8<albumin<3.3, n=89), group C(albumin<2.7, n=73). Cox proportional hazards regression model was used to analyse prognostic risk factors and establish prognostic model.
Results: There were significant differences between group B and A (Hazard Ratio: 2.61, p = 0.016, 95% CI: 1.232-6.09), group B and C (Hazard Ratio: 6.031, p = 0.001, 95% CI: 2.975-13.53), group C and A (Hazard Ratio: 2.309, p = 0.0029, 95% CI: 1.33-4.09). In addition these groups were analysed by adjustment factor such as age, sex, blood pressure, hemoglobin, Ca, P, whole PTH, TC with multivariable analysis. The results proved that there were tended to be correlation between group B and A (Hazard Ratio: 1.963, p = 0.09, 95% CI: 0.901-4.61). There were significant differences between group B and C (Hazard Ratio: 4.00, p = 0.003, 95% CI: 1.866-9.35), group C and A (Hazard Ratio: 2.037, p = 0.0029, 95% CI: 1.165-3.63).

Conclusions: Low level of albumin increases the mortality of PD patients gradually. Therefore we may decrease mortality of PD patients by improving nutritional condition and infection control when PD patients are introduced.

PUB607

Peritoneal Dialysis: A Decade Experience at a Reference Centre in Brazil
Patricia O. Costa, Carla M.V. Melo, Flavia A. Nobrega, Jordiano P. Oliveira, Jandson P. Oliveira, Kleyton Andrade Bastos, Dept of Medicine, Federal Univ of Sergipe, Aracaju, Sergipe, Brazil.

Background: Peritoneal Dialysis (PD) is underutilized in most countries. The Brazilian prevalence is around 9%. This study aims to describe the ten years experience on PD in a dialysis center in Northeast of Brazil (Aracaju-Sergipe). Unlike other national programs, negative selection for DP is not an attribute of this dialysis unit.

Methods: Retrospective cohort study that evaluated the sociodemographic and clinical profiles, comorbidities, peritonitis, hospitalizations and death causes of 565 patients who remained in PD for at least 30 days from 01/01/2003 to 12/31/2012.

Results: Patients were mostly men (55%), living outside Sergipe's capital (56%), had a mean age of 54 ± 19 years old when started on dialysis, were illiterate or had less than 4 school years (62%) and had a family income less than 5 national minimum wages per month (88%). The etiology of nephropathy was identified in 54% of cases, diabetic nephropathy (46%) and hypertensive nephrosclerosis (22%) were the most prevalent. Hypertension was the most common comorbidity (76%). D/Pcre was the initial dialysis modality for 53% of patients, namely as an emergency (58%), and only 9% of patients had undergone predialysis care for at least six months. Patients remained in PD by an average of 710.5 (± 714.2) days, and 61% of them also underwent hemodialysis (HD) at some point during their dialysis treatment. 676 peritoneal catheters were implanted (1.19 patient), 75% by trocar, by nephrolith, mostly Tenckhoff (58%). The main cause of dropout was infectious complications related to therapy (17%). The peritonitis index was 1 episode every 27.03 months, and S. aureus was the most prevalent etiological agent (22%). There were 1045 hospitalizations during follow up, most frequently due to infections (48%). The cause of death was identified in 64% of cases, mostly from cardiovascular diseases (50%).

Conclusions: In this study, patients had predominantly low socioeconomic status and did not have access to predialysis treatment, however, peritonitis rates and catheter complications are similar to those reported in other international series. HD and PD are shown as complementary techniques.

PUB608

Implementation of Clinical Practice Guidelines on Antimicrobial Prophylaxis in Peritoneal Dialysis Patients
Denise Campbell, Fiona Brown, John F. Collins, Jonathan C. Craig, Martin P. Gallagher, David W. Johnson, Geoffrey S. Kirkland, Subramanian K. Kumar, Wai Hon Lim, Dwarakanathan Ranganathan, Walaa W. Saweire, Germaine Wong, David Mudge, School of Public Health, Univ of Sydney, Sydney, New South Wales, Australia; Nephrology, Monash Univ, Clayton, Victoria, Australia; Renal Medicine, Auckland City Hospital, Auckland, New Zealand; Renal and Metabolic Div, George Inst for Global Health, Sydney, New South Wales, Australia; Nephrology, Princess Alexandra Hospital, Woolloongabba, Queensland, Australia; Nephrology, Royal Hobart Hospital, Hobart, Tasmania, Australia; Renal Unit, Gosford Hospital, Gosford, New South Wales, Australia; Renal Medicine, Sir Charles Gairdner Hospital, Perth, Western Australia, Australia; Nephrology, Royal Brisbane & Women's Hospital, Herston, Queensland, Australia; Renal Unit, Whangarei Hospital, Whangarei, New Zealand.

Background: Despite the existence of international guidelines, peritoneal dialysis (PD)-related infections vary widely across Australian and New Zealand units, with multiple units reporting suboptimal rates and variable practice.

Methods: The current practice and barriers to guideline uptake were evaluated in eight PD units located in Australia and New Zealand in 2011. A multifaceted intervention was developed which included case report forms, a patient diary, a ‘Preventing Peritonitis Checklist’, an Emergency Department flyer, a letter to the patient’s general practitioner, a medical card, and a poster summarizing ISPD and KHA-CARI guidelines.

Results: At baseline (1 Jan-31 Dec 2011), exit-site infection (ESI) rates ranged from 0.06-0.53 episodes/patient-year; peritonitis from 0.31-0.86 episodes/patient-year; and fungal peritonitis from 0.00-0.08 episodes/patient-year. After implementation (9 Dec 2013-8 Dec 2014), the ESI rates were 0.00-0.22 episodes/patient-year; peritonitis was 0.29-0.49 episodes/patient-year; and fungal peritonitis was 0.00-0.14 episodes/patient-year.

Conclusions: Implementing the various tools resulted in improvement in the ESI and peritonitis rates but the difference was not statistically significant (P=0.15 and P=0.08). There was no statistically significant difference in the fungal peritonitis rate (P=0.64).

Funding: Government Support - Non-U.S.
Factors Influence the Baseline Peritoneal Transport Status

Hao Zhang, Bin Yi, Cuiling Hou. The Third Xiangya Hospital, Central South University, Changsha, Hunan, China.

Background: Baseline peritoneal solute transport rate (PSTR) is an independent risk factor for total cardiovascular (CV) mortality in the PD (peritoneal dialysis) population. The determinants of PSTR in incident PD patients are still under debate. Our objective was to explore the influence factors of baseline PSTR.

Methods: (1) 205 incident PD patients who had a standard peritoneal equilibration test (PET) within 1-3 months after commencing PD and without peritonitis history were enrolled. Pre-PET clinical parameters and biochemical indexes were assessed. 205 individuals were divided into two groups according to the baseline PSTR. High transport group: PET > 0.65. Low transport group: PET ≤ 0.65. (2) Pre-PET serum advanced oxidation protein products (AOPP) and dialysate AOPP: GPx, hsCRP, IL-1beta, TG-beta 1 of 59 patients among the enrolled 205 individuals were detected.

Results: (1) High baseline PSTR are more likely to be malefemal: 77.3% vs 52.5%, p = 0.001, had lower serum albumin (34.0 ± 4.40 g/L vs 35.9 ± 4.55 g/L, p = 0.005) and TG levels (1.11 ± 0.62 mmol/L vs 1.28 ± 0.57 mmol/L, p = 0.047) compared to the low baseline PSTR. Gender (r = 0.299, p = 0.299), serum albumin (r = 0.199, p = 0.199) and TG level (r = 0.140, p = 0.140) are correlated with the baseline PSTR respectively. Multiple stepwise linear regression analysis showed that gender (β = 0.085), serum albumin (β = 0.005, p = 0.005) are associated with baseline PSTR independently. Multivariate Logistic analysis showed that men (OR = 3.314, p = 0.001), hypoalbuminemia (OR = 2.552, p = 2.552) are independent risk factors for high baseline PSTR. ROC curve display that when serum albumin < 35.8 g/L, it is likely to have a high baseline PSTR. (2) High baseline PSTR had a relatively high level of dialysate TGF-beta1 (1.58 ± 0.35 mg/mL vs 1.75 ± 0.30 mg/mL, p = 0.049) than the low transport status. No statistical differences were found in serum AOPP and dialysate AOPP: GPx, hsCRP, IL-1beta between groups. Dialysate TGF-beta1 (r = 0.135, p = 0.001) contributed to the baseline PSTR independently.

Conclusions: (1) Male, hypoalbuminemia, high dialysate TGF-beta1 level are independent predictors of fast baseline PSTR. (2) When serum albumin < 35.8 g/L, it is likely to have a high baseline PSTR.
follow up and dialysis start. PD patients (p=0.02) received more modality information than HD (92% vs. 78%) and were mainly under 50 years (p = 0.001). Incidence varied according with different studied groups

The Adsorption Kinetics Profile of Aminoglycoside Antibiotics During Lixelle S-35 Cartridge Hemoperfusion
Marco Sartori, 1, 2 Angela Casas, 3 Silvia De Rosa, 1 Mirella Zancato, 2 Leopolda Zampieri, 1 Davide Giavarina, 1 Claudio Ronco. 1
*International Renal Research Inst of Vicenza, St. Bortolo Hospital, Vicenza, Italy; 1Dept of Pharmaceutical and Pharmacological Sciences, Univ of Padua, Padua, Italy.

Background: The bacterial activity against Gram(-)ino of Tobramycin(TOB)and Gentamicin(GEN)is concentration-dependent. It is therefore fundamental achieving the maximum antibiotic plasma levels. Lixelle S-35 is a new sorbent for dialysis-related amyloidosis which can modify the drug plasma levels. The aim of in vitro study was to evaluate the TOB and GEN adsorption removal by Lixelle S-35.

Methods: We performed mock direct hemoperfusion (DHP;Q=100ml/min;Bellco prototype dialysis machine)for 120 min using Lixelle S-35 cartridge. Human blood was diluted with fresh frozen plasma in order to achieve appropriate rheological characteristics(Hct 30%;650ml each bag;n=6).Blood was separately spiked with TOB(1.00±0.42 mg/L;n=3) and GEN(12.80±1.00mg/L;n=3).In 30 min it was circulated into the system. Samples were taken from arterial(Cpin)and venous(Cout)lines at 5,10,60 and 120 min. Sample levels were measured by TOBR and GENT Flex methods(Siemens prototype dialysis machine)for 120 min using Lixelle S-35 cartridge. Human blood was diluted with fresh frozen plasma in order to achieve appropriate rheological characteristics(Hct 30%;650ml each bag;n=6).Blood was separately spiked with TOB(1.00±0.42 mg/L;n=3) and GEN(12.80±1.00mg/L;n=3).In 30 min it was circulated into the system. Samples were taken from arterial(Cpin)and venous(Cout)lines at 5,10,60 and 120 min. Sample levels were measured by TOBR and GENT Flex methods(Siemens Healthcare,Newark,NJ,USA)for TOB and GEN,respectively. The adsorption kinetics profiles were calculated.

Results: At the of DHP TOB and GEN levels were 7.13±0.18 and 7.20±0.90mg/L. Ratio Cout/Cpin rose rapidly during the first 5 min then reach plateau for both antibiotics as shown Fig. On mass balance analysis, the total mass of antibiotics introduced into the system decreased from 5.12±0.25 to 3.22±0.50 and from 6.16±0.51 to 3.52±0.41mg for TOB and GEN, respectively. The TOB mass adsorption was 37.20% whereas GEN was 46.20% in human serum by capillary HPLC/mass spectrometry(MS). Although this method works well for identification of the drug, it is semi-quantitative unless a suitable isotopic internal standard is used.

Methods: A simple, rapid, sensitive and quantitative method is presented for the analysis of six AG AMBs (streptomycin, ribostamycin, kanamycin, amikacin, dibekacin, arbekacin) in human plasma samples. Hydrophilic interaction liquid chromatography tandem mass spectrometry (HILIC-MS/MS) is a small volume (50µL) of plasma spiked with six drugs was diluted with 350µL of acetonitrile containing 0.1% formic acid. After centrifugation, 100µL of the clear supernatant extract was directly injected into the HILIC-MS/MS, without any solvent evaporation and reconstitution steps. The chromatographic separation of the AG AMBs was achieved on Unison UK-Amino HILIC column (50mm x 3mm i.d.; particle size 3µm) with a linear gradient elution system composed of 0.1% formic acid and acetonitrile.

Results: All drugs showed base peaks due to [M+H]+ ions with HILIC-MS with positive ion electrospray ionization, and the product ions were produced from each drug by the following collision-induced dissociation (CID) experiments. TOBR and GENT product ions were identified using the standard method of selected reaction monitoring (SRM) and the product ion spectra of all drugs were consistent with the literature. The method was validated for six AG AMBs in human plasma by HILIC-MS/MS. The sensitivity of the method was 0.1 µg/mL for TOB and GEN, and 0.001 µg/mL for all other AG AMBs. The accuracy of the method was 99.6% for TOB and GEN, and 97.5% for all other AG AMBs. The precision of the method was 1.2% for TOB and GEN, and 1.5% for all other AG AMBs. The method was applied to the analysis of six AG AMBs in human plasma samples from healthy volunteers and patients. The results showed that the method was accurate and precise for the analysis of six AG AMBs in human plasma samples.

Conclusions: The method would seem to be useful in clinical and forensic medicine because of its ability to both identification and quantification of the drugs.

PUB616

Prevalence of Chronic Musculoskeletal Pain Among Hemodialysis Patients
Masayo M. Ishibara, 1 Cherry Reda, 1 Haitham Ezzat, 2 Amr Mohab. 2
*Nephrology Dept, Ain Shams Univ, Egypt.

Background: Chronic musculoskeletal pain (MS pain) is common in patients with end stage renal disease (ESRD) undergoing hemodialysis; however information regarding its frequency and prevalence is relatively scarce.

Methods: A cross-sectional study was conducted on 100 ESRD patients on maintenance hemodialysis 3 times per week for at least 3 months. Chronic musculoskeletal pain was defined as pain that the VON KROFF questionnaire for grade 3. Chronic musculoskeletal pain correlation was done between chronic MS pain and serum parathormone (PTH), serum corrected calcium, serum phosphorus, serum alkaline phosphatase, serum albumin & hemoglobin level.

Results: Mean age was 57.46 years. Mean dialysis duration was 3.80 years. 42% were females and 58% males. In our study, 37% of the patients had low disability low intensity of pain i.e. little affection on the daily, social & work activity (grade 1).37% of the patients had low disability high intensity of pain (grade 2) while 26% of them had high disability high intensity of pain i.e. moderate limitation of the daily, social, recreational & work activities (grade 3). Chronic musculoskeletal pain showed positive correlation with muscle state, tenderness and power (r=0.001, p<0.001, r=0.001 respectively). Grade 3 disability patients had the highest level of serum Ca and i-PTH which were significantly different from grade 1 and 2 patients (p<0.001, p=0.013 respectively) While albumin serum level was lowest in grade 3 patients (p=0.025).

Conclusions: Chronic MS pain is common in ESRD patients. Disturbed mineral metabolism is strongly associated with chronic MS pain in long-term HD patients. Musculoskeletal system involvement remains a common problem that limits the physical function of patients with ESRD.

Practice Patterns of United States Nephrologists in Blood Pressure Medication Use when Transferring Patients to Dialysis
Mary C. Mallapallil, 1 Steven Fishbane, 1 Rimda Wachacho, 2 Andrea Roche-Recinos, 2 Subodh J. Saggi, 2 Moro O. Salifu, 3
*Internal Medicine: Div of Nephrology, SUNY Downstate School of Medicine, Brooklyn, NY; 2Internal Medicine -Div of Nephrology, Hofstra North Shore LIJ School of Medicine, Great Neck, NY.

Background: As there is no standard approach to transition a patient in chronic kidney disease (CKD)-5 to CKD5-Dialysis in regards to adjustment of diuretics, BP medication, optimal frequency of medication reconciliation (MR) and determination of dry weight (DW) we conducted a survey to determine how US nephrologists transition a patient from CKD5 to CKD5-D in these aspects.

Methods: We designed an anonymous electronic survey with 39 questions and sent it to practicing nephrologists in the US after IRB approval.

Results: 120 US Nephrologists replied to the survey; 60% were in Nephrology for more than 10 years. Most (79%) used furosemide in CKD 5, (66%) used a combination of furosemide and metolazone. The first choice of diuretics in CKD5 was furosemide (79%), then hydrochlorothiazide (12%) and torsemide (8%) (p=0.005). In CKD5, 45% used diuretics daily, 29% on non-dialysis days and 26% discontinued them(p=0.002). In CKD 5, 63% would continue ACEI or ARB. In CKD5D, 84% of respondents had at least 30% of patients on ACEI/ARB and most (64%) would not stop these medications despite hyperkalemia. The majority (79%) did not change ACEI to those that were not dialyzed out. The perceived most effective BP medication in CKD5-Dialysis in decreasing order: Nifedipine/amlodipine (36%), ACEI/ARB (32%), beta blockers (17%), diuretics (13%) and others (4%) (p<0.0005). Most responders (79%) prescribed BP medication on non-dialysis days only and 88% thought that BP should be controlled with ultralow sodium. The furosemide dose in the first month was on average 1.00 mg/day. In the first month of dialysis, CKD5 was monthly (78%), weekly (12%) and as needed only (8%). DW was determined in the first week(31%) and the first month(52%). Of those surveved, 59% felt HTN in CKD5D had multiple causes.

Conclusions: Transitioning patients from CKD5 to CKD5 continues to remain challenging in terms of adjustment of BP medication. Variations in practice regarding the frequency of medication use may benefit from guidelines.
First Dialysis Prescription and Access Use: A Survey of United States Nephrologists

Mary C. Mallapalli,1 Steven Fishbane,2 Rinda Wanchoo,2 Andrea Roche-Recinos,3 Subodh J. Saggi,4 Moro O. Salifu,5 1 Internal Medicine-Renal Div, SUNY Downstate School of Medicine, Brooklyn, NY; 2 Div of Nephrology, Hofstra North Shore LIJ School of Medicine, Great Neck, NY.

Background: As there is no standard approach to initiate renal replacement therapy in CKD patients in regard to location of first treatment, access and dialysis prescription were evaluated in a survey of US nephrologists to better identify current practice patterns.

Methods: We created an anonymous electronic survey with 39 questions that was validated then approved by the IRB. Aggregate data was analyzed using descriptive statistics, avoiding duplicate responses.

Results: 120 US nephrologists replied to the survey, 60% were in nephrology practice for more than 10 years. The first hemodialysis (HD) treatment was at inpatient (22%), outpatient (29%) or either (47%). At the first HD, most nephrologists (92%) used a blood flow (BF) of 300 mL/min; 65% would use lower than usual dialysate flow rates (DFR) and 47% would use a smaller dialyzer. Ninety percent prescribed less time less than usual, even with blood area nitrogen less than 100 mg/dL. About 45% replied that only 10-50% of patients meeting criteria for peritoneal dialysis were actually started on this modality (p<0.005). Of the participants 47% noted that only 10-50% of patients who were eligible for transplant were listed, and the majority of responders (83%) noted that less than 10% of their patients got a preemptive transplant (p<0.0005). A patient educator was available to 64% of the patients. First dialysis with a permanent access was noted among 30-60% of patients by 43% of responders and in more than 60% of patients by 22% of responders. Of the participants 73% replied that the majority (>60%) of their patients got vein mapping before access creation. The time between vein mapping and access creation was one week to one month (61%) and more than one month (26%), (p<0.005). The number of angioplasties that were acceptable prior to primary access failure was noted as 2, (25%) 3 to (25%) or more than (4/24%).

Conclusions: There is variation in practice in several areas in regard to the initial dialysis session in CKD5D which may benefit from guidelines.

How to Dialyze a Patient with Left Ventricular Assist Device in a Chronic Dialysis Unit? A Practical Protocol

Sadiaq Ahmed,1 Debbie Baker,2 1 Univ of Kentucky; 2 Davita.

Background: To provide chronic HD treatments to ESRD patients with LVAD in a chronic unit in the community is a challenge and a relatively new experience for nephrologists. As LVADs have revolutionized the treatment of advance heart failure there are rising numbers of these patients developing ESRD with need for HD in the community. Development of a practical, simple and safe protocol is needed to dialyze these patients in the chronic units.

Methods: This protocol and safety check list is developed to provide routine HD treatment for patients with LVAD and successfully implemented in a chronic dialysis unit in the community setting. The special policy and procedure relevant to this protocol, safety check list and standing orders for the dialysis nurses were approved by the governing body before dialysis staffs were trained. The VAD coordinator is present during first training.

Results: This protocol is a step by step guidance for the dialysis staff. The whole process has 3 components. A supplemental informed consent signed by the patient to cover for any adverse reactions and/or side effects potentially related to Lixelle S-35. Presence of support person who waits in lobby after power base is connected. LVAD check list

Conclusions: This protocol to provide incenter HD to patients with LVAD in a chronic unit is simple & safe. It can be implemented in a chronic HD unit.

More Nephrologist Visits Are Associated with Lower Cost of Care for Dialysis Patients  

**Fresenius Medical Care North America, Waltham, MA.**

**Background:** Medicare patients with end stage renal disease (ESRD) are treated by nephrologists, primary care providers (PCPs), cardiologists and other specialists on a regular basis. We investigated the relationship of visits to these providers and total costs of care.

**Methods:** Medicare 100% ESRD data for patients with evidence of dialysis at any time during January 1, 2010 through December 31, 2011 were analyzed. Nephrologist, PCP and cardiologist visits were determined by specialty codes of Part B claims (including both in- and out-patient patients). All data was aggregated at the Metropolitan Statistical Area level (MSA). We computed a ratio of nephrologist visits to PCP visits per MSA as well as nephrologist visits to cardiologist visits per MSA during the above period (visits were calculated on a per patient per month basis). Total costs of care (per member per month [PMPM]) were determined by aggregating Medicare Part A and B costs. Comparisons of ratios were performed using t-tests for quartiles of PMPM for two specialty visit ratios.

**Results:** Claims for 368,711 patients were analyzed. Patients in the lower quartiles of total cost had significantly more nephrology visits relative to PCPs and cardiologists.

**Conclusions:** These results indicate that higher ratios of nephrologist visits to cardiologist/PCP visits are significantly associated with decreased cost on a MSA level. Taken that nephrologist visits tend to be constant (due to the monthly capitated payment), these results may be revealing a “sicker” and therefore more expensive population of patients on a MSA level that require more medical attention from a cardiologist or PCP, likely due to hospitalizations. Adjustments for underlying disease should be considered.

Prediction of Non-Adherence to Hemodialysis Treatment Regimens  

Yue Xiao,1 Daniel E. Geary,2 Theresa J. Hetzel,1 Sheetal Chaudhuri,1 Mahathi Mothali,1 Terry Ketchersid,1 Dugan Maddux,1 John W. Larkin,1 Peter Kotanko,3 Brian Scott Ash,1 Len A. Usyvat,2 Franklin W. Maddux.1  

1Fresenius Medical Care North America, Waltham, MA; 2Renal Research Inst, New York, NY; 3Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** Non-adherence with hemodialysis (HD) treatment regimens is known to be associated with increased morbidity and mortality. The aim of this project was to develop a predictive model (PM) to identify HD patients who will likely have unexcused no shows to routine dialysis treatments within the next week.

**Methods:** Using data between 1/1/2014 and 12/31/2014 from the Fresenius Medical Care Knowledge Center and 2014 weather data from the National Oceanic and Atmospheric Administration National Centers for Environmental Information, PMs were designed and developed for prediction of unexcused no shows in patients not residing in a nursing home. Various PMs were investigated and included the generalized linear model, partitioning and regression trees, artificial neural networks, and generalized additive model (GAM). In all, 1,554,833 records stratified in weekly intervals on 60 variables from 172,854 patients were utilized. Variables included data on the patient’s history of unexcused no shows, demographics, comorbidities, laboratories, holidays, sporting events, and weather. A multi-tier prediction process was performed with respect to the availability of data. The area under the curve (AUC), sensitivities and specificities were investigated to determine the model with the highest performance.

**Results:** Best performing model had AUC of 0.87 for the multi-tier PMs utilizing a 30% test dataset. A small pilot test on 860 patients for three weeks utilizing optimal Yoden index as the cutoff value to predict the high probability of the unexcused no show events achieved an average sensitivity of 0.57 and specificity of 0.95.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

1033A
Conclusions: This pilot test of the developed modeling demonstrates that PM can assist in identifying patients with a high probability for unexposed missed HEV cases. Additional studies are needed to further analyze the potential of predictions forand interventions associated with reducing unexposed no show events.

Factors Influencing Residual Renal Function Decrease in Hemodialysis Treated Patients

Fernando Caravaca-Fontan, Milagros Fernandez-Lucas, Jose L. Tenel, Saul Enrique Pampa, Estefania Yerovi, Maria Delgado yagüe, Fernando Liano. Nephrology, Hospital Universitario Ramon y Cajal, Madrid, Spain.

**Background:** We have shown in previous studies that maintenance of residual renal function in hemodialysis treated patients is conditioned by the number of weekly sessions, and is better in patients who start treatment with a twice weekly schedule. The aim of this study is to analyse the influence of other variables in the preservation of residual renal function.

**Methods:** Of the 174 consecutive patients who started hemodialysis treatment in the hospital, 98 began with 2-weekly sessions (2HD group), and 76 with 3-weekly sessions (3HD group). Residual renal function was measured every two months (mean urea and creatinine clearance).

**Results:** Decrease in residual renal function was lower in the 2HD group (median 0.19 ± 0.46 ml/min/month, p=0.005). In both groups the residual renal function decrease was higher in the patients from the transplant program than in those from predialysis: 2HD group: median 0.93 ± 0.17 ml/min/month, p=0.003; 3HD group: median 0.76 ± 0.32 ml/min/month, p=0.005. Neither the initial schedule, sex or etiology of the renal disease influenced the decrease in residual renal function in either of the two groups of patients. Moreover we found no correlation between the decrease in residual renal function with age, the residual function at the start of dialysis or with the Charlson comorbidity index. Of the 98 patients who began with the 2HD schedule, 45 went on to dialysis three times a week when the residual renal function was less than 3 ml/min/these patients had a mean of 10.8 months on the 2HD schedule. The length of time on this model was not influenced either by age, sex, etiology of the nephropathy, comorbidity index, scheduled start or basal renal function.

**Conclusions:** The decrease in residual renal function in the patient treated with hemodialysis depends basically on the number of weekly sessions with which the dialysis treatment was started. Of all the variables analysed only the return to dialysis due to graft loss conditioned a higher decrease in residual renal function in both groups of patients.

**PUB628**

Circadian Blood Pressure Behaviour in Hemodialysis Patients

Dimitrios Petras,1 Kyriakos Dimitriadis,2 Panagiota E. Giannou,1 Eirini Andrikou,2 Konstantinos Tsiofis.2 Nephrology Dept, Hippokration Hospital, Athens, Greece; 2First Cardiology Clinic, Hippokration University Hosp of Athens, Athens, Greece.

**Background:** Blood pressure (BP) evaluation and management in haemodialysis (HD) patients is often a matter of debate. During HD hypotension as well as a paradoxical rise in BP can be observed. Ambulatory BP monitoring in ESRD patients is a promising non invasive technique to assess the presence of this phenomenon.

**Methods:** We included 38 patients with ESRD (68% men, mean age 62.19 years, 52% hypertensive) that underwent HD three times a week in the HD unit of our hospital and were on their ideal dry weight. Ambulatory BP monitoring was applied one hour before an HD session and was set to measure BP every 30 minutes and until arrival for the next HD session, for a total of two subsequent 24-hour periods. Blood pressure dipping was defined as [(daytime systolic BP – nighttime systolic BP)/ daytime systolic BP]. Patients were defined as dippers if BP dipping was >10% and risers if BP dipping <0%.

**Results:** Body weight before and after the HD session was 72±2kg and 77±2mg Hg respectively. Ambulatory systolic/diastolic BP increased not significantly from 127±23/70±13mmHg to 130±19/71±11mmHg (p=0.05) from the first to the second 24-hour period. Mean dipping was 1.5±7.8% in the first day and further decreased to -0.94±6.8% in the second day. Accordingly, in the first 24-hour period, only 6 patients (16%) were dippers and reduced to 2 patient in the following day (5%). Sixteen patients (42%) and 18 patients (47%) were risers at the first and second 24-hour period respectively.

**Conclusions:** Daytime systolic BP does not substantially change during the 48-hour period extending from HD to HD session. Yet, prevalence of the non-dippers as well as the riser pattern is high and further increases during the interdialytic period. Patients with this BP pattern are at high risk for coronary artery disease, especially if other comorbidities coexist. Ambulatory BP monitoring in ESRD patients is a promising non invasive technique for the recognition of future heart disease.

**PUB629**

In Vitro Dialysability of SNF472, a Novel Inhibitor of Vascular Calcification, Using Conventional Hemodialysis and Hemodiafiltration

Joan Perello,1 Miquel Gomez Umbert,1 Nestor Yesid Rodriguez,2 Carolina Salcedo,1 Miquel D. Ferrer,1 Juan Manuel Buades,3 Maria del mar Perez,2 Eva Martin Becerra,4 Francisco Maduell.1 1Sanitf, Palma, Spain; 2Nephrol. and Renal Transpl., Hosp. Clinic, Barcelona, Spain; 3Nephrol., Hosp. Son Llatzer, Palma, Spain; 4Kirel, Madrid, Spain.

**Background:** SNF472 is being developed for the treatment of calciphylaxis and cardiovascular calcification in end stage renal disease patients on hemodialysis. The intended use of SNF472 is intravenous infusion during dialysis; therefore our aim was to assess its possible dialyzability and its effects on calcium (Ca) chelation.

**Methods:** Dialysability of SNF472 was assessed using online hemodiafiltration (OL-HDF) and conventional hemodialysis (HD) systems. The interaction of SNF472 with the system was assessed under bypass conditions (dialysis in off-mode). One liter of heparinized fresh blood spiked with 8 mg/dl creatinine was introduced in a container maintained at 37°C and a one hour dialysis session was simulated. 66.6, 30 and 10 ml/min SNF472 were infused during the first 20 minutes of dialysis. Samples were obtained at different time points and creatinine, total and ionized Ca and SNF472 levels were quantified.

**Results:** No dialyzation of SNF472 was detected at 30 and 66.6 mg/mL neither in OL-HDF nor in HD systems. Dialyzation was measured at 10 ml/min SNF472 both in OL-HDF and in HD, with an estimated clearance (CI) of 39 and 18 ml/min, respectively. Creatinine showed a CI of 231 and 220 ml/min, respectively. In bypass conditions, blood Ca was chelated during the 20 minutes of SNF472 infusion when added at 66.6 mg/mL. However, when the system was switched to the dialysis mode, the Ca in the dialysis bath compensated the chelating effect of SNF472 and Ca levels remained unaltered.

**Conclusions:** SNF472 dialyses with a low CI. SNF472 levels increase in blood during infusion and dialysis and does not prevent from attaining potentially therapeutic levels. As SNF472 will be infused during the whole dialysis session, this low CI is not expected to affect systemic exposure.

A Simple and Cost Effective Approach to Ultra-Pure Dialysate

Anthony M. Valeri,1 Bobby C. Lee,2 John Duffy,2 Robin Ferrer,3 Ronald Villota,4 Greg C. Riccardi,5 Edmond P. Wong.1 1Dept of Medicine, Columbia Univ, New York, NY; 2Dept of Pharmacy, New York-Presbyterian Hospital (Columbia), New York, NY; 3Dept of Biomedical Engineering, New York-Presbyterian Hospital (Columbia), New York, NY; 4Dept of Nursing, New York-Presbyterian Hospital (Columbia), New York, NY.

**Background:** Ultrapure dialysate has been shown to reduce inflammation and improve nutritional and anemia parameters in patients on chronic maintenance hemodialysis. The Nephros® DSU (Dual Stage Ultrafilter, Nephros Inc, River Edge, NJ) has been shown to reduce bacterial counts and endotoxin levels by at least a 5-log order of magnitude.

**Methods:** We performed an observational trial of this filter in a hospital-based acute dialysis facility in the USA.

**Results:** There were 23 chronic stable hemodialysis outpatients treated during the 6 months before and after the installation of the Nephros® filters. The mean age was 51 (range 29-91), 61% male, predominantly Hispanic (70% Hispanic, 17% African-American, 9% Caucasian, 4% Asian) and 30% diabetic. Comparing data from the 6 month period after the installation of the filters to the preceding 6 months, there was an increase in the mean hemoglobin level of 0.5 g/dl (p=0.010) with a reduction in the mean weekly darbopentin dose of 14.6 mg or 40% (P<0.001) translating to a reduction in the ESA resistance index (weekly ESA dose/hemoglobin level) of 1.52 (P<0.001). During this time period, indirect inflammatory markers showed a reduction in the mean WBC count from 7,000 to 6,600 x 10³/L (p=0.008) and an increase in serum albumin from 3.6 to 3.7 (p=0.024). The mean spKt/V was unchanged during the 2 time periods (from 1.690 to 1.607, p>0.30).

**Conclusions:** In conclusion, the use of the Nephros® DSU filter to further reduce endotoxin exposure in chronic hemodialysis patients can result in improved ESA responsiveness and a lower ESA dose.
Care Delivery Models for End Stage Renal Disease: A Systematic Review

Maria Lourdes Gonzalez Suarez,1 Priya Ramar,2 Sagar Chawla,1 LaTonya J. Hickson,1,2 Nilay D. Shah,3 Bjoern Thorsteindottir.1,2 1Dept of Medicine, Mayo Clinic; 2Mayo Clinic Kern Center for the Science of Health Care Delivery; Mayo Clinic; 3Mayo Medical School, Mayo Clinic, Rochester, MN.

Background: Reimbursement for dialysis care has led the way for the broader transition to a value-based payment model. As payment policy for dialysis evolves, a better understanding of the evidence around care delivery models that optimize outcomes and increase the value of care for dialysis patients is essential. Limited evidence exists about which care delivery models are most effective.

Methods: Multiple databases were searched for comparative studies of care delivery models for ESRD published between 2000 and 2014. The intervention had to include >5 dialysis patients over age 18 years and receiving treatment. >6 months follow up, and reported patient important outcomes i.e. mortality, important clinical outcomes, hospitalizations and quality of life. Data was abstracted by reviewer pairs; study quality was assessed using Canadian and Newcastle Ottawa tools.

Results: 1841 abstracts were screened, 59 full-text articles were reviewed, and 23 studies with 87,281 patients were included for final analysis. The interventions included nutritional (n=4), multidisciplinary care (n=6), satellite programs (n=3), home dialysis (n=3), access monitoring (n=2), physician contact (n=4), and nocturnal dialysis (n=1). Most were observational studies of decent quality with representativeness and incomplete follow up being the main potential sources of bias. Two randomized studies on home dialysis and pharmacist care, had attention as the main risk of bias. Most interventions showed positive effect raising concern of publication bias. Overall, hospitalizations were significantly lower in the intervention group despite large heterogeneity: 0.824, 95% CI 0.781, 0.868, p=0.001, 12.95-65.9%.

Conclusions: Multiple interventions have the potential to improve the outcomes of dialysis patients but have not been compared in terms of safety and effectiveness. Limited evidence is available to inform dialysis practice redesign to adapt to new payment structures. Further studies are needed to define best delivery models for dialysis care.

Syntemet Dimethylarginine (SDMA) Is Poorly Cleared by Standard Hemodialysis

Mirela A. Dobrog1, Peter B. De Oro,2 Timothy W. Meyer,3 Thomas H. Hostetter.1 1Case Western Reserve Univ; 2Centers for Dialysis Care, Cleveland; 3Stanford Univ School of Medicine.

Background: High SDMA levels have been associated with an increased risk for cardiovascular disease in patients with normal or reduced renal function. The effect of hemodialysis on SDMA has not been thoroughly studied.

Methods: We measured SDMA levels and its handling by hemodialysis and by the normal kidney in subjects with ESRD on chronic hemodialysis (n = 7) and in normal controls (n=6).

Results: The mean (SD) SDMA levels in ESRD were six times higher than in normal controls, 3.350 (0.65) vs 0.530 (0.25) μM, p<0.001. For comparison pre-dialysis BUN levels was 44.12±1.31mg/dl in ESRD, and 14.9±3.2mg/dl in controls. The fractional reduction in SDMA was significantly lower than that of urea, 47.4(15.1)% vs 76.7(4.7)% p<0.001; and the volume of distribution was much higher 58.5(14.5) l vs 35.10(4.4) l. For urea also the urinary clearance of SDMA was 78.2(m3.5) ml/min in normal controls was higher than that of urea 55.2(13.7) ml/min. SDMA production rates were similar 46.7(9.4) vs 52.3(13.9) mmol/day, ESRD vs normals, p>0.05.

Conclusions: In summary, SDMA circulates at high levels in hemodialysis patients due at least in part to its relatively high clearance by the kidney, relative to urea, and its larger volume of distribution. The latter suggests that SDMA is likely to be localized in the intracellular compartment, and therefore less available for clearance by standard hemodialysis.

On-Line Hemodiafiltration Is Efficient for Inflammation and Phosphorus Control

Nadia Guimaraes-Souza, Dhais Nenmotu Matsui, Adriano Luiz Ammiriti, Maria C.C. Andreoli, Ana C M S Ramos, Fabiana Dias Carneiro, Bento C. Santos. Dialysis Center, Hospital Israelita Albert Einstein, Brazil.

Background: High efficiency on-line hemodiafiltration is efficient to remove uremic toxins and phosphorus. Many studies had demonstrated the impact of this modality in mortality. The main objective of this study was to analyze the high efficiency on-line hemodiafiltration ability to remove phosphorus and reactive C protein.

Methods: This is a prospective study with end stage chronic kidney disease patients undergoing dialysis with high levels of phosphorus. High efficiency on-line hemodiafiltration was used as a separation dialyzer with a surface area of 2200, was used for a period of at least one year of follow-up. Beta-2 microglobulin, pre dialysis urea, post dialysis urea, reactive C protein, hemoglobin and phosphorus were collect from patients before starting on-line hemodiafiltration treatment and every month.

Results: Patients included in this study were 375 years old; they were on hemodialysis for at least for one year. 58% had hypertension or coronaryopathy. Hemodialysis dose as single pool Kt/V were significantly higher (12.1±0.20 vs 1.36±0.16; p<0.001) and this difference was kept for all follow-up. In six months of high efficiency hemodiafiltration we also found a decrease on phosphorus levels (7.9±2.4 vs 7.3±2.01; p<0.001) in one year follow up, phosphorus levels were still significantly lower than in the conventional hemodialysis (7.3±2.01 vs 5.6±2.05; p<0.001). We also observed a decline in the need for phosphorus doses in six months (p=0.04) associated with a higher hemoglobin levels (p<0.001). Reactive C protein showed significantly lower levels after six months of online hemodiafiltration (p=0.004).

Conclusions: High efficiency on-line hemodiafiltration is an efficient method of reduction of reactive C protein and may reduce costs due to reduced doses of erythropoietin analogus.

On-Line Hemodiafiltration Filters a Comparative Study

Nadia Guimaraes-Souza, Adriano Luiz Ammiriti, Thais Nenmotu Matsui, Maria C.C. Andreoli, Fabiana Dias Carneiro, Ana C M S Ramos, Bento C. Santos. Dialysis Center, Hospital Israelita Albert Einstein, Brazil.

Background: High efficiency on-line hemodiafiltration is the best method for middle molecules and phosphorus removal. Many studies had demonstrated the efficiency of this method in mortality reduction. The main objective of this study was to compare the three filters available for on-line HDF comparing the ability to remove urea, phosphorus and beta-2-microglobulin.

Methods: Prospective cross-over study including four patients and three available filters for hemodiafiltration. All section of on-line hemodiafiltration was made with high efficiency (23-25Hz). Filters HDF 100, FX100 e HDF90COR were compared. Urea, phosphorus and beta-2 microglobulin were collected before and after first use of each filter A reduction of >33% was related to comparison.

Results: 76% of patients were male, the middle age (61±3.5); 76% of patients were diabetics and had peripheral neuropathy and 34% had coronaryopathy. FX100 filter showed significantly higher dialysis compared to FX80COR (p<0.05); the same was observed for urea reduction ratio(p<0.04). Beta-2-microglobulin and phosphorus reduction ratio were similar between all filters.

Conclusions: FX100 and HDF100 filter were similar for urea remotion ratio. There were no differences for other molecules.

Satisfaction of Patients on Dialysis Unit

Jorge Nicolas Abdala, Nephrology, Militar Hospital, Cordoba, Capital, Argentina.

Background: The asessment of the satisfaction of patients in Dialysis, is a useful tool to meet patient needs; axis on which the care service is based.In turn it allows to identify the deficient areas.

Methods: Objektive 1) To know the views of patients about the service that is offered in each of the areas of focus. 2) To analyze the profile of satisfaction of patients they expressed their overall dissatisfaction. Prospective, descriptive study conducted at the Dialysis Unit of the Military Hospital Córdoba, conducted between 15/11/2014 to 15/12/2014. Inclusion: All Patients attending the service, wich received some form of dialysis (hemodialysis-DPD) in the period. Exclusion criteria: a) diagnostis of cognitive dementia, b) Carrying less than three months of treatment c) not be psychological and physical conditions to answer the survey. A qualitative survey, structured ajar, applied voluntary and anonymous.

Results: We measured SDMA levels and its handling by hemodialysis and by the normal kidney in subjects with ESRD on chronic hemodialysis (n = 7) and in normal controls (n=6).

Conclusions: As a management tool, it should be rated as positive aspects stimulate and work on correcting the negative aspects. 2. The level of dissatisfaction is directly related to dialysis treatment time of the patient, the longer, higher degree of dissatisfaction. 3. It is advisable conduct regular surveys on the degree of patient satisfaction Dialysis, and that will help improve their quality of life.

Correlation Between Calcium Phosphorus Product and Hypertension in ESRD Patients on Maintenance Hemodialysis

Ahmad,1,2 Hafiz I. Ahmad,1 Syed Rizwan Bokhari,1 Arif Asif.2 1Dept of Nephrology, Allama Iqbal Medical College/ Jinnah Hospital, Lahore, Pakistan; 2Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.

Background: Increased levels of serum calcium, phosphorus and product of serum calcium and phosphorus (Ca x P) in end stage renal disease (ESRD) patients has been shown to be associated with increased mean arterial blood pressure (MAP). The available data is limited and no study has been done in Pakistan. We conducted a cross sectional study to determine the correlation between mean arterial blood pressure (MAP) and serum calcium-phosphorus product in our ESRD patients on hemodialysis.

Methods: Blood Pressure of all the prevalent ESRD patients in a single dialysis center was recorded and mean arterial blood pressure (MAP) was calculated pre and post dialysis. All patients were clinically euvelonic. Serum calcium and phosphorus levels were measured and Calcium-phosphorus product (Ca x P) was calculated. The product above 50 and the MAP above 93 were taken as high.
Results: Of the 60 ESRD patients, 35 (58.3%) were males with mean age was 39.5±5 years. The ABI protocol as previously reported could be performed in 18 (30%) patients with high pre-diagnosis MAP in 8 (44%) and high post-diagnosis MAP in 4 (22%) patients respectively. Of 42 (70%) patients with Ca×P product below 50 high pre-diagnosis MAP was seen in 31 (73%) and high post-diagnosis MAP was seen in 29 (69%) patients.

Conclusions: The Ca×P product was too low and cannot be considered with high pre and post-diagnosis MAP. The results are not consistent with earlier studies done in developed countries. Larger studies are needed to re-evaluate these findings.

PUB637

Behaviour of Ankle-Brachial Index During Hemodialysis: Effect of Calcium Dialysate Concentration Zaida Noemí Cabrera Jiménez, Rosa M. A. Moyes, Bruno C. Silva, Luciene dos Reis, Wagner Dominguez, Fabiana Gracioli, Rosieli M. Elias. 1 Nephrology, Univ of Sao Paulo, Sao Paulo, SP, Brazil; 2 Unive Nofe de Julho- UNINOVE, Sao Paulo, SP, Brazil.

Background: Ankle-brachial index (ABI) is a simple way to access cardiovascular risk. Both low (<0.9) and high (>1.3) ABI are associated with increased mortality risk in patients on hemodialysis (HD). However, little is known regarding the acute variation of ABI from pre to post hemodialysis, and also whether the calcium dialysate content [Ca] may interfere with this variability. We aimed to investigate the impact of [Ca] 3.5 vs. 2.5 on the variability of ABI during HD.

Methods: Incident patients on HD for up to 90 days were included. ABI was evaluated pre and post HD in the midnight session of two consecutive weeks with [Ca] 3.5 and 2.5, respectively. Biochemical variables, electrical bioimpedance and non-invasive hemodynamic (Finapress®) were assessed.

Results: 17 patients (10 men) aged 42 ± 17 years were included. ABI pre- and post- HD with [Ca] 3.5 and 2.5 were 1.2 ± 0.1, 1.1 ± 0.1, 1.1 ± 0.2, and 1.2 ± 0.1, respectively. Although the mean ABI values were within normal range, there was a great variability in the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing the ABI. We observed a significant expansion of Tr1 cells expressing a memory phenotype ([CD45RO]) and the immunomodulatory receptor PD-L1 in tolerant but not other animals.

Conclusions: Our data show that the surface markers CD409 and CD43- can be used to distinguish Tr1 from “classical” FoxP3+ Tregs in cryopreserved monocytes. Tr1 cells are likely to inhibit T cell responses mediated by PD-1/PD-L1 interactions. The contribution of these activated Tr1 cells to induction and maintenance of organ allograft tolerance in non-primate humans is under investigation.

Urinary MicroRNA-25 as a Potential Biomarker for Detection of Renal Damage in Rats and Renal Transplant Patients Kumiko Nishihara,1 Masayuki Kanki,1 Moto Kajiwara,1 Kei Kurihara,2 Takahisa Yano,1 Hidehito Kitada,3 Satoshi Masuda,4 Akira Unami.1 1Drug Safety Research Laboratories, Astellas Pharma Inc., Osaka, Japan; 2Dept of Pharmacy, Kyushu Univ Hospital, Fukuoka, Japan; 3Dept of Research and Development of Next Generation Medical and Surgical Sciences, Kyushu Univ, Fukuoka, Japan; 4Dept of Surgery and Oncology, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.

Background: Circulating microRNAs (miRNAs) were proposed as potential biomarkers of various biological functions and diseases in the kidneys. We have found that some urinary miRNAs were useful for detection of cisplatin-induced proximal tubular injury in rats (Kanki M et al., Toxicology, 324, 158, 2014). In this study, we examined the feasibility of urinary miRNAs for renal damage in Japanese patients receiving kidney transplantation as well as rats.

Methods: Gentamicin (100 mg/kg; model of tubular injury) was daily given for 7 days and puromycin (50 mg/kg; model of glomerular injury) was given as a single injection on day 1. Seven days after the treatment, the urinary levels of 15 miRNAs were determined by real-time PCR. The receiver-operator characteristics (ROC) curve analysis for proximal tubular necrosis was performed including previous cisplatin study. Human urine samples were collected from 30 healthy volunteers and 11 renal transplant patients at days 1, 2, 10, and 11 weeks after surgery. The levels of 4 miRNAs were determined. Results: In gentamicin treated rats, the levels of miR-238, let-7a-1, miR-1839, miR-25, miR-140, and miR-378 were increased more than 2-fold with high values of the area under the ROC curve, which were the same or more than those of BUN and serum creatinine, while they were not changed in rats treated with puromycin. Among these miRNAs, miR-25, miR-140-3p, miR-328 and miR-378 were measured in the human urine samples. In human samples, miR-25 at postoperative day 7 in some patients exhibited higher levels than the highest value of those in the volunteers.

Conclusions: Urinary miRNAs other than miR-25 but not other miRNAs might be available for detecting renal damage in the postoperative course of renal transplant patients as well as that in the rats with proximal tubular injury.

PUB641

Early Activation of Complement in Renal Ischaemia/Reperfusion (I/R) Injury Is Mediated by Pentraxin 3 (PTX3) Synthesized by Peripheral Blood Mononuclear Cells (PBMCs) Giuseppe Castellano,1 Chiara Divella,1 Alessandra Stasi,1 Paola Pontrelli,2 Matteo Accetturo,1 Marco Fiorentino,1 Mattia Rossini,2 Vincenzo Montinaro,1 G. Lucarelli,1 Mattea Battaglia,1 Loreto Gesualdo,1 Giuseppe Grandaldo,2 Dept of Emergency and Organ Transplantation, Univ of Bari, Bari, Italy; 2Dept of Medical and Surgical Sciences, Univ of Foggia, Foggia, Italy.

Background: PTX3 has been recently implicated in the promotion of vascular inflammation in the acute stage and the aim of this work was to investigate the possible involvement of PTX3 in renal I/R injury.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

1036A
Methods: PBMCs were isolated from blood of patients with Delay graft function (DGF, n=10) and Early graft function (EGF, n=10) at T0 and T24h from transplant. Gene expression profiles of PBMCs from both groups were assessed by Affymetrix technologies. Results were evaluated by statistical analysis and functional pathway analysis and validated by confocal analysis on a swine model of IR injury. Renal I was induced in 8 pigs by arterial clamping for 30 min and tissues were analyzed at different time points after R (T15' , 30' , 60' ).

Results: Microarray analysis (FDR<5% and a FC>1.5) revealed that the expression of PTX3 and C3 were downregulated in DGF compared to DGF patients. On the contrary, the gene CR1 was upregulated in DGF. Furthermore, in the pig model, confocal laser microscopy demonstrated deposits already at 0.5, 1, 1.5, 3, 6, and 12 days after T0, localized at peritubular capillary levels. We found a significant increase in infiltrating interstitial leucocytes such as CD16+ /PTX3+ monocyte-macrophages (6.2±1.2;p=0.05) and SWC3α/PTX3+ dendritic cells (3.7±0.5;p=0.05) compared to T0. Finally, we identified tubulo-interstitial FSP1+/PTX3+ myofibroblasts (4.1±1.3;p=0.04) Co-localization between C5b-9/PTX3, PTX3/C1q and PTX3/MBL clearly demonstrated the activation of Classical and Lectin Complement pathways in presence of PTX3 deposits.

Conclusions: Our data would suggest a key role of PTX3 synthesized by peripheral blood mononuclear cells (PBMCs) during DGF leading to an early activation of complement in transplant kidney.

PUB642
The Effect of Combined Treatment of Dipeptidyl Peptidase IV Inhibitor and Metformin in Sildiusin-Induced Diabetes Mellitus
Lim Jin, Jin Sun, Woo Lim, Byung Ha Chung, Chul Woo Yang.

Background: Optimal treatment of post-transplant diabetes mellitus is still controversial. This study was performed to evaluate whether the combined treatment of DPP IV inhibitor with metformin (MET) is effective in sildiusin (SRL)-induced diabetes mellitus.

Methods: SRL-induced diabetes mellitus was made by treating SRL (0.3 mg/kg) for 3 weeks in rats, and then started to treat DPP IV inhibitor (LC15-0444[LC], 5mg/kg), and/or MET (200 mg/kg) for further 3 weeks. The effect of combined treatment of LC and MET on SRL-induced diabetes mellitus was evaluated by IPGTT and islet size. The oxidative stress was evaluated by measuring 4-OHdG, 4-HHE, MnSOD, and catalase in samples. Insulin secretion capacity was evaluated by glucose-stimulated insulin secretion (GSIS) test using normal isolated rat islets treated with SRL, exendin-4 and/or MET.

Results: SRL treatment for 6 weeks decreased body weight and increased water intake and food consumption, and islet volume compared with vehicle group. SRL treatment significantly increased AUCg from the values obtained during the IPGTT, but LC or MET treatment recovered these values compared with the SRL treatment alone. Combined treatment with LC and MET has more significantly decreased blood glucose level than LC or MET treatment alone. Islet size which was significantly decreased in the SRL group was recovered with combined treatment of LC and MET. SRL treatment significantly increased intense nuclear expression and larger positive area for 8HdG and 4-HHE, but combined treatment LC and MET has more significantly decreased blood glucose level than LC or MET treatment alone. The result of GSIS also showed that combined treatment of LC and MET showed higher insulin level than exendin-4 or MET treatment alone.

Conclusions: Combined treatment with LC and MET exerts better glucose control by decreasing oxidative stress compared to SRL, which provides the rationale for the combined use of DPP IV inhibitor and MET in SRL-induced diabetes mellitus.

Incidence and Outcomes of Hyponatremia Early Post Lung Transplantation
Ekamol Tantisattamo,1 Aneesha A. Shetty,1 Bing Ho,1 John J. Friedewald,1 Opas Traitaron,1 Sangeeta Bhorade,1 Alexander Haynes,2 Amber Nieland,2 Lorenzo G. Gallon.1

1Div of Nephrology and Hypertension; 2Pulmonary and Critical Care, Dept of Medicine, Northwestern University Feinberg School of Medicine.

Background: Outcomes of in-hospital hyponatremia in lung transplant recipients are unclear. The aim of this study is to describe the frequency of hyponatremia and outcomes associated with hyponatremia during the early postoperative period.

Methods: We performed a retrospective chart review of all lung transplant recipients at Northwestern Memorial Hospital since the first case performed in July 2014 until May 2015. The severity of hyponatremia was defined as mild, moderate, and severe with serum Na of < 135, < 130, and < 125 mEq/L, respectively.

Results: A total of 13 lung transplant recipients were included. Age at the time of transplantation was 61.5±2.2 (SEM) years and 69% was female. The most common indication for transplantation was severe COPD (54%). Serum creatinine at the time of transplantation and at hospital discharge was 0.8±0.6 and 1.0±0.2 mg/dL, respectively. Seven patients had acute kidney injury (AKI) with Acute kidney injury (AKI) had > 2 times longer length of hospitalization (26.2±4.8 vs. 10.0±1.1 days; p = 0.0046) and were more likely to develop postoperative hyponatremia (100% vs. 71%; p = 0.051). Among 11 patients with postoperative hyponatremia, 7 were readmitted (5 with hyponatremia and 4 with AKI). At the time of transplant, 8% of the patients had hyponatremia, while the incidence was up to 46% at the time of discharge (Table1). Almost half of the patients had persistent hyponatremia during 1 month follow-up.

Conclusions: Lung transplant recipients commonly develop hyponatremia during the immediate post operative period and are more likely to be readmitted with hyponatremia. The incidence of hyponatremia remains high up to 1 month post transplantation, AKI is also a risk for readmission and predicts longer length of hospital stay.

PUB644
Motivations, Challenges, and Attitudes to Self-Management in Kidney Transplant Recipients: A Systematic Review of Qualitative Studies
Nathan Jameson,1,2 Camilla Sara Hanson,1,2 Michelle A. Josephson,3 Elisa J. Gordon,4 Jonathan C. Craig,1,2 Fabian Halleck,3 Klemens Budde,4 Allison Tong,1,2 1Centre for Kidney Research; 2The Children’s Hospital at Westmead, Sydney, New South Wales, Australia; 3School of Public Health, Univ of Sydney, Sydney, New South Wales, Australia; 4Dept of Medicine, The Univ of Chicago, Chicago, IL; 2Centre for Healthcare Studies and Comprehensive Transplant Centre, Northwestern Univ Feinberg School of Medicine, Chicago, IL; 3Dept of Nephrology, Charité, Universitätmedizin Berlin, Berlin, Germany.

Background: Kidney transplantation offers superior life expectancy and quality of life outcomes compared to other renal replacement therapy modalities. However, the complex and ongoing medication and self-management regimes impose a treatement burden on patients, and non-adherence remains a leading cause of graft loss.

Methods: MEDLINE, Embase, PsycINFO, and CINAHL were searched from database inception to October 2014. We used thematic synthesis to analyse the findings.

Results: Fifty studies involving 1238 participants aged from 18 to 82 years across 19 countries were included. We identified five themes: empowerment through autonomy (achieving mastery, tracking against tangible targets, developing bodily intuition, routinising and problem-solving, adaptive coping), prevaling fear of consequences (inescapable rejection anxiety, averse to dialysis, minimising future morbidity, trivialisation and denial, defining acceptable risks), burdense treatment and responsibilities (frustrating ambiguities, inadvertent forgetfulness, intrusive side-effects, reversing ingrained behaviours, financial hardship), over-medicalising life (dominating focus, evading patienthood, succumbing to burnout), and social accountability and motivation (demonstrating gratitude towards medical team, indebtedness to donor, peer learning).

Conclusions: Self-efficacy and social accountability are motivators for self-management, but ongoing adherence can be mentally and physically taxing. Multi-component interventions that incorporate education, psychosocial support, decision aids, and self-monitoring tools may foster self-management capacity and improve transplant outcomes.

PUB646
Characteristics of Patients with Vitamin D Deficiency After Kidney Transplantation in Qatar

Background: Vitamin D deficiency is common among normal people and in patients with chronic kidney disease including dialysis patients. Vitamin D deficiency continues to be prevalent after kidney transplantation (studies showed prevalence of 50-80%) especially with immunosuppression use and sun protection needed for elevated risk of skin cancer.

We studied characteristics of kidney transplant patients with vitamin D deficiency in Qatar.

Methods: We reviewed all available records of kidney transplant patients presented to our clinic at Hamad General Hospital in Doha, Qatar between 1/9/2013 and 1/3/2014 and have vitamin D level less than 30 ng/mL. Background data and laboratory tests of patients were obtained. All patients were receiving vitamin D supplements and prednisone within their immunosuppression per institution protocol.

Results: We studied 83 patients. Mean age was 55.5 ± 16.1 years. There were 55 males (66%) and 28 females (34%). Vitamin D deficiency was severe (level than 10 ng/mL) in 15 patients (18%) and moderate in 38 (46%) and mild in 30 patients (36%). Duration of transplant was 7.9 ± 2.5 years. Glomerular Filtration Rate was 65.5 ± 20.6 ml/min. We found no correlation between vitamin D and PTH levels or between vitamin D and GFR levels. Table 1 summarize bone mineral panel in our patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: In a study of kidney transplant patients with vitamin D deficiency in Qatar we found that they were predominantly males, have normal calcium, phosphorus and alkaline phosphatase levels, while they have variable degree of elevated PTH with no correlation to vitamin D level. Most patients have mild to moderate vitamin D deficiency (82%) despite receiving vitamin D supplement although the supplement could have decreased the number of patients with severe vitamin D deficiency (18%). Further study could help to evaluate the role of vitamin D supplement in improving vitamin D level in kidney transplant recipients.

**PUB647**

**Background:** Vitamin D deficiency is common in normal population and in patients with chronic kidney disease including kidney transplant recipients. Elderly patients are vulnerable to vitamin D deficiency with less sun exposure and having multiple medical problems. We compared young versus elderly kidney transplant recipients with vitamin D deficiency in Qatar.

**Methods:** We reviewed all available records of kidney transplant recipients presented to our clinic at Hamad General Hospital in Qatar between 1/9/2013 and 1/3/2014. Background data and laboratory tests of patients were collected. All patients were receiving vitamin D supplements and prednisone per institution protocol.

**Results:** 83 patients were included. 41 patients in the young group (< 60 years old) and 42 in the elderly group (> 60 years old). There were 21 females versus 20 males in the young group and 35 males versus 7 females in the elderly group (pValue<0.05). Time on transplant was 9.1 +/- 4.93 years in the young group versus 8.6 +/- 2.7 in the elderly. Table 1 summarizes laboratory values for kidney transplant patients with vitamin D deficiency.

Conclusions: We compared vitamin D deficiency in young versus elderly kidney transplant recipients in Qatar. Although elderly patients have higher vitamin D levels, it was not statistically significant. This could be due to better compliance with vitamin D supplement in the elderly. Although duration on transplant, calcium, phosphorus and intact parathyroid hormone were similar, Glomerular Filtration Rate (GFR) was higher in the elderly. We explain that it almost all kidney transplants in Qatar are from live donors which lead to a higher GFR in the elderly as they are receiving kidneys from younger donors. There was statistically significant smaller number of females than males in the elderly group.

The Current Status of Plasmapheresis Before Living Donor Kidney Transplantation in Japan. Norio Hanafusa, 1 Tomoko Usui, 1 Akihiko Matsumoto, 2 Satoko Sakurai, 1 Eisei Noiri, 1 Hideo Yasunaga, 1 Masaoi Nangaku 1 1Dept of Hemodialysis and Apheresis, The Univ of Tokyo Hospital, Bunkyo-ku, Tokyo, Japan; 2Dept of Clinical Epidemiology and Health Economics, School of Public Health, The Univ of Tokyo, Bunkyo-ku, Tokyo, Japan.

**Background:** Plasmapheresis (PP) is utilized to remove alloantibodies before the living donor kidney transplantation (LDKT). The detailed practice patterns of PP before LDKT remains unknown. There also are concerns about the depletion of coagulation factors [Transfus Apher Sci 49: 254, 2013] by PP. We investigated the current status of PP before LDKT with use of the nationwide database.

**Methods:** The Japanese Diagnosis Procedure Combination Database includes all the patients discharged from hospitals participating in this program between July 2010 and March 2013. Those who received LDKT and PP before LDKT were included into this study. The modalities of PP, fresh frozen plasma (FFP) use, and albumin use were examined. We also investigated the relationship between modalities selected and outcomes such as the length and total costs of the hospital stay, or the amount of blood transfusion as the proxy of bleeding.

**Results:** In total 775 patients received PP before LDKT during the period. Among them 209 patients were treated only by simple plasma exchange (PE). Remaining 566 patients received double filtration plasmapheresis (DFPP), or cascade filtration. Interestingly, 274 patients treated by DFPP received also PE before transplantation. FFP was used during PP on 109, 180, and 42 patients treated by PE only, DFPP followed by PE, and DFPP only, respectively. Moreover, FFP was infused before the operation on 161 patients who were not used FFP during PP. As a whole 63.5% of total patients received FFP from the start of PP to the day of operation. DFPP followed by PE groups received less amount of blood transfusion (p<0.047), though the length of stay was longer and total costs were higher, compared to DFPP only (p<0.05).

**Conclusions:** Many of the patients received FFP, which suggests concerns about the depletion of coagulation factors during PP. The practice patterns were quite heterogeneous and the standardization of the practice patterns is needed to maximize the benefits of PP.

**1038A**
A DNI value of 2.7% was selected as cut-off value for AGPN, and renal transplant recipients with a DNI ≥ 2.7% were found to be at a higher risk of infection than those with a DNI < 2.7% (odd ratio [OR] 40.50; 95% CI 1.68-189.08; P <0.001). In a multivariate logistic regression analysis, DNI was a significant independent factor for predicting AGPN after adjusting age, sex, log WBC count, log neutrophil count, log lymphocyte count, DNI value, CRP concentration and procalcitonin concentration (OR 4.32; 95% CI 1.81-10.34, P < 0.001).

Conclusions: The present study demonstrated that a DNI value above 2.7% was an independent predictive marker for AGPN and an effective marker to differentiate between AGPN and acute graft rejection. Thus, these finding suggest that DNI may be a useful marker in the management of these patients.

PUB652

Effect of Pre-Transplant Dialysis Modality on Outcomes of Living-Donor Kidney Transplantation Recipients Chiaki Kawabata, General Internal Medicine, Japanese Red Cross Kumamoto Hospital, Kumamoto, Japan.

Background: There are few studies on living-donor kidney transplantation that compare the outcomes after pre-transplant dialysis modality. We examined the short-term outcomes of living-donor kidney transplantation recipients after peritoneal dialysis (PD) and hemodialysis (HD), respectively.

Methods: 112 patients have undergone living-donor kidney transplantation procedures in our hospital between January 2001 and May 2014. We studied 40 patients, under 40 years of age, with dialysis durations of less than 5 years. We compared 13 PD patients with 27 HD patients and investigated the short-term outcomes.

Results: These two groups showed no significant differences as regards baseline characteristics including dialysis duration, body mass index, type of calcineurin inhibitor or ABO blood type incompatibility. The PD group was younger than the HD group as regards recipient age and donor age (22.5±8.0 years vs 29.1±6.0 years p=0.005) and, 50.7±8.2 years vs 56.9±7.1 years p=0.02), respectively. There were no differences in early post-transplant complications, such as wound infection, bleeding, thrombosis, delayed graft function, or acute rejection. The PD group was better than the HD group in the estimated glomerular filtration rate (eGFR) at discharge (74.3±27.3 ml/min/1.73 m2 vs 48.3±12.3 ml/min/1.73 m2 p=0.001) and eGFR 1 year post-transplantation (68.4±21.8 ml/min/1.73 m2 vs 45.6±13.2 ml/min/1.73 m2 p=0.003).

Conclusions: In the case of younger and less than 5 years of dialysis duration, PD and HD demonstrated no differences in early post-operative complications. PD is significantly better than HD as regards eGFR up to 1 year post-transplantation.

PUB653

Bright Field Microscopy of the Unstained Urine Sediment: A Basic Tool to Identify Decoy Cells due to Polyomavirus BK on Kidney Allograft Recipients During Routine Urinalysis José A. Poloni,1,2,3 Gabriel Godinho Pinto,1 Maria Giordani,1 Elizete Keitel,1,2 Alessandro C. Pasqualotto,1 Liane Rotta,2 Irmandade da Santa Casa de Misericórdia de Porto Alegre, Porto Alegre, RS, Brazil; 1Univ Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, RS, Brazil; 1Control Lab, Rio de Janeiro, RJ, Brazil.

Background: Polyomavirus BK (BKV) is an important pathogen that can be reactivated in kidney allograft recipients, potentially leading to BKV nephropathy (BKVN), an important cause of graft loss. Decoy cells (DC), urothelial cells or renal tubular epithelial cells modified by the proliferation of BKV, are one of the hallmarks of BKV reactivation and can be identified in the fresh urine sediment.

Methods: A cohort of 102 kidney transplant patients was followed during months 3 and 6 after the transplant procedure. Urine samples were obtained to detect the presence of DC in the fresh and unstained urine sediment under bright field microscopy (BFM) by two experienced analysts, as well as by BKV viruria by qPCR.

Results: DC were found in 15 patients.

Conclusions: Despite its limited sensitivity, fresh and unstained urine sediment analysis under BFM is a method that can be used to identify DC due to BKV reactivation. The analysis procedure is fast, cheap and painless. The information obtained during routine urinalysis can be used to lead to the early diagnosis of BKV reactivation helping on the clinical management of the patients. The ability of less trained observers to perform such diagnosis requires further validation.

PUB654

Intravenous Immunoglobulin in the Management of Pneumocystis Pneumonia: A Case Series Musab Elgaali, Muhammad Inman, Matthew Edey. Hull Royal Infirmary, Hull, United Kingdom.

Background: Pneumocystis pneumonia (PCP) is a well-recognized complication of renal transplantation. We present 2 cases of severe PCP treated successfully with intravenous immunoglobulin (IVIg), trimethoprim-sulfamethoxazole (TMP-SMX) and withdrawal of immunosuppression. Graft function was maintained despite a high baseline immunological risk.

Methods: Case A: A 32 year-old woman presented 2 years post-transplant with acute cellular rejection treated with steroids. 2 months later she was admitted with respiratory failure due to PCP. She required intubation and ultimately oscillatory ventilation. CMV DNA was detected at low levels in bronchoalveolar lavage (BAL) fluid. IVlg 30g on alternate days (10 doses) was added, in addition to withdrawal of immunosuppression and hydrocortisone replacement. She made a full recovery, with preservation of transplant function throughout. Case B: A 47 year-old woman received a second kidney transplant. Early post-transplant she developed acute antibody mediated rejection managed with plasma exchange then maintenance prednisolone, tacrolimus and mycophenolate. 9 months later she was admitted with respiratory failure and Pneumocystis jirovecii in BAL. She required invasive ventilation and inotropic support. She was treated with intravenous TMP-SMX, but her clinical condition deteriorated with acute kidney injury (AKI) requiring hemofiltration and escalating ventilator requirements. She received IVlg 25g/day for 5 days, replacement hydrocortisone and immunosuppression was withdrawn. Her AKI resolved and later she became ventilator-independent. Graft function was at baseline on discharge. Maintenance immunosuppression was recommenced.

Conclusions: It is understood that immunity against Pneumocystis jirovecii is both B- and T-cell mediated. Thus pooled immunoglobulin might be expected to have some anti-Pneumocystis activity. It is also recognized that IVlg has immunomodulatory properties. In both cases the administration of IVlg allowed withdrawal of immunosuppression apart from replacement steroid without graft rejection despite high immunological risk. Both patients survived life-threatening PCP. We suggest adjunctive therapy with IVlg be considered in severe PCP.

Ethical Issues Related to Kidney Donation/Transplantation: Perspective of Indian Doctors  
Richard S. Fernandes Almeida, 1 Nirmala Almeida, 2 Karen Almeida, 3 Alan F. Almeida, 4 *Lifesupporters Inst of Health Sciences; Human Development, Nirmala Niketan College of Home Science; Psychology, Mumbai Univ; Nephrology, PD Hinduja Hospital, Mumbai, India.

**Background:** Dearth of kidneys for transplantation has provoked the need to evaluate new policies and practices. This spurred the current study which addressed the perspective of doctors regarding emerging ethical issues pertaining to kidney donation/transplantation.

**Methods:** The sample consisted of 140 doctors from Mumbai (Age range: 21–80 years, M=38.1, SD=17.95, MAles=44.3%, Femaless=55.7%). A questionnaire, presenting ethical issues related to kidney donation/transplantation, in an agree/disagree format with supporting reasons was employed. The research design was exploratory; data was analyzed quantitatively and qualitatively.

**Results:**

Cardiovascular Risk Management of Renal Transplant Patients  
Joseph P. Almeida, Karen Leffondre, 1 INSERM U897, Bordeaux School of Public Health, Bordeaux, France; 2Nephrology and Transplantation, Bordeaux Univ Hospital, Bordeaux, France; 3Agence de la Biomédecine, Paris, France.

**Background:** Kidney transplantation (KT) is the treatment of choice for end-stage renal disease. In France, preemptive kidney transplantation (PKT) should be considered when glomerular filtration rate is under 20 ml/min/1.73m² but European reports on the efficacy of PKT are scarce. Our objective was to evaluate the impact of PKT on graft and patient survival.

**Methods:** We analyzed all first kidney-only transplants performed in adults in France between 2002 and 2012. A Cox multivariable model was used to study the impact of PKT on the hazard of graft failure defined as death, return to dialysis, or retransplant, whichever came first.

**Results:** Between 2002 and 2012, 22 288 patients received a first KT, including 3112 (14%) who had a PKT. Mean recipient age at KT was 50.5 ± 13.4 years, 61.9% were men. Median time of follow-up was 4.7 years. **First**, in living donor recipients for age and sex of recipients, primary kidney disease, donor type (living or deceased donor, expanded criteria donor or standard), HLA mismatches, cold ischemia time, center and year of transplantation, KT was associated with a 43% reduction in the hazard of graft failure when compared with patients who were treated by dialysis before KT (HR 0.57; 95% CI 0.51-0.64). **Second**, in deceased donor recipients (HR in living donor 0.34; 95% CI 0.19-0.55; HR in deceased donor 0.59; 95% CI 0.52-0.66). Among the subgroup of patients registered on the waiting list before the initiation of dialysis, PKT was associated with a 29% reduction in the hazard of graft failure (HR 0.71; 95% CI 0.58-0.87).

**Conclusions:** In France, PKT is associated with better graft survival than KT performed after the initiation of dialysis. Nephrologists should prepare patients to PKT rather than to dialysis.

Novel Potential Theranostic Targets in Individuals with Kidney Allograft Dysfunction  
Roberto Bassi, 1,2 Monika A. Nieczcza, 2 Stefania Bussolino, 2 Valentina De Zan, 2 Giuseppe Paolo Segoloni, 2 Antonio Secchi, 2 Amil K. Chandraker, 2 Luigi Biancone, 2 Paolo Fiorina. 3, 4 Nephrology, Boston Children’s Hospital, Boston, MA; 5Medicine, San Raffaele Scientiﬁc Inst, Milan, Italy; 6Internal Medicine, Sapienza University of Rome, Rome, Italy; 7Nephrology, PD Hinduja Hospital, Mumbai, India; 8Transplantation Research Center, Brigham and Women’s Hospital, Boston, MA; 9Internal Medicine, San Giovanni Battista Hospital, Turin, Italy; 10Univ of Torino.

**Background:** The lack of early diagnostic and therapeutic targets for chronic allograft dysfunction (CAD) is among the major determinants of poor long-term graft survival. Metabolic abnormalities in serum and kidney graft parenchyma may worsen allograft function, while alterations of urinary metabolites may be used as diagnostic biomarkers. **Objectives:** To explore this hypothesis, we recruited individuals with stable allograft function (n=20), chronic allograft dysfunction (n=20) and healthy controls (n=10), and analyzed their metabolic profile by ex vivo liquid/gas cromatography-mass spectrometry (LC/GS-MS) of serum and urine in vivo two dimensional correlated spectroscopy (2D COSY) of the kidney graft.

**Results:** LC/GS-MS revealed serum and urinary abnormalities of amino acids, biogenic amines and acylcarnitines in individuals with worse allograft function (T3) compared to conserved graft function (T1). Particularly, CAD was associated with reduction of serum choline, creatine and lipids results for the local transplant cohort of 69 patients. Significance of statins, antihypertensives and aspirin were audited against guidelines from the UK Renal Association (RA) and KDIGO. Cardiovascular risk was calculated using the Joint British Societies Guidelines (JBS2).

**Results:** Amongst hypertensive patients, 2/28 (7.1%) were not on antihypertensive therapy. Significant proteinuria (pAUC >50) was not common (6/68 = 8.8%), but of these only 2/6 (33.3%) were receiving an ACE inhibitor or ARB. Glycaemic control of diabetic patients was generally good, with 9/12 (75%) achieving target HbA1c of <48 mmol/mol. For non-diabetic patients, 11/56 (19.6%) were found to have a random glucose ≥7. Of these 4/11 (36.4%) had HbA1c checks, one of which confirmed new diabetes. The remaining 7 patients (63.6%) have not had a follow up HbA1c 20.69 (29.0%) of patients were calculated as >20% cardiovascular risk on the basis of comorbidities or using JBS2. Of these only 12/20 (60%) were on statin therapy. Almost all (67/68 = 85.7%) of patients with vascular disease were taking regular aspirin.

**Conclusions:** We have identified room for improvement in the management of hypertension and proteinuria. Rates of statin prescription suggest that we often underestimate cardiovascular risk clinically, however, further analysis will determine whether valid reasons exist to support decisions to omit statins or renin-angiotensin

Background: Compared with non-diabetic subjects, patients with type 2 diabetes and end-stage renal disease (ESRD) have seldom been selected for renal transplantation. The aim of this study is to compare patient and graft outcome in kidney transplant patients with diabetes mellitus.  

Methods: We retrospectively studied 358 patients who underwent kidney transplantation between 1979 and 2014, including 88 with diabetes ESRD (DM group) (type 1, n = 8; type 2, n = 80) and 270 without non-diabetic ESRD (NDM group). Mean follow-up was 92 (10.1-389) months.  

Results: Mean age was higher in the DM group (52.8 vs 44.6 years; P < .0001), and there was no significant difference in recipient gender, donor age or donor source. At the end of follow-up, there were no differences between the groups in terms of blood pressure (DBP: DM 139.3±16.7 vs NDM 138.3±17.6 mmHg; P = 0.83; SBP: DM 83.5±17.8 vs NDM 82.1±18.1 mmHg; P = 0.9). Mean creatinine clearance was 66±24 vs 71±24 ml/min/1.73 m², respectively, (P = 0.9). In total, 26 patients had acute transplant rejections [8 patients with diabetes mellitus].  

Conclusions: Renal transplantation in diabetic ESRD patients yields good results in terms of patient survival and complications, suggesting that renal transplantation can be performed in these patients and should become a more established treatment option.

Impact of Pre-Transplant Peritoneal Dialysis Compared with Hemodialysis on the Incidence of Delayed Graft Function in Kidney Transplant Recipients with Lupus

Background: Delayed graft function (DGF) increases the risk of allograft failure in recipients of kidney transplants.  

Methods: In this study, we assessed the impact of pre-transplant peritoneal dialysis (PD) compared with hemodialysis (HD) on the risk of DGF in patients with lupus using logistic regression models.  

Results: Three-hundred-fifty-three of 2513 (14 %) recipients transplanted between 3/22/1994 and 9/27/2006 with complete records in the United Network for Organ Sharing files had DGF. The incidence of DGF was lower in recipients who used HD (68.6±13.1%) compared with HD (285/1900 = 15%) prior to transplantation (P = 0.013). After adjusting for donor and recipient age, gender and race-ethnicity, type of donor, recipient education and insurance, time of dialysis prior to transplantation, panel reactive antibodies (PRA), human leukocyte antigen (HLA) mismatch, and ABO blood type compatibility, the lower risk for DGF associated with the use of PD compared with HD remained significant ( Odds ratio 0.70 [95% confidence interval 0.53-0.94]; P = 0.015). Donor age (1.01 [1.00-1.02] per 1 year), deceased donor transplantation (1.64 [2.59-5.12] living donor as reference), HLA mismatch (1.08 [1.01-1.15] per 1 antigen mismatch), and PRA (1.01 [1.00-1.01] per 1%) were also independently associated with DGF.  

Conclusions: In lupus recipients of kidney transplants, the use of PD compared with HD is associated with lower risk of DGF after adjusting for important predictors.

**Successful Treatment of BK Nephropathy with Tacrolimus and mTOR Inhibitors**

*Nephrology, Hospital Univ 12 de Octubre, Madrid, Spain.*

**Background:** BK nephropathy (BKN) is a relevant cause of graft dysfunction in kidney transplantation. mTOR inhibitors (mTORi) have been suggested as the best immunosuppression in BKN. However, Tacrolimus-free therapy could increase risk of rejection. Since 2009 in patients with BKN we conducted a protocol discontinuing Mycophenolate and decreasing Tacrolimus (TAC) dose in association with mTORi, both with target levels of 5 ng/mL.

**Methods:** From 2007 to 2013 we diagnosed 22 BKN. Patients diagnosed since 2009 (n=14, group 1) were treated beginning mTORi and decreasing TAC dose. The others 8 patients suffered significant reduction of immunosuppression (group 2). We analyze renal function, plasma quantitative BK PCR, antiHLA antibodies, reactions and dialysis or death at final follow-up.

**Results:** 22 patients were identified. The BKN was diagnosed at 7th month after transplantation (range 2-55). The medium duration of follow-up was 53 months (6-85). Baseline characteristics and evolution are listed in table 1.

Although group 1 had a greater immunologic risk and a higher plasma BK viral load at diagnosis, the renal function during follow-up was more favorable than patients from group 2. No rejection episodes were diagnosis in group 1. Only one patient in each group started chronic dialysis at the end of the follow-up (52 and 85 months after BKN diagnosis).

**Conclusions:** An immunosuppression regimen based in TAC and mTORi is an effective and safety treatment in patients with BKN. This treatment reduces viral load and increases graft survival without increases the rejection risk.

**A Rare Case of Guillain-Barré Syndrome Associated with Cytomegalovirus Disease in a Renal Transplant Patient**

Jessica Bian, George P. Bayliss.

*Medicine, Rhode Island Hospital, Providence, RI.*

**Background:** While cytomegalovirus (CMV) infection is associated with Guillain-Barré syndrome (GBS) in the general population, there are few reports of GBS associated with CMV disease in the renal transplant patients. We describe the case of one renal transplant patient who developed GBS after treatment for documented CMV disease.

**Methods:** The patient is a 62-year-old woman with ESRD from polycystic kidney disease status post deceased donor renal transplant (CMV donor positive/recipientseronegative) on tacrolimus and prednisone. She completed 6 months of CMV prophylaxis with valgancyclovir. Fourteen days after stopping valgancyclovir, she presented with fevers, myalgias, and headache. Tacrolimus level was 6.6 ng/mL on admission. She was diagnosed with CMV disease (serology CMV PCR 2200 copies; CSF CMV PCR undetectable) and started on treatment-dose valgancyclovir. Ten days later, she returned with numbness of her hands and feet. CSF studies were notable for albuminocytologic dissociation. MRI brain and spine was normal. Electromyography showed diffuse sensory motor polyneuropathy consistent with GBS. She developed ascending motor weakness, sensory loss, and areflexia without progression to respiratory compromise, improving with IVIG therapy. She was discharged to rehabilitation.

**Results:** She returned 7 days later with compartment syndrome of her right arm due to deep venous thrombosis of her right subclavian, axillary, and brachial veins with associated hematoma requiring emergent fasciotomy and hematoma evacuation. This was attributed to recent IVIG therapy, as thromboses may occur even in the absence of other risk factors (US boxed warning). She was bridged to warfarin prior to discharge. Of note, she maintained excellent alloantibody function throughout this complicated course.

**Conclusions:** This vignette details a case of CMV-associated GBS after renal transplantation. The case is notable for the development of CMV disease shortly after cessation of valgancyclovir prophylaxis in a CMV donor positive/recipientseronegative renal transplant despite only being on only being on a two-drug immunosuppressive regimen. This may support a longer course of CMV prophylaxis in donor positive/recipientseronegative transplants.

Mammalian Target of Rapamycin Inhibitors Withdrawal in Kidney Transplant Recipients: Risk Factors and Related Transplant Outcomes

Lee-Mooy Lim,1 Mei-Chuan Kuo,1,2 Hung-Tien Kuo,1,2 1Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan; 2Faculty of Renal Care, College of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan.

Background: With its antiproliferative and antineoplastic properties, Mammalian Target of Rapamycin Inhibitors (MTORI) potentially have important long-term therapeutic consideration in kidney transplantation. Treatment cessation frequently occurs following its unique adverse effects. The objective of this study was to investigate the risk factors for MTORI withdrawal and its impacts on transplant outcomes.

Methods: This retrospective observational study consisted of kidney transplant recipients followed up from January 1999 till May 2015. We examined the risk factor for MTORI withdrawal using multivariate logistic regression analysis. The impacts of MTORI withdrawal on transplant outcomes were analyzed using multivariate Cox regression and logistic regression. P<0.05 was considered as statistically significant.

Results: A total of 111 kidney transplant recipients who received MTORI treatments were included, with 46 patients withdrew (41.0%). The risk factors for MTORI withdrawal included initial proteinuria (adjusted OR=4.61, P<0.007), higher initial serum creatinine (per 1 mg/dl increment, adjusted OR=2.73, P=0.035), and glomerulonephritis as primary renal disease (adjusted OR=5.00, P=0.035). MTORI withdrawal was associated with an increased risk of graft failure (adjusted HR=3.79, P=0.027), but not with patient survival (adjusted HR=0.61, P=0.595).

Conclusions: MTORI withdrawal is a strong risk factor for renal graft failure. Proteinuria, poor initial graft function and primary renal disease of glomerulonephritis are predictors for MTORI withdrawal. Earlier identification of risk factors may assist physician to decide the best candidate for MTORI conversion in order to optimize transplantation outcomes.

Impact of Donor Age on Longterm Outcomes in Living Donor Kidney Transplants: A Propensity Score Matched Analysis Using Multicenter Transplant Recipients

Dong-Wan Chae,1 Yong-Soo Kim,2 Bum soon Choi.1 1Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary’s Hospital, The Catholic Univ of Korea, Seoul, Republic of Korea.

Background: The proportion of donor over 50 years was 21.2% (N=553). The mean age of donors was 45.9±4.3 years old. Despite of difference of donor age, mean recipient age was similar between the groups. Elderly donors were more likely to donate to unrelated recipients. The proportions of recipients with diabetes mellitus (22.8%), serum creatinine and BMI of donor were significantly higher in the elderly donor group than in the young donor-age group. In elderly donor group, recipients’ patient survival was worse than younger age group before PSM (p=0.014). After PSM, donor age did not affect the recipients’ survival (p=0.305) and allograft survival (p=0.077), however, BPAR was than younger age group before PSM (p=0.014). After PSM, donor age did not affect the recipients’ patient survival (p=0.305) and allograft survival (p=0.077), however, BPAR was than younger age group before PSM (p=0.014). After PSM, donor age did not affect the recipients’ patient survival (p=0.305) and allograft survival (p=0.077), however, BPAR was than younger age group before PSM (p=0.014). After PSM, donor age did not affect the recipients’ patient survival (p=0.305) and allograft survival (p=0.077), however, BPAR was than younger age group before PSM (p=0.014).

Conclusions: MTORI withdrawal is a strong risk factor for renal graft failure. Proteinuria, poor initial graft function and primary renal disease of glomerulonephritis are predictors for MTORI withdrawal. Earlier identification of risk factors may assist physician to decide the best candidate for MTORI conversion in order to optimize transplantation outcomes.

Conclusions: MTORI withdrawal is a strong risk factor for renal graft failure. Proteinuria, poor initial graft function and primary renal disease of glomerulonephritis are predictors for MTORI withdrawal. Earlier identification of risk factors may assist physician to decide the best candidate for MTORI conversion in order to optimize transplantation outcomes.
Results: 10 CV events occurred in the overall group, and 7 events in the post KT balance group. The most affected CV events of this group were diabetes, high body mass index (BMI) and high baPWV. Overall arterial stiffness measured by baPWV after KT showed significant improvement (1417.5 ± 234.5 cm/s) compared to those of before KT (1503.5 ± 252.2 cm/s) (p=0.05 vs after KT).55 out of 79 patients (69.6%) showed improvement of baPWV after KT, but 24 patients did not. Between two groups, improvement group showed higher pre-transplant baPWV than no-improvement group (1561.0 ± 263.9 vs. 1371.6 ± 177.1), and multivariate analysis revealed that gender and BMI, degree of decrement of calcium level were an independent risk factor of change of baPWV.

Conclusions: We could expect CV event risk in KT recipients by diabetes, BMI and baPWV, and these were very strong prediction marker of CV event. Arterial stiffness in ESRD patients improves after transplantation, and lower BMI, the amount of calcium decreased, gender affected the improvement of baPWV.

PUB675
Left Ventricular Global Longitudinal Strain as Early Detection of Subclinical Myocardial Dysfunction in Renal Transplant Recipients
Secundino Cagigalan,Jose Lomban,Ana Maria Sanjurjo Amado,DiegoCoronel,SheilaCasas,JuanLatorre,Milagros Lopez hernandez,JesusCalvino.
Nephrology, Hospital Da Costa, Barela, Lago, Spain; Nephrology, Hospital Jesus Augusti, Lago, Spain; Cardiology, Hospital Da Costa, Barela, Lugo, Spain.
Background: Echocardiographic global longitudinal strain (GLS) is recognized as a technique to detect subtle changes in left ventricular function. As in CKD pts, kidney transplant recipients (TXKR) has an increased mortality risk by CV events. Early detection of CV risk is the utmost importance in the TXKR outcomes. The aim of this cross section study is to assess the grade of myocardial dysfunction in TXKR without previous CV events & normal left ventricular ejection fraction (LVEF).
Methods: 37 TXKR following >1 year were included. 44.4% F, 25.4% DM, age 55.4(±12.0) y.o, GFR-EPI 51.93±32.2 cm2/ml/min, No previous CV events & LVEF>55%. All of them were on stable treatment with ACE/ARB, CCBH, diuretics added to immunosuppressive drugs (TAC, CSA). Echocardiography 2D Vivid 9 (GE Vimed Ultrasound ,Horton, Norway), was performed;GLS;LAVI(ml/bsa),E/E’,A/LVEF following recommendations of American Society of Echocardiography. Body composition analysis were performed by BIVA and serum biomarkers of inflammation,anaemia,mineral bone disease, renal function (GFR-EPI) and CV risk markers.Normal GLS (-20%)LAVI 24 ml/m2 were considered as published for general population Rev Esp Cardiologia 2014;67:651-8.
Results: Mean GLS was -18.6 ± 3.78%, LVEF 70.8 ± 8.7%LAVI 30.16±20.4 ml/GFR correlated negatively with GLS (r=-0.338, P=0.016) and LAVI (r = 0.372, p = 0.14). GLS progression is a sensitive as GFR decline (P adjusted 0.025) E’ 13.06 ± 0.68; E/A 0.93 ± 0.28. Multivariate analysis was significant the relationship between GLS with ACR (P < -1.51, p = 0.43) E Ejection index (P< -0.377; p=0.14)LAVI correlated with age (b=0.467 p=0.004), No acid load (b=0.345; p=0.23) and AEGs (b=0.314; p=0.35). No other correlations were met. Conclusions: 66% TXKR showed GLS< -20%, and 41.6 % LAVI > 24 ml/m2.GLS & LAVI echocardiography derived are two valuable measures to assess early subclinical myocardial damage in TXKD. GLS appears more sensitive predictor than LVEF.Studies on TXKD pts are required.

PUB676
Seronegative Invasive Gas tro-Intestinal Cytomegalovirus Disease in Renal Allograft Recipients – A Diagnostic Dilemma! Tissue PCR the Saviour! Nirmal Kaur, Dharndra Bhaduria, Narayana Prasad, Anir Gupta, Raj K. Shankar, Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, UP, India.
Background: CMV as opportunistic infection affecting the gastrointestinal tract is the most common cause for tissue invasive CMV disease occurring in 10-30% of organ transplant recipients. Gastrointestinal CMV disease can be diagnosed in presence of clinical suspicion along with histopathological findings (CMV inclusions) and presence of mucosal lesion(s) on endoscopic examination with collaborative evidences via molecular technique.
Methods: Few cases of CMV infection affecting the gastrointestinal tract show no evidences of dissemination despite use of highly sensitive molecular techniques.
Results: We encountered 6 cases where in despite strong clinical suspicion of Gastrointestinal CMV disease there were seronegative and endoscopic negative evidences for CMV ,blind tissue biopsy yielded positive results for CMV disease with excellent improvement with antiviral therapy.
Conclusions: Blind biopsy specimen for tissue PCR could serve as an invaluable companion diagnostic tool for strong clinical symptomatology for GL-CMV disease in absence of viremia ,normal endoscopy and histopathology ,so that the early therapeutic interventions could help in excellent patient and graft survival.

PUB677
Allograft Outcome After Desensitization with IV Ig: A Single Center Experience

Background: The presence of antibodies to donor human leukocyte antigens (HLA) is a significant barrier to transplantation. High dose intravenous Ig (IVIG) is widely used for desensitization. There is no general consensus on the best approach for desensitization, and there is no data on efficacy of IV Ig are unknown.
Methods: We reviewed kidney transplants done from Jan, 2010 to Dec, 2014 at Tufts. Sensitization was defined as PRA>20% and/or presence of donor specific antibody (DSA). Patients who were desensitized with IV Ig were identified as cases; those without desensitization served as controls. No attempt was made to desensitize patients with a long deceased donor kidneys. Baseline characteristics and follow up data were collected at months 3, 6, 12 and 24. A sensitivity analysis was done for patients who received a living donor kidney.
Results: There were 19 patients in the desensitized group and 37 patients in the control group. Mean age at transplant in two groups was 47±12 and 49±12 respectively. In the desensitized group, there were more patients with prior transplant (37% vs 22%), receipt of living donor (95% vs 54%) and positive DSA (89% vs 22%). One patient developed severe side effects from IV Ig, requiring discontinuation. Leukopenia and BK viremia were
seen more in non-desensitized patients at 3 months, but significance was not sustained after 3 months (Table). The leukopenia effect was not significant when adjusted for age. There was no difference in eGFR in either group, however mean eGFR was higher in those desensitized. Incidence of rejection was very low in both groups (5% vs 8%). When living donor recipients from both groups were compared, the eGFR and leukopenia effect was similar in both groups, and there was no significant difference in BK Viremia.

### Conclusions:
Desensitization with IVlg appears to be safe and effective. The lower incidence of leukopenia in desensitized group can be explained by greater use of steroids.

**Results of Chinese Renal Transplant Recipients with Post-Transplantation Malignancies**

**LiHui Qu, Hong Jiang, Jianghua Chen. The Kidney Disease Center, The First Affiliated Hospital, Medical College, Zhejiang Univ, Hangzhou, Zhejiang, China.**

**Background:** Malignancies are a severe complication of immunosuppressive therapy among renal transplant recipients, representing an important cause of long-term morbidity and mortality.

**Methods:** A retrospective study of 2700 recipients who underwent renal transplantation between July 1977 and July 2013 was carried out. 51 patients developed the following malignancies at a mean of 55.2 months (range = 1-207) after kidney transplantation. According to the regimen of immunosuppressive agents, all the recipients occurred malignancies were divided into azathioprine group (Aza group, n=21) and mycophenolate mofetil group (MMF group, n=30). The recipient age, gender, interval from renal transplantation to tumor development, long term survival of patient and graft and the ratio of converting to rapamycin of patients were made a comparison in detail between two groups.

**Results:** 29 patients survived without a recurrence including 28 with graft function (Survival group, n=29), and 22 patients died of malignancies including 21 with graft function (Death group, n=22). In the survival group, only one patient lost the graft after 26 months after immunosuppressant adjustment due to chronic rejection. Renal graft function remained stable in all other patients from diagnosis throughout follow-up. Moreover, 10 patients in the survival group were switched from calcineurin inhibitor-based immunosuppression to rapamycin after the diagnoses of malignancy, otherwise no patient in death group switched to rapamycin. At a mean follow-up of 34.0 months (range = 4-74), all the 10 patients are cancer-free and survived with functional graft. The incidence of death was similar in the Aza group and MMF group.

**Conclusions:** Our results demonstrate that the incidence of malignancy in renal allograft recipients is much higher than normal population, closely related to the long term use of immunosuppressant. Treating cancer thoroughly and maintaining the function of the transplanted kidney can decrease the risk of death with functional graft. Rapamycin-based immunosuppression blocks the recurrence of nonmetastatic tumors.

**Basiliximab Induction Therapy, Graft and Patient Survival**

**Sergio Santiago Pedroza-Orozco, Paloma Arleth Zavalza-Camberos, Benjamin Gomez-Navarro. Nephrology and Transplantation, Inst Mexicano del Seguro Social, CMNO, Guadalajara, Jalisco, Mexico.**

**Background:** Basiliximab is widely used in clinical practice for induction therapy of renal transplant recipients, expecting to reduce the incidence of acute rejection and improved graft function without increasing adverse events. We evaluate the impact of induction therapy using Basiliximab on relevant clinical outcomes: graft and patient survival, incidence of acute rejection (AR) and incidence of infectious or malignancy complications.

**Methods:** This retrospective study included all renal allograft recipients who were transplanted between January 2010 and April 2014 and who received Basiliximab as induction therapy. We collected the baseline characteristic of recipients, type of donor, donor’s age, HLA matches and immunosuppression at the time of transplantation. The clinical outcomes were evaluated at the first year of transplantation and include: AR incidence, infectious or malignancy complications, serum creatinine and estimated glomerular filtration rate (eGFR) using the 4-variable MDRD formula, as well as graft and recipient survivals.

**Results:** The demographic characteristics of recipients and donors are in Table 1. Among 662 renal transplant recipients including in this study, only 10.6% (n=70) experienced AR during the first year follow up. The incidence of infectious complications in the first year after transplantation was 32.3%, mostly urinary tract infection (82%). No episode of malignancy was reported. Graft and patient survival rates were 96.9% and 98.5% respectively.

**Conclusions:** In our hospital, 1 year mortality postkidney transplantation is low, but there are many individual patient factors that contribute to the risk of mortality increases significantly in them and there we could intervene.

**PUB681**

**Granzyme B Level and Acute Kidney Allograft Rejection: Impact on One Year Survival in Mexican Population**

**Perla Edith Simancas Ruiz,1 Caridad Aurea Leal,2 Benjamin Gomez-Navarro.1 1Nephrology and Transplant, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico; 2Surgical Research, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.**

**Background:** Exposure to insufficient levels or discontinuation of immunosuppressants often increases the risk of rejection. Creatinine is the most useful test to monitor graft function. However, it is a poor predictor of rejection and often raises only after significant damages occurred to the graft. The Granzyme B is an enzyme that can mark acute rejection. Granzyme B has been tested as a marker of acute rejection, with high specificity and sensitivity in different types of sample and has also enabled the identification of subclinical
rejection. The elevation of both the mRNA and protein has been associated with a worse prognosis. Exploring the association between serum levels of Granzyme B and acute rejection after one year post-transplant.

Methods: Kidney recipients transplanted between January 2008 and March 2009. Donors (n=58) and healthy subjects (n=6) were also included. The relation of granzyme B levels determined by ELISA with graft function and rejection was studied.

| Granzyme level in patients (n = 43) was 12.5 pg/ml while the reference group (n = 6) was 1.5 pg/ml (p<0.001). Comparison between patients with rejection (n = 14) and non-rejection (n = 20) was not statistically significant, nor the development of interstitial fibrosis year. The correlation between creatinine, GFT and granzyme level showed a trend to significance (n = 66, r = 0.30, p = 0.06).

Conclusions: The level of granzyme B was not associated with one year post-transplant rejection. However immune system activation is suggested by the higher level of granzyme in patients vs control group. Continuous analysis of patients.

PUB682
Epidemiological Analysis of Post Transplant Glomerulonephritis Prathak Das, Santosh Kumar, Rohit Rungta. Nephrology and Transplantation, Rabindranath Tagore International Inst of Cardiac Sciences, Kolkata, West Bengal, India.

Background: Post-transplant glomerulonephritis is an important cause of graft dysfunction and consequent graft loss. Aim of the study is to identify the incidence and outcome of glomerulonephritis in post-transplant patients.

Methods: We retrospectively evaluated all the patients who underwent renal allograft biopsy between January 2010 to January 2014, for graft dysfunction, proteinuria or active urinary sediments. All protocol biopsies were excluded from the study. Graft biopsies were evaluated by light microscopy and indirect immunofluorescence study. Out of 285 graft biopsies 242 biopsies were taken into study. Biopsies showing evidences of glomerulonephritis were further evaluated for incidence of individual types of glomerulonephritisand their outcome at the end of one year post diagnosis.

Results: Based on biopsy findings among 242 renal allograft biopsies taken in study 42(17.35%) had post-transplant glomerulonephritis. Further the incidence of individual glomerulonephritis were 14(33.3%) for focal segmental glomerulosclerosis, 13(31%) for IgA nephropathy, 8(19%) for mebranoproliferative glomerulonephritis, 4(9.6%) for pauci-immune crescentic GN, 2(4.8%) for anti-glomerular basement membrane disease and 2(2.3%) for membranous nephropathy. On follow up for one year 30(71.4%) patients lost their graft and became dialysis dependent irrespective of treatment. When compared to this outcome with other causes of graft dysfunction (rejection or infection) , results are inferior in terms of graft and patient loss.

Conclusions: We conclude that post-transplant glomerulonephritis is strongly associated with poor kidney allograft survival. Therefore, optimal management of recurrent or de novo glomerulonephritis should be the critical focus of post-transplant care.

PUB683
Impact of Hemoglobin Concentration on Mortality After Renal Transplantation Vitoria C. Vilela,1 Marcos A. Meniconi,1 J. Medina-Pestana,1 Miguel Cendoroglo Neto,1,2 Miguel A Goes,1,2 Nephrology Div, Federal Univ of Sao Paulo, Sao Paulo, Brazil; 1Nephrology Div, Hospital Israelita Albert Einstein, Sao Paulo, Brazil.

Background: Kidney transplant recipients have chronic anemia, irrespective of the time from transplantation. Objective: To assess the impact of hemoglobin concentration on mortality after renal transplantation.

Methods: A total of 233 patients who underwent renal transplantation at one center (Hospital do Rim) were prospectively analyzed. Follow-up time was 6 years, from January 2008 through December 2014. Data on demographics, ESRD etiology, pre-transplant dialysis, transplant characteristics, and immunosuppression regimen. Two-sample t test were used to compare differences between two groups (mortality versus non-mortality groups) and X² to analyze categorical variables. Binary logistic regression was used to determine the impact of factors on outcome mortality.

Results: The main causes of ESRD were diabetes (35%) and hypertension (20%). Transplants from living donors occurred in 59%. During the entire follow-up period, there were 24 (10%) deaths within 3±1 yr after renal transplantation. 7 (29%) from cardiovascular disease and 17 (71%) died from infection. We observed that mortality group were older (p <0.01) and longer time on dialysis (4±2.5, 2.5±2.0 yr; p=0.006). Hemoglobin (Hb) concentration was lower in mortality (10.7 ±2.3) than non-mortality (12.0±2.4; p<0.01) group. Patients who used mycophenolate had lower mortality (p = 0.04). There is no correlation between Age and Hb (r=0.02; p=0.8). Age (p = 0.01) and Hb concentration (p <0.02) were independent predictors of mortality.

Conclusions: This study shows that a lower Hb concentration is an independent predictor of mortality in renal transplant patients.

PUB684
Prediction of Recipients Survival in Deceased Donor Kidney Transplant Using Korean Network for Organ Sharing Database Kyung Don Yoo,1 Junhyung Noh,1 Hajeong Lee,1 Dong Ki Kim,1 Chun Soo Lim,1 Young hoon Kim,1 Yon Su Kim,1 Gunhee Kim,1 Jung Pyo Lee.1 1Seoul National Univ College of Medicine; 2Seoul National Univ College of Engineering; 3Univ of Ulsan.

Background: The Korean Network for Organ Sharing (KONOS) was founded in 2000 for organ allocation in Korea. It has been allows medical doctors and researchers to fully access the national population-based raw data about KT recipients. We propose a novel prediction approach of recipient survival based on machine learning techniques using KONOS data.

Methods: Our dataset is collected from 2000 to 2014 by the KONOS. We design a novel prediction model that uses all of the follow-up recipients' data including censored ones, on which estimated death risks are weighted accordingly. We compare this approach with the baseline model that uses only uncensored data by the CART (Classification And Regression Trees) modeling.

Results: We analyze 5,430 recipients’ records with more than 15 attributes, among which we take the 15 independent attributes to learn our models. The proposed weighted algorithm leads a better performance when predicting survival rates of transplant recipients within 6 years, but fails to show any significant difference from the baseline for those more than 7 years after transplantation. Using the decision-tree models, we find that the inotropic agent usage of donor management is the most important predictor, which estimates in 51.3% of 10-year mortality. In the age ≥51.5 group, non-diabetes recipients, waiting period < 4years, and donor age < 23.5 years show significant associations with better 10YRS. The results are consistent with our hypothesis that poor donor status, recipients’ longer waiting time and advanced age are associated with poor prognosis.

Conclusions: In this study, we show that the proposed machine learning based models with weights of estimated-death risks can present more accurate and flexible than baseline models for predicting in long-term survival rates of kidney transplant recipients.

PUB685
Perforin Expression in Renal Allograft Biopsies Michele T. Rooney,1 Ping L. Zhang,2 Dilip Samarapungavan,3 Randolph Alexander Hennigar.1 1Incyte Diagnostics, Spokane, WA; 2Anatomic Pathology, William Beaumont Hospitals, Royal Oak, MI; 3Nephrology, William Beaumont Hospitals, Royal Oak, MI; 4Nephropathology Associates, Little Rock, AR.

Background: Perforin is a cytotoxic protein in effector lymphocytes that facilitates targeted cell killing and it has an established role in allograft rejection. A diagnostic value has not been delineated. We examined perforin expression in renal transplant biopsies by immunohistochemistry (IHC) and found that positive lymphocytes are confined largely to the microvasculature in cases of active cellular rejection (ACR). The goal of this study is to investigate whether perforin IHC is a useful metric in identifying and classifying acute rejection in renal transplant biopsies.

Methods: Renal transplant biopsies accessioned over a one-year period were selected to include cases showing no acute rejection, acute tubular injury, BK nephritis, ACR types 1 and 2, and C4d+ antibody-mediated rejection (AMR), according to the 2013 revised Banff Classification. IHC using a mouse monoclonal anti-perforin antibody was performed on each case. Perforin positive cells/10 high power (400X) fields (hpf) were counted from slides identified by number only.

Results: Most rejection-negative cases had <10 perforin-positive cells/hpf. Biopsies showing type 1A ACR, excluding one outlier, did not exhibit a significant increase in perforin-positive cells relative to rejection-negative cases. In contrast, cases of type 1B and 2 ACR, and C4d+ AMR displayed significantly increased perforin-positive cells (p = 0.0001) with most showing > 40/10 hpf. Cases of AMR contained the highest number of perforin-positive cells (p = 0.0352). Cases of BK nephritis varied widely from < 10 to > 500/10 hpf. 2 of 3 cases with > 50 had a recent history of ACR developing BK infection upon increasing immunosuppression, raising the possibility of coexisting BK and rejection.

Conclusions: Further study is needed, but our data suggests that increased numbers of perforin-positive lymphocytes correlate with more aggressive forms of rejection, and that perform IHC may be a useful ancillary test for acute allograft rejection of type 1B or higher.
due to TS were identified. Incidence rates and standardized incidence ratios (SIR) were computed using Poisson distribution and standardized using 2001-2002 as reference. Hazards ratios adjusting for age, sex, race and ethnicity (AHR) were calculated for outcomes.

**Results:** In 2001-2002, the overall incidence rate of ESRD due to TS was 1 per 10 million person years (PMPY) and the SIR remained largely unchanged over the observation period. Those with ESRD due to TS were more likely to be <40 years (23.2% vs. 9.2%), white ethnicity (81.5% vs. 65.5%), and lack diabetes (81.2% vs. 48.1%). Compared to those with ESRD due to other causes, odds ratios adjusted for age, sex, race and ethnicity (AOR) were highest for females (1.83) and those with eGFR > 15ml/min/1.73m2. Factors associated with AOR included age 40-64 years (0.29), age ≥ 65 years (0.25), and black race (0.33). Over the study period, 53.7% of TS patients died, 27.3% were listed and 10.6% were transplanted. The AHR for outcomes demonstrated those <40 years of age were more likely to be listed for renal transplant, receive renal transplant and survive.

**Conclusions:** The incidence of ESRD due to TS remained largely unchanged from 2001 through 2010. Our results indicated gender and racial differences in the odds of ESRD due to TS.

**PUB689**

The Impact of Hepatitis C Virus Infection on the Clinical Course, Short-Term and Long-Term Outcome in Renal Transplant Recipients – A Retrospective Study

Pratik Das, Rohit Rungta, Santosh Kumar. Nephrology and Transplantation, Rabindranath Tagore International Inst of Cardiac Sciences, Kolkata, West Bengal, India.

**Background:** Hepatitis C infection is common in patients of end stage renal disease with increased morbidity and mortality post-transplant. The aim of the study was to find out the impact of HCV infection on graft and patient outcome and compare it with the non-HCV infected post-transplant recipients.

**Methods:** We retrospectively analysed patient and graft survival of HCV infected (after virological remission) post renal transplant patients from 2008 to 2014 with a median follow up of 24 months and compared them with our HCV negative statistically matched cohort.

**Results:** Outcome analysis was done at 6, 12, 18 and 24 months in terms of liver dysfunction, acute rejections, infections, hospitalization and death. Results were further tabulated as shown.

**Conclusions:** HCV infected end stage renal disease patients may undergo renal transplantation safely after virological remission and outcome is not different from other renal transplant recipients.

**PUB690**

Patient and Graft Survival in Pediatric Kidney Transplantation: A Single-Center Experience According to Transplant Era

Juan Carlos Lopez; Gerardo Nyman; Liliana Briones. 1Nephrology Unit, Hospital JP Garrahan, Buenos Aires, CABA, Argentina; 2Urology Unit, Hospital JP Garrahan, Buenos Aires, CABA, Argentina.

**Background:** Improvements in the management of kidney transplantation has improved in the last 20 years. However the long term results in terms of graft survival and morbidity still require more research.

**Methods:** We evaluated 744 pediatric renal transplants (RTX), 551 with deceased donor (DD) and 222 with living-related donor (LRD), between 1988-2015. We divided this time in 2 periods: 1988-2000 and 2001-2015. Patient and graft survival were calculated for each period for LD and DD recipient. We analyzed causes of mortality, causes of graft failure and risk factors for graft loss. Mean age at RTX was 1.6y (r: 0.5-19.5). Median time of follow-up was 54.5 months (IQR: 22.4-90.1) months.

**Results:** Patient and graft survival for DD have significantly increased in the recent era (p=0.0002; p=0.0013 resp). Chronic rejection was the first cause of graft loss in both era (61.6% vs 52.1%), Vascular thrombosis decreased (14.9% vs 5.5%; p < 0.001), and also Death with a Functioning Graft (15.8% vs 8.3%; p = 0.001). Acute rejection during the first 30 days post RTX + relapse of the original disease increased (0% vs 9.7%). First cause of death in both eras was bacterial infection (77% vs 66%). No death due to PTD were seen in 2001-2015. Independent Risk factors for graft loss for DD recipients were: FSGS

Results were found not to be statistically different from non HCV infected renal allograft recipients.

**Conclusions:** HCV infected end stage renal disease patients may undergo renal transplantation safely after virological remission and outcome is not different from other renal transplant recipients.
as cause of ESRD (HR: 3.1; CI 95%: 2.4-3.8), DGF (HR: 2.8; CI 95%: 2.4) and Receiving no induction therapy (HR: 2.1; CI 95%: 3.3-5.3). For donor recipients: DGF (HR: 5.2; CI 2.9-9.3) and Age at RTX = 12y (HR: 2.2; CI95%: 1.2-3.9).

Conclusions: Patient and graft survival has significantly improved for DD in the recent era. Chronic rejection remains a major cause of graft failure. No death from malignancy were observed in the recent era.

### PUB691
Impact of Rituximab Induction on Short Term Outcome of Kidney Transplant Recipients

**Background:** Acute graft rejection remains a major problem in kidney transplant (KT) recipients. Induction with Thymoglobulin or Basiliximab is a KDIGO recommendation to minimize the risk of acute rejection. However, these induction agents do not eliminate the risk of antibody mediated rejection. Recent studies of ABO incompatible (ABO) transplant using Rituximab, in addition to standard induction and maintenance immunosuppression (IS) have shown better outcome than ABO compatible (Kohbi N, Tanabe K J Am Transplant Soc 2015; 15: 125-130). Transplantation. The aim of this study was to assess the outcomes and safety of Rituximab induction in addition to single dose Thymoglobulin induction in living donor (LD) KT patients.

The study included 53 adult LD KT recipients transplanted between 3/1/14 and 2/28/15 and followed for at least 3 months after KT. Of these, 39 were (ABOc) transplants and 14 were (ABO0) transplants. Rituximab 200 mg was given within a week before transplant. ABOc recipients received an additional 200 mg Rituximab on the day of transplant. Thymoglobulin 1 mg/kg was used only on the day of transplant. Maintenance immunosuppression included Tacrolimus, MMF and tapering doses of prednisolone in all patients. All recipients received valganciclovir and cotrimoxazole prophylaxis. The short-term outcomes of these patients (Ritusx group) was compared to that of 53 historic controls (control group) who received only thymoglobulin 1 mg/kg on the day of KT.

**Results:** There was no difference in characteristics (age, sex, etiology of CKD, donor characteristics, HLA mismatch) of patients in the 2 groups. Six patients in the Ritux group developed acute rejection (5, cellular and 1 antibody mediated). Six patients in the control group developed acute rejection (2 cellular and 4 antibody mediated). The patient and graft survival at 3 months was 100% in Ritux group. The patient survival was 100% in control group. One graft was lost from antibody mediated rejection in control group. Infections within 3 months after KT were similar in both groups.

**Conclusions:** Rituximab induction is safe in KT. It reduces the risk of antibody mediated rejection without increasing infectious complications in the early period after KT.

### PUB692
Epo Use in Pregnant Renopancreas Transplant Patients

**Background:** Renopancreas transplant improves life and reproductive function. Abnormalities in this population. Prenatal counselling addresses potential fetal complications; as well as worsening anaemia, hypertension, pre-eclampsia, proteinuria, gestational diabetes, acute rejection or graft loss. The aim of this study was to evaluate the use of Erythropoietin (HrEpo) during pregnancy in Tx recipients.

**Methods:** Four two-center (cadaveric donors) recipients underwent successful pregnancies after a complex medical history of diabetes in their childhood with retinopathy & polyneuropathy, two with hypothyroidism, and end stage renal disease. They were all normoglycemic, as compared to baseline (26.4 ± 3; 38; 76, 92) and 0.78 (0.4, 9.7), respectively. The estimated glomerular filtration rate levels by MDRD formula at 1 year (57.4 ± 12ml/min/1.73 m², P=0.0001) were significantly decreased as compared to baseline (82.2 ± 10 ml/min/1.73 m²). We did not find significantly differences in mean 24hs ABPM (84 ± 8 mmHg, P=0.940) and mean LVMV (96.6 ± 17 mm, P=0.727), mean AS (7.78 ± 2.3 m/s, P=0.210) and median EF (5.1% (0.8, 13.3), P=0.374) compared to baseline (85 ± 7 mmHg, 99.8 ± 3.16 g/m², 0.03 ± 2.3 m/s and 10% (-1.6, 36.4), respectively).

**Conclusions:** Our study demonstrated that after an year, reduced nephron mass because of kidney donation was not associated with changes in cardiovascular structure and endothelial function.

**Funding:** Government Support - Non-U.S.

### PUB695
A Rare Case of Chronic Lymphocytic Inflammation with Pontine Perivascular Enhancement Responsive to Steroids (CLIPPPERS) After Kidney Transplantation

**Background:** Chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids (CLIPPPERS) is a recently described inflammatory condition of the central nervous system. To date 50 cases have been reported in the literature, however none have been reported following renal transplantation.

**Methods:** A 47 year old Hispanic man, status post deceased donor kidney transplant in 2008, with history of hypertension and diabetes, presented to our clinic with several months of progressive dizziness, unsteady gait and right facial numbness that progressed to diplopia and right facial palsy. An MRI of the brain with gadolinium revealed a 1.3 cm mass with a ring-like target appearance in the right brachium pontis and dorsal pons. MR spectroscopy revealed mild elevation of choline, suggesting demyelinating disease versus lymphoma or other high-grade malignancy. Given his long term immunosuppression, malignancy or an infectious process were considered as the main diagnostic possibilities.

An extensive evaluation included serial lumbar punctures for cytology and a variety of tests.
viral, fungal and bacterial cultures. Cytologic and serologic studies were unremarkable. Flow cytometry analysis of the spinal fluid showed no evidence of lymphoma. A brain biopsy was performed revealing non-specific perivascular lymphoplasmocytic infiltrate with no evidence of lymphoma or infection. Additionally, myelin stain was positive ruling out demyelinating disease. Our patient was started on high-dose steroids with remarkable improvement of his symptoms. Diagnosis of CLIPPERS was made.

**Conclusions:** CLIPPERS is a rare and poorly recognized CNS inflammatory condition. To our knowledge, this is the first case reported after kidney transplantation. More studies are needed to determine the pathophysiology of CLIPPERS in immunosuppressed patients and whether it could represent a pre-malignant state. Duration of treatment and follow up is yet to be determined. In this case, treatment with steroids has led to symptomatic improvement over a month and close follow-up continues.

**PUB696**

The Impact of Post-Transplant Hemoglobin and Creatinine Level on Renal Allograft Survival

Luiz Fernando Christiani, Fernanda Paula Feres Rios Da Costa, Ana Flavia Baldoni, Alicja Imada, Kelly Rodrigues, Maria Izabel Neves de Holanda Barbosa, Gesísska Marcelo Gomes, Cláudia Fagundes.

**Nephrology, Hospital Federal de Bonnusco, Rio de Janeiro, Brazil.**

**Background:** Anemia is a common finding after kidney transplantation. The role and the prevalence of Posttransplantation anemia (PTA) in predicting renal allograft outcomes still vary between different studies. In this study, we aim to assess the prevalence of anemia at one and six months post transplant and its correlation with 1 year renal allograft survival.

**Methods:** Anemia was defined by an absolute level of hemoglobin less than 11 g/dL. Hemoglobin and creatinine level were assessed at one, six and twelve-months after transplantation.

**Results:** We included 261 consecutive patients who underwent renal transplant from January/2010 to June/2012. Mean recipient age was 42±10 years and 56% were male. Prevalence of anemia was 42% at 1 month, 16% at 6 months and 9% at 12 months. Mean hemoglobin and creatinine level at first month of transplantation were 11.2±2.1 and 4.8±3.4 for those who return to dialysis within 12 months (p<0.001 for both comparisons). Overall patient and graft survival was 8% and 10%, respectively. On multivariate analysis, creatinine and hemoglobin level were independently associated with poor graft survival at 12 months. The best cut-off selected by receiver operating characteristic curve analysis was 10.8 g/dL for Hemoglobin level, (AUROC 0.74 (0.63-0.86), p<0.001) and 2.25 mg/dL, for serum creatinine (AUROC 0.77 (0.62-0.91), p<0.001). Combining the best points of those two variables could identify patients at risk of graft loss. Patients who met both criteria (Hb < 10.8 g/dL and Creatinine > 2.25 mg/dL) had 59% graft survival at 1-year, whereas allograft survival was 98.5% for patients without any criteria (Hb > 10.8 g/dL and Creatinine < 2.25 mg/dL).

**Conclusions:** Prevalence of anemia was high in the first month after transplant and persisted in a substantial proportion of functioning kidney transplant recipients. Early (1-month) hemoglobin and creatinine level can predict 1-year graft survival.

**PUB697**

Examining Adverse Weight Gain After Kidney Transplantation

Birah Workneh, Linda W. Moore, William E. Mitch.

**Medicine/Nephrology, Baylor College of Medicine, Houston, TX; Transplant Medicine, Houston Methodist Hospital, Houston, TX.**

**Background:** Between 15,000-17,000 patients with end-stage renal disease (ESRD) receive a kidney transplant in the United States every year. Among the most consequential complications to these patients are adverse weight gain and the development of diabetes, commonly termed New-Onset Diabetes After Transplantation (NODAT) with consequent CV mortality. However, there is no consensus about the exact nature of the weight gain that routinely occurs after kidney transplantation (i.e., relative changes in fat vs. muscle vs. fluid volume) and how this relates to insulin resistance. We wish to test the hypothesis that weight gain is primarily due to an increase in fat mass.

**Methods:** We are conducting a longitudinal study in ESRD patients anticipating receiving a live donor kidney transplant. We are studying subjects before kidney transplant, at 12 weeks and 1 year after they have received living donor kidney transplant to measure changes body composition and other indices. Body composition was characterized by DEXA as well as total body potassium (a gold standard measure of muscle mass).

**Results:** Results from 5 subjects who completed baseline assessment and 3 months post-transplant reveals there is significant gain in adipose weight gain in all cases.

**Additional:** Additionally, we discovered there is significant loss in skeletal muscle mass (p=0.032) measured by total body potassium.

**Conclusions:** We have not studied enough to conclude whether changes in energy expenditure and diet contribute to adipose weight gain and whether there is acute nitrogen (muscle) loss perioperatively. Ultimately, methods to identify patients at high risk for adverse weight gain and related metabolic disorders before transplant are greatly needed.

**Funding:** Private Foundation Support

**PUB698**

Effect of Mycophenolate Mofetil Dose on BK Virus Infection in Kidney Transplant Recipients

Vedran Pasara, Danica Galesic Ljubanovic, Madlen Knotek, Dept of Medicine, Renal Div, Univ of Zagreb Medical School, Merkur Hospital, Zagreb, Croatia; Dept of Pathology, Univ of Zagreb Medical School, Dubrava Univ Hospital, Zagreb, Croatia.

**Background:** Intensity of immunosuppression is a risk factor for BK virus infection (BKVI). However, the exact impact of exposure to tacrolimus and mycophenolate mofetil (MMF) to BKVI is unclear. The aim of this study was to determine if BKVI in kidney transplant (KT) recipients is associated with drug exposure to MMF.

**Methods:** This prospective randomised controlled clinical trial (NCT01860183) included 36 KT who underwent KT from May 2013 to February 2015 at Clinical Hospital Merkur. Immunosuppression consisted of basiliximab induction, with tacrolimus, MMF±steroid maintenance. KT were randomized in two groups, with respect to MMF dose (2g or 3 g daily). Urine cytology for decoy cells was performed at prespecified time points posttransplant. KT were followed up to 12 months post KT. Graft biopsy was performed per protocol at 2, 6 and 12 months, or in case of graft dysfunction. Kaplan-Meier analysis with log-rank test was used to assess graft survival. A Cox regression was used to determine variables associated with graft survival.

**Results:** 13 (37.1%) KT had decoy cells in urine, 4 (11.4%) KT had biopsy-proven BK virus-associated nephropathy (BKVAN). The mean time-to-occurrence was 4.8 months for decoy cells and 4.3 months for BKVAN. Cumulative one-year overall graft survival was 93.5%. Incidence of decoy cells, BKVAN, or acute rejection was similar in the two MMF groups. Rejection was not a risk factor for decoy cell positivity or for BKVAN.

**Conclusions:** MMF dose may not increase risk for BKVI after kidney transplantation.

Lipidapheresis in 3 Sisters with Familial Hypercholesterolemia
Chantal A. van de Waal,1 Andriez Schulte,2 Thomas Meissner,3 Lutz Thorsten Weber,3
1Pediatric Nephrology, Univ Hospital of Cologne, Cologne, Germany; 2Dept of Pediatrics, Neuroradiology and Cardiology, Univ Hospital of Duesseldorf, Duesseldorf, Germany.

Background: Familial hypercholesterolemia (FH) is the most common monogenic form of hypercholesterolemia. It carries the risk of premature coronary heart disease. As the atherosclerotic burden is dependent on the degree and duration of exposure to raised LDL-cholesterol levels, early diagnosis and effective treatment are imperative. Statins are the mainstay in the management of these patients. Lipoprotein-apoheresis becomes recently more established in patients with severe dyslipidemia. Together these treatments improve the prognosis of FH. Most children fail to attain targeted lipid goals owing to persistent shortcomings in diagnosis and treatment.

Methods: Three siblings with a LDLR mutation (p.Try577Arg) being on statins (20 mg/d Atorvastatin) and Ezetimib (10 mg/d) for 12 months with still LDL-C plasma concentrations of above 300-500 mg/dl started once a week a double filtration plasmapheresis (DFFP) with with a single plasma volume to be treated.

Results: After each LDL-apheresis LDL-C concentration of 100-150 mg/dl could be reached. (66-70% reduction). After 6 months plasma volume to treat was doubled because of a rebound within 7 days with LDL-C concentration up to 300-350 mg/dl. But though after each session LDL-C concentration decreased to 50-100 mg/dl the rebound was still evident after 7 days of therapy pause. With a treatment regime with twice plasma volume every 3-4 days the children finally attained a stable pre-treatment LDL-C concentration of 120-170 mg/dl. Another 2 months later statin therapy was stopped because of underlying mutation with assumed non receptor function. Neither the effectiveness of each apheraxis nor the LDL-C concentration after 4 days showed any change.

Conclusions: In pediatric FH patients with high levels of LDL-cholesterol plasma concentration it might be necessary to treat instead of conservative medication with apopheresis in high frequency and with high plasma volumes to reach a durable decrease in LDL-cholesterol plasma concentration. The use of cholesterol uptake-inhibitors should be considered.

Thrombomodulin Up-Regulation in Preeclamptic Nephropathy Is Associated with Parietal Cell Activation
Rosanne Jane Turner,1 Maria Elisabeth Penning,1 Malu Zandbergen,1 Elifuyeh V. Khankin,2 S. Ananth Karumanchi,3 Jan A. Bruijn,1 Kitty Bloemenkamp,1 Hans J. Baelde,1 Pathology, LUMC, Leiden, Netherlands; 2Howard Hughes Medical Inst and Dept of Medicine, Obstetrics and Gynecology, Beth Israel Deaconess Medical Center, Boston, MA; 3Obstetrics, LUMC, Leiden, Netherlands.

Background: Preeclampsia is a pregnancy-specific syndrome characterized by angiogenic imbalance and endothelial dysfunction. This endothelial dysfunction leads to kidney injury, i.e. glomerular endotheliosis, increased podocyte turnover and proteinuria. Thrombomodulin (TM) facilitates maintenance of glomerular endothelium by inhibiting coagulation, inflammation and apoptosis. In preeclampsia, levels of soluble thrombomodulin in the circulation are increased. We hypothesize that glomerular thrombomodulin expression is increased in preeclampsia and set up to correlate thrombomodulin expression with endothelium and podocyte damage.

Methods: A nationwide, ethics committee-approved search of the Dutch Pathology Registry (PALGA) was conducted; this revealed renal autopsy material from 11 women with preeclampsia according to the ISSHP definition, from 22 normotensive pregnant controls. Registry (PALGA) was conducted; this revealed renal autopsy material from 11 women with preeclampsia according to the ISSHP definition, from 22 normotensive pregnant controls.

Results: TM expression was increased in glomeruli from preeclampsia patients (82%) compared to pregnant, (41%, P=0.03) and hypertensive controls (21%, P=0.004). In sFLT-1 transfected mice TM expression was the same as in controls. TM expression correlated with activation of parietal epithelial cells (P=0.023), but not with endothelium or endothelial fibronectin deposits (P=0.03).

Conclusions: TM expression in the kidney is increased in preeclampsia. This is associated with parietal cell activation and not with endothelial damage or fibronectin deposits. TM apparently exerts cytoprotective and not anticoagulant effects in the kidney in preeclampsia. Glomerular damage induced by sFLT-1 did not increase TM expression in a mouse model; this indicates that the increased TM expression in humans is probably not caused by this anti-angiogenic factor alone.

Cadmium Induces Matrix Metalloproteinase-9 Expression via NADPH Oxidase/ROS-Dependent EGFR Signals in Human Endothelial Cells
Nam ho Kim. Internal Medicine, Chonnam Natunial Univ Hospital, Gwangju, Korea.

Background: Cadmium, a widespread cumulative pollutant, is a known human carcinogen, associated with inflammation and tumor. Matrix metalloproteinase-9 (MMP-9) plays a pivotal role in inflammatory reaction and tumor metastasis, however, the mechanisms underlying MMP-9 expression induced by cadmium remains obscure in human endothelial cells.

Methods: Here, cadmium elevated MMP-9 expression and enzyme activity, as well as MMP-9 promoter-driven luciferase activity, in a dose and time dependent manner in ECV304 human endothelial cells. Moreover, cadmium activated phosphorylation of EGFR, Akt, Erk1/2, JNK1/2, P38MAPK and promoted NF-κB and AP-1 binding.

Results: Specific inhibition and mutation studies show that EGFR, Akt, Erk1/2, JNK1/2 and transcription factor NF-κB and AP-1 were related to cadmium-induced MMP-9 expression in ECV304 cells. Akt and MAPKs (Erk1/2 and JNK1/2) functioned as upstream signaling molecules in the activation of NF-κB and AP-1, respectively. Furthermore, Cadmium increased ROS production and the ROS-producing NADPH oxidase. Cadmium translocates p47phox, ayeyakutim, NADPHxidoase, to the cell membrane. The exogenous HO2 increased MMP-9 mRNA expression. And that, inhibition of ROS by ROS scavenger (NAC) or NADPH oxidase inhibitor (DPI) attenuated EGFR, Akt, MAPK (Erk1/2, JNK1/2, P38MAPK) activation, and MMP-9 expression. Likewise, inhibition of EGFR phosphorylation prevented the activation of AKT, MAPKs (Erk1/2, P38MAPK). Finally, ECV304 celllincited with cadmium displayed markedly invasiveness, which was partially abrogated by MMP-9 neutralizing antibodies.

Conclusions: These results demonstrated that cadmium induces MMP-9 expression via NADPH oxidase ROS-dependent EGFR Akt/NF-κ Band MAPKs Erk1/2,JNK1/2 signaling pathways and, in turn, stimulates invasiveness in human endothelial ECV304 cells. These findings provide further insight into the molecular mechanisms in the carcinogenesis effect of cadmium.

Exosomes from Activated Kidney Fibroblast Have Ambivalent Potential Effect on Atherosclerosis
Fumitoshi Nishio, Noritoshi Kato, Yoshio Funahashi, Takuji Ishimoto, Tomoki Kosugi, Naotake Tsuibo, Shoichi Maruyama, Seiichi Matsuo. Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi-Pref., Japan.

Background: Exosomes are small (50-140nm) membrane vesicles of endothelial origin that contain host cell’s proteins, mRNAs, and microRNAs (miRNAs). The body of exosomes is known that these particles were biologically active, and had roles in intracellular communication. Especially tumor-derived exosomes has been intensively explored and proven to be associated with distant metastasis. On the other hand, it is well known that CKD patients are at risk of cardiovascular diseases, but the mechanism of this distant organ crosstalk is not fully understood. Under the hypothesis that exosomes are involved in cardio-renal syndrome (CRS), the aim of this study is to explore the role of exosomes from kidney fibroblasts, which are activated in diseased kidney, on vascular endothelial cells.

Methods: We isolated Exosomes from culture media of TGF-β-stimulated rat kidney fibroblast cell line (RKF-49) by ultracentrifugation technique. Cultured vascular endothelial cells (RAOEC; Rat Aortic Endothelial Cells) were stimulated by these exosomes and cultured vascular endothelial cells (RAOEC; Rat Aortic Endothelial Cells) were stimulated by these exosomes or exosomes from unstimulated fibroblast. Then we evaluated the expression of genes, which associated with atherosclerosis by qPCR.

Results: RAOEC stimulated with exosomes form TGF-β activated kidney fibroblast (RAOEC-T) showed higher expression of PIGF and lower expression of FB-1, ABCA-1 than control (RAOEC-C). This expression pattern is compatible with atherosclerotic change. On the other hand, RAOEC-T showed reduced expression of adhesion molecules such as ICAM-1,VCAM-1 and E-selectin compare with RAOEC-C.

Conclusions: So far, CRS is supposed to cause by uremic factor, RAS system, chronic inflammation, and so on. From this study, we showed that exosomes from activated kidney fibroblasts have ambivalent roles in atherosclerosis by modulating the expression of adhesion molecules, metabolic factor, and VEGF system on endothelial cells. Further studies are needed to elucidate the contribution level of exosomes on CRS.

Prevalence of Metabolic Syndrome in Patients with End Stage Renal Disease: Relevance of Biomarkers, Vinod K. Bansal1, Jennifer Saluk,2 Debra Bongiovi,2 Danuyeal Syed1, Schubhataz Abd,1 Jawed Fareed.1 Nephrology, Loyola Univ Medical Center, Maywood, IL; 2Pathology, Loyola Univ Medical Center, Maywood, IL.

Background: Since the metabolic syndrome (MetS) and chronic kidney disease (CKD) share many of the same risk factors and similar inflammatory pathogenesis, many studies have suggested a correlation between CKD and MetS, and shown that patients with MetS are more likely to develop CKD. The purpose is to investigate metabolic biomarker levels in ESRD patients to evaluate their relevance to ESRD and to prevent CRFs and to elucidate the pathogenic ESRD processes and the development of associated comorbidities.

Methods: Plasma samples were retrospectively collected from 89 ESRD patients prior to maintenance hemodialysis. Normal human plasma samples (female & male, 18-35 years old) were purchased from George King Biomedical Inc. (Overland Park, KS). Samples

1050A
were stored at -80°C. Biochips were purchased from RANDOX (Co. Antrim, Northern Ireland) to test C peptide, ferritin, IL-6, resistin, insulin, TNFs, IL-1α, leptin, PAI-1. These biomarkers were tested on 82 ESRD and 17 normal samples.

Results: All biomarkers, except insulin, were significantly elevated in Patients with ESRD compared to normal (p values are 0.05 - 0.0001). MetS patients with ESRD, as compared to non-MetS Patients with ESRD, had significantly elevated Leptin (P=0.002), and the correlation between MetS and Leptin levels was significant (P=0.0001; r=0.43). All other biomarkers showed no significant difference between ESRD+MetS and ESRD-MetS patients. Furthermore, when leptin levels for Patients with ESRD were broken down into ESRD+MetS and ESRD-MetS, ESRD+MetS vs. normal was significant (P=0.003), but ESRD-MetS vs. normal was not (P=0.6).

Conclusions: Elevated biomarkers suggest an ongoing inflammatory process in ESRD patients. Insulin levels were not significantly elevated in ESRD patients, possibly attributed to the high Leptin levels, which can interfere with insulin secretion and signaling. ESRD-MetS and ESRD-MetS populations are not statistically different for all other biomarkers. This suggests that biomarker elevation is due to ESRD pathogenesis, rather than due to MetS as a comorbidity.

Decreased Mitochondrial Membrane Potential in Monocyte Subsets from Patients with Chronic Kidney Disease

Ying Wang,1 Eric Joseph Lai,2 Annie Febus,1 Yuan Zhang,2 Linda Vernocchi,3 Anjali Ganda1,2

1 Div of Nephrology, Dept of Medicine, Columbia Univ Medical Center, New York, NY; 2 Div of Biostatistics, Mailman School of Public Health, Columbia Univ, New York, NY;

Methods: Monocyte subsets from 18 adult CKD patients (eGFR=30 ml/min/1.73 m²) and 26 matched controls (eGFR ≥60 ml/min/1.73 m²) were freshly analyzed by flow cytometry. Mitochondrial membrane potential (DYM), as a measure of mitochondrial functionality, was determined by the mean fluorescence intensity (MFI) of TMRM (tetramethylrhodamine methyl ester).

Results: DYM was significantly reduced by 10% in patients with CKD vs. controls in total monocytes (P<0.05). Interestingly, the intermediate monocyte subset (CD14+CD16–) which has the highest DYM among all the monocyte subsets and has been shown to predict future cardiovascular events in CKD patients, had the most pronounced reduction in DYM (14% lower, P<0.01) in patients with CKD vs. controls.

Conclusions: Patients with CKD demonstrate mitochondrial dysfunction in total monocytes and monocyte subsets. Mechanistic and prospective studies are needed to examine the relationship between monocyte mitochondrial dysfunction, atherosclerosis, and future cardiovascular events in CKD patients.

Paricalcitol Upregulates Renal Klotho and Restores Uremia-Induced Endothelial Integrity Disruption

Marc Villa cuenca1, Robert Hj. Beelen,1 Marc G. Vervoelt2 1 Molecular Cell Biology & Immunology, YU Univ Medical Center, Amsterdam, Netherlands; 2 Nephrology, YU Univ Medical Center, Amsterdam, Netherlands.

Background: Klotho deficiency in chronic kidney disease (CKD) is associated with the disruption of the endothelial integrity. Active vitamin D induces klotho expression. Hence, active vitamin D may limit endothelial layer disruption.

Methods: Male wistar rats were assigned into one of four groups: Control; Vitamin D deficiency, induced with Vitamin D deficient diet; Uremic, + Vitamin D deficiency. Animals were treated with Paricalcitol or vehicle control during 7 weeks. Serum samples were analyzed for 25D and 1,25D. Evans Blue was injected for estimation of the endothelial thoracic aorta and lung permeability and quantified using spectrophotometry. To determine the levels of Klotho, qPCR and WesternBlot was performed in kidney tissue.

Results: Average 25D levels were 9.83 nmol/L while 1,25D levels were below the detection levels (20pmol/L) after the induction Vitamin D deficiency. mRNA and protein levels of Klotho in the kidney were decreased in Vitamin D deficient and uremic rats and restored after Paricalcitol treatment. Aortic Evans blue leakage increased in all uremic rats regardless of vitamin D level, compared with the control group and restored after Paricalcitol treatment (p<0.03). Uremia did not induce pulmonary leakage, but paricalcitol lowered it compared to control and uremic condition (p<0.04). Figure shows uremic without D-deficiency together.

Conclusions: CKD induces aortic endothelial leakage, while the deficit of vitamin D on its own did not. Paricalcitol completely rescued endothelial leakage induced by CKD. In parallel, Klotho expression increased upon this treatment and may mediate the beneficial effect on the endothelium. To explain the difference between aortic and pulmonary tissue, additional studies are required.

Uregulation of Microparticles, Tissue Factor, Adhesion Molecules, Nitric Oxide and Adiponectin in End Stage Renal Disease

Vinod K. Bansal1, Daneyal Syed,2 Debra Hoppensteadt,2 Jawed Fareed1 1 Nephrology, Loyola Univ Medical Center, Maywood, IL; 2 Pathology, Loyola Univ Medical Center, Maywood, IL.

Background: End stage renal disease (ESRD) represents the final stage of chronic kidney disease characterized by kidney failure (GFR <15 ml/min/1.73 m²). To understand the pathophysiology of ESRD, we measured the circulating levels of microparticles (MP), tissue factor (TF), adhesion molecules, such as p-selectin (P-Sel), soluble ICAM (s-ICAM), nitric oxide (NO) and adiponectin (AD).

Methods: Plasma samples were collected from 119 ESRD patients undergoing maintenance hemodialysis to profile various inflammatory biomarkers. 100 normal plasma samples were collected from healthy individuals. MP levels were measured using an annexin

Coronary Artery Calcification and All-Cause Mortality in RRT Patients with Diabetes: 5 Year Survival Analysis

**Background:** Vascular calcification is a significant sequela of ESRD. A Coronary Artery Calcification (CAC) Agatston score ≥ 300 has been associated with adverse cardiovascular events & increased mortality. The purpose was to evaluate all-cause mortality rates in ESRD with diabetes.

**Methods:** 113 diabetic pts undergoing RRT had CAC scoring by sub-second gated helical CT standard Agatston scoring system, slice thickness 3mm. Patients were categorized into 3 groups according to CAC score: 0, 1-299, ≥ 300 (Low, Medium, High Risk). Survival of 3 groups was calculated using Kaplan-Meier curves for all-cause mortality for 5 year period after CAC. Unadjusted and risk-factor adjusted for age & length of time on dialysis Cox proportional hazard modeling was used to estimate time to all-cause mortality.

**Results:** 5 year survival was 92%, 60%, 46% for Low, Medium, High Risk CAC groups.

**Conclusions:** These studies suggest that MP, TF, NO, p-selectin and s-ICAM levels are increased in the ESRD patient. It is of interest to note that despite that a significant number of ESRD patients were diabetic; the AD levels were increased. These results also suggest that while ESRD represents a pro-inflammatory/hypercoagulable state, the repeated administration of heparin and other drugs may contribute to the regulation of the hemostatic process and inflammatory balance.

PUB710

**Elevated Toll Like Receptor 4 Expression and Macrophage Infiltration Is Found in High Dose Vitamin D-Induced Non-Uremic Vascular Calcification**

**Background:** Vascular calcification is strongly associated with cardiovascular morbidity and mortality. Several studies have suggested that monocytes/macrophages are involved in arterial vascular calcification, while the involvement of the TLR4 pathway in vascular calcification has also been proposed.

**Methods:** Male C57BL/6 mice aged 8 weeks were injected with a high dose of vitamin D (50000IU/kg/day) subcutaneously for 3 days at 0, 24 and 48 hours. All mice were sacrificed 3 days after the final administration of vitamin D. Kidneys were assessed histologically. Whole aortas were dissected. Macrophage infiltration and TLR4 expression was assessed by immunohistochemistry and histology and vascular calcification by Von Kossa staining.

**Results:** High dose vitamin D treatment did not induce kidney fibrosis or injury in C57BL/6 mice within the short time frame, as assessed by GT lisiboscore and PAS tubular damage score. High dose vitamin D treated mice demonstrated significantly higher calcium deposition in the aortic arteries (17.45% of vessel area) compared to controls (1.2% p<0.05). This was accompanied by a greater level of macrophage infiltration and TLR4 expression in these arteries compared to controls.

**Conclusions:** Accelerated vascular calcification was induced in mice with high dose vitamin D treatment. These data also identify a potential role for macrophages and the TLR4 pathway in vascular calcification.

PUB711

**Lack of Correlation of Pyrophosphate Levels with Survival and Coronary Artery Calcification in Hemodialysis Patients**

**Background:** Vascular calcification is an important predictor of cardiovascular mortality in ESRD. Decreased levels of inorganic pyrophosphate (PPi) are thought to increase vascular calcification. The purpose of this study was to evaluate the association of PPi & coronary calcification scores in maintenance HD patients and all-cause mortality over 5 years.

**Methods:** 98 maintenance HD patients were studied (mean ±SD): Age (yrs) 57 ±10.7, HD vintage (month) 36 ±37.6. Platelet free plasma PPi was measured by radiometric, enzymatic method as described by Tolouian. Coronary arterial calcification score (CACS) was measured by sub-second gated helical computed tomography with an Imatron C-150 XL ultra fast CT scanner using a standard protocol for vascular calcification. Patients were categorized into 3 groups according to their CAC score: 0, 1-300, and ≥ 300.

**Results:**

*p<0.05 Low vs High, **Medium vs High ANOVA, Dunnet T3*

The covariate PPi had no significant effect on the hazard rate, log rank p=0.61. After adjusting for covariates of PPi, age, length of time on HD at time of measurement the log rank statistic for the survival curves is not great enough to exclude the possibility that the difference is due to random sampling variability; there is not a statistically significant difference (P = 0.614).

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Aortic Artery Calcification and Cardiac Valve Calcification Is Associated with Mortality in Chinese Haemodialysis Patients: A 3.5 Year Follow-Up

Xiaonong Chen,1 Zijin Chen,1 Xiaobo Ma,1 Bei Ding,2 Huawe Ling,2 Zhongwei Shi,1 Nan Chen.1 1Nephrology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ, Shanghai, China; 2Radiology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ, Shanghai, China; 3Cardiology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ, Shanghai, China.

Background: Aim to investigate the relationship among aortic artery calcification (AAC), cardiac valve calcification (CVC) and mortality in maintenance haemodialysis (MHD) patients.

Methods: The study included 110 MHD patients. All MHD patients were treated in Shanghai Ruijin Hospital in July 2011. Follow-up these patients for 42 months.

Results: Totally 110 MHD patients were involved in this study. 64 (58.2%) patients were male, and the mean age was 55.2 ± 15.0 years old, the mean dialysis duration was 41.7 ± 38.1 months. 25.5% patients had cardiac valve calcification, while 61.8% had visible calcification. After 42 months follow-up, 26 (22.7%) patients died, including 16 cases death from cardiovascular events, 5 cases respiratory failure, 3 cases tumor metastasis, 1 case deep venous thrombosis and 1 case abandon treatment. Kaplan-Meier analysis showed that patients with AAC or CVC had a significant greater number of all-cause and cardiovascular deaths than those without. In multivariate analyses, the presence of AAC was a significant factor associated with all-cause mortality (HR 3.149, P = 0.025) in addition to lower albumin level and lower 25(OH)D level. The presence of CVC was a significant factor associated with cardiovascular mortality (HR 3.800, P = 0.029) in addition to lower albumin level and lower 25(OH)D level.

Conclusions: The presence of AAC and CVC were independently associated with mortality in MHD patients. Regular follow-up by X-ray and echocardiography could be useful method to stratify mortality risk in MHD patients.

Beneficial Effect of the Vasopressin AV1a and AV2 Receptor Blocker Conivaptan (C) on the Renal Alterations Resulting from Mild Heat-Induced Dehydration (MHID) and Rehydration with a 10% Fructose (F) Beverage

Gabriela Sanchez-Lozada,1 Fernando E. Garcia-arroyo,1 Monica Gabriela Bias-Marron,1 Jose Pedraza-chaverri,2 Cecilia Zazueta,2 Magdalena Cristobal,1 Edilia Tapia.1 1Renal Physiopathology, INCICh, Mexico City, DF, Mexico; 2Biology, UNAM, Mexico City, DF, Mexico; 3Cardiovasc BioMed, INCICh, Mexico City, DF, Mexico.

Background: The aims of this study were: 1. To define a possible synergistic effect between fructose and vasopressin during MHID, and 2. To evaluate the potential therapeutic benefit of C (3mg/kg BW) on this condition.

Methods: Six groups of male Wistar rats were MHID (37°C/1 h/day) and rehydrated with the selected beverage during 30 days: Water (W)+Veh, W+C, F+Veh, F+C, Stevia (S)+Veh and S+C. A group of normal control (NC) rats was studied as reference. After 30 days plasma and urine parameters were evaluated, renal cortex mitochondria were isolated and respiratory control rate (RRC) was evaluated with malate/glutamate (M/G) and succinate/rotenone (S/R) substrates.

Conclusions: The presence of AAC and CVC were independently associated with mortality in MHD patients. Regular follow-up by X-ray and echocardiography could be useful method to stratify mortality risk in MHD patients.

PUB716
Low Osmolar Diet and Adjusted Water Intake for Vasopressin Suppression in ADPKD

Objective: To identify a novel dietary approach that can reduce vasopressin levels in patients with ADPKD.

Materials and Methods: This randomized controlled trial examined the effect of a novel approach of combining low osmolar diet and adjusted water intake on vasopressin, measured by change in urinary osmolality and serum sodium.

Results: Baseline characteristics of the two groups were similar. Compared with baseline, the mean urine osmolality significantly declined from 426 (±193) to 258 (±110) mOsm/kg (P=0.007) but not in the control group. At 2 weeks, levels significantly differed between groups (P=0.04).

Conclusions: A low osmolar diet was effective in reducing vasopressin levels, which may be useful in the management of ADPKD.

Funding: NIDDK Support

PUB715
Urinary Excretion Pattern of Exosomal Aquaporin-2 in Nephronphthisis

Objective: To investigate the urinary excretion pattern of exosomal aquaporin-2 (AQP2) in patients with nephronphthisis.

Materials and Methods: Urine samples were collected from patients with nephronphthisis and healthy controls. Exosomal AQP2 was analyzed by immunoblotting.

Results: The level of urinary exosomal AQP2 was significantly increased in patients with nephronphthisis compared to controls.

Conclusions: Urinary exosomal AQP2 may be a potential biomarker for nephronphthisis.

Funding: Tufts Medical Center; Tufts University School of Medicine
CRISPR-Cas9-Mediated Deletion of Myosin Light Chain Kinase in Cultured Collecting Duct Cells Kiyoshi Isobe, Viswanathan Raghuram, Pablo Sandoval, Chin-Rang Yang, Chung-Lin Chou, Mark A. Knepper. Systems Biology Center, NHLBI, NIH.

Background: Regulation of osmotic water transport in the renal cortical collecting duct by vasopressin is in part dependent on membrane trafficking of aquaporin-2 (AQP2) to the apical plasma membrane of the principal cells. It is known that trafficking of AQP2 is in part dependent on changes in AQP2 phosphorylation. We previously proposed that AQP2 trafficking is dependent on the protein kinase Myosin Light Chain Kinase (MLCK; gene symbol: Mylk). Here, we test the role of MLCK in AQP2 phosphorylation and trafficking, utilizing CRISPR-Cas9-mediated mutations in the cultured mouse mpkCCD cells.

Methods: We used CRISPR-Cas9 genome-editing to mutate the catalytic region of the Mylk gene. Clones were generated with 4 different guide RNAs and were characterized by genomic sequencing and immunoblotting. Effects of the deletions were assessed by immunoblotting and immunofluorescence immunocytochemistry of AQP2.

Results: Multiple clones with mutations in the catalytic domain of MLCK were generated. Western blots showed absence of MLCK protein in MLCK-deleted clones. Controls were clones that express MLCK without mutations in the catalytic domain, but may contain off-target modifications. AQP2 protein abundance varied over a broad range, among all MLCK-deleted (n=4) and control (n=4) lines, but, on average, was not affected by the deletion. Immunocytochemistry showed that vasopressin stimulates redistribution of AQP2 to the apical plasma membrane in both control cells and MLCK-deleted cells. Vasopressin-dependent phosphorylation of AQP2 at Ser256 and Ser269 was not significantly reduced in MLCK-deleted cells.

Conclusions: The results demonstrate the feasibility of CRISPR-Cas9-mediated genome editing in mouse mpkCCD cells. Our experiments in mouse cultured collecting duct cells provide evidence that vasopressin-induced phosphorylation of AQP2 and redistribution of AQP2 to the apical plasma membrane can occur independently of myosin light chain kinase.

The PDZ Domain-Containing Protein Harmonin Is a Binding Partner of Sodium-Coupled Monocarboxylate Transporter 2 Nobuyuki Onizawa,1,2 Naoyuki Otani,1 Promsku Jutabha,1 Motoshi Ouchi,1 Hajime Hasegawa,2 Naohiko Anzai.1 1Dept of Pharmacology and Toxicology, Dokkyo Medical University School of Medicine, Mibu, Tochigi, Japan; 2Dept of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical Univ, Kawagoe, Saitama, Japan.

Background: Lactate is freely filtered and extensively reabsorbed in the proximal tubule to prevent the loss of this valuable metabolite from the body. Sodium-coupled monocarboxylate transporter SMCT2 (SLC5A12) mediates the transport of pyruvate, lactate, and acetate from the extracellular compartment to the cytoplasm of the renal epithelial cells. As the terminal PDZ motif abolished the interaction with harmonin in the yeast two-hybrid assay, we tested whether harmonin interacts with SMCT2.

Methods: We used the yeast two-hybrid screening to investigate the putative SMCT2-associated proteins that modulate its transport function. Using the SMCT2 C-terminal tail (SMCT2-CT) as bait, we performed a yeast two-hybrid screen of a cDNA library constructed from mouse kidney and identified the interaction with harmonin in the yeast two-hybrid system. Furthermore, co-immunoprecipitation studies revealed that the SMCT2 interacted directly with harmonin.

Conclusions: Harmonin was identified as the binding partner for SMCT2. The elucidation of these interactions may further our understanding of the function and regulation of monocarboxylate (e.g., lactate) transport in the human kidney.

Stimulation of V1a Receptor Increases Renal Uric Acid Clearance via ABCG2 Transporter - Insight into Hypouricemia in SIADH Kei Taniguchi, Yoshihiro Tamura, Shigeru Shibata, Shunyu Uchida. Dept of Internal Medicine, Teikyo Univ School of Medicine, Itabashi, Tokyo, Japan.

Background: Hypouricemia seen in the subjects with syndrome of inappropriate secretion of antidiuretic hormone (SIADH) is pathogenicomic but the mechanism of hypouricemia remains to be clarified. V2 receptor agonist ‘desmopressin’ induced hypouricemia but not hypouricemia in human unlike SIADH (G Deicas, JASN, 1996). Therefore, we hypothesized that V1 receptor but not V2 receptor may play a role in inducing hypouricemia. In the present study, we examined the changes in serum uric acid, urinary uric acid excretion and expression of uric acid transporters in response to V1a receptor agonist ‘terlipressin’.

Methods: Terlipressin was subcutaneously infused by osmotic mini pump to 7-weeks-old male Wistar rats (n = 9). Control rats were infused with normal saline (n = 9). The rats were sacrificed to obtain renal cortical tissues at 3 days.

Results: Serum uric acid significantly decreased and the excretion of urinary uric acid significantly increased in the terlipressin group. Thus, fractional excretion of uric acid increased from 1.20 ± 0.28 % to 3.10 ± 0.56 % (P < 0.001). The expression of ATP-binding cassette transporter, sub-family G, member 2 (ABCG2) significantly increased in the terlipressin group. Other uric acid transporters did not significantly change.

Conclusions: These results suggest that stimulation of V1a receptor increases renal uric acid clearance probably via upregulation of ABCG2, leading to hypouricemia seen in SIADH patients.

Background: Fluorescein angiography (FA) is an indispensable tool for diagnosis and management of diabetic retinopathy (DR). However, safety of fluorescein sodium on renal functions is not fully understood.

Methods: 100 type 2 diabetic patients presenting to the ophthalmology outpatient clinic at Alexandria main university hospital were included in our study. Serum creatinine and cystatin-C were measured before and 2 days after FA. Urinary NGAL as a tubular biomarker was measured before and 4 hours after FA. Renal injury was defined as 25 % increase in serum creatinine or cystatin-C.

Results: The mean of serum creatinine was 0.99 ± 0.36 mg/dl and 1.0 ± 0.36 mg/dl before and after FA respectively with no statistically significant change (P=0.061). Only one patient (out of 100) experienced more than 25 % rise in serum creatinine from baseline. Cystatin-C and urinary NGAL increased significantly after FA (P<0.001). Mean of serum Cystatin-C was 0.89 ± 0.34 mg/l and 0.95 ± 0.36 mg/l before and after FA respectively. 11 patients experienced more than 25% rise in serum cystatin-C from baseline. Mean of urinary NGAL was 21.78 ± 23.90 ng/ml and 27.15 ± 28.17 ng/ml before and after FA respectively.

Conclusions: Using ordinary renal biomarkers as serum creatinine, FA was thought to be kidney friendly. Nevertheless, using more sensitive early biomarkers as serum cystatin-C and urinary NGAL, FA is not as innocent as previously thought. A creatinine negative, biomarker positive change may implicate a form of subclinical AKI.
Hemodialysis was required in 9.3% of cases. The recovered AKI was observed in 75.9% at the time of hospital discharge. The length of hospital stay (9.9 ± 7.6 days; p < 0.05) and mortality (18.5 ± 7.2%; p < 0.02) were greater in patients with AKI compared with patients without. Patients with H-AKI had a longer hospital stay (15±12 vs. 8±8; p < 0.05) and a statistical trend to higher mortality (36.4% vs 14%; p < 0.08) in relation to patients with C-AKI.

**Drug Utilization Patterns and Factors Associated with Acute Kidney Injury in an Intensive Care Unit at a Brazilian Public Hospital – A Prospective Cohort Study**

**Authors:** Danielly Botelho Soares, Gabriela Rebouças Botelho, Flávia Fialho Girundi, Fernando Antonio Botoni, Maria Auxiliadora Parreiras Martins, School of Pharmacy, Univ Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil; School of Medicine, Univ Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil.

**Background:** Acute kidney injury (AKI) is associated with a significant increase in morbidity, mortality and health care costs. In intensive care units (ICU), the cause of AKI is commonly associated with multiple factors, among which the use of potentially nephrotoxic drugs is often neglected as a preventable cause of AKI.

**Methods:** This is a prospective cohort study that evaluated the AKI as a primary outcome in ICU patients at a teaching hospital in Belo Horizonte, Brazil. Length of stay greater than 24 hours and hospital stay lower or equal to 7 days were evaluated for potential eligibility. To be enrolled, patients should not present kidney dysfunction at the time of ICU admission.

**Results:** Data collection was performed from October 2014 to February 2015, including 122 patients, mostly originated from the surgical department (46.7%). An average of 22.0 ± 9.4 drugs was prescribed and 2-24 potentially nephrotoxic drugs were used per patient. Mechanical ventilation was required for 67.2% of patients and at least one vasoactive drug was used in 68.0% of cases. An incidence of AKI was observed in 23.8% of patients, among them 34.5% required dialysis, 24.1% reached the third stage of AKI and 31.8% were referred to additional treatment after ICU discharge. Eleven (9%) patients died and 63.6% of them developed AKI. The bivariate analysis showed that (p = 0.06) and APACHE II score (p = 0.0013) had higher median among patients who developed AKI compared with those who did not develop AKI. In the logistic regression, the number of medications (OR: 1.15; 95% CI: 1.05 to 1.26) presented a statistically significant correlation with the development of AKI.

**Conclusions:** These results demonstrate that the identification of factors associated with AKI in ICU patients is very important for the early identification of renal dysfunction induced by drugs, providing conditions for appropriate prevention and treatment of the extent of kidney damage.

Clinical, Dialytic and Laboratorial Factors Associated with Poor Health Related Quality of Life in Mexicans Hemodialysis Patients

Edgar Dehesa Lopez,1 David Olvera,2 Carlos Gonzalez parra,2 Rafael Baizabal.4 

1Dept of Nephrology, Research and Teaching Center in Health Sciences (CIDOCS), Culiacan, Sinaloa, Mexico; 2Dept of Nephrology, Hospital ISSSTE, Ciudad Valles, San Luis Potosi, Mexico; 3Dept of Nephrology, IMSS, Puebla, Mexico; 4Department of Nephrology, Hospital ISSSTE, Xalapa, Veracruz, Mexico.

Background: The evaluation of health related quality of life (HRQOL) in hemodialysis patients has recently gained great importance because it has proven to be an independent predictor of clinical outcomes.

Methods: Cross-sectional study. The validated Mexican version of the KDQOL-SF36 v1.3 questionnaire were applied to 194 adult patients with ESRD on hemodialysis in different regions of Mexico. According to the global score of questionnaire, patients were grouped in: patients with poor HRQOL (global score below the median) and patients with good HRQOL (global score greater than the median). Logistic regression was used to investigate the effects of clinical, dialytic and laboratorial factors on HRQOL.

Results: The average age was 54+16 with 54.6.1% male. Comorbidities were: hypertension in 86.6%, diabetes mellitus 2 in 57.2% and dyslipidemia in 7.2%. The vascular access was a catheter in 55.2% and fistula in 44.8% of the cases. Diabetes mellitus and the use of catheters as vascular access were more frequent in patients with poor quality of life. On the other hand, phosphorus >5.5 mg/dl and albumin >4g/dl were more frequent in patients with good quality of life. There were no differences in age, Kt/V, hemoglobin and calcium between groups. Table 1 shown the clinical, dialytic and laboratorial factors studied in the multivariate logistic analysis.

Conclusions: The associated factors with poor HRQOL in Mexicans hemodialysis patients were: the time spent in hemodialysis, serum albumin <4 g/dl and use of catheter for vascular access.

Table 1-Multivariate logistic regression analysis of clinical, dialytic and laboratorial factors associated with poor HRQOL.

Later part of the text includes various references and molecules, but the main focus is on renal diseases such as;

- **Gitelman syndrome**
- **glomerular disease**
- **glomerular disease (continued)**
- **glomerular disease (continued)**
- **glomerular hyperfiltration**

Additionally, the text touches on various topics like gene transcription, renal diseases, and hyperfiltration. The references and keywords are spread throughout the text, indicating a comprehensive discussion of nephrology topics.

Empagliflozin and Cardiovascular Outcomes in Patients with Type 2 Diabetes and Chronic Kidney Disease

Christoph Waninger,1 John M. Lachin,2 David H. Fitchett,3 Silvio E. Inzucchi,4 Maximilian von Eynatten,4 Michaela Matteus,5 Odd Erik Johansen,6 Hans-Juergen Woerle,7 Ulric Christian Broedl,8 Bernard Zinnan,9 1Dept of Medicine, Würzburg Univ Clinic, Würzburg, Germany; 2Biostatistics Center, The George Washington Univ, Rockville, MD; 3St Michael’s Hospital, Div of Cardiology, Univ of Toronto, Toronto, Canada; 4Section of Endocrinology, Yale Univ School of Medicine, New Haven, CT; 5Boehringer Ingelheim Pharma Gmbh & Co. KG, Ingelheim, Germany; 6Boehringer Ingelheim Norway KS, Asker, Norway; 7Lunenfeld-Tanenbaum Research Inst, Mount Sinai Hospital, Toronto, Canada; 8Div of Endocrinology, Univ of Toronto, Toronto, Canada.

Background: Patients with type 2 diabetes (T2D) and chronic kidney disease (CKD) are at high risk of cardiovascular (CV) events and premature death. Empagliflozin is a sodium-glucose co-transporter (SGLT)-2 inhibitor used in the treatment of T2D.

Methods: In EMPA-REG OUTCOME10, we explored long-term CV outcomes with empagliflozin vs placebo when added to standard of care in 7020 T2D patients with established CV disease. Inclusion criteria included ≤eGFR 30/min/1.73m². Patients (mean age 63 years, mean HbA1c 8.1%) were randomized 1:1:1 to empagliflozin 10 mg, or mg placebo. Selected Results: Most patients had impaired kidney function (52.2% stage 2, 17.8% stage 3a, 7.7% stage 3b CKD) while 28.7% and 11.0%, respectively, had moderately (30-300mg/g) or severely (>300mg/g) increased urine albumin to creatinine excretion. After a median follow-up of 3.1 years, the primary outcome (first occurrence of non-fatal myocardial infarction, non-fatal stroke, or CV death) occurred in a lower percentage of patients on empagliflozin (10.5%) than placebo (12.1%) (HR 0.86 [0.74-0.99]; p=0.04). This result was driven by a 38% reduction in CV death vs placebo (HR 0.62 [0.49-0.77]; p<0.001), with no difference in the risk of heart attack or stroke. Empagliflozin reduced hospitalization for heart failure by 35% (HR 0.65 [0.50-0.85]; p=0.0017). Pre-defined subgroup analyses on CV outcomes in patients with T2D and CKD will be presented.

Conclusions: Empagliflozin reduces CV morbidity and mortality in patients with T2D and various degrees of CKD.

High-Dose Perioperative Atorvastatin and Acute Kidney Injury Following Cardiac Surgery

Frederic Tremaine Billings, Chad E. Wagner, Patty Hendricks, Yaping Shi, Michael R. Petracek, Nancy J. Brown. Vanderbilt Univ, Nashville, TN.

Background: Hydroxy-methylglutaryl-coenzyme A reductase inhibitors (statins) affect several mechanisms underlying acute kidney injury (AKI), a common and dangerous complication after cardiac surgery. We hypothesized that short-term high-dose perioperative atorvastatin would reduce AKI following cardiac surgery.

Methods: We randomized elective cardiac surgery patients, stratified by chronic kidney disease (CKD), to atorvastatin or matching-placebo starting the day prior to surgery until hospital discharge in pre-study statin-naïve subjects or until the day after surgery in pre-study statin-using subjects. Our primary endpoint was AKI by AKIN criteria.

Results: The study was stopped on recommendations of the DSMB after 653 of 820 subjects completed the study due to futility and an increased incidence of AKI among statin-naïve subjects with CKD randomized to atorvastatin. AKI occurred in 20.8% of subjects randomized to atorvastatin versus 21.6% randomized to placebo (P=0.70). Among statin-naïve subjects (n=199), however, AKI occurred in 21.6% randomized to atorvastatin versus 13.4% randomized to placebo (P=0.14), and 52.9% vs. 15.8%, P=0.03, in patients with CKD (n=36). Serum creatinine concentrations increased a median of 0.11 (-0.11 – 0.56) versus 0.05 (-0.12 – 0.33) mg/dl in statin-naïve patients randomized to atorvastatin versus placebo (P=0.007), and this effect was magnified among those with CKD, whereas serum creatinine concentrations increased by 0.26 (0.22 – 0.94) versus -0.06 mg/dl (-0.16 – 0.41), P=0.04.

Conclusions: Empagliflozin reduces CV morbidity and mortality in patients with T2D and various degrees of CKD.

Funding: Pharmaceutical Company Support - Boehringer Ingelheim and Eli Lilly and Company.

Effect of Methylprednisolone on Acute Kidney Injury in Patients Undergoing Cardiac Surgery with Cardiopulmonary Bypass

Amit X. Gang,1 Richard P. Whitlock,2 1Western Univ, London, Canada; 2McMaster Univ, Hamilton, Canada and the Population Health Research Inst; for the SIRS Investigators.

Background: Acute kidney injury is a common complication of the 20 million cardiac surgeries performed worldwide each year. We conducted a substudy of the Steroids In Cardiac Surgery (SIRS) trial to determine whether methylprednisolone alters the risk of acute kidney injury in patients undergoing cardiac surgery with cardiopulmonary bypass (substudy protocol BMJ Open 2014 Mar 5;4(3):e004842).

Methods: This was a randomized clinical trial of 7,286 high-risk patients undergoing cardiac surgery with cardiopulmonary bypass from 79 centres in 18 countries between June 2007 and December 2013. Patients were assigned to take intravenous methylprednisolone (250 mg at anesthetic induction and 250 mg at initiation of cardiopulmonary bypass) or placebo. Patients, care givers and outcome-assessors were blinded to allocation. Acute kidney injury was defined as ≥25% or ≥ 26.5 mmol/L (≥ 0.3 mg/dL) increase in the postoperative serum creatinine concentration from the preoperative concentration in the 14 days following surgery, or new dialysis in the 30 days following surgery.

Results: Methylprednisolone (n=3,647) versus placebo (n=3,639) did not alter the risk of acute kidney injury (40.9% versus 39.5%, respectively; relative risk 1.03 [95% CI, 0.96 to 1.11]). Results were consistent with multiple alternate continuous and categorical definitions of acute kidney injury, and in the subgroup with baseline chronic kidney disease.

Conclusions: Amongst patients undergoing cardiac surgery with cardiopulmonary bypass the use of corticosteroids in the perioperative period did not alter the risk of acute kidney injury. Trial Registration: NCT00427388.

Funding: Government Support - Non-U.S.

High-Impact Clinical Trials Oral/Saturday

The NEFNIAN Trial: NEFCON, a Targeted Released Formulation of Budesonide, Reduces Proteinuria and Stabilizes eGFR in IgA Nephropathy Patients at Risk of ESRD

Benet C. Feliu,1 Rosanna Coppo,1 John Fech alley,1 Jürgen Floege,1 Johan W. De Fijter,2 Alan G. Jardine,3 Francesco Locatelli,2 Bart D. Maes,1 Alex Merce,2 Fernanda Ortiz,1 Manuel Praga,4 Soren Schwartz Soerensen,5 Vladimir Tesar,6 Uppsala Univ Hospital;7 Univ Turin;8 Univ Leicester;9 RWTH Univ Aachen;10 Leiden Univ Medical Center;11 Univ Glasgow;12 Ospedale A Manzoni, Lecco;13 AZ Delta Roeselaare;14 Pharmalink;15 Helsinky Univ Hospital;16 Hospital 12 de Octubre, Madrid;17 Rigshospitalet, Copenhagen;18 Charles Univ, Prague.

Background: IgA nephropathy (IgAN) is the most prevalent primary chronic glomerular disease. Despite RAS blockade, >25% of patients progress to ESRD within 20 years. This study evaluated a novel budesonide formulation (NEFCON) targeted for release in the distal ileum, where Peyer’s patches reside, in patients at risk of ESRD despite optimized RAS blockade.

Methods: Double-blind, placebo-controlled study in 150 patients (62 sites, 10 EU countries) with primary IgAN, proteinuria (UPCR >0.5 g/G or urine protein >0.75 g/d) and eGFR >50 mL/min/1.73m² randomised to EPE=45 mL/m/min/1.73m² randomisation to 8 or 16.73m² randomisation to 1:1:1; after 6 mo run-in phase to optimize RAS blockade. Primary endpoint: reduction in UPCR at 9 mo of treatment; secondary: mean change in eGFR.

Results: Baseline data were similar across groups; BP was 127-128/78-80 mmHg, UPCR 0.76-0.83 g/d, and eGFR 72-78 mL/min/1.73m². Primary endpoint was met at the pre-specified interim analysis. Mean UPCR decreased by 24% (NEFCON 8+16 mg/d) vs 3% increase (placebo) at 9 mo (p=0.007); reduction in the 16 mg/d group was 27% (p=0.003). Adverse event rates were higher in NEFCON groups (88–94%) than placebo (84%). Two serious adverse events were assessed as possibly related to NEFCON; deteriorated renal function (in follow-up) and deep vein thrombosis.

Conclusions: NEFCON reduced UPCR and maintained eGFR in patients with primary IgAN at risk of progression to ESRD despite optimized RAS blockade. Treatment was generally well-tolerated.

**Randomized Trial on Efficacy of Mycophenolate Mofetil versus Tacrolimus in Maintaining Remission in Children with Steroid Resistant Nephrotic Syndrome Aditi Sinha, Arvind Bagga. *All India Inst of Medical Sciences, New Delhi, India.*

**Background:** Since prolonged therapy with tacrolimus (Tac) causes nephrotoxicity, this RCT examined non-inferiority of mycophenolate mofetil (MMF) to Tac in maintaining remission in patients with steroid resistant nephrotic syndrome (SRNS).

**Methods:** Following approvals, 84 patients with SRNS (1-18 yr; minimal change 48, FSGS 36) & eGFR >60 ml/min/1.73m² received Tac (0.15 mg/kg/d; trough 4-8 ng/ml) for 6-months. Stratifying for histology & type of response, patients with complete (Up/Uc 36) & eGFR >60 ml/min/1.73m² were randomized to continue Tac or receive MMF (0.75-1 g/m²/d), prednisone & enalapril. Primary outcome, at 12-mo, was proportion with remission or infrequent relapses. Therapy failure was recurrent SRNS, frequent relapses or >1 SAE. Enrolment was closed after interim intention-to-treat analysis of outcome in 1/3 sample.

**Results:** Baseline features were similar. Therapy with MMF led to significantly higher treatment failure, prednisone dose & SAE; eGFR change was similar. On multivariate analysis of outcome in 1/3 sample.

**Conclusions:** Therapy with MMF is inferior to Tac in maintaining Tac induced remission in patients with SRNS.

**HI-OR06**

**Prevention of Bone Mineral Density Loss in De Novo Kidney Transplant Recipients with Twice-Yearly Denosumab: A Randomized Controlled Trial (ClinicalTrials.gov number NCT01377467) Rudolf P. Wuthrich,1 Diana P. Frey,2 Jens Günther Brockmann,3 Thomas Feith,4 Thomas F. Mueller,5 Lanja Salde,6 Arnold von Eckardstein,7 Nicole Graf,8 Marco Bonani.1 1Div of Nephropathology; 2Div of Visceral and Transplantation Surgery; 3Inst of Clinical Chemistry, Univ Hospital, Zurich, Switzerland; 4Graf Bio-statistics, Winterthur, Switzerland.

**Background:** Kidney transplantation is associated with bone loss and an increased risk of fracture. Since current therapeutic options to prevent bone loss are limited we assessed the efficacy and safety of Receptor Activator of Nuclear Factor kB Ligand (RANKL) inhibition with denosumab to improve bone mineralization in the first year after kidney transplantation.

**Methods:** We enrolled 108 kidney transplant recipients and randomized 90 patients two weeks after surgery in a 1:1 ratio to receive denosumab (subcutaneous injections of 60 mg denosumab at baseline and after 6 months) or no treatment. The primary endpoint was the percentage change in bone mineral density (BMD) measured by DDXA at the lumbar spine at 12 months.

**Results:** After 12 months, the primary outcome of total lumbar spine BMD increased by 4.6% (95% CI 3.3-5.9%) in 46 patients in the denosumab group and decreased by -0.5% (95% CI -1.8-0.3%) in 44 patients in the control group (between-group difference 5.1%, 95% CI 1.7-8.0%, p=0.0001). Denosumab also significantly increased BMD at the total hip by 1.9% (95% CI 1.0 to 3.7%; p=0.035) over that in the control group at 12 months. HR-pQCT in a subgroup of 24 patients showed that denosumab also significantly increased BMD and cortical thickness at the distal tibia and radius (p<0.05). Biomarkers of bone resorption (β-CTX, urine deoxypyridinoline) and bone formation (P1NP, BSAP) markedly decreased with denosumab (p<0.0001). Episodes of cystitis and asymptomatic hypocalemia occurred more often with denosumab, whereas graft function, rate of rejections and incidence of opportunistic infections were similar.

**Conclusions:** Antagonizing RANKL with denosumab effectively increased BMD in de novo kidney transplant recipients, but was associated with more frequent episodes of urinary tract infection and decreased calcium.

**Funding:** Government Support - Non-U.S.

**HI-OR07**

**Randomized, Double-Blind, Placebo-Controlled, Parallel, 3-Arm Study of Safety and Anti-Pruritic Efficacy of Nalbuphine HCl ER Tablets in Hemodialysis Patients with Uremic Pruritus Vandana S. Mathur,1 Jayant Kumar,2 Paul W. Crawford,1 Howard Halt,3 Thomas Sciascia.3 1Mathur Consulting; 2Trevi Therapeutics; 3Research by Design; 4Edenridge Consulting; 5Renal Medical Associates.

**Background:** Uremic pruritus (UP) is associated with decrements in quality of life and sleep and higher mortality. UP pathogenesis may involve endogenous α/δ opioid ligand ratio imbalance. Nalbuphine ER tablets (NAL) are an α-σ opioid agonist/α-δ opioid antagonist being developed for chronic pruritic conditions.

**Methods:** 373 hemodialysis patients (HDP) with mean baseline numerical rating scale score (NRS) ≥ 4.5 for worst itching (0: no itching to 10: worst possible itching) were randomized 1:1:1 to NAL 60 mg (n = 128), NAL 120 mg (n = 120), or placebo (n = 125) and treated for 8 weeks.

**Results:** Demographics, dialysis adequacy and vintage, phosphorus, parathyroid hormone, pruritus duration, and antihistamine use were similar in the 3 arms at baseline. The primary efficacy endpoint was the change from Baseline to the Evaluation Period (Weeks 7 and 8) in the NRS for each dose of NAL, with pre-specified hierarchical ordering – the most common adverse events were nausea, vomiting, dizziness and somnolence with incidence rates of these events quickly approaching that of placebo. The most common adverse events were nausea, vomiting, dizziness and somnolence with incidence rates of these events quickly approaching that of placebo. The most common adverse events were nausea, vomiting, dizziness and somnolence with incidence rates of these events quickly approaching that of placebo. The most common adverse events were nausea, vomiting, dizziness and somnolence with incidence rates of these events quickly approaching that of placebo.

**Conclusions:** Nalbuphine ER tablets at a dose of 120 mg BID were safe and significantly reduced itching intensity.

**Funding:** Pharmaceutical Company Support - Trevi Therapeutics

**The Omega-3 Fatty Acids (Fish Oils) and Aspirin in Vascular Access Controlled Trial** Ashley B. Irish,1,2 1Nephrology, Fiona Stanley Hospital, Perth, Western Australia, Australia; 2Australasian Kidney Trials Network, Univ of Queensland, Brisbane, Queensland, Australia.

**Background:** Patients with end-stage renal disease require haemodialysis to remove waste products and excess fluid. Platelet aggregation is an important cause of vascular access failure; platelet aggregation can be reduced by antiplatelet drugs such as aspirin and/or omega-3 polyunsaturated fatty acids (w3FA) may prevent these complications by inhibition of platelet aggregation, vasoconstriction, intimal hyperplasia and inflammation.

**Methods:** The Omega-3 Fatty Acids (Fish Oils) and Aspirin in Vascular Access Outcomes in Renal Disease (FAVoured) Trial: A Randomised Placebo-Controlled Trial

**Results:** Omega-3 polyunsaturated fatty acids (w3FA) may prevent these complications by inhibition of platelet aggregation, vasoconstriction, intimal hyperplasia and inflammation.

**Funding:** Pharmaceutical Company Support - Trevi Therapeutics

---

**Underline represents presenting author/disclosure.**
Methods: This international, randomised, double-blind, placebo-controlled trial examined whether 3 months therapy with w3FA (4g/day) reduced primary AVF failure at 12 months after AVF creation. AVF failure was defined as AVF thrombosis and/or abandonment and/or cannulation failure. A subset of patients received aspirin (100mg/day) or matching placebo in addition to w3FA or placebo in a factorial design (n=388).

Results: The 567 randomised participants had a mean age of 55 years, 63% were male and 46% diabetic. AVF failure occurred in 128/270 (47%) participants assigned to w3FA compared with 125/266 (47%) assigned to placebo (relative risk adjusted for aspirin use 95% CI 0.72-1.34, p=0.90). AVF abandonment (19% vs 22%, RR 0.87, CI 0.62-1.22, p=0.43) or cannulation failure (40% vs 39%, RR 1.03, 0.83-1.26, p=0.81) was not significantly different between groups. Other markers of kidney and myocardial injury were also examined.

Conclusions: These results fail to provide proof-of-concept that RIPC may impact clinically important endpoints.

SA-PO1091

The Remote Ischemic Preconditioning in Cardiac Surgery Trial (Remote IMPACT) Michael Walsh,1,2 Michael C. Rydzak,1,2 McMaster Univ;1 Population Health Research Institut.

Background: Cardiac surgery is frequently complicated by ischemia-reperfusion injury which can lead to kidney and myocardial injury. Preoperative Remote Ischemic Preconditioning (RIPC), cycles of brief ischemia to a limb alternating with reperfusion, may reduce the frequency or severity of organ injury after cardiac surgery.

Methods: We randomly allocated 258 patients at high risk for death after cardiac surgery to receive either RIPC or a sham procedure immediately after induction of anesthesia. RIPC consisted of 3 cycles of thigh tourniquet inflation to 300 mmHg for 5 minutes followed by 5 minutes reperfusion. The sham group tourniquets were inflated to 15 mmHg. Patients and care providers were blinded. The main clinical outcomes were change in creatinine over the first 4 postoperative days and the peak CK-MB within 24 hours of surgery.

Other outcomes assessed were 30 days after randomization. Analyses were performed according to the intention-to-treat principle.

Results: We randomized 128 patients to RIPC and 130 to sham. No patients were lost to follow-up. There were no significant between group differences in postoperative change in creatinine (p=0.79) or peak CK-MB (p=0.18) (Figure 1). We found no significant differences in the frequency of acute kidney injury (34% vs 31%), myocardial injury (24% vs 19%), stroke (4% vs 3%) or mortality (6% vs 5%) at 30 days.

Figure 1. Mean and 95% confidence intervals of creatinine over time for the RIPC (green diamonds) and sham (blue circles) groups.

Conclusions: In this trial RIPC did not affect markers of kidney and myocardial injury. These results fail to provide proof-of-concept that RIPC may impact clinically important outcomes in the cardiac surgery setting.

SA-PO1092

Nephrotoxicity of Invasive and Noninvasive Coronary Angiography: Randomized Controlled Study of Intracoronary and Intravenous Contrast Agent Administration Eva Schönberger,1 Patricia D. Bady,2 Peter Martus,3 Elke Zimmermann,1 Michael Laule,3 Marc Dewey,3 Anesthesiology, Charité, Berlin, Germany;4 Radiology, Charité, Berlin, Germany;1 Inst for Clinical Epidemiology and Applied Biostatistics, Eberhard Karls Univ, Tübingen, Germany;2 Cardiology, Charité, Berlin, Germany.

Background: Intracoronary contrast agent administration may reduce the frequency or severity of organ injury after cardiac surgery.

Methods: We randomly assigned patients with suspected coronary disease to either intracoronary contrast agent for invasive coronary angiography (ICA) or intravenous administration for coronary computed tomography angiography (CTA). The sham group received intravenous contrast agent administration.

Results: There was no difference in any serious adverse event (AE), 9.2% vs 13.0%, p=0.14; bleeding, 2.2% vs 2.5%, p=0.61; hypertension, 23.6% vs 25.8%, p=0.47; diabetes mellitus, 17.7% vs 17.3%, p=0.63; and atrial fibrillation, 14% vs 14.9%, p=0.71. Of 134 patients in the ICA group (13%) and 6 of the 139 patients in the CTA group (4%; RR 0.87, CI 0.62-1.22, p=0.43) the group randomised to aspirin or placebo-aspirin as part of the factorial design. There was no difference in any serious adverse event (AE), 9.2% vs 13.0%, p=0.14; bleeding, 2.2% vs 2.5%, p=0.61; hypertension, 23.6% vs 25.8%, p=0.47; diabetes mellitus, 17.7% vs 17.3%, p=0.63; and atrial fibrillation, 14% vs 14.9%, p=0.71. Of 134 patients in the ICA group (13%) and 6 of the 139 patients in the CTA group (4%; RR 0.87, CI 0.62-1.22, p=0.43) the group randomised to aspirin or placebo-aspirin as part of the factorial design.

Conclusions: These results fail to provide proof-of-concept that RIPC may impact clinically important endpoints.

Efficacy and Safety of Bosutinib in Autosomal Dominant Polycystic Kidney Disease: A Phase 2, Randomized, Double-Blind, Placebo-Controlled Study Karl-Heinz Eichner,1 W. I. W. I. X. I. C. E. S. I. E. N. A. K. O. F. I. O. M. O. N. P. S. O. M. O. N. 1,1,2,3,4,5,6 Andreas L. Serra,1 Pomeranian Medical Univ, Szczecin, Poland;1 Charles Univ, Prague, Czech Republic;1 Univ Health Network, Toronto, Ontario, Canada;1 Icahn School of Medicine at Mount Sinai, New York, NY;1 Pfizer Inc, San Diego, CA;1 Pfizer Inc, Cambridge, MA;1 Sanofi US, Bridgewater, NJ;4 Roche Pharma Research and Development, Basel, Switzerland;1 Inst for Allgemeine Innere Medizin und Nephrologie, Suisse ADPKD Hirslanden, Zurich, Switzerland.

Background: Src overactivation has been linked to the pathogenesis of autosomal dominant polycystic kidney disease (ADPKD). We assessed efficacy and safety of bosutinib (BOS), an oral dual Src/Abi tyrosine kinase inhibitor, in ADPKD patients (pts).

Methods: In this phase 2, multicenter study (NCT01233869), ADPKD pts with estimated glomerular filtration rate ≥60 mL/min/1.73 m² and magnetic resonance image (MRI)-confirmed total kidney volume (TKV) >750 cc were randomized 1:1:1 to placebo (PBO), 200 mg/d or 400 mg/d of oral BOS for 24 mo. The primary endpoint was normalized TKV % change. Pts treated for 2 wk who had an MRI after a 30-d washout period were in the modified intent-to-treat (mITT) analysis.

Results: 169 of 172 enrolled pts received ≥1 dose of treatment. 24 pts who initially received 400 mg/d BOS were later reduced to 200 mg/d BOS per protocol. 88 pts (52%) were in the mITT population (200 mg/d, n=27; 400 mg/d, n=7; 400 to 200 mg/d, n=21; PBO, n=33) after discontinuations (unrelated to study drug, 27%; study drug-related adverse events, 17%; consent withdrawal, 14%). Annual rate of kidney enlargement was significantly reduced for pooled BOS vs PBO (0.84% vs 4.74%, respectively, 95% CI for difference in annualized rates [2.02-5.74]; p<.0001) and was 65.2% lower for BOS 200 mg/d vs PBO (1.63% vs 4.74%, respectively, 95% CI [0.93 to 5.23]; p<.005). Gastrointestinal (GI) effects were dose-dependent for BOS, the overall safety profile, including GI toxicities, was consistent with the known profile of BOS.

Conclusions: BOS reduced the annual rate of kidney enlargement vs PBO in ADPKD pts, and the safety profile was consistent with the BOS label.

Low Osmolar Diet and Adjusted Water Intake for Vasopressin Suppression in ADPKD: A Randomized Controlled Trial Osama W. Amro,1,2 Jessica K. Paulus,1 Farzad Noubary,1 Ronald D. Perrone,1 Nephrology, Tufts Medical Center, Boston, MA;1 Tufts Univ School of Medicine.

Background: Autosomal dominant polycystic kidney disease (ADPKD) affects 12.5 million people worldwide. Vasopressin promotes disease progression.

Methods: This randomized trial examined the effect of combining a low osmolar diet and adjusted water intake on vasopressin as measured by change in plasma copeptin, and
SA-PO1095

A Phase 2, Double-Blind, Randomized Study of Fresolimumab or Placebo in Patients with Steroid-Resistant Primary Focal Segmental Glomerulosclerosis

James A. Tumlin,1 Flavio Vincenti,2 Fernando C. Fervenza,3 Kirk N. Campbell,4 Montserrat M. Diaz Encarnacion,5 Manuel Praga,6 Denyse Thibodeau-Brown,7 Francisco Veríssimo Veronez,8 Beverly Accomando,9 Sara Engstrand,10 Steven R. Ledbetter,11 Julie Lin,12 John F. Neylan,13 UT Coll. of Med., Chattanooga, TN;14 UCSF, San Francisco, CA;15 Mayo Clinic, Rochester, MN;16 Icahn Sch. of Med. at Mt. Sinai, New York, NY;17 Fundación Puigvert, Barcelona, Spain;18 Hosp. Univ 12 de Oct., Madrid, Spain;19 Univ of Alabama at Birmingham, AL;20 Hosp. de Clinicas de Porto Alegre, Brazil;21 Sanofi, Cambridge, MA;22 Formerly Genzyme, Sanofi.

Background: Steroid-resistant primary FSGS confers substantial risk of morbidity & progressive kidney failure. Fresolimumab (freso), a neutralizing mAb to all 3 isoforms of TGF-β, is a potential new treatment.

Methods: 36 pts with biopsy-proven nephrotic-range FSGS randomized to freso 1mg/kg (n=14) v 4 mg/kg (n=12) v placebo (PL) (n=10) for D112, allowed immunosuppressives after D112 & followed up double-blind for D252. 1° outcome: proteinuria remission; 2° outcomes included changes in Up/c & eGFR.

Results: Pts: 53% male; median age 47 y; 78% Black, 31% Hispanic. Baseline (BL) median Up/c 6.19 mg/kg; eGFR, 63 ml/min/1.73 m². 72% pts received prior CNL. Durable partial remission ≥50% Up/c decrease from BL to <3 mg/kg: 3 pts, 1mg/kg; 2 pts, 4 mg/kg; 1 pt, PL; 1 additional pt on 1mg/kg had steep & consistent Up/c decline from 17-4 mg/kg. All 7 freso responders were Black/Hispanic. Mean Up/c changes at D112: -18.5% (1mg/kg, P=0.008), +10.5% (4 mg/kg, P=0.52), +9.0% (PL, P=0.91). eGFR showed nonsignificant trend for stability in freso v decline in PL. Freso was generally well tolerated with no significant difference in AEs in low v high doses.

Effects of Sustained-Release Beraprost Sodium in Patients with Primary Glomerular Disease or Nephrosclerosis: The CASSIOPEIR Study

Toshiro Fujita,1 Xuqing Yu,2 Suhyungwon Kim,3 Hidehiko Orikasa,4 Hajimu Kurumatani,4 Takashi Kiriyama,5 ‘The Univ of Tokyo, Tokyo, Japan;6 The First Affiliated Hospital, Sun Yat-sen Univ, Guangzhou, Guangdong, China;7 Seoul National Univ Hospital, Seoul, Korea;8 Saiitama Medical Univ, Saiitama, Japan;9 The Univ of Toyama, Toyama, Japan;10 Toray Industries, Inc, Tokyo, Japan; Astellas Pharma Inc., Tokyo, Japan.

Background: No single treatment, except RAS inhibitors, can delay progression of CKD. TRK-100STP, a sustained-release tablet of an orally-active prostacyclin analoge, beraprost sodium, is suggested to suppress worsening of renal filtration function. We aimed to demonstrate superiority of TRK-100STP over placebo in patients with CKD, either as primary glomerular disease or nephrosclerosis; determine the recommended dose of TRK-100STP, and evaluate its safety profile.

Methods: We performed a randomized, double-blind, placebo-controlled, parallel-group comparative study at 160 sites in seven Asian-Pacific countries and regions (CASSIOPEIR: CRF Asian Study with Oral PG); Derivative for Evaluating Improvement of Renal Function). Patients entered a run-in period with oral administration of placebo twice daily for two to eight weeks. Patients meeting the inclusion/exclusion criteria at the end of the run-in period (n=892) were randomized to TRK-100STP 120 mg, TRK-100STP 240 mg, or placebo for a treatment period of two to four years. The primary efficacy endpoint was the time to first occurrence of a renal composite endpoint: doubling of SCr or occurrence of end-stage renal disease. ClinicalTrials.gov identifier: NCT01090037.

Results: No significant differences were evident in renal composite endpoints between TRK-100STP and placebo (2-sided 5% significance level, P=0.5674). The overall incidence of adverse events and adverse drug reactions was comparable between the treatment arms.

Conclusions: TRK-100STP did not demonstrate superiority over placebo, and the recommended therapeutic dose for patients with CKD either primary glomerular disease or nephrosclerosis was not determined. However, no findings raised safety concerns in the comparison between TRK-100STP and placebo.

SA-PO1097

Corticosteroid Monotherapy versus Combined Immunosuppression in IgA Nephropathy: Insights from the STOP-IgAN Trial

Jürgen Floege,1 Thomas Rauen,2 Frank Ettner,3 Christina Fitzner,4 Ralf-Dieter Hilgiers,2 ‘Nephrology, RWTH Aachen Univ, Aachen, Germany;2 Biostatistics, RWTH Aachen Univ, Aachen, Germany;3 Bayer AG, Wuppertal, Germany; 4 For the STOP-IgAN Investigators.

Background: In high-risk IgA nephropathy (IgAN) the value of immunosuppression is controversial.

Methods: We recently reported a randomized, controlled trial in IgAN patients (STOP-IgAN trial). Following 6 months of optimized supportive treatment 162 trial participants, who still displayed a proteinuria >0.75 g/d, entered a 3 year study phase and were randomized to continue on supportive therapy (SUP) or to receive additional immunosuppression (IMM). IMM-patients with an eGFR <60 ml/min/1.73 m² received a 6-month corticosteroid monotherapy (“Pozzi-protocol”). Patients with an eGFR of 30 to
59 ml/min/1.73m² received cyclophosphamide for 3 months, followed by azathioprine, plus oral prednisolone (“Ballardie protocol”). Primary endpoints were (i) full clinical remission (proteinuria < 0.2 g/day and eGFR loss of < 5 ml/min) and (ii) eGFR loss > 15 ml/min from baseline to trial end.

Results: Here we report a secondary analysis of the two IMM subgroups versus corresponding SUP patients matched for eGFR. The intention-to-treat (ITT) analysis assuming a worst-case scenario at 3 years is shown in the table.

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>GFR &gt;60 ml/min/1.73m²</th>
<th>GFR 30-60 ml/min/1.73m²</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMM vs. SUP (n = 55 vs. 54)</td>
<td>GFR &gt;60 ml/min/1.73m²</td>
<td>GFR 30-60 ml/min/1.73m²</td>
</tr>
<tr>
<td>Full clinical remission</td>
<td>OR 5.23 (95%-CI 1.29-21.15), p=0.020</td>
<td>OR 2.77 (95%-CI 0.38-22.29), p=0.319</td>
</tr>
<tr>
<td>eGFR loss &gt;15 ml/min</td>
<td>OR 0.65 (95%-CI 0.27-1.56), p=0.333</td>
<td>OR 1.62 (95%-CI 0.49-5.61), p=0.428</td>
</tr>
</tbody>
</table>

Patients treated with the Pozzi protocol had a transient decrease in proteinuria after 12 months and significantly less microhematuria at trial end compared to matched SUP patients. In the group with the low eGFR range, there were no significant differences between both arms. Compared to supportive care, more patients receiving immunosuppression developed severe infections, impaired glucose tolerance and weight gain in year one.

Conclusions: Our secondary analyses provide little evidence for a stabilization of renal function with immunosuppression in the group with an eGFR >60 ml/min and no evidence for a benefit in patients with a lower eGFR.

Funding: Government Support - Non-U.S.

A Randomized Trial of Rituximab in Advanced IgA Nephropathy

Richard A. Lafayett,1 Pietro A. Canetta,2 Brad H. Rovin,3 Gerald B. Appel,4 Marie C. Hogan,5 Stephen B. Erickson,6 Fernando C. Fervenza,4 Stanford Univ, Stanford, CA;7 Columbia Univ, New York, NY;8 Ohio State Univ; Columbus, OH;9 Mayo Clinic, Rochester, NY.

Background: IgA nephropathy (IgAN) frequently leads to progressive renal dysfunction. Present immunosuppressive treatment remains uncertain in terms of benefit and risks side effects. B cells are an attractive target in IgAN so we performed a pilot trial of rituximab in subjects at high risk of progression.

Methods: Patients with biopsy proven IgAN, more than 1 g/day of proteinuria despite RAASi (or >0.5 g/day if on dual RAASi), well controlled blood pressure (BP) and eGFR >90ml/min were randomized to 1 year of rituximab therapy (4g total) vs ongoing BP control, fish oil and use of RAASi. They were followed for B cell depletion, effects on proteinuria and changes in eGFR. Safety signals were also followed.

Results: 34 patients were randomized. Baseline serum creatinine was 1.5±0.5 mg/dl and proteinuria was 2.1, 0.6-5.5 g/day. There was no change in BP during the study. Treatment with rituximab resulted in significant B cell depletion and was generally well tolerated. There was no change in renal function during the study in either group. Rituximab treatment had no significant effect on proteinuria compared to baseline or control patients, and 3/17 patients in each group experienced ≥ 50% reduction in proteinuria during the study.

Figure 1: Proteinuria in (A) Control vs. (B) Rituximab Groups. The heavy weight red line represents median data.

Conclusions: In this small study, rituximab therapy had no influence on renal function or proteinuria in subjects with advanced disease due to IgA nephropathy. There were numerically greater reductions in proteinuria, but this did not reach significance. Few patients had substantial responses in either group. These results do not support the use of rituximab as treatment for patients with IgA nephropathy.

Establishing Endpoints for Lupus Nephritis Clinical Trials: Progress by the Kidney Health Initiative/Lupus Nephritis Trials Network Collaboration

Brad H. Rovin,1 Meggan Mackay,2 Joanna Stein,3 Maria Diall’Era,4 Kenneth Kalunian,5 Martin L. Lesser,6 Melissa West7 Ohio State Univ; Feinstein Inst; 1 Univ Calif San Diego; 2 Univ Calif San Francisco; 3 American Society of Nephrology.

Background: There are no universally accepted endpoints for lupus nephritis (LN) clinical drug trials. To obtain approval of new therapies a uniform endpoint that can be applied to future LN trials is needed. The optimal endpoint is a short-term measurement that accurately reflects long-term kidney survival. The present work was undertaken to define LN trial end points.

Methods: Clinical data at LN flare (baseline) and during serial follow-up (minimum 22 months) from 751 patients were analyzed. Clinical variables at baseline and after 6 and 12 months were tested as predictors of adverse long-term renal outcomes, in this case time to new chronic kidney disease (CKD), defined as a sustained increase in serum creatinine (SCr) ≥30%. Multivariable Cox regression analysis was used to model time to CKD.

Results: After accounting for missing data 507 patients were included in the final analysis. This cohort was 89% female, 56% White, 20% Asian and 14% Black. The average baseline eGFR was 61.2±20.7 ml/min, proteinuria was 4.1±3.4 g/day, and eGFR by CKD-EPI was 81.35 ml/min. Median follow-up was 42 months (range: 22-147 months). By univariate analysis urine RBCs, race, complement C3, SCr, eGFR and proteinuria were potential significant predictors of time to CKD. By multivariate modeling the significant predictors of future CKD were: SCr at 12 months (p=0.0005, Hazard Ratio (HR) 1.8 (95%-CI 1.3-2.5)), proteinuria at 12 months (p=0.0001; HR 1.6 (1.3-1.8)); and an increase in eGFR>10% from baseline to 12 months compared to no change in eGFR (p=0.0001; HR 0.4 (0.3-0.6)).

Conclusions: We have identified 3 highly significant predictors of time to CKD in LN patients that can be measured during the first 12 months of treatment for flare. These can be developed into a composite endpoint for future LN therapeutic trials. Unexpectedly, small improvements in eGFR appear to predict renal survival. Also, because urine RBCs do not appear to predict time to CKD, it may be possible to exclude urinalysis as an endpoint component in future clinical trials.

Grazoprevir (GZR)/Elbasvir (EBR) Treatment of Hepatitis C Virus (HCV) Infection in Patients with Chronic Kidney Disease Stage 4/5: Final Results of the C-SURFER Phase 3 Study

David Roth,1 Annette Bruchfeld,2 Paul Martin,3 David R. Nelson,4 Marcelo Silva,5 Howard Monsour,1 Laurent Alric,4 Shuyan Wan,1 Beth Jackson,1 Bach-Yen Nguyen,1 Janice Wahl,4 Elia1,2 Wayne L. Greaves,7 Univ of Miami, Miami, FL; Karolinska Inst, Stockholm, Sweden; 3Univ of Florida, Gainesville, FL; Hospital Univ Austral, Pilar, Buenos Aires, Argentina; 4Houston Methodist Hospital, Houston, TX; 5Hôpital de Purpan, Toulouse, France; 6Merck & Co., Inc., Kenilworth, NJ.

Background: Limited options are available for treating HCV infection in patients with advanced kidney disease. C-SURFER is the first randomized, placebo-controlled phase 3 study to evaluate an all-oral, ribavirin-free regimen in CKD 4/5 patients.

Methods: 224 patients with HCV genotype (G)1 and CKD 4/5 ± hemodialysis (HD) were randomized to GZR/EBR 100/50mg (Immediate Treatment Group, ITG; n=111) or placebo for 12 weeks. Placebo subjects (deferred treatment group, DTG; n=113) received GZR/EBR after placebo therapy. 11 additional subjects received GZR/EBR with intensive pharmacokinetic (PK) sampling. The primary safety comparison was GZR/EBR vs. placebo. The primary efficacy endpoint, sustained virologic response (SVR) 12 weeks post-therapy in the ITG+PK group, was reported previously. Here we report the final results, including data from subjects who received GZR/EBR after placebo.

Results: In the placebo-controlled phase, serious adverse events (AES) occurred in 16 (14%) GZR/EBR and 17 (15%) placebo subjects; discontinuation due to an AE in GZR/EBR and placebo subjects was 0% and 4%, respectively. SVR12 in GZR/EBR and placebo subjects was 96.0% (ITG+PK; 94.3% [95%CI 91.8-96.9], DTG after placebo. 95.0% [96.0%]). 12 subjects failed to attain SVR12: virologic relapse, n=3; discontinuation for AE, n=1; admin reason, n=8. Excluding subjects who discontinued for reasons unrelated to study drug, overall SVR12 was 98.6% (211/214). PK data indicate no need for dose adjustment in HD patients (geometric mean ratio [HD/ND] ranged from 0.67-0.85 for GZR and 1.43-1.67 for EBR).

Conclusions: Once-daily GZR/EBR for 12 weeks was highly effective with a low rate of adverse events in patients with advanced kidney disease and HCV G1 infection.

Long-Term (52-Week) Efficacy and Safety of ZS-9 in the Treatment of Hyperkaemia: Interim Results From a Phase 3 Open-Label, Multi-Center, Multi-Dose Maintenance Study

James A. Tumin,1 Mikhail Kosiorobod,2 Pablo E. Pergola,3 Wajeh Y. Qunibi,3 David K. Packham,3 Simon D. Roger,3 Edgar V. Lerna,4 Steven Fishbane,5 Henrik S. Rasmussen,2 Bruce S. Spinowitz,6 1U of Texas Medical College of Dallas, Dallas, TX; 2Mayo Lakeview Health, Chicago, IL; 3Multi-Institution, ongoing, open-label study evaluating ZS-9 treatment for 52wks in ambulatory pts with HK (K+ ≥ 5.1 mEq/L) with or without concurrent RAASi therapy. In the acute phase (AP), pts with HK received 10g ZS-9 TID over a 24-72hr period until NK (K+ 3.5-5.0 mEq/L) was achieved. Pts achieving NK were enrolled in a 52wk maintenance phase (MP) starting at 5g ZS-9 QD. There were no restrictions on diet and ZS-9 could be titrated to maintain NK. Primary outcomes were proportion of pts with mean K+ ≤5.1 mEq/L during MP and safety of ZS-9.

Results: To date, 583 pts with a mean baseline K+ of 6.4 mEq/L (15% ≥6.0 mEq/L) entered the study. Overall, 575 (99%) normalized K+ in AP and transitioned to the MP. To date, K+ was maintained at ≤5.1 and ≤5.5 mEq/L in 87% and 99% of patients, respectively. The incidence and severity of adverse events were similar to that of previous studies.

Conclusions: ZS-9 acutely reduced K+ levels in pts with HK and maintained NK for up to 52wks irrespective of RAASi use. ZS-9 may control HK, both emergent and long-term, while allowing continued use of cardio- and renoprotective RAASi.

Interleukin-1 Inhibition and Vascular Function in Patients with Chronic Kidney Disease (CKD): A Randomized Controlled Trial

Kristen L. Nowak,1 Michel Chonchol,2 Talat Alp Ikizler,2 Heather Farmer,1 Natjaie Salas,1 Rafia I. Chaudhry,1 Wei Wang,1 Gerard John Smiths,1 Adriana Hung,2,3 Univ of Colorado Denver; 1Vanderbilt Univ; 2VA Tennessee Valley Healthcare System.

Background: Vascular endothelial dysfunction and increased arterial stiffness contribute to increased cardiovascular risk in CKD patients who exhibit chronic systemic inflammation. As chronic inflammation is a key mechanism contributing to vascular dysfunction, blocking inflammation may reduce cardiovascular risk in CKD.

Methods: In a two-site, double-blind trial, n=42 patients with stage 3-4 CKD were randomized to receive either the interleukin-1 (IL-1) trap rilonacept (subcutaneous injection; loading dose of 320 mg followed by 160 mg/wk) or placebo for 12 weeks. All patients were receiving optimal treatment of hypertension, diabetes, and/or hypercholesterolemia, with 64% and 62% receiving a statin and an ACE inhibitor or ARB, respectively. The co-primary endpoints were change in brachial artery flow-mediated dilation (FMD) and aortic pulse-wave velocity (aPWV) after 4, 8 and 12 weeks using mixed effects models. Secondary endpoints were change in high-sensitivity C-reactive protein (hsCRP), AFMDa, following an acute infusion of ascorbic acid known to inhibit superoxide production, and interleukin-6).

Results: Participants were 63±11 (mean±SD) years of age, 24% female and 24% Black, with eGFR 38±13 ml/min/1.73m2. Rilonacept improved FMDa (baseline: 3.8±3.1%, 12 wks: 4.9±3.2%) compared to placebo (baseline: 3.4±2.1%, 12 wks: 2.5±2.3% p<0.01), without changing aPWV (p=0.52). Rilonacept also reduced hsCRP levels (baseline: 4.6 (1.9, 8.22) median (interquartile range)); 12 wks: 2.16 (0.96, 7.38) mg/L; p<0.01), and endothelial cell NADPH oxidase expression (p=0.05). Acute infusion of ascorbic acid tended to improve FMDa in the placebo (p=0.07) but not the rilonacept group (p=0.56), indicating reduced vascular oxidative stress. Overall, rilonacept was well tolerated.

Conclusions: 12 weeks of treatment with an IL-1 trap improved FMDa without changing aPWV in patients with stage 3-4 CKD. This was associated with a reduction in systemic inflammation and vascular oxidative stress.

Impact of Vitamin D Supplementation on Endothelial and Vascular Function in Patients with Chronic Kidney Disease: A Randomized, Double Blind, Placebo-Controlled Trial

Vivek Kumar,1 Ashok Kumar Yadav,1 Vinod Sharma,2 Manphool Singh1, Anupam Lal,1 Debashis Banerjee,1 Vivekanand Jha,1 Nephrology, Postgraduate Inst of Medical Education and Research, Chandigarh, Chandigarh, India; 2Radiodiagnosis, Postgraduate Inst of Medical Education and Research, Chandigarh, Chandigarh, India; 3Nephrology, St. George’s Univ Hospitals NHS Foundation Trust, London, London, United Kingdom.

Background: Vitamin D deficiency is associated with mortality in CKD patients. We investigated the effect of Vitamin D supplementation on endothelial and vascular function in patients with non-diabetic CKD stage 3-4.

Methods: In a prospective, randomized, double blind, placebo-controlled trial, 120 patients with non-diabetic CKD stage 3-4 and vitamin D deficiency [serum 25(OH)D <20ng/ml] aged 18-70 years were randomized (1:1) to receive either two directly observed oral doses of 3000 IU of cholecalciferol at 0 and 8 weeks or matching placebo. The pre-specified primary outcome was 40% change in endothelium dependent brachial artery flow mediated dilatation (FMD) at 16 weeks. Secondary outcome measures included changes in pulse wave velocity (PWV), augmentation index (AI), and serum biomarkers.

Results: Baseline FMD was identical in both arms (7.6±2.24% vs 7.8±2.34%). Intervention arm showed a 21.8±20.6% increase in serum 25(OH)D (+ 24.9 mg/ml, 95% CI: 21.8±28.06, p=0.0001), and the number of subjects meeting the primary endpoint (70% vs 5%, p<0.0001). FMD change was 5.42% (95% CI: 4.44 to 6.40%) in the intervention arm and -0.07% (95% CI, -0.70 to 0.58%) in placebo arm. Intervention led to favorable changes in PWV (-0.94 m/s, 95% CI: -1.30 to -0.58, p<0.0001), E-selectin (-3.68 mg/ml, 95% CI: -8.1 to 0.7 p<0.002), IL-6 (-2.96 to -0.8 p=0.001), FGF-23 (-14.7 pg/ml, 95% CI: -28.5 to -1.9 p=0.036) and 1,25(OH)D3 (+15.5 pg/ml, 95% CI: 5.4 to 25.5, p<0.003). These did not change significantly in the control group. No changes were observed in AI, s-WF and s-CRP in either group.

Conclusions: In non-diabetic patients with stage 3-4 CKD and vitamin D deficiency, vitamin D supplementation leads to improvement in endothelial function, markers of inflammation and arterial stiffness.

Effect of Cholecalciferol versus Calcitriol on Vascular Endothelial Function in CKD: A Randomized Active-Controlled Trial

Jessica B. Kendrick,1,2 Gerard John Smiths,1 Emily Decker,1 Heather Farmer,1 Michel Chonchol,1 Univ of Colorado School of Medicine, Aurora, CO; 2Denver Health Medical Center, Denver, CO.

Background: Epidemiological studies have shown that vitamin D is associated with decreased vascular morbidity and mortality, but direct evidence supporting vitamin D supplementation on patient outcomes in chronic kidney disease (CKD) are lacking. We conducted a prospective, double-blind, randomized trial to determine the effects of oral cholecalciferol vs. calcitriol on vascular endothelial function over 24 weeks in patients with CKD stage 3-4.

Methods: 128 patients with CKD stage 3-4 (estimated GFR 15-44 ml/min/1.73m2) with vitamin D deficiency, defined as serum 25-hydroxyvitamin D level (25(OH)D) <30 ng/ml, were randomly assigned to receive either cholecalciferol (4000 IU daily x 4 weeks then 2000 IU daily x 20 weeks) or calcitriol (0.25 mcg daily x 4 weeks then 0.5 mcg daily x 20 weeks). The primary endpoint was change in brachial artery flow mediated dilatation (FMDa) over 24 weeks. Secondary endpoints included changes in parameters of mineral bone disease and plasma concentrations of inflammatory cytokines (C-reactive protein and interleukin-6).

Results: 115 patients completed the study. The mean (SD) age and eGFR was 58.1±12.4 years and 33.1±10.2 ml/min/1.73m2, respectively. In the cholecalciferol group, mean 25(OH)D levels increased from 22.7±7.5 ng/ml to 33.5±7.9 ng/ml. There was no change in 25(OH)D levels in the calcitriol group. Parathyroid hormone levels decreased significantly in the calcitriol group compared to the cholecalciferol group (p=0.001). At 24 weeks, the change in FMDa did not differ significantly between treatment groups (cholecalciferol group -0.72%, 95% CI -1.97 to 0.54 vs calcitriol group 0.29%, 95% CI -0.72 to 1.29, p=0.44). There was no significant change in C-reactive protein or interleukin-6 concentrations between the two groups. Episodes of hypercalcemia were more frequent in the calcitriol group (n=4) compared with the cholecalciferol group (n=1).

Conclusions: Twenty-four week therapy with calcitriol or cholecalciferol did not improve vascular endothelial function or reduce inflammation in patients with CKD.

SA-PO1106

Vitamin D Receptor Activation and Dietary Sodium Restriction to Reduce Residual Albuminuria in Chronic Kidney Disease  
Martin H. De Borst,1 Charlotte A. Keyzer,1 Fenna van Breda,2 Marc G. Vervoet,2 Gozewijn Dirk Lavernman,3 Marc H. Hemmelder,4 Wilbert M. Janssen,5 Hiddo Jan Lambers Heerspink,3 Stephan J.L. Bakker,1 Gerjan Navis,1 1UMC Groningen; 2VUMc Amsterdam; 3ZGT Almelo; 4MC Leeuwarden; 5Martini Hospital Groningen; Netherlands.

Background: Reduction of residual albuminuria during single-agent RAAS-blockade is associated with improved cardioireal outcomes in CKD. Both vitamin D receptor activators (VDRA) and dietary sodium restriction reduce residual albuminuria. Previous data suggested that sodium restriction is not required for optimal albuminuria reduction by VDRA. We studied the individual and combined effects of paricalcitol and sodium restriction on residual albuminuria during optimally dosed ACEi in CKD.

Methods: In a multi-center, randomized, placebo-controlled cross-over trial, 45 patients with non-diabetic CKD stage 1-3 and residual albuminuria >300 mg/24h despite ramipril 10 mg/d and BP <140/90 mmHg were treated during four 8-week periods with paricalcitol (PARI, 2 µg/day) or placebo (PLAC), each combined with a low (LS, 2.5 gr Na+/-d) or regular sodium (RS, 4 gr Na+)/d diet, in random order. Linear mixed-effect models for repeated measurements were used to determine treatment effect.

Results: In the intention-to-treat analysis, albuminuria was 1.060 [778 to 1.443] (geometric mean [95% CI]) mg/24h during RS+PLAC. During RS+PARI, albuminuria was 990 [755 to 1.299] mg/24h [-12.5% [-26.0% to 26.3%] vs. RS+PLAC, P<0.2]. LS+PLAC reduced albuminuria to 717 [512 to 1.005] mg/24h [-25.4% [-52.6% to -2.3%] vs. RS+PLAC, P<0.001]. LS+PARI provided the strongest albuminuria reduction to 683 [502 to 929] mg/24h [-31.7% [-55.0% to -9.9%], P<0.001 vs. RS+PLAC], although the additional reduction by PARI beyond the effect of LS was non-significant (P=0.6). However, in a per-protocol analysis (≥95% compliance, N=34) PARI did reduce residual albuminuria beyond the effect of LS (P=0.04).

Conclusions: The combination of paricalcitol and moderate dietary sodium restriction provided the strongest reduction of residual albuminuria during optimal ACEi; the effect was mainly driven by sodium restriction. Our findings underline the relevance of sodium restriction, possibly combined with paricalcitol, to optimize albuminuria reduction.

SA-PO1107

Vascular Function and Uric Acid Lowering via Allopurinol in Stage III CKD: Results of a Double-Blinked Randomized Placebo-Controlled Study  
Diana I. Jalal,1 Emily Deckey,1 Loni J. Perrenoud,1 Nina Bispahm,1 Tapan Mehta,1 Gerard John Smits,1 Richard J. Johnson.1 1(Integrative Physiology, UC Boulder, Boulder, CO; University of Toronto, Toronto, Canada; Farmers School of Medicine, 2020 Bayview Ave, Toronto, ON, Canada; The Hospital for Sick Children, 555 University Ave, Toronto, ON, Canada; St. Joseph’s Healthcare, 250 Stanley Ave, Hamilton, ON, Canada; and the University of Toronto, Toronto, Canada.

Background: Observational studies suggest that asymptomatic hyperuricemia associates with vascular disease in chronic kidney disease (CKD). A recent study suggested that lowering serum urate with allopurinol improves endothelial function in elderly adults with stage III CKD. It remains unknown if lowering serum urate improves endothelial function in adult subjects with stage III CKD. Methods: 80 adult subjects (18-70 years of age with stage III CKD and asymptomatic hyperuricemia (>7 mg/dL in men and ≥6 mg/dL in women) were randomized to receive placebo or allopurinol (100 mg) tablets for 12 weeks. The study was double-blinded and subjects were instructed to take 1 tablet for 1 week, 2 tablets for another week, and 3 tablets thereafter. Changes (from baseline) between both groups were compared by Wilcoxon rank-sum test.

Results: No significant differences existed between both groups at baseline. After 12 weeks, allopurinol lowered serum urate significantly. FMD increased in the allopurinol group compared to placebo; but this was not statistically significant. NMD increased with allopurinol but decreased with placebo; p value = 0.14. These data are shown in Table 1. There were no significant differences between allopurinol and placebo for systolic or diastolic blood pressure, markers of inflammation, or markers of oxidative stress. 10 subjects withdrew from the study. A few adverse events were noted in both groups including 1 gout attack in each group. 1 subject died during the study due to a cardiac event.

<table>

</tr>
<tr>
<td>NMD (% change)</td>
<td>-1.29 (5.33)</td>
<td>0.93 (6.05)</td>
<td>0.14</td>
</tr>
</tbody>
</table>

Conclusions: Allopurinol effectively and safely lowered serum urate in adult subjects with stage III CKD and asymptomatic hyperuricemia but this did not improve endothelial function significantly. There was tendency towards improved NMD suggesting that hyperuricemia may negatively impact vascular smooth muscle function in stage III CKD.

Vadadustat, a Novel Oral Treatment for Anemia of Chronic Kidney Disease, Maintains Stable Hemoglobin Levels in Dialysis Patients Converting from Erythropoiesis-Stimulating Agents

Methods: A multi-center, open-label, 16-week trial was designed to assess Hb response, safety, and tolerability of vadadustat. The trial enrolled 94 hemodialysis patients (Hb 9 - 12 g/dL), who were maintained on erythropoiesis-stimulating agents (ESAs) prior to study entry. Patients were converted from ESA to vadadustat, and assigned to 1 of 3 dose cohorts: 300 mg once daily (QD); 450 mg QD, or 450 mg three times weekly (TIW). The primary efficacy analysis was to evaluate mean Hb changes from baseline at weeks 7/8, and weeks 15/16. From week 8, dose could be adjusted as needed to maintain Hb. All patients were maintained on stable hemoglobin levels in dialysis patients across the 3 cohorts. Serious adverse events have been reported.

Results: Vadadustat safely and effectively maintained Hb levels in dialysis patients who were converted from injectable ESAs.

Conclusions: Vadadustat, a novel, oral agent that stimulates erthropoiesis by stabilizing hypoxia-inducible factor (HIF). Prior studies in patients with Non-Dialysis Dependent Chronic Kidney Disease (NDD-CKD) have shown that vadadustat results in controlled, dose-dependent increases in hemoglobin (Hb) and enhances iron mobilization and utilization. Here we present data from a Phase 2 trial of vadadustat in hemodialysis patients.

Mean Hb levels (g/dL) in Modified Intent-To-Treat (MITT) population

One subject in the 300mg QD cohort had a single Hb excursion to 13.1 g/dL. Adverse events were balanced across the 3 cohorts. Serious adverse events (SAEs) were reported in 13 subjects (13.8%), which was within the expected range (13 - 17 subjects). No drug-related SAEs, nor deaths, were reported.

Autologous Erythropoietin Production by the TARGT Gene Therapy Platform Maintains Stable Hb for 6-12 Month in ESRD Patients without the Need for ESA Administration

Background: Recombinant human erythropoietin (rHuEPO) administration to iron replete patients corrects anemia in most patients with ESRD, but doses result in supra-physiological peak serum concentration (Cmax) of EPO that may cause thromboembolic complications. The Transduced Autologous Restorative Gene Therapy system (TARGT™) is an ex-vivo gene therapy, providing autologous, continuous protein therapies at physiological ranges that was used encoding for the human erythropoietin gene (TARGT™) for these studies. Patient dermal tissue biopsies (MOs) are transduced with a Helper-Dependent Adenoviral Vector containing the EPO gene and then re-implemented subcutaneously to deliver the required EPO dose.

Methods: We present initial data from 2 ongoing open label ascending dose studies of TARGT™ in patients with anemia due to CKD undergoing either Hemo or Peritoneal Dialysis.

Results: Thus far 14 patients were enrolled in all protocols. Follow up is ongoing with the first implanted patient being followed with stable EPO secretion and stable Hb for over 14 months from a single implantation without the need for rHuEPO or blood transfusion. Results obtained suggest that treatment with TARGT™ stabilize serum EPO levels at the physiological range of 20 mIU/ml resulting in Hb levels between 9-12 g/dL. Comparative analysis of serum EPO levels revealed significantly lower Cmax with TARGT™ compared to rHuEPO and an order of magnitude less overall EPO exposure as calculated by Area Under the Curve which may confer significant clinical benefit. No treatment related serious adverse events have been reported.

Conclusions: TARGT™ is a promising novel therapy for the treatment of anemia of CKD and potentially for other protein deficient diseases.

Monitoring in Dialysis (Mid) Study: Exploring the Timeline and Etiology of Increased Arrhythmias in Hemodialysis (HD) Patients

Background: Sudden cardiac death (SCD), likely due to cardiac arrhythmias (CA) is the most important cause of mortality in the HD population. We herein present data on the timeline and potential etiology of CA in HD patients (pts).

Methods: The Mid study (n=66) characterized the type and frequency of CA in 3x/wk HD pts over 6 mths, using an implanted loop recorder (Medtronic Reveal). Reviewer confirmed arrhythmias (RCA;all documented CA) and clinically significant arrhythmias (CSA;brady/asystole/VT/symptomatic), were linked to the dialysis cycle, pt wt and pre/post-session electrolytes, using negative binomial mixed effects regression analyses.

Results: Mean age was 56.3±12.2; 64% diabetic; 70% male; HD vintage 4.3±5.1 yrs. 97% and 67% of pts had a RCA/CSA. Most CA occurred during the intradialytic period of the first weekly HD and then decreased in subsequent sessions. Univariate analyses identified increased pre and post wt, high pre HD potassium (K) and drop in K as risk factors for RCA. Multivariate analyses (adjusted for DM, yrs on HD, pre-wt), identified higher pre HD K levels as a predictor for increased RCA. The highest risk of arrhythmia occurred in pts with high K drops AND substantial volume removal (p=0.03).

Funding: Pharmaceutical Company Support - Akebia Therapeutics Inc., Cambridge, MA, United States
Conclusions: These data establish linkages between intra-diabetic CSA and the long interdialytic period, and also identify a unique interaction between fluid removal and K in the generation of RCA. This suggests for the first time, that future data driving targets of these parameters might reduce CA and potentially SCD in HD pts.

The Occurrence of Cardiac Arrhythmias in Hemodialysis Patients is Linked to the Hemodialysis Procedure and to Electrolyte Abnormalities as Recorded by Implantable Loop Recorders

Christian Combe,1,2 Antoine Benard,1,2 Hélène Savel,1,2 F. Sacher,1,2 1CHU & Univ. Bordeaux, Bordeaux, France; 2Rythmodial Study Group.

Background: Sudden cardiac death (SCD) is the commonest mode of death among hemodialysis (HD) patients. Little is known about the terminal arrhythmic events in these pts. Our objective was to identify mechanisms which may lead to SCD in HD pts using an implantable loop recorder (ILR, Reveal XT®, Medtronic).

Methods: Pts from 9 HD centers have been included in the study. Continuous monitoring of the cardiac rhythm has been performed using the remote monitoring capability of the ILR device (CardiOlink®). Clinical, biological, and technical HD parameters and medications have been recorded for at least 1 year. General joint frailty model for recurrent event data were used to analyze associations between these parameters and the occurrence of cardiac rhythm events.

Results: 72 pts (65 ±8.6 yrs, 52M) have been included. Causes of ESRD were diabetes (n=32) and hypertension (n=19). 22 pts had an ischemic cardiomyopathy. In 8 pts (11%), SCD was recorded (death (n=5), ventricular fibrillation (n=2), and pulseless electrical activity (n=1)). In 7 pts, the event was preceded by a short-lasting (3-10 s) atrial fibrillation (Abbott, Minneapolis, MN; Boston Scientific, Natick, MA; Medtronic, Minneapolis, MN).

Conclusions: Our data show that the various types of arrhythmias and conduction abnormalities occurring in HD pts are linked to different pathophysiological mechanisms. Compared with a central role of serum K+ levels, lower levels (<4 mEq/l or >5 mEq/l) were associated with patient-dependent and HD-dependent variables. In 6 SCD patients, ILR tracings demonstrated progressive bradycardia followed by asystole.

Abstract Withdrawn

SA-PO1115

Comparison of the Efficacy and Safety of Intravenous (IV) Etecloceide (AMG 416) and Oral Cinacalcet (CIN) in Patients on Hemodialysis (HD) with Secondary Hyperparathyroidism (sHPT)

Kevin J. Martin,1 Geoffrey A. Block,2 Sunfa Cheng,3 Bastian Dehnel,2 Reshma Kusalakram,1 David M. Spiegel,1 Hao Wang,1 Glenn Matthew Corthout,1 1St Louis Univ SOM, St. Louis, MO; 2Denver Neph, Denver, CO; 3Amgen; 4Relypsa; Stanford Univ SOM, Palo Alto, CA.

Background: This is a randomized, active controlled, double-blind, double dummy study comparing the efficacy and safety of a novel IV calcimimetic, AMG 416, with CIN. Patients receiving HD with PTH >500 pg/ml, albumin-corrected calcium (cCa) >8.3 mg/dl, and no CIN use for 3 months were randomized 1:1 to AMG 416 IV/oral placebo or oral CIN/IV placebo for 26 weeks (wks). Doses were titrated at wks 5, 9, 13, 17 based on the prior wk’s PTH and cCa. AMG 416 was started at 3mg and titrated by 2.5mg or 5mg up to 15mg 3 times weekly with HD. CIN was started at 30mg and titrated up to 180mg daily target. PTH 100 was 100 mg/dl. Primary endpoint was noninferiority on >30% reduction in PTH during wks 20-26. Secondary endpoints were >50% reduction in PTH (utility analysis), >50% reduction in PTH, mean days of nausea or vomiting (n/v) (patient reported outcome) per wk in the first 8 wks.

Results: 683 subjects were randomized (340 AMG 416, 343 CIN), 553 completed the trial (84% AMG 416, 86% CIN). AMG 416 was noninferior to CIN on the primary endpoint. AMG 416 was superior on >30% reduction in PTH (68% AMG 416, 58% CIN, p=0.004) and >50% reduction in PTH (52% AMG 416, 40% CIN, p=0.001). Mean days of n/v in the first 8 wks did not differ (0.4 AMG 416, 0.3 CIN, NS). The most common adverse event (AE) in either group was blood calcium decreased (69% AMG 416, 60% CIN), mostly mild to moderate severity. Heart failure related AEs were reported in 10 (3.0%) AMG 416 subjects and 0 (0.6%) CIN subjects, of which 5 and 1, respectively, were serious. 9 (3%) subjects receiving AMG 416 and 8 (2%) receiving CIN had fatal treatment-emergent AEs – all unrelated to study drug.

Conclusions: AMG 416 achieved a >50% and a >30% reduction in PTH in more subjects compared to CIN. Hypocalcemia was seen more often with AMG 416. Nausea and vomiting did not differ. IV AMG 416 is more efficacious than oral CIN for the treatment of sHPT in patients on HD.

A Trial Assessing Use of a Wearable Artificial Kidney (WAK) in Patients Undergoing Maintenance Hemodialysis

Victor Gura,1 Matthew B. Rivara,2 Raj P. Munshi,3 Scott D. Bieber,4 Masoud Beizai,2 Carlos J. Ezon,4 Larry Kessler,2 Jonathan Himmelfarb,2 2Cedars Sinai- UCLA, Los Angeles, CA; 3Univ of Washington, Seattle, WA; 4BLOOD Purification Technologies Inc, Beverly Hills, CA.

Background: Current stationary dialysis machines hinder mobility and limit activities of daily life during dialysis treatments. There is a critical need for new technologies to increase patient autonomy, enhance quality of life, and allow for increased patient rehabilitation.

Methods: This is the first FDA-approved human trial of the WAK, a miniaturized, wearable artificial kidney machine based on dialysate-regenerating sorbent technology (NCT02280005). We aimed to determine the safety and efficacy of the WAK in maintaining euolemia and achieving solute clearance and electrolyte homeostasis over 24 hours.

Results: All patients remained hemodynamically stable, and there were no serious adverse events. Serum electrolytes and hemoglobin remained stable over the treatment period for all subjects. Six out of seven patients ambulated while receiving WAK treatment. Fluid removal was consistent with prescribed ultrafiltration rates. Mean blood flow was 42 ±24 and dialysate flow was 43:±20 ml/min with no laboratory evidence of hemolysis. Mean BUN, creatinine, and phosphorus clearances were 21 ± 13, 20 ± 11, and 22 ± 12 ml/min respectively during the first hour of treatment. In one subject, treatment was discontinued due to clotting after 4 hours. In a second subject, treatment was discontinued due to discoloration of dialysate observed after 10 hours. The trial was stopped after the 7th subject due to device-related malfunctions. These included excessive CO2 bubbles in the dialysate, variable blood and dialysate flows, and tubing leaks during the priming phase. Redesign and re-manufacturing of the WAK prototype will be required prior to additional human studies.

Conclusions: Treatment with the WAK was well tolerated, resulted in effective uremic solute clearance and maintenance of electrolyte and fluid homeostasis. These results serve as proof-of-concept of the WAK as a viable novel dialysis technology.

CR845, A Novel Kappa Opioid Receptor Agonist Reduces Moderate-to-Severe Pruritus and Improves Quality of Life in Chronic Kidney Disease Patients Undergoing Hemodialysis

Robert Spencer,1 Vandana S. Mathur,2 James A. Tumlin,1 Joseph W. Stauffer,3 Frederique Menzaghi,1 1Cara Therapeutics, Inc., Shelton, CT; 2Mather Consulting, San Francisco, CA; 3Univ of Tennessee, Chattanooga, TN.

Background: Approximately 40% of US hemodialysis (HD) patients experience moderate-to-severe itching, which negatively affect their mental and physical health (e.g., sleep loss, depression, higher antibiotic and erythropoietin use and increased mortality). The etiology of this condition is likely multi-factorial, including immune system dysfunction and imbalance of mu/kappa endogenous opioids. CR845 is a novel and well-tolerated kappa opioid receptor (KOR) agonist with limited central nervous system entry, thereby preferentially activating KOR on peripheral neurons and immune cells.

Methods: In this Phase 2 double-blind, randomized (1:1:1), placebo-controlled clinical study, 65 prevalent US HD patients with persistent (≥ 5 months) moderate-to-severe pruritus (baseline VAS ~68 mm, 0=no itch; 100 mm =worst itch) were treated with 1 mcg/kg intravenous CR845 or placebo following each HD session for 2 weeks. Antihistamines were discontinued 1 week prior to the study.

Results: The primary endpoint was VAS (change in worst itch intensity from Baseline to Days 12-15), with a significant difference in itch intensity between placebo and CR845-treated patients (p=0.016). CR845-treated patients had a 50% mean reduction in itch intensity from baseline. The 1st secondary endpoint was also met with a significant improvement in Skindex-10, a validated patient-reported outcome measure of pruritus-related quality of life (p <0.031). Furthermore, a trend for a sleep improvement was observed (SLEEP).

Conclusions: Short-term treatment with CR845 significantly reduced itch intensity and improved quality of life in HD patients with moderate-to-severe pruritus. Thus, CR845 appears to have substantial potential to alleviate the symptoms and consequences of this frequently incapacitating condition for which existing treatments have often provided little or no relief. These data also support the opioid/immune etiology of this condition.

The ASSertID Study: Feasibility Randomised Controlled Trial of Drug Treatment for Depression in Patients on Haemodialysis
Ayan Guirguis,1,2,3 Michael K. Almond,4 Joseph Chilcot,5 Andrew Davenport,5 Clara Day,6 Naomi Finchett,2,3 Karin Friedli,7 Benjamin Spencer,8 David Wellsted,2 Ken Farrington,1,2 1East & North Hertfordshire NHS Trust, United Kingdom; 2University of Hertfordshire, United Kingdom; 3Herfordshire Partnership University NHS Trust, United Kingdom; 4Southend Univ Hospitals NHS Trust, United Kingdom; 5King’s College London, United Kingdom; 6Royal free London NHS Trust, United Kingdom; 7Univ Hospitals Birmingham NHS Trust, United Kingdom.

Background: Major Depressive Disorder (MDD) is common in patients on Haemodialysis (HD) but there is little evidence of benefit from antidepressants. Hence we undertook a multicentre feasibility Randomised Controlled Trial (RCT) of sertraline versus placebo.

Methods: A screening phase identified patients with Beck Depression Inventory (BDI-II) score >16.Those meeting eligibility criteria, underwent psychiatric assessment (MIni International Neuropsychiatric Interview). Consenting patients with mild to moderate MDD and Montgomery-Åsberg Depression Rating Scale (MADRS) score >18 were randomised to sertraline or placebo. Follow-up by study psychiatrist: week 2, month 2, 4 and 6 and monthly by study nurses. Initial dose was 50 mg with titration to 100 mg if required.

Results: Of 1355 patients approached, 715 consented for screening. BDI-II ‘16 was present in 231(32%), 58 (25.1%) were ineligible due to current treatment for MDD. Sixty-three underwent psychiatric assessment. MDD was diagnosed in 37; 30 consented to the RCT (mean age 61 ± 15; 71% male; 60% white). Twenty-one (70%) completed the trial, 8(of 15) on sertraline and 13(of 15) on placebo. Over 6 months, BDI-II and MADRS scores decreased (-17.6 ± 3.3, p <0.01 and -20(11.3 ± 3.1, p <0.01 respectively). There was no reliable difference between the sertraline and placebo groups. Fewer on sertraline completed 6 withdrawals and one death versus 2 withdrawals on placebo [C2=3.97, p=0.046]. There was a trend towards a greater fall in MADRS scores by month 2 on sertraline (effect size 0.37; lower bound >0).

Conclusions: This feasibility study is the largest RCT investigating the use of anti-depressants in HD patients with MDD. Similar significant improvement in MDD occurred over 6 months in both groups. Recovery may have been quicker on sertraline.

SA-PO1119

Randomised Controlled Trial to Determine the Appropriate Time to Initiate Peritoneal Dialysis after Insertion of Catheter to Minimise Complications
Thin M. Han,7 Lakshmanan Jeyaseelan,3 Kavitha Ramanathan,2 Dwarakanath Ranganathan,1 1Renal Dept, Royal Brisbane & Women’s Hospital, Brisbane, Queensland, Australia; 2Renal Dept, Rockhampton Hospital, Rockhampton, Queensland, Australia; 3Dept of Statistics, Christian Medical College, Vellore, India.

Background: The optimal time for the commencement of peritoneal dialysis (PD) after catheter insertion is not well known. If dialysis is started too soon after insertion, dialysate leaks and infection may occur. However by starting PD earlier, morbidity and costs can be reduced through less need for haemodialysis. This is the first randomised controlled trial to determine the safest and shortest interval to commence PD after catheter insertion.

Methods: All consecutive patients undergoing PD catheter insertion at the Royal Brisbane and Women’s Hospital and Rockhampton Hospital from 1st March 2008 to 31st May 2013, and who met the inclusion and exclusion criteria were invited to participate in the study. Participants were randomised to one of three groups. Group 1 (G1) commenced PD within 24h of catheter insertion, group 2 (G2) at two weeks and group 3 (G3) at four weeks after Tenckhoff catheter insertion. The groups were stratified by hospital and the presence of diabetes.

Primary outcomes were the incidence of peritoneal fluid leaks or PD related infection. Secondary outcomes were acid base disturbances; delayed graft function and hospital length of stay.

Results: Forty-nine patients were randomised: 25 to NS and 24 to PL. Baseline characteristics were similar in both groups. The median [IQR] total volume of fluid administered was 6446ml [4807,8075] for NS and 7776ml [5140,9080] for PL (p=0.3). The incidence of hyperkalemia in the first 48 hours postoperatively was higher in the NS group: 20 patients (80%) vs. 12 patients (50%) in the PL group (p=0.04). Sixteen patients (64%) in the NS group required treatment for hyperkalemia compared to 5 patients (21%) in the PL group (p=0.003). The peak serum potassium in the 48 h postoperative period was higher in the NS group (6.1±0.8 vs. 5.4±0.9 mmol, p=0.009). Patients receiving NS were more acidic (pH: 7.32 ±0.06, vs. 7.39 ±0.05, p=0.001) and had higher serum chloride (107 mM vs. 101 mM, p<0.001) at the end of surgery. There were no significant differences in delayed graft function or hospital length of stay.

Conclusions: Deceased donor renal transplant patients that received NS developed hyperchloremic metabolic acidosis with an increased incidence of hyperkalemia when compared to PL. This study supports the use of acetate buffered crystalloid solutions for peroperative fluid management in patients undergoing deceased donor renal transplantation.

Marks,9 Hôpital Saint-Louis, Paris, France; 2Hôpital St-Louis, Paris, France; 3Metropolitan; 4Alexion Pharmaceuticals, Inc., Cheshire, CT; 5The International Eculizumab Transplant Study Group.

Background: Complement activation by preformedDSA is the major mechanism of acute antibody-mediated rejection (aAMR) in sensitized, kidney transplant recipients (SKTR). In a previous interim study report, the CS inhibitor eculizumab (Ec) appeared effective in preventing aAMR in deceased donor (DD) SKTR compared to historical controls. We now report 12-mo efficacy and safety data from a Sept 2015 update of this ongoing, open-label, single-centre trial.

Methods: SKTR defined as current DSA>3000MFI detected by SAB; or B- or T-cell flow cytometric crossmatch >/=300 and </=500 mean channel shift; or historical positive complement-dependent cytotoxicity crossmatch to donor HLA. All recipients received Ec 1200mg postoperative day (POD) 0 prior to reperfusion. 900mg on POD 1, 7, 14, and 28, and 1200mg at wks 5, 7, and 9. Recipients received Rabbit ATG for induction and corticosteroids, tacrolimus, and mycophenolate for maintenance immunosuppression. Plasmapheresis was not allowed through Post-transplant week 9. The primary composite endpoint was clinically significant, biopsy-proven aAMR grade IIIB (Banff 2007, based on centrally read bx), graft loss, death, or loss to follow-up at 9wks. Graft and patient (pt) survival were estimated by K-M.

Results: 80 pts were transplanted (48 F, 32 M); median age 52y (range, 24–70). 7 of 80 SKTR had aAMR (8.8%) compared to 30% expected for historical controls. 11.80 SKTR met the 9wk composite primary endpoint based on local bx (13.8% [95% CI 7.1–23.3]). Graft survival at 6 and 12mo was 93.7% and 88.7%, respectively; pt survival at 6 and 12mo was 97.4%. SCR levels (mg/dL) at baseline, 1 and 12mo were 7.43 (±2.51), n=79; 1.63 (±0.97), n=76. No safety concerns.

Conclusions: Ec appeared to be effective in reducing aAMR in SKTR. Pt and graft survival and kidney function at 12mo were similar to those expected for non-sensitized KTR. Ec was well tolerated.

Impact of De Novo Donor Specific Antibodies on Graft Outcomes in Kidney Transplant Recipients following Early Switch from Calcineurin Inhibitor to Everolimus: Analysis of the ELEVATE Trial
Johan W. De Fijter, Hallvard Holaas, Patricia M. Lopez, Peter Bernhardt, Zailong Wang, Frans Claas, Wolfgang Arns, Josep M. Cruzado, Markus van der Giet. For the ELEVATE Study Group.

Background: Development of de novo donor specific HLA-antibodies (dnDSA) after kidney transplantation (KTx) is associated with an increased risk of antibody-mediated rejection (AMR) and graft failure. The ELEVATE study evaluated the impact of early conversion from CNIs to everolimus (EVIR) after KTx and prospectively explored the status and development of DNAs.

Methods: In this 24 month (M), multicentre study KTx recipients were randomized at 10–14 weeks post-Tx to convert from CNI to EVIR (n=360; C0 6–10 ng/mL) or continue CNI (n=373; C0, tacrolimus 5–10 ng/mL; ciclosporin 100–250 ng/mL); all received enteric-coated mycophenolate sodium (MPS) ≥ corticosteroids. Blood samples were collected at

baseline, randomization (RND), M12 and M24 or at time of rejection episodes and analysed by Luminex/SAB assay in one central lab. dnDSA was defined by a MFI value ≥500 any time post-RND in patients with MFI <500 at RND. 

Results: Baseline characteristics were comparable between groups. Incidence of preformed DSA (MFI ≥500 at baseline) against HLA class-I or -II was low (table A). Overall, incidence of dnDSA HLA class-I was higher with EVR/MPS treatment vs CNI/ MPS at M12 and M24. The incidence of dnHLA Class-II antibodies was dominated by anti-DQ in the CsA/MPS [lrm]group (table B). No association between de novo (either HLA class-I or -II) antibodies and a diagnosis of AMR or tBPAR was evident in this population up to M24 (table C, D).

Conclusions: Early conversion to EVR at 3M post-Tx did not increase the risk of dnDSA formation vs CNI continuation. Moreover, no association was observed between development of dnDSA and AMR or tBPAR, even with the lowest detection thresholds.

Donor-Derived Cell-Free DNA in Plasma Increases with Rejection and Decreases after Treatment in Kidney Transplant Recipients

Donor-Derived Cell-Free DNA (dd-cfDNA) is an emerging biomarker of acute cellular rejection in organ transplant recipients. The utility of determining plasma levels of dd-cfDNA aimed at diagnosing rejection and evaluating treatment response was assessed in kidney transplant recipients in a longitudinal observational trial.

Methods: Clinical status, biopsy grade (performed in response to elevated serum creatinine) and plasma were collected at 326 routine surveillance visits from 101 patients. Samples from nine patients assigned a biopsy grade I, II or III (NIH criteria) were classified as rejection (R). Samples from seventeen patients assigned a biopsy grade 0 were classified as quiescent (Q). cfDNA extracted from plasma was amplified at targeted SNPs and analyzed using a sensitive and accurate Next Generation Sequencing assay to quantify dd-cfDNA levels without the need to separately genotype the donor. Standard statistical measures of significance were used.

Results: dd-cfDNA levels were significantly higher (p=0.029) in patients with biopsy-confirmed rejection (R, mean 4.23%) compared to quiescent patients (Q, mean 0.96%). Creatinine levels were not significantly different between R and Q patients (p=0.69; mean 4 and 3.1 mg/dL, respectively). Longitudinal sample analysis from 15 patients showed increased dd-cfDNA levels following transplant (mean 2.8%) with reduction to levels below 1% by two weeks post transplantation. In 3 cases with clinically treated biopsy-confirmed rejection and 2 serial samples following the rejection, levels of dd-cfDNA decreased following rejection treatment.

Conclusions: dd-cfDNA shows promise as a biomarker of rejection that may be used for non-invasive surveillance of kidney allograft status and treatment response. The ongoing measurement of cfDNA may allow clinicians to better personalize care and improve patient outcomes.
