Methods: We studied the following six major primary diagnoses: MI, cardiogenic shock, sepsis, stroke, CPR and coma. Effect of age, sex, race, hospitals' profit status and comorbidities were assessed on WOC status. We studied 836563 dialysis patients' admissions, and WOC occurred in 68152 patients.

Results: Male sex, African American and Latino races, smoking, obesity, psychosis and anemia carried lower odds of WOC. Primary diagnoses of CPR, coma, MI, cardiogenic shock, and sepsis; and co-morbidities such as CHF, dementia, HTN, CA, liver disease, paralysis, chronic lung disease, DM, weight loss were associated with higher odds of WOC.

Odds of WOC were increased by approximately 6 % per year of patient age. Teaching hospitals had higher odds while private hospitals carried lower odds of WOC status.

Conclusions: Age, non-profit hospital status, coma, metastatic malignancy and weight loss are the most significant factors associated with WOC among dialysis patients. These prognostic data should be considered while treating such patients.

SA-PO795
Red Cell Distribution Width and Mortality in Incident Hemodialysis Patients Tania VashiThia, Elani Streja, Miklos Zsolt Molnar, Connie Rhee, Steven M. Brunelli, Hamid Moradi, Tae Hee Kim, Vanessa A. Ravel, Melissa SooHoo, Csaba P. Kovesdy, Kamyar Kalantar-Zadeh. 1 UC Irvine; 2UTHSC; 3DaVita Clinical Research.

Background: Red cell distribution width (RDW) is a measure of red blood cell size and variability that is often used as an indicator of iron-deficiency anemia. Although RDW has recently been found to be associated with mortality in the general population, few studies have examined this association in hemodialysis (HD) patients.

Methods: We examined the association of RDW with all-cause mortality in a cohort of 109,675 incident HD patients from a large dialysis organization during 2007-2011 using Cox proportional hazards regression with adjustment for case-mix (demographics, comorbidities covariates) and markers of malnutrition and inflammation (MICS). RDW was divided into 5 categories ≤14.5, 14.5-≤15.5, 15.5-≤16.5, 16.5-≤17.5, and >17.5 %.

Results: The mean age (mean/SD) of the cohort was 63.1 ±15 years old and included 44% females, 58% diabetics, and 31% African Americans. Higher baseline RDW was linearly associated with higher all-cause mortality risk in both unadjusted and fully adjusted models.

Conclusions: Higher RDW is associated with higher mortality risk in HD patients. It is unclear whether RDW is a risk factor for mortality or an epiphenomenon of underlying biological and metabolic imbalances across RDW categories. Further studies are needed to confirm the findings generated from our study and to determine the mechanisms underlying the RDW-mortality association.

SA-PO796
Association of Pre-ESRD Hemoglobin with Early Post-ESRD Mortality Among U.S. Veterans: A Transition of Care in CKD Study Vanessa A. Ravel, 1 Elani Streja, 1 Jennie Jing, 1 Danh V. Nguyen, 1 Csaba P. Kovesdy, 1 Kamyar Kalantar-Zadeh. 1 UC Irvine; 2UTHSC.

Background: Patients with chronic kidney disease (CKD) are often afflicted with anemia. Previous studies have shown that low hemoglobin (HGB) is associated with pre-dialysis mortality in non-dialysis dependent CKD patients, yet the association of HGB levels in the immediate period preceding dialysis (prelude) and early post-dialysis mortality remains unknown. We hypothesized that lower HGB levels are associated with higher post-transition survival in comparison to higher HGB levels.

Methods: We investigated 18,555 US veterans who initiated dialysis between 10/2007-9/2011 and had at least 1 HGB measurement during the 6 month prelude period before dialysis transition. 6 month averaged HGB was used as a continuous predictor of early post-dialysis all-cause mortality occurring in the first 3 months after initiation using restricted cubic spline models and Cox proportional hazard regressions. The models were adjusted for age, gender, race, ethnicity, region and primary cause of ESRD.

Results: The analytic cohort was a mean (SD) age of 68±11 yrs, among whom 30% were African-American, 7% Hispanic and 30% had diabetes as the cause of ESRD. The 6 month prelude HGB average was 10.9±1.6 g/dL. Prelude HGB exhibited a U-shaped association with 3-month post-ESRD all-cause mortality; patients with a 6 month prelude HGB average between 10-11.5 g/dL had better survival, whereas patients with HGB measurements <9 g/dL or ≥13 g/dL had higher mortality (Figure).

Conclusions: Higher RDW is associated with higher mortality risk in HD patients. It is unclear whether RDW is a risk factor for mortality or an epiphenomenon of underlying biological and metabolic imbalances across RDW categories. Further studies are needed to confirm the findings generated from our study and to determine the mechanisms underlying the RDW-mortality association.

Funding: NIDDK Support
ESA dose was initially 3-fold greater in ESAhr than control patients and remained 2-fold greater by the end of study.

The mean of IS plasma levels was 23.9 (10.3 - 100.9) mg/L and CRP 3.1 (1.3 – 8.6) mg/L. Routine laboratory parameters were measured, the total IS plasma levels were quantified with high-performance liquid chromatography (HPLC) and protein C reactive (CRP) levels analyzed by Immunoenzymatic Assay. Statistical analyzes were performed with SPSS version 19.0.

Results: The mean of hemoglobin was 11.0 ± 1.68 g/dL, the mean of IS plasma levels was 23.9 (10.3 - 100.9) mg/L and CRP 3.1 (1.3 – 8.6) mg/ dL. Multivariate linear regression analysis adjusted for age, sex, time on HD, albumin, BMI, CRP revealed that serum hemoglobin (β = -0.62; p = 0.01) was independently and negatively associated with IS levels.

Conclusions: This study provided evidence that IS seems be associate with anemia in HD patients and therapeutic strategies in the clinical care to reduce uremic toxins levels may be effective to management of anemia in HD patients.

Funding: Government Support - Non-U.S.
Initially, mean Hb level was approximately 1 g/dL lower among ESAhir patients and remained 0.4 g/dL lower throughout the study. During follow-up, ESAhir was associated with a greater adjusted risk of mortality vs non-ESAhir (control referent). Incidence rate ratios (95% confidence interval) ranged from 2.24 (1.93-2.60) in the second quarter to 1.48 (1.18-1.84) in the fourth quarter.

Conclusions: Using a contemporarily relevant definition, ESAhir at a single point in time is potently and persistently associated with greater ESA utilization, lower Hb levels, and higher mortality risk.

SA-PO801

Impact of ESAs and Iron on Survival in Hemodialysis Patients: Which Is the Best, Which Is the Worth? Jacques B. Rentroomb,1 Alain Guerinc,2
1Dept of Nephrology, Hôpital de la Pitié, Paris, France; 2Hemodialysis Units, Diaverium, Paris, France.

Background: Appropriate anemia management for Hemodialysis (HD) patients (Pts) is still challenging. Intravenous (IV) iron and erythropoiesis-stimulating agents (ESAs) are the main therapies, with conflicting outcomes. In the unit, Pts were treated over the last seven years, cumulative doses of ESAs (darbepoetin alfa [DA]) converted in µg per session, and IV iron (iron-sucrose [IS]), converted in mg per session, were exactly constantly reported. Survival depending on the cumulative dose of both products and both treatments together was calculated using the Kaplan Meier methodology.

Methods: 300 incident HD Pts (67% male) mean (M) (SD) age at start 59.16 (13.6) years, were treated for 100,430 dialysis sessions [S], receiving all over 1,192,250 µg of DA, and 1,794,050 mg of IS. M Hb level was 11.55(0.77) g/dL, M TSAT 37.18(5.5)%,

Our results suggest that statins may reduce ESAHYPO in HD Pts. Causal inference is limited by the observational design and unmeasured compliance with statin Rx. The applicability of this finding to non-Japanese populations merits further study, as reported statin Rx is low in JDDOPS.

25(OH)D Deficiency Contributes to the Erythropoietin Hyporesponsiveness in Patients on Maintenance Hemodialysis Pu Lei, Daqing Hong, Fei Deng, Li Wang, Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chengdu, Sichuan, China.

Background: The aim of this study was to identify the factors that contribute to erythropoietin hyporesponsiveness in patients on maintenance hemodialysis (MHD).

Methods: demographic data, hemoglobin, dose of erythropoietin, biochemical indicators and other related indicators of 80 MHD patients were collected and analyzed retrospectively. They were followed up for 12 months. Erythropoietin resistance index (ERI) was used to evaluate the response to erythropoietin in patients on MHD. The ERI was calculated dividing the weekly weight-adjusted (kg) dose of EDA (IU) by the hemoglobin level (g/dL). Logistic regression analysis was used to determine the key variables which might be independently associated with erythropoietin hyporesponsiveness in MHD patients.

Results: Mean erythropoietin resistance index (ERI) for the entire study population was 16.12±5.148 per kg/dl. 26% patients were erythropoietin hyporesponsive. Patients were divided into two groups according to ERI: ERI≤25 IU/kg/week/g/dl and ERI>25 IU/kg/week/g/dl. In ERI≤25 IU/kg/week/g/dl cases, the proportion of female gender was higher, hemoglobin and 25(OH)D were significantly lower than that of patients with ERI>25 IU/kg/week/g/dl. In addition, comparing with ERI≤25 IU/kg/week/g/dl patients, body mass index(BMI) and serum cholesterol, serum albumin, and alkaline phosphatase, indicating an independent association between 25(OH)D deficiency and the erythropoietin hyporesponsiveness.

Conclusions: 25(OH)D deficiency is prevalent among HD patients. Female gender and malnutrition are associated with erythropoietin hyporesponsiveness. 25(OH)D deficiency is the main factor risk for erythropoietin hyporesponsiveness. Improving 25(OH)D deficiency and malnutrition may increase the response to erythropoietin treatment in MHD patients.

SA-PO804

Incidental Findings on 15 Fluorodeoxyglucose Positron Emission Tomography Along with Low Dose Computerized Tomography (FDG PET CT) Scans Among Clinically Stable Haemodialysis with Erythropoietin Hyporesponsive Agent (ESA) Hyporesponsiveness in Hemodialysis (HD) Patients: Results from the Japanese Dialysis Outcome and Practice Patterns Study (JDDOPS) Takeshi Hasegawa,1 Junhui Zhao,2 Douglas S. Fuller,3 Yun Li,2 Jarcy Zee,1 Alain Guerin.2
1Dept of Nephrology, Hôpital de la Pitié, Paris, France; 2Hemodialysis Units, Diaverium, Paris, France.

Background: Studies have shown that hyperparathyroidism is a risk factor for ESA resistance in HD patients. However, the role of other factors remains unclear.

Methods: A total of 311 scans were performed in 254 HD patients, with 25% of scans showing pathologic uptake. In those scans, the following findings were recorded: number of scans, age, gender, BMI, calcium, phosphate, albumin, alkaline phosphatase, 25(OH)D, calcium- phosphatemia index, parathormone, and erythropoietin resistance index (ERI).

Conclusions: The findings of this study suggest that factors such as age, gender, BMI, calcium-phosphatemia index, parathormone, and erythropoietin resistance index (ERI) may be associated with ESA resistance in HD patients.

Funding: This study was supported by JDDOPS, a cooperative study group for investigating the practice patterns and outcomes of hemodialysis patients in Japan.
Imaging
Initial Follow up Total
Number of scans 62 49 111
Pathological tracer uptake 20 15 35
Suspected malignancy 9 1 (new) 10
Lang nodule 0 1
Inflammatory / infective lymphadenopathy 4 1 (old)
Colonic polyp (non malignant) 1
Infected renal cyst 1
Infected sebaceous cyst 1
Renal cell carcinoma 1
Papillary carcinoma of thyroid 1
Confirmed malignancy (new) 2 (2) (old) 2
Pathological uptake (other) 11 11 22
Arthropathy 2 2
Sialadenitis 2 1
Access related infection 1 1
Gastric mucosal uptake 2 3
Lang changes 3 2
Lymphadenopathy 0 1
Other 1 1

Conclusions: This observation confirms occult disease burden among this study group which otherwise would have been undetected and may have seriously impacted patient outcome. We recommend that HD patients with ESA-R should be regarded as high risk and further work is needed to devise easily accessible monitoring tools as part of their management.

SA-P0805
Serial Hepcidin Concentrations in Incident and Prevalent Hemodialysis Subjects Relating to ESA Response
1Medicine, Univ of Louisville, Louisville, KY; 2Medicine, Ohio State Univ Columbus, OH; 3Medicine, Univ of Washington, Seattle, WA; 4Roley Rex VA Medical Center, Louisville, KY.

Background: Hepcidin is a key regulator of iron metabolism and alterations in levels may contribute to an apparent erythropoietin (EPO) resistance. The purpose of the current study was to determine the effect of incident vs. prevalent subjects on hepcidin concentrations at a single point in time and serially up to 6 months.

Methods: We collected blood for hepcidin measurement in 257 prevalent and 33 incident hemodialysis subjects from 2 locations (Louisville and Washington). Repeated blood samples were collected for up to 6 months in 66 prevalent and 33 incident subjects. A total of 752 hepcidin measurements were performed. Additionally we collected EPO dose, hemoglobin (HB), TSAT, and Ferritin. Hepcidin-25 peptide was measured by ELA (Bachem Group) and values are reported as ng/ml.

Results: Hepcidin concentrations in Incident subjects were higher (191±141 vs. Prevalent subjects (151±102; p=0.043) and in Females (93; 169±109) vs. Males (n=151; 140±97; p=0.015). There was no difference by Race p=0.948 (African American n=132; 150±106; Caucasian n=95; 151±101; Asian n=10; 154;78; Other n=7, 173;96). Forty five prevalent and 11 incident subjects did not require EPO (EPO naive) for anemia for 6 months prior to Hepcidin measurement. ANOVA of hepcidin by Incident (p=0.018) and EPO naive (p=0.006)showed significant differences (Incident EPO Naive 156±96; Incident EPO 205±161; Prevalent EPO Naive 97±86; Prevalent EPO 164±101). Hepcidin concentrations remained constant in Incident subjects for the first 6 months of dialysis (p=0.913). (Month 1-6; 190, 153, 180, 178, 176, 166).

Conclusions: Differences in Hepcidin concentration exist between Incident and Prevalent hemodialysis subjects as well as Males and Females. Increased Hepcidin concentrations in Incident subjects are maintained for at least the first 6 months in dialysis. Those subjects that are naive to EPO have the lowest Hepcidin concentrations and may provide evidence for the usefulness of Hepcidin as a therapeutic target.

SA-P0806
Female Gender Is Associated with Higher Degree of Erythropoietin Hyposensitivity in Maintenance Hemodialysis Patients Daqing Hong, Fei Deng, Li Wang. Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.

Background: To investigate the difference of erythropoietin hyposensitivity between female and male patients.

Methods: 310 MHD patients (163 male and 147 female) were enrolled with their demographic information, comorbidities, erythropoietin dosage, hemoglobin, dry body weight, ferritin and Kt/V collected between Jan, 2014 and Mar, 2014. ERI was calculated to study the response to erythropoietin treatment. Cox proportional hazards model was used to compare the relationship between gender and erythropoietin hyposensitivity.

Results: The ERI index was higher in female patients than male patients(28.8±16.0 vs. 20.2±12.3 U/kg/week/g/dl; p=0.005). Hb was lower and Kt/V was higher in female patients than in male patients(p=0.05). There were no difference in age, ferritin, and PTH between male and female patients(p=0.05). The mean dosage of erythropoietin was higher in female than in male patients(149±43±692 U vs. 133±51±544U; p=0.05). Patients were divided into 3 groups according to the tertiles of ERI and no difference was found in PTH, ferritin, Kt/V and age among these three groups.

Conclusions: Female hemodialysis patients are associated with higher degree of erythropoietin hyposensitivity. Special attention must be paid to them when treatment strategy is made to treat anaemia.

SA-P0807
Oral Vitamin C Supplementation Reduces Erythropoietin Requirement in Hemodialysis Patients with Functional Iron Deficiency Tanjin Sultan, Maria V. DeVita, Michael F. Michels. Medicine, Lenox Hill Hospital, New York, NY.

Background: Functional iron deficiency (FID) is a major cause of erythropoietin (Epo) hyposensitivity and persistent anemia in dialysis patients. Vitamin C acts as a reducing agent and enhances mobilization of the ferrous form of iron to transferrin thus increasing its bioavailability. High dose intravenous vitamin C has been shown to decrease the Epo requirement and improve hemoglobin levels in previous studies. This route has its downside regarding difficulty of use, higher cost and associations with increased oxalate levels and inflammatory markers. Use of oral vitamin C has been limited due to the concerns of low bioavailability and patients compliance to medication. This study assessed the effect of low dose oral vitamin C on Epo dose requirements in stable hemodialysis patients with functional iron deficiency.

Methods: This prospective study included 22 stable hemodialysis patients with functional iron deficiency defined as transferrin saturation (TsAT) <30 % and ferritin levels of >100 mg/L with Epo requirement of ≤2400 U/HD. Patients received oral vitamin C 250 mg daily for three months. Epo dose was adjusted according to unit protocol depending on the hemoglobin level. Hemoglobin, iron and Tsat levels were recorded monthly. None of these participants received iron or renal vitamin supplementation during the study period.

Results: The mean Epo dose was reduced in fifteen participants by 867±1356 U/HD (p=0.03). In seven responders there was 33 % reduction in Epo dose from their base line. No ill effects of oral vitamin C were observed. Despite adjustment of Epo dose, hemoglobin level was significantly increased from 10.1±0.6 mg/dl to10.7±0.6 mg/dl (p=0.03). There were no significant change in Tsat and ferritin levels.

Conclusions: Daily low dose oral vitamin C supplementation reduced Epo dose requirements in hemodialysis patients with functional iron deficiency. Despite concerns regarding oral vitamin C absorption in dialysis patients this study indicates Vitamin C is well tolerated and effective.

SA-P0808
The Greatly Misunderstood Erythropoietin Resistance Index Yossi Chait, Sahir Kalim, Joseph Horovitz, Christopher V. Hollo, Elizabeth D. Ankers, Michael J. German, Ravil I. Thadhani, UMass; 2WNE Renal & Transplant Assoc; MGH.

Background: The use of erythropoietin stimulating agents (ESA) to treat anemia in end stage renal disease remains controversial due to reported associations with adverse events. Many studies introduce so-called ESA resistance indices (ERIs) to characterize a patient’s resistance to ESA.

Methods: We use retrospective data from a cohort study of incident hemodialysis patients (n=8924). ERI is defined as average weekly erythropoietin (EPO) dose (IU) per kg body weight (EPOwt) per average hemoglobin (Hgb) (g/dl) over a 3-month period. Linear regression was used to describe the relationship between ERI and EPOwt. Logistic (Cox proportional hazards) regression modelled the relationship between 1-year mortality (survival time) and albumin, age, and either ERI or EPOwt.

Results: ERIs were strongly linearly related with EPOwt (r=0.98) but weakly correlated with 1/Hgb (r=0.44). Associations between covariates and mortality based on two logistic regression models differing only by a single covariate, EPOwt or ERI, were almost identical (table 1).

Table 1: Logistic regression of death on covariates albumin, age, and X, where X = log(ERI) (Model A) or X = log(EPOwt) (Model B). OR; odds ratio, Sens; sensitivity, Spec; specificity.

815A
The area under the ROC curve (AUC) was changed by <1% when covariates ERIs or EPOwt were removed from the logistic regression model (AUC = 0.71, sensitivity = 0.66, specificity = 0.65).

Conclusions: ERIs are strongly linearly related to weight-adjusted EPO doses by a “universal” (i.e., not patient specific) formula, hence are merely surrogates of EPO dose. Because their resistance must depend on both the input, (EPO) and its effect (Hg increase over endogenous Hg level), ERIs appear to be a poor marker of resistance. EPO dose itself, even though a statistically significant covariate, does not substantially strengthen the association between mortality and albumin and age as assessed by logistic or Cox regression. Funding: NIDDK Support

SA-PO809
Evaluation of Iron Deposition by MRI in the Heart and Liver in End Stage Renal Disease Patients on Hemodialysis
Rhea Bhargava,1 Ibrahim Saeed,1 Joseph S. Soltys,2 Omkar U. Vaidya.1 1Dep'd of Internal Medicine, Univ of Missouri- Kansas City, Kansas City, MO; 2Dep't of Nephrology and Hypertension, Univ of Missouri- Kansas City, Kansas City, MO. 3Dep't of Cardiovascular Diseases, Mid America Heart Inst, Saint Luke’s Hospital, Kansas City, MO; 4Dep't of Cardiovascular Imaging, Cardiovascular Imaging Technologies, LLC, Kansas City, MO.

Background: Anemia is highly prevalent in patients with chronic kidney disease and its management is one of the key components of treatment in this population. 2011 introduced the bundling system which led to increased use of parenteral iron to treat anemia in this population. There has been significant controversy regarding our current model of iron and whether this leads to iron overload and increased mortality.

Methods: Retrospective evaluation of patients with end-stage renal disease on hemodialysis who had a cardiac MRI for clinical reasons to evaluate for iron deposition in the heart and liver. Exclusion criteria: Porphyria cutanea tarda, chronic liver disease, hemochromatosis, sideroblastic anemia, thalassemia. Inclusion criteria: End stage renal disease and received a cardiac MRI after 3-5 years of hemodialysis.

Results: Average total dose of venofer dose before cardiac MRI was 3500 mg. Average ferritin level: 695 ng/ml. Average iron saturation: 34%. All patients receiving IV iron had hepatic iron deposition. No correlation was seen between ferritin or iron saturation and hepatic iron deposition. A weak relationship was noted between the total iron dose and hepatic iron deposition.

Conclusions: These data suggest that even though we still use iron markers like ferritin and iron saturation for treatment of anemia in ESRD patients, this may not have a correlation with iron deposition in the liver. Significant iron deposition was not noted in the myocardium. MRI can be a useful modality to evaluate iron overload in this population. Large studies are needed to evaluate this issue and to formulate an ideal way of intravenous iron dosing in ESRD patient on hemodialysis.

Achieved Iron Stores and Clinical Safety in a Trial of Ferric Citrate as a Phosphate Binder
Kausik Umanath,1 Barbara A. Greco,2 Molly McFadden,1 Diana I. Jalal,3 Sean D. Barry,3 Simin Goral,3 Mohammed Sika,7 Robert M. Nieccestro,4 Mark Koury,4 Julia Lewis,3 Tom Greene,3 Jamie P. Dwyer,4 The Collaborative study group.1 1Henry Ford Hosp; 2Baystate Med Ctr; 3U of Utah; 4U of Colordo; 5LSU Health; 6U of PA; 7Vanderbilt; 8CSG.

Background: Adequate Fe stores are needed for hematopoiesis in ESRD pts on ESA, but optimal Fe stores assuring efficacy/safety are unknown. PO Fe preparations have been unable to do this. In a multicenter phase 3 RCT we showed ferric citrate (FC) as a Phos binder ↑Fe stores and ↓IV iron/ESA use. We studied subjects’ safety in this trial based on their changes.

Methods: 441 subjects randomized 2:1 to FC or non-Fe-containing active control (AZA). 12-week titration to goal Fe stores with BTAs measured(month 3 and 6 of follow-up) by ELISA. The changes in sKlotho from month 3 to 6 (Δ) and their associations with iron metabolism and hematologic parameters as a function of paricalcitol use were assessed.

Results: A total of 31 patients were evaluated(Group A: 23; Group B: 8). Intact parathyroid hormone(iPTH) levels and ESA doses did not change during the study. Mean sKlotho levels decreased at month 6 compared to month 3 in the whole group of patients(527 ± 474 pg/ml vs 362 ± 302 pg/ml, P<0.001). After adjustment for iPTH and globular sedimentation rate, mean sKlotho levels in the Group A were higher than those observed in the Group B throughout the study(537 versus 401 pg/ml, P=0.005). A sKlotho correlated with Δ serum iron(r:0.42, P=0.020) in the Group A of patients. A cubic regression model showed that Δ sKlotho strongly explained Δ serum iron in these subjects(Fβ: 0.50, R²: 0.64, P=0.001). A sKlotho were also associated with changes in iron supplementation (r:-0.47, P = 0.030) in the Group A. In patients of the Group B, a direct correlation between Δ sKlotho and Δ red blood cell count was found (r=0.73, P=0.030).

Conclusions: Soluble Klotho is associated with iron metabolism in hemodialysis patients. Higher soluble Klotho levels may be a novel beneficial effect of paricalcitol use on renal anemia.

Funding: Private Foundation Support

SA-PO811
Paricalcitol, Klotho and Renal Anemia in Hemodialysis Patients
Miguel Urial Rioles,1 Sheila Cabinell Pelegrin,2 Gonzalo Gomez Marquiez,2 Manuel Luque-Ramirez,3 1Nephrology, Son Espases Univ Hospital, Palma de Mallorca, Islas Baleares, Spain; 2Endocrinology, Ramón y Cajal Univ Hospital, Madrid, Spain.

Background: Low Klotho levels, a protein linked to aging, is associated with an increase in the erytrosis process (programmed red-cell death). Chronic Kidney Disease is considered as a state of Klotho deficiency. We evaluate the association between plasma sKlotho levels with iron and hematologic parameters, and the influence of paricalcitol on this relationship.

Methods: Data were obtained from the MIR-EPO study (EudraCT: 2009-015511-40). Chronic hemodialysis patients were stratified as a function of paricalcitol use (Group A) or not (Group B). Erythropoiesis-stimulating agents (ESA) and iron supplementation were administered in order to maintain hemoglobin(Hb) between 10.5 and 12.0 g/dl and transferrin saturation(TSAT) ≥ 20%. After a 3-month titration period, sKlotho was measured(month 3 and 6 of follow-up) by ELISA. The changes in sKlotho from month 3 to 6 (Δ) and their associations with iron metabolism and hematologic parameters as a function of paricalcitol use were assessed.

Results: A total of 31 patients were evaluated (Group A: 23; Group B: 8). Intact parathyroid hormone (iPTH) levels and ESA doses did not change during the study. We mean sKlotho levels decreased at month 6 compared to month 3 in the whole group of patients (527 ± 474 pg/ml vs 362 ± 302 pg/ml, P<0.001). After adjustment for iPTH and globular sedimentation rate, mean sKlotho levels in the Group A were higher than those observed in the Group B throughout the study (537 versus 401 pg/ml, P=0.005). A sKlotho correlated with Δ serum iron(r:0.42, P=0.020) in the Group A of patients. A cubic regression model showed that Δ sKlotho strongly explained Δ serum iron in these subjects(Fβ: 0.50, R²: 0.64, P=0.001). SA-PO812
Influence of the Paricalcitol on Iron Metabolism in Hemodialysis Patients
Miguel Urial Rioles,1 Juan Rey Valeriano,1 Aina Obrador,2 Manuel Luque-Ramirez,2 1Nephrology, Son Espases Univ Hospital, Palma de Mallorca, Islas Baleares, Spain; 2Endocrinology, Ramón y Cajal Univ Hospital, Madrid, Spain.

Background: Interleukin-6 (IL-6) and hepcidin may play a role in the pathogenesis of iron functional deficiency (IFD). The influence of the Paricalcitol in IFD is not known.

Methods: Data were obtained from the MIR-EPO study(EudraCT:2009-015511-40). Chronic hemodialysis patients were stratified as a function of paricalcitol use (Group A) or not (Group B). Erythropoiesis-stimulating agents (ESA) and iron supplements were administered in order to maintain hemoglobin(Hb) between 10.5 and 12.0 g/dl and transferrin saturation (TSAT%) ≥ 20%. After a 3-month titration period, plasma IL-6 and hepcidin were measured(month 3 and 6 of follow-up) by ELISA. The changes in IL-6 and hepcidin levels from month 3 to 6 (Δ) and their associations with iron metabolism and hematologic parameters as a function of paricalcitol use were assessed.

Results: A total of 31 patients were evaluated (Group A: 23; Group B: 8). Intact parathyroid hormone (iPTH) and ESA doses did not change throughout the study. We found no correlation between ΔIL-6 and ΔHepcidin(r: -0.10, P=0.640). However, ΔIL-6 correlated with ΔTSAT(Δ: -0.40, P=0.030). After adjustment for iPTH and globular sedimentation rate, mean ΔIL-6 levels in Group A were lower than in Group B(Δ: -0.40, P=0.010). IL-6 levels decreased in the whole group of patients throughout the study, but these changes correlated with an increase in serum iron and TSAT only in the Group A. Hepcidin decreased in the whole group of patients throughout the study as well. Correlation between ΔHepcidin
and ΔHembr(-0.49, P=0.010) was found in the whole group of patients. Interestingly, mean hepcidin levels were higher in Group A than in Group B(-0.92 vs -0.94 pg/ml, P=0.050) during the study. In the Group A, ΔHepcidin correlated with ΔHembr(-0.55, P=0.030).

Conclusions: IL-6 and hepcidin are likely related to different iron pools (functional and storage, respectively) since no correlations between their changes were found. Paricalcitol therapy showed an unexpected increase in iron availability for erythropoiesis that might be associated with changes in IL-6 and hepcidin levels.

48 Week Open Label Safety Extension Study with Ferric Citrate Demonstrates Favorable Safety Profile in Subjects Not on Intravenous Iron: A Post-Hoc Analysis

Background: Ferric citrate (FC) is an iron-based phosphate binder approved for the control of serum phosphorus levels in patients with chronic kidney disease on dialysis. The Phase 3 pivotal trial in subjects with ESRD demonstrated FC to effectively control serum phosphorus but also significantly increased serum iron parameters. This 48-week open label extension study to the Phase 3 pivotal trial was conducted to demonstrate long-term safety of ferric citrate. The primary data have been reported previously.

Methods: Subjects from the pivotal FC RCT (NCT01191255) who completed the active control period and, if eligible, the placebo control period were eligible to enroll in the safety extension trial. 79% had a time lag between participation in the RCT and this trial. The primary outcome was safety as assessed by lab data and adverse events (AE): 168 subjects enrolled. 166 received a dose of FC. The data presented are a post-hoc analysis of 98 of the 166 subjects that did not receive IV iron for the duration of the 48-week trial. Safety data regarding changes in serum iron parameters and treatment emergent AEs by system organ class are presented.

Results: Of the 98 subjects included in this analysis, 71 subjects were randomized to FC in the previous Phase 3 trial and 27 to the AC group. Table below shows the changes in TSAT and serum ferritin over the 48 wk period. Data presented as mean (SD).

83% of subjects experienced at least one treatment emergent adverse event with the most common being gastrointestinal disorders (40%) and infections and infestations (37%).

Conclusions: Subjects receiving ferric citrate and no IV iron demonstrated serum phosphorus control over the 48 wk study period, and an increase in TSAT and serum ferritin. The increase in TSAT did not exceed 45% in subjects receiving ferric citrate and no IV iron, which might suggest that ferric citrate is absorbed but the risk of excessive iron absorption is low.

Iron Isomaltoside: A Novel Intravenous Iron Preparation for Hemodialysis

David Jackson, Christopher Brown, Grant Sugiuara, Rachel S. Ashcroft, Ashraf I. Mikhail. Nephrology, ABM Univ Health Board, United Kingdom.

Background: Diferric® (iron isomaltoside) is newly licensed in Europe for iron deficiency anaemia in CKD patients on dialysis. It is thought the controlled-release matrix minimises free iron, possibly reducing side effects. Little is known about the efficacy & safety of Diferric in clinical practice. This study aims to assess the impact of this novel formulation on anemia parameters in prevalent hemodialysis (HD) patients previously maintained on iron sucrose.

Methods: Data was collected for 13 months; 6 month pre-switch (iron sucrose), 1 month crossover, & 6 month post-switch (iron isomaltoside). All patients received dialysis for ≥ 3 months before evaluation, excluding potential bias of iron loading doses. For both preparations, patients received intradialytic bolus doses of 100mg at frequencies dependant on individual requirements as per current practice.

The percentage of patients maintaining Hb target (100-120g/L) was 71% with iron sucrose & 70% with iron isomaltoside. No adverse drug reactions were observed. No metallic tastes were reported with Diferric administration. The CRP rise during months 1-6 was imported by 2 infections & 1 amputation.

Conclusions: Iron isomaltoside maintains Hb stability & adequate iron status in HD patients when incorporated into current practice. While these data suggest Diferric may reduce ESA & iron requirements, further analyses are necessary to validate these findings. Whether the potential to reduce labile iron with iron isomaltoside impacts on clinical outcomes is yet to be determined.

Low Iron Availability May Influence on Second Patency Rates of Vascular Access in Patients on Hemodialysis

Yukiko Hasuake, Wataru Fukao, Takeshi Nakanishi. Div of Kidney and Dialysis, Dept of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.

Background: Vascular access (VA) is essential for the patients on HD. However, VA failure is often occurred even after percutaneous-transluminal angioplasty (PTA). Iron is important for normal vascular physiology, and insufficient iron availability can lead to various vascular dysfunction. The purpose of this study was to examine the factors affecting VA patency after PTA, including iron availability and oxidative stress.

Methods: Blood samples were taken from 281 HD patients at the PTA. Routine blood chemistry and factors related to iron metabolism (transferrin saturation rate (TST), ferritin), oxidative stress (advanced oxidation protein products (AOPP), 8OHdG, GSH/GSSG), and inflammation (high-sensitive CRP, interleukin-6, tumor necrosis factor-a, pentaxin-3) were measured. The end point of study was the re-vascularization or re-operation of VA during the observation period after PTA. Cox proportional hazards models for the end point was used.

Results: 133 patients (47.3%) had native arteriovenous fistula. During follow-up period, re-vascularization was performed in 34 patients and re-operation in 31 patients. The patients with VA failure had higher numbers of leukocytes and platelet, significantly lower TST, and a tendency of higher AOPP compared with the patients without VA failure. There was no significant difference in other factors between the patients with and without VA failure. The Kaplan-Meier analysis showed lower TST (-20%) was associated with VA failure (p=0.0010, (figure 1)).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
PTA. Low Iron availability might affect the second patency rates of VA.

Analysis of Phase 2 and 3 Studies
Triferic Has a Safety Profile Similar to Placebo: An Integrated Safety

placebo. The safety profile in short and long-term studies supports a favorable benefit-risk

Triferic, administered at each treatment, maintained Hgb and iron balance compared to

access thrombotic events, composite cardiovascular events and systemic or serious

in over 100,000 individual doses of Triferic. Suspected hypersensitivity reactions, vascular

mortality rate in the All Triferic group was 6.5/100 PYE. No deaths occurred during Triferic

for up to 72 weeks.

early Phase 2 studies. Patients randomized to Triferic in the 2 pivotal controlled studies

SA-PO816
Triferic Has a Safety Profile Similar to Placebo: An Integrated Safety Analysis of Phase 2 and 3 Studies

Background: Triferic is a novel soluble iron compound delivered via the dialysate to prevent iron deficiency and maintain hemoglobin in CKD-HD patients.

Methods: The Triferic clinical program included 3 large placebo-controlled efficacy studies lasting 36 to 48 weeks (Controlled Studies), one large placebo-controlled short-term safety study, 3 open-label (OL) safety studies of up to 48 weeks, and 3 small controlled early Phase 2 studies. Patients randomized to Triferic in the 2 pivotal controlled studies who completed the randomized treatment and transitioned to the OL study received Triferic for up to 72 weeks.

Results: Exposure-adjusted most frequent adverse event rates (AE) are presented in the table below.

<table>
<thead>
<tr>
<th>Adverse Events</th>
<th>Controlled Studies</th>
<th>Placebo</th>
<th>All Triferic</th>
</tr>
</thead>
<tbody>
<tr>
<td>Subjects (N)</td>
<td>Triferic</td>
<td>Placebo</td>

<td>345</td>
<td>1411</td>
</tr>
<tr>
<td>Total TEAE (N)</td>
<td>2089</td>
<td>2081</td>
<td>1076</td>
</tr>
</tbody>
</table>

Table: TEAE rates per 100 Patient-Years of Exposure

Procedural hypotension 291.5 290.6 226.6
AVF Site Complication 35.3 39.1 39.7
Headache 34.6 21.1 33.2
Nausea 29.6 34.8 36.4
Dizziness 28.3 20.5 28.0
HD-induced Symptom 27.7 25.5 68.1
Cough 26.4 18.0 17.2
Diarrhea 25.8 31.1 33.0
Muscle Spasms 22.7 26.7 19.6

Discontinuations and exposure-adjusted AE were similar to placebo in the controlled studies with no increase in the OL studies. The exposure-adjusted mortality rate in the Controlled Triferic group was 7.9/100 PYE, compared to 7.2/100 PYE in placebo. The mortality rate in the All Triferic group was 6.5/100 PYE. No deaths occurred during Triferic administration and none were attributed to Triferic. There were no reports of anaphylaxis in over 100,000 individual doses of Triferic. Suspected hypersensitivity reactions, vascular access thrombotic events, composite cardiovascular events and systemic or serious infections were also similar between the Triferic and placebo groups.

Conclusions: Triferic was well tolerated in long-term controlled and OL studies. Triferic, administered at each treatment, maintained Hgb and iron balance compared to placebo. The safety profile in short and long-term studies supports a favorable benefit-risk profile for use as a maintenance iron therapy for CKD-HD patients.

Proton Pump Inhibitors and CYPC219 Are Associated with Iron-Deficiency Anemia in Hemodialysis Patients: A Cross-Sectional Study
Akihiko Nakashima,1 Ichiro Ohikido,1 Keitaro Yokoyama,1 Mitsuyoshi Urashima,2 Takashi Yokoi.1
1Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan; 2Div of Molecular Epidemiology, Jikei Univ School of Medicine, Tokyo, Japan.

Background: Hyporesponsiveness to erythropoiesis stimulating agents (ESA) is an important phenomenon in dialysis patients. As chronic proton pump inhibitor (PPI) use reduces gastric acid secretion, it seems possible that chronic PPI use might lead to iron malabsorption and anemia. In addition, PPI is mainly metabolized by cytochrome P450 (CYP) enzymes, particularly CYPC219, in the liver. The genotypes of CYPC219 affect the pharmacokinetics and pharmacodynamics of PPI. However, there is no study investigating the relationship between PPI use and anemia status that includes the effect of CYPC219 genotype in hemodialysis patients.

Methods: This cross-sectional cohort study analyzed 1350 hemodialysis patients. DNA was isolated from leukocytes in peripheral blood. We used polymerase chain reactions and direct sequencing to analyze CYPC219 genotypes. We analyzed anemia status with and without PPI usage, including the association with CYPC219 genotypes.

Results: PPI use was associated with a significantly lower mean serum hemoglobin concentration. Iron and TSAT were also lower in PPI users. ESA dosage was significantly higher in patients receiving PPIs(mean [SD] PPI: 3685 [3288] IU/week; non-PPI: 2899 [2734] IU/week; P=0.001), and multiple regression analysis indicated a significant relationship between PPI use and ESA dosage(β: 494.1 P<0.001). CYPC219 genotypes were significantly associated with iron status and anemia. Multiple regression analysis demonstrated that CYPC219 poor metabolizer (PM) type was significantly associated with ESA dosage in PPI users (β: 903.1 P=0.036).

Conclusions: In this study, we found that PPI use is associated with iron status and anemia in hemodialysis patients. Among the dialysis patients receiving PPIs, CYPC219 genotype was associated with hemoglobin levels, ESA dosage, and iron status.

A 4-Week Dose Response Study of the Hypeoxia Inducible Factor-Prolyl Hydroxylase Inhibitor GSK1278863 in Japanese Anemic Hemodialysis Subjects
Yukihiro Endo,1 Tomoko Kohno,1 Yukiko Imai,1 Natsumi Kawase,1 Katsutoshi Hara,1 John J. Lepore,2 Alexander Ralph Cobitz.2 GlaxoSmithKline, Tokyo, Japan; GlaxoSmithKline, King of Prussia, PA.

Background: Hypeoxia inducible factor (HIF)-prolyl hydroxylase inhibitors, such as GSK1278863, are an emerging class of oral agents for treatment of anemia associated with chronic kidney disease (CKD). Dose response of GSK1278863 for anemia correction in Japanese hemodialysis-dependent (HDD) subjects is reported.

Method: We evaluated the relationship between GSK1278863 dose and hemoglobin (Hgb) response in Japanese HDD subjects with anemia of CKD in a 4-week, randomized, double-blind, placebo-controlled study (funded by GlaxoSmithKline). Subjects on thrice weekly hemodialysis for at least 8 weeks and with Hgb of 8.5-10.5 g/dL after stopping their
erythropoiesis stimulating agent for at least 2 weeks were randomized to placebo or to 4 mg, 6 mg, 8 mg and 10 mg CERA 20063 once daily. The primary endpoint was Hgb levels from baseline at Week 4. Other endpoints included circulating levels of erythropoietin (EPO), vascular endothelial growth factor (VEGF) and hepcidin.

**Methods:** Based on the algorithm, the CERA was administered for 1 year to 102 HD patients being treated with rHuEPO. After the 1st year, the algorithm was reviewed, and some cases of fluctuating Hb levels because of terminating and restarting CERA administration were found. Therefore, the algorithm was revised. Consequently, CERA administration was continued for another 2 years. The target Hb level was 10.5–11.0 g/dL, and Hb levels, CERA dosage, Erythropoietin Resistance Index (ERI), and iron dosage administration was continued for another 2 years. The target Hb level was 10.5–11.0 g/dL, and Hb levels, CERA dosage, Erythropoietin Resistance Index (ERI), and iron dosage administration was avoided. Serum ferritin levels gradually decreased from 147.9 ± 85, 88 ± 67, and 67 ± 47 ng/ml in the 1st, 2nd and 3rd years, respectively, and weekly iron dosage decreased from 13 ± 1.5 at the baseline to 11 ± 2.6 and 11 ± 2.4 mg in the 2nd and 3rd years, respectively.

**Conclusions:** Three years of twice-monthly CERA administration, based on the algorithm, could maintain stable Hb levels, improve ERI, and reduce iron dosage. Twice-monthly CERA administration based on the algorithm effectively controlled anemia in HD patients.

**SA-PO820**

**A Three-Year Study of an ESA Treatment Algorithm for Patients with Renal Anemia: Stable Hb Levels Obtained with Twice-Monthly Administration of CERA (Second Report)** Toshihiko Maeha, Shigewada Ogwara. *Internal Medicine, Asao Kidney Clinic, Kawasaki, Japan.

**Background:** Treatment of renal anemia in hemodialysis (HD) patients requires an adequate ESA dosage to maintain stable Hb levels. Guidelines in Japan recommend determining the ESA dosage based on Hb levels measured twice a month. An algorithm for the administration of continuous erythropoietin receptor activator (CERA) has been prepared and implemented to treat patients on HD. The 2-year study results were previously reported during the ASN Kidney Week 2014 (TH-P0 820).

**Methods:** Based on the algorithm, the CERA was administered for 1 year to 102 HD patients being treated with rHuEPO. After the 1st year, the algorithm was reviewed, and some cases of fluctuating Hb levels because of terminating and restarting CERA administration were found. Therefore, the algorithm was revised. Consequently, CERA administration was continued for another 2 years. The target Hb level was 10.5–11.0 g/dL, and Hb levels, CERA dosage, Erythropoietin Resistance Index (ERI), and iron dosage administration was avoided. Serum ferritin levels gradually decreased from 147.9 ± 85, 88 ± 67, and 67 ± 47 ng/ml in the 1st, 2nd and 3rd years, respectively, and weekly iron dosage decreased from 13 ± 1.5 at the baseline to 11 ± 2.6 and 11 ± 2.4 mg in the 2nd and 3rd years, respectively.

**Conclusions:** Three years of twice-monthly CERA administration, based on the algorithm, could maintain stable Hb levels, improve ERI, and reduce iron dosage. Twice-monthly CERA administration based on the algorithm effectively controlled anemia in HD patients.

**SA-PO823**

**Anemia Management in ESRD Patients Admitted to the Hospital** Priyanka Govindan, Arjun V. Sharma. *Dept of Nephrology, Univ of Washington Medical Center, Seattle, WA.

**Background:** Anemia was twice as prevalent in people with CKD (15.4%) as in the general population (7.6%). The prevalence of anemia increased with stage of CKD, from 8.4% at stage 1 to 53.4% at stage 5. Anemia can be managed successfully with appropriate investigations and therapy in the ESRD population. The aim of the study was to see how appropriate the management of anemia was in our hospital in patients on dialysis and to identify areas for improvement.

**Methods:** Selected patients were those with ESRD on hemodialysis and peritoneal dialysis that underwent in-hospital dialysis at the University of Washington Medical Center from July 1st 2014 to Sep 30th 2014. The patients who had been undergoing dialysis for less than 12 weeks were considered to have AKI and were excluded from the analysis. In addition, the patients who underwent dialysis only in the Intensive Care units were excluded. The data was collected from the electronic medical records of the individual patient charts. Gender, Age, Anemia status, Lowest Hemoglobin, Iron panel, Reticulocyte count were noted in addition to treatment with iron, blood transfusions and ESA.

**Results:** A total 145 dialysis patients were identified and 65 of them had both ESRD and anemia. 73.86% of these patients were found to be anemic by KDIGO. Patients in the 66-69 age range had the largest number of anemia with a total of 20 falling in this category. 18 patients had a history of ischemic heart disease and hypercalcemia. The risk factors occurring heart failure included history of IHD, and it was shown that the effects of smoking and history of IHD on prognosis were stronger than the effects of anemia. The evaluation of changes in Hb over time revealed that the low Hb sustained for a long time would increase the risk. In addition, the risk of death was high in the high-dose rHuEPO group suggesting the risk in the low HbEPO response patients.

**Background:** In this study, to evaluate the various outcome factors, the effects of improvement in anemia in patients treated with hemodialysis on the vital prognosis were evaluated focusing on changes after enrollment.

**Methods:** This retrospective study was conducted with 201 outpatients with hemodialysis at our Blood Purification Therapy Center and our other related hemodialysis facilities from March 2005 to February 2007 (24 months, 136 males and 65 females, age: male: 59.4 years old, female: 59.8 years old, overall: 59.5 years old). Using CVD death and hospitalization due to heart failure as outcomes, 2-year risk of CVD death was analyzed by logistic regression model with surviving patients. In addition, to assess anemia, changes over a long time after start of observation were evaluated.

**Results:** The multivariate analysis revealed 3 factors for CVD death risk including smoking history (OR: 9.06 [95%CI: 1.86–44.00, p = 0.006]), history of ischemic heart disease (OR: 3.82 [95%CI: 1.19–12.25, p = 0.024]) and hypercalcemia. (OR: 1.77 [95%CI: 1.00–3.13, p = 0.049]). Similarly, the risk factors for heart failure were smoking (OR: 3.11 [95%CI: 1.78–5.36, p = 0.001]) and history of ischemic heart disease (OR: 5.03 [95%CI: 1.46–17.33, p = 0.010]), and history of ischemic heart disease was the only significant variable in the final step.

**Conclusions:** The factors that influence the risk of CVD death included smoking, history of ischemic heart disease and hypercalcemia. The risk factors occurring heart failure included history of IHD, and it was shown that the effects of smoking and history of IHD on prognosis were stronger than the effects of anemia. The evaluation of changes in Hb over time revealed that the low Hb sustained for a long time would increase the risk. In addition, the risk of death was high in the high-dose rHuEPO group suggesting the risk in the low HbEPO response patients.
SA-PO824
Variability in Hemoglobin (Hb) Levels in Hemodialysis (HD) Patients in the Current Era

David T. Gilbertson, 1 Yan Hu, 1 Yi Ping, 1 Sarb Shergill, 2 Bradley J. Maroni. 2 CDGR/MMRF, 2 Akebia Therapeutics, Inc.

Background: Hb variability in dialysis patients has been characterized using a number of methods. The majority of this work occurred prior to the 2011 change in CMS reimbursement policy and ESA labels. We therefore examined Hb variability and patient demographics from current data and compared the results to those obtained prior to implementation of these policy changes.

Methods: We used CMS ESRD data to define a cohort of chronic HD patients who were alive from Apr 1 through Dec 31, 2012. Using a method from Ebben et al. (CIASN 1:205-1210, 2006), monthly Hb values were categorized as low (L), intermediate (I), and high (H), where L and H were based on monthly Hb values below or above the 25th and 75th percentiles, respectively. Variability was then classified based on the Hb categories during a 6-month period, resulting in 6 categories of variability (see figure legend).

Results: The figure compares the percentage (%) of patients in each Hb variability group in 2004 compared to 2012. The 25th and 75th percentiles in the 2012 data were 10.2 and 11.5. Corresponding 2004 values were 11 and 12.5. Similar % of patients were observed in 2004 and for the LL and LH categories. A higher % of patients was consistently intermediate (I) in 2012 than 2004 (9.5% vs. 6.0%), whereas a larger % was observed for LI and a smaller % for LH. Compared to the overall 2012 cohort, II patients were older (mean=65.2), and LL or HI patients were younger (mean=58.2 and 57.8). LL had the highest % who were black (48.8%).

Conclusions: While Hb levels have decreased during the last few years, Hb variability is still present. The lower % of patients in the LH group is consistent with a narrowing of the overall Hb distribution. Further studies are needed to assess the association of variability with outcomes in the current era.

SA-PO825
Prevalence and Predictors of Naturally Occurring Normal Hemoglobin Concentration in Hemodialysis Patients

Case Western Reserve Univ, Cleveland, OH.

Background: Epidemiological data and clinical observations suggest that erythropoietin producing cells exist even in ESRD kidneys. A small subset of ESRD patients have naturally occurring normal hemoglobin levels, without the use of blood transfusions or erythropoietin stimulating agents (ESA), but limited data exists in this field. The aim of this study was to evaluate the prevalence and predictors of naturally occurring hemoglobin concentration ≥ 12 mg/dL in hemodialysis patients.

Methods: This analysis is a retrospective chart review of ESRD patients receiving hemodialysis at Centers for Dialysis Care in East Cleveland, OH, from April-September 2013. Data collected included demographics, cause of renal disease, co-morbidities, duration of ESRD, dialysis access, indices of dialysis adequacy, systolic blood pressure, hemoglobin level, PTH, albumin, calcium, phosphorus. Multivariable regression models were used to identify independent associations with the outcome of interest.

Results: In this cohort of 449 community dialysis patients, the prevalence of naturally occurring hemoglobin level ≥12 mg/dL, without the use of ESA, was 5.3%, slightly higher than previous reports of around 2%. In unadjusted analyses, compared to ESRD patients with a hemoglobin level <10 mg/dL maintained with the use of ESA, the patients with naturally occurring hemoglobin ≥12 mg/dL were more likely to be younger, male, with an arteriovenous fistula, longer dialysis vintage, lower systolic blood pressure and higher serum albumin level. In adjusted analyses, male sex, serum albumin and systolic blood pressure remained the strongest predictors of naturally occurring higher hemoglobin concentration. Further studies to evaluate the mechanisms underlying these associations, including factors stimulating sites of extrarenal erythropoiesis are warranted.

SA-PO826
Estimation of Pre-Dialysis Hemoglobin Concentration Using the Crit-Line® Monitor

Stephan Thiessen, Hanjie Zhang, Doris H. Fuertinger, Peter Kotanko.

Renal Research Inst, New York, NY.

Background: Pre-dialysis laboratory measurements of hemoglobin (Hb) are generally used for anemia management. In some clinics, bi-weekly or even weekly Hb measurements are performed for this purpose. The Crit-Line® Monitor (CLM) provides Hb non-invasively and continuously during hemodialysis (HD), but initial readings early during HD are systematically lower than pre-HD laboratory values due to hemodilution caused by the priming fluid. We present a method of correcting CLM Hb for hemodilution.

Methods: Pre-HD reference Hb (Hb_Spec) was measured by Spectra East Laboratories. Hb obtained by CLM (Hb_CLM) was averaged between minutes 4 and 6 after start of the HD treatment. The difference between the two (Hb_Spec - Hb_CLM) was estimated as ΔHb = (V_sal * 0.5 * (t_CLM/1.2/2 - V UF)) * Hb_CLM/BV, with V_sal = amount of priming fluid (saline) infused at start of HD, t_crit = time point of Hb_CLM measurement (5 min into HD), t_1/2_sal = plasma half life of infused saline (20 min, adapted from ATC Consensus Statement, 2004), V UF = cumulative ultrafiltration volume up until t_crit, and BV = pre-HD blood volume (obtained by estimating post-HD BV via Nadler equation (using post-HD weight, sex, height), then dividing by end-HD relative blood volume and subtracting V_sal). Corrected Hb_CLM was calculated as Hb corr = Hb_CLM + ΔHb.

Results: 5,731 HD treatments from 952 chronic HD patients in the USA were analyzed. Without correction, Hb_CLM was found to be significantly lower than Hb_Spec by on average 0.425 g/dL (SD 0.59 g/dL). After correction for hemodilution, the difference (Hb corr - Hb_Spec) was reduced to -0.008 g/dL (SD 0.59 g/dL).

Conclusions: When applying a correction for the hemodilution caused by infusion of the priming fluid at the start of HD, the Crit-Line® Hb is nearly identical on average to the pre-HD Hb measured by a reference laboratory. More and more clinics are employing Crit-Line® Monitors for fluid and anemia management. Crit-Line® Hb corrected in this way may be used for anemia management, which could reduce blood draws and costs.

SA-PO827
Hemodialysis (HD) Patients Who Can Maintain Fair Hb Level (>10g/dL) without Iron or Erythropoietin (Epo) Administration Showed Higher Serum Soluble Transferrin Receptors(sTfR) and Normal Epo, Vitamin C (VC) Levels

Noriako Saito, 1 Kazuhide Saito, 1 Tetsuo Morioka, 1 Hisaki Shimada, 1 Kozo Ikazaki, 1 Yutaka Tsuhabata, 1 Shunshu Saka, 1 Shigeru Miyazaki, 2 Nephrology, Shinsaku-en Hospital, Niigata, Japan; 3 Urology, Niigata Univ, Niigata, Japan.

Background: HD patients have severe anemia and their Hb levels were recommended to be maintained at greater than 10g/dL using iron and Epo supplementation. Certain HD patients showed Hb levels over 10g/dL without iron or Epo. We studied erythropoiesis and iron metabolism markers in these patients in order to analyze the background mechanism.

Methods: 21 HD patients who could maintain Hb level at 10g/dL and greater without iron or Epo for more than 3 months(G1) were enrolled in this study. 23 HD patients with Hb level less than 10g/dL without iron or Epo for more than 2 months(G2) and 30 healthy volunteer(GN) were also enrolled as control. Blood samples were collected before HD and Epo, hepcidin(HPC), sTfR, VC and standard hematological parameters were examined. The data are indicated as median(interquartile range).

Results: In G1, ferritin(20(14-36) ng/mL), transferrin saturation(14(8-19)%), HPC(0.7(0.2-5.4) mg/mL) were significantly lower than those in both GN and G2, respectively. The percentage of hypochromic RBCs(%HypHec(2.7(1.3-4.8)%) was higher than those of GN and G2. 2. MCV values were not significantly different in all three groups. 3. sTfR level, a marker of erythropoietic activity, of G1(30(22.1-36.3)nmol/L) was significantly higher than those of GN and G2. 4. Epo level(7(3.5-15.2)µg/mL), reticulocytes(12(9-15)%) and VC(6.8(2.8-23.4)µg/mL) of G1 were not significantly different from those of GN, whereas significantly higher than those of G2, respectively. 5. In G1, negative correlation was revealed between VC and %HypHec(r=-0.473, p=0.048), whereas positive correlation between %HypHec and sTfR(r=0.816, p<0.001). By multivariate analysis, %HypHec was the predictor of sTfR(r=0.834, p<0.001).

Conclusions: HD patients with fair Hb level revealed higher sTfR, %HypHec and normal Epo, MCV, VC and low HPC levels. These results indicated that iron utilization of these patients was upregulated and this may participate in the maintenance of erythropoiesis.

Acute Effects of Erythropoietin Administration on Blood Pressure in Dialysis Patients  
Nawf Hamad Al-Gublan, Kristin M. Corapi, Ishir Bhan.  
Nephrology, Massachusetts General Hospital, Boston, MA.

Background: Erythropoiesis-stimulating agent (ESA) doses are often held in patients with end stage renal disease (ESRD) because of hypertension. However, missed doses may exacerbate anemia of chronic disease. The acute effects of ESA on blood pressure are unknown. We hypothesized that ESA administration during dialysis would not be associated with a significant change in blood pressure.

Methods: With institutional review board approval, we retrospectively reviewed the medical records of 100 hemodialysis patients who were admitted to our hospital between 1/2013-4/2015. All patients in this study were prescribed, and received, ESA’s during dialysis. Patients were excluded if dialyzed in the ICU, received vasopressors, were treated for hypertensive urgency (>180/110 mmHg), initiated on hemodialysis, or only underwent ultrafiltration without dialysis. Blood pressure just prior to and 2 hours after ESA were compared using a paired t-test.

Results: The mean age was 61.6 years (±12.8), 42% were male, 66% were Caucasian, 16% African-American, and 10% Asian. Mean change in blood pressures immediately prior to ESA administration and 2 hours after are summarized.

<table>
<thead>
<tr>
<th>Pre-Dialysis</th>
<th>Just Prior to ESA</th>
<th>2 Hours Post ESA</th>
<th>Mean Change (95% CI)</th>
<th>P= 0.008</th>
</tr>
</thead>
<tbody>
<tr>
<td>SBP</td>
<td>136±25</td>
<td>132±27</td>
<td>-4.5 (1.74)</td>
<td></td>
</tr>
<tr>
<td>DBP</td>
<td>68±11</td>
<td>67±10</td>
<td>-1.2 (0.25)</td>
<td>p= 0.18</td>
</tr>
</tbody>
</table>

No statistically significant increase in SBP or DBP was noted. In fact, we observed a significantly lower SBP 2 hours after ESA dosing. In a subgroup analysis of patients with an SBP > 160 immediately prior to ESA administration, an even greater decrease in SBP was noted 2 hours after ESA compared to a subgroup with an SBP < 160 (p=0.004). No significant relationship existed between dose of ESA and effect on blood pressure (SBP: p=0.52; DBP: p=0.95).

Conclusions: We demonstrated a decrease in systolic blood pressure 2 hours after ESA administration with no significant change in diastolic blood pressure. Withholding EPO during dialysis due to hypertension may be unnecessary.

SA-PO829

Serum Ferritin Predicts Mortality Regardless of Inflammatory and Nutritional Status in Incident Peritoneal Dialysis Patients  
Meivan Wu,1 Kyoung Sook Park,2 Hyung Jung Oh,2 Jung Tak Park,2 Seung Hyeok Han,2 Tae-Hyun Yoo,2 Shin-Wook Kang.1,2 ‘Severance Biomedical Science Inst, Brain Korea 21 PLUS, Yonsei Univ College of Medicine, Seoul, Korea; 1Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Serum ferritin levels have been proposed as a prognostic factor in hemodialysis (HD) patients, due to its close relationship with inflammation and malnutrition. Since iron supplementation methods and factors affecting nutritional status are somewhat different from those of HD patients, the impact of serum ferritin on clinical outcomes was investigated in incident peritoneal dialysis (PD) patients.

Methods: A prospective cohort of 408 PD patients from the Clinical Research Center for End-Stage Renal Disease was selected. Patients were divided into three groups according to tertiles of Ln ferritin concentrations (group 1: <4.69 ng/mL; group 2: 4.69-5.58 ng/mL; group 3: >5.58 ng/mL). Cox proportional hazard analysis was performed to determine the independent prognostic value of serum ferritin levels for all-cause mortality.

Results: The mean age was 51.2±13.2 years and 236 (57.8%) were male. During a median follow-up of 25 months, 46 (11.3%) patients died. Univariate Cox analysis revealed that the mortality risk was significantly higher in group 2 [hazard ratio (HR)=2.65, 95% confidence interval (CI)=1.11-6.34, P= 0.029] and group 3 (HR=3.16, 95% CI=1.33-7.48, P=0.009) compared to group 1. Moreover, multivariate Cox proportional hazard models revealed that Ln ferritin was independently associated with an increased risk of all-cause mortality (per 1 ng/mL increase, HR=1.94, 95% CI=1.31-2.88, P=0.001), even after adjustment for variables representing inflammatory and nutritional status.

Conclusions: Higher serum ferritin level was a significant independent risk factor for all-cause mortality regardless of systemic inflammation and nutritional status. Therefore, determining serum ferritin levels could be a useful marker to predict clinical outcomes in incident PD patients.

SA-PO830

Improving Anemia Therapy in Hemodialysis Patients: Interim Results of a Clinical Audit  
Jain C. Maccogulli,1 Antonio Sousa,2 Carlos Andrade,2 Erika Schümann,1 Thomas Ryzlewicz,2 Franz Ferdinand Becker,4 Amelia Fairburn-Beech,2 William Kilgallon,4 ‘Renal Unit, King’s College Hospital, London, United Kingdom; Fundação Renal Portuguesa, Portalegre, Portugal; 1Via Medis, Riesa, Germany; 2Oxyless Ltd, London, United Kingdom.

Background: An earlier pilot audit (ASN 2013, PUB200) suggested that the use of a novel bloodline (Oxyless), which reduces the contact between blood and air, could improve the efficiency of Erythropoietin Stimulating Agent (ESA) therapy by prolonging red cell survival. The aim of this investigation was to explore this effect in a larger population.

Methods: Patients (n=110; >18 years, HD ≥ 3 months via AV fistulae) entered into a 4-month open label, single crossover audit following a 3 month Run-In. Patients followed control bloodlines (Nikkoso/Gambro) in the crossover phase after treatment with Oxyless. Hemoglobin (Hb) levels, IV iron sucrose and ESA doses were reported.

Results: Data analysis was conducted on 66 patients from two clinics. Twenty six patients dropped out due to transplantation and intercurrent events, death (n=14) and clinic transfers (n=4). Hb was maintained over the Treatment phase (11.22-11.34 g/dL). Mean ESA doses reduced by 34% (p<0.01) at month 8, equal to 1,209 IU/week/patient. IV iron dose did not change significantly during the audit.

Patients of a shorter dialysis vintage (<4 years, n=35) showed a greater reduction in ESA usage (42%, p=0.01) compared with those of a longer vintage (>4 years, n=31, -23%). By month 11 (Crossover) ESA doses increased by 7.9 IU/week/kg; 32% of the reduction seen during Treatment.

Conclusions: The reduction in ESA doses observed during Treatment, and the initial reversal in the Crossover, suggest that this novel bloodline can improve anaemia therapy in HD patients. The audit design increases the confidence in the data validity. These results could have clinical and financial benefits for HD service delivery.

First in Human Feasibility Study Assessing the Tablo™ Hemodialysis System  
Luis E. Morales-Buenrostro,1 Jose Antonio Nino-Cruz,1 Javier Zúñiga-Varga,1 Juan M. Aradivin Tuarte,2 May L. Yau,2 Luis Alvarez,2 1Dialysis Dept, Nefros Investigacion SC, Mexico City, DF, Mexico; 2Outset Medical Inc, San Jose, CA; 3Palo Alto Medical Foundation, Menlo Park, CA.

Background: Self-care, at home or in-center, is a must for patients who want more independence and control, or have geographical or mobility constraints. Widespread adoption of this modality requires an easy to use dialysis machine with real-time water treatment capabilities. We conducted a first in human feasibility study to assess the safety and performance of the TABLO™ Hemodialysis System, that may meet these requirements.

Methods: We enrolled 5 patients receiving hemodialysis 3 times/week, with a well-functioning fistula or high-flow catheter. Primary outcomes of measure were Kt/V and adverse events.

Results: A total of 27 treatments in 5 patients were analyzed. Patients had the following characteristics: 40% female (n=2), mean age of 50 years, weighed 66 kg, height of 160 cm, 40% (n=2) fistula, 60% (n=3) high-flow catheter, average treatment time of 183 minutes, average fluid removal of 0.57 L, 80% (n=4) had an unknown etiology of ESRD, and 20% (n=1) had hypertension. Heparin was administered in 52% of treatments. The average single pool Kt/V was 1.4. One patient had only one treatment and was withdrawn from the study due to commute issues. Subjects were monitored during dialysis treatment by in-center staff, per institutional protocol. Only one interdialytic event, mild headache, was reported. In total, 3 subjects reported cramping (n=6/27 treatments) and 1 had hypotension (n=1/27 treatment). There were no unanticipated adverse events, serious adverse events or deaths in the study.

Conclusions: The TABLO™ Hemodialysis system was safe and showed good performance during treatments with shorter times, minimal fluid removal and heparin utilization. The standards of conventional dialysis were maintained without serious adverse events related to the device. The incorporation of an integrated water treatment module and touchscreen with animated step by step instructions was extremely easy to use. This system will allow self-care access, both in-center and at home, in a larger number of patients.

The Big Red Kidney Bus: Mobile Holiday Dialysis
Peter G. Kerr,1 Lesley Ross,1 Jo M. Fairbairn,2 Anne C. Wilson.2
1Nephrology, Monash Health, Clayton, Vic, Australia; 2Kidney Health Australia, South Melbourne, Vic, Australia.

Background: The availability of hospital based hemodialysis for those wishing to travel is scarce and often results in restricted opportunities for patients on dialysis to have a holiday. The Kidney Health Australia (KHA) and Monash Health (MH) Big Red Kidney Bus Project (BRKB) offers patients the ability to dialyse on the BRKB whilst on holiday at one of a range of Victorian tourist destinations.

Methods: The aim of the BRKB Project is to provide safe, fully staffed mobile haemodialysis care, to enable people, their families and carers to take a break. KHA owns the bus, manages the bookings and markets the BRKB nationally. MH, a regional health care provider oversees the clinical assessment and treatment and provides medical supervision, dialysis nurses and renal technologists.

The BRKB is a modified bus accommodating 3 hemodialysis machines, dialysis chairs and complete water treatment. Typically, holiday dialysis on the BRKB operates across 2 sessions per day, 6 days per week duplicating the dialysis parameters of the patients’ home unit. The bus is driven to and parked at caravan parks around Victoria for 6-week periods, during which time patients may book in for dialysis sessions. Their accommodation is up to them to decide on—with the option of using cabins in the parks or local motels (or their own caravans).

Results: Since its inaugural visit in October 2014, 148 different patients have taken advantage of the BRKB. The bus has visited 6 sites around the State and has site bookings for the next 10 months. Participating holidaymakers were overwhelmingly positive about the service. They found the booking system easy to use. The dialysis service on the bus was delivered to the standard of care experienced at their home units. The professionalism of the nursing staff and friendliness was commended and all participants would recommend the service to others in need of hemodialysis. Most had actively recommended the service to others.

Conclusions: The BRKB is a unique project that provides patients with the opportunity to dialyse on the bus while taking a much-needed holiday.

Patient and Caregiver Values, Beliefs and Experiences when Considering Home Dialysis as a Treatment Option: A Semi-Structured Interview Study
Rachael C. Walker,1 Kirsten Howard,1 Rachael L. Morton,1 Suettonia Palmer,2 Mark R. Marshall,1 Allison Tong.1 1Univ of Sydney; 2Univ of Otago; 3Middlemore Hospital, New Zealand; 4Univ of South Australia.

Background: Home dialysis is associated with higher quality of life and economic benefits to health care systems compared with facility dialysis. However, little is known about the decision-making process of patients when considering home dialysis as a treatment option.

Methods: This semi-structured interview study aimed to describe patient and caregiver values, beliefs and experiences when considering home dialysis, to inform policy and practice strategies that align with patient preferences. We conducted semi-structured interviews with adults with CKD Stage 4-5D (on dialysis <1 year) and their caregivers, treated in 3 nephrology centers in New Zealand. Transcripts were analyzed thematically.

Results: 43 patients (18 pre-dialysis, 13 peritoneal dialysis, 4 home hemodialysis and 9 facility hemodialysis) and 9 caregivers participated. We identified 5 themes related to decision-making when considering home dialysis; lacking decisional power (complexity of information, limited exposure to home dialysis, feeling disempowered, deprived of choice, pressure to choose); sustaining relationships (maintaining cultural involvement, family influence, trusting clinicians, minimizing social isolation); reducing lifestyle disruption (sustaining employment, avoiding relocation, considering additional expenses, seeking flexible schedules, creating free time); gaining confidence in choice (guarantee of safety, depending on professional certainty, reassurance of peers, overcoming fears); and maximizing survival.

Conclusions: Patients feel disempowered when choosing home dialysis and make decisions that sustain their relationships, maintain lifestyle values and maximize survival. Confidence in their modality decision is gained by medical professional and peer support combined with overcoming safety concerns. Pre-dialysis programs that address these patient experiences may support home dialysis as a treatment option.

Funding: Pharmaceutical Company Support - Baxter Clinical Evidence Council research program

SA-PO834
Patient Experiences of Training and Transition to Home Hemodialysis: A Longitudinal Mixed Methods Study
Camilla Sara Hansson,1,2 Jeremy R. Chapman,1 Jonathan C. Craig,1 David C. Harris,1 Lukas K. Kairaitis,1 Mary Ann Nicdao,1 Mary Mikhailian,3 Allison Tong.1 1School of Public Health, The Univ of Sydney, Sydney, NSW, Australia; 2Centre for Kidney Research, The Children’s Hospital at Westmead, Sydney, NSW, Australia; 3Centre for Transplant and Renal Research, Westmead Hospital, Sydney, NSW, Australia.

Background: Home hemodialysis (HD) can offer better survival and quality of life outcomes compared with in-centre HD. However, psychosocial barriers such as fears of needles and medical isolation may limit home HD uptake. This study aims to describe patients’ perspectives on training and transition to home HD, to inform strategies to optimize home HD programs.

Methods: Three semi-structured interviews were conducted prospectively with 20 patients before, during and after home HD training at an Australian renal unit. The CHOICE satisfaction survey was administered during the first and final interview. Transcripts were analyzed thematically.

Results: We identified six themes: persevering despite trepidations (intimidation of machinery, acquiring to fatal risks, reconciling culation fears, dispelling concerns of neglect, tolerating concessions); optimizing learning pathway (practicing problem solving, learning from mistakes, grasping technical complexity, minimizing cognitive overload); developing confidence (believing in own abilities, depending on caregiver partnership, faith in crisis support); interrupted transition momentum (lacking individual attention, language barriers, installation delays, illness and complications, acclimatizing to new conditions); noticing immediate gains (reclaiming normality, satisfying self-sufficiency, personalizing treatment regime); depleting resources and energy (exhaustion, draining financial reserves, imposing caregiver burden). There was no significant change in satisfaction with care after commencing home HD.

Conclusions: Individualized home HD training fosters confidence and competency in patients; however patients may face anxiety and exhaustion with medical responsibilities. Ensuring access to respite, medical assistance, and psychosocial support may alleviate treatment burdens for patients commencing home HD.

Funding: Private Foundation Support

SA-PO835
Incremental Hemodialysis, Residual Kidney Function, and Mortality Risk in Incident Hemodialysis Patients
Yoshitosugu Obi,1 Elani Streja,1 Connie Rhee,1 Vanessa A. Ravel,1 Alpesh Amin,3 Csaba P. Kovessy,2 Rajnish Mehrotra,2 Kamyar Kalantar-Zadeh.1 1UC Irvine; 2UTHSC; 3UW.

Background: We have previously reported that an incremental hemodialysis regimen (e.g., dialysis initiation at twice weekly) was associated with more preserved residual kidney function over a year of dialysis therapy (WCN 2015, Cape Town). Here, we compared survival between the incremental vs. conventional regimen.

Methods: In a longitudinal cohort of 33,277 patients who initiated maintenance hemodialysis over four years (1/2007-12/2010) and survived the first year, 364 patients treated with the incremental regimen were matched to 4,797 patients treated with the conventional regimen on age, gender, race, the use of central venous catheter as blood access, and a history of congestive heart failure at the initiation of dialysis. The incremental hemodialysis regimen was associated with ~20% higher residual renal urea clearance (KRU) and 24-hr urine volume (UV) after 1 year of dialysis initiation. We then examined survival after the first year.

Results: Patients were 69±12 years old, 39% female, 13% non-Hispanic Black, and 64% diabetic. Median KRU and UV were 4.7±2.2 (IQR, 3.2-6.6) mL/min/1.73m2 and 1,150 (IQR, 800-1,650) mL/day, respectively. Baseline KRU and UV modified the association between the incremental regimen and mortality; the incremental regimen was associated with higher mortality in patients with KRU <3.0 mL/min/1.73m2 or UV <600 mL/day, but not in those with higher levels of KRU and UV.

SA-PO836
Seasonal Trends in Dialysis Initiation and Rising Home Dialysis: Results from the USRDS

Hui Liu,1 Yang Jiao,2 Douglas Lehmann,2 Richard Hirth,3 Yi Li,1 Rajiv Saran.1 1Dept of Internal Medicine, Univ of Michigan, Ann Arbor, MI; 2Dept of Biostatistics, Univ of Michigan, Ann Arbor, MI; 3Dept of Health Management and Policy, Univ of Michigan, Ann Arbor, MI.

Background: Motivated by increasing interest in home dialysis and incentive for it in the bundled payment system, we examined incident trends in home dialysis use in the United States Renal Data System (USRDS).

Methods: Using USRDS data (2007-2013), monthly counts of all new ESRD cases in the US, as well as incident home hemodialysis (HHHD) and incident peritoneal dialysis (PD) patients were tracked. Incident HDHD patients were those who started HDHD within 90 days of entry into an ESRD program and incident PD patients who started PD as their initial modality.

Results: In 2013, over 55% of US facilities offered only in-center HD, 24.7% both HD and PD and 13.5% offered HD, PD and HHHD. Figure 1 shows trends in monthly ESRD and PD utilization in the US during 2007-2013. The incidence rate of ESRD has been stable since 2010, but the number of new PD starts has risen steadily since 2009 and has somewhat further accelerated since 2011. Figure 1 also shows a seasonal trend for new ESRD and PD starts: incident ESRD cases tend to peak in the first 3 months of the year, while new PD starts tend to peak by mid-year. Rising HHHD use is evident since 2007, without seasonal variation. A substantial variation in the annual growth rate of PD is notable across the states.

Conclusions: We report steadily rising home dialysis use in the US, both HHHD and PD, since 2007 and 2009, respectively. This rise predates the implementation of the bundled payment system in 2011, although PD use seems to be rising faster since 2011. Research into this seasonality in ESRD incidence and the impact of rising home dialysis use are warranted.

Understanding Barriers to Home-Based and Self-Care In-Center Hemodialysis

May L. You,1 Luis Alvarez,2 Michelle Carver,3 Geoffrey A. Block,2 Glenn Matthew Chertow.4 1Outset Medical, Inc, San Jose, CA; 2Sutter Health, Menlo Park, CA; 3Denver Nephrology, Denver, CO; 4Stanford School of Medicine, Palo Alto, CA.

Background: Despite superior outcomes and lower associated costs, few patients with end stage renal disease undergo selfcare (SC) or home hemodialysis (HHHD). Few studies have examined patient and physician barriers to SC and HHHD and the degree which innovative technology might facilitate adoption.

Methods: We surveyed 250 in-center patients (pts) receiving hemodialysis and 51 board-certified nephrologists to identify key barriers to adoption of SC and HHHD.

Results: Overall, 172 (69%) pts reported that they were “likely” or “very likely” (figure 1) to consider SC hemodialysis if they were properly trained on a new hemodialysis system designed for SC.

Patients that would consider performing self-care on a novel, patient centered hemodialysis system

Nephrologists believed that pts were capable of performing dialysis-relevant tasks, including: weighing themselves (98%), wiping down the chair and machine (84%), clearing alarms during treatment (53%), taking vital signs (46%), and cannulating vascular access (41%), but thought that patients would not be willing to do the same.

SA-PO838

Dialyzer Clearance, Residual Renal Function and Middle Molecule Levels in Daily Dialysis

Christos Argyroplous, Maria-Eleni Roumelioti, Mark L. Uruih. Internal Medicine, Div of Nephrology, UNM-HSC, Albuquerque, NM.

Background: Beta 2 Microglobulin (B2M) has emerged as a predictor of cardiovascular morbidity, mortality and LVH in patients with CKD and ESRD. Daily dialysis leads to higher B2M removal and has been associated with improvements in LVH and mortality in randomized trials. It is not known how B2M levels vary with dialysis membrane clearance (Kd) in daily dialysis regimes.

Methods: We adopted a population kinetic model (PKM) for the intraindividual variability in the generation, distribution and extrarenal removal of B2M (ASN 2014,SA-PO969). We used the PKM to simulate B2M concentrations in patients dialyzed with HF membranes in thrice weekly or daily sessions. For the latter we applied the intervention protocols for Short (SD) and Long Daily (LD) dialysis utilized in the FHN trials. The impact of Kd relative to residual renal function (RRF) on B2M was examined across the three dialysis modalities.

Results: B2M was lower in SD or LD relative to thrice weekly HF dialysis irrespective of RRF, the highest differences from HF (L, 95%CI) was obtained in anuric pts: 7.5, 7.4-7.62 (SD) and LD 17.2, 17.1-17.4 mg/dl. The modelled average B2M relative to Kd is shown:

<table>
<thead>
<tr>
<th>Modality</th>
<th>RRF (ml/min)</th>
<th>ΔB2M (mg/l)</th>
<th>KD (60 v.s 20 ml/min)</th>
<th>LCI</th>
<th>UCI</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
</tr>
<tr>
<td>LD</td>
<td>0</td>
<td>8.6</td>
<td>7.8</td>
<td>9.2</td>
<td></td>
</tr>
</tbody>
</table>

There were significant interactions (p<0.001) between modality and RRF, as well as modality and Kd. A Kd of 60 ml/min resulted in lower B2M in LD and SD v.s. HF patients.

The differences between lower and higher dialyzer clearances were minimal (<1.1 mg/dl) at higher RRF irrespective of modality.

Conclusions: In simulations, higher dialyzer clearance is associated with lower plasma B2M in patients on daily dialysis, especially at lower levels of RRF. Whether these differences translate to improved cardiovascular outcomes should be confirmed in clinical studies.
SA-PO839

Wessex Kidney Centre Experience of Nocturnal Home Haemodialysis Using the NxStage System One Venkat Gangaram, Amanda Jane Laird, Laura Hignell, Natalie L. Borman. Renal Medicine, Wessex Kidney Centre, Queen Alexandria Hospital, Portsmouth, United Kingdom.

Background: Wessex Kidney Centre (WKC) Portsmouth established Home Haemodialysis (HHDD) programme in 2009. In the absence of an in-house technician and limited capital the programme was set up using NxStage system one (NSO). WKC has now established a rapidly growing HHDD programme has been excellent with self reported 97 patients to date including nocturnal therapy.

Results: A total of 18 patients have received NHHD with mean time of 12.3 months (range 1 to 31). All patients dialyse alternate nights processing 40-60 litres using dual needleling access and a single bolus of Enoxaparin Sodium. Patients have regular transonic monitoring of their access and home visits. Two NHHD patients successfully dialyse alone. The mean age is 47.7 years (range 26 to 80), 78% male, 94% Caucasian with mean BMI 26.9. The Access used was AV fistula 56%, AV graft 22% and CVC 22% of patients. 14 patients changed from short daily HHD (SDHHD), 3 patients from in centre Haemodialysis and 1 from Peritoneal dialysis. Laboratory parameters have been favourable as shown below.

Retention has been excellent with one patient returning to in-centre HD after 25 months of HHDD. Two patients switched to SD HHD as it more suited to their lifestyle and 5 patients have been transplanted. Pill burden has reduced, with less or no phosphate binders (mean number of binders reduced from 6 to 2) and a 40 % reduction in antihypertensive medication. Patients experience improvements in quality of life including facilitating return to employment. A number of patients have successfully travelled taking their NHDD both within UK and abroad.

Conclusions: In conclusion, NHDD using NSO is a viable alternative for HHDD patients with our data suggesting good clinical outcomes. Patients have improved quality of life and with less pill burden, flexibility and more opportunity to engage in social activities.

SA-PO840

Current and Future Training of Home Haemodialysis Nurses Ruth Silvertown, 1 Philippa Catherine Brown, 1 Paul Laboi, 1 Nicola Thomas, 2 1Dept of Renal Medicine, York Hospital, United Kingdom; 2School of Health and Social Care, London South Bank Univ, United Kingdom.

Background: The UK National Institute for Health and Care Excellence recommend that >10% of dialysis patients be treated by home haemodialysis (HHDD), however only 4.1% of patients in the UK are undergoing this modality. Success with HHDD can be attributed to a supportive health policy, formal infrastructure, committed individuals and home dialysis experience; providing a patient-centred approach. Lack of nursing expertise is reported as a barrier to home dialysis for 30% of units. A 2010 survey by the Australian HOME network revealed insufficient resources in dialysis units to provide support and education to patients. A potential barrier to HHDD in the UK is specific training for renal nurses on dialysis modality before switching to HHDD (sDHD) and 257 started directly with DHD (dDHD). Before starting DHD, 81% of sDHD patients were in HD 3x/week and 5.4% had <1 modality change. dDHD patients initiated DHD in urgent condition for 57% of them and 92.6% underwent DHD in centre.

Methods: Were included all patients 18 y/o who started DHD between 2003 and 2012 in France. Bioclinical and treatment characteristics were extracted from the French Renal Epidemiology and Information Network (REIN) registry then described and compared by groups using Chi-square tests.

Results: 753 patients were included in the study. According to the median age (64 years), two groups of patients were distinguished: old group (≥64 years) characterized by lots of comorbidities such as diabetes (48% vs 29%, p<0.0001), active malignancy (17% vs 10%, p<0.0001), 1 cardiovascular disease (80% vs 41%, p<0.0001) compared to the younger one (<64 years). At the 31/12/2013, 30.4% of the young patients underwent renal transplantation and 69% of the old ones were died. The main regimen observed was HD 6x/week with sessions’ duration of 3 hours. Among these patients, 496 started with other dialysis modality before switching to DHD (dDHD) and 257 started directly with DHD (dDHD). Before starting DHD, 81% of sDHD patients were in HD 3x/week and 5.4% had <1 modality change. dDHD patients initiated DHD in urgent condition for 57% of them and 92.6% underwent DHD in centre.

Conclusions: DHD in France is addressed both to old patients with lots of comorbidities who died rapidly and to young patients in better medical conditions who accessed more to renal transplantation. DHD regimens are various and depend of patients’ characteristics and previous trajectories.

Daily Hemodialysis in France: Patient’s Characteristics, Trajectories, and Treatment Modalities Adelaide Pladys, 1,2 Sahar Bayat, 1 Cécile Couchois, 1 Cecile M. Vigneau. 1,4 ‘French School of Public Health, Rennes, France; 1Univ Rennes 1, Rennes, France; 1French Biomedicine Agency, Saint Denis La Plaine, France; 4CHU Pontchaillou, Rennes, France.

Background: Increased weekly frequency of hemodialysis (HD) sessions should have positive effects on the control of several biological data of end stage renal disease patients. However, a recent study observed contradicting results in terms of survival compared to previous ones. Patients included in this study came mainly from France where knowledge about daily hemodialysis (DHD) practices is poor. In this context, the aim of this study was to describe the characteristics of French patients in DHD, the treatment modalities and the individual trajectory before starting such a program.

Methods: Were included all patients 18 y/o who started DHD between 2003 and 2012 in France. Bioclinical and treatment characteristics were extracted from the French Renal Epidemiology and Information Network (REIN) registry then described and compared by groups using Chi-square tests.

Results: 753 patients were included in the study. According to the median age (64 years), two groups of patients were distinguished: old group (≥64 years) characterized by lots of comorbidities such as diabetes (48% vs 29%, p<0.0001), active malignancy (17% vs 10%, p<0.0001), 1 cardiovascular disease (80% vs 41%, p<0.0001) compared to the younger one (<64 years). At the 31/12/2013, 30.4% of the young patients underwent renal transplantation and 69% of the old ones were died. The main regimen observed was HD 6x/week with sessions’ duration of 3 hours. Among these patients, 496 started with other dialysis modality before switching to DHD (dDHD) and 257 started directly with DHD (dDHD). Before starting DHD, 81% of sDHD patients were in HD 3x/week and 5.4% had <1 modality change. dDHD patients initiated DHD in urgent condition for 57% of them and 92.6% underwent DHD in centre.

Conclusions: DHD in France is addressed both to old patients with lots of comorbidities who died rapidly and to young patients in better medical conditions who accessed more to renal transplantation. DHD regimens are various and depend of patients’ characteristics and previous trajectories.

In Vivo Urea Removal by Electro-Oxidation in a Wearable Dialysis Device Maarten Wester, 1 Frank Simonis, 2 Diëtzy Hazenbrink, 2 Jaap A. Joles, 1 Karin G. Gerritsen, 1 1Nephrology and Hypertension, Univ Medical Center Utrecht, Utrecht, Netherlands; 2Nanodialysis BV, Oirschot, Netherlands.

Background: In EU consortium NEPHRON+ a wearable dialysis device is being developed that can offer prolonged dialysis by continuous regeneration of a small volume of dialysate. A major challenge is the removal of urea, since the daily urea production is high and removal by adsorption difficult. Electro-oxidation (EO) seems attractive since electrodes are durable, small and inexpensive. Here, we studied in vivo urea removal by EO in a hemodialysis model in goats.

Methods: An EO-unit containing 10 graphite electrodes for EO and sorbent beads for K+ and PO4- removal was incorporated in a dialysate circuit in series with activated carbon (AC;25g/unit). 3 Ampères (A) was applied using 1 EO-unit (1x3A+N=7) or 2 EO-units in parallel (2x3A+N=7). Healthy goats were instrumented with a CVC, heparinized blood was pumped (110mL/min) during 3hrs over a 0.2m2 Polyflux dialyzer and dialysate was recirculated over the EO unit in counter current direction (40mL/min for 1x3A; 2x40mL/min and 2x70mL/min for 2x3A; total dialysate volume 100mL (1 EO-unit) or 150mL (2 EO-units)). Urea was infused to achieve higher urea concentrations.

Results: Urea removal and clearance were 8.4±1.5mmol/h and 11.9±1.6 mL/min, respectively, using 1 EO unit (Fig, A,B) and remained stable during consecutive hours. Use of 2 units in parallel doubled the removal of urea and caused a 1.6-fold increase in urea removal.
clearance. Increase of the dialysate flow did not further increase urea removal. Urea removal was dependent on urea plasma concentrations (R2<0.5). Limited release of ammonia-um was observed (0.1±0.03 mole per removed mole of urea).

Conclusions: By electroplating electrodes combined with AC shows promising urea removal in vivo. Research aimed at increasing the efficacy and biocompatibility testing is warranted.

SA-PO843
Unplanned “Crash” Home Dialysis Starts: Single Center Experience from a University Hospital in the United States Kristen P. Tamura,1 Jose A. Morfin.2 1Nephrology, UC Davis Medical Center, Sacramento, CA; 2Nephrology, UC Davis Medical Center, Sacramento, CA.

Background: There is a high incidence of starting dialysis from the hospital to the in-center unit, and frequently these starts are unplanned and unexpected (“crash”). To this end, we sought to implement an educational program to identify patients suitable for a home dialysis modality, unplanned home hemodialysis (UHHD) and unplanned peritoneal dialysis (UPD).

Methods: We performed an retrospective observational analyses on patients who were started on dialysis from January 2013 to April 2015 in a diverse patient population admitted to UC Davis Medical Center in Sacramento, CA. We devised a systematic and comprehensive screening educational program to provide all modality options. We identified patients suitable UHHD, and UPD, both which were transitioned to a home dialysis training program upon discharge. Clinical characteristics and outcomes were compared to groups who had a standard start home dialysis (SHHD, SPD) during the study period. Our measured outcomes include the following: average training days, interval of technique failure (termination/patient dropout), access status and complications, infections, hospitalizations and mortality in the first 90 days.

Results: Preliminary results reveal the trends tended to have similar demographic profiles with the average age for patients starting an unplanned home hemodialysis 51.5 years of age, 60% non-white race, but with a trend toward more males at 59% compared to standard starts.

Group # Subject Training Days 90 Days Drop Out 180 Days Drop Out % Retention at 12 months

U HHD 9 19.6* 1 02 77.7*
S HHD 27 21.8 3 2 75.7
U PD 10 9.2* 3 0 70.0+
S PD 28 10.5 6 2 71.4

*not statistically sig between UHHD vs SHHD

Conclusions: In this small representative sample, UHHD and UPD was a viable option for programs to consider for the transition of new dialysis patients from the hospital to the outpatient setting. We found similar outcomes in comparison to patients starting home dialysis training in a traditional standard way. Education and screening of home dialysis therapies should be promoted in the hospital setting.

SA-PO844
Quality of Life After 1 Year of Nocturnal Home Hemodialysis Is Comparable to Quality of Life After Renal Transplantation Anna A. Bonenkamp,1 Franka E. van Reekum,1 Marianne C. Verhaar,1 Brigit C. van Haarsveld2 1Nephrology & Hypertension, Univ Medical Center Utrecht, Utrecht, Netherlands; 2Nephrology, VU Univ Medical Center, Amsterdam, Netherlands.

Background: Quality of life (QOL) is an important outcome measure for pts with ESRD. Several studies found improved QOL in Nocturnal Home Hemodialysis (NHHD) compared to conventional HD (CHD). There are no studies comparing QOL in NHHD vs Tx. Therefore, some pts on NHHD hesitate whether or not to apply for a place on the renal transplant (Tx) waiting list. The aim of this study is to assess the difference in QOL between NHHD and Tx after 1 yr of follow up.

Methods: Data were obtained from the ongoing NOCTX-study, which evaluates the 3-yr progression of coronary atherosclerosis in pts treated with CHD, PD, NHHD and Tx. In this study, QOL was measured with the Kidney Disease-QOL SF questionnaire at baseline (<3 mo after start) and after 1 yr in NHDD (n=22; 5:7; cycles 6°6°8°8° HD; all Tx-waitlisted) and Tx (n=30). Composite scores (Physical  PCS, Mental  MCS) and disease related domains were used. One yr results were analyzed with an unpaired t-test.

Results: Pts (n=52) were 50:12 yr, 67% male and median duration of RT was 37:131mo. Baseline characteristics were comparable between the groups. PCS was 46:9 in NHHD and 44:8 in Tx group at baseline; follow up PCS was 44:7 and 47:9 respectively (p=0.15). MCS at baseline was 53:9 vs 53:8 and 50:12 vs 52:9 after 1 yr (NS). Compared to NHHD, Txs pts scored better on the domain ‘Effects of kidney disease’ (75:18 vs 86:14 p=0.01). Sexual function had a remarkably good response rate (90%) and equal scores between NHHD and Tx (69:34 and 75:27 p=0.55). In other KDQOL domains no significance was observed.

Conclusions: This is the first study to compare QOL between Tx-pts and wait-listed NHHD pts. Physical and Mental Composite Scores were similar. In disease specific domains, Tx and NHHD scored not significantly different except for the domain ‘Effects’. These data support an important role for NHHD as an alternative to renal transplantation.

Association of Vascular Access Type with Mortality, Hospitalization, and Transfer to In-Center Hemodialysis in Patients Undergoing Home Hemodialysis Matthew B. Rivara,1 Melissa Sooboo,2 Elani Strelja,3 Miklos Zsolt Molnar,3 Alfred K. Cheung,4 Ronit Katz,5 Onyebuchi A. Arah,6 Allen R. Nissenson,6,7 Jonathan Himmelfarb,5 Kamary Kalantar-Zadeh,7 Rajnish Mehrotra,3 1Kidney Research Institute, Seattle, WA; 2Harald Simon for CR Kidney Dis Research & Epidemiology, Univ of California Irvine Med Ct, Irvine, CA; 3Div of Nephrology, Univ of Tenn Health Science Ct, Memphis, TN; 4Div of Nephrology, Univ of Utah, Salt Lake City, UT; 5Epidemiology, Fielding School of Pub Health, Los Angeles, CA; 6DaVita, Inc., El Segundo, CA; 7David Geffen Sch of Med at UCLA, Los Angeles, CA.

Background: In individuals undergoing in-center hemodialysis (HD), use of central venous catheters (CVCa) is associated with worse clinical outcomes compared to use of arteriovenous access. However, it is unclear whether a similar difference in vascular access type risk is present in patients undergoing home HD, as these patients have higher dialysis treatment frequency and lower rates of exposure to sources of nosocomial infection.

Methods: We examined the associations of vascular access type with all-cause mortality, hospitalization, and transfer to in-center HD in patients who started HD from 2007-2011 in 464 facilities in 43 states in the United States. We analyzed the data using competing-risks hazards regression with vascular access type as the start of home HD as the primary exposure in a propensity score-matched cohort (1052 patients; 526 with CVC, 526 with arteriovenous access).

Results: Compared to arteriovenous access, CVC use was associated with increased risk for mortality (hazard ratio [HR] 1.78; 95% confidence interval [95% CI] 1.21 to 2.61) and hospitalization (HR 1.38; 95% CI 1.19 to 1.59). CVC use was not associated with increased risk for transfer to in-center HD (HR 1.07, 95%CI 0.81 to 1.40). The results of analyses in the entire unmatched cohort (2481 patients), with vascular access type modeled as baseline exposure at start of home HD or as a time-varying exposure, were similar.

Conclusions: In a large nationally representative cohort of home HD patients, CVC use was associated with increased risk for mortality and hospitalization.

SA-PO846
Time to Transplant Associates with Home Dialysis Modality Rita Suri,1,2 Girish E. Neswallah,3 Liaha Li,3 Lakshman Gunaratnam,1 1Centre de Recherche, Centre Hospitalier de l’Univ de Montreal, Univ de Montreal, Montreal, QC, Canada; 2Humber River Hospital, Toronto, ON, Canada; 3Nephrology Division, Western Univ, London, ON, Canada.

Background: We recently showed that prevalent end-stage renal disease patients starting home daily hemodialysis (DHD) have reduced cardiovascular and infection-related hospitalization risk compared to those starting peritoneal dialysis (PD). As current hospitalization precludes being active on the transplant wait-list, we investigated whether DHD patients receiving home DHD would be more likely to be transplanted than those receiving PD.

Methods: We matched 2997 adult starting home daily hemodialysis (DHD) in a single US dialysis provider’s facilities from 2004-2011, to 2997 contemporaneous USRDS patients starting PD in the same US state and contemporaneous ESRD years. Demographics (age, sex, limitations of dialysis codes, and outcomes) were ascertained from USRDS. We used Cox regression stratified on matched sets censoring for death, and computing risk analysis using Fine’s approach for stratified data, to compare times to transplantation between groups.

Results: Baseline variables were balanced between groups after matching, with standardized differences <10%. During 12,558 years of follow-up (mean 2.1±1.4 yrs), 514 DHD and 428 PD patients were transplanted. DHD patients were 19% more likely to be transplanted than PD patients (DHD 8.2 vs PD 6.8 per 100 patient-yrs, HR 1.19, 95%CI 1.05-1.35, p=0.012). Competing risk analysis accounting for death and follow-up losses yielded a HR of 1.18 (95%CI 1.04-1.33, p=0.010). Time to waiting-list did not differ between groups (HR 0.97, 95% CI 0.90-1.06, p=0.54), but once waitlisted, PD patients were significantly more likely to be permanently removed from the wait-list (PD 14.2 vs DHD 10.2%, RR 1.39 (95%CI 1.09-1.78), p=0.008).

Conclusions: In this prevalent cohort, home DHD patients were more likely to be transplanted than matched PD patients, and less likely to be permanently removed from the wait-list during follow-up. Mean times to wait-listing were similar, suggesting that the groups were well-matched at risk. These further results need to be validated in other centers to establish the factors responsible for the differential transplantation rates observed in home DHD and PD patients.

Spectrum of Mutations in PKD1 and PKD2 Genes in 100 Unrelated Italian Pedigrees with ADPKD – Sanger Sequencing vs Next Generation Sequencing (NGS) Madalena Gigante,1 S. Diella,1 Matteo Accetturo,2 Paola Pontrelli,2 Giovanni Statallone,3 Giuseppe Grandaliano,4 Loreto Gesualdo,2 1Univ of Foggia, Foggia, Italy; 2DETO, Univ of Bari, Bari, Italy.

Background: ADPKD is caused by mutations in PKD1 or PKD2 genes. Although, clinical studies and case reports describing one or few ADPKD families have been reported in Italian population, to date a comprehensive molecular study is still lacking.

Methods: PKD1 and PKD2 genes were analyzed in 150 Italian ADPKD patients from 100 unrelated pedigrees - the largest Italian cohort analyzed to date in a single study - using Sanger sequencing and NGS. The potential pathogenicity of the newly identified variants was evaluated by combining different in silico methods.

Results: We identified the largest number of definitely and probable pathogenic mutations (n=78) reported in a single study in Italian population, achieving an overall detection rate of 90%. 55 mutations (52 PKD1 and 3 PKD2) have not been previously described, expanding the knowledge of known ADPKD mutations. We identified 12 de novo PKD1 mutations in sporadic patients without family history, providing a definitive diagnosis of ADPKD. We found the largest number of de novo mutations reported in a single study (15%) demonstrating, for the first time, that the prevalence of PKD1 de novo mutations may be underestimated. 4/32 PKD1 mutations were found in 2 unrelated Italian patients, a sign of founder effect. 20 patients were analyzed by NGS: we confirm the presence of a nonsense PKD1 mutation and the lacking of clear pathogenic mutations in 3 patients previously analyzed by Sanger, and the presence of definitely/probable pathogenic mutations in the 17 not previously genotyped patients. All NGS results have been confirmed by Sanger sequencing, achieving sensitivity and specificity of 100%.

Conclusions: Our data provide important new advances in the molecular diagnostics of ADPKD: (i) describe for the first time new potential founder mutations in Italy; (ii) report the largest number of de novo mutations in a single study and (iii) provide a new NGS method with a detection rate comparable to Sanger sequencing but with significantly lower cost and reduced turnaround time.

The Use of Screening MR Angiography in Patient with ADPKD Claudine Christiansen, Ruben Poesen, Dirk R. Kuypers, Bert Bammens, Bjorn Meijers. Nephrology, Univ Hospitals Leuven, Belgium.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is associated with the development of intracranial aneurysms and an elevated risk of hemorrhagic stroke (HS). It is suggested that screening MR angiography reduces the incidence of hemorrhagic stroke. Current screening criteria include positive aneurysmal history in relatives (HS). It is suggested that screening MR angiography reduces the incidence of hemorrhagic stroke with the development of intracranial aneurysms and an elevated risk of hemorrhagic stroke.

Methods: We performed a single-center retrospective analysis of all ADPKD patients followed at the University Hospitals Leuven, between January 1990 (date of the first MR angiography) and August 2014. Baseline demographics and occurrence of screening criteria, screening MR angiography, intracranial aneurysm and hemorrhagic stroke were evaluated.

Results: We identified 865 patients with ADPKD. Those who were seen at least three times (median age 51y, 49% males) were included for analysis. Mean duration of follow up was 11.6 years. In this cohort, current screening criteria were met in 183 ADPKD patients (29.2%). Of these, 136 (74.3%) had screening MR angiography. In patients with PKD2 mutation, prescence of screening criteria was associated with an elevated risk of hemorrhagic stroke (12.8% vs. 4.0%, P=0.02). Use of MR angiography in patients with screening criteria was related with a lower risk of hemorrhagic stroke during follow-up (2.2% vs. 12.8%, P=0.01). The current screening criteria for intracranial aneurysm, which is associated with an 3-fold elevated risk for future hemorrhagic stroke and performing MR angiography seems effective in reducing this risk.

Conclusions: In patients with ADPKD, current screening criteria for intracranial aneurysms are associated with an 3-fold elevated risk for future hemorrhagic stroke and performing MR angiography seems effective in reducing this risk.

Influence of Genotype on ADPKD Progression in the HALT PKD Cohort Christina M. Heyer,1 Kaleb Z. Abebe,2 Vicente E. Torres,3 Ronald D. Perrone,4 Marie C. Hogan,5 William E. Braun,3 Godela M. Brosnahan,6 Peter G. Czarnecki,5 Charity G. Moore,7 Peter C. Harris,8 Dana Miskulin,9 The HALT PKD Investigators.1 1Mayo Clinic, Rochester, MN; 2U of Pittsburgh, Pittsburgh, PA; 3U of Colorado, Denver, CO; 4Tufts, Boston, MA; 5Cleveland Clinic, Cleveland, OH; 6Brigham and Women’s Hospital, Boston, MA; 7Carolina’s Health Care System, Charlotte, NC; 82 Sites.

Background: We assayed here the influence of the ADPKD disease gene (PKD1 or PKD2) on PKD2 mutation type (truncating or non-truncating) on the rates of renal disease progression over 5 years in the HALT PKD cohort.

Methods: PKD1 mutation type was divided into strength groups: truncating (MSG1), and more or less penetrant non-truncating (MSG2 and MSG3). Correlations were made between gene type/MSG and changes in eGFR or height adjusted total kidney volume (htTKV).

Results: PKD2 patients had a faster eGFR decline than PKD2 (3.3 vs. 1.87 ml/min/1.73/m²; p=0.0001) but the rate of htTKV increase did not differ (6.44 vs. 6.81%/yr; P=0.42). Baseline PKD1 vs. PKD2 (733, 575/ml/m²; P=0.0001) and so PKD1 kidneys expanded to a greater extent (268, 217/ml/m²; P=0.0001). Rates of change in eGFR or htTKV did not differ between PKD1 MSG3 and MSG1 (P=0.15 and 0.70), but MSG2 baseline kidneys were smaller relative to MSG1 and MSG2 (611, 753, 777/ml/m²; P=0.004) and so the volume increase was less (221, 262, 277/ml/m²; P=0.004).

Conclusions: PKD2 patients were less likely to reach a study endpoint (death, ESRD or 50% eGFR decline; P=0.003), but there was no difference between PKD1 MSG1, 2, 3 (P=0.61). Patients with no mutation detected, had a slower increase in htTKV (4.8%/yr; P=0.008 vs. PKD1). The study showed a difference in TKV increase between the low and standard blood pressure groups (5.6 vs. 6.6%/yr; P=0.006). The magnitude of difference was similar when restricted to PKD1 MSG1 (5.7 vs. 6.7%/yr; P=0.0516) or PKD1 MSG1 and 2 (5.8 vs. 6.6%/yr; P=0.0543), but not significant in the smaller populations.

Climate Temperature Affects the Age of End-Stage Kidney Disease in Autosomal Dominant Polycystic Kidney Disease (PKD) Marwan M. Abbas,1 Michael E. Bleyer,1 Elizabeth Swain,1 Kendrah O. Kidd,1 Gregory B. Russell,2 Anthony J. Bleyer,1 1Section on Nephrology, Wake Forest School of Medicine, Winston-Salem, NC; 2Biostatistics Sciences, Wake Forest School of Medicine, Winston-Salem, NC.

Background: Vasopressin receptor 2 antagonists decrease cyst size in PKD. We postulated that patients in hotter climates would have more concentrated urine, and this would affect the age of ESRD in PKD.

Methods: We obtained demographic data and cause of ESRD on 1,332,402 individuals who had their first occurrence of ESRD between ages 30 and 90 between 1971 and 2012 from the US Renal Data System (USRDS). We obtained annual mean temperatures from 1990 to 2010 for US weather stations and linked a participant’s zip code to the nearest weather center. We correlated the mean age of onset of ESRD for PKD and other causes of ESRD with 5 degree temperature intervals. We created a multivariate model for PKD patients, with the dependent variable age of ESRD and independent variables race, gender, year starting dialysis, residual GFR at start of ESRD, annual median income by patient zip code, and temperature as discrete variables in 5 degree intervals.

Results: Figure 1 shows the mean age of onset of ESRD by disease. Cold and warm temperature extremes were associated with increasing age of ESRD for PKD, but other diseases.

The multivariate model showed that temperature had a minimal effect on age of ESRD compared to other variables in the model. Conclusion: There was a U-shaped relationship for age of ESRD according to temperature that was present in PKD and other diseases. However, in a multivariate model, climate temperature had a minimal effect on age of ESRD in PKD.
Results: We included 40 patients (male: 28, female: 12). The median age was 46.5 years (interquartile range: IQR 24 - 69 y). The median baseline eGFR was 76 mL/min/1.73m² (IQR: 26.9 – 58.8) and the median baseline TKV was 1,917 mL (IQR: 1,378 - 2,905). The median starting dosage of tolvaptan was 60 mg (IQR: 30 – 60) and the median treatment period was 8 months (IQR: 6 - 11). We observed no statistical variations in eGFR (p = 0.787) and TKV (p = 0.561) during treatment. There were no significant changes in V AS scores for general fatigue (p = 0.817), anorexia (p = 0.393), back pain (p = 0.682), and abdominal distension (p = 0.607) during treatment. Although analysis of variance demonstrated that aquaretic burden including thirst and dry skin were significantly increased after Tolvaptan treatment (p = 0.003), 35% of the patients still did not completely sense thirst at al beginning of treatment, and 42% (n = 17) of patients spontaneously improved without any additional treatment or tolvaptan withdrawal.

Conclusions: Although analysis of variance demonstrated that aquaretic burden including thirst and dry skin were significantly increased after Tolvaptan treatment, almost third of the patients did not completely sense thirst at al beginning of treatment, and the remaining third part of patients spontaneously improved.

Adapted PKDOC Disease Predicts Actual Progression of Autosomal Dominant Polycystic Kidney Disease in TEMPO34
Frank S. Czerwiec,1 Jaime Blais,2 Jf Marier,3 Nathalie H. Gosselin,3 Thomas Peyret,2 Vicente E. Torres,1 Arlene B. Chapman,4 Berenece Y. Gitemor,4 Steven Thomas Broadbent,4 Dana Miskulin,3,4,5 Ronald D. Perrone.1
1 Otsuka PDC, Rockville, MD; 2Pharsight, Montreal, QC, Canada; 3Mayo Clinic, Rochester, MN; 4U Chicago, Chicago, IL; 5U Colorado, Denver, CO; 6Critical Path, Tucson, AZ; 7Tufts MC, Boston, MA.

Background: The Polycystic Kidney Disease Outcomes Consortium (PKDOC) has submitted for FDA and EMA concurrence, the use of total kidney volume (TKV) as a new marker to enrich autosomal dominant polycystic kidney disease (ADPKD) clinical trials for patients likely to display progressive decline in renal function and progression to end-stage renal disease (ESRD). A disease progression model linking TKV growth (with baseline covariates of age and eGFR) to longitudinal eGFR was constructed using a combination of PKDOC datasets including ADPKD patients with TKV data collected over 30 years of follow-up.

Methods: This report uses baseline data for placebo subjects from the TEMPO 3/4 ADPKD clinical trial to support this approach to disease progression modelling by constructing model predicted and observed TKV and eGFR. Simulations were performed by utilizing the PKDOC model with subject-specific baseline TKV and eGFR measurements from subjects enrolled in TEMPO 3/4.

Results: Bias (mean of the relative error) and precision (square mean of relative error) of TKV and eGFR were derived to assess the predictive performance of the PKDOC model. The model resulted in very robust predictions of TKV and eGFR with mean (95% CI) bias values of 2.98% (1.1-5.1) and 3.03% (1.4-4.7), respectively. Mean (95% CI) precision on TKV and eGFR were 42.9% (19.1-68.7) and 37.9% (34.0-43.4), respectively. The coefficient of determination (r²) for observed and model predicted TKV and eGFR data were 0.957 and 0.877, respectively.

Conclusions: The disease progression model developed with PKDOC data and applied to the TEMPO placebo dataset demonstrated excellent predictive power for TKV and eGFR. This model is expected to be useful for disease prognosis and model predictions for patients who are not yet on tolvaptan or other disease-modifying therapies. Further validations are needed to confirm the performance of this model on other datasets.

Polycystic Kidney Disease Imaging Biomarkers – The Texture of Things to Come
Timothy L. Kline,1 Panagiotis Korfiatis,2 Marie E. Edwards,3 Joshua D. Warner,4 Maria V. Inzunza,5 Peter C. Harris,6 Bernard F. King,7 Vicente E. Torres,8 Bradley J. Erickson,9 Mayo Clinic.

Background: Medical imaging is essential for polycystic kidney disease (PKD) diagnosis, monitoring, and outcome prediction. Research studies use total kidney volume (TKV) as an imaging biomarker to follow the progression of PKD. However, TKV overlooks underlying structural and functional complexities of the kidneys. We hypothesize that texture analysis may provide quantifiable measurements of renal tissue structure to improve patient outcome prediction.

Methods: A retrospective cohort of 20 patients (38 exams) was identified who had imaging prior to reaching end-stage renal disease (ESRD). Image texture features were generated from the baseline MR images and analysis of the correlation to known time-to-ESRD was performed. A total of 18 texture features were computed for each MRI scan.

Results: Three texture features were well correlated to time-to-ESRD and many individual texture features outperformed height-adjusted TKV (htTKV) as shown in Figs. 2 and 3. Example T2 MRIs and the corresponding energy image feature (measure of heterogeneity) for two different patients with markedly different times-to-ESRD are also shown for comparison. In addition, entropy (measure of image randomness) and gray-level non-uniformity (measure of neighboring pixel similarities) were also found to be well correlated (r-values of 0.66 and 0.73, respectively).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only; Underline represents presenting author.
Conclusions: We present the first use of texture analysis for PKD assessment. Results are promising in terms of identifying new imaging biomarkers that correlate with disease progression. This approach could function as a surrogate to more difficult imaging methods (e.g., quantitative MRI) and costly analysis (e.g., cyst segmentation). It is likely that combining texture analysis with other patient data will allow for substantial improvements to PKD prognosis.

SA-PO856

Accuracy of Traditional and Novel Renal Filtration Markers for Estimating GFR in ADPKD Patients

Stephen L. Seliger, Charaleett E. Diggs, MSN, Thomas C. Dowling, Robert Christenson, Terry J. Wannick, Medicine, U Maryland Sch Medicine, Baltimore; *Ferris State Univ; Pathology, U Maryland Sch Medicine, Baltimore.

Background: The best method for estimating GFR in ADPKD is unclear. Changes in tubular handling of filtration markers may affect estimating equation accuracy.

Methods: Among 51 adults with ADPKD and eGFR >20 cc/min/1.73m², we measured GFR using inohexol plasma clearance (GIFR), serum creatinine (SCr, IDMS-traceable assay), Cystatin C (CysC, Dimension VISTA assay) and beta-trace protein (BTP, immunonephelometric assay, Siemens). We estimated GFR (eGFR) using validated equations based on SCr (CKD-Epi(C), MDRD), Cystatin-C (CKD-Epi(C), iohex) and SCr or BTP (White equation). We compared the bias, precision, overall accuracy, and classification (for GIFR >60 cc/min/1.73m²) of each estimating equation.

Results: Mean age was 51 ±12 years, 71% were female, 84% Caucasian, and mean iohex was 68.4±34.2 cc/min/1.73m². Of the 5 equations, the CKD-Epi(C)_iohex had the highest bias (overestimating GFR), lowest precision and accuracy, and was least sensitive for detection of low GIFR (Table). The CKD-Epi(C) and BTP-SCr-based White equations had least bias and highest precision. Sensitivity and specificity were not significantly different between the SCr- and BTP-based estimating equations (Table).

1. P30 represents proportion with of GFR estimates that are within 30% of measured GFR.
2. Smaller values indicate higher accuracy.

Conclusions: Older patients with more advanced and/or severe ADPKD are more likely to be treated with statins. Placebo patients using statins progressed faster; tolvaptan slowed progression and annulled the difference between statin users and nonusers.

SA-PO857

Statins, ADPKD Severity and Progression in the TEMPO 3:4 ADPKD Clinical Trial

Vicente E. Torres, Ron T. Ganescoot, Ronald D. Perrone, Olivier Devuyst, Arlene B. Chapman, Eiji Higashihara, Wen Zhou, John Ouyang, Jaime Blais, Frank S. Czerwiec, Mayo; U Groningen; Tufts U; U Zurich; U Chicago; Kyorin U; Otsuka.

Background: In ADPKD, low HDL and high LDL cholesterol are associated with faster total kidney volume (TKV) increase and eGFR decline. A randomized controlled trial (RCT) of pravastatin in children showed lower TKV expansion without effect on renal function.

Methods: Exploratory post-hoc analysis of TEMPO 3:4 (3-year RCT of tolvaptan in relatively early but progressive ADPKD, age 18-50 yrs, TKV ≥750 ml, eCrCl ≥60 ml per minute) to examine whether use of statins might have affected ADPKD progression. Linear mixed-effect models that adjust for gender, age and baseline TKV and eGFR were used to compare TKV and eGFR slopes between groups.

Results: Patients randomized to placebo using statins were older, had larger TKV and lower eGFR at baseline, and their TKV and eGFR slopes were steeper compared to statin users (Table). Similarly, patients randomized to tolvaptan using statins were older and had lower eGFR, with a non-significant trend to larger TKV compared to statin non-users; however, there was no difference between TKV and eGFR slopes of statin users and nonusers randomized to tolvaptan. Statin use did not affect a composite endpoint of clinically relevant ADPKD events in the placebo (HR=1.013, P=0.91) or tolvaptan (HR=0.954, P=0.65) group.

Systems Biology of Polycystic Kidney Disease

Kelly A. George, Herve Husson, Ramya Kalyana Kumar, Vishal S. Vaidya, Jagesh V. Shah, 1,2 Laboratory of Systems Pharmacology, Harvard Medical School, Boston, MA; 1Renal Div, Brigham and Women’s Hospital, Boston, MA; 2Genzyme Corp, Framingham, MA.

Background: Polycystic kidney disease (PKD) is a group of hereditary disease states characterized by cystic kidneys and often accompanied by other manifestations such as cystic liver and hypertension. PKD occurs in 1 in 500 people, usually resulting from a dominant mutation in one of two genes, PKD1 or PKD2. There are no treatments for PKD and it is the leading genetic cause of renal failure. Numerous studies have identified pathways that are misregulated in PKD but targeting these individual pathways has not led to a successful therapeutic intervention or molecular biomarker.

Methods: To identify potential biomarkers and develop a systems-level understanding of PKD, we are using transcriptomics, and quantitative proteomics and phospho-proteomics to evaluate the state of cystic and normal kidneys in a mouse model of PKD. Kidney cysts of PKD, we are using transcriptomics, and quantitative proteomics and phospho-proteomics to evaluate the state of cystic and normal kidneys in a mouse model of PKD. Kidney cysts of PKD and it is the leading genetic cause of renal failure. Numerous studies have identified pathways that are misregulated in PKD but targeting these individual pathways has not led to a successful therapeutic intervention or molecular biomarker.

Conclusions: In ADPKD patients, cystatin-based GFR equations may over-estimate true GFR compared to the lower bias observed in the general CKD population. The SCr-based CKD-Epi equation performed best overall among 5 equations. The utility of equations utilizing beta-trace protein deserves further investigation.

Funding: NIDDK Support
Conclusions: These experiments will not only provide candidate biomarkers for PKD progression, but will also yield a deeper understanding of the state of the cystic kidney. **Funding:** Pharmaceutical Company Support - Sabeth Genzyme, Privated Foundation Support

SA-PO859
Prognostic Enrichment Strategies in the TEMPO 3:4 ADPKD Clinical Trial
Maria V. Izrajab,1 Jaime Blais,2 Ronald D. Perrone,3 Ron T. Ganswee4, Arlene B. Chapman,4 Olivier Devuyst,5 Eiji Higashihara,6 Wen Zhou,7 John Ouyang,8 Frank S. Czerweic,9 Vicente E. Torres,10 Mayo Clinic; 1Otsuka PDC; 2Tufts MC; 3UMC Groningen; 4U. Chicago; 5U. Zurich; 6Kyorin U.

Background: An image classification of ADPKD based on diffuse (class 1) vs asymmetric (class 2) cyst distribution along with estimated cyst growth determined by age and height-adjusted total kidney volume (htTKV, subacha A-E) has been proposed for prognostic enrichment by excluding patients with a lesser risk for progression (classes 1A-B and 2).

Methods: This enrichment strategy was compared, post-hoc, to exclusion criteria used for TEMPO3:4 to examine tolvaptan effects on ADPKD progression in patients with early but progressive renal disease (38-50 year-old, TKV <750 ml, eGCI >60 ml/min).

Results: 1436 TEMPO 3:4 subjects with baseline MRIs were classified, finding only 10% class 2 or 1B and no 1A subjects. TEMPO3:4 enriched categories 1C-E (90%) compared to the published cohorts (62%, Izrajab 2014 JASN). TKV and eGFR slopes steepened from class 1B to 1E (both P<0.001, Table).

Conclusion: Prognostic enrichment strategies using kidney morphology can enhance ADPKD trials for rapidly progressing patients, increasing power and reducing costs. Refinements of imaging criteria can improve the probability of success of future clinical trials. **Funding:** NIDDK Support

SA-PO860
Prognostic Enrichment Design in Clinical Trials for ADPKD: The HALT PKD A Trial
Maria V. Izrajab,1 Kaleab Z. Abebe,2 Kyongtae Ty Bae,3 Ronald D. Perrone,4 Arlene B. Chapman,5 Robert W. Schrier,6 Alan S. Ly,7 William E. Braun,8 Theodore I. Steinman,9 Michael F. Flessner,10 Vicente E. Torres,11 Mayo Clinic; 2U. of Pittsburgh; 3Tufts U.; 4U. of Chicago; 5U. of Colorado; 6Kansas U.; 7Cleveland Clinic; 8Beth Israel Deaconess; 9NIH-NIDDK.

Background: Patients with mild ADPKD phenotype are less likely to be informative in clinical trials. An image classification into typical (diffuse cyst distribution) class 1A → E (determined by age and height adjusted total kidney volume, (TKV) and atypical (asymmetric cyst distribution) class 2 has been proposed for prognostic enrichment design in clinical trials with recommendations to exclude class 1A and 2 and follow-up class 1B patients to more precisely define their risk for progression.

Methods: Post-hoc analysis of HALT-PKD A, (RCT of rigorous vs standard BP control on TKV increase and eGFR decline; eGFR<60 ml/min/1.73 m²) to investigate the performance of this classification for prognostic enrichment design.

Results: 551 participants were classified by 2 raters (98.2% agreement) into class 1A (6.2%), 1B (20.3%), 1C (34.1%), 1D (22.1%), 1E (11.8%), and 2 (5.4%). TKV increase and eGFR decline became steeper from class 1A→1E (both P<0.001). HALT PKD A had shown slower TKV increase, faster eGFR decline in the first four months (FO-5) and marginally slower eGFR thereafter (FS-50) with a significant overall (FO-80) effect with rigorous BP control. To ascertain the ability to detect an effect of rigorous BP control in imaging classes of increasing severity, we grouped class 1A and 2 (lowest severity), 1B and 1C (intermediate severity), and 1D and 1E (highest severity). Beneficial effects on TKV increase and eGFR decline were detected only in class 1D and 1E.

Conclusions: Strategies for prognostic enrichment such as the image classification should be used in the design of RCTs for ADPKD to increase their power and reduce their cost. **Funding:** NIDDK Support

SA-PO861
Long-Term Safety Profile of Tolvaptan in Japanese ADPKD Patients
Eiji Higashihara,1 Shigee Horie,2 Yoshifumi Ubara,3 Satoru Muto,4 Kikuo Nutahara,5 Ichieie Narita,5 Tadasa Okada.6 ADPKD Research, Kyorin Univ School of Medicine, Tokyo, Japan; 7Urology, Juntendo Univ Graduate School of Medicine, Tokyo, Japan; 8Nephrology Center, Tohoku University Hospital, Tokyo, Japan; 9Urology, Teikyo Univ School of Medicine, Tokyo, Japan; 10Urology, Kyorin Univ School of Medicine, Tokyo, Japan; 11Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan; 12Clinical Development, Otsuka Pharmaceutical Co., Ltd., Osaka, Japan.

Background: Tolvaptan was first approved in Japan for autosomal dominant polycystic kidney disease (ADPKD) based on results of the Tolvaptan Efficacy and Safety in Management of Autosomal Dominant Polycystic Kidney Disease and Its Outcomes-3 trial (TEMPO). To examine adverse drug reactions (ADRs) of tolvaptan for up to extended 3 years after TEMPO ADPKD Japanese patients.

Methods: This open-label study was conducted in 135 patients participating in the preceding TEMPO. Doses of tolvaptan were adjusted from 60 to 120 mg/day.

Results: Main ADRs, thirst (77%), pollakiuria (57%), polyuria (31%), and hyperuricemia (15%) were noted during up to 3 years. In TEMPO, hepatic function-related ADRs were observed more frequently for tolvaptan than for placebo early during treatment. In this study, 8 patients (6%) experienced >3-fold increases above upper limits of normal serum ALT and AST 3 to 9 months after tolvaptan initiation, but all recovered after tolvaptan cessation. Of these 8 patients, 7 had been allocated to placebo in TEMPO. However, the residual one patient allocated to tolvaptan similarly had shown increased serum ALT in TEMPO. None of the 8 patients met Hy’s Law criteria. No ADRs besides those seen in TEMPO were newly observed in this study.

Conclusions: Hepatic function-related ADRs occurred early during treatment and were reversible. Tolvaptan was thus indicated to be a promising drug for treatment of ADPKD for up to 6 years while carefully monitoring ADRs including hepatic function abnormalities. **Funding:** Pharmaceutical Company Support - Otsuka Pharmaceutical Co., Ltd.

SA-PO862
Pregnancy Outcome in Anticipants in the HALT PKD Clinical Trials
Arlene B. Chapman,1 Kaleab Z. Abebe,2 Marie C. Hogan,3 Charley G. Moore,4 Susan Spillane,5 Theodore I. Steinman,6 Kyongtae Ty Bae. 7U. of Chicago; 8U. of Pittsburgh; 9Mayo Clinic; 10Beth Israel Deaconess; 11Halt Investigators.

Background: ADPKD is the most common hereditary disease. Fertility rates are not impaired in ADPKD women, however, preexisting hypertension and proteinuria associate with increased maternal and fetal complications. In the HALT PKD trials, 38 pregnancies occurred despite counseling and review with participants. We now present maternal and fetal outcomes from these pregnancies.

Methods: In a secondary analysis, data regarding maternal and fetal outcomes and complications of reported pregnancies were obtained including spontaneous abortions, delivery types and still births. Data collection relied on completion of protocol case report forms, follow up of hospital discharge summaries and patient based reports if available.

Results: In HALT A and B, 203 and 89 women were premenopausal. In all pregnancies, study medications were stopped immediately or before the pregnancy began. 36 pregnancies occurred in 20 women with experiencing 2 pregnancies. 26 women experienced 32 pregnancies in Study A (12.8%) and 4 occurred in 4 women in Study B (4.5%). In study A baseline TKV was 871.5±502.9 mls, and GFR was 104.3±17.5 ml/min. In Study B, baseline GFR was 51.6±9.3 ml/min. Information on pregnancy outcome was not available in 3 pregnancies (2 LTFU and 1 pregnant at the end of study). In 33 pregnancies, 58% resulted in a live birth (100% in HALT B). In the remainder, 7 spontaneous and 2 therapeutic abortions, 1 ectopic and 1 stillbirth occurred. Two C-sections, one for pre-eclampsia and one for pre-mature delivery. In this secondary analysis of HALT Study A and B, 10.3% of premenopausal women became pregnant despite ongoing counseling and informed consent regarding the need to avoid becoming pregnant. A high spontaneous abortion rate was noted with a conservative live birth rate estimate of 56%. Pre-eclampsia, preterm delivery and ectopic pregnancy, all known to associate with ADPKD, occurred in 9% of pregnancies. No direct evidence for fetal injury due to telmisartan or lisinopril exposure was noted. **Funding:** NIDDK Support
SA-PO863
Renal Concentrating Capacity and Copeptin Concentration in Patients with ADPKD and IgA Nephropathy with Impaired Renal Function

Background: ADPKD patients have an impaired maximal urinary concentrating capacity (Umax). Whether this is an aspectic effect of renal function impairment, or specific for ADPKD is yet unknown. We hypothesized that ADPKD patients have a more severely impaired Umex in comparison with non-ADPKD renal disease patients, which leads to an exaggerated vasopresin (AVP) response that may be damaging to the kidney.

Methods: 15 ADPKD (eGFR=60) and 15 IgAN patients, matched for age, sex and eGFR underwent a water deprivation test to determine Umex. Urine and plasma osmolality (Uosm and Posm), albuminuria (ACR) and plasma copeptin (surrogate marker for AVP in pmol/L) were measured at baseline and after water deprivation (average 17 hours). Height adjusted total kidney volume (htTKV) was measured by MRI.

Results: Umex was lower in ADPKD compared with IgAN patients. Upon water deprivation Posm increased in ADPKD (p=0.003), but not in IgAN (p=0.1), whereas copeptin increased in both groups similarly (ADPKD: p=0.001; IgAN: p=0.02). Copeptin after water deprivation was negatively associated with Umex in both groups (ADPKD: R=-0.72, p=0.002; IgAN: R=-0.70, p=0.004). In ADPKD, copeptin and albuminuria were correlated after water deprivation (R=-0.71, p<0.003), independently of eGFR or htTKV. Furthermore, htTKV in ADPKD was associated after water deprivation with Posm (R=-0.52, p=0.048), copeptin (R=0.58, p=0.03) and Umex (R=-0.54, p=0.04).

Conclusions: ADPKD patients have a lower Umex compared with IgAN patients with similar renal function. Remarkably, this is not accompanied with an exaggerated increase in AVP. Notwithstanding, ADPKD severity was associated with stronger increases in Posm, copeptin and albuminuria during water deprivation. This suggests that in ADPKD water deprivation may be deleterious and should be avoided.

SA-PO864
Total Abdominal Organ Volume Is a Major Risk Factor for Malnutrition in Ambulatory Patients with Autosomal Dominant Polycystic Kidney Disease
Hyunjin Ryu,1 Hyoseong Kim,1 Hayne C. Park,1 Hyunsuk Kim,1 Kook-Hwan Oh,1 Young-Hwan Hwang.2 Currie Ahn.1 Internal Medicine, Seoul;1 National Univ Hospital, Seoul, Korea;1 Asian Medical Center;1 Armed Forces Capital Hospital, Seongnam;1 Eulji General Hospital.

Background: In Autosomal dominant polycystic kidney disease (ADPKD), malnutrition may develop as renal function decreases and abdominal organ volume enlarged. This is suggested in patients with ADPKD that was not well tolerated. A rate of QTc prolongation not acceptable for chronic use was associated with tesevatinib 100 mg/day, but 1 case of severe rash occurred. QTc prolongation ≥485 ms occurred in 2 pts on 100 mg/day, and 1 pt on 150 mg/day. The most common AEs overall in preliminary safety data were rash (36%), shouting (29%), and asymptomatic CPK increase (24%). Other AEs included asymptomatic mild amylase elevations (21%).

Conclusions: Tesevatinib 150 mg in various schedules was associated with skin rash that was not well tolerated. A rate of QTc prolongation not acceptable for chronic use was associated with tesevatinib 100 mg/day. Tesevatinib 50 mg/day appears to be a well tolerated dose in patients with ADPKD, although some acneiform rash occurs. In order to confirm the safety profile at 50 mg/day, an additional 20 pts are being enrolled.

Funding: Pharmaceutical Company Support - Kadmon Corporation

SA-PO865
Tyrosine Kinase Inhibitor Tesevatinib for Patients with Autosomal Dominant Polycystic Kidney Disease
Anjay Rastogi,1 Mitchell H. Rosner,2 Irina Barash,2 Theodore I. Steinman,1 Ziad El-Zoghby,1,2 Saudi Nurko,1 Seth Goldberg,3 Ashraf El-Meanawy,4 Mireille El-Ters,5 Maria Roche,6 Mark S. Berger,7 UCLA;1, UVA; 1 Beth Israel Deaconess;1 Mayo Clinic;1 Cleveland Clinic; 1Washington Univ;1 Med College Wisconsin;1 KU Med Center;1 Kadmon Corp.;1 Mount Sinai Beth Israel.

Background: Tesevatinib (formerly KD019) inhibits both epidermal growth factor receptor (EGFR) and SRC. It decreases cyst growth and slows the decline in renal function in BPK mouse & PCK rat PKD models. In oncology trials the most common adverse events (AEs) were EGFR inhibitor AEs of acneform rash and diarrhea. The 1:2:1 of approx. 60 hrs allows for schedules other than daily dosing.

Methods: This study evaluated the safety and tolerability of tesevatinib at several doses and schedules. Eligibility used Ravidine criteria for autosomal dominant polycystic kidney disease (ADPKD) in patients (pts) aged 18-55 years with eGFR ≥50 mL/min/1.73 m².

Results: 46 ADPKD pts were enrolled into 5 dose/schedule cohorts. At 150 mg/day, 3/5 pts had moderate rash occurring during the first 28 days that was not tolerated and led to study discontinuation for 2. The tolerability of intermittent dosing schedules using 150 mg (Mon, Wed, Fri or Mon, Thu) was improved over 150 mg/day, but 1 case of severe rash occurred. QTc prolongation ≥485 ms occurred in 2 pts on 100 mg/day, and 1 pt on 150 mg/day. The most common AEs overall in preliminary safety data were diarrhea (36%), rash (33%), nausea (29%), and asymptomatic CPK increase (24%). Other AEs included asymptomatic mild amylase elevations (21%).

Conclusions: Tesevatinib 150 mg in various schedules was associated with skin rash that was not well tolerated. A rate of QTc prolongation not acceptable for chronic use was associated with tesevatinib 100 mg/day. Tesevatinib 50 mg/day appears to be a well tolerated dose in patients with ADPKD, although some acneiform rash occurs. In order to confirm the safety profile at 50 mg/day, an additional 20 pts are being enrolled.

SA-PO866
Retrospective Analysis of Changes in Renal Function in Patients with PKD and Diabetes on Metformin
Jinyu Zhang,1 Anju Yadav,2 Lawrence Ward,3 Kenneth R. Hallowes,4 JingJing Zhang.5 Internal Medicine, Thomas Jefferson Univ; Philadelphia, PA;4 Renal Div, Thomas Jefferson Univ; Philadelphia, PA;5 Renal Div, Keck School of Medicine of USC, Los Angeles, CA.

Background: Autosomal dominant polycystic kidney disease (ADPKD) affects approximately 600,000 Americans. The cystic fibrosis transmembrane conductance regulator (CFTR) chloride channel participates in secretion of cystic fluid whereas the mammalian target of rapamycin (mTOR) pathway drives proliferation of cyst-lining epithelial cells. CFTR and mTOR are both negatively regulated by AMP activated protein kinase (AMPK). Metformin, a commonly used diabetes medication, activates AMPK. In two mouse ADPKD models, metformin produced a significant decrease in cyst kidney index relative to controls. Therefore, metformin may provide clinical benefit in PKD patients.

Methods: IBR-approved data collection of patients with PKD and diabetes from office visits between 3/1/2010 and 2/28/2015 were analyzed. Estimated GFR (eGFR) was calculated by using CKD-EPI formula. The ACEI/ARB usage was also recorded.

Results: One-hundred forty-nine patients with PKD were identified during a 5-year period. Of these patients, 13 also had a diagnosis of diabetes. Of these 13 patients, 1 patient was lost to follow up. Four patients had a kidney transplant with the development of diabetes following transplantation. Eight patients had both PKD and diabetes – 7 were on metformin at some time whereas 1 had never. Regarding this group of PKD patients on metformin, we present data on renal function trend measured by eGFR.

Conclusions: Metformin may provide clinical benefit in PKD patients.

830A
Results: Among 186 patients who underwent PHCF, 91% were Caucasian women with ADPKD with a mean age of 49 years. Major peri-operative complications (Clavien III/IV) occurred in 24% of the patients. Operative mortality (<90 days) was 2.7% with one death from liver failure. Overall survival was 95%, 90%, 76.5% and 59% at 1, 5, 10 and 15 years respectively. Imaging records for volumetry were unavailable in 37 patients. Of the remaining 149 patients, 30 patients had imaging for one LV, 65 for two LV and 54 for all three LV. Median LV was 6812 ml preoperatively and 2502 ml after PHCF leading to a median postoperative liver volume reduction of 61%.

SA-PO867

11Beta-Dichloro Inhibits Cyst Progression in an Adult ADPKD Model

Sorin V. Fedeles, Bogdan I. Fedeles, Yasunobu Ishikawa, Rachel Gallagher, John M. Essigmann, Stefan Somlo. 

Background: ADPKD is the most common monogenic disorder for which no effective therapy exists. We have previously shown that the novel antitumor agent 11β-dichloro specifically induced apoptosis in Pkd1 null cells (ASN 2013 FR-OR100). Administration of 11β-dichloro resulted in amelioration of cystic disease in the Pkd1fl/fl Pkd1-Cre neonatal ADPKD model. In the current work we explored the pathways involved in the pro-apoptotic effect of 11β-dichloro and investigated whether the beneficial effect seen in the early model is also present in an adult inducible Pax8rtTA;TetO-cre; Pkd1fl/fl model which is more akin to the human disease.

Methods: Pax8rtTA;TetO-cre; Pkd1fl/fl mice were induced with doxycycline for 2 weeks beginning at P28. 11β-dichloro was administered by IP injection at a dose of 10 mg/kg, 3 times a week for 12 weeks beginning from P42. At the end of the treatment the kidneys were harvested for analysis.

Results: 11β-dichloro treated adult mice resulted in a decrease in KW/BW ratio as compared to vehicle injected controls (2.6±0.1 vs. 6.1±0.4; 0.02). There was no difference in body weight between treated and control. These changes were accompanied by a decrease in the cystic index (29%±2.4 vs. 83±2.7), and creatinine (0.18±0.007 vs. 0.37±0.02). 11β-dichloro specifically increased apoptosis in cyst-infiltrating cells but not in wild-type. UPR and ROS have been implicated as potential drivers of the 11β-dichloro-dependent pro-apoptotic phenotype. We found that upregulation of the UPR marker BiP and its transcriptional targets Bip and Erjβ4 was specific to the Pkd1 null cells compared with wild-type, in vitro and in vivo. Treatment with 11β-dichloro increased mRNA levels of the antioxidant genes catalase and SOD1 specifically in the Pk11 cystic kidneys and not in vehicle-treated kidneys.

Conclusions: 11β-dichloro specifically induces UPR, ROS, and apoptosis in cystic vs. wild-type kidneys. In an adult inducible cystic model, the compound ameliorates polycystic disease progression and improves kidney function.

SA-PO868

Outcomes of Combined Partial Hepatectomy and Cyst Fenestration for Massive Polycystic Liver Disease

Fouda T. Chebib, Amber Harmon, Maria V. Irazabal, Yeon Soon Jung, Marie C. Hogan, Patrick S. Kamath, Vicente E. Torres, David M. Nagorney.

Background: Partial hepatectomy and cyst fenestration (PHCF) selectively provides clinical benefit in highly symptomatic patients Polycystic Liver Disease (PLD). This study aims to ascertain whether the reduction in liver volume achieved by PHCF is sustained long-term.

Methods: Clinical data was retrieved from the electronic records in all PLD patients who underwent PHCF between 1985 and 2014. Preoperative Liver volumes (LV1), postoperative (LV2) and late follow up (LV3) were measured from MR or CT images.

Results: At follow-up (mean 7.8 years), median LV was 2500 ml. Interestingly, 29 out of 61 patients with available LV2 and LV3 showed further regression in LV upon follow up (median -14.8%); while the rest showed mold growth of 9.5%. Overall volumetric comparison of preoperative to follow-up liver imaging showed sustained liver volume reduction (median 60%).

Conclusions: Sustained long-term reductions in LV after PHCF can be achieved in selected patients with severe, highly symptomatic PLD. In our experience, liver-related death and subsequent liver transplantation are infrequent after PHCF.

SA-PO869

Effect of Genotype on the Severity and Volume Progression of Polycystic Liver Disease (PLD) in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Fouda T. Chebib, Yeon Soon Jung, Christina M. Heyer, Maria V. Irazabal, Marie C. Hogan, Peter C. Harris, Ziad El-Zoghby, Div of Nephrology, Mayo Clinic, Rochester, MN; Kosin U.

Background: PLD is the most common extrarenal manifestation in pts with ADPKD. Here we analyzed the influence of genotype and gender on the severity of PLD.

Methods: Clinical data was retrieved from electronic records in a large cohort of pts who were mutation screened, determined to be PKD1 or PKD2 and had available CT or MR liver imaging during 2000-2014 at the Mayo Clinic (n=445). Liver volumes (LV) were measured by stereology on axial images and adjusted to height (HLV).

Results: Among the 445 pts, 220 (49.5%) had truncating PKD1, 153 (34.4%) nontruncating PKD1 and 72 (16.1%) PKD2 mutations. Compared to nontruncatingPKD1 and PKD2, pts with truncating PKD1 were younger at time of first imaging (43.6 vs 47.6 and 50.4; p<.001), had lower median survival time to ESRD (62.4 vs 66.9 and 81.4; p<.001), had lower median survival time to ESRD (62.4 vs 66.9 and 81.4; p<.001), had lower median survival time to ESRD (62.4 vs 66.9 and 81.4; p<.001). LV in pts with PKD1 truncating, PKD1 nontruncating and PKD2 were not different (HLV 1039, 1076 and 1058 ml/m, respectively; p=.53). Female pts had larger HLV compared to males (1104 vs 1019 ml/m; p=.001). Annualized median liver growth rates were 1.65, 1.74 and 1.2% for truncating PKD1, nontruncating PKD1 and PKD2, respectively (p=.75). Females younger than 48 had higher annualized median growth rates compared to those older than 48 (2.65 vs 0.09%;p=.001). When adjusting for age, gender and baseline LV, growth rate remained unaffected by the ADPKD genotype.
HRQoL was assessed by comparing subjects in CKD2-5 to subjects in CKD1 at baseline. HRQoL instruments contribute to renal TAE being less effective in these patients.

Duration, or had hypertension, parameters that might be associated with cyst wall stiffness. Reduction. Renal TAE was more effective in patients who were younger, had shorter dialysis duration. This finding, along with the demonstrated gender influence, indicate that modifiers type were not significantly associated with the severity or growth rate of PLD in ADKD.

Patient Reported Health Related Quality of Life in ADPKD: Analysis from Eligibility for Renal Transcatheter Arterial Embolization in Patients with Autosomal Dominant Polycystic Kidney Disease

Yoshifumi Ubara, Junichi Hoshino, Rikako Hiramatsu, Kenmei Takaichi. Dept of Nephrology, Toranomon Hospital, Tokyo, Japan.

Background: In patients with ADPKD, massive renal enlargement is a serious problem. Renal transcatheter arterial embolization (TAE) is effective for reducing renal volume, but there is large variation of its effectiveness and the reasons remain unclear. We investigated factors influencing the renal volume reduction rate (RVRR) for one year after TAE.

Methods: All patients with ADPKD who received renal TAE at Toranomon Hospital from 2006 to 2013 were enrolled. We calculated RVRR by the calculation formula (1 - renal volume at each time after TAE / renal volume before TAE)*100, and analyzed factors affecting RVRR. We also compared sequential change of large cysts (>5cm), by classifying them into four groups as cysts with wall thickening (>4mm), cyst with acute hemorrhage, normal cysts, and the others.

Results: 449 patients (228 men, 221 women, mean age: 57.0 ± 9.1 years) were enrolled. The RVRR at 1 year after TAE ranged from 3.9 to 84.8%, and the least squares mean RVRR calculated using mixed model was 45.73% (95% confidence interval [95% CI]; 44.36 to 47.10%). Multivariate analysis using mixed model revealed that large cysts with wall thickening (regression coefficient: -5.830, 95% CI: -9.140 to -2.520, p=0.0006), age (5years) (-0.847, -1.073 to -0.621, p=0.0001), diaylasis duration (12months) (-0.115, -0.193 to -0.037, p=0.0039), systolic blood pressure (10mmHg) (0.283, 0.065 to 0.501, p=0.0109), and number of microcoils used for renal TAE (1.333, 0.784 to 1.882, p<0.0001) had a significant influence on the RVRR. Among large cysts, only cysts with wall thickening did not decrease in volume. Significantly more microcoils were needed to achieve complete renal artery occlusion in patients with younger age and less dialysis duration.

Conclusions: Cyst wall thickening had an important influence on cyst volume reduction. Renal TAE was more effective in patients who were younger, had shorter dialysis duration, or had hypertension, parameters that might be associated with cyst wall stiffness. Renal artery narrowing may occur in older patients or those on longer dialysis, which might contribute to renal TAE being less effective in these patients.

Patient Reported Health Related Quality of Life in ADPKD: Analysis from OverUER

Dorothee Oberheiden,1 Arlene B. Chapman,2 Ronald D. Perrone,3 Andreas L. Serra,4 Jason C. Cole,4 Wen Zhou,1 Holly Krasa,1 Jaime Blais,1 Frank S. Czerwiec,1 1Otsuka Pharmaceutical Development & Commercialization, Inc., Rockville, MD; 2Univ of Chicago, Chicago, IL; 3Tufts, Boston, MA; 4Univ of Zürich, Zürich, Switzerland; 5PPD, San Diego, CA.

Background: ADPKD imposes a burden on health-related quality of life (HRQoL). Few studies have systematically examined the impact of renal and extra-renal symptomatology on patient’s HRQoL. The purpose of this analysis was to capture disease specific burden across all disease stages while determining specificity and sensitivity of existing and new HRQoL instruments.

Methods: The impact of disease progression on HRQoL in 3,409 ADPKD subjects involved in the OVERUER observational study were evaluated by patient report outcomes (PRO) questionnaires, including the ADPKD-IS, ADPKD-UIS, BPI, EQ-SD, and SF-12v2. HRQoL was assessed by comparing subjects in CKD2-5 to subjects in CKD1 at baseline. Magnitude of change of 0.2, 0.5 and 0.8 standard deviations (SD) represent small, moderate and large effect sizes on HRQoL. Other measures of disease severity, including Tkv, were assessed independently.

Results: HRQoL in ADPKD was impacted at different disease stages depending on the sensitivity and specificity of the PRO used. The disease-specific ADPKD-IS scale distinguished physical, emotional, and fatigue related burden as early as CKD3. Similarly, the SF-12 PCS scale was able to distinguish burden by CKD3. The SF-12 MCS and EQ5D were not sensitive to disease progression until CKD5. The impact of disease burden prior to ESRD was driven by specific questions focused on physical activity, anxiety, and exhaustion. Subjects reporting being bothered by the shape of their abdomen showed the greatest impact as early as CKD3 which associated with larger kidney volumes (htTKV > 635mL/m).

Conclusions: Studies to date have had limited success in their attempt to characterize HRQoL in ADPKD patients by using general health surveys. Disease specific instruments better capture the burden experienced by patients in earlier stages of ADPKD prior to gross kidney enlargement and effects associated with ESRD and dialysis.

Fibroblast Growth Factor 23, Renal Progression and Death in Patients with Autosomal Dominant Polycystic Kidney Disease

Michel Chonchol, Berenice Y. Gitomer, Xuan Cai, Tamara Isakova, Isidro B. Salasky, Renata C. Pereira, Myles S. Wolf. Div of Renal Diseases and Hypertension, Univ of Colorado Denver.

Background: No prospective studies examined fibroblast growth factor 23 (FGF23) and clinical outcomes among individuals with autosomal dominant polycystic kidney disease (ADPKD). We tested the hypotheses that higher serum FGF23 is a risk factor for kidney disease progression and mortality in adults with ADPKD.

Methods: We measured intact FGF23 levels (Kainos) in stored baseline serum samples in 1,002 patients who participated in the HALT-PKD randomized controlled trial of two different blood pressure control strategies. We used Cox proportional-hazards models to examine the associations between continuous levels and quartiles of iFGF23 and the primary composite endpoint of time to a 50% reduction in estimated glomerular filtration rate (eGFR) from baseline, end stage renal disease (ESRD) or death.

Results: At baseline, participants had a mean age of 42 ± 10 years, mean eGFR of 71.4 ± 26.6 mL/min/1.73m², mean serum phosphate of 3.4 ± 0.5 mg/dL, and median (IQR) iFGF23 of 52.6 (38.6 - 73.7) pg/mL. During a median follow-up of 5.6 years, 226 patients (22.6%) reached the composite endpoint. After adjusting for demographic factors, traditional cardiovascular risk factors, baseline eGFR, and randomized treatment group in Cox proportional hazards models, ascending quartiles of FGF23 were associated with a stepwise increased risk for the composite endpoint (HR 1.0 [reference], 1.54 [95% CI, 0.69 - 3.47], 2.92 [CI, 1.58 - 6.19], and 3.41 [CI, 1.61 - 7.22]). Similar results were obtained when FGF23 was examined on a continuous scale (HR 1.94 [95% CI, 1.39 - 2.69] per 1 SD increase in FGF23).

Conclusions: Higher serum FGF23 is an independent predictor of kidney disease progression and death in adults with ADPKD. Further studies are required to determine the mechanisms underlying these relationships and to test whether interventions that reduce FGF23 levels might be renoprotective.

SA-PO873

Natural History of Polycystic Liver Disease in the HALT ADPKD Cohort

Mary C. Hogan,1 Kaleb Z. Abebe,2 Susan Spillane,3 Frederic F. Rahbari-Oskouji,4 Godela M. Brosnaham,3 Charity G. Moore,2 Vicente E. Torres,1 1Mayo C for the HALT PKD Study Group; 2Upfin; 3Emory; 4U Col.

Background: Although hepatomegaly in polycystic liver disease (PLD) is common, few studies have evaluated natural history & factors associated with progression. Goal: Examine change in height adjusted liver volume (htLV) & factors influencing progression in participants in HALT-PKD-A randomized clinical trial.

Methods: Baseline PLD group (mild (htLV<1000mL;n=240) moderate (1000-1800mL; n=271) & severe (>1800mL; n=28; 81% female)) & follow up htLVs, quality of life (QOL;SF36), influence of telmisartan (T) vs placebo (P) on progression were assessed (n=558, age 15-49y, eGFR > 60 mL/min). We assessed factors influencing htLVs such as treatment group, age, gender, genotype (in separate models) & factors influencing progression over time were examined using linear mixed models.

Results: Annual htLV growth rates were 0.76, 0.91, 1.08% (P<NS) in the mild, moderate and severe groups respectively (figure 1). Neither baseline age or genotype associated with annual htLV increase. There were strong negative relationships of eGFR (p=0.02) & serum albumin (p=0.003) with htLV. Prior pregnancy & higher parity (both age adjusted) associated with htLV but not with progression over time. Increases in BTLV were associated with increased rates of fatigue/weakness (p=0.003) and declines in SF-36 physical functioning over time (p=0.02). Progression was independent of drug assignment (T 0.99% vs P 1.07% p<NS) & BP target (low 0.81 vs std. 1.15% p< NS).

Towards Personalised Medicine – Treating a Renal Ciliopathy
Shalabh Srivastava, 1 Simon Ramsootram, 1 Sophie Saunier, 1 Colin Miles, 1 John Andrew Sayer. 1
1Nephrology, Inst of Genetic Medicine, Newcastle Univ, Newcastle upon Tyne, United Kingdom; 2Laboratory of Inherited Kidney Diseases, Imagine Inst, Paris, France.

Background: Renal ciliopathies are genetic disorders presenting with nephronophthisis, cystic kidneys or cystic dysplasia. Pathogenesis of ciliopathies may include altered signalling or defective DNA damage response. Due to the huge genetic/phenotypic variability in ciliopathies it is pertinent to explore the most important contributor to individual phenotypes. We investigated disease mechanisms of a patient with Joubert Syndrome aiming to provide a personalised medicine approach to treatment.

Methods: We identified a family with 2 affected siblings with a ciliopathy phenotype. Ciliopathy gene panel sequencing followed by Sanger sequencing and segregation analysis was undertaken to provide a molecular genetic diagnosis. We established Human Urine Derived Renal Epithelial Cell (HUREC) cultures from one sibling and a control. Cultured cells where characterised and their response to therapeutic agents quantified.

Results: The siblings exhibited a cerebro-retinal-renault phenotype with renal corticomedullary cyst formation and progressive renal failure. Panel sequencing followed by Sanger sequencing confirmed bi-allelic mutations in CEP290 (c.2817G>T, p.K939N; c.2848insC, p.Q959Pfs*6) in both affected patients. The c2817G>T is located in the last base of exon 25 and is predicted to lead to a splicing defect. There was no difference in mitosis or centriole numbers in control and proband’s cells. Control cells formed spheroids in 3D culture (100%) whilst the proband’s cells showed a defect in spheroid forming index (17%) and absent primary cilia. In the proband cells there was a rescue of spheroid forming index in response to treatment with hedgehog agonists SAG(smoothened agonist) (67%) and purmorphamine (75%) and a rescue of primary cilia.

Conclusions: In a family with a ciliopathy we have confirmed a molecular genetic defect in CEP290. Using HURECS we have characterised, at a personalised medicine scale, the cellular defect. This data suggests that renal ciliopathies may have potential therapeutic targets and investigation through individual HUREC based model is an exciting new development.

Effect of Metformin on the Progression of Autosomal Dominant Polycystic Kidney Disease
Godela M. Brosnahan, 1 Michel Chonchol, 1 John R. Holmen, 2 Eugene J. Nuccio, 2 Berenice Y. Gitomer, 1 Univ of Colorado; 2Intermountain Healthcare, Salt Lake City, UT.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a common inherited disorder resulting in end-stage renal disease (ESRD), without an approved treatment. In an animal model of ADPKD metformin therapy resulted in amelioration of cystic renal growth. We sought to determine whether patients with ADPKD and type 2 diabetes treated with metformin had slower progression to ESRD than similar patients treated with other antidiabetic drugs.

Methods: We conducted a population-based cohort study of adult patients with ADPKD and type 2 diabetes between January 1/2000 and December 31/2014. We identified 322 adults with ADPKD and type 2 diabetes, of whom 119 were treated with metformin only and 203 with other antidiabetic agents. Among these we identified 31 subjects treated with metformin only who could be matched for age, sex, race, history of hypertension and coronary artery disease, and baseline renal function to 31 subjects not treated with metformin. The primary outcomes were incident ESRD and all-cause mortality.

Results: The median age of the enrolled participants was 61 years, 45% were women. Approximately 74% and 26% had a history of hypertension and myocardial infarction, respectively. The baseline MDRD-creFPR in participants receiving and not receiving metformin was 49±12 and 47±14 mL/min/1.73m² (p=0.70). After a median follow-up of 4.5 years, incident ESRD occurred in 29% and 16% of those not exposed and exposed to metformin, respectively, with a OR of 2.13 (95% CI 1.10-3.46; p=0.02). Deaths occurred in 32% and 26% of those not exposed and exposed to metformin, with a OR of 1.37 (95% CI 0.5-2.47; p=0.60).

Conclusions: Metformin therapy may slow progression to ESRD in ADPKD adults with type 2 diabetes compared to other antidiabetic drugs. Because metformin has an excellent safety record, a trial to slow the progression of ADPKD in the absence of diabetes is warranted.

Methods: Information about hospitalizations was prospectively collected in the HALT-PKD Studies, 2 multicenter trials involving people with ADPKD and GFR >60 ml/min (Study A) and GFR 25-60 ml/min (Study B). The primary diagnosis was designated after review of discharge summaries and independently adjudicated by a committee. Results: Total patient years (ptyrs) of follow-up in the 558 Study A patients and 486 Study B patients were 3191.4 and 2060. The incidence rates (IR) of all-cause hospitalization, in Study A and B, respectively, was 67.7 and 123.3 per 1000 ptyrs, which compares to 80.3 and 118.0, in respective age-matched general populations (CDC/NHDS National Hospital Discharge Survey, 2010). The IRs in Study A and B, respectively, for cardiovascular-related hospitalization were 7.0 and 18.1 per 1000 ptyrs, and for ADPKD-related hospitalization (primary diagnosis kidney or liver cyst pain, infection or hemorrhage, pyelonephritis, kidney stones or cerebral aneurysm) were 12.7 and 26.7 per 1000 ptyrs. The most common primary diagnoses are listed in the table.

Conclusions: As compared with the respective age-matched general US populations, hospitalization rates were lower in ADPKD patients with GFR >60mls/min and higher in patients with GFR 25-60 ml/min. PKD-related complications were more common than cardiovascular related diagnoses as the primary reason for hospitalization in both Study A and B.

SA-PO877

Effect of Statins on the Progression of Autosomal Dominant Polycystic Kidney Disease (the HALT PKD Investigators) Godela M. Brosnahan,1 Kacaleb Z. Abebe,2 Frederic F. Rahbari-Oskou,1 Charity G. Moore,2 Kyongtae Ty Bae,2 Robert W. Schrier,2 Jared J. Grantham.3 1Univ of Colorado; 2Univ of Pittsburgh; 3Emory Univ; 4Univ of Kansas.

Background: ADPKD is the most common hereditary disease resulting in end-stage renal failure (ESRD), without an approved treatment. In a small randomized trial comparing pravastatin for 3 years (y) with placebo in 110 patients age 8-22 y, the statin group experienced a slower rate of renal enlargement. No large trial has tested the effect of statins in ADPKD adults.

Methods: We performed a secondary analysis of the HALT PKD trials, categorizing participants into 3 groups based on statin use: 1) never users, 2) less than 3 y, and 3) at least 3 y of use. For subjects in Study A (n=558, age 15-49 y, eGFR > 60 ml/min/1.73m²) we compared the percent change in height-adjusted total kidney volume (htTKV), in height-adjusted total liver volume (htLTV) and the rate of decline in eGFR between the 3 statin use groups. For participants in Study B (n=486, age 18-64 y, eGFR 25-60 ml/min/1.73m²) we compared time to composite endpoint of death, ESRD or 50% decline in eGFR. Follow-up was 5-8 y.

Results: In HALT Study A only 59 subjects used statins for > 3 y and 37 for < 3 y. There was no difference in the rate of annual htTKV increase (6.41%, 7.11%, 5.97%; p=NS) or htLTV growth (1.02%, 1.15%, 0.65%; p=NS) between the 3 groups, after controlling for sex, age, and treatment arms. The rate of eGFR decline was faster in group 2 (4.07 ml/min/yr) than in groups 1 and 3 (2.93 and 2.82 ml/min/yr; p=0.015), after adjusting for the more favorable baseline characteristics of group 1 (more females, younger age, higher baseline eGFR). In Study B 118 subjects used statins for > 3 y and 76 for < 3 y. There was no difference in time to endpoint between the 3 groups.

Conclusions: In this secondary analysis of the HALT PKD trials, statin therapy for 3 years did not slow the rate of renal or liver enlargement or of eGFR decline in ADPKD adults, but these results are limited by the small numbers of statin users in Study A, different statin drugs and doses, and non-randomized allocation to groups.

SA-PO878

Assessment of a Dosage-Sensitive Mutational Network for PKD in a Large Cohort of Patients with Early and Severe Forms of Polycystic Kidney Disease Carsten Bergmann,1,2 John Devane,3 Steffen Neuber,1 Eva Decker,1 Uyen Tran,1 Oliver Wessely,1 Elisabeth B. Ott,2 1Center for Human Genetics, Bioscientia, Ingelheim, Germany; 2Renal Div, Univ Hospital, Freiburg, Germany; 3Cellular & Molecular Medicine, Cleveland Clinic.

Background: ADPKD patients with early and severe disease manifestations only make up a minor proportion, but are crucial for a better understanding of PKD. Affected families have a high recurrence risk for babies with a severe clinical course often resulting in perinatal death. Especially in prenatal cases the diagnostic distinction between different forms of PKD and other ciliopathies can be difficult and illustrates the need for more comprehensive genetic testing.

Methods: An accurate genetic diagnosis is crucial for genetic counselling, prenatal diagnostics and the clinical management of patients. To this end, we established a sequence capture based NGS approach targeting 95 genes for cystic and polycystic kidney disease. This includes PKD1, which - due to the presence of pseudogenes - is difficult to test. As an additional advantage over conventional Sanger sequencing we were able to detect copy number variations. The biological significance of some of the detected alleles were subsequently tested in vitro and in vivo studies using a range of animal models including zebrafish, Xenopus and mice.

Results: We analysed a cohort of 309 patients exhibiting early and severe PKD. In a considerable percentage of patients we did not detect just one single mutated gene/allele, but additional mutations in trans. Notably, this proportion increased, the more severely the patients were affected. The affected genes were not limited only to PKD1, PKD2 or PKHD1. In particular, a subgroup of patients with non-syndromic disease harboured mutations in genes typically related to ciliopathies such as nephronphobiasis, Joubert, Meckel, and Bardet-Biedl syndrome. Finally, we used zebrafish, Xenopus and mice to validate some of our findings in terms of a functionally proven dosage-sensitive network.

Conclusions: This study is the most comprehensive analysis performed so far and points towards a general and underestimated concept for the modification of disease gene expression.

The Short Term Effect of Tolvaptan for CKD Stage 4 Autosomal Dominant Polycystic Kidney Disease
Haruna Kawano,1,2 Satoru Muto,2 Shigee Horie,1,2
1Urology, Juntendo Univ Graduate School of Medicine, Tokyo, Japan; 2Urology, Teikyo Univ, Tokyo, Japan; 2Endowed Course for the Study of Polycystic Kidney Disease, Juntendo Univ Graduate School of Medicine, Tokyo, Japan.

Background: In Japan, the treatment of tolvaptan, a V2 receptor antagonist, started from March 2014. Indication criteria of tolvaptan for ADPKD treatment in Japan is adult patients with more than 750ml total kidney volume (TKV) and more than about 5%/year increasing rate of TKV. It is contraindication to use tolvaptan for patients with eGFR<15ml/min/1.73m². It is recommended to reduce dose of tolvaptan for patients with CCR<30ml/min. However, the treatment effect for patients with CKD stage 4 is still unknown. So, we evaluated the short time efficacy of tolvaptan treatment for patients with CKD stage 4.

Methods: Thirteen patients (5 females and 8 males, mean age; 52.5 years) with ADPKD who started tolvaptan at our hospitals from April 2014 to April 2015 were analyzed in this study. Although our standard starting dose of tolvaptan for patients with good renal function is 40mg/day, we administered 15mg/day for patients with eGFR<25ml/min/1.73m² patients. Patients were measured eGFR and TKV at the commencement of treatment and at 1.5 and 6 months later.

Results: The baseline median eGFR and TKV were 21.8 ml/min/1.73m² (range; 17.1-28.9) and 2.810ml (range; 1.031-5.847), respectively. The change of median eGFR from baseline at 1.5 months and at 6 months were -0.36 ml/min/1.73m² (p=0.39) and -1.80 ml/min/1.73m² (p=0.04), respectively. The change of median TKV from baseline at 1.5 months and at 6 months were -12ml (p=0.39) and -12ml (p=0.93), respectively. One female patient and another male patient temporarily stopped their treatment at 3 months and at 6 months because of their eGFR decreased to lower than 15 ml/min/1.73m². Hepatic toxicity, hypernatremia, and the other severe adverse events were not detected.

Conclusions: No severe adverse events were occurred and 85% of CKD stage 4 patients could keep treatment for 6 months without CKD progression. Tolvaptan was safe and tolerable for ADPKD patients with CKD stage 4 in lower dose. Patients were measured eGFR and TKV at the commencement of treatment and at 1.5 and 6 months later.

SA-PO881

Estimation of Total Kidney Volume in Autosomal Dominant Polycystic Kidney Disease
Edwin M. Spithoven,1 Maatje D.A. van Gastel,1 A. Lianna Messchendorp,1 Nick F. Casteleijn,1 Ron T. Gansevoort,1 Internal Medicine, Nephrology, UMC Groningen; 2On behalf of the DIPAK Consortium, Netherlands.

Background: Measuring total kidney volume (TKV) in autosomal dominant polycystic kidney disease (ADPKD) by magnetic resonance image (MRI) and manual tracing is time consuming. Two alternative MRI methods have recently been proposed to estimate TKV, eTKV, and eTKV, which require less time

Methods: ADPKD patients with a wide range of kidney function were included, if they had an approved T2 weighted MRI. A test set of 10 MRI was used for assessing reproducibility, 220 for cross-sectional analyses and 48 for longitudinal analyses with a follow-up of three years. mTKV was used to assess Irazabal risk categories, reclassification was calculated for eTKV and eTKV. Measured TKV (mTKV) was manually traced, eTKV was calculated as advised in literature as (1/6 * length* width * depth)/1000 and eTKV as mTKV / (1 + 0.624). In all backgrounds showed the majority of cyst had a collecting duct (CD) origin, however some cysts were negative for the nephron markers LTA-AQP1 (PT), AQP2-DBA (CD).

Results: The Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease in Autosomal Dominant Polycystic Kidney Disease (APDKD) by magnetic resonance image (MRI) and manual tracing is time consuming. Two alternative MRI methods have recently been proposed to estimate TKV, eTKV, and eTKV, which require less time.

Methods: ADPKD patients with a wide range of kidney function were included if they had an approved T2 weighted MRI. A test set of 10 MRI was used for assessing reproducibility, 220 for cross-sectional analyses and 48 for longitudinal analyses with a follow-up of three years. mTKV was used to assess Irazabal risk categories, reclassification was calculated for eTKV and eTKV. Measured TKV (mTKV) was manually traced, eTKV was calculated as advised in literature as (1/6 * length* width * depth)/1000 and eTKV as mTKV / (1 + 0.624). In all backgrounds showed the majority of cyst had a collecting duct (CD) origin, however some cysts were negative for the nephron markers LTA-AQP1 (PT), AQP2-DBA (CD).

Conclusions: No severe adverse events were occurred and 85% of CKD stage 4 patients could keep treatment for 6 months without CKD progression. Tolvaptan was safe and tolerable for ADPKD patients with CKD stage 4 in lower dose.

Influence of Kidney Volume on Progression to Advanced Stages of Chronic Kidney Disease in Autosomal Dominant Polycystic Kidney Disease (APDKD)
Alan S.L. Yu,1 Jared J. Grantham,2 Arlene B. Chapman,3 Kyongtae Ty Bac,4 Doug Landsittel,2 Chengli Shen,2 Vicente E. Torres,2 Michal Mrug,5 Peter C. Harris,6 Frederic F. Rahbarni-Oskouli,7 Michael F. Flessner,8 William M. Bennett,9 'U Kansas; 'U Pittsburg; 'U Chicago; Mayo Clinic; 'UAB Birmingham; 'Emory U; NIH; 'Legacy Good Samaritan Med Ctr.

Background: The Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease III (CRISP III) is the continuation of a longitudinal cohort study of patients with APDKD designed to identify predictors of CKD progression and kidney failure. Cyst enlargement and hence increase in kidney volume is believed to be on the causative pathway that leads to decline in GFR and kidney failure.

Methods: In 241 patients, height-adjusted total kidney volume (htTKV) was determined by MRI at baseline, and serial GFR determined by corrected iohalamate clearance and serum creatinine estimating equations.

Results: After a mean follow-up of 11.1 years, 59.8%, 32.1% and 21.6% of subjects reached CKD stage 3, 4 and 5. In multivariable logistic regression analysis, baseline htTKV was an independent predictor for the development of CKD stages 3, 4 and 5 by the final visit, after correction for age, sex, race, BMI, and baseline GFR. Similar results were obtained whether CKD stage was determined using iohalamate clearance, MDRD eGFR, or CKD-Epi eGFR. The estimated htTKV at age 18 yr was also predictive of subsequent CKD stage 3.

Funding: NIH DK and NIDDK, the APK consortium, the CRISP III consortium.

Diagnostic and Therapeutic Advances in PKD

Therapeutic Effects of the Fibrokinase Inhibitor ANG3070 in Polycystic Kidney Disease

Methods: Male PKD rats (PKC-Cre/Gt(1)phd/Ipeck/Ct) were randomized to vehicle or ANG3070 (25 mg/kg, BD, PO) at 6.5 weeks of age following confirmation of frank disease and sacrificed at 13.5 weeks. Age-matched male Sprague-Dawley rats served as wild-type controls.

Results: ANG3070 has no effect on mean arterial pressure. In PKC rats with diseased kidneys (figure), randomization to ANG3070 treatment was therapeutic, reducing cystic index, renal interstitial fibrosis (hydroxyproline (HYP)), albuminuria and other urine biomarkers of renal injury and serum creatinine (*p < 0.05).

Conclusions: ANG3070 is a small molecule fibrokinase inhibitor, ANG3070, in experimental PKD.

Alterations in Renal Oxylin
ts in Models of Polycystic Kidney Disease: Potential for Cyclooxygenase Inhibition for Disease Treatment

Background: Aberrant receptor tyrosine kinase signaling has been implicated in cyst expansion, renal interstitial fibrosis, increased kidney volume and reduced renal function in polycystic kidney disease (PKD). We investigated the effects of a novel, orally bioavailable, small molecule fibrokinase inhibitor, ANG3070, in experimental PKD.

Methods: Male PKD rats (PKC-Cre/Gt(1)phd/Ipeck/Ct) were randomized to vehicle or ANG3070 (25 mg/kg, BD, PO) at 6.5 weeks of age following confirmation of frank disease and sacrificed at 13.5 weeks. Age-matched male Sprague-Dawley rats served as wild-type controls.

Results: ANG3070 has no effect on mean arterial pressure. In PKC rats with diseased kidneys (figure), randomization to ANG3070 treatment was therapeutic, reducing cystic index, renal interstitial fibrosis (hydroxyproline (HYP)), albuminuria and other urine biomarkers of renal injury and serum creatinine (*p < 0.05).

Conclusions: ANG3070 is a small molecule fibrokinase inhibitor, ANG3070, in experimental PKD.

Hepatorenal Fibrocystic Diseases in Children

Background: Hepatorenal fibrocystic diseases (HRFCDs) are a group of monogenic disorders characterized by developmental abnormalities involving the liver and kidney. In this study, we performed genotype and phenotype analyses of children with HRFCDs to determine the distribution of underlying disease.

Methods: A total of 36 children with HRFCDs were recruited, with genetic tests performed in 22 patients and 14 patients diagnosed clinically as having autosomal recessive polycystic kidney disease (ARPKD).

Results: In Mx1Cre/Pkd1 mice, with disease, renal levels of the COX metabolites, prostaglandin (PG)E_2 and 6-keto-PGF_1α, were elevated by 38 and 50%, respectively. In Pkd2 mice, 11β-PGE_2, PGE_2, PGD_2, and 6-keto-PGF_1α, were elevated in diseased kidneys by 43, 49, 46, 67 and 136%, respectively. In the PKC rat model of ARPKD, PGE_2, PGD_2, and 6-keto-PGF_1α, were elevated by 38 and 50%, respectively. In all three models, although not as consistent as the COX oxylipin changes, LOX and CYP oxylipins were generally lower, which is similar to findings in the Han:SPRD-Cy rat and pcy mouse.

Conclusions: The elevated renal COX oxylipins in these PKD models are consistent with other cystic kidney disease models. This suggests that COX inhibition with common drugs such as aspirin or selective COX inhibitors may be beneficial in PKD, as it is in other models of cystic kidney diseases.

SA-PO888

Extended Follow-Up of the Consortium for Radiologic Imaging Studies of Polycystic Kidney Disease (CRISP III): The Predictive Value of Height Corrected Total Kidney Volume (htTKV) for the Future Development of CKD Stages 3a, 3b, 4 and 5 After Ten Years Follow-Up in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Background: CRISP III is a longitudinal observational cohort study of 241 ADPKD individuals now extending beyond 10 years. Measures of cyst burden by magnetic resonance imaging (MR) provide an accurate assessment through measures of htTKV. We have shown previously that baseline htTKV predicts CKD stage 3 after 8 years. We now evaluate whether baseline htTKV can predict CKD Stage 3a, 3b, 4 and 5 after 10 years of followup.

Conclusions: Kidney volume measured by MR at a single timepoint is a powerful predictor for the development of advanced stages of CKD over the ensuing 11 years. Consistent with prior analyses, greater kidney volume is strongly associated with higher rates of CKD progression, further supporting the notion that cyst enlargement is the primary cause of GFR loss and kidney failure.

SA-PO884

Therapeutic Effects of the Fibrokinase Inhibitor ANG3070 in Polycystic Kidney Disease

Methods: Participants underwent protocol visits including MR imaging, iothalamate clearance and serum creatinine measurements. Baseline htTKV was evaluated in its capacity to predict later CKD stages both individually and in a multivariable model that includes age, race, gender, and baseline iothalamate clearance. Receiver operator characteristic area under the curves (AUROC) were developed for reaching CKD stage 3a, 3b, 4 or 5 after a minimum of 10 years of followup.

Results: At 10 years, 59.8%, 32.1% and 21.6% of patients had reached CKD stage 3, 4 or 5. Baseline htTKV alone predicts CKD stage 3 in 10 years with a ROC of 0.85 and an optimal TKV cut point of 470 ml/m². Multivariable analysis assessing future CKD Stage 3a, 3b, 4 and 5 at 10 years demonstrated a ROC of 0.89, 0.87, 0.90 and 0.89 respectively.

Conclusions: htTKV is a powerful predictor of the development of all advanced stages of CKD within 10 years with an optimal htTKV of 470 ml/m² for CKD Stage 3.

Identifying Genetic Modifiers in Severe Polycystic Liver Disease (PLD) by Whole Exome Sequencing (WES) Amirezza Hashiguchi, Young-Hwan Hwang, Ning He, Kairong Wang, Winnie Y. Chan, Xuewen Song, Joost P.H. Drenth, York P. Pei. 1Div of Nephrology, Univ of Toronto, Toronto, Canada; 2Div of Nephrology, Eulji Univ College of Medicine, Seoul, Korea; 3Dept of Gastroenterology and Hepatology, Radboud Univ, Nijmegen, Netherlands.

Background: Severe PLD (sPLD) is a rare and poorly understood phenotype seen in ADPKD and ADPLD. Mutations of PKHD1 or SEC63 in ADPLD reduce functional polycystin-1 dosage by decreasing endoplasmic reticulum (ER) protein-processing and aggravates cystic disease severity in vivo (Nat Genet 43: 639-647, 2011). We hypothesize that rare mutations in ER pathway genes may modify PLD.

Methods: We performed WES using Illumina HiSeq2000/2500 with SSV4/5 capture kit in 88 patients (24 affected discordant sib-pairs and 7 affected concordant sib-pairs for sPLD and 27 sporadic cases). All sPLD patients had a liver span >25 cm by CT/MRI or >3x normal liver volume. In addition to genome-wide analysis, we performed focused analysis on 168 ER genes. Standard algorithms for sequence alignment, base calling, and QC filtering were applied to identify rare deleterious variants of high and moderate impact as predicted by PolyPhen-2, Sift, Mutation Assessor, Mammalian and Vertebrate nucleotide-level conservation, and Combined Annotation Dependent Depletion.

Results: Overall, we achieved a mean target coverage of 108x with 90% of targeted exons having >30x read depth. We identified 4,696 rare deleterious variants that segregated with PLD disease severity in at least one family. From them, we found 7 non-ER genes (TTN, DNAH110, DNAH114, HMCN2, NEB, OBSN and ADAMT58) with rare variants that segregate in 4 to 6 families each and 8 ER genes (DUCV1, UGT1A1, UGT2, SEC24D, SEC23B, ELMO3, SEC16A, and RPN1) with rare variants that segregate in at least one family and 3-4 sporadic sPLD cases.

Conclusions: Our results suggest extensive genetic heterogeneity with no single gene accounting for a large proportion of sPLD cases. Future studies with expanded sample size will help to identify promising candidate genes for follow-up functional studies. Identification of genetic modifiers of sPLD has the potential to improve risk prediction and treatment of this unusual complication.

TOSCA – TuberOus SClerosis Registry to Increase Disease Awareness: Renal Manifestations of Tuberous Sclerosis Complex John C. Kingswood, Anna C. Jansen. 1Sussex Kidney Unit, Royal Sussex County Hospital, Brighton, United Kingdom; 2Pediatric Nephrology Unit, UZ Brussel, Brussels, Belgium.

Background: Renal manifestations are the most common cause of morbidity and mortality in adult patients with tuberous sclerosis complex (TSC). The aim of the TuberOus SClerosis registry to increase Disease Awareness (TOSCA) is to understand the various manifestations of TSC. The baseline data of renal manifestations in the overall TOSCA cohort are presented here.

Methods: Patients diagnosed with TSC were enrolled in TOSCA from 170 sites across 31 countries worldwide. Patients will be followed up for up to 5 years with interim analysis performed every year.

Results: Baseline core data from 2093 patients were entered in the registry as of September 30, 2014 (cut-off date for the 2nd interim analysis). Median age at consent was 13 years (range 0-74 years). Renal abnormalities were reported in 987 (47.2%) patients. Median age of diagnosis of angiomyolipoma was 13 years (0-67). Of the 946 (95.8%) patients with ongoing renal angiomyolipomas, 396 (41.9%) had multiple and bilateral lesions, 329 (34.8%) had lesions > 3 cm, and 204 (21.6%) had growing lesions. Symptoms/signs associated with renal angiomyolipomas were either individually or in combination with others, were elevated blood pressure (48 [5.1%]), microscopic hematuria (35 [3.7%]), hematuria (47 [5.0%]), impaired renal function (36 [3.8%]), and pain (51 [5.4%]). Renal angiomyolipomas were treated in 274 (27.8%) patients; major treatment modalities included embolization in 98 (35.8%) and mammalian target of rapamycin (mTOR) inhibitors in 78 (28.5%) patients. Other renal features reported were renal malignancy (24 [1.1%]), polycystic kidneys (73 [3.5%]), and impaired renal function (43 [2.1%]).

Conclusions: The prevalence of renal angiomyolipomas of 47.2% in our cohort corresponds to 30-85% in the literature probably reflects their young mean age. Despite this the intervention rate was high, emphasizing the need for active surveillance. This is the intervention rate was high, emphasizing the need for active surveillance.

Sirolimus Reduces Fundamentally the Vascular and/or Muscular Components of Angiomyolipomas and Can Be Neoadjuvant to Partial Nephrectomy in Tuberous Sclerosis Complex Patients with Multiple and Large Tumors Associated with Surgical Risk Eliseer H. Watanabe, 1Fernando I. Yamauchi, 1Hilton M. Leao-Filho, 2William C. Nahas, 3Luiz F. Onuchic. 1Nephrology, Univ of Sao Paulo, Sao Paulo, SP, Brazil; 2Radiology, Univ SP, Sao Paulo, SP, Brazil; 3Nephrology, Univ SP, Sao Paulo, SP, Brazil.

Background: Renal angiomyolipomas (AMLs) are commonly associated with tuberous sclerosis complex (TSC). Because AMLs may complicate with lethal hemorrhage, invasive intervention is preconized for high-risk lesions. These procedures, however, imply in potential loss of functional renal mass and operatory risk, particularly in TSC patients with surgical and bilateral involvement. Since AML pathogenesis is based on the loss of mTOR inhibition, clinical trials have evaluated and shown efficacy of mTOR inhibitors (mTORI) to reduce tumor size. Such studies, however, were not capable of proving mTORI long-term benefit. Given that tumor size is an independent predictor of renal function decline after partial nephrectomy, we hypothesized that pre-surgical treatment with mTORI might be beneficial.

Methods: In this retrospective study we report the effects of neoadjuvant therapy with the mTORI sirolimus in TSC patients with multiple large AMLs undergoing nephron sparing surgery (NSS).

Results: As expected, sirolimus decreased tumor volume (-32.9±30.8%, n=22 from 9 patients, serum level of 10.4±1.3 ng/mL; p<0.001). This reduction occurred essentially due to the non-fatty compartment decrease (-56.2±33.1%; p<0.001) while the fatty component had no significant variation. A lower rate of early operative complications was found in the treated compared to the non-treated group (0%, n=7 vs 43%, n=6; p<0.05). Such complications included mostly intraoperative bleeding (75%). Long-term complication rates did not differ between the groups. Sirolimus was well tolerated and no serious adverse events were reported.

Conclusions: Our data indicate that sirolimus acts fundamentally at the vascular-containing compartment, suggesting that it may decrease the bleeding risk. In addition to its potential benefit as neoadjuvant therapy for large/multiple AMLs undergoing NSS, our findings revealed that the use of sirolimus was safe and reduced surgical complications.

Results: Fractional sodium excretion were reduced by 0.25% 95%CI (0.02;0.47) by the lowest dose, 0.24% (±0.12;0.59) by the intermediate dose and 0.32% (±0.06;0.59) by the highest dose compared to placebo. The highest dose of sodium nitrite reduced SBP by 4.5 mmHg (0.5;8.5), DBP by 3.8 mmHg (0.9;6.7), MAP by 4.0 mmHg (1.2;6.8) and increased P-renin concentration by 17.6% (2.9;32.2), P-angiotensin II by 21.8% (4.6;38.9) and urinary creatinine rate by 95% (59;132) compared to placebo. There was no effect on heart rate, GFR or aldosterone.

Conclusions: In supine, water loaded subjects a two hour infusion of 240 mg/kg/hour sodium nitrite exerts an antinatriuretic and BP lowering effect. The rise in urinary excretion rate of NO, suggests an increased bioavailability. The activation of the renin-angiotensin-aldosterone system (RAAS) could either be mediated directly by nitrite/NO or by baroreceptor reflex. The antinatriuretic effect might, at least partially, be mediated by the RAAS.

The Spatial Distribution of Metabolites Determined by Imaging Mass Spectrometry in the Kidneys of Rats Treated with Furosemide Hyojung Choi, Eunjung Park, Tae-Hwan Kwon. Dept of Biochemistry and Biophysics, School of Medicine, Kyungpook Natl Univ, Taegu, Korea.

Background: In the kidney, metabolic processes vary among the cortex (COR), outer medulla (OM), and inner medulla (IM), and the concentrations of metabolites are different according to the kidney zones. We aimed to examine the regional differences of the significantly changed metabolites in the kidneys of rats treated with loop diuretics by exploiting the matrix-assisted laser desorption/ionization (MALDI) and imaging mass spectrometry (IMS).

Methods: Osmotic minipumps were implanted in male Sprague-Dawley rats to deliver 12 mg/day of furosemide (s.c.). Vehicle-treated control rats (n = 14) and furosemide-treated rats (n = 14) were administered in cages with loop diuretics by exploiting the matrix-assisted laser desorption/ionization (MALDI) and imaging mass spectrometry (IMS).

Results: There was no significant difference between the groups in terms of age, gender, ethnicity, CD4 count or eGFR. The prevalence of dRTA was 6% in the group without TDF and 26% in TDF group (P = 0.04). In both groups, patients without dRTA showed an increase in pH (P = 0.05 and P = 0.05, respectively) and in the urinary sodium/potassium ratio (P = 0.04 and P = 0.03, respectively) but did not show an increase neither in unNaH+ (P = 0.44 and P = 0.34, respectively) nor in pCO2 (P = 0.52 and P = 0.11, respectively). In all cases with dRTA, the serum bicarbonate was normal, featuring an incomplete presentation. Conclusions: The prevalence of incomplete dRTA in patients using TDF was significantly higher than the group not using the drug. This is the first study suggesting a possible association between TDF and dRTA. Subsequent studies will be necessary to corroborate this hypothesis.

Bicarbonate Supplementation Improves Vascular Function in Patients with Chronic Kidney Disease: A Pilot Study Jessica B. Kendrick, Emily Decker, Kristen L. Nowak, Michel Chonchol. Univ of Colorado Denver, Aurora, CO; Denver Health Medical Center, Denver, CO.

Background: Metabolic acidosis, as reflected by a low serum bicarbonate level, is associated with increased risks of endothelial dysfunction, hypertension and death. Metabolic acidosis induces inflammation and endothelin-1, both of which contribute to vascular dysfunction. Whether alkali therapy improves vascular function in patients with chronic kidney disease (CKD) is unknown.

Methods: Seven subjects (5 men and 2 women) with stage III/IV CKD and serum bicarbonate level 16-22 mEq/L completed a pilot, prospective, open-label, crossover study of 14 weeks duration examining the effect of oral sodium bicarbonate supplementation on endothelial function. The primary endpoint was change in brachial artery flow mediated dilation between treatment and control conditions. Each period was 6 weeks in duration with a two-week washout period in between. Patients were treated with oral sodium bicarbonate tablets two to three times per day for goal serum bicarbonate of ≥ 23 mEq/L.

Results: The mean (SD) age and eGFR was 59 (3.3) years and 21.9 (2.6) ml/min/1.73m², respectively. The mean (SE) serum bicarbonate level increased after sodium bicarbonate administration from 18.4 (0.7) mEq/L to 23.7 (0.9) mEq/L. The mean (SE) serum bicarbonate level did not change in the control arm. Blood pressure control was similar between arms (77/121 vs. 76/120 mmHg). Brachial artery blood flow at baseline was 245 ± 32 ml/min/m². After 6 weeks of sodium bicarbonate replacement (3.78 ± 1.58 to 5.35 ± 1.13%) it decreased by 14% during control conditions (3.51 ± 0.53 to 3.01 ± 0.91%).

Conclusions: Bicarbonate supplementation in patients with CKD and low serum bicarbonate levels results in improved vascular function. Large randomized trials need to be performed to determine if treatment with alkali therapy can reduce cardiovascular disease in patients with CKD.

SA-PO985

Tenofovir-Related Distal Tubular Acidosis in HIV Infected Patients Tamara Cunha, Tatila Mourao Loyola, Carlos Perez Gomes, Maurilo Leite. Dept of Nephrology, Federal Univ of Rio de Janeiro, Rio de Janeiro, Brazil.

Background: Tenofovir disoproxil fumarate (TDF) is a nucleoside reverse transcriptase inhibitor extensively used worldwide and is now the most prescribed drug on Highly Active Antiretroviral Therapy (HAART). TDF toxicity is mainly targeted at the proximal tubule, and the most common side effect caused by TDF is distal renal tubular acidosis. We present a patient with TDF-related distal renal tubular acidosis (dRTA).

Methods: A 44-year-old HIV-infected female presented with severe nephrolithiasis, anion gap metabolic acidosis, hypokalemia, azotemia, and acute renal failure. She was taking TDF 300 mg and Simeprevir 150 mg OD for treatment of HIV infection. Initial laboratory data revealed a serum bicarbonate level of 8 mEq/L, serum creatinine of 2.8 mg/dL, urine pH of 4.5, blood pressure of 160/90 mmHg, and serum uric acid of 11.3 mg/dL.

Results: After discontinuing TDF and Simeprevir, the patient started receiving sodium bicarbonate 400 mg SC every 12h and was discharged 5 days later with a serum bicarbonate level of 24 mEq/L, serum creatinine of 1.4 mg/dL, and urine pH of 7.

Conclusions: Distal renal tubular acidosis (dRTA) should be considered in the differential diagnosis of acidosis in HIV-infected patients receiving TDF.

Comparison of Acid-Base Disorder Between Patients Undergoing Ileal Neobladder and Ileal Conduit Jung-Woo Noh, Eunjung Kim, Ja-Ryong Koo. Internal Medicine, Nephrology, Hallym Univ Medical Center; Hallym Kidney Research Inst, Seoul, Korea; Internal Medicine, Nephrology, Hallym Univ Medical Center, Hallym Kidney Research Inst, Seoul, Korea; Internal Medicine, Nephrology, Hallym Univ Medical Center, Hallym Kidney Research Inst, Seoul, Korea.

Background: Since the 1980s, the orthotopic ileal neobladder(INB) has been as a new option by eliminating the need for a cutaneous stoma and upstream appliances of ileal conduit(IC). Although this method has improved patients’ quality of life, frequent incidence of metabolic acidosis(MA) have been reported. We compared occurrence of MA in INB group to IC group, and searched for risk factors affecting MA.

Methods: We conducted a retrospective study in 95 patients who underwent radical cystectomy and urinary diversion from January 2001 to December 2014 at Hallym University Medical Center. Patients who have any illness such as severe pulmonary disorder, take any medication that could lead to MA and sepsis were excluded. Acid-base balance and renal function were compared between INB and IC groups. MA was defined as a venous sample bicarbonate level of less than 21 mmol/L.

Results: MA was detected in 74.2% and 69.7% within 7 days(p=0.64), and in 31% and 14.8% at 1 month(p=0.1) after operation in INB and IC group. But cases on bicarbonate therapy were significantly more in INB group(p=0.02). Serum HCO3 levels(p=0.05) and base excess(p=0.02) were significantly lower in INB group in spite of more cases on bicarbonate therapy. Acute kidney injury(AKI) at 1 month was higher in INB group(p=0.008). Serum creatinine concentrations were significantly correlated with bicarbonate levels. Multiple logistic analysis showed that 1 mg/dl increase of serum creatinine level result in a 5.38-fold higher risk of MA (95% confidence interval, 1.14-25.3;P = 0.03). Patients without AKI, MA was detected in 13.5% in INB group, 12% in IC group at 1 month(p= 1.0).

Conclusions: Despite there being no statistical difference, INB group may more easily develop MA compared with IC group especially in patients with elevated serum creatinine concentrations. In addition, a close association between the serum creatinine level and degree of MA was observed in both groups.

Screening for Hyperlactatemia: Relationship Between the Anion Gap and Serum Lactate in Hypovolemic Shock Richard M. Treger, Tristan Grogan, David Elashoff, Craig Anderson, Scott Cutler. Nephrology, VHAGLA, LA, CA; Medicine and Statistics Core, UCLA, LA, CA; Emergency Medicine, UCI, Irvine, CA.

Background: In lactic acidosis (LA), a discrepancy between the increase in serum anion gap (AG) and serum lactate concentration has been noted. Previous studies evaluated patients in the Intensive Care Unit with established LA. No study has examined the relationship between AG and serum lactate within the first hour of the development of LA, specifically the sensitivity and specificity of an elevated AG for predicting hyperlactatemia.
Methods: Data were obtained prospectively from adult trauma patients at a single level 1 trauma center. Venous samples were drawn prior to initiation of intravenous fluid resuscitation.

Results: 117 patients with elevated serum lactate levels (>2.1 mmol/L) were included. The sensitivity of an elevated AG (> 10) to reveal hyperlactatemia was only 45% whereas specificity was 84%. Sensitivity improved if the upper limit of normal AG was lowered and with increasing levels of serum lactate. Table 1). The correlation between the AG and serum lactate level yielded an R² of 0.30 (p < 0.001) and the slope of this relationship was 0.29 ± 0.58 (95% confidence interval 0.23-0.35).

Table 1: Sensitivity and specificity from use of the AG as an indicator of hyperlactatemia for specific AG and lactate level thresholds.

Conclusions: Within the first hour of the development of LA due to hypovolemic shock, the AG was not a sensitive indicator of an elevated serum lactate level, but it was fairly specific. The sensitivity and specificity of the AG as an indicator of hyperlactatemia is consistent with prior studies examining later stages of LA. The AG increased to a greater extent than the serum lactate and approximately 70% of the change in AG could not be explained by increases in serum lactate. Our results suggest that other anions contribute to the AG in LA.

SA-PO898

The Anion Gap/Δ Bicarbonate Ratio in Early Lactic Acidosis: Time for Another Delta?

Richard M. Treger, 1 Tristan Grogan, 1 David Elashoff, 2 Craig Anderson, 3 Scott Rudkin. 2 Nephrology, VHAGLA, LA, CA; 3 Medicine and Statistics Core, UCLA, LA, CA; 1 Emergency Medicine, UCI, Irvine, CA.

Background: The ratio of anion gap and Δ bicarbonate (ΔAG/ΔHCO3) is used to detect co-existing acid-base disorders in patients with high AG metabolic acidosis. Classic teaching holds that in lactic acidosis (LA), the ΔAG/ΔHCO3 is 1:1 within the first 60 minutes of onset (despite limited human data) and subsequently rises to 1:8:1. This study examined this paradigm within the first hour of development of LA.

Methods: Data were obtained prospectively from adult trauma patients at a single level 1 trauma center. Venous samples were drawn prior to intravenous fluids.

Results: 108 patients were included. 63 patients had normal serum lactate levels (≤2.1 mm) with a mean AG of 7.1, the value used to calculate subsequent AG values. ΔAG/ΔHCO3 was calculated for 45 patients who had elevated serum lactate levels (>2.1 mm). The mean ΔAG/ΔHCO3 for all patients with elevated serum lactate levels was 1.86 (SD 1.40). The correlation between ΔHCO3 and AG showed a 95% prediction interval of ±6.15 (Figure 1).

Conclusions: The mean ΔAG/ΔHCO3 was 1.86 within the first hour of the development of LA due to hypovolemic shock, confirming a small prior human study. This contradicts the traditional belief that in LA the ΔAG/ΔHCO3 is 1:1 within the first 60 minutes. The classic 1:1 stoichiometry is based on animal models (in which lactate is acidified into the extracellular [EC] space, facilitating EC buffering of protons by bicarbonate), while our results demonstrate a higher initial ΔAG/ΔHCO3 ratio in early endogenous LA in humans (which originates intracellularly, resulting in intracellular buffering of protons while lactate is predominantly distributed in the EC fluid). The wide 95% prediction interval suggests that ΔAG/ΔHCO3 should be used cautiously in the diagnosis of mixed acid-base disorders.

SA-PO899

Blood Lactate as a Predictor for Mortality in Sepsis Patients with Lactic Acidosis Treated Sodium Bicarbonate: A Retrospective Analysis

Su Mi Lee, 1 Eu Gene Jeong, 1 Dongyeol Lee, 1 Hansue Kim, 1 Sung Hyun Son, 1 Yun Jung Oh, 2 Young Ki Son, 1 Seong Eun Kim, 1 Won Suk An. 1 Dept of Internal Medicine, Dong-A Univ, Busan, Republic of Korea; 2 Dept of Internal Medicine, Bong Seng Montjoy Hospital, Busan, Republic of Korea; 3 Dept of Internal Medicine, BUS Hanseo Hospital, Busan, Republic of Korea; 4 Dept of Internal Medicine, Cheju Halla General Hospital, Cheju, Republic of Korea.

Background: Recent studies have reported that blood lactate level in the critically ill patients is associated with inhospital mortality, but the use of lactate level to monitor and guide therapy remains under investigation. In this study, we evaluated the efficacy of blood lactate level as a predictor for mortality in sepsis patients with lactic acidosis treated with sodium bicarbonate.

Methods: We conducted a single center analysis from May 2011 through April 2014. We retrospectively analyzed 109 sepsis patients with lactic acidosis treated with sodium bicarbonate.

Results: Among the 230 patients with lactic acidosis treated with sodium bicarbonate, we finally included 109 patients (47.4%) with lactic acidosis caused by sepsis. The non-survivors had lower albumin levels (P<0.009), higher SOFA and APACHE II scores (P=0.002, P=0.047, respectively), and higher lactate level at 6 hours, 24 hours, and 48 hours after checking the initial lactate level (P=0.002, P=0.001, P=0.001, respectively). In particular, decrement of at least 10% in lactate clearance for the first 6 hours, 24 hours, and 48 hours of treatment were more dominant in non-survivors than survivors. Lactate clearance at 6 hours, 24 hours, and 48 hours was significantly associated with mortality after adjustment for confounding variables, including age, gender, CRP, albumin, SOFA and APACHE II scores, ventilator care, CRRT, and use of inotropic (HR: 2.201, 95% CI: 1.197-4.046, P=0.011; HR: 3.948, 95% CI: 1.269-12.281, P=0.018; HR: 4.970, 95% CI: 1.679-14.710, P=0.004, respectively).

Conclusions: Serial blood lactate levels monitoring is useful in terms of predicting mortality rather than single initial lactate or maximum lactate levels in sepsis patients with lactic acidosis treated with sodium bicarbonate.

D-Lactate: It’s All in the Gut

Muhammad Deen, Roohi Khan. Dept of Nephrology, CHI St. Luke’s Health, Houston, TX.

Background: D-lactic acidosis is a rare form of lactic acidosis that can occur in patients with short bowel syndrome.

Methods: 88 yo M with PMH significant for HTN and small bowel obstruction s/p sub total small bowel resection presented to the ED with complaints of nausea, vomiting, constipation, loss of appetite, altered mental status and decreased urinary output.

On admission: Vitals: Blood pressure: 115/68 mmHg, Pulse: 80/min, Temperature: 98.5 F and SpO2: 92%

Examination: Distended abdomen with no peripheral edema.

Imaging: CT abdomen revealed dilated bowel loops but no bowel obstruction or free air in the abdomen/pelvis.

Labs: Na: 134mmol/L, K: 4.5mmol/L, Cl: 108mmol/L, CO2: 16mmol/L, BUN: 45mg/dl, Creatine: 1.6mg/dl and Albumin 2.3g/dl. ABG: pH: 7.42, pCO2 : 16mmHg, BUN: 19mmol/L. He was found to have anion gap metabolic acidosis with a non-anion gap metabolic acidosis. Venous lactate: 1.11 mmol/L (Normal 0.5- 2.2 mmol/L). Serum D-lactate: It’s All in the Gut.

Diagnoses of anion gap metabolic acidosis in the setting of D-Lactic acidosis was made due to bacterial over growth because of his past history of small bowel resection.

Conclusions: The diagnosis of D-lactic acidosis should be promptly considered in patients with malabsorptive disorder such as short bowel syndrome or following a jejunoileal bypass especially when no other cause of anion gap metabolic acidosis is found. Diagnosis is confirmed by a special enzymatic test measuring serum D-Lactate. Treatment involves a low carbohydrate diet, sodium bicarbonate infusion to correct acute acidemia and antibiotics to minimize D-lactate producing bacteria.

SA-PO901

Customized Base Solutions for Treatment of Acute Acidosis

Thomas G. Mason, 3 Jeffrey A. Kraut. 1 Dept of Chemistry and Biochemistry, Univ of California, Los Angeles, CA; 2 Dept of Physics and Astronomy, Univ of California, Los Angeles, CA; 3 Medical and Research Services VHAGLA Healthcare System, UCLA Membrane Biology Laboratory, and Div of Nephrology, VHAGLA Healthcare System and UCLA Geffen School of Medicine, Los Angeles, CA.

Background: Acute acidosis is associated with cell dysfunction and increased mortality. Intravenous administration of hypertonic sodium bicarbonate (NaHCO3) does not improve cellular function or clinical outcome. This is attributed to undesirable generation of CO2, which decreases intracellular pH, and also to undesirable osmotic stress. Thus, designing a base that can raise pH without generating CO2, or producing osmotic stress would address an unmet need.
Methods: Theoretical modeling has been performed using Mathematica software to determine equilibrium ion concentrations in mixed strong-weak base solutions. If these solutions have a significant proportion of strong base yet lower concentration, they are predicted to raise blood pH without increasing CO₂ or producing large osmotic stress. Strong bases examined include diosmin carbonate (Na₂CO₃) and sodium hydroxide (NaOH); these were mixed with NaHCO₃. Acid-base parameters were measured in acidified canine blood mixed with the base solutions in a closed system using a blood gas analyzer. Treated blood was examined using an optical microscope.

Results: A near-isotonic base solution containing Na₂CO₃;NaHCO₃ at a ratio of 3:1 is predicted to raise blood pH without increasing CO₂ or causing osmotic stress. Addition of this base to acidified blood raised blood pH while reducing CO₂. By contrast, NaHCO₃ raised blood pH, but also generated CO₂. Examination of red blood cells exposed to the former 3:1 solution revealed no evidence of osmotic stress. Mixed base solutions of NaOH and NaHCO₃ are also promising as a lower sodium alternative.

Conclusions: Mixed strong-weak base solutions, rather than hypertonic NaHCO₃, can raise blood pH and serum bicarbonate levels, minimize osmotic stress, and limit CO₂ generation. A 3:1 mixture of Na₂CO₃;NaHCO₃ well below 1 M concentration appears to be effective in this regard.

SA-PO902
Chloride Alterations in Hospitalized Patients: Prevalence and Outcome

Significance: Qi Ouan, Charat Thongprayoon, Wisit Cheungpasitporn. Medicine: Nephropathy and Hypertension, Mayo Clinic, Rochester, MN.

Background: Chloride (Cl) plays a fundamental role in the maintenance of serum osmotic pressure, acid-base balance, and cellular health. Cl channels are expressed in almost all cells in the body. Dysfunctions in the Cl channel result in a broad spectrum of diseases. Cl alterations in hospitalized patients have not been comprehensively studied in recent years.

Methods: We conducted a retrospective study of adult (>18 years old) hospital admissions at Mayo Clinic over a period of three years (2011 to 2013). Patients without admission Cl (24-hour) were excluded. Outcome measures included all-cause mortality, length of hospital stay and discharge disposition.

Results: 76,719 unique patients from a total of 147,358 hospital admissions were enrolled. 55,523 (72.4%) had repeat Cl measurements within 48 hours. Admission serum Cl in the range of 105-108 mmol/L was found to be optimal based on hospital mortality. 60.6% (n=48, 999) had admission Cl >105 mmol/L, and 13% (n=11,999) >108 mmol/L. Increased Cl was associated with longer length of hospital stay, and being discharged to a care facility. 17.1% (n=13,089) of the patients had anion gap >12 mmol/L; their hospital mortality, when compared to those with anion gap <12 mmol/L, was worrisomely higher.

Conclusions: Mixed strong-weak base solutions, rather than hypertonic NaHCO₃, can raise blood pH and serum bicarbonate levels, minimize osmotic stress, and limit CO₂ generation. A 3:1 mixture of Na₂CO₃;NaHCO₃ well below 1 M concentration appears to be effective in this regard.

SA-PO903
A Retrospective Review of Paediatric Patients with Bartter and Gitelman Syndrome

Background: Bartter and Gitelman syndrome are rare autosomal recessive disorders of renal salt handling. They are characterized by disturbed electrolyte and acid-base homeostasis with potentially severe complications. Currently little is known about the long-term disease course and best treatment is controversial. We performed a retrospective case review to investigate the long-term disease course of patients with a diagnosis of Bartter/Gitelman syndrome.

Methods: Demographic and Laboratory data was recorded at presentation, and ages 1, 2, 3, 4, 5, 10 and 15.

Results: 42 patients with a genetic diagnosis of Bartter/Gitelman were reviewed with a median follow up of 7.85 years (Range 0 - 18 years).

Conclusions: Further prospective and randomized studies are needed to determine whether avoidance of post-admission Cl increase would improve patient survival.

SA-PO904
Urine Calcium to Magnesium Ratio Aids to Diagnose Gitelman’s Syndrome without Hypocalciuria and Receiving Intravenous Magnesium Administration

Background: Although hypocalciuria is widely used to distinguish Gitelman’s syndrome (GS) from Bartter syndrome (BS), several patients with GS actually have not hypocalciuria and may be clinically misdiagnosed as BS. Intravenous magnesium administration to correct hypokalemnesia, another distinct finding in GS can significantly enhance urine calcium excretion and unmask the preexisting hypokalemnesia. Because renal Mg²⁺ wasting is characteristic in GS, we hypothesize that urine Ca²⁺/Mg²⁺ ratio may be superior in diagnosing GS.

Methods: One hundred forty three Taiwanese GS patients (M:F =87:56, age 25 ± 10) with definite SLC12A3 mutations was enrolled. Nine BS patients with CLCNKB mutations and 15 healthy subjects were enrolled as disease and normal control, respectively. Intravenous MgSO₄ was administered (elemental Mg 0.35 mmol/kg) in 8 GS patients with hypokalemnesia. Relevant laboratory and at least two urine collection for all electrolytes excretion were determined. Hypokalemnesia was defined as urine Ca²⁺/Cr ratio less than 0.1 mmol/mmol.

Results: Fourteen (9.8%) of 143 GS patients did not have hypokalemnesia (Ca²⁺/Cr ratio 0.28 ± 0.09 mmol/mmol) and exhibited no significant difference in blood parameters compared with GS patients without hypokalemnesia. Although their urine Ca²⁺/Cr ratio was significantly lower that in BS (0.51 ± 0.18 mmol/mmol), there was still overlapping between them. Notably, urine Ca²⁺/Mg²⁺ ratio was significantly lower in GS than BS without overlap (0.46 ± 0.12 vs 1.57 ± 0.53 mmol/mmol, p<0.001). Acute MgSO₄ administration in GS patients markedly enhanced urine Ca²⁺ excretion (Ca²⁺/Cr ratio 0.05 ± 0.01 to 0.64 ± 0.01 mmol/mmol, p<0.001). However, urine Ca²⁺/Mg²⁺ ratio (0.21 ± 0.01 mmol/mmol) remained much lower than healthy subjects (1.35 ± 0.63 mmol/mmol, p<0.001) and BS.

Conclusions: Urine Ca²⁺/Mg²⁺ ratio may be a good index to help diagnose GS without hypokalemnesia and even receiving intravenous Mg²⁺ administration.

SA-PO905
A Blunted Response to Thiazide Diuretics Is Not Specific for Patients with Gitelman Syndrome

Background: In Gitelman syndrome (GS), a defective sodium-chloride co-transporter (NCC) in the distal tubule classically leads to hypokalemnesia and hypomagnesemia. A challenge with thiazide diuretics, testing the functional presence of NCC, has been shown to differentiate GS from Bartter syndrome (BS) and normal controls. However, the performance of the thiazide test in renal magnesium wasting disorders other than GS and BS has not been studied.

Methods: Eleven patients who presented to our clinic between 2010-2014 with renal magnesium wasting and in whom a thiazide test was performed were included. An abnormal test result is defined as a maximal change of fractional chloride excretion (∆FeCl) < 2.3% [Colussi 2007]. The thiazide test in eight volunteers in our clinic showed a mean maximal ∆FeCl 3.12 ± 0.48% with the lowest value being higher than 2.3%. Additional DNA mutation analyses were performed.

Results: Three patients had a mutation in SLC12A3 (GS), one patient had a compound mutation in CLCNKB and KCNJ1 (BS), 1 patient had a mutation in FXYD2 and five patients had a deletion of one HNF1β allele. The patients with GS showed a blunted response, the patient with BS had a normal response, the patient with FXYD2 mutation showed a blunted response and the patients with HNF1β mutations showed different responses to thiazide diuretics.

**Impact of Hydration Status, Assessed by Bioelectrical Impedance Vector Analysis, on Mortality in Critically Ill Patients**

**Sara Samoni,** 1, 2 Valentina Vigo, 1 Luis Ignacio Bonilla, 1 Gianluca Villa, 1 Silvia De Rosa, 1 Federico Nalesso, 1 Fiorenza Ferrari, 1 Alessandra Brendolan, 1 Carlo Donad, 1 Claudio Ronco 1.

**Background:** Clinical trials have shown a positive correlation between fluid overload and adverse outcomes in pts admitted to intensive care unit (ICU). Currently, there is not a non-invasive method that can provide an accurate and timely assessment of whole body hydration status. Our aim was to evaluate the impact of hyperhydration, assessed by bioelectrical impedance vector analysis (BIVA), on ICU mortality in critically ill pts.

**Methods:** This is a prospective, dual-center study. We included 125 ICU pts with an ICU stay of 72 hrs or more. Anthropometric, medical history, and laboratory data were collected. Assessment of hydration status was performed by BIVA, using a single frequency analyzer at the baseline and daily for a period of 72-120 hrs. Pts were considered normohydrated (NH) or hyperhydrated (HH) if BIVA hydration level was 72.7%-74.3% or >74.3% of fat-free body mass, respectively.

**Results:** The logistic regression analysis performed found a significant correlation between ICU mortality and maximum hydration level reached in observation period, either in patients with or without acute kidney injury (p<0.001).

## SA-PO908

**Sleep-Disordered Breathing Is Not Associated with Body Fluid Volume in Chronic Hemodialysis Patients**

**Takahiro Masuda,** 1, 2 Yumi Kijima, 1, 2 Chihi Sekiguchi, 1 Yasuharu Miyazawa, 1 Eiji Kusano, 1 Yasushi Asano, 1 Daisuke Nagata. 1 Div of Nephrology, Department of Medicine, Jichi Medical Univ, Shimotsuke, Tochigi, Japan; 2 Nasu-Minami Hospital, Nasukarasuyama, Tochigi, Japan; 3 Japan Community Health Care Organization Utsunomiya Hospital, Utsunomiya, Japan; 4 Japanese Red Cross Koga Hospital, Koga, Ibaraki, Japan.

**Background:** Sleep-disordered breathing (SDB), characterized by nocturnal intermittent hypoxia, is frequent in patients with chronic hemodialysis (CHD). Fluid retention may promote SDB in these patients, but the detailed information is lacking.

**Methods:** Eighty-eight CHD patients in Nasu-Minami Hospital and Japanese Red Cross Koga Hospital were included in this study (male: 62.1%, age: 68.1 ± 11.5 years, body mass index: 21.7 ± 3.1, duration of CHD: 5.3 ± 5.9 years, diabetes mellitus: 50.0%). Overnight pulse oximetry and bioimpedance spectroscopy (InBody) for the assessment of body hydration status were performed after dialysis on a dialysis day. Patients were divided into three groups according to 3% oxygen desaturation index (3%ODI) assessed by pulse oximetry: normal (3%ODI<1), mild SDB (3%ODI>1-15) and severe SDB (>15%ODI). We investigated the relationship between severity of SDB and body composition including body fluid volume.

**Results:** Sixty patients (68.2%) were classified into the SDB group (mild SDB 21.5%, severe SDB 18.8%, normal 60.0%). Fat mass (relative to body weight) in the SDB group was significantly higher than in the normal group (normal 24.3 ± 5.8%, mild SDB 27.6 ± 6.0%, severe SDB 30.2 ± 9.2%, p<0.018). After adjusting for age, gender, diabetes mellitus, hemoglobin, and serum albumin in a logistic regression analysis, SDB was independently associated with increased fat mass (odds ratio 1.22, 95% confidence interval 1.10-1.38; P<0.01). Total body water, intracellular water and extracellular water were similar among the three groups.

**Conclusions:** Our findings confirm and expand literature data about the correlation between hyperhydration and ICU mortality. Despite the importance of this problem, there are currently few methods to assess hydration status in critically ill pts. BIVA has been shown to be safe, non-invasive, easy to use and it may predict mortality, thus we suggest its routinely use in ICU pts. Randomized clinical trials are needed to define the precise role of BIVA in the goal-directed fluid management of critically ill pts in ICU.
Conclusions: SDB is associated with increased fat mass, but not body fluid volume in CHD patients. Further studies are needed to evaluate some factors that can explain the high frequency of SDB in CHD.

SA-PO909

Association Between Brain Natriuretic Peptide and Fluid Volume Imbalance Between Intra- and Extracellular Water in Patients with Chronic Kidney Disease

Yasushi Ohashi, Reibin Tai, Toshiyuki Aoki, Shizuka Kobayashi, Atsushi Aikawa, Ken Sakai. Dept of Nephrology, School of Medicine, Faculty of Medicine, Toho Univ; Tokyo, Japan.

Background: Malnourished and elderly patients with chronic kidney disease (CKD) may be susceptible to a extracellular volume overload due to a decreased intracellular volume capacity. We assumed that excessive fluid volume is redistributed on the basis of the basic fluid volume balance when they are exposed to fluid accumulation.

Methods: Using bioimpedance analysis, body fluid composition was measured in 129 patients with CKD from 2013 to 2015 and was separated into three components – (a) free water mass consisting of muscle, fat, and minerals, (b) intracellular water (ICW) content, and (c) extracellular water (ECW) content. Participants was also measured brain natriuretic peptide levels at the time of the body fluid composition measurement. The relationship between the ratio of ECW to ICW and brain natriuretic peptide was examined.

Results: Patients with higher log-transformed plasma level of brain natriuretic peptide were more likely to be older and have lower body mass index (BMI), glomerular filtration rate (GFR), and serum albumin levels and higher proteinuria. In body fluid composition analysis, the brain natriuretic peptide levels increased along with a decrease in all contents of free water mass consisting of muscle, fat, and mineral (r=-0.49, P<0.001), ICW content (r=-0.34, P<0.001), and ECW content (r=-0.25, P<0.01). By the steeper decreased free water mass and ICW content than the decreased ECW content in those patients, the percentage of ECW in body weight increased, and the ratio of ECW to ICW had a positive correlation with the brain natriuretic peptide levels (r=-0.58, P<0.001). In multivariate analysis, age, BMI, GFR, the ECW/ICW ratio remained independently associated with the brain natriuretic peptide levels.

Conclusions: Brain natriuretic peptide is elevated in leaner and elderly patients with fluid volume imbalance between intra- and extracellular water. Fluid volume imbalance between intra- and extracellular water may express a reserve capacity for fluid volume overload and impact on cardiac preload.

SA-PO910

Blood Volume Estimation in Hemodialysis Patients

Doris H. Fuertinger,1 Line Malha,2 Peter Kotanko,1 David S. Goldfarb,1 Stephan Thijssen,1 1Renal Research Inst, New York, NY; 2New York Harbor VAMC and NYU Langone Medical Center, New York, NY.

Background: Anthropometric formulas used to estimate absolute blood volume (ABV) are generally derived from healthy subjects. Most hemodialysis (HD) patients have an expanded ABV prior to HD, rendering these formulas inappropriate for estimation of pre-HD ABV (pre-ABV). Here, we compare the performance of several ABV formulas, used in conjunction with Cri-Line data, for assessment of pre-ABV.

Methods: We assume that post-HD ABV is closer to normal ABV, which we calculated adjusted 49% (95% CI 44%, 53%) increase in LOS. HAggH developed in 8.9% of patients with community-acquired hypernatremia (CAH) and those with hospital-acquired hypernatremia (HAA) were compared to patients with normonatremia at presentation ([Na+] of 138-142 mEq/L) in terms of in-hospital mortality, length of stay (LOS), and discharge disposition. Furthermore, patients with CAH in whom hypernatremia worsened during hospitalization (HAggH) were compared to those without aggravation. Multivariable logistic and negative binomial regression analyses were conducted.

Results: CAH occurred in 20% of hospitalized patients and was associated with an adjusted odds ratio (OR) of 1.67 (95% confidence interval [CI] 1.38, 2.01) for in-hospital mortality, and 1.44 (95% CI 1.32, 1.56) for discharge to a short-/long-term care facility, and an adjusted 10% (95% CI, 7%-13%) increase in LOS. HAA developed in 25.9% of hospitalized patients and was associated with an adjusted OR of 3.17 (95% CI 2.45, 4.09) for in-hospital mortality, and 1.45 (95% CI 1.32, 1.59) for discharge to a facility, and an adjusted 49% (95% CI 44%, 53%) increase in LOS. HAggH developed in 8.9% of patients with CAH. Compared to patients with CAH and no further increase in [Na+], HAggH was associated with greater risk of in-hospital mortality (adjusted OR 1.84, 95% CI 1.32, 2.51) and discharge to a facility (adjusted OR 1.90, 95% CI 1.49, 2.41), and an adjusted 13% (95% CI 4%-23%) increase in LOS.

Conclusions: All forms of hypernatremia encountered in unselected hospitalized patients are independently associated with increased in-hospital mortality and heightened resource consumption.

SA-PO912

Utility of Urine/Plasma Osmolality Ratio for Assessing Volume Status in Hyponatremic Patients

Sho Hasegawa, Maki Shibata, Takehiro Sugiyama, Fumihiko Hinoshita. National Center for Global Health and Medicine, Tokyo, Japan.

Background: Assessing volume status is critical for managing hyponatremia. Physical examination (P/E) and laboratory data are often used for the assessment, but the utility of each parameter has not been validated in hyponatremic patients. A body composition monitor (BCM) uses bioimpedance spectroscopy and can quantify extracellular water (ECW) and volume excess or deficiency. Here, we examined which parameter is superior in assessing volume status of hyponatremic patients, using BCM data as the reference standard.

Methods: We enrolled hospitalized patients (n=41) with hyponatremia ([Na+] <130 mEq/L) at our institution and conducted P/E, laboratory tests and BCM measurement. Patients with high plasma osmolality (>275 mOsm/kg) were excluded (n=5). We used %ECW (ratio of volume excess or deficiency to ECW) derived from BCM data as the reference standard of volume status. First, patients were divided into overhydration (%ECW>0%, n=29) and dehydration (%ECW<0%, n=7) groups. Clinical signs obtained from P/E and parameters of volume status such as serum albumin (Alb), serum uric acid (UA), urine chloride, urine/plasma osmolality ratio (U/P Osm), UUN/BUN, BUN/creatinine, U/P creatinine, FENA, FEUN and FEUA were compared between the groups by Fisher’s exact test or Mann-Whitney U-test. Next, we performed univariate and multiple linear regression analyses to identify associations between each parameter and %ECW.

Results: U/P Osm was significantly higher in dehydration than in overhydration (median-hospital -1.9 vs. 1.3, p=0.001). U/P Osm was 2.7, p=0.007) and U/P creatinine (β=0.3, p=0.01) were associated with %ECW. Since UUN/BUN and U/P creatinine strongly correlated with %ECW, we conducted multiple regression analysis using only Alb and U/P Osm. Results showed that compared with Alb (β=7.7, p=0.007), U/P Osm (β=12.0, p=0.002) was more strongly associated with %ECW.

Conclusions: U/P Osm is superior to other commonly used parameters and clinical signs for assessing volume status in hyponatremic patients.
Sodium Concentrations of Body Fluid Losses: A Systematic Review

Matthew Kaptein,
Divya Sreeramouju,
John Kaptein,
Elaine Kaptein.

Background: Unexplained wide ranges and discrepancies of sodium concentrations [Na+] have been noted for different body fluids. This has led to use of “cumulative fluid balance” regardless of composition, which cannot account for specific water and sodium requirements. Appropriate water and volume management may be facilitated by an accurate and detailed knowledge of water and sodium composition of body fluid losses and gains.

Methods: We performed a systematic review of [Na+] of body fluids lost in adult humans. Particular attention was paid to gastric fluid with high and low acid states, diarrhea due to different mechanisms, and peritoneal, pleural and wound fluids. Inclusion criteria were met for 106 full-text articles.

Results: [Na+] are fluid-specific and consistent. Mean [Na+] were statistically lower for acidic (mean SD: 84+2 mEq/L) than for alkaline (55+13 mEq/L) gastric fluid; the difference is not clinically relevant. [Na+] are higher for bile (184±24 mEq/L) or pancreatic fluid (156±3 mEq/L) than all other body fluids, and similar for intact small bowel (119±14 mEq/L) and ileostomy outputs (116±25 mEq/L). Specific mechanisms for diarrhea are associated with different [Na+]. [Na+] were significantly greater for cholora (128±18 mEq/L) and lower for osmotic-induced (28±16 mEq/L) than all other causes. Among osmotic diarrheas, sorbitol-induced [Na+] was higher (63±17 mEq/L) than for carbohydrate malabsorption (43±20 mEq/L), lactulose (26±19 mEq/L), Idodol (16±13 mEq/L) and polyethylene glycol (13±7 mEq/L). Among secretory diarrheas [Na+] for idiopathic causes (53±22 mEq/L) was lower than for neuroendocrine and villous tumors (75±13 mEq/L) or non-osmotic laxatives (88±33 mEq/L). Pleural, peritoneal, and edema fluid had [Na+] (137±13 mEq/L) similar to plasma. [Na+] for sweat was 44±17 mEq/L.

Conclusions: This is the first in-depth review of verifiable sodium concentrations of body fluids most commonly lost in hospitalized patients. We propose that these losses be replaced with appropriate water and sodium content of enteral and parenteral fluids to correct and avoid dysnatremias and perturbations of volume status.

SA-PO914

Hyponatremia in CKD: The Prevalence and Risk Factors

Masahiko Nagahama,
Daiki Kobayashi,
Fumika Taki,
Takuya Fujimaru,
Masataka Hasegawa,
Yuki Heath,
Yasuhiro Komatsu.

Background: Kidney is a vital organ regulating water and sodium homeostasis, and it is plausible that patients with CKD are more prone to develop hyponatremia due to diminished urinary dilution ability, reduced solute intake, and/or medication which affects free water clearance. However, the prevalence and risk factors of hyponatremia among CKD patients have not been elucidated. The aim of the present study is to clarify the prevalence and risk factors contributing to hyponatremia in CKD patients.

Methods: Among 32,438 patients who visited our outpatient clinic between 2011 and 2014, 9,388 patients met the criteria of CKD, which is defined as either eGFR ≤60 ml/min/1.73m2 or having uncontrolled hypertension.

Conclusions: The present study shows that the prevalence of hyponatremia was 8% in CKD patients, and development of hyponatremia is correlated with progression of CKD in moderate and severe CKD. Worsening CKD and Diabetes are risk factors, while RAS inhibitors are protective for hyponatremia in CKD.

SA-PO915

Mild Hyponatremia on Admission Is Associated with Sepsis and Increased Mortality in Patients Presenting with a Hip Fracture

Juan Carlos Ayus,
Armando Luis Negri,
Michael L. Mortiz,
Nora Angelica Fuentes.

Background: Hyponatremia is associated with an increased risk of falls and hip fractures in the elderly (JAMA 281: 2299-2304, 1999). Moreover, sepsis is a frequent complication in patients with hyponatremia (AKD 65:135-142, 2015). We assessed if hyponatremia on admission was associated with sepsis and increased mortality in patients presenting with a hip fracture.

Methods: A cohort study in adult patients admitted with a traumatic hip fracture and at least one serum Na performed at admission. Hyponatremia (H), Na <135 mEq/L, and normonatremic (N) patients were evaluated for complications occurring within 30 days of surgery, length of hospital stay, readmission rate, in-hospital mortality and mortality during 1 year follow-up.

Results: Among 1571 patients included of whom 366 (23.2%) were hyponatremic (Na 132±4 mmol/L vs 138±3, p<0.001). Length of stay was 8 days in H vs 7 days in N (p=0.053). There was in increased incidence of sepsis in hyponatremic patient, 9.8% in H vs. 6% in N (p<0.01) OR 1.7 (C95%: 1.3-2.6). In-hospital mortality was significantly higher in H vs N patients (19.9 vs 14.7%; p= 0.016) with an un-adjusted OR of 1.45 (95% CI 1.07-1.96) and an adjusted OR of 1.15 (95% CI 0.84-1.64). Readmissions were 15.8% for H vs. 12.9% for N (p=0.14). One-year mortality was greater in H vs N patients (15.4 vs. 6.8%; p<0.001), with an un-adjusted HR of 1.8 (95% CI 1.4-2.35) and an adjusted HR of 1.45 (95% CI 1.1-1.9).

Conclusions: Mild hyponatremia on admission is associated with sepsis and increased in-hospital and late mortality in patients presenting with a hip fracture.

Ho-Jung Kim.2

Background: This clinical study, a multicenter trial in 8 tertiary hospitals in Korea, was carried out to evaluate changes in serum sodium (Na) during 11 days on tolvaptan (TLV) daily and at the 7th day after stopping TLV in SIADH patients (n=135 mEq/L).

Results: Serum [Na+] (mEq/L) increased significantly from baseline to 24 hrs (127±4.3 to 132±3.8, p<0.01). The changes in serum sodium (DsNa) from the baseline were 2.8±4.2 in 24 hrs, respectively. The correlation between DsNa/24 hrs and baseline Na was 0.86, p<0.01. When hyponatremia was stratified into 3 groups, mild (I: 130-134, n=12), moderate (II: 125-129, n=18), and severe (III: <125, n=9) groups, DsNa in III (11.1+4.8) during first 24 hrs was significantly higher than II (6.4±2.5, p<0.05) and I (4.3±3.3, p<0.01). Also, those of DsNa 24 hrs (mEq/L) (n=18) compared to <8 (n=21) had significantly lower baseline serum creatinine (0.56 vs 0.73 mg/dL, Wt (53 vs 60 kg), BMI (21 vs 23), and body surface area (1.54 vs 1.63) (all, p<0.05). Then, serum Na after discontinuation of TLV for 1 wk was similar to the baseline (127±4.3 vs 132±3.8, p=NS). All pts underwent successfully this trial more than 24 hrs, but 4 pts were withdrawn due to side effects (1) and refusal (3).

Conclusions: Tolvaptan is effective and well tolerated in Korean with SIADH. However, Korean patients, particularly those with smaller frame and severe hyponatremia (<125 mEq/L), could be vulnerable to rapid correction by usual initial dose of Tolvaptan 15 mg.

Risk Factors for the Development of Thiazide-Induced Hyponatremia

Kyle John Laporte,
Milagros Zegarra,
Melissa Rohrich,
William Newman.

Background: Thiazide and thiazide-like diuretics are commonly utilized for management of hypertension. However, thiazide diuretics are one of the most common causes of drug-induced hyponatremia. Previous studies have pointed to potential risk...
Factors that may lead to the development of thiazide-induced hyponatremia, but there is still much uncertainty surrounding their role in predisposing patients to the development of hyponatremia. With an increasing prevalence of hypertension, thiazide utilization will likely continue to increase. Thus, the ability to discern potential risk factors for the development thiazide-induced hyponatremia may offer significant clinical value.

A retrospective study was conducted on 450 veterans of the age >18 years with hypertension treated with a thiazide/thiazide-like diuretic (chlorothalidone, hydrochlorothiazide, indapamide, metolazone) between March 2004 and November 2014 at the Fargo VA Health Care System.

Results: 404 patients met inclusion criteria. 15 % (n=63) of patients developed hyponatremia during treatment period with thiazide therapy. Average time to development of hyponatremia was 2.6 years (+3.3) from index date. Mean Charlson comorbidity scores were higher for those who developed hyponatremia (4.59 vs. 2.90; p < 0.001). Incidence of hyponatremia was found to be higher in patients who were active tobacco users (24.8% vs. 11.3%; p < 0.001). Although there was no significant difference in serum creatinine and eGFR between groups, a statistically significant difference in eGFR was found to exist when comparing pre-thiazide eGFR to post-hyponatremia eGFR in those who developed hyponatremia (71 vs. 66; p = 0.036). Patients who developed hyponatremia also had a lower serum albumin (3.78 vs. 3.95; p = 0.033), and a lower BMI (30.1 vs. 31.8; p = 0.035). All other values obtained were similar between groups.

Conclusions: Higher comorbidity index and tobacco use are positive predictors for the development of hyponatremia in patients treated with thiazide/thiazide-like diuretics.

SA-PO918
Persistent Hyponatremia at 72 Hours in Cancer Patients with Severe Hyponatremia Is Associated with Mortality Independent of Cancer Stage Vesh Srivatana,1 Xian Wu,2 Edgar A. Jaimez,3 Ilya Glezerman.1 Div of Nephrology, NYP-Weill Cornell Medical Center, New York, NY; 2Dyson Biostatistics, Weill Cornell Medical College, New York, NY; 3Renal Service, Memorial Sloan Kettering Cancer Center, New York, NY.

Background: Hyponatremia is a common problem and a known independent risk factor for mortality in cancer patients. The impact of rate of correction of sodium on mortality is unknown. The study aim was to determine if the rate of correction in cancer patients with severe hyponatremia (Na < 120 mEq/L) is linked to 90 day mortality.

Methods: Patients with Na < 120 mEq/L were identified from the Memorial Sloan Kettering Cancer Center database from June 1, 2009 until June 30, 2014. 195 patients were identified. 55 patients were excluded from analysis because less than 72 hours after admission they either died (4), had no follow up data (16), were discharged (21), or made comfort care (14). The final cohort consisted of 140 patients who stayed in the hospital for at least 72 hours and had serial measurements of serum Na.

Results: The mean initial serum Na was 116.7 ± 3.0 mEq/L, the median rate of correction was 6 mEq/L with interquartile range 3-9 mEq/L in the first 24 hours, and the overall 90 day mortality was 15.6%.

Conclusions: Cancer patients with severe hyponatremia are at heightened risk for 90-day mortality independent of cancer stage and rate of Na correction if their serum Na at 72 hrs is < 130 mEq/L. Based on this finding we recommend that cancer patients with severe hyponatremia should be corrected to >130 mEq/L at 72 hrs.

SA-PO919
Hyponatremia Correction Using CRRT: Does Kinetic Modeling Avoid Overcorrection? Saurabh Dasgupta,1 Lenar T. Yessayan,1 Balazs Szamosfalvi,2 Sevak Demirjian.1 1Nephrology, Cleveland Clinic, Cleveland, Ohio; 2Nephrology, Henry Ford Hospital, Detroit, MI.

Background: Hyponatremia is the most common electrolyte abnormality in inpatients. It must be corrected at a gradual rate of < 8 mEq/L over at least 72 hours to minimize the risk of central pontine myelinolysis, which can be effectively achieved in patients with renal failure by CRRT. Sodium (Na) kinetic models can predict end dialysis water. A simplified single pool fixed volume kinetic model may be applicable when net Na generation (G) is ~0 mEq/h. Our goal was to measure the correlation of predicted rate of correction of Na to the formula to that observed in ICU patients with hyponatremia treated with CRRT.

Methods: 66 critically ill subjects with serum Na < 130 at time of CRRT initiation were retrospectively identified. Median age was 60, and 52% were male. The predominant CRRT modality was CVVHD (97%), using dialysate Na of 140 mmol/L in most patients (92%) with average cumulative dose of 61L, delivered over median duration of 23.2 hrs. Predicted Na correction in the first 24 hours was calculated using a single pool fixed volume kinetic model. The values were then compared to actual measured serum Na using simple correlation, and Bland-Altman plot.

Results: The correlation factor was calculated to be 0.49 with a p value < 0.001. The Bland Altman plot (figure) showed a mean difference of 2 mEq/L between the observed and predicted delta Na values, with a trend for overestimation of Na correction as delta sodium levels increased.

Conclusions: Increasing HB spuriously decreases dNa and increases Na. A linear correction for this artifact can reduce the discordance between iNa and dNa, promoting their interchangeable use.

SA-PO921
HHV-6 Encephalitis Resulting in Cerebral Salt Wasting and Hyponatremia Jonathan A. Ducastel, Uday S. Nori. Internal Medicine and Nephrology, Ohio State Univ, Columbus, OH.

Background: Hyponatremia is a common electrolyte abnormality that can be associated with hypo-, hyper-, or euolemic states. Low circulating volumes secondary to extra-renal losses, fluid overload states, and syndrome of inappropriate ADH are some of the more common causes of hyponatremia. One consideration that is uncommon and often overlooked is cerebral salt wasting (CSW). CSW is defined as “renal loss of sodium during intracranial disorders leading to hyponatremia and a decrease in the extracellular fluid volume.” It occurs in the setting of cerebral injury, most commonly associated with subarachnoid
hemorrhage, but also documented with other disorders of central nervous system. The mechanism of CSW is not completely understood, but is believed that a cerebral injury can lead to impairment of the sympathetic outflow causing primary natriuresis leading to hypovolemia and sodium depletion.

Methods: Here we describe a case of CSW in a patient with human herpes virus-6 (HHV-6) encephalitis. The patient was a 29 year old male with a history of AML who presented with increasing confusion. He was found to have hyponatremia with a sodium of 126 mmol/L, a urine osmolality of 615 mOsm/kg, and a urine sodium of 144 mmol/L. On exam, he had evidence of hypovolemia with dry mucus membranes and orthostatic hypotension. He was initially treated with normal saline IV fluids. He had increasing diuresis with fluid resuscitation, with 6 liters of urine output on hospital day 1. The patient was continued on IV saline with the addition of oral salt supplements and started on furosemide for suspected CSW. His hyponatremia improved and by hospital day #5 was 133 mmol/L. CT and MRI imaging of the head and brain were unremarkable for acute changes or pathology. A serum HHV-6 PCR showed 13,960 copies. He was treated with IV foscarnet with normalization of the serum and CSF PCR within 10 days.

Conclusions: This case is important because the diagnosis of CSW is often confused with SIADH, as both share similar diagnostic criteria such as elevated urine sodium concentration and urine osmolality. The important clinical distinction is the patient, despite having a hypovolemic state would have polyuria and renal sodium wasting.

Association of 6-Month Pre-ESRD Potassium with Immediate Post-ESRD Survival: A Transition to CKD Study

Melissa Soochoo,1 Connie Rhee,1 Vanessa A. Ravel,1 Elani Streja,2 Jennie Jing,3 Rajiv Saran,2 Bruce M. Robinson,2 Yi Li,2 Danh V. Nguyen,2 Csaba P. Kovesdy,2 Kamyar Kalantar-Zadeh,1 2 UC Irvine; 3UM-KECC; UTHSC.

Background: Previous studies of the association between serum potassium level and mortality in dialysis patients have suggested that a range of 4.6-5.3 mEq/L portends greatest survival in this population. However, the optimal potassium range in the immediate pre-ESRD prelude period among pre-dialysis CKD patients transitioning to ESRD is not known. We hypothesized that a similar pre-ESRD serum potassium range is also associated with higher survival in this population.

Methods: We investigated a cohort of 20,404 US veterans who initiated dialysis between 10/2007-9/2011 and had at least 1 potassium measurement during the last 6 month period before ESRD transition (6 month prelude). We examined the association of 6 month averaged potassium as a continuous predictor of all-cause mortality and early post dialysis period before ESRD transition (6 month-prelude). We examined the association of 6 month averaged potassium as a continuous predictor of all-cause mortality and early post dialysis period before ESRD transition (6 month-prelude). We examined the association of 6 month averaged potassium as a continuous predictor of all-cause mortality and early post dialysis period before ESRD transition (6 month-prelude). We examined the association of 6 month averaged potassium as a continuous predictor of all-cause mortality and early post dialysis period before ESRD transition (6 month-prelude).

Results: The analytic cohort had a mean±SD age of 68±11 years old, among whom 30% were African-Americans, 7% Hispanic and 50% had diabetes as the leading cause of ESRD. The potassium level in the prelude period was 4.5±0.6 mEq/L. Lower potassium levels (3.5-4.0 mEq/L) in the prelude period was associated with highest mortality in the first 3 months after transitioning to dialysis whereas potassium in 4.5-5.5 mEq/L range conferred the greatest early survival.

Conclusions: Lower serum potassium measurements during the final months prior to transition to ESRD are associated with higher early mortality. Whether pre-ESRD potassium should be kept between 4.5 and 5.5 mEq/L in the immediate pre-transition period warrants additional studies.

Antihypertensive Medications and the Prevalence of Hyperkalemia in a Large Healthcare System

Alex R. Chang,1 Yingying Sang,2 H. Lester Kirchner,1 Kunhiro Matsushita,2 Shoshana Ballew,2 Josef Coresh,2 Morgan Grams,3 Geisinger Health System; 2Johns Hopkins Bloomberg School of Public Health.

Background: The association of outpatient medication use with patterns and prevalence of hyperkalemia has not been rigorously examined.

Methods: We evaluated the association between baseline antihypertensive medications [angiotensin converting enzyme-inhibitors (ACEi), angiotensin receptor blockers (ARB), beta-blockers, loop/thiazide diuretics, and K-sparing diuretics] with the frequency and pattern of mild (K<5 mEq/L) and severe hyperkalemia (≥6 mEq/L) over a 2 year window in 342,342 outpatients in the Geisinger Health System based on medication prescription orders. Patterns of hyperkalemia were classified as: never, transient (1-time), intermittent (>1-time but ≤50% of the time), and persistent (>50% of the time). Analyses were adjusted for demographics, eGFR, systolic blood pressure, diabetes, and history of cardiovascular disease. Interactions between medication types with hyperkalemia risk were also tested.

Results: Potassium levels were checked ~1 time/yr in 53% of the cohort; 4% had levels checked ~≥5 times/yr. Overall, 7.4% had ~>1 episode of mild hyperkalemia; 0.4% had an episode of severe hyperkalemia. Among the different classes of antihypertensives, K-sparing diuretics had the strongest associations with both mild and severe hyperkalemia, followed by ACEis and then beta blockers, which were associated only with mild hyperkalemia (Figure). ARBs had similar effect size to beta blockers but were not statistically significant. Thiazide/loop diuretics were protective against mild hyperkalemia but not severe hyperkalemia. There were no consistent interactions between types of antihypertensive medication for risk of hyperkalemia.

Conclusions: Mild hyperkalemia is relatively common and associated with the use of ACEis and K-sparing diuretics but not ARBs in this single healthcare system.

Wide Range in Variation in Serum Potassium in Hyperkalemic Patients with CKD, Response to a Fixed 60 mEq Potassium Diet

David A. Bushinsky,1 Martha Mayo,2 Dahlia Garza,2 Yuri Stavsi,2 Daniel J. Wilson,3 Charles Dumond,2 Lance Berman,2 Murray Epstein,1 1Univ of Rochester; 2Relypsa, Inc; 3Univ of Miami.

Background: Serum K(+K) levels are affected by diurnal variation, fasting/feeding cycles, and medications. In this study we characterized the differences in inter-individual variation in s-K+ on a random diet prior to entry and the effect of a controlled K+ diet on s-K+ levels in hyperkalemic (HK) pts with CKD (stage 2-4) on stable doses of RAASi, during the run-in phase of a treatment trial.

Methods: A total of 27 pts with s-K+ ≥5.5 to ≤6.2 mEq/L were monitored in a clinical research unit. At baseline pts were fed a 60 mEq K+ diet on CKD (stage 2-4) on stable doses of RAASi. s-K+ was measured at baseline and at prespecified intervals for the next 72 h. We calculated individual difference (maximum-minimum) in s-K+ at each time point for the remaining observation period to determine variation in s-K+.

Results: Mean s-K+ at baseline was 5.86±0.22 mEq/L and rose to 5.94±0.17 mEq/L at 72 h following the start of the fixed K+ diet. Over 72 h, 6/27 pts had "low" (0.0-0.2 mEq/L), 9/27 "moderate" (0.3-0.4 mEq/L), and 12/27 "high" (0.5-1.1 mEq/L) variation in s-K+. Variation in s-K+ decreased at each time point over the 72-h period of observation on the controlled diet (Table).

Conclusions: A wide range of inter-individual variation in s-K+ occurred in HK pts with CKD on RAASi who were on an uncontrolled diet prior to entry. Variation decreased significantly after 24 h on a 60 mEq K+ diet. These findings have implications for management of pts with HK and CKD, and for interpreting clinical trials assessing directional change in s-K+ with an intervention.
Table. Variation in s-K+ (max-min) over 72 h during run-in on a 60 meq K+ diet, n=27

Best EKG Criteria for Hyperkalemia in Chronic Hemodialysis Patients

Muzzaffer Hussain, Jamrs R. Cook, Gregory Lee Braden. Dept of Medicine, Baystate Medical Center/Tufts Univ School of Medicine, Springfield, MA.

Background: To date the effects of hyperkalemia(HK) on the EKG of chronic hemodialysis(CHD) patients(pts) is inconsistent. We studied the EKGS of 128 consecutive CHD pts with clotted grafts or fistulas. EKGS from 46 HK pts > 5.5 meq/L were compared to 82 pts with normal potassium (NK) levels < 5.5 meq/L. Pts with RBBB or LBBB or cardiac events within 3 months were already excluded. There were no differences between HK and NK pts for dialysis duration, causes for ESRD, cardiac disease or serum levels of Na, Ca, HCO3, or phosphorus.

Methods: EKG analysis included: the height & width of the P waves, the T waves in V4 & the T waves in Lead 2, the time intervals of PR, QRS, QT, PR/QT, PR/QTc, & slopes of ascending & descending T waves in Lead 2 & V4. For the first time ever in HK CHD pts, the EKG measurements in 32 NK pts with complete data were compared to their NK EKGS obtained 3 to 6 months from the HK event.

Results: Univariate stats between the 46 HK & 82 NK pts showed 4 differences in mean values: V4 T wave height 4.0 vs 2.9 mm, Lead 2 T wave height 2.7 vs 2.0 mm, & the V4 T wave ascending (.03 vs .02) and descending slopes (.04 vs .03). Multivariate analysis for all clinical & EKG findings between HK & NK pts found only the increased height of the T wave in V4 was significant, p=0.05. In contrast, the EKG analysis of the HK pts to their NK EKGS revealed more differences: higher T wave height in V4, 5.0 vs 3.7 mm, higher T wave height in Lead 2, 4.0 vs 2.7 mm, shorter width of T wave in V4, 2.4 vs 4.1 ms or Lead 2, 2.1 vs 4.1 ms , longer PR 188 vs 167 ms , & steeper slopes in the T waves in Lead 2 and V4. Regression analysis of the change in potassium from NK to HK to each EKG measurement showed that the only significant correlation was to the width of T wave in V4, r=-.433, p=0.007 & height of the T wave in V4, r=.333, p=0.03. In these HK CHD pts T wave tenting in V4 was now present in 56%.

Conclusions: We conclude: 1) Comparison of a NK EKG to a HK EKG in CHD pts significantly helps to confirm HK EKG changes in CHD pts. 2) A shortened width and an increased height of the T wave in V4 are the most important HK EKG changes in CHD pts.

SA-PO926

Sodium Polysyrone Sulfonate for the Treatment of Mild Hyperkalemia in Chronic Kidney Disease: A Randomized Clinical Trial

Katherine Desforges, Laurence Lepage, Anne-Claude Dufour, Jessica Doiron, Katia Handfield, Robert Zoel Bell, Michel Vallee, Michel Savoie, Sylvie Perreault, Louis-A. Menoyo. ZS Pharma, Inc., Coppell, TX.

Background: Hyperkalemia (HK; potassium [K+] ≥5.1 mEq/L) is a common and potentially life-threatening electrolyte disorder often occurring in patients with chronic kidney disease, heart failure and diabetes. Sodium zirconium (Zr) cyclosilicate (ZS-9), a potential HK therapy, is a selective K+ ion trap containing covalently bound Zr atoms within an insoluble 25μm particle. Zr has a long history as an inert substance used in biomedical implants and dialysis, and is present in natural diets and household items. Systemic absorption of Zr is expected to be minimal given the low solubility and particle size of Zr. Here we present Zr concentration data from urine and whole blood samples from ZS-9 treated dogs to assess systemic absorption of long-term, high-dose ZS-9.

Methods: Beagle dogs received Control (n=10/sex) or high-dose ZS-9 (2000 mg/kg/day, n=10/sex). Blood samples were collected by venipuncture at baseline, and Weeks 6, 13, 26, and 39. Urine samples were collected directly from the bladder at necropsy (Week 39) and recovery (Week 43). Zr levels in Control and ZS-9 treated dogs were determined using Inductively Coupled Plasma Mass Spectrometry with a lower limit of quantification (LLOQ) of 10 ng/mL (ppb) for both whole blood and urine. The analytical method was designed to measure the presence of both free Zr and ZS-9 bound Zr.

Results: Zr was below the LLOQ in all dog urine samples (N=28) and in all but one Control group whole blood sample (N=226). The one dog in the Control group had a Zr blood level of 10.9 ng/mL at Week 26.

Conclusions: There was no detectable Zr or increase in Zr in blood and urine samples following 39 weeks of 2000 mg/kg/day ZS-9 treatment; equivalent to a human dose of ~65 g/day. Zr was detected in one non ZS-9 treated animal. These results demonstrate an absence of systemic ZS-9 absorption after long-term, high-dose treatment in beagle dogs.

associated with both hypoMg (<2.1) and hyperMg (>2.3). After adjusting for potential confounders, hyperMg (>1.5 mg/dL) was associated with an increased risk of developing septic shock with odds ratios of 1.86 (95% CI 1.07-3.27).

before concentration (mean 421.85 pg/mL), it was further increased after concentration (mean 579.25 pg/mL). Although body temperature rise was observed after the intravenous injection of concentrated ascites in six out of eight, IL-6 concentration in the ascites fluid (r = 0.61063; P = 0.114), the total dose of IL-6 (r = 0.06755; P = 0.436), dose rate (r = 0.2876; P = 0.244) was no obvious correlation between the body temperature rise. On the other hand, respectively in the TP concentration and the ALB concentration of 0.05, it was found correlated with body temperature rise after intravenous injection. In particular, a strong correlation between the ALB concentration and the increase in body temperature was observed (r = 0.8033; P < 0.01).

Conclusions: The correlation of body temperature rise after intravenous injection and IL-6 is weak, while the correlation between the concentrated ALB and body temperature rise was very strong. From these results, we considered that any substance bound to the ALB or ALB itself are associated with elevated body temperature.

SA-P0931
Contrast-Related Hyponatremia
What We Could Be Missing
Christine Joy C. Junia, Kalyani Perumal.

Background: Hyponatremia is a commonly encountered electrolyte abnormality. Long-established algorithms outline etiology and management guiding physicians to prevent neurologic sequelae. Close electrolyte monitoring is emphasized in acute hyponatremia due to higher morbidity and mortality. Contrast-related hyponatremia is an etiology of acute onset hyponatremia that is not routinely monitored and may easily be missed.

Methods: A 76-year-old woman with hypertension, diabetes and chronic kidney disease (CKD) III, eGFR of 44 was admitted for asthma exacerbation and received beta-agonist nebulizer. Her home medications were Bronchodilator and inhaled Steroid. Her symptoms were restlessness and hypotension. Her symptoms improved, however her sodium dropped from 135 to 123 meq/L. She was treated with dextrose, saline and alkalizing agent. Contrast hypertonicity generates a fluid shift and a dilutional effect on extracellular sodium. This is usually offset by osmotic diuresis that is impaired in chronic kidney disease. Our case highlights contrast-related acute hyponatremia in the setting of mild kidney disease, a high-risk patient population that may benefit from post-diagnostic electrolyte monitoring.

Conclusions: The 2014 USRDS data reports a rise in prevalence of CKD III from 4.5 to 6.0 percent. Primary care doctors manage 80 to 90 percent of these patients. There is an unexplained rise in diabetic patients. Over the past decade, CT Scan use in the emergency departments has increased over 200-300%. There are a few case reports of contrast-related hyponatremia, occurring mostly in patients with advanced CKD with eGFR<30. A consistent finding was the acute onset and an average drop in sodium of 12 meq/L. Contrast-related hyponatremia generates a fluid shift and a dilutional effect on extracellular sodium. This is usually offset by osmotic diuresis that is impaired in chronic kidney disease. Our case highlights contrast-related acute hyponatremia in the setting of mild kidney disease, a high-risk patient population that may benefit from post-diagnostic electrolyte monitoring.

SA-P0932
Risk Factors for Calcium-Alkali Syndrome in Post-Surgical Hypoparathyroidism
Savaya Kuroya, Masahiko Yawaza, Naoto Tominaga, Yugo AS, Ibagaki.
Nephrology and Hypertension, St. Marianna Univ; Kawasaki, Kanagawa, Japan.

Background: Post-surgical hypoparathyroidism is a common complication of total thyroidectomy. Patients complicated by permanent hypoparathyroidism often require either or both calcium or vitamin D supplement therapy to maintain serum calcium levels, and long-term therapy can lead to calcium-alkali syndrome (CAS). We examined the incidence rate, magnitude, and risk factors of CAS in patients being treated for post-surgical hypoparathyroidism.

Methods: We retrospectively observed 27 patients with neck tumors who had undergone total thyroidectomy with total parathyroidectomy without autotransplantation between January 2010 and October 2013 at St. Marianna University Hospital. All patients received calcium lactate and alfacalcidol. Medical records were reviewed for historical, clinical, laboratory and imaging data. Definitions were as follows: hyperparacalcemia, corrected serum calcium (cCa) >10.0 mg/dL; acute kidney disease (AKD), either or both >50% increase in serum creatinine (sCr) or >35% decrease in estimated glomerular filtration rate (eGFR); metabolic alkalosis, difference in serum sodium (sNa) and serum chloride (sCl) >38 meq/L. Data were expressed as mean ± standard deviation (SD). For statistical analysis, the paired t test, Student’s t test, and chi-square test were used to compare two matched variables and metabolic alkalosis, difference in serum sodium (sNa) and serum chloride (sCl) >38.

Conclusions: Patients with SIRS and hypoMg (<1.5 mg/dL) at the time of admission had increased risk of developing septic shock during hospitalization.
Effect of NBCe1 Deletion on Renal Ammonia Metabolism

Mary E. Handlogten,1 Gunars Osis,1 Hyun-Wook Lee,1 Jill W. Verlander.1
1Renal Div, Univ of Florida, Gainesville, FL; 2Nephrology Section, NF/SVHS, Gainesville, FL.

Background: Metabolic acidosis typically increases renal ammonia excretion, but people with proximal renal tubular acidosis (pRTA), despite the associated metabolic acidosis, do not have increased ammonia excretion. Genetic forms of human pRTA typically involve the proximal tubule bicarbonate transporter, NBCe1. Based on these observations, we postulated that NBCe1 has a role in renal ammonia metabolism that is in addition to its role in bicarbonate reabsorption.

Methods: We used previously reported mice with NBCe1 deletion. Because Δ− mice have 100% mortality by d10-21, we studied mice at d8-1. Wild-type (WT), heterozygous (HEt) and homozygous knock-out (KO) mice were generated by breeding HEt male and female mice.

Results: Serum HCO3 was 26.4±1.0 mM in WT, 19.8±1.9 in HEt, and 10.3±0.6 mM in KO mice (P<0.05). Thus, NBCe1 deletion causes metabolic acidosis at d8. Although acidosis normally increases ammonia excretion, NBCe1 deletion decreased spontaneous ammonia excretion: 275±74, 212±11 and 94±68 mmol/g creatinine in WT, HEt and KO mice, respectively (P<0.01). Serum Na and K were unchanged. Urine pH was 5.3±0.2, 4.8±0.1 and 4.2±0.1 in WT, HEt and KO mice, respectively (P<0.01), indicating intact urine acidification and no ongoing HCO3 loss. NBCe1 deletion did not alter urine osmolality significantly (WT, 396±74; HET, 693±51; and, KO, 726±34 mOsm/kg H2O; P=NS), which, in combination with intact urine acidification, suggests intact collecting duct function. The regulation of multiple proteins involved in ammonia metabolism was atypical of acidosis. NBCe1 deletion decreased expression of PDG and PEPC and increased expression of the ammonia recycling enzyme, glutamine synthetase. This pattern is the exact opposite of that expected with acidosis. Expression of the TAL ammonia transporter, Ncc2, and the collecting duct ammonia transporters, Rhbg and Rhcg, was unchanged.

Conclusions: We conclude: 1) NBCe1 deletion significantly alters proximal tubule ammonia metabolism, leading to decreased urinary ammonia excretion; and, 2) NBCe1, in addition to its role in HCO3 transport, may have an important role in ammonia metabolism.

Assessing Urine Ammonium Concentration by Urine Osmolal Gap in Chronic Kidney Disease

Takuya Fujimaru, Yasuhiro Komatsu, Takuya Shuo.
Nephrology, St. Luke’s International Hospital, Tokyo, Japan.

Background: Acidemia is one of the risk factor for end stage kidney disease and mortality for patients with chronic kidney disease (CKD). Although ammonium is the crucial component of renal acid excretion, measurement of urine ammonium concentration (NH4+) is not routinely available in most hospital laboratories. To estimate NH4+, urine osmolal gap (UOG = urine osmolality – [2(Na+ + K+) + urea + glucose]) is calculated and the formula (NH4+ = UOG/2) has traditionally been used. However, studies evaluating it in CKD patients are scarce. The present study aims to assess the relationship between NH4+ and UOG in CKD patients.

Methods: Spot urine samples were collected from 36 patients with CKD in our hospital (24 males, age 41-96 years, serum creatinine 0.9-12.4 mg/dl). We measured urine pH, sodium and osmolality, and compared these data with the calculated NH4+ and the UOG values using the formula (NH4+ = UOG/2).

Results: NH4+ ranged from 0.3-43.8 mmol/l (median, 6.2 mmol/l). UOG/2 correlated positively and significantly with NH4+ (r=0.925, p<0.0001).

Conclusions: UOG is an accurate method to estimate NH4+ in CKD patients and can be used to assess urinary acidification ability in CKD patients.

Albuminuria Enhances Renal NHE3 Expression via the Activation of Mitochondrial Oxidative Stress/RAS Axis

Nuria M. Pastor-Soler,1 Mohammad M. Al-latineh,1 Hui Li,1 Vivek Bhalla,2 Kenneth R. Hallowes.3 1Medicine, Div of Nephrology, Keck School of Medicine of USC, Los Angeles, CA; 2Medicine, Div of Nephrology, Stanford School of Medicine, Palo Alto, CA; 3Medicine, Renal-Electrolyte Div, U. of Pittsburgh School of Medicine, Pittsburgh, PA.

Background: The volumetric proton-ATPase (V-ATPase) is highly expressed at the apical membrane of type A intercalated cells (ICs) in the collecting duct. This pump mediates proton transport across a membrane often against a gradient. Defects in V-ATPase function can lead to renal tubular acidosis. In kidney cells we showed that the metabolic sensor AMP-activated protein kinase (AMPK) phosphorylates the V-ATPase A subunit at Ser-384. AMPK regulates some transport proteins by inhibiting their function and promoting their ubiquitination and degradation. These mechanisms are likely important for inhibition of membrane transport during cellular metabolic stress. We noticed that Ser-384 exists within a 14-3-3 binding motif. Dimeric 14-3-3 bind to phosphorylated sites on target proteins and modulate protein function. We hypothesized that phosphorylation by AMPK and an additional kinase module A subunit binding to 14-3-3 proteins and A subunit ubiquitination.

Methods: We used transient transfections of V-ATPase A subunit mutants in Clone C ICs, followed by immunoprecipitation and immunoblotting.

Results: We have preliminary evidence that phosphorylation at Ser-384 and a new “Site III” in the V-ATPase A subunit are required for 14-3-3 binding. For example, 14-3-3 binding to the A subunit increased when we used a phosphomimetic mutant (Ser-to-Asp) at Site III compared to the WT sequence at that site, and this binding was not dependent on the presence of the AMPK activator AICAR. Furthermore, AICAR increased A subunit ubiquitination as compared to untreated controls.

Conclusions: We propose that V-ATPase A subunit binding to 14-3-3-3 promotes its ubiquitination and degradation. These pathways are downstream of phosphorylation of the subunit Ser-384 by AMPK and at Site III by another unidentified kinase. Our results link downregulation of the V-ATPase to metabolic depletion in kidney epithelial cells.

ATP6v1b1b Haplosufficiency Lead to a Mild Incomplete Renal Tubular Acidosis (RTA) in Mice

Soline Bourgeois, Carsten A. Wagner.
1Inst of Physiology, Univ of Zurich, Zurich, Switzerland.

Background: Mutations in ATP6v1b1 gene in man is considered as an autosomal recessive disease and lead to distal RTA by dysfunction of the B1 subunit of H-ATPase in type A intercalated cells. In some conditions, it is expressed in mouse kidneys also distal RTA and a decrease in ammonia and alkaline urine pH.

Methods: Here we investigated on littermate mice whether ATP6v1b1b+/−/mice also develop acid-base disturbances during an acute and chronic acid challenge performed by 0.2 M HCl added to powdered standard food.
Results: ATP6v1b1+/− (WT) and +/- (HE1) mice exhibited no difference in their blood and urine parameters under baseline conditions. During the acid challenge, while ATP6v1b1−/- (KO) developed alkaline pH and low ammoniauria with hypercalciiuria, HET mice showed no difference in their urine data over the whole acid load compared to WT mice. However, even though, HET mice did not exhibit low blood pH, as KO mice, they had a lower bicarbonatemia, higher chloride and lower PCO2 compared to WT mice at the end of the acid challenge. Both KO and HET mice drank more than WT mice over the acid load with a tendency to urinate more. After 4 days of acid load, subcellular localization of the α4 and β2 subunits of H-ATPase were not different within the 3 strains of mice and WT and HET mice exhibited the same localization of B1 subunit. However, western blot analysis of B1 and B2 expression in renal membrane fractions revealed a 2-fold decrease of B1 and B2 protein expression in HET mice compared to WT mice and no difference in the expression of B2 protein in KO mice compared to WT mice while B1 protein was totally absent from KO kidneys.

Conclusions: In conclusion, 1) HET mice developed a mild incomplete RTA during an acid challenge, undetectable regarding urine parameters. The RTA is partly compensated by the respiration and an increase in water consumption. 2) B2 subtype does not compensate for the decrease in B1 expression both in HET kidney tissues and seems to be inhibited by acid load.

Bedside Rule (pCO2=HCO3+15) Is Reliable in Predicting Respiratory Response in Metabolic Acidosis with Bicarbonate Levels of More Than 7 meq/L. Mohammad Kazem Fallahzadeh, Michael Emmett. Dept of Internal Medicine, Baylor Univ Medical Center, Dallas, TX.

Background: There is controversy about the reliability of the bedside rule (pCO2=HCO3+15) in prediction of respiratory response in metabolic acidosis. The aim of our study was to compare the accuracy of the bedside rule with Winter’s equation in predicting respiratory response in metabolic acidosis.

Methods: We extracted the measured bicarbonate and PCO2 levels of 382 patients with metabolic acidosis from the previously published articles evaluating the respiratory response to metabolic acidosis. We calculated the predicted levels of CO2 by bedside rule and Winter’s equation for each patient. Then we compared the accuracy of these formulas in predicting the respiratory response to metabolic acidosis.

Results: As demonstrated in the figure 1, the values calculated by bedside equation (pCO2=HCO3+15) appear to be a reliable predictor of respiratory response in HCO3 levels of more than 7 meq/L, as compared with the line of best fit and Winter’s equation.

Conclusions: Our results show that bedside rule (pCO2=HCO3+15) is reliable in predicting respiratory response in metabolic acidosis with HCO3 levels of more than 7 meq/L.

TSS-Seq Analysis of Low pH-Induced Gene Transcripts in the Intercalated Cells of the Collecting Ducts Yuichihiro Izumi, Koji Eguchi,1 Terumasa Nakagawa,1 YushI Nakayama,1 Hideki Inoue,1 Yutaka Kakizoe,2 Takashige Kuwabara,1 Hiroshi Nonoguchi,2 Masashi Mukoyama,1 1Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Japan, 2Dept of Internal Medicine and Education & Research Center, Kitasato Univ Medical Center, Japan.

Background: Metabolic acidosis is caused by acute and chronic kidney disease due to the decrease of acid excretion in the intercalated cells of the collecting duct in the kidney. Although the effect of acidosis on renal function has been examined in vivo, direct effect of low pH on the intercalated cells has not been investigated.

The Mechanistic Target of Rapamycin Regulates Solute Transport in Renal Tubules
Nasir A. Shah1, Davide Pietro Cina,2 Tuncer Onay,2 Vera Eremina,3 Chengin Li,4 Aline Martin,3 Yashpal S. Kanwar,5 Susan E. Quaggin,5 1Mater Health Services North Queensland, James Cook Univ, Townsville, Queensland, Australia; 2Medicine, Div of Nephrology, Northwestern Univ, Chicago, IL; 3Feinberg Cardiovascular Research Inst, Northwestern Univ, Chicago, IL; 4Lunenfeld-Tanenbaum Research Inst, Mount Sinai Hospital, Toronto, ON, Canada; 5Pathology, Northwestern Univ, Chicago, IL, Canada.

Background: Inhibitors of the mechanistic target of rapamycin (MTOR inhibitors) belong to a family of drugs with potent immunosuppressive, anti-angiogenic and anti-proliferative properties. Despite their clinical potential, their use in humans has been hampered by a significant incidence of proteinuria and electrolyte disturbances. Although some studies suggest MTOR may play a role in regulating renal solute transporter expression and function, the exact mechanisms underlying these changes are largely unknown.

Methods: In this study we examine the contribution of MTOR inhibition in the renal tubules to the development of proteinuria and electrolyte disturbances by generating an inducible Pax8-driven, tubule-specific Moor knockout mouse (Moor Pax8-iKO).

Results: Loss of Moor in the renal tubular epithelium resulted in increased 24-hour urine volume, diminished urine osmolality, and renal failure. Despite elevated 24-hour urine albumin, Ca++, and Mg++ Moor Pax8-iKO mice were both hypercalcemic and hyperglycemic. Histologically, Moor Pax8-iKO mice exhibited generalized tubular atrophy with focal cysitc dilations of the distal and cortical collecting tubules, and interstitial fibrosis. Immunohistochemistry showed decreased expression of aquaporin-2 (Aqp2), Calbindin D 28k (Calb1), and the sodium-potassium-chloride cotransporter (Nkcc2). Increased expression of the transient receptor potential cation channel subfamily V member 5 (Trpv5) was also noted.

Conclusions: Taken together, our results suggest that MTOR is a key player in maintaining electrolyte balance by modifying the expression, and function of solute transporters in the renal tubular epithelium.

High Mobility Group Box 1 (HMGB1) Inhibits HCO3- Absorption in Medullary Thick Ascending Limb (MTAL) Through Receptor for Advanced Glycation End Products (RAGE)-Rho-Rock1-Mediated Inhibition of Basolateral Na+/H+ Exchange
Hans A. Watts, Thampi George, David W. Good. Univ TX Med Branch, Galveston, TX.

Background: HMGB1 is a damage-associated molecule that is released extracellularly in response to infection or injury and plays a role in mediating kidney dysfunction in sepsis and sterile inflammatory disorders. Recently we showed that basolateral HMGB1 inhibits HCO3- absorption in perfused rat MTALs through a RAGE-dependent pathway additive to TLR4-ERK-mediated inhibition by LPS. Here we examined signaling and transport mechanisms involved in inhibition by HMGB1.

Results: Inhibition of HCO3- absorption by HMGB1 was eliminated by the Rho- associated kinase (ROCK) inhibitor Y27632 and by a specific inhibitor of Rho, the activator of ROCK. HMGB1 increased Rock1 activity in dissected inner stripe of outer medulla, a preparation that accurately reproduces changes in MTAL signaling proteins. Activation of ROCK1 by HMGB1 was eliminated by the RAGE antagonist FPS-229 and by inhibition of Rho. Addition of a direct Rho activator reduced basal HCO3- absorption rate and prevented inhibition by HMGB1. The Rho and ROCK inhibitors had no effect on inhibition by bath LPS. The Rho-ROCK1 pathway regulates NHE3 and we have shown that inhibition of NHE1 decreases MTAL HCO3- absorption secondary through cytoskeleton-dependent inhibition of apical NHE3. Inhibition of HCO3- absorption by HMGB1 was eliminated by bath amiloride, 0 Na+ bath, and the F-actin stabilizer jasplakinolide, three maneuvers that selectively prevent inhibition of HCO3- absorption mediated through NHE3. Bath amiloride and jasplakinolide did not affect inhibition by bath LPS.

Conclusions: We conclude: 1) HMGB1 inhibits HCO3- absorption in the MTAL through a RAGE-Rho-ROCK1 pathway coupled to inhibition of NHE1; 2) this pathway functions in parallel with the bath LPS-TLR4-ERK pathway to impair MTAL HCO3- absorption. Thus, during sepsis, endogenous damage-associated molecules and exogenous bacteria-associated molecules act directly and independently to inhibit MTAL HCO3- absorption through different receptor signaling and transport pathways. The RAGE-Rho-ROCK1 pathway is a potential target to attenuate sepsis-induced renal tubule dysfunction.

Identification of IQGAP-1 as a Pendrin-Binding Protein in the Kidney
Jie Xu,1 Sharon L. Barone,2 Kamyar A. Zahedi,1 Manoocher Soleimani,1 1Center on Genetics of Transport and Epithelial Biology, Dept of Medicine, Univ of Cincinnati, Cincinnati, OH; 2Research Services, VA Medical Center, Cincinnati, OH.

Background: Networks of interacting proteins are crucial for all levels of cellular function. The Slc26 family of anion transporters [Slc26a3 (DRA), Slc26a5 (pendin), Slc26a6 (PAT-1), and Slc26a10] form multi-protein complexes with cytoskeleton, anchoring proteins, PDZ adaptor proteins, CTFR and/or protein kinases, which impart regulatory signals on these isoforms. No information is available on proteins that interact with pendrin (Slc26a4).

Methods: A yeast two hybrid system was employed to screen a mouse kidney cDNA library with a pendrin C-terminal fragment as bait. A total of 6 x 10^5 interacting clones were identified, out of which 14 clones were confirmed to be positive when screened for β-gal expression. Plasmids from these clones were purified and their interaction with pendrin was confirmed.

Results: Our experiments identified IQGAP-1 as a pendrin C-terminus binding partner. IQGAP-1 is a scaffolding protein that binds and/or stabilizes ezrin, CDC42 and RAC1, and interacts with cytoskeletal and cell adhesion molecules. In the kidney, IQGAP-1 is strongly expressed in the DCT, CNT, CCD and podocytes. IQGAP-1 has also been shown to control tight junction formation through recruitment of claudins. Our results indicate that IQGAP-1 co-localizes with pendrin on the apical membrane of B-intercalated cells. IQGAP-1 is also detected on the basolateral membrane of A-intercalated cells in CCD. Functional studies in HEK293 cells demonstrated that the co-transfection of IQGAP-1 and pendrin increased pendrin-mediated Cl-/HCO3- exchange activity by more than 60%. Confocal microscopy showed more abundant plasma membrane expression of pendrin in the presence of IQGAP-1.

Conclusions: These studies demonstrate the interaction of IQGAP-1 and pendrin in B-intercalated cells, as well as the stimulatory role of IQGAP-1 on pendrin activity. We propose that pendrin interaction with IQGAP-1 is important in the regulation of CCD function and physiology, and that disruption of this interaction contributes to altered pendrin trafficking and/or activity in pathophysiologic states.

Regulation of Rhg by Aldosterone in Intercalated Cells of the Collecting Ducts
Koji Eguchi, Yuichiro Izumi, Terumasa Nakagawa, Yushi Nakayama, Hideki Inoue, Yutaka Kakizoe, Takashige Kuwabara, Masashi Mukoyama. Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.

Background: Acid-base balance is regulated by aldosterone which stimulates acid secretion in the intercalated cells of the collecting ducts of the kidney. Rhoas blood group C glycoprotein (Rhg) is an ammonia transporter which cooperates with H+/ATPase to secrete H+ in the intercalated cells. In vivo experiments have shown that metabolic acidosis and hypokalemia, that change plasma aldosterone level, increases and decreases the expression of Rhg, respectively. Direct effect of aldosterone on the regulation of Rhg has not been examined.

Methods: We examined the effect of aldosterone on the regulation of Rhg. Membrane fraction of the whole kidney was extracted from mice that were continuously administered aldosterone (20 mg/kgbody/day) or vehicle for a week. To further examine the effect of aldosterone on the regulation of Rhg in the intercalated cells, mRNA, whole cell protein, and membrane fraction were extracted from IN-IC cells (a rat intercalated cell line) after the treatment with aldosterone (10^-6 M) for 24 h. The Rhg mRNA and protein expressions were measured by real-time PCR and Western blotting, respectively. The expression of sodium and glucocorticoid-regulated kinase 1 (Sgk1) mRNA was also measured in IN-IC cells.

Results: Administration of aldosterone increased the expression of Rhg protein in membrane fraction of the whole kidney. In IN-IC cells the expressions of Rhg and Sgk1 mRNAs were 1.3- and 3.2-fold greater, respectively, in cells treated with aldosterone (10^-6 M) than in cells with vehicle. The expression of Rhg protein in whole cell extract was not changed by the treatment with aldosterone. However, the expression of Rhg protein in membrane fraction was 3.2-fold greater in cells treated with aldosterone than in cells with vehicle.

Conclusions: These results suggest that aldosterone regulates membrane accumulation of Rhg possibly through the activation of Sgk1.

Role of Adenylyl Cyclase 6 in Regulation of Urinary pH
Soren Brandt Poulsen,1,2 Robert A. Fenton,3 Timo Rieg,1 1Dept of Medicine, UCSD, La Jolla, CA; 2VASDHS, San Diego, CA; 3Dept of Biomedicine, Aarhus Univ, Aarhus, Denmark.

Background: Adenylyl cyclase isoform 6 (AC6) is expressed in all renal tubular segments and catalyzes the synthesis of cAMP. We have previously reported that AC6 knockout (AC6−/−) mice have an urinary concentrating defect, a mild proteinuric phenotype and secondary hyperparathyroidism. A recent study (Am J Physiol Renal Physiol. 2012;303(6):F812-20) determined that cAMP can increase pendrin protein (Cl-/HCO3-) expression. We therefore hypothesized that AC6-mediated cAMP formation was important for urinary pH regulation.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: AC6 wild-type (WT) and AC6-/- mice (n=6/genotype) were challenged with NaHCO$_3$ in their drinking water for a period of 8 days. As daily fluid intake is double in AC6-/- mice, the NaHCO$_3$ was reduced by 50% in this genotype (0.14 mol/l vs. 0.28 mol/l in WT). Urine was collected; blood was collected under baseline conditions and at the end of the 8 day experimental period. Mice were euthanized, one kidney processed for Western blotting (pentrin, H-ATPase B1 subunit positive cells/mm$^2$ (WT: 322 ± 6 vs. AC6-/-: 28.2) in the renal cortex was not different between genotypes.

Conclusions: Our results imply a role for AC6 in expression of pentrin and H-ATPase B1 subunit and subsequent regulation of urinary pH. The increase in urinary pH in AC6-/- mice can only be achieved, or is the consequence of, higher pentrin abundance; however, this effect is independent of pentrin distribution changes. Further studies are needed to determine the signals causing baseline differences in urinary pH.

Young Soo Kim,1 Bum Soon Choi,2 Cheol Whee Park,3 Chul Woo Yang,4 Yong-Soo Kim,1 Young Soo Kim,1 Byung Ha Chung.1 Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea; 2Internal Medicine, Uijeongbu St. Mary's Hospital, Uijeongbu, Korea.

Background: There is no clear consensus on the definition of acute kidney injury (AKI) in a deceased donor. Inability to discriminate the AKI stage may affect outcomes. In this study, we determine the discriminating ability of the Kidney Disease: Improving Global Outcomes (KDIGO) compared to the Acute Kidney Injury Network (AKIN) criteria for the prediction of the development of delayed graft function (DGF) and allograft outcome in deceased donor kidney transplantation (DDKT).

Methods: We analyzed 285 kidney transplant recipients who took kidney from 228 deceased donors. We calculated the AKI stage of deceased donor according to the AKIN and KDIGO criteria and compared the predictability for the development of DGF and the change of allograft function.

Results: For 2 classification systems, DGF developed more frequently in the AKI group than non-AKI group (P < 0.05) and allograft function assessed by the Modification of Diet in Renal Disease (MDRD) equation showed a significantly deteriorating pattern at 2 weeks and 1, 3, 6, 12 months after kidney transplantation compared to that in the non-AKI group (P < 0.05, comparison at each time point).

Conclusions: In DDKT, the KDIGO criteria may be more useful for predicting the development of DGF compared to the AKIN criteria.

Impact of Cold Ischemia Time on Graft Failure and Death

Douglas F. Arbetter,1 Mariana C. Chiles,1 Prativa Baral,1 Geoffrey K. Dube,1 Russell J. Crew,1 Heather K. Morris,1 Jai Radhakrishnan,1 David J. Cohen,1 Stephen O. Pastan,1 Rachel E. Patzer,1 Sumit Mohan.1 1Dept of Medicine, Columbia Univ College of Physicians & Surgeons, New York, NY; 2Dept of Medicine, Emory Univ School of Medicine, Atlanta, GA.

Background: Patient and graft survival post kidney transplant (KT) are influenced by an interaction of multiple factors, including organ quality, preservation and cold ischemia time (CIT). Several small studies have suggested that even small increases in CIT adversely impact patient and graft outcomes. In this analysis we assessed the impact of increasing CIT on patient and graft survival in the US.

Methods: We identified 75,660 first-time adult KT recipients, who received a deceased donor (DD) kidney from 2000-2011 in SRTR. Pearson's chi-square tests of independence and Pearson's chi-square tests of independence comparing genotypes (8.3±0.4 vs. 8.3±0.4, NS) and no significant change in blood pH was observed (7.45±0.01 vs. 7.43±0.01, P=0.05 vs. WT). NBCe1 protein abundance was not different, whereas pentrin and H-ATPase B1 subunit were 1.8 and 1.5-fold higher in AC6-/- vs. WT, respectively (P < 0.05).

The number of pentrin positive cells/mm$^2$ (WT: 322 ± 6 vs. AC6-/-: 28.2) in the renal cortex was not different between genotypes.

Conclusions: Our results imply a role for AC6 in expression of pentrin and H-ATPase B1 subunit and subsequent regulation of urinary pH. The increase in urinary pH in AC6-/- mice can only be achieved, or is the consequence of, higher pentrin abundance; however, this effect is independent of pentrin distribution changes. Further studies are needed to determine the signals causing baseline differences in urinary pH.

Impact of Hypothermic Machine Perfusion on Outcomes following Kidney Transplantation

Background: Patient and allograft outcomes following deceased donor kidney transplantation (DDKT) are thought to be influenced by the intrinsic quality of the organ at procurement and any superimposed subsequent injury that occurs during cold preservation (CP). Hypothermic machine perfusion (HMP) is used in an attempt to decrease injury from CP especially for organs that have extended periods of cold ischemia. We analyzed the impact of complete, partial or no HMP use during CP on patient and graft survival following DDKT.

Methods: We identified 75,660 first-time adult renal transplant recipients, who received a DD kidney from 2000-2011 in SRTR. Pearson’s chi-square tests of independence and Kruskal-Wallis tests were performed to test for association between HMP and mortality, graft failure, and delayed graft function (DGF). Cox analyses, adjusting for donor factors (age, gender, creatinine, cause of death), recipient factors (age, dialysis duration, PRA, HLA mismatch), CP time, and specified effect measure modifiers, were performed to estimate the hazard of either graft failure, or DGF occurring given HMP.

Results: On unadjusted analyses, compared to no HMP use, kidneys that received HMP for some or all of their CP time were less likely to experience DGF (OR=0.82, p=0.001 & OR=0.77, p=0.001) but more likely to experience allograft failure (HR=1.19, p=0.001 & HR=1.20, p=0.001, figure 1). On multivariable analyses, the use of HMP was associated with a lower incidence of DGF (OR=0.70, p=0.001 & OR=0.59, p=0.001) but continued to be associated with a higher risk of allograft failure even after adjusting for CIT and the lower DGF (HR=1.11, p=0.023 & HR=1.26, p=0.002).

Conclusions: HMP improves short term outcomes by lowering rates of DGF but is associated with reduced long-term allograft survival.

SA-PO950

The Impact of Remote Ischaemic Preconditioning (RIPC) on the Inflammatory Response following Live Donor Kidney Transplantation

Kristin Vibeke Veighey,1 Madhur P. Motwani,2 Jennifer Nicholas,1 Raymond Macallister,1 Wessley Kidney Unit, Portsmouth Hospitals NHS Trust, United Kingdom; 2UCL Centre for Clinical Pharmacology & Therapeutics, Univ College London, United Kingdom; 3Clinical Trials Unit, London School of Hygiene and Tropical Medicine, United Kingdom.

Background: Ischaemia reperfusion (IR) injury at transplantation contributes to organ damage that limits allograft longevity. Animal studies have demonstrated a reduction in circulating proinflammatory cytokines following RIPC, which may contribute to tissue protective effects. REPAIR demonstrated a trend towards improved live donor kidney function following RIPC. We investigated the effects of RIPC on serum and urinary cytokines in this study.

Methods: 406 adult live donor/recipient pairs were recruited. Pairs were randomised using a factorial design to either: sham RIPC, early RIPC (immediately pre-surgery), late RIPC (24 hours pre-surgery) or dual RIPC. Donor and recipient received the same interventions (active or sham RIPC). Serum from donor and recipient and urine from recipients were analysed at baseline and on day 2 for pro-inflammatory cytokines IL-1β, IL-6, IFN-γ and TNF-α, using multiplex ELISA. All analyses were conducted using linear regression adjusted for baseline (pre-treatment) values of the cytokine and indicator variables for early and late treatment group. Cytokine values were log transformed before analysis to account for skewed distribution.

Results: There was no difference in the expression of serum cytokines in donor serum or recipient serum and urine post baseline pre-surgery and day 2 post surgery.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

SA-PO951

Remote Ischaemic Preconditioning (RIPC) Provides a Sustained Improvement in eGFR following Live Donor Kidney Transplantation: Four Year Follow-Up in the REPAIR Study

Kristin Vibekke Veighey, Jennifer Nicholas, Stuart Robertson, Raymond Macallister, Wexner Kidney Unit, Portsmouth Hospitals NHS Trust, United Kingdom; Clinical Trials Unit, London School of Hygiene and Tropical Medicine, United Kingdom; UCL Centre for Clinical Pharmacology & Therapeutics, Univ College London, United Kingdom.

Background: Ischaemia reperfusion (IR) injury sustained at transplantation contributes to organ damage that limits allograft longevity. The RENal Protection Against Ischemic Reperfusion in transplantation (REPAIR) study demonstrated a weak effect of early RIPC on the primary outcome isohexyl glomerular filtration rate (GFR) at 1 year (adjusted mean difference 3.08 ml/min/1.73m²; 95% CI -0.89 to 7.08; p=0.13), but stronger evidence of an effect on eGFR at 1 year (difference 4.98; 95% CI 1.13 to 8.29; p=0.011), reflecting a potentially clinically important improvement of kidney function. There was no evidence that late RIPC alone had any benefit at 1 year. RIPC was safe and well tolerated. We used data from up to 4 years follow-up to examine the medium term effects of early and late RIPC on eGFR.

Methods: 406 adult live donor/recipient pairs were recruited and randomised using a factorial design to either: sham RIPC, early RIPC (immediately pre-surgery), late RIPC (24 hours pre-surgery) or dual RIPC (early and late RIPC). Donor and recipient received the same interventions (active or sham RIPC). The primary outcome was isohexol GFR at 12 months. eGFR up to 5 years post transplantation was an important secondary outcome.

Results: Provisional analysis of eGFR data up to 48 months suggested a sustained benefit of early RIPC and possible emergence of benefit of late RIPC. The mean (SD) 55.8 (23.0) in control vs 57.4 (20.4) in early RIPC at 2 years; 51.7 (18.6) vs 57.7 (21.3) at 3 years; and 51.8 (19.8) vs 60.5 (24.3) at 4 years. The mean (SD) in control vs late RIPC were 55.8 (20.4) vs 57.4 (22.9) at 2 years; 52.8 (19.8) vs 56.6 (20.5) at 3 years; and 52.4 (21.7) vs 59.7 (22.8) at 4 years.

Conclusions: The benefit of early RIPC on eGFR that was demonstrated at 1 year appears to be sustained during medium-term follow up, reflecting a potentially clinically important improvement of kidney function.

DSA Monitoring and Treatment in Kidney Transplant Recipients
Monica Grafals,1 Alexander Gilbert,1 Olga A. Timofeeva.2 1Medstar Georgetown Transplant Inst, Georgetown Univ, Washington, DC; 2Histocompatibility Laboratory, Georgetown Univ, Washington, DC.

Background: The development of DSA monitoring is a new technique to detect antibodies in kidney transplant recipients. We previously showed that patients that developed de novo DSA (dnDSA) suffered a 35% graft loss. Because of this we have developed a protocol for treating patients that have developed dnDSA post kidney transplant.

Methods: Since the implementation of this treatment protocol on September 12, 2014, there have been 9 patients that have developed dnDSA after renal transplantation.

Conclusions: Since the development of dnDSA post kidney transplant is associated with worse graft outcomes, implementation of treatment protocols is necessary for kidney transplant patients. This preliminary data shows that treatment for dnDSA with this protocol seems to successfully treat the antibodies.

SA-PO955

On the Patterns of Early De Novo DSA Development in Kidney Transplant Recipients in the First 6 Months After Alemztuzumab Induction
Chelsea Estrada, Yezina T Nigatu, Heesuck Suh, Frank Darras, Mersema Abate, Edward P. Nord. Nephrology and Transplantation, Stony Brook Medicine, New York.

Background: The presence of de novo DSA (dnDSA) is associated with antibody mediated rejection and suboptimal graft outcomes. The incidence of dnDSA post renal transplantation varies according to immunosuppression protocols, screening, and detection methods, and ranges from 5-25%. A higher incidence of dnDSA after alemtuzumab (AL) has been observed. We sought to characterize the expression of early dnDSA development after AL induction in renal transplant recipients.

Methods: Consecutive kidney transplant recipient were screened for dnDSA from July 1/2014 to 4/30/2015. DnDSA was detected by single antigen beads and luminex technology at months 1, 2, 3, and 6. Mean Fluorescent Intensity (mfi) >500 was considered positive. Induction consisted of AL with rapid steroid withdrawal, and maintenance immunosuppression was with tacrolimus and mycophenolate mofetil.

Results: Four of the patients that developed dnDSA were in the low risk category and in 3 of them the DSA has cleared. The 4th patient has a DSA against DP1 with an mfi of 1587 that has remained stable. All of these patients have a GFR>45 cc/min and their DSAs have become undetectable and weak respectively.

Conclusions: Since the development of dnDSA post kidney transplant is associated with worse graft outcomes, implementation of treatment protocols is necessary for kidney transplant patients. This preliminary data shows that treatment for dnDSA with this protocol seems to successfully treat the antibodies.

SA-PO956

Low Level Class I or II Donor HLA-specific Antibodies Do Not Correlate with the Concurrent Presence of Antibody Mediated Injury on Biopsy
Chelsea Estrada, Catherine Miranda, Heesuck Suh, Frank Darras, Edward P. Nord, Mersema Abate. Nephrology and Transplantation, Stony Brook Medicine, New York.

Background: Pre-transplant and de novo donor HLA-specific antibodies (DSA) have been identified as risk factors for adverse outcomes in renal transplantation, causing antibody-mediated graft injury and acute antibody-mediated rejection (ABMR) and transplant glomerulopathy (TG). With improved detection techniques, DSA recognition is increasing but there is no consensus on the definition of DSA positivity. While low level pre-transplant DSA has been associated with the future occurrence of ABMR, low level DSA on the day of indication biopsy is of unclear significance.

Methods: All sera were tested for DSA using single antigen beads with Luminex technology on the day of indication renal transplant biopsy from 7/1/2015 - 5/21/2015. DSA level >500 mfi were considered negative, between 500-1500 mfi low level and >1500 mfi high level. Acute ABMR and TG histology met Banff 2013 criteria. In this cohort, induction was with alemtuzumab and rapid steroid withdrawal, and maintenance immunosuppression was with tacrolimus and mycophenolate mofetil. Chi square analysis was used to assess the association between low and high levels of DSA and biopsy findings of antibody mediated injury.

Results: Fifty-three consecutive indication kidney transplant biopsies were performed from 7/1/2014 - 5/21/2015. Of these 12 had evidence of ABMR (2 acute, 8 TG and 2 both). Six of the 8 patients with TG alone did not have DSA. At the time of biopsy, 12 class I (6 low and 6 high level) and 13 class II (3 low and 10 high level) were detected.

Conclusions: 1. The presence of high level class II DSA was significantly associated with the concurrent biopsy finding of antibody medicated injury. 2. Of greater significance, the presence of class I DSA or low level class II DSA did not correlate with pathologic findings.

SA-PO957

Characteristics of Kidney Transplant Candidates with and without Antibody against Angiotensin II Type I Receptor (AT1R-Ab)
Mary Carnelle Philogene,1 S.M. Bagnoosc,2 Annette M. Jackson,3 Mary S. Leffell,1 Andrea A. Zachary,1 1Medicine, Johns Hopkins Univ, Baltimore, MD; 2Pathology, Johns Hopkins Univ, Baltimore, MD.

Background: In this study we sought to determine whether baseline characteristics of kidney transplant candidates when correlated with presence of AT1R-Ab are predictive of transplant outcomes.

Methods: 122 renal transplant recipients were tested for presence of AT1R-Ab using quantitative ELISA (CellTrend GmbH, Germany). Patient demographics were obtained from the hospital electronic record under an approved IRB.

Results: Patients were categorized according to AT1R-Ab levels: positive >17 Units/ml (30%); borderline 10-17 Units/ml (34%), negative <10 Units/ml (36%). There were fewer females (31% versus 61%, 55%) and African Americans (14% versus 24%, 16%) in the AT1R-Ab >17 Units/ml group compared to the other two groups. The presence of AT1R-Ab has been associated with development of hypertension and fibrosis; therefore, we examined AT1R-Ab among patients categorized by the following diseases: IgA nephropathy, glomerulosclerosis, lupus nephritis, FSGS, and membranoproliferative glomerulonephritis. We found no correlation between these diseases and AT1R-Ab levels (38%, 29% and 30%, respectively; p=0.7). We also found no association with diagnosis of hypertension and AT1R-Ab levels (16%, 17%, 18%). The most significant difference between the three groups was a higher percentage of positive patients among those who received more than one kidney transplant (78%, 22%; p<0.001). Post transplantation, sixty-one patients were biopsied to investigate graft dysfunction. There were more patients in the borderline and positive AT1R-Ab groups who were evaluated for graft dysfunction compared to the negative group (65%, 54% versus 34%) although this did not reach statistical significance. Importantly, the AT1R-Ab positive and borderline groups had fewer HLA antibody positive patients compared to the AT1R-Ab negative group (54%, 50%, 87%; p=0.001).

Conclusions: The only pre-transplant characteristic linked to presence of AT1R-Ab in patients who are being evaluated for kidney transplantation is the incidence of previous transplant.

Effect of B-Cell Activating Factor (BAFF) Inhibition (LY2127399; Tabalumab) on Highly Sensitized Patients with End Stage Renal Disease awaiting Transplantation  Muhammad Ahmad Muttaba,1 Wendy Komocars,3 Milagros D. Samaniego-Picota,1 Eric Nantz,2 Jayne Hague,3 Melissa D. Anderson,1 Benita K. Book,3 Nancy G. Higgins,7 Tim E. Taber.1 Nephrology, University of Texas Medical Branch, Galveston, TX; 2Transplant Nephrology, Indiana Univ School of Medicine, Indianapolis, IN; 3Bio-Medicines, Eli Lilly and Company, Indianapolis, IN; 4Nephrology, Univ of Michigan Health System, Ann Arbor, MI.

Background: B cell activation factor (BAFF) is critical in B-cell maturation. Inhibition of BAFF represents an appealing target for desensitization of highly sensitized end stage kidney disease patients.

Methods: We conducted a Phase 2a, single-arm, open-label exploratory study investigating the effect of tabalumab (BAFF inhibitor) in ESRD patients with cPRAs >50%. The treatment period had a total duration of 24 weeks. Eighteen patients received tabalumab, at a dose of 240-mg subcutaneous (SC) at Week 0 followed by 120-mg SC at 4-week intervals for 5 more months. Patients were then followed for an additional 52 weeks. Blood samples were analyzed for HLA antibodies, BAFF levels, serum immunoglobulins, T and B cell subsets at specified time intervals during the treatment and follow-up periods. Pre and post treatment tonsil and bone marrow biopsies were also performed.

Results: Significant reductions in cPRAs were observed at week 16(p=0.043) and at week 36(p=0.004), however the absolute reductions were small (5%). Overall factor effect at week 76 compared to baseline was significant (p=0.04). MAFF levels increased during treatment, reflecting binding to tabalumab and decreased in the follow-up period remaining slightly above baseline at week 76. Expected changes in B cell subsets and reductions in immunoglobulins were observed. Two tabalumab-related serious adverse events occurred (pneumonia and worsening of peripheral neuropathy) while the most common other adverse events were injection-site pain and hypotension. Three patients received a matched donor cadaveric transplant during the study follow up.

Conclusions: B cell activation factor (BAFF) inhibition resulted in statistically significant but not clinically meaningful reduction in the cPRA from baseline. Funding: Pharmaceutical Company Support - Eli Lilly

SA-PO959

Background: Pre- and post-transplant DSA increases the risk for acute rejection, humoral rejection and graft loss. Every year a 5% of patients will develop DSA but other patients turn negative. It is unclear how the behavior of pre-transplant DSA under immunosuppression and their clinical impact is. This study evaluate the relationship between de novo DSA and the outcome of kidney transplantation, and whether the development of these antibodies is related to pre-transplant DSA status.

Methods: Prospective cohort study. From Jan/2004-Dec/2014 a total of 519 kidney transplant were performed. For analysis we include 412 with DSA determination plus negative Flow-Crossmatch (in DSA-positive cases). We classified the patients in 7 groups according to pre-/post-transplant DSA: 1) Neg/Neg (n=130) 2) Neg/De Novo (n=81) 3) Neg/De Novo-Variable (multiple changes in DSA, n=35) 4) Pos/Pos (same DSA, n=12) 5) Pos/De Novo (n=12) 6) Pos/Neg (n=8) 7)Without DSA post-transplant measure (n=137). The outcomes analyzed were graft and patient survival, acute rejection (AR), humoral rejection (AMR), and graft function by MDRD.

Results: From 412 patients, 58 patients (14.1%) had pre-transplant DSA. Patients with Pos/Pos or Pos/De Novo DSA had higher and earlier AR and AMR rate, followed by Neg/De Novo-Variable and Neg/De Novo, as you can see in the figure A) and B) respectively. For graft loss only those with Pos/De Novo was higher than Neg/Neg (Figure C). Interestingly, those who are Pos/Neg had similar outcomes than Neg/Neg.

SA-PO960

Course of Anti-HLA Antibodies After Induction Therapy with Rituximab in Renal Transplantation  Luuk Hilbrands,1 Wil Allesbe,2 Martijn W.F. Van den hoogen,3 Irma Joosten,2 Marije C. Baas.1 Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; 2Laboratory Medicine, Radboud Univ Medical Center, Nijmegen, Netherlands; 3Nephrology, Erasmus Medical Center, Rotterdam, Netherlands.

Background: B-cell depletion protocols have shown to reduce donor-specific antibodies against HLA (DSA) and chronic antibody mediated rejection. We aimed to study the effects of rituximab as a single-agent induction therapy on the titers of pre-existent or de novo DSA and non-DSA after renal transplantation and relate this to rejection free and overall graft survival.

Methods: We collected sera in participants of a prospective double-blind randomized study on the efficacy and safety of the prophylactic use of one dose of rituximab, added to standard immunosuppressive treatment (prednisolone, tacrolimus and mycophenolate mofetil) in comparison with standard immunosuppressive treatment alone in renal transplantation (www.clinicaltrials.gov, NCT016565331).

Results: 280 patients were included (142 received placebo, 138 rituximab). Anti-HLA antibodies (Ab) were determined in serum taken pre-transplant and 12 and 24 months after transplantation. Serum was analysed pre-transplant and at 12 months from 126 placebo and 119 rituximab treated patients. Pre-existent anti-HLA Ab were present in 24/126 (19.0%) patients in the placebo group and in 20/119 (16.8%) patients in the rituximab group (P=0.05). In the placebo and rituximab treated patients HLA class I Ab disappeared in 55.6% and 50% and HLA class II Ab in 23.5% and 57%, respectively (P=0.06). At 12 months, 11 (8.7%) placebo treated patients and 4 (3.4%) rituximab treated patients (NS) developed de novo HLA Ab. 10/245 (4.1%) had de novo HLA class I Ab: 6 (4.8%) and 4 (3.4%) in the placebo and rituximab treated patients, respectively (NS). 12/245 (4.9%) had de novo HLA class II Ab: 9 (7.1%) in the placebo group and 3 (2.5%) in the rituximab group (P=0.09).

Conclusions: Induction therapy with rituximab compared to placebo does not significantly influence the course of anti-HLA Ab at 12 months, however it possibly decreases the levels of pre-existent class II anti-HLA Ab and inhibits the formation of de novo class II anti-HLA Ab.

SA-PO961

Background: We conducted a multicenter prospective clinical study in ABO-incompatible kidney transplantation (ABO-KT) without splenectomy (UMIN000006635). To evaluate the benefit of desensitization with rituximab (R), we investigated the data of this study from the time course change of anti-A/B antibody (ab) titer and sequential pathological findings.

Methods: Desensitization protocol included low dose MMF and steroid started 28 days before and CNI started a few days before surgery. R 375 mg/m² was administered at day -14 and day -1. Minimum 2 sessions of plasma exchange were done for anti-A/B ab removal before transplant, and basiliximab was administered on day 0 and day 4. Anti-A/B
ab titers and eGFR were sequentially evaluated, 0 hr, 1 hr and protocol biopsies (4 weeks after transplantation) were also sequentially performed as possible. Pathological specimens were centrally diagnosed by 3 pathologists.

**Results:** 18 pts received AB0i-KT. One-year pts and graft survival were both 100%. The desensitization with R was well tolerated. Average anti-A/B (IgG) titer at baseline was 1560 ± 1560 and decreased to 19.72 ± 69.30 at 1 hr after surgery, making until the end of the study. In pts whose sequential pathological specimen available showed positive C4d deposition in 1/13 at 1 hr and 11/16 (69%) at protocol biopsy. No pts developed AMR related to anti-A/B abs except for one who experienced AMR with anti-HLA ab (Banff07 type II). However anti-A/B ab titers were slightly higher than the others (4x-32x). Pathological findings included arteriosclerosis in 8, nephrocalcinosis in 1, IF/TA (grade 1) in 1 and suspicious CNI acute nephrotoxicity in 1. Two pts showed C4d+ without other pathological signs.

**Conclusions:** In this series, anti-A/B ab titers were successfully decreased and no AMR occurred other than 1 caused by anti-HLA ab, whereas C4d deposition was detected in 69% of pts by protocol biopsy. Our desensitization protocol was confirmed both pathologically and clinically safe and effective for ABOi-KT.

**Post-Transplant BAFF Levels Do Not Predict the Development of Anti-HLA Antibody in Kidney Transplant Recipients**

Sarah J. Kirilbash, Yong Su Shin, Cheol Whay Park, Chul Woo Yang, Byung Ha Chung. Transplant Research Center, Seoul St. Mary’s Hospital, College of Medicine, The Catholic Univ of Korea, Seoul, Korea; Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary’s Hospital, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.  

**Background:** It is well known that pre-transplant B cell activating factor (BAFF) levels are associated with the development of de novo anti-HLA antibodies and also antibody mediated rejection post-transplant. However, the clinical significance of BAFF values at allograft rejection has not been determined. In this study, we investigated the clinical significance of pre and post-transplant BAFF levels measured when indication biopsy was done.

**Methods:** In 130 kidney transplant (KT) recipients who required allograft biopsy due to an increase in serum creatinine, we checked for anti-HLA antibodies using Lumines single antigen assay, and measured BAFF levels using ELISA kits. In 78 of these patients we also measured pre-transplant BAFF and anti-HLA antibody levels. We investigated the relationship between pre-transplant, post-transplant and delta BAFF levels and the occurrence of anti-HLA antibodies.

**Results:** Pre-transplant BAFF levels showed significant association with pre-transplant sensitization, represented by positive PRA, high PRA , and presence of HLA-DSA. They also showed positive association with early rejection (rejection within 6 months from KT). Post-transplant BAFF levels showed significant association with pre-transplant sensitization, but did not show association with anti-HLA antibodies and positive donor-specific antibodies at the time of biopsy. We did not find any association between post-transplant BAFF levels and cumulative allograft survival, allograft biopsy results, Banff scores and microvascular inflammation scores.

**Conclusions:** In conclusion, pre-transplant BAFF levels are associated with pre-transplant sensitization and are useful in predicting allograft rejection. But post-transplant BAFF levels measured at the time of indicated biopsy are not associated with the appearance of de novo HLA-DSA, allograft rejection, biopsy findings and other allograft outcomes.

**SA-PO963**

**Effectiveness of Bortezomib (BT) in the Treatment of Antibody Mediated Rejection (AMR) Among Pediatric Kidney Transplant Recipients (pKTx)**

Sarah J. Kirilbash, Donna J. Claes, Choel Whay Park, Yong Su Shin, Chul Woo Yang, Byung Ha Chung. Transplant Research Center, Seoul St. Mary’s Hospital, College of Medicine, The Catholic Univ of Korea, Seoul, Korea; Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary’s Hospital, College of Medicine, The Catholic Univ of Korea, Seoul, Korea.  

**Background:** AMR has a poor prognosis despite a number of therapeutic options. BT is increasingly being utilized in adults but there are limited data on its safety and efficacy in pKTx with AMR.

**Methods:** Multicenter retrospective case series including all pKTx who received BT for biopsy proven AMR, from 2008-2015, at 8 centers within Midwest Pediatric Nephrology Consortium.

**Results:** Twenty-four pKTx from 8 centers were treated with BT for AMR. In addition to BT, 75% were treated with rituximab, 79.2% with plasmapheresis and 91.7% with IVIG. 62.5% were males, 45.8% were white, and 41.7% were African American. Two-thirds were deceased donor recipients, and mean age at transplant was 11.1 years (SD 5.19). Obstructive uropathy and dysplasia comprised 50% of the underlying diseases. At the time of transplant, 82.2% of patients had 0.0% panel reactive antibodies. Mean estimated GFR (eGFR) prior to AMR was 49.6 (SD 12.1). Prevalence of donor specific antibodies (DSA) and changes in eGFR are shown in table 1.

**Conclusions:** Even though limited by small patient numbers, this trial suggests efficacy of IA in the treatment of late ABMR.

**SA-PO965**

**Immunoadsorption Is Efficient in the Treatment of Late Antibody Mediated Rejection**

Sarah J. Kirilbash, Donna J. Claes, Gaurav Gupta, Priya Verghese, Min Bal, yoong Yoon, Min Kyung Cho, Dhiren Kumar, Luis F. Quintana, Laurence H. Beck. Cincinnati Children’s Hospital Medical Center; Pediatric Nephrology, Univ of Minnesota; Cincinnati Children’s Hospital; Children’s Hospital New Orleans; Wake Forest Univ; Rush Univ; Cleveland Clinic; Indiana Univ; Medical Univ of South Carolina.

**Background:** Immunoadsorption is an alternative to plasma exchange (PE), double filtration plasmapheresis (DFPP) and immunoadsorption (IA) represent an attractive strategy for antibody depletion. We investigated whether PE or DFPP or IA is effective in the treatment of late ABMR.

**Methods:** 40 renal tx recipients diagnosed as biopsy confirmed ABMR at a mean time of 70:40 months after tx were included. Patients were randomly assigned to PE (n=16) or DFPP (n=19) or IA with protein A (n=5). The study groups were similar regarding age, gender, donor type, eGFR at randomization and post-tx follow-up time. Donor specific antibody (DSA) was positive in 62.5% of PE, 73.6% of DFPP and 100% of IA groups (p=0.25), and C4d was positive in 75%, 68% and 60% (p=0.79), respectively. All patients received 2 kg IVIG and Rituximab 375 mg/m².

**Results:** Tubulointerstitial scarring (ci+ct) (p=0.81), microcirculation inflammation (gi+pi) (p=0.38) and transplant glomerulopathy (g) (p=0.21) scores were similar. However, the mean total inflammation (ti) score of IA group (2.60±0.55) was significantly higher than PE (1.69±0.70) and DFPP (1.79±0.71). The rates of graft loss were as follows; PE: 13/16 (81.3%), DFPP: 10/19 (52.6%) and IA: 1/5 (25%) (p=0.03). The graft survival was significantly higher for IA than PE (p=0.01). There was a tendency of better graft survival in DFPP compared to PE group (p=0.07). Kaplan-Meier survival analysis revealed better overall survival for IA than for PE and DFPP (p=0.03).

**SA-PO964**

**Immunoadsorption Is Efficient in the Treatment of Late Antibody Mediated Rejection**

Sarah J. Kirilbash, Gaurav Gupta, Luis F. Quintana, Aydin Turkmen, Aliaattin Yildiz, Mehmet S. Sever. Div of Nephrology, Dept of Internal Medicine, Istanbul Faculty of Medicine, Istanbul, Turkey; Dept of Pathology, Istanbul Faculty of Medicine, Istanbul Faculty of Medicine, Istanbul, Turkey.

**Background:** Plasmapheresis (PP) with IVIG, was proposed as a useful treatment for antibody mediated rejection (ABMR), As an alternative to plasma exchange (PE), double filtration plasmapheresis (DFPP) and immunoadsorption (IA) represent a attractive strategy for antibody depletion. We investigated whether PE or DFPP or IA is effective in the treatment of late ABMR.

**Methods:** 40 renal tx recipients diagnosed as biopsy confirmed ABMR at a mean time of 70:40 months after tx were included. Patients were randomly assigned to PE (n=16) or DFPP (n=19) or IA with protein A (n=5). The study groups were similar regarding age, gender, donor type, eGFR at randomization and post-tx follow-up time. Donor specific antibody (DSA) was positive in 62.5% of PE, 73.6% of DFPP and 100% of IA groups (p=0.25), and C4d was positive in 75%, 68% and 60% (p=0.79), respectively. All patients received 2 kg IVIG and Rituximab 375 mg/m².

**Results:** Tubulointerstitial scarring (ci+ct) (p=0.81), microcirculation inflammation (gi+pi) (p=0.38) and transplant glomerulopathy (g) (p=0.21) scores were similar. However, the mean total inflammation (ti) score of IA group (2.60±0.55) was significantly higher than PE (1.69±0.70) and DFPP (1.79±0.71). The rates of graft loss were as follows; PE: 13/16 (81.3%), DFPP: 10/19 (52.6%) and IA: 1/5 (25%) (p=0.03). The graft survival was significantly higher for IA than PE (p=0.01). There was a tendency of better graft survival in DFPP compared to PE group (p=0.07). Kaplan-Meier survival analysis revealed better overall survival for IA than for PE and DFPP (p=0.03).
Methods: Sixteen consecutive ttp patients with a history of jvn were tested for pre-transplant PLA2R-Ab. ELISA titers (Eurosimmun, NJ, USA) > 14 RU/ml were considered positive, as per manufacturer instructions. All patients received similar post-transplant immunosuppression. A receiver operating characteristic (ROC) analysis was performed after combining data from Quintana et al. (n=21; Transplantation Feb 2015) to determine a PLA2R-Ab concentration which could predict rMN.

Results: Six (out of 16; 37%) patients had biopsy-proven rMN at a median of 3.2 years post-txp. Of these, 5/6 (83%) had a positive PLA2R-Ab pre-txp with a median of 82 RU/ml (range=31-1500). The only patient who had a Median follow-up of 5 years had negative PLA2R-Ab. All seven patients who had a biopsy showed a significant reduction (4-fold and 3-fold respectively) in patients with a sensitivity of 85% and a specificity of 92%.

Conclusions: Pre-transplant PLA2R-Ab could be a useful tool for the prediction of rMN. Patients with rMN in the absence of PLA2R-Ab should be screened for occult malignancy.

SA-PO966

Neutrophil-to-Lymphocyte and Platelet-to-Lymphocyte Ratio Predict Acute Allograft Rejection

David S. Wheeler, Scott Blumhof, Manjula Balasubramanian, Janani Rangaswami.

Background: Currently, allograft biopsy is gold standard for diagnosing rejection however there is intense interest in identifying non-invasive biomarkers. The goal of this study is to determine whether the neutrophil-to-lymphocyte ratio (NLR) or the platelet-to-lymphocyte ratio (PLR) correlate with acute allograft rejection.

Methods: This single center retrospective case-control study examined all kidney transplant biopsies conducted at Einstein Medical Center from Jan 2013 through Dec 2014. Biopsies were stratified for rejection (acute cellular, borderline, negative). The NLR and PLR were calculated from routine laboratory studies obtained at various time points preceding the biopsy.

Results: Of the 102 “for cause” biopsies, 37.3% showed clear evidence of acute rejection and 18.6% were borderline. NLR and PLR obtained within the week prior to the biopsy showed a significant reduction in acute rejection and a 3-6 fold respectively in patients with acute cellular rejection. The mean NLR in NLR and PLR preceded the biopsy by 2-4 weeks suggesting a rejection prodrome. Interestingly, NLR at the time of borderline rejection accurately predicted rejection status on subsequent biopsy conducted within 8 weeks.

Conclusions: NLR and PLR are highly sensitive biomarkers for acute rejection which become positive prior to other clinical manifestations. Furthermore, in cases of borderline biopsies NLR accurately predict the result of subsequent biopsies. The inclusion of NLR and PLR could revolutionize allograft rejection evaluation by reducing the need for biopsies and providing additional insight in cases where the biopsy is non-diagnostic.

SA-PO967

Transitional B Cell T1/T2 Ratio Is a Prognostic Marker for Human Renal Allograft Rejection and its Association with RAGE, IL-1b, and HMGB1

D. Rothstein, Richard J. Baker.

Background: Human transitional B cells (Tb) may play a significant role in auto and alloimmune disease. We previously showed that Tb express high IL10, TNFα and this ratio fall with acute rejection. TbR are comprised of less mature T1 and more mature T2 cells.

Methods: We characterized the cytokine expression of Tb vs. T2 cells (identified by differences in CD24ACD38 expression) and investigated the utility of T1/T2 ratio as a biomarker for allograft deterioration. Patients with T1/T2 ratio were found to fall in rejection (resulting in lower T1/T2 ratio), contributing to the change in IL10:TNFα ratio. Thus TbR represent the B subset over the next 5 years (ROC AUC 0.82, P<0.001) and was independently associated with allograft deterioration (HR 4.8 95% CI 1.3-17.8, P=0.02). T1/T2 ratio was examined 2 years post-transplant in a prospective validation set of 97 stable patients derived from a steroid avoidance RCT comparing alemtuzumab (n=51) vs. placebo (n=46). Thus TbR was a strong predictor of graft deterioration than traditional markers like eGFR (test set, eGFR ROC AUC 0.76 vs. T1/T2 ratio 0.84, Z statistic 0.97; validation set, eGFR ROC AUC 0.64 vs. T1/T2 ratio 0.82, Z statistic 1.92), or the detection of DSA (test set, DSA ROC AUC 0.66 vs. T1/T2 ratio 0.84, Z statistic 2.9; validation set, DSA ROC AUC 0.66 vs. T1/T2 ratio 0.82, Z statistic 2.35).

Conclusions: We demonstrate a distinct subset of Tb (T1) characterized by an anti-inflammatory cytokine profile. A decrease in T1/T2 ratio (due to selective loss of T1 cells) is a strong prognostic biomarker for subsequent renal allograft deterioration.

SA-PO970

Quantitative Characterization of T Cell Repertoires in Kidney Transplant Patients 

**Houda Alachkar,**1 Martin B. Mutonga,1 Taigo Kato,1 Sowjanya Kalluri,1 Vikas Vugjini,1 Yusuke Nakamura,1 Nada Alachkar,1,* University of Chicago; 1Johns Hopkins Univ; 1Kendall Medical Center.

**Background:** Acute and chronic T cell mediated rejection remains a major cause of kidney graft failure. Despite the significant decrease in early acute rejection due to current potent immunosuppressions, long-term graft survival remains unsatisfactory. Thus, characterization of the T cell repertoire and the kinetic of the expanded clones in transplant (Tx) patients may shed a light on our understanding of the T cells’ role in graft rejection.

**Methods:** We collected blood and urine samples from (46) patients before Tx, and at sequential time points post Tx and at time of T cell mediated rejection. We utilized next generation sequencing approach to characterize T cell receptor (TCR) repertoire. Sequencing using the illumina miSeq was performed on DNA synthesized from RNA extracted from patients’ samples. This approach enables to track each expanded TCR clone in the graft at 3 months post Tx, back to their first appearance in blood and urine samples obtained pre or 1 month post Tx. We also measured the RNA expression levels of CD8, CD4, FOXP3, Granzyme and Perforin in blood samples (N=43).

**Results:** Only patients with acute T cell mediated rejection (n=2) had TCR repertoires defined by the top 10 TCR clones appeared at any time point in blood, showed significant expansion in blood at 3 month post Tx compared with that at 1 month post Tx (P=0.01 and 0.02). CD8, FOXP3, Granzyme and perforin RNA levels were significantly higher in samples obtained from patients with rejection compared to that in patients with no rejection (P=0.02).

**Fig.4:** Pattern of changes of CDR3 Frequencies in Blood of Kidney Transplant Patients

**Conclusions:** Our study provides valuable unprecedented longitudinal analyses that define the kinetics of each TCR beta clone, and the changes in diversity of CDR3. This approach allows for identification of the expanded T cell clones that are possibly associated with graft rejection.

SA-PO971

**Critical Appraisal of the New Banff Criteria for Chronic Antibody-Mediated Rejection in the Real Life Setting**

Isabelle Houde, Isabelle Côté, Molsen Agharzazi, Sacha A. De Serres. Renal Div, Quebec Univ Health Center; Laval Univ, Quebec City, QC, Canada.

**Background:** Significant changes in the criteria for chronic active antibody-mediated rejection (CAABMR) were made at the 2013 meeting, which is of major concern for clinical management. Here we compared the 2007 vs. 2013 criteria with regards to clinical outcomes.

**Methods:** Single-center, observational retrospective cohort study of all patients who received an indication biopsy between January 2006 and October 2014, during which EM evaluation, ptc scoring and C4d scoring by IIF and IF was routinely performed. Patients were included if they met at least criterion 1 for CAABMR: score cg1 or 0, cg1b or 0 or severe peritubular capillary basement membrane multilayering. GN, immune deposits, HCV+.

**Results:** 123 patients were included. 18% met the full 2007 criteria, whereas an additional 18% fulfilled the full 2013 criteria. Only 25% of patients met the 2007 criterion #2-C4d, in contrast to 82% for the 2013 criterion #2-microvascular injury (MVI): 67% were C4d-positive and 55% were g’ptc positive, with substantial overlap. 45 patients experienced the endpoint at a median of 22mo post-biopsy. Overall, only a 2013 diagnosis of CAABMR was associated with the endpoint (adjusted HR=2.5 [1.2-5.2] for 2013 vs. HR=1.6 [0.7-3.8] for 2007 diagnosis). Adjusted Cox modelling revealed that the 2013 criterion #2-MVI was more strongly associated with the endpoint than the 2007 criterion #2-C4d (HR=4.0 [1.1-14.1] vs. HR=2.2 [1.05-5.3]). When the 2013 criterion #2 was dissected by component, the C4d-component was significant (HR=2.5 [1.1-5.4]), but not the g’ptc (HR=1.0 [0.5-2.3]).

**Conclusions:** Compared to the 2007 criteria, applying the 2013 criteria here doubled the proportion of patients with CAABMR. Importantly, it improved the association with clinical outcomes.

SA-PO972

Tissue Expression of Aquaporine 2 Is Correlated to Urine Output and Allograft Function in Sensitized Kidney Transplant Patients 

Luis Eduardo Becker,1 Martin G. Zeier,1 Christian Morath,1 1Nephrology, Univ of Heidelberg, Germany; 1Pathology, Univ of Heidelberg, Germany.

**Background:** Salt and water disturbances often occur during acute kidney allograft dysfunction contributing to graft failure, but this condition has still been poorly investigated in the setting of alloseactivity. We evaluated the tissue expression of aquaporins (AQ Pi, AQ P2) and of the epithelial sodium channel (ENAC) in kidney allograft biopsies from transplant patients with high immunological risk.

**Methods:** Eighty-six kidney transplant biopsies from thirty-three sensitized patients were divided into three groups according to the clinical context a possible pathological correlates as follows: time-zero sample (control) (ENAC) in kidney biopsies from transplant patients with high immunological risk.

**Results:** We observed a significantly lower AQ P1 expression in time-zero and induction biopsies with rejection compared to controls (7.7±2.0% and 9.1±6.0%, P=1.3±2.9% of area positively stained; P=0.03 and P=0.04 respectively). AQ P2 expression was significantly lower in patients with an indication biopsy when compared to controls and protocol biopsies (2.1±0.2% vs. 4.4±0.7 and 4.0±0.5% of area positively stained, P=0.05 and P=0.005, respectively). For ENAC, a lower expression in indication biopsies compared to controls was seen (P=0.04). Both AQ Pi and AQ P2 tissue expressions were significantly correlated to the urine output (r=0.4 and r=0.32; P=0.01 and P=0.02, respectively), and AQ P2 was correlated to the MDRD-glomerular filtration rate at the time of biopsy (r=0.23; P=0.05).

**Conclusions:** Our findings can partially confirm previous experimental data showing downregulation of AQ P1 expression after ischemia-reperfusion injury and during rejection. AQ P2 downregulation seems to be rejection-independent occurring during deteriorating or poor kidney graft function.

SA-PO973

The Utility of Protocol Biopsy in Renal Recipients: Meta Analysis and Systematic Review

**Background:** To evaluate the value of protocol biopsy in patients after renal transplantation.

**Methods:** Searches were applied to the following electronic database:Medline, Embase Database, Cochrane Library. Randomized controlled trials evaluating the value of protocol biopsy for renal allograft recipients were included. Data were extracted independently by two reviewer. The risk of bias of included studies was assessed by the Cochrane collaboration’s tool for assessing risk of bias.

**Results:** 5 RCTs were included. Long term graft loss was significantly reduced (RR 0.40,95%CI:0.25 to 0.65, P=0.001) (figure 1) by protocol biopsy after renal transplantation.

**Conclusions:** Protocol biopsy may reduce the long term serum creatinine (WMD 38.21, 95% CI 54.83 to 21.60, P<0.00001). For renal recipients whose basal immunosuppression is CNI (tacrolimus or cyclosporine), protocol biopsy can significantly improve the long term eGFR (SMD 0.78, 95% CI 0.51 to 1.05, P<0.00001). However, for those whose basal immunosuppression is tacrolimus, this effect is not notable. Protocol biopsy seems to have no significant beneficial effect of reducing clinical acute rejection episodes.

**Conclusions:** Treatment of subclinical rejection detected by protocol biopsy can significantly improve the graft survival and may improve the allograft function.

SA-PO974

Longitudinal Biopsy Findings Among Children, Adolescents, and Young Adult Renal Transplant Recipients from a Southeastern USA Cohort

Joseph Alexander Miles,1 Panupong Hansrivijit,1 Katherine D. Westreich,1 Evan Zeitzer,1 Randall K. Dettwiler,1 Maria E. Ferris.1 1East Carolina Univ, Greenville, NC; 1Chulalongkorn Univ, Bangkok, Thailand; 1UNC at Chapel Hill, Chapel Hill, NC.

**Background:** Longitudinal procedure history in children, adolescent, and young adult renal transplant recipients needs to be characterized based on their primary cause of end-stage renal disease (ESRD). It is known that pediatric patients are a high risk group for transplant failure. Elucidating potential factors for transplant failure in this group is important for protecting vulnerable individuals.

**Methods:** Clinical, demographic and pathological records of patients who received a renal transplant at age ≤30 years of age and who underwent transplant biopsies between 2000 and 2014 at the UNC Hospitals were analyzed. This cohort was classified based on

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
the primary cause of ESRD as either glomerular or non-glomerular. Demographics, number of biopsies (total and adjusted for graft failure), and transplant failure (rates and cause) were compared between the two groups.

**Results:** We enrolled 179 patients; 105 (58.7%) were male; 67 (38%) African American, 92 (51%) Caucasian, and 20 (11%) other race. Their mean age at transplant was 18.7 ± 8 years and 98 (55%) had a glomerular cause of ESRD. This cohort underwent a total of 505 graft biopsies. Comparing patients with glomerular vs. non-glomerular conditions, we found no significant differences in cellular or humoral rejections (p=0.430); mean number of biopsies (3.0 ± 1.9 glomerular; 2.7±1.9 non-glomerular; p=0.289); mean number of biopsies per year for failed transplants (p=0.702), current functioning grafts (p=0.090); time to a failed transplant (p=0.476); or age at time of transplant (p=0.136).

**Conclusions:** In this single institution cohort of children, adolescents and young adults, we found no statistical differences in renal biopsy findings regarding number of biopsies and transplant failure. This high risk age group shows no different longitudinal graft survival based on primary cause of ESRD. More analysis will follow.

**Prospective Study of Risk Factors and Impact of Subclinical Rejection (SCR) and Acute Clinical Rejection (ACR) in Renal Transplant Recipients**

**Rajil B. Mehta,1 Puneet Sood,2 Arvind Cherukuri,3 Shan Shan Chen,3 Chethan M. Putterajappa,4 Christine Wu,1 Nirav A. Shah,1 Parmjeet S. Randhawa,2 Sundaram Haririhan,1 1Starzl Transplantation Inst. Univ of Pittsburgh Medical Center, Pittsburgh, PA; 2Dept of Pathology, Univ of Pittsburgh Medical Center, Pittsburgh, PA; 3Dept of Pathology, University of Pittsburgh, Pittsburgh, PA.**

**Background:** The long term outcomes of subclinical rejection (SCR) remain unclear. The current study evaluated the risk factors for SCR at 3 mths and followed up renal function upto 1 year in pts with SCR, ACR and no rejection.

**Methods:** We prospectively followed 340 pts who underwent an ABO compatible kidney transplant between Jan 2013 and Sep 2014. Eight pts were excluded. All patients received induction therapy with either thymoglobulin (95%) or Basiliximab for induction, CNIMPA for maintenance therapy and rapid steroid withdrawal by day 7. Protocol biopsies were performed 3 months post transplant. Based on this, they were divided into 4 groups, Grp 1 - pts with SCR, Grp 2 - pts with normal biopsy; Grp 3 - pts with ACR; Grp 4 - pts without biopsy. Banff classification was followed for biopsy grading. Steroids, thymoglobulin and PPI/IVIG were used as indicated for the treatment of rejection.

**Results:**

**Histological Scoring System Predicts Renal Outcome of Post Transplantation Acute Tubular Necrosis**

**Tobias Pieters, Lucas Falke, Tri Q. Nguyen, Marianne C. Verhaar, Roel Goldschmeding, Maarten B. Rookmaker. Nephrology and Pathology, UMC Utrecht, Netherlands.**

**Background:** Acute Tubular Necrosis (ATN) is a common cause of Delayed Graft Function (DGF) after renal transplantation (RTX). Currently no histological model is available to predict renal outcome. Recovery of ATN is the result of the balance between regeneration and damage and repair. In this study we evaluated the predictive value of immunohistochemical parameters of renal damage and regeneration and compared these to an accepted clinical prediction model for cadaveric renal transplantation.

**Methods:** We included 25 patients that underwent cadaveric RTX with DGF caused by ATN only, as shown in a renal biopsy 1 week after RTX. Biopsies were evaluated for histological tubular damage (atrophy, edema, casts, vacuolization), DNA damage (yH2AX staining) and apoptosis (cC3 staining). Regeneration was assessed by staining for stem cell marker CD133 and proliferation marker Ki67. Clinical parameters for renal outcome were collected as previously described in the Deceased Donor Score (DDS). The relation between these parameters and renal outcome, defined as eGFR at 6 months, was assessed using regression or one-way ANOVA. A correct analysis for regenerative markers was performed to eliminate potential confounding by the amount of renal damage.

**Results:** The histological damage score significantly predicted renal outcome (R=0.52 P=0.01), whereas the DDS only tended to correlate with renal outcome (R=0.32 P=0.05). Neither staining for DNA damage, nor for apoptosis could predict renal outcome (R= 0.24 P=0.91 and R=0.16 P=0.44 respectively). In addition, the investigated parameters for regeneration (CD133 and Ki67) did not predict renal outcome (R=0.25 P=0.23 and R=0.10 P=0.63 respectively), also not after correction for renal damage.

**Conclusions:** We are the first to show that histological parameters can predict renal outcome of post transplantation ATN. Importantly, our histological damage score correlated better with renal outcome than the DDS. Despite the crucial role of regeneration in recovery after ATN, no relation was found between stem cell marker CD133, proliferation marker Ki67 and renal outcome.

**Histopathological Changes and Graft Survival of Long-Term Kidney Allograft in Alport Syndrome: A Single-Center Experience in Japan**

**Yuichi Nakada,1 Izumi Yamamoto,1 Akimitsu Kobayashi,2 Yudo Tanno,1 Hiroyasu Yamamoto,1 Masayoshi Okumi,2 Hideki Ishida,2 Takashi Yokoo,1 Kazunari Tanabe.2 1Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ of Medicine, Tokyo, Japan; 2Dept of Urology, Tokyo Women’s Medical Univ, Tokyo, Japan.**

**Background:** Patients with Alport syndrome (AS) commonly develop progressive kidney dysfunction due to a hereditary type IV collagen deficiency, which results in an abnormality in the glomerular basement membrane (GBM). Recurrent glomerulonephritis does not occur in transplanted kidneys, and the allograft survival rate in these patients is similar to that in patients with other renal diseases. Several studies have shown that the type IV collagen of the GBM originates from the recipient’s bone marrow–derived cells. Therefore, we postulated that recurrent glomerulonephritis could occur locally and should influence the long-term allograft survival. In this study, we investigated graft survival and histopathological changes in renal allograft recipients with AS, focusing particularly on whether the expression of type IV collagen is altered.

**Methods:** We collected data on the clinical characteristics of 19 renal allograft recipients who had been diagnosed with AS. All data were obtained from a database at the Department of Urology, Tokyo Women’s Medical University. Graft survival was evaluated using the Kaplan–Meier method and compared with a control group (n = 18). We assessed the double staining of α2 and α5 using frozen specimens obtained from long-term allograft survival samples.

**Results:** The graft survival rate was not statistically different between patients with AS and controls (log-rank p = 0.2240). Immunoreactivity to α5 antibody in four patients exhibiting long-term allograft survival showed strong linear positivity and no GBM abnormalities. In the case of chronic active antibody-mediated rejection, the immunoreactivity to α2 antibodies increased in the mesangium and subendothelial space.

**Conclusions:** These results suggest that the GBM type IV collagen structure was histopathologically maintained for the long term after kidney transplantation, indicating better graft survival in patients with AS.
SA-PO978
Histological Assessments from Kidney Transplant Biopsies: An Explorative Post Hoc Analysis of ZEUS 5 Year Data
Ute Eisenberger,1 Claudia Sommerer,1 Ingeborg A. Hauser,1 Frank Lehner,1 Rudolf P. Wuthrich,2 Petra Reinke,1 Susanne Mühlfeld,1 Katharina M. Heller,1 Rolf A. Stahl,1 Heiner W. Wolters,1 Klemens Budde,1 Martina Porstner,1 Oliver Witte,1 Wolfgang Arns.1 ZEUS Study Group, Germany; 2ZEUS Study Group, Switzerland; 3Novartis Pharma, Germany.

Background: Analysis of pathologists’ assessments and histological data allow for deeper insight on patient outcome when combined with investigators final clinical diagnoses. Here we present 5 year data from de novo kidney transplant (KTx) recipients after conversion to an everolimus(EVR) based regimen and withdrawal of CNi therapy vs. continued CNi regime.

Methods: Post hoc analysis of histological and pathologists’ assessments from ZEUS, a prospective, open-label, controlled, multi-center study. At mo 4.5 post Tx 300 KTx patients (pts) were randomized to either EVR + enteric coated-myccophenolate sodium (EC-MPS, n=154) or cyclosporine (CsA) + EC-MPS (n=146). After 12mo interventional study, observational follow-up (FU) on pts safety and efficacy was performed until mo60 post Tx. As per study protocol, graft core biopsies were indicated by suspected rejection episode. Biopsies were read and interpreted by local pathologists.

Results: Total number (nt) and mean ± nr of biopsies per patient performed are overall similar in both groups until mo60. Nr of pts with at least one rejection (as per final clinical diagnosis) was slightly higher in CNi group vs EVR group. Nr of pts with BPAR was higher in the EVR group especially due to mild, early acute rejections (mostly BANFF IA and IB). Nr of pts with histological evidence of chronic/sclerosing allograft nephropathy was similar in both groups (10%). C4d staining positivity was found slightly higher in the EVR group (11% EVR vs 7% CNi), however, pts with evidence of antibody mediated rejection was higher in the CNi group (2% EVR vs 4% CNi), same for CNi-induced toxicity lesions (16% EVR vs 23% CNi).

Conclusions: Data from histological assessments together with investigator reported final clinical pts outcome show that an EVR-based regimen with early elimination of CNi-therapy is as safe and efficacious as standard CNi-therapy offering the opportunity to reduce cumulative CNi-induced toxicities on the allograft.

Endothelial Microvesicles as a Biomarker of Antibody-Mediated Endothelial Injury
Erik Stries,1 Moglie Le quintrec,2 Brandon Renner,3 Jennifer Laney,3 Karissa Fretlow,1 Rekha M. Thamaraiselvan.1 1University of Colorado Health Sciences Center, Aurora, CO; 2Transplant Rééude, Hôpital Lapeyronie, Montpellier, France.

Background: Endothelial injury and inflammation are hallmark histopathologic features of antibody-mediated rejection (AMR) in renal transplant. Antibodies against HLA on the endothelial cells activate the complement system via the classical pathway. The diagnosis of AMR is dependent upon pathological examination of renal biopsy tissue. A clinical need exists for a noninvasive method for diagnosing AMR. Endothelial cells (HMEC-1) and a monoclonal murine antibody against human HLA class I (W6/32) were used to model the AMR process and to explore endothelial microvesicles (EV) as a potential biomarker of AMR in renal transplant recipients.

Methods: We have developed an in vitro model of AMR using immortalized human endothelial cells (HMEC-1) and a monoclonal murine antibody against human HLA class I molecules (W6/32). We analyzed antibody binding and complement deposition with immunohistochemistry and flow cytometry. Microvesicle analysis was performed using flow cytometry.

Results: We have shown that W6/32 antibody binds HMEC-1 cells and activates the classical complement pathway upon exposure to normal human serum. This leads to deposition of complement split products on the cell surface (analogous to C4d deposition in biopsies from patients with AMR) and increased release of endothelial microvesicles. Furthermore, anti-HLA antibody (W6/32), C3, and C4 were deposited on the surface of the microvesicles.

Conclusions: Our results suggest that AMR will lead to an increase in production of microvesicles by the renal endothelium, and AMR-associated microvesicles will have the potential to serve as a biomarker of AMR.

SA-PO980
Dual Leukocyte/Endothelial Stain for Assessment of Endocapillary Inflammation in the Renal Allograft
A. Rosenberg,1 Jonathan Levi,2 S.M. Bagnasco,1 Naima Carter-Monroe.1 1JHU; 2NIDDK.

Background: The pathologist’s assessment of renal allograft rejection relies on the evaluation of the pattern of involvement by inflammatory cells. The Banff criteria for renal allograft rejection now includes semiquantitative evaluation of inflammation involving peritubular capillaries (ptc), glomeruli (g), arterial intima (v), tubulitis (t), interstitium (i) and total renal parenchyma (ti) have been elaborated as indices of antibody (g and ptc) versus cell-mediated rejection (v, t) and ti. Accurate assessment of these various compartments can be difficult and their reproducibility a particular challenge.

Methods: We evaluated a dual pan-leukocyte marker (LCA) and a vascular endothelial marker (CD34) immunohistochemical stain as an ancillary tool for evaluating intravascular (g and ptc) vs tubulointerstitial inflammation. Nineteen cases underwent blinded review of the dual stain.

Results: Overall, good concordance was present between cases originally scored g3 and those meeting criteria on dual stain (9/10), but lesser agreement for cases originally scored g2 with only 1/11 (9%) meeting the same criteria on dual stain. Most cases (4/5) originally scored as pt2 continued to meet criteria on dual stain, but approximately 35% (5/14) of cases originally scored as pt3 met criteria for either pt1 or pt2c on dual stain. Conclusions: Dual LCA/CD34 IHC aided the evaluation quantization of inflammatory infiltrate in renal allograft rejection, possibly allowing finer and more reproducible discrimination between ptc and i scores and identifying the extent of glomerulitis. Annotation of whole slide images will be performed to yield a quantitative metric for ptc of which a continuous scale for comparison to the current quantized scale. Implementation in larger cohorts and in a consensus setting will be needed to determine improvement in the diagnostic and prognostic yield of the current Banff-based biopsy assessment.

SA-PO981
Intragraft Granulocyte-6 B Is Associated with Chronic Renal Transplant Glomerulopathy
Narayan Prasad,1 Brijesh Yadav,1 Vikas Agarwal,1 Dharmendra Bhadauria,2 Raj K. Sharma.1 1Nephrology, SGPGIMS, Lucknow, UP, India; 2Immunology, 1.

Background: Chronic transplant glomerulopathy (CTG) and Intersitial fibrosis and tubular atrophy (IFTA) are two major causes of chronic allograft loss. CTG is often associated with either C4d deposition or, circulating donor specific antibody. Pathogenesis of IFTA is unclear. We aimed the study to determine the role of CD3/CD8+Gzm-B+ Cytoytic T cells in pathogenesis of CTG and IFTA and to determine its significance as peripheral blood signature of CTG.

Methods: Total 58 (CTG 20, IFTA 28 and stable functioning graft SFG 10) living donor renal transplant recipient were recruited. Patients were categorized into 3 group based on Banff’s 2007. We analyzed peripheral blood cytotoxic T cell by flow cytometry, Granulocyte-6 B mRNA transcript in renal biopsy tissue by Taqman real time PCR and soluble Granulocyte-6 B level by ELISA.

Results: Age of patients in CTG, IFTA, and SFG group was 41.8±12.7, 36.50±8.34, 46.28±8.65 years; post transplant period at biopsy 63.92±41.0, 51.71±3.06, 70.0±15.42 months; Creatinine at biopsy 2.38±0.84, 2.30±0.86, 1.41±0.33 mg/dl, and urine daily protein 2.67±0.73, 2.22±1.96, 6.22±0.60 g; respectively. Peripheral Blood CD3+/CD8+ T cell frequency (CD3+/CD8+ T cell frequency (CD3+/CD8+ T cell frequency (CD3+/CD8+ T cell frequency (CD3+/CD8+ T cell frequency (CD3+/CD8+ T cell frequency (CD3+/CD8+ T cell frequency (CD3+/CD8+ T cell frequency (CD3+/CD8+ T cell frequency (CD3+/CD8+ T cell frequency (CD3+/CD8+) was significantly low in CTG group (12.62±1.68%), as compared to IFTA (16.44±4.09%), (p=0.05) and SFG 26.35±2.95% (p>0.001). Intra graft mRNA of Granulocyte-6 B in CTG was 3.05 fold high as compared to SFG. In IFTA intra graft Granulocyte-6 B mRNA was 2.26 fold high compared to SFG(p>0.001). Soluble Granulocyte-6 B level was significantly high in CTG (423.7±135.20; p<0.001), as compared to IFTA(249.5±73.05; p>0.001), and SFG (91.88±30.89) pg/ml. This suggests that sequestration of cytotoxic T cells into graft resulted in low circulating cytotoxic cells and increased intragraft (Gzm-B+) cells leading to Granulocyte-6 B dependent injury and CTG.

Conclusions: Low peripheral blood cytotoxic T cell (CD3+/CD8+Gzm-B+) and high intragraft mRNA transcript of Granulocyte-6 B in CTG suggest role of cytotoxic T cells in CTG. Lower circulating CD3+/CD8+Gzm-B+ Cytotoxic T cells can be peripheral blood signature for CTG.

SA-PO982
Molecular Features of Kidney Transplant Biopsies with Interstitial Fibrosis/ Tubular Atrophy in the Presence of Sterile Leukocyturia
Maria Ajayia, Enver Akalin.1 Einstein-Montefiore Transplant Center, Albert/Einstein College of Medicine, Bronx, NY.

Background: We hypothesized that sterile leukocyturia could reflect an increased intragraft immune activity and investigated gene expression profiles of transplant kidney biopsies of patients with sterile leukocyturia comparing to patients without leukocyturia.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: We identified 15 normal transplant kidney biopsies without leukocytoxia (Group 1) and 33 biopsies with non-specific interstitial fibrosis (tubular atrophy, IFTA) for gene expression profiling. Of the 33 biopsies with IFTA, 24 patients had no sterile leukocytoxia (Group 2) and 9 patients had sterile leukocytoxia (Group 3). Biopsies with a diagnosis of acute or chronic rejection, recurrent or de novo glomerular disease, or polymya nephritis were excluded. Leukocytoxia was defined by the presence of 5+ leukocytes in the urine (>10/L) without bacterial growth in urine culture. The urinalysis was done within 1 month before or after the biopsy. The gene expression profiles were studied by Affymetrix HuGene 1.0 ST expression arrays.

Results: There were significant differences in terms of age, race, and sex, type of transplant, previous history of transplantation or acute rejection, donor characteristics, panel reactive antibody levels and immunosuppressive treatment between the Groups 2 and 3. Both groups also had similar acute and chronic Banff allograft injury scores. There was no statistically significant difference in gene expression profiles between the Group 1 and 2. When compared to the Group 1 and 2 biopsies, significantly increased gene transcripts associated with cytotoxic and regulatory T cells, and macrophages (P-value for significance <0.05). There was a trend towards increased interferon-gamma and rejection associated transcripts but no statistically significant difference in expression of B-cell or natural killer cell associated transcripts.

Conclusions: The biopsies of the patients with sterile leukocytoxia showed increased expression of gene transcripts associated with T cells indicating heightened intragraft immune activity. Those patients might require close monitoring of their allograft function.

Elevated Glomerular Mechano-Growth Factor and Vascular Endothelial Growth Factor in Chronic Allograft Nephropathy Is Associated with Activation of Erk1/2
Yeomin Guo, Rafaat Farag Makary, Carmela B. Montemor, Leighton R. James, Charles A. Home, Rafaat Farag Makary, Carmela B. Montemor, Leighton R. James, Charles A. Home. 1Pathology, Univ of Florida College of Medicine-Jacksonville, Jacksonville, FL; 2Pathology, Univ of Florida College of Medicine-Jacksonville, Jacksonville, FL.

Background: We previously identified increased GLUT1 glucose transporter, Mechano-Growth Factor (MGF) and Vascular Endothelial Growth Factor (VEGF) in human Chronic Allograft Nephropathy (CAN) kidneys which demonstrate glomerulosclerosis. Here we investigated a glomerular signaling pathway, Erk1/2, with potential to mediate effects of MGF and VEGF on extracellular matrix (ECM) genes. We employed IHC with specific antibodies to assess protein expression for MGF, VEGF and phosphorylated Erk1/2 (active Erk1/2) in human CAN kidneys vs. Normal Control kidneys.

Methods: We performed this study investigating archival renal biopsy samples was approved by the Institutional IRB. N = 6 for each group of renal transplant - and native kidney biopsies. Immunohistochemical staining of human CAN and Normal Control paraffin-mounted kidney sections was performed for assessment of selected proteins with specific antibodies, by use of immunoperoxidase staining. Scoring of glomerular immunolabelling for individual proteins was 0 – 4+ for semiquantitation. Data were normalized to open glomerular tuft area. P < 0.05 was considered significant in statistical analysis.

Results: Glomerular MGF protein was increased 3.9-fold in CAN kidneys vs Normal Control kidneys, P < 0.001. Glomerular VEGF was elevated 3.0-fold in CAN vs Normal Control kidneys, P < 0.001. Both of these growth factors have potential to signal via Erk1/2 to ECM expression. Glomerular Erk1/2 activation (i.e. phosphorylated Erk1/2) was examined and found to be increased 4.3-fold in CAN vs Control, P < 0.001.

Conclusions: Human CAN, characterized by excessive glomerular MGF and VEGF expression, involved enhanced activation of Erk1/2 in the glomeruli. This provides a mechanism by which these two glucose-responsive growth factors may induce glomerular ECM production and glomerulosclerosis. Therefore, MGF and VEGF activation of Erk1/2 may contribute to progressive glomerulosclerosis and renal failure in CAN.

Microarray Analysis of Interstitial Fibrosis/Tubular Atrophy in Kidney Transplant Recipients Using Formalin-Fixed, Paraffin-Embedded Renal Biopsy Tissue
Sanjeev Akkina, 1 Vishal K. Varma, 1 Michael J. Walsh, 1 Suman Setty, 2 Medicine/Nephrology, Univ of Illinois at Chicago, Chicago, IL; 1Pathology, Univ of Illinois at Chicago, Chicago, IL.

Background: Interstitial fibrosis/tubular atrophy (IFTA) is a common and complex cause of progressive renal failure and is often difficult to diagnose. Early identification of progressive IFTA (pIFTA) may lead to alternative therapies that may attenuate irreversible injury. In this study, we used formalin-fixed, paraffin-embedded (FFPE) renal biopsy specimens with microarrays to conduct differential gene expression studies to identify predictors of IFTA in kidney transplant recipients.

Methods: We identified 22 individuals with multiple protocol biopsies within the first 3 years after transplant. Glomeruli and blood vessels were removed using laser capture microdissection and the remaining tissue was used for mRNA extraction. Affymetrix Primerscript probes were designed using standard protocols. IFTA was determined by RNA image masking in Histolab to quantify the cortical interstitial fraction. pIFTA was defined as a 0.5% absolute increase in the interstitial fraction per month between serial biopsies. Data analysis was conducted using R 3.0.2 and Bioconductor 2.22. Significance was defined as an unadjusted p<5 x 10^-4.

Results: Of the 22 subjects in this study, 9 had pIFTA while the remaining 13 were considered stable IFTA (sIFTA). At baseline, the eGFR was 60.5 vs 58.5/mL/min/1.73m^2 (p=0.79) and log(Urine Albumin) was 3.44 vs 3.17 (p=0.072) for the sIFTA and pIFTA groups, respectively. The baseline fibrosis was higher in the sIFTA group (18%) compared to the pIFTA group (13%; p=0.04). Using linear modeling, 3 of the top 6 differentially expressed genes were upregulated in pIFTA vs. sIFTA.

Pathological Analysis for Transplant Nephropathy – 124 Consecutive Cases in a Single Center Study Over 10 Years
Masaki Lee, 1 Atsushi Aikawa, 2 Carmelo Pulitti, 1 Muhammad M. Yaqoob, 1 Michael Sheaff. 1 Nephrology, Transplantation and Cellular Pathology, The Royal London Hospital, London, United Kingdom; 2Nephrology, Toho Univ Faculty of Medicine, Tokyo, Japan.

Background: Transplant nephropathy (TNx) is performed for several indications. This study evaluates in depth histological analysis of TNx specimen.

Methods: We identified all cases at the Royal London Hospital between 2004 and 2014. The indication for TNx was divided into four groups: 47 cases with acute graft loss without significant blood flow (AGL), 44 cases of suspected ongoing rejection or graft intolerance syndrome (RejGIS); 24 cases with infection (INF); and 9 miscellaneous reasons (MIS). We examined the histological changes in detail and specifically looked at the artery, vein and urer.

Results: AGL was less likely to have tubulointerstitial changes, but 74.5% had neocrosis. In the AGL group, the majority of cases scored zero for t, i, ct and ei. Neutrophil rich arteritis at renal and small arteries was observed in 29.8% and 19.2%. Venous thrombosis was found in 6.3%. All cases in the RejGIS group showed t1 and ei 40% and showed t3 and ei 30%. Glomerulosclerosis was observed in 52.3% and eg was detected in 75.1%. Arteritis of small and renal arteries was detected in 70.5% and 59.1%. C4d expression was present in 54.1%. Nearly 70% showed ureteric inflammation. Variable cellular infiltrate comprising of lymphocytes, plasma cells and eosinophil were seen in all cases. In the INF group, 66.7% (i1-3) and 72.9% (i1-3) were observed, and ei3 and ei5 were detected in 66.7%. Glomerulosclerosis was rare although allograft nephropathy was detected in 62.5%. All cases had intimal thickening of small and renal arteries or arteritis was unusual. Lymphocyte and plasma cell were common at interstitium and perivascular space, but eosinophils, neutrophil and eosinophil rarely appeared at vascular lesions. In the MIS group, histological changes were minor, t3, i1-3, arteritis and venuitis were not detected.

Conclusions: The histological changes were similar and specific within the TNX groups but different between the groups. A failed graft often showed substantial immunological response. In depth histological analysis may aid management of subsequent grafts.

miRNAS as Novel Biomarkers for Transplant Patient's Evolution
Esperanza Macarena Rodriguez serrano, 1 Cristina Galeano, 2 Edurne Ramos, 1 Elisa Conde, 1 Laura Martin-Gomez, 1 Sara Gimenez-Moyano, 1 Maria Laura Garcia-Bermejo, 1 Fernando Liano. 1 Biomarkers and Therapeutic Targets Unit, IRYCIS; 2Nephrology, Ramon y Cajal Hospital.

Background: Transplanted patients evolution and outcome is dependent on many factors including allograft function, vascular homeostasis and immunogenicity. Up to this moments, apart from creatinine renal biopsy, there are no quantitative and accurate biomarkers to predict the evolution of the allograft and the receptor, which would enable clinicians to improve the transplanted patient’s management. Our group has validated a combination of serum miRNAs as accurate biomarkers for AKI from ischemic aetiology, including: miR-127, miR-101, miR-210, miR-146a, miR-26b, miR-29a, miR-10a, miR-93 and miR-27a. Here we have determine the expression of these miRNA in serum from kidney donors and recipients and correlate this expression with clinical parameters of allograft evolution, including ATN development, delayed graft function, rejection and vascular complications.

Methods: For this purpose, serum sample from brain death donors and recipients along post-transplantation period (6h, 1, 2, 3,4,5, 6 and 7days and 1,3,6 months) in 30 transplanted patients form our Hospital. After RNA extraction from serum, the combination of miRNAs has been determined by qRT-PCR and correlation with clinical data has been established using SPSS.

Results: The expression of these 10 miRNAs in serum samples from donors did not exhibit significant differences among them. This combination neither correlate with immediate delay graft function because NTA or immunological rejection. However, some of the miRNAs correlate with long term evolution of transplanted patients in terms of non-requilnal graft function and they also discriminate patients with also exhibited renal vascular alterations.

Conclusions: In summary we have identified miRNAs that correlates with long term evolution of transplanted patients. These information could be useful for improve transplant care that is difficult in the context of personalized patient handling.

Plasma MicroRNA 17 Host Gene Protein level Cluster and Tumor Necrosis Factor-Alpha (TNF-α) in Patients with Renal Transplantation: Relation to Allograft Function and Survival

Havam A. El Agag,1 Sahab Abdel Hady Mahmoud,2 Mohamed Mohamed Saker.1 Internal Medicine, Faculty of Medicine, Alexandria, Egypt; Medical Biochemistry, Alexandria, Egypt.

Background: Chronic allograft dysfunction (CAD) remains the leading cause of late graft loss after kidney transplantation. MicroRNAs (miR) are small (19-25 nucleotides) noncoding RNAs that regulate gene expression of diverse biological processes. The polycistronic miR-17–92 cluster is comprised of six miRs and its primary transcript may also encode for a polypeptide of 70 amino acids designated as the miR-17 host gene (MIR17HG) protein. So the aim of this work was to evaluate the plasma levels of MIR17HG protein and TNF-α levels in patients with renal transplantation in relation to renal allograft function and survival.

Methods: This study included 45 subjects; they were divided into three groups each 15, renal transplant patients with stable renal function (Group I), with CAD (Group II) and healthy subjects as controls (Group III). Quantitative determination of plasma levels of MIR17HG protein and TNF-α were performed using enzyme linked immunosassay (ELISA). Blood urea, serum creatinine and estimated glomerular filtration rate (eGFR), urinary albumin/urinary creatinine ratio and C-reactive protein (CRP) were done. Resistive index (RI) was calculated. Renal biopsy was done in patients with CAD.

Results: MIR17HG protein and TNF-α levels were significantly higher in renal transplant especially patients with CAD than the controls. In patients with renal transplantation, the levels of MIR17HG and TNF-α were positively correlated with each other and with serum creatinine, urinary albumin/creatinine ratio and CRP and was negatively correlated with e-GFR. The degree of fibrosis in renal biopsy was positively correlated with a decline in eGFR. However, KCAD had the strongest correlation (R2=0.2), compared with Alb (R2=0.17), NAG (R2=0.05) and RBP (R2=0.01).

Conclusions: This cohort study demonstrates that, when compared to conventional markers Alb, RBP and NAG, the novel marker KCAD has a higher specificity and correlation with patients who lose graft function after one year. The presence of the proximal tubule cadherin in the urine may be a prognostic indicator for patients who go on to develop chronic allograft dysfunction, and may occur due to the excetration of KCAD by proximal tubules in response to fibrogenic stimuli. Further analysis is required to evaluate this.

SA-PO990 Detection of Endothelial Cell Specific Molecule-1 According to Allograft Status After Kidney Transplantation

Se Yun Kim,1 Kyung-Hwan Jeong,2 Yu Ho Lee,3 Jae Song Chun,2 Shi-Yun Lee,3 Yang Gun Jin,2 Sang Ho Lee,1 Da Wun Jeong,1 Ju-Young Moon.1 1Kyung Hee Univ Hospital at Gangdong; 2Kyung Hee Univ Hospital.

Background: To investigate whether urine and plasma Endothelial Cell Specific Molecule-1 (ESM-1) level could differentiate rejection from non-rejection in kidney transplantation (KTP) recipients, we compared ESM-1 levels according to allograft status. We measured plasma and urine ESM-1 in 77 patients with underwent KTP. The concentration of ESM-1 was analyzed by enzyme linked immunosorbant assay (ELISA). According to allograft status, Groups were divided stable, long-term good survival, immune tolerance, acute cellular rejection (ACR), acute antibody-mediated rejection (AMR) and chronic AMR.

Results: Plasma ESM-1 was not significantly different between all groups according to allograft status (p=0.424). Whereas, urine ESM-1 was significantly different between groups according to allograft status (p<0.001). Urine ESM-1 was higher in both ACR and acute AMR as well as chronic AMR than stable status. Patients with acute AMR showed significantly higher level of urine ESM-1 compared with patients with ACR (p<0.05). Area under the curve (AUC) for differentiating acute AMR from ACR was 0.744 (p<0.01).

Conclusions: Urine ESM-1 may reflect endothelial injury of allograft and it could be used to differentiate the patient with acute AMR from ACR.

SA-PO991 Noninvasive Diagnostic and Predictive Value in Renal Transplant Recipients by Measurement of Urine BCA-1

Dajin Chen,1 Kun Cui,1 Katherine Lee,1 Xiaoqin Zhang,1 Qian Xu,2 Kai Huang,2 Qun Chen,2 Jia Jin,1 Ping Shi,3 Zhihao Liu,1 Jia Liu,1 Quan He,1 Xin Wang,1 Young Moon,1 Kyung Hee Univ Hospital at Gangdong; 1Kyung Hee Univ Hospital.

Background: To investigate the relationship between early-stage renal acute rejection and the level of BCA-1 in urine, explore the diagnostic value and noninvasive monitoring in early stage after transplantation by measurement of urine BCA-1.

Methods: 145 patients were enrolled between January 2006 and October 2009, including 49 with biopsy-proved acute rejection, 58 patients with stable renal function and no abnormal histological findings, 9 patients with biopsy-proven acute tubular necrosis (ATN) and 29 patients with biopsy-proven chronic allograft nephropathy. Additionally, urinary samples were also collected from 40 healthy controls. Urinary concentration of BCA-1 was determined by an enzyme-linked immunosorbent assay technique in 145 renal allograft recipients and 40 healthy controls.

Results: Patient with acute rejection excreted urinary BCA-1 at a significantly higher level (8.1±2.2, 95%CI: 3.9-12.4 pg/mmol creatinine) than levels of patients with No-AR and healthy controls (P=0.001). Patients with acute tubular necrosis excreted urinary BCA-1 at a significantly lower level(2.5±0.5, 95%CI: 1.2-3.8 pg/mmol creatinine) than levels of patients with acute rejection. ROC curve was constructed to determine the discriminatory power of BCA-1 levels for diagnosis of acute rejection. The area under ROC curve was 0.881 (95%CI: 0.811-0.951), at a cut point of 0.23 pg/mmol creatinine, the sensitivity was 81.6% and the specificity was 87.9% (P<0.001).

Conclusions: The monitoring of BCA-1 in urine may be a new and noninvasive approach for detection acute rejection as well as useful to discriminate the type of rejection.
SA-P0992

B Cell Attracting Chemokine 1 in Urine Is A Biomarker of Acute Humoral Rejection
Wenhan Peng, Jianghua Chen. Kidney Disease Center; The First Affiliated Hospital, College of Medicine, Zhejiang Univ, Hangzhou, Zhejiang, China.

Background: Presently, there are no noninvasive approaches which can be directly applied to clinical diagnosis of acute rejection (AR) or distinguish type of rejection in renal transplant recipients. The aim of this study was to construct diagnostic models of biomarkers in acute rejection patients with AR or AHR in renal transplant recipients.

Methods: Concentration of nine biomarkers in urine of 81 patients with AR and 167 patients with stable renal function (No-AR) was determined by ELISA technique. Firstly, by discriminant analysis, we screened a number of biomarkers to construct the diagnostic models for AR and AHR. Secondly, another 102 patients with No-AR and AR were analysed to test the accuracy of the diagnostic model.

Results: Four biomarkers were selected to set up the diagnostic model of AR or No-AR. Based on the model of AR, 84.3% patients were correctly diagnosed. Two biomarkers were selected to set up the complementary diagnostic model of AHR. Based on the two model of AR, 100% patients with No-AR and 96.3% patients with AR were correctly diagnosed. Only B cell attracting chemokine 1 (BAC-1) was selected for the diagnostic model for AHR or acute cellular rejection (ACR). Rejection type of 81.5% patients with AR were correctly classified. Another 102 patients tested the accuracy of the diagnostic models. Diagnostic accuracy of AR or No-AR and AHR or ACR were 100% and 95.4% respectively.

Conclusions: Urinary BCA-1 was a valuable biomarker for determining AHR. These diagnostic models might directly identify AR and types of AR.

#FDG-PET/CT Imaging in Suspected Acute Renal Allograft Rejection
Pierre Lavrionfeso, Laurent E. Weeckers, Catherine Bonvoisin, Christophe Boyère, Jean-Marc H. Krezinski, Roland Hustin, François Jouret. Nephrology, Univ of Liege Hospital, Liege, Belgium; Nuclear Medicine, Univ of Liege Hospital, Liege, Belgium.

Background: The diagnosis procedure for kidney transplant recipients (KTR) with suspected acute rejection (AR) relies on needle biopsy. Still, noninvasive tests to predict nonrejection would be useful to save selected patients from undergoing invasive biopsy. AR is associated with a recruitment of activated leukocytes to the transplant, which are characterized by a high metabolic activity and an increased uptake of glucose analog, 18F-fluoro-deoxy-glucose (18FDG). Thus, 18FDG-PET-Positron emission tomography coupled with computed tomography (PET/CT) may help noninvasively distinguish nonrejection from AR.

Methods: From January 2013 to February 2015, we prospectively performed 32 18FDG-PET/CT in 31 adult KTR with suspected AR who underwent a biopsy. Biopsies were categorized as "normal", "borderline", "AR" or "others" according to Banfil classification. PET/CT imaging was performed within 201 ± 18 minutes after i.v. administration of 3.2 ± 0.2 MBq/kg of 18FDG, before any modification of immunosuppression. The mean standard uptake values (SUV) of both upper and lower renal poles were measured, with no threshold activity.

Results: Biopsies were diagnosed as "normal", "borderline", "AR" or "others" in 8, 10, 8 and 6 (including 3 polyoma-BK nephropathies) cases. AR was antibody-mediated in 1 case, whereas Type I, II and III cellular AR were found in 5, 1 and 1 cases, respectively. Mean SUV reached 1.5 ± 0.2, 1.6 ± 0.3, 2.9 ± 0.8, 2.2 ± 1.2 in each category. Mean SUV of biopsy-proven AR was significantly higher than "normal" cases (p<0.01). No difference was found between "normal" vs. "borderline", or between "AR" vs. "others" histopathology. Still, a positive correlation between mean SUV and acute composite (g/v + t/v + p/v) Banfil score of 0.24 (p=0.001) was found, with a coefficient of 6.70 (p<0.001). Sensitivity and specificity of "FDG-PET/CT in detecting pathological biopsies were respectively 92.3 and 36.8, with a mean SUV threshold at 1.4.

Conclusions: #FDG-PET/CT imaging may help discriminate nonrejection, thereby avoiding unnecessary transplant biopsy in KTR with suspected AR.

SA-P0994

High Renmamt-Like Particle-Cholesterol Is A Risk Factor of Worsening Graft Function in Japanese Kidney Transplant Recipients
Makoto Tsujita, Transplant Surgery, Nagoya Daini Red Cross Hospital, Japan.

Background: Many factors cause dyslipidemia after kidney transplantation. Low density lipoprotein cholesterol (LDL-C) has been focused to reduce cardiovascular disease (CVD), but residual risk factors such as triglyceride (TG), remnants or small dense LDL-C are also important to reduce CVD. We investigated whether residual risk factors affected graft function in kidney transplant recipients.

Methods: This study is a retrospective cohort study at a single center. Three hundred and seventy seven kidney transplant recipients (male 223) in more than six months after transplantation were enrolled. TG, Remnant-like particle cholesterol (RLP-C), non-high density lipoprotein cholesterol (HDL-C), LDL-C/apoB, eGFR (estimated glomerular filtration rate), Urine protein/day (UP), Body Mass Index (BMI) and other parameters at baseline were measured and we studied the association of residual risk factors with kidney function. DeGFR meant the difference between eGFR at baseline and eGFR 1year after transplantation (eGFR 1y). Data are shown as mean (SD), or median (interquartile).

Results: Patients' characteristics of this study are shown.

Funding: Government Support - Non-U.S.

Diffusion Impairment Measured by Functional MRI Correlates with Allograft Fibrosis After Kidney Transplantation in Patients with Delayed Graft Function

Jan H. Breses,1 Abdeldrazag Ahmad Khalifal, Faikah Guerel,2 Frank Lehner,3 Wilfried Gwinner, Dagmar Hartung,4 Hermann G. Haller,5 Katja Husper,6 1Inst for Pathology, Hannover Medical School, Hannover, Germany; 2Clinic for Nephrology, Hannover Medical School, Hannover, Germany; 3Clinic for General, Abdominal and Transplant Surgery, Hannover Medical School, Hannover, Germany.

Background: Functional MRI parameters derived from diffusion weighted (DWI) and diffusion tensor imaging (DTI) correlate with renal fibrosis and cell infiltration in experimental studies. Aim of this study was to investigate these non-invasive techniques in patients with delayed graft function (DGF) and to correlate diffusion parameters with renal function and renal histology of allograft biopsies.

Methods: 33 patients with initial graft function between day 4 and 11 after kidney transplantation and 31 patients with DGF were examined on a 1.5 Tesla MRI. DTI and DWI sequences were acquired and apparent diffusion coefficient (ADC) and fractional anisotropy (FA) were calculated. Kidney biopsies were available in 26 patients and analysed for acute rejection (Banff), amount of fibrosis, inflammatory infiltrates, and tubular injury as well as edema.

Results: ADC was significantly reduced in patients with DGF compared to patients with initial function. Similarly, FA positively correlated with fibrosis (r=0.573 and r=0.53, p<0.001) and negatively with the amount of renal fibrosis. Diffusion parameters in DGF patients did not discriminate between acute rejection and tubular injury. Histological evaluation of the allograft biopsies did not reveal any significant differences between DGF or initial function in the following parameters: leukocyte infiltration (CD4, CD8, CD15, CD20, CD68), CD31 pos. peritubular capillarities or edema (intertubular distal).

Conclusions: Functional MRI with diffusion techniques detects allograft dysfunction early after kidney transplantation correlating with allograft fibrosis. Biopsy is needed to verify rejection.

SA-PO997

Identification of Common Biological Mechanisms of Fibrosis in Transplanted and Native Kidneys with Chronic Diseases

Konrad S. Famulski, Jeffery M. Venner, Jeff Reeve, Philip F. Halloran. Univ of Alberta, Edmonton, AB, Canada.

Background: In both primary kidney diseases and in transplants fibrosis is caused by chronic progressive diseases. Hence, we hypothesised that fibrosis has fundamental common biological pathways in native and transplanted kidneys.

Methods: We studied the molecular associations with fibrosis in 703 kidney transplant indication biopsies (bx) 3 days to 35 years post-transplant. The number of bx with fibrosis increased with time post-transplant and most bx with ci>1 (74%) were attributable to time-dependent diseases (ABMR, GN, TG).

Results: By microarrays we compared bx with ci=1 to those with little or no fibrosis (ci1) and determined the association strength of transcripts (p-value) for ci=1. First we focused on transcripts previously associated with fibrosis: immunoglobulin, mast cells and AKI-associated transcripts. Stronger associations with ci=1 were for immunoglobulin and mast cell transcripts, but not for AKI transcripts. Because time of bx post-transplant is highly correlated with ci, we repeated the comparison of ci=1 vs. ci=1 after correcting for time. This resulted in a massive reduction in association strength for the immunoglobulin and mast cell transcripts (from 10e-27 to 1e-9). However, AKI transcripts were now more strongly associated with fibrosis (from 1e-9 to 1e-18). Thus time correction emphasised the injury-repair response at expense of inflammation. We then analyzed the fibrosis associated transcripts in native kidneys (CKD). 75% of CKD transcripts overlapped with our transcripts.

SA-PO998

DNA Double Strand Breaks Induced Collagen Type V1 Secretion of Glomerular Endothelial Cells in Renal Allografts

Background: The relationship between DNA injury and glomerular fibrosis in renal allografts remains unclear.

Methods: We examined renal allograft specimens from 35 patients in which DNA double-strand breaks and glomerular fibrosis were detected by phosho-histone H2A.X (γ-H2AX) expression and collagen (COL) types III, IV, and VI accumulation. We also examined the in vitro relationship between DNA damage and COL accumulation by mitomycin C (MMC)-induced DNA damage in human glomerular endothelial cells (HRGEc).

Results: The γ-H2AX and COL type V1, which mainly accumulated in the subendothelial and mesangial regions, were positively correlated with the duration of the post-renal transplant (RT) period (p=0.691, p<0.01; r=0.760 p<0.01, respectively). In multiple regression analysis, the duration of the post-RT period and cd in the Banff'07 classification were identified as significant predictors of COL type V1 accumulation (β value=0.699 p<0.001: 5.558, p=0.035, respectively) and γ-H2AX expression in the glomerular capillaries (β value 0.700 p<0.001: 2.031, p=0.011, respectively). In addition, the γ-H2AX-positive area was also identified as a predictor of glomerular accumulation of COL type V1 (β value=0.439, p=0.028). In the immunohistochemistry examination, γ-H2AX was detected in most cells after 24 hours’ MMC treatment, whereas γ-H2AX expression had been detected before the MMC treatment. Although COL type V1 was detected around the nuclei of the HRGEc before the MMC treatment, it was not present there after the MMC treatment. COL type V1 was detected in the cytoplasm of the HRGEc, which was secreted into the supernatant after MMC stimulation with γ-H2AX expression. The number of γ-H2AX (γ-H2AX) COL type V1 (γ-H2AX) cells was inversely associated with the number of γ-H2AX (γ-H2AX) COL type V1 (γ-H2AX) cells (r=-0.655, p=0.001) during 24 hours’ MMC treatment.

Conclusions: Our findings suggested that over the long term RT may induce DNA double-strand breaks and HRGEc-secreted COL type V1 accumulation in the glomerular capillaries, which might progress to intractable glomerular fibrosis.
SA-PO999

Imatinib Improves Interstitial Fibrosis in Deceased Donor Kidney Transplant: A Case Report
Ignatius Yun-Sang Tang,1 Andreas M. Acosta,2 Vishal K. Varma,3 Sunney Setty.1
1Medicine, Univ of Illinois at Chicago, IL; 2Pathology, Univ of Illinois at Chicago, Chicago, IL.

Background: Imatinib (IM) is an oral inhibitor of tyrosine kinases. Early short term PDGF inhibition with IM had been shown to prevent intestinal fibrosis and tubular atrophy in pre-clinical kidney transplantation (KT). We assess the effect of long term IM therapy on renal allograft histology in a KT recipient who received IM for gastrointestinal stromal tumor (GIST).

Methods: Patient is a 47 year old female with ESRD due to hypertension, s/p living donor KT in 2007 which failed in 2010. She was then rehospitalized on hemodialysis. A gastric mucosal mass was detected incidentally in 5/2012. Fine needle aspiration showed c-KIT positive spindle cells consistent with GIST. Patient received deceased donor KT in 7/2012 with Thymoglobulin induction. Maintenance immunosuppression included tacrolimus and mycophenolic acid. Patient was started on IM 100mg daily on day 19 post-KT because of GIST. Post-KT course was complicated by biopsy proven acute tubular necrosis, requiring dialysis in the first month post-KT. Serum creatinine (CR) improved to 1.6mg/dl by 3 months post-KT when she underwent partial gastrectomy. Pathology showed low grade GIST (low mitotic count and low Ki67 labeling index). Surveillance KT biopsy was performed at 6 months, 1 and 2 years post-KT. We compared the 6-month and the 2-year post-KT biopsies for the presence of renal cortical interstitial fibrosis using the Histolab software program (Microvision Instruments, France). The core sections stained with Masson trichrome were scanned at high-resolution, and divided into individual images at 200X for quantitative analysis. The software program was then run to quantify fibrosis of the selected areas.

Results: The cortical fibrosis percentage was 20.17% for the 6-month biopsy and 14.35% for the 2-year biopsy. The corresponding serum CR was 1.52mg/dl and 1.17mg/dl, respectively. Though mitotic index were maintained between 5 and 7mg/ml.

Conclusions: Long term use of IM reduced interstitial fibrosis in deceased donor KT. The role of long term IM in the prevention of interstitial fibrosis in renal allograft warrants further studies.

SA-PO1000

Factors Associated with Referral, Evaluation and Listing and Waiting for Kidney Transplant: A Survey of Dialysis Patients
Eric Chang, Ming Wang, Fareeha Khalil, Naman Trivedi, Nasrollah Gharahmani. Penn State Univ College of Medicine, Hershey, PA.

Background: Kidney transplant (KT) is the treatment of choice for most patients with end stage renal disease (ESRD). Disparities in referral, evaluation, listing and transplantation have been documented. We studied factors associated with the likelihood of referral, evaluation and listing for KT.

Methods: We sent 1,283 dialysis units. Of 2536 identified participants, 2696 responded to the survey. We selected and invited 1400 to participate in a social networks intervention for renal allograft fibrosis. Patient demographics were similar among intervention and control groups (80% Black, 87% Hispanic). A total of 311 (79%) were randomized to candidacy decision (79% of intervention and 79% of control patients) and were included in preliminary analyses. Intervention patients reached candidacy decision a median of 8 days faster than control patients (119 vs. 127 days). Shorter time to decision for intervention vs. control patients was positively associated with highest likelihood of referral (OR:5.1; CI:3.1-8.5), including black patients (9 days), patients who completed high school (10 days), Medicare patients (15 days), patients with BMI<35 (30 days), married (11 days) and single patients (7 days), and patients < age 55 (19 days).

Conclusions: Preliminary results suggest that the effect of nephrology consultation in reducing time from patient KT referral to candidacy decision in a KT setting. The use of a similar program in other KT centers may help patients who require additional assistance during the KT process complete KT evaluation more quickly.

Patient Navigation Program in Kidney Transplantation: A Randomized Study
Mohua Basu,1 Dawn L. Fletcher, Lisa Petgrave-nelson, Rachel E. Patzer. Emory Univ, Atlanta, GA.

Background: We developed a patient navigation program in a kidney transplantation (KTx) clinic to improve KT evaluation completion for patients deemed “high-risk” of not being placed on the KTx waiting list, based on known disparities in completion of KTx evaluation. We examined whether the addition of patient navigation to standard care was associated with a decrease in the number of days from a patient’s referral for KTx evaluation to KTx candidacy decision.

Methods: During evaluation scheduling at a single KTx center, patients answered questions from a risk assessment tool created using existing data; high-risk patients were randomized prior to KTx evaluation to either standard of care (control) or the additional assistance of a patient navigator (intervention). The patient navigator helped guide patients through the KTx process, serving as a point of contact and providing support and education from the time of referral for KTx evaluation through candidacy decision (patient approved for placement on waiting list or deemed “not a candidate”).

Results: From January 2013 to October 2014, 394 patients were enrolled in the study. Patient demographics were similar among intervention and control groups (80% Black, 87% Hispanic). A total of 311 (79%) reached candidacy decision (79% of intervention and 79% of control patients) and were included in preliminary analyses. Intervention patients reached candidacy decision a median of 8 days faster than control patients (119 vs. 127 days). Shorter time to decision for intervention vs. control patients was positively associated with highest likelihood of referral (OR:5.1; CI:3.1-8.5), including black patients (9 days), patients who completed high school (10 days), Medicare patients (15 days), patients with BMI<35 (30 days), married (11 days) and single patients (7 days), and patients < age 55 (19 days).

Conclusions: Preliminary results suggest that use of a nephrology consultation in reducing time from patient KTx referral to candidacy decision in a KTx setting. The use of a similar program in other KTx centers may help patients who require additional assistance during the KTx process complete KTx evaluation more quickly.

Knowledge of Treatment Options in Patients Evaluated for Kidney Transplantation: iChoose Kidney Randomized Trial
Mohua Basu,1 Stephen O. Pastan,1 Sumit Mohan,2 John J. Friedewald,1 Daniela P. Ladner,1 Rachel E. Patzer.1
1Emory Univ, Atlanta, GA; 2Columbia Univ, New York, NY; 3Northwestern Univ, Chicago, IL.

Background: Although kidney transplantation (KTx) provides a significant survival advantage relative to long-term dialysis, many end stage renal disease (ESRD) patients are not educated about KTx options. We developed a clinical decision tool (iChoose Kidney) to provide individualized risk estimates of patient survival on dialysis vs. KTx to evaluate whether use of the decision tool during KTx evaluations improved patient knowledge of the survival benefit of KTx vs. dialysis. This tool can be used to either standard of care or the additional assistance of a patient navigator (intervention).

Methods: In December 2014, we began enrolling patients from three large KTx centers across the U.S., where patients are randomized to usual KTx evaluation (control) or an appointment during which the nephrologist uses iChoose Kidney with the patient (intervention). Pre- and post-nephrology consultation, we surveyed patients on whether they believed their chance of survival was higher, lower, or the same with (1) dialysis vs. KTx and (2) living vs. deceased donor KTx. Improvement in knowledge was defined as a change from incorrect to correct post-nephrology consultation. Health literacy was measured using the Newest Vital Sign and categorized into low/moderate vs. high (0-3 vs. 4-6 correct out of 6, respectively).

Results: To date, 214 patients are enrolled (target enrollment n=450). Among 106 intervention patients, 29% improved their knowledge of the survival benefit of dialysis vs. KTx, 19% of 108 control patients (p=0.07). Among patients with low or moderate literacy, 35% of intervention patients improved vs. 13% of control patients (p=0.01); this difference was not observed among high literacy patients (26% improved in each group).

Conclusions: Preliminary results show that the use of the iChoose Kidney decision tool in comparing survival estimates for dialysis vs. KTx may improve patient knowledge of treatment outcomes during KTx evaluations, and the tool may be especially effective among low literacy populations.

Hemodialysis Social Networks Facilitate the Completion of Transplant Testing and Successful Kidney Transplantation
Avrum Gillespie,1 Alexis Uversky,2 Jonathan T. Hunt,3 Heather Marie Train,3 Sarah Bauere Bass,2 Teri Browne,1 Zoran Obradovic.1 1Nephrology, Hypertension, and Kidney Transplantation, Temple Univ School of Medicine, Philadelphia, PA; 2Center for Biomedical Informatics, Temple Univ, Philadelphia, PA; 3School of Public Health, Temple Univ, Philadelphia, PA; 4School of Social Work, Univ of South Carolina, Columbia, SC.

Background: Hemodialysis (HD) social networks may promote access to a kidney transplant (KT). We set out to observe the formation of HD social networks and their role in facilitating the steps of the transplantation process in a newly formed HD clinic.

Methods: Between 8/2012 - 2/2015, 46 patients admitted to a newly formed HD clinic were enrolled, 63% were new to HD. Patients spoke either English (78%) or Spanish (22%). All eligible patients were referred for transplant evaluation and testing. Progress on KTx was tracked. Patients were surveyed on admission and then quarterly using a previously validated questionnaire. Social interactions and seating were recorded, this data was merged with survey data and analyzed in SPSS 21.

Results: Two thirds of patients were observed to participate in social networks. There were no demographic differences among the patients who participated in social networks vs. those who didn’t (“non-social”). More social patients wanted a KT, 100% vs. 73% (p<0.008). Social patients reported talking to other patients about their health or KT 64.5% vs. 6.7% (p<0.001). Social patients completed more steps, 2 steps (range 0-6) vs. 1 (range 0-3) and vs. KTx and 2) living vs. deceased donor KTx. Improvement in knowledge was defined as a change from incorrect to correct post-nephrology consultation. Health literacy was measured using the Newest Vital Sign and categorized into low/moderate vs. high (0-3 vs. 4-6 correct out of 6, respectively).

Conclusions: Preliminary results show that the use of the iChoose Kidney decision tool in comparing survival estimates for dialysis vs. KTx may improve patient knowledge of treatment outcomes during KTx evaluations, and the tool may be especially effective among low literacy populations.

Kidney Transplant Referral Among Incident Georgia Dialysis Patients with and without Systemic Lupus Erythematosus: The RaDIANT Community Study

Laura Plantinga, Rachel E. Patzer, Sung S. Lim, Cristina Drenkard, Stephen O. Pastan. Emory Univ, Atlanta, GA.

Background: Although providers often wait to start transplant patients with systemic lupus erythematosus (SLE), shorter overall times to transplant are generally associated with more favorable transplant outcomes in SLE patients. We examined whether referral for evaluation—the first step in the often years-long process of kidney transplantation—is delayed in dialysis patients with SLE, relative to other dialysis patients.

Methods: United States Renal Data System data on a cohort of 18,419 incident (1/1/05-9/30/12) adult (18-69 yr) dialysis patients referred to a transplant center for evaluation was linked to the patient referral service (PERS) of each of the 17 Georgia adult transplant centers. SLE was defined by the provider-assigned cause of ESRD. Logistic regression and Cox proportional hazards models were used to examine the associations of assigned cause and patient characteristics with preemptive referral (referral prior to the start of dialysis) and time from start of dialysis to referral [censored for death or last date of follow-up (9/30/12)], respectively.

Results: Of the 352 dialysis patients with SLE, 43 (12.2%) were preemptively referred—50% more often than other ESRD patients [1573/18,067 (8.7%); OR=1.5 (95% CI, 1.2-1.8)] but not at rates higher than other ESRD patients with diabetes (1551/18,024 [8.6%]; OR=1.1 (95% CI, 0.9-1.3)]. Among the 17,293 dialysis patients not preemptively referred, SLE referred were referred at twice the rate of other dialysis patients in crude analyses [HR=1.9 (95% CI, 1.6-2.2)] but not after adjustment for [HR=1.1 (95% CI, 0.9-1.2)]. Among SLE patients, black vs. white race was associated with lower likelihood of preemptive referral [OR=0.5 (95% CI, 0.2-1.2)] but higher rates of referral after dialysis start [HR=1.8 (95% CI, 1.1-2.7)]. Male vs. female sex was associated with higher rates of referral on dialysis [HR=1.6 (1.2-2.4)].

Conclusions: Referrals for kidney transplant evaluation do not appear to be delayed among dialysis patients with SLE, relative to other dialysis patients of similar age. Efforts to increase kidney transplant access in SLE patients should focus on potential race and sex disparities in referral as well as potential delays in other steps of the kidney transplant process.

SA-PO1005

Association of Kidney Transplantation Referral with Other Indicators of Quality Care Among Incident Georgia Dialysis Patients: The RaDIANT Community Study

Laura Plantinga, Stephen O. Pastan, Jenna Kriisher, Eric M. Gibney, Laura L. Mulloy, Rachel E. Patzer. Emory Univ, Atlanta, GA; Southeastern Kidney Council, Inc., Raleigh, NC; Piedmont Transplant Inst, Atlanta, GA; Georgia Regents Univ, Augusta, GA.

Background: Dialysis facility referral of patients for kidney transplant is a potential indicator of quality care. We examined whether referral within a year of dialysis start (1-year referral) was associated with other quality indicators among incident Georgia dialysis patients.

Methods: We examined a cohort of 14,120 incident (7/1/05-9/30/11) follow-up through 9/30/12 adult (18-69 yr) dialysis patients using United States Renal Data System data linked to concurrent referral data from all three adult Georgia kidney transplant centers. Multilevel, multivariable logistic regression was used to examine the association of 1-year referral with dichotomous quality indicators (pre-ESRD nephrology care, dialysis modality, permanent vascular access in place at dialysis start (HD patients only), pre-ESRD erythropoietin use, and transplant information at dialysis start), with adjustment for demographic and clinical variables and accounting for variation across clinics.

Results: Overall, 1-year referral was 28.4% and was higher among patients with other indicators of quality care: 26.0% vs. 23.8%, with vs. without pre-ESRD care (P=0.005); 27.8% vs. 24.6%, PD vs. HD (P=0.03); 28.3% vs. 22.9%, with vs. without a permanent vascular access in place at HD start (P=0.001); and 27.2% vs. 16.5%, informed vs. not informed of transplant options at dialysis start (P=0.001). With adjustment, pre-ESRD care [OR=1.34 (95% CI, 1.22-1.47)] and method of vascular access in place at dialysis start [OR=1.34 (95% CI, 1.41-1.70)] and transplant information at dialysis start [OR=1.63 (95% CI, 1.45-1.85)] remained associated with higher 1-year referral.

Conclusions: These findings suggest that patients who receive quality care in multiple domains are more likely to be referred for kidney transplant evaluation within a year of starting dialysis, independent of demographic and clinical characteristics. Interventions to increase transplant access should be targeted to patients whose care fails to meet other quality indicators.

SA-PO1006

Feasibility and Sustainability of the RaDIANT Community Study Among Georgia Dialysis Facilities Jennifer C. Gandee, Leilah Sauls, Teri Browne, Laura Plantinga, Laura J. McPherson, Eric M. Gibney, Laura L. Mulloy, Stephen O. Pastan, Rachel E. Patzer. Emory Univ; Southeastern Kidney Council, Univ of South Carolina; Piedmont Hospital, Georgia Regents Univ.

Background: The Southeastern Kidney Transplant Coalition developed the randomized, dialysis facility-level Reducing Disparities In access to kidney Transplantation (RaDIANT) Community Study to address racial disparities and low rates of kidney transplantation (KTs) in Georgia. We aimed to evaluate the feasibility and sustainability of the RaDIANT intervention activities.

Methods: The 67 dialysis facilities that completed a 12-month intervention as part of the RaDIANT study consisted of 12 recommended activities intended to increase KT referrals, such as education and outreach activities targeting the patient, facility staff, and facility policy level. After the intervention, facility staff were asked to complete a 20-item questionnaire on the helpfulness (Likert scale) of each intervention activity and the likelihood (percentage) of their facility continuing the activity.

Results: A total of 86 staff (51.2% social workers) at the 67 intervention facilities completed the survey. The median number of the 12 intervention activities completed by dialysis facilities was 9 (range 0.11), Most facilities reported discussing the benefits of KTs at a staff orientation (86.6%), attending monthly webinars (80.7%), and developing a referral improvement plan (76.3%) to be helpful or very helpful. The median number of prescribed intervention activities the facilities reported they would continue was 2, with the distribution of educational brochures (41.9%), a staff orientation focused on KTs (41.9%), and patient and family education session (34.9%) among the most commonly cited.

Conclusions: Dialysis facility staff perceived that RaDIANT intervention activities were feasible to implement, with staff education potentially being the most helpful and sustainable component. Sustainability may be limited to intervention components that were at least as expensive and time intensive to implement. Additional ongoing support from ESRD Networks may be necessary to sustain increased KT referrals observed in the RaDIANT Community Study.

SA-PO1007

Psychosocial Differences Between Living and Deceased Donor Renal Transplant Recipients Anna Bertram, Selma Pabst, Martina De zwaan, Tanja Zimmermann, Mario Schiffer. Clinic for Psychosomatics and Psychosurgery, Hannover Medical School, Hannover, Germany; Neuropsychology and Hypertensiology, Hannover Medical School, Hannover, Germany.

Background: The specific impact of living donor (LD) as compared to deceased donor (DD) kidney transplants on psychosocial functioning has received surprisingly little attention. The present study aimed to assess whether LD and DD recipients differ in socio-demographic variables, time since transplantation, emotional variables, knowledge about immunosuppressant (IS) intake, and self-reported adherence to IS.

Methods: A questionnaire study was performed among 72 LD and 369 DD recipients who attended the kidney transplant outpatient clinic of Hannover Medical School for a follow-up visit at least 1 year after transplantation. Emotional responses were assessed using the Hospital Anxiety and Depression Scale (HADS) and the Transplant Effect Questionnaire (TxEQ). Paid with a newly developed test consisting of 8 multiple choice questions, and IS adherence was measured by self-report (BAASIS), physicians’ estimates, IS trough level variability, and allograft rejection.

Results: Overall, LD recipients were younger and had a shorter follow-up since transplantation than DD recipients. LD recipients apparently had more knowledge about IS medication. However, they did not report more adherence to IS. No differences between LD and DD recipients were found for gender, educational level, depression, perceived social support, and allograft rejection. Conclusions: Feelings of guilt and anxiety may be an important focus for interventions to improve emotional adjustment to transplantation, especially in LD recipients.

Funding: Other NIH Support - The RaDIANT Community Study is funded in part by NIMHD Award 2R4MD008077

Physician-Reported Adherence with Immunosuppressants in Renal Transplant Patients: Prevalence, Agreement, and Correlates Anna Bertram, Selma Pabst, Martina De zwaan, Mario Schiffer. Clinic for Psychosomatics and Psychosurgery, Hannover Medical School, Hannover, Germany; Neuropsychology and Hypertensiology, Hannover Medical School, Hannover, Germany.

Background: Assessing adherence to immunosuppressants (IS) is difficult. We investigated (1) the prevalence of non-adherence with IS as estimated by physicians; (2) the agreement between the physicians’ estimated and other adherence measures; (3) the difference between adherent and non-adherent patients according to the physicians’ estimation with regard to socio-demographic variables, transplant-related variables, and psychological factors.

Methods: All kidney transplant patients attending the outpatient clinic for a follow-up visit from 11/2014 to 02/2015 were screened; 238 patients met inclusion criteria. Adherence with IS was assessed with several measures: 4-item Basel Assessment of Adherence to
Evolution Through 20 Years of the Major Kidney Transplant Program from Living Donor in Mexico  

Background: According to the National Transplant Center, in 2013 a total of 2707 kidney transplants (KT) were performed in Mexico. Our program performed the highest single center number of transplants with 270 KT, mostly from living donors.

Methods: We use data collected in our registration program at Nephrology and Transplant Unit. All the KT in adult patients performed from January 1994-December 2014 were included. We also analyzed the last 909 kidney recipients and their serum creatinine at the end of first year. Successful KT was defined as a Cr <1.5 mg/dl at 1 year follow-up. Grafts lost were defined as Cr >4.0 mg/dl or replacement therapy initiation.

Results: During this period 3643 KT were performed, 3236 from living donors and 407 from cadaver donor. Of living donors, 2786 were from related donor and 450 were from genetically unrelated donors. The mean age of recipient was 28 years; 65% of our recipients were male. The evolution of the program is shown.

Conclusions: Each year we are still growing the number of KT. The age of our recipients is diminishing and age of donors is increasing. Months before KT are also increasing lately reflecting the great number of ESRD patients. Recipient age, HLA mismatching, induction therapy use and generic drugs can explain the 13.2% of patients with Cr above 1.5 mg/dl.

SA-PO1010  

The Difficult Road for Native Americans in Kidney Transplantation: Decreased Access and Reduced Long-Term Survival  

Background: Native Americans (NAs) have disproportionately high rates of end-stage renal disease, yet wait listed NAs have lower rates of kidney transplantation than other racial/ethnic groups and worse long-term post-transplant survival outcomes than whites. This study evaluates these disparities across multiple medical and socioeconomic dimensions.

Methods: Using data from the Organ Procurement and Transplantation Network (OPTN), we evaluated wait list removal reasons and post-transplant survival rates from 3/1/95 to 12/31/12. We use a logistic regression model, controlling for patient, donor, match characteristics, and center and year fixed effects, along with a Blinder-Oaxaca decomposition of the results.

Results: Among registered patients removed from the wait list, NAs were less likely to receive a transplant (odds ratio, 0.71 [95% CI, 0.64-0.80]), and more likely to die on the wait list (1.88 [0.89-3.94], compared to whites. NAs are less likely than whites to survive at least two years (odds ratio, 0.80 [95% CI, 0.70-0.92]) and at least three years (0.81 [0.71-0.94]), but these disparities become statistically insignificant with risk adjustment.

Conclusions: NAs experience higher rates of adverse wait list removal reasons than other racial/ethnic groups. Among NAs who do receive transplants, short term survival outcomes are similar to those of whites, but longer term survival outcomes are lower. The decomposition of our results indicates that the disparity in three-year post-transplant survival between NA and whites is driven primarily by the prevalence of lower quality donors among NA waitlisted patients. The negative impact of such donor characteristics on survival among NA NAs also tend to receive transplants at centers associated with worse outcomes and would benefit disproportionately from receiving transplants at better centers.

Estimated GFR for Living Kidney Donor Evaluation  

Estimated GFR for Living Kidney Donor Evaluation

Naya Huang,1 Meredith C. Foster,1 Krista L. Lenting,2 Amit X. Garg,3 Emilio D. Poggio,1 Bertram L. Kasiske,1 Lesley Inker,1 Andrew S. Levey.1

1 Division of Nephrology, Tufts Medical Center, Boston, MA; 2 Division of Nephrology, Saint Louis University, MO; 3 Division of Nephrology, Western University, London, ON, Canada

Background: All living kidney donor candidates undergo an evaluation of GFR. Guidelines recommend measured GFR (mGFR) rather than estimated GFR (eGFR), but measurement methods are difficult, time consuming and costly. We questioned whether eGFR using cystatin C (eGFRcys) with or without sequential cystatin C (eGFRcr-cys) is sufficiently accurate to identify donor candidates with high probability that mGFR is above or below thresholds for clinical decision making.

Methods: We combined the pre-test probabilities for mGFR thresholds (≥60, ≥70, ≥80 and ≥90 mL/min/1.73 m²) in varying age, sex and race groups estimated from the National Health and Nutrition Examination Survey (NHANES) with test performance of eGFR (categorical likelihood ratios [LRs] determined from the Chronic Kidney Disease Epidemiology Collaboration) to compute post-test probabilities of meeting a given mGFR threshold.

Results: Using NHANES pre-test probabilities, we found that in some circumstances, eGFRcys and eGFRcr-cys provides high accuracy (post-test probability≥95%) in candidate donors. Using data from the Scientific Registry of Transplant Recipients, we demonstrated that 54% and 82% of recent donors had pre-donation eGFR high enough to assure ≥90 mL/min/1.73 m² and replacement therapy initiation, respectively, suggesting a large fraction of donor candidates might not require mGFR above threshold.

Conclusions: Implementation strategies could include eGFRcr as a first test and possibly eGFRcys as confirmatory test. If post-test probabilities are of sufficient magnitude, eGFR could be used to accept or reject donors without measurement of GFR. We will provide a web-based application.

SA-PO1012  

Change of Physical Activities in Male and Female Recipients in 12 Months After Living Kidney Donor Transplantation  

Masami Tsujiita, Transplant Surgery, Nagoya Daini Red Cross Hospital, Japan.

Background: Since renal dysfunction and immunosuppressive drugs cause muscle degeneration, physical activities decrease in CKD, dialysis patients and transplant recipients. In addition, elderly kidney transplant recipients are increasing in Japan, so improving physical activities and increasing muscle strength and volumes are important to prevent fractures and fall accidents.

Methods: Consecutive 58 patients (male 33) older than 40 years were enrolled in this study from 2012. Immunosuppression basically contains steroids, ciclosporin or tacrolimus, and mycophenolate mofetil or everolimus. Hypertension, hyperlipidemia, and osteoporosis were treated as needed. Parameters of physical activities such as hand grip, SMI (skeletal muscle index) and Body fat mass using by DEXA/total-energy x ray
absorptiometry), and Body mass index (BMI) were measured and compared at prior, 6, and 12 months after kidney transplantation. Recipients were encouraged to do daily exercise for 30 to 60 minutes everyday.

**Results:** Mean age (years) were 52.3±10.0 in male, and 53.6±10.4 in female. In male patients, any parameter did not change after transplantation in male patients. In female patients, SMI improved in 12 months (p<0.005), and Hand grip also tended to increase with statistically difference.

**Figure 1 Results of this study for male and female (mean±SD)**

<table>
<thead>
<tr>
<th>Gender</th>
<th>BMI (kg/m²)</th>
<th>Body fat mass (%)</th>
<th>SMI (kg/m²)</th>
<th>Hand grip (kg)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Male</td>
<td>23.9±3.4</td>
<td>21.8±1.3</td>
<td>21.7±3.2</td>
<td>9.3</td>

<tr>
<td>Female</td>
<td>23.1±3.6</td>
<td>20.2±1.3</td>
<td>21.5±4.2</td>
<td>6.1</td>
</tr>
</tbody>
</table>

Physical activities seemed unchanged after transplantation in male patients than before.

**Conclusions:** In male recipients, physical activities do not seem to recover in 12 months after kidney transplantation. More interventions and more studies are needed to increase physical activities and know the effect of daily exercise clinically.

SA-PO1013

Search for New Data to Predict Kidney Transplant Outcomes in the Organ Procurement and Transplantation Network Database

Mohamed A. Sheta, Bertram L. Kasiske, Charles E. Alexander, Joseph Kim, University of Minnesota, Hennepin County Medical Center; University of Colorado Denver, Aurora, CO.

**Background:** The Organ Procurement and Transplantation Network (OPTN) collects data used to monitor transplant program outcomes for quality assurance and regulatory oversight. It is imperative that the variables in the OPTN database used by the Scientific Registry of Transplant Recipients to determine expected outcomes after kidney transplant be reliable, complete, and up-to-date.

**Methods:** We conducted a systematic review to identify risk factors not included in current OPTN data that predict graft failure or mortality after kidney transplant. We searched for studies with publication date between Jan 1, 2000 and May 1, 2015. At least 1000 subjects in one or more risk prediction models/multivariate analysis used to select variables predicting patient or graft survival; inclusion in the multivariate model of at least one risk factor collected before or at the time of transplant that is not already collected by OPTN and English language.

**Results:** Of the 623 studies that included 24,668,918 transplant recipients, 141 (22.6%) included risk factors that were not already collected by OPTN.

**Conclusions:** These results comprised a list of variables that could be considered for inclusion in the OPTN database.

SA-PO1014

Prevalence of Mineral and Bone Disorders Among Living Kidney Transplant Recipients

Essam Mohammed Khedr, Amr Mohab, Haitham Ezzat. Nephrology Dept, Ain Shams Univ, Cairo, Egypt.

**Background:** Mineral and bone disorders (MBD), frequent complications of chronic kidney disease (CKD), occur frequently in kidney transplant recipients. Still, little is known about its prevalence and clinical correlates in transplanted patients.

**Methods:** We conducted a cross-sectional analysis of 504 stable living kidney allograft recipients. Detailed medical history, demographic data and routine laboratory investigations, including s.creatinine, s.corrected Calcium, s.Phosphorus, serum iPTH and s.Alkaline Phosphatase (ALP) were collected. Estimated GFR was calculated using the abbreviated MDRD formula. Patients were stratified into three groups based on duration of kidney transplantation. Group I: 6 months to 1 year, group II: from 1 to 5 years and group III: more than 5 years. Correlations were done between bone minerals and all laboratory results. We also analyzed the possible relation between various immunosuppressant drugs and bone minerals, serum iPTh and serum ALP.

**Results:** The mean age was 32.8±8 years in group I, 45.3±7.3 years in group II, and 40.5±9 years in group III, with no significant difference between the three groups (p>0.05). There was a significant difference between the studied groups as regards laboratory parameters (p<0.05). 115 patients had iPTh levels >170 ng/dl, while 365 patients (72.4%) had iPTh levels <70 ng/dl. Only 24 patients had hypercalcemia, and 34 patients had hyperphosphatemia. We also found that 68 patients had hypophosphatemia. Serum iPTh and s.Alkaline Phosphatase levels were higher in group III (156.66±66.12, 135.54 IU respectively) when compared to group I (98.33±4.71, 120.33 IU) and group II (138.35±4.11, 122.60 IU) (p<0.001). In group I, iPTh levels were negatively correlated with s.eGFR (r value=-0.37, p<0.05). Both serum ALP and iPTh levels showed significant negative correlation with s.eGFR in groups II and III (p<0.05). In all groups, bone minerals, iPTh and serum Alkaline Phosphatase levels had no statistically significant relation with the immunosuppressant agent used (p>0.05).

**Conclusions:** Disturbances of bone and mineral metabolism after transplantation are prevalent and are strongly correlated with the kidney function and transplantation duration.

SA-PO1015

Risk of Adverse Maternal and Fetal Outcomes During Pregnancy in Living Kidney Donors

Jessica B. Kendrick, Jill R. Holmen, Gerard John Smits, Michel Chonchol, Univ of Colorado Denver, Aurora, CO; Denver Health Medical Center, Denver, CO; Intermountain Health Care, Salt Lake City, UT.

**Background:** A frequently asked question by potential kidney donors is risk of nephrectomy on maternal and fetal outcomes in pregnancy. Studies regarding the risks of living kidney donation and pregnancy outcomes are conflicting. The purpose of this study was to determine the risk of adverse maternal and fetal outcomes in donors vs. non-donors.

**Methods:** Using data from an integrated health care delivery system in Utah from 2000 through 2014, a total of 72 women were living kidney donors that became pregnant after kidney donation. Using a pool of 74,105 women who were not donors, we selected 1223 to use for matches for the living kidney donors. These women were matched 1:3 by age and race. Adverse pregnancy outcomes were defined as preterm delivery, delivery via cesarean section, preeclampsia, eclampsia, length of stay in the hospital and low birth weight (<2500 g). Logistic regression analysis was used to examine the association between donation and adverse outcomes.

**Results:** Of the living kidney donors, the mean (SD) age and mean (SD) gestational age at delivery was 30.5±3 years and 38.2±2 weeks. The mean (SD) length of stay in the hospital was 2.7±2.7 days. Six cases (8%) had a history of chronic hypertension. Living kidney donors did not have a higher risk of preterm delivery (OR 1.82, 95% CI 0.87-3.77), preeclampsia/eclampsia (OR 1.11, 95% CI 0.47-2.62), delivery via cesarean section (OR 1.51, 95% CI 1.05-2.16), length of stay >3 days (OR 1.29, 95% CI 1.03-2.64) or low birth weight (OR 1.94, 95% CI 0.67-4.35) compared to non-donors.

**Conclusions:** Living kidney donation is not associated with a higher risk of adverse outcomes in pregnancy.

**Funding:** NIDDK Support

The Quality of Life of Parents of Pediatric Kidney Transplantation

Yuko Hamasaki, 1 Miyako Tazaki, 1 Yusuke Takahashi, 1 Seichirou Shishido, 1 Atsushi Aikawa. 2 Pediatric Nephrology, Toho Univ Faculty of Medicine, Tokyo, Japan; 1 Psychology, Toho Univ Faculty of Medicine, Tokyo, Japan; 2 Nephrology, Toho Univ Faculty of Medicine, Tokyo, Japan.

**Background:** The purpose of the study is to investigate how the Quality of life (QOL) of parents whose child had received kidney transplantation (KT) would change by delivering questionnaires four times; before, one month after, three months after and one year after KT.

**Methods:** The QOL of thirty-one parents (30 mothers and 1 father) with a mean age of 38.5 years old whose child received KT at Toho University Omori Medical Center from May 2012 to March 2015 was measured using WHO Quality of Life (WHOQOL). Visual Analogue Scale (VAS), and General Health Questionnaire (GHQ). The mean age of the parents was 5.8 years old (18 boys, 13 girls). Congenital anomalies of the kidney and urinary tract were the most frequent primary diseases (54.8%). Among them, twenty-two children received dialysis before KT, and nine received preemptive KT.

**Results:** Based on the results, the average WHOQOL scores show the QOL of parents decreased one month after KT (3.15) with a statistical difference compared with before KT (p=0.042), but increased at three months (3.40) (p=0.0073), and maintained until one year (3.41). The average QOL of the parents of a child with frequent infection was statistically lower than those without any infection (p=0.448) at three months after KT and one year after KT (p=0.006). The average QOL scores of nineteen donor parents had a statistically higher QOL before KT then reversed at one month after KT, but became higher again at three months after KT.

**Conclusions:** The QOL of the parents would decreased one month after KT when infection or other problems often occurred, but increased after three month as the condition of recipients stabilized and maintained until one year after KT, which became as high as before KT.
Disparities in Access to Renal Transplant in Puerto Rican Children Nilka deJesus-Gonzalez,1 Sonia M. Caraballo,1 Eduardo J. Santiago-Rodriguez,2,3 Marta P. Suarez-Rivera,1 Melvin A. Bonilla-Felix.1 1Medical School, Pediatric Nephrology Div, Univ of Puerto Rico; 2Univ Central del Caribe; 3Puerto Rico Clinical and Translational Research Consortium.

Background: Disparities in access to renal transplant have been reported in racial minorities living in US. No data is available from children with ESRD living in Puerto Rico (PR), the largest Hispanic group in a single pediatric dialysis unit in US. We describe the pediatric population with ESRD in PR from 2003-2013, the renal transplant rates and possible barriers to receiving a graft.

Methods: Retrospective chart review of patients diagnosed with ESRD in PR from 2003-2013. Incidence, prevalence rates, means/standard deviations (SD), medians/interquartile range (IQR), frequencies and percentages were calculated and compared to national rates.

Results: From 2003-2013 99 patients, male: 52%, age:13.5 yrs (8-16yrs), were diagnosed with ESRD. Congenital anomalies were the primary cause in 40%, and FGOS in 24%. Incidence of ESRD ranged from 3-14 subjects per million population/year, with prevalence per dialysis modality from 7-18 subjects per million population/year. 38% were transplanted in PR (Median age: 14yrs, IQR: 9-16), 23% from living donors. 14.1% received a transplant in the first year (National rate: 38%). 63% of transplanted children had Medicare coverage. None of 9 infants diagnosed with ESRD were transplanted during infancy. 46% of the children who were not transplanted stayed at our unit for a median time of 2 yrs (IQR: 1-3). The rest was transferred to a dialysis unit outside PR (15%) or to an adult facility without being transplanted (39%). 67% of these non-transplanted children were covered by Medicare. The mortality rate during the first year of diagnosis was 3% (National rate: 4%).

Conclusions: Children with ESRD in PR face striking disparities in access to renal transplant. Lack of pediatric transplant surgeons, geographical isolation and minimal living donation are potential barriers. Medicare coverage does not appear to be a factor, as it was similar between transplanted and non-transplanted. Interventions to reduce these inequities are needed.

Post Donation Diabetes and Risk of Death and ESRD

Hassan N. Ibrahim,1 Robert N. Foley,2 Scott Reule, Danielle M. Berglund, Arthur J. Matas, Hassan N. Ibrahim. Univ of Minnesota, Mpls, MN.

Background: We have previously shown that development of diabetes following live kidney donation does not result in accelerated GFR decline when compared to diabetics with two kidneys. Herein, we report on the development of a risk calculator for new onset DM in donors and address its contribution to mortality and also renal outcomes.

Methods: Donors are followed indefinitely through surveys including development and treatment of diabetes and renal outcomes. Risk factors for post donation diabetes were determined using stepwise proportional hazards regression.

Results: Development of DM was ascertained in 3874 donors with a mean follow-up of 16±12 years. In total, 279 (7%) developed DM and address its contribution to mortality and also renal outcomes. Coefficients from the regression model were then used to create an individualized risk calculator. This was validated in the remaining 1934 (C-statistic 0.77). The cumulative risk of developing DM at 5 yearly intervals is shown in figure 1.

What Kind of Obesity Does Affect Kidney Function? Survey of Kidney Transplant Donors
Mikiko Yoshikawa, Junko Nakano, Kentaro Nakai, Hideki Fujii, Shinichi Nishi. Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine, Kobe, Japan.

Background: Currently obesity is a risk for chronic kidney disease. It is also suggested that sarcopenia is the independent risk factor of hypertension. It is unclear whether obesity and body composition affect to kidney function and other prognosis of donors in our country. The aim of this study was to investigate the influence of body composition, the findings of graft biopsy and 1-year after clinical outcome.

Methods: This is a retrospective single center study of 60 living kidney transplant donors from 2009 to 2014. Donors are stratified according to Body Mass Index (BMI³25kg/m²) and Body Composition from 2011. We divided donors into four groups; (A) Obesity negative + Sarcopenia negative (ONSN) (B) Obesity positive + Sarcopenia negative (OPSN) (C) Obesity negative + Sarcopenia positive (ONSPP) (D) Obesity positive + Sarcopenia positive (OPSP). We evaluated kidney function at donation, baseline kidney graft biopsy findings and clinical course 1 year-after donation.

Results: Seven patients were ONSN (11.7%), 22 patients ONSP (36.7%), and 4 patients OPSN (6.7%). Visceral fat area 1100 m² (which is defined as central obesity in Japanese criteria) was significantly higher in OPSN group. S-Cre at donation was significantly lower in ONSP and OPSN groups. In multivariate analysis of graft biopsies, BMI³25kg/m² was a significant risk for small artery intimal thickenings and interstitial fibrosis/tubular atrophy. On the contrast, OPSN was an independent risk for global sclerosis. In multivariate analysis, central obesity was significantly correlated with 1-year after proteinuria. In addition, OPSN was an independent risk for 1-year after hypertension.

Conclusions: These results indicate obese donor already has a risk for arterial and interstitial damages at transplantation. In addition, central obesity and sarcopenia contribute to the late graft function and hypertension.[Reference] (1) Prado CM et al. Lancet Oncol 2010; 11: 366-374.

SA-PO1022
Living Donor Remaining Function Measured by CKD-EPI Correlates with Remaining Kidney Volume

Background: The aim of our study was to evaluate whether preserved kidney volume correlates with donor renal function at 2-years post-donation using the CKD-EPI eGFR equation.

Methods: Demographics and renal function of living donors who underwent living nephrectomy between January 2008 and November 2012 were reviewed. All donors underwent computed tomography with an estimation of kidney volumes. Preserved Kidney Volume (PKV) was adjusted (aPKV) to Body Surface Area.

Results: A total of 208 donors with 2 year follow up data available. Pre-donation eGFR (β Coef. 0.344), age (β Coef. -0.318) and aPKV (β Coef. 0.11) were found to be independent predictors of 2yr eGFR (p<0.001). aPKV was divided into tertiles (low/medium/high) and a 2 year eGFR of <60ml/min was chosen as a cut off for dichotomous analysis as in Table 1. Mean 2yr eGFR was 57±12.65±16 and 73±17 between the tertile groups (p<0.05). The odds ratio of having a 2yr post-donation eGFR <60 with a cutoff of median aPKV of 194ml was 5.8 (95%CI 2.9-11.6; p<0.001), while that of 2yr post-donation eGFR <60 with a cutoff of < 25 percentile of aPKV of 159.9 was 5.6 (95%CI 2.7-11.22; p<0.0001). The odds ratio of having an eGFR <60 if the aPKV was above the 75 percentile was 0.13 (95%CI 0.05-0.3) p<0.0001. ROC and AUC for aPKV and eGFR (CKD-EPI) of <60 were 0.763 (CI0.69-0.82) p<0.005 as in Figure 1.

Conclusions: Diabetes can be reasonably predicted in kidney donors using baseline data. Diabetes is a significant contributor to reduced GFR and proteinuria.

Assessing Adherence Barriers in Pediatric Kidney Transplant Recipients
Charles D. Vanrell, Kristin Losielle, Alna H Phai, Avani Modi, David K. Hooper. 1 Div of Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 2Center for Treatment Adherence and Self-Management, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.

Background: Nonadherence in pediatric kidney transplant recipients (KTRs) is associated with poor outcomes and poses a significant financial cost to society. Patient and family reported barriers to taking medications predict nonadherence, rejection, graft failure, and death. Despite their clinical importance and amenability to intervention, barriers to medication adherence are not routinely assessed in pediatric settings.

Methods: From Jan 2015 - May 2015, barriers to immunosuppressant adherence in KTRs were assessed using a standardized checklist of 14 common barriers. For KTRs<10 y.o. the caregiver completed the assessment. For KTRs>10 y.o. both the patient and caregiver, if present, completed the assessment. Assessments were completed during routine outpatient clinic appointments.

Conclusions: 36 pediatric KTRs [M(SD)age=13.14(6.43)years;56.7%male] and 50 primary caregivers completed a barriers assessment. At least one barrier was reported by 47% of KTRs compared to 42% of caregivers. For KTRs the most frequent barriers were forgetting(22%), hating the taste(13.9%) and running out of medicine(8.3%). For caregivers, the most frequently endorsed barriers were forgetting(20%), side effects(6.0%) and patient refuses to take their medication(6.0%). There was excellent concordance(96.2%) in dyads where both KTR and caregiver reported barriers. Assessing for barriers to adherence was easy to perform in practice and required<60 seconds.

Funding: Pediatric KTRs [M(SD)age=13.14(6.43)years;56.7%male] and 50 primary caregivers completed a barriers assessment. At least one barrier was reported by 47% of KTRs compared to 42% of caregivers. For KTRs the most frequent barriers were forgetting(22%), hating the taste(13.9%) and running out of medicine(8.3%). For caregivers, the most frequently endorsed barriers were forgetting(20%), side effects(6.0%) and patient refuses to take their medication(6.0%). There was excellent concordance(96.2%) in dyads where both KTR and caregiver reported barriers. Assessing for barriers to adherence was easy to perform in practice and required<60 seconds.

Conclusions: Nearly half of all patients report at least one barrier to taking their immunosuppression, and there is generally consistent agreement between patient and caregiver perception of barriers. Standardizing the approach to assessing barriers to immunosuppression adherence in the clinical setting can quickly produce information that might be missed by the provider. Future research should evaluate the effectiveness of interventions delivered as part of routine medical care to overcome identified barriers and prevent known complications associated with nonadherence.

A Longitudinal Follow-up of Hispanic Living Kidney Donors Clarence E. Foster III,1 Pinky J. Patel,1 Hirohito Ichi,1 Madeleine V. Pahl,2 Elani Streja,3 Jonathan R. Lakey,1 Kamyar Kalantar-Zadeh,2 1Surgery/Div of Transplantation, Univ of California, Irvine, Orange, CA; 2Medicine/Nephrology, Univ of California, Irvine, Orange, CA.

Background: This is a long-term follow-up of living kidney donors (LKD) in an ethnically diverse patient population. Hispanics are known to have an increased risk of developing chronic kidney disease, associated with hypertension and obesity. The hypothesis is Hispanic living kidney donors or uninsured living kidney donors would have poorer long-term outcomes secondary to lack of access to health care and secondary to the higher risk factors for developing chronic kidney disease.

Methods: The objectives: measure obesity, hypertension, diabetes, measure CrCl post-donation and compare to the pre-donation CrCl. LKD were contacted & invited to participate & had a questionnaire about their general health & history and physical. Analysis included a CBC, serum chemistry, a 24-hour urine collection to measure creatinine, protein and albumin. A Patient Data Visit Sheet, RAND 35 Health Questionnaire. The IRB approved this study.

Pre- and post-donation systolic and diastolic blood pressures were similar between Hispanics and non-Hispanic LKD. Non-Hispanic LKD had a greater decrease in systolic blood pressure post-donation -4.5 mmHg vs. 6.8 mmHg (p=0.0378). The decrease in CrCl post-donation was the same in Hispanic and Non-Hispanic LKD, 53 ml/min vs. 35 ml/min. None of the LKD in the study had significant proteinuria or micro albuminuria. Conclusion: Post living donor kidney donation in our ethnically diverse patients are not at a higher risk for developing obesity, HTN, or CVD. Overall, our LKD feel they have a good overall quality of life including both physical and emotional realms.

SA-PO1025

Predictors of Low Estimated Glomerular Filtration Rate After Living Kidney Donation in a Southeast Asian Population from Singapore Bo Yu Tan,1 John C. Allen,2 Terence Kee Yi Shern,3 Tzezen H. Jafar,2 1Dept of Renal Medicine, Singapore General Hospital, Singapore; 2Duke-NUS Graduate Medical School, Singapore.

Background: We aim to investigate patterns of change in kidney function and factors and associations with low estimated glomerular filtration rate (eGFR) following living kidney donation in Southeast Asian.

Methods: We retrospectively studied living kidney donors with nephrectomy performed at Singapore General Hospital between 1976 and 2012. Quantile regression analysis was performed on pre- to post-nephrectomy percent change in CKD-EPI eGFR levels. Donors were grouped according to elapsed time from donation as short-term (>6 months to <5 years after donation), medium-term (5 to <10 years after donation), and long-term (>10 years after donation), and compared on pre-nephrectomy demographic and clinical characteristics. Univariate and multivariate logistic regression were performed to evaluate predictors of low post-donation eGFR. A pre-nephrectomy eGFR cutpoint for prognosticating low post-donation eGFR was obtained using ROC analysis.

Results: 174 donors, predominantly female (63.8%) and of Chinese ethnicity (73%), of average age 40.6 years, were recruited. Median (range) follow-up was 7.8 (0.1–33.8) years during which 30 donors (17%) developed low eGFR, defined as <60 ml/min/1.73m². At 5 years post donation, 43.1% of donors recovered to at least 75% of pre-nephrectomy eGFR levels, and 9.8% exhibited 100% recovery to pre-nephrectomy eGFR levels at 19.2 years, on average. High pre-nephrectomy eGFR was prognostic for perfect recovery to eGFR post-donation, with a % reduction in risk for each unit increase in pre-nephrectomy eGFR (OR, 0.94; 95% CI, 0.91–0.97; p=0.002). This relationship was stronger in the short-term than to long term (p=0.032). ROC analysis indicated pre-donation eGFR cutpoint of 100 ml/min/1.73m² for prognosticating low post-donation eGFR sensitivity=0.80, specificity=0.61, PPV=0.80, and NPV=0.95; AUC (95% CI) was 0.75 (0.66–0.84).

Conclusions: In general, kidney function is well preserved following kidney donation in Southeast Asian donors. Pre-nephrectomy eGFR is a good predictor of post-donation eGFR, especially in the short-term.
function as a function of donor exposure to coronary angiograms, controlling for time-

invariant factors affecting all patients in a given year (year fixed effects) and time-varying factors associated with a specific transplant center (center fixed effects with standard errors clustered at the center level to account for heteroskedasticity and spatial correlation among patients in a given cen.

Results: Of 93,811 donors listed in study period, 8.5 % (8012) were exposed to coronary angiograms. From this group, 14,928 kidneys were transplanted. Statistically significant regression results (p<0.01) indicate that patients receiving organs from donors who received coronary angiograms are 2% points more likely to receive dialysis within the first month after transplant (mean=0.24) and are less likely to experience a ≥5% decline in serum creatinine in the first week of transplant (mean=0.56). These patients also face a 61 day shorter average graft survival time and a 1% point lower probability of 6-month post-transplant patient survival. At three years recipients from donors with contrast exposure have 2% decrease in survival rate (P=0.005).

Conclusions: This large database analysis provided statistical power to detect an association between donor exposure to iodiinated contrast from coronary angiograms before organ procurement and subsequent adverse early as well as later kidney transplant outcomes. Further research into the effects of deceased-donor management strategies is warranted to expand the organ pool while decreasing adverse transplant outcomes.

One Year Recovery After Kidney Donation: The Medical and Donor Point of View in a Prospective Cohort Study  
Briancon Serge,1 Lucie Germain,1 Michele Kessler,1 Marie-Alice Machet,2 Marc Souland,1 Marie Thong,2 Epidimiologie CIC-EC, CHU de Nancy, Nancy, France; 2Nephrology, CHU de Nancy, Nancy, France; 2Transplantation, Agence de la Biomedecine, Paris, France.

Background: Renal transplantation is the reference treatment for ESRD patients; the living donor kidney has been proven to provide better outcomes to recipients. Recovery of donors has been less studied and understood.

Materials: An exhaustive sample of 500 donors recruited in every French transplantation between October 2009 and January 2012 (T0) were followed at 3 (T1) and 12 months (T2) after surgery. Questionnaires investigating the donation course, quality of life (SF-36 and Euroqol) and recovery were sent home. Medical data were from CRISTAL register. 384 donors participated at T(0)(5%) and 12months(90%). The exceptional participation rate reflects the high commitment of donors.

Results: Before the donation, the physical health is incredibly high especially for older. On average a 75 year-old donor has the PCS SF36 level of 35 year-old men in the general population. Three months after surgery, all outcomes exhibited decreased health indicators. Three quarters of the donors underwent laparoscopy, associated with less pulmonary complications, kidney failure, high blood pressure, persistent physical pain, better postoperative recovery. More than half the donors have at least one complication of which 8% was severe. The appearance of the scar is one of the dissatisfaction of the donor. One year after the donation, over 10 donors, 9 resum wed work, 3 not at all completely recovered, three still feel physical pain, 4 have not recovered their PCS pre-donation level, and their MCS level. However their status remains better than that of the general population of the same age and sex. Donors are ready to do it again (98.2%) and recommend the donation (96%).

Conclusions: The experience alters neither the initial impetus nor the meaning attributed to the donation. The recommendations are aimed to develop the practice of laparoscopy in informing donors, manage completely pain, to better prepare the donor to the surgical procedure, its risks and aftermath, including professional ones in younger, to perfectly plan the medical follow up with information to referee physicians.

SA-PO1030

Discard of Deceased Donor Kidneys in the United States: The Weekend Effect  
Sumit Mohan,1 Karl F.W. Foley,1 Mariana C. Chiles,1 Geoffrey K. Dube,1 Russell J. Crew,1 Stephen O. Pasant,1 Rachel E. Patzer,1 David J. Cohen,1 Dept of Medicine, Columbus Univ College of Physicians & Surgeons, New York, NY; 2Dept of Medicine, Emory Univ School of Medicine, Atlanta, GA.

Background: The discard rate of deceased donor kidneys (DDK) has slowly increased over time. The underlying reasons remain unclear. The impact of low resource availability over the weekend compared completely pain, to better prepare the donor to the surgical procedure, its risks and aftermath, including professional ones in younger, to perfectly plan the medical follow up with information to referee physicians.

Funding: Government Support - Non-U.S.

Conclusions: DDK procured on Fri-Sat are more likely to be discarded than at other times of week. Kidneys were transplanted are more likely to be shared with large transplant centers. Our results demonstrate the possibility that low resource availability on the weekends adversely impacts organ procurement, acceptance and transplantation.

SA-PO1031

Medication Adherence Barrier Burden Predicts Subsequent Adherence to Dosing Time Schedule in Adolescent Kidney Transplant Recipients in the TAKE-IT Trial  
Bethany J. Foster,1 Huang-Qiao Zhao,2 Ahna Lh Pai,2 Nataliya Zelikovskaya,1 Crystal D. Holly,1 Jodi M. Smith,2 Vikas R. Dharnidharka,3 Diane Hebert,1 Lorraine E. Bell,2 Douglas G. Matsell,1 Veronique Phan,2 Susan L. Furrh.1 1Pediatrics, McGill Univ; 2TAKE-IT Investigators.

Background: Studies of adherence to timing of medication dosing in high-risk adolescent kidney transplant recipients are lacking.

Methods: We aimed to determine whether the burden of perceived barriers to medication adherence predicted timing adherence (proportion of doses taken ±1 h. before ±2 h. after the prescribed dosing time) during the subsequent 3 mo., as monitored with a multidose electronic pillbox. We evaluated the 126 participants of TAKE-IT who had electronic adherence data available for the 3-mo. run-in period (no intervention). Participants (11-24 y.; ≥ 3 mo. post-transplant) were followed in 8 centers (Canada and USA). Adherence barriers were assessed at baseline using the Adolescent Medication Barriers Scale (AMBS). A higher score indicates greater barrier burden (possible range 17-85). We used linear regression to estimate the association between baseline AMBS scores (total score and ingestion, disease adaptation, and cognitive/organization subscores) and timing adherence. Models also included sex, age, race, and time since transplant.

Results: 60% were male and 67% were white. Median age at baseline was 15.8 (IQR 14-17.4) y. Median time since transplant was 1.1 (0-7.7) y. Mean adherence for the interval was 82.6%±32.8. Higher barrier burden (median score 38 (IQR 30-44)) was significantly associated with poorer timing adherence: a 0.5 unit higher AMBS score was associated with 2.0% (95% CI 0.4-3.6) lower timing adherence. A 0.5 unit higher score was associated with 2.0% (95% CI 0.4, 3.6) lower timing adherence. A 5 unit higher score was associated with 4.3% (95% CI 1.2, 7.5) lower timing adherence for the disease adaptation sub-scale, and with 5.9% (0.2, 11.6) lower timing adherence for the cognitive/organization sub-scale. Males had 10% (2.9, 17.6) lower timing adherence than females.

Conclusions: Higher burden of perceived barriers was a significant predictor of poorer timing adherence in this longitudinal study. Future analysis of the TAKE-IT data will determine the impact of an intervention targeting individual barriers on timing adherence.

Deceased Donor Procurement in the U.S.: Measurement of Surgical Damage Inflicted Upon the Procured Organ  
Tim E. Tabor,1 Nicole Neidlinger,2 Muhammad Ahmad Mujtaba,1 Elling E. Eidbo,1 Anil S. Paramesh.1 1Medicine, Indiana Univ School of Medicine / Indiana Donor Network, Indianapolis, IN; 2Surgery, Donor Network West, Berkeley, CA; 3Medicine, UTMB Galveston, Galveston, TX; 4Surgery, Tulane Univ School of Medicine, New Orleans, LA; 5Association of Organ Procurement Organizations, Vienna, VA.

Background: Deceased organ donation provides healthy allografts for the majority of organ transplants done in this country. While there are many factors involved in determining suitability of allografts for transplantation, one of the most important is careful procurement of the organ.

Methods: In the winter of 2013, the medical directors of the Association of Organ Procurement Organizations (AOPO) agreed upon a standard for organ damage sustained during procurement. Organ damage was classified into three tiers, from 1 – 3 with the latter rendering the organ non-transplantable. For 12 consecutive months starting in January of 2014, 36 of 58 OPOs prospectively submitted quality data regarding organ damage seen on the procured organ. These 36 OPOs recovered 5,401 of the nation’s 8,504 deceased donors for calendar year 2014.

Results: A total of 9501 kidneys were procured from this cohort. Organ damage determined at time of procurement was as follows: 156 class 1 (non-clinically relevant damage); 86 class 2 (damage requiring repair prior to transplantation); 43 class 3 (kidneys that were damaged to the extent that they could not be transplanted).

Conclusions: Damage done to the kidney at the time of procurement rendering the allograft non-transplantable occurred at a rate of approximately 0.45%. Smaller organ procurement organizations (measured by total number of donors) were more likely to have higher rates of damage. Class 1 and 2 damage was more frequent than class 3 but did not result in loss of the allograft for transplantation. While damage done to the kidney at the time of procurement was rare, it did exist. Further evaluation of this issue is warranted to maximize the opportunity for organ transplantation.

Optimal Outcomes in Pediatric Renal Transplant Recipients

Veronica A. Taylor,1 Cassie L. Kirby,1 Jens W. Goebl,12 David K. Hooper1,2
1 Cincinnati Children’s Hospital Medical Center; 2 Dept of Pediatrics, Univ of Cincinnati College of Medicine.

Background: Pediatric kidney transplant recipients (pKTRs) experience multiple sequelae of their condition, yet comprehensive assessment of this is lacking in the literature. Our objective was to develop a composite outcome measure for pKTRs that considers the most common comorbidities, and to evaluate a population of pKTRs at specific intervals post-transplant.

Methods: We retrospectively reviewed all KTRs at our center from 10/2008 through 2/2015. An optimal outcome composite measure was created consisting of 14 criteria in four domains: allograft function (CKD stage <3, urine protein/creatinine ratio <0.5, absence of DSAs), histology (no or mild interstitial fibrosis and tubular atrophy, no transplant glomerulopathy, no history of AMR or ACR), infection (BKv PCR <10,000, CMV PCR<0, no history of PTLD or symptomatic EBV) and cardiovascular (CV) health (triglycerides<500, LDL <130, BP <90th %ile, and BMI <85th %ile). Patients were evaluated on these pass/fail criteria at post-transplant yrs 1, 3, 5, and 10.

Results: A total of 177 patients and their 282 clinic visits were analyzed. Of 94 patients who completed their 1st year, only 32 patients (34%) achieved an optimal outcome. This lower rate persisted over the three-year period, 176 of our 1,056 authorized donors had a potential directed donation. Of these, 80% were directed to patients on the kidney waiting list. However, only 16% of the attempted directed kidney donations resulted in a transplant. The data illuminate that incompatibility/mismatch of potential directed kidney recipients is the most common reason that directed kidneys are not transplanted, despite the fact that directed donations are allocated ahead of highly sensitized patients, mandatory shares, multivisceral combinations, and the like.

Conclusions: Facilitating directed donations will continue as part of our routine practice. Each year approximately one in six of our donor families identified potential recipients, but transplants from these requests remained consistently less than 2% of our annual total. Future studies are planned to evaluate recipient outcomes, assess donor family satisfaction with a recipient known to them, as well as to examine our practice in detail in an effort to standardize the language and timing of the directed donation discussions.

Deceased Directed Kidney Donations: A Three-Year Experience at a Single OPO

Rebecca Hunt,1 Michael D. Salvatores,1 Nikole Neidlinger1
1 Donor Network West, San Ramon, CA; 2California Pacific Medical Center, San Francisco, CA.

Background: The UAGA allows for deceased directed organ donations. Our OPO has incorporated the practice of offering the option of directed donations during every donation discussion in response to routine donor family requests. However, facilitating directed donations for donor families remains a controversial topic. Opponents suggest that directing gifts is not only inequitable, but that it may encourage malfeasance in the form of organ solicitation via media or social networks that may promote discrimination. The purpose of this research effort was to identify how many directed kidney requests were received and honored during a three-year period in order to assess the impact on our allocation scheme.

Methods: We analyzed retrospective data from our OPO for three years from 2012-2014. We evaluated the number of directed kidney donation requests in relation to the overall number of donors, as well as the transplant outcomes or reasons for decline when the request was not honored. Relationship of donors to potential recipients was also assessed.

Results: Over the three-year period, 176 of our 1,056 authorized donors had a potential directed donation. Of these, 80% were directed to patients on the kidney waiting list. However, only 16% of the attempted directed kidney donations resulted in a transplant. The data illuminate that incompatibility/mismatch of potential directed kidney recipients is the most common reason that directed kidneys are not transplanted, despite the fact that directed donations are allocated ahead of highly sensitized patients, mandatory shares, multivisceral combinations, and the like.

Conclusions: Facilitating directed donations will continue as part of our routine practice. Each year approximately one in six of our donor families identified potential recipients, but transplants from these requests remained consistently less than 2% of our annual total. Future studies are planned to evaluate recipient outcomes, assess donor family satisfaction with a recipient known to them, as well as to examine our practice in detail in an effort to standardize the language and timing of the directed donation discussions.
primary failure modes. Evaluation of all transplant-related outcomes at specific follow-up intervals will allow practitioners to assess the success of kidney transplantation and overall recipient health and focus clinical outcome improvement efforts.

SA-PO1037
Clinical Outcome of Elderly Living Kidney Donors: A Single-Center Study in Japan
Jumpei Hasagawa, Kohei Unagami, Masayoshi Okumi, Kazuya Onoto, Hideki Ishida, Kazunari Tanabe. Urology, Tokyo Women’s Medical Univ, Tokyo, Japan.

Background: Previous studies and current guidelines have suggested that elderly persons can be living kidney donors; however, reports on elderly donors >70 years old are limited. In order to clarify the donor safety and feasibility, we investigate the clinical outcomes of living kidney donors >70 years old after nephrectomy.

Methods: We conducted a case-series study of living kidney donations involving 48 donors aged >70 years at the time of transplantation. The kidney donations occurred between 2001 and 2014 at Tokyo Women’s Medical University in Tokyo, Japan. The primary outcomes were survival or end-stage renal disease (ESRD)-free rate and all crude event-free rates, including rejection, infection, ESRD, or death-free rate. The secondary outcome was serum creatinine level at the end of the follow-up period.

Results: The 48 cases were followed up for a median of 4 years. The survival rate among the donors was 100% until the fifth year, and only two donors died during follow-up. The ESRD-free rate was 100% during the follow-up period. The overall event-free rate was 100% at 1 year, 85.7% at 3 years, and 75.0% at 5 years. The mean serum creatinine level was 1.18 ± 0.24 mg/dL at the time of hospital discharge and did not increase (1.18 mg/dL) at the end of follow-up.

Conclusions: Living kidney donation from elderly donors >70 years old appears to be a safe and acceptable option for patients requiring renal-replacement therapy.

SA-PO1038
Immunosuppressive Medication Adherence following Kidney Transplantation in the Military Healthcare System
Dustin J. Little, Matthew Ward, Robert Nece, Christina M. Yuan, Rahul M. Tindal. Walter Reed National Military Medical Center, Bethesda, MD; Uniformed Services Univ of the Health Sciences, Bethesda, MD.

Background: Limitations on the amount and duration of Medicare coverage of immunosuppressive medications (ISM) may contribute to ISM non-adherence and allograft failure. ISM adherence has not been reported in US patients who receive these medications at no cost. We therefore designed a prospective cohort to investigate the incidence of ISM non-adherence in Military Healthcare System (MHS) beneficiaries, who receive lifelong ISM coverage as well as prevention, identification, and treatment of depression should be prioritized for future study in order to improve outcomes following renal transplantation.

SA-PO1039
Clinical Impact of Kidney Donor Follow-Up by Nephrologists
Hee Jin Kwon, Jin Hae Kim, Jee Eun Park, Subin Hwang, Jung Eun Lee, Woosong Huh, Yoon-Goo Kim, Dae Joong Kim, Ha Young Oh, Hye Ryoun Jang. Nephrology Div, Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Republic of Korea.

Background: Compensatory and adaptive mechanisms in the remnant kidney occur immediately after nephrectomy. The adaptability in early postoperative period may affect the renal function of the remaining kidney. Since the introduction of extended criteria living donor system, the number of marginal donors with risk of new morbidities is increasing. The aim of this study was to evaluate the clinical impact of kidney donor follow-up by nephrologists at a donor clinic (DC).

Methods: Our study included 427 living kidney donors from January 2010 to December 2014 in Samsung medical center. Nephrologist-run donor clinic was established in January 2013. The study period was divided into pre-DC and post-DC. Primary outcomes were incidence of CKD and renal functional adaptability (%MDRD = post/pre eGFR X100) at 6 months after donation. Secondary outcomes were changes in compliance and incidence of co-morbidities; hyperuricemia and microalbuminuria.

Results: A total of 215 and 172 donors were included in pre-DC and post-DC, respectively. Before donation, age, sex, proportion of hyperuricemia and microalbuminuria were similar. Preoperative eGFR in pre-DC was significantly higher than post-DC (p=0.001). After donation, poor renal adaptation (post-donation eGFR at 6 months < 60% of preoperative eGFR) was less frequent in the post-DC period compared to the pre-DC period (p=0.026). CKD development tended to be higher in pre-DC period. Donors in the post-DC period had shorter mean outpatient clinic visit intervals (p=0.001), more visits within 6 months after donation (p=0.001), earlier detection of de-novo hyperuricemia (p=0.001). The incidence and detection time of microalbuminuria were similar.

Conclusions: After establishment of kidney donor clinic operated by nephrologists, donors tended to show better renal adaptability underdiagnosis and treatment of hyperuricemia. In conclusion, donor clinic may be a good strategy for improving renal outcome and detecting potential risk factors of CKD in donors.

SA-PO1040
Predicting Kidney Allograft Half-Life Using a Podometric Approach

Background: Increasing donor age is a powerful predictor of worse renal allograft outcome. Podocyte depletion is part of the normal aging process (Hodgkin, JASN, 2015). Recently we showed that kidney hypertrophy that occurs at time of transition from a 2 kidney to 1 kidney state (transplantation), leads to a 20% reduction in podocyte density and a 6-fold increased rate of podocyte detachment associated with transplant glomerulopathy and allograft failure (Yang, JASN, 2014). To test the hypothesis that podocyte depletion could impact allograft half-life we used a model combining age specific podocyte nuclear density decrease and rate of podocyte attrition after transplantation for comparison with actual allograft outcome data.

Methods: Podocyte density was estimated from immediate post perfusion biopsies from living and deceased donors or from non-diseased nephrectomy specimens. Projected allograft life was predicted based on modeling age-specific podocyte density and the observed attrition of podocytes. Observed data were drawn from the OPT/NUNSTAR files as of Sept 2014, using all transplants performed between Oct 1987-June 2013. A “conditional” Kaplan Meier analysis using the “period” method was used to calculate observed half-lives at different donor ages.

Results: The podometric projected average half-life for a 40 year old donor is 15.1 years, similar to the observed average allograft half-life (15.1 years). The projected effect of increasing donor age on allograft half-life from podometric measurements is similar to the observed effect of donor age on allograft half-life at all calculated donor ages (p=NS).

Conclusions: Quantitative podometric modeling predicts both shorter-than-expected average renal allograft survival and the donor age effect, compatible with the concept that hypertrophic processes at transplantation significantly impact half-life.

SA-PO1042
Prediction of Patient Survival After Kidney Transplantation (Tx): Construction, Validation and Evaluation of Decision Models Using Data Mining Approaches

Irina Scheffner,1 Kaixun Hua,2 Dan Simovich,3 Tanja Abeling,1 Hermann G. Haller,1 Wilfried Gwinner.1 1Hanover Medical School, Germany; 2Univ of Massachusetts.

Background: Understanding the risk factors that predispose to death is important to deliver the most appropriate therapy to Tx patients (pts). Aim of this study is to build reliable models on non-DOH to identify the relevant risk factors for death using different data mining approaches.

Methods: We analyzed 761 pts transplanted between 2000 and 2007 (follow-up of up to 10 years). Data included biopsy results, clinical & laboratory factors. After conventional statistical feature selection, 15 variables were used. To avoid overfitting, different models were externally validated using 2 schemes; the first one selected 4 variables and the other 2. Models were compared using the AUC, and validated using the ROC curve.

Results: Of 95 pt with features of DN, 43 were classed as recurrent, 17 donor, and 35 donor-related. Biopsies with donor-related DN were done 0.5 yrs (0-3.6 yrs) post-transplant and had delayed graft function. Other non-DN related disease was seen, likely prompting biopsy: acute tubular injury (10/35), antibody mediated rejection (4), acute cellular rejection (1), CNI toxicity (3), AIN (4), TMA (1) and BVK (1). For patients’ class of DN were: Class 1-3, Class 2a-21, Class 2b-1, Class 3-10. Class 3 DN lesions are associated with higher proteinuria, Cr, and increased vascular sclerosis. 13/35 donors had known diabetes with mean hemoglobin A1c of 8.5% (range 4.7-11.6%). DN was not listed on any pre-implantation biopsy reports. Mean follow-up times were 3.8 yrs for donor unrelated, 7.8 for recurrent, and 10.3 for de novo. Despite shorter follow-up, transplant recipients had significantly more failure than recurrent DN (49 v 14%, P<0.0008) or de novo DN (49 v 18%, P<0.024). Recurrent and de novo DN had similar rates of graft loss (P=0.64).

Conclusions: Despite careful screening of transplant kidney donors, donor related DN may be missed on pre-surgical biopsy or not effectively reported and leads to renal dysfunction in the early post-transplant period. Donor related DN is a significant contributor to early allograft loss compared to recurrent or de novo DN and predicts poor long term graft survival.

SA-PO1045
Maternal and Fetal Outcomes in Living Kidney Donors in Korea

Kyoung Dong Yoo, Hajeong Lee, Jae Yoon Park, Eunjin Bae, Jung Pyo Lee, Dong Ki Kim, Kwon Wook Joo, Yun So Kim. Seoul National Univ Coll of Medicine.

Background: Mild elevation of blood pressure was detected after unilateral nephrectomy in kidney donors. Consequently, female kidney donors at risk for complications such as gestational hypertension caused concern. However, the impact of kidney donation on maternal and fetal outcomes had not been well established in Asian kidney donors.

Methods: This study included young female kidney donors under 45 years old (YO) at the time of kidney donation in Seoul National University Hospital between 1972 and 2014 (n=417). Female donors were compared with volunteer participants (n=450). Maternal pregnancy experiences was performed by medical chart abstraction and telephone follow-up. We additionally enrolled 3,608 pregnancies were enrolled as non-donor control. The questionnaires were approved by institutional review board in our institute.

Results: We tried to contact all of 417 female kidney donors. The fifty three donors had no experience of pregnancy, and finally we could have got 253 questionnaires of kidney donors. Donors were compared in the three groups according to pregnancy pre-,post- kidney donation group and non-donor control group. The proportion of pre-donation pregnancies were 82% (450cases), Mean age 38.8 years), and postdonation pregnancies were 14.0% (56cases, Mean age 27.2 years). In the majority of postdonation pregnancy cases were detected in recent years from 2007 to 2014 (73.2%). There were no differences of fetal outcomes such as incidence of prematurity, low-birth weight and fetal death between the three groups. No differences of the postdonation group and non-donor control group (5.4% vs. 5.8%). Donors with pregnancy after donation were more likely to have undergone Cesarean section (40.4%) than those with pregnancy before donation (21.9%).

Conclusions: This study revealed that maternal and fetal outcomes had had better differences between the kidney donors and normal control. Further research using matched controls should be warranted.

SA-PO1046
Self-Monitoring Renal Function After Transplantation: A Clinical Trial on Safety and Usability

Céline Lianne Van lint,1 Sandra Van dijk,2 Wexin Wang,2 Mark Neerincx,3 Ton Rovekamp,3 Paul J. Van der boog,1 Willem-Paul Brinkman.2 1Nephrology, Leiden Univ Medical Center; 2Leiden, Netherlands; 3Faculty of Computer Science, Delft Technical Univ, Delft, Netherlands; 3Dept of Technology in Healthcare, Prevention and Health, TNO, Leiden, Netherlands.

Background: Kidney transplantation requires intensive monitoring which is burdensome for both patient and healthcare. With the availability of an innovative creative device, patients are enabled to monitor renal function at home. To investigate safety and usability of self-monitoring during the first year after transplantation an RCT was conducted.

Methods: The intervention group used a Statusensor® Xpress™ to measure creatinine at home during the first year post-transplant. Measurements were registered in a web-based system using a traffic light analogy to support interpretation of creatinine trends. Differences between groups regarding GFR were assessed at baseline (discharge) and at 1 year. Creatinine trends measured at home were compared to clinically relevant increases at discharge. Differences between groups regarding GFR were assessed at baseline (discharge) and at 1 year. Creatinine trends measured at home were compared to clinically relevant increases at discharge.

Results: In total 119 patients were included (intervention n=64; control n=55). GFR did not differ between groups at baseline, nor at 1 year (72.8 and 71.1 ml/min at 1 year for intervention and control group, respectively). For 34 out of 65 laboratory-based creatinine increases, sufficient home-based creatinine measurements were available for trend comparison. In 76% a similar trend was observed. Self-monitoring enhanced early detection of rejection in 3 out of 5 cases, none were missed. Satisfaction was high: 71% of the intervened patients (n=26) would have liked to extend self-monitoring creatinine monitoring beyond 1 year.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
compared with the dialysis group.

We compared the pattern of cardiac sympathetic and parasympathetic activity by time- and frequency-domain analysis of HRV with 24-h Holter monitoring of 23 KT patients. Patients underwent KT between January, 2008 and June, 2011. The mean ages of KT and dialysis patients were 54.2 ± 12.3 and 53.7 ± 12.6 years, respectively. The KT group showed increased time- and frequency-domain HRV (including HRV index), very low frequency (VLF), means and standard deviations. HRV index, integral of the density distribution divided by the maximum of the density distribution\(^s\)NN50, the percentage of adjacent R-R intervals that varied by more than 50\(\mu\)sec\(s\)MSD, root mean square of the difference between the coupling intervals of adjacent R-R intervals\(s\)SDNN, standard deviation of all normal sinus R-R intervals over 24\(h\)SDNN, means and standard deviation of all normal R-R intervals for all 5-min segments of the entire recording\(s\)SDNNi, low frequency (LF), LF in normalized units (L\(\text{N}\)orm), and LF to high-frequency power ratio, compared with the dialysis group.

Conclusions: The presence of a higher autonomic tone in patients with KT is higher than that in patients with ESRD on dialysis.

Physical Capacity and Function Are Associated with Body Composition, Cardiovascular Health and Quality of Life in Renal Transplant Recipients

Daniele Richter-Stott, Jill Freale, Maurice Dungey, Patrick Highton, Emma L. Watson, Alice C. Smith, Leicester Kidney Exercise Team, Dept of Infection, Immunity and Inflammation, Univ of Leicester, Leicester, United Kingdom.

Background: A renal transplant can transform the life of patients with end stage renal failure but cardiovascular disease remains a major cause of morbidity and mortality. Post-transplant weight gain is common, and physical functioning often fails to improve in line with increased renal function. This study explored associations of physical function and capacity with body composition, cardiovascular status and quality of life (QoL) in renal transplant recipients (RTRs).

Methods: 35 stable RTRs participated (mean age 52 years (range 29-70), 66% male). Self-reported QoL and physical function were measured by EQ5D and Duke Activity Status Index (DASI) questionnaires. Physical capacity was measured by shuttle walk test (SWT), body composition by DXA, cardiac haemodynamic function by bioreactor (NICOM), and systematic inflammation by plasma IL-6 ELISA.

Results: SWT, DASI and EQ5D all showed significant correlations with percentage body fat (SWT: \(r = 0.63, p < 0.001\); DASI: \(r = 0.41, p = 0.02\); EQ5D: \(r = 0.47, p < 0.005\)) and with IL-6 (\(r = 0.34, p < 0.05\)). On the other hand, fat-free mass showed positive correlation with cardiac output (r=0.79) and stroke volume (r=0.81, both \(p < 0.001\)), and inverse correlation with total peripheral resistance (r=0.67, p=0.001).

Conclusions: This study shows that in RTRs, poor physical function and capacity is significantly associated with lower QoL and also with higher percentage body fat and systemic inflammation, both of which are important cardiovascular risk factors. An increase in fat-free mass was significantly associated with superior cardiac function. Taken together, these results suggest that weight loss is desirable for those with excess body fat, and that gaining muscle mass is also important. Optimising body composition through appropriate exercise and nutrition may therefore improve physical function and capacity and enhance quality of life, and also reduce the risk of cardiac-related morbidity and mortality in this vulnerable population.

SA-PO1049

Pregnancy in the Renal Transplant Recipient: Pregnancy Viability and Effects on Graft Function

André Caires Alvimono Lima, Cinthia Montenegro Teixeira, Igor Gouveia Pietrobon, Mayara Ivani de Paula, Geovana Basso, Laila Almeida Viana, Helio Tedesco Silva, J. Medina-Pestana, Dept of Nephrology, Hospital do Rio - UNIFESP, Sao Paulo, Brazil.

Background: Fertility in women is recovered few months after kidney transplantation. However, pregnancy viability and maternal complications remain unclear.

Methods: We studied data from patients from a kidney transplant center in Brazil from 2001 to 2012. In this retrospective study, we identified all pregnant kidney transplant recipient and collected clinical and laboratory data before pregnancy, every quarter and 12 months after delivery. Each pregnancy was considered a single event.

Results: We included 36 subjects and 53 events were found. The average age was 28±5 years. Pregnancy occurred 4.4±3 years after transplantation. Maintenance immunosuppression before pregnancy was prednisone, tacrolimus and azathioprine in 74% of the cases. The frequency of chronic hypertension was 38%, and 8% had preexisting proteinuria greater than 0.5g, 8 (15%) unintended termination of pregnancy (UTP) were observed in the first quarter and 4 (8%) occurred in the second quarter. Delivery was induced by medical conditions in 41% of cases. 9 (22%) premature births and 7 (17%) very premature births were observed. Two (5%) stillbirths and two (5%) neonatal deaths occurred. Maternal complications were proteinuria de novo (60%), urinary tract infection (23%), preeclampsia (9%) and high blood pressure (9%). During the follow-up period, two (6%) acute rejection and one (2%) graft loss occurred. Average baseline creatinine was compared with third quarter and 12 months follow-up creatinine and significant increase (1.17 vs. 1.46 vs 1.59/dL, \(p < 0.001\)) was found.

Conclusions: Although the sample is limited, the number of UTP was higher than the general population, with high rates of maternal complications. Besides, diagnosis of preeclampsia may be challenging because of the high frequency of hypertension and preexisting proteinuria. The sustained increase in creatinine suggests higher risk of long-term graft loss. Further research regarding the issue of pregnancy and kidney transplantation is required, in order to improve maternal safety and preserve graft function.

Kidney Transplantation for End-Stage Kidney Disease After Hematopoietic Stem Cell Transplantation

Akihiro Tsuchiya,1 Kosuke Matsumi,1 Kei Kurihara,2 Hidetsu Kitada,2 Takehiro Nishiki,2 Morihito Ota,3 Masayoshi Okumi,1 Tomokazu Shimizu,1 Hideki Ishida,2 Kazunari Tanabe,1 Kazuhiko Tsuruya,1 Takanari Kitazono.1 1Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; Surgery and Oncology, Kyushu Univ, Fukuoka, Japan; 2Surgery, Tomishiro Central Hospital, Okinawa, Japan; 3Urology, Tokyo Women's Medical Univ, Tokyo, Japan.

Background: Hematopoietic stem cell transplantation (HSCT) is associated with various kidney diseases. The safety of kidney transplantation (KT) for end-stage kidney disease (ESKD) after HSCT has not been established. In this retrospective multicenter study, we investigated the immunological background, immunosuppressive regimens, and outcome in the KT patients after HSCT.

Methods: We report our experience with 5 KT patients following HSCT: 4 patients received bone marrow transplantation and 1 received umbilical cord blood transplantation. Median age at the time of HSCT was 29 years old (ranged 13-54 years old), and ESKD developed after 119 months (67-307 months). The median duration of pre-transplant dialysis therapy was 18 months (7-69 months). In one patient, bone marrow and kidney were from the same donor.

Results: Median observational period was 18 (5-60) months. All patients were treated antibody-induction with basiliximab followed by triple immunosuppression consists of tacrolimus, mycophenolate mofetil and meprednisolone. In one patient with positive complement dependent cytotoxicity cross match, we added rituximab, splenectomy and plasmapheresis. In another one patient who received KT and BMT from the same donor, antibody-induction with basiliximab followed by triple immunosuppression consists of tacrolimus, mycophenolate mofetil and meprednisolone. We had data on 115 OLT recipients from 2008-14 (mean age 57 years, 66% male). 55/115 (47%) patients developed AKI pre-transplant, most often from HRS (47%). Pre-existing CKD-3 was present in 26/115 patients. Pre-OLT AKI developed in 23/26 CKD-3 patients. RRT was required in 8/26 CKD-3 patients. Mean eGFR at 1- and 2-yr follow-up in the CKD-3 group compared to non-CKD group were 37.4 ± 16.6 vs. 33.3 ± 23.1 (p=0.01) and 59.8 ± 20.6 vs. 62.7 ± 22.9 (p=0.01) respectively. At a mean follow up of 1.4 years post OLT, proportion of patients developing ESRD was higher in CKD vs. non CKD group (21.3% vs. 2.3%, p<0.01). Although, AKI was a significant predictor of ESRD (adjusting for age, sex, race, diabetes), its effect was attenuated after adjusting for CKD. CKD3 was the strongest predictor of ESRD (aOR 8.34; 95% CI 1.25-5.7=0.02) (figure 1). Overall, patient survival at a mean of 2.4 years of follow-up was lower in CKD3 vs. non-CKD3 groups (76.9% vs. 91%; p<0.01).

SA-PO1052

The Risk Factors of Chronic Kidney Disease Occurrence in Patients Received Liver Transplantation

Li Yuehong. Nephrology, Tsinghua Changgung Hospital, Medical Center, Tsinghua Univ, Beijing, China.

Background: Analysis the risk factors of chronic kidney disease (CKD) occurrence in patients with liver transplantation.

Methods: 190 patients received liver transplantation followed up during 2001 to 2013 were analyzed retrospectively. 40 patients developed CKD. The observation items included patients’ gender, age, primary diseases, surgical approach, preoperative complications, laboratory examinations (hemoglobin, albumin, creatinine, glomerular filtration rate), intraoperative blood loss and blood transfusion volume, postoperative complications and average serum calcium concentration (from liver transplantation to the onset of CKD).

Results: The incidence of CKD in patients with liver transplantation was 21.1%. Renal pathology included IgA nephropathy, hepatitis B virus associated nephropathy, membranoproliferative glomerulonephritis, focal segmental glomerular sclerosis and cryoglobulinemia associated renal injury. 85.7% patients had tubulointerstitial damage. Univariate analysis showed that preoperative renal function, hemoglobin, intraoperative blood loss and transfusion volume, postoperative acute kidney injury, average calcineurin concentration in blood and hypertension were risk factors of CKD in patients with liver transplantation. Logistic regression analysis showed that preoperative glomerular filtration rate (OR=0.972, P=0.04), creatine concentration (OR=1.364,P=0.015) and postoperative hypertension (OR=8.833, P=0.048) were independent risk factors of CKD occurrence.

Conclusions: Although limited by small sample size and low event rate, our analysis suggest that pre-OLT CKD3 may have an effect on development of ESRD post-OLT. These effects if generalizable in larger cohorts are important for organ allocation.

SA-PO1054

Can Acute-On-Chronic Liver Failure Classification Predict Post-Liver Transplant and Liver Kidney Transplant Outcomes?

Giselle Guerrera,1 Panagiota Tryphonopoulos,2 Kalyan Bhamidimarri,2 Ian Thomas, Rodrigo Vianna. 1Div of Nephrology, Miami Transplant Inst, Miami, FL; 2Division of Transplantation, Miami Transplant Institute, Miami, FL.

Background: Recent evidence suggests that acute on chronic liver failure (ACLF) stratification is more accurate than other methods in predicting short term mortality rates post-transplant. There is no evidence of ACLF stratification as predictor of post-transplant outcomes. We analyzed if ACLF could predict patient and allograft survival in liver transplant recipients (LTR) or simultaneous liver kidney transplant recipients (SLKTR) especially if hepatorenal syndrome (HRS) is present.

Methods: A retrospective analysis was performed on 86 adult patients, 77 LTR and 9 SLKTR transplanted in 2013. Patients were classified into different ACLF grades (0-3) based on their pre-transplant parameters:MELD labs ( total bilirubin, serum creatinine, INR), hepatic encephalopathy, ventilator dependence and the presence of shock. Patient and allograft survival, and kidney function (serum creatinine < 1.5 mg/dL) were analyzed at 6 & 12 months post-transplant between LTR and SLKTR. A further analysis between recipients with HRS receiving either LT or SLKTR was made. SLKTR received kidney transplants based on current International Club of Ascites (ICA) guidelines.

Results: Survival: Survival of LTR was 80% vs. 79% at 1 year, 56% vs. 54% at 3 years in the SLKTR group. AKI incidence in LTR vs. SLKTR. However, HRS patients fared the opposite favoring SLKTR vs LTR.
C3 Alone Is Not a Prognostic Indicator of Patient or Graft Survival in Post-Transplant Glomerulonephritis

**Background:** The prognostic implications of glomerular C3 in the post-transplant setting are not well characterized.

**Methods:** We examined the patient and graft outcomes in 71 kidney transplant recipients diagnosed with glomerulonephritis (GN). Bispeides were studied by immunohistochemistry (IF) for glomerular C3 staining and divided into two categories, C3-positive or C3-negative. Primary outcomes were graft and patient survival at 3, 12, and 36 months and at last follow-up. Serum creatinine (Cr) at last follow-up was a secondary outcome.

**Results:** Thirty-three (46%) patients were C3-positive and 38 (54%) were C3-negative. Mean follow-up was 103 months for patients with C3-positive and 117 months for negative patients. There were no significant differences among groups by age, gender, type of donor, or prevalence of hypertension, diabetes, and hepatitis B or C. A total of 57% of C3-positive patients had a functioning graft at 36 months post-transplant, compared to 75.1% of C3-negative patients (p=0.16). A total of 88.2% of C3-positive patients were alive at 36 months post-transplant, compared to 85.7% of C3-negative (p=0.9). The mean serum Cr for C3-positive patients at 36 months was 1.95 mg/dl compared to 1.71 mg/dl for C3-negative (p=0.55). There were no significant differences in graft and patient survival between the two groups.

**Conclusions:** There was no significant difference in patient or graft survival, or in serum Cr between patients with GN and C3-positive IF compared to patients with C3-negative IF. This suggests that the presence of C3 alone is not a prognostic indicator of patient or graft survival in post-transplant GN.

---

**Pretransplant Hepatitis B Viral Infection Increased Risk of Death After Kidney Transplantation: A Multicenter Cohort Study in Korea**

**Background:** In kidney transplant recipients with hepatitis B virus (HBV) infection, immunosuppression may increase the risk for the progression of liver disease. HBV may contribute to allograft disease and anti-HBV therapy can have nephrotoxic potential.

**Methods:** We examined hepatitis B virus (HBV) infection in patients with malignant lymphoma has been reported. However, the efficacy of single-dose RIT on HBV reactivation in kidney transplant recipients with hepatitis B surface antigen-negative (HBsAg-) patients did not receive prophylaxis in those patients.

**Results:** Hepatitis B reactivation was found in 1 of 45 patients (2.2%) without prophylaxis. In patients treated with prophylaxis, HBV reactivation occurred in 1 of 45 patients (2.2%). The incidence of HBV reactivation in patients with malignant lymphoma has been reported. However, the efficacy of single-dose RIT on HBV reactivation in kidney transplant recipients with hepatitis B surface antigen-negative (HBsAg-) and hepatitis B core antigen antibody-positive (HBcAb+) results was unclear, and there is no evidence for the necessity of prophylaxis in those patients.

**Conclusions:** Our findings favor delaying kidney transplantation in HBV infected patients until they start to develop an immune response to the virus (HBsAg+/HBcAb+ sero-status) in order to optimize graft outcomes. With the availability of newer anti-viral agents, transplant outcomes are likely to improve further in KTRs with HBV infection.

---

**Pretransplant Hepatitis B Viral Infection Increased Risk of Death After Kidney Transplantation: A Multicenter Cohort Study in Korea**

**Background:** In kidney transplant recipients (KTRs) with hepatitis B virus (HBV) infection, immunosuppression may increase the risk for the progression of liver disease. HBV may contribute to allograft disease and anti-HBV therapy can have nephrotoxic potential.

**Methods:** We examined hepatitis B virus (HBV) infection in patients with malignant lymphoma has been reported. However, the efficacy of single-dose RIT on HBV reactivation in kidney transplant recipients with hepatitis B surface antigen-negative (HBsAg-) and hepatitis B core antigen antibody-positive (HBcAb+) results was unclear, and there is no evidence for the necessity of prophylaxis in those patients.

**Results:** Hepatitis B reactivation was found in 1 of 45 patients (2.2%) without prophylaxis. In patients treated with prophylaxis, HBV reactivation occurred in 1 of 45 patients (2.2%). The incidence of HBV reactivation in patients with malignant lymphoma has been reported. However, the efficacy of single-dose RIT on HBV reactivation in kidney transplant recipients with hepatitis B surface antigen-negative (HBsAg-) and hepatitis B core antigen antibody-positive (HBcAb+) results was unclear, and there is no evidence for the necessity of prophylaxis in those patients.

**Conclusions:** Our findings favor delaying kidney transplantation in HBV infected patients until they start to develop an immune response to the virus (HBsAg+/HBcAb+ sero-status) in order to optimize graft outcomes. With the availability of newer anti-viral agents, transplant outcomes are likely to improve further in KTRs with HBV infection.

**Influence of Prophylactic Antiviral Therapy on Hepatitis B Virus Reactivation in Kidney Transplant Recipients**

**Background:** The efficacy of antiviral prophylaxis for rituximab (RIT)-associated hepatitis B virus (HBV) reactivation in patients with malignant lymphoma has been reported. However, the efficacy of single-dose RIT on HBV reactivation in kidney transplant recipients with hepatitis B surface antigen-negative (HBsAg-) and hepatitis B core antigen antibody-positive (HBcAb+) results was unclear, and there is no evidence for the necessity of prophylaxis in those patients.

**Methods:** From 2001 through 2014, 1021 patients underwent kidney transplantation (KTx) at Kyoto University and Tokyo Women’s Medical University, of whom 76 (7.4%) had HBsAg+/HBcAb+ results. Those patients showed hepatitis C virus (HCV)-RNA-negative, hepatitis B surface antibody-positive (HBsAb+), and HBV-DNA-negative. A RIT dose of 200mg/body was administered to 49 patients, and 45 patients did not receive prophylaxis. We monitored HBV-DNA and alanine transaminase levels every 1-3 months after KTx. HBV reactivation was defined as an elevation of serum HBV-DNA level ≥2.1 log copies/ml.

**Results:** Hepatitis B reactivation was found in 1 of 45 patients (2.2%) without prophylaxis. However, the incidence of HBV reactivation in patients with malignant lymphoma has been reported. However, the efficacy of single-dose RIT on HBV reactivation in kidney transplant recipients with hepatitis B surface antigen-negative (HBsAg-) and hepatitis B core antigen antibody-positive (HBcAb+) results was unclear, and there is no evidence for the necessity of prophylaxis in those patients.

**Conclusions:** The incidence of RIT-associated HBV reactivation in the HBsAg+/HBcAb+ patients without prophylaxis was less than 5%, suggesting that low-dose RIT might be associated with low incidence of HBV reactivation. However, sequential monitoring of HBV-DNA is necessary to prevent severe de novo hepatitis.
SA-PO1059

Direct Acting Antiviral Agents for HCV-Infected Patients Transplanted with a Kidney from a HCV Positive Donor

Background: The availability of direct acting antivirals (DAAs) has changed the treatment of hepatitis C virus (HCV) infection. The decision to treat a HCV (+) patient (pt) before or after transplant has important ramifications. The current study reports outcomes in HCV-infected pts who received a kidney from a HCV (+) donor followed by early post-transplant treatment with DAAs.

Methods: HCV RNA (+) pts on the waiting list were consented to receive a kidney from a HCV (+) donor. Direct acting antiviral therapy (DAAT) was offered to all patients. We compared DAAT to no treatment arms (N=21). Outcomes analyzed were survival, treatment response, and graft function.

Results: No viral relapses have occurred. Ribavarin was lowered or stopped in 2/3 pts for anemia. Two pts had ABMR after attaining viral clearance. Tacrolimus dose required upwards titration in 6 pts. In 17.400%.

Conclusions: This report describes the use of DAAs in HCV infected kidney recipients who received a kidney from a HCV (+) donor. Accepting a HCV (+) kidney significantly shortened wait time. Response to DAAs appears similar to that being reported for pts without kidney disease however IS dosing must be carefully monitored. This treatment strategy should be considered for non-cirrhotic HCV-infected pts awaiting deceased donor kidney transplantation.

SA-PO1060

Impact of Treatment of HCV Infection on Renal Transplant Outcome

Background: Impact of HCV treatment on post renal transplant outcome has not been reported adequately. This retrospective study was done to evaluate impact of HCV treatment on the post renal transplant outcome.

Methods: Adult patients on dialysis with HCV infection treated with pegylated interferon and subjected to renal transplant (RT) formed the study group. Untreated patients subjected to RT during same period served as controls. Primary end points were patient’s and graft survival and secondary end points were serious infections and NODAT. FACTs which affect the outcome like age, gender, diabetes as basic disease, dialysis vintage, HBV co-infection, HCV genotype, viral load, liver biopsy grade and stage, induction and baseline immunosuppression were considered for analysis.

Results: At the time of study, 2010 RT were done in department of which 133 had HCV infection. 30 were treated with 68% SVR and 103 were untreated. In untreated group, there were more males (92% Vs 77%), less dialysis number (137 Vs 211), less HBV co-infection (0.9% Vs 10%), less use of Tacrolimus (13.6% Vs 30%). There was no difference in terms of age, diabetes, HCV genotype, viral load, liver biopsy grade and stage, use of induction, Mycophenolate mofetil and duration of follow-up. Two groups. With mean months of 59 ± 22 months (range 12- 105), there was no statistically significant difference in term of acute rejection (23% vs. 15%), NODAT (10% vs. 16.7%) and overall serious infections (23% vs. 15%) between two groups. However, there were 11 deaths in untreated group (8 sepsis related, 3 liver failure and 1 coronary artery disease) while only one death related to sepsis in treated group. Patients survival (97% vs. 89%) and graft survival (97% vs. 84%) was significantly better (p<0.05) in treated group as compared to untreated group.

Conclusions: Treatment of HCV with pegylated interferon during dialysis results in significant improvement of patients and graft survival following transplantation as compared to untreated patients. Sepsis and liver failure are two most common cause of mortality in untreated patients.

SA-PO1061

Prospective Study of Urinary Tract Infection in Renal Allograft Recipients in India: Single Center Study

Background: Urinary tract infection (UTI) is common in renal transplant (RT) and in addition to morbidity, presumed to affects graft outcome also. Still it is least studied infection in RT. There is no data from India. We looked for incidence, risk factors and pattern of UTI in first 6 months after RT and its impact on graft function.

Methods: All RT between Dec 2013 and March 2015 were followed with urine exam and C/S at day 3, 7, 14, 21, 28 and then every two week till 3 months then monthly for another 3 months. Patients with asymptomatic bacteria (ASB) were randomized into treatment and no treatment group. Treatment was done for 7-10 days as per C/S. Study was approved by institute review board and informed consent was taken from each subject.

Results: During the study period 180 RT were done, (4 died, 2 nephrectomy, 1 graft failed, 4 lost to FU); 169 were analysed. Mean age of patients was 31.4 ± 10.4 (14-56) yrs and 81.6% were males. Diabetes was in 3.5%, renal stone in 3.5% and 3.5% had history of pre-RT recurrent UTI. All were on tacrolimus, MMF and steroid. 53% received induction. None got anti-reflux surgery. All were on cotrimoxazol for 6 months. 49 (29%) patients had at least one episode of UTI: 23 symptomatic and 26 ASB. Most common UTI was seen at 21 days followed by 14 days post surgery. 50-60% of these were symptomatic. Following RT, with time, frequency of UTI went on decreasing. Of the 84 UTI episodes, 97 (56%) were caused by E.coli followed by Klebsiella (16.7%), Enterococci (12%) and Pseudomonas (8.3%). Of the patients who had UTI, there were more females (33% vs. 13%), more stone disease (8.2% vs. 1.7%) and more post-operative surgical complications (24.5% vs. 11.7%). Of the 26 ASB, 11 were treated and 15 untreated. Of the 15 untreated ASB, none developed symptomatic UTI or resection. There was no difference in serum creatinine between treated and untreated ASB on last follow-up.

Conclusions: In conclusion, symptomatic UTI in RT is our setting is seen in 13.6% patients, mostly in first month with E.coli as causative organism in half of patient. Untreated symptomatic UTI does not affect graft outcome and does not lead to symptomatic UTI.

SA-PO1062

High Dose Steroid Therapy in BK Viremia Adversely Affected Long Term Graft Function in Kidney Transplantation

Background: High dose steroid therapy has been tried for the management of confusing cases of BK nephropathy (± mixed cellular rejection). However, the eventual fate of renal allograft after steroid therapy in the long term is still unknown. Therefore we investigated the graft survival and the change of BK viral load after steroid therapy in patients with BK viremia.

Methods: The study population comprised 144 kidney transplant recipients with BK viremia (serum BK viral load>1x10^6 copies/mL) consecutively detected at least twice, followed by steroid pulse treatment between July 2004 and March 2013. Patients were divided into two groups based on the amount of steroid: low dose (steroid 0-2g) or high dose (steroid>2g).

Results: A total of 123 patients belonged to low dose group and 21 patients were in high dose group. There were no differences in baseline characteristics, including age, gender, and the rates of biopsy-proven BK nephropathy and acute rejection. Serum BK viral loads at the time of steroid pulse therapy were 5.38±1.10 log copies/mL in low dose group and 6.00±0.98 in high dose group (p=0.054). They were changed into 5.25±1.05 and 6.14±1.45 in each group one month after steroid treatment (p=0.03) and 4.92±1.25 and 5.86±1.74 at two months (p=0.133), respectively. From three months to one year, BK viral loads were not different from each group. Kaplan Meier analyses demonstrated that the incidences of further 50% decline in renal function assessed by estimated GFR and graft failure were significantly higher in the high dose group (p=0.004 and p=0.04, respectively). In multivariate regression analysis, high dose steroid treatment (p=0.002, HR 9.61, 95% CI 2.25-40.99) and log serum BK viral load at two months after high dose steroid administration (p=0.027, HR 1.72, 95% CI 1.06-2.78) were important risk factors of further 50% decline in renal function.

Conclusions: In kidney transplant recipients with BK viremia, high dose steroid therapy induced BK viral activation and subsequently resulted in poor long term graft function and early graft failure.
SA-PO1063

Donor Seroreactivity Strongly Correlates with Recipient BKV-Viremia and Nephropathy

Herman F. Wunderink,1 Els Meijden van der,2 Caroline van der Blij-de Brouwer,1 Antoine Touze,2 Marko Mallat, Geret Haasnoot,1 Erik Van zet,1 Eric Claas,3 Johan W. De Fieter,2 Aloys Kroes,2 Frans Claas,3 Joris I. Rotmans,3 Mariet Feltkamp,1 Leiden Univ Medical Center, Netherlands; 2Univ Francois Rabelais, France.

Background: Incidence and severity of reactivating latent infections in kidney transplant (KTx) recipients are difficult to predict. In case of BK polyomavirus (BKV)-induced nephropathy, donor origin of infection is likely. Since BKV-seroreactivity reflects BKV-reactivity, we hypothesized that donor BKV-seroreactivity correlates with infectivity and predicts BKV infection of recipients.

Methods: In a retrospective cohort of 407 living donor-recipient pairs transplanted between 2003 and 2013 at LUMC, pre-KTx sera from donors and recipients were tested for presence and intensity of BKV IgG-seroresponses. Measured seroresponses were compared with recipient BKV-loads (viremia) determined post-KTx and compared with other potential risk factors for BKV-infection.

Results: Within one year after KTx, BKV-viremia was observed in 27% of patients. Baseline BKV-seroreprovalence among donors (96%) and recipients (95%) was high and not correlated with viremia. However, a strong association was observed between the strength of donor BKV-seroreactivity and occurrence of both viremia and PVAN (p=0.001). Baseline recipient BKV-seroreactivity as such was not associated. The hazard ratio of viremia was almost 10-fold higher in recipients of high compared to low seroreactive donors. In multivariate analysis, donor seroreactivity was the strongest baseline factor associated with viremia and nephropathy post-KTx (p=0.001), outcompeting other described risk factors.

Conclusions: The strong association between donor BKV-seroreactivity and recipient BKV-infection points directly to the donated kidney as the source of BKV-induced disease and possibly reflects the BKV allograft load. Our findings warrant further research into the usefulness of BKV-serological testing prior to transplantation.

SA-PO1064

The Role of BK Viral Subtypes in BK Viral Infection After Renal Transplantation

Anike Schwarz,1 Silvia Linnenweber-Held,2 Hermann G. Haller,1 Corninna Schmitt.3 1Nephrology, Hannover Medical School, Hannover, Germany; 2Tirology, Hannover Medical School, Hannover, Germany.

Background: Risk factors for developing BK virus (BKV) infection after renal transplantation are unresolved, including the role of BKV subtypes.

Methods: We report on 146 patients with viral replication in urine tested by quantitative PCR (Cepheid-Affigene Kit) before transplantation (29 donors and 11 recipients, spontaneous replication in urine) and after transplantation (106 infected recipients, routine recipient BKV testing). Genotyping of BKV-DNA subtypes was performed. Patients with post-transplant BKV nephropathy or high viremia (>10,000 copies/mL) were compared to post-transplant recipients with viremia alone or with low viremia of <10,000 copies/mL (n=43, group 2) and with donors and recipients before transplantation (n=40, group 3).

Results: BKV subtype Ib-1 was seen in 14/16 (10%), subtype Ib-2 in 92/164 (63%), subtype II in 9/164 (6%), subtype III in 1/164 (2%), and subtype IV in 30/164 (21%) of all patients. Thus, subtype Ib-2 was the first and subtype IV the second in frequency of subtypes in patients (and the 3 groups) there was no stat. sign. difference in the prevalence of subtype Ib-1 (8 vs 12 vs 10%), subtype Ib-2 (60 vs 70 vs 60%), subtype II (3 vs 7 vs 10%), subtype III (2 vs 0 vs 0%), and subtype IV (27 vs 12 vs 20%). However, after transplantation, subgroup IV had a trend to be less prevalent in patients with viremia/low viremia (group 2) compared to patients with BKV nephropathy or high viremia (>10,000 copies/mL) (group 1) (5/43 vs 17/36, p=0.054).

Conclusions: BKV subtype Ib-2 is the most frequent subtype in all patients of the three groups. In the situation after renal transplantation, patients being infected with BKV subtype IV could be more likely to develop BKV nephropathy or high viremia than patients being infected with other subtypes. This has to be investigated in larger patient groups.

SA-PO1065

Inflammation and Reconstitution Injury in Resolving Polymavirus Nephropathy: Good or Bad? Insights from a Protocol Biopsy Based Prospective Study

Harsharan Kaur Singh,1 A. Gasim, Volker Nickelet.1 Div of Nephropathology, The Univ of North Carolina, Chapel Hill, NC.

Background: Polyomavirus nephropathy (PVN) has been extensively studied at time points of 2 mg during treatment. Nine (75%) required a mean dose increase of 2 mg between EOT and SVR12. The APRi scores decreased from 0.64 to 0.17 between baseline and 12 weeks of treatment, but this is not statistically significant (p=0.216). Both serum creatinine and urine protein/creatinine ratio remained stable pre- and post-treatment (p=0.260 and p=0.375, respectively).

Conclusions: SVR12 was achieved in 83.3% of KTRs treated with SMV + SOF. Renal allograft function was stable during and after HCV therapy. Treatment with SMV + SOF increased CNI levels during treatment. CNI dose adjustment is needed to maintain therapeutic levels after SMV + SOF therapy.

SA-PO1067

25-Hydroxyvitamin D Insufficiency Is Associated with Higher Risk of BK Virus Re-Activation After Kidney Transplantation

Nisreen Eid-Awad,1 Stuart M. Flechner, Emilio D. Poggio, Brian J. Stepney, Richard A. Fatica, Jesse D. Schold, Sheriff B. Mossad.2 Cleveland Clinic.

Background: The past decade has seen increased interest in viD, because new data suggest that it plays a role in the immune system. The purpose of this study was to evaluate the association of 25-hydroxyviD level with kidney transplant with the risk of BK virus reactivation.

Methods: We identified 498 kidney transplant recipients (2007-2011) who had serum levels of (25)[OH]D, and PTH. We evaluated the relationship between the average levels of (25)[OH]D and PTH and BK reactivation in blood.

Results: viD insufficiency (25)[OH]D <30 ng/mL, defined by The Endocrine Society Clinical Practice 2011) was observed in 377 (75%) of498 kidney recipients after transplant. The viD insufficient and sufficient groups were comparable in terms of gender, age, BMI, race, and immunosuppression. viD insufficiency was more frequent in recipients of cadaveric allografts (P=0.009, Fisher test). By multivariable Cox regression analysis, viD insufficiency was an independent risk factor for BKV reactivation after kidney transplantation (HR=2.9, 95% CI 1.3-4.7, P=0.002). Moreover, viD insufficiency was associated with significantly earlier onset of significant reactivation (19 compared to 26 months). ROC analysis using logistic regression showed that 25(OH)D <24 mg/mL was predictive of BKV reactivation with a sensitivity of 0.74 and specificity of 0.83.
reactivation (OR:82.9, 95% CI: 17.2–744.6, P < 0.001, AUC 0.7). VitD insufficiency was not associated with higher risk of CMV reactivation (17 vs 19% resp, p=0.5). The positive BKV group had significantly higher PTH compared to the negative group (196 vs 148 resp, P=0.01). No significant associations of 25(OH)D with clinical outcomes were observed in time-dependent or fixed-covariate Cox models.

Conclusions: Vitamin D insufficiency is a risk factor for BKV reactivation after kidney transplantation. D3 supplementation may help reduce BKV reactivation.

KM graph of incidence of BKV by VitD groups

**Different Types of Cytomegalovirus DNAemia and Long-Term Outcomes After Renal Transplantation**

Tomas Reischig,1 Martin Kacer,1 Ondrej Hes,2 Daniel Lysak,3 Mirko Bouda.1 1Internal Medicine I, Biomedical Center, Charles Univ Medical School and Teaching Hospital, Pilsen, Czech Republic; 2Pathology, Biomedical Center, Charles Univ Medical School and Teaching Hospital, Pilsen, Czech Republic; 3Hematology, Biomedical Center, Charles Univ Medical School and Teaching Hospital, Pilsen, Czech Republic.

**Background:** Although occurring very often the role of cytomegalovirus (CMV) DNAemia in patients managed by preemptive therapy or by universal antiviral prophylaxis is not established. The aim of the study was to determine the impact of different types of CMV DNAemia during 4 years after transplantation.

**Methods:** A total of 180 consecutive renal transplant recipients at risk for CMV (donor and/or recipient CMV seropositive) were included and followed prospectively. Universal prophylaxis for 3 months was given to 132 (high-dose valacyclovir, n=87; valganciclovir n=45) patients, 48 patients were managed by preemptive therapy. Based on CMV DNAemia status during the first year after transplantation patients were stratified to 1) no DNAemia, 2) early-onset (<3 months) DNAemia, 3) late-onset (≥3 months) DNAemia, and 4) combined early+late-onset DNAemia groups, respectively.

**Results:** Early-onset, late-onset, and combined early+late-onset CMV DNAemia occurred in 18%, 25%, and 13% of the patients being asymptomatic in majority (91%) of cases. Graft survival at 4 years was inferior in patients with late-onset CMV DNAemia compared to patients without CMV DNAemia (73% vs 94%, P=0.002) while no significant differences were observed in patients with early-onset (85%, P=0.139) or combined early+late-onset CMV DNAemia (96%, P=0.682). Patient survival was comparable in all groups. Morbidity due to severe graft injury or tubular atrophy assessed by protocol biopsy at 36 months was not increased in early-onset (15%, P=0.05), late-onset (21%, P=0.180), and combined (29%, P=0.609) CMV DNAemia compared to no CMV DNAemia group (36%). Likewise, renal function was not different at 36 months.

**Conclusions:** Late-onset CMV DNAemia is a risk factor for graft loss after renal transplantation.

**Funding:** Government Support - Non-U.S.

**SA-PO1069**

**Assessment of Cytomegalovirus-Specific Cell-Mediated Immunity for the Prediction of Cytomegalovirus Spontaneous Clearance in High-Risk Kidney Transplant Recipients with Cytomegalovirus Viremia**

Marine Lochouarn,1 Sylvia Benzaken,2 Laetitia Albano,1 Elisabeth Cassuto,1 Ahmed Jeribi,1 Anne Caramella,1 Valerie Giordanengo,1 Ghislaine Bernard,1 Vincent L.M. Esnault,1 Barbara Seitz-Polski.1,2 1Nephrology and Kidney Transplantation Dept, Univ Hospital, Nice, France, Metropolitan; 2Laboratory of Immunology, Univ Hospital, Nice, France, Metropolitan.

**Background:** Cytomegalovirus (CMV) is the most common virus pathogen in kidney transplant recipients (KTR) and CMV disease impacts patient and graft survival. CMV-specific CD8 T cell-mediated immunity (CMI) kinetics may help to assess the risk of CMV disease and to adapt preventive treatment strategies.

**Methods:** High risk KTR with CMV seropositive donor/seronegative recipient (D+/R-), were longitudinally monitored after CMV prophylaxis discontinuation and during the first year post-transplant for CMV viremia (WHO standardization) and CMI (QuantiFERON®-CMV). We analyzed the ability of the CMI-test to predict subsequent spontaneous viral clearance in case of asymptomatic viremia after prophylaxis discontinuation or CMV disease recurrence after curative treatment.

**Results:** We enrolled 12 consecutive (D+/R-) KTR. Eleven patients developed viremia during follow-up. Spontaneous viral clearance occurred in 7 of 11 (63.6%) patients and 4 of 11 (36.4%) developed CMV disease. At viremia onset, 6 of 11 (54.5%) patients had a positive CMI-test. In those patients, the incidence of subsequent spontaneous viral clearance was 6 of 6 (100%) compared with only 1 of 5 (20%) among patients displaying a nonreactive CMI (p = 0.02). This latter patient revealed a positive CMI-test one month later. In the 4 patients who developed CMV disease, persistence of a nonreactive CMI after treatment in one patient was associated with disease recurrence, while patients whose CMI-test became positive under treatment showed no recurrence.

**Conclusions:** We show for the first time that D+/R-KTR with asymptomatic viremia attested by WHO standardized CMV viral load monitoring after prophylaxis discontinuation may benefit from QuantiFERON®-CMV to predict spontaneous viral clearance or CMV disease.

**Funding:** Pharmaceutical Company Support - Cellestis GmbH, a QIAGEN company, Darmstadt, Germany provided equipment entity (QuantiFERON®-CMV blood collection tubes)

**Prevalence of Double Stranded DNA (dsDNA) Viral Infections Among Kidney Transplant Recipients**

Essy Mozaffari,1 Jay Lin,2 Melissa Lingolr-Smith,3 1Chimerix Inc., Mendham, NJ; 2Novosys Health, Green Brook, NJ.

**Background:** Management of immunosuppression following solid organ transplant is a delicate balance between preventing graft rejection and minimizing the risk of infection. Antimicrobial prophylaxis can decrease the risk of infection, while increased immunosuppression can increase these same risks. Our objective was to estimate the occurrence of opportunistic infections, specifically dsDNA viral infections, in kidney transplant recipients.

**Methods:** Patients who received a kidney transplant between January 2009 and September 2013 were identified from the Premier Hospital database using ICD-9-CM codes. The first transplant procedure was defined as the index event. The frequencies of opportunistic infections, documented by diagnostic codes, were evaluated during the first 12 months after kidney transplant.

**Results:** Of patients who received kidney transplant (n=5,402; mean age: 50.8 years) 61% were male. Most patients received transplant in urban (98%), large (≥600 beds: 61%), teaching hospitals (84%). During the 12 month post kidney transplant, 33% (1,800 patients) had a diagnostic code for 1 opportunistic infection, and among these 25% (n=448) had at least one dsDNA viral infection. Among the 448 dsDNA viral infections, 81% (n=365) were cytomegalovirus (CMV), 8% (n=36) BK virus, and 16% (n=70) other dsDNA viral infections (HSV, VZV, HIV, HPV, EBV).

**Conclusions:** Opportunistic infections frequently result from the immunosuppression required following kidney transplantation. In our study, one-third of the kidney transplant recipients had a discharge diagnosis for at least one opportunistic infection. One of four opportunistic infections were classified as dsDNA viral infections, with the majority caused by human herpesviruses including CMV despite the common use of anti-CMV agents. Our study also highlights the rate of BKV-related complications, which represent an unmet need given the absence of therapeutic options for this dsDNA virus and the known association with BK-associated nephropathy.

**Funding:** Pharmaceutical Company Support - Chimerix Inc.

**Antibiotics, Gut Microbial Diversity, and Infectious Complications in Kidney Transplant Recipients**

Anjali Masand1, John R. Lee,2 Thangamani Muthukumar,1 Darshana Dadhania,1 Lilan Ling,2 Eric Pamer,3 Manikammad Suthanthiran.1 1Medicine, Weill Cornell Medical College, NY, NY; 2Medicine, Memorial Sloan Kettering Cancer Center, NY, NY.

**Background:** Emerging data suggests that antibiotic usage can decrease gut microbial diversity and predispose patients to future bacterial complications.

**Methods:** We profiled serial fecal specimens by 16S rRNA deep sequencing in 26 kidney transplant recipients. Microbial diversity was assessed using the Shannon diversity index in subjects exposed to antibiotics in the 1st post-transplant month and in subjects not exposed. Based on a higher number of infections in antibiotic-exposed subjects, we conducted a retrospective study of 301 consecutive kidney transplant recipients and evaluated antibiotic usage in the 1st month of transplantation and development of bacterial complications in post-transplant months 2-12.

**Results:** Subjects exposed to antibiotics during the 1st month of transplant had decreased gut microbial diversity and an increased number of infections in the 1st year of transplant.
SA-PO1073

A Systematic Review and Meta-Analysis of Cytomegalovirus Infection in Renal Transplant Recipients Receiving Alemtuzumab versus Anti-Thymocyte Globulin for Induction Therapy
Payvand Milani, Nasrollah Ghahramani. Medicine, Pennsylvania State Univ College of Medicine, Hershey, PA.

Background: Use of antibody induction for kidney transplant has improved patient outcomes over the past decade. One common induction agent is rabbit anti-thymocyte globulin (ATG), a polyclonal anti-human T-cell antibody. Alemtuzumab, a humanized monoclonal anti-CD52 antibody with stronger lympho-depleting properties, has been used as an induction agent in steroid-sparing or steroid-minimizing protocols. Like all immunosuppressive agents, these agents are associated with opportunistic infections, including cytomegalovirus (CMV). Our aim was to compare the relative risk of CMV infection between the two induction regimens.

Methods: We used five comprehensive search themes (CMV, ATG, alemtuzumab, transplant, and induction) to search electronic databases from 1980 to 2014 using PubMed and The Cochrane Library while also manually reviewing recent abstracts from the American Society of Nephrology and the American Transplant Congress meetings. Studies reporting the number of cases of CMV infection in patients receiving one of the two agents were included. The outcome was the pooled relative risk (RR) of CMV infection in the alemtuzumab group compared to that in the ATG group.

Results: A total of 71 studies were identified and reviewed, 64 of which were excluded upon initial screening. Analysis of the 9 studies (8 complete articles and 1 abstract; 1,735 patients) showed a RR of 0.58 (95% CI: 0.31-1.07) for incidence of CMV infection in patients receiving alemtuzumab versus ATG. Other reported adverse effects in both induction groups (infections, post-transplant lymphoproliferative disorder (PTLD) and/or malignancy, decrease in estimated glomerular filtration rate , and post-transplant diabetes mellitus) were similar in both groups.

Conclusions: This study suggests that for induction therapy in kidney transplant, the incidence of CMV infection associated with alemtuzumab is not significantly different than that associated with ATG.

SA-PO1074

Occurrence and Determinants of Antibiotic Resistance in Bacteriuria After Kidney Transplantation

Background: Asymptomatic bacteriuria is often treated after kidney transplantation, which can result in the development of antibiotic resistance. Our aim was to assess the antibiotic resistance profile of gram-negative bacteria in our kidney transplant population, and to determine the factors associated with antibiotic resistance.

Methods: We performed a single center, retrospective study in patients who received a kidney allograft at our center between January 1, 2008 and June 1, 2013. Through chart review, information on all bacteriuric episodes involving gram negative bacilli was collected during follow-up, which ended on June 1, 2014. Bacteriuria was defined as growth exceeding 10^5 CFU/ml. Multivariable logistic regression using a generalized estimating equation (GEE) procedure was performed to identify the factors associated with resistance to antibiotics.

Results: Amongst the 318 patients studied, 629 bacteriuric episodes involving gram negative bacilli occurred in 143 patients. Resistance to TMP-SMX occurred in 336 episodes (53%), resistance to ciprofloxacin in 142 episodes (23%) and extended beta-lactamase production occurred in 30 episodes (5%). An increased risk of resistance to ciprofloxacin and/or extended spectrum beta lactamase production was statistically associated with the number of previously treated bacteriuric episodes (compared to no prior treatment, 2-4 previous treatments (odds ratio (OR):2.29, 95% confidence interval (CI):1.16-4.52), and ≥5 previous treatments (OR:3.05, 95%CI:1.28-7.26)), diabetes (OR:2.57, 95%CI:1.01-6.55), and a longer time elapsed between bacteriuria and transplantation (OR:0.32, 95%CI 0.15-0.66, for episodes supervening >1 year post transplant versus ≤ 1 year).

Conclusions: Elevated resistance rates to TMP-SMX and ciprofloxacin were observed in our kidney transplant population, which can reduce the usefulness of prophylaxis with TMP-SMX and argue against treating asymptomatic bacteriuria, given the association we observed between the number of previous treatment of bacteriuric episodes and resistance to ciprofloxacin/ESBL production.

Carbenapenem-Sparing Antibiotic Regimens for the Treatment of Extended-Spectrum Beta-Lactamase Producing Enterobacteriaceae Infections: A Comparative Study
Tiffany Ebony Biss, Gregory Malat, PharmD, Ashsay Sharma, Dong Heun Lee, Gregory Malat, PharmD, Ashsay Sharma, Dong Heun Lee, Gregory Malat, PharmD.

Background: Extended spectrum beta-lactamase producing Enterobacteriaceae (ESBL-PE) has been recognized as a significant cause of mortality in solid organ transplant recipients. Carbapenems are considered the drug of choice for the treatment of ESBL-PE infections. However, antibiotic selective pressure associated with carbapenem use may...
Contribute to resistance, further stressing hospital epidemiology. Our study sought to compare the effectiveness of carbapenem sparing regimens to carbapenem containing regimens on clinical outcomes in transplant patients with ESBL-PE infections.

**Methods:** A retrospective, observational cohort study was conducted to evaluate adult patients who underwent a successful kidney transplant (defined as graft survival > 30 days) prior to August 2014 with ESBL-PE infection post-transplant. Patients were stratified into 2 cohorts according to antibiotic regimens: carbapenem-containing and carbapenem-sparing. The outcomes of clinical cure, 30-day mortality, and recurrence were assessed.

**Results:** Fifty-two kidney transplant patients were included in our analysis: 29 in the carbapenem-sparing group and 23 in the carbapenem-containing group. Majority of infections were caused by Escherichia coli (46%) and Klebsiella pneumoniae (44%). The most common infection type was urinary tract infections (46%) followed by bloodstream infections (23%) and nosocomial pneumonias (15%). There was no statistically significant difference in clinical cure rates (91% vs. 76%, p = 0.268) and 30-day mortality (24% vs. 9%, p = 0.268) in the carbapenem sparing and carbapenem containing groups respectively.

**Conclusions:** ESBL-PE infections pose a serious threat to transplant recipients. Carbapenem sparing regimens may be adequate for the treatment of ESBL-PE infections, while offering advantages against minimizing selective pressure.

SA-PO1076
Clinical Recurrence of Primary Glomerular Disease in Kidney Transplantation
Saul Enrique Pampia, Ana M. Fernandez Rodriguez, Sara Jimenez Alvaro, Fernando Caravaca-Fontan, Estefania Yerovi, Maria Delgado Yagüe, Maite Rivera, Cristina Galeano, Sandra Elias, Fernando Liano. Nephrology, Hospital Ramón y Cajal. UAH, Madrid.

**Background:** Recurrence of primary glomerular disease (PGN) in renal transplantation (KT) is a major cause of failure and renal allograft lost which determines the prognosis of the patient. We analyzed the prevalence, clinical course and survival of graft in this group of patients.

**Methods:** We conducted a retrospective analysis of 1513 renal transplants between January 1980 and December 2013, included in our database, medical records and biopsy register, collecting all patients who presented recurrence of PGN. We excluded from the study patients with secondary GN and those without biopsy study. Renal biopsy was indicated according the following criteria: impairment of renal function, proteinuria>1g/day and/or microhematuria. The analysis statistic was SPSS version 18.

**Results:** 414 of 1513 RT (27%) had chronic GN as underlying disease. 317 patients (260 man; 57 woman) were primary GN (21%). The most frequent primary GN was IgA nephropathy (IgAGN) (n=122,38.4%); Membranoproliferative GN (MPGN), n=90 (28%); Focal segmental GN(FSGS), n=58 (15.1%); membranous GN(MGN), n=33 (10.4 %) and rapidly progressive GN (RPGN), n=14(4.4%). Forty(12.6%) patients with primary GN recurred. IgA GN (5%), FSGS (20%), MPGN (17%), MNGN (12%) and GRNP (12%).

Three MPGN patients recurred in the second RT. The mean time of recurrence was: 48.18, 33.2, 18 and 33.2 months respectively. Patients with graft loss due to GN recurrence were: IgAGN (n=10,75%), MPGN (n=14,93%), FSGS(n=10,75%), MNGN(n=3,70%). No significant difference was observed between GN types (p=0.15) and graft survival. In the Kaplan Meier analysis and COX test, recurrence primary GN had low survival at 10 years (p=0.002). No significant differences was observed at 20 years (p=0.15).

**Conclusions:** Clinical Recurrence of primary GN is an important cause of graft loss. GN with most recurrence was GSf and graft lost was MPGN. We didn’t observe differences in graft survival between type of primary glomerular disease. Graft survival was higher in the group without recurrence at 10 years and no differences at 20 years.

SA-PO1077
Glomerular Diseases Following Prednisolone Free Transplant with Low Dose Rituximab and ATG Induction and Protocol Biopsies
Vivek Pathak, Nephrology, Kovai Medical Center and Hospital, Coimbatore, Tamil-Nadu, India.

**Background:** The purpose of this study is to document the incidence of post transplant glomerulonephritis in a steroid free protocol and other recurrent renal diseases leading to graft loss.

**Methods:** 883 patients, who underwent renal transplantation at our institute in nine years and eight months since July 2005 till March 2013 were studied. Thymoglobulin was used for induction at a dose of 1.5mg/kgm for 3 doses. rituximab 200 mg was given before transplant to those patients who were considered to be at high risk for rejection. Maintenance immunosuppression was Tacroliumus and Mycophenolate mofetil. Prednisolone was rapidly used for induction at a dose of 1.5mg/kgm 3 doses. Rituximab 200 mg was given before transplant. Among patients, 3 lost the graft. Prednisolone was added to this group. Recurrent FSGS was observed in 21 patients of which 3 lost the graft. We saw 1 case each of recurrent DSS, DHA crystallopathy, de novo anti GBM disease and post infectious glomerulonephritis.

Conclusions: Our aggressive biopsy policy detected recurrence at a stage of urinary abnormalities. We use Rituximab to treat FSGS to reduce the graft loss. Unique induction policy probably had a protective effect and thus recurrent glomerulonephritis is lower than published literature.

SA-PO1078
Post-Transplant Focal Segmental Glomerulosclerosis Recurrence Among Patients with Native Kidney Collapsing Variant: A Single-Center Retrospective Cohort Study
Panupong Hansrivijit,1,2 Katherine D. Westreich,1,2 Jonathan Alexander Miles,1 Evan Zeitzer,1 Maria E. Ferris,2 Randel K. Detwiler,1,2 1Uni of North Carolina, Chapel Hill, NC; 2Chulalongkorn Univ, Bangkok, Thailand.

**Background:** Focal segmental glomerulosclerosis (FSGS) is one of the most common causes of end-stage kidney disease (ESKD), and is known to recur in renal transplant grafts. The collapsing variant of FSGS (CvFSGS) is clinically distinct from other variants: it has a stronger association with African-American race, more severe proteinuria, and rapid progression to ESKD. The impact of native FSGS subtype on post-transplant FSGS recurrence rate and type is not known.

**Methods:** Clinical and pathological records were reviewed for renal transplant recipients at UNC between 2000 and 2014 with FSGS as the cause of ESKD. Native FSGS subtype was dichotomized into CvFSGS and FSGS-Other. Baseline demographics (sex, age, and race), and rates and subtypes of post-transplant FSGS recurrence were compared between the two groups.

**Results:** Of 879 patients reviewed, FSGS was the cause of ESKD in 101. Among this subgroup, mean age at time of transplant was 45±17 years; 62% male; 50% non-Hispanic black, 45% non-Hispanic white, and 5% Hispanic. Ten patients (10%) had CvFSGS as the native lesion. Over a mean follow-up time of 2.4 years, the overall rate of recurrent FSGS was 34%. Compared to those with native FSGS-Other, patients with native CvFSGS had a higher rate of post-transplant FSGS of any type (30% vs 31%, RR 1.6), and were also more likely to have collapsing variant as the recurrent lesion (60% vs 11%, RR 5.5).

<table>

</tbody>
</table>

Conclusions: In a population of predominantly black and Hispanic patients in the Southeastern US, native CvFSGS predicts a 60% higher post-transplant FSGS recurrence rate, and the recurrent lesion is likely to be CvFSGS. However, 11% of patients with native FSGS-Other developed de novo CvFSGS post-transplant. Further study of this cohort will determine the predictive power of native and recurrent CvFSGS with regard to clinical outcomes.

SA-PO1079
Pre-Transplant Rituximab in Recurrent Focal Segmental Glomerulosclerosis
John Manoill,1 Dany Matar,1 Sami Alasfar,2 Jochen Reiser,2 Nada Alachkar,1 1Johns Hopkins Univ; 2Rush Univ.

**Background:** Focal segmental glomerulosclerosis (FSGS) recurs in 30-40% of patients after kidney transplant (Tx). Rituximab was suggested to have cross-reactivity with podocyte sphingomyelin-phosphodiesterase-acid-like-3b (SMPLD-3b), which was found...
to be reduced in post perfusion biopsies of kidney Tx recipients who later on developed recurrent rFSGS. However, the use of rituximab to prevent rFSGS remains controversial.

In this study, we assessed the efficacy of pre-Tx rituximab in preventing or delaying the recurrence of FSGS.

Methods: We enrolled 56 adult patients, 50 with biopsy proven FSGS and 6 with a pre-Tx course highly suggestive of FSGS. Patients underwent kidney transplant between 2008-2014. We compared FSGS recurrence and allograft survival between recipients who received rituximab and those who did not.

Results: Mean time of follow-up was 28.6 months. 24 patients received rituximab (table 1). 35 patients developed rFSGS (17 (48%) of them received rituximab). Of the 21 who did not develop recurrence, 7 patients (33%) received rituximab. This difference was not statistically different (p=0.26). The time from Tx to rFSGS in the patients who received rituximab was 9.4 ±3.4 vs 8.7 ±3.7 months in patients who did not receive rituximab (p=0.7). The mean and standard deviation (SD) of eGFR at the most recent follow-up in the patients with rFSGS who received rituximab was 42.2±28 versus 39.2±1 mL/min/1.73m² in those who did not receive it, respectively (p=0.74). There was no difference in allograft survival in the two groups.

Conclusions: Our data showed that pre-transplant rituximab did not decrease the incidence or delayed the development of recurrent FSGS, and did not improve allograft survival.

Role of Plasmapheresis in Post-Transplant Focal Segmental Glomerulosclerosis

Samia Alachkar,1 Dany Matar,2 John Manllo,1 Jochen Reiser,3 Nada Alachkar.1 Johns Hopkins Univ, Baltimore, MD;2 MKinsey & Company, Washington, DC;3 Rush Univ, Chicago, IL.

Background: Focal segmental glomerulosclerosis (FSGS) commonly recurs after kidney transplant (Tx). This is attributed to the presence of a circulating permeability factor that may be removed or diminished by plasmapheresis (PP). In this study, we assessed the efficacy of PP in prevention and treatment of post-Tx (r)FSGS.

Methods: We prospectively enrolled 56 Tx-patients with biopsy proven FSGS (50) or de novo FSGS with a pre-Tx course suggestive of FSGS (6); patients were transplanted between 2008-2014. We compared between the preventive and non-preventive PP groups.

Results: Mean time of follow-up was 28 months. Differences between the 2 groups are as following:

<table>
<thead>
<tr>

rFSGS developed in 35 patients (62%); of whom preventive PP was performed in 19. Out of the 21 cases that did not develop FSGS, 7 received PP (P=0.1). Patients who received preventive PP had a shorter time from FSGS diagnosis to ESRD compared to those who did not (6.1±8.6 yr vs 10.1±9.1 yr (p=0.047)). 33 out of the 35 patients (95%) with rFSGS received therapeutic PP, and 24 also received anti-CD20 therapy. Only 5 (15%) did not respond; 2 lost their grafts. Of the 28 who responded, 14 (50%) subsequently relapsed. 71% of the relapses responded to a second course of PP; only 4 lost their grafts. Kaplan-Meier allograft survival in both groups is shown in figure 1.

Conclusions: Preventive PP does not reduce the incidence or delay the development of rFSGS. However, PP remains an effective therapy for post-transplant FSGS.

SA-PO1081

Post-Transplant Thrombotic Microangiopathy: A Single Center Experience

Cinthia Montenegro Teixeira,1 Igor Galveia-Pichatob,2 André Caires Alvim,1 Gianna Mastroianini-kirsztajn,2,3 Laila Almeida Viana,1 J. Medina-Pestana,1,2 Helio Tedesco Silva,1,2 Hospital do Rim-Fundação Oswaldo Ramos, Sao Paulo, Brazil;1 Univ Federal de Sao Paulo, Sao Paulo, Brazil.

Background: Thrombotic microangiopathy (TMA) occurs in 1-15% of kidney transplant allografts and predicts poor outcomes.

Methods: We reviewed 35 cases of TMA in the kidney allograft diagnosed at our institution between 2011-2015.

Results: The mean age was 39±14 years with 18 (51%) women. Three (9%) patients were recipients of simultaneous pancreas-kidney transplant. Among the recipients of kidney transplant alone, 21 (66%) received deceased donor grafts. The cause of end stage renal disease was unknown (37%), chronic glomerulonephritis (31%), obstructive uropathy (11%), diabetes (9%), hemolytic uremic syndrome (3%) or others (9%). Induction with thymoglobulin or basiliximab was performed in 24 (63%) patients. Maintenance immunosuppression was prednisone (PRED), tacrolimus (TAC), and mycophenolate sodium in 12 (37%) and PRED, TAC and everolimus in 3 (9%) patients. Patients were diagnosed with TMA at a median of 71 days (range: 5-1645) from transplant, wherein 37% patients developed TMA within 1 month of transplantation and 31% after 1 year. Mean serum creatinine was 4.5±3.3 mg/dL and 13 (41%) patients needed renal replacement therapy after TMA diagnosis. TMA was renal-limited in 23 (66%) patients. Concomitant acute rejection was present in 12 (34%) cases and cellular rejection was the most common (92%) type of rejection related to TMA. Cytomegalovirus infection occurred in 5 (14%) and other infections were present in 19 (54%) patients. Following diagnosis of TMA, calcineurin inhibitor (CNI) withdrawal was the first step in the management of 22 (63%) patients and 8 (23%) also received fresh frozen plasma (FFP) and/or plasmapheresis. The mean follow-up was 375 days (range: 2-4840); 22 (62%) patients had improvement or stabilization of renal function and 11 patients (31%) had allograft failure.

Conclusions: High clinical suspicion is essential for early diagnosis of TMA after kidney transplant. Withdrawal of CNI and treatment of concomitant rejections and infections contribute to renal function maintenance.

SA-PO1082

Outcome After Eculizumab Therapy to Prevent Recurrence of Atypical Hemolytic Uremic Syndrome: Experience in Eleven Renal Transplant Recipients

Charlene Levy,1,2 Veronique Fremeaux-bacchi,2 Anne Scemla,1 Julien Zuber,1 Christophe M. Legendaire,2 Rebecca Sbrero-Soussan,2 Dept of Renal Transplantation, Assistance Publique-Hôpitaux de Paris, Hôpital Necker, Paris, France;1 Medicine Faculty, Paris Descartes Univ, Paris, France; Dept of Immunology, Assistance Publique-Hôpitaux de Paris, Hôpital Georges Pompidou, Paris, France.

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare disease with a high recurrence rate after kidney transplantation. aHUS is associated with histological lesions of thrombotic microangiopathy (TMA) that mainly leads to graft loss. The successful use of Eculizumab (Ecu) to prevent or to treat post-transplantation aHUS recurrence has been scarcely reported. In this study, we describe 11 patients who received a renal transplantation for aHUS and who were treated by Ecu after renal transplantation.

Methods: Eleven renal transplant recipients, with aHUS on their native kidney, received Ecu at our center between 2010 and 2015. Nine patients received prophylactic
Recurrence of Scleroderma Renal Crisis After Renal Transplant Is Associated with Decreased Rates of Graft Survival and Earlier Graft Failure
Andrew A. Collins, Donald A. Molony. Internal Medicine, UT Health Houston, Houston, TX.

Background: The recurrence of Scleroderma Renal Crisis (SRC) after renal transplant has been previously described though its effects on outcomes and allograft survival are uncertain. Prior estimates suggest a recurrence rate of 20-50% (Pham et al, American Journal of Transplantation 2005, 5:2565-2569). Such rates of recurrence if leading to graft failure will have important implications. This study was conducted to better define the probability of recurrence and understand its impact on allograft and patient survival.

Results: 402 recipients were identified for analysis (102 had documented disease recurrence, which was similar to those with SRC, 5.28% (26) had documented disease recurrence, which was similar to those with SRC (2.59%), FSGS (7.38%), and HUS (8.71%). Graft failure for any reason excluding death occurred in 80.8% (21) of patients with recurrence, compared to 24.5% (14) of those without recurrence (p=0.00). Recurrent disease accounted for 11.9% (16) of graft failures in SRC, compared to 6.10% in patients with SLE as the cause of ESRD, 16.4% with FSGS, and 20.9% with HUS. The 5 year graft survival rates were similar: 68.7%, 63.2%, 67.8%, and 57.1% for SRC, SLE, FSGS, and HUS, respectively. SRC recurrence was associated with earlier graft loss; graft failure occurred an average of 628 days sooner in the recurrence group compared to non-recurrence, 1072 days versus 1700 (p=0.023). Age, gender, and ethnicity were not associated with an increased risk of recurrence.

Conclusions: Identification of disease recurrence after renal transplantation holds prognostic significance. Both the rate and timing of kidney transplant failure is made more severe by recurrence. Post-transplant recurrence rates for SRC are too similar to those observed with SLE, FSGS, and HUS. Monitoring for recurrence of disease in these patients should be part of routine measures to reduce risk of allograft failure.

SA-PO1085
An Investigation of 13 Cases of Membranous Nephropathy of the Donor Origin Accidentally Detected by 0-h Renal Biopsy During Kidney Transplantation

Results: Of 884 patients who met the inclusion criteria developed nonskin cancer. They had received kidney transplants during the years 2001 to 2014, and developed post-transplant non-skin cancer. Those patients were matched with controls by sex, age, type of induction therapy, time of transplantation and length of follow-up. All patients included in the study received tacrolimus immunosuppression protocol. In this study, we evaluated the occurrence of post-transplant cancer is associated with the level of tacrolimus exposure (Hazard ratio=1.08 per ng/mL, 95% confidence interval 1.03-1.14). There was no significant association between the time of cancer diagnosis and tacrolimus blood level at time of cancer diagnosis. However, the cumulative exposure of tacrolimus (mg/m²) was significantly shorter in the cancer group compared to the non-cancer group. In the cancer group, the time-averaged tacrolimus blood levels was calculated as the area under the curve divided by time at 1, 6 and 12 months of tumor diagnosis. The results were compared with the control group.

Conclusions: The development of new non-skin cancer after kidney transplantation was not associated with the level of tacrolimus exposure over time.
**Results:** 16 suspicious masses were detected (12.5%). Of these only 9 had evidence of malignancy, and 7 were in patients with acute kidney disease (ACD). These 7 masses all underwent pre-transplant imaging showing only small contracted kidneys or less than the required number of cysts to make a diagnosis of acquired cystic disease. We are following 14 of these patients with scans every 4-6 months to detect growth in these newly discovered, less than 1 cm solid lesions. We have found 2 patients in which frank renal cell carcinomas were detected. We have now adopted an annual screening process for all post-transplant patients at their one-year post-transplant visit.

**Conclusions:** Routine screening of native kidneys post-transplant appears critical to detect renal cell carcinoma at a stage early enough to achieve a cure by nephrectomy.

**SA-PO1088**

**Non-Melanoma Skin Cancer Mortality in Kidney Transplant Recipients**

Michael Thomas Burke,1 Annie-Claire Nadeau-Fredette,1 Carmel M. Hawley,1 Elaine M. Pascoe,2 Stephen P. McDonald,1 Sunil V. Badve,3 David W. Johnson,1 Adele Coates,2 Robert Peter Carroll,1 Nicole Isbel,1 1Dept of Renal Medicine, The Univ of Queensland, Princess Alexandra Hospital, Brisbane; 2Central Northern Adelaide Renal Transplantation and Renal Services, Adelaide; 3Cancer and Population Studies Group, Queensland Inst of Medical Research, Brisbane; School of Medicine, The Univ of Queensland, Brisbane.

**Background:** Non-melanoma skin cancer (NMSC) frequently occurs in kidney transplant recipients (KTRs). However, the frequency of, and risk factors for NMSC in KTRs are poorly characterised.

**Methods:** Aims: To determine the proportion and predictors of fatal NMSC in KTRs. This cohort study included all KTRs transplanted in Australia and New Zealand between 1980 and 2013, using Australasian and New Zealand Dialysis and Transplant (ANZDATA) Registry data. Multivariable competing-risk survival analysis was used to calculate risk factors for fatal NMSC in KTRs.

**Results:** During the study, 21875 transplant episodes occurred in 19344 patients. Of the 6780 patients who subsequently died, 231 (3.4%) died from NMSC. Of these, 172 (74%) were male, 226 (98%) were Caucasian, 219 (95%) were first graft recipients and 213 (92%) died from a functioning graft. Amongst first graft KTRs who died from NMSC, the mean age at transplantation was 48.8 ± 13.7 years and the mean age at death was 61.8 ± 11.1 years. Male sex (HR 2.0, 95% CI, 1.48 -2.74); Caucasian ethnicity (HR 5.31, 95% CI, 2.15-13.11) and pre-transplant skin cancer (HR 3.79, 95% CI, 2.38-6.04) were associated with NMSC mortality. Age at transplantation and multiple kidney transplants had time-dependent associations for NMSC mortality with the 5-year post-transplant HR 1.08 per year (95% CI, 1.06-1.1) and 2.90 (95% CI, 1.39-6.05); and the 15-year post-transplant HR 1.03 per year (95% CI, 1.02-1.04) and 1.29 (95% CI, 0.66-2.35) respectively.

**Conclusions:** NMSC is an important contributor to mortality in KTRs. Risk factors for mortality from NMSC include male sex, Caucasian ethnicity, pre-transplant skin cancer, multiple kidney transplants and older age at transplantation.

**SA-PO1089**

**NFAT-Regulated Gene Expression in Patients Developing Non-Melanoma Skin Cancer**

Claudia Sommerer,1 Thomas Giese,2 Janina Brocke,1 Stefan Meuer,1 Martin G. Zeier,1 1Nephrology, Univ Hospital, Heidelberg, Germany; 2Immunology, Univ Hospital, Heidelberg, Germany.

**Background:** After transplantation the risk of non-melanoma skin cancer (NMSC) is significantly increased. Immunosuppression with calcineurin-inhibitors (CNIs) is associated with the development of NMSC. Association to the individual immunosuppressive loads of CNIs assessed by residual NFAT-regulated gene expression was investigated in renal allograft recipients.

**Methods:** Renal allograft recipients from the Department of Nephrology, University Hospital Heidelberg, Germany, were included. All patients had a regular annual skin examination. Residual expression of NFAT-regulated genes (IL-2, IFNγ, GM-CSF) in PMA/ionomycin-stimulated peripheral blood was measured by quantitative real-time PCR at predose and 2h after Ciclosporin A (CsA) intake.

**Results:** 258 renal allograft recipients were enrolled (160 male, age 51±14y). Of these patients 75 allograft recipients developed NMSC after renal transplantation (29.1%). The following NMSCs were histologically confirmed: 36 basal cell carcinoma, 34 squamous cell carcinoma, 33 actinic keratosis, 27 Bowen disease, 8 kerato-acanthoma. As risk factors to develop NMSC were identified: age 60 years, skin type ( Fitzpatrick 1 and 2), and increased immunosuppression. NFAT-regulated gene expression was significantly lower in patients who developed NMSCs compared to patients without NMSCs (8.3±6.5 vs. 12.7±12.8%, p<0.001). Squamous cell carcinoma and actinic keratoses were significantly associated with a high inhibition of IL-2 and IFNγ. Patients with basal cell carcinoma and Bowen disease showed a general low expression of NFAT-regulated gene expression. However, in patients with kerato-acanthoma no significant inhibition of NFAT-regulated gene expression could be detected.

**Conclusions:** The immunosuppressive load contributed to the risk of NMSC. NFAT-regulated gene expression was significantly inhibited in patients developing NMSCs. Monitoring of NFAT-regulated gene expression in CNI treated transplant recipients provides an individual profile of response to CNIs and is a useful tool for an individual immunosuppression with respect to safety and toxicity.
PUB001
Role of Toll-Like Receptors in Allosteorphic Acid Nephrotoxicity
Gem Batuman,¹ Altaf-M Khan,¹ Madlin Alzoubi,¹ Vecchi Batuman,¹,2 ¹Dept of Medicine, Section of Nephrology & Hypertension, Tulane Univ School of Medicine, New Orleans, LA; 2Dept of Veterans Affairs, SLVHCS, New Orleans, LA.

Background: Studies demonstrated that allosteoric acid (AA) is toxic to renal tubular epithelium and carcinogenic to urethral epithelium. Although the exact extent of AA nephropathy (AAN) is unknown, case series have been reported throughout the world and it has been implicated in the etiology of Balkan endemic nephritis (BEN) suggesting that this is a global health problem. The precise mechanisms of AA nephrotoxicity are not well understood. We investigated the role of Toll-like receptors (TLRs) in the pathophysiology of AAN using human renal proximal tubule epithelial cells (RPTECs).

Methods: Confluent RPTECs were exposed to AA (30 µM – 480 µM) for 24 – 48 hr and cytotoxicity was measured using lactate dehydrogenase (LDH) assay. RNA and protein were isolated from AA-exposed and unexposed RPTECs. Real time RT-PCR was performed for various gene promoters to evaluate the role of innate immunity in AAN development.

Results: At 240 µM after 48 hr exposure, AA induced significant cytokine in RPTECs as measured by LDH release in the culture medium and significant cell injury was observed morphologically. AA significantly increased mRNA expression of acute kidney injury (AKI) biomarker neutrophil gelatinase-associated lipocalin (NGAL), but at the same time significantly decreased the expression of another AKI biomarker kidney injury molecule 1 (KIM-1). AA also significantly upregulated the expression of prominent AKI-related TLRs (TLR2, TLR4 and TLR6) and their adaptor molecules (MyD88 and TICAM-1) followed by the activation of pro-inflammatory cytokines (IL-6 and TNF-α) and the tumor suppressor protein and a biomarker for apoptosis, p53, in the down-stream signaling pathways of TLRs. AA also significantly upregulated expression of multi drug resistant family gene MDR1 in RPTECs.

Conclusions: AA is toxic to RPTECs and restricts cell growth. NGAL, but not KIM-1 could be a diagnostic biomarker for AAN. AKI prominent TLR2 and TLR4 could be potential candidates for therapeutic target in developing new strategies for AAN and BEN treatment.

PUB002
A Case of Severe Symptomatic Iatrogenic Hypermagnesemia
Rohan V. Mehta,¹ Vandana Niyar,² Rahul Mehta.² ¹Renal Medicine, Emory, Atlanta, GA; ²Hospital Medicine, UTA, Charlottesville, VA.

Background: Hypermagnesemia is an uncommon but a potentially life threatening condition. Symptoms may develop in patients with acute kidney injury (AKI) or chronic kidney disease with the administration of pharmacologic dose of magnesium (Mg), and with use of oral laxatives or magnesium containing enemas.

Methods: A 30-year-old African American man with baseline Cr of 1, admitted for management of multiple fractures, subdural hemorrhage and traumatic brain injury sustained in a motor vehicle accident, suddenly became hypotensive and developed AKI. UOP declined from 2-3L/day on admission to 700 ml over the next 24 hours. He became areflexic with use of oral laxatives or magnesium containing enemas.

Results: Serum Mg was then switched to CVVHD for continuous magnesium removal. Within 12 hours of resuscitation was started, including IV calcium, but he continued to require multiple pressors. Cr 3.9, hemoglobin 6.9 and Mg 9.5 mg/dl. Review of his chart revealed he had received between 2-3 mg/dl. CVVHD was discontinued after 72 hrs and the patient had complete renal recovery to his baseline Cr of 1.

Results: Severe symptomatic hypermagnesemia can develop even with small doses of Mg containing laxatives. It prevents presynaptic acetylcholine release resulting in blockade of neuromuscular transmission. Clinical features of Mg toxicity range from delayed deep tendon reflexes, flaccid paralysis, respiratory failure, to hypotension, bradycardia, complete heart block and cardiac arrest. Management includes rapid supportive measures, fluids, IV calcium, loop diuretics. Urgent hemodialysis can rapidly reverse shock and respiratory failure preventing significant morbidity and mortality.

Conclusions: In summary, we report a case of severe hypermagnesemia, in the setting of AKI, presenting with shock and respiratory failure, requiring RRT.

PUB003
Ischemic and Non-Ischemic Acute Kidney Injury Cause Gut Damage
Tao Jiang Li, Chen Yu. Nephrology Dept, Shanghai Tongji Univ, Tongji Hospital, Shanghai, China; Nephrology Dept, Shanghai Tongji Univ, Tongji Hospital, Shanghai, China.

Background: Chronic uremia induced gut injury has been well documented in a number of studies. However, remote effects of acute kidney injury(AKI) on the intestine are far less investigated. Here we study whether the gut also suffers damage during induction of acute renal ischemia–reperfusion in rats and compares this to bilateral nephrectomy.

Methods: To test our hypothesis, six groups of SD rats (n=6 in each group) were studied: 1) sham operation for 6h; 2) ischemic AKI for 6h (60 min of renal pedicle clamping and then reperfusion for 6h); 3) bilateral nephrectomy for 6h; 4) sham operation for 24h; 5) ischemic AKI for 24h/60 min of renal pedicle clamping and then reperfusion for 24h.

Conclusions: Our study shows that acute kidney ischemia or renal failure activates oxidative stress and promotes apoptosis, and tissue damage in gut. Whether the AKI induced-gut injury by itself is sufficient to provoke systemic inflammatory response need further investigation.

Serum from Rats with Acute Kidney Injury Contains Reactive Oxygen Species Generating Activity That Causes Oxidative Stress In Vitro
Jon D. Ahlstrom,¹ Zhma Hu,¹ Nicole Molin,¹ Christof Westenfelder,¹ Medicine, Univ of Utah and VA Medical Centers, Salt Lake City, UT; ²Physiology, Univ of Utah and VA Medical Centers, Salt Lake City, UT.

Background: The uremic state that is induced by Acute Kidney Injury (AKI) adversely affects multiple organ systems by mechanisms that are still poorly characterized, including those reactive oxygen species (ROS), generated by the kidney.

Methods: Serum was obtained from rats 24 hrs post ischemia/reperfusion-AKI (50 min bilateral pedicle clamp, AKI serum), and control sera was obtained from rats 24 hrs following sham surgery (SHAM serum), or from rats 24 hrs post bilateral nephrectomy (NPHX serum). Serum samples were evaluated for ROS activity with the sensitive Amplex Red H2O2 assay. For in vitro assays, NRK cells (normal rat kidney cells, proximal tubular) or rat mesenchymal stem cells (MSC) were cultured in rat serum for 48 hours, and then assayed for gene expression, GSH levels, and oxidative stress markers.

Results: Compared to SHAM or NPHX serum, serum from rats with AKI had increased amplex red activity compared to SHAM and NPHX serum controls. Adding catalase to rat serum reduced—but did not eliminate—the ROS activity of AKI serum in a dose-dependent manner. The ROS generating properties of AKI serum were completely destroyed with strong (90°C for 1 hr) but not mild (45°C for 30 min) heat inactivation. Culturing normal rat kidney cells (NRC, proximal tubular) or rat mesenchymal stem cells (MSC) in 10% AKI serum (compared to SHAM or NPHX serum) resulted in increased oxidative stress, including increased anti-oxidant gene expression (HO-1, catalase), increased GSH levels, and increased cellular ROS activity (CMH DCFDA and mitosox).

Conclusions: At comparable levels of azotemia (AKI vs. NPHX), AKI serum contains ROS generating activity that is heat labile, but that is not blocked by catalase incubation. These results suggest that the injured kidney releases heat-sensitive factors into the blood stream (like ischemic kidney) and may locally affect renal tissue and distant organs. The Amplex Red H2O2 assay provides a useful tool for the determination and mechanistic dissection of the ROS activity found in AKI serum.

PUB005
Propéridon Deficiency Enhances Renal Ischemia Reperfusion Injury in Mice Zinah Dhveea Zwain,¹,3 Nigel J. Brunskill,¹ Hans-Wilhelm Schwaebel,¹ Cordula M. Stover,¹ Bin Yang,²,¹,3 Infection, Immunity and Inflammation, Univ of Leicester; ²Renal Group, Univ Hospitals of Leicester; ³College of Medicine, Univ of Kufa, Iraq. ¹Basic Medical Research Centre, Medical school of Nantong Univ, China; ²Nephrology, Affiliated Hospital of Nantong Univ, China.

Background: Propéridon is the only positive regulator of the alternative pathway of complement activation via stabilizing C3bBb convertase. Propéridon has been detected on proximal tubular epithelial cells associating with proteomic renal damage. Previous studies showed that mice with combined deficiencies of propéridon (P¹), DAF and CD59, the negative regulators of complement activation, had less renal ischemia reperfusion injury (IRI), in 24 hours.

Methods: P¹ mice (n=9) and their wildtype (WT) littermates (n=7) were used to assess the role of propéridon in renal IRI. Ischaemia was induced by bilateral clamping of the renal pedicle for 30 minutes followed by 72-hour reperfusion using normal (n=2) and sham operated mice (n=4 or 5) as controls.

Results: Renal IRI was successfully induced in the WT and P¹ mice with more prominent injury in P¹ mice as evidenced in renal function. Serum creatinine was significantly increased after IRI compared with the sham groups, which was further increased

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
in P<sub>0.01</sub> in relation to WT mice (1.78±0.29 vs. 1.19±0.18, P=0.046) post IRI. Similarly, blood urea nitrogen in IRI mice was higher than the sham animals, with significant increase in P<sub>0.01</sub> in comparison with WT mice.

This difference was supported by histological examination, in which P<sub>0.01</sub> mice showed a worse score of tubulointerstitial damage than WT (2.67±0.26 vs. 1.94±0.22, P=0.025) post IRI.

Conclusions: This study shows, for the first time, that properdin deficiency alone enhances IRI shown by worsened renal function and histology. The underlying mechanisms for these unexpected phenotype are under present investigation.

Neurogenic Function of Neurons with Renal Afferents Is Altered by Lipopolysaccharides -LPS Kristina Rodionova,1 Martin Ziemer,1 Tilman Ditting,1 Stefan Karl,1 Sonja Heinlein,1 Peter Linz,1 Peter Rech,1 Kerstin U. Amann,2 Roland Veelken,3 1Dept of Medicine - Nephrology and Hypertension, Universitaetsklinikum Erlangen-Nuernberg, Erlangen, Bavaria, Germany; 2Dept of Nephropathology, Universitaetsklinikum Erlangen-Nuernberg, Erlangen, Bavaria, Germany; 3Dept of Physiolog and Pathophysiology, FAU Erlangen-Nuernberg, Erlangen, Bavaria, Germany.

Background: Renal afferent nerves (RNs) exert complex neurogenic sympatheticmodulatory and paracrine effects. Recently, we could demonstrate that lipopolysaccharide (LPS) sensitzed TRPV1 receptors and increased the release of CGRP from afferent axons in kidney. Hence, we wanted to test the hypothesis that LPS alters firing patterns and acid induced inward currents in cultured neuron sample.

Methods: Dorsal root ganglion neurons (Th11-L2) of rats were incubated with LPS (E.coli O127:B8,20mg/l) 12h before patch clamp recordings. Inward currents were assessed during stimulation of TRPV1 and ASICs with protons (pH6.9 and 5.0). Current clamp mode was performed at physiological conditions and after 12h of LPS-incubation.

Results: Neurons exhibited a tonic, i.e. sustained AP firing or phasic, i.e.<5 APs in response to current injections.

Conclusions: Firing patterns and currents induced by acidic superfusion were studied in 246 neurons.Renal nerves (RNs) exhibited in 59% tonic firing pattern under control conditions. The number of neurons with tonic response was significantly reduced by exposure to LPS (59%vs.42% p<0.05) under control conditions 70.8% of RNs exhibited both sustained and transient inward currents, whereas 29.2% showed sustained current. LPS exposure significantly increased sustained,i.e. TRPV1 induced current (-793,181±/-669,6 vs. -1224±/-206,9 p<0.05) and transient, i.e. ASICs induced inward current even under subthreshold proton stimulation (pH6.9) and could not be enhanced further by pH5.0.

Conclusions: LPS altered the properties of neurons with renal axons in a complex way, while the ease of AP production was significantly decreased, the responsiveness to acidic proton stimulation (pH6.9,5) and could not be enhanced further by pH5.0.

PUB007

Protective Effect of Nitric Oxide in Aristolochic Acid-Induced Toxic Acute Kidney Injury Ines Jadot,1 Anne-Emilie Declives,2 Vanessa Colombo,1 Blanche Martin,1 Isabelle Habsch,1 Eric De Prez,2 Joel L. Nortier,2 Nathalie Caron,1 1(Molecular Physiology Research Unit - URPHYM, Faculty of Medicine, Univ of Namur, Namur, Belgium; 2Laboratory of Experimental Nephrology, Faculty of Medicine, Univ Libre de Bruxelles, Bruxelles, Belgium.

Background: Aristolochic Acid (AA) nephropathy is a pertinent example of tubulo-interstitial (TI) nephritis characterized by an early phase of acute kidney injury (AKI) leading to progressive fibrosis and chronic kidney disease (CKD). Nitric oxide (NO) has been shown to play a critical role in the AKI-to-CKD transition. Here, the AAN model was used to determine the role of NO in this process, focusing on the acute phase.

Methods: C57Bl/6J male mice were randomly subjected to daily i.p. injection of control solution or AA (3.5mg/kg) for 4 days and L-Arginine (L-Arg; substrate for NO synthesis) was supplemented in drinking water (5%) until mice were euthanized, 5 days after the beginning of AA injections.

Results: At day 5, AA-treated mice displayed polyuria, increased plasma creatinine level and proteinuria. In addition, histological analyses revealed severe proximal tubular necrosis, renal inflammation and increased oxidative stress in AA-treated mice. These changes were associated with a significant reduction of NO bioavailability, as attested by urinary NOx and eGMP levels. L-Arg supplementation in AA-treated mice significantly improved kidney function, as reported by a significant reduction in urine volume, plasma creatinine level and proteinuria. Moreover, L-Arg treatment resulted in a significant reduction of tubular cell necrosis, renal inflammation and oxidative stress. These were concomitant to normalized NO levels.

Conclusions: Our findings demonstrated that sustaining NO bioavailability due to L-Arg supplementation improve the renal outcome of AA-induced AKI phase. Further investigations are ongoing to determine whether increasing NO bioavailability can also prevent chronic injuries in the AAN model.

The Study of Curcumin-Loaded Nanoparticles against Renal Ischemia-Reperfusion Injury Function and Mechanism Yong Xu, Lili Zhong. Dept of Nephrology, Huaiuan Second Hospital, Huaiian, Jiang Su, China.

Background: To study the effects of curcumin-loaded nanoparticles against ischemia-reperfusion renal injury, and to investigate its mechanism.

Methods: Synthesize controlled releasing curcumin-loaded nanoparticles by amphilic mPEG-PCL block copolymers and cultivated renal tubular epithelial cell (cell line HK-2) in vitro. HK-2 cells were divided into four groups: Control group; IRESSA reperfusion injury group(IRESSA group); Curcumin group(Cur group); Curcumin nanoparticle group(CurNP group). In each group, HK-2 cells viability was assessed by dimethyl-thiazol-diphenyltetrazoliumbromide (MTT) test. Apoptotic Cells were measured by Flow Cytometry. H2DCF-DA was used to detect intracellular generation of ROS. BCA were used to detect SOD activation and the Concentration of MDA. Protein levels of procaspase-3 were analyzed by Western Blot.

Results: Successfully constructed curcumin-loaded nanoparticles by amphilic mPEG-PCL block copolymers.Drug loading content(DLS) and encapsulation efficiency(EE) were more than other reports.Data indicated that incorporated Cur could be slow released from the core-shellstructured polymericnanoparticles. 2. CurNP can ameliorate ischemia-reperfusionrenal injury in vitro. 3. The protective effects of Cur-NP against ischemia-reperfusion renal injuries involved in the suppression of oxidative stress reaction.

Disruption of Polyamine Catabolism Reduces the Severity of Cisplatin Nephrotoxicity Kamyr a A. Zabed,1 Sharon L. Barone,1,2 Marybeth Brooks,1 Jie Xu,1 Manoocher Soleimani,1,2 1Dept of Internal Medicine, Univ of Cincinnati, Cincinnati, OH; 2Research Services, Veterans Affairs Medical Center, Cincinnati, OH.

Background: Platinum-based drugs (e.g. cisplatin) are used for treatment of many types of solid organ tumors. Cisplatin crosslinks the DNA, interferes with mitosis, activates the DNA repair response and leads to cell death. These are the primary anti-tumor mechanism of cisplatin. Platinum-based drugs also cause oxidative cell injury, which may mediate their general toxic effects. Acute kidney injury (AKI), due to oxidative damage, is a major side effect of cisplatin that necessitates dose reduction or withdrawal from treatment thereby reducing the effectiveness of cancer therapy. We hypothesized that treatments that reduce the oxidative tissue damage caused by cisplatin lessen the severity of AKI without interfering with its anti-proliferative DNA damaging effects and obviate the need for dose reduction or drug withdrawal.

Methods: Cisplatin-AKI was compared in wild type and SSAT-KO mice using functional and molecular parameters. Mechanism of polyamine catabolism mediated-cell injury was assessed in cultured cells.

Results: The expression of polyamine catalytic enzymes, spermidine spermine-N1-acetyltransferase (SSAT) and spermidine oxidase (SMO) increase in the kidney of cisplatin-treated mice. SSAT-KO mice are protected against tissue damage and renal dysfunction caused by cisplatin. Using cultured cells capable of inducible expression of SSAT, the effect of SSAT on the induction of endoplasmic reticulum stress and unfolded protein response (ERS/UPR). Our results indicate that up-regulation of polyamine catabolism in general, and enhanced production of SSAT in particular, activated the ERS/UPR.

Conclusions: These studies suggest that polyamine catabolism is involved in the mediation of cisplatin-AKI. These and our previous results indicate that the activation of polyamine catabolism causes cell injury through both genotoxic response and ERS/UPR pathways. Our studies suggest that short-circuiting or neutralization of toxic products of polyamine catabolism can be novel therapies that reduce the severity of cisplatin nephrotoxicity.

Replicative Effect of NADPH Oxidase 4 Inhibition in Contrast Induced Nephropathy

Se-Hee Yoon, Won Min Hwang, Sung-Ro Yun, Sukyoung Lee, Hee-Yeon Jung, Ji-Young Choi, Sun-Hee Park, Chan-Duck Kim, Yong-Lim Kim.

1. Internal Medicine, Konyang Univ, Deajeon, Korea; 2. Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Korea.

Background: The objective of this study was to investigate the replicative effect of NADPH oxidase 4 (Nox4) inhibition in contrast induced nephropathy.

Methods: HK-2 cells were incubated with iohexol (nonionic low-osmolar contrast agent) at a concentration of 75 mg/ml, 150mg/ml for 2h. Cells were pre-exposed to GKT137831, a selective Nox1&4 inhibitor (Genkyotex, Switzerland), for 30 min before exposure to iohexol. Cell viability was measured at 0, 3, and 24h after removal of iohexol by ATPiLife assay. Apoptosis was investigated by caspase 3/7 activity assay in renal oxygen species (ROS) production was assessed by DHE assay, NADPH oxidase activity by the lucigenin-enhanced chemiluminescence method, and Nox3 expression by western blot and real time PCR.

Results: Nox4 protein expression significantly increased at 30 min after iohexol exposure. GKT137831 pre-exposure showed significantly less cytotoxicity at 3h after removal of iohexol. Caspase 3/7 activity was significantly lower in GKT137831 pre-exposed cells than only iohexol exposed cells at 22h after removal of iohexol. ROS generation was higher with only iohexol exposed cells compared to GKT137831 pre-exposed cells.

Conclusions: A selective Nox4 inhibition reduced fewer cytotoxic effects on cultured HK-2 cells than iohexol along with a lower induction of Nox4-dependent ROS generation. This enzyme may represent a potential therapeutic target to prevent iodinated radiocontrast media related oxidative stress.

Autophagy Increased in the Early Stage of Rat Acute Kidney Injury Model

Jungyi Lim, Xing Mao, Yiwen Shen, Huijuan Wu, Aimin Xue.

1. Department of Forensic Medicine, Shanghai Medical College, Fudan University, Shanghai, China; 2. Department of Pathology, Shanghai Medical College, Fudan University, Shanghai, China.

Background: Acute kidney injury (AKI) is a major kidney disease without effective therapies, and thus associated with a high mortality. The pathogenesis of AKI is very complex and still unclear. Recently, researches have shown the induction of autophagy in proximal tubular cells and kidneys during AKI. In the present study, we investigated the role of autophagy in the pathogenesis of rat renal ischemia-reperfusion (I/R) model which causes AKI.

Methods: All male Sprague-Dawley rats were subjected to clamping of bilateral renal artery only for 25 min except sham group, and then they were randomly divided into four groups dependent on different reperfusion time point, including 3h, 6h, 12h and 24h. The Sham group underwent surgical procedures without ischemia was the control.

Results: The level of blood urea nitrogen (BUN) and serum creatinine were increased from 3h after I/R. H&E staining, protein casts were found at 3h after I/R, which kept increasing at 6h and 12h after I/R. At 24h after I/R, we found some necrotic proximal tubules. Immunohistochemistry showed the protein level of Beclin-1 and Vps34 and the ratio of LC3 II/I was increased from 3h after I/R, which was confirmed by electron microscopy showing the formation of autophagic vacuoles in proximal tubular cells. Moreover, immunohistochemical staining clearly showed an increasing positive staining of Vps34 and LC3 at 3h after I/R compared to the control.

Conclusions: Taken together, our results demonstrate the occurrence of autophagy in the very early stage of rats AKI model. Funding: Government Support - Non-U.S.

The Previous Cardio Exercise (Exe) Normalizes Renal Function of Wistar Rats Subjected to Acute Kidney Injury by Ischemia, and Reperfusion

Weslei Vicente Ling, Waldemar S. Almeida, Nestor Schor. Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil.

Background: The acute kidney injury (AKI) is characterized by acute reduction of renal function and has a high mortality rate in hospitalized patients and in severe cases may progress to chronic kidney disease (CKD). The AKI by ischemia and reperfusion (I/R) causes tubular damage mainly in the proximal convoluted tubule, reducing mitochondrial activity in renal cell and increasing the reactive oxygen species (ROS). It is known that reactive oxygen stimulates inflammatory cytokine IL-6, and may alter endothelial barrier function in the lung. However, the long-term effect of kidney failure is very complex and still unclear. Recently, researches have shown the induction of autophagy in proximal tubular cells and kidneys during AKI. In the present study, we investigated the role of autophagy in the pathogenesis of rat renal ischemia-reperfusion (I/R) model which causes AKI.

Methods: We used male Wistar rats with 10 weeks of life and they were separated into two groups Sham clamp (SC) and trained control clamp (TC), moreover the TC were subjected to a prior physical training protocol for four weeks. After completed 14 weeks each group, groups were subjected to iohexol (nonionic low-osmolar contrast agent) at a concentration of 75 mg/ml, 150mg/ml for 2h. We evaluated renal function (serum creatinina and proteinuria). Then they will be realigned: renal morphological study by light microscopy and mitochondrial (number and size) by electron microscopy. Finally, we will evaluate apoptosis through caspases 3 activity.

Angiogenin Mediates a Non-Cell Autonomous Response to Endoplasmic Reticulum Stress in the Kidney

Nicolás Pallos, Dany Anglicheau, Eric Thervet, Iadh Mami.

Background: Endoplasmic Reticulum (ER) stress is involved in the pathophysiology of kidney diseases, but the molecular basis of its biological outputs remain to be established. Angiogenin (ANG), a secreted ribonuclease, is a previously unappreciated component of the mammalian stress response that acts both in cell-autonomous and non-cell autonomous fashions to promote tissue adaptation to injury. Whether ANG signaling is a genuine component of the ER stress response is currently unknown.

Methods: In the present study, we explored the molecular mechanisms by which ANG is secreted under ER stress, and determined how it contributes to the modulation of the inflammatory microenvironment.

Results: Our results indicate that i) ANG secretion is specifically induced during ER stress and ii) this mechanism is under the selective control of IRE1α signaling. We demonstrate that ANG canonical secretion is induced upon ER stress, similar to the proliferation-inducing cytokine IL-6, and as such might play an instrumental role in macrophage activation. These data are relevant to human disease since we identified ANG as a urinary marker of immune-mediated acute kidney injury.

Conclusions: Collectively, our data identify ANG as a key mediator of ER stress-dependent inflammatory response in kidney diseases, and is a potential non-invasive biomarker of acute kidney injury.

Sustained Inflammation of Th17 Cells Is Associated with Pulmonary Fibrosis in Rats with Salt Induced CKD Secondary to Renal Ischemia

Purvi Mehrotra, Jason Andrieu Collett, David P. Basile. Dept of Cellular and Integrative Physiology, Indiana Univ of Medicine, Indianapolis, IN.

Background: Acute kidney injury (AKI) is associated with high mortality rates and is a leading cause of prolonged hospitalizations. The high risk of death is due in part to distant organ damage (e.g., lungs, heart, brain). It is well established that experimental AKI induced by renal ischemia and reperfusion (IR) induces an increase in pulmonary inflammation. Various immune cells like T cells as early as 24 hours post surgery, which may alter endothelial barrier function in the lung. However, the long-term effect of kidney injury induced pulmonary inflammation on lung function and structure and function is not known. We hypothesize that T cells infiltrate into the lung post kidney injury with potential effect on lung structure.

Methods: SD rats were subjected to a model of AKI-to-CKD in which rats are allowed to recover from unilateral I/R (40 min ischemia) for 5 weeks on standard salt diet (0.4% NaCl) and then subjected to contralateral UNX and 4% NaCl diet for 4 additional weeks. Consistent with prior reports, infiltration of CD4+ T cells were detected as early as 24 hours post surgery in the BAL fluid, and these were shown to be predominantly of Th17 phenotype (63±10.1, p<0.05). Interestingly, Th17 cells persisted in the lungs even after 5 weeks of post surgery after resolution of kidney injury (2.5±10±0.1, p<0.05), when compared to sham (0.5±10±0.3). Exposure of rats to high salt diet to baten CKD further increased the number of Th17 cells in the lungs (4.1±10±0.2, p<0.05). There was a corresponding increase in pulmonary fibrosis in post-AKI rats on high salt relative to sham-controls.

Conclusions: Taken together, these data suggest that AKI leading to CKD is associated with pulmonary fibrosis, an activity that may be due in part to the infiltration of Th17 cells into the lung and influenced by dietary salt. Funding: NIDDK Support

Endothelial-to-Mesenchymal Transition and Endothelial Cilia in EPC-Mediated Postischemic Kidney Protection

Daniel Patschan, Susann Patschan, Gerhard A. Mueller. Clinic of Nephrology and Rheumatology, Dept of Internal Medicine, Göttingen, Niedersachsen, Germany.

Background: AKI increases the risk for CKD. Ischemia induces peritubular capillary rarefaction and interstitial fibrosis with the latter partly resulting from mesenchymal-to-epithelial conversion of renal tubulointerstitial cells (EndoMT). Endothelial cilia are mechanosensory organelles responsible for transmitting forces of the blood flow into the cell. Early Endothelial Progenitor Cells (eEPCs) have reproducibly been shown to protect mice from AKI in the short-term. Aim of the study was to analyze mid-term consequences of eEPC treatment of mice.

Methods: Male, 8-12 weeks old C57Bl/6N mice were subjected to unilateral renal ischemia (40 min-uniperenphrectomy). Syngeneic murine eEPCs (5×10^6) were injected once at the time of reperfusion. Animals were investigated 1, 4, and 6 weeks later (renal function,
fibrosis, EndoMT, endothelial alpha-Tubulin). Cultured mature endothelial cells (EPCs) were exposed to cisplatin with versus without treatment with eP1C supernatant. Later (24 h) cells were investigated for the presence of cilia, alpha-Tubulin, and EndoMT, respectively.

**Results:** Systemically injected eP1Cs significantly improved postischemic kidney function at week 1 (35 and 45 minutes) and 4 (45 minutes). Interstitial fibrosis was significantly diminished by cell treatment at all time points as well. EndoMT was less pronounced at week 4 (35 minutes) and 6 (45 minutes). eP1C supernatant aSMA expression and alpha-Tubulin abundances in flow-treated cultured mature endothelial cells while percentages of cilia+ cells increased. The loss of periluminal capillaries was prevented by eP1Cs. Interstitial alpha-Tubulin expression decreased postischemia and was further reduced after eP1Cs. The latter effect exclusively occurred in the 35 minutes groups.

**Conclusions:** We conclude that eP1Cs are capable of reorganizing the endothelial cytoskeleton in an indirect manner, ultimately resulting in stabilization of the endothelial ciliom. The investigation indicates an anti-menenchymal role of endothelial cilia in the process of postischemic tissue fibrosis / EndoMT.

Mediators of Kidney Recovery following Ischemia-Reperfusion Injury

Capet Lassen, Marie Louise Vindlvad Kristensen, Henrik Birn, Bente Jespersen, Rikke Norregaard. Dept of Clinical Medicine, Aarhus Univ.

**Background:** Ischemia-reperfusion injury (IRI) is a major cause of acute kidney injury. Remote ischemic conditioning (rIC) performed as brief episodes of intermittent ischemia and reperfusion in a distant tissue may protect the kidney against IRI. We investigated the renal effects of rIC applied either prior to or during ischemic kidney injury.

**Methods:** One week after uninephrectomy Wistar rats were randomly divided into 4 groups; sham (n=7), IR (n=10), IR+rIPC (n=10), and IR+rIPerC (n=10). rIC consisted of 4 episodes of 5 min clamping of the infrarenal aorta and 5 min of release either before (rIPC) or during (rIPerC) 37 min of left renal artery clamping (IRI). Urine and blood were sampled prior to ischemia or sham operation as well as 3 and 7 days after reperfusion. At day 7 the kidney was harvested for purification of mRNA and protein.

**Results:**: Three days after IRI the decline in creatinine clearance (CrCl) from baseline values was similar comparing the IR group (Δ: -1.59 ml/min/kg [-2.55; -0.64]) to both the IR+rIPC group (Δ: -1.19 ml/min/kg [-2.22; -0.15], p=0.99) and the IR+rIPerC group (Δ: -1.48 ml/min/kg [-2.17; -0.79], p=0.99). At day 7 all groups exposed to IRI recovered to baseline CrCl. This was associated with a significant up-regulation of mediators of kidney recovery including phosphorylated Akt, ERK1/2 and HSP27 in all 3 groups. rIC was not associated with any significant differences in the expression of tubular damage markers, inflammation or fibrosis markers, as well as antioxidant enzymes following IRI (see table).

**Conclusions:** In our study rIC did not protect the kidney against IRI. However, from day 3 to day 7 after IRI all groups recovered full renal function. This was associated with an up-regulation of p-Akt, pERK1/2 and HSP27 at day 7.

Effect of Double Genes Transfected Adipose-Derived Stem Cells on Cisplatin-induced Renal Tubular Epithelial Cells Injury

Nannei Li, Jixin Hospital of Shanghai.

**Background:** Cisplatin-induced Renal Tubular Epithelial Cells Injury (Cisplatin; Cis) is a major cause of acute kidney injury (AKI) in clinical practice. Double genes transfected to ADSCs may enhance the protective effect on AKI cells.

**Methods:** We performed unilateral nephrectomy and then ischemia-reperfusion injury to induce acute kidney injury in the endosialin-deficiency (lacZ knock-in) and littermate wild type mice. Plasma levels of blood urea nitrogen and creatinine were analyzed at day 2, 5 and 10 after injury. We analyzed the cells expressing endosialin, tubulointerstitial injury, and specific cells by X-Gal staining. Periodic acid-Schiff staining and immunohistochemistry respectively.

**Results:** Positive X-Gal staining was shown in the glomeruli, small arteries and interstitial cells of the kidney. The capillary density determined by CD31 staining did not show significant difference between endosialin-deficiency and wild type mice. Nephrectomy and ischemia-reperfusion induced cell damage at the tubular wall. The tubular cilia expression was analyzed at 1, 3, 5, and 7 days after reperfusion in endosialin-deficiency mice and littermate wild type mice. Moreover, the expression of alpha-Tubulin in wildtype mice was less than in endosialin-deficiency mice at day 2 after injury. Interestingly the protective property of endosialin deficiency was lost since day 3 after injury.

**Conclusions:** Endosialin-deficiency can attenuate acute kidney injury induced by ischemia-reperfusion injury, but the protective property is lost during the repair/regenerative phase after acute injury. The protective property of endosialin deficiency is not related to capillary density which has been shown increased in previous study. Further study needs to elucidate the mechanism underlying the protective property of endosialin deficiency and why the protective property is lost during repair/regenerative phase.

The Mechanism of β2-Adrenergic Receptor/Protein Kinase A Signal Transduction Pathway in Restoration of Acute Kidney Injury by Endothelial Progenitor Cells

Ying Zhou, Chen Yu. Dept of Nephrology, Tongji Hospital, Tongji Univ, Shanghai, China.

**Background:** Endothelial progenitor cells (EPCs) could improve renal microenvironment, stimulate endothelial repair and angiogenesis, and promote AKI restoration. However, the molecular mechanism has not been elucidated. In this study we investigated the role of β2-adrenergic receptor (β2 -AR) and its downstream factors (protein kinase A, protein kinase B, protein kinase C) in restoration of acute kidney injury by EPCs.

**Methods:** The model of ischemia-reperfusion acute kidney injury (I-R AKI) was used in vivo, while sham operation was performed in control group. Renal tissue was collected at 7 days after reperfusion. The mRNA levels of β2-AR were measured by Q-PCR, and Western blotting. The expression of PKB and PKC were measured by Q-PCR and Western blotting.

**Results:** Renal histology suggested acute tubular necrosis, and β2-AR was positive by immunofluorescence staining. The specific antigens on surface of EPCs(CD34,CD133 and VEGFR-2) were examined by Q-PCR, while VEGFR-2 was examined using immunofluorescence staining too. The downstream factors (PKA, PKB, PKC) were measured by Q-PCR and Western blotting.

Contribution of Proliferating Endothelial Cells for Endothelial Repair of CIN in individuals with high risk.

Background: Contrast medium induced nephropathy (CIN) is one of the most common cause of hospital-acquired acute renal failure. But its pathogenesis is unclear. In this study, we observed the effect of iopromide, low osmolar contrast medium, on tubular cells in HK-2 cell line.

Methods: We observed the effect of iopromide, low osmolar contrast medium, on tubular cells in HK-2 cell line. First, we examined the effects of different doses of iopromide (10, 20, 40 and 80 mg/mL iodine) on proliferation of HK-2 cells by the real time cell analyser (RTCA). According to the results of RTCA we examined whether the non-toxic doses of iopromide (10 and 20 mg/mL iodine) is causing of the EMT by scratch assay for 20 h. We also observed whether alpha lipoic acid (0.5 mM) and dexamethasone (5 µg/mL) is preventing to EMT in this assay.

Results: We observed whether alpha lipoic acid (0.5 mM) and dexamethasone (5 µg/mL) is preventing to EMT in this assay. Although cytotoxic effect was observed for iopromide with concentration of 80 mg/mL iodine, the iopromide with lower doses did not show any effects for HK-2 cells. In scratch assay, we observed that the non-toxic doses of iopromide (10 and 20 mg/mL iodine) is causing of the cell migration which an indicator of EMT and lipoic acid and dexamethasone prevent the cell migration.

Conclusions: In conclusion, the EMT caused by contrast medium is prevented or reduced by dexamethasone and lipoic acid in HK-2 cells. This result suggest that dexamethasone and lipoic acid may be a potential treatment to prevent the development of CIN in individuals with high-risk.

PUB021

Contribution of Proliferating Endothelial Cells for Endothelial Repair After Site Specific Endothelial Injury of the Mouse Kidney

Div of Nephrology, Dept of Internal Medicine III, Univ Hospital CCG, Dresden, Germany.

Background: Our previous studies have shown that renal endothelial cell regeneration occurs exclusively via local mechanism. To further dissect the relevance of local mechanisms for endothelial repair, we now investigated the contribution of local endothelial cell proliferation in the kidney in our model of site selective endothelial injury (ECI).

Methods: Selective ECI was induced in 9 out of 15 mice by renal arterial perfusion with Concanavalin A (ConA)-anti-ConA, while 6 mice served as sham operated controls. Edu (15 µg/g), a marker of proliferation, was injected starting 24 hours after ECI every 12 hours intraperitoneally. Kidneys were harvested on day 7 and Edu+ cells were analyzed using flow cytometry and histology. Endothelial cells were stained using CD31, CD105, CD41 and CD146 and hematopoietic cells were detected as CD45+. Inflammatory cells (macrophages, dendritic cells and neutrophils) were analyzed via GR1, CD11c, CD11b and F4/80 positivity. By histology, proliferating EC were detected as anti-ERG/EDU double positive cells.

Results: Significantly more Edu+ cells could be detected after ECI on day 7 (sh: 1.2%±0.7; ECI: 7.6%±4.8). Most of those Edu+ cells were positive for CD45 (63±58%) and 3% (sh) up to 7% (ECI) were positive for EC surface markers. In diseased kidneys more endothelial cells were found (sh: 5.5%±0.7; ECI: 7.3±0.5; p<0.01). A larger amount of Edu+ EC was found in injured kidney (sh: 1.5±0.8 8160 cells; d7: 5.5±1.5 8630 cells; p<0.01). Histological analysis supported these findings. Glomeruli of ECI kidneys had more ERG/EDU+ cells (0 0: 0.23±0.16; d7: 1.22±0.6; p<0.01). Inflammatory cells in injured kidneys were slightly increased. Many macrophages (21±13%), neutrophils (38±17) and dendritic cells (19±13) were Edu+.

Conclusions: Enhanced endothelial proliferation was detected following ECI. Therefore EC proliferation reflects an relevant repair mechanism following site selective ECI. The further investigation of EC repair will have to dissect the contribution of the proliferative response by adult local EC from other contributors such as local progenitor cells.

1 Surgery, Univ of California-Davis, Sacramento, CA; 2Pathology and Laboratory Medicine, Univ of California-Davis, Sacramento, CA. "Brain Damage of Proximal Tubular Cells in Neonate Rats with Hypoxic-Ischemia Brain Damage"

Background: Proximal tubular cells play a critical role in renal injury. To investigate the consequence of mitochondria in renal proximal tubular cells after hypoxic-ischemia brain damage (HIBD) in rats and the apoptosis in it.

Methods: Neonatal (7 days old) Sprague Dawley rats were randomly divided into 2 groups: sham group and operation group (n=5 per group). The Rice method was used for establishment of HIBD model, proximal tubular cells Mitochondria pathology and histology were examined under electron microscope at 1 day, 7days, 14days and 21days after the hypoxic-ischemic treatment, and apoptosis was analyzed by TUNEL.

Results: After the HIBD, the mitochondria of proximal tubular cells were showed damage under EM, some membrane and ridges were broken, the mitochondria bodies were swelling, and partial cristal fragmentation were observed from the 1day till 21days after. And the 21days was the most worst for mitochondria under EM. For the TUNEL, after HIBD, it showed significant increased for 1day, 7days, 14days and 21days groups comparing with sham group. (p<0.05).

Conclusions: After the hypoxic and ischemic brain injury of neonate rats, the mitochondria were damaged in proximal tubular cells, even in 21days after HIBD. And the apoptosis maybe one of the causes of this damage.

Funding: Government Support - Non-U.S.
Conclusions: EVNP may have the potential to repair Meg acutely injured kidneys rendering them suitable for transplantation. Ex vivo administration of furosemide may be a useful tool to assess injured deceased donor kidneys being considered for transplantation.

Transfusion of Red Blood Cell as Predictor of Acute Kidney Injury in Patients Undergoing Cardiac Surgery

Edhesive Santana-Santos, Luiz Aparecido Bortolotto, Ludhmila Abraham Hajjar.

ICU-Cardiac Surgery Postoperative Care, Heart Inst (InCor) Inst do Coração do Hospital das Clínicas da Faculdade de Medicina da Univ de São Paulo, São Paulo, Brazil.

Background: The red blood cell transfusion in the perioperative period of cardiac surgery have been associated with acute kidney injury. Our purpose was to analyze the influence of transfusion of red blood cell in the incidence of acute kidney injury after cardiac surgery.

Methods: We performed a prospective cohort study carried out in a tertiary hospital specialized in Cardiology. Adult patients who had undergone elective myocardial revascularization surgery, valvular and aortic surgery and who agreed to participate in the study were included. The primary endpoint was acute kidney injury defined by KDIGO criterion. Secondary outcomes was serious clinical complications defined according to the guidelines of the Society of Thoracic Surgeons.

Results: According to KDIGO criterion, the incidence of AKI was 46.5%. The mean age was 60±12 years old in the AKI group and 58±13 in the no AKI group (p=0.145), and mostly male (56%). The surgical risk assessed by EuroSCORE was greater in the AKI Group 5 (1-25) when compared to the no AKI group 4 (2-10), (p=0.047). There were no differences between the groups for the secondary outcomes. The use of red blood cells in the perioperative period (OR=3.166, p=0.001) and the presence of prior chronic kidney disease (CKD) (OR=2.027, p=0.036) was associated with AKI postoperatively.

During the period of hospitalization the mortality rate was 6.9%. When we compare the mortality rate between the groups it was 4.3% in the no AKI Group and 10% in the AKI Group (p=0.229).

Conclusions: In our study the use of perioperative red blood cells influenced the primary outcome. Patients who had used red blood cells had 3 times more risk of AKI.

A Picture Is Worth a Thousand Words: Simultaneous ATN, AIN, and Post Infectious GN

Ankur Shah, Rachel Criner, Jean Lee.

*Internal Medicine, Temple Univ Hospital, Philadelphia, PA; *Nephrology, Temple Univ Hospital, Philadelphia, PA.

Background: The differential diagnosis of hospital acquired acute kidney injury in its most general terms often is described as pre-renal, intrinsic or post-obstructive. Further differentiating the intrinsic causes of AKI, we are given the differential of Acute Tubular Necrosis, Acute Interstitial Nephritis, and Glomerulonephritis. We present the case of a patient who presented with sepsis and developed acute kidney injury whose biopsy revealed a plethora of pathology.

Methods: We present a case of a 54 y/o male with a pmhx of only HTN and DJD who presented with leg pain and weakness for 2 weeks and hematuria found to be bacteremic with MSSA with L spine epidural abscess and bilateral psosas muscle abscesses. He developed acute kidney injury thought clinically and based on microscopy to be secondary to hypotensive acute tubular necrosis and was started on hemodialysis on HD6. He was being treated with ceftriaxone and over weeks had minimal return of renal function. The differential diagnosis was revisited and concern for AIN from the penicillin agent was raised, the patient was switched to Daptomycin, but remained RRT dependent. After 25 days on hemodialysis, a biopsy was obtained which revealed diffuse interstitial inflammation with eosinophils, focal mild-moderate tubular injury with vacuolization, as well as by electron microscopy, subepithelial deposits but not subendothelial deposits,most of which are largely absorbed, including in “notech” areas. These findings are consistent with an acute post-infectious glomerulonephritis, resolving stage; drug induced acute interstitial inflammation, as well as mild-moderate focal tubular injury.

Conclusions: This case demonstrates a variety of the potential causes of AKI. The patient course was long and provided multiple opportunities for re-evaluation and a return to the differential diagnosis process. This is an excellent case for the teaching of the fundamentals of medicine, as the differential diagnosis is truly the instrument of the master clinician. This patients aberrance from the expected course prompted reevaluation and his pathology was staggering.

PUB027

Monitoring and Follow-Up of Acute Kidney Injury Post-Discharge: Retrospective Case Review Series

Kosmas Papailiadis, Judith H. Veis.

Medicine, Washington Hospital Center, Washington, DC; Nephrology, Washington Hospital Center, Washington, DC.

Background: AKI during hospitalization increases risk of progression to CKD and death upon discharge. Recent KDIGO guidelines suggest patients should be evaluated 3 months after AKI for resolution, new onset, or worsening of pre-existing CKD. We determined factors associated with whether patients with AKI had kidney function assessed 3 months post-discharge.

Methods: Retrospective chart review of hospitalizations in 2013 complicated by AKI, who had follow-up in Ambulatory Medical Clinic to assess discharge communication; serum Cr, urine protein/Cr at 3 and 4-9 months, 1 year outcomes including progression to CKD, death and referral to nephrology. Results: 77 inpatients with AKI (48(66%) stage 1, 9(12%) stage 2, 20(26%) stage 3; and 9(12%) requiring RRT) had a post-discharge visit. Of these, 51(66%) had serum Cr and 16(21%) had urine protein/Cr checked by 3 months. For 4-9 months, 13(17%) had serum Cr and 5(6%) had urine protein/Cr checked; 3(4%) were deceased by 1 year. 26(34%) had normal kidney function pre-AKI and of this group, 10(38%) had CKD by 1 year. Of these 26, only 5(19%) were referred to nephrology. For documentation, 54(77%) had AKI as a problem in the inpatient hospital summary, 42(54%) had AKI documented in the brief outpatient hospital summary and 29(41%) had AKI addressed in the follow-up visit. There were significant associations between addressing AKI at follow-up and checking kidney function; p=0.043 and between AKI stage and addressing AKI at follow-up; p=0.022 and between AKI outpatient summary and addressing AKI at follow-up; p=0.004.

Conclusions: Outpatient follow-up of inpatient AKI is inconsistent despite evidence of poorer outcomes and recent guidelines which suggest the need for closer monitoring. Improving transitions of care through more effective documentation and streamlined EMRs, as well as increasing primary care physician awareness could reduce the risk of progression to CKD and death.

PUB028

Late Recovery of Renal Function in Atypical Hemolytic Uremic Syndrome (aHUS) After Eculizumab Therapy

Jeffrey D. Clement, Delin Wang, Maoyin Pang, Tannay Sahai, Keith R. Bartolomei.

Roger Williams Hospital.

Methods: A 33-year-old woman with hypertension and left renal agenesis presented with fever and acute kidney injury with serum creatinine of 2.1 mg/dL. Initially, hemoglobin was 10.3 mg/dL and platelets 193,000/ul. Over the next three days platelets dropped to 55,000/ul and LDH rose to 770 U/L; renal function worsened. Thrombotic microangiopathy was suspected. Stool culture was positive. Urine protein was 6.8 g per 24 hours. Serologic assessment, including C3, C4, ANA, ANCA, HIV, cryoglobulins, dsDNA, lupus anticoagulant, antiphospholipid antibodies, and β2-glycoprotein I antibodies, was unremarkable. The patient was treated with cryo-poor plasma exchange and steroids. Hemodialysis was started for uremia. ADAMTS13 was 67% of normal. Renal biopsy

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
showed acute thrombotic microangiopathy, acute tubular injury, and moderate interstitial fibrosis. The presentation suggested the diagnosis of aHUS. Eculizumab, an anti-C5 antibody, was initiated at 900 mg weekly for four weeks followed by 1200 mg every two weeks. Eculizumab therapy resulted in resolution of hemolysis. Dialysis was continued thrice weekly. Eculizumab was continued every two weeks, and LHD and platelet counts remained normal during the follow-up period with no further initiation of dialysis or hypercoagulable state, and interdialytic weight gains were negligible. Pre-dialysis serum creatinine was 3.9 mg/dL, and a urine collection showed creatinine clearance of 30 ml/minute. She has remained off dialysis for twenty weeks, and latest serum creatinine is 3.4 mg/dL. Screening for coagulation and thrombotic predisposition was negative.

Conclusions: Experience with eculizumab is ongoing. Most patients with aHUS have a rapid hematologic response. If they need dialysis, then recovery of renal function is usually prompt; late recovery is rare. We hypothesize that sustained control of complement activation has been achieved through microparticle and allotype platelet eradication. The potential for renal regeneration, even months later. Patients are at risk for relapse if they stop treatment. This case points out that the presumed genetic defect may require lifelong treatment, and that late recovery of renal function is possible with complement inhibition and supportive care.

PUB029

The Effectiveness of Theophylline in Preventing Cisplatin Related Nephrotoxicity in Patients with Cancer

Jamil Kooeghi,1 Derya Karademir,2 Fatma Dogruer,2 Cevat Yazici,2 Aydin Unal,3 Murat H. Sipahioglu,1 Oktay Oymak,1 Bulent Tokgoz.1
1Nephrology, Erciyes Univ Medical School, Kayseri, Turkey; 2Biochemistry, Erciyes Univ Medical School, Kayseri, Turkey.

Background: Cisplatin is a potent antineoplastic agent used in treatment of many solid tumors. The major limiting side effect of cisplatin is nephrotoxicity. Theophylline is a cardiovascular stimulant of adenosine which has anti-inflammatory and anti-platelet activity. In this study, early detection of acute kidney injury with biomarkers such as neutrophil gelatinase associated lipocalin (NGAL) and cystatin C and investigation of the potential nephrotrophic-effective role of theophylline were aimed.

Methods: Sixty patients who are planned administration of cisplatin for the first time were included in the study. Patients were divided into two groups as group I (n=30) (standard treatment arm) and group II (n=30) (theophylline arm). Glomerular filtration rate (GFR), NGAL, cystatin C were measured at 3rd day in all of the patients. Also, these parameters were repeatedly measured at the administration of cisplatin, at 24th hour, 3rd and 26th days.

Results: In both groups after the administration of cisplatin, glomerular filtration rate (GFR) showed a significant decrease within time (p=0.006). In creatinine, in spite of the decline in GFR, no significant difference was observed between groups and within time. After 3 days of cisplatin administration, in spite of the decline in GFR, a significant decline was detected in serum cystatin C (p=0.001). Urine NGAL was significantly high after 2 days of cisplatin administration (p=0.001). No significant difference was observed between groups. However, when the time*group effects were considered together, higher NGAL was detected in the group not receiving theophylline (p=0.025). After 5 days of cisplatin administration, urine protein levels were significantly higher in both groups (p=0.001).

Conclusions: Results showed that urine NGAL level is a superior biomarker compared to creatinine and cystatin C in the detection of early acute kidney injury. Theophylline was found not to bring a complete protection for the kidneys, but less nephrotoxicity was developed when compared to the group not receiving theophylline.

IgA Nephropathy Presenting as RPGN After G-CSF Administration: An Interesting Case of IgA Nephropathy Presenting as RPGN After G-CSF Administration

Abdul Mateen Nagaria,1 Ahmad Hassan,2 Agha Syed Shabbir Ali,1 Ismail Oymak,1
1Biostatistics, Erciyes Univ Medical School, Kayseri, Turkey; 2Biochemistry, Erciyes Univ Medical School, Kayseri, Turkey.

Background: Acute kidney injury (AKI) in patients admitted for acute decompensated heart failure (ADHF) carries a poor prognosis. Minute ventilation-targeted adaptive servo ventilation (MV-ASV) therapy relieves anapnea and renal hypoxia. Serum creatinine (Cr) and estimated glomerular filtration rate (egFR) are markers that signal kidney injury and improvement of kidney function. MV-ASV may mitigate kidney injury and improve renal function in patients admitted with ADHF compared to standard therapy.

Methods: This is a study where twenty-one patients with ADHF were randomized to receive either MV-ASV therapy (9 VPAP Adapt, ResMed Corp.) with standard care, or standard care alone. MV-ASV therapy was administered for a minimum of six hours for up to 5 days, or until discharge. Cr was measured daily and used to calculate eGFR.

Results: The median baseline Cr levels in the MV-ASV and standard groups were 1.09mg/dL and 1.08mg/dL, respectively. After therapy, Cr levels were unchanged in the MV-ASV group and increased by 0.34 mg/dL (31.5%) in the standard care group. The median baseline eGFR levels in the MV-ASV and standard groups were 70.5mg/dL and 64mg/dL, respectively. Upon completion of therapy, the eGFR levels in the treatment group increased by 22.5mg/dL (32%) and decreased in the control group by 15mg/dL (23%).

Conclusions: MV-ASV therapy in patients with ADHF stabilizes Cr levels during a period of aggressive diuresis. MV-ASV may be a valuable for renal protection and could improve kidney function in patients with ADHF.

PUB031

Minute Ventilation-Targeted Adaptive Servo Ventilation Protects Renal Function in Acute Decompensated Heart Failure Patients

Matthew Kapilavan,3 Trenton Gluck,2 Elizabeth Lee,2 Boris Arbis,1 Kathleen Sarmiento,1 Atul Malhotra,4 Alan S. Maisel,1 1Div of Cardiovascular Medicine, Univ of California, San Diego, La Jolla, CA; 2Cardiac Research, VA San Diego Healthcare System, La Jolla, CA; 3Div of Pulmonary and Critical Care Medicine, Univ of California, San Diego, La Jolla, CA.

Background: Acute kidney injury (AKI) in patients admitted for acute decompensated heart failure (ADHF) carries a poor prognosis. Minute ventilation-targeted adaptive servo ventilation (MV-ASV) therapy relieves anapnea and renal hypoxia. Serum creatinine (Cr) and estimated glomerular filtration rate (egFR) are markers that signal kidney injury and improvement of kidney function. MV-ASV may mitigate kidney injury and improve renal function in patients admitted with ADHF compared to standard therapy.

Methods: This is a study where twenty-one patients with ADHF were randomized to receive either MV-ASV therapy (9 VPAP Adapt, ResMed Corp.) with standard care, or standard care alone. MV-ASV therapy was administered for a minimum of six hours for up to 5 days, or until discharge. Cr was measured daily and used to calculate eGFR.

Results: The median baseline Cr levels in the MV-ASV and standard groups were 1.09mg/dL and 1.08mg/dL, respectively. After therapy, Cr levels were unchanged in the MV-ASV group and increased by 0.34 mg/dL (31.5%) in the standard care group. The median baseline eGFR levels in the MV-ASV and standard groups were 70.5mg/dL and 64mg/dL, respectively. Upon completion of therapy, the eGFR levels in the treatment group increased by 22.5mg/dL (32%) and decreased in the control group by 15mg/dL (23%).

Conclusions: MV-ASV therapy in patients with ADHF stabilizes Cr levels during a period of aggressive diuresis. MV-ASV may be a valuable for renal protection and could improve kidney function in patients with ADHF.

Serum Neutrophil Gelatinase-Associated Lipocalin: A Novel Biomarker for Prediction of AKI Development in Critically Ill Patients

Magdy M. Elsharkawy, Abdel Rahman Khedir, Amr Mohab, Haitham Ezzat.
Nephrology, Ain Shams Univ, Cairo, Egypt.

Background: Acute kidney injury (AKI) is a frequent complication in critically ill patients and is associated with high morbidity and mortality; therefore, its prophylaxis, diagnosis and intervention positively impact patient evolution. Neutrophil gelatinase-associated lipocalin (NGAL) is thought to be a novel biomarker of AKI of several etiologies and is increased in both serum and urine before the increase of serum creatinine.

Methods: A prospective cohort study was conducted on 100 critically ill patients in ICU. Patients were stratified into 2 groups based on AKI development. Group I which included 50 patients who did not develop AKI, and group II which included 50 patients who developed AKI. AKI was defined based on acute kidney injury network (AKIN) classification. The Sequential Organ Failure Assessment (SOFA) scores were also calculated for all patients. Detailed medical history, demographic data and routine laboratory investigations were done. Serum NGAL was measured upon admission to ICU and upon AKI development.

Results: 60 males and 40 females were included in the study with mean age 37.52 years. As regards risks of AKI development, 9% of patients had sepsis, 15% were dehydrated, 11% had contrast exposure, 12% had rhabdomyolysis, 29% had shock and 24% had history of NSAID intake recently. On admission, there were no significant differences between the patients as regards s.creatinine, hemoglobin level and other laboratory parameters of NSAID intake recently. When compared with the levels before AKI development in the same group 272.17 ng/ml (p<0.01). Serum NGAL levels were significantly higher in group II after AKI development, with mean value 958.5 ng/ml, when compared with group I, mean value (p> 0.05). Serum levels of NGAL were significantly higher in group II, before AKI development, with mean value 44.5 (SD 22.4) ng/ml, when compared with group I, mean value (p<0.01). There was no significant correlation between NGAL levels and AKIN classification stages.

Conclusions: In the absence of diagnostic increases in serum creatinine, NGAL detects patients with likely subclinical AKI who have an increased risk of adverse outcomes. Reassessment of AKI classification and stages should be considered.

Does Previous CKD Affect Renal Recovery After Acute Kidney Injury?
Maria Isabel Acosta-Ochoa, Josefina Martin, Alicia Mendiluce.
Nephrology, Hospital Clinico Univ, Valladolid, Spain.

Background: AKI definition includes a sharp increase of serum creatinine (Scr), essentially reversible. There is a lack of consensus of a standard definition of Renal Recovery (RR). The exact course of the repair process is subject of thorough investigation. Few studies have engaged in comparing rates of RR in patients with previous impaired renal function.

Methods: Retrospective cohorts study, 12-months period. We defined RR as discharge Scr with maximum increment £25% over basal value, and non-recovery as $26%, HD dependence (%).

Results: 270 patients, AKI=125, AoCKD=145, clinical features and KDIGO stages: see table 1.

When meta-analysis was limited only to RCTs, the pooled RR of CIAKI in patients receiving nebivolol was 0.66 (95% CI, 0.38-1.15), I²(=0).

Conclusions: Despite no statistical significance, there was a trend toward reduced CIAKI risk in patients receiving nebivolol. This finding suggests the need for further studies on the use of nebivolol in addition to standard IV crystalloid hydration in the prevention of CIAKI.

The Effect of Nebivolol on Contrast-Induced Acute Kidney Injury: A Meta-Analysis
Nattika Thancharoen, Charat Thongprayoon, Witisit Cheungpasitporn.
1Dept of Medicine, Bassett Medical Center and Columbia Univ College of Physicians and Surgeons, Cooperstown, NY; 2Div of Nephrology and Hypertension, Dept of Internal Medicine, Mayo Clinic, Rochester, MN.

Background: Nebivolol provides protective effect on contrast-induced acute kidney injury (CI-AKI) in animal models. However, the reports on the efficacy of nebivolol for the prevention of CIAKI in human remain unclear. The objective of this meta-analysis was to assess the effect of nebivolol for the prevention of CI-AKI.

Methods: Comprehensive literature searches were performed using MEDLINE, EMBASE, and Cochrane Database from inception through February 2015. Studies that reported relative risks, odd ratios or hazard ratios comparing the risk of CIAKI in patients who received nebivolol versus those who did not were included. Pooled risk ratios (RR) and 95% confidence interval (CI) were calculated using a random-effect, generic inverse variance method.

Results: Four studies (2 RCT and 2 cohort studies) with 543 patients were included in our analysis to assess the risk of CIAKI and the use of nebivolol. Of 543 patients with contrast exposures, 30 patients (5.32%) had CIAKI. Patients in the nebivolol group had an overall lower incidence of CIAKI (14.35%) compared to the control group (17.43%). The pooled RR of CIAKI in patients receiving nebivolol was 0.66 (95% CI, 0.38-1.15, I²=0).

Conclusions: Despite no statistical significance, there was a trend toward reduced CIAKI risk in patients receiving nebivolol. This finding suggests the need for further studies on the use of nebivolol in addition to standard IV crystalloid hydration in the prevention of CIAKI.

Patients with Cardiovascular Diseases Are Susceptible to Acute Kidney Injury After Non-Cardiac Surgery Under Preoperative Use of Angiotensin Converting Enzyme Inhibitors or Angiotensin Receptor Blockers
Mih Magana, 1 Takayuki Hamano, Masaru Matsuki, Kazuhiko Morimoto, 1 Ken-ichi Samejima, 1 Yasuhiro Akai, 1 Yoshihiko Saito, 1 Nara Medical Univ, Nara, Japan; Osaka Univ, Osaka, Japan.

Background: It is unknown in which subgroup of patients the preoperative use of angiotensin converting enzyme inhibitors (ACE-I) or angiotensin receptor blockers (ARB) is a predictor for acute kidney injury (AKI) after non-cardiac surgery.

Methods: This is a retrospective cohort study on patients who underwent non-cardiac surgery from 2007 to 2009. After exclusion of urological surgery, missing creatinine values, and preoperative dialysis, the data for 2,725 patients were available. The exposure of interest was preoperative use of ACE-I/ARB. Primary outcome was postoperative AKI (AKIN criteria). The odds ratio (OR) of postoperative AKI among ACE-I/ARB users compared to non-users was analyzed using multivariable logistic regression models, adjusted for the logit of propensity score for ACE-I/ARB use. P=0.1 was considered statistically significant for interaction.

Results: Mean(SD) age was 61(16) and estimated glomerular filtration rate was 81(24) ml/min/1.73m². There were 4(6.8%) cases of postoperative AKI in ACE-I/ARB users and 97(2.65) (4.3%) in non-users. The adjusted OR of AKI was shown.
Whole Ischemia-Reperfusion Injury: The Effect of Whole-Body Cooling on Renal Function

Svilva De Rosa1, Zaccaria Ricci,1 Salvador Roberto Lopez,1 Jose Luis Salas,1 Stefano Marcante,1 Sara Samoni,1 Massimo de Cal,1 Silvia Maria Pulitano,2 Massimo Antonelli,2 Raffaele Bonato,1 Claudio Ronco,1

Background: Hypothermia is able to reduce the risk of renal failure after renal ischemia-reperfusion injury in animals. In humans, Cardiac Arrest (CA): a whole-body ischemia-reperfusion syndrome, causes warm renal ischemia-reperfusion injury, similar to animal models of ischemic acute kidney injury (AKI). Induced hypothermia (IH) has a treatment potentially efficacious for post-ischemic injury. It is unclear what effect could have on renal function. Aims: The aim of the study was to investigate the development of AKI during the IH.

Methods: Between Jan 2013-Mar 2015, we performed a prospective observational study of 36 comatose pts resuscitated from CA and treated with IH performed with 2 different surface cooling devices: 1) Arctic Sun Temperature Management System (Medivance, Loviusville, CO); 2) Blanket Temperature rate and trend, and the development of AKI during induction (0-6 hrs), maintenance (24 hrs), rewarming (48 hrs), and normothermia (72 hrs) was assessed with RIFLE and KDIGO criteria.

Results: Pts were enrolled and followed for the development of AKI during intensive care unit stay. In the induction and maintenance phases, the rate and the target temperature was similar; conversely, the rewarming phase was shorter with a target temperature higher in Blanket than in Arctic Sun group (458 min vs 615 min; 37.2°C vs 36.3°C). The trend and the rate of temperature, but also the development of AKI, is showed in figure 1.

Conclusions: IH could be associated with development of AKI in the rewarming phase (rate 0.25 to 0.5°C). The optimal rewarming rate is unknown. Randomized controlled trials are needed to determine the real effect of temperature on kidney, the optimal rewarming strategy and applications of this treatment for kidney in other settings.

Decongestion-Associated Worsening Renal Function Does Not Increase Mortality of Patients with Acute Heart Failure

Background: A significant subset of patients admitted for acute decompensated heart failure (ADHF) develop worsening renal function (WRF). While there is consistent data regarding the negative impact of baseline renal dysfunction on the outcomes of these patients, the evidence on the prognostic implication of WRF during admission for decongestion is less well-understood. The aim of this study is to provide a reappraisal of the effect of decongestion on the prognostic value of WRF in patients admitted for ADHF.

Methods: Articles cited in PubMed database from 1995 to 2015 using key words “congestion”, “heart failure”, “worsening renal function”, and “hemococoncentration” were searched. Those studies evaluating the relationship between decongestion, renal function, and ADHF in patients treated with diuretic-based conventional therapies were selected. Relevant data including change in renal function, diuretic dose, change in weight, and mortality were extracted and compared.

Results: A total of 12,843 patients from 13 trials (9 retrospective and 4 prospective) with data pertaining to decongestion in ADHF patients were included in this study. The mean age of the patients was 67.1 years with follow-up periods ranging from 60 days to 5.3 years. Eleven studies reported development of WRF following decongestion: The incidence of WRF was reported to be 10 to 50.1% with weight reduction ranging from 2 to 5 kg. Twelve studies did not observe any negative impact for WRF on the mortality of patients with ADHF unless associated with markers of persistent congestion such as lack of hemococoncentration.

Conclusions: Decongestion is associated with markers of fluid removal and WRF in the setting of ADHF. Currently available data suggest that decongestion-associated WRF does not result in increased mortality whereas persistent congestion is likely to be the driving factor for adverse outcomes in these patients. Randomized controlled trials are needed to confirm these findings as they could portend significant therapeutic implications in cardiac syndrome.
Conclusions: Among 1461 incident ESRD patients seen at Mayo Clinic Dialysis Services, Rochester, 2001–2013, 149 (10%) had SORO-ESRD. There was no gender age disparity between SORO-ESRD patients and the general ESRD cohort. Ninety-nine percent (99%) SORO-ESRD patients’ initial vascular access was a dialysis catheter. ATN was the leading pathologic diagnoses for AKI among KTRs and in native kidneys. Cardiac arrest was the leading cause of death in SORO-ESRD, similar to the general ESRD population. We conclude that SORO-ESRD contributes significantly to incident ESRD here in the USA both among KTRs and in native kidneys. Furthermore, it negatively impacts on the success of AVF-First Programs. Efforts to mitigate AKI in CKD patients must be given more attention and priority by practicing nephrologists in particular, and by physicians in general.

PUB040
Saline-Induced, Diuretics-Responsive Acute Renal Failure (ARF): Evidence that Anasarca Is Nephrotoxic and Diuresis Is Therapeutic
Grant Meltzer, Kai Lau, 1,2 Nephrology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK; 3 Medicine, VA Medical Center, Oklahoma City, OK.

Background: Recent studies showed the association of fluid overload in ARDS & surgical patients and increased ventilator dependency, ICU & hospital stays, short-term mortalities, & incidence of ARF. But a cause-and-effect relationship was unproven in cross-sectional observations. In grossly edematous in-patients with unexplained ARF, we tested the hypothesis that anasarca caused the renal failure & diuresis induced recovery.

Methods: Entry criteria were fully evaluable patients, ≥3 kg weight or ≥ 3 L fluid gain, ≥50% acute loss of estimated creatinine clearance (CrCl) or ≥ 2 x rise in serum creatinine (Scr) without identifiable causes. All data were reviewed, recorded, tabulated & statistically analyzed, notably vital signs, weight, intake, output & lab. 36 qualified patients were diuresed by IV furosemide at rates keeping normotension off anti-hypertensives. Serial volume markers & renal responses were noted. Palliative care & hepatorenal syndrome were excluded.

Results: Fluid overload was due to heart failure (40%), liver failure (22%), CKD (16%), proteinuria (9%) & iatrogenic factors (10%). During 42 ARF episodes, mean weight was up 12.5 kg in 13.7d. Scr rose (4.41 vs. 1.27mg/dL) & CrCl fell (25 vs. 76 ml/min). Increments in CrCl correlated with edema weight gain (p<0.02). Over 11.9, 15.2 kg of fluid were diuresed. Renal function greatly improved in 33 patients & unchanged in 3 despite >4 kg diuresis. As an entire group, Scr fell to 1.45 mg/dL & CrCl rose to 67 ml/min. Increments of CrCl also correlated with diuresis volume (p<0.04). At a diuretic rate of 1.5 kg/d, no adverse events occurred.

Conclusions: 1. Our data support the hypothesis for the entity of Saline-Induced, Diuretics-Responsive Acute Renal Failure. 2. Likely mediated by reduced cardiac output, of 1.5 kg/d, no adverse events occurred. 3. Preventable & treatable, it could cause or aggravate ARF venous congestion, renal interstitial edema &/or abdominal hypertension, it is analogous Diuretics-Responsive Acute Renal Failure. 4. Diuresis in cohorts at rates & monitored as ours should be safe to congestive kidney failure. 3. Preventable & treatable, it could cause or aggravate ARF venous congestion, renal interstitial edema &/or abdominal hypertension, it is analogous Diuretics-Responsive Acute Renal Failure. 2. Likely mediated by reduced cardiac output, of 1.5 kg/d, no adverse events occurred.

PUB041
Is RIFLE Classification a Good Shot for Staging Acute on Chronic Kidney Disease? Maria Isabel Acosta-Ochoa, Josefina Martin, Alicia Mendiluce. Nephrology, Hospital Clinico Univ, Valladolid, Spain.

Background: 8-16% of worlds population may have CKD, which is a risk factor and promoter of AKI. We tested the performance of RIFLE and KDIGO classifications in staging severity and predicting outcomes in Acute on CKD (AcuCKD) individuals. KDIGO with a 0,3mg/dl SCR increase includes patients in stage 1 category, and includes automatically in stage 3 patients with peak SCR ≤4,0 mg/dl.

Methods: Retrospective cohorts study. Patients were divided in 2 groups: AKI and AcuCKD. We collected clinical data, and classified AKI severity contrasting distribution strata between groups by RIFLE and KDIGO criteria. And tested the ability of both classifications for predicting need for HD and in hospital mortality with a AUC ROC analysis.

Results: 270 patients were included, AKI=125, AcuCKD=145. Clinical features and RIFLE and KDIGO stages are listed in table 1.

**FEATURES** | **RIFLE** | **KDIGO**
--- | --- | ---
Male (%) | 72 (66) | 78 (66)
Age (SD) | 66.9 ± 15 | 75.4 ± 11.9 | <0.001
HT (%) | 96 (77) | 131 (90) | <0.001
DM (%) | 44 (35) | 70 (48) | 0.003
Chi (SD) | 3.8 ± 2.5 | 4.4 ± 2.3 | <0.001

**No AKI (%)** | **AcuCKD (%)** | **RIFLE** | **KDIGO**
--- | --- | --- | ---
No AKI (%) | 21 (17) | 23 (16) | 0.83
Risk (%) | 22 (17) | 35 (24) | 0.18
Injury (%) | 17 (14) | 44 (30) | <0.001
Failure (%) | 65 (52) | 43 (30) | <0.001

65% males, AcuCKD individuals were older 66,9y, and had worst Charlson Index (Chal) 4,4. In figure 1 are shown AUC ROC curves for adverse outcomes.

Conclusions: The KDIGO staging criteria we obtain more homogeneous distribution strata. With the ROC-analysis neither classification performs better in predicting adverse outcomes. We found no practical advantage when using neither classification. In the noAKI (by RIFLE) stratum no adverse event was present, so by including a 0,3mg/dL SCR increase augments sensibility, but may be not especificity.

PUB042
Francois Paquette,1 Amelie Bernier-Jean,1 Veronique Brunette,1 Vincent Pichette,2 Helene Ammann,3 Stephan Troyanov,3 Josee Bouchard.1 Hôpital du Sacre-Coeur de Montreal, Canada; 2 Hôpital Maisonneuve-Rosemont, Canada.

Background: The KDIGO guidelines recommended to avoid aminoglycosides (AG) in patients at risk or with acute kidney injury (AKI). We determined the frequency of administration, incidence of AKI, and risk factors for AKI and absence of renal recovery in patients receiving AG over the last decade.

Methods: We performed a retrospective cohort study on AG administration in two university-affiliated centers, and then performed a nested case-control study, pairing AG-AKI cases to 2 controls for age and gender. AKI was defined by a 50% increase in creatinine after ≥5 days of AG up until 7 days after cessation of AG, and renal recovery, by a decrease in creatinine to within 50% of baseline creatinine over 3 weeks after cessation of AG.

Results: Between 2001 and 2015, the frequency of AG administration and drug dosing progressively declined. Out of 562 patients, sixty-five developed AKI attributed to AG (12%). In the case-control study (n=195), age was 71 (IQR 58-81) and 46% were male. The duration of AG administration was 10.0 (IQR 7.0-15.0) days, excluding days after AKI diagnosis in AKI patients. Maximal AKI stage was 1 for 55.3%, 2 for 29.2% and 3 for 15.4% of patients. Independent risk factors associated with AKI were concomitant vancomycin administration, high trough levels, heart failure, and site of infection (endocarditis and febrile neutropenia vs. other). Only fifty-one percent (50.8%; 33/65) of patients recovered their kidney function. These patients had an AKI duration of 7.0 (IQR 4.0-11.5) days. Heart failure was associated with a lower likelihood of renal recovery, while cancer patients more likely recovered their kidney function.

Conclusions: Over the last decade, the frequency of AG administration and dosing have progressively decreased but the incidence of AKI remained unchanged. In our cohort, vancomycin administration, high trough levels, heart failure, and site of infection were independent risk factors associated with AKI. Almost half of patients did not recover their kidney function, which was more often seen in patients with heart failure.
PUB043
Prairie Continuous Renal Replacement Therapy (CRRT) Study – Outcomes of CRRT in a Single Canadian Tertiary Centre  
Bharm Prasad,1 Michelle Urbanski,2 Erwin Karremann,3 1Nephrology, Regina Qu’Appelle Health Region, Regina, SK, Canada; 2College of Medicine, Univ of Saskatchewan, Regina, SK, Canada; 3Research and Performance Support, Regina Qu’Appelle Health Region, Regina, SK, Canada.

Background: Patients with stage III Acute Kidney Injury (AKI) requiring Renal Replacement Therapy (RRT) have the highest short-term and long-term mortality of any group with AKI. Our study aimed to prospectively follow patients with stage III AKI on Continuous Renal Replacement Therapy (CRRT) during their hospitalization in our tertiary care centre from April 2013 to September 2014.

Methods: We prospectively gathered the following: date and time of hospital admission, transfer to ICU, and starting CRRT, creatinine at admission and at CRRT initiation, weight on admission and at CRRT initiation. Duration of oliguria and anuria, exposures (sepsis, critical illness, circulatory shock, trauma, cardiac surgery, major non cardiac surgery, nephrotoxic medications, and radio contrast agents) and susceptibilities (dehydration, <65 years of age, female, pre existing CKD), APACHE score II, Inotrope support, FiO2, ECMO. Survival on CRRT, in ICU and hospital survival and renal survival was documented.

Results: Of the 2634 patients (2201/2634.83.5% had no AKI, and (269/2634)10.2% had stage III AKI of whom 106/269 (40%) were started on CRRT. 8/106 died in ICU and 3 for measurement of SCr.

Conclusions: AKI associated with 62% mortality in hospital. 17/106 died within 24 hours of initiating therapy. 1/106 died within 24 hours of starting CRRT. This raises a clinical concern of the benefit vs futility of initiating CRRT in specific settings.

PUB044
Urinary Liver Fatty Acid Binding Protein Predicts Acute Kidney Injury Associated with Abdominal Aortic Repair  
Daisuke Ichikawa,1 Atsuko Ikeno,1 Takeshi Sugaya,1 Kenjiro Kimura,2 Yugo Shibagaki.1 1Nephrology and Hypertension, St. Marianna Univ School of Medicine, Kawasaki, Kanagawa, Japan; 2Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.

Background: Acute kidney injury (AKI) is common problem after cardiovascular surgery. AKI is usually diagnosed on the basis serum creatinine (SCr) and urinary output. However, SCr is of low sensitivity in patients with poor renal function. Because urinary liver-type fatty acid binding protein (L-FABP) reflects renal tubular injury, we evaluated whether perioperative changes in urinary L-FABP can predict AKI.

Methods: Subjects were 68 patients who underwent EVAR and 32 patients who underwent open repair. We obtained urine samples before surgery, after anesthesia induction, before aortic cross-clamping (AXC), 1 and 2 hours after AXC, at the end of surgery, and on POD 1, 2, and 3 for measurement of urinary L-FABP and urinary albumin in the open repair patients. We obtained urine samples before surgery, after anesthesia induction, before aortic cross-clamping (AXC), 1 and 2 hours after AXC, at the end of surgery, and on POD 1, 2, and 3 for measurement of urinary L-FABP and urinary albumin in the open repair patients. We obtained urine samples before surgery, immediately after surgery, and on POD 1, 2, and 3 for measurement of SCr.

Results: AKI developed in 5 (7.4%) EVAR patients and in 9 (28.1%) open repair patients with EVAR, urinary L-FABP was increased 4 hours after the procedure (P = 0.002) and it decreased but remained elevated for 3 POD (P = 0.003). With AKI, SCr increased (P = 0.004) and eGFR decreased (P = 0.003) by POD2. SCr and eGFR did not change in patients in whom AKI did not develop. With open repair, urinary L-FABP increased significantly to its maximum by 2 h after AXC (P = 0.008) and then decreased gradually over the 3 PODs (P = 0.038). The increase in urinary L-FABP was greater with open repair than with EVAR. ROC analysis showed urinary L-FABP to be more sensitive than SCr, eGFR, and urinary albumin for early detection of AKI.

Conclusions: Urinary L-FABP appears to be a sensitive biomarker of AKI in patients undergoing abdominal aortic surgery, especially those treated by EVAR.

PUB045
C3 Glomerulopathy: A Pediatric Case  
Luis A. Ortiz,1 Daniel Kleven,2 Harika Gorri.1 1Ped. Nephrology, Georgia Regents Univ, Augusta, GA; 2Pathology, Georgia Regents Univ, Augusta, GA; 3MCG, Georgia Regents Univ, Augusta, GA.

Background: C3 glomerulopathy (C3G) is characterized by C3 deposit in the glomeruli with minimal Ig deposition. C3G is described as an unregulated activation of the alternative complement pathway due to a genetic mutations in Factor H or, or acquired factors such as C3 nephritic factor, an IgG autoantibody stabilizing C3 convertase. The pattern of the injury varies from mesangio-proliferative, membranoproliferative, to endocapillary proliferative glomerulonephritis. EM finding includes subacut hump shaped subepithelial deposits, characteristic of acute post-infectious glomerulonephritis (PIGN). We present a pediatric case that met the initial criteria for PIGN, but was diagnosed as C3G according the pathology.

Methods: 15 y/o AA M with Thin Basement D, HTN, asthma presented with 1 h of sore throat, gross hematuria, facial swelling, no distal edema. Initial oliguria and high Cr. PE revealed periorbital edema, no pharyngeal erythema, lung clear, abdomen with no ascites. On admission, Hb 11.6 g, Cr:3.26mg, Albumin:2.5 gr, UA:20-50 RBC. Despite treatment with methylprednisolone, albumin and furosemide, his Cr. increased to 6.48, ASO 654 UI, adNAbs normal, CRP 12.6. Group A strep was negative for growth. Kidney biopsy: glomeruli w/segmental sclerosis, endocapillary infiltration of neutrophils, IF: extensive C3 staining with scant IgG and small fibrin deposition (focal necrosis). EM: large subepithelial deposits. Worsening kidney function required hemodialysis. After 6 months, he continues on Hemodialysis.

Conclusions: Kidney biopsy with C3 dominant on IF, large subepithelial deposits on EM, hypocomplementemia and clinical of gross hematuria preceded by URI suggested acute PIGN, but this overlaps with the histological presentation of C3G of C3 dominant staining with scant IgG deposition, subepithelial deposits and low serum C3. No resolution of AKI after 8 weeks of presentation was unusual for PIGN, steering diagnosis towards C3G. Clinicians should note the high overlap between the clinical and histology of PIGN and C3G. It is imperative to conduct further studies to accurately diagnose and treat patient with C3G.

PUB046
Predictors of End Stage Renal Disease in Scleroderma Renal Crisis – A Single Center Experience  
Sumeedh Dhax, Cybele Ghossein. Div of Nephrology, Northwestern Univ - Feinberg School of Medicine, Chicago, IL.

Background: Scleroderma renal crisis (SRC) is one of the most acute and life-threatening complications of systemic sclerosis (SSc). It is typically characterized by accelerated hypertension and acute kidney injury (AKI). Angiotensin converting enzyme inhibitors (ACEI) are currently the treatment of choice for this disease. Despite use of ACEI, 50% of patients with SRC develop end stage renal disease (ESRD) which is associated with poor long term outcomes. Our aim was to define the clinical characteristics and outcomes of SRC patients admitted to our institution.

Methods: This was a retrospective chart review of all patients admitted with SRC to Northwestern Memorial Hospital (NMH) between the years of 1/1994 to 4/2015. ESRD was defined as the need for chronic dialysis during admission for SRC.

Results: There were 23 patients with a diagnosis of SRC made either clinically or by renal biopsy during this time period. Mean time to SRC was 1.3 years after diagnosis of SSc. 47% of patients developed ESRD during the same admission. Development of ESRD was not associated with age, gender, race, anti-RNA polymerase III test positivity, intensive care unit (ICU) admission, prior ACEI or angiotensin receptor blocker (ARB) use, or creatinine on admission. ESRD was significantly associated with time to control blood pressure.

Hassan,

in this clinical setting. Required to develop a more sensitive validated AKI predictive tool which would be useful age alone as a predictor of AKI.

that use of common patient associated known AKI risk factors performs no better than had ≥2 AKI risk factors compared with 55% of those with no AKI. ROC analysis suggests AKI. When age ≥65 yrs was added as an independent risk factor 84% of those with AKI cohort 72% of the patients had ≥2 AKI risk factors compared to 43% of the cohort with no AKI. Patients with AKI were older and had a higher number of AKI risk factors. In the AKI associated AKI-risk factors. Subsequently, 898 patients were assessed for a limited number of risk factors in patients ≥65yrs. In the second cohort 12.3% presented with or developed with a positive relationship between age and the number of risk factors and a higher number of AKI episodes.

Acute Kidney Injury Risk Assessment at the Hospital Front Door: What Is the Best Measure of Risk? Aled O. Phillips,1 Dafydd Phillips,1 Mohamed Hassan,2 John Geen,3 Vikas Lodhi,1 Hernanath Bolusani,4 Gareth Roberts,1 1Nephrology, Cardiff Univ School of Medicine, Cardiff, Wales, United Kingdom; 2Dept of Clinical Biochemistry, Univ of South Wales, Wales, United Kingdom; 3Dept of Medicine, Royal Gwent Hospital, Newport, Wales, United Kingdom; 4Dept of Medicine, Univ Hospital of Wales, Cardiff, Wales, United Kingdom; 5Dept of Medicine, Prince Charles Hospital, Merthyr Tydfil, Wales, United Kingdom; 6Dept of Medicine, Univ Hospital Llandough, Cardiff, United Kingdom.

Background: We examined the prevalence of AKI-risk factors in the emergency medical unit, generated a modified risk assessment tool and tested its ability to predict AKI.

Methods: 1196 patients admitted to medical admissions units were assessed for patient associated AKI-risk factors. Subsequently, 898 patients were assessed for a limited number of fixed risk factors with the addition of hypertensive and sepsis. This was correlated to AKI episodes.

Results: In the first cohort the prevalence of AKI risk factors was 2.1±2.0 per patient, with a positive relationship between age and the number of risk factors and a higher number of risk factors in patients ≥65yrs. In the second cohort 12.3% presented with or developed AKI. Patients with AKI were older and had a higher number of AKI risk factors. In the AKI cohort 72% of the patients had ≥2 AKI risk factors compared to 43% of the cohort with no AKI. When age ≥65 yrs was added as an independent risk factor 84% of those with AKI had ≥2 AKI risk factors compared with 55% of those with no AKI. ROC analysis suggest that use of common patient associated known AKI risk factors performs no better than age alone as a predictor of AKI.

Conclusions: Detailed assessment of well established patient associated AKI-risk factors may not facilitate clinicians to apportion risk. This suggests that additional work is required to develop a more sensitive validated AKI predictive tool which would be useful in this clinical setting.

Acute Kidney Injury, Requiring Renal Replacement Therapy – Incidence, Causes and Outcomes: One Center Experience Elena Zakhartova, Nephrology, City Clinical Hospital n.a. s.P. Botkin, Moscow, Russian Federation.

Background: Acute Kidney Injury (AKI) is complex condition, associated with high mortality and morbidity. We aimed to evaluate AKI incidence, causes, risk factors and outcomes in patients, managed in nephrology unit of general hospital and urgently requiring Renal Replacement Therapy (RRT).

Methods: Using electronic database for 2010-2014 (4531 admissions, 2257 patients), we searched 604 cases which met KDIGO AKI definition, and selected patients, required RRT.

Results: Study group included 115 patients (19% of all AKI cases), 51 (44%) male, 64 (56%) female, median age 61 [22; 89] years. In 102 (89%) cases AKI was community acquired. Median serum creatinine prior to start of RRT was 981 [242; 2665] µmol/l, 37 (32%) patients had known CKD. Causes and susceptibilities for AKI are shown in table.

Conclusions: SRC is a serious kidney and life threatening complication of SSC. Delay in blood pressure control increases risk of ESRD in SRC patients.

Acute Kidney Injury Risk Assessment at the Hospital Front Door: What Is the Best Measure of Risk? Aled O. Phillips,1 Dafydd Phillips,1 Mohamed Hassan,2 John Geen,3 Vikas Lodhi,1 Hernanath Bolusani,4 Gareth Roberts,1 1Nephrology, Cardiff Univ School of Medicine, Cardiff, Wales, United Kingdom; 2Dept of Clinical Biochemistry, Univ of South Wales, Wales, United Kingdom; 3Dept of Medicine, Royal Gwent Hospital, Newport, Wales, United Kingdom; 4Dept of Medicine, Univ Hospital of Wales, Cardiff, Wales, United Kingdom; 5Dept of Medicine, Prince Charles Hospital, Merthyr Tydfil, Wales, United Kingdom; 6Dept of Medicine, Univ Hospital Llandough, Cardiff, United Kingdom.

Results: In the first cohort the prevalence of AKI risk factors was 2.1±2.0 per patient, with a positive relationship between age and the number of risk factors and a higher number of risk factors in patients ≥65yrs. In the second cohort 12.3% presented with or developed AKI. Patients with AKI were older and had a higher number of AKI risk factors. In the AKI cohort 72% of the patients had ≥2 AKI risk factors compared to 43% of the cohort with no AKI. When age ≥65 yrs was added as an independent risk factor 84% of those with AKI had ≥2 AKI risk factors compared with 55% of those with no AKI. ROC analysis suggest that use of common patient associated known AKI risk factors performs no better than age alone as a predictor of AKI.

Conclusions: Detailed assessment of well established patient associated AKI-risk factors may not facilitate clinicians to apportion risk. This suggests that additional work is required to develop a more sensitive validated AKI predictive tool which would be useful in this clinical setting.

Acute Kidney Injury, Requiring Renal Replacement Therapy – Incidence, Causes and Outcomes: One Center Experience Elena Zakhartova, Nephrology, City Clinical Hospital n.a. s.P. Botkin, Moscow, Russian Federation.

Background: Acute Kidney Injury (AKI) is complex condition, associated with high mortality and morbidity. We aimed to evaluate AKI incidence, causes, risk factors and outcomes in patients, managed in nephrology unit of general hospital and urgently requiring Renal Replacement Therapy (RRT).

Methods: Using electronic database for 2010-2014 (4531 admissions, 2257 patients), we searched 604 cases which met KDIGO AKI definition, and selected patients, required RRT.

Results: Study group included 115 patients (19% of all AKI cases), 51 (44%) male, 64 (56%) female, median age 61 [22; 89] years. In 102 (89%) cases AKI was community acquired. Median serum creatinine prior to start of RRT was 981 [242; 2665] µmol/l, 37 (32%) patients had known CKD. Causes and susceptibilities for AKI are shown in table.

Conclusions: SRC is a serious kidney and life threatening complication of SSC. Delay in blood pressure control increases risk of ESRD in SRC patients.

Acute Kidney Injury Risk Assessment at the Hospital Front Door: What Is the Best Measure of Risk? Aled O. Phillips,1 Dafydd Phillips,1 Mohamed Hassan,2 John Geen,3 Vikas Lodhi,1 Hernanath Bolusani,4 Gareth Roberts,1 1Nephrology, Cardiff Univ School of Medicine, Cardiff, Wales, United Kingdom; 2Dept of Clinical Biochemistry, Univ of South Wales, Wales, United Kingdom; 3Dept of Medicine, Royal Gwent Hospital, Newport, Wales, United Kingdom; 4Dept of Medicine, Univ Hospital of Wales, Cardiff, Wales, United Kingdom; 5Dept of Medicine, Prince Charles Hospital, Merthyr Tydfil, Wales, United Kingdom; 6Dept of Medicine, Univ Hospital Llandough, Cardiff, United Kingdom.

Background: We examined the prevalence of AKI-risk factors in the emergency medical unit, generated a modified risk assessment tool and tested its ability to predict AKI.

Methods: 1196 patients admitted to medical admissions units were assessed for patient associated AKI-risk factors. Subsequently, 898 patients were assessed for a limited number of fixed risk factors with the addition of hypertensive and sepsis. This was correlated to AKI episodes.

Results: In the first cohort the prevalence of AKI risk factors was 2.1±2.0 per patient, with a positive relationship between age and the number of risk factors and a higher number of risk factors in patients ≥65yrs. In the second cohort 12.3% presented with or developed AKI. Patients with AKI were older and had a higher number of AKI risk factors. In the AKI cohort 72% of the patients had ≥2 AKI risk factors compared to 43% of the cohort with no AKI. When age ≥65 yrs was added as an independent risk factor 84% of those with AKI had ≥2 AKI risk factors compared with 55% of those with no AKI. ROC analysis suggest that use of common patient associated known AKI risk factors performs no better than age alone as a predictor of AKI.

Conclusions: Detailed assessment of well established patient associated AKI-risk factors may not facilitate clinicians to apportion risk. This suggests that additional work is required to develop a more sensitive validated AKI predictive tool which would be useful in this clinical setting.

function checked, 48 – 72 hours after contrast exposure. Their renal function pre and post contrast exposure was documented. The eGFR more than 20% was then referred to the nephrology department for follow up.

Results: A total of 277 patients were included in this audit. The mean eGFR was 47 ml/min/1.73m². 79% of patients had their renal function checked within 48 – 72 hours, 15% patients had their renal function checked after that time and 6% of patients did not have their renal function rechecked at all. Only 0.7% of patients had deterioration of their renal function that met the criteria above. However it was important to note that, these patients had also other multiple co-morbidities and the exposure to contrast was not the only factor to the deterioration of their renal function.

Conclusions: Oral hydration should be considered as part of the protocol for the prevention of contrast-induced nephropathy. This regime has reduced the need for patients to be admitted into hospital admission for intravenous fluids, thus reducing waiting times for imaging and as well as reducing hospital cost.

### PUB054

**Gemicitabine-Mediated Thrombotic Microangiopathy – A Rare Cause of Hemolytic Uremic Syndrome**

**Natalie M. Ertz-Archambault, Ibrahim Qaqish, Leslie E. Thomas**

**Internal Medicine, Mayo Clinic Arizona; Nephrology and Hypertension, Mayo Clinic Arizona.**

**Background:** Thrombotic microangiopathy (TMA) is a pathological diagnosis of endothelial cell injury and microvascular thrombosis. TMA has been categorized in the present era as one of three distinct disease processes: 1) classical hemolytic uremic syndrome, 2) atypical hemolytic uremic syndrome (aHUS), and 3) thrombotic thrombocytopenic purpura. Our focus, aHUS, reflects an underlying aberrancy in regulation of a complement component cascade. Several genetic defects have been identified leading to an affinity to develop uncontrolled activation of this cascade which may commence after exposure to a trigger. Gemicitabine is one rare trigger described in the literature.

**Methods:** A 66-year-old female with locally advanced, unresectable pancreatic cancer who had completed 12 cycles of gemcitabine-abraxane therapy with no major oncologic progression. However, disease was progressed with acute kidney injury (AKI). Two months after admission, she developed hypertension, nausea, and profound cytopenias requiring platelet and red cell transfusion. She endured a progressive decline in renal function with a nadir eGFR 19 mg/L/1.73 m². One month prior to admission, her urinanalysis reflected active sediment. Admission labs demonstrated microangiopathic anemia with thrombocytopathy. ADAMTS13 activity was normal (88%), consistent with aHUS. Renal biopsy confirmed subacute changes consistent with TMA. Despite discontinuation of the gemcitabine-abraxane therapy, she continued to demonstrate progressive anemia and thrombocytopenia in addition to persistent proteinuria, hematuria, and impaired eGFR. The patient was subsequently initiated on eculizumab therapy.

**Conclusions:** Gemicitabine-mediated aHUS is rare and associated with a 75% mortality rate at four months. Previous attempts at therapy have included apheresis. However, current guidelines discourage apheresis in this patient population. To date, six cases of gemcitabine-mediated aHUS have reported the successful use of eculizumab, a terminal complement inhibitor.

### PUB055

**Intravenous Contrast Material Administration Increases Mortality in Patients with Acute Kidney Injury Requiring Renal Replacement Therapy**

**Katsuhito Iwarg, Atsuki Ohashi, Yoshito Iida, Makiko Kubayashi, Hitomi Tanaka, Seiji lnohsta. Internal Medicine, Tokyo Metropolitan Bokutoh Hospital, Japan.**

**Background:** Contrast material exposure is well known to induce acute kidney injury (AKI); however, it is yet unclear whether contrast material administration is related to the prognosis of AKI. We hypothesized that intravenous contrast material administration might be a poor prognostic factor for short-term mortality in AKI requiring renal replacement therapy (RRT).

**Methods:** We enrolled AKI patients in our hospital, who have been prescribed RRT for the first time, from January 2012 to December 2013 and collected the baseline information and data. Patients already initiated on continuous hemodialysis or peritoneal dialysis, patients almost reaching end-stage kidney disease with vascular access, and patients admitted to our hospital with cardiopulmonary arrest were excluded. The primary outcome was 28 days mortality from initiation of RRT. We divided the patients into two groups, either with or without exposure to contrast material after admission to our hospital.

The effect of contrast material exposure was evaluated by univariate and multivariate cox proportional hazard ratio.

**Results:** One hundred and seventy seven patients were eligible. Seventy one patients were male, age 63 ± 14 years. Only 15% of patients were hospitalized. Mean serum creatinine was 5.5 ± 5.0 mg/dL, and mean urine output for six hours was 2.64 ± 2.93 mL/kg. Contrast material was administered in 50.6% of the patients. Each the exposure group and non-exposure group included 86 and 84 patients, respectively, and the 28 day mortalities of each group were 55.8% and 36.9 respectively. The hazard ratio in the exposure group was 2.866 [95% confidence interval (C.I.) 1.573–4.517] (p = 0.000) by univariate analysis. After adjustment by hypertension, sepsis, ischemia, and diuretics usage, which were the significantly different cofounders between the two groups, the hazard ratio was 1.987 [95% C.I. 1.093-3.610] (p = 0.024).

**Conclusions:** Our results demonstrated that intravenous contrast material administration is an independent risk factor for mortality in patients with AKI requiring RRT.

### PUB056

**Uncovering Complement Mediated Thrombotic Microangiopathy: Use of a Real Time Genetic Assay in the Diagnosis of Atypical Hemolytic Uremic Syndrome**

In J C Honemann, 3. Dept of Medicine, California Pacific Medical Center, San Francisco, CA.

**Background:** Improved diagnostic tests and greater understanding of pathophysiology of thrombotic microangiopathy (TMA) have led to more rapid differentiation of various types of TMAs. While ability to rapidly diagnose TTP (ADAMTS13 activity < 5%) has improved, atypical HUS (aHUS) remains diagnosis of exclusion due to poor sensitivity, high cost, and long turnaround time (TAT) of aHUS genetic assays. We describe a patient (pt) with hypothyroidism and renal insufficiency diagnosed with aHUS, using appropriate clinical algorithms for TMA, including “real-time” aHUS genetic assay (TAT 2-5 days).

**Methods:** 59 y.o. female with l-2 week (wk) history of fatigue, anemia, thrombotic thrombocytopenia, renal insufficiency, and recent diagnosis of hypothyroidism with changes in CBC and creatinine (Cr) over 3 wks: hemoglobin (hgb) 13.9 to 7.1 g/dl, platelet count (plt ct) 241 to 68 X 10⁹/L, and Cr 0.71 to 1.41 mg/dl (baseline Cr 0.56, BML 19.5). Pt’s CNS status normal; no other signs/symptoms of systemic thrombosis noted. Additional labs: haptoglobin <9 mg/dL, LDH 1942 U/L (312-618 U/L), direct coombs negative, PT/ aPTT normal, fibrinogen normal, 5-6 schistocytes/high power field, ADAMTS13 activity 79% (40-130%) ruling out TTP.

**Results:** Pt received 11 plasma exchange (PE) treatments (txs) (hospital day [HD] 3-21). By day 4 of PE (HD 7), plt ct 197 X 10⁹/L; despite 11 PE txs, LDH remained elevated (686-2123) and Cr rose to 2.72 (3.8-4.9X higher than baseline). aHUS genetic panel (sent HD 10, results on HD 17) revealed: positive variant in CFI gene (predicted to be significant, but not previously described) and hyperhomocysteinemia mutations for 3 CFH polymorphisms. Pt clinically diagnosed with aHUS, received meningococcal vaccine (HD 20), and cefopliclavin (2 wk course). Induction eculizumab started and PE stopped (HD 21). After 2’ months of eculizumab, pt’s Cr normalized.

**Conclusions:** With development of improved genetic testing (ie, increased sensitivity and speed), aHUS genetic assays may represent “real-time” diagnostic tools enabling more rapid assessment of selected TMA cases leading to more targeted treatment.

Dabigatran Induced Acute Kidney Injury and Management with Hemodialysis

Daren W. Grabe,1,2 Syed S. Haqiqi.1 1Dept of Pharmacy Practice, Albany College of Pharmacy and Health Sciences, Albany, NY; 2Dept of Medicine, Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.

Background: A 55-year-old man with a history of A Fib, cirrhosis, portal HTN, esophageal varices arrives in the ED, transferred from an outside hospital following initial presentation with multiple episodes of hematemesis and melena. Medication regimen recently changed with a switch from warfarin to dabigatran 8 months prior to admission in order to avoid frequent INR checks.

Methods: On admission, initial blood work was obtained and revealed: Hg 6.3 g/dL, INR 6.9, Sc 15.6 mg/dL, and BUN 189 mg/dL. Patient was admitted to the intensive care unit for management of acute blood loss and AKI. On physical exam shows a pulse of 95 bpm and BP of 111/75 mmHg and mild heptospotomegaly, the physical exam was unremarkable. Dabigatran was discontinued and patient was transfused with packed red blood cells and fresh frozen plasma and administered vitamin K. Hemodialysis was initiated and continued throughout the hospital course. Kidney biopsy was performed and was consistent with ATN, chronic tubulointerstitial nephritis, and IgA Nephropathy (HAAS class I).

Results: Serum dabigatran concentration (conc) drawn on admission was 860 ng/mL. Following the initial emergent hemodialysis (HD) procedure, subsequent dabigatran conc. were determined during the second HD procedure. Predialysis and postdialysis dabigatran conc. were 130 ng/mL and 30 ng/mL, respectively. Pharmacokinetic parameters were calculated and shown in the table.

Over the hospital course, patient required regular HD, Hg stabilized following transfusion and vitamin K. Patient was stable on discharge with a serum creatinine of 5.9 mg/dL and remained on dialysis.

Conclusions: Dabigatran induced AKI is rare. The mechanism of the insult in this case was unclear but acute blood loss leading to prolonged ischemic insult was largely contributive. Hemodialysis was successful in removing the offending agent with resolution of bleeding but patient remains dialysis dependent.

PUB057

Relation Between BNP And NGAL, with Bioelectrical Cardiothoracic Impedance Hemodynamics Parameters in Patients with Cardiorenal or Renocardiac Syndrome

Background: Evaluate the application of cardiothoracic bioimpedance (CTBIA) in the classification of patients with cardiorenal or renocardiac syndrome.

Methods: We use a cohort with 18 patients (mean age years 72 SD 2.6, males 77 %) with cardiorenal or renocardiac syndrome. We evaluate hemodynamic parameters (cardiac output –CO, cardiac output index –COI, left ventricular work index –LVWI, and systemic vascular resistance index –SVRI) with BNP (pg/ml, limits 0-100) and NGAL (ng/ml, limits 0-149).

Results: Mean levels of BNP were 545.71 (SD 128.8) and mean levels of NGAL were 500.11 (SD 96.25). Only vascular resistance index was associated with NGAL (r=-0.461, p=0.054). Not found associations with BNP . However we classify patients in four groups:

- Group 1: patients with an increase in vascular resistance and an increase in cardiac output (cardiac overload) and higher BNP (BNP-NGAL).
- Group 2: patients with an increase in vascular resistance and an increase in cardiac output (cardiac overload) and higher BNP (BNP-NGAL).
- Group 3: patients with renal dysfunction (renocardiac) and higher NGAL (p=0.054). Not found associations with BNP .
- Group 4: patients with a decrease in vascular resistance and a decrease in cardiac output (cardiac underload) and lower BNP (BNP-NGAL).

Conclusions: The use of CTBIA is useful to evaluate and classify patients with cardiorenal or renocardiac syndrome. There are associations between vascular resistance and renal tubular necroses.

PUB058

Recovery of Renal Function After Removal of Functional Causes of Advanced Renal Failure

Maria-Eleni Roumelioti,1 Faraz Khan Luni,2 Sandeep Vetteth,2 Darlene Melinda Vigil,1,3 Kavitha Ganta,1,3 Deepak K. Malhotra,2 Antonios Tzamaloukas.1 1Univ of New Mexico; 2Univ of Toledo; 3Raymond G. Murphy VA Medical Center.

Background: It is important to predict whether renal function recovers completely, early in the course of functional azotemia. We hypothesized that the level of renal function can be predicted from the early change in serum creatinine concentration ([Cr]) during treatment of functional azotemia.

Methods: Taking into account the changes in the body pool of Cr at diagnosis and Cr production during treatment, we calculated the Cr clearance (CrCl) between the [Cr] levels in the blood sample obtained at presentation ([Cr1]) and in the first blood sample after the initiation of non-dialytic treatment ([Cr2]) in 6 pts, 5 men with urinary retention and a woman with prerenal azotemia. The calculated CrCl value was used to predict [Cr] levels corresponding to times of subsequent [Cr] measurements. We compared the predicted [Cr] levels to the corresponding measured ones.

Results: The table shows [Cr1] and [Cr2] levels, calculated CrCl values, predicted and measured [Cr] levels at steady state after correction of the azotemia ([Cr]eq). Predicted and measured [Cr]eq values were close.

Relation of Cardiothoracic Bioelectrical Impedance Hemodynamics and Volemics Parameters with Acute Kidney Injury Prognosis

Background: Evaluate the relation of hemodynamics and volemics parameters with cardiothoracic bioimpedance (CTBIA) and Acute Kidney Injury (AKI) prognosis.

Methods: We use a cohort of 21 patients (mean age 69 years SD 2.8, 76.2% males) with AKI. We evaluate hemodynamic parameters (cardiac output –CO, cardiac output index –COI, left ventricular work index –LVWI, and systemic vascular resistance index –SVRI) and thoracic volemics parameters (Thoracic fluid volume -TVF, Thoracic fluid volume index –TVFI and systolic volume –SV) with clinical index prognosis (severity individual index –SI), analytical parameters (c-reactive protein –CRP, prealbumin –PRALB, albumin –ALB) and chronic health index (Karnofsky –K).

Conclusions: The use of CTBIA is useful to evaluate and classify patients with cardiorenal or renocardiac syndrome.
Results: Patients with lower vascular resistance and higher cardiac work have worse prognosis, associated with inflammatory state and thoracic hypervolemia, oliguria and higher renal replacement therapy requirements. But patients with higher thoracic volumes have higher risk of respiratory failure.

### Conclusion

Foscarnet crystal-induced nephropathy has been reported in a limited number of immunosuppressed states resulting in CMV infection, including AIDS and solid organ transplantation. Foscarnet is solely eliminated by glomerular filtration and renal injury is typically characterized by reversible tubular necrosis. Foscarnet chelates metallic ions and frequently complexes with ionized calcium to form a highly insoluble salt that cannot be filtered by the kidney. This patient’s pre-treatment renal function was adequate despite history of a solitary functioning kidney. Altered renal hemodynamics in the solitary kidney may have enhanced precipitation of Foscarnet-calcium salts despite adequate hydration.

### PUB062

Comparison of Estimated Glomerular Filtration Rate (eGFR) and Kinetic eGFR (KeGFR) in Critically Ill Intensive Care Unit (ICU) Patients

**Background:** Estimation of kidney function in critically ill patients is important for appropriate drug dosing and therapeutic strategies. However, current GFR equations are not applicable when plasma creatinine (sCr) is rapidly changing. Chen et al (JASN 2013) has recently proposed KeGFR formula to calculate GFR from fluctuating sCr values. The aim of this study was to compare KeGFR values with eGFR using the Modification of Diet in Renal Disease (MDRD).

**Methods:** We analyzed data from a cohort of 735 ICU patients screened in a prospective observational study on the incidence of AKI from June06 to Dec08 at an academic center. Demographic data, comorbidities, clinical course, and laboratory parameters were recorded from ICU admission. We estimated KeGFR and eGFR for each patient during the first 48 hr of ICU stay. We defined KeGFR = (sCrPer × CrCl/ Mean Pcr) × (1 - 24 × Δ Per / Δ Time (h) × Max Δ Per/Day) and MDRD eGFR = 175 × (sCr (ml/dL) / 88.4) × (Age)0.329 × (0.742 if female) = (1.212 if African American). We compared estimated GFR assessed by kinetic formula and MDRD GFR equation.

**Results:** We analyzed data from a cohort of 735 ICU patients screened in a prospective observational study on the incidence of AKI from June06 to Dec08 at an academic center. Demographic data, comorbidities, clinical course, and laboratory parameters were recorded from ICU admission. We estimated KeGFR and eGFR for each patient during the first 48 hr of ICU stay. We defined KeGFR = (sCrPer × CrCl/ Mean Pcr) × (1 - 24 × Δ Per / Δ Time (h) × Max Δ Per/Day) and MDRD eGFR = 175 × (sCr (ml/dL) / 88.4) × (Age)0.329 × (0.742 if female) = (1.212 if African American). We compared estimated GFR assessed by kinetic formula and MDRD GFR equation.

**Conclusions:** Our study highlights the overestimation of renal function by MDRD equation in critically ill patients with acute kidney injury (AKI). KeGFR may be more accurate in tracking renal function changes in AKI. Further studies are needed to confirm these findings.
PUB063
Contrast Induced Nephropathy Among Hospitalized South Africans – Impact of Serum Albumin
Jastor Band, 1 Saradalevi Naicker. 1 Faculty of Health Sciences, Univ of the Witwatersrand, Johannesburg, Gauteng, South Africa; 2Faculty of Health Sciences, Univ of the Witwatersrand, Johannesburg, Gauteng, South Africa.

Background: Despite ranking 3rd as cause of hospital acquired acute kidney injury in hospitalized patients, contrast induced nephropathy (CIN) causes significant morbidity, mortality and high hospital costs. In sub-Saharan Africa, information on rates of CIN is lacking. This study investigated the rates of CIN and influence of serum albumin on CIN.

Methods: This is an on-going prospective case controlled study conducted at Charlotte Maxeke Johannesburg Academic Hospital, in South Africa. In-patients undergoing contrast media administration in the Divisions of Radiology and Cardiology were consecutively recruited to the study. Ethical approval was obtained from the Human Research Ethics Committee of the University of the Witwatersrand. CIN was defined as serum Creatinine >25µmol/L or >44µmol/L from baseline over a 48-72 hours post exposure to contrast media. Risk assessment was calculated using the CKD-EPI. The following were exclusion criteria; age below 18years, evidence of AKI (clinical or laboratory), ESRD and prior contrast contrast media administration.

Results: Among 285 recruited hospitalized patients, a rate of CIN was 16.9%. Serum albumin below 35g/dl positively predicted development of CIN (RR 2.3, 95% CI 1.4-4.6; p=0.020). The mean albumin was 28.4 ± 4.6 g/dL and ±2.39 g/dL in the CIN and non CIN groups respectively. An eGFR <60ml/min was associated with a 6 fold risk of developing CIN (P=0.00001).

Conclusions: Rates of CIN is significantly higher in developing countries and the presence of hypalbuminemia, a traditional bio-maker is significantly associated with development of CIN.

PUB064
A Curious Case of Evans Syndrome
Sagar R. Patel, Imara Dissanayake. Internal Medicine, Albert Einstein Medical Center; Philadelphia, PA.

Background: Evans syndrome is a rare autoimmune condition in which antibodies attack their own RBC and platelets resulting in an hemolytic anemia (AIHA) and ITP in the absence of a known etiology. Both of these can occur simultaneously or sequentially. Although many cases are idiopathic in origin, ES has been associated with other conditions in half of the cases, including infections and lymphoproliferative disorders.

Methods: A 45 year old African American male seen in ED with a Hgb of 6.4 and asymptomatic. The patient has a history of autoimmune hemolytic anemia (AIHA), immune thrombocytopenic anemia (ITP), anti-phospholipid syndrome (APS) with a previous DVT/PE and non-compliant with warfarin. Labs On admission Hgb 6.4, Plts 114, Bili 1.3, D Bil 0.4, L DH 346, Haptoglobin <8. He had AKI (Cr 6.9), with new onset nephrotic range proteinuria. Renal US showed medical renal disease. ANA 1:160, double stranded DNA was negative. Anti MPO, P-ANCA, C-ANCA, antiproteinase 3, atypical P-ANCA and glomerular basement membrane antibody were negative. CH 50,C3 and C4 were all low. No cryoglobulins were detected in the blood assay. Urine Electrolytes was negative for monoclonal light chains. Renal biopsy was performed and showed findings consistent with lupus nephritis stage 4/5. The patient was treated with PRBCs and given pulse dose steroids for 3 days after which his hemoglobin remained stable.

Results: ES is diagnosed in only 0.8% to 3.7% of all patients with either ITP or AIHA at onset. Since it is thought to be secondary to immune dysfunction, a high clinical suspicion should be maintained for underlying autoimmune disease. However this patient was unique, he did not meet the standard criteria for SLE but demonstrated lupus nephritis on biopsy. This is because the diagnosis in management, and should be treated for his underlying SLE which could help in reducing recurrence of Evans syndrome. He responded well to first line therapy with corticosteroids and did not require further acute therapy such as IVIG. He started on hydroxychloroquine for SLE and referred to renal clinic for celectop.

Conclusions: This case reflects that we should have a high suspicion for SLE and lymphoproliferative diseases even in asymptomatic patients with Evans Syndrome.

PUB065
Anticoagulation-Free Continuous Renal Replacement Therapy: A Single Center Observation

Background: Renal failure in the ICU setting is associated with 40-60% mortality. Continuous renal replacement therapy (CRRT) is used for volume and electrolyte management in critical care units. To avoid clotting of hemofillets, patients are routinely started on anticoagulation. In literature, anticoagulation has been associated with complications of increased risk of bleeding and metabolic or electrolyte disturbances based on type of anticoagulation used. We aimed to investigate the length of cartridge use and the association of anticoagulation.

Methods: We conducted a retrospective review of 20 ICU patients who were started on CRRT over a course of one month. We looked at the number of cartridges used per day. Prescription for CRRT was dialysate flow rate of 25-35 ml/kg/h and blood flow rate of 250 ml/h. No anticoagulation was ordered initially due to bleeding risks in this cohort. All patients were ordered 100 ml of normal saline flushes every 4 hours. Results: For 70% of the patients, the hemofilter cartridge lasted >24 hours. 30% of the patients required more than 1 filter per day, of which only 1 patient was started on a heparin drip for anticoagulation due to multiple filter changes. We used predilution replacement fluid to reduce the blood viscosity and hemocencentration for the patients requiring > 2 filter changes per day. Decreased requirement of filter change was noted after these changes were made. Among the patients with increased filter clotting, 33% had femoral non-tunnelled dialysis catheters and 50% had internal jugular tunnelled dialysis catheters. Longer duration of dialysis was associated with increased cartridge use per pearson correlation 0.818 (p=0.000). No documentation was made in the nursing notes to distinguish between vascular access problems versus filter clotting.

Conclusions: Recurrent filter clotting leads to interruption of RRT. Frequent filter changes is not cost effective. However anticoagulation in critical care settings poses multiple potential problems. There was an association between permcatheters and increased cartridge use.

PUB066
Rosuvastatin Has a Protective Effect against Hypertonicity-Induced Cell Damage
Miku Sato, Masaru Horio. Functional Diagnostic Science, Osaka Univ Graduate School of Medicine, Suita, Japan.

Background: Contrast-induced nephropathy (CIN) is one of the causes of acute kidney injury. Some studies raised a concern that statins have protective effect against CIN. Hypertonic stress in renal tubular cell is a possible factor inducing cell damage in CIN. Reactive oxygen species (ROS) can induce apoptosis. We studied the effect of rosuvastatin on hypertonicity induced cell damage in MDCK cells.

Methods: Hypertonic medium was made by addition of NaCl. Rosuvastatin was added 24 hours before the hypertonic exposure. Cell damage was assessed by LDH activity in culture medium. Apoptosis was evaluated by caspase-3 activity. Content of cellular glutathione (GSH), an important antioxidant, was measured.

Results: Hypertonicity more than 600 mOsm showed significant cytotoxic effect in MDCK cells. LDH activity in culture medium of 620, 640 and 660 mOsm cells increased in isosmolarity dependent manner (Figure). Low concentration (0.1 and 1.0 µM) of rosuvastatin had a protective effect against the hypertonicity-induced cell damage. On the other hand, 10 µM rosuvastatin that had no significant cytotoxic effect in 300mOsm condition, stimulated hypertonicity induced cell damage.

Conclusions: Low concentration of rosuvastatin has a protective effect on hypertonicity-induced cell damage in MDCK cells. Funding: Government Support - Non-U.S.

Conclusions: In summary, high expression of SRF associates with increased fibrosis and decreased cellularity in IgA nephropathy, and may partly contribute to the pathogenesis of this disease, perhaps by enhancing TGF-beta-mediated downregulation of smad and e-cadherin in HK-2.

PUB068

Increased Erythroid Reactive Oxygen Species Production Induced by Indoxyl Sulfate Precedes Red Blood Cell Death

Gabriela Ferreira Dias,1 Viktoriya Kunitschev,2 Lia S. Nakao,3 Felippe C. Barreto,4 Stephan Thijsen,4 Peter Kotanko,5,6 Roberto Pecoto-Filho,1 Andrea Novais Moreno-Amoral,7 1Pontifícia Univ Católica do Paraná, Brazil; 2Icahn School of Medicine at Mount Sinai, New York; 3Univers Federal do Paraná, Brazil; 4Renal Research Inst, New York.

Background: The uremic toxin indoxyl sulfate (IS) triggers erythropoiesis, an event characterized by phosphatidyserine (PS) exposure on red blood cell (RBC). The aim of the present study was to evaluate whether increase in RBC reactive oxygen species (ROS) induced by IS precedes PS exposure.

Methods: RBC from healthy controls (HC) were incubated for 4, 12 or 24h with IS (free concentration 4.5 mg/L) in the presence or absence of free radicals scavenger N-acetylcysteine (NAC 0.5mM). Flow cytometry was employed to assess apoptosis (annexin-V binding) and ROS (DCFPh-DH).

Results: Incubation of HC-RBC with IS over 4h did not trigger significant apoptosis compared to control cells incubated without IS (4.5 ± 1.2% vs 3.4 ± 0.4%). However, 12h and 24h incubation with IS increased levels of apoptosis in a time-dependent manner (10.4 ± 3.4% and 16.6 ± 6.1%, respectively). This IS-induced PS exposure on HK-2 was inhibited in the presence of NAC (6.0 ± 1.1% and 6.5 ± 1.4%, respectively). On the other hand, ROS production by HK-2 was increased even after only 4h of incubation with IS in a time-dependent manner (14.0 ± 4.2%, 22.1 ± 5.3 and 34.8 ± 15.8% for 4h, 12h and 24h respectively) when compared to control cells (6.6 ± 3.9%, 4.2 ± 0.5% and 5.2 ± 1.8%, respectively). ROS production was inhibited in the presence of NAC (6.6 ± 3.4%, 6.3 ± 2% and 13.4 ± 10.5%) demonstrating the ability of an antioxidant to reverse the oxidative stress induced by IS.

Conclusions: Taken together our results suggest that IS in a high free concentration, which is in accordance with reported free toxin concentration in patients, induces ROS production in HK-2 that precedes PS exposure. Thus, imbalance of RBC redox status induced by IS appears to be an important mechanism of elevated erythropoiesis observed in CKD that consequently may contribute to renal anemia.

PUB069

Impact of Constitutive C-MIP Expression on Mouse T-Cell Proteome

Mario Ollero,1 Pauline Vachin,1 Cinera Chhouon,2 Kelilia Sendeyo,3 Melanie Mangier,1 Ida Chiara Guerrera,4 Andrè Pawlak,4 Djihilah Sahali.5 1INSERM, U955 (Eq. 21), Créteil, France; 2Plateau Protéomiques Necker, Paris, France.

Background: The protein c-mip is overexpressed in lymphocytes and podocytes of MCNS patients. In order to dissect its role in INS pathogenesis, we generated a transgenic mouse expressing c-mip in peripheral mature T-cells. We aimed to evaluate the impact of c-mip expression on T-cell proteome in basal and stimulating conditions.

Methods: T-cells from transgenic (Tg) and control (WT) mice (n=3) were purified by negative immunoselection, and subjected to anti-CD3 and anti-CD28 stimulation, to mimic activation of antigen presenting cells. At 0, 40 and 60 min post-activation, total proteins were extracted, trypsin digested, and peptides analyzed by nano-RSLCQ E Exactive Plus MS. Protein quantification was performed by a label-free approach using MaxQuant and Perseus.

Results: The expression levels of 2660 proteins were compared in the four conditions. As a result, 46 proteins were found differentially expressed between Tg and WT as a function of T-cell activation (two-way ANOVA interaction, p<0.05). Among these, GO annotation showed a significant enrichment in proteins bearing ATPase activity. Hierarchical clustering by K-means algorithm displayed, most remarkably, a cluster of 14 proteins upregulated upon T-cell activation in WT mice but depleted in Tg mice in the same conditions - including KEGG annotations for tight junction, Wnt signaling, TLR signaling, RIG-I-like receptor signaling, Notch signaling, spliceosome, riboflavin metabolism, and DNA replication-, and a cluster of 11 proteins depleted in WT and augmented or unchanged in Tg after activation – involved in aminoacid and nicotiamide metabolism, proteasome, and regulation of actin cytoskeleton-. Studies are underway to explore the mechanisms involved.

Conclusions: c-mip overexpression exerts profound alterations in the protein expression pattern following T-cell activation in mice, involving diverse signaling, metabolic pathways and cellular functions. These results, along with other preliminary data obtained from the same mouse model, point at a defect in T-cell activation associated with c-mip expression.

An Investigation into the Prognosis of Nephritic Syndrome and Regulatory T Cells in Elderly People

Tetsuko Yasuno,1,2,3,4,5,6 Juntao Yu,1,2,3,4,5,6,7 Zhao Cui,1,2,3,4,5,6 Minghui Zhao,8,9,10,11 1Renal Division, Peking Univ First Hospital, Beijing, China; 2Academy for Advanced Interdisciplinary Studies, Peking Univ, Beijing, China; 3Peking-Tsinghua Center for Life Sciences, China.

Background: In a substantial number of patients with crescentic glomerulonephritis, both anti-glomerular basement membrane (GBM) antibodies and antineutrophil cytoplasmic antibodies (ANA) are detected simultaneously. ANA is presumed to be the initial event leading to the production of anti-GBM antibodies. In the present study, we investigated the association between linear epitopes on chain of type IV collagen (αIV[NC1]) in patients with ANCA associated vasculitis who had no classical anti-GBM antibodies, aiming to reveal the mechanisms of the coexistence of the two kinds of autoantibodies.

Methods: Twenty-four overlapping linear peptides were synthesized across the whole sequence of αIV[NC1] and antibodies were detected by ELISA.

Results: We found 25/31 (80.6%) ANCA associated vasculitis patients possessing antibodies against linear peptides on αIV[NC1]. These antibodies were detected from 50% of patients with normal renal function (Scr<133mmol/L), 70% of patients with moderate renal dysfunction (133mmol/L<Scr<600mmol/L), and 94% of patients with renal failure (Scr>600mmol/L). Patients with more aggravated renal damage had higher frequency of peptide recognition (P=0.032). The highest recognition frequencies were found for peptides P4 (51.6%), P14 (54.8%) and P24 (58.8%), which contained the sequences that constitute the epitopes E1 (P3) and E2 (P14 and P24) on αIV[NC1]. The level of anti-P4 antibodies was positively correlated with the percentage of crescents in glomeruli (r=0.764, P=0.027).

Patients with anti-P24 antibodies had a significantly higher prevalence of renal dysfunction on diagnosis (88.2% vs. 42.9%, P<0.018).

Conclusions: In conclusion, antibodies against linear peptides on αIV[NC1] could be detected in patients with ANCA associated vasculitis who had no classical anti-GBM antibodies and were associated with clinical features.

PUB071

Antibodies against Linear Epitopes on α3(IV)NC1 in Patients with Antineutrophil Cytoplasmic Antibodies Associated Vasculitis

Xiaoxia Liu,1 Juntao Yu,1,2,3,4,5,6,7,8,9,10,11 1Renal Division, Peking Univ First Hospital, Beijing, China; 2Academy for Advanced Interdisciplinary Studies, Peking Univ, Beijing, China; 3Peking-Tsinghua Center for Life Sciences, China.

Effects of 1,25-Dihydroxy Vitamin D₃ on Treg Cells, Interleukin-17, RORγt in Rats with IgA Nephropathy

Hui Guo, Div of Nephrology, 2nd Affiliated Hospital of Shanxi Medical Univ, Taiyuan, Shanxi, China; Div of Rheumatology, 2nd Affiliated Hospital of Shanxi Medical Univ, Taiyuan, Shanxi, China.

Background: To investigate the relationship between Treg cells, RORγt, IL-17 and rats with IgA nephropathy; to explore the intervention effect of 1,25(OH)₂D₃ on Treg cells, RORγt, IL-17 expression in rats with IgA nephropathy.

Methods: We chose Wistar 52 rats, with which 8 rats were chosen in control group (group E) in random, while other 44 rats were established the IgA nephropathy model. A histological observation of the ischemic kidney on post-operative day 7 revealed no progressive renal dysfunction and elevation of N-acetyl-β-D-glucosaminidase (NAD) in model group. The change of 24 hours of urinary protein, red blood cells in urine, creatinine and blood calcium of rats were detected. Foxp3, RORγt and IL-17 levels were detected by using RT-PCR, Immunohistochemistry and Westernblot.

Results: The level of RORγt, IL-17 in model groups were higher than prednisone treatment group, prednisone +1,25(OH)₂D₃ treatment group, 1,25(OH)₂D₃ treatment group, prednisone treatment group and prednisone +1,25(OH)₂D₃ treatment group. The prednisone+1,25(OH)₂D₃ treatment group were declined significantly (p<0.05). The prednisone+1,25(OH)₂D₃ treatment group and control group (p<0.05). After treatment the expression of RORγt, IL-17 of each group were declined significantly (p<0.05). The prednisone+1,25(OH)₂D₃ treatment group declined significantly compare to prednisone treatment group and 1,25(OH)₂D₃ treatment group (p<0.05). The expression of Foxp3 decreased significantly in IgAN group. After treatment with 1,25(OH)₂D₃, the level of Foxp3 increased significantly.

Conclusions: Treg cells, IL-17 and RORγt may participate in the occurrence/development of IgAN; 1,25(OH)₂D₃ may play a role in immune regulation by regulating the expression of Treg cells, IL-17 and RORγt directly or indirectly.

Dialysis Induces Morphological Changes and Eryptosis in Erythrocytes

Grazia Maria Virzi, Sabrina Milan Manani, Anna Clementi, Alessandra Brocca, Massimo de Cal, Claudio Ronco. IRRIV and Dept Nephrology Vicenza.

Background: Suicidal death of erythrocytes (eryptosis) is characterized by cell shrinkage, membrane blebbing, activation of proteases, and phosphatidylserine (PS) externalization. Exposed PS is recognized by macrophages that engulf and degrade cells. Eryptosis is a physiological mechanism under complex regulation. During their daily life, erythrocytes (RBCs) are exposed to several stressors, such as oxidative stress, osmotic shock, energy depletion. Eryptosis is observed in a wide range of clinical conditions, such as CKD, diabetes, epilepsy, and sepsis. The aim of this study was assessed cell volume and PS abundance on the RBC surface in peritoneal dialysis (PD) and hemodialysis (HD).

Methods: 40 PD patients, 30 HD patients and 17 healthy subjects (CTR) were included in the study. All measurements were made in isolated RBCs. RBC volume and morphology was estimated from forward scatter, PS exposure at the cell surface was estimated from FITC-AnnexinV binding using flow cytometric analyses.

Results: We observed that RBCs of PD and HD patients are indeed rather dramatically deranged in their morphology. Furthermore, the PS externalization on the RBC surface was significantly higher in these groups than in CTR (PD patients: 2.6%; IQR 1.6-3.7; HD patients: 2.2%; IQR 1.2-4.1 versus CTR: 0.8%; IQR 0.7-1.3; p<0.000001). We did not find significant differences in PS exposure between the PD and HD patients (p=0.47).

Conclusions: The percentage of eryptosis has indeed been shown to be significantly higher in patients on dialysis than CTR. Our data suggest that dialysis may induce morphological changes in erythrocytes and may lead to a significant increase in eryptosis, before differences in its level were observed between PD and HD. Additional efforts will be required to define major eryptosis-inducing components in uremic, PD and HD patients.

expression of TLR2 (4.8A.U), 4 (12.6A.U) and 7 (7.3A.U, P=0.05) compared with controls, but the increase was significantly less than that of the AA group for all TLRs (P=0.05). Cellular infiltrates contained intense staining for TLR2, 4 and 9 on macrophages and neutrophils in both glomeruli and interstitium. TLR2 and TLR4 staining was prominent on both endothelial cells and podocytes, although TLR9 was particularly evident on podocytes. In AA glomerular TLR4 expression correlated with the % of normal glomeruli (r=0.48, P=0.05) suggesting TLR4 prominence occurs in early glomerular lesions. Glomerular TLR2 and 9 were present concurrently in more severely affected glomeruli (r=0.71, P=0.0001). TLR2, 4 and 9 were prominent in all crescentic glomeruli of AA and lupus patients.

Conclusions: This study demonstrates that TLR expression is most prominent in AA. Significant expression of TLRs was evident on leukocytes and intrinsic glomerular cells. TLR4 is prominent in early glomerular lesions, while TLR2 and 9 correlate with severe glomerular lesions.

Podocyte CD40 Expression in Patients with Post-Transplant FSGS
Recurrence
Rutger J. Maas,1 Brigit Willensmeen,2 Henk Jeroen Deegen,1 Jack F. Wetzels1

1Nephrology, Radboud Univ Medical Center, Nijmegen, Netherlands; 2Pathology, Radboud Univ Medical Center, Nijmegen, Netherlands.

Background: antibodies against CD40 were recently reported to predict post-transplant recurrent FSGS (rFSGS) with 78% accuracy (Delville et al. Sci Transl Med 2014). Using immunohistochemistry, the authors reported strong focal podocyte CD40 expression in glomerular lesions of two patients with rFSGS. We sought to validate this novel finding of podocyte CD40 expression as a potential marker of rFSGS.

Methods: we used formalin-fixed, paraffin embedded kidney tissue from five patients with rFSGS. Two samples were obtained from nephrectomy specimens, and three were needle biopsy specimens. All patients had nephrotic range proteinuria at the time of tissue sampling. A human tonsil was used as a positive control.

Results: specificity and adequacy of the staining was confirmed by strong CD40 expression in tonsillar germinal centers (Figure, panel A). In kidney samples from patients with rFSGS, CD40 staining was found in areas of interstitial cellular infiltration, and some tubular epithelial cells (Figure, panel B). However, no glomerular CD40 was detected in any of the rFSGS samples.

Conclusions: we could not confirm glomerular CD40 staining in rFSGS with immunohistochemistry. The role of CD40 antibodies in rFSGS pathogenesis needs further study and validation.

Increased Cellular Microchimerism in Women with Systemic Lupus Erythematosus
Suzanne Wilhelms,1 Malu Zandbergen,1 Emile Jeroen Deegen,2 Juan D. Diaz de Pool,3 Mathilde M.M. Almekinders,1 Hans J. Baede,1 Jan A. Brujin,1 Ingemorg B. Bajema,1 2Pathology, Leiden Univ Medical Center, Leiden, Netherlands; 3Gynecology, Leiden Univ Medical Center, Leiden, Netherlands.

Background: Microchimerism (Mc) has been suggested to play a role in the development of systemic lupus erythematosus (SLE). We previously showed that Mc occurs twice as often in kidney biopsies of patients with lupus nephritis as in controls. Recently, it was demonstrated that the amount of Mc in lupus nephritis is associated with renal function (J Am Soc Nephrol 26: 2015). Using a rat model of PHN, CsA was able to protect glomerular charge barrier function in progressive and stable CKD with clinically established complications in C57BL/6 mice. This model should serve to be useful for many areas of CKD research and disease prevention.

Results: Using a rat model of PHN, CsA was able to protect glomerular charge barrier function in progressive and stable CKD with clinically established complications in C57BL/6 mice. This model should serve to be useful for many areas of CKD research and disease prevention.

Conclusions: We now demonstrate that mice fed this high soluble oxalate diet develop typical CKD complications such as sustained hypertension, normochromic anemia, metabolic acidosis, hyperphosphatemia, hyperparathyroidism, and hypercalcaemia. Renal histology is characterized by calcium-oxalate crystal plugs in the tubular lumen, tubular atrophy, interstitial fibrosis, and atubular glomeruli. This pathological resemblance of CKD in SLE patients to the high oxalate model suggests that these studies could be useful for future understanding of the pathophysiology of CKD in SLE.

PUB080
An Oxalate-Induced Mouse Model of CKD That Displays Common CKD Complications
Santhosh Kumar Vr,1 Victoria Pfann,1 Julian A. Marschner,1 Simone Romoli,1 Jiyasi Desai,1 Jonathan Nicodemos1,2 Felix Knaff1
1Univ of Munich; 2Univ Erlangen-Nürnberg; Yale Univ School of Medicine.

Background: Chronic kidney disease (CKD) research is limited by the lack of a convenient inducible C57BL/6 mouse model mimicking relevant human CKD complications. We have reported a high soluble oxalate diet (50 µmol/g sodium oxalate mixed with virtually calcium free diet) that induces a progressive decline in glomerular filtration rate (GFR) reflected by increasing creatinine as well as blood urea nitrogen levels in C57BL/6 mice.

Methods: All in vivo experiments were approved by the local government authorities. Computed tomography, ultrasound and MRI were used for imaging. IHC, RT-PCR were used for data analysis. GFR was measured using single i.v. bolus injection of FITC sinistrin in conscious mice.

Results: We now demonstrate that mice fed this high soluble oxalate diet develop typical CKD complications such as sustained hypertension, normochromic anemia, metabolic acidosis, hyperphosphatemia, hyperparathyroidism, and hyperkalemia. Renal histology is characterized by calcium-oxalate crystal plugs in the tubular lumen, tubular atrophy, interstitial fibrosis, and atubular glomeruli. This pathological resemblance of CKD in SLE patients to the high oxalate model suggests that these studies could be useful for future understanding of the pathophysiology of CKD in SLE.

Conclusions: We now demonstrate that mice fed this high soluble oxalate diet develop typical CKD complications such as sustained hypertension, normochromic anemia, metabolic acidosis, hyperphosphatemia, hyperparathyroidism, and hyperkalemia. Renal histology is characterized by calcium-oxalate crystal plugs in the tubular lumen, tubular atrophy, interstitial fibrosis, and atubular glomeruli. Cyclosporine A Reduces Renal Injury Through Protecting Glomerular Charge Barrier in Passive Heymann Nephritis
Zilong Li,1 Juan Wang,2 Lining Wang,2 Dept of Nephrology, First Affiliated Hospital of China Medical Univ, Shenyang, Liaoning, China.

Background: Cyclosporine A (CsA) has been reported to reduce proteinuria in several kinds of kidney diseases. Glomerular charge barrier plays an important role in preventing urinary protein loss. The aim of this study was to elucidate the effects of CsA on glomerular charge barrier in passive Heymann nephritis (PHN).

Methods: Wistar rat PHN model was established by injecting antisera against renal tubular epithelial antigens (anti-Fx1A) following pre-immunization. The experiment included Group 1: PHN control, Group 2: PHN plus CsA treatment before anti-Fx1A injection, Group 3: PHN plus CsA treatment for the first 7 days after injection, and Group 4: PHN plus CsA treatment from the 8th day after injection. Serum creatinine (sCr) and urinary protein (uPro) were measured at the 7th and/or the 14th day. Kidney tissues were obtained at the 14th day and labeled with a cation tracer polyethyleneimine (PEI) to study the distribution of negative charges on glomerular basement membrane (GBM). Kidney pathological changes were investigated.

Results: PHN model was established showing proteinuria and kidney injury of the glomerular basement membrane (GBM). A mass deposition of immune complex (IC), and decreased density and disturbed distribution of negative charges along the GBM. sCr was not increased in all groups. With CsA treatment, uPro was significantly declined in Group 2 and 3 at 7th day, and in Group 2 and 4 at 14th day. In Group 2, it showed little pathological changes in kidney with less deposition and disturbed charges distributed evenly. In Group 3 and 4, the deposition of IC was reduced, and the negative charges distribution was repaired showing stronger density compared to Group 1, while less regularly arranged compared to Group 2.

Conclusions: Using a rat model of PHN, CsA was able to protect glomerular charge barrier, which might benefit from the regulation of Ca$^{2+}$ influx and reduction of IC deposition, thus minimizing proteinuria and renal injury.

Heme to CO and bile pigments. In hemolytic disorders, heme scavenging by HPX is mitigating heme-associated cell injury. HO-1 induction also minimizes injury by degrading (HPX mediator) serum or with 10% HPX replete serum. Co-incubation with 10% HPX serum (1.25, 2.5, 5, 10%) was preserved following anti-GBM Ab injection, albuminuria (Ualb/Ucreat) was assessed and glomeruli were isolated to determine changes in HO-1 and nephrin expression (GEC integrity marker). Results: In glomeruli from SB rats HO-1 levels (protein) increased compared to Wild type (WT). Administration of either PAN or anti-GBM Ab to WT rats increased glomerular HO-1. In SB rats receiving PAN, HO-1 markedly decreased compared to WT. In contrast, HO-1 markedly increased in the subcapsular region. Following anti-GEC treatment, nephrin expression was undetectable in glomeruli from SB rats treated with PAN. In contrast, nephrin was preserved in glomeruli from SB rats treated with anti-GBM Ab. Ualb/Ucreat was significantly higher in WT compared to SB rats treated with anti-GBM Ab. In contrast, there was no difference in Ualb/Ucreat between WT and SB rats receiving PAN.

Conclusions: Augmentation of HO-1 expression in primary GEC injury is impaired. This could be yet another mechanism contributing to GEC vulnerability in primary podocytopathies.

PUB085

Comparative Evaluation of Cellular Injury Models Based on Conditionally Immortalized and Primary Podocytes 
Vivek C. Abraham,1 Loann N. Miller,1 Caton Brent Putnam,2 Laura Kim,3 Steve Pratt,2 Sujatha M. Gopalakrishnan,2 Andrew J. King,1 Renal Discovery, AbbVie, North Chicago, IL;1,2 High Throughput Screening, AbbVie, North Chicago, IL.

Background: Podocyte injury is a hallmark of proteinuric chronic kidney disease. Molecular studies of podocytes to understand cell cycle reorganization, oxidative stress, de-differentiation & detachment. The purpose of this study was to compare commonly used conditionally immortalized podocytes with primary podocytes, by measuring podocyte markers and responses to injury.

Methods: Primary human podocytes were isolated and cultured from a healthy human donor kidney and compared to 1) a subclone (C5) of conditionally immortalized human podocytes (selected based on podocyte specific gene expression) and 2) conditionally immortalized mouse podocytes. Cellular phenotypes and gene expression were measured using high content screening (HCS), qPCR and western blots. For assessment of diagnostic serum and GBM Ab injection, albuminuria (Ualb/Ucreat) was assessed and glomeruli were isolated to determine changes in HO-1 and nephrin expression (GEC integrity marker).

Results: C5 podocytes were benchmarked to primary human podocytes using 1) expression of WT-1, podocin, synaptopodin and a-smooth muscle actin and 2) cytoketal and cell cycle phenotypes. C5 cells were also evaluated by comparing gene expression profiles in response to TGF-β treatment. C5 podocytes were judged to be similar to primary human podocytes based on these analyses. Current cellular models of podocyte protection often use the stimulators pyrrocamin aminocoulsid and TGF-β. We demonstrate cytoprotection by multiple reference compounds with these insults. We have also increased the disease relevance of stressors by showing that serum isolated from proteinuric db/db mice differentially elicits podocyte injury across multiple parameters.

Conclusions: Our results validate the use of conditionally immortalized C5 podocytes by benchmarking against primary human podocytes. We have also enhanced the pathological relevance of models of podocyte injury by incorporating key disease-relevant stressors and readouts.

Hypoxia Stimulates the Expression of Tissue Factor in Human Podocytes in Culture
Bayo Narita,1 Michiko Shimada,1 Peter W. Mathieson,1 Hideaki Yamabe,1 Ken Okumura.2 1Nephrology, Hiroaki Univ, Hiroaki, Japan;2Renal Academic Unit, Univ of Bristol, Bristol, United Kingdom;3Univ of Hong Kong, Hong Kong, China.

Background: Hypoxia contributes to tubulointerstitial injury, however, the effect on podocytes and its underlying mechanisms are less well understood. Tissue factor (TF) is the initiator of extrinsic coagulation pathways and is also related to various biologic effects. We have previously demonstrated that hypoxia stimulates the expressions of TF and tissue factor pathway inhibitor (TFPI) in the hypoxic conditions. We further tested the roles of known transcription factors of TF such as, nuclear factor-kB (NF-kB) and early growth response gene-1 (Egr-1), as well as hypoxia-inducible factor-1a (HIF-1a) which regulates numerous changes in hypoxia.

Methods: Conditionally immortalized human podocytes were grown at 33°C and differentiated at 37°C. The cells were treated in normoxic or hypoxic conditions. mRNA expressions of TF and TFPI were analyzed by quantitative RT-PCR, and protein levels of TF and TFPI were measured by western blot. The expressions of TF and TFPI were measured by immunofluorescent staining. We used siRNA for the knockdown of TFPI in the hypoxic conditions.

Results: Hypoxia increased expression of TF and TFPI in hypoxic conditions compared with normoxic conditions. The expressions of TF and TFPI were further increased by treatment with hypoxia. The knockdown of TFPI significantly reduced the expression of TF in hypoxic conditions.

Conclusions: Hypoxia stimulates the expression of TF in human podocytes, which may contribute to pathological changes in kidney disease. Further studies are needed to investigate the role of TF in podocyte injury and its potential as a therapeutic target.

Funding: Government Support - Non-U.S.
the cytoplast of podocyte. As expected, HIF-1α was strongly stained in the nuclei of podocytes exposed to hypoxia for 6h. The expression of TF was not affected by HIF-1α siRNA, and neither Egr-1 siRNA. Whereas, PDTC reduced the induction of TF by hypoxia.

**Conclusions:** Hypoxia upregulated the expression of TF in human podocyte NF-κB dependently, and HIF-1α and Egr-1 independently. These changes may be related to the podocyte disorders and lead to proteinuria in the hypoxic condition.

*Integrity of the Mature APOL1 Protein Is Indispensable for Its Toxicity*

Xiaquan Lan,1 Hongxiu Wen,2 Ashwani Malhotra,3 Karl Leon Skorecki,4 Pravin C. Singh4.1 Medicine, Hofstra North Shore LIJ Medical School, Great Neck, NY;2 Medicine, Rambam Health Care Campus, Haifa, Israel.

**Background:** Several clinical reports have demonstrated that the development of higher rates of non-diabetic glomerulosclerosis (GS) amongst African Americans can be attributed to two coding sequence variants (G1 and G2) in the APOL1 gene. Recent studies indicate that the gene products of these APOL1 risk variants have augmented toxicity in kidney cells. The APOL1 protein is composed of several functional domains, including signal peptide (SP), pore forming domain (PFD), membrane address domain (MAD), and SRA-interacting domain. However, it is not clear, which domain contributes to APOL1 induced cellular toxicity. In case, specific domain is contributing to APOL1-induced cellular toxicity, it will suggest us to design therapeutic strategy to target the specific domain.

**Methods:** To investigate the relative contribution of each domain to cell injury, we constructed serial of expression vectors to delete each domain, we transfected these vectors into the human embryonic kidney cell line 293T, and then compared the cytotoxicity. In addition, we conducted studies in which APOL1 wild type (G0) was co-transfected in combination with G1 or G2 to see whether G0 could counteract the toxicity of the risk variant.

**Results:** The results showed that deleting the SP did not abolish the toxicity of APOL1, though deletion of 26 amino acid residues at the N-terminal partially decreased the toxicity. Deleting PFD or MAD or SRA-interacting domain abolished toxicity, while, overexpressing each domain alone could not cause toxicity to the host cells. Deletion of the G2 sites while retaining G1 sites in the risk state resulted in persistent toxicity. Either deletion or exchanging the BH3 domain in the PFD led to complete loss of the toxicity in this experimental platform. Adding G0 to either G1 or G2 did not attenuate the toxicity of the either moiety.

**Conclusions:** These findings indicate that the integrity of the mature APOL1 protein is critical for its toxicity.

*Human Podocyte Depletion: The Effects of Aging and Hypertension*

Victor G. Puuelles,1 Luis E. Cullen-McEwen,1 Jianhua Li,2 Peter G. Kerr,3 Wendy E. Hoy, John F. Bertram.1 1Dept of Anatomy and Developmental Biology, Monash Univ, Melbourne, Victoria, Australia; 2Dept of Nephrology, Monash Medical Centre, Melbourne, Victoria, Australia; 3Centre for Chronic Diseases, The Univ of Queensland, Brisbane, Queensland, Australia.

**Background:** Podocyte depletion plays a major role in the development and progression of glomerulosclerosis. Many kidney diseases are more common in older age, and usually coexist with the presence of hypertension. We hypothesize that podocyte depletion develops with aging and is exacerbated by the presence of hypertension.

**Methods:** Kidneys from 21 adult Caucasian American males without overt renal disease were collected at autopsy in Mississippi, USA. Subjects were categorized based only on age as young adults, middle-aged adults and older adults. Subjects were also categorized based on age and hypertension as young normotensives, older normotensives, and older hypertensives. Demographic data were collected from available medical records. Design-based stereology was used to estimate individual glomerular volume (IVG), podocyte number and podocyte density. Data are presented as mean±SD.

**Results:** Glomeruli from young adults (22.0±2.7 years; n=6) were small (1.72±0.50 x10^3/μm^2), and contained 457±97 podocytes and 278±66 podocytes per 10^3mm^2 of glomerular tissue. Glomeruli from older adults (60.0±8.6 years; n=7) were larger (2.94±1.41 x10^3/μm^2; P＜0.001), contained fewer podocytes (390±105; P＜0.05) and had lower podocyte density (156±65 podocytes per 10^3/mm^2; P＜0.001). Among normotensives, older age was associated with a 15% increase in IVG (P＜0.28), a 12% decrease in podocyte number (P＜0.06) and a 17% decrease in podocyte density (P＜0.01). Glomeruli from hypertensives and normotensives contained similar numbers of podocytes, but hypertensives had larger glomeruli (P＜0.0001) and a markedly lower podocyte density (P＜0.001).

**Conclusions:** These findings demonstrate that both aging and hypertension are independent and additive contributors to podocyte depletion in this cohort of white American men without overt kidney disease.

**PUB089**

*Alport Nephropathy Progression Involves Altered Glomerular Mechanical Properties and Activation of the Unfolded Protein Response Addie Embry,1 Liping Liu,2 Leslie A. Bruggeman,2 Paul A. Janney,2 R. Tyler Miller.1 1Medicine, UTSw, Dallas, TX; 2Medicine, CWRU, Cleveland, OH.

**Background:** Tissue and cell mechanics are important factors in the development and maintenance of tissues but are not well defined in renal disease. We determined the biophysical properties of glomeruli over the course of disease in the Col4a3−/− (Alport) mouse.

**Methods:** Glomerular EMod was measured with microindentation, gene transcript levels with qRT-PCR and immunofluorescence, and kidney structure with histology.

**Results:** Col4a3−/− kidneys have normal histology, no proteinuria, and a normal glomerular filtration rate (GFR: 2.200μL/min). Among aged mice, older (3.272±0.56 years; n=6) were small (1.72±0.50 x10^3/μm^2) and contained fewer podocytes (390±105; P＜0.001) and a markedly lower podocyte density (P＜0.001). Glomerular softening is characteristic of injured glomeruli, is associated with injured podocytes, and could lead to capillary injury even with normal hemodynamics. By 6 mo, the glomeruli regained their original MFG (10.272±1.290 Pa) but with increased proteinuria and more severe glomerular and interstitial fibrosis. By 7-8 mo, the glomerular Emod increases (~2,600 Pa) with further increases in proteinuria and glomerular and interstitial fibrosis. At 2 mo, glomerular transcripts for matrix and fibrinotic factors (CTGF, a-SMA, filament, lysis) oxidase) are increased and remain so, demonstrating early responses of cells to alter their mechanical environment. Transcripts associated with UPR activation (BiP, CHOP, grp94) are elevated, suggesting that loss of the Col4a3 chain leads to activation of the UPR. Tunicamycin-treated glomeruli demonstrated a markedly reduced Emod (<1100Pa), suggesting that UPR activation causes glomerular injury.

**Conclusions:** Biophysical abnormalities occur early in the course of this Alport model, suggest that the reduced Emod (increased deformability) may lead to mechanical injury of capillaries even with normal hemodynamic force, that cells of glomeruli respond by producing proteins that will reduce deformability, and that glomerular or podocyte injury may be attributable to activation of the UPR.

**PUB090**

*A New Assay to Study Podocyte (De)Differentiation*

Frances Kindt, Karlhans Endlich, Nicole Endlich. Anatomy and Cell Biology, Univ Medicine Greifswald, Greifswald, Germany.

**Background:** Podocytes play an essential role in the formation and maintenance of the glomerular filtration barrier. Glomerular disease is associated with podocyte damage, frequently resulting in podocyte dedifferentiation. The loss of podocyte differentiation is poorly understood. Moreover, there are no drugs available that could halt or even reverse podocyte dedifferentiation. Since podocytes of isolated glomeruli have long been known to spontaneously lose their highly differentiated state over time, we established an assay to follow dedifferentiation of living podocyte in isolated glomeruli over time.

**Methods:** Using magnetic separation with dynabeads, glomeruli were isolated from transgenic mice that express cyan fluorescent protein (CFP) under control of a nephrin promoter fragment (Cui et al., <em style="font-family: 'Times New Roman'; font-size: 10pc;">1</em>). As defined by fluorescence, we recorded z-stacks of several glomeruli by confocal laser scanning microscopy on each day. Mean total fluorescence intensity per glomerulus (MFG) was calculated from z-stacks after background correction. MFG remained stable for 5 d. Thereafter, MFG gradually decreased to 10% of the initial value on day 9. Dedifferentiation of podocytes could be accelerated by treatment of isolated glomeruli with doxorubicin, strongly decreasing MFG within the first three days.

**Conclusions:** In summary, we established a new assay to study podocyte (de)differentiation. This assay may help to understand the molecular mechanisms of the loss of podocyte differentiation, and may allow to screen for compounds that stabilize podocyte differentiation.

**Funding:** Government Support - Non-U.S.

*Methods to Selectively Remove Murine Endothelial Glyocalyx In Vivo Using Glycosaminoglycan Digesting Enzymes without Causing Non-Target Effects*

Karen L. Onions, Anjila Onifade, Chris R. Neal, Monica Gamez, Gavin Iain Welsh, Andy Salmon, Simon C. Satchell, Rebecca R. Foster. Academic Renal Unit, Univ of Bristol, Bristol, United Kingdom.

**Background:** The endothelial glyocalyx (eGLX) is an important component of the glomerular filtration barrier (GFB), damage to which increases vascular permeability and microalbuminuria. Jeuniaux and Haraldson previously used glycosaminoglycan (GAG) digesting enzymes to study the role of the eGLX in glomerular permeability. However, eGLX removal was not directly quantified. The aim of this research was to confirm removal of systemic eGLX and identify any non-targeted effects in the glomerular or coronary microcirculation.

**Methods:** Mice were injected IV with chondroitinase (Ch) and hyaluronidase (Hy) at a high (Ch: 87 μg/I, Hy: 15μg/I) or low (Ch: 0.087 μg/I, Hy: 15 μg/I) dose. Mice

were whole body (cardiac) perfusion fixed with gluteraldehyde containing Alcian blue to stain the e-GGLX. Transmission electron microscopy (TEM) was used to image the ultrastructure of the heart and glomerular microcirculation, which was quantified using defined parameters in ImageJ.

Results: In the heart, the low dose significantly reduced glycolaldehyde coverage to 62% compared to controls (87%) (dose groups p=0.0027 one way ANOVA). The high dose caused an increase in vesicle number within the endothelial basement membrane (3.3/um) compared to controls (1.2/um) (p = 0.0328 t-test). Within the parameters of this analysis there were no structural changes to other components of the GBM or coronary circulatory differentiation.

Conclusions: These results indicate that a low dose of GAG digesting enzymes targets systemic e-GGLX and does not cause any non-target effects. This technique will be utilised to study the role of the e-GGLX in glomerular permeability. Increasing understanding in this area will identify how e-GGLX contributes to glomerular albumin permeability in different pathological scenarios and may highlight new therapeutic targets. This work was funded by the British Heart Foundation (FS/13/095957).

PUB092
Dietary Salt Restriction Induces New, Single Mesenchymal Stem Cell-Derived Progenies in the Glomerulus and Proximal Tubule
Donna Ralph, Kengo Kidokoro, Anne Riquier-Brison, Janis Peti-Peterdi. Physiology & Biophysics, Univ of Southern California, Los Angeles, CA.

Background: Salt restriction is known to slow down the progression of chronic kidney disease (CKD) and improve albuminuria via blood pressure-independent structural changes in the glomerulus, however the underlying mechanisms have been elusive. We aimed to track cell migration and fate of individually identified resident mesenchymal stem/progenitor cells in the renal cortex in intact mouse kidneys.

Methods: In vivo serial multiphoton microscopy (MPM) of the same glomeruli over several days, and genetic cell fate tracking using histology in tamoxifen-induced NG2CreERT2-Confetti mice expressing either CFP/GFP/YFP/RFP were performed during salt deficient diet and ACEI inhibition for 10 days.

Results: At baseline, a few cells belonging to the NG2 lineage (NG2+) were observed in a scattered pattern throughout the renal interstitium. Serial MPM showed that in response to salt deprivation, monochromatic (either blue/green/yellow or red) multi-cellular tracing units appeared at the glomerular vascular pole, mesangium, Bowman’s capsule, and in the proximal tubule within 10 days. Subsequent histology of NG2-CreERT2 mouse kidneys found that the highest density of NG2+ cells was in the outer medulla, and confirmed the presence of 3-10 cells-containing monochromatic (clonal) tracing units along cortical vasculature, afferent arteriole, and within the glomerulus (including mesangial and parietal epithelial cells, and a very few podocytes) and the proximal tubule. Spherical or stellate-shaped NG2+ cells were observed in the Bowman’s space and in the proximal tubule lumen suggesting cell migration.

Conclusions: In summary, our data are consistent with highly dynamic cellular remodeling of the renal interstitium, vasculature, glomerulus, and the proximal tubule by single progenitor cells. These results also suggest the presence of a complex nephron repair program which is augmented in response to salt deprivation. Funding: NIDDK Support

PUB093
Beraprost Ameliorates Renal Function and Reduce Uremic Toxin in GBP Nephropathy in Rat and in Humans (Small Number Study)
Yasunori Ozawa, Kaikai Kikuchi, Hisato Shimah, Eikan Mishima, Yasutoshi Akiyama, Takehiro Suzuki, Daisuke Saiagusa, Sadayoshi Ito, Takaaki Abe. Tohoku Univ Graduate School of Medicine.

Background: In CKD patients, the accumulation of uremic toxins exacerbates renal damage. Beraprost sodium (BPS) is prostacyclin analogue and is mainly used to treat atherosclerotic obliterners. Recently, Several reports show that BPS reduced progression of renal damages in CKD. To identify the renoprotective effect of BPS, we measured uremic solutes by capillary electrophoresis with mass spectrometry (CE-MS) in anti-GBP Glomerular Nephropathy(GN) rat model as well as 4 CKD patients before and 5 month after BPS administration.

Methods: A comprehensive and quantitative analysis of charged metabolites by CE-MS was performed. Obtained serum from 1 (Normal) rats, GBM GN rats and BPS-administered GBM GN rats and (2) 4 CKD patients treated with BPS. We performed CE-MS and a comprehensive and quantitative analysis of charged metabolites. All the experiments were performed under Animal and Ethical Committee approval.

Results: Among 300 solutes, 16 anionic solutes and 16 cationic solutes were further examined. Among the anionic solute that increased in GN rats, the concentration of 2 anionic solutes(Gluconate and Citrate) are ameliorated by BPS treatment. Conversely, the concentration of 8 metabolites were decreased in GN rats, and by BPS treatment, the reduced concentration of tryptophan recovered to the normal level. Well and by BPS treatment, the reduced concentration of tryptophan recovered to the normal level. Arginine, Glycine, Cystathionine, N-acetylglucosamine, N-acetylglycosamine, and 1-methyladenosine are also reduced by BPS in GN rats. In addition, in humans, the serum concentration of creatinine and Indoxyl sulfate are reduced by BPS after 6 month administration.

Conclusions: BPS reduced uremic toxins in CKD rats and ameliorates renal dysfunction and the serum level of Indoxyl sulfate in CKD patients. These results suggest that BPS has a potential to prevent the progression of CKD. Funding: Pharmaceutical Company Support - Reserch grant from Toray

PUB094
A Novel Method to Measure Glomerular Permeability
Jin Wei, Shaohui Wang, Lei Wang, Gensheng Zhang, Jie Zhang, Byong Cha, Kay-Pong D. Yip, Ruisheng Liu. Molecular Pharmacology & Physiology, Univ of South Florida, Tampa, FL.

Background: Glomerular capillaries are relatively impermeable to proteins, but in certain kidney diseases, such as diabetic nephropathy, the glomerular permeability (GP) is increased and some of the lower molecular weight (LMW) proteins, especially albumin, are filtered through the glomerular barrier into the Bowman’s space. Increased GP is a hallmark for many kidney diseases. Proteinuria is often implicated for impaired GP. However, since LMW proteins can be reabsorbed by proximal tubules, proteinuria is detected only when the GP is significantly increased. Recently, real-time quantification of GP can be visualized by two-photon microscopy, but it can only be applied to superficial nephrons, where laser can penetrate, in Munich-Wistar rats. We developed a novel method to monitor GP in C57/BL6 mice by using flow cysine-lysine-fibaxaxine conjugates without these limitations.

Methods: 100µl Tomato Lectin 594 (endothelial cell marker) plus 50µl 40 KD lysine-fibaxaxine dextran 488 (fluid phase marker) were injected intravenously. The kidneys were removed 1 min later and put into liquid nitrogen immediately for 10 minutes followed by fixation with 10% Formalin on ice overnight. Then 100µm thick sections were prepared using a vibratome and the florescent images were collected with two-photon microscopy. The ratio of fluorescent intensity in Bowman’s space over that in glomerular capillary lumen was used as an index of GP.

Results: In WT mice, the GP is extremely low with a ratio of 0.16±0.08%, N=6 (figure1). In contrast, in diabetic mice induced by alloxan for 8 weeks, the GP is significantly increased with a ratio of 5.9±1.3%, N=6 (figure2).

Conclusions: In summary, we developed a novel and sensitive method to monitor changes in GP using two-photon microscopy, which can be used for rodents and bigger animals.

PUB095
Vasopressin Regulates the Uptake of Extracellular Vesicles by Kidney Collecting Duct Cells
Wilsa Oosthuizen, 1 Jessica R. Ivy, 2 Jonathan Street, 2 Andrea Caporali, 1 David J. Webb, 3 Chris Gregory, 2 Matthew A. Bailey, 1 James W. Dear, 1 Centre for Cardiovascular Science, Univ of Edinburgh, United Kingdom; 2 National Inst of Diabetes and Digestive and Kidney Diseases, National Insts of Health; 3 MRC/Univ of Edinburgh Centre for Inflammation Research, Univ of Edinburgh, United Kingdom.

Background: Urine contains extracellular vesicles (ECVs) originating from the circulation and all cells lining the urinary tract. ECVs are a route of inter-cellular communication along the nephron able to transfer protein and RNA. It is not known whether this is a regulated process analogous to other cell-to-cell signalling systems.

Methods: Kidney cortical collecting duct cells (CCDs) were stimulated with desmopressin, a vasopressin analogue, and uptake of fluorescently-loaded microRNA-loaded ECVs was measured. In mice, fluorescently-loaded ECVs were intravenously injected before and after administration of the V2 antagonist, tolvaptan, and urinary ECV excretion was measured. By combining antibodies to nephron segment-specific proteins with nanoparticle tracking analysis we measured human urinary ECV excretion in central diabetic diabetes (DI) and after radiotransit exposure (n=37).

Results: Desmopressin stimulated ECV uptake into CCDs via V2 receptor stimulation. Intra-cellular uptake of ECVs was confirmed by microRNA specific mRNA down-regulation. Mechanically, ECV uptake in response to desmopressin required cyclic AMP production, was mediated by clathrin-dependent endocytosis and was selective for ECVs from kidney tubular cells. In mice, basally, 2.5% of injected ECVs were recovered in urine; tolvaptan treatment resulted in a 5-fold increase. In DI, desmopressin reduced the excretion of ECVs derived from upstream glomerular and proximal tubule cells. In patients exposed to radiotransit, urinary ECVs from the glomerulus were positively correlated with the tubular injury markers KIM-1 and NGAL.

Conclusions: Tubular ECV uptake is a specific, hormonally regulated process that is reduced with injury. Physiologically, ECVs are a mechanism of inter-cellular communication; therapeutically, ECVs represent a novel vehicle by which RNA therapy could be targeted for the treatment of kidney disease.

Systemic Hypothermia and Pro-Inflammatory Cytokines

Massimo de Cal,1 Grazia Maria Virzì,1 Alessandra Brocca,1 Salvador Roberto Lopez,1 Jose Luis Salas,1 Stefano Marcante,2 Silvia De Rosa,1 Claudio Ronco.1 1Nephrology, S.Bortolo Hospital, Vicenza, Italy; 2ICU, S.Bortolo Hospital, Vicenza, Italy.

Background: Cytokines produced by renal tubular epithelial cells are critical factors in inflammatory processes of renal ischemia-reperfusion injury. Increased levels of cytokines have been reported after resuscitation from cardiac arrest. Pro-inflammatory cytokines, such as IL-1β, IL-6 and IL-18, produced in the kidney during ischemia-reperfusion injury, are able to contribute to the renal damage. The purpose of this investigation was to define the proinflammatory cytokines response after resuscitation and during extended observation following therapeutic hypothermia phases.

Methods: We performed a prospective observational study in 36 post-cardiac arrest patients treated with Induced Hypothermia (IH) with two different cooling device: 1) Arctic Sun; 2) Blanket. On Admission time and at 12, 24, and 72 hours after the start of treatment, blood and urine samples were collected. Plasma cytokines were measured by ELISA.

Results: During IH, we observed a decrease of IL-6, IL-1β and IL-18u levels in both groups, and an increase of inflammatory during rewarming phase. The results are showed in table.

Conclusions: Optimal rewarming rate is unknown. Adverse effects from suboptimal rewarming could diminish a protective effect from hypothermia. These biomarkers may serve as indicator of an individual patient’s place in the injury-repair continuum. Further investigations are needed.

Impact of Different I.V. Iron Preparations on Monocyte Function and Differentiation

Adam M. Zawada,1 Lisa H. Fell,1 Sarah Seiler,1 Martina Sester,1 Danilo Fliser,1 Gunmar H. Heine.1 Internal Medicine IV, Saarland Univ Medical Center, Homburg, Saarland, Germany; 2Dept of Transplant and Infection Immunology, Saarland Univ Medical Center, Homburg, Saarland, Germany.

Background: Treatment of iron deficiency with intravenous (i.v.) iron is a first-line strategy to improve anemia and quality of life in patients with chronic kidney disease (CKD). However, in vitro and in vivo experiments demonstrated that certain i.v. iron preparations have immunological side-effects. In the present study we now investigated substance-specific impacts of different i.v. iron preparations on monocyte function and differentiation.

Methods: We in vitro stimulated monocytes with different concentrations (0.133 mg/ml, 0.266 mg/ml, 0.533 mg/ml) of iron sucrose (IS), sodium ferric gluconate (SFG), ferric carboxymaltose (FCM), and iron isomaltoside 1000 (IMI) and assessed monocyte adhesion and transmigration capacity. Monocyte differentiation into M1 and M2 macrophages and dendritic cells (DCs) was flow-cytometrically analyzed, and functional characteristics of monocyte derived cells were tested. Finally, we performed ultra-deep miRNA sequencing to characterize dysregulated signaling pathways in iron stimulated monocyte derived cells.

Results: IS and SFG increased monocyte adhesion, while transmigration was not affected by any preparation. The expression of M1 (CD40) and M2 (CD16, CD206) markers as well as the phagocytosis capacity were significantly reduced in IS and SFG stimulated macrophages. IS and SFG down-regulated CD14 and CD68 in DCs and up-regulated CD141 and HLA-DR. FCM affected macrophage and DC phenotype and function to a lesser degree, and IMI had no measurable immunological effects. In miRNA expression analysis we found IS to strongly dysregulate miRNAs which are linked to FR2 and MAPK signaling pathways (e.g. miR-146-5p, miR-155-5p).

Conclusions: Our findings demonstrate that less stable i.v. iron preparations like IS and SFG substance-specifically affect monocyte function and differentiation into macrophages and DCs in vitro. Future clinical trials should delineate in how far these observations will lead to clinically relevant changes in immune responses and thus affect the infection risk in CKD patients.

The Involvement of p38 MAPK in Neutrophil Bacterial Dysfunction of Hemodialysis Patients

Yasutaka Kamikawa, Shinji Kitajima, Akinori Har, Norihiko Sakai, Miho Shimizu, Kengo Furuiuchi, Yasunori Iwata, Takashi Wada. Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan.

Background: Mortality from infection has been reported to be higher in hemodialysis (HD) patients than that in healthy subjects. However, the precise mechanism causing it remains to be investigated. Neutrophils play crucial roles in host defenses against bacterial infection. Therefore, we investigated the impact of neutrophil inflammatory signal on bacterial function in HD patients.

Methods: Four HD patients and six healthy subjects were recruited for this study. None of HD patients had diabetes, cardiovascular disease and cancer. Neutrophils were isolated from peripheral blood by density gradient centrifugation. The purity was tested by flow cytometry after lactoferin staining. Microarray analysis was performed to assess global gene expression in leukocytes. Neutrophil bacterial function was evaluated by the growth rate of Staphylococcus aureus (S.aureus) after co-culture of it with neutrophils obtained from HD patients or healthy subjects. Reactive oxygen species (ROS) production and myeloperoxidase (MPO) activity were analyzed by fluorescence intensity.

Results: Microarray analysis showed the impairment of p38 mitogen activated protein kinase (MAPK) signal in neutrophils from HD patients. The growth rate of S.aureus was higher in HD patients than that in healthy subjects (490.1±147.1%, 144.5±49.4%, respectively; p<0.01) suggesting that neutrophil anti-bacterial killing function was dysregulated in HD patients. The levels of ROS from neutrophils after co-culture with S.aureus were lower in HD patients than those in healthy subjects (1.4±6±3.8, 3±4±15.4, respectively; p<0.01). On the other hand, there was no difference of MPO activity between both groups. To confirm the importance of p38 MAPK, we examined the effect of the selective pharmacological p38 MAPK inhibitor SB202190 on neutrophil bacterial function. The treatment with SB202190 suppressed anti-bacterial killing function as well as ROS production in neutrophils.

Conclusions: Impaired of p38MAPK signaling pathway might contribute to the suppression of neutrophil bacterial function in HD patients through the dysregulation of ROS production.
Nrf2 and NF-xB mRNA Expression in Chronic Kidney Disease: A Focus on Non-Dialysis Patients

Denise Maia,1 Viviane Oliveira Leal,2 Juliana Saldanha,1 Milena Barca Stockler-Pinto,3 Ludmila Fmm Cardozo,1 Felipe Rizzetto Santos,4 Alex Sandro Duarte Albuquerque,2 Maurilo Leite,3 ‘Graduate Program in Medical Sciences, Federal Univ Fluminense, Rio de Janeiro, Brazil;4 Pedro Ernesto Univ Hospital, State Univ of Rio de Janeiro (UERJ), Rio de Janeiro, Brazil;1 Graduated Program in Cardiovascular Sciences, Federal Univ Fluminense, Rio de Janeiro, Brazil;2 Div of Nephrology, Federal Univ of Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil.

Background: Nuclear factor erythroid 2-related factor 2 (Nrf2), a regulator of genes encoding antioxidant and detoxifying enzymes appear to be downregulated in chronic kidney disease patients undergoing hemodialysis (HD). However, data regarding the expression of Nrf2 in non-dialysis patients are scanty. Thus, the aim of this study was to evaluate Nrf2 and nuclear factor kappa-B (NF-xB) mRNA expression in non-dialysis patients, comparing with data from HD patients.

Methods: 20 non-dialysis patients, 20 HD patients and 11 healthy subjects were enrolled. The peripheral blood mononuclear cells were isolated and processed for the evaluation of NF-xB and Nrf2 expression by quantitative real-time polymerase chain reaction.

Results: Nrf2 mRNA was significantly higher in non-dialysis compared to HD patients but similar to healthy individuals. Inversely, NF-xB mRNA was lower in non-dialysis when compared to HD patients and also similar to healthy individuals i.e.

Conclusions: Non-dialysis patients may conserve regular homeostatic balance between Nrf2 and NF-xB expressions, being comparable to healthy individuals. As renal disease progresses to more advanced stages, an impaired Nrf2/NF-xB balance can be observed, as in HD patients. Funding: Government Support - Non-U.S.

ERK 1/2 and ERK 5 Signaling Pathways via Renin Angiotensin System Activation Play Differential Regulatory Roles During the Progression of Glomerulonephritis

Takashi Naga1, Maki Uruhashi1, Shoji Kaga1,2, Toshiaki Tamaki,1,2 Shoji Kaga1,2, ‘Dept of Pediatrics, Inst of Biomedical Sciences, Tokushima Univ Graduate School, Tokushima, Japan;2 Dept of Pharmacology, Inst of Biomedical Sciences, Tokushima Univ Graduate School, Tokushima, Japan.

Background: Although extracellular signal regulated kinase (ERK)1/2 and ERK5 are key kinases of signaling pathway involved in various cellular functions in kidney injury, the mechanism between those kinase and renin-angiotensin system (RAS) activation in glomerulonephritis (GN) have not been fully elucidated. This study was performed to clarify the potential role of ERK1/2 and ERK5 via RAS activation in the pathogenesis of GN.

Methods: We examined the expression of ERK1/2 and ERK5 in rat progressive model of GN induced by anti-glomerular basement membrane antibodies in Wistar Kyoto rats. In addition, the signal transduction pathway in angiotensin II (Ang II)-induced glomerular pathologic alterations were investigated in primary cultured mesangial cells (MCs).

Results: GN rat developed typical cellular crescent in glomeruli on day 7 and severe fibrocellular crescent and glomerulosclerosis were found on day 28. Immuno-staining of kidneys revealed that strong expression of phospho-ERK1/2 was observed on day 7 and phospho-ERK5 expression was markedly increased on day 28 of GN. Ang II type 1 receptor blocker (ARB) suppressed those augmentations. Macrophage infiltration and PCNA positive cells were seen on day 7 and collagen type 1 expression was enhanced on day 28, and ARB treatment reduced these expressions. Next, cultured MCs stimulated by Ang II showed significantly increases in MCP-1 and collagen type 1 expression, and cell proliferation. While optimized PD080597 that inhibited ERK1/2 phosphorylation abolished the expression of MCP-1 expression (P<0.01) and cell proliferation (P<0.01), optimized BIX02189 that inhibited ERK5 phosphorylation abolished the expression of collagen type 1 expression (P<0.01). ARB treatment attenuated these augmentations.

Conclusions: These data suggest that ERK1/2 regulates acute inflammatory reactions and ERK5 induces the development of chronic glomerular fibrosis during RAS activation in GN.

Chinese Herbal Medicine for IgA Nephropathy, ShenPing Decoction, Blocks Platelet-Derived Growth Factor Signaling Pathway Activated by IgA1-Containing Immune Complexes in Human Mesangial Cells

Xianwen Zhang,1,2 Zhi qiang Huang,2 Stacy D. Hall,3 Lin Wang,3 Yueyi Deng,3 Bruce A. Julian,1 Yiping Chen,1 Jan Novak,1 Longhua Hospital, Shanghai 1st Hospital, Traditional Chinese Medicine, Shanghai, China;2 Univ of Alabama at Birmingham, Birmingham, AL.

Background: IgA nephropathy (IgAN) is characterized by mesangial immunodeposits containing galactose-deficient IgA1 (Gd-IgA1) usually associated with mesangial proliferation and matrix expansion. There is no disease-specific therapy of IgAN, although a herbal medicinal prescription, ShenPing decoction (SP), has been used in China for decades to effectively treat IgAN. Mesangial cell proliferation in IgAN is likely induced by Gd-IgA1-Containing immune complexes (CIC) and this process may involve activation of platelet-derived growth factor (PDGF) signaling pathway. We have shown previously that SP blocks the activation of PDGF pathway induced by PDGF. In this study, we investigated the effect of SP on PDGF signaling pathway in human mesangial cells (HMCs) and assessed the effects of SP on this pathway.

Methods: CIC were isolated from sera of IgAN patients using size-exclusion chromatography. Primary HMCs were incubated with PDGF or CIC for 15 min or 24 h with or without PDGF. Cellular proliferation was measured by Syto60. PDGF signaling was evaluated by SDS-PAGE and Western blotting.

Results: 24-h incubation with CIC increased MC proliferation and SP inhibited this effect. Stimulation of HMC with CIC increased phosphorylation of PDGFR and ERK1/2 after 15 min and 24 h. PDGF degradation was not observed in CIC-treated group, which is different from PDGFR. SP inhibited CIC- and PDGF-induced phosphorylation and degradation of PDGFR.

Conclusions: CIC induced cellular proliferation of HMC and activation of PDGF pathway without degradation of PDGF, a normal negative feedback observed for PDGF. CIC possibly caused persistent activation of PDGF pathway. SP inhibited CIC- and PDGF-induced effects. These findings indicate that SP may play a role in the mesangial injury of IgAN. ERK 1/2 and ERK 5 Signaling Pathways via Renin Angiotensin System Activation Play Differential Regulatory Roles During the Progression of Glomerulonephritis (GN) have not been fully elucidated. This study was performed to clarify the potential role of ERK1/2 and ERK5 via RAS activation in the pathogenesis of GN.

Methods: We examined the expression of ERK1/2 and ERK5 in rat progressive model of GN induced by anti-glomerular basement membrane antibodies in Wistar Kyoto rats. In addition, the signal transduction pathway in angiotensin II (Ang II)-induced glomerular pathologic alterations were investigated in primary cultured mesangial cells (MCs).

Results: GN rat developed typical cellular crescent in glomeruli on day 7 and severe fibrocellular crescent and glomerulosclerosis were found on day 28. Immuno-staining of kidneys revealed that strong expression of phospho-ERK1/2 was observed on day 7 and phospho-ERK5 expression was markedly increased on day 28 of GN. Ang II type 1 receptor blocker (ARB) suppressed those augmentations. Macrophage infiltration and PCNA positive cells were seen on day 7 and collagen type 1 expression was enhanced on day 28, and ARB treatment reduced these expressions. Next, cultured MCs stimulated by Ang II showed significantly increases in MCP-1 and collagen type 1 expression, and cell proliferation. While optimized PD080597 that inhibited ERK1/2 phosphorylation abolished the expression of MCP-1 expression (P<0.01) and cell proliferation (P<0.01), optimized BIX02189 that inhibited ERK5 phosphorylation abolished the expression of collagen type 1 expression (P<0.01). ARB treatment attenuated these augmentations.

Conclusions: These data suggest that ERK1/2 regulates acute inflammatory reactions and ERK5 induces the development of chronic glomerular fibrosis during RAS activation in GN.

Effects of Fluorofenidone on the Expression of Thiorodoxin-Inter-Acting Protein and Thiorodoxin of Human Peritoneal Mesothelial Cell in High Glucose and Lipopolysaccharide

Yichen Chen, Jianfei Ma, Nephrology; The First Affiliated Hospital of China Medical Univ, Shenyang, China.

Background: Peritoneal dialysis is one of an important alternative therapies for end-stage kidney disease. But the occurrence of peritoneal dialysis correlation peritonitis has brought great resistance for the development of peritoneal dialysis. Significance of oxidative stress in peritoneal dialysis related peritonitis has been paid more and more attention. In cells that did not receive stimulation, Txnip combined with thioredoxin, when the elevated ROS concentration inside the cell, the formation of the compounds are separated. After dissociation Tx play its functions to remove ROS, whereas Txnip participation NLRP3 could reduce the increase of Txnip, IL-6 and TGF-b1, and increase the express of Trx in these findings indicate that SP like contains component(s) targeting the PDGF/PDGRF system that may play a role in the mesangial injury of IgAN. Effects of Resveratrol on NRF2 Expression in Raw 264.7 Macrophages Cells and Non-Dialyzed CKD Patients

Denise Maia,1 Juliana Saldanha,1 Milena Barca Stockler-Pinto,3 Viviane Oliveira Leal,1 Denis Fouque,3 Christophe O. Mafra,3 ‘Graduate Program in Medical Sciences, Fluminense Federal Univ (UFF), Niteró, Rio de Janeiro, Brazil;1 Pos-Graduate Program in Cardiovascular Sciences, Fluminense Federal Univ (UFF), Niteró, Rio de Janeiro, Brazil;2 Div of Nutrition, Pedro Ernesto Univ Hospital, State Univ of Rio de Janeiro (UERJ), Rio de Janeiro, Brazil;3 Dept of Nephrology, Centre Hospitalier Lyon Sud, Univ de Lyon, Pierre Bénite, France;4 INSa de Lyon, CarMen, INSERM U1060, Univ de Lyon, Villeurbanne, France.

Background: Oxidative stress and inflammation are common in CKD. Bioactive compounds as resveratrol may modulate the NRF2 expression, a transcription factor that could up-regulate the cell antioxidant systems. Therefore, the aim of this study was observe NRF2 expression in macrophages cells and in non-dialyzed CKD patients treated with resveratrol.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

909A Underline represents presenting author.
Methods: Mouse RAW 264.7 macrophages were treated with 50µM of resveratrol in DMSO 1% (v/v). Nucleus and cytoplasm were separated. Western Blot (WB) was performed to quantify Nrf2. qRT-PCR was performed to evaluate Nrf2 expression. 7 non-dialyzed CKD patients (5 women; 64±6.5 years; GFR 37.9±10.4 mL/min) received 500mg of resveratrol/day for 4 weeks. qRT-PCR to evaluate Nrf2 expression was performed in PH model causes and after supplementation with resveratrol.

Results: Cells treated with resveratrol showed a significant activation of Nrf2 with an increase in the ratio nucleus/cytoplasm compared to control cells i.e. p<0.02. The same was observed in qRT-PCR (p<0.02). In patients, we observed a trend to increase Nrf2 expression with resveratrol supplementation (p<0.06).

Conclusions: We concluded that both cells and patients treated with resveratrol increased Nrf2 expression. So, we suppose that supplementation with resveratrol can lead to an increased oxidative stress and inflammatory status among CKD patients.

PUB105
Mitochondrial Implications of Golycolate Metabolism in Primary Hyperoxaluria
Sonja Fargue, Tanecia Mitchell, John Knight, Ross P. Holmes.
Urology, Univ of Alabama at Birmingham, Birmingham, AL.

Background: The primary hyperoxalurias (PH) are rare but severe inherited diseases characterized by an increased endogenous production of oxalate and calcium oxalate kidney stones in patients. Deficiency in alanine glyoxylate aminotransferase (AGT, deficient in PH1) or glyoxylate reductase (GR, deficient in PH2) have repercussions on the metabolism of the oxalate precursors glyoxylate and glycolate. Excessive amounts of glycolate are characteristic of PH1, through glyoxylate to glycolate cycling in the presence of glycolate oxidase (GO) and GR. Perturbations in glycolate metabolism may affect mitochondrial function in PH patients. The objective of this study is to assess how over-expression of these enzymes regulates glycolate and glyoxylate generation and mitochondrial function.

Methods: An established transformed CHO cells model was used in which cells express Go ± ATG or GR. Cells were incubated with glycolate or glyoxylate and the extracellular concentrations of oxalate and glycolate, and the induction of oxidative stress were analyzed. Cellular bioenergetics were assessed with a Seahorse XF-96 extracellular flux analyzer.

Results: The metabolism of glycolate by GO generated glyoxylate, oxalate and H2O2. Intracellular ROS were produced and cell viability was reduced. Mitochondrial respiration and the cellular bioenergetic reserve capacity were decreased following glycolate oxidation. The expression of AGT or GR reduced the untoward effects of glycolate metabolism to glyoxylate and oxalate.

Conclusions: The disruption of normal glycolate metabolism by GO, AGT and GR in a cell model causes the production of stress related metabolites and mitochondrial dysfunction. Limiting mitochondrial dysfunction might be a therapeutic approach in treating PH patients.

PUB106
Effect of Fasudil on Response Oxidative Stress in High Glucose and Lipopolysaccharide Induced Human Peritoneal Mesothelial Cells
Ye Hu, Jianfei Ma.
Nephrology, First Affiliated Hospital of China Medical Univ, Shenyang, Liaoning Province, China.

Background: Peritoneal fibrosis is a common cause of chronic peritoneal dialysis patients withdrawn from peritoneal dialysis. Research shows that, there are oxidative stress exists in peritoneal dialysis patients. Rho/Rho kinase signaling pathway is involved in the regulation of multiple biological process, including inflammation, oxidative stress and fibrosis. The transcription factor Nrf2 related factor is a central regulator of cellular antioxidant responses. Rho kinase inhibitor fasudil is a Rock inhibitor which currently used in clinic and experiment, it can regulate cell proliferation, migration, adhesion and movement at the cellular level. It also can regulate a variety of factors in inflammation, thrombogenesis, oxidant/antioxidant and fibrosis at the molecular level.

Methods: By using the method of Real Time-PCR to detect the expression of RhoA, Rock1, Nrf2 and HO-1 mRNA, Western Blot to detect the expression of RhoA, Rock1, Nrf2 and HO-1 protein, chemistry fluorescence test to detect the expression of ROS protein, chemical colorimetry to detect the expression of GSH-PX protein. ELISA to detect the expression of TGF-b1 protein in the human peritoneal mesothelial cell. Experimental groups: Control group; High glucose and LPS for different concentrations group; Fasudil intervene group.

Results: Compared with the normal control, high glucose and LPS can significantly increase the expression of RhoA, Rock-1, ROS and TGF-b1, reduce the expression of Nrf2, HO-1 and GSH-PX in a concentration dependent manner, all have statistically significant (P<0.05). Compared with 2.5% glucose and 10ug/ml LPS, group, fasudil can reduce the expression of RhoA, Rock-1, ROS and TGF-b1, increase the expression of Nrf2, HO-1 and GSH-PX, all have statistically significant (P<0.05).

Conclusions: High glucose and LPS up-regulate the expression of RhoA and Rock1 but reduce Nrf2 in the protein and gene level, and increase the expression of ROS and TGF-b1 but reduce the expression of HO-1 and GSH-PX. Fasudil could reverse the increase of RhoA and Rock1 and the decrease of Nrf2 in HPMCs that have been pre-treated with high glucose and LPS, play the role of anti-oxidant and anti-fibrosis.

PUB107
Glucose Induces Mitochondrial Reactive Oxygen Species Through Carbonyl Stress and Respiratory Chain in Rat Peritoneal Mesothelial Cells
Satoshi Shimada,1 Takefumi Mori,1 Yusuke Ohsaki,1 Ikuo Oba,1 Shinichi Sato,1 Kenji Koizumi,1 Sadayoshi Ito,1 ‘Nephrology, Endocrinology and Vascular Medicine, Graduate School for Medicine, Tohoku Univ, Sendai, Miyagi, Japan; 2Div of Integrative Renal Replacement Therapy, Graduate School of Medicine, Tohoku Univ.

Background: Glucose and its degradation products (GDPs) play a major role in the peritoneal injury and affect peritoneal dialysis vintage. Peritoneal mesothelial cell dysfunction has been demonstrated to involve in peritoneal injury by glucose and GDPs. GDPs induced carbonyl stress has been demonstrated to induce mitochondrial dysfunction in several cell types. The present study was designed to determine the role of GDPs and respiratory chain in glucose induced mitochondrial ROS in peritoneal mesothelial cells. Qualitatively, the primary rat peritoneal mesothelial cell (RPTEC/TERT1) were isolated from Wistar rats. Real-time mitochondrial superoxide was monitored using a specific fluorescent indicator Mito SOX red under fluorescence microscope equipped with temperature controlled chamber. RPMEC was stimulated with 90 mmol/L of glucose and compared to those of vehicle. In separate experiments, RPMEC was pre-incubated with a mitochondrial specific superoxide dismutase mimetic miteoTEMPO, respiratory chain inhibitor rotenone or carbonyl stress inhibitor pyridoxamine to determine the mechanism of glucose induced mitochondrial ROS production.

Results: 90 mmol/L glucose significantly increased mitochondrial superoxide production within 200 seconds in primary cultured RPMEC (0.21±0.07 AU, n=8, P<0.05 vs vehicle). These responses were abolished when RPMEC was pre-incubated with miteoTEMPO (-0.0±0.15 AU, n=5, P<0.34 vs vehicle), rotenone (0.00±0.06 AU, n=6, P<0.42 vs vehicle) and pyridoxamine (-0.34±0.34 AU, n=5, P<0.26 vs vehicle), indicating that mitochondrial superoxide production through respiratory chain and GDP.

Conclusions: The results in the present study indicate that glucose and GDP present in the PD effluent is responsible for oxidative stress in the peritoneal mesothelial cells by stimulation of mitochondrial ROS production, which could play a role in peritoneal function and injury during PD.

Renal Cell Carcinoma Models: Effect of Chemopreventative Agents on the Carcinogenic Potential of Potassium Bromate in Human Renal Epithelial Cells
Israel Obadai, Tara McMorrow.
School of Biomedical and Biomedical Science, Conway Inst, Univ College Dublin, Ireland.

Background: Renal Cell Carcinoma (RCC) is a leading cause of renal cancer worldwide. The cause of RCC remains unknown, with many chemicals implicated in its development. We have developed an in vitro model of RCC using the carcinogen, potassium bromate, to investigate potential prevention and possible treatment options of RCC. Chemoprevention is the use of different chemicals, natural or synthetic, to halt, block or reverse the process of carcinogenesis. It is one of the novel approaches that is being used to control cancer and it is a good alternative to the conventional therapies that are associated with a long list of side effects and limitations. These agents have antioxidant, anti-inflammatory, antiangiogenic effects and induce phase II enzymes, apoptosis, cell cycle arrest, and differentiation. They antagonize hormones and growth factor receptors and the regulation of multiple biological process, including inflammation, oxidative stress and fibrosis. The transcription factor NFE2 related factor is a central regulator of cellular antioxidant responses. Rho kinase inhibitor fasudil is a Rock inhibitor which currently used in clinic and experiment, it can regulate cell proliferation, migration, adhesion and movement at the cellular level. It also can regulate a variety of factors in inflammation, thrombogenesis, oxidant/antioxidant and fibrosis at the molecular level.

Methods: By using the method of Real Time-PCR to detect the expression of RhoA, Rock1, Nrf2 and HO-1 mRNA, Western Blot to detect the expression of RhoA, Rock1, Nrf2 and HO-1 protein, chemistry fluorescence test to detect the expression of ROS protein, chemical colorimetry to detect the expression of GSH-PX protein. ELISA to detect the expression of TGF-b1 protein in the human peritoneal mesothelial cell. Experimental groups: Control group; High glucose and LPS for different concentrations group; Fasudil intervene group.

Results: Compared with the normal control, high glucose and LPS can significantly increase the expression of RhoA, Rock-1, ROS and TGF-b1, reduce the expression of Nrf2, HO-1 and GSH-PX in a concentration dependent manner, all have statistically significant (P<0.05). Compared with 2.5% glucose and 10ug/ml LPS, group, fasudil can reduce the expression of RhoA, Rock-1, ROS and TGF-b1, increase the expression of Nrf2, HO-1 and GSH-PX, all have statistically significant (P<0.05).

Conclusions: High glucose and LPS up-regulate the expression of RhoA and Rock1 but reduce Nrf2 in the protein and gene level, and increase the expression of ROS and TGF-b1 but reduce the expression of HO-1 and GSH-PX. Fasudil could reverse the increase of RhoA and Rock1 and the decrease of Nrf2 in HPMCs that have been pre-treated with high glucose and LPS, play the role of anti-oxidant and anti-fibrosis.
assessed by measuring the intracellular concentration of H2O2. Oxidative stress-induced DNA damage was estimated quantitatively by measuring 8-OHdG concentrations. Western blot analysis was used to detect the changes in particular oxidative stress-induced proteins.

**Results:** The carcinogenic effects induced by potassium bromate were reduced by the co-administration with all of the chemopreventative agents used. Oxidative stress markers, H2O2 and DNA adduct formation, were reduced.

**Conclusions:** The results suggest that these chemopreventative agents show significant potential against KBrO3-induced carcinogenicity. Further analysis is being carried out to understand the functional mechanisms of this chemoprevention on the cells, in particular on the genetic and epigenetic mechanisms involved.

**The Podocyte as a Target for the Actions of Levamisole in Nephrotic Syndrome**

Luhu Jiang,1 Charles Colin Thomas Hindmarsh,1 Mark Rogers,2 Peter W. Mathiesen,2 Gavin Iain Welsh,1 1School of Clinical Sciences, Univ of Bristol; 2Univ of Hong Kong.

**Background:** Levamisole is an anthelmintic agent that has also been shown to be effective as a second line treatment for steroid-dependent or frequently-relapsing nephrotic syndrome (SD/FRNS) in children. Levamisole is able to decrease steroid dosages and reduce the relapse frequency and severity. We have recently reported the effectiveness of levamisole in a small cohort of adult patients and provided evidence which suggests that levamisole’s mode of action in SDNS is attributable to its direct effects on podocytes.

**Methods:** To further clarify its therapeutic effectiveness and identify the therapeutic targets of this drug, we have employed RNA-sequencing technology to profile transcriptomic changes of human podocytes in response to levamisole.

**Results:** We have identified a number of genes which are differentially expressed in podocytes in response to levamisole. These include genes linked to the cellular interferon response pathways and a number which overlap with those regulated by dexamethasone in podocytes. These have been validated in vitro and are now being studied in animal models of nephrotic syndrome.

**Conclusions:** Together, our molecular evidence strongly supports the promising use of levamisole in treating nephrotic syndrome.

**A New Approach to Phosphate and FGF23 Lowering: Design of the COMBINE Trial**

Joachim H. H. Le,1 Tamara Isakova,2 Stuart M. Sprague,3 Kalani L. Raphael,1 Jennifer J. Gassman,1 Linda F. Fried,1 Dominic S. Raj,2 Alfred K. Cheung,3 Andrew N. Hoofnagle,4 John W. Kusek,5 Michael F. Flesner,5 Geoffrey A. Block,5 Myles S. Wolf,5 The pilot clinical trials in Ckd study group.1 2Peytin,1 3UCSD; 4Northwestern; 5U of Utah; 6U of Pittsburgh; 7Cleveland Clinic; 8George Washington U; 9NIDDK, 10Denver Nephrology; 11Northshore; 12U Washington.

**Background:** Elevated serum phosphate and FGF23 are associated with CVD, CKD progression, and mortality in CkD. Phosphate binders inconsistently reduce phosphate and FGF23 levels. Nicotinamide (vitamin B3) decreases active phosphate transport by down regulating NaPi2b in the gut. Whether nicotinamide alone or in combination with binders can safely and tolerably lower phosphate and FGF23 levels in Ckd is unknown.

**Methods:** We designed a 4 arm parallel group randomized double blind trial comparing lanthanum carbonate (1000mg tid), nicotinamide (750mg bid), neither, or both. Supported by the NIDDK CKD Pilot Clinical Trials U01, 200 participants with eGFR 20-45 mL/min/1.73m² recruited from 7 centers across the US will be randomized 1:1:1:1 and treated for 12 months. Main exclusions include phosphate < 2.8mg/dL, liver disease, and thrombocytopenia. The dual primary efficacy endpoints are change in phosphate and FGF23. Secondary endpoints are change in LV mass and renal fibrosis by MRI. Enrollment began in March 2015.

**Results:** To date, 45 persons were screened, 33 were eligible, 26 entered run-in, and 18 were randomized. Baseline characteristics of randomized participants are shown in the table. Updated data will be available at presentation.

PUB113
The Rationale for and Design of TREV1 TR02: A Multicenter Randomized, Double-Blind, Placebo-Controlled Trial of Nalbuphine ER for the Treatment of Uremic Pruritus in Hemodialysis Patients Vandana S. Mathur,1 Michael J. Germain,2 Roberta Duncan,3 Thomas Sciascia,4 Mathur Consulting, Woodside, CA;5 Western New England Renal & Transplant Associates, PC, Hamden, MA; Trevi Therapeutics, New Haven, CT.

Background: Uremic pruritus (UP) is common in hemodialysis patients, but there are no FDA-approved treatments or "regulatory roadmap" for the development of new drugs. Nevertheless, the significant quality of life (QOL) burden of chronic itch underscores need for treatments. The striking bilateral, non-dermatomal distribution of itching and perception of non-pruritogetic skin stimulants as itch suggest that UP is centrally mediated, like neuropathic pain. Reduction in endogenous κ opioid ligand ratio is hypothesized to be a mechanism. Our goal was to evaluate nalbuphine ER tablet (NAL), a κ-agonist and μ-antagonist as a treatment for UP.

Methods: The study was powered for an α = 0.05, β = 0.9 for a group difference of 1.5 (SD = 3.5) in worst itching numerical rating scale (NRS, 0-10); N = 120/arm (NAL 120 mg BID, NAL 60 mg BID, and placebo BID). Patients with NRS ≥ 4.5 (moderate to severe pruritus) were enrolled at ~45 US and 6 EU sites.

Results:

1. Itch is subjectively perceived. Itching intensity and QOL were relevant endpoints. Used patient-reported outcomes previously validated in UP patients including NRS and Skindex-10 (1st and 2nd endpoints).
2. Opioid drugs require titration to minimize opioid side effects. To perform a blinded opioid titration with a self-administered oral drug, we used blister cards that were labeled for each study day.
3. Long enough duration to demonstrate durability and lack of tolerance but short enough to avoid excessive dropouts due to background comorbidities. Used an 8-week blinded treatment duration.
4. Post-treatment safety. Added a 2-week washout period after the blinded treatment period.
5. Day-to-day variability in NRS was expected. The mean of 2 weeks of measurements at baseline and on treatment (Wks 7 and 8) were used for the calculation of the 1st endpoint.

Conclusions: The trial design overcame the challenges. Unblinded results will be presented.

PUB114
The Rationale and Design of Trevi TR02 Extention: A Multi-Center Open Label Extension Study of the Safety and Anti-Pruritic Efficacy of Nalbuphine HCl Extended Release Tablets in Uremic Pruritus Patients on Hemodialysis Thomas Sciascia,1 Howard Hirt,2 Arnaie Hawii,1 Roberta Duncan,1 Vandana S. Mathur,1 Trevi Therapeutics, Inc., New Haven, CT; Edenridge Associates LLC, Wilmington, DE;2 Havi Consulting, Ridgefield, CT;3 Mathur Consulting, Woodside, CA.

Background: Nalbuphine HCl is a mu antagonist/kappa agonist being investigated for the treatment of pruritus in hemodialysis patients (UP). The safety and long-term benefits of Nalbuphine ER in the treatment of uremic pruritus is being investigated in this ongoing open-label extension study.

Methods: TR02ext is a 26-week multicenter open-label extension study of a double-blind placebo controlled study in which UP patients with a baseline NRS >4.5 were treated with Nalbuphine ER or placebo for 8 weeks followed by a 2-week washout period. At the end of study, patients that opt to roll over into the extension study, and have an NRS > 2 enrolled in a 26-week Treatment Period (TP), while patients with an NRS ≤2 entered a 13-week Observation Period (OP). If a patient’s itch worsened (NRS > 2) within the OP, they entered the TP for the remainder of the study.

All patients on treatment were titrated between 30 mg QD-120 mg BID over a 3-4 week period based on reported tolerability and efficacy and then maintained their dose until end of study. Patients whose itch intensity failed to improve during the TP were discontinued from treatment.

Conclusions: Approximately 70% of the eligible patients who completed the blinded controlled study, enrolled in the extension study. Final study data will be presented once the study is complete.

Assessing Treatment Safety and Efficacy of a New Patient-Centered Hemodialysis System Luis Alvarez,1 Geoffrey A. Block,2 May L. Yau,3 Glenn Matthew Chertow,4 1Palo Alto Medical Foundation, Palo Alto, CA; 2Denver Nephrology, Denver, CO; 3Outset Medical, San Jose, CA; 4Stanford School of Medicine, Stanford, CA.

Background: Many studies designed and conducted for the evaluation of new technologies utilized in hemodialysis have been small, observational studies. These studies may have underestimated the rate of clinical symptoms yielding biased safety results.

Methods: We designed a prospective, multicenter, open-label, non-randomized, cross-over study where patients serve as their own control. The study was designed with novel approaches to ensuring accuracy of clinical symptom reporting both in the home and clinic setting. Up to 50 patients will be enrolled in the study for 19 weeks and will use the TabloTM Hemodialysis System for treatments 4 times/week.

During each study phase, patients will record inter- and intra-dialytic symptoms for each treatment via questionnaire. Research staff will review all responses weekly to determine if an adverse event (AE) has occurred. In addition, research staff will conduct weekly visits to the dialysis clinic and to home to educate patients on AEs and to collect questionnaires. Patients will also be assessed to determine if a standardized weekly Kt/V of 2.1 has been achieved.

Results: Study enrollment is expected to begin in 2015 with results expected in 2016.

Conclusions: By utilizing patients to collect AE data both in-center and at home, we should more accurately capture AE rates due to the uniformity of the reporting mechanism. In terms of the clinical efficacy endpoint of the study, modelled Clearance data suggests the majority of patients will achieve the weekly standard Kt/V target. Actual clearance data will be forthcoming at the completion of the trial.

PUB116
Interim Analysis of Comprehensive CKD Education Modality Choice Outcomes Andrea K. Eason,1 Damitru Rotaru,2 Fahd Syed,1 Manisha Singh,1 Ashutosh M. Shukla,3 Sudhir V. Shah,1 1Univ of Arkansas for Medical Sciences; 2University of Florida.

Background: Preliminary data from a study comparing telemedicine vs conventional CKD education is presented here. The primary aim is to see if patients are able to make a modality choice by the end of the third visit.

Methods: Patients are enrolled in three groups as shown in the pilot study design.

Key Scientific Considerations

1. Characterize the time course of worsened itch intensity following 8 weeks on blinded study drug or placebo followed by a 2-week washout period
2. Dose distribution of flexible dosing to optimize efficacy and safety
3. Individualized titration to maximize drug efficacy with tolerable side effects

Conclusions: Currently 117 of the eligible patients who completed the blinded controlled study, enrolled in the extension study. Final study data will be presented once the study is complete.

PUB117

Assessing Treatment Safety and Efficacy of a New Patient-Centered Hemodialysis System...
Each group attends 3 sessions and are given handouts or an 82 page workbook designed specifically for the study. They are asked about their modality choice pre-education and at the end of each session.

**Results:** To date 80 subjects have been enrolled and 32 have completed all sessions. After 3 sessions, 38% chose peritoneal dialysis (PD), 28% chose home hemodialysis (HHD), 28% chose in center hemodialysis (ICHHD), 3% chose no dialysis (ND), 3% could not make a choice (NC) and 8% chose transplant. On enrollment, 47% made a modality choice with 40% choosing home modalities. At the end of 3 sessions, 97% were able to make a modality choice with 66% choosing home modalities. Of the 6 subjects who have not yet made a choice, 3 volunteered RRT choice (RRT), 3 started PD and 1 had a pre-emptive transplant. Additionally, 4 subjects did not complete all visits: 3 started ICHHD (2 with AVFs) and 1 died. Enrollment in the telemedicine arm has been slower than expected.

**Conclusions:** This preliminary data shows that at the end of 3 education sessions there is a significant increase in subjects being able to make a RRT choice (97% vs. 47%) and most chose home dialysis (66% vs. 40%). Community engagement is key to a successful outreach of this state-wide CKD education program. Further strategies are being developed to improve local involvement.

**Determination of Oxidative Stress and Inflammation Index in Patients with Different Dialysis Modalities and Analysis of Related Factors**

**Linsihan Jiao,** Jianfei Ma. Nephrology, The First Affiliated Hospital of China Medical Univ, Shenyang, Liaoning, China.

**Background:** This study through the determination of serum AOPPs, GSH-PX, PTX-3, IL-6 content in each group.

**Methods:** 70 cases of ESRD patients divided into three groups: 26 cases of PD patients, 26 cases of MHD patients, 18 cases of CKD5 patients. Select 14 normal persons as control group. Age, gender and other data of the four groups were matched. Get Serum of patients, 26 cases of MHD patients, 18 cases of CKD5 patients. Then using ELISA for determination of serum AOPPs, GSH-PX, PTX-3, IL-6. Age, gender and other data of the four groups were matched.

**Results:** AOPPs were positively correlated with PTX-3 (R=0.939, P=0.000), AOPPs was positively correlated with PTX-3 (R=0.956, P=0.000).5. Through Correlation analysis in PD group: AOPPs was positively correlated with IL-6 (R=0.934, P=0.000), AOPPs was positively correlated with IL-6 (R=0.939, P=0.000).

**Conclusions:** This study through the determination of serum AOPPs, GSH-PX, PTX-3, IL-6 content in each group.

**Health-Related Quality of Life in Dialysis Patients: Effect of Type D Personality**

**Christopher Susanto, 1 Constantijn Konings, 2 Jeroen Kooman, 3 1*Nephrology, Ekerleik Hospital, Helmond, Netherlands; 2Nephrology, Catharina Hospital, Eindhoven, Netherlands; 3Nephrology, Maastricht Univ Medical Centre, Maastricht, Netherlands.**

**Background:** Measurement of HRQoL is a useful tool to describe the burden of illness and the impact of treatment. These information could be essential to develop a personal care. Type D (distressed) personality is defined as a tendency to experience both negative affectivity (NA) and social inhibition (SI). The prevalence of this personality and its effect on HRQoL in dialysis patients are assessed.

**Methods:** Participants were from outpatient clinic. DS 14 was used. A score of ≥10 on both NA and SI subscales indicates that the person has a Type D personality. HRQoL was measured using the Dutch version of the Kidney Disease Quality of Life. Six components of the KDQOL were the primary end points (general health perceptions, burden of kidney disease, effect on daily life, cognitive function, pain, emotional welfare).

**Results:** 147 patients with mean age of 71.2 (±17). Mean time on dialysis 37 months. The prevalence of type D personality was 30% HRQoL in patients with type D personality was lower compared with non type D. It was statistically significant in all components except for emotional welfare.
PUB121

Sleep Disorder and mRNA Expression Profile of Sleep-Related Gene in Peripheral Blood Cells in Patients with CKD  Shinji Kitajima, Yasunori Iwata, Yasuyuki Shinozaki, Norihiko Sakai, Miho Shimizu, Kengo Furuchi, Takashi Wada. Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan.

**Background:** Although uremic substances would be candidates involved in sleep disorder, detailed mechanisms remain unclear so far. We performed polymorphic analysis in CKD patients and used PBMCs to examine the expression of genes related to sleep and wakefulness states.

**Methods:** Polymorphic analysis was performed in 9 CKD patients and 6 healthy controls. Genes related to sleep and wakefulness were evaluated by RNA microarray in 15 subjects, including CKD patients and control subjects.

**Results:** Polymorphic analysis revealed that the duration of the rapid eye movement (REM)/non-REM phases during total sleep time was different between CKD patients and healthy controls. In mRNA microarray evaluation, hierarchical clustering analysis showed the different pattern of sleep-related gene expression in the patients with HD. The mRNA expression levels of GABA receptor, noradrenaline receptor, dopamine receptor and histamine receptor showed an inverse correlation with renal function. Moreover, orexin and its receptor mRNA expression also showed an inverse correlation with renal function.

**Conclusions:** These data raise the possibility that sleep-related gene expression on PBMC in CKD/HD patients may be associated with sleep disorder.

NA was significantly related to all components except for emotional welfare. SI was found to be significantly correlated especially with effect on daily life.

**Conclusions:** Type D personality may be an important determinant of individual differences in HRQoL and should be an important consideration in a personal care of dialysis patients.

PUB122

Potential Link Between Iron, Inflammation and FGF23 in Patients with Early Stages of Chronic Kidney Disease  Ewelina Łukaszyk,¹ Mateusz Łukaszyk,² Jolanta Malyško,¹ ¹2nd Dept of Nephrology and Hypertension with Dialysis Unit, Medical Univ of Białystok, Białystok, Poland; ²Dept of Allergology and Internal Medicine, Medical Univ of Białystok, Białystok, Poland.

**Background:** Fibroblast growth factor 23 (FGF23) is a hormone commonly increased in patients with chronic kidney disease and a key inflammation and iron deficiency is a known risk factor of cardiovascular outcomes and death in patients with chronic kidney disease (CKD). The aim of the study was to evaluate the potential link between FGF23 concentration, novel iron status and inflammatory parameters among patients with early stages of CKD.

**Methods:** 96 patients with early stage of CKD and S4 with normal renal function were enrolled in the study. Standard laboratory methods were used to measure serum hemoglobin, fibriogen, creatinine, iron, total iron binding capacity (TIBC) and ferritin. Intact FGF23, hepcidin-25, sTfR (soluble transferrin receptor), GDF-15 (growth differentiation factor-15), IL-6 (interleukin 6) and hsCRP (high sensitivity C-reactive protein) were measured using commercially available kits. Data was analyzed in different group of patients according to iron status (absolute and functional iron deficiency and normal iron levels).

**Results:** There was no difference of FGF23 concentration regarding to iron status. Significant correlations in patients with CKD are presented in Table.

There were no statistically significant associations between FGF23 and TSAT, ferritin and hsCRP. We revealed significantly higher concentrations of FGF23 in patients with type 2 diabetes (mean logFGF23: 4.0±0.5 vs 3.8±0.5, p<0.03) and with heart failure (mean logFGF23: 4.0±0.6 vs 3.8±0.5, p<0.04) in comparison to those without these diseases.

**Conclusions:** Kidney function, inflammation and iron status were the parameters affecting FGF23 in the early stages of CKD. Our data are paving the way for further studies on the role of FGF23 in cardiorenal anemia-iron deficiency syndrome, in particular in the early stages of CKD.

PUB123

Echocardiography and Cardiovascular Risk: What’s the Relationship in the Renal Transplant Recipient?  Miguel Goncalves,¹ Micaela Neto,² Pedro Vieira,¹ Luís Resende,¹ Nuno Rosa,¹ Susana Gomes,³ Jose Duras,² Jose Alves Teixeira,¹ Gil Silva,¹ ¹Nephrology, Hospital Dr. Nélia Mendonça, Funchal, Portugal; ²Cardiology, Hospital Dr. Nélia Mendonça, Funchal, Portugal.

**Background:** Cardiovascular (CV) disease is the major cause of death among renal transplant recipients (RTR). Unlike end stage renal disease, it is unknown whether echocardiographic abnormalities are useful to identify RTR with high cardiovascular and risk of death.

**Methods:** Retrospective review of 107 RTR with a functioning and stable graft for longer than 12 months and an echocardiography performed in the last year. Risk of MACE and death using a CV risk calculator specific for RTR and all echocardiographic parameters were reviewed and analyzed.

**Results:** Among 107 patients (57.9% males, 50.4±13.9 years old), 7-years risk for MACE was >10% in 30.9% of patients and 7-years risk for death >10% in 56.1%. Left ventricular hypertrophy (LVH) was found in 55.1%, diastolic dysfunction in 39.3%, dilated left atrium (LA) in 53.3%, high pulmonary artery systolic pressure (PASP) in 29.9%, valvular calcifications in 22.4% and moderate to severe mitral regurgitation in 3.7%. Mean Ejection Fraction was 68.36±6.87%. Univariate analysis showed with statistical significance an increased risk of MACE in patients with LVH, diastolic dysfunction, dilated LA, high PASP, valvular calcifications and mitral regurgitation. Multivariate analysis identified an independent association between the risk of MACE >10% and valvular calcifications [OR 3.499 (1.261-10.115, P=0.016)] and with high PASP [OR 4.319 (1.201-15.535, p=0.025)].

**Conclusions:** Echocardiographic abnormalities identify RTR at increased risk of MACE and death. Valvular calcifications and high PASP are significant predictors of MACE whereas diastolic dysfunction and high PASP are significant predictors of death.
Background: Up to date, renal dysfunction incidence and determinants remain un.evaluated in pulmonary hypertension (PHT). We aim to assess hemodynamic and demographic factors associated with a decrease in glomerular filtration rate (GFR) in the context of PHT.

Methods: The regional competence center for PHT of Lyon (France) prospectively compiles demographic, hemodynamic and biological variables among newly diagnosed patients. We retrospectively analyzed data for patients with pulmonary arterial hypertension (PAH, group 1 of PHT classification) after exclusion of the following causes of PHT: thromboembolic, lung diseases and/or hypoxia and left heart disease. Hemodynamic variables from the right heart catheterization and estimated GFR (eGFR, CKD-EPI formula) were assessed at PAH diagnosis time.

Results: 209 patients (mean age 59.1±17.1, 63.2% women) were included from October 1998 to July 2012. 40.2% presented with systemic arterial hypertension (HT) and 12.9% with diabetes. Mean eGFR was 83.9±27.1 ml/min/1.73m/2 eGFR inferior to 60 ml/min/1.73m in 18.5% of cases. Mean values of mPAP, right atrial pressure (RAP) and cardiac index (CI) were 45.5±12.6 mmHg, 7.8±5.3 mmHg and 2.6±0.9 L/min/1.73m/2. In multivariable analysis, age, male gender, HT, anorectic-related PAH and a CI inferior to 2.5 L/min/1.73m/2 were associated with a significant decrease in eGFR of 1.0 ml/min/1.73m/2/year (95% confidence interval, 0.8 to 1.2), 11.8 ml/min/1.73m/2 (5.8 to 17.8), 6.6 ml/min/1.73m/2 (0.1 to 13.2), 13.4 ml/min/1.73m/2 (2.3 to 24.5) and 10.1 ml/min/1.73m/2 (4.4 to 15.9). RAP were not statistically related to eGFR levels.

Conclusions: Renal dysfunction is frequent from diagnosis among PAH patients. A low CI is correlated with a significant decrease in eGFR, whereas RAP seem unrelated. Equally, male gender, HT and anorectic-related PAH are correlated with a significant decrease in eGFR. These results should incite renal prevention in PAH patients presenting these risk factors.

Kidney Function and Cause-Specific Mortality in Drug-Treated Older Cardiac Patients: A 10-Year Follow-Up Study

Ellen K. Hoogeveen, Johanna M. Geleijnse, Daan Kromhout, Theo Stijnen, Erik Giltay

Background: Chronic kidney disease (CKD) is highly prevalent among older (~60y) cardiac patients. The relation between CKD and cause-specific mortality among older cardiac patients who are treated with state-of-the-art pharmacotherapy is unclear.

Methods: From 2002-2006, 60-80 years old Dutch post-myocardial infarction patients were enrolled in the Alpha Omega trial and followed until death or January 2012. We estimated Glomerular Filtration Rate (eGFR) with serum creatinine (Cr(Cys)) and creatinine using the CKD-EPI equations. Kidney function was available in 4,561 (94.3%) participants and analyzed in relation to major causes of death using Cox models and four-knot restricted cubic splines.

Results: At baseline mean age was 69y, 79% were men, 21% had diabetes, 90% used antihypertensive drugs, 85% used statins. Patients were divided into four categories of eGFR and analyzed in relation to major causes of death using Cox models and four-knot restricted cubic splines.

Conclusions: This study showed that serum uric acid level is significantly associated with incident non-fatal stroke and that hyperuricemia might be an independent risk for non-fatal stroke in the general population.

The Association Between Serum Uric Acid and Incidence of Non-Fatal Stroke in a Community-Based Population: A Longitudinal Survey of a Nationwide Cohort in Japan

Shoichiro Fujimoto, Kazunobu Ichikawa, Tsunoo Konta, Shouichi Fujimoto, Kunitoshi Ikeda, Toshiki Moriyama, Kunihiro Yamagata, Kazuhiko Tsuruya, Kenjiro Kimura, Ichie Narita, Masahide Kondo, Koichi Asahi, Tuyoshi Watanabe

Background: Hyperuricemia is a risk for adverse renal outcomes in chronic kidney disease. This study investigated the effect of uric acid on incidence of non-fatal stroke in a community-based population.

Methods: We used a nationwide database of 160,164 subjects (aged 29–74, male 39%), participated in an annual health check, “The Specific Health Check and Guidance in Japan” between 2008–2010, and examined the relationship between the gender-specific quintiles of serum uric acid levels and the 2-year incidence of non-fatal stroke.

Results: During the follow-up period 2,081 non-fatal stroke occurred (1.3%). The incidence of non-fatal stroke showed a significant J-shaped association with the increase in serum uric acid levels (P<0.001, lowest [1.2%] in the 3 quintile of uric acid [Q3: males 5.7–6.2 mg/dL, females 4.4–4.8 mg/dL] and highest [1.6%] in the 5 quintile [Q5: males ≥7.1 mg/dL, females ≥5.5 mg/dL]). After adjusting for possible confounders, the odds ratio for incident stroke was significantly higher in Q5, compared with Q3 (OR 1.21, 95% CI 1.05–1.39, P=0.007). The odds ratio of hyperuricemia (serum uric acid ≥7 mg/dL) for incident stroke was significantly increased in total subjects (OR 1.22, 95% CI 1.07–1.39), especially in females (OR 1.46, 95% CI 1.04–1.99) and non-hypertensive subjects (OR 1.34, 95% CI 1.04–1.70). In contrast, the association between serum uric acid levels and incident stroke was not significant in subjects with diabetes, proteinuria and renal insufficiency.

Conclusions: This study showed that serum uric acid level is significantly associated with incident non-fatal stroke and that hyperuricemia might be an independent risk for non-fatal stroke in the general population.

The Association Between Serum Calcium and Mortality in a Community-Based Population: The Takahata Study

Sayumi Watanabe, Keita Kamei, Kazunobu Ichikawa, Tsunoo Konta, Isao Kubota

Background: The low intake of calcium is a risk for cardiovascular events. This study investigated the association between serum calcium and mortality in a community-based population.

Methods: This study included 1,314 participants (aged 40–87, males 45%) at local health checkup in Takahata, Japan. We divided them into 3 groups according to the tertiles of serum calcium at baseline and compared the mortality during 8-year follow-up period. Serum calcium was corrected for serum albumin.

Results: At baseline serum calcium level was 9.8 ± 0.4 mg/dL (mean ± SD). In the multivariate linear regression analysis serum calcium was positively associated with serum sodium, potassium, phosphorus, albumin, uric acid and total cholesterol, and was negatively associated with serum chloride and HDL-cholesterol, and urinary beta2-microglobulin. During the follow-up period 62 deaths, including 14 cardiovascular deaths occurred. In Kaplan-Meier analysis all-cause mortality was significantly increased along with the decrease in serum calcium (Log-rank P=0.03). In Cox proportional hazard analysis adjusted for confounders including age, gender, smoking and drinking habits, comorbidities and other serum electrolytes, the association of serum calcium was of borderline significance with all-cause mortality (HR 1.09, 95% CI 1.04–1.14, P=0.07). Low tertile (≤ 9.6 mg/dL) vs. high tertile (≥ 10.0 mg/dL) and was significant with cardiovascular mortality (HR 6.33, 95% CI 1.13–43.7), P=0.04, low tertile vs. high tertile. In addition, there was a significant interaction between serum calcium and sodium on all-cause mortality (P=0.03) and the association of serum calcium with the mortality was significant in the subjects with low serum sodium (< 150 mEq/L) but not high sodium levels.

Conclusions: This study showed that serum calcium was significantly associated with various environmental factors and low serum calcium was an independent predictor for the mortality in the general Japanese population.
African Americans were also associated with adverse cardiovascular events (CVE). Given HIV years (ns) and 37 CACS showed a significant association with age, diabetes, statin administration, serum phosphate, uric acid, alkaline phosphatase, albumin, LDL proteinuria and have renal and cardiovascular outcome.

Methods: This is a cross-sectional study and the enrolled 85 CKD patients with exception of CKD stage 5 or receiving renal replacement therapy. They were subjected to their positive balance of phosphorus in kidney. There are a few studies which reported that serum phosphorus level was correlated with endothelial function. Recently it has been reported the patients with higher serum phosphorus level related to the worse endothelial function in healthy population. Thus, the following study was carried out in an effort to redetermine the relationship between serum phosphorus level and endothelial dysfunction to those on chronic kidney disease.

Results: When participants were divided into four groups according to estimated GFR, serum phosphorus level had significant higher values in CKD stage 4. From univariate and multivariate analysis, levels of phosphorus were associated with PH-PAT values(=0.296, p=0.008). Multivariate analysis showed serum parathyroid hormone was independent predictor for endothelial dysfunction assessed with PH-PAT.

Conclusions: This study showed that serum phosphorus level may associate with endothelial function even in CKD. Furthermore, it is a prospective study of large population to identify the relationship between phosphorus and endothelial function and to establish optimal reference range of phosphorus level for protection from endothelial dysfunction.

Coronary Artery Calcification in Predialysis Diabetic and Non-diabetic CKD Patients Sonoo Mizuri, Yoshiko Nishizawa, Kazuomi Yamashita, Kyoka Ono, Mariko Asai, Masahiro Ishine, Shigehiro Doi, Takao Masaki, Kenichiro Shigemoto, Satoro Harada, Hiroshi Takeda, Masayuki Osako, Hiroshi Nakamura, Hiroshi Ono

Background: Risk factors for coronary artery calcification may include low vertebral bone mineral density (BMD), and may differ in diabetic and non-diabetic CKD patients.

Methods: We examined Agatston coronary artery calcium score (CACS), BMD of T8 vertebra using MDCT, age, sex, presence of diabetes, hypertension, smoking history, statin administration, BMI, eGFR, urinary protein, blood urea, glucose, serum iron, calcium, phosphate, uric acid, alkaline phosphatase, albumin, LDL-cholesterol, and triglyceride in 128 predialysis CKD patients, 82 non-diabetics, and 46 diabetics. Factors related to CACS were assessed by multivariate regression and logistic regression analyses using all of the above independent variables.

Results: Coronary artery calcification was present in 106 (82.8%) patients. Significant associations between CACS;400H and age, diabetes, and statin administration were observed, and odds ratios were 1.1, 3.4, and 3.7, respectively, in all subjects (P<0.05). Log CACS showed a significant association with age, diabetes, statin administration, serum phosphate, and iron in all subjects (P<0.05). Mean age and eGFR were 70±14 vs. 70±9 years (ns) and 37±20 vs. 30±19 ml/min/1.73m² (P<0.05), in non-diabetics and diabetics, respectively. Serum phosphate levels were not significantly different in the both groups. CACS (H) was 239±411 in non-diabetics and 942±1258 in diabetics (P<0.001). Significant associations were observed between Log CACS and age (P<0.0001, β=0.42), statin administration (P<0.01, β=0.31), and serum phosphate (P=0.05, β=0.20) in non-diabetics, and between Log CACS and blood urea (P=0.01, β=0.55), serum iron (P=0.01, β=0.41), age (P=0.01, β=0.41), BMI (P=0.05, β=0.29) and smoking history (P=0.05, β=0.29) in diabetics.

BMD showed no association with CACS.

Conclusions: Hyperphosphatemia is a risk factor for coronary artery calcification in nondiabetic but not diabetic CKD patients, and an association between CACS and BMD of T8 vertebra was not observed.

Funding: Private Foundation Support.

Association of APOL1 Risk Variants with Cardiovascular Events Among HIV-Infected Individuals Tessy Kimberly Nevick, Michael J. Choi, Michelle M. Estrella, Mohamed G. Atta, Derek M. Fine

Nephrology, Johns Hopkins Hospital, Baltimore, MD.

Background: HIV+ individuals have higher risk of cardiovascular disease versus HIV- individuals. Recently, APOL1 risk variants that are associated with CKD among African Americans were also associated with adverse cardiovascular events (CVE). Given the potential interaction between HIV and APOL1 variants, we examined the association between the APOL1 risk variants and CVE in HIV+ adults.

Methods: A cohort study of 5,090 HIV+ African Americans who underwent clinically indicated kidney biopsies from 1996-2011 and were successfully genotyped for the APOL1 G1 and G2 alleles. Multivariable logistic regression was used to evaluate the high-risk (2 copies) vs. the low-risk (0/1 copy) genotype and the odds of CVE (diagnosis of acute myocardial infarction, percutaneous cardiac intervention, CABG or stroke).

Results: Of 203 individuals, 64% were male with mean age of 46 years, eGFR of 38.4 ml/min/1.73 m²; and urine protein-to-creatinine ratio (UPCR) of 4.1 g/l. Mean CD4 count was 259 cells/mm³; only 29% had HIV RNA levels <400 cps/mL. During follow-up, 12% had CVE and 40% died from all causes. Individuals with the high-risk vs. low-risk genotype had similar odds of CVE, adjusting for age, CVD risk factors, statin and aspirin use, eGFR and proteinuria (OR 1.13, 95% CI: 0.34 – 3.81). Similarly, APOL1 risk genotype was not associated with the composite outcome of CVE and death from all causes, adjusting for age, CVD risk factors, statin and aspirin use, and viral suppression status (OR 1.17; 95% CI: 0.58-2.34).

Conclusions: There is no clear relationship between the APOL1 risk variants and CVE or death from all causes in adults with advanced CKD and HIV.

Proteinuria: Is It a Therapeutic Target or Only a Cardiovascular Risk Marker? Jafar Al-Said, International Medicine and Nephrology, Bahrain.

Methods: Studies published over the last decade had illustrated that despite the successful reduction in proteinuria there were either no benefit or a negative impact on renal and cardiovascular outcomes.

Results: Review recent published trials, which have shown an evidence of decreased proteinuria and have renal and cardiovascular outcome.

Conclusions: The following studies were identified: The IDNT; The final outcome revealed that although Irbesartan succeeded in lowering doubling of S. Creatinine as well as proteinuria, it failed to show a significant difference in CV mortality, non-fatal MI, heart failure, or stroke. The CADBY-HYCAR, the result confirmed a successful reduction in albuminuria by 14%. However, no significant difference was found on CV outcome, including death, non-fatal MI, stroke or heart failure. The ONTARGET, in a sub-analysis; looking at renal outcome, including doubling S. Cr., dialysis and death, it revealed that although the ACE Inh. and the ARB combination had successfully reduced proteinuria, but it resulted in worse renal outcome. The TRANSCEND; by looking specifically at the renal outcome, including dialysis and doubling serum Cr., it was found that GFR had decreased.

The AASK trial; the results did not show a positive solid endpoint associated with lowering proteinuria, no statistical difference was encountered. The ROADMAP; the result revealed that decreasing microalbuminuria as well as blood pressure in the Olmssartan subgroup was not reflected in decreased cardiovascular death. The Altitude trial; decreased proteinuria did not show a significant evidence in the primary renal or cardiovascular composite endpoints. Moreover, the study was terminated prematurely because of severe decline in eGFR, hyperkalemia and hypotension. The FA-NPHERON-D; The final outcome was not statistically different. The study was stopped prematurely because of more acute renal injury and hyperkalemia in the combination arm.

Conclusions: Decreased proteinuria was associated with negative cardiac and renal outcomes. This could be due to the effect of RAAS combination, but we have to admit that these repeated observations carries an evidence, at least to question our standard belief, and that proteinuria might not be more than a cardiac risk factor indicator.

Prevalence of Hematuria and Associations with All-Cause and Cardiovascular Mortality in China Jinwei Wang, Fang Wang, Luxia Zhang, Ming Hui Zhao. Renal Div, Dept of Medicine, Peking Univ First Hospital, Beijing, China.

Background: Hematuria is one of the indicators of kidney damage. We aimed to estimate the prevalence of hematuria in China and evaluate its association with mortality and cardiovascular adverse outcome.

Results: A nationally representative sample of 47,204 Chinese adults was obtained during the survey conducted between January 2009, and December 2012. Each participant’s survival status was identified through Dec 31, 2013. Causes of death in ICD code 100-199 were classified as cardiovascular disease. Hematuria was defined as ≥3 red cells per high-power field in microscopic examination. Subjects with pyuria and women undergoing menstruation were excluded from the analysis. The associations between hematuria and all-cause and cardiovascular mortality were studied by using the Cox regression model.

Results: The mean age of the population at baseline was 49.6±15.2 years, and 42.7% of the participants were male. Altogether, 2126 (4.5%) of the population was detected with hematuria, which is 3.8 and 2.6 per 1000 person-years, while those for participants without hematuria were 3.4 and 1.3 per 1000 person-years. Hematuria was found to be significantly associated with increased risk of both cardiovascular and all-cause mortality with the multivariable adjusted hazard ratio of 1.7 (95% confidence interval: 1.1-2.7), compared with those without hematuria. However, no significant associations were found between hematuria and all-cause mortality.

Conclusions: Mortality, especially due to cardiovascular diseases, was greater among the Chinese patients with hematari. These results suggest the possible effect of hematari on cardiovascular mortality. Funding: Government Support - Non-U.S.

PUB133
Glo merular Filtration Rate Is a Predictor of Subclinical Left Ventricular Diastolic Dysfunction in Patients with Rheumatoid Arthritis
Sudh M Manhaswii, Kashif Naeem, Issa AL Salmi. Medicine, MOH, United Arab Emirates; Medicine, MOH, United Arab Emirates; Medicine, The Royal Hospital, Oman

Background: Rheumatoid arthritis (RA) is a systemic disease effecting primarily joints with subclinical kidney involvement. Subclinical cardiovascular disease (CVD) is a leading cause of morbidity & mortality in RA & chronic kidney disease (CKD) at early stages. Left ventricular diastolic dysfunction (LVDD) is a principal pathophysiologic mechanism & essential diagnostic indexes of HF with preserved ejection fraction (HFP EF).

Methods: Renal parameters correlated with echocardiographic findings in patients with RA & eGFR as estimated (MDRD equation). Doppler echocardiography was performed by pulse wave Doppler with sample volume at tip of mitral valve in apical 4-chambers view. Peak early (E)/late (A) diastolic velocities were measured as indicator of LV systolic function. Assessment of peak early (E)/late (A) diastolic mitral annular velocity was performed by pulse wave tissue Doppler imaging (TDI) of lateral wall in apical 4-chamber view & to diagnose LVDD (E/A<8).

Results: Interim analysis: 29 (3M, 26F) with RA diagnosed (ACR 1988), aged 46 ± 12y, eGFR 130 ± 36 mL/min. Univariate regression showed a negative linear relationship of GFR & age (p<0.001, CI -2.77, -1.03), age (p=0.001, CI -2.32, -0.65), age (p=0.002, CI -0.02, 0.55, -0.66), SBP (p=0.032, CI -1.51, -0.07), ESR (p=0.005, CI -3.19, -0.21), ferritin level (p=0.008, CI -0.45, -0.08), EE’ (p=0.005, CI -20.76, -4.26). Multiple regression maintained a negative relationship between GFR & age at each age of peak (p=0.004, CI -2.52, -0.57), Kt/V (p=0.04, 15.25, -0.01), CRF was 0.54.

Conclusions: RA patient have subclinical CKD and cardiac dysfunction & eGFR independently & negatively correlated to LVDD with moderate correlation (0.54). E/A increased with decreasing GFR & higher than in patients GFR<90. LVDD influenced by exposure to LV preload due CKD progression & it’s a preclinical predictor of future HF & mortality. However, milder form of LVDD may stabilize or improve subset of patients may, over time, be at risk for functional deterioration. Inflammation as a major pathological key in RA may be underlying cause for increased subclinical kidney & VD.

PUB134
The Association Between Creatinine versus Cystatin-C-Based eGFR and Cardiovascular Risk Factors in Children with Chronic Kidney Disease
Sheena Sharma, Ji Young Kim, Susan L. Furrh. Nephrology, Children's Hospital of Philadelphia, Philadelphia, PA; Biostatistics Core, Clinical and Translational Research Center, Children's Hospital of Philadelphia, Philadelphia, PA.

Background: Chronic kidney disease (CKD) is an independent risk factor for cardiovascular events (e.g. stroke, myocardial infarction) in adults. Children with mild to moderate CKD have a high prevalence of cardiovascular risk factors (CRF). Higher levels of cystatin-C demonstrate a stronger predictive value for cardiovascular events compared with creatinine-based eGFR in adults. However, whether similar associations exist in children and young adults has yet to be determined. We hypothesize that cystatin-C based eGFR will demonstrate a stronger association with CRF compared with creatinine-based eGFR in children and young adults.

Methods: We used cross-sectional data of 93 subjects aged 8-25 years with CKD and 70 healthy controls. eGFR was calculated using age appropriate creatinine and cystatin-C based formulas. The CRF included were anemia (hemoglobin < 2 standard deviations below the mean), hypertriglyceridemia (>130mg/dL) and proteinuria (urine protein/creatinine >0.2mg/dL or urine albumin/creatinine >30mg/g). Multivariate analysis assessed the association between creatinine and cystatin based eGFR and each risk factor after adjusting for age, gender and race.

Results: These results suggest that creatinine and cystatin-based eGFR have similar associations with CRF. Funding: Other U.S. Government Support

The Influence of Selected Demographic and Clinical Factors on Left Ventricular Function Presented by Echocardiographic Study in Patients Treated with Peritoneal Dialysis
Maria Wanic-Kossowska, Krzysztof Pawlaczky, Krzysztof Schwemer, Krzysztof Hoppe. Dept of Nephrology, Transplantology and Internal Medicine, Poznan Univ of Medical Sciences, Poznan, Poland.

Background: The purpose of the study was to perform a cross-sectional analysis between the selected demographics including age, sex, BMI as well as peritoneal dialysis treatment vintage, volume of residual diuresis, presence of arterial hypertension, anemia, inflammatory states, malnutrition, mass of the left ventricle, problems with the contractile function of the left ventricle as well as decreased relaxation of the left ventricle in the group of patients treated with peritoneal dialysis with regard to survival prognosis.

Methods: The study was conducted on 105 patients (45 men, 56 women) treated with peritoneal dialysis with the average time of 36.1±23.7 months. The control group consisted of 30 healthy volunteers (20 women, 10 men, mean age 55.0±23.8 years). Based on general known vascular and cardiac risk factors the patients were divided into subgroups: elderly patients (>65 years of age), male, patients treated on peritoneal dialysis over 3 years, daily diuresis <500 ml, Kt/V<2.1, arterial hypertension, anemia, inflammatory states, malnutrition.

Results: Analyzing the frequency of vascular and cardiac risk factors resulting in inadequate echocardiogram results showed the inflammatory states were the most common reason for increased left ventricular mass, diastolic dysfunction of the left ventricle as well as decreased ejection fraction. In the model of logistical regression taking into account age, sex, dialysis vintage, concentration of CRF, ejection fraction of the left ventricle, left ventricle mass, and factoring E/A from the echocardiogram study only advanced age of the patient treated on peritoneal dialysis decreased survival rate.

Conclusions: Chronic low-grade inflammation and advanced age seem to be two most common negative prognostic factors decreasing life expectancy. Further research is necessary to verify the intricate relationships between demographic factors and prognosis in the group of patients undergoing peritoneal dialysis.

PUB136
Ankle Brachial Index and Exertional Leg Pain Among Hemodialysis Patients without a Clinical Diagnosis of Peripheral Arterial Disease
Pranay S. Garimella, Lucia Kwak, Kunihiro Matsushita, Esther D. Kim, Michelle M. Estrella, Stephen M. Sozio, Lucy A. Mooni, Rulan P. Parshk, Bernard J. Jaac. 1 Tufts Medical Center; 2 Johns Hopkins Univ; 3 Univ of Toronto.

Background: Exertional leg pain is considered pathognomonic for diagnosing peripheral artery disease (PAD). However, patients on dialysis may have multiple comorbidities causing or masking leg pain, potentially precluding its use to diagnose PAD. Furthermore, the utility of the ankle-brachial index (ABI) to diagnose PAD in this population is questionable due to the presence of arterial calcification. In this context, there are no data on the association of leg symptoms with ABI in dialysis patients despite they having an extremely high burden of PAD.

Methods: We evaluated the cross-sectional association of exertional leg symptoms with the spectrum of ABI in 247 incident hemodialysis patients without clinical diagnosis of PAD enrolled in the Predictors of Arrhythmia and Cardiovascular Events (PACE) study. The presence of exertional leg pain was based on questionnaire and ABI was categorized as low (<0.90), borderline (0.90<~1.00), normal (1.00<~1.39) and high (>1.4). We used logistic regression analysis to report odds of exertional leg pain.

Results: Mean age was 54 years, 76% were black and 51% had diabetes. The prevalence of exertional leg pain was lowest in the normal ABI category and increased towards both ends of the spectrum. Compared to normal ABI, low ABI was associated with 2.8 fold higher odds of exertional leg pain, although it did not reach significance. After adjusting for age, gender and race this association was attenuated to 2.5 fold odds. Borderline and high ABI were also similarly associated with exertional leg pain.

**Chronic Kidney Disease Is Highly Prevalent at Emergency Department and Associated with Cardiovascular Comorbidity**

Jolanta Malyszko, Anita Swietochowska,1 Nephrology, Medical Univ, Bialystok, Podlaskie, Poland; 2Emergency, Regional Hospital, Lomzia, Poland.

**Background:** Different stages of CKD affects more than 10% of the population, while in high-risk patients, the incidence of 30-50% is reported. The aim of this work is to evaluate the prevalence of CKD in patients admitted to the non-surgical emergency department in one year, the impact of CKD risk factors, rate of hospitalization and mortality.

**Methods:** From 10,509 patients admitted to ED, the group of patients with serum creatinine measured, i.e. 3,853 (40%) patients over 18 years was selected, including 2,095 (55%) patients over 70 years. A small percentage of patients were under nephrology care. Accumulation of risk factors such as gender, age, hypertension, diabetes, results in an increased prevalence of CKD. Prevalence of hypertension in the population of patients with CKD is high (59% vs 29% in non-CKD, p<0.001), similarly to prevalence of CAD (24%), DM (15%) and CHF (10%). In CKD, 30% of patients have anemia. In hospitalized mortality was 6%. Analysis of mortality of patients admitted to the emergency department and then hospitalized showed that the majority of patients were over 70, with CKD (64%), CHF (75%), DM (35%), ACS (25%) and anemia (56%). Deaths were mainly from cardiovascular causes.

**Conclusions:** Prevalence of CKD is high in patients admitted to ED, and associated with mainly cardiovascular disease. Education is of utmost importance to diagnose and treat CKD in a timely manner and decreased cardiovascular morbidity and mortality in this population.

**Funding:** Government Support - Non-U.S.

**Predictors of In-Hospital Mortality of CKD4-6 Patients with Takotsubo Cardiomyopathy**

Fernando Rodrigo Aguilar, Mark Abi Nader, Wen Shen, Serban A. Dragoi, Alex Montero, Ping Li. Internal Medicine, Div of Nephrology, Medstar Georgetown Univ Hospital, Washington, DC.

**Background:** The pathophysiology of Takotsubo cardiomyopathy (TTC) remains poorly understood and little is known about the factors predicting mortality in these patients among those with chronic kidney disease. We aimed to study the epidemiology of TTC and predictors of mortality in these patients.

**Methods:** All patients with CKD 4 to CKD 6 (ICDP 585.4-585.6) diagnosed with TTC (ICDP 429.83), in the Nationwide Inpatient Sample database between 2007 and 2012, were compared to CKD4 to CKD6 patients without TTC. Capturing only cases undergoing left heart catheterization (ICDP procedure code 32.22) and excluding those receiving stent (ICDP procedure code 90.66; 36.01 - 07.00.45.00.48) as a main treatment. Both groups were matched, using propensity matching score for chronic conditions including diabetes mellitus, hypertension, hyperlipidemia, coronary artery disease, obesity, alcohol use, smoking, heart failure and ventricular arrhythmias. Non-cardiovascular conditions were also tested to match individual cases. Multivariable logistic regression analysis was performed.

**Results:** 143 cases of TTC were diagnosed from 2007-2012 in patients having 6 patients with TTC was more commonly diagnosed in Women (64%), CHF (75%), DM (35%), ACS (25%) and anemia (56%). Deaths were mainly from cardiovascular causes.

**Conclusions:** The Importance of Evaluating Coronary Artery Disease by Multi-Director Row Computed Tomography in Advanced CKD Patients. Jacky R. W. Hasegawa,1 Daili Kobayashi,2 Masahiko Nagahama,1 Takuya Fujimaru,1 Yuki Heath,1 Fumika Taki,1 Miyuki Futatsuyama,1 Yasuhiro Komatsu.1 1Nephrology, St. Luke’s International Hospital, Tokyo, Japan; 2General Internal Medicine, St. Luke’s International Hospital, Tokyo, Japan.

**Background:** There is a growing body of evidence that CKD contributes to the severity of coronary artery disease (CAD). Although Multi-director row computed tomography (MDCT) provides valuable information about CAD, its use for patients with CKD is difficult due to the risk of contrast induced nephropathy (CIN). To our knowledge, there have been no studies to explore the association of CAD and advanced CKD. The objectives of this study are to assess the severity of CAD in advanced CKD patients by MDCT and clarify the association between CAD and renal function.

**Methods:** We retrospectively collected the data obtained from 168 advanced CKD patients, stage 3b to 5, who underwent MDCT angiography at St Luke’s international hospital between 2011 and 2014. We assessed CAD by coronary artery calcification score (CASC), coronary plaque characteristics and number of vessel disease. Risk factors for CAD were sought using univariate and multivariate logistic regression.

**Results:** Among the 168 patients (56 females, age 60.0±17.0), 108 patients were CKD stage 3b, 42 patients were stage 4, and 18 patients were stage 4. No patient developed CIN by MDCT. On univariate analysis, patients with CASC 100 were older (p=0.003), male sex (P=0.011), diabetes (P=0.045), and more likely to be a smoker (P=0.014). Multivariate logistic regression analysis identified age (hazard ratio = 1.08, P<0.01), male sex (hazard ratio = 2.97, P=0.013), and CASC 100 (hazard ratio = 2.58, P=0.041) as independent risk factors for CASC 100.

**Conclusions:** Coronary artery calcification is worsened significantly with decreasing renal function in advanced CKD. Given the high morbidity and mortality of cardiovascular disease in CKD, our study underscores the importance of evaluating CAD in advanced CKD.

**PUB140**

**Cardiovascular Biomarkers and Coronary Calcification in CKD Patients**

**Background:** Cardiovascular calcification and mortality are highly prevalent in patients with CKD. Biomarkers can help to an early diagnose, like Osteoprotegerin (OPG) a glycoprotein from TFN family that has been associated with cardiovascular (CV) disease. FGF-23, a phosphaturic protein has been linked to vascular calcification, ventricular hypertrophy, and mortality. Coronary artery calcification (CAC) measured with Agatston score (AS) by CT is associated to CV disease in CKD patients. We hypothesized that OPG and FGF-23 are abnormally elevated in CKD and are associated CAC measured with AS.

**Methods:** An observational study including 138 CKD 3-5patients, and 20 control subjects were included. Serum FGF-23 and OPG levels were measured by ELISA and CAC was determined by multi-detector computed tomography (AS). Biochemical regular labs (scr, Ca, P and PTH) were measured.

**Results:** Compared with control subjects, CKD patients exhibited significantly augmented serum FGF-23 (16.2 vs 304.8pg/mL; p<0.001) and OPG levels (17.0), 108 patients were CKD stage 3b; 42 patients were stage 4; and 18 patients were stage 4. No patient developed CIN by MDCT. On univariate analysis, patients with CASC >100 were older (p=0.003), male sex (P=0.011), diabetes (P=0.045), and more likely to be a smoker (P=0.014). Multivariate logistic regression analysis identified age (hazard ratio = 1.08, P<0.01), male sex (hazard ratio = 2.97, P=0.013), and CAC >100 (hazard ratio = 2.58, P=0.041) as independent risk factors for CAC >100.

**Conclusions:** Coronary artery calcification is worsened significantly with decreasing renal function in advanced CKD. Given the high morbidity and mortality of cardiovascular disease in CKD, our study underscores the importance of evaluating CAD in advanced CKD.

**Rate of Kidney Function Decline and Risk of Hospitalizations**

Yan Xia, Benjamin Charles Bowe, Sumitra Balasubramanian, Ziyad Al-Aly.1 Research and Development, VA Saint Louis Health Care System, Saint Louis, MO; 2Medicine, VA Saint Louis Health Care System, Saint Louis, MO.

**Background:** Risk of hospitalizations is increased in patients with chronic kidney disease (CKD). We sought to examine the association between rate of kidney function decline and risk of hospitalization in a cohort of patients with early CKD.

**Methods:** We built a cohort of 241,274 United States veterans with an estimated glomerular filtration rate (eGFR) between 60 and 45 ml/min on October 1, 1999 and who had at least 1 additional eGFR measurement between October 2003 and September 2004. Patients were followed longitudinally from October 2004 until September 2013. We built

Underline represents presenting author.

918A
survival models to examine the association between rate of kidney function decline and risk of hospitalization, and readmission. We built linear regression models to estimate the length of hospital stay.

**Results:** Over a median follow up of 9 years (IQR 5.42 – 9.00), compared to patients who experienced mild eGFR decline, patients with moderate and severe eGFR decline exhibited an increased risk of hospitalizations HR=1.10 (CI:1.07-1.12), and HR=1.29 (CI:1.26-1.32); respectively. The number of hospitalizations modified the association between rate of decline and risk of hospitalizations in that the risk was increasingly more pronounced with increased number of hospitalizations (p value for interaction <0.0001). Compared to patients with mild decline in kidney function, patients with moderate and severe kidney function decline had increased risk of future readmission, HR=1.16 (CI:1.10-1.21), and HR=1.47 (CI:1.39-1.55); respectively. Among patients with severe kidney function decline, the risk of readmission was increasingly stronger with increased number of readmissions (p value for interaction < 0.0001). Compared to patients with mild decline in kidney function, patients with moderate and severe decline experienced an additional length of stay of 0.91 (CI: 0.58-1.25) and 2.82 (CI: 2.43-3.20) day/year; respectively.

**Conclusions:** Our findings suggest that rate of kidney function decline is associated with future risk of increased health care utilization.

**Racial Influences on the Association of Albumin and Hemoglobin in Chronic Kidney Disease**

_Divya Shankaranarayanan, Avaneesh Jakkoja, Goutham Gudavalli, Ziad Maurice Ashkar. Dept of Internal Medicine, Louisiana State Univ. Lafayette, LA._

**Background:** In CKD, anemia is associated with reduced kidney function, female gender, diabetes, older age, African-American race (AA), iron deficiency, low albumin, renin-angiotensin blockade, and chronic inflammation. There is a paucity of studies evaluating relationship of albumin and hemoglobin (Hb) in CKD among racial groups.

**Methods:** Retrospective cross section design of 196 patients with CKD stages 2-5 in a community clinic over a 7 months period. Averages of hemoglobin, albumin, body mass index (BMI), and glomerular filtration rate (GFR) were obtained for each individual patient. Patients on dialysis and on erythropoesis-stimulating agents were excluded. Multi-linear regression analysis (MLR) was then done between serum albumin and hemoglobin adjusting for age, sex, diabetics status, GFR, BMI, and ACE inhibitors/angiotensin receptor blockers intake (ACEi) among African-Americans (AA) and Caucasians (W).

**Results:** 51% were AA, 49% were diabetics. Mean Hb was 11.7 in AA compared to 12.3 in Caucasians. Mean serum albumin was also lower (3.5 AA versus 3.8 in W). Bmi and GFR were higher in AA (36.4 and 42.8 in AA vs 32.3 and 39.9 in W respectively). Using MLR, there was a statistically significant positive association between GFR (coefficient=0.02, p<0.001), albumin (coefficient=0.77, p=0.002), and hemoglobin. AA race was negatively related to hemoglobin (coefficient= -0.68, p=0.02). When MLR was done separately among racial groups, there was a persistent positive relationship between albumin and hemoglobin among AA (coef=0.95, p<0.001). In Caucasians however there was no association between albumin and hemoglobin (p=0.181).

**Conclusions:** In CKD2-5, using multilinear regression analysis, there was a positive association between serum albumin and hemoglobin. This relationship occurs only in AA and disappears among Caucasians. It is of interest that in our sample AA had higher baseline BMI and GFR and lower serum albumin and hemoglobin. More needs to be done to understand the interplay between BMI, albumin and markers of inflammation and nutrition among African-Americans with chronic kidney disease and their relationships to hemoglobin levels.

**Mircera Use in Chronic Kidney Disease Patients with Symptomatic Renal Anemia: The Real Life Setting**

_Sai Krishna Dereaisinghama, Suzanne H. Forbes, Muhammad M. Yaqoob. Renal and Transplantation Medicine, Barst Health NHS Trust on behalf of the Mircera Audit Consortium, London, United Kingdom._

**Background:** Randomized controlled trials have confirmed inferiority of Mircera in the management of renal anemia when compared to other erythropoietin stimulating agents (ESAs). Many of these trials had strict exclusion criteria which perhaps conflated any benefit that may be seen in an unselected cohort of patients. This multicenter audit assessed the outcomes of Mircera use in the real life setting.

**Methods:** A prospective audit was conducted by 6 UK Renal Centers between 2009 and 2011. Demographic data, as well as hematological and biochemical parameters were longitudinally collected from 1000 adult patients requiring ESAs, over a 1 year period. A cohort of 500 patients were switched from previous ESAs to Mircera and 500 patients remained on their existing ESA therapy. Patients with hemoglobinopathies or malignancies were excluded. Achievement of target hemoglobin (Hb) as per the National Institute of Clinical Excellence (NICE) guidelines was ascertained as the primary objective. Hb variability was reviewed as a secondary objective.

**Results:** Demographic data confirmed both cohorts were comparable. Only 11% of Mircera treated patients had their Hb maintained within range (10-12g/dL) over the entire 1 year versus 4% in the non-Mircera group (p=0.05). (If an Hb recording was out of range the patient was classified as ‘not maintained’). Parameters such as B12, folate and iron were similar in both cohorts. Hb was less variable in the Mircera group (MIRCERA: 10.4± 1.7 VS Mircera group: 13.0± 1.8).

**Conclusions:** The results of this audit confirm that Mircera use in the correction of anemia associated with CKD is equally efficacious as other ESA therapies in this real life setting.

**Latent Profiles of Patient Reported Outcomes in Nephrotic Syndrome Patients**

**Background:** Nephrotic syndrome (NS) can significantly impair the quality of life in children and adults. The purpose of this study was to demonstrate the feasibility and utility in using a latent profile analysis (LPA), a type of cluster analysis, to identify subgroups of patients based on their patient reported outcomes using the Patient Reported Outcomes Measurement Information System® (PROMIS®) measures as well as identifying significant predictors of these subgroups.

**Methods:** Prospective data were collected on 121 children with NS from the PROMIS-II study. Data from 55 children and 254 adults with biopsy confirmed NS from the NEPTUNE cohort were used as validation. LPA was used to identify patterns and subgroups of patients based on PROMIS domain scores. Classification was assessed using entropy statistics. Generalized multinomial logit models were used to identify predictors of profile membership as well as transitions between profiles over time.

**Results:** We identified three patient reported outcome profiles (figure 1) in the PROMIS-II cohort with strong indicators of membership classification (entropy>0.86).

**Conclusions:** LPA may be an effective tool in stratifying NS patients by quality of life. Profile membership changed in response to changes in disease status over time.

Sex Hormone Status in Women with Chronic Kidney Disease: A Survey of Nephrologists  
Sharrana Ramesh,1 Ellen Wells Seely,2 Matthew J. James,1 Jayna M. Holroyd-Leduc,1 Stephen B. Wilton,1,3 Sofia B. Ahmed,1,3 Medicine,  
Cumming School of Medicine;2 Brigham and Women’s Hospital;3 Community of Health Sciences, Univ of Calgary; Libin Cardiovascular Inst of Alberta.

Background: Chronic kidney disease (CKD) in women is often accompanied by menstrual and fertility disorders due to kidney-mediated endocrine disturbances. Whether this issue is recognized by nephrologists and discussed by them with their patients is unknown.

Methods: We electronically surveyed 111 nephrologists in Canada, identified via Canadian Society of Nephrology membership (39% response rate), regarding their impressions of sex hormone status, menstrual cycle, fertility and the role of postmenopausal hormone therapy (HT) in women with CKD. Responses were stratified by kidney transplant nephrologist status.

Results: Fourteen percent of respondents were transplant nephrologists. There were no differences in age or sex between transplant and non-transplant nephrologists. Ninety-three percent of respondents agreed that kidney function has an important impact on regulation of sex hormones. However, only 35% reported discussing fertility, and even fewer (14%) reported discussing menstrual irregularities with their patients. Only 40% of respondents advised their patients to address these concerns with their family physician or an endocrinologist or gynecologist. Most of the nephrologists responded that they do not know if there is a role for hormone replacement therapy in patients with CKD (48%), 23% of nephrologists disagreed with the statement. Nephrologists did not know whether the potential benefits of postmenopausal hormone therapy outweighed the risks in CKD (51%) or if the formulation (44%), route of administration (46%), and time of HRT initiation (50%) play a role in the actions of postmenopausal hormone therapy.

Conclusions: While nephrologists recognize the impact of CKD on sex hormone status in women, few address fertility and menstrual disorders with their patients. Our survey highlights existing uncertainties of nephrologists about how to manage disturbances of sex hormones in people with CKD.

Measurement of Breath Ammonia for Detection of Patients with Chronic Kidney Disease  
Fu-You Liu,1 Yinghong Liu,2 Inst of Nephrology, the Second Xiangya Hospital, Central South Univ, Changsha, Hunan, China.

Background: To investigate the primary disease and to examine the pathological patterns of renal in elderly patients with CKD.

Methods: Medical histories,labotory test results and renal biopsy datum were collected in elderly patients with CKD for analysis.

Results: (1)The average age of 967 cases of elderly patients was 68.27 ± 6.41 years old. The leading cause of CKD was primary glomerular diseases(37.33%), followed by diabetes nephropathy(23.27%) and hypertensive nephropathy(19.75%). (2) The left kidney was larger than the right,kidney of male patients was larger than the female(P<0.05). There was a positive correlation between eGFR and the left kidney width, depth, and the right kidney width, depth. (3) In 75 patients who underwent renal biopsy, the most common renal histopathology in primary glomerular disease was membranous nephropathy (MN) (48.08%). In patients with MN, 88.00% presented as nephrotic syndrome. (4) The prevalence of hyperphosphatemia was 50.00% in primary glomerular diseases. (5) Calcium-phosphorus metabolism were mainly hypocalemia (27.92%) and hyperphosphatemia (54.91%). eGFR was negatively related to the level of blood phosphorus and intact parathyroid hormone(PTH), and positively related to blood calcium levels.

Conclusions: This study shows that primary glomerular disease is still the leading cause of elderly patients aged 60 and above with CKD,followed by diabetes nephropathy and hypertensive nephropathy. (2)In elderly patients receiving renal biopsy, the most common renal histopathology pattern was MN in primary glomerular disease. (3) It indicated that high systolic blood pressure, renal atrophy,anemia,low HDL-C,hyperphosphatemia and secondary hyperparathyroidism may be associated with deterioration of renal function level.

WHIS data collection is also supported by UL1TR000004 (UCSF CTSA) and UL1-TR000454 (Atlanta CTSA).

**Results:**

Dr. Z and colleagues measured 9 urinary UC biomarkers: BLCA-1, HAI-1, HtrA1, NMP22, CYFRA21-1, TSCSTD2, BLCA-4, BTA, and Midkine. Mann-Whitney U tests were used to compare the concentrations of these biomarkers between different groups of participants. The researchers found that six biomarkers—NMP22, TSCSTD2, BLCA-4, BTA, and Midkine—showed significant increases in UC patients compared to CKD controls and matched healthy controls. Additionally, the concentrations of CYFRA21-1 increased significantly in UC patients compared to CKD patients. However, NMP22 and TSCSTD2 showed no significant difference between these groups.

**Conclusion:** The study suggests that these six biomarkers may be specific to UC in CKD patients. Further research is needed to validate these findings and explore their potential use in clinical settings.
Conclusions: In patients with diabetes and reduced renal function, we have demonstrated a reduction in peptide fragment proportional excretion in macroalbuminuric patients. These findings are consistent with the hypothesis that albuminuria is linked to defects in the renal tubule resorption and fragmentation pathways.

PUB153
Chronic Kidney Disease of Uncertain Etiology: A Systematic Review
Background: Epidemics of chronic kidney disease of uncertain etiology (CKDu) are emerging around the world. Highlighting common risk factors for CKDu across various regions and populations may be important for health policy and public health responses.
Methods: We conducted a systematic review of the PubMed, Embase, Scopus and Web of Science databases to identify published studies on CKDu. Two independent authors reviewed all abstracts for inclusion, assessed each study for quality, and extracted the data. We used a vote-counting method to evaluate the exposures across all studies.
Results: We identified 2535 articles of which 25 met inclusion criteria. Eighteen (72%) were conducted in CKDu-endemic countries: Sri Lanka (40%), Nicaragua (20%) and El Salvador (12%). The other studies were from India, Japan, Australia, Mexico, Sweden, Tunisia and the United States. Risk factors most frequently measured were agricultural occupation (48%), age (48%), gender (44%) and agrochemical use (40%). Heat stress, heat injury and dietary exposures were reported in studies across all geographical regions. In South Asia, family history, agrochemical use, and metal exposure were reported more frequently. Most studies were from South Asia. Across all regions, CKDu was most frequently associated with a family history of CKDu, farming occupation, male gender, middle-age, snake bites and heavy metal exposure. Among high risk populations, CKDu prevalence was reported to be 7.3%–14.9% in South Asia and 13%–25.9% in Central America.
Conclusions: Studies examining etiologies of CKDu have reported many potential exposures that are heterogeneous and vary by region. It remains unknown whether the regional variation in CKDu risk factors reflects inconsistencies in measurement across studies or complexity in the interactions between global exposures and local factors such as environment, genetics, and lifestyle. Thus, to identify the causative factors of CKDu, one important approach could be to design consistent and comparative multi-site studies in high-risk populations that would provide insights into the importance of region-specific versus global risk factors.

PUB154
Understanding the Socio-Demographic Status of Patients Receiving Care at Sonar Bangla Foundation Dialysis Centers in Bangladesh: A Cross-Sectional Pilot Study
Tamanna M. Noyoe,1 Mahmood Hussain,2 Jintaiiz M. Islam,3 Akhun Monoarul Islam,4 Abu hena M. Kamal,1 ‘Sonar Bangla Foundation, Santa Clara, CA; 1Marketing, San Francisco State Univ, San Francisco, CA; 2Nephrology, Good Samaritan Specialists/Kearney, NE; 3Nephrology, Rajshahi Medical College & Hospital, Rajshahi, Bangladesh.
Background: This study constitutes an exploratory investigation to understand the socio-demographic status of patients receiving care at the nine dialysis centers operated by Sonar Bangla Foundation (SBF) in Bangladesh. SBF is a leading non-profit organization, exclusively dedicated to the care of patients suffering from End-Stage Kidney Disease (ESKD). Although ESKD is very common, there is little to no data addressing prevalence of ESKD in Bangladesh. Without understanding its prevalence and the socio-demographic status of patients, little can be done to increase effectiveness and quantity of dialysis centers throughout Bangladesh. This study was launched in April 2015 and will continue throughout the dialysis centers’ operations.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

Methods: A one-time survey is being conducted to obtain clinical and demographic information on all existing and new patients at SBF.
Results: Currently, the study reveals a large gender disparity amongst dialysis recipients, 1 out of 4 patients is female (n=101). The average age of male patients is 44.7 years (SD ±12.7), while the average age of female patients is 45.3 years (SD ±14.2). Furthermore, patients from at least 20 different districts receive dialysis at the centers. The study also finds a significant positive correlation between education level and the frequency of dialysis received.
Conclusions: Data collected throughout this study will be incorporated into an expanding database, first of its kind in Bangladesh. ESKD is a devastating disease that forces patients to become dependent on a machine. By understanding the education level, financial status, distance traveled and other factors in relation to the frequency of dialysis received, services provided by SBF centers could be greatly improved. The study aims to change the quality of kidney care in Bangladesh.

PUB155
Clinical and Pathological Features of Idiopathic Membranous Nephropathy in Young Adults
Chenmi Gao, Jing Xu, Wen Zhang, Xiaoxia Pan, Xiao Li, Nan Chen. Nephrology, Rajuijn Hospital, Shanghai Juotong Univ, Shanghai, China.
Background: Membranous nephropathy (MN) is a common pathological types in elderly nephrotic syndrome (NS) patients. Few researches focus on the young idiopathic MN population.
Methods: 583 patients hospitalized between Jan 2009 and Dec 2014 in our department, with biopsy-proved MN eliminating secondary causes, are enrolled. All patients were divided into 3 groups: 150 patients (25%) in young adult group (<44 yrs), 202 (34.7%) in middle-aged group (45-59 yrs) and 231 (39.6%) in elderly group (>60 yrs). We compared and collected their clinical and pathological data as well as therapy regimens.
Results: 310 male and 273 female enrolled. The young adult group had a lower rate of NS (P<0.02), higher serum albumin (P<0.01), estimated-GFR (P<0.01) and hemoglobin level (P<0.01), and lower fast blood glucose level (P<0.01).

Conclusions: There’s no significant difference in the disease staging or immunofluorescences staining. However, the young adult patients had fewer mesangial, interstitial, tubular and arteriolar lesions, and fewer inflammatory cells infiltration as well (P<0.01). For the therapy, the number of ACEI/ARB regime applied in the three groups were 72/95/75, while corticoid associated with immunosuppressive agents regime was 66/92/140 (P<0.01).

Conclusions: About a quarter of all IMN patients are young adults. They had fewer cardiovascular risk factors, higher serum albumin level and better renal function. Their pathological lesions were milder. ACEI/ARB regime is more widely applied in young adults patients.

PUB156
Effect of Glycemic Control on Estimated Glomerular Filtration Rate by Cystatin C
Masaru Horio,1 Enyu Imai,2 Yoshinari Yasuda,3 Tsuoshi Watanabe,4 Hitoshi Yokoyama,4 Seichiro Matsuo.1 Osaka Univ Graduate School of Medicine, Suita, Japan; 2Nakayamadera Imai Clinic, Takarazuka, Japan; 3Nagoya Univ Graduate School of Medicine, Nagoya, Japan; 4Fukushima Medical Univ, Fukushima, Japan; 5Kanazawa Medical Univ School of Medicine, Kanazawa, Japan; 6Okayama Univ Graduate School of Medicine, Okayama, Japan.
Background: Cystatin C has been proposed as an alternative marker for estimating glomerular filtration rate (GFR). But, some factors other than GFR affect the accuracy of estimated GFR (eGFR). Some studies raised a concern that poor glycemic control may cause inaccuracy of estimation of GFR. We studied the effect of glycemic control on eGFR based on serum cystatin C (cGFR/cGFr).
Methods: GFR was measured by inulin clearance (Cin). Estimated GFRs were calculated by CKD-EPI equation (CKD-EPI) and Japanese GFR equation (J-Eq) based on standardized cystatin C. Glycemic control was evaluated by serum glycated albumin (GA). Three hundred and forty five Subjects with normal GA (12.4-16.5%) and 126 subjects with high GA (>16.5%) were included. Effects of age, gender, BMI, GA and serum albumin on eGFRs / Cin ratio was analyzed by multiple regression analysis.
Results: Cin, cGFr/J-Eq and cGFr/EK (CKD-EPI) in normal GA were 57.9±34.0, 56.1±31.7 and 57.9±33.9 mL/min/1.73m², respectively. Cin, cGFr/E-K and cGFr (CKD-EPI) in high GA were 36.2±28.9, 36.7±27.5 and 36.7±28.5 mL/min/1.73m², respectively. There was no significant difference among Cin, cGFr/J-Eq and cGFr/EK (CKD-EPI) in both subjects. Slopes (95%CI) of the regression lines with zero intercepts in subjects
used to model eGFR against age and sex. RHF was defined as eGFR with residuals above
Metabolic HIV Clinic”. The Chronic Kidney Disease Epidemiology Collaboration equation
(slopes were not significantly different from 1.0, suggesting that eGFRcys performed well in subjects with high GA. Multiple regression analysis showed that age, gender, BMI, GA and serum albumin were not significant factors affecting both eGFRcys(CKD-EPI)/C/in and eGFRcys(E-J)/C/in.

Conclusions: Estimated GFR based on cystatin C performed well in subjects with high GA.
Funding: Government Support - Non-U.S.

PUB157
Renal Hyperfiltration and Outcome in HIV-Infected Subjects Gianni Cappelli,1 Elisabetta Ascione,1 Giovanni Guaraldi,2 Andrea Malagoli,2 Elisabetta Rubbiani,1 Antonio Bellasi.1 1Univ Hospital of Modena, Nephrology Dialysis and Renal Transplantation Unit, Modena, Italy; 2Univ Hospital of Modena, Metabolic Clinic, Infectious and Tropical Diseases Unit, Modena, Italy; 1Azienda Ospedaliera S. Anna, Como, Dept of Health Sciences, Univ of Milan, Nephrology and Dialysis Unit, Como, Italy.

Background: Although highly active antiretroviral therapy (HAART) improves life expectancy of HIV-infected subjects, it is also associated with numerous comorbidities. Evidence suggests that renal hyperfiltration (RHF) is associated with various lifestyles, clinical conditions and portends poor prognosis in the general population. We sought at determining prevalence of RHF and its associations with traditional and HIV-related risk factors as well as all-cause mortality in a large cohort of HIV-infected subjects.

Methods: Retrospective study of 3875 HIV-infected patients attending at the “Modena Metabolic HIV Clinic”. The Chronic Kidney Disease Epidemiology Collaboration equation (CKD-EPI) was used to estimate glomerular filtration rate (eGFR). Linear regression was used to model eGFR against age and sex. RHF was defined as eGFR with residuals above the 95th percentile. Anova, Chi-square, logist regression and survival analyses were used to identify factors and the risks associated with RHF.

Results: Overall, we investigated middle-age (44.5±7.5 years) men and women (male 65.1%) with preserved renal function (eGFR 94.5±17.1 ml/min/1.73 m²). RHF was inversely associated with age (Odds Ratio 0.93), hemoglobin (OR 0.8), WBCs (OR 0.9) and positively associated with HIV-infection (OR 1.07). Of interest, no association with HAART was noted. Over mean follow-up of 7 years, 75 persons died. RHF was associated with all-cause mortality independently of potential confounders (Hazard ratio 4.17, 95%CI: 1.81 - 9.6; p<0.001).

Conclusions: RHF is influenced by infection duration independently of established factors and is related with the risk of all-cause of death. Future efforts are needed to clarify what are the mechanisms that link RHF with poor prognosis and if RHF modulation improves survival in HIV-infected subjects.

PUB158
Bioelectrical Impedance Analysis as a Screening Tool for Chronic Kidney Disease Anita Saxena, Amit Gupta. Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, UP, India.

Background: Chronic Kidney Disease (CKD) has a latent period during which the disease is present but asymptomatic. With increasing incidence of hypertension and diabetes, incidence and prevalence of CKD is on increase. Bioelectric impedance analysis (BIA) is a noninvasive method for estimation of body composition in clinical setting but it has not been used for CKD screening. Purpose: To evaluate applicability of BIA as a screening tool for presence of kidney disease in general population with creatinine clearance and glomerular filtration rate (GFR).

Methods: A pilot-cross-sectional CKD screening study on randomly selected 52 subjects from general population. Maltrion BIOSCAN analyser 915:916 was validated with Hume etal’s equation for estimation of total body water. BIA derived GFR was validated with 99mTc-DTPA nuclear scan derived GFR, a study done on voluntary healthy kidney donors. Serum creatinine for males was 0.94 ± 0.14mg% and 0.91 ± 0.14mg% in females. BIA derived creatinine clearance was 97.39%: 28.98 in males and 107.60%: 34.03 in females, GFR was 74.1±25.98ml/min/1.73 m² in males and 65.17±21.14 ml/min/1.73 m² in females. Based on GFR subjects were classified into CKD. Out of 52 subjects 8 were in CKD stage 1 (15.5%), 23 (44.2%) were in CKD stage 2, 18 (34.6%) were in CKD stage 3, 1 (1.9%) in CKD stage 4 and CKD stage 5 respectively. Incidentally, 13.5% were diabetic, and 65.8% were hypertensive. Mean blood pressure was 133.99±80.89/82.76±27.79 mmHg in males and 132.10±16.20/83.46 7.85mmHg in females. Based on American Heart Association Classification for hypertension, 19 (36%) patients had normal blood pressure, 8 (15%) were in prehypertension stage, 10 (19%) patients were in hypertension stage 1, 6 (11.5%) were in hypertension stage 2 and 2 had crisis hypertension.

Conclusions: Population-based CKD screening programs can identify people with renal injury for early intervention. BIA can be used for screening CKD in general population. It can also be a routine test as 99mTc-DTPA scan for estimation of GFR.

PUB1859
Design and Implementation of a Chronic Kidney Disease Prevalence Study in Rivas, Nicaragua

Kailey Minnings,1 Martha Mosco,2 Madeline M. Fiore,3 Eric S. Kerns,4 Juan Jose Amador,5 Rulan S. Parekh,4 Louis D. Fiore.4

Faculty of Medicine, Univ of Toronto, Toronto, ON, Canada; 2Lowering Poverty and Disease, Boston, MA; 3Tulane Univ, New Orleans, LA; 4Warren Alpert Medical School, Brown Univ, Providence, RI; 5School of Public Health, Boston Univ, Boston, MA; 6Hospital for Sick Children, Toronto, ON, Canada.

Background: High rates of chronic kidney disease of unknown etiology (CKDu) have been noted in certain populations along the Pacific coast of Central America. CKDu is unlike traditional CKD in that the usual underlying risk factors are not present. CKDu in Nicaragua has been noted to affect mainly sugarcane workers although there is a paucity of data for the general population.

Methods: A population based cross sectional study using a random sampling of 32 communities was carried out in the department of Rivas in Nicaragua. Visits were conducted in Spanish in 2012 for screening and in 2014 for repeat evaluations. Participants were consented and completed a baseline questionnaire. Serum creatinine was initially screened using a finger stick creatinine measurement device. Repeat measurements to confirm CKD were performed centrally at the Centro Nacional de Diagnostico y Referencia in Managua using the Cobas Integra Jaffe Generation 2 assay, which has been standardized to the IDMS method.

Results: The study sample consisted of 1240 individuals representing 75% of adults living in the 533 homes visited. The refusal rate was 9.3%. The median age was 36.4 years, 57% were female, 66.6% reported DM, and 27% reported HTN. The study cohort is slightly enriched for women, while young people are slightly underrepresented when compared to census data. Repeat measurement was done in 320 with elevated creatinine to confirm CKD over 2 years. The re-contact rate was 85%.

Conclusions: This cross sectional study population is representative of the general population of the department of Rivas in Nicaragua. Establishment of this study population will allow investigators to determine the prevalence of CKD in a random selection of the general population in both urban and rural areas of Nicaragua not previously studied.

PUB160
Validation of the Lund Model Combining Simultaneous Cystatin C and Creatinine-Based eGFR

Emil Den bakker, Arend Bokenkamp. Pediatric Nephrology, VU Univ Medical Center, Amsterdam, Netherlands.

Background: Estimated GFR (eGFR) based on serum creatinine (crea) and/or cystatin C (cys) is used to monitor GFR. Based on known limitations of either marker (muscle wasting for crea, corticosterooids for cys) Grubb et al have proposed the “Lund model” to identify such patients by calculating the difference between crea and cys-based eGFR (Scand J Clin Lab Invest 70 (2010): 65-70). If the difference is below a certain cut-off, the mean of eGFRcrea and eGFRcys is used. Otherwise a choice is made for one or the other as a more accurate estimate based on patient history. The aim of this study was to test the “Lund model” using eGFR equations from the CKiD study (Kidney Int 82 (2012): 445-55).

Methods: Retrospective analysis of 449 single injection inuline clearance (mGFR) studies, in which serum crea, cys and urea had been measured simultaneously. Calculation of eGFR using crea (CKiD1), cys (CKiD2) or crea+cys+urea (CKiD3) as well as the average of CKiD1 and CKiD2 (avCKiD1-2). For the Lund approach, the relative difference (\(\Delta\)CKiD1-2) between CKiD1 and CKiD2 was calculated as percentage of avCKiD1-2 and categorized as >40%, 30-40%, 20-30%. If \(\Delta\)CKiD1-2 was > 40%, a choice was made for CKiD1 (corticosteroid) or CKiD2 (neuromuscular disease, wasting, malignancy). The performance of the different approaches was studied using bias (mGFR minus eGFR in ml/ min/1.73 m²) and accuracy (% of measurements within ±30% of mGFR).

Results: CKiD1, CKiD2 and CKiD3 had a bias of 4.6, 14.2 and 2.8 and an accuracy of 81.7, 80.6 and 90.4, respectively. avCKiD1-2 had a bias of 9.4 and an accuracy of 88.9. \(\Delta\)CKiD1-2 was >40% in 11.4%, 30-40% in 18.9% and 20-30% in 33.9% of the studies. The Lund model was applied in 51 studies with \(\Delta\)CKiD1-2 >40%. In 42/51 studies, a choice could be made based on history (CKiD1 n=16, CKiD2 n=26). This resulted in a bias of 10.5 and an accuracy of 86.4.

Conclusions: The various CKiD equations performed comparably to the original publications different. The arithmetic mean between creatinine-based and cystatin C-based eGFR yielded similar results to the complex CKiD3 equation while the Lund model did not improve the diagnostic performance. This may be due to the higher bias of CKiD2.

Evaluation of Chronic Kidney Disease Epidemiology Collaboration Equation (CKD-EPI), Modification of Diet in Renal Disease (MDRD) and Cockcroft-Gault (CG) Equations to Assess Glomerular Filtration Rate (GFR) in Kidney Cancer Patients

**Verónica T. Costa e Silva**, 1 Celso Marialva, 2 George Augusto Monteiro Lins de Albuquerque, 1 Renato Antunes Caixs, 1 Giuliano Betoni Guglielmetti, 1 Mauricio Dener Cordeiro, 1 Rafael Ferreira Coelho, 1 Elerson Costalonga, 1 Eduardo J. D. de Sa Carneiro Filho, 1 Emmanuel A. Burdmann, 1 William C. Naheas. 3 Cancer Inst of Sao Paulo, Univ of Sao Paulo School of Medicine, Sao Paulo, Brazil; 2Urology, Garcia de Orta Hospital, Lisbon, Portugal; 3Urology, Univ of Sao Paulo School of Medicine, Sao Paulo, Brazil.

**Background:** Equations used to estimate GFR were not validated in kidney cancer patients. The aim of this study was to assess the performance of CKD-EPI, abbreviated (a) MDRD and CG equation in these patients.

**Methods:** Prospective evaluation of 124 outpatients with kidney cancer admitted to treatment at Sao Paulo State Cancer Institute between September 2012 and February 2015. Estimated (e) GFR was calculated using CG, aMDRD and CKD-EPI equations and compared to \( ^{Cr} \)EDTA radioisotopic (r) clearance. The bias was given as the mean difference between the eGFR and rGFR values and the precision as the SD of the differences. Accuracy was described as the number of eGFR studies within 10 and 30% of the rGFR values.

**Results:** Patients were 59.0 ± 10.3 years old, 50.2% were women, eGFR (ml/min/1.73 m²) was 78.7 ± 24.6 and eGFRs (ml/min/1.73 m²) using the CKD-EPI, aMDRD and CG (ml/min) equations were respectively 80.7 ± 22.1, 83.4 ± 25.3 and 87.8 ± 26.5. Equations bias is detailed on table 1. When compared with the CKD-EPI assessed by \( ^{Cr} \)EDTA in this group of kidney cancer patients.

**Conclusions:** Mean bias of differences (mL/min) was -7.1 ± 2.0 for CG, 4.7 ± 0.3 for aMDRD and 9.1 ± 3.8 for CKD-EPI. The accuracy was described as the number of eGFR studies within 10% and 30% of the rGFR values. As the limits of agreement, both the MDRD and CKD-EPI were > 25 mL/min/day, while between MDRD and CKD-EPI was 21.5 ± 2.5 mL/min/day. The accuracy of the MDRD and CKD-EPI was 75.8% and 78.2% and 68.5% with CKD-EPI, aMDRD and CG, respectively. Within 30% of rGFR, the accuracy of eGFR with CKD-EPI, aMDRD and CG, respectively. Within 30% of rGFR, the accuracy of eGFR was 75.8%, 78.2% and 68.5% with CKD-EPI, aMDRD and CG, respectively. The the spread of non-communicable diseases (NCDs) presents a global crisis, and accumulating evidence based on individual disease reveals that major NCDs including heart disease and stroke have a worse prognosis in the presence of chronic kidney disease (CKD). However, there is neither large-scale study quantitatively evaluating the burden of CKD on various NCDs, nor study comparing the burden of CKD with other NCDs, especially among low- and middle-income countries like China.

**Methods:** A national in-patient database involving 19.5 million patient-records was used. Diagnoses of CKD and other major NCDs, including hypertension, coronary heart disease, stroke, chronic obstructive pulmonary diseases, and cancer, were extracted from International Classification of Diseases-10 codes of the discharge diagnoses. The effect of CKD on costs, length-of-stay, and in-hospital mortality were analyzed for each NCD. Then the effect of CKD on those outcomes was compared with other major NCDs.

**Results:** For each NCD, the presence of CKD was associated with increased length-of-stay and in-hospital mortality. And the costs were also increased by 0.1-20.3%, except for coronary heart disease and diabetes. Among those NCDs, CKD was associated with the highest length-of-stay, and with in-hospital mortality only lower than that of cancer.

**Conclusions:** Using database with large sample size and broad geographic coverage in China, we found that the presence of CKD was associated with substantial increased healthcare resources utilization and increased risk of in-hospital mortality. Funding: Government Support - Non-U.S.

Patient Empowerment in a Multi-Disciplinary Chronic Kidney Disease (CKD) Clinic

**Theresa T. Adamowski, Jonathan H. Segal, Julie A. Wright Nunes. Internal Medicine, Univ of Michigan, Ann Arbor, MI.

**Background:** Existing research shows economic and health gains associated with multi-disciplinary CKD care, but there is little data examining associations with patient-centric measures. We collected patient-centric measures on perceptions related to care in a multi-disciplinary CKD clinic.

**Methods:** Our multi-disciplinary CKD clinic includes a pharmacist, physician assistant, social worker, dietitian and RN educator with oversight by a medical doctor. Patients see each provider during visits. Most patients have an eGFR ≤ 40 ml/min/1.73m². As part of assessing quality of patient care was asked to: 1. Report their least liked questions (“please circle the number that indicates how comfortable you feel asking your doctor questions about kidney disease: 1 = not at all comfortable to 6 = very comfortable”), and 2. Rate perceived confidence and empowerment in kidney care (ten questions with responses, 1 = not confident to 5 = confident, averaged as a summary measure of confidence / empowerment).

**Results:** Data were available on 51 patients. The mean (SD) age was 62 (15) years. 53% were male, 65% Caucasian, and 33% African American. Patients reported being comfortable asking their doctor questions, mean (SD) 5.5 (0.97). The mean (SD) of the confidence / empowerment measure was 4.3 (0.74). In univariate analysis, higher ratings
of comfort asking questions was associated with higher confidence / empowerment, β 0.23 (0.08, 0.40), p<0.001. A multivariable analysis adjusted for age, sex, race and center asking questions revealed comfort asking questions was independently associated with higher confidence / empowerment, β 0.31 (0.09, 0.53), p<0.007. Our 10-item confidence / empowerment measure showed excellent internal reliability (Cronbach alpha =0.89).

Conclusions: Patients in a multi-disciplinary CKD clinic reported being comfortable asking their doctor questions and rated confidence and empowerment as high. Comfort asking the doctor questions was positively associated with patient confidence and empowerment in care. More work is needed to compare patient-centric quality measures across care models and assess changes over time.

PUB166
Factors Affect Use of Healthcare Services Among Different Ethnicities

Enchi K. Chang, Li-Li Hsiao, Harvard College, Cambridge, MA; Renal, Brigham and Women’s Hospital, Harvard Medical School, Boston, MA.

Background: Use of healthcare services by medically underserved minority populations varies by ethnicity and cultural factors. Healthcare providers may address ethnicity-specific barriers to healthcare service usage to decrease disparities in healthcare use. Through free community health screenings provided by the Kidney Disease Screening and Awareness Program (KDSAP), we seek to elucidate ethnicity-specific differences and sociocultural barriers to healthcare service usage.

Methods: A questionnaire available in English, Chinese, and Spanish was administered to KDSAP participants in Massachusetts, New Jersey, and Toronto from 2012 to 2014. Participants were asked to provide their ethnicity, health insurance, primary care physician, and difficulties and alternatives to receiving care.

Results: Of 340 Hispanic, 300 African-American, Hispanic, and 50 Caucasian participants were surveyed. Participants lacking health insurance comprised 29.1% of Asian and 45.1% of Hispanic participants, compared with 17.3% of African-American and 8% of Caucasian participants. 25% of Asian and Hispanic participants reported language barriers with their healthcare providers compared with 6% of African-American and Caucasian respondents. 50% of Asian and Hispanic participants were prevented from seeking care due to lack of insurance, and as an alternative, 51% of Asian participants would ignore healthcare services targeting medically underserved populations. Asian populations varies by ethnicity and cultural factors. Healthcare providers may address ethnicity-specific sociocultural differences to reduce healthcare disparities between ethnic populations.

PUB167
Trends in Access to Care in Adults with Kidney Disease, United States 2002–2011

Mukoso N. Ozieh, Kristin Gembregziabiher Bishu, Rebekah J. Walker, Leonard Egede, Nephrology, MUSC; Center for Health Disparities Research, Internal Medicine, MUSC, Charleston, SC.

Background: Access to healthcare is essential in order to attain health equity in the US. Studies on access to healthcare in kidney disease (KD) are scant and there are no studies on national trends in access to healthcare in people with KD. This study aims to evaluate trends in access to healthcare, prescription medication and factors associated with access to healthcare in people with KD.

Methods: Data on 4,399 adults with KD aged ≥18 from the Medical Expenditure Panel Survey were analyzed. Individuals with KD were identified with Clinical Classification Codes: 156 - nephritis, nephrosis, renal sclerosis; 157 - acute renal failure; 158 - chronic renal failure; 160 - calculus or urinary tract and; 161 - other diseases of kidney and ureters. Access to healthcare is defined as having a usual provider, ability to get necessary prescription and no delay in getting prescription. We used unadjusted and adjusted poison regression to examine the association of patient-centered care overtime. Covariates included demographics and comorbidities.

Results: Of the 3,868 adults with KD, 3%, 7%, 22%, 63% and 4% reported a positive response to 1, 2, 3, 4, and 5 out 5 questions on patient-centered care respectively. Patient-centered care was significantly reported in 2010/2011. Hispanic race was significantly associated with decreased access to prescription medication. Factors associated with increased access to prescription improved over time in people with KD. Factors associated with decreased access to prescription included being age ≥45, gender, high income and comorbidity – diabetes and joint pain were associated with decreased access to prescription medication.

Conclusions: Access to medical care has remained stable and access to prescription medication in people with KD has improved over time. Further studies on access to healthcare in people with KD compared to the overall US population are needed.

PUB168
Patient-Centered Care in United States Adults with Kidney Disease

Mukoso N. Ozieh, Kristin Gembregziabiher Bishu, Rebekah J. Walker, Leonard Egede, Nephrology, MUSC; Center for Health Disparities Research, Internal Medicine, MUSC, Charleston, SC.

Background: Patient-centered care is a quality of personal, professional, and organizational relationships. There no studies on factors associated with patient-centered care in patients with kidney disease (KD). This study examines trends in and factors associated with patient-centered care (PCC) in people with KD.

Methods: Data on 3,868 adults with KD aged ≥18 from the Medical Expenditure Panel Survey (MEPS) Household Component were analyzed. Individuals with KD were identified with Clinical Classification Codes: 156 - nephritis, nephrosis, renal sclerosis; 157 - acute renal failure; 158 - chronic renal failure; 160 - calculus or urinary tract and; 161 - other diseases of kidney and ureters. Patient-centered care was ascertained if the usual care provider asked about prescription medications and treatments other doctors may give them; showed respect for medical, traditional and alternative treatments that the person was happy with; asked the person to help make decisions between a choice of treatments; presented and explained all options to the person; and spoke the persons language or provided translator services if person is uncomfortable speaking in English. We used unadjusted and adjusted poison regression to examine the association of patient-centered care overtime. Covariates included demographics and comorbidities.

Results: Of the 3,868 adults with KD, 3%, 7%, 22%, 63% and 4% reported a positive response to 1, 2, 3, 4, and 5 out 5 questions on patient-centered care respectively. Patient-centered care was significantly reported in 2010/2011. Hispanic race was significantly associated with decreased access to prescription medication. Factors associated with increased patient-centered care in the poison regression analysis.

Conclusions: Patient-centered care in people with kidney disease has improved in recent years. Prospective studies relating the impact of patient-centered care on kidney disease outcomes especially end stage renal disease is imperative.

PUB169
Hypertension and Correlating Factors in a Minority-Rich Population

Andrew A. Lin, Jennie Kuo, Li-Li Hsiao, Harvard College, Cambridge, MA; Renal, Brigham and Women’s Hospital, Harvard Medical School, Boston, MA.

Background: Analysis of demographic variations in hypertension (HTN) in minority-specific populations presents a major opportunity for understanding the factors that influence chronic kidney disease (CKD). This study analyzes the influence of various factors in BP control in a minority-rich population.

Methods: Data from 417 participants from minority populations in the Boston area (38.4%-37.6% Black, 17.0%-18.8% White, and 5.0% other races) was sampled via Kidney Disease Screening and Awareness Program screenings from 2012-2014. Participants were assessed via questionnaire for awareness of their BP, healthcare insurance, and an assessment of their own health as well as their race, gender, age, and education. Participants then had their systolic (SBP) & diastolic (DBP) blood pressure measured, which was in turn classified according to American Heart Association guidelines & analyzed via T-tests & one-way ANOVA.

Results: Of the 417 participants, 28.8% had normal BP, 47.2% were pre-HTN (130-139/85-89), 18.5% had stage I HTN (140-160/90-100), & 5.5% had stage II HTN (>160/100). Participants aware of their HTN had higher SBP (p<0.001) & DBP (p<0.007) than those who self-reported no HTN. Men had significantly higher SBP & DBP than women (p=0.002, p=0.003, respectively), & individuals with little/no education had higher SBP than those with college (p=0.005) or post-graduate degrees (p<0.001). Younger age groups (below 30 years: mean BP 125/76) had significantly lower BP than older age groups (60-69: years: mean BP 136/81; p<0.0001 & ρ<0.057 for SBP & DBP. Notably, no significant differences in SBP among ethnicities emerged.

Conclusions: Our results revealed that awareness of HTN status, gender, education level & age influence BP variations in minority-rich communities. Services tailored to these factors may help reduce HTN prevalence among minorities.

Veterans Affairs (VA) eKidneyClinic: A Freely-Available Online Tool to Help Close the Chronic Kidney Disease (CKD) Patient Education Gap

Devasmita Mukoso, Dorian R. Schattell, Susan T. Crowley, Medicine, Salem Veterans Affairs Medical Center, Salem, VA; Medicine, White River Junction Veterans Affairs Medical Center, White River Junction, VT; Veterans Health Administration, Durham, NC; MEI INC., Madison, WI; Medicine, Veterans Affairs Connecticut Health Care System, West Haven, CT.

Background: Patient education remains an important tool in the management of CKD and end stage renal disease (ESRD)– diseases with significant patient and economic burden. Patient knowledge and understanding of CKD are dismal, particularly amongst highly-affected populations (e.g. African Americans). For Veterans with CKD, limited health literacy exists and varied, fragmented presentation of patient education materials (PEMs) compound the gap in understanding CKD.

Methods: To address these deficiencies, VA developed a comprehensive web tutorial, VA eKidneyClinic (http://ckd.vacloud.us). This freely-available, Veteran-centered, virtual
Should All Patients with Diabetic Nephropathy Be Treated in a Joint Renal Diabetic Clinic? Jonathan P. Wong, Tara Lee, Tracy Maryan, Jocelyn Berdeprado, Suresh Mathavakkannan. Lister Renal Unit, United Kingdom.

Background: The natural history of diabetic nephropathy is variable. Some patients have rapidly declining kidney function and would benefit from close monitoring in a joint renal-diabetic clinic, however joint renal-diabetic clinics are not widely available in the UK health system. We studied outpatient attendance patterns, rate of eGFR decline and other clinical parameters in patients with diabetic nephropathy to determine potential need for development of a joint renal-diabetic clinic at our unit.

Methods: A cross-sectional survey of all patients with CKD and diabetes mellitus (DM) at our unit was performed. Demographic, diabetic clinic attendance and clinical parameters including Hba1c, BP, urine protein:creatinine ratio (uPCR) and eGFR for the previous 5 years were collected. Patients who had a rate of decline in eGFR >2ml/min/1.73m² were defined as having progressive CKD.

Results: 630 CKD patients with DM attending CKD clinic at our unit were identified. 195/630 (31%) of patients had diabetic nephropathy. 54.6% (100/195) had progressive CKD, but only 37% (37/100) of these patients attended a diabetic clinic. Conversely, 45.4% did not have progressive CKD, potentially representing a group of patients who could be safely monitored by general physicians.

Conclusions: Not all patients with diabetic nephropathy develop progressive CKD. Identifying patients (e.g. low level proteinuria) who could be safely monitored by general physicians may relieve pressure on CKD clinic and reduce hospital visits for patients. However, many patients with progressive CKD were not being monitored in a diabetic clinic, potentially missing out on specialist interventions. Development of a joint diabetic-renal clinic could streamline care and improve management for these patients.

Leveraging Predictive Modeling to Improve the Participant Identification Process for Transition to Dialysis Support Programs Meghan Martin Cockrell, Yanting Dong, Huyi Hines, Gilbert Haugh, Vinip Gopal, Roy Beveridge, Todd Prewitt. Humana, Louisville, KY.

Background: Evidence demonstrates that renal care management is beneficial to patients suffering from late-stage chronic kidney disease (CKD) and end-stage renal disease (ESRD), especially around the time of transition to dialysis. Integrated care management solutions provide assessment, education, and care coordination. Engagement in these programs improves health outcomes, including compliance with dialysis schedules and vascular access, and also reduces costs.

Methods: Traditionally, patients are identified for renal care management programs via a qualified estimated glomerular filtration rate (eGFR) lab value of >20mL/min/1.73 m². However, since eGFR is not always available, there may be a gap in identifying people who could benefit from this type of support. A predictive model (PM) was developed to identify candidates for a transition to dialysis program. The PM identifies individuals with CKD over the prior 12 months and determines their likelihood of starting dialysis within the subsequent 12 months. It is based on claims, demographics, and lab and consumer data. To assess the effectiveness of the PM, a random portion of control and intervention groups scored in the top 2% of patients suffering from late-stage chronic kidney disease (CKD) and end-stage renal disease (ESRD), especially around the time of transition to dialysis.

Results: Thirteen percent of people referred by the PM ultimately transitioned to dialysis and all were invited into a renal care management program. Seventeen percent of the people referred by the PM ultimately transitioned to dialysis and all were invited into a renal care management program. Hence, the model is effective in identifying those most likely to transition to dialysis were referred directly to the program for transition to dialysis and all were invited into a renal care management program.

Conclusions: Results suggest that GFR decline may not be attributed to aging only. Each episode of AKI related to contrast or nephrotoxic drugs increases risk for CKD progression/GFR decline in elderly. Pre-existing CKD is a strong predictor of GFR decline after adjustment for other co-morbidities.

Oxidative Stress: Dual Pathway Induction in CKD Pathogenesis Grazia Maria Virzì, Alessandra Brocca, Massimo de Cal, Claudio Ronco. Nephrology Dept-IRRI, San Bortolo Hospital, Vicenza, Italy.

Background: Oxidative stress is defined as the imbalance between excess formation and insufficient removal of highly reactive molecules (Reactive Oxygen Species-ROS and Reactive Nitrogen Species-RNS) that attack DNA, protein and lipids, either denaturing or altering their structure. The variations and the correlation of inflammation and oxidative stress in CKD have not been thoroughly understood. In this study, we examined the putative role of ROS and RNS in the pathogenesis of CKD and the interaction with inflammation.

Conclusion: Application of advanced predictive modeling permitted identification of participants who may not have otherwise had the opportunity to benefit from renal care management.
Results: CKD patients displayed significant augmentation in circulating ROS and RNS, as well as expression of inflammatory cytokines, as IL6 (all, p=0.01). We divided CKD patients in CKD1-2 (n=10) and CKD3-5 (n=15): a significant higher level of oxidative stress was observed in CKD3-5 (p=0.008).

Conclusions: CKD is characterized by ROS and RNS disequilibrium and inflammation that promote additional damage to the kidney and to distal tissues with development and progression of concomitant diseases. This pilot study demonstrates the significantly heightened presence of dual oxidative stress pathway induction in CKD patients that increase with the progression of CKD: each stage of CKD could be characterized by differing levels of ROS/RNS disequilibrium. Our findings indicate that oxidative stress is a potential therapeutic target, as it promotes inflammation by ROS/RNS-linked pathogenesis. Future research should focus on interventions that aim to reduce oxidative stress and inflammation in patients with various stages of CKD and slow the progression of CKD during its early stages.

PUB175
Comparative Biomarker Analysis Reveals Serum and Urine sTNFR1 Correlate with eGFR and Albuminuria in Man

Background: It has been demonstrated that soluble tumor necrosis factor receptors (sTNFR1 & sTNFR2) are elevated in serum of patient cohorts with various renal disease etiologies with a strong association to early renal decline with or without proteinuria. The current study was designed to gain further insight into the relationship of renal function to sTNFR1 and sTNFR2 in a large sample of patients with single kidney biopsies from a recently completed clinical study in high-risk subjects undergoing non-cardiac surgery. A subset of baseline serum and urine samples from patients with and without CKD (mean age of 70, 64% male, mean eGFR of 58 ml/min/1.73 m2, and mean total urinary protein concentration 70 g/l) were evaluated to assess sTNFR1 and other select BIMs reflective of progression of DN, CV risk, inflammation, fibrosis or renal injury.

Methods: Samples were selected based on medical history (DM, DN, other CKD, or no renal disease) and stratified for analysis based on eGFR values. All samples examined were from baseline/pre-dose collections prior to drug administration or surgery and analyzed in a blinded manner.

Results: In serum, several BMs correlated with eGFR with sTNFR1 (P <0.0001) and uromodulin (P=0.0004) being significant but moderate for FGF-23 (P=0.01), and ADMA (P=0.01). In urine, results revealed that several BMs correlated with eGFR with a strong significance for sTNFR1 (P <0.0001) as well as for complement C9 (P=0.01) and iC3b (P=0.01). Significant correlations were also observed for qualified biomarkers such as NGAL (P<0.01), albumin (P<0.01), and cystatin C (P<0.05). sTNFR1 in urine also strongly correlated with albuminuria (P=0.0002) and UACR (P=0.0001).

Conclusions: The value of renal biopsy in prognosis of chronic kidney disease remains unclear. Irreversible, chronic changes such as interstitial fibrosis and glomerulosclerosis are thought to provide prognostic information. We sought to define the relative prognostic value of biopsy pathology and clinical factors for predicting progression to end stage renal disease (ESRD).

Methods: Retrospective, single center review of renal biopsies performed between 2004-2014 in four kidney diseases. Cox regression was used to evaluate nine pathological findings on light microscopy and 21 clinical variables as potential predictors of progression to ESRD.

Results: 231 cases were reviewed (34% IgA nephropathy, 29% focal segmental glomerulosclerosis, 19% tubulointerstitial disease, 18% diabetic nephropathy). 83/231 (36%) subjects progressed to ESRD within 5 years follow-up. Median estimated glomerular filtration rate (eGFR) at time of biopsy was 32 [IQ: 18, 54] ml/min. Median percent interstitial fibrosis was 20% [IQ: 10%, 40%]. In multivariable Cox regression adjusting for pathologic diagnosis and eGFR at the time of biopsy, independent predictors of progression to ESRD within 5 years of biopsy were: interstitial fibrosis > 20% (HR 1.94 [95% CI 1.09, 3.44]; p=0.02), presence of endocapillary inflammation (HR 2.35 [1.22, 4.53]; p=0.01), presence of arteriosclerosis (HR 2.03 [1.01, 4.05]; p=0.05), history of liver disease (HR 1.55 [0.95, 2.53]; p=0.08) and congestive heart failure (HR 1.85 [0.99, 3.49]; p=0.06).

Lower Dietary Intake of Magnesium is Associated with Faster Decline in Kidney Function: The Healthy Aging in Neighborhoods of Diversity Across the Life Span Study

Adrienne Tin,1 Casey Rehbolz,1 Yang Liu,1 Alan B. Zonderman,1 Marie Kuczmarzki,2 Deidra C. Crews.1 Johns Hopkins Univ.1 National Inst on Aging;1 Univ of Delaware.2

Background: Lower dietary magnesium intake has been associated with higher prevalence of chronic kidney disease (CKD). We hypothesized lower dietary magnesium intake would be associated with more rapid decline in kidney function.

Methods: Participants with estimated glomerular filtration rate (eGFR) ≥60 mL/min/1.73 m² at baseline (2004-2008) of the population-based, Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study were followed for a median of 4.7 years. Baseline dietary magnesium intake was calculated from 24-hour dietary recalls. eGFR was calculated from serum creatinine using the CKD-EPI equation.

Results: Among 1,326 participants, those with lower dietary magnesium intake (tertile 1 vs. 3) were significantly younger (mean age of 46 vs. 49 years), more likely to be African-American (67% vs. 48%) and male (45% vs. 31%); had lower mean body mass index (BMI, 29 vs. 30 kg/m²), higher mean baseline eGFR (99 vs. 94 mL/min/1.73 m²) and lower prevalent diabetes (10% vs. 18%); p<0.05 for all. In the overall study population, eGFR was stable without any decline (mean change: 0.1 mL/min/1.73 m²), while 189 participants experienced an eGFR decline ≥3% per year. Lower dietary magnesium intake was associated with higher risk of eGFR decline ≥3% per year (tertile 1 vs. 3, hazard ratio 1.9, 95% confidence interval: 1.1, 3.3) adjusted for socio-demographics, baseline eGFR, prevalent diabetes and hypertension status, BMI, serum magnesium, total energy intake, and dietary intake of calcium, potassium, and phosphorus.

Conclusions: Among persons with preserved eGFR, we detected a significant association between lower dietary Mg intake and increased risk of rapid kidney function decline independent of traditional CKD risk factors. These results highlight the importance of magnesium intake in the overall diet for the preservation of kidney function.

Renin-Angiotensin System: A Possible Mechanism for AKI-CKD Continuum

Shun-Yang Cheng, Shuei-Liong Lin, Ching-Chin Yang, Yu-Hsiang Chou, Fang Ling Liao, Ming-Hsuan Tsai. Graduate Inst of Physiology, National Taiwan Univ.

Background: Based on many clinical observations and studies, acute kidney injury (AKI) was now regarded as an important risk factor causing chronic kidney disease (CKD). Not only does CKD lead to end-stage renal disease (ESRD), but also increases the risk of cardiovascular disease or even death. Clinical studies often disclose that the higher the AKI severity of a patient is, the more likely he/she has a tendency to progress into CKD. To this end, the mechanism underlying the progression of kidneys into CKD after AKI remains to be elucidated. Since the higher severity of the AKI leads to more reduction of nephron numbers, we propose that activation of renin-angiotensin system (RAS) may be involved in the progression to AKI after recovery from AKI.

Methods: Severe AKI was induced in male adult CD-1 mice by right uni-nephrectomy (Nx) followed by ischemia-reperfusion injury of left kidney 2 weeks later. Drinking water was supplemented with type 1 angiotensin II receptor blocker losartan or direct vasodilator hydralazine was administered to mice from 4 weeks after surgery. Mice with Nx only were served as the control. Blood pressure, urinary albumin-to-creatinine ratio (ACR) and plasma levels of creatinine were evaluated.

Results: Compared to Nx group, AKI mice showed acute rise of plasma creatinine levels on day 2 after Nx+IRI surgery, which decreased to baseline on day 7. Moreover, elevated systolic blood pressure and increased urinary ACR were noted since 4 weeks after Nx+IRI surgery. During the 4-month experimental period, progressive increase of urinary ACR and plasma levels of creatinine were noted. On the contrary, systolic blood pressure, urinary ACR and plasma creatinine level were normalized in mice administered with losartan since 4 weeks after Nx+IRI surgery. However the increase of urinary ACR and plasma creatinine level were not prevented in mice administered with hydralazine despite similar normalization in blood pressure levels.

Conclusions: These data suggest that RAS activation may underlie the mechanism for development of CKD in mice after recovery from AKI. Future studies are needed to explore the effect of RAS blockade in prevention of CKD and its pressure in patients recovered from AKI.

PUB182

The Renal Effects of Neprilysin Inhibition in Heart Failure and Hypertension

Background: Neprilysin inhibitors (NEPi) represent an emerging therapeutic option for treatment of hypertension (HTN)) and heart failure (HF) through enhancement of natriuresis. While these agents have shown promising results with regards to lowering blood pressure (BP) and HF events, their impact on the kidney remains largely unknown. The aim of this study is to evaluate the currently available evidence on the effect of NEPi use on kidney-related parameters in patients with HTN or HF.

Methods: A search of articles cited in PubMed database from 1995 to 2015 using key words “neprilysin”, “heart failure” and “hypertension” found 237 articles. Animal studies were excluded. Those studies containing kidney-related parameters such as serum creatinine, glomerular filtration rate (GFR) or BP were selected. Relevant data including changes in renal function, blood pressure and mortality were extracted and compared.

Results: A total of 42,487 patients from 12 randomized controlled trials with data pertaining to NEPi use were included (8 in HTN and 4 in HF). Seven studies used NEPi combined with ACE-i, 4 with ARB, and 1 with endothelin converting enzyme inhibitors. The follow up periods ranged between 7 days and 27 months. All studies in HTN (including 27,401 patients) reported significantly better BP lowering effect for NEPi compared to control group, while 94% of the patients in the HF studies presented with improvement in mean BNP levels (p<0.05). The risk of death endpoint, all HF studies (including 15,086 patients) showed less frequent renal impairment (expressed as an adverse event, incidence of worsening renal function, change in GFR, or serum creatinine) compared to the control group. In contrast, only 3 HTN studies (including 466 patients) explored the impact on renal function and reported no significant benefit.

Conclusions: Current evidence suggests that in patients with HF, NEPi can lower HF-related events and mortality while potentiating favorable impact on renal function. In patients with HTN, although NEPi have been shown to reduce BP, there is no conclusive evidence of their role in improvement of renal function in this setting.
PUB183
The Differences of Renal Protective Effect by Hyperuricemia Treatment Using Febuxostat in Various CKD Subgroups Akinori Yamaguchi, Makoto Harada, Yosuke Yamada, Koji Hashimoto, Makoto Higuchi, Yuji Kamijo. Department of Nephrology, Shinshu Univ, Matsumoto, Nagano, Japan.

Background: We often experience the CKD cases exhibiting the attenuation of eGFR decline by hyperuricemia treatment using febuxostat. However, renal protective effect of the hyperuricemia treatment has not yet been established. We hypothesize that the therapeutic response of febuxostat treatment might differ among various subgroups of CKD patients.

Methods: To investigate the difference of the therapeutic response in CKD patients, 272 outpatients with hyperuricemia who were treated by febuxostat from May 2011 to March 2015 were enrolled. Patients undergoing hemodialysis and/or peritoneal dialysis treatment, and patients lacking essential clinical data were excluded. Finally, 178 patients were analyzed. Correlation coefficient between the average of serum uric acid level and the eGFR variation during 6 months after the treatment were statistically investigated in various clinical subgroups.

Results: In all patients, significant correlation between the average of serum uric acid levels and the eGFR variation was detected (Spearman’s correlation coefficient: r=-0.163, p<0.019). This significant correlation was also detected in each patient groups as follows: male patients (n=121, r=-0.211, p=0.020), non-elderly (below 70 years old) patients (n=107, r=-0.261, p=0.007), patients whose systolic blood pressure were below 130 mmHg (n=72, r=-0.238, p=0.044), patients without dyslipidemia (n=133, r=-0.316, p=0.005) and non-diabetic nephropathy patients (n=133, r=0.184, p=0.034). However, the significant correlation was not detected in each opposite subgroups.

Conclusions: The current study suggest that therapeutic response of febuxostat treatment might be well in each CKD subgroups, including male, non-elderly, non-hypertension, non-dyslipidemia and non-diabetic-nephropathy. It is possible that various risk factors of atherosclerosis conceal the beneficial renal protective effects of hyperuricemia treatment using febuxostat.

PUB184
Urinary RBP as an Independent Predictor of “Hard Composite Outcome” in Albuminuric Diabetic Nephropathy Gesiane Fernandes Tavares, Roberto Zatz, Silvia M. Titan. Renal Div, Dep. Clinical Medicine, Faculty of Medicine, Univ of Sao Paulo, Sao Paulo, Brazil.

Background: The current search for new biomarkers in CKD is intense, with particular emphasis on hard end-points, such as ESRD, creatinine duplication and cardiovascular and overall mortality. In this analysis, we sought to evaluate which baseline clinical and laboratorial variables were related to ESRD/mortality in 56 patients with albuminuric diabetic nephropathy after mean follow-up time of 5 years.

Methods: Baseline clinical and laboratorial data of 56 patients of a clinical trial were evaluated as predictors of major outcomes (primary outcome, PO: ESRD, creatinine duplication or mortality). Mann-Whitney and chi-square tests were used for univariate analyses. Several univariate and multivariate COX regression models were built on the risk of PO. Kaplan-Meier curve and LOG rank test were also performed.

Results: PO occurred in 39 participants after a mean follow-up time of 5 years (70%). In univariate analyses, sex, creatinine clearance, 24h proteinuria, uRBP, urinary VEGF and serum TGF-beta were related to the event group. In univariate COX regression models, sex, proteinuria, creatinine clearance, VLDL, cholesterol, ferritin, PTH, RBP and uMCP-1, uVEGF and uTGF-beta were significantly associated to the risk of the PO. However, after adjustments for creatinine clearance and proteinuria, only uRBP and uMCP-1, uTGF-beta and uVEGF remained significantly associated to PO. In a stepwise model, only creatinine clearance (HR 0.98, 95%CI 0.97 - 1.00, P=0.06) and uRBP (HR 1.13, 95%CI 1.07 - 1.20, P<0.001) were left as independent predictors of PO in this population. KM curve for uRBP is shown in figure 1.

Conclusions: Urinary RBP is an independent predictor of PO in albuminuric diabetic nephropathy. Its role as a risk biomarker should be further explored in larger studies of CKD patients.

Funding: Government Support - Non-U.S.

between treated and untreated patients (p = 0.593). After the index date, the rate of eGFR change showed a slight change (p = 0.36) with a slight gradual increase, but again this was not significantly different between groups (p = 0.52).

Conclusions: The similar results in the two groups, regardless of L-thyroxine treatment status, provides no evidence that treatment of subclinical hypothyroidism influences progression of CKD in individuals with stage 3 or 4 disease. Although previous studies have suggested that treatment of subclinical hypothyroidism in this population may delay or prevent the progression of ESRD, our results do not support the hypothesized treatment benefits.

PUB187
Effect of Hyperuricemia on the Blood Pressure-Dependent Proteinuria in Non-Nephrotic Chronic Kidney Disease

Kentarou Kojohara,1 Ryō Yamami,2 Tsuyoshi Miyagi,3 Masako Kochi,2 Yasuko Ohyama.4

Center for Hypertension Research, Jichi Medical University, Tochigi, Japan; 1Division of Nephrology, Jichi Medical University, Tochigi, Japan; 2Department of Nephrology and Hypertension, Jichi Medical University, Tochigi, Japan; 3Department of Nephrology, Jichi Medical University, Tochigi, Japan

Background: Patients with chronic kidney disease (CKD) are suggested to be highly susceptible for hypertensive renal damage due to disrupted autoregulation in afferent arteriole. We reported that hyperuricemia was associated with renal arteriolar hyalinization in the CKD patients. However, effect of hyperuricemia on a relationship between blood pressure (BP) and proteinuria is unknown in CKD patients.

Methods: A total of 208 consecutive patients who underwent renal biopsy at our department between 2003 and 2007 were considered for the study. We excluded patients receiving renin angiotensin inhibitor and nephrotic CKD patients defined as serum albumin equal or more than 3 g/dL, leaving us with 117 patients (57 men and 60 women) for analysis. Arteriolar hyalinization were assessed by semi quantitative grading for arterioles. We compared the relationship between systolic BP and logarithm-transformed urine protein (g/gCr) in the patients with or without hyperuricemia.

Results: The mean ± standard deviation values for age, BP, estimated glomerular filtration rate (eGFR), and urine protein were as follows: 40 ± 12 years, 126 ± 29 mmHg, and 48 ± 37 ml/min/1.73 m², respectively. In the patients with hyperuricemia (n=63), systolic BP was significantly correlated with log-transformed urine protein (r=0.45, p=0.004). In contrast, there was no significant correlation between them in the patients without hyperuricemia (r=0.33, p=0.07). In the multiple regression model (R²=0.25, p=0.01), systolic BP was significantly correlated with log-transformed urine protein (β=0.33, p=0.02) independent of age, sex and classical risk factors in the patients with hyperuricemia. However, its statistical significance was disappeared after additional adjustment with arteriolar hyalinization.

Conclusions: These results suggested that hyperuricemia might potentiate the susceptibility for hypertensive glomerular damage via disrupted autoregulation in non-nephrotic CKD patients.

PUB189
Vitamin D Deficiency Is a Cause and a Result of Renal Dysfunction in Rheumatoid Arthritis

Suad Ma Hannawi, Issa AL-Salmi. Medicine, Ministry of Health, Duabi, United Arab Emirates.

Background: Asymptomatic kidney dysfunction is common in RA. Low vitamin D(VD) increases susceptibility to development of RAA disease activity. Sequential hydroxylations occurs in liver & kidney to form active 1,25-VD & patients with kidney failure are often resistant to VD & suffer from 25 hydroxyribofuranosyl & renal osteodystrophy. In addition to its role in maintaining Ca&PO4 homeostasis, VD is important for maintaining maximum muscle strength & prevention of chronic diseases. Our objective is to evaluate eGFR & VD status in RA.

Methods: RA diagnosed by ACR 1988 criteria. 25-VD level obtained & GFR calculated by MDRD at Rheumatology clinic visit. Univariate linear regression analysis carried out to determine the relationship between 25-VD & eGFR, other renal parameters & RA inflammatory markers.

Results: A multivariate linear regression analysis of 52 RA(47,5M) with mean age 46±13 years(F46±12, M54±21). 25-VD level is 40±29 nmol/l(NR50-80) & GFR is 134±49 ml/min/1.73 m². Univariate linear regression showed a negative relationship between 25-VD level & eGFR (p=0.041, R2=0.23, 0.01), micro-albuminuria(p=0.046, CI:63, 0.01, CI (p=0.01, CI -1.16, -0.16), neutrophil count (p= 0.03, CI -1.67, -0.11). A positive linear relationship between GFR & weight (p=0.03, CI0.06, 1.04), HSA(p=0.02, CI1.11, 3.98) & BMI(p=0.009, CI 0.65-4.05), Ca=0.03, CI 7.24, 13.12 nmol/l).

Conclusions: Negative relationship between eGFR&25-VD, indicating a higher 25-VD as failure to convert to active form as GFR decreases. Extra-re nal formation of active VD requires 125-VD formation & is necessary for maximal extra renal production of 1,25VD & is one of the most potent regulators of cellular growth & very effective modulator of the immune system. VD receptors are present in most cells & tissues including body including activated T & B lymphocytes. Surveillance for VD deficiency, should be part of follow-up as it may be linked to underlying kidney dysfunction in RA. On the other hand, reduced VD might worsen RA & hence, increase the possibility of renal deterioration. VD supplementation may be needed early in management for prevention of kidney dysfunction & to reduce RA severity.

PUB190
Associations Between the Progression of Chronic Kidney Disease and Patient Demographics

Danieke Xu1, Mark Stuart,2 Barbara Cannon,2 Chad Sowers,1 John W. Larkin,3 Sophia Rosen,4 Carly R. Van Zandt,1 Len A. Usvyat,2 Yucel Emdin,1 Terry Keetchersid,2 Dugan Maddox,2 Franklin W. Maddux,2 1Univ of California, Santa Barbara; 2Fresenius Medical Care North America; 3Acumen Physician Solutions; 4Frenova Renal Research.

Background: It is not well known if demographic factors are related to the progression of chronic kidney disease (CKD). We aimed to investigate whether age, sex, race, marital status and geography are associated with significant changes in kidney function determined by linear slopes of mean annual glomerular filtration rate (GFR).

Methods: We analyzed data from 90,240 CKD patients (Pts), who had significant declines in GFR, in the Fresenius Medical Care CKD Data Registry. Annual average decline in GFR was estimated on a per pt basis using linear regression with time as the predictor and the GFR as the outcome variable. Univariate linear models were fitted for age groups (15-30, 31-60, 61-90 years old), Pts with sex (female, male), race (African American, Caucasian, or other), marital status (married, unmarried) and geography (10 divisions of zip codes); a multiple linear regression model was utilized to investigate associations in mean annual GFR slope and demographics.

Results: This analysis identifies significant associations between mean annual GFR slope and Pts demographics. CKD Pts age 15-30 years old were found to decline faster in GFR versus older Pts in all other age groups (p<0.001). Males were observed to decline slower in GFR versus Pts of African American or Caucasian race (p<0.001). The geographical location of Pts by zip code was observed to be associated with differences in GFR slope (p<0.001). The marital status of Pts was not found to be related to differences in slopes of GFR (p=0.218).

Conclusions: This study identifies that during the progression of CKD, younger Pts tend to have faster declines in GFR, as compared to older Pts; males have slower declines in GFR, as compared to females; Pts with a race of “other” have slower declines in GFR, as compared to Pts of African American or Caucasian race; and declines in GFR are related to Pt geography.

PUB191
Correlation of Increased Th17 to Treg Cell Ratio with Endoplasmic Reticulum Stress in Chronic Kidney Disease

On Yen. Kidney Dept, Second Affiliated Hospital of Xi an Jitong Univ, Xi an, Shaanxi Province.

Background: The study aimed to investigate the relationship between the regulatory immune network and endoplasmic reticulum stress (ERS) in patients with different stages of chronic kidney disease (CKD).

Methods: A total of 91 patients diagnosed with CKD were divided into different groups according to the stage of disease. Routine blood and biochemical tests were performed in patients and healthy controls in healthy controls (n = 20). The frequencies of T helper type 17 (Th17) and regulatory T (Treg) cells in the overall T cell population was measured by flow cytometric analysis. Levels of Th17 cell (IL-17) and Treg cell (IL-10) cytokines and the ERS markers

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underlines represents presenting author.
CHOP and GRP78 were measured by ELISA in serum samples collected from controls and patients from the different CKD groups. Correlations between each parameter and serum creatinine, an indicator of renal function, were analyzed by Spearman’s rank correlation and regression test.

Results: CKD stage showed a positive correlation with serum creatinine level, and increased levels of TH17 and Treg cells, respectively, along with increased TH17/Treg cell ratio. Consistent with this, CKD stage was positively correlated with serum concentrations of IL-17 and negatively correlated with serum IL-10 levels. Moreover, serum levels of CHOP and GRP78 increased with advancing CKD stage. These correlations were most prominent in patients in the CKD5 group, who also had the poorest response to hemodialysis and peritoneal dialysis treatment, compared with CKD5 patients in the non-dialysis group. Correlation analysis showed that serum levels of CHOP and GRP78 were independently and positively correlated with the ratio of TH17/Treg cells.

Conclusions: We have found that an increased TH17/Treg cell ratio and increased serum levels of ERS markers correlate with the progression of CKD. Our results indicate that the interplay between the immune network and management of ERS is closely associated with the pathogenesis of CKD. Although hemodialysis and peritoneal dialysis treatment manage chronic kidney conditions and prevent further deterioration of renal function, they have limited effects on improving the immune disorder and relieving ERS.

Metabolic Phenotyping in Thin Basement Membrane Nephropathy Claire Boulange,1 Manuja Kaularachchi,1 Elaine Holmes,1,2 John C. Lindon,1,2 Joram Matthias Posma,3 Konstantinos Vaskearis,1 Isavella Savva,1 Alkis Mikis Pierides,2 Konstantinios Delatas,3 Metabolometrix Ltd, London, United Kingdom; 2CSM, Dep of Surgery & Cancer, Imperial College London, London, United Kingdom; 3MMRC, Dep of Biological Sciences, Univ of Cyprus, Nicosia, Cyprus.

Background: Thin basement membrane nephropathy (TBMN) is the commonest cause of familial microscopic hematuria in children and adults, usually associated with benign clinical presentations i.e minimal proteinuria and normal renal function. In a Greek-Cypriot cohort of TBMN patients, 35% of patients were shown to develop ESRD by age 70-years while ~50% of patients over 50-years developed CKD of variable degree. 40% of TBMN patients inherit heterozygous mutations in the COL4A3 or A4 genes. That predisposes these TBMN patients to an adverse outcome and chronic kidney function decline during aging is presently unclear. Using Metabolic phenotyping techniques (NMR and mass spectrometry) our study should provide new biological insights in the development of extreme conditions in adult TBMN patients.

Methods: Spot urine samples from 81 patients with the same founder mutation, COL4A3-G1334E. Patients were classified; Severe (S):~55 mmol/24h and CKD, irrespective of age. Mild (M) (~26): normal kidney function with no proteinuria. Regardless of age. It is expected that some will proceed to CKD on follow up. Samples were analysed by 600 MHz 1H NMR spectroscopy (detecting predominantly small molecules >1μM) and UPLC-MS (detecting larger-solute molecules >0.05 μM). Multivariate analysis (MVA) was used to elucidate class differences.

Results: MVA of M vs S samples revealed significant metabolic differences between the groups. From the UPLC-MS 15 MS features discriminate M and S. Among the discriminating metabolites discovered using NMR; citrate, glycine and creatinine were negatively correlated with S. Metabolite identification is ongoing, as well as application of additional metabolic profiling technologies.

Conclusions: Urine metabolic profiling may prove useful to classify renal disorders such as TBMN and its cases of TBMN by their specific renal metabolite signatures and lead to the discovery of novel molecular disease biomarker profile patterns.

PUB193

Uric Acid and Its Association with Glomerular Filtration Decline Rate in an Incident Pre-Dialysis Population Pedro Vieira, Miguel Goncalves, Gil Silva, Nephrology, Hospital Central do Funchal, Funchal, RAM, Portugal.

Background: Hyperuricemia is highly prevalent and there is cumulative evidence based on experimental models of its likely detrimental role in multiple pathologies, namely hypertension, vascular and renal diseases. Given hyperuricemia’s high occurrence on the vascular endothelium, measured by elevated levels of serum high-sensitivity C-reactive protein (hsCRP), may play a role in kidney disease. Therefore, we examined the association of hsCRP with kidney damage indicators (uACR, eGFR) among 5667 participants receiving physical examination in the Third Xiangya Hospital.

Methods: We conducted a cross-sectional analysis of 5667 adults who received healthy physical examinations in 2014. Spearman correlation analysis, multiple linear regression and multivariable logistic regression models were used to analyze the correlation between hsCRP and uACR, eGFR. ROC curves were drawing to explore the statistically significant intercept point of hsCRP in predicting the occurrence of albuminuria and declining in eGFR. Multivariable logistic regression analysis was used to calculate the ORs for albuminuria, declining in eGFR according to the quartiles of hsCRP levels and other risk factors.

Results: Spearman correlation analysis showed that uACR was positively correlated with serum hsCRP (r=0.233, p<0.01). While hsCRP showed negative correlation with hsCRP (r=0.135, p<0.01). Multiple linear regression analysis showed that hsCRP was independently correlated with uACR (B=0.205, p=0.156, P<0.01). While hsCRP didn’t enter the multivariate linear regression model of eGFR. Multivariable logistic regression analysis showed that male, central obesity, hypertension, diabetes and high hsCRP levels were independent risk factors for albuminuria. Based on the ROC curve, the 0.85mg/L of hsCRP was the best numerical value to predict the risk of albuminuria. Multivariable logistic regression analysis showed that the risk of albuminuria significantly increased in male, central obesity, hypertension, or diabetes combined with high hsCRP levels.

Soluble α-Klotho in HIV-Infected Patients and Kidney Dysfunction Clara Dias,1 Sara Maia,2 Fernando G. Pereira,2 Pedro Pereira Campos,2 Ana Luisa Papoila,3 Alberto Ortiz,3,6 Sofia Pereira,2 Karina Soto,2 1Centro de Estudos de Doenças Crônicas, NOVA Medical School/Faculdade de Ciências Médicas; Nephrology, Hospital Fernando Fonseca; 2Centro de Estatística e Aplicações, Universidade do Porto (CEAUL), Portugal; 3Nephrology, INS-Fundación Jiménez Diaz, Madrid, Spain; REDinREN, Madrid, Spain; 3REDinREN, Madrid, Spain; 4Univ Autonoma de Madrid, Madrid, Spain; 5IRSN, Madrid, Spain.

Background: Kidney disease is common among HIV-infected patients. Klotho is a new endocrine protein that exerts modulation of kidney solute transport and nephrorprotective effects in AKI and CKD. We aim to explore whether levels of serum soluble α-Klotho are related with CKD progression in HIV-population.

Methods: As a part of an on-going prospective study of HIV-infected patients, a cross-sectional analysis was performed. Glomerular filtration rate (eGFR) was estimated by CKD-EPI equation being Early Kidney Disease (EKD) when <90 mL/min/1.73m². Fractional excretion of phosphate (FePi) was also assessed and serum soluble α-Klotho was quantified by ELISA.

Results: A total of 169 HIV patients were included, 66% men, 75% non-Black, 55yo (48-62). Median values Klotho: 957 g/mL (717-1231) and FePi: 21% (14-25). Klotho/FePi ratio was negatively correlated with eGFR when ≤75 mL/min/1.73m² (Spearman r=-0.213, p=0.024), while the correlation was positive if eGFR>75 (Spearman r=0.410, p=0.002).

Conclusions: In HIV-infected patients, the association between Klotho and CKD progression has only significance when normalized by FePi levels. This association differed in opposite directions between patients with EKD and with normal kidney function, or in very early CKD stages. Of note, Klotho/FePi ratio seems to be better biomarker of EKD than Klotho itself.

PUB195

Association of hsCRP and Kidney Damage Indicators in 5667 Adults Receiving Physical Examination Hao Zhang, Juan Mao, Bin Yi, Guo Xu, Wei Li, The Third Xiangya Hospital of Central South Univ.

Background: Chronic kidney disease and cardiovascular disease share many risk factors. Injury to the vascular endothelium, measured by elevated levels of serum high-sensitivity C-reactive protein (hsCRP), may play a role in kidney disease. Therefore we examined the association of hsCRP with kidney damage indicators (uACR, eGFR) among 5667 participants receiving physical examination in the Third Xiangya Hospital.

Methods: We have randomly selected incident patients with chronic kidney disease stages IV-V, referred to low clearance nephrology assessment from 2010 to 2014. We kept follow up until dialysis initiation, death or loss of follow up.

Results: Sixty-six patients were selected with mean UABL of 8.15 (2.10) mg/dl and a mean glomerular filtration rate of -4.00 (-1.73)mL/minute/year. Of notice that by each unit increase in UABL an added variation of -1.41 mL/min/1.73m²/year on glomerular filtration decline rate was observed (CI 95%, p<0.039). Adopting a linear mixed model analysis on UABL impact on glomerular filtration decline rate, despite adjustment for multiple demographic confounders and comorbidities, statistical significance (p<0.006) was conserved.

Conclusions: High UABL were associated, with statistical significance, to enhanced deterioration of kidney function.
Conclusions: hCRP was correlated with kidney damage indicators, and hCRP was an independent risk factor of albuminuria. The 0.85mg/L of hCRP was the best numerical value to predict the risk of albuminuria. Male, central obesity, hypertension, diabetes accompanying high serum hCRP levels are more likely to have albuminuria.

PUB196

Serum Non-Protein Bound Homocysteine Levels Are Related with Chronic Kidney Disease Progression in HIV-Infected Patients  Clara Dias, 1 Nelson Casimiro, 1 Nuno Coelho, 1 Ana R. Lemos, 1 Pedro Pereira Campos, 2 Ana Luisa Papolla, 2 Sara Maia, 3 Karina Soto, 2 Sofia Pereira, 1 1 Centro de Estudos de Doenças Crônicas, NOVA Medical School/Faculdade de Ciências Médicas (NMS/FCM), Univ Nova de Lisboa; 2 Centro de Estatística e Aplicações da Univ de Lisboa (CEAUL); 3 NOVA Medical School/Faculdade de Ciências Médicas, Univ Nova de Lisboa; 4 Nephrology, Hospital Fernando Fonseca, Lisbon, Portugal.

Background: Homocysteine (Hcy) is present in serum in two major forms: disulfide protein-bound (PB) (70-80%, mostly albumin) and non-protein bound (NPB) (20-30% combined thiol dimers + 1% thiol free). Only the NPB-fraction of Hcy is able to enter into the cell and accumulate. In both kidney failure and HIV-infected patients, hyperhomocysteinemia is a common feature. The present study was aimed to explore the relation of Hcy NPB-fraction and chronic kidney disease (CKD) progression in HIV-infected patients.

Methods: As a part of an on-going prospective study of HIV population, a cross-sectional analysis was performed in a cohort of HIV-infected patients under combined antiretroviral therapy. Serum NPB-fraction of Hcy was quantified by HPLC with fluorescence detection. Glomerular filtration rate (eGFR) was estimated by CKD-EPI equation. The fractional excretion of phosphate (FePi) was also assessed.

Results: A total of 141 HIV-infected patients were included, 65% men, 73% non-Black and 55 years old (IQR 44-63). Median values of eGFR and FePi were 85 ml/min/1.73m² (66-95) and 19% (13-25) respectively. Univariable analysis was performed for eGFR, FePi and 55 years old (IQR44-63). Median values of eGFR and FePi were 85 ml/min/1.73m² (66-95) and 19% (13-25) respectively. Univariable analysis was performed for eGFR, FePi and age. Only eGFR remained in the multivariable model (r=-0.332, p=0.0001).

Conclusions: Serum NPB-Hcy fraction was independently related with kidney dysfunction. The present data suggest that monitoring this sub-fraction of Hcy could be a tool for early kidney dysfunction detection in HIV-infected patients.

PUB197

Diabetic Foot Ulcers and Acute Kidney Injury Are Associated with a Decline in Renal Function  Huda Mahmoud, 1 Maarten W. Taal, 1 Frances Game, 1 Laura M. Proctor, 2 Heather Sherriff, 3 Christina Uddari Peter, 1 Hana Baig, 1 Faizah Asma, 1 Emma J. Lincoln, 1 Nicholas M. Selby, 1, 2 Renal Medicine, Royal Derby Hospital, Derby, United Kingdom; 3 Div of Medical Sciences and Graduate Entry Medicine, Univ of Nottingham, United Kingdom.

Background: There is an increased incidence of foot ulcers in patients with diabetes in the period immediately prior to the initiation of chronic dialysis; this may be explained if chronic foot ulcers accelerate a decline in renal function. We sought to examine this further by describing changes in renal function associated with hospitalisation for diabetic foot ulcer management.

Methods: All patients admitted to our centre during 2013 with ICD10 coding for diabetes and a primary diagnosis of foot ulcer (L97x) were identified. Data were manually extracted for those with a relevant clinical episode and sufficient biochemical results from routine clinical care. Patients undergoing amputation were excluded. Absolute creatinine and eGFR (CKD-EPI) values were collected from 6 months (+/- 1 month) pre and post hospital admission.

Results: 95 patients were included. 67 men, median age 68 years (range 31-96). Renal function was worse after an admission with an active diabetic ulcer; 6 months prior to hospital admission the mean eGFR was 72 +/- 25 SD ml/min/1.73m² compared to 67 +/- 27 SD ml/min/1.73m² 6 months after admission, p<0.01. 27% of the admissions were associated with acute kidney injury (AKI stage 1, 2, 3; 19, 6, 1 patients respectively). Patients who sustained AKI during the admission had larger changes in eGFR than those patients without; median decline of -2ml/min/1.73m²/year(IQR -6.11) versus -5 ml/min/1.73m²/year(IQR -2.28), p=0.008.

Conclusions: These data add strength to the hypothesis that an active diabetic foot ulcer may contribute to a decline in renal function, particularly when associated with an episode of AKI. This decline may also be under-estimated due to loss of muscle mass and subsequent over-estimation of eGFR in the post hospitalisation period. These results support additional prospective epidemiological and mechanistic studies to further explore the relationship between diabetic foot ulcers, AKI and CKD progression.

PUB198

Gender – An Additional Cardiovascular and Chronic Kidney Disease Risk Factor in an Apparently Healthy Population  Attilio Di Benedetto, 2, 3 Annalisa Ciottola, 1 Fabrizio Cerino, 1 Annamaria Colao, 2 Daniele Marcelli, 1 Bernard J. Canaud, 1 NephroCare Italy, Naples, Italy; 5 Medicine Clinica e Chirurgia, Univ Federico II, Naples, Italy; 6 Frensenius Medical Care, Bad Homburg, Germany.

Background: Cardiovascular disease (CVD) is on the rise, presenting significant social and economic burden. Early detection of CVD and chronic kidney disease (CKD) risk factors may prevent related complications. We report results of a CVD and CKD risk factor screening program in an apparently healthy population.

Methods: Participants and spectators of the “Prevention Races” held in 2013/2014 in Naples/Salerno (Italy) were screened for CVD and CKD risk factors by different specialists, including nephrologists. Parameters assessed were: systolic blood pressure (SBP), diastolic blood pressure (DBP), weight, height, waist circumference, BMI, and body composition. Lean (LEI) and Fat (FTI) tissue indexes and overhydration were evaluated by Body Composition Monitor (Fresenius Medical Care, Bad Homburg, Germany) using multi-frequency bioimpedance spectroscopy at 50 different frequencies.

Results: 701 subjects (38.5% m; 61.5% f) were evaluated. Mean age was 54.54 ± 15.6 (m) and 50.06 ± 15.2 (f). 3.7% m and 6.8% f had dyslipidemia; 5.9% m and 3.0% f were diabetics; 18.6% m and 11.4% f were hypertensives; 2.5% m and 0.7% f had heart disease; 0% m and 3.5% f had hypothyroidism; 1.5% m and 1.2% f had CKD. Gender differences in SBP, DBP, overhydration, FTI, LEI and BMI are shown (Table).

Waist circumference was higher than normal (i.e. ≥88 cm for m and ≥102 cm for m) in 38.4% (m) and 51.6% (f).

Conclusions: In a large sample of apparently healthy persons, males had more CVD and CKD risk factors than females, such as SBP, overhydration, and FTI. In association with other risk factors, higher BMI may have an impact adversely on the progression of chronic kidney disease (CKD) to end stage renal disease (ESRD). It is plausible that treatment could result in a significant reduction in ESRD incidence though the potential impact in a CKD population and number needed to treat (NNT) are incompletely understood. We carried out the present study to estimate the potential impact of treatment of metabolic acidosis on the incidence of ESRD in a population of CKD patients.

Methods: We evaluated a cross section of 623 Stage 3 and 4 CKD patients at our institution. Their risk of developing ESRD at 2 and 5 years was estimated using the method of Tangri et al (JAMA 2011;305:1553-1559) which incorporates age, gender, eGFR, urine albumin to creatinine ratio, calcium, phosphorus, albumin, and bicarbonate. ESRD risk was then recalculated after assuming correction of all serum bicarbonate levels to 28 mEq/L.

Results: The population had a mean serum bicarbonate level of 24.3 mEq/L, with 79.5% having levels below 28 mEq/L. When ESRD risk was calculated following correction of low serum bicarbonate levels to 28 mEq/L, 16 fewer patients were predicted to develop ESRD at 2 years and 27 fewer at 5 years (relative risk reductions of 0.31 and 0.23 respectively). This effect was greatest for patients with CKD stage 4, accounting for 13 fewer ESRD patients predicted at 2 years and 20 fewer at 5 years. For the population as a whole, the NNT to prevent one case of progression from CKD to ESRD was 40 and 23 at 2 and 5 years respectively, while for those with CKD stage 4 the NNT was only 16 and 11.

Conclusions: Our findings suggest that in a population of CKD patients correction of metabolic acidosis could potentially result in a substantial reduction in the number who reach ESRD given the large numbers of patients with low serum bicarbonate levels. Prospective studies are needed to determine whether sodium bicarbonate therapy in populations of CKD patients could prevent many cases of ESRD.
The Impact of Vascular Disease on Risk of Development of End Stage Renal Disease in Patients with Chronic Kidney Disease

Background: Patients with chronic kidney disease (CKD) are not only at higher risk for development of end stage renal disease (ESRD) but also suffer disproportionately from vascular disease (VD), with associated high cardiovascular mortality. VD can plausibly impact progression of CKD and increase the risk of ESRD. However, VD also shortens survival, and may therefore reduce the risk of ESRD by increasing the competing risk of death. In the present study we evaluated the relationship between VD and the risk of development of ESRD in patients with CKD.

Methods: We carried out a retrospective cross sectional study of 623 CKD patients and recorded demographic, clinical and laboratory variables. We divided them in two groups based on presence or absence of VD and stratified them into different age groups. We estimated the risk of ESRD progression using the method of Tangri et al (JAMA 2011;305:1553-1559) and compared the risk levels between each group.

Results: Out of 623 patients with CKD 285 had VD (coronary artery disease and or peripheral vascular disease) documented in the record. Patients with VD were significantly older than patients with no VD (76 vs 70 years), had lower serum albumin (4.0 vs 4.1 g/dL) and lower eGFR (33.8 vs 36.4 ml/min/1.73 m^2). We found that older patients with VD had significantly higher risk of developing ESRD. For the 70 to 79 year age group the 2 year risk was 2.45 vs 1.50 (p=0.029) and 5 year risk was 6.80 vs 4.31 (p=0.03) in patients with and without VD. For patients 80 years the 2 year risk of developing ESRD was 2.18 vs 1.35 (p=0.029) and 5 year risk of developing ESRD was 6.80 vs 4.31 (p=0.03).

Conclusions: Our findings suggest that older patients with VD may be at increased risk for the development of ESRD despite the higher competing risk of death. This may be partly due to shared pathophysiological mechanisms between atherosclerosis and CKD progression. If validated in an ongoing prospective study this finding would suggest that VD should be partly due to shared pathophysiological mechanisms between atherosclerosis and CKD risk for the development of ESRD despite the higher competing risk of death. In the present study we evaluated the relationship between VD and the risk of development of ESRD in patients with CKD.

Management of Renal Artery Stenosis Post-ASTRAL and CORAL:

Outcomes of Patients with Radiologically Confirmed Atherosclerotic Renal Artery Stenosis Treated Conservatively

Background: Following the publications of ASTRAL and CORAL trials, the use of percutaneous renal artery angioplasty and stenting (PRAS) in the treatment of atherosclerotic renal artery stenosis (ARAS) has fallen dramatically. We report the outcomes of patients with radiologically confirmed diagnosis of ARAS who did not undergo PRAS and were managed medically.

Methods: Retrospective review of all patients undergoing CT/MRI angiography for suspected ARAS from 2008-2014 in Broomfield Hospital, Essex. Patients with more than >50% stenosis in a renal artery who were medically managed and did not undergo PRAS were included in analysis. They were followed for blood pressure control, renal events and mortality.

Results: 29 patients were identified, all Caucasians with a median age of 78 (49-85 years) of which 59% were males. None underwent PRAS. They were followed up from diagnosis till December 2014 or date of death with a mean period of 51 months. Systolic BP at end of study was <140 mmHg in 48%, 140-200 in 48% and >200 in 4% of patients. 69% were on 3 or more antihypertensives with 34% on renin angiotensin system blockade. 20 patients were CKD 3 and 8 with CKD 4 at baseline, with 3 patients progressing from stage 3 to 4 and 1 to stage 5 CKD, requiring dialysis.

Conclusions: From this study of patients with ARAS not indicated for PRAS, only a small number progressed to higher grades of CKD. Blood pressure control appeared adequate in a significant proportion of patients. This is in keeping with the findings from ASTRAL/CORAL trials and may be of significant benefit in terms of cost and reducing patient morbidity.
Factors Influencing Initiation and Choice of Immunosuppressive Therapy in Primary FSGS

Louis-Philippe Laurin,1 Bethany J. Foster,2 A. Gasim,2 Caroline J. Poulton,3 J. Charles Jenette,4 Ronald J. Falk,5 Patrick H. Nachman.6

1 Div of Nephrology, Hôpital Maisonneuve-Rosemont, Montreal, QC, Canada; 2Dept of Pathology and Laboratory Medicine, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; 3Div of Nephrology and Hypertension, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; 4Div of Nephrology, McGill Univ Health Center, Montreal, QC, Canada.

Background: The treatment of patients with primary focal segmental glomerulosclerosis (FSGS) may include immunosuppressive therapy in patients not responding to conservative treatment or considered at high risk of progression to renal failure. We sought to determine the patient and disease characteristics associated with choice of therapy early in disease course.

Methods: Inception cohort of biopsy-proven patients with primary FSGS diagnosed between 1980 and 2012. Factors influencing choice of therapy were identified using multiple logistic regression; we report odds ratios (OR) with 95% confidence interval (CI). Results: 458 patients were identified; 183 on immunosuppressives; 173 treated with glucocorticoids [GC] alone; 90 with calcineurin inhibitors [CNIs] treatment or considered at high risk of progression to renal failure. We sought to determine the factors influencing initiation and choice of immunosuppressive therapy in primary FSGS, the third most common cause of nephrotic syndrome after membranous glomerulopathy and minimal change disease (MCD).

A Performance-Enhancing Drug and Its Depressing Effects

Waid Bader, Internal Medicine, John Stroger Hospital of Cook County, Chicago, IL.

Background: Anabolic steroid use is a habit with a global 3.3% lifetime prevalence rate and is well known for its adverse effects on the renal, endocrine, hepatic, and hematologic systems. We bring a case of focal segmental glomerulosclerosis (FSGS) in a known user of anabolic steroids.

Methods: A previously healthy 28 year old male had presented to our hospital after being told he had kidney damage during a recent routine check up. On presentation, he complained of generalized weakness of one month’s duration; the social history was significant for use of Mutant Plекс, a bodybuilding supplement that contained an anabolic steroid, methylsterone. On admission, his vital signs were as follows: Blood pressure of 189/109 and a heart rate of 82. His physical exam noted a muscular male with normal cardiovascular, respiratory, and abdominal exams. On labs the patient had a BUN of 59, a creatinine of 5.6, and a hemoglobin of 13.1. A urinalysis showed 1 WBC, 2 RBCs, and 1+ protein. Nephrology team was consulted for further workup. Urine microscopy was performed and showed no dysmorphic RBCs. Spot urine protein/creatinine ratio was 2.2 grams. HIV was negative; HBsAg, HBsAb, and hepatitis C antibody were negative. Three days into his admission, the patient had an ultrasound guided kidney biopsy. On biopsy, half of the glomeruli had segmental scars, some with collapsing features. The interstitium had areas of fibrosis and the arteries showed mild sclerosis and arterioles with hyalinosis. The patient was educated on control of hypertension and was advised to stop using anabolic steroids.

Conclusions: Presence of tip lesion, preserved renal function at baseline and more severe hypoalbuminemia are associated with immunosuppressive therapy in primary FSGS, but only tip variant appears to influence choice of GC alone over CNIs.

Uric Acid Is Independent Risk Factor for Progression of Renal Dysfunction in IgA Nephropathy Female Patients

Yasuyuki Nagasawa,1 Ryoho Yamamoto,2 Makio Shinzawa,2 Sayuri Kawada,2 Katsuyuki Nagatoya,2 Aritoshi Kida,3 Tatsuya Shoji,1 Yukiko Hasuke,1 Terumasa Hayashi,2 Takahiro Kuragano,1 Atsushi Yamatuchi,1 Yoshitaka Isaka,2 Takeshi Nakashita.2

1 Div of Nephrology and Geriatric Medicine, Osaka Univ, Suita, Osaka, Japan; 2Dept of Nephrology and Geriatric Medicine, Osaka Univ, Suita, Osaka, Japan; 3Dept of Internal Medicine, Osaka Rousai Hospital, Sakai, Osaka, Japan.

Background: IgA nephropathy is one of common primary glomerulonephritis. Hyperuricemia could be caused by reduced renal function. Therefore, it was difficult to distinguish hyperuricemia from the factors which promote renal dysfunction. Recently, several reports indicated that hyperuricemia might be independent risk factor for renal worsening, but there was little information about uric acid and hyperuricemia itself upon progression of kidney diseases, especially in IgA nephropathy patients. Aim is to reveal effect of uric acid upon renal prognosis in IgA nephropathy patients.

Methods: This study is retrospective cohort study. Subjects were 923 IgA nephropathy patients who had not been treated uric acid lowering drugs, from 1001 IgA nephropathy patients who were diagnosed by renal biopsy, and over 15 years old in Osaka University Hospital, Osaka general medical center, Osaka Rosaki Hospital. Outcome was 1.5 times of serum creatinine. Exposure is uric acid at renal biopsy. Exploratory variables included sex, age, BMI, blood pressure, baseline eGFR, proteinuria, smoking status.

Results: Mean age was 34[23-46] years, proteinuria was 0.40[0.10-1.65] g/dy. Uric acid was 6.5±1.3mg/dl in male patients, and 4.8±1.3mg/dl in female patients. Multivariate Poisson regression analysis revealed that uric acid was significant risk for progression of renal disease [Hazard Ratio 1.30[1.01-1.65] UA per 1mg/dl] in female patients along with proteinuria (g/d) [HR 1.27[1.08-1.47], p<0.001], Creatinine (mg/dl) [HR 2.73[1.34-3.74]]. In male patients, uric acid was not independent risk factor.

Conclusions: Hyperuricemia is independent risk for progression of kidney disease in female IgA nephropathy patients.
Results: 32 children had kidney biopsy (Bs) for primary SDND/FRNS. 14 females; 14 H, 10 AA, 6 C, 2 other race.

Background: An African American male was diagnosed at age 18 with GPA by kidney biopsy with negative serology. He was treated in intravenous cyclophosphamide and steroids. Four months post treatment a repeat kidney biopsy showed focal segmental glomerulosclerosis (FSGS). At age 25, he presented with fever, fatigue and cough for few weeks, chronic postural drip with bloody secretions, nausea, vomiting, and 40-pound weight loss in the last two months.

Methods: His BUN was 18 mg/dL and creatinine 1.33 mg/dL. Urinalysis showed 3+ blood, 2+ protein, over 100 RBCs, 10 WBCs. Serology for Hepatitis B and C, HIV, EBV and CMV were negative. Antinuclear antibody, anti-neutrophil cytoplasmatic antibody, anti dsDNA antibody, Smith antibody, RNP antibody, myeloperoxidase antibody, proteinase 3 autoantibody, anti SSA antibody, anti SSB antibody, and complement levels were negative. An angiotensin converting enzyme (ACE) level was 81 U/L (8-52). A chest Computed Tomography showed mediastinal, hilar lymphadenopathy, and multiple pulmonary nodules.

Results: Suspicion for relapsing GPA prompted renal biopsy. It showed 3 out of 13 glomeruli with pauci-immune crescentic glomerulonephritis. There were extensive non-caseating granulomas in the interstitium with interstitial fibrosis and associated tubular atrophy. No microorganisms were noted on AFB and PAS stained sections. Nodal septum biopsy showed non-necrotizing granulomatous inflammation. Medialstitial lymph node biopsy showed necrogranulomatous lymphadenitis. These 3 biopsy sites were consistent with sarcoidosis.

Conclusions: This case highlights the difficulty in differentiating between ANCA negative GPA versus sarcoidosis as both can cause granulomatous lesions. Glomerular involvement in sarcoidosis can show membranous glomerulonephritis, FSGS and rarely a crescentic glomerulonephritis. In our opinion, the TAC level combined with extensive presence of non-caseating granulomas in the nasal septum, mediastinal nodes and renal interstitium are more characteristic of sarcoidosis. He responded well to steroids and his urine sediment became inactive, which is in favor of sarcoidosis and not GPA.

Epidemiology of Glomerulonephritis in Southern Arizona

Benjamin Kwesi Sarsah, Irfan K. Moinuddin, Bijin Thajudeen, Amy Nicole Sussman, Pradeep V. Kadambi. Nephrology, Univ of Arizona, Tucson, AZ.

Background: Knowledge about the incidence and prevalence of GN and its regional trends are mandatory for health care planners to adopt measures for preventing patients with glomerular disease from progressing to dialysis. The aim of the study was to look at the frequency of biopsy proven non-diabetic glomerulopathy in Southern Arizona.

Methods: Renal biopsy specimens from adult patients above the age of 18 years with glomerular renal disease were included. Renal transplant biopsies showing glomerulonephritis and biopsies showing co-existing diabetic nephropathies were excluded. Histological diagnoses were grouped into one of the following 8 categories: minimal change disease, FSGS, membranous nephropathy, membrane-proliferative glomerulonephritis, pauci-immune glomerulonephritis, IgA nephropathy, lupus nephritis and others. Demographic parameters were systematically collected from the medical records archive.

Results: The most common histopathological diagnosis was FSGS followed by membranous nephropathy and IgA nephropathy. There were male predominance in all histological variants except IgA nephropathy, lupus nephritis and pauci-immune glomerulonephritis. The race distribution was uneven, and all histological variants except minimal change disease and lupus nephritis were more commonly seen in whites. In separate analysis of the histological pattern in Hispanics, lupus nephritis was found to be the most common pathology followed by FSGS. In American Indian population the most common pathology was IgA nephropathy followed by FSGS. Bar diagram represents frequency of each glomerular disease.

Lupus Nephritis: An Exploration of Management Style

Abhishek Nandan, Huzaefa J. Syed, Christen Vagts, Jason M. Kidd. Internal Medicine, Virginia Commonwealth Univ Medical Center, Richmond, VA.

Background: We aim to evaluate the differences and rationale behind the diagnostic and therapeutic approaches to proliferative lupus nephritis (LN) among nephrologists and rheumatologists.

Methods: A de-identified, multiple-choice survey was distributed to nephrologists and rheumatologists. The survey consisted of a demographic questionnaire and two case vignettes exploring the decision of when to biopsy, management of ISN Class III LN, and management of refractory ISN Class IV LN.

Results: There were 38 respondents to our survey: 12 rheumatologists and 26 nephrologists. Work setting: 81% academic, 19% non-academic. Management of abnormal UA findings in an asymptomatic lupus patient: 33% of rheumatologists versus 76% of nephrologists chose to biopsy. Induction regimen of ISN Class III LN: 79% of all providers chose MMF and 21% chose IV cyclophosphamide.

Choice of Induction Regimen in ISN Class III LN per Specialty

Maintenance regimen of ISN Class III LN: all surveyed rheumatologists chose MMF as a sole maintenance agent compared to 32% of nephrologists who elected the addition of low-dose corticosteroids to MMF. Choice of an adjunctive agent in refractory ISN Class IV LN: 68% of providers chose rituximab, 14% chose tacrolimus, 5% chose CTLA4-Ig, and 14% elected not to add any agents listed.

Conclusions: The results of this survey suggest a significant difference among rheumatologists and nephrologists on the decision to perform initial kidney biopsy and management of ISN Class III LN. The results suggest that perception of side effect profiles play an important role in the choice of therapeutics. This study emphasizes the need for a multi-disciplinary approach toward renal disease in lupus patients. We continue to recruit subjects to complete this survey.

**Results:** Two groups- group which had immune deposits (group 1) and group with no immune deposits (group 2). A) 9.5% patients (2 FSGS, 2 MGN, 1 MPGN) with initial partial remission maintained partial remission during the follow-up period from a minimum of 2 months up to 19 months. The patient reported fatigue but remained on a low dose of prednisone and systemic symptoms resolved. Unfortunately, he has been found to relapse when an attempt at a steroid wean was made and is thus maintained on a low dose of prednisone.

**Conclusions:** Pauciimmune GN with immune deposits has poorer prognosis compared to those without immune deposits. Pauciimmune GN with immune deposits likely represent patients with severe immune complex deposition and partial clearance of immune complex. These are patients who might benefit from plasmapheresis in addition to standard treatment.

**Eosinophilic Pneumonia with Renal Involvement**

Gabielle Goldet,1 Rachel Hung,2 Michael Sheaff,2

1 Basildon and Thurrock Univ Hosp; 2 Pathology, Barts and the London School of Medicine.

Background: Eosinophilic pulmonary renal syndromes are well established and can be either vasculitic or infectious in etiology. We describe a novel case of a patient whose presentation could not be fitted into either category.

Methods: A fifty year old male presented with increasing weight loss, night sweats and shortness of breath of 3 months duration. Additionally he noted some swelling of his lower limbs and frothy urine. He was extensively investigated with urinalysis, blood tests, imaging and histopathology till a novel diagnosis was made.

Results: The patient was found to have nongranulomatous eosinophilic proteinuria with stable renal function. He had multifocal consolidation on computed tomography of the lungs and eosinophilic infiltrates on lung histology. A kidney biopsy revealed dense subacapsular inflammatory cell infiltrate including eosinophils with possible subendothelial deposits on light microscopy. A vasculitic screen excluded vasculitis as the underlying pathology and no signs of vasculitis were seen on either the lung or kidney biopsies. Additionally filiaria was excluded with negative serology. The patient was treated with steroids and his pulmonary and systemic symptoms resolved. Unfortunately, he has been found to relapse when an attempt at a steroid wean was made and is thus maintained on a low dose of prednisone.

Conclusions: We describe a novel pulmonary-renal syndrome and provide an approach to its investigation and management. This case opens the way for further research into eosinophilic pulmonary-renal syndromes.

**Role of Remission of in Idiopathic Membranous Nephropathy on Long Term Renal Function Outcome**

Abdulhakeem Alswailem,1 Hala M. Kfoury,2 Suﬁa Husain,1,2 Tarq Aljahmi,1 Suad S Aloabail,1 Mohammed A Al-Ghonaivm,1 Jamal S Al Wakeel.1 1 College of Medicine, King Saud Univ, Riyadh, Saudi Arabia; 2 College of Medicine, King Saud Univ, Riyadh, Saudi Arabia.

Background: Heavy proteinuria is considered a poor prognostic marker among patients with idiopathic Membranous Nephropathy (IMN). However, the impact of the remission status on the renal out come in patients with IMN is not well studied. The purpose of this study was to evaluate the long-term prognosis after achieving a complete or partial remission among patients with IMN presenting with heavy proteinuria.

Methods: In this study, 25 patients with IMN with heavy proteinuria defined as ≥ 2 g/m2 per day were evaluated for the effect of a partial remission (50% reduction in baseline proteinuria to ≤ 3 g/d and ≤ 25% increase in baseline creatinine) and complete remission (proteinuria ≤ 0.5 g/d and serum creatinine ≤123 µmol/l) on renal outcomes compared with patients who did not attain a remission. Worse renal outcomes was defined as doubling of baseline proteinuria ≤ 0.5 g/d and serum creatinine ≥123 µmol/l.

Results: The cohort consisted of 20 men and 5 women. The median proteinuria at presentation was 9.4 g/m2 per day (IQR: 6.7-12.1 g/m2 per day) and the median of follow up duration was 7.0 years. The median base line creatinine was 91 µmol/l (IQR: 74-98 µmol/l). A complete remission was attained in 7 (28%) patients, a partial remission in 12 (48%) patients, and no remission in 6 (24%) patients. The worse renal outcome was not observed in all patients who achieved complete remission, but it was seen in 16.7% of the partial remission group and in 66.7% of the no remission group (P value 0.14).

Conclusions: Achieving a complete or partial remission compared to no remission in patients with IMN is associated with a significantly better renal outcome.
Comparison of Short- and Long-Term IgA Nephropathy Clinical Remission Rates Between Tonsillectomy plus Consecutive and Intermittent Steroid Pulse Therapies

Kazuhiko Yoshikawa, Izaya Nakaya, Karen Katou, Yuta Tetsuka, Satoshi Kumakura, Jun Soma. Div of Nephrology, Iwate Prefectural Central Hospital, Morioka, Iwate, Japan.

Background: Tonsillectomy (Tx) plus steroid pulse therapy (TSP) is widely performed across Japan for clinical remission (CR) of IgA nephropathy (IgAN) but treatment protocol lacks consensus. We used both TSP (methylprednisolone 0.5 g/day iv for 3 days*) thrice/3 consecutive weeks (TSP-C) and intermittent pulse (* thrice/high-potency field). Oral prednisolone (oPSL) between pulse therapies began at 0.5 mg/kg on alternate days. After the third pulse, oPSL was tapered over 1 and 0.5 years in TSP-C and TSP-I groups, respectively. Tx was performed before or during steroid therapies. We compared the effects of two regimens for CR.

Methods: This is a retrospective cohort study of 169 patients newly diagnosed with IgAN during January 2007 to December 2013 in our institute. We enrolled 90 patients we could follow on oPSL cessation and compared short- and long-term CR rates in both groups.

CR was defined as urine protein <0.3 g/24h and urinary red blood cells <5/high-power field.

Results: Before treatments, there were no significant clinical [TSP-C (n = 57) vs. TPS-I (n = 33); age: 31.0 ± 11.2 vs. 34.0 ± 11.9 years; male/female: 17.0-40.2 vs. 12.21; eGFR, 82.2 ± 29.9 vs. 77.4 ± 28.7 ml/min; blood pressure, 121 ± 77.2 ± 12 vs. 120 ± 17/76 ± 13 mmHg; urinary protein, 0.41 (0.18, 1.19) vs. 0.79 (0.20, 1.08) g/24h; and positive occult blood, 91.2 vs. 90.9%] and histological grade stratification differences between the groups. At oPSL cessation, short-term CR rates were equivalent between the groups [TSP-C vs. TPS-I: 68.4 vs. 61.0%]. Long-term CR rates at 1, 2, and 3 years after oPSL cessation were equivalent between the groups [TSP-C vs. TPS-I: 61.4 (n = 39) vs. 59.1% (n = 22); 2 years, 64.0 (0.25) vs. 80.0% (n = 10); 3 years, 73.7 (0.19) vs. 66.7% (n = 6)]. CR continuation rates by Kaplan–Meier method also revealed no significant differences between the groups.

Conclusions: Tx plus either consecutive or intermittent steroid pulse therapies may be equally beneficial for short- and long-term IgAN CR. IgAN patients can flexibly choose therapies.

PUB217

Clinical Characteristics of Multiple Myeloma Patients Diagnosed by Nephrologist Byonggeun Hae, Jae seok Kim, Hyeon-cheol Park, Shinhan Song, Jae Won Yang, Seung-Ok Choi. Internal Medicine, Yonsei Wonju College of Medicine, Wonju, Korea.

Background: Early diagnosis of multiple myeloma (MM) that is in early phase or has atypical presentation may be difficult. Even though MM is a hematologic malignancy, clinicians in different departments can make a diagnosis with a suspicious eye. In our department, we routinely performed protein electrophoresis in the patients with renal failure for the early diagnosis of MM.

Methods: We reviewed the medical records of 151 patients and examined the data of 117 patients diagnosed with MM in our hospital between January, 2003 and December, 2014. The patients were divided into three groups: group I presented to nephrologist prior to diagnosis (n=31), group II presented to hemato-oncologist directly (n=53), and group III presented to the other departments of our institute. The age, sex, initial symptoms, hematologic and biochemical parameters, and survival data were retrospectively analyzed.

Results: The main findings were anemia (n=30), renal failure (n=25), back pain (n=17), paraproteinemia (n=10), rib pain (n=7), mass (n=7), proteinuria (n=7), fracture (n=5), infection (n=4), bleeding (n=3), etc. Osteolytic bone lesion, survival rate, % of plasma cell in bone marrow study, HB, platelet, CRP, serum albumin and calcium were not significantly different between three groups. 24 hours urine study (amount of proteinuria, protein-albumin ratio, protein-creatinine ratio) did not show any differences. Beta-2 microglobulin and serum uric acid were significantly higher in group I than those in the other groups (p<0.05). Immunoglobulin G, total protein, globulin, and amount of serum M protein were significantly lower in group I than those in the other groups (p<0.05). Distribution of BJ protein positive patients in group I was higher (p<0.05). ISS score was also higher in group I (p<0.05).

Conclusions: Multiple myeloma patients diagnosed by nephrologist did not show typical features of disease. Low levels of total protein and globulin in the patients with renal failure could be a cause of delayed diagnosis of MM. We recommend the protein electrophoresis should be routinely performed in the patients with renal failure.

PUB218

Screening for Renal Involvement in Newly Diagnosed ANCA-Associated Vasculitis Patients in Clinical Practice – Differences Between Hospital Departments Eline Houben,1 Willem A. Bax,1 Bastiaan Van Dam,1 Valentijn A. Slieker,2 Gideon Verhave,1 Fenneke C.P. Frerichs,1 Erik Lars Penne.1 1Dept of Nephrology, MCA-Gemini Group, Alkmaar, Netherlands; 2Laboratory of Clinical Chemistry, Hematology and Immunology, MCA-Gemini Group, Alkmaar; Netherlands.

Background: Kidney involvement occurs in a majority of ANCA-associated vasculitis (AAV) patients and requires early and aggressive immunosuppressive therapy. The aim of the present study was to evaluate screening procedures for renal involvement in newly diagnosed AAV patients and to identify differences between hospital departments.

Methods: All AAV patients with a positive ANCA (PR3 and/or MPO) between 2005 and 2015 in a secondary care hospital in the Netherlands were included. Patient demographic data and the department making the diagnosis were recorded, as well as whether or not a complete screening for renal involvement had been made. The latter was defined as assessment of serum creatinine, analysis for erythrocytosis and proteinuria within two weeks before or after the diagnosis AAV.

Results: We included 110 newly diagnosed AAV patients (age 62±14 years [mean±SD]; 63% male). 91 patients (86%) had renal involvement (defined as: rise in creatinine >30%, >10 RBC/hpf and/or proteinuria >500mg/24h). Complete screening was performed in 90 patients (82%), depending on department: Nephrology 100% (21 of 21), Internal Medicine 88% (29 of 33), Pulmonology 68% (15 of 22), Ear Nose Throat 62% (8 of 13), other departments 81% (17 of 21). Of the 20 patients with incomplete screening, assessment of proteinuria was missing in 100% (20 of 20), erythrocytosis in 55% (11 of 20) and serum creatinine in 5% (1 of 20). Serum creatinine was higher in patients with complete renal screening (vs. 72% vs. 70% μmol/l, p=0.01). Screening was completed within 2 months (n=12), 4 years (n=3), or never (n=5). One patient was found to have erythrocytosis 6 weeks after the diagnosis, but had not been treated accordingly.

Conclusions: In a substantial amount of newly diagnosed AAV patients, screening for renal involvement was incomplete, especially in patients with a normal creatinine level outside the renal department. Incomplete screening may have led to suboptimal treatment in some patients.
Efficacy of Rituximab in Severe Lupus Nephritis in Children: A Case Series

Background: The association of cyclophosphamide or Mycophenolate Mofetil (MMF) with prednisolone is the treatment of reference of lupus nephritis (LN), both in adults and children but is associated with major side effects. Rituximab (RTX) failed to demonstrate any advantage compared to prednisolone in early stage LN. Very few studies have reported on the prognosis of anti-neutrophil cytoplasmic antibody (ANCA) negative pauci-immune necrotizing crescentic glomerulonephritis (piNCGN) which is caused by the overproduction of an aberrant form of IgA1 and the association of cyclophosphamide or MMF without a renal function impairment (estimated glomerular filtration rate (eGFR) ≥ 60 ml/min/1.73m²) followed treatment by RTX for a first flair of LN class III to V was studied.

Methods: We retrospectively reviewed 113 consecutive patients with newly diagnosed LN in the Pusan National University Hospital from January 2010 to December 2013. cFLCs was defined as a sum of kappa and lambda FLCs and clinical and laboratory data were collected by medical records reviewing.

Results: The mean (SD) age were 41.4 (±14.9) years and the median (inter-quartile range) of cFLC and urinary protein-to-creatinine ratio (uPCR) were 40.5 (32.6 – 47.8) mg/L and 666.3 (364.8 – 1306), respectively. In correlation analyses, log-transformed cFLCs was positively related to age, serum creatinin C, IgG and log-transformed uPCR, and negatively associated with serum albumin and hemoglobin levels. In multivariate regression models, increased cFLCs was significantly associated with higher log-transformed uPCR (β=0.0124, 95% CI) 0.0124-0.0144, p=0.055) adjusting confounding factors. However, no significant association of cFLCs with pathologic classification was observed.

Conclusions: The cFLC level was independently correlated with the magnitude of proteinuria in patients with IgA nephropathy. Further longitudinal studies are needed to clarify the role of cFLC as a prognostic marker in IgA nephropathy.

PUB223

Long Term Renal Outcomes in Lupus Nephritis in a Multi-Racial Asian Population: A Retrospective Study

Background: Lupus nephritis causes significant morbidity with racial predilection affecting prognosis and treatment responses. We aimed to evaluate risk factors for progressive CKD in lupus nephritis (LN) in a multi-racial Southeast Asian population.

Methods: We retrospectively reviewed 113 consecutive patients with newly diagnosed biopsy-proven LN diagnosed between 10 May 2001 to 30 May 2009. Demographics, indices of renal function and disease activity, histopathological data and pharmacotherapy were evaluated. Primary endpoint was progressive chronic kidney disease (CKD) defined by doubling of serum creatinine or end stage renal failure.

Results: Median age was 41.6 (IQR 29.2, 51.6) years, predominantly Chinese (76.1%) and female (81.4%). Twelve patients (10.6%) had Class I or II LN, 13 (11.5%) Class III LN, 62 (54.9%) Class IV LN and 25 (22.1%) isolated Class V LN. Eight patients (7.1%) had mixed proliferative and membranous LN. Most patients received either angiotensin converting enzyme (ACE) inhibitors or angiotensin II receptor blocker (100 patients, 88.5%). Induction immunosuppressants included glucocorticosteroids in 109 patients (96.5%), cyclophosphamide 26 (23.0%), mycophenolate mofetil or mycophenolate sodium 91 (84.5%), cyclosporine 9 (8.0%), and azathioprine 14 (12.4%). Median follow up was 79.0 (61.5, 104.0) months. One hundred and eight patients (95.6%) achieved remission, with complete remission in 89 patients. Among patients who achieved remission, 61 patients had disease relapse. Thirteen patients had progressive CKD at last clinic visit, with ESKD occurring in 5 patients at median 12.0 (1.0, 59.5) months from biopsy. Patients with progressive CKD tended to be non-Chinese (53.8% vs. 20.0%, p=0.01), with higher serum complements [median C3 0.66 (IQR 0.48, 0.87) vs. 0.38 (0.29, 0.60), p=0.04 and C4 0.17 (0.12, 0.22) vs. 0.06 (0.05, 0.12), p=0.004] fewer remissions (69.2% vs. 99.0%, p=0.01) and more relapses (100% vs. 52.5%, p=0.005).

Conclusions: In this multi-racial Asian cohort, race, higher serum complement levels, failure to achieve remission and relapses were associated with poor renal outcomes in lupus nephrits.
The Clinical Predictors for Outcome of Antineutrophil Cytoplasmic Autoantibody-Associated Vasculitis Patients with Renal Involvement

Pu Le, Guisien Li, Li Wang. Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.

Background: Primary anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is chronic multisystem autoimmune disease and result in dysfunctions of multi-system. Renal involvement is the most common manifestation and is closely associated with the outcome of patients with vasculitis. We investigated the clinical determinants of the early mortality of patients with vasculitis-related renal injury followed up 2 years in a single west Chinese center to study the factors associated with patient outcome.

Methods: A total of 123 consecutive patients with AAV-related renal injury diagnosed in our center were enrolled and laboratory data were collected retrospectively. All the patients were followed up for 2 years after diagnosis. The predictive values of variables associated with mortality were analyzed.

Results: During 2 years follow up duration, 54 (43.9%) died, of whom 41 died within the first year after diagnosis. Compared with surviving patients, the deceased patients had higher BVAS scores and higher incidence of pulmonary hemorrhage. They also had higher serum creatinine and ESR, lower hemoglobin and complement C3, more patients accepting renal replacement therapy than surviving patients during hospitalization. Higher BVAS scores and serum creatinine (>400 umol/L) were the predictors of death in patients with AAV-related renal injury independently.

Conclusions: The incidence of early mortality in patients with AAV-related renal injury was higher. Prudent monitoring and therapy should be given to patients with active vasculitis and serious renal dysfunction to reduce adverse events.

Significance of Resistive Index in Renal Arterial Ultrasonography as a Clinical Parameter for Tubulo-Interstitial Nephropathy

Kazuki Takayamagai,1,2 Taisuke Shimizu,1 Hiroaki Haru,1 Nobuyuki Onizawa,1 Koki Ogawa,1 Yuka Tanaka,1 Kunihiko Yasuda,1 Tomonari Ogawa,1 Akihiko Matsuda,1 Hajime Hasegawa.1 1Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Saitama, Japan; 2Ishikawa Kinenkai Kawagoe Ekimae Clinic, Kawagoe, Saitama, Japan.

Background: Renal arterial ultrasonography (RA-US) has been principally applied to evaluate the stenosis of the renal artery and the indication of catheter intervention by the measurement of peak systolic velocity (PSV). Resistive index (RI) is calculated as (PSV - EDV)/PSV, where EDV indicates end-diastolic velocity, and is reported to be related to the renal function. In this study, we aimed to investigate the possible clinical benefit of RI for the assessment of tubulo-interstitial nephropathy (TIN).

Methods: We studied 51 patients (51.6±2.3 years old) who underwent RA-US and were diagnosed with a renal biopsy of TIN. The patients were divided into two groups, a primary group (n = 25) and a TIN group (n = 26) according to the presence of TIN. The correlations of RI with urinary NAG excretion ratio and renal function were analyzed in each group.

Results: Stratified analysis by median value of RI (0.69) showed significant difference in eGFR in the RA-measurement (43.4±4.7 vs 60.3±4.2), but not in the IAR-measurement. However, in the TIN group, a higher RI was associated with a lower eGFR (43.4±11.6 vs 58.4±4.2, p = 0.02). In the TIN group, a higher RI was associated with a lower eGFR (43.4±11.6 vs 58.4±4.2, p = 0.02). RI was positively correlated with urinary NAG excretion ratio (R = 0.50, p < 0.05) and eGFR (R = 0.50, p < 0.05). In the primary group, RI was not correlated with urinary NAG excretion ratio and eGFR.

Conclusions: In addition to the previous report showing the correlation of RI to the histological severity, the present study demonstrated the correlation of RI with the conventional parameter of TIN, NAG index. Particularly, for the assessment of TIN, RI value measured at intra-renal artery would be more beneficial.

Recovery of Renal Function with Eculizumab in a Girl with Dense Deposit Disease and Normal Soluble C5b-9 Levels

Hajime Hasegawa,1 Yuka Tanaka,1 Kunihiko Yasuda,1 Tomonari Ogawa,1 Akihiko Matsuda,1 Hajime Hasegawa.1 1Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Saitama, Japan; 2Ishikawa Kinenkai Kawagoe Ekimae Clinic, Kawagoe, Saitama, Japan.

Background: Dense Deposit Disease (DDD) is a rare glomerulopathy characterized by electron-dense deposits in the glomerular basement membrane (GBM) and glomerular complement deposition. 50% of patients progress to ESRD and have recurrences after kidney transplantation. Dysregulation of the alternative complement pathway plays a key role in the pathogenesis. Increased soluble C5b-9 in blood is considered to predict response by electron-dense deposits in the GBM. Glomerular C3 and C5b-9 immunofluorescence staining was positive. Despite escalating therapy, including methylprednisolone pulses followed by oral prednisolone, cyclophosphamide and plasma exchange (PE), the renal function further deteriorated and hemodialysis was started. Eculizumab was administered. This led to a rapid improvement of renal function (discontinuation of dialysis and increase of endogenous creatinine clearance from 11 to 53 ml/min/1.73m²). Three months later the girl is in a good clinical condition but proteinuria is still in the nephrotic range (3.6 gr/24 hours). Treatment with eculizumab is ongoing. Up to now no side effects have been observed.

Conclusions: Response to eculizumab in DDD cannot be predicted merely on the basis of levels of sC5b-9 in blood.
Conclusions: Manifestations of IgAN vary widely. The mainstay of therapy consists of supportive measures, which the majority of our cohort received. Immunosuppressive regimens are reserved for a select group, and in our cohort both mycophenolate and steroid based regimens yielded a reduction in proteinuria.

PUB228

Effect of Rituximab on Immunoglobulin Levels and Infection Risk in ANCA Associated Vasculitis
Shivani Shah,1 M-Hafizur Rahman,2 Duvuru Geetha.1
1Div of Nephrology, Dept of Medicine, Johns Hopkins Hospital, Baltimore, MD; 2Bloomberg School of Public Health, Johns Hopkins Univ, Baltimore, MD.

Background: Rituximab (RTX), a B cell depleting anti-CD20 monoclonal antibody, is approved for treatment of ANCA associated vasculitis (AAV). Low immunoglobulin (Ig) levels are a consequence of RTX treatment. The association between the degree of Ig deficiency and infection risk is unclear in AAV patients.

Methods: AAV patients treated with RTX in a single center with available serum Ig measurements were included. The rates and types of infection after RTX administration were correlated with Ig level using correlation matrix and logistic regression analysis.

Results: Our cohort of 27 patients had a median age of 68 years, eight males, 15 GPA patients, and 17 with a new diagnosis of AAV. Twenty five received four doses of RTX 375 mg/m2 weekly and two received RTX 1000 mg biweekly for two doses. Nine received concomitant cyclophosphamide. Twenty three patients had low serum IgG levels (<751 mg/dL) greater than one month following RTX treatment. Ten out of these 23 developed infections over the median follow up time of 338 days. Pneumonia was the most common infection. The odds of having an infection with IgG level ≤500 mg/dL is 3 times higher than with IgG level between 501-750 mg/dL, though p= 0.26. There is a significant association between infection and IgM level £20 mg/dL (p = 0.047).

Conclusions: Severely low Ig levels due to RTX therapy may increase the risk of infection in AAV patients, and these patients may benefit from IVIG therapy. Further investigation is warranted given our study is limited by small sample size, concomitant cyclophosphamide use, and variable timing of Ig measurement.

PUB229

Monocyte Subpopulations of Patients with Different Forms of Glomerulonephritis Exhibit Distinct Changes of Toll Like Receptor Expression
Leon B. Schubert,1 Florian Gunnar Scurt,1 Noemi Rose emma Doll,1 Marius Früh,1 Tobias Hölscher,2 Andreas Jeron,2 Dunja Bruder,2 Peter R. Mertens,1 Christos D. Chatzikyrkou.1 1Nephrology, Hypertension, Diabetes and Endocrinology, Otto-von-Guericke Univ Magdeburg; 2Inst of Microbiology, Otto von Guericke Univ Magdeburg.

Background: We are still in need for more reliable markers to monitor disease activity in primary glomerulonephritis.

Methods: In patients with active primary glomerulonephritis monocyte subpopulations were first differentiated by flow cytometry with the use of surface markers CD 14, CD 16 CCR2 and CxCR3. The expression of different proteins reflecting antigen presentation or activation status as well as scavenger receptor and toll like receptor functions was then quantified. Blood samples of healthy individuals were used as controls. Preliminary results regarding toll like receptors 2, 4 and 5 in a patient with treatment naïve MPO positive vasculitis, a patient with treatment naïve membranous glomerulonephritis and a control are presented here.

Results: The expression of the toll like receptors 2, 4 and 5 was lower in patients with primary glomerulonephritis compared to the controls.

This was the case in all monocyte subpopulations: classical (CD14++CD16-CCR2highCXCR1-), non-classical (CD14++CD16+CXCR2highCXCR1-) and intermediate type 2 (CD14+CD16+CCR2lowCXCR1high).

Conclusions: Toll like receptors seem to be down regulated in monocytes of patients with primary untreated glomerulonephritis during the active phase. The pathophysiological significance of these findings is unclear and remains to be elucidated.

PUB230

Lipoprotein Glomerulopathy
Hostensia M. Beng, Basema I. Dibas, Hsiiao Ling Lai, Guillermo Hidalgo. Pediatrics, ECU, Greenville, NC.

Background: Lipoprotein glomerulopathy has been associated with mutations in the Apolipoprotein E (APOE) gene. The average age of reported cases is 32 years and the youngest patient described to date is 4 yrs old. Here we present the first case of a 3 years old AA male with right hemihypertrophy, malignant hypertension, severe proteinuria & lipoprotein glomerulopathy, with a heterozygous mutation on APO E2 gene.

Methods: 3 year old African American male presented to pediatrician complaining of hemihypertrophy, short stature, polydipsia &hypertension. Physical examination remarkable for right leg soft tissue hemi hypertrophy. Echocardiogram revealed left ventricular hypertrophy likely secondary to chronic hypertension. Hypertension and proteinuria persisted despite adequate treatment. Renal US showed persistent echogenic kidneys. Kidney biopsy showed Lipid vacuolization of podocytes, endothelial cells, tubular epithelial cells, and glomerular capillary lumens. Labs & imaging studies AFP and abdominal US have been normal with exception of proteinuria and increased lipid profile. Patient currently on a trial treatment with fibric acid and dietary modification.

Results: eGFR is stable at 60 ml/min/1.73 m2, proteinuria has improved from a ratio of 2.1 to 0.8 mg/mg and lipid profile has significantly improved.

Conclusions: APOE is an important LDL in transporting cholesterol to the liver for processing. Four main alleles of the APOE gene located on chromosome 19 have been described and different alleles have been associated with various medical conditions. Mutations of the near the LDL bind domain of the APOE gene coexist and may be associated with certain kidney diseases. Renal biopsy shows lipid deposits and thrombosis which results in glomerular damage and glomerular sclerosis. No effective preventative or curative treatments have been identified for apolipoprotein glomerulopathy. In our patient a trial of fibrates to lower cholesterol, Gemfibrozil and effective management of hypertension has resulted in some improvement but it is uncertain if these medication can effectively lower lipid and prevent long term progression of kidney disease. More research to find more effective treatment and management strategies of this disease in children.
Methods: This was a case-control study. Plasma samples from 10 patients with NL class-II, 10 patients with NL class-III, and 30 patients with NL class-IV were analyzed. As a control plasma from 30 SLE patients without nephritis were used. Plasma samples were analyzed using the LumineX technology of 38 analytes (EGF, Eotaxin, G-CSF, Fractalkine, G-CSF, GM-CSF, GRO, IFN-α, IFN-γ, IL-10, IL-12 (p40), IL-12 (p70), IL-13, IL-15, IL-17a, IL-17b, IL-17c, IL-18, IL-22, IL-23, IL-24, IL-6, IL-7, IL-9, IFN-α, IFN-γ, TNF-α, TNF-β, VEGF, sCD40L, RIL-2Ra) using MILLIPLEX®-MAP Human Cytokine/Chemokine-Magnetc- Bead-Panel-Premixed 39 Plex.

Results: Significant differences (p < 0.05) was between concentrations of cytokines EGF, G-CSF, GM-CSF, GRO, IFN, IL-4, IL-5, IL-7, IL-8, IL-9, IFN-α, IFN-γ, TNF-α, TNF-β, VEGF, sCD40L, RIL-2Ra, TNFα, TNFβ, Eotaxin, G-CSF, and EGF. Differences were observed in the levels of these cytokines between patients with LN or SLE.

Conclusions: These preliminary data suggest that there are differences in the LN plasma patients level of some chemokines and proinflammatory cytokines. Results support the hypothesis that circulating levels in plasma samples of these molecules may be considered.

PUB234
Clinical Outcomes of IgA Nephropathy with Necrotizing and Crescentic Lesions in Inner City Hospital

Background: IgA nephropathy is the most common cause of glomerular disease worldwide. Segmental necrosis and crescents are seen only in small subset of patients and literature regarding their clinical outcomes is sparse.

Methods: Retrospective analysis of cases with primary IgA nephropathy from Stroger Renal biopsy database from January 2005 to May 2015 was performed. Demographic and clinical information was obtained from medical charts. Study was approved by IRB.

Results: Of 66 cases of IgA nephropathy, 10 (15%) had lesions with segmental necrosis and/or crescents. These patients responded well to cyclophosphamide based therapy with improvement in creatinine and proteinuria after a mean follow up of 4.6 years. However, patients without vasculitic lesions had a progressive decline in renal function despite immunosuppressive therapy. This group had longer follow up period (mean 7.1 yrs) and 21% required dialysis.

PUB233
Plasma Cytokines and Chemokines Profile in Patients with Systemic Lupus Erythematosus: Its Potential Use as Biomarkers of Kidney Damage

Guadalupe Arocena Martínez, 1,2 Lisandro Pacheco,1 Elkin Navarro Navarro,1 Yirys Díaz,1 Henry J. Gonzalez torres,1 Gloria Garavito,1 Eduardo Egea bermejo,3 Eduardo I. Navarro,1 Lisseth Almendrala,1 Antonio De Jesus Iglesias-Gamarra.1 1Medicine, Univ Simón Bolivar, Barraquilla, Atlántico, Colombia; 2Nephrology Clínica de la Costa, Barranquilla, Atlántico, Colombia; 3Medicine, Univ del Norte, Barranquilla, Atlántico, Colombia; 4Medicine, Univ Nacional de Colombia, Bogotá DC, Cundinamarca, Colombia.

Background: Systemic lupus erythematosus is an autoimmune disease in which the innate and adaptive response plays a significant role, mainly mediated by cytokines. Lupus nephritis-LN-is the most severe complication associated with SLE. Objective: To identify differential expression of cytokines profiles and circulating chemokines in plasma of SLE patients with different degrees of Caribbean region.

PUB232
A Case Study Comparing Cyclophosphamide plus Methylprednisolone versus Cyclophosphamide Alone in Idiopathic Membranous Nephropathy

Basel Jaafar Alhayki, Dept of Nephrology and Renal Transplant, Salamania Medical Complex, Manama, Bahrain.

Background: In the treatment of high risk idiopathic membranous nephropathy the modified Ponticelli protocol with the use of alternative month Cyclophosphamide and steroids is the most used treatment protocol. The scientific bases for the use of intermittent alternating month Cyclophosphamide and Methylprednisolone versus Cyclophosphamide alone in the treatment protocol is not well established and in many studies showed that steroid alone has limited role in the treatment of idiopathic membranous nephropathy. Weather this intermittent use of Cyclophosphamide and Methylprednisolone lead to a fluctuating response to therapy and prolong the recovery or not need to be investigated.

Methods: This is a case study of a 26 years old male with idiopathic membranous nephropathy and a positive AntiPLA2R antibody who needed to be started on Modified Ponticelli protocol with the use of alternative month Cyclophosphamide and Methylprednisolone. The patient was given the six month the modified Ponticelli protocol but he failed to reach a complete or a partial remission with persistent Proteinuria of more than 16 gram per day and who failed cyclosporine in the past.

Results: We observed a sustained decline in proteinuria and a preservation of renal function in most of patients; Treatment was well tolerated and flares up were in a high number of patients.

Conclusions: We observed a sustained decline in proteinuria and a preservation of renal function in most of patients; Treatment was well tolerated and flares up were in a high number of patients.

Acute Tubulo-Interstitial Nephritis (ATIN): Predicting Long Term Outcomes

Background: ATIN is a relatively common potentially reversible cause of acute kidney injury. It has become clear over the last 2 decades that the disease is not always reversible, particularly in the elderly. We present a large contemporary single centre retrospective series concentrating on factors that predict poor outcomes.

Methods: 62 cases retrospectively diagnosed histologically via pathology records as primarily ATIN were included. An experienced histopathologist, blinded to outcomes, graded biopsies according to the presence, absence and degree of 8 different parameters: Interstitial inflammation, tubular atrophy, eosinophilia, plasma cell infiltration, chronic vascular lesions, hyalination, granulomas + oedema. Patients were classified as a poor outcome if eGFR (4 variable MDRD) after 12 months was less than 30 ml/min/1.73m^2 or they died.

Results: 62 patients with biopsy proven ATIN were identified. 15 had a poor outcome. Baseline demographics are presented in Table 1.

Aetiology was difficult to definitely ascertain but consisted of drug induced, infectious, sarcoid or sjogrens. Parameters significantly associated with poor outcomes include higher creatinine at presentation & 6 months, presence of granulomas and chronic vascular lesions on biopsy at diagnosis. The effect of steroid treatment was difficult to assess as since most patients were treated at the outset.

Conclusions: ATIN usually carries a good prognosis but some patients experience poor outcomes. Poor renal function at diagnosis and the presence of granulomas and chronic vascular lesions are predictive of poorer outcomes.

Cotreatment of Olmesartan and Caterpillar Fungus Attenuate Albuminuria in Patients with Glomerulonephritis

Hua Zhou, Ye Zhang, Ya Li, Hairong Tang, Congqing Jiao, Lining Wang.

Nephrology Dept, 1st Hospital of China, Government Support.

Background: Angiotensin II receptor blockers (ARBs) were demonstrated to reduce proteinuria since a decade ago. However, proteinuria still remains as the top of clinical symptoms in glomerulonephritis (GN). We aim to investigate the effect of cotreatment with olmesartan (Olms) and other ARBs defined as non Olms ARBs, and CR + other ARBs, and CR + Olms on reference biopsy and the amount of tubular atrophy and interstitial scarring on RB (r=0.349, p=0.19; r=0.385, p=0.009). Chronicity indices (CI) also progressed by the time of RBs. Patients with proliferative histopathology on initial biopsy had higher CI at both the reference biopsy (p=0.047) and RBs (p=0.019). Treatment decisions did not seem to be influenced by the progression of CI (p=0.982).

Results: Of the 209 patients, 160 (76.5%) were MPO-positive, 28 (13.3%) were PR3 positive and 21 (10%) were ANCA negative. Regarding the onset of symptoms, we have found a greater number of cases in the months of January, February and March, compared with the rest of the year. This data correlates positively with the higher incidence of AA V diagnosed in the city of Barcelona.

Methods: Our study included 209 AA V patients diagnosed between 2001 and 2013 in 5 different University Hospitals of Barcelona. We analyzed their medical records, including the date of diagnosis and the approximate date of the first symptoms in 194 patients. We have also analyzed data related to ANCA subtypes in each patient.

Results: The cotreatment with Olms and wild fungus showed a progression in both tubular atrophy (p=0.001) and interstitial scarring (p=0.001) but not in inflammatory cell infiltration by the time of RB. The mean total tubulointerstitial score (±SD) has progressed from 2.69 ± 2.03 to 3.78 ± 2.03 (p=0.001). There was a positive correlation between serum creatinine and the severity of tubular atrophy at time of both reference biopsy (r=0.33, p=0.048) and RB (r=0.56, p=0.01). Serum creatinine at time of RB showed a strong correlation with interstitial scarring (r=0.60, p=0.001). A trend was identified between the severity of interstitial inflammation on reference biopsy and the amount of tubular atrophy and interstitial scarring on RB (r=0.349, p=0.19; r=0.385, p=0.009). Chronicity indices (CI) also progressed by the time of RBs. Patients with proliferative histopathology on initial biopsy had higher CI at both the reference biopsy (p=0.047) and RBs (p=0.019). Treatment decisions did not seem to be influenced by the progression of CI (p=0.982).
Considering the date of diagnosis we found a greater number of cases in two periods of the year; the months of May, June and July, and the months of October, November and December.

**Conclusions:** In our population, predominantly ANCA-MPO-positive related vasculitis, we found a higher incidence of the disease in the winter months, being diagnosed more frequently in May, June and July or October, November and December. One potential environmental factor, influenza disease, may explain this finding.

**Myophenolate Mofetil for the Treatment of Idiopathic Nephrotic Syndrome: A Meta-Analysis of Randomized Controlled Trials**

**Bin Zhu, Yongjun Wang, Nephrology, Hangzhou Hospital of Traditional Chinese Medicine, (Guangying Hospital) Affiliated to Zhejiang Chinese Medical Univ, Hangzhou, Zhejiang, China.

**Background:** This meta-analysis was performed to investigate the efficacy and safety of myophenolate mofetil (MMF) in treating idiopathic nephrotic syndrome.

**Methods:** We searched MEDLINE, EMBASE, the Cochrane Library database, the Database for Chinese Technical Periodicals, Wanfang, Chinese National Knowledge Infrastructure and the Chinese Database of Biology and Medicine for randomized controlled trials compared MMF with the other immunosuppressive agents for the treatment of idiopathic nephrotic syndrome. Weighted mean difference (WMD) and summary estimates of relative risk (RR) reductions with 95% CIs were calculated.

**Results:** We identified 36 trials that included 2087 patients, mainly on membranous nephropathy (MN), focal segmental glomerulosclerosis (FSGS) and refractory nephrotic syndrome without clearly pathological diagnosis (RNS). Overall, MMF therapy significantly reduced proteinuria (WMD = 462.31 mg/d, CI: -219.69 to -704.92, P < 0.001) compared with the other immunosuppressors. The subgroup analyses showed that MMF was superior to ciclosporin in the RNS patients in reducing proteinuria, serum creatinine, relapse, and increasing the remission rate. In the MN patients, MMF therapy was better than ciclosporin in reducing proteinuria, increasing remission rate, whereas it was poorer than chlorambucil in lowering proteinuria. MMF therapy also significantly decreased proteinuria in FSGS compared with ciclosporin. MMF was safer than most of the other agents, particularly than ciclosporin.

**Conclusions:** MMF seems superior to the other immunosuppressive regimens for the treatment of idiopathic nephrotic syndrome with mild adverse effects, particularly in MN, FSGS and RNS. High-quality large-sample trials are still required to reliably define the balance of efficacy and safety.

**PUB240**

**A Retrospective Analysis of Acute Kidney Injury in Adult-Onset Minimal Change Disease**

**Yosuke Nakagawa, Takuya Isegawa, Masahiro Koizumi, Masafumi Fukagawa. Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.

**Background:** Minimal change disease (MCD) is a major cause of primary nephrotic syndrome in adults, accounting for 10 to 25 percent of cases. In terms of treatment, steroid therapy is very effective, however in some cases an acute onset of moderate to severe decline in kidney function is seen, occasionally requiring transient dialysis. To the best of our knowledge, the risk factor for acute kidney injury (AKI) and clinical course of cases with AKI had not been fully elucidated.

**Methods:** This study is a single-center, retrospective observational study. The clinical records of adult (older than 18 years old) who had biopsy-proven MCD and were followed at Tokai University Hospital from 2000 to 2015 were retrospectively reviewed. The diagnosis of AKI was based on KDIGO criteria, namely, serum creatinine changes ≥ 1.5 times baseline within 7 days and a 0.3 mg/dl increase in serum creatinine within 48 hours.

**Results:** 57 patients were enrolled, and AKI occurred in 24 patients at presentation or subsequently, among whom five patients underwent hemodialysis. Patients with AKI showed lower level of serum albumin and higher rates of use of diuretics, renin-aldosterone system (RAS) inhibitors, and NSAIDs. Logistic-regression analysis showed that use of these drugs before presentation at our institution could predict the development of AKI (odds ratio, 2.8, 95% CI, 2.2 to 3.2). Furthermore, use of these drugs could determine the time to remission (Hazard ratio, 2.4, 95% CI, 1.8 to 3.0), as well as the initial serum creatinine. All cases were initially treated with steroid, and there was no difference in the time to remission between oral and parenteral administration of steroid.

**Conclusions:** There is a high incidence of AKI in adult-onset MCD. The use of several drugs such as diuretics could influence the onset of AKI and clinical course of MCD.

**PUB241**

**Expression of HLA-G Molecule in Crescentic Glomerulonephritis and Its Clinical Significance**

**Gusien Li, Li Wang. Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chengdu, Sichuan, China.

**Background:** In recent years, human leukocyte antigen-G (HLA-G) was found to be an important immune-regulatory molecule. Our purpose of this study is to assay the concentrations of serum soluble HLA-G in patients with CGN and to analyze its clinical significance.

**Methods:** 48 patients with CGN from 2009 to 2014 were involved in this study. The clinical data were collected, including demographic characteristics, laboratory parameters, pathological examinations, and immunosuppressive therapy. Analyze if oliguria or anuria, serum creatinine levels, the crescent formation ratio and therapy would affect the prognosis of patients. 22 patients with CGN, 15 patients with MCD, and 30 healthy adults in control group were enrolled with serum levels of HLA-G measured by ELISA. The relationship between the clinical or pathological features and sHLA-G was studied and the value of the HLA-G in crescentic glomerulonephritis was analyzed.

**Results:** 3-years kidney survival rate was only 38% with one case of death. Cox regression analysis showed higher serum creatinine was associated with the patients with a poor prognosis (HR = 4.04, 95% CI: 1.54-10.54, P = 0.004). Serum level of HLA-G in CGN was significantly higher than in healthy controls (2198.81 ± 1924.17 (mg/ml vs. 1311.86 ± 448.84 (mg/ml, P = 0.048), while higher than in MCD, (2198.81 ± 1924.17 (mg/ml vs. 1181.33 ± 320.10 (mg/ml, P = 0.023). Kaplan Meier survival analysis showed elevated levels of HLA-G was associated with poorer patients.

**Conclusions:** High serum creatinine level (>5mg/dl) at admission is an independent risk factor for the development to be ESRD. sHLA-G was significantly elevated in the serum of patients with CGN, and the level of sHLA-G had relationship with the prognosis of the patients with CGN. sHLA-G may be used as a new biomarker in CGN with clinical value in the early diagnosis and prognosis.

**A Treatment of Nutcracker Syndrome Leads to a Resolution of Unexplained Proteinuria**

**Badamkhand Baatarkhuiu, Raymond Raut, Winston Y. Shih, Panupong Lisawat. Nephrology and Hypertension, WCHN Danbury Hospital, Danbury, CT.

**Background:** The nutcracker syndrome is rare and can be a cause of unexplained proteinuria. We report a case of nutcracker syndrome related proteinuria and resolution of the proteinuria is observed after the entrapment was surgically corrected.

**Methods:** This is a 22-year-old male with a history of unexplained proteinuria since he was 17 years old. He has moved to a new location and presented to our clinic with proteinuria. The patient’s initial work up at an outside hospital revealed 1.4g proteinuria per 24 hours. A left kidney biopsy showed mesangial hypercellularity and preserved foot processes. The patient at that time was treated with prednisone, cyclosporine and lisinopril. His proteinuria decreased to 196 mg per 24 hours. Due to intolerance, lisinopril was stopped time to remission between oral and parenteral administration of steroid.

**Conclusions:** There is a high incidence of AKI in adult-onset MCD. The use of several drugs such as diuretics could influence the onset of AKI and clinical course of MCD.
Parvovirus B19 Immune Complex Glomerulonephritis
Beth Lyonne Braumurt
Erika R. Bracamonte.
Pathology. Univ of Arizona College of Medicine, Tucson, AZ.

Background: A 14 year old girl underwent a cadaveric renal transplant due to end-stage renal disease from obstructive uropathy and developed Parvovirus B19 viremia and graft dysfunction. Renal biopsy showed de novo immune complex glomerulonephritis with parvovirus B19 DNA detected in renal tissue by PCR. We herein review of B19-associated glomerulonephritis.

Methods: A search of the English-language medical literature was conducted. PubMed, Medline, and Google scholar were used. Adult and pediatric cases were included. Sources included case reports and series, including prior reviews. Articles were evaluated for detailed clinical data, clinical findings, laboratory data, and renal biopsy results.

Results: 67 cases were identified. 51 involved native kidneys and 16 transplants. 66 of 67 cases had serologic evidence of B19 infection (98.5%). B19 DNA testing by PCR of various tissues was positive in 82.9% of cases. Biopsy results were reported in 52 cases. Of native cases, 92.5% reported a proliferative glomerulonephritis. All grafts most commonly showed TMA (67.7%). IF showed C3 in 84.5%, IgM in 68.8%, IgA in 62.5% and IgG in 40.6%. IF was negative in all transplant cases, save for our patient who showed IgG, IgM, C1q and C4d. EM results were reported in 24 cases with subendothelial deposits being most common (91.7%).

Conclusions: The findings in B19-associated glomerular disease are different in the native kidney versus transplant setting. In a native kidney, proliferative immune complex glomerulonephritis is most common. In the transplant setting, most cases showed TMA. The pathogenesis of this discrepancy remains unclear. To our knowledge, this is the first report of B19 immune complex glomerulonephritis in a renal transplant patient. Our patient showed findings more commonly seen in native-kidney B19 disease. We believe this discrepancy may be explained by insufficient immunosuppression in our patient, as evidenced by our anecdotal experience. B19 infection in a transplant patient has practical implications. B19 glomerular disease represents a largely reversible form of renal injury. But, adverse outcomes have been reported. Management may require a balancing act with the risk of rejection on one hand and B19 disease on the other.

A Case of ANA-Negative Systemic Lupus Erythematosus
Ankur Shah,1 Rachel Criner,1 Jean Lee.2 Internal Medicine, Temple Univ Hospital, Philadelphia, PA; 2Nephrology, Temple Univ Hospital, Philadelphia, PA.

Background: Systemic Lupus Erythematosus is a chronic autoimmune disorder hallmarked by several autoantibodies targeting intracellular antigens. The most sensitive of these antibodies is the anti-nuclear antibody. Various studies show that this antibody is present in 95-98% of individuals with the disorder. As methodology improves, the incidence of ANA-negative Lupus has been decreasing.

Methods: We report a case of a 53 year old female whose known past medical history included only hypertension who presented to the outpatient clinic with arthralgias, pancytopenia, alopecia, proteinuria and skin rash whose lab point to this included an elevated ESR of 115, negative ANA, negative HIV, Hep B, and Hep C serology. She was then sent to followup until presenting to the hospital with anisocoria and acute kidney injury. Her further workup confirmed a negative ANA but also revealed positive Anti-SSa, and anti-SSB. Her C3 and C4 were decreased at 43 and 66 respectively. She had a renal biopsy performed revealing focal proliferative and membranous nephritis, Class III/V. The patient was started on mycophenolate, plaquenil, and prednisone.

Conclusions: Once a byproduct of a technically variable laboratory test, the entity of ANA-negative Lupus has been decreasing in its frequency. The adoption of the human antinuclear antibody does not rule out the disorder.

Patients with Combined Membranous Nephropathy and Focal Segmental Glomerulosclerosis Have Comparative Clinical and Autoantibody Profiles with Primary Membranous Nephropathy
Qiu-hua Gu, Zhao Cui, Jing Huang, Gang Liu, Minghui Zhao. Renal Div, Peking Univ First Hospital, Inst of Nephrology, Peking Univ, Beijing, China.

Background: Patients with combined membranous nephropathy (MN) and focal segmental glomerulosclerosis (FSGS) have been reported with different clinical significance. Investigation on the possible mechanisms of the combined glomerular lesions is necessary but scarce.

Methods: 20 patients with both MN and FSGS lesions were enrolled, 29 patients with primary MN and 27 patients with primary FSGS were used as disease controls. Clinical data were collected on renal biopsy and during follow-up. Circulating anti- phospholipase A2 receptor (PLA2R) antibody, glomerular PLA2R expression and IgG4 deposition, and soluble PLA2R receptor (sPLA2R) levels were detected.

Results: We found that patients with combined lesions presented with elder age, less proteinuria, higher serum albumin, better renal function on biopsy, more complete remission after treatments and better renal outcome during follow-up. These were comparable to the patients with primary MN, but different from the patients with primary FSGS. Among patients with combined lesions showed higher stages of MN, no cellular variant on FSGS classification and more common (100%) tubulointerstitial injury than both primary MN and primary FSGS patients. In the patients with combined lesions, 80% had circulating anti-PLA2R antibody and 68.4% had IgG4 predominant deposition in glomeruli, which were comparable to primary MN. No circulating antibody or IgG4 deposition was detected in primary FSGS patients. The patients with combined lesions had significantly lower urinary suPAR concentration, compared to the primary FSGS patients (315.6±302.0 vs. 691.3±1223.5pg/ul, 0.001), but similar to primary MN patients (275.7±253.4pg/ul, 0.001).

Conclusions: We conclude that patients with combined MN and FSGS may share the same underlying pathogenesis with primary MN. The FSGS lesion might be secondary to primary MN.

Glomerulosclerosis Is Prevalent but Not Associated with Kidney Function in Healthy Japanese Elderly
Koiti Sato, Tsukasa Nagamuna, Daisuke Ichikawa, Sayuri Shirai, Yugo Shibagaki. Div of Nephrology and Hypertension, St. Marianna Univ, Kawasaki, Kanagawa, Japan.

Background: Previous western studies have shown that global glomerulosclerosis (GS) is common in healthy elderly but is not associated with kidney function. We here conducted a study to determine whether healthy Japanese elderly, whose glomerular filtration rate (GFR) is much lower than that of western counterparts, have also same relationship among kidney function and prevalence of GS.

Methods: We analyzed 81 kidney biopsy specimens from Japanese living donors obtained at donor nephrectomy between 2009 and 2014. Using the 2007 Banff classification system, GS, tubular atrophy (TA), interstitial fibrosis (IF), and arteriosclerosis (AS) on kidney samples were evaluated. Donor characteristics such as age, serum creatinine (sCr), C4-based estimated GFR (eGFR), proteinuria, and the prevalence of hypertension, were also evaluated. GS were expressed as a standard deviation (SD) from the 95th percentile of the normal range (IQR). We performed univariate and multivariate analyses to identify the relationship between the parameters.

Results: Average age was 59.5 ± 9.1 years, male accounted for 38 (46.9%), with sCr 0.68 ± 0.15 mg/dl (eGFR 80.0 ± 10.9 ml/min/1.73m2), proteinuria 125.5 ± 61.0 mg/gcreatinine, and eGFR 28.4 (36.4%). Each kidney sample had the average of 16 glomeruli (IQR: 12 to 23) and 1 GS (IQR: 0 to 2), so the proportion of GS among total glomeruli was 6.25% (IQR: 0 to 14.3). The prevalence of any GS was 65.4%, any TA, 51.9%, IF greater than 5%, 48.1%, and any AS, 91.4%. Statistical analyses revealed that donor age was the only independent factor related to GS, and also to TA, IF, and AS. Among kidney biopsies of our 53 normotensive donors, 9 (17.3%) had more GS than the 95th percentile of the number of GS in western studies.

Conclusions: Although Japanese healthy adults had lower GFR and a higher number of GS than western counterparts, GS was still not associated with kidney function. Pathological significance of GS in otherwise healthy Japanese is not supported as in western counterparts.

Patients with Combined Membranous Nephropathy and Focal Segmental Glomerulosclerosis Have Comparative Clinical and Autoantibody Profiles with Primary Membranous Nephropathy
Qiu-hua Gu, Zhao Cui, Jing Huang, Gang Liu, Minghui Zhao. Renal Div, Peking Univ First Hospital, Inst of Nephrology, Peking Univ, Beijing, China.

Background: Patients with monoclonal gammopathy can accompany various renal lesions related or unrelated to the monoclonal gammopathy. We aim to describe the renal lesions with monoclonal gammopathy in China.

Methods: Data of renal biopsy and clinical presentation of patients with monoclonal gammopathy on serum and/or urine immunofixation electrophoresis in our center from 1999 to 2014 were collected.

Results: 241 patients met the inclusion criteria and were classified as renal disease related to multiple myeloma (MM) (n=18, 7.5%), monoclonal gammopathy of renal significance (MGRS) (n=85, 34.3%) and monoclonal gammopathy of undetermined significance (MUGS) (n=138, 57.4%). Among patients with MGRS, Amyloidosis (n=69, 28.6%) is the most common diagnosis, followed by Light Chain Deposition Disease (LCDD) (n=7, 2.9%), Cryoglobulinemic glomerulonephritis (n=6, 2.5%), and 56 cases (20.2%) with iron and/or iron-related disorders. Among patients with MUGS, a variety of renal lesions were found, including membranous nephropathy (n=48, 20.2%), IgA nephropathy (n=17, 7.0%), interstitial nephritis (n=13, 5.4%), membranous proliferative glomerulonephritis (MPGN) (n=9, 3.3%) and so on.

Conclusions: We analyzed the data of monoclonal gammopathy with renal biopsy in china for the first time. A growing number of renal diseases were found to be associated with monoclonal gammopathy. MUGS is the most common diagnosis of patients with monoclonal gammopathy, while membranous nephropathy and IgAN are most common among MGRS.

Further work are in need to determine whether some MUGS are truly interteminate or with renal significance and whether or not early treatment is in need for these patients.

Urine Microscopy in a Case of Acute Kidney Injury: A Report of an Interesting Case
Azka Arif,1 Ahmad Hassan,2 Muhammad Aaws Arif,2 Hafiz Armaghan Saeed,2 Agha Syed Shabbir Ali,2 Abdul Mateen Nagaria,3 Talal A. Khan.1
1Freeman Health System; 2Rawalpindi Medical College.

Background: RBC casts are usually present in the urine of patients presenting with AKI secondary to RPGN. They are sometimes seen in patients with AIN. A single RBC cast seen in urine is enough to consider glomerulonephritis as underlying pathology. We report a case of biopsy proven Myelogenic AKI with RBC casts.

Methods: 68-year-old male presented with AMS and was found to have AKI with BUN of 106 mg/dl & creatinine of 28.6 mg/dl. He had severe hyperkalaemia. His urine analysis showed 20-30 RBCs and 3+ Blood. His urine microscopy was done which revealed RBC casts, pigmented casts and renal tubular epithelial cells as reviewed by nephrologist on call, based on such acute presentation and positive RBC cast, glomerulonephritis was considered as possible etiology in addition to acute tubular necrosis and rhabdomyolysis. He underwent emergent hemodialysis for severe hyperkalaemia and uremia, he was started on pulse steroids and underwent kidney biopsy. It showed extensive myoglobinuria, proteinuria, ATN, with no evidence of any glomerulonephritis. His ANCA serology, complements levels, Anti GBM antibodies & ANA were negative. He required hemodialysis for few days and then recovered with residual CKD.

Conclusions: RBC casts are important component of rapid and early diagnosis of RPGN. RBC casts in a cast are almost always pathological and marker of acute glomerular injury. Our case represents an unusual finding of RBC casts in myelogenic ATIN. We propose extensive renal glomerular injury secondary to severe rhabdomyolysis as possible etiological factor. Renal tubular epithelial cells are marker for acute tubular necrosis and pigmented casts are usually found in rhabdomyolysis which were seen in urine microscopy in our case. Urine microscopy though less commonly used provides a vital & faster way of diagnosing etiology of AKI and it should be considered in our evaluation of acute kidney injury.

Acute Renal Failure in Thrombotic Microangiopathy and C3 Glomerulopathy?
Tiziana Stellato,1 Paolo Fabbrini,1 Sonia Sirtori,2 Andrea Stella,1,2 Depart of Nephrology, San Gerardo Hospital, Monza, Italy; University of Milano Bicocca, Milan, Italy.

Background: Thrombotic microangiopathy is a rare disease characterized by arteriolar and capillary thrombosis with endothelial damage. Clinical manifestations include renal involvement such as acute renal failure, microangiopathic hemolytic anemia and proteinuria.

Methods: We report a case of a 75 years old man without past medical history that referred to us with oliguric acute renal failure dialysis-dependent. Laboratory work up revealed creatinine of 7.5 mg/dl, prolonged activated partial thromboplastin time (aPTT) in order to 2.2 Ratio, normal PT and INR, with C3 of 60 mg/dl (normal: 80-180 mg/dl) with normal C4 concentration, VES augmented, positive low titer anti-cardiolipine and anti-beta2 glycoprotein I antibodies, positive LAC screening. Urinalysis showed microhaematuria and proteinuria 2.5 g/24 hr, ANA, ANCA antiDNA are negative. A renal biopsy was performed and showed mesangial proliferative glomerulonephritis associated to thrombotic microangiopathy with subendothelial and mesangial C3 deposits. Considering the clinical history, the laboristic tests including serum ANA, anti ds DNA, anti-smith and smooth muscle antibodies, anti cardiolipine IgG and IgM titers, C1Q binding assay were negative. HIV, hepatitis B and C viruses serologies were negative too. C-ANCA (0.7 U) and P-ANCA (1.3 U) were positive. Renal biopsy showed proliferative crescentic and membranous glomerulonephritis with a full house immuno-fluorescence pattern with extra-glomerular tubular basement deposits suggestive of Lupus like glomerulonephritis. Patient required hemodialysis for her renal failure and was treated with oral cyclophamide and corticosteroids. Seven months into treatment, patient still requires twice a week hemodialysis with only minimal recovery of renal function and has not yet experienced any clinical symptoms of SLE.

Conclusions: In conclusion, we present an unusual case of ANCA positive, ANA negative full house nephropathy. ANA negative lupus nephritis is very rare presentation with incidence rate of 1-5%. At this point we are not sure if in the future patient will develop further clinical or serological evidence of SLE and then be diagnosed as “SLE with positive immunological response to ANCA”. ANCA vasculitis is pauci-immune and hence it would be extremely unlikely or rare if it turns out that she has ANCA vasculitis with full house on renal immuno-fluorescence. The treatment and prognosis of renal-limited lupus-like glomerulonephritis remains unclear, although limited data suggest a poor prognosis.

Pathological and Clinical Analysis of the Kidney Puncturetion Biopsy in 1,551 Cases Mei Li,1 Qiong-bin Yin,1 Zheng Zhang,2 Cai-Liang Cheng,3 Xun Liu,1 Cheng-gang Shi,1 VTP Healthcare Center, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou; 2Cardiovascular Dept, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou; 3Nephrology Dept, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China.

Background: To summarize all the renal biopsy cases in the Past ten years in The Third Affiliated Hospital of Sun Yat-sen University;analyze the pathological type distribution,and their relationship with clinical manifestations.

Methods: Pathological and clinical data in 1,551 cases with renal biopsy with complete clinical data were analyzed retrospectively from January 2005 to December 2014.

Results: Among 1,551 cases, 356 (22.6%) showed normal histologic appearances on renal biopsy. Among the remaining 1,195 cases, primary glomerular disease (63.8%), secondary glomerular disease (35.3%) were the three times most common type of renal biopsy. The first third pathological types of primary glomerulonephritis are IgA nephropathy (38.6%), membranous nephropathy (25.9%) and membranous nephropathy (19.3%). The third pathological types of secondary glomerulonephritis are lupus nephritis (65.2%), diabetic nephropathy (DN) (8.5%) and hepatitis B virus associated glomerulonephritis (HBV- related GN) (7.3%). Acute and chronic rejection are the most common pathological type of renal transplantation in 26 cases. Chronic nephritis syndrome and nephrotic syndrome are the most common clinical manifestations. For male versus females, the ratio is 1.321 in the primary glomerulonephritis, while 0.731 in the secondary glomerulonephritis.

Conclusions: Primary glomerulonephritis is still the most common form of renal disease, and almost in male. IgA nephropathy is the most common pathological type of primary glomerulonephritis followed by membranous glomerular lesion. While for the secondary glomerulonephritis, male is more than male, and LN is the most common pathological type followed by DN. And Chronic nephritis syndrome is the most common clinical manifestations of renal biopsy.
Iodine-123 MIBG Imaging of Renal Cell Carcinoma with Pathological Correlation

Ken Hirasuka,1 Isao Kurihara,1 Sayuri Suzuki,2 Shinutar Yamauchi,2 Toshiaki Monkawa,1 Koichi Suzuki,1 Hiroshi Itoh,1 1Dept of Internal Medicine, Keio Univ School of Medicine, Japan; 2Dept of Mycobacteriology, Leprosy Research Center, National Inst of Infectious Diseases, Japan.

Background: The incidence of renal cell carcinoma has continuously increased during the last fifty years. Despite the increase in number, the five year survival rate has been reduced by the advances in renal imaging. Chromophore renal cell carcinoma (ChRCC) is an uncommon variant of RCC, accounting for approximately 5% of renal cancer. Although its prognosis is usually favorable, preoperative diagnosis is difficult because there is no marker for this variant. Here, we reported a novel method to distinguish ChRCC from other RCC (especially, clear cell carcinoma).

Methods: We experienced a case of ChRCC with adrenal phaeochromocytoma in a 69-year-old Japanese female. We noticed that iodine-123 MIBG scintigraphy showed uptake in ChRCC in addition to RCC. It is not cytotoxic uptake but the presence of iodine-123 uptake even in clear cell carcinoma. As a candidate transporter that mediate iodine-123 uptake in ChRCC, we identified specific transporter, pendrin, which is highly expressed in ChRCC.

Results: The protein expression of pendrin, the candidate transporter, which related to iodine-123 uptake, was highly detected in ChRCC compared with clear cell carcinoma. Moreover, the mRNA expression was also exclusively increased in ChRCC.

Conclusions: We identified specific transporter, pendrin, which is highly expressed in ChRCC. Our results indicates that iodine-123 MIBG scintigraphy may be a useful tool for the diagnosis of ChRCC and represents a substantial additional in the diagnosis of ChRCC.

Clinical Significance of Glomerular IgG Deposits in IgA Nephropathy

Anthony Alvarado,1 Nicole K. Andeen,2 Sergey V. Brodsky,2 Alice Hinton,3 Tibor Nadasy,1 Charles E. Alpers,2 Christopher D. Blosser,1 Behzad Najafian,2 Brad H. Rovin,1 1Faculty of Medicine, Nephrology Div, The Ohio State Univ, Columbus, OH; 2Pathology Dept, Univ of Washington, Seattle, WA; 3Dept of Biostatistics, College of Public Health, The Ohio State Univ, Columbus, OH; 4Faculty of Medicine, Nephrology Div, Univ of Washington, Seattle, WA.

Background: IgAN is characterized by IgA dominant or IgA-IgG co-deposits in Glomeruli. We evaluated the significance of IgG co-deposits in IgAN.

Methods: Consecutive IgAN biopsies (n=80) from Ohio State University and University of Washington (2001-2013) were retrospectively classified into IgA only and IgA-IgG deposits (IgG > trace). The presence or absence of IgG was correlated to the combined primary outcome of renal replacement therapy, death, OR doubling of serum creatinine (SCr). The change in estimated GFR (eGFR) was also assessed. Covariates were age, sex, race, SCr and proteinuria at biopsy, length of follow-up, treatment, Oxford score, and presence of crescents.

Results: This cohort was 64% male, 69% Caucasian and 14% Asian. IgA-IgG deposits were seen in 25 of the patients. There was no difference between IgA and IgA-IgG with respect to any of the covariates or between initial and follow-up proteinuria. There was a tendency for more endocapillary hypercellularity to be seen in IgA-IgG biopsies (p=0.08). The primary outcome was reached in 24 patients, 16 with IgA and 8 with IgA-IgG (p=0.82). Using multivariate modeling the change in eGFR over time was not different between IgA and IgA-IgG.

Conclusions: In this cohort of IgAN patients the presence of IgG co-deposits in the mesangium did not affect clinical outcomes.

Idiopathic Cryoglobulinemic Crescentic Glomerulonephritis – A Rare and Atypical Case

Pedram Aljada,1 Akshatha Rao,2 Sandeep Aggarwal,3 1Internal Medicine, Drexel College of Medicine/Hahnemann Univ Hospital, Philadelphia, PA; 2Nephrology, Drexel College of Medicine/Hahnemann Univ Hospital, Philadelphia, PA.

Background: Cryoglobulinemic glomerulonephritis is an rare entity, manifesting in middle-aged females. We report an atypical case of cryoglobulinemic crescentic glomerulonephritis in an 18-year-old African American Male without an identifiable viral, autoimmune or lymphoproliferative etiology.

Methods: Our case is an 18 y/o AAM with no significant PMH who presented for an isolated hematuria and proteinuria. Patient did not complain of edema, recent illness, joint pains, rash, night sweats or weight loss. No history of IVDA. BP was 114/72, without significant physical exam findings. Urine microscopy: cellular casts and dysmorphic RBCs. Serum creatinine was 1.27 mg/dl.

Conclusions: The uniqueness of this case is underscored by a variety of factors: clinical presentation, laboratory, serologies, and pathology. Laboratory and serological studies in cryoglobulinemia generally follow a characteristic pattern, detection of circulating cryoglobulins, low levels of complement, viral, autoimmune or lymphoproliferative etiology – yet a limited number of cases have presented with normal serological results, similar to the case presented here.

Renal Biopsy

Figure 1. (a) H&E Crescentric GN (1b) Jones Silver: MFGN with Crescents. Trichrome staining (1c) reveals eosinophilic intra-glomerular deposits with collagen deposition and obliteration of Bowman’s space. Substantial mesangial (2a: 30000x) and subendothelial (2b: 30000x) electron dense deposits of randomly arranged, slightly curved microtubular/fibrillar structures of approximately 20-25nm in diameter (2c: 120000x), and fingerprinting (2c: 30000x).

L:M: crescents and endocapillary proliferation. EM showed subendothelial, subepithelial and paramesangium 20.5-25nm microtubular fibrils. IF: only C1q 2-3+ granular GN and mesangial deposits. Labs: UPCR: 2.1 grams/day, ESR and CRP levels were markedly elevated. Viral hepatitis/HIV PCR, ANA, anti-dsDNA, anti-nRNaj-3-smith, SSS/SSB, anti Sm and Rh factor/CCP, C3, C4, ASO, cryocrit, SPEP/UEP/free light chains/Immunofixation, peripheral flow cytometry were negative. Patient was treated with IV methylprednisolone pulse and rituximab with improvement of renal function and proteinuria.

Conclusions: The uniqueness of this case is underscored by a variety of factors: clinical presentation, laboratory, serologies, and pathology. Laboratory and serological studies in cryoglobulinemia generally follow a characteristic pattern, detection of circulating cryoglobulins, low levels of complement, viral, autoimmune or lymphoproliferative etiology – yet a limited number of cases have presented with normal serological results, similar to the case presented here.

Development of a Clinicopathologic Kidney Biopsy Database Using Billing and Diagnosis Codes: A Descriptive Study

Nessavab Enafi,1 Anju A. Oommen,2 Jason Cobb,1 Jose E. Navarrete,3 Demilade Adesinsewo,4 Oluwatobiloba A. Osikoya,1 Helene B. Fevrier,1 Frederic F. Rahbari-Oskoui,1 Alton Brad Farris,1 Laura Plantinga,1 Titlaylo O. Ilior,1 1Dept of Nephrology, Emory Univ School of Medicine, Atlanta, GA; 2Morehouse School of Medicine, Atlanta, GA; 3Lee Univ, Cleveland, TN; 4Dept of Epidemiology, Rollins School of Public Health, Emory Univ, Atlanta, GA; 5Dept of Pathology and Laboratory Medicine, Emory Univ School of Medicine, Atlanta, GA.

Results: Patients in the registry had a mean age of 44.2 years; approximately half were male and majority were African American (40.7%). Overall, lupus nephritis (n=278, 12.4%) was the most prevalent renal clinicopathologic diagnosis. Among primary glomerular diseases, FSGS (136, 9.2%) was the most prevalent, followed by IgA nephropathy (123, 8.3%), membranous glomerulonephritis (GN) (69, 4.6%), membranoproliferative GN (24, 1.6%) and minimal change disease (27, 1.8%). Diabetic nephropathy was the second most common secondary GN (97, 6.5%) followed by ANCA-associated vasculitis (31, 2.1%). Other diagnoses were all less than 2%.

Conclusions: We successfully established a kidney biopsy registry at our center, which will be instrumental to studying outcomes in this rare group of diseases, the most prevalent of which were lupus nephritis and FSGS.
The Use of Multiplex Ligation-Dependent Probe Amplification Technology for Genetic Analysis of the Entire PKD1 Gene and PKD2 Gene

Tetsuhiro Yasuno, Yukito Fujita, Yuki Kiyokawa, Takahiro Takeda, Akihiro Kurokawa, Tetsuhiro Ueda, Yasuyuki Sugiyama, Hiroki Araki, Hiroshi Tanizawa, Takashi Kato, Jiro Hasegawa, and Yasuo Ogasawara

Department of Pediatrics, University of Tsukuba, Japan

Background: Autosomal dominant polycystic kidney disease (ADPKD) accounts for about 10% of end-stage renal disease. Genetic testing for ADPKD is currently performed using Sanger sequencing of PKD1 and PKD2 genes. To overcome the labor-intensive and time-consuming nature of conventional Sanger sequencing, multiplex ligation-dependent probe amplification (MLPA) technology is used for genetic analysis of the entire PKD1 and PKD2 genes.

Methods: In this study, we characterized the usefulness of MLPA technology for genetic analysis of the entire PKD1 and PKD2 genes. We analyzed 100 ADPKD patients and 100 non-ADPKD controls using the commercial Kit P261 (MRC Holland, Amsterdam, The Netherlands). The kit contains 23 hepatic and 22 renal-specific probes.

Results: Among the 100 ADPKD patients, 57 (57%) were found to have one or more mutations. The most common mutations were deletions in PKD1 (45%). Among the 100 non-ADPKD controls, none were found to have mutations.

Conclusions: MLPA technology is a useful tool for genetic analysis of the entire PKD1 and PKD2 genes. It allows for rapid and accurate identification of mutations in ADPKD patients. Further studies are needed to validate the results in a larger population.

PUB257

Is There Clinical Significance of IgM and Complement Staining in Idiopathic Focal Segmental Glomerulosclerosis? A Case of Intra-Ocular Lucentis (Ranibizumab) Induced Minimal Change Disease

Ashwin Reddy Ganta, Department of Nephrology, Archbold Memorial Hospital, Thomasville, GA.

Background: Intravital monoclonal antibodies like Lucentis (Ranibizumab), Eylea and Avastin are being increasingly used for the treatment of Wet Age related Macular Degeneration (wAMD) and Diabetic Macular Edema (DME) of the eye. Though the systemic use VEGF inhibitors and their renal toxicity is well documented.

Methods: A 78 y/o WM presented with worsening shortness of breath and anasarca. Underline represents presenting author.

Results: See Table 1

CD was present in approximately 50% of the biopsies, but there was no significant association between CD and baseline clinical or demographic characteristics, furthermore, there are no association between CD and markers of disease progression (change in proteinuria, serum albumin or GFR between baseline and 1 year follow up). IgM staining was strongly co correlated with presenting author.

Conclusions: Our results indicate that, unlike animal models of iFSGS; IgM and complement deposition does not alter outcomes. However, these findings will need to be confirmed in a larger study.

PUB258

A Case of Intra-Ocular Lucentis (Ranibizumab) Induced Minimal Change Disease

Ashwin Reddy Ganta, Department of Nephrology, Archbold Memorial Hospital, Thomasville, GA.

Background: Intravital monoclonal antibodies like Lucentis (Ranibizumab), Eylea and Avastin are being increasingly used for the treatment of Wet Age related Macular Degeneration (wAMD) and Diabetic Macular Edema (DME) of the eye. Though the systemic toxicity of these VEGF inhibitors is well known, not much is known about the renal toxicity profile of these agents when administered intravitreally.

Methods: A 78 y/o WM presented with worsening shortness of breath and anasarca. Underline represents presenting author.

Results: See Table 1

CD was present in approximately 50% of the biopsies, but there was no significant association between CD and baseline clinical or demographic characteristics, furthermore, there are no association between CD and markers of disease progression (change in proteinuria, serum albumin or GFR between baseline and 1 year follow up). IgM staining was strongly co correlated with presenting author.

Conclusions: Our results indicate that, unlike animal models of iFSGS; IgM and complement deposition does not alter outcomes. However, these findings will need to be confirmed in a larger study.
Methods: Multiplex ligation-dependent probe amplification (MLPA) kits have been developed for genetic analysis by MRC-Holland using proprietary MLPA technology. We obtained informed consent from nine patients (mean age, 45 years) and collected 8 mL of blood from each patient for analysis of genetic mutations in PKD1 and PKD2 genes using the MLPA method.

Results: In case 1 (a 39-year-old man), we found deletions in exons 3 and 39 of the PKD1 gene. The kidney was extracted due to enlargement and cyst infection. Dialysis was initiated when the patient was 39 years of age. The kidney capacity was 5013 mL. Nine ADPKD patients who started administration of tolvaptan were examined. TBW in whole body and TBW in limbs. However, TBW in trunk were examined. Body weight and renal function were measured before (baseline) and 2 days after initial tolvaptan administration. Height was initiated when the patient was 39 years of age. The kidney capacity was 5013 mL. Multiplex ligation-dependent probe amplification (MLPA) kits have been developed for genetic analysis by MRC-Holland using proprietary MLPA technology. We obtained informed consent from nine patients (mean age, 45 years) and collected 8 mL of blood from each patient for analysis of genetic mutations in PKD1 and PKD2 genes using the MLPA method.

Conclusions: Genetic screening of the PKD1 and PKD2 genes using the MLPA method may decrease cost and labor. Indeed, the MLPA method was especially useful in cases exhibiting juvenile onset and rapid kidney enlargement.

PUB264
A Rare Presentation of Acute Kidney Injury: Have a Look at the Skin
Alper Van, Turkey.

Background: Tuberous sclerosis (TS) is a multisytemic, rare, genetic disorder of autosomal dominant inheritance which can involve different organs. Most commonly involved organ system is skin. We describe a case presented with periangiomyalipomas, multiple renal cysts and Shagreen patch without other features of TS.

Methods: A 33 yo woman presented with fatigue and renal failure. On physical examination, she had multiple non traumatic periangiomyalipomas in both hands and feet. Also Shagreen patch was seen in the right lumbosacral region.

Conclusions: As stated in diagnostic criteria, physical examination has a strong impact on diagnosis of TS. Hypomelanotical macules (~3), Shagreen patch, forehead plaque, non traumatic periangiomyalipomas, adrenal sebaceous, facial angiofibromas should remind the physicians TS. Kidneys are involved in almost 50-80% of the adult patients. Most frequent renal lesions in TS are angiomylipomas. Bilateral and multiple characteristics of angiomylipomas are pathognomonic. They may progress to end stage renal disease. However in some rare cases frank renal lesions may be absent. With a detailed inspection it is possible to recognize these specific dermatological signs, making the Tuberous sclerosis diagnosis and taking these patients under nephrological follow up.

PUB265
Use of Antidepressant Medications During the HALT-PKD Randomized Trials
M. F. Flesnner, 1 Michael Fleissner, 2 Ronald D. Perrone, 3 Arlene B. Chapman, 4 Robert W. Schirrer, 5 Alan S.L. Yu, 6 William E. Braun, 7 Kyongtue Ty Bae, 8 Peter C. Harris, 9 Charity G. Moore, 10 Michael F. Fleissner, 2 The HALT PKD Investigators, 20 Mayo; 21 Pittsburgh, “BIDMC; 22 Tufts U.; 23 U. Chicago; 24 Colorado; 25 US U. Med. Ctr.; 26 Cleveland Clinic; NINH; 27 Multi-Ctr.

Background: Depression occurs in CKD more commonly than in the general population and is associated with poor outcomes. The use of antidepressants (ADs) has been associated with inappropriate release of vasopressin and hyponatremia. Since vasopressin is thought to aggravate the progression of ADPKD, AD use could be deleterious.

Methods: Examine the use of ADs in the participants of the HALT-PKD randomized clinical trials (RCTs) and whether their administration is associated with faster disease progression. Post-hoc analysis of two HALT-PKD RCTs (A and B) studying the effect of rigorous vs standard BP control (A) and of ACE inhibitor alone vs ACE inhibitor/ARB combination (A and B) on rates of change of TKV (A) and eGFR (A and B) in ADPKD patients with eGFR >60 (A) or 25-60 (B) mL/min/1.73 m2.

Results: Female used ADs more frequently than male participants (39.7% of 526 vs 28.4% of the 518, P<0.0001). Study A used ADs as frequently as study B participants (31.7% and 28.4%, respectively). Participants with PKD2 mutations used ADs (42.4%) more frequently than those with PKD1 mutations (27.9%, P<0.0009) despite having milder disease. Ages of those using or not using ADs were similar. To assess the effect of ADs on disease progression we divided the participants into three groups, no exposure to ADs, exposure for less £30% and exposure for >30% of the time:

On admission biochemical tests: urea 132 mg/dL, creatinine 4.7 mg/dL, potassium 4.7 mmol/L, pH 7.32, HCO3 18.4. Urinary output was satisfactory, no uremic symptoms were present. Renal ultrasonography revealed bilateral renal cysts with normal size and parenchymal thickness. Histopathology of the Shagreen patch revealed dense collagen bundles in the dermis. Due to the skin lesions and renal cysts the patient was diagnosed as TS. Other manifestations of TS were not present. Renal biopsy was suggested but she did not accept the procedure.

Conclusions: As stated in diagnostic criteria, physical examination has a strong impact on diagnosis of TS. Hypomelanotical macules (~3), Shagreen patch, forehead plaque, non traumatic periangiomyalipomas, adrenal sebaceous, facial angiofibromas should remind the physicians TS. Kidneys are involved in almost 50-80% of the adult patients. Most frequent renal lesions in TS are angiomylipomas. Bilateral and multiple characteristics of angiomylipomas are pathognomonic. They may progress to end stage renal disease. However in some rare cases frank renal lesions may be absent. With a detailed inspection it is possible to recognize these specific dermatological signs, making the Tuberous sclerosis diagnosis and taking these patients under nephrological follow up.

In conclusion, this axis may be a therapeutic target in PKD.

Nozu, Millennium Inst, Australia; function, cyst growth, and nephrotoxicity. Almost all topics/outcomes had already been identified 27 outcomes including quality of life, progression of kidney disease, kidney function, cyst growth, and nephrotoxicity. Dysregulation of miR-378a-3p and ADAMTS1 Gene in

Results: miRNA microarray analysis revealed that 22 (up 4, down 18) miRNAs were differentially expressed (more than 4 fold) in cpk (day 21, n=7) kidneys. Of 22 miRNAs, miR-378a-3p was significantly downregulated in cpk (5.1-fold). Real-time PCR confirmed that miR-378a-3p was significantly downregulated in cpk (day 14, n=14, 5.0-fold, p=0.002; day 21, n=12, 9.1-fold, p=0.0001) and that one of the target molecules of miR-378a-3p, ADAMTS1 gene, was significantly upregulated in cpk (14 day, n=20, 1.4-fold, p=0.01; day 21, n=12, 3.5-fold, p=0.0002). Western blotting showed that ADAMTS1 was increased in cpk (day 21, n=6, 1.8-fold, p=0.03) kidneys.

Conclusions: Results suggest that miR-378a-3p/ADAMTS1 axis is involved in cpk.

In conclusion, this axis may be a therapeutic target in PKD.

Identifying and Integrating Consumer Perspectives in Clinical Practice Guidelines on Autosomal Dominant Polycystic Kidney Disease

Background: Integration of consumer perspectives into clinical practice guidelines is widely advocated as it ensures that recommendations are relevant to all stakeholders. We aimed to identify consumer perspectives on topics and outcomes to include in clinical practice guidelines on autosomal polycystic kidney disease (ADPKD).

Methods: A workshop involving three concurrent focus groups with consumers was convened. Guideline topics, interventions and outcomes were identified, and integrated into guideline development. Thematic analysis was used to analyze the reasons for their choices.

Results: Eighteen consumers (patients with ADPKD [n=15], caregivers [n=3]) participated and 22 priority topics (including interventions) were identified, with most focused on non-pharmacological management (diet, fluid intake, physical activity, complementary medicine), pain management, and psychosocial care (mental health, counseling, cognitive and behavioral training, education, support groups). They also identified 22 outcomes including quality of life, progression of kidney disease, kidney function, cyst growth, and nephrotoxicity. Almost all topics/outcomes had already been identified by health professionals in the guideline working group with the exception of five topics/outcomes (surgical management of cysts, patient education about end-stage kidney disease, psychosocial impact of diagnosis, need for dialysis, knowledge). Many more topics (33) and outcomes (44) were identified as priorities by health professionals than consumers. Six themes reflected reasons for consumer choices: clarifying ambiguities, resolving debilitating pain, concern for family, preparedness for the future, taking control, and significance of impact.

Conclusions: Although there was considerable concordance between the priority topics and outcomes of health professionals and consumers for guidelines of ADPKD, there was also important discordance with consumers focused on fewer issues but particularly on lifestyle, psychosocial support, pain management, and quality of life and renal outcomes. PUB268

Urinary AQP2 Is One of the Candidates for a Surrogate Marker in the Treatment of ADPKD Patients by Tolvaptan

Background: Tolvaptan, arginine vasopressin (AVP) V2 receptor antagonist is accepted for autosomal dominant polycystic kidney disease (ADPKD) patients in Japan since 2014. TEMPO study showed tolvaptan from 60 to 120 mg per day slowed renal cyst expansion and renal function decline. Tolvaptan dose is decided by preliminary study (TEMPO), which showed the maximum dose that meet both urinary osmolality (Uosm) under 300 mOs/m/kg and patient’s tolerance. So that adequate dose for individual patient has not been suggested. Moreover, tolvaptan cause polyuria, thirst, polydipsia due to aquesis. Thus, it is necessary to find surrogate markers for determine the maximum effects and minimum side effects for long-term administration.

Methods: Seventeen ADPKD patients initiated tolvaptan of 60 mg were investigated. Physical data, plasma osmolality (Posm), Uosm, AVP, ureic cyclic AMP (UCAMP), and urinary AQP2 were assessed. UCAMP was measured by radioimmunoassay (Yamasita corp.) and UAO2 was measured by a sandwich enzyme-linked immunosorbent assay method (Otsuka Pharmaceutical Co. Ltd.).

Results: After initiation of tolvaptan, average urine volume was 8621 ml/day and delta body weight was -1.42 kg/day on day 1. One month after, AVP increased from 3±3 to 7.3±11.2 pg/ml (p<0.001). Uosm decreased from 367.349 to 243±436 mOs/m/kg (p<0.001). Posm and UCAMP were not statistically associated. UAO2 decreased from 0.029±0.068 to 0.012±0.028 pmol/MgCr (p<0.001). In our preliminary data (n=5), the serum copeptin, a precursor of vasopressin, was shown to be no consistent level.

Conclusions: It has been recognized that 30% of total production of AQP2 excreted into the urine, it reflected directly the intracellular action of AVP. Thus, UAO2 is likely to be one of surrogate markers of tolvaptan effect, moreover it could provide additional information of determination of individual dosage and monitoring for long-term usage.

Abnormalities in the Radius of Patients with Autosomal Dominant Polycystic Kidney Disease Measured by High-Resolution Peripheral Quantitative Computed-Tomography Imaging

Background: ADPKD is a multi-organ disorder and the most common of all cystic kidney diseases. Mutation of the PKD1 or -2 gene causes epi- and endothelial ciliopathies, which lead to the dysfunction of various organs. Animal studies show that primary cilia of osteoblasts play an important role in osteoblast differentiation. We speculate that primary cilia of osteoblasts play an important role in osteoblast differentiation.

Methods: In this pilot-study, we examined the bone structure in 6 ADPKD patients in comparison to 6 matched patients with glomerular disease (GD), both in CKD stages I-II, by HR-μCT of the radius and the tibia. The aim of the study was to identify microarchitectural target parameters for a subsequent larger study in patients with ADPKD.

Results: Demographic data see Table 1.

We found reduced cortical and trabecular microstructural parameters by HR-μCT, mainly affecting the radius. The outer trabecular density, the cortical thickness and the total density of the radius showed the biggest differences between the two groups, see Figure 1.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.

949A
The total density of the radius was the best parameter to distinguish between the bone structure of ADPKD— in comparison to GD patients (AUC=0.861).

**Conclusions:** We provide evidence of microstructural bone deterioration of the radius in patients with ADPKD. We thus hypothesize that ADPKD is associated with microstructure bone changes in men.

**PUB270**

An Accurate Formula for a Quick Estimate of Total Liver Volume in Polycystic Liver Disease Patients

**Background:** Polycystic liver disease (PLD) appears in two disorders; autosomal dominant polycystic kidney disease (ADPKD) and autosomal dominant polycystic liver disease (ADPLD). The primary aim of treatment of PLD is reduction of total liver volume (TLV) as patients often suffer from hepatomegaly. The gold standard to assess TLV is CT volumetry which involves manual delineating of the liver outline. Unfortunately this is a time-consuming method (45-60 minutes per CT scan) and requires a certain level of expertise. An easily accessible and fast method to estimate TLV in routine clinical practice is needed. Therefore we aimed to develop an accurate formula for quick estimation of TLV.

**Methods:** We collected a cohort of PLD patients in whom CT scans were available. Manual delineation of TLV served as gold standard. PLD patients were distributed in 2 cohorts, a development cohort (N=80) and a replication cohort (N=50). We measured anterior-posterior (AP), transverse (T) and cranio-caudal (CC) distance (in meters) of the liver on CT. TLVs were logarithmically transformed as data were not normally distributed. R² was measured as it indicates the goodness of fit of the prediction model. The prediction model was tested in a replication cohort.

**Results:** Median liver volumes in the development and replication cohort were 4749mL (1,2±7.68 vs 2.09±7.68 ml/m²Cr) groups. Additionally, urine liver type fatty acid binding protein (L-FABP), as a biomarker of the tubular ischemia, showed significant difference in all stratified groups (KV: 7.29±1.99 vs 1.76±1.68, eGFR: 4.15±7.76 vs 2.45±2.34, KGR: 4.46±7.68 vs 2.09±2.30, NAG index: 4.33±1.70 vs 1.88±2.10).

**Conclusions:** Progression of ADPKD has been primarily assessed by the kidney volume. However, the present study may show that the assessment of TiN might be more helpful to evaluate the severity and prognosis of ADPKD. It might be suggested that TiN-related markers such as NAG index or L-FABP index should be actively utilize in the clinical management of patients with ADPKD.

Classic and Alternative Criteria for the Diagnosis of Autosomal Dominant Polycystic Kidney Disease: Genetics and Disease Progression in HALT-PKD

**Background:** The HALT-PKD trials based the diagnosis of ADPKD on classic criteria (CC) as well as on alternative criteria (AC) with no mutation detected (NMD) were analyzed as a distinct subset (AC-NMD).

**Methods:** Of 959 HALT-PKD patients with genetic testing 835 (87.1%) had CC, and 124 (12.9%) had AC. Three groups: Alternative (AC-NMD), Classical (CC-PKD1/ PKD2 mutation), and Intermediate (combined CC-NMD + AC-PKD1/ PKD2 mutation) were compared for annual change in total kidney volume (TKV, lnTKV) in early ADPKD (n=17, 410, 81, respectively), and eGFR in early/late ADPKD (n=1/78, 414/375, 81/84, respectively).

**Results:** TKV baselines were not significantly different (P=0.66). The TKV annual increase was 4.21% in Alternative (AC-NMD) compared to 6.39% in Classical (CC-PKD1/ PKD2), and 6.68% in Intermediate (CC-NMD + AC-PKD1/ PKD2) (lnTKV P=0.0346; lnhTKV P=0.0035)and was not affected by BP level.

**Conclusions:**

**PUB271**

Clinical Significance of Urine NAG and L-FABP Excretion for the Assessment of ADPKD-Progression

**Background:** Autosomal dominant polycystic kidney disease (ADPKD) shows various renal prognosis. Because the progression of renal damage in ADPKD is principally caused by tubulo-interstitial nephropathy (TIN), the present study focused to study the relationship between TiN-related clinical parameters and progression of ADPKD.

**Methods:** In this study, 59 ADPKD cases with consents were retrospectively analyzed. Average age, duration of the observation, median values of kidney volume (KV) and kidney growth rate (KGR), average estimated GFR (eGFR) and urine excretion ratio of N-acetylglucosaminidase (NAG) to Cr (NAG index) for the clinical assessment of TIN. We stratified patients by the average or median value of the parameters mentioned above, and analyzed their differences in each stratified group. KV, eGFR and KGR showed significant difference only in the eGFR-, KV- and eGFR-stratified group. However, NAG index showed significant difference in both KV-stratified (median: 7.42 vs 6.09 U/mgCr) and eGFR-stratified (8.00±5.98 vs 3.93 U/mgCr) groups. Additionally, urine liver type fatty acid binding protein (L-FABP), as a biomarker of the tubular ischemia, showed significant difference in all stratified groups (KV: 7.29±1.99 vs 1.76±1.68, eGFR: 4.15±7.76 vs 2.45±2.34, KGR: 4.46±7.68 vs 2.09±2.30, NAG index: 4.33±1.70 vs 1.88±2.10).

**Conclusions:** Progression of ADPKD has been primarily assessed by the kidney volume. However, the present study may show that the assessment of TiN might be more helpful to evaluate the severity and prognosis of ADPKD. It might be suggested that TiN-related markers such as NAG index or L-FABP index should be actively utilize in the clinical management of patients with ADPKD.

Lifestyle Counselling in Polycystic Kidney Disease Patients

**Background:** Polycystic Kidney Disease (PKD) is a common genetic disease. We designed this study to determine the prevalence of lifestyle counseling in patients with PKD.

**Methods:** In this study, 59 ADPKD cases with consents were retrospectively analyzed. Average age, duration of the observation, median values of kidney volume (KV) and kidney growth rate (KGR), average estimated GFR (eGFR) and urine excretion ratio of N-acetylglucosaminidase (NAG) to Cr (NAG index) for the clinical assessment of TIN. We stratified patients by the average or median value of the parameters mentioned above, and analyzed their differences in each stratified group. KV, eGFR and KGR showed significant difference only in the eGFR-, KV- and eGFR-stratified group. However, NAG index showed significant difference in both KV-stratified (median: 7.42 vs 6.09 U/mgCr) and eGFR-stratified (8.00±5.98 vs 3.93 U/mgCr) groups. Additionally, urine liver type fatty acid binding protein (L-FABP), as a biomarker of the tubular ischemia, showed significant difference in all stratified groups (KV: 7.29±1.99 vs 1.76±1.68, eGFR: 4.15±7.76 vs 2.45±2.34, KGR: 4.46±7.68 vs 2.09±2.30, NAG index: 4.33±1.70 vs 1.88±2.10).

**Conclusions:** Progression of ADPKD has been primarily assessed by the kidney volume. However, the present study may show that the assessment of TiN might be more helpful to evaluate the severity and prognosis of ADPKD. It might be suggested that TiN-related markers such as NAG index or L-FABP index should be actively utilize in the clinical management of patients with ADPKD.

Amniotic Fluid Stem Cells Transplantation in Fetal Kidney to Regenerate Nephrons Loss - Kathleen Laborde,1 Sebasitien Sammut,2 Mehrak Hekmati,2 Agnieszka Anna Ksiazek,2 Benedikt Weber,1 Luc Behr.1 1Necker Hôpital-Paris5 Univ, Paris, France; 2IMMR, Paris, France; 3Swiss Center for Regenerative Medicine, Univ Hospital, Zurich, Switzerland.

**Background:** Amniotic fluid stem cells (AFSC) harbour the potential to differentiate toward renal lineages and contribute to the development of primordial kidney structures. To investigate whether AFSC can improve prenatal renal compensatory growth, cells were transplanted in a model of subtotal nephrectomy (5/6NX) in the fetal sheep.

**Methods:** Ovine AFSC label with GFP were selected using c-kit. In absence of LIF, AFs formed embryonic bodies which cultured in an optimized medium generated a renal epithelial progenitor population (oAFSCd), expressing Pax-2. 5/6NX was performed at 70 days of gestation in 10 fetal lambs; 5 were injected with oAFSCd in the kidney poles. sham-operated did not receive oAFSCd (SHAM, n=8). At 134 days of gestation, fetuses were euthanized, kidneys removed and processed.

**Results:** Body weight did not differ significantly among the groups and no morphologic abnormalities were observed, in spite of a severe reduction in amniotic fluid in 5/6NX oAFSCd. Compensatory renal growth of the remaining kidney was observed in all 5/6NX, but in spite of oAFSCd injection, catch-up kidney growth was similar in both 5/6NX groups. SHAM: 3.2±0.6, 5/6NX: 4.6±2.4, 5/6NX oAFSCd: 5.5±1.4 K/W/BW. Glomeruli number/section was similar in all groups: SHAM: 2711, 5/6NX: 2155±694; 5/6NX oAFSCd:1962±199. In 5/6NX oAFSCd, GFp cells were present in renal proximal tubules, and proximal tubule hypertrophy was observed.

**Conclusions:** Transplantation of oAFSCd predifferentiated toward renal epithelial progenitor cells during nephrogenesis increases proximal tubule mass but has no effect on the number of glomeruli in the 5/6NX and do not restore fully kidney damage. **Funding:** Private Foundation Support

Increasing Podocyte Number in Neonatal Kidney Reduced Renal Injury in Adulthood - Jianyong Zhong,1,2 Ji Ma,1 Taiji Matusaka,1 Agnes B. Fogo,1 Valerie Kon,1 Haichun Yang.1 1Pathology, Microbiology and Immunology, Vanderbilt Univ, Nashville, TN; 2Pediatric Nephrology, Vanderbilt Univ, Nashville, TN; 3Dept of Molecular Life Science, Inst of Medical Science, Tokai Univ School of Medicine, Isehara-shi, Kanagawa, Japan.

**Background:** Preterm birth increases the risk of hypertension and renal disease, which has been linked to decreased GFR globally. We previously found that perinatal injury in mice at birth improves glomerular maturation, and has renal pathology phenotype which is similar to that observed in human preterm births. In the present study, we tested the hypothesis that increasing podocyte number during glomerular maturation can rescue glomerular loss and thus reduce renal injury in adulthood.

**Methods:** We mated podocin-rtTA with TRE-SV40T mice to generate double-transgenic mice (RS), in which podocyte proliferation can be activated by doxycycline (Dox). rtTA mice (R) served as controls. After a single puromycin injection, doxycycline were continued until P8. At 1 week of age, mice under puromycin (UNx) were started on a high salt diet. At 14 weeks of age, angiotensin II (Ang II) was given by minipump for the next 8 weeks. All mice were sacrificed at week 22.

**Results:** At week 3, there were more WT positive glomerular cells in RS than R mice (RS 10.34±0.41 vs. R 8.15±0.58 X10^4/µm, p<0.05), while only 49% of RS neonates survived the first week after birth. Within the first week after birth, LBW neonates had an up to 40% reduction in renal blood flow and elevation of circulating cyto-/chemokines, renal blood flow and renal function.

**Conclusions:** Our findings indicate that increasing podocyte number in kidney developing reduces puromycin-induced reduction of glomerular growth, which in turn reduces renal injury following a second hit in adulthood.

Exploring Ciliopathies – Cep164 Tissue Expression in a Murine Model - Simon Ramsbottom, Shalabh Srivastava, Colin Miles, John Andrew Sayer. Inst of Genetic Medicine, Newcastle upon Tyne, United Kingdom.

**Background:** Nephropathies (NPH) is the major cause of paediatric renal failure, yet the disease remains poorly understood, partly due to the lack of appropriate animal models. Joubert Syndrome (JBS) is an inherited ciliopathy giving rise to NPHP and neurodevelopmental abnormalities and mutations in CEP164 are one of the known genetic causes. Clinical phenotypes of patients with CEP164 mutations include NPHP with retinal degeneration and cerebellar vermis aplasia. In cultured cells CEP164 localises to centrosomes as well TIP-60 positive nuclear foci, and CEP164 has an established role in DNA damage response signalling. However, there has been no previous documentation of CEP164 spatial expression during development.

**Methods:** We have recently acquired heterozygous Cep164 mice from the International Mouse Phenotyping Consortium (MRC/Harwell) (B6N(Cg)-Cep164<tm1a(EUCOMM)Wtsi/H>tm1a(EUCOMM)Wtsi/H>). We used these animals for tissue expression studies, including X-gal staining of kidneys from heterozygote adults and whole embryos. Homozygote Cep164 animals had 100% perinatal lethality.

**Results:** In heterozygote Cep164 animals, specific X-gal staining representative of Cep164 expression was observed in all tissues examined. This included the brain (olfactory bulbs and cerebellum); the eyes (within the retina layers); the testis and renal tissues. In E13.5 embryos, staining was observed globally at a low level. Stronger staining can be seen in discrete regions including the developing eyes and limbs, areas undergoing high levels of proliferation and apoptosis, further indicating a role for Cep164 in these processes.

**Conclusions:** These data support a role for Cep164 in multiple organs throughout development and explains the wide phenotypic spectrum of JBS mutations in man.

**Funding:** Government Support - Non-U.S.

Exploring Early B Cell Factor 1 from Podocytes Does Not Recapitulate the Developmental Defects Observed in the Globally Deficient Animals but Does Provide Protection from Injury - Jackie A. Fretz, Tracy Nelson, Li Li. Orthopaedics and Rehabilitation, Yale School of Medicine, New Haven, CT.

**Background:** Globally deficient mice lacking the transcription factor Ebf1 (Ebf1 KO) are extremely sick owing to the multiple functions of Ebf1 across the body. We recently described a novel function of Ebf1 as an essential component of the latest stages of mesangialogenic development. Mice globally deficient in Ebf1 have impaired formation of peripheral glomeruli and a thinned cortex. Within the kidney Ebf1 is present within multiple cell types including distinct tubular epithelium, interstitial pericytes, glomerular mesangium, and podocytes. This investigation aimed to identify if the actions of Ebf1 in the podocyte were driving the developmental defects present in the global knockout.

**Methods:** In this study we made a specific deletion of Ebf1 within the podocytes using the podocin-driven cre mouse. These were mated with mice where the 3rd exon of Ebf1 (encoding part of the DNA-binding domain) is flanked by flox sites. This is the same genetic construct that is excised with Bsr in whole body knockout and injury was also performed on 3 month old animals (100mg/kg. IP daily for 4 weeks).

**Results:** In this study we made a specific deletion of Ebf1 within the podocytes using the podocin-driven cre mouse. These were mated with mice where the 3rd exon of Ebf1 (encoding part of the DNA-binding domain) is flanked by flox sites. This is the same genetic construct that is excised with Bsr in whole body knockout and injury was also performed on 3 month old animals (100mg/kg. IP daily for 4 weeks).

**Conclusions:** These data support a role for Cep164 in multiple organs throughout development and explains the wide phenotypic spectrum of JBS mutations in man.

**Funding:** Government Support - Non-U.S.
Results: Restricted deletion of Ebf1 from podocytes did not result in any observable developmental changes, including defects in cell number and morphology. However, Ebf1 deletion led to a functional and histological level of glomerular number, and glomerular development were unchanged regardless of genotype. The mice were followed for up to 6 months. During this time renal function did not decline in the mice with podocyte-specific deletion of Ebf1, and in fact baseline proteinuria was reduced in Podocin-cre+/- Ebf1-/- animals compared to littermate controls. To examine if Ebf1-deficient podocytes harbored differential response to injury 3 month old animals were subjected to BSA-overload and exhibited reduced proteinuria.

Conclusions: Taken together these results suggest that Ebf1 regulates nephropathic development through other cell types than the podocyte. While Ebf1 does not control glomerular development through its actions in the podocyte, it appears to participate in proper damage response by podocytes as its removal appears to be protective.

Remote Ischemic Preconditioning and Pharmacological Treatment in Prevention of Renal Damage in Experimental Diabetics Marcelo Rodrigues Bacci, David Feder, Fernando Luiz Alfonso Fonseca, Matheus Polly, Jaqueline Victoria Ciancaglini, Giuliana Petri, Guilherme Zaremba. ABC Medical School, Brazil.

Background: The main features of diabetic nephropathy are glomerular hypertrophy, thickening of the basal membrane, tubular atrophy, interstitial fibrosis and nodular and focal glomerulosclerosis. Remote ischemic preconditioning (RIPC) is a procedure that generates a brief period of ischemia followed by reperfusion. Its role in preventing glomerular and tubular changes is still under debate. The aim of the study was to evaluate the nephroprotective effect of RIPC in a diabetic rat model.

Methods: Five groups of 10 Wistar male rats were formed: control without diabetes; untreated diabetes; diabetes treated with pharmacological treatment (PT); diabetes with RIPC and diabetes with RIPC and PT. For the induction of diabetes, alloxan was infused intraperitoneally at a dose of 160mg/kg. PT consisted of daily use of metformin (250mg/kg), sitagliptin (60mg/kg) and valsartan (30mg/kg). RIPC was performed with an external tourniquet placed on the back leg for three 5-minute rounds alternated with the same rounds of reperfusion, resulting in a total duration of 30 minutes. This was performed every week on all animals in RIPC groups. All mice were kept in a biological cage with controlled temperature and humidity and routine feeding. Blood and urine samples were collected weekly to evaluate serum glucose, creatinine and urine albumin/glucose and albumin/creatinine urine ratio (ACR). At the end of the observation period, animals were sacrificed and their kidneys were biopsied for microscopic analysis.

Results: Animals subjected exclusively to PT showed a significant reduction in serum and urine glucose levels but these reductions were not greater in the group that underwent RIPC in addition to PT. There were no significant differences in creatinine level between any of the groups but ACR was significantly reduced in all treated animals compared to controls. Tubular atrophy was observed in all diabetic rats and was greatest in the untreated group.

Conclusions: PT was more effective at reducing ACR and tubular atrophy than RIPC. RIPC alone or in combination with PT did not cause the expected effect of preventing histological and urinary abnormalities.

Cross Talk Between TLR4 Signaling and Angiotesin II Induces Pathophysiological Changes in Human Tubular Epithelial Cells Under High Glucose Conditions, Jinlei Lv, Guohua Ding. Nephrology, The First Affiliated Hospital of NanChang Univ, Nanchang, Jiangxi, China; Nephrology, Renmin Hospital of Wuhan Univ, Wuhan, China.

Background: To investigate the cross talk between TLR4 and angiotensin II by observe the expression of TLR4 in tubular epithelial cells under high glucose conditions, and observe the changes of fibrogenic and inflammatory factors in human renal tubular epithelial cells, revealing the innate immune pathogenesis in diabetic nephropathy.

Methods: Cells were divided into five groups after cultivated with normal glucose medium: 1. normal-glucose group 2. mannitol group 3. AngII group 4. high-glucose group (25mmol/L) 5. high-glucose+Irsbasran group, extract total RNA and total protein after 24 hours. Real time PCR was used to analyze the expressions of TLR4, Myd88, HSP47, NF-kB in RNA, a western blot was used to observe the expressions of TLR4, Myd88, NF-κB, CoIV, HSP47 protein, analyze the effect of high-glucose and AngII to TLR4 / Myd88 / NF-κB signaling pathway.

Results: Compared with normal group, TLR4, Myd88, HSP47 mRNA and TLR4, Myd88, NF-κB, CoIV, HSP47 protein were highly expressed under high glucose condition and after AngII stimulate (p<0.01). The expression of IL-6 and MCP-1 also increased (p<0.01). Compared with Hg group, the expression of TLR4, Myd88, HSP47 mRNA and TLR4, Myd88, NF-κB, CoIV, HSP47 in the high-glucose+Irsbasran group were significantly reduced (p<0.01). The difference of above indicators between the negative transfected group and high-glucose group and AngII group were statistically significant (p<0.05). The expression of NF-κB and MCP-1 in the group that cells were transfected with TLR4-siRNA also reduce(p<0.01).

Conclusions: Cross talk between angiotensin II and TLR4 can up-regulate the expression of inflammatory factors and fibrogenic factors in HK-2 cells. Irsbasran can block the activation of TLR4 signaling pathway induced by high glucose and angiotensin II. TLR4 signaling pathway is the major pathway induce the release of inflammatory and fibrogenic factors in tubular epithelial cells under high glucose conditions.

Possible Renoprotective Effects of Acetazolamide Administration in Obese Diabetic Mice with Nephropathy. Yushu Nakayama, Koji Eguchi, Terumasa Nakagawa, Tomoaki Onoue, Yuichi Izumi, Hideki Inoue, Yutaka Kakinose, Takashige KawaiBarada, Masashi Mukoyama. Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan.

Background: Administration of carbonic anhydrase inhibitors (CAI) is thought to decrease glomerular filtration rate (GFR) by activation of the tubuloglomerular feedback (TGF) system. Acetazolamide (ACZ), a major CAI, has been shown to decrease urinary albumin excretion in the patients of type 1 diabetes with nephropathy. Previously, we showed that ACZ treatment in mice could ameliorate the onset of diabetic nephropathy due to the reduction of intraglomerular pressure by activating the TGF system.

Methods: In the current study, we treated obese diabetic mice (KK-Ay/TaJcl) with ACZ for 14 weeks, and evaluated the long-term effects on urinary albumin excretion and glomerular hyperfiltration.

Results: The blood glucose levels were significantly higher in KK-Ay/TaJcl mice compared to the control mice (BALB/cA/Jcl) at 14 weeks. The blood glucose levels were significantly reduced in KK-Ay/TaJcl mice treated with ACZ (547±37 vs 250±75 mg/dL). Interestingly, urinary albumin excretion levels in the ACZ group were not significantly different compared to the non-treated group. Creatinine clearance was higher in KK-Ay and ACZ group, but not changed by ACZ (0.73±0.07 vs 0.69±0.15ml/min) (Figure A). Urinary albumin excretion was reduced with ACZ treatment by 29% (Figure B). The plasma renin activity was not reduced by ACZ in this model.

Conclusions: These results suggest that the long-term oral treatment with ACZ may exert renoprotective effects in obese diabetic models with nephropathy, not due to activation of the TGF system but to better glycemic control.

Inhibition of miR-34a Reduces Podocyte Apoptosis by Targeting Bel-2 and Autophagy. Yang Liu,1 Ruixi Li,2 Wai Han Yiu,2 Hao-Jia Wu,1 Dickson W.L. Wong,1 Joseph C K Leung,1 Loretta Y.Y. Chan,1 Kar Neng Lai,1 Moin Saleem,2 Peter W. Mathieson,1,2 Sydney C.W. Tang.1 1Dept of Medicine, The Univ of Hong Kong, Queen Mary Hospital, Hong Kong, China; 2Academic and Children’s Renal Unit, Univ of Bristol, Bristol, United Kingdom.

Background: Podocyte apoptosis is a key event in the pathogenesis of diabetic nephropathy. MiR-34a has been reported to be involved in cell proliferation and apoptosis, but its potential roles in podocytes under the diabetic condition remains unknown.

Methods: Type 2 diabetic nephropathy was established by uninephrectomy (Unx) in nine-week-old db/db mice. In cultured immortalized human podocytes, miR-34a was overexpressed or knocked down by transfection with miR-34a precursor (pre-34a) or inhibitor (anti-34a), respectively. Podocytes were exposed to glycated human serum albumin (AGEs) and then examined for the expression of apoptosis and autophagy markers. The expression of miR-34a in mouse renal cortex and cultured podocytes were determined by quantitative PCR (Q-PCR) using specific Taqman miRNA assay.

Results: Compared with control group, Unx db/db mice (n=7) showed significantly higher expression level of miR-34a in renal cortex. In cultured human podocytes, exposure to AGEs also markedly increased miR-34a expression. The anti-apoptosis genes Bcl-2 and survivin, podocyte cytoskeleton molecule synaptopodin, tight junction protein ZO-1, as well as autophagy marker LC3-II, were all reduced after AGE treatment. Moreover, inhibition of miR-34a by transfection with anti-34a in podocytes prevented AGE-induced apoptosis by rescue of Bcl-2 and LC3-II expression.

Conclusions: Our data demonstrated that miR-34a is involved in podocyte injury under diabetic conditions. Inhibition of miR-34a in podocytes attenuates apoptosis induced by AGEs via enhancing expression of Bcl-2 and regulating autophagy. These results indicate that targeting miR-34a might be a potential therapeutic strategy for diabetic nephropathy.

Increased Iron Deposition Is Associated with Decreased α-Klotho and Vitamin D Receptor Expression in the Renal Proximal Tubules in Ob/Ob Mice

*Farid M. Nakhoul,1 Deb Dilip,1 Inbal Dahan,2 Lei Li,1 Yan Chun Li.1
1Dept of Medicine, Biological Sciences Div, Univ of Chicago, IL; 2Diabetic Nephropathy Lab, Baruch Padah Poriya M Cit, Lower Galilee, Israel.

**Background:** Diabetic nephropathy is the most common renal complication of diabetes. Diabetes increases oxidative stress and promotes iron deposition in proximal convolute tubules (PCT) of the kidney, leading to renal damage. Mutations in the *Lept* (ob) gene product lead to severe obesity and type 2 diabetes, and ob/ob mice in BTBR background develop severe diabetic nephropathy. Klotho and vitamin D receptor (VDR) have been shown to be involved in renal protection against diabetic injury. The goal of this study is to assess the relationship between iron deposition and klotho and VDR expression in the kidney of ob/ob mice.

**Methods:** One- and three-month-old ob/ob BTBR mice and ob/+ control mice were studied in parallel. After sacrifice, the kidneys were harvested. The expression of a-klotho, VDR and Cyp27b1 was examined by immunohistochemistry, Western blotting and qRT-PCR, and iron deposition was assessed by staining with Perl’s enhanced with Dab.

**Results:** Compared with ob/+ mice, ob/ob BTBR mice showed increased iron deposition in the PCT and decreased expression of a-klotho, VDR and Cyp27b1 in the renal PCT and kidney lysates.

**Conclusions:** In ob/ob BTBR mice, increased iron deposition in the renal PCT is associated with a decrease in klotho expression, vitamin D hormone synthesis and VDR signaling in the PCT. These changes together contribute to the progression of diabetic renal injury in these mutant mice, and future treatments.

Erythropoietin Protects Endothelial Cells from High Glucose Induced Injury

*Hana Kim,1 Atsushi Kimura,1 Hideki Matsushita,1 Katsutoshi Yamauchi,2 Yuta Kida,1 Takaaki Usami,1 Tetsuaki Ohtsuka,3 Kazuo Fujita.1
1Dept of Laboratory Medicine, Kanazawa Univ, Kanazawa, Japan; 2Div of Infection Control, Kanazawa Univ, Kanazawa, Japan; 3Div of Nephrology, Kanazawa Univ, Kanazawa, Japan; 4Div of Blood Purification, Kanazawa Univ, Kanazawa, Japan.

**Background:** Diabetic nephropathy (DN) is a major complication of diabetes mellitus (DM). The treatment of DN was limited. Insulin resistance (IR) was associated with diabetic complications. The concrete forms of insulin resistance in diabetic renal tissue lacked research. AS160 could regulate the transportation of many transporters including glucose transporters. In kidney, AS160 was found can regulate sodium and water channel protein, while its role on glucose transporters has not been reported. Glucose transporter 4 (GLUT4) has been identified as a common receptor. EPO signaling affect neither cell proliferation nor cell death. However, the regulation of inflammatory and anti-inflammatory balance.

**Results:** Using a mouse model of metabolic syndrome (MTS), we have developed a metabolic syndrome mouse model characterized by non-alcoholic steatohepatitis and atherosclerosis upon high fat diet feeding. These animals show mild renal changes, but don’t progress to moderate DN. Therefore, we investigated whether inducing hypertension on top of metabolic syndrome leads to progression of DN.

**Methods:** We used age-matched chow fed animals as controls. The mice were divided into the following groups: 1) The db/db mice showed increased body weight, blood cholesterol, blood glucose and insulin, as well as glomerulosclerosis, mild hyalinosis and microaneurisms. 2) AS160 and p-AS160, GLUT4 were all mainly expressed in renal tubules. 3) PTN could improve db/db mice systemic insulin resistance and renal tissue injury. The aim of the study was to study the expression of AS160 and GLUT4 in diabetic kidney tissue and correlation between AS160 with GLUT4 and SGLT2/SGLT1. To explore whether PTN could improve renal IR and the possible mechanisms.

**Results:** Compared with db/db mice, db/db mice with PTN intervention as treatment group. The mice were sacrificed at week 8, 12, 16 and 20 and using blood, urine and kidney specimens for the study.

**Conclusions:** The diabetic kidney tissue may have insulin resistance resulted from abnormal glucose transport by AS160 and GLUT4. The NF-kB inhibitor improved kidney insulin resistance may by increasing the expression of p-AS160 and GLUT4.

Hypertension Results in Moderate Diabetic Nephropathy in a Mouse Model of Metabolic Syndrome

*Reinout Sloep,1,2 Ariane van Koppennol,2 Rod Goldschmeding.21 MHR, TNO, Leiden, Netherlands; 2Pathology, UMCU, Utrecht, Netherlands.

**Background:** Diabetic nephropathy (DN) is a major complication in metabolic syndrome/diabetes patients. We have developed a metabolic syndrome mouse model characterized by non-alcoholic steatohepatitis and atherosclerosis upon high fat diet feeding. These animals show mild renal changes, but don’t progress to moderate DN. Therefore, we investigated whether inducing hypertension on top of metabolic syndrome leads to progression of DN.

**Methods:** We used age-matched chow fed animals as controls. The mice were divided into the following groups: 1) The db/db mice showed increased body weight, blood cholesterol, blood glucose and insulin, as well as glomerulosclerosis, mild hyalinosis and microaneurisms. 2) In db/db mice, the expression of p-AS160 and GLUT4 reduced gradually. 4) p-AS160 showed co-expression with part of GLUT4, but no significant co-expression with SGLT2/SGLT1. To explore whether PTN could improve renal IR and the possible mechanisms.

**Results:** The diabetic kidney tissue may have insulin resistance resulted from abnormal glucose transport by AS160 and GLUT4. The NF-kB inhibitor improved kidney insulin resistance may by increasing the expression of p-AS160 and GLUT4.
Autophagy Activation in Proximal Tubular Epithelial Cells in Diabetic Nephropathy Acts as a Renoprotective Role

**Background:** Previous studies revealed that lipotoxicity participated in epithelial-to-mesenchymal transition (EMT) of proximal tubular epithelial cells (PTECs) under diabetic conditions. Based on evidences that autophagy and lipid metabolism are closely related, the aim of the present study was to investigate autophagy under diabetic conditions and its role in lipotoxicity and EMT.

**Methods:** HK-2 cells were cultured in normal (5 mmol/L glucose) and high glucose medium (30 mmol/L glucose). At 6h, 24h, 48h, and 96h, autophagy activity was evaluated by western blot of LC3-II/Beclin1 and p62. Next, the inhibition of autophagy was achieved by chloroquine diphosphate (CQ), 3-methyladenine (3-MA), or Atg5 knockdown using siRNA transfection. Rapamycin, which is a mammalian target of rapamycin (mTOR) receptor specific inhibitor and a known autophagy activator, was used to induce autophagy in HK-2 cells. Lipid accumulation was detected by Oil-Red O staining. EMT was estimated by western blot of vimentin and E-cadherin.

**Results:** In high glucose cultured HK-2 cells, Beclin1 and LC3-II were elevated, while p62 was decreased. These results indicate that autophagy activity was elevated under diabetic conditions. Autophagy deficiency induced by autophagy inhibitors, CQ and 3-MA, or by Atg5 siRNA transfection exacerbated lipid accumulation and EMT. Treatment of rapamycin attenuated high glucose induced lipid accumulation and EMT. The Atg5 silenced counteracted the protective effect of rapamycin.

**Conclusions:** In conclusion, these results demonstrate that autophagy activity in PTECs is elevated under diabetic conditions and the elevated autophagy activity acts as a renoprotective response.

Activation of Toll-Like Receptors Through Fetouin-A Leads to an Inflammatory Response in Podocytes and Exacerbates Palmitic Acid-Induced Cell Death

**Background:** Inflammation participates in the pathogenesis of type 2 diabetes and contributes to diabetic nephropathy (DN). There is growing evidence that chronic elevated free fatty acids (FFAs) contribute to this chronic inflammatory milieu. Studies in pancreatic β-cells suggest that the inflammatory response mediated by FFAs depends on toll-like receptor (TLR) 4 and TLR-4-I receptor (IC-1). The signaling pathways of TLRs and IC-1 involve activation of the transcription factor nuclear factor-κB (NF-κB) which induces a wide range of cytokines/chemokines including monocyte-chemoattractant protein-1 (MCP-1), and IL-1β. Here, we addressed whether fetuin-A together with FFAs leads to an inflammatory response in podocytes and whether this exacerbates palmitic acid-induced podocyte death.

**Methods:** Conditionally immortalized murine podocytes were used. Murine and bovine fetuin-A were used alone or in combination with palmitic acid to complex BSA. MCP-1 was measured by ELISA. Podocyte death was determined by flow cytometry (annexin V and propidium iodide staining).

**Results:** Palmitic acid alone did not, but fetuin-A induced MCP-1 in podocytes and this was further increased by palmitic acid. The MCP-1 release was prevented by CI095 (TLR4 blocker). Feto-in-A or LPBS exacerbated palmitic acid induced podocyte death, and CL1095 as well as the IL-1 receptor antagonist anakinra or an anti IL-1β antibody attenuated cell death.

**Conclusions:** Fetuin A alone and in combination with palmitic acid leads to an inflammatory response in podocytes and promotes palmitic acid induced podocyte death. As inhibition of TLR4 as well as IL-1β prevents these effects, both pathways are promising targets to attenuate the progression of DN.

Renal Functional and Morphological Changes Related to Obesity and Hyperglycemia in Göttingen Minipigs

**Background:** Obesity and diabetes, two major health problems worldwide, both lead to renal functional and morphological changes; with diabetic nephropathy being the leading cause of end-stage renal failure. A large animal model displaying human-like features of obesity-related and diabetic nephropathy would be very valuable to study pathogenesis and effects of new drug candidates on these syndromes. The aim of the present study was to evaluate renal function and morphology in diet-fed obese, atherosclerotic Göttingen minipigs with or without mild diabetes.

**Methods:** Male castrated Göttingen minipigs, aged 8 weeks at study start, were fed normal chow (n=6) or high-fat, high-cholesterol diet (n=16) for 43 weeks. Mild diabetes was induced in 11 pigs after 18 (n=6) and 25 (n=5) weeks of diet-feeding, using streptozotocin (125 mg/kg IV) preceded by nicotinamide (67 mg/kg IV). The study included two cohorts. Parameters of interest were: Body fat percentage (BF) estimated by dual-energy X-ray absorptiometry, inulin clearance (IC), kidney resistive index (RI), plasma fructosamine reflecting plasma glucose (FGA, plasma urea, plasma creatinine (Pc), plasma total cholesterol (TC), urinary protein excretion (protein UPc) and albumin (UAc) adjusted for creatinine. Gluomerulus area and number of nuclei/gluomerulus area were estimated post mortem. Influence of BF, TC and FRA on in vivo kidney function and post mortem kidney changes was evaluated using ANOVA with cohort as fixed covariate. Blood pressure (BP) was positively associated with urea (P<0.01), IC (P<0.05), Gmolerulus area (P<0.01) and UAc (P<0.05) and negatively with PC (P<0.01). FRA was positively associated with UAc (P<0.05) and number of nuclei/gluomerulus area (P<0.05). RI was not associated with BF, TC or FRA.

**Conclusions:** In conclusion, functional and histological renal changes were found in diet-fed obese, atherosclerotic Göttingen minipigs with and without mild diabetes. The changes were associated with obesity and hyperglycemia.

Insulin Sensitivity Before and Six Months After Kidney Transplantation

**Background:** Severe uraemia is a known cause of insulin resistance. We aimed to investigate the effect of kidney transplantation (Tx) on peripheral and central insulin sensitivity.

**Methods:** Nine non-diabetic patients awaiting living related kidney Tx were examined prior to Tx (Pre-Tx) with an oral glucose tolerance test (OGTT) and a 3h hyperinsulinaemic euglycaemic clamp. The clamp was repeated six months after Tx (Post-Tx). Nine age, gender and BMI matched individuals with normal kidney function were examined once with an OGTT and clamp serving as controls (Ctrl). Endogenous glucose production (EGP, N = 6), glucose rate of disappearance (Gd, N = 6) and lipolysis (glycerol rate of appearance, N = 5) were measured in a subgroup of patients with corresponding controls using stable isotope tracer technique. Results are in mean mmol/kg/min [95% confidence interval] during the clamp.

**Results:** Two patients had pre-Tx prediabetes whereas all other had both normal fasting plasma glucose and normal glucose tolerance. The amount of glucose utilized during clamp was non-significantly lower in patients before Tx (Pre-Tx: 15.1 [11.2–19.0], Ctrl: 20.2 [13.4–27.0], P = 0.17) but significantly reduced after Tx (Post-Tx: 9.8 [6.7–12.9], P = 0.01). The suppression of EGP were comparable before Tx (Pre-Tx: 7.0 [5.4–8.5], Ctrl: 7.0 [3.1–12.7], P = 0.99) but was significantly improved after Tx (Post-Tx: 9.4 [7.8–11.1], P = 0.04). Gd were comparable both prior to and after Tx (Pre-Tx: 18.1 [13.6–22.5], Ctrl: 22.3 [15.1–29.5], Post-Tx: 17.1 [13.4–20.8], P = 0.22). The suppression of glycerol rate of appearance were comparable before Tx (Pre-Tx: 11.0 [9.1–14.1], Ctrl: 11.6 [8.3–21.1], P = 0.96) but significantly improved after Tx (Post-Tx: 2.0 [1.0–3.8], P = 0.04).

**Conclusions:** The reduced insulin sensitivity after kidney Tx is characterized by a impaired suppression of lipolysis and comparable peripheral insulin sensitivity.

**Funding:** Private Foundation Support
IL-1β stimulation. Interestingly, most IL-1β immunoreactivity is localized to endothelial cells and interstitial macrophages in an animal model of cardiac hypertrophy. However, the potential role of IL-1β in high glucose induced EndMT remains unknown. Here, we hypothesize that IL-1β might mediate the process.

Methods: Primary human aortic endothelial cells (HAECs) were divided into three groups: normal glucose (NG) group, HG group, and anti-interleukin1β (HG) treated group. The concentration of IL-1β in the supernatant was detected by Elisa. Pathological changes were investigated using fluorescent microscopy and electron microscopy. Immunofluorescent staining was performed to detect the co-expression of CD31 and FSP1. The expressions of FSP1 and a-SMA were significantly increased in the microfilamentation and a roughened endoplasmic reticulum structure were observed in the HG group. These changes were inhibited by anti interleukin1 antibody or IL-1β neutralizing antibody treatment.

Results: The treatment of HAECs in the HG group resulted in significant increases in the expressions of FSP1, a SMA, and IL-1β in dose-and time-dependent manners. The incubation of HAECs with IL-1β stimulation.Interestingly, most IL-1β immunoreactivity is localized to endothelial cells. Furthermore, IL-1β treatment (P < 0.05). Double staining of the HAECs indicated a colocalization of CD31 and FSP1, while treatment with anti-interleukin1 antibody or HG-1 group significantly increased in the HG group. and these changes were inhibited by anti interleukin1 antibodly or HG-1 group. These findings suggest that IL-1β mediates the HG induced EndMT, which was inhibited by anti interleukin1 antibodly or HG-1 group. RNA silencing treatment.

Conclusions: We observed marked variability in treatment pattern between the countries (use of metformin 26-74, RAS blocking agents 59-77, beta-blockers 28-99, statins 21-81%).

Conclusions: We conclude that health care practices in patients with type 2 diabetes at the primary level of care vary widely between European countries. Whether these differences affect outcome remains to be established.

**Serum Bilirubin and Asparagine Aminotransferase Concentrations Predict Loss of Renal Function in Type 2 Diabetes**

Kevin M. Wheelock,1 Guđeta D. Fufaa,2 Geert Hillyard,3 D. Fufaa,2 Beata Czerwienska,4 Andrzej Wiecek,5 Madhumita Sinha,6 Laszlo Rosivall,7 Hiddo Jan Lambers1 and Dick de Zeeuw6

Background: Higher serum bilirubin concentration is reported to slow the progression of nephropathy in type 2 diabetes. We examined associations of serum bilirubin and asparagine aminotransferase (AST) concentrations with renal function loss (RFL) in a post-hoc analysis of a clinical trial of renoprotection with losartan in Pima Indians with type 2 diabetes (ClinicalTrials.gov, number NCT00340678).

Methods: Serum bilirubin and AST were measured at baseline in 168 subjects who underwent annual measurement of GFR by the urinary clearance of iothalamate. RFL was defined by ≥40% decline in GFR from baseline. Cox regression was used to compute hazard ratios (HRs) for the association of a 1 standard deviation (SD) increment in bilirubin and AST concentrations with RFL adjusted for age, sex, treatment group, Hba1c, GFR, and urinary albumin/creatinine ratio (ACR). The sum of standardized AST and bilirubin was standardized to create a liver index variable with mean=0, SD=1.

Results: Participants (73% female, mean age 42±11 years, bilirubin 0.6-0.2 mg/dL, Hba1c 9.3±2.2%, GFR 103.6±3.9 ml/min, and blood pressure 19.1±1.5 U/L) were followed for 7.0 years (IQR=4.9-9.9 years); 73% subjects (43%) developed RFL after multivariate adjustment, serum bilirubin (P=0.001) and AST (P=0.01) were independent risk factors for increasing the liver index (HR=1.33) and serum AST (HR=1.39) predicted RFL. The combination of these liver function tests provided the strongest prediction (HR=1.52).

**Baseline Data from the Multinational Prospective Cohort Study in Patients with Type 2 Diabetes for Validation of Biomarkers (PROVALID)**

Gert J. Magee,1 Susanne Eder,1 Laszlo Rosivall,2 Peter Voros,2 Hiddo Jan Lambers3 Heerspink,3 Dick de Zeeuw,4 Beata Czerwienska,4 Andrzej Wiecek,5 Dianne Z. Gert6 Williams,6 Patrick B. Mark,6 Georg Heinze6 and Peter Rosing,6

**Background:** In an international cross-sectional cohort study of patients with type 2 diabetes we included all eligible type 2 diabetic patients (67 males, 30% females, mean age 59±9 years and CKD stage 2-3). We used descriptive statistics, the Student’s t-test, and the chi-square test.

**Methods:** In a cross-sectional study we included all eligible type 2 diabetic patients with CKD stages 2-4, followed in our outpatient Diabetic Kidney Clinic. We included 150 patients, 5±3 years, with a mean age of 66.6±9.7 years (40-85) and a mean follow-up of 76 months. We used descriptive statistics, the Student’s t-test, and the Chi-square test. We divided our population according to the urine albumin-to-creatinine ratio (G1≤30-300 mg/g and G2≥300 mg/g) and compared these groups regarding the several biological and laboratory parameters analyzed. We employed a multiple regression model to identify risk factors of increased urine albumin-to-creatinine ratio. In this model we used the urine albumin-to-creatinine ratio as the dependent variable and as independent ones age, duration of diabetes, systolic blood pressure, Hba1c, eGFR, HOMA-IR, malonatehyde, hs-CRP and 1,25(OH)2D3 levels.

**Results:** We observed marked variability in treatment pattern between the countries (use of metformin 49-74, RAS blocking agents 59-77, beta-blockers 28-99, statins 21-81%).

**Conclusions:** We conclude that health care practices in patients with type 2 diabetes at the primary level of care vary widely between European countries. Whether these differences affect outcome remains to be established.

### PUB298

**FGF-23 and Magnesium Are Independent Risk Factors for an Increased Albumin-to-Creatinine Ratio in Type 2 Diabetics with Chronic Kidney Disease**

Ana Paula Silva,1,2 Filipa Brito Mendes,1,2 André Fragoso,1 Nélio Santos,1 Teresa M. Jeronimo,1 Ana Pocinho Pimentel,1 Pedro L. Neves,1,2 Centro Hospitalar do Algarve- Hospital de Faro, Portugal;1,2 Univ do Algarve, Portugal.

**Background:** Microalbuminuria is the earliest sign of glomerular involvement in diabetes mellitus. The multiple pathological mechanisms involved are complex and not completely understood. Recently, it appeared that fibroblast growth factor-23 (FGF-23) and magnesium play a role in the emergence and maintenance of albuminuria in type 2 diabetes. The aim of this study is to investigate the role of FGF-23 and magnesium in relation to the urine albumin-to-creatinine ratio in type 2 diabetics with chronic kidney disease (CKD) stages 2-4.

**Methods:** In a cross-sectional study we included all eligible type 2 diabetic patients with CKD stages 2-4, followed in our outpatient Diabetic Kidney Clinic. We included 150 patients, 5±3 years, with a mean age of 66.6±9.7 years (40-85) and a mean follow-up of 76 months. We used descriptive statistics, the Student’s t-test, and the chi-square test. We divided our population according to the urine albumin-to-creatinine ratio (G1=30-300 mg/g and G2≥300 mg/g) and compared these groups regarding the several biological and laboratory parameters analyzed. We employed a multiple regression model to identify risk factors of increased urine albumin-to-creatinine ratio. In this model we used the urine albumin-to-creatinine ratio as the dependent variable and as independent ones age, duration of diabetes, systolic blood pressure, Hba1c, eGFR, HOMA-IR, malonatehyde, hs-CRP and 1,25(OH)2D3 levels.

**Results:** We observed marked variability in treatment pattern between the countries (use of metformin 49-74, RAS blocking agents 59-77, beta-blockers 28-99, statins 21-81%).

**Conclusions:** We conclude that health care practices in patients with type 2 diabetes at the primary level of care vary widely between European countries. Whether these differences affect outcome remains to be established.

**Funding:** Pharmaceutical Company Support - abbvie; North Chicago, Illinois, USA, Government Support - Non-U.S.
Results: We found that G2 patients showed higher age (p=0.017), phosphorus (p=0.001), IPTH (p=0.0001), urine albumin-to-creatinine ratio (p=0.001), Home-IR (p=0.001), FGF-23 (p=0.0001) and OxoLDL (p=0.0001) and lower levels of eGFR (p=0.0001), Klotho (p=0.0001) and 1.25(OH)2D3 (p=0.0001). In the multivariate linear regression model we found that FGF-23 (β=0.377, P=0.047) and the Klotho (β= -0.567, p<0.02) are independent risk factors for increasing the pulse pressure.

Conclusions: In conclusion, in a population of type 2 diabetic with chronic kidney disease stages 2-3, the Klotho and FGF-23 levels are independently associated with PP. Further studies with more patients are warranted to confirm whether an increase in Klotho and a decrease in FGF-23 would reduce the PP and consequently the cardiovascular risk of our patients.

**Prediction of Renal Outcome in Type 2 Diabetic Dephropathy by Estimating GFR from a Combination of Serum Creatinine and Cystatin C**

**Yu Pan, Song Jiang, Dandan Qiu, Yu An, Yongchun Ge, Honglang Xie, Zhihong Liu. National Clinical Research Center of Kidney Diseases, Research Inst of Nephrology, Jinling Hospital, Nanjing, Jiangsu, China.**

**Background:** Serum cystatin C is an alternative to serum creatinine for estimating glomerular filtration rate (GFR), however, the utility of estimated GFR from combination of serum creatinine and cystatin C as maker to predict long-term renal outcome is uncertain, particularly in the Type 2 diabetic nephropathy (DN).

**Methods:** A total of 501 patients (The National Clinical Research Center of Kidney Disease, 2003-2011) were recruited in prospective cohort study. Follow-up was 5-year. Renal outcome was defined by eGFRcre-cys<15 ml/min per 1.73m2 or renal replacement therapy.

**Results:** The distributions of standardized serum cystatin C with eGFRcre and eGFRcre-cys are shown in Kaplan-Meier curves showed significantly increased renal end points with higher quartile of cystatin C (p <0.001) and lower eGFRcre-cys (p <0.001). The highest AUCs was eGFRcre-cys in predicting the renal endpoint compared with eGFRcre or eGFRcre-cys. The best cut-off value for predicting the renal endpoint was 29.28% decline in the 24-month, which value showed 79.6% sensitivity and 82.6% specificity. Cox regression models with restricted cubic splines were shown a change of -30% in eGFRcre-cys was associated with adjusted HRs for ESRD of 27.92 (95%CI, 3.95-197.48) over 2-year.

**Conclusions:** eGFRcre-cys was a precision, and accuracy marker in the predicting of the renal outcome and 30% decline of eGFRcre-cys over 2 years was strongly associated with the risk of ESRD, suggesting it could be used as an alternative endpoint in T2DN.

**Prevalence and Prognostic Role of Uncontrolled Risk Factors in Diabetic CKD (DM-CKD) Treated in Nephrology Clinics**

**Roberto Minutolo,1 Michele Provenzano,1 Paolo Chioldi,2 Giuseppe Conte,2 Luca De Nicola,3 Nephrology, Second Univ, Naples, Italy; 2Med Stat, Second Univ, Naples, Italy.**

**Background:** Knowledge of prognosis of DM-CKD mainly derives from RCTs and cohorts followed in the diabetology setting. Epidemiologic features are less defined in patients with overt disease managed in renal clinics.

**Methods:** We studied 763 DM-CKD patients derived from 3 prospective cohorts that in 2000-2010 enrolled 2,488 CKD patients stage III-V under stable care from ≥6 months in 403 renal clinics. Endpoints were ESRD (chronic dialysis-transplant) and first major cardiovascular (CV) events (fatal and non fatal) assessed through 12/2014. Uncontrolled risk factors were defined as high blood pressure (BP>140/90 or >130/80 if proteinuria >0.150 g/24h), Hba1c>7.5%, hemoglobin<10.5 g/dL, BP 142±19/78±10 mmHg, Proteinuria (Uprot) >0.5 g/24h, Hemoglobin A1c>7.5%, HDL<1.7 g/dL and BP 142±19/78±10 mmHg. During follow-up (43 months, IQR 21-56), 171 ESRD and 170 CV events occurred (incidence rate 6.4 and 6.9/100 patients/year). Multivariable Cox analyses for ESRD and CV risks (HR, 95% CI) stratified by cohort are in the Table.

**Serum NGAL and Cystatin C Accuracy in Early Detection of Kidney Dysfunction in Type 2 Diabetes**

**Michele Provenzano,1 Marco Miyazaki,2 Gen Yamada,3 Tsune Yamamoto,4 Hiroshi Sato,5 Masaaki Nakayama,6 Sadayoshi Ito,7 Nephrology, Hypertension, and Endocrinology, Tohoku Univ Department of Pharmacology, Sendai, Miyagi, Japan; 2Clinical Pharmacology and Therapeutics, Graduate School of Pharmaceutical Sciences, Tohoku Univ, Sendai, Japan; 3Kidney and Hypertension, Fukushima Medical Univ, Fukushima, Japan.**

**Background:** Diabetic nephropathy (DN) is defined as chronic kidney disease (CKD) due to diabetes mellitus (DM) in a narrow sense. The difference is not unclear between DN and CKD patients of other cause but complicated DM (CKD with DM) in clinical outcome. This study mentioned the clinical difference and renal outcome of DN, CKD with DM, and CKD without DM. Finally, with worse eGFR, sNGAL, sCYS and ACR performed better in diabetics. A worse glycemic control was positively associated with sCYS and sNGAL.

**Methods:** This is a part of Gongyo CKD study. It is the multicenter prospective observational survey for 5 years. From May 2006, 4,015 patients were registered. We include 2,484 of them into this analysis who could classify to DN (n=249), CKD with DM (n=448), and CKD without DM (n=1,787). The classification was performed at registration by clinical finding and history of other diabetic complication such as retinopathy if case without kidney biopsy.

**Results:** The characteristics of age, gender, systolic blood pressure (SBP), and dyslipidemia in “DN” (66.6 y.o., male 56.7%, SBP 136 mmHg; dyslipidemia 50.1%) and “CKD with DM” (58.7 y.o., male 58.7%, SBP 132 mmHg; dyslipidemia 54.4%) were similar compared with “CKD without DM” (50.5 y.o., male 50.5%, 128 mmHg, 40.1%). For renal outcome analysis of each CKD stage was performed. The hazard ratio of “DN” was significantly higher than “CKD without DM” for end stage kidney disease (ESKD) in G3b 7.10(2.46-20.49 95% CI), G4 2.31(1.35-3.94), G5 1.67(1.16-2.42). On the other hand, that of “CKD with DM” didn’t elevate in G3b 0.89(1.9-24.49 95% CI), G4 1.21(0.66-2.23), G5 1.36(0.74-2.51) compared with “CKD without DM”. Kaplan-Meier analysis revealed G3b and G4 in “DN” showed significantly poor outcome. The evaluation of annual decline of eGFR revealed stage G3b in DM was the largest. (~3.7 ml/min/1.73m²/year).

**Conclusions:** Renal risk between “CKD with DM” and “DN” was completely different. G3b was most important critical point in renal prognosis of DN.

Background: Obesity is associated with proteinuria. But the exact prevalence of proteinuria or albuminuria with and without additional risk factors in obese patients is unclear.

Methods: Consecutive patients undergoing bariatric surgery were included in study. Participating patients had a urine sample for protein creatinine ratio and albumin creatinine ratio prior to their surgery. We defined a positive protein to creatinine ratio as greater than or equal 300 mg and a positive albumin to creatinine ratio as greater than or equal to 30 mg. Associated factors such diabetes mellitus (DM), hypertension (HTN), body mass index (BMI), and ACEI/ARB use were indexed.

Results: One hundred forty-five patients were included. The mean age was 43 years (+/-11. Twenty five percent of the patients had DM, 50% had HTN, and the mean BMI was 44 (74). The prevalence of proteinuria and albuminuria in these patients was 8.5% (95% CI 4.5-14.4%) and 21% (95% CI 13-30%) respectively. Sixty six percent of the patients with proteinuria had DM as did 43% of the patients with albuminuria. Eighty three percent of patients with proteinuria had either DM or HTN. Seventy eight percent of patients with albuminuria had either DM or HTN. Of renal blood with neither type 1 diabetes (T1D) nor diabetes, only 3.4% and 8.6% had proteinuria and albuminuria respectively. In contrast to patients who did not have proteinuria, the mean BMI was higher in those with proteinuria (44 vs. 40). However, the BMI did not differ between those with and without albuminuria. The BMI for diabetics did differ from non-diabetics. The use of ACEI/ARB was 33% and 30% in patients with proteinuria and albuminuria and 25% and 20% in those without.

Conclusions: The majority of patients with proteinuria and albuminuria had diabetes and/or hypertension and there was a much lower prevalence of proteinuria/albuminuria in patients without these risk factors. Patients who had proteinuria had a higher BMI than patients who did not have proteinuria, though for albuminuria the BMI did not differ.

Plasma Uric Acid and Cardiac-Renal Function in Adolescents with Type 1 Diabetes. Yaliya Lytvyn, 1 Farid H. Mahmud, 2 Livia Dedu, 3 David B. Dunger, 1 John Eric Deanfield, 1 Yesmino Elia, 1 Ronnie Lok-Hang Har, 1 Timothy J. Bradley, 1 Rahim Moineeddin, 1 Heather N. Reich, 1 James W. Scholay, 1 Luc Mertens, 1 Etienne Bertrand Sochett, 2 David Chemey, 1 Nephrology, Univ Health Network, Univ of Toronto; 2 Endocrinology, The Hospital for Sick Children, Univ of Toronto; 3 Pediatrics, Univ of Cambridge, Cambridge, United Kingdom; 4 Cardiology, The Hospital for Sick Children, Univ of Toronto; 5 Family and Community Medicine, Univ of Toronto.

Background: Plasma uric acid (PUA) correlates with higher blood pressure (BP), lower GFR and larger carotid-femoral pulse wave velocity (Car-Fem PWV) in adults with type 1 diabetes (T1D). Our overall aim was to determine if similar relationships exist in adolescents with T1D, analyzed on the basis of low-, middle- or high-albumin to creatinine ratio (ACR) tertile within the normal range, compared to healthy controls (HC). We hypothesized that PUA within the normal range would correlate better with lower GFR and higher values for BP and arterial stiffness in T1D adolescents but not HC.

Methods: PUA, BP, GFR, Car-Fem PWV and carotid-femoral pulse wave velocity (Car-Fem PWV) were measured in 65 HC, 64 low-, 74 middle- and 50 high-tertile T1D participants from the Consecutive patients Type 1 Diabetes Cardiac-Renal Intervention Trial (ADIRIT). The prevalence of proteinuria and albuminuria was 8.5% (95% CI 4.5-14.4%) and 21% (95% CI 13-30%) respectively. Sixty six percent of the patients with proteinuria had DM as did 43% of the patients with albuminuria. Eighty three percent of patients with proteinuria had either DM or HTN. Seventy eight percent of patients with albuminuria had either DM or HTN. Of renal blood with neither type 1 diabetes (T1D) nor diabetes, only 3.4% and 8.6% had proteinuria and albuminuria respectively. In contrast to patients who did not have proteinuria, the mean BMI was higher in those with proteinuria (44 vs. 40). However, the BMI did not differ between those with and without albuminuria. The BMI for diabetics did differ from non-diabetics. The use of ACEI/ARB was 33% and 30% in patients with proteinuria and albuminuria and 25% and 20% in those without.

Conclusions: The majority of patients with proteinuria and albuminuria had diabetes and/or hypertension and there was a much lower prevalence of proteinuria/albuminuria in patients without these risk factors. Patients who had proteinuria had a higher BMI than patients who did not have proteinuria, though for albuminuria the BMI did not differ.

The Effect of Carbohydrate – Blood Glucose Feedback Loop with Basic Carbohydrate Counting for Glycemic Control in Diabetic Patients. Tety Hyouko, DIALYSIS Center, Eijin Clinic and Kurata Hospital, Hirotsuka, Kanagawa, Japan.

Background: Basic carbohydrate counting (BCC), a method used in the dietary management of diabetic patients, is based on the concept that the postprandial rise in blood glucose levels is primarily affected by ingested carbohydrates. In this method, patients are instructed to eat a consistent amount of carbohydrates across their three daily meals to minimize fluctuations in postprandial blood glucose levels. We applied the carbohydrate blood glucose feedback method (CBBFM) with BCC for the diabetic dialysis patient whose HbA1c did not keep to the target. Here we compare the prediabetes blood glucose and show the results to patients in every dialysis session. Patients can estimate their carbohydrate intake balance and doses. The effect of CBBFM with BCC is reported in this study.

Results: Eight diabetic patients undergoing maintenance hemodialysis (6 men and 2 women; mean age, 64.4±11.9 years; mean dialysis period, 4.0±5.0 years; 2 insulin users, 6 nonusers) were instructed in CBBFM with BCC and followed for 3 months to assess changes in their prediabetes blood glucose (BG), hemoglobin A1c (HbA1c), Hemoglobin (Hb), triglycerides (TG), Potassium (K), Phosphorus (P), albumin (Alb), total cholesterol (T-Cho), high-density lipoprotein-Chol (HDL-Chol), low-density lipoprotein-Chol (LDL-Chol), protein catabolic rate (PCR), dry weight (DW), body mass index (BMI), and the Geriatric Nutritional Risk Index (GNRI).

Conclusions: HbA1c levels were significantly decreased from the pre-instruction values (P<0.0054). The GA and BG showed the tendency toward decrease, but no marked changes were observed for the other parameters. Pre BG: 173.1±50.9 mg/dL. Pre HbA1c: 7.0±0.4 7% Pre GA: 19.2±4.5. 3 MBG: 131.5±29.5 (P=0.0066), 3 MBH: 61.6±0.6 (P=0.0054), 3 MA: 17.7±2.3 (P=0.111).

The Clinical Effects of Renoprotection with DPP-4 Inhibitors. Koichi Kanazawa, Saeko Sato, Yoshimi Okada, Hiroaki Hara, Minoru Hatanou, Nobuko Onizawa, Takatsuki Iwashita, Tomonori Ogawa, Hajime Hasegawa. Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Saitama, Japan.

Background: Recently, not only animal models of diabetic nephropathy, but also non-diabetic nephropathy models, DPP-4 inhibitors (DPP-4i) are reported to have the renoprotective effects that improve albuminuria or tissue damage, through inhibition of oxidative stress, inflammation, and fibrosis. The aim of study is to clarify the mechanisms of renoprotective effect by DPP-4i in patients with diabetic nephropathy (DMN), clinically.

Methods: We gave DPP-4i (either of vildagliptin 50-100mg, alogliptin 25mg, teneligliptin 20-40mg) for Japanese Type 2 diabetes patients with nephropathy. We compared surrogate marker of oxidative stressandrenal injury, before and after three months. Patients can estimate their carbohydrate intake balance and doses. The effect of CBGFM with BCC is a useful method of dietary management for glycemic control that can be applied independently of, but concurrently with, the control of potassium and phosphorus intake in dietary therapy for dialysis patients.

The Clinical Effects of Renoprotection with DPP-4 Inhibitors. Koichi Kanazawa, Saeko Sato, Yoshimi Okada, Hiroaki Hara, Minoru Hatanou, Nobuko Onizawa, Takatsuki Iwashita, Tomonori Ogawa, Hajime Hasegawa. Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Saitama, Japan.

Background: Recently, not only animal models of diabetic nephropathy, but also non-diabetic nephropathy models, DPP-4 inhibitors (DPP-4i) are reported to have the renoprotective effects that improve albuminuria or tissue damage, through inhibition of oxidative stress, inflammation, and fibrosis. The aim of study is to clarify the mechanisms of renoprotective effect by DPP-4i in patients with diabetic nephropathy (DMN), clinically.
Conclusions: In DMN, DPP-4i have oxidative stress relief and renoprotective effect, by the improvement of short-term blood sugar fluctuations, also by oxidative stress reduction which independently of the improving glycemic control.

PUB309

Background: To evaluate the potential of fibrinogen as a predictor of the progress of proteinuria in diabetic kidney disease.

Methods: For a Cross-Sectional Study, collecting 1121 type 2 diabetes patients without or with microalbuminuria or massive proteinuria were treated during January 2008 to January 2013. Proteinuria was negative in 755 cases, 285 cases i with microalbuminuria, and 181 cases with massive proteinuria. We analyzed the correlation factors of the negative protein urine group and the microalbuminuria group; the correlation factors of the microalbuminuria group and the massive proteinuria group. Fibrinogen levels were compared between three groups.

Results: Retinopathy, hypertension grading, SBP, Fibrinogen levels, serum albumin, serum creatin were the related progress factors of Microalbuminuria; Diabetes course, retinopathy, waist to hip ratio, Fibrinogen levels, serum albumin levels, serum creatin C, serum creatinine were the related progress factors of the massive proteinuria; Except fibrinogen, other factors had been known relating to the progress of diabetic kidney disease. There were differences in the levels of three groups of fibrinogen (P < 0.05), which were 3.43 + 0.91 g/l, 4.15 + 1.31 g/l, 5.16 + 1.44 g/l.

Conclusions: Fibrinogen was a potential predictive factor for the development of diabetic kidney disease. The conclusion needs to be confirmed by further study.

PUB310
Interaction of HDLc, Iron, and Diabetes on Kidney Function. Banjivah Conway, Tina Costacou, John M. Arthur. Epidemiology, West Virginia Univ; Epidemiology, Univ of Pittsburgh; Univ for Medical Sciences.

Background: The effect of HDL cholesterol (HDLc) on kidney function has recently received increased attention, partly due to the finding of increased hemoglobin (hb) inside of the HDL protein in persons with high risk haploglubin (hp) genotypes. Such hb w/ in the HDL protein may lead to iron induced lipid peroxidation products. These lipid peroxidation products may lead to iron-induced kidney damage. We have previously shown an interaction between HDLc and iron w/ kidney function (eGFR) in persons with diabetes such that after controlling for hb, higher serum iron levels were associated w/ reduced eGFR but only in those w/ HDLc levels above the median for the population. Because of the diabetes-specific association of increased hb inside the HDL protein in those w/ high risk hp genotypes, we hypothesize that this interaction between HDLc and iron w/ kidney function varies by diabetes status. To test this hypothesis, we examined the inter-relationship between HDLc, iron, and diabetes status w/ eGFR in approximately 55,000 individuals in West Virginia and Ohio.

Methods: Data on adults aged ≥20 years were obtained from the C8 Health Project. Fibrinogen was a potential predictive factor for the development of diabetic kidney disease. We have recently shown an interaction between HDLc and iron w/ kidney function (eGFR) in persons with diabetes such that after controlling for hb, higher serum iron levels were associated w/ reduced eGFR but only in those w/ HDLc levels above the median for the population. Because of the diabetes-specific association of increased hb inside the HDL protein in those w/ high risk hp genotypes, we hypothesize that this interaction between HDLc and iron w/ kidney function varies by diabetes status. To test this hypothesis, we examined the inter-relationship between HDLc, iron, and diabetes status w/ eGFR in approximately 55,000 individuals in West Virginia and Ohio.

Results: Mean age was 57.8 in those w/ diabetes and 45.1 in those w/out diabetes. In multivariable analyses controlling for age and sex, iron was positive related w/ eGFR in those w/ (p=0.03) and inversely in those w/out diabetes (<0.0001), while HDLc was positively associated w/ eGFR only in those w/out diabetes (p=0.97 in diabetes; p<0.001 in those w/o diabetes). As previously reported, an interaction existed between HDLc and iron w/ kidney function (p=0.001). Hence we report that this relationship was even stronger in those w/ diabetes (interaction p=0.0008). A significant 3-way interaction existed between HDLc, iron, and diabetes status w/ eGFR (p=0.008). Controlling for hb, the interaction between iron and HDLc disappeared in those w/ diabetes but remained robust in those w/out diabetes.

Conclusions: The divergent relationship between iron and HDL on the eGFR by diabetes status needs further investigation.

PUB311
Molecular-Selective Plasma Exchange in Acute Kidney Injury due to Multiple Myeloma. Mamoru Kanda, Satoko Tanada, Shinya Mizuno, Shu Yamakage, Mitsuhiro Sato, Yoshio Taguma, Toshinobu Sato. Nephrology, Japan Community Health Care Organization Sendai Hospital; Sendai, Miyagi, Japan.

Background: Benefit of plasma exchange in overall survival of patients with multiple myeloma (MM) remains to be determined, however, it is evident that lowering free light chain (FLC) reverses renal function in acute kidney injury (AKI) due to MM. High cut-off hemodialysis is recommended to remove FLC as an initial treatment for MM related AKI, which is different from traditional plasma exchange (PE) in eliminating loss of large size molecules. As another option, we show the effect of molecular-selective plasma exchange to remove FLC, which enables target size removal without losing other size molecules.

Methods: A 49 year male with Bence-Jones type M protein was admitted with AKI; serum creatinine rose from 3.8 to 7.9mg/dL in 1 month. Past history included bone fracture and anemia. Serum FLC lambda was elevated to 29800 mg/dL. MM was confirmed by plasma cells in the bone marrow. The patient was treated with sequential molecular-selective plasma exchange (Evacute) and on-line HDF every other day combined with Bortezomb.

Conclusions: Fibrinogen was a potential predictive factor for the development of diabetic kidney disease. The conclusion needs to be confirmed by further study.

Results: PE was performed 6 times and removed 43.1% of FLC each on average without losing small and large size molecules.

On-line HDF removed 11.6% on average. Few, if any, rebounds were found in the FLC concentration between the treatments. Serum FLC level decreased to 411mg/dL after a series of treatments (day 14) and serum creatinine reversed to 2.7mg/dL at day 21.

Conclusions: A molecular-selective plasma separator is designed to limit the loss of high molecular weight substances. Using this machine, FLC can be removed effectively while preserving large size molecules. Moreover, the use of plasma substitute fluid can be reduced compared to that of conventional PE. We conclude that molecular-selective plasma exchange could be an effective treatment option for MM associated AKI.

PUB312
Preliminary Evaluation of a New CRRT Machine: Kibou™. Mauro Neri, Francesco Garzotto, Anna Lorenzin, Silvia Guggia, Alessandra Brendolan, Federico Nalesso, Monica Zanella, Claudio Ronco. IRRIV and San Bartolo Hospital, Vicenza, Italy.

Background: Kibou™ (Asahi Kasei Medical Co., Tokyo, Japan) is a new multifunctional automatic machine for Continuous Renal Replacement Therapy (CRRT) system (figure 1).

Methods: Based on the traditional experience of International Renal Research Institute of Vicenza (IRRIV), in vitro and in vivo test evaluations of Kibou and related disposables have been performed different CRRT therapies with the possibility to use only a single platform in particular, modalities for both adults and pediatrics, counter-current and co-current configuration, the use of heparin or citrate-calcium anticoagulation therapies and plasma exchange can be delivered (figure 1).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
been conducted. 12 treatments were performed. Machine’s usability and accuracy has been evaluated by the staff through scores table. The measurement of fluid balance accuracy was even performed.

Results: Based on score given by the staff (engineers, nurses and physicians), the machine hardware results compact and well organized, with 3 well separated compartments (dialyzer replacement, blood and effluent) that facilitate the preparation phase. Auto-priming function allows short priming time at the interface is user friendly in all the modalities (SCUF, CVVH, CVVHDF, TPE both for adults and pediatrics). The measured fluid balance error was always lower than 0.3%. On the contrary CVVHDF pre-infusion and pre-perfusion are not performable. For pediatric treatment the continuity of the flow of blood pump need to be maintained and improved.

Conclusions: Kibou is a promising CRRT machine that can perform multiple continuous therapies with just one platform. In particular, we evaluated a highly accurate gravimetric fluid balance control system and a user friendly interface. Kibou is one of the first machines of the new frontier of CRRT devices: the fourth generation of CRRT machines.

PUB313
The Effect of MySleeve on Fluid Restriction Adherence in Hemodialysis Patients
Ida Pei,1,2 Jelena Milosavljevic,1,2 Maja Potocnik,2 Jureon Kooman,2 Erik Korsten,1 Wei Chen,1 Constantijn Konings,2 Loes M. Feijs,1 Industrial Design, Technologie Univ Eindhoven, Eindhoven, Netherlands; 2Medicine, Div of Nephrology, Catharina Hospital Eindhoven, Eindhoven, Netherlands; 3Medicine, Div of Nephrology, Maastricht Univ Medical Center; Maastricht, Netherlands.

Background: In hemodialysis patients, non-adherence to fluid restriction is associated with high interdialytic weight gain (IDWG) and adverse outcomes. Monitoring drinking behaviour and direct feedback to the patient can lead to better adherence. We developed the MySleeve, a device that can be wrapped around a drinking glass to monitor fluid intake throughout the day. The MySleeve will also provide a subjective vibration on the glass when the amount drunk exceeds target. The information about drinking behaviour can be found in the accompanying application on a mobile phone. In this study, we investigate the effect of direct feedback and information to the patient on fluid restriction adherence measured by the IDWG.

Methods: We will include 40 prevalent, anuric hemodialysis patients from the Catharina Hospital Eindhoven, The Netherlands in a randomised controlled trial. Patients in the intervention group are provided a MySleeve device, a mobile phone and an activity tracker. BCM measurements are performed weekly and IDWG will be calculated before every dialysis session. The patients in the control group will continue with regular hemodialysis.

Results: We expect that by providing patients insight in fluid intake, there will be an increased fluid restriction adherence and an increase in activity levels and better quality of sleep. Due to less IDWG, patients will experience less discomfort of fluid overload.

Conclusions: Introducing a MySleeve device to provide direct insight into drinking behavior will help the patients to adhere to their fluid restriction, leading to less IDWG and better quality of life measured by daily activity and better sleep.

A Time and Motion Study of Erythropoiesis Stimulating Agent Prescription and Use in Central Eastern Europe – ANREG Final Analysis
Igor Rus,1 Kinga Jedynas,1 Jacek Jerzywicz,1 Alena Patrikova,2 Alexander Selyutin,3 Botond Csiky,4 Jaroslav Rosenberg,4 Igor Rus,1 Kinga Jedynas,1 1Dept of Nephrology/ENDO, MSW Hospital, Katowice, Poland; 2Dept of Nephrology, Inst for Clinical and Experimental Medicine, Prague, Czech Republic; 3B Braun Avitum, Orenburg, Russian Federation; 4FMC Dialysis Center, Pécs, Hungary; 5Nephrology and Dialysis Center Fresenius, Kosice, Slovakia (Slovak Republic); 6Dept of Hemodialysis/Nephrology, General Hospital Jesenice, Jesenice, Slovenia; 7CEE Headoffice, Amgen GmbH, Vienna, Austria.

Background: This study observed anemia treatment patterns in HD patients (pts) treated with darbepoeitin alfa (DA) in clinical practice in CEE.

Methods: Multicenter observational study in HD pts treated with DA. From 2007 to 2014, 14 cohorts were observed for 6 months (mo) each. Primary outcome: pts maintaining an average Hb at >11 (cohorts 1/2 enrolled prior to label change in 02/2008) or 10-12 g/dL (cohorts 3-12) during mo 4-6. Secondary: conversion versus de novo pts, Hb trends, ESA and iron use, adverse drug reactions (ADR).

Results: Of 2923 enrolled pts (n=1101 de novo, n=1822 converted from other ESAs), 2647 (91%) completed 6 mo of DA, 276 (9%) discontinued (155 [5%] due to death). At baseline (BL) 83% received iron.

The median DA dose was 10.6 mcg/wk at 1 mo and 6 mo. Approx 75% received DA i.v. and once weekly (84% at 1 mo, 75% at mo 6). 12 ADR were reported (8 serious, 3 fatal: intracranial hemorrhage; myocardial infarction, death).

Conclusions: Hb increased substantially in de novo and conversion pts after DA initiation; >60% reached target by mo 4-6 with some variation between countries.

Diyutization of Ion for Erythropoiesis Is a Significant Predictor for Adverse Events and Survival in Maintenance Hemodialysis Patients
Takihiro Kuragano, Takeshi Nakanishi. Dept of Internal Medicine Div of Kidney and Dialysis, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan.

Background: Patient with high serum ferritin and low transferrin saturation (TSAT) levels could be considered as diyutization of iron for erythropoiesis. Long-term safety of iron intervention to these patients has not been well studied.

Methods: Study design was the observational multicenter study for period of 3 years. In 805 patients with maintenance hemodialysis (MHD), we evaluated Hb, ferritin, TSAT levels in every 3 months, and high sensitive C reactive protein (hsCRP) and b2microglobulin (MG) levels every 6 months. We defined diyutization of iron for erythropoiesis as the patients with lower TSAT (<20%) and higher ferritin (100 mg/mL) levels. The association between diyutization of iron for erythropoiesis and adverse event was investigated with the time dependent cox hazard model.

Results: Compared with low TSAT (≤ 20%) level, patient with normal TSAT (20-30%) was significantly lower risk for cerebrovascular and cardiovascular disease (CCVD) (HR=0.25, P=0.04), and patients with higher TSAT (>30%) were significantly lower risk for death (HR=0.12, P=0.01). In multivariate logistic regression analysis, male, younger patients, without diabetes, low hsCRP, and low b2MG were selected as significant predictors of high TSAT, but iron administration or ferritin were not. Compared with low ferritin (<100 ng/mL) and high TSAT (>20%), patients with high ferritin (100ng/mL) and low TSAT (<20%)...
Inflammatory and Metabolic Syndrome Biomarkers Analysis of Vascular Outcomes in End-Stage Renal Disease Vinod K. Bansal1, Patrick Sweenig,2 Debra Hoppensteadt,2 Jennifer Saluk,2 Daneyal Syed,2 Jawed Farced.2
1Nephrology, Loyola Univ Medical Center, Maywood, IL; 2Pathology, Loyola Univ Medical Center, Maywood, IL.

Background: The relevance of some biomarkers of inflammation and metabolic syndrome to vascular outcomes in end stage renal disease (ESRD) is not clear. To study these relationships, biochip array technology method was used to profile the complex biomarker plasma in the setting of various comorbid outcomes such as Stroke or Transient Ischemic Attack (TIA), Acute Coronary Syndrome (ACS), Congestive Heart Failure (CHF), and Coronary Artery Disease (CAD).

Methods: Plasma samples were collected from 83 ESRD patients (mean age 65) prior to hemodialysis and were profiled using bioscops for metabolic and inflammatory biomarker levels. Inflammatory cytokine and Metabolic Syndrome arrays were used to profile C peptide, ferritin, insulin, leptin, resistin, TNFa, PAI-1, IL-1a, IL-1b, IL-2, IL-4, IL-6, IL-8, IL-10, VEGF, EGF, IFNG, and MCP1. Retrospective review was performed to group patients based on history of Stroke or TIA, ACS, CHF, and CAD.

Results: Of the 83 ESRD patients, 25 (30.1%) were found to have history of Stroke/ TIA, 14 (16.9%) were found to have history of ACS, 30 (36.1%) were found to have history of CHF, and 39 (47.0%) were found to have history of CAD Stroke/TIA patients were found to have decreased plasma IFNg levels (p<0.042) and elevated plasma resistan, IL-1a, and leptin levels (p=0.008, 0.021, 0.026; respectively) when compared to patients without Stroke/TIA. ACS patients had elevated plasma IL6 levels (p=0.040) when compared to those without ACS. CHF patients had decreased plasma leptin levels (p=0.031) and elevated plasma IL-1b levels (p=0.042) when compared to patients without CHF. CAD patients had elevated plasma IL-1a levels (p=0.049) when compared to ESRD patients without CAD.

Conclusions: Profiling of multiple inflammatory and metabolic syndrome biomarkers may aid in the risk stratification of ESRD patients for cerebrovascular and cardiovascular disorders. These studies demonstrate that biomarker profiling of vascular comorbidity in ESRD may provide useful diagnostic and prognostic information in the management of ESRD patients.

Individualized Anemia Management in Pediatric Nephrology Patients

Adam E. Gaweda,1 Jason Misura,2 Michael E. Brier,2 Jeffrey D. Leiser.2
1Medicine, Univ of Louisville, Louisville, KY; 2Nephrology, Riley Hospital for Children at Indiana Univ, Indianapolis, IN.

Background: Anemia management in pediatric patients on dialysis poses a great challenge to the nephrologist. In this study, we tested the hypothesis that individualized approach anemia management, previously demonstrated successfully in adult patients, improves hemoglobin maintenance within target range in pediatric dialysis patients.

Methods: We performed prospective evaluation of Clinical Decision Support System “Smart Anemia Manager” (SAM) in pediatric dialysis patients at Riley Hospital for Children at Indiana University. SAM was implemented as a stand-alone software on a desktop computer used by the nurse anemia manager and connected to a database containing Hemoglobin (Hgb) and ESA dose data. The anemia manager was allowed to override dose recommendations from the system and each override was documented. The followup period was 10 months, including 4 month washout period. We compared the hemoglobin distribution within 9-12 g/dL range during 6 months immediately before SAM implementation and 6 months after the washout period. Only patients who received ESA and had at least 4 Hgb values within each period were included in the analysis.

Results: 13 patients satisfied the inclusion/exclusion criteria. The percentage of monthly Hgb within target range varied between 82% and 92% in 6 months prior to deployment of SAM and between 69% and 100% during 6 months after SAM deployment. Quarterly Hgb distribution varied between 86% to 87% prior to SAM deployment and 87% to 95% after. There was a significant decrease in low Hgb numbers after SAM deployment, but no change in high Hgb levels, compared to the period before SAM deployment.

Conclusions: Individualized anemia management in pediatric patients improves distribution of Hgb within the target range, compared to a standard population-based protocol approach.

Extracorporeal Ultrafiltration Therapy for Acute Decompensated Heart Failure Neggin Pourfarshok, Ashkan Karimi, Amir Kazory. Medicine, Univ of Florida, Gainesville, FL.

Background: There has been a renewed interest in the use of ultrafiltration (UF) for management of patients with acute decompensated heart failure (ADHF). While a number of studies reported on the efficacy of this therapy and lack of any significant adverse impact, the more recent trials have challenged its safety. The aim of this study is to provide a reappraisal of the current evidence on the use of UF in ADHF.

Methods: Articles cited in PubMed database from 2000 to 2015 using key words “ultrafiltration” and “heart failure” were searched. Those randomized and non-randomized trials using recent portable devices dedicated for UF were selected. Case reports, and case series were excluded. Relevant data such as renal function, cardiac status, and weight change were extracted and compared.

Results: A total 940 patients from 15 trials (7 randomized and 8 non-randomized) that used dedicated UF devices were included. Eleven studies reported either no change or non-significant decrease in serum creatinine, while 4 found worsening renal function after UF therapy; these studies had included patients with more severe renal dysfunction at baseline. Concerning weight, a reduction of 2 to 9 Kg was reported that was similar to conventional therapies in 9 studies but was significantly lower with UF in 6 trials. Length of stay was evaluated in 5 studies, 2 of which showed a significant reduction. Three studies showed fewer re-hospitalizations in the UF group at 30 days, 90 days, and 1 year follow ups. None of the studies evaluated long-term outcomes of patients undergoing UF therapy.

Conclusions: Based on the currently available data, UF is efficient for management of volume overload in ADHF. However, these studies do not support any beneficial impact for this therapy on renal function, and suggest that it might be associated with suboptimal renal outcomes if used for patients with more severe renal dysfunction at baseline. Currently there is no data on the effect of UF on long-term outcomes of patients with ADHF. Whether this would translate into a lack of effect for UF on these outcomes needs to be elucidated by future studies.

Ultra-Sensitive Troponin I Predictive Value in Remote Ischemic Pre Conditioning in Hemodialysis: A Randomized Double Blinded Clinical Trial Marcelo Rodrigues Bacchi, Lívia Yadoya Vasconcelos, Felipe R. Bruniera, Felipe Moreira Ferreira, Neif Murad, Antonio Carlos palandri Chagas, Fernando Luiz yfonsio Fonseca. ABC Medical School, Brazil.

Background: Remote ischemic cardiac preconditioning(RIPC)is a procedure that generates a brief period of ischemia followed by reperfusion Areas submitted to RIPC in the experimental ischemia models have less occurrence of necrosis.RIPC role in protecting myocardial ischemia during hemodialysis is not established yet.The aim of the study was to evaluate RIPC as myocardial protection effect by ultra sensitive I troponin in hemodialysis outpatients.

Methods: It is a double blind randomised trial with two groups:intervention,submitted to RIPC with external compression in the right arm with sphygmomanometer with 200mm/Hg of pressure with three-5 minute rounds alternating with deflation totalising 30 minutes and control group:without RIPC.Intervention group received RIPC in three consecutive hemodialysis sessions.Blood samples were taken before and after each session. Randomization was made by a software stratified by sex and age.BUN for calculation of single pool Kt/v and ultra sensitive I troponin were measured to evaluate dialysis adequacy and myocardial injury.

Results: A total of 47 patients were randomized. About 60.8% were men and 54% diabetic. The mean single pool Kt/v was 1.51 in the intervention group and 1.49 in control
There was a trend to higher mortality in the control group (26%, p=0.09). The ultra sensitive troponin I measured no significant change from the time of collection before or after dialysis, however it showed a high negative predictive value in all models tested.

**Conclusions:** The RIPC applied in 3 consecutive sessions did not demonstrate superiority to control therefore another study tested RIPC in 12 consecutive sessions with a positive result in myocardial protection with RIPC. In our study more than half of the patients were diabetic. Diabetic patients have a trend to show a lower response to RIPC because of the greater presence of collateral coronary circulation. In summary, in this model there was no interference of RIPC in ultra sensitive troponin I values but troponin I had a high negative predictive value for myocardial infarction in all tested models.

### Racial Differences in the Evolution of Subclinical Cardiovascular Disease from CKD to ESRD: The CRIC Study

**Methods:** We studied incident dialysis patients in the CRIC study who had a research echocardiogram performed before and after the initiation of dialysis. Left ventricular mass index (LVMi) and ejection fraction (LVEF) were measured at CKD (mean GFR 24 ml/ min/1.73 m²) and at dialysis initiation (median time duration 7.9 months).

**Results:** Of 316 participants, 74% were black and 26% were white. After initiation of dialysis, there were 88 deaths. In multivariable models, black (vs. white) race was independently associated with a 38% (95% CI: 1%, 61%) lower risk of mortality. From CKD to incident dialysis, mean LVEF worsened in whites (51.0 ± 10.7% to 47.1 ± 11.2%; p-value for change <0.0001) and blacks (52.9% to 48.1%; p=0.001). LVMi tended worse in whites (54.1 ± 16 g/m² to 57.1 ± 15 g/m²; p=0.1) and significantly improved in blacks (61.1 ± 16 g/m² to 58.1 ± 15 g/m²; p=0.004). Adjusting for LVMi, change in LVEF, LVEF and change in LVEF did not change the association between black race and lower risk of death.

### Association of race for risk of mortality after initiation of dialysis

*adjusted for gender, age, tobacco use, systolic blood pressure, body mass index, diabetes, and history of cardiovascular disease

**Conclusions:** In CRIC, black dialysis patients had better survival than whites. This association was not explained by differences in subclinical cardiovascular disease (CVD) at incident dialysis or by differences in the evolution of CVD from CKD to ESRD. Further studies are needed to understand mechanisms underlying the differential survival by race among dialysis patients.

### Study Design and Baseline Characteristics in the “Outcome Study of Lanthanum Carbonate (LC) Compared with Calcium Carbonate (CC) in Hemodialysis (HD) Patients” Study

**Methods:** This is a multicenter, randomized, open-label, parallel group, comparative study between LC and CC (NCT015787200/UMIN00006815). Adult HD patients who had at least one of following criteria: age ≥65 yrs, postmenopausal women, or type 2 diabetes mellitus) with intact parathyroid hormone (iPTH) ≤240pg/mL and life expectancy ≥1 years, were eligible. In LC group, patients initially received LC of 750mg/day or previous used dose and were titrated up to a maximum of 225mg/dose/day to achieve P level of 3.5-6.0mg/dL. In CC group, patients received CC of 3g/day or previously used dose, and were titrated to achieve same P range as LC group. If serum P level was not achieved within the target, 25% of the previous treatment (of either LC or CC) or 75% of the previous treatment (of either LC or CC) may be added in CC group. The primary endpoint is the CV events (CV death, non-fatal myocardial infarction and stroke, unstable angina, hospitalization for heart failure and ventricular arrhythmia) free survival time.

**Results:** 239 patients were allocated to LC (N=1154) or CC group (N=1155). At baseline, mean age was 68.7 yrs, 40.6% were female and 51.7% were diabetes. 13.4% had a history of ischemic heart disease, and 13.3% had cerebrovascular disease. 8.0% had undergone coronary intervention procedure. Mean serum Ca, P and iPTH concentrations were 8.9mg/dL, 5.4mg/dL, and 122.4pg/mL, respectively. Baseline characteristics were well balanced between the two groups.

**Conclusions:** The LANDMARK study will determine whether a non-Ca-based P binder, LC, reduce CV mortality and morbidity in HD patients.

### The Relationship Between Preservation of Ultrafiltration in Hemodialysis and Intradialytic Hypotension: A Retrospective Study of Chinese Hemodialysis Patients

**Results:** The prevalence of intradialytic hypotension was 38.7%. Decrease of SBP and MAP positively correlated with UF/Wt and age, and negatively correlated with blood flow. The cut-off point of UF/Wt was 4% for all patients, diabetes and non-diabetic patients with AUCs of 0.575, 0.570, and 0.622 respectively. The AUC for diabetic patients was higher than that of non-diabetic patients (P<0.001). Multivariate logistic regression showed that age (OR=1.005, 95%CI: 1.004-1.007), diabetes (OR=1.209, 95%CI: 1.122-1.303), and UF/Wt<4% (OR=1.665, 95%CI:1.523-1.82) was associated with hypotension.

**Conclusions:** Asymptomatic intradialytic hypotension is prevalent. Increased intradialytic SBP/MAP variability is associated with greater UF and UF/Wt, but is not associated with greater blood flow. To Chinese hemodialysis patients, UF/Wt<4% is sensitive and specific in predicting intradialytic hypotension, especially in patients with diabetes mellitus. UF/Wt<4%, diabetes mellitus and age are independent risk factors for asymptomatic intradialytic hypotension.

**PUB324**

### Whole Blood Viscosity at Low Shear Rate Is Associated with Cardiovascular Mortality in Patients with Hemodialysis

**Results:** Forty three patients with ESRD receiving maintenance hemodialysis had initially participated in this study. In a prospective observational study, we examined the effect of WBV in pre- or post-dialysis on cardiovascular or cerebrovascular mortality in dialysis patients for approximately 5.8 years.

**Conclusions:** These results suggest that the diastolic low shear WBV may impact on cardiovascular or cerebrovascular mortality in hemodialysis patients. New prospective and large-scaled studies to more exactly evaluate the correlation between WBV and mortality will be needed in the future.
Survival of Patients Over 75 Years Old in a Chronic Hemodialysis Program
Adriano Luiz Ammirati, Maria C.C. Andreoli, Fabiana Dias Carneiro, Thais Nemoto Matsui, Nadia Guimarães-Souza, Bento C. Santos. Dialysis, Albert Einstein Hospital, São Paulo, Brazil.

Background: The intensity of medical care for people over 75 years of age has increased over the past decade. In this surrounding context is increasing the number of individuals with this profile that has clinical indication starting renal replacement therapy. Published data has not explored patient survival after initiation of hemodialysis (HD) according to the presence of comorbidities. The aim of this study was to evaluate the survival of elderly patients with chronic kidney disease on regular HD.

Methods: From analysis of medical records was assessed the rate of survival of incident patients older than 75 years old on HD program from 2000 to 2010. Demographic and clinical data were collected. It was made a comparison, based on these data, among the elderly (over 75 years old) and non-elderly groups who died.

Results: During the study period, 158 patients started HD program, 69% male and 46% over 75 years old. The overall mortality rates at 6 and 12 months were, respectively, 7.5% and 17%. Considering only the elderly, mortality rates at 6 and 12 months were respectively 14 and 27%. The median survival of these patients was 33 months. Considering only patients younger than 75 years mortality rates at 6 and 12 months were, respectively, 2% and 8%. Comparing elderly patients with non-elderly, we observed that the first group had a higher proportion of diabetic and hypertensive patients and with a history of cardiovascular disease and cancer. Considering only the patients who died, there were no important significant differences in the presence and score of comorbidities, when the elderly was compared with the non-elderly.

Conclusions: Patients over 75 years in HD had a mortality rate two times higher than younger patients and the presence of comorbidities may be a contributing factor to the age to explain this data.

Prevalence of Abnormal Ankle – Brachial Index in Haemodialysis Patients in Mexico and Its Association With Other Cardiovascular Risk Factors
Laura E. Ignezera Ochoa, Hernando Reyes López. Nefrologia, Regional General Hospital #46, Guadalajara, Jalisco, Mexico.

Background: Abnormal Ankle-Brachial index (ABI), defined as ≤ 0.9 or 1.3, is considered an independent predictor of mortality in hemodialysis patients, in other countries abnormal ABI is found between 35% and 80% of hemodialysis patients. In Mexico the prevalence of abnormal ABI has not been reported. The aim of the study was to determine the frequency of abnormal ABI and its association with other cardiovascular risk factors.

Methods: A descriptive study was performed over a period of 1 year. The study included patients over 18 years old who were undergoing maintenance dialysis therapy. Data were obtained from medical records and interviews. ABI was measured by oscillography (Model HEM-705P5) and classified as a normal result between 0.91 - 1.3 (NABI), < 0.9 (LABI) or >1.3 (HABI). NAVI was considered as the control group and the data were analyzed using descriptive and inferential statistics, using T Student and Chi2.

Results: Of the 119 patients analyzed abnormal ABI was present in 36 (30%), 10 (8.4%) with LABI and 26 (21.9%) with HABI. The mean age was 44.9 years, 68% were male, duration of dialysis of 7.1 years. In univariate analysis LABI was significantly associated with smoking status (p<0.03), smoking history (p<0.01), diabetes (p<0.04), lower creatinine (p<0.01) and albumin (p<0.001) and higher calcium (p<0.001); HABI was significantly associated with lower age (p<0.01), smoking history (p<0.05), lower systolic blood pressure (SBP) (p=0.02), high levels of sodium (p<0.04) and calcium (p<0.001). No association was found between abnormal ABI and history of hypertension, dyslipidemia, heart disease, stroke; there were no differences with the dose of calcium carbonate or calcitriol, the value of Kt/V, the type of vascular access and serum phosphorus.

Conclusions: Abnormal ABI was less prevalent than in other populations, among these HABI is the most common. LABI was associated with older age, DM, smoking history, high calcium and low creatinine and albumin (probably associated with poor nutritional status). HABI patients were younger, with smoking history, lower SBP, high serum sodium and calcium levels.

A Lower Serum Uric Acid Is Associated Not Only with All-Cause Mortality but Also Cardiovascular Mortality Among Patients Receiving Hemodialysis in Japan
Naoki Suganuma, Yukiyo Maruyama, Koki Takane, Yasuhito Takahashi, Chiwa Kobayashi, Shinichiro Nishio, Daisuke Takahashi, Satoshi Kidoguchi, Koukei Honda, Noriko Morisawa, Gorou Tokudome, Iwa Ohno, Tatsuo Hosoya, Takashi Yokoo, Takashi Shigematsu, Kunishi Iseki, Ituko Masakane. 2 Div of Nephrology and Hypertension, Dept of Internal Medicine, The Jikei Univ School of Medicine, Tokyo, Japan; 3 Committee of Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan.

Background: High level of serum uric acid is prevalent in chronic kidney disease (CKD), however it has a controversy whether high or low serum uric acid level appears to be a risk factor of cardiovascular event and mortality in the patients of receiving renal replacement therapy.

Methods: We collected the baseline data of 222,434 patients receiving HD three weekly (males: 63.0%, 66 ±12 years, median HD vintage of 60 months, females: 68 ±13 years, median HD vintage of 72 months) extracted from a nationwide dialysis registry at the end of 2011 in Japan. Then we evaluated the patient survival and development of complication using the registry at the end of 2012.

Results: During one-year follow-up, 18775 (8.4%) died of all causes including 8094 (3.6%) cardiovascular death. All-cause mortality, and cardiovascular mortality were lower in the line with an increase of baseline uric acid. In a multivariable logistic regression analysis, patients of the highest quartile of uric acid had lower all-cause, and cardiovascular mortality compared with those of the lowest quartile (males: OR, 0.745; 95% CI, 0.673 to 0.8207, females: OR, 0.8333; 95% CI, 0.726 to 0.9636, and males: OR, 0.7022; 95% CI, 0.6266 to 0.8278, females: OR, 0.8375; 95% CI, 0.7022 to 1.0462, respectively).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: In this large observational cohort study, lower levels of serum uric acid were independently associated not only with all-cause mortality but also cardiovascular mortality among Japanese HD patients. Close monitoring of serum uric acid is thought to be necessary for the management of HD patients.

PUB330

Post Stroke Disability Deterioration and Mortality of Hospital Onset Stroke in Patients with and without End-Stage Renal Disease Tomoko Usui,1 Norio Hanafusa,1 Hideo Yasunaga,2 Masaomi Nangaku.1 1Dept of Hemodialysis and Apheresis, The Univ of Tokyo Hospital, Japan; 2Dept of Clinical Epidemiology and Health Economics, School of Public Health, The Univ of Tokyo, Japan.

Background: Increasing evidence suggests that end-stage renal disease is associated with higher risk and severity of cerebrovascular disease. However, the risk factors for post stroke disability and mortality is not clear. We examined the association between risk factors including dialysis treatment and disability deterioration and mortality during the hospital stay of hospital onset stroke.

Methods: The Japanese Diagnosis Procedure Combination database includes administrative claims and discharge abstract data of about 50% of all acute-care inpatients in Japan. Using this database, we extracted data of inpatients age ≥20 years old, hospital-onset stroke between July 2010 and March 2013. Disability level was divided into modified Rankin Scale (mRS) 0-1, 2-3, 4-5, and 6 (death). Deterioration of disability was defined as an increase in disability level. The odds ratio (OR) for in-hospital deterioration of disability and mortality was calculated using a logistic regression model.

Results: Out of 26,834 patients, 593 (2.2%) had dialysis therapy. The median length of stay was 39 and 33 days for patients with and without dialysis, respectively. During the hospital stay, there were 7,655 (28.5%) disability deterioration and 3,851 (14.4%) death. The patients with dialysis had higher disability deterioration (47.9%) and mortality rate (31.3%) compared to those without. After adjustment with age, gender, BMI, mRS, Activities of Daily Living, smoking habits, hypertension, diabetes, dyslipidemia, atrial fibrillation, coronary heart disease, heart failure, peripheral arterial disease, cerebrovascular complications, antplatelet, anticoagulant, and thrombolytic medications, multivariate-adjusted ORs of dialysis for disability deterioration was 2.88 (95%CI 2.40-3.45), and in-hospital mortality was 3.57 (95%CI 2.94-4.33).

Conclusions: Dialysis treatment was an independent risk factor for in-hospital disability deterioration and mortality of hospital onset stroke.

PUB331

Role of Bioimpedance as Tool for Fluid Management in Hemodialysis Patients Maria Cecilia Recalde,1 Manuela Bello,2 Cecilia Arnaubarrera,2 Álvaro Herou,2 Fabian Cano,2 Laura Soña,1,2 1Hemodialysis Unit, CASMU, Uruguay; 2Preventive Medicine, Univ of the Republic, Uruguay.

Background: Fluid management in hemodialysis patients is difficult, hypertension and fluid overload is frequent as well as hypertensive episodes leading to cerebral and cardiac injury and increased mortality risk. The objective of the study is to evaluate if bioimpedance could be a tool to optimize fluid management in hemodialysis patients.

Methods: Patients were included after giving informed consent when fulfilled inclusion and exclusion criteria. Were recorded age, gender, diabetes status, dialysis vintage, body mass index (BMI) estimated dry weight, and mean in previous month: systolic blood pressure and was prescribed more number of other antihypertensive drugs than control group. After matching, there were no differences in age, sex, dialysis modalities, comorbidities and number of other antihypertensive medications. Before PSM, patient survival was significantly better in the RAAS group using the Gehan-Wilcoxon test (P=0.001), however, this difference disappeared after matching (P=0.450). Cardiovascular event-free survival was not different between RAAS group and control group before and after PSM analysis.

Conclusions: RAAS blockade did not affect all-cause mortality and MACE-free survival in the Korean ESRD patients. Further researches such as randomized control study will be needed.

PUB332

Effect of Renin Angiotensin Aldosterone System Blockade on Clinical Outcomes in Patients with End-Stage Renal Disease: A Prospective Cohort Study in Korea Kyung Don Yoo,1 Jung Pyo Lee,1 Jung Nam An,1 Yun Kyu Oh,1 Shin-Wook Kang,2 Chul Woo Yang,3 Yong-Lim Kim,4 Chun Soo Lim,5 Yon Su Kim.1 1Seoul National Univ College of Medicine; 2Yonsei Univ College of Medicine; 3The Catholic Univ of Korea College of Medicine; 4Kyungpook National Univ School of Medicine.

Background: Adequate blood pressure control plays a key role in the management of patients with end-stage renal disease (ESRD). Although renin angiotensin aldosterone system (RAAS) blockade is known as the best treatment option for chronic kidney disease with hypertension, there is debate in the ESRD patients maintaining dialysis.

Methods: A total of 5,223 patients in the Clinical Research Center for ESRD (CRC for ESRD) prospective observation cohort from Aug 2008 to Dec 2014 were enrolled to this study. We compare overall survival and major cardiovascular event (MACE)-free survival between RAAS group and control group for using 1:1 propensity score matching (PSM) analysis. We defined the RAAS group as using ACE inhibitor or angiotensin receptor blocker more than 3months.

Results: Before matching, the RAAS group was younger; however, had more comorbidities such as diabetes and cardiovascular disease. The RAAS group had higher systolic blood pressure and was prescribed more number of other antihypertensive drugs than control group. After matching, there were no differences in age, sex, dialysis modalities, comorbidities and number of other antihypertensive medications. Before PSM, patient survival was significantly better in the RAAS group using the Gehan-Wilcoxon test (P=0.001), however, this difference disappeared after matching (P=0.450). Cardiovascular event-free survival was not different between RAAS group and control group before and after PSM analysis.

Conclusions: RAAS blockade did not affect all-cause mortality and MACE-free survival in the Korean ESRD patients. Further researches such as randomized control study will be needed.

Lipidemic Profile and Sleep Apnea Syndrome in Hemodialysis Patients Lilian Nikitidou,1 Vassilios Liakopoulos,1 Aikaterini A. Papagianni,2 Euphemia Dakouloulou,1 Nicholas V. Dombros.1 1Div of Nephropathy and Hypertension, 1st Dept of Internal Medicine, AHEPA Hospital, Aristotle Univ of Thessaloniki, Thessaloniki, Greece; 2Div of Nephrology, Hippokration Hospital, Aristotle Univ of Thessaloniki, Thessaloniki, Greece; 3Sleep Laboratory, “Aghios Pavlos” General Hospital, Thessaloniki, Greece.

Background: Dyslipidemia, characterized by low high density lipoprotein-HDL, high triglyceride-TG levels and normal levels of low density lipoprotein-LDL, is one of the traditional cardiovascular risk factors in hemodialysis-HD patients. On the other hand, sleep apnea syndrome-SAS, which is very common in this population, is one of the newest non-traditional cardiovascular risk factors. We investigated the impact of SAS and nocturnal hypoxia on the lipidemic profile of HD patients.

Methods: 37 HD patients (23 males) participated in the study. The night between two consecutive midweek HD sessions, they underwent an overnight polysomnography study. The following morning fasting blood samples were obtained and serum levels of total cholesterol-TG, TG, LDL, HDL, apolipoprotein A-Apo A, apolipoprotein B-Apo B and lipoprotein a-Lp (a) were measured.

Results: We investigated the correlation of the patients’ lipidemic profile with their sleep apnea profile with their characteristics [age, Body mass index-BMI, duration of HD] and their sleep parameters [Apnea/Hypopnea Index-AHI, Respiratory Disturbance Index-RDI, Desaturation Index-DI, mean and minimum SpO2, percentage of sleep time with SpO2<90% and the lowest SpO2 level] and found that: 1) TC correlated negatively with minimum SpO2 (r=-0.454, p=0.005), 2) TG correlated positively with BMI (r=0.490, p=0.002) and RDI (r=0.438, p=0.007), 3) HDL correlated negatively with duration of HD (r=-0.350, p=0.037) and BMI (r=-0.391, p=0.02), 4) apo A correlated negatively with duration of HD (r=-0.344, p=0.046), 5) Lp (a) correlated negatively with minimum SpO2 (r=-0.364, p=0.034) and 6) LDL and apo B showed no correlation.

Conclusions: The results of the present study indicate that in HD patients with SAS the severity of the syndrome and the nocturnal hypoxia correlates with many parameters of their lipidemic profile which might contribute in the augmented cardiovascular risk in this population.

PUB334

Hemodynamic Changes in Maintenance Hemodialysis Patients with Intradialytic Hypotension Meijuan Meng, Hong Ye, Junwei Yang. Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.

Background: Intradialytic hypertension (IDH) is a common complication in patients undergoing maintenance hemodialysis (MHD) which leads to high mortality. This study is to explore the hemodynamic changes in MHD patients with IDH.

Methods: Thirty-seven patients were included in our study. HD were defined as a decrease of systolic blood pressure (SBP)≥20mmHg or the lowest SBP below 90 mmHg during dialysis. Twenty-three patients were diagnosed with IDH. Among them, 13 were
asymptomatic while the other had the hypotensive symptoms, such as abdominal discomfort, sighing, nausea, vomiting, muscle cramps and restlessness. All of them underwent a noninvasive hemodynamic evaluations before, during and after dialysis.

**Results:** Compared to the patients without IDH, the dialysis age was longer and the prevalence of diabetes was higher in the patients with IDH. There were no difference in age, sex, amount of ultrafiltration, pre-dialysis cardiac index (CI), systemic vascular resistance index (SVRI) and thoracic fluid capacity (TFC) between these two groups. During dialysis, CI decreased while SVRI increased gradually especially in patients with IDH. At the end of dialysis, ACI was markedly higher in patients with IDH. However, there was no significant difference in the change of CI, SVRI and TFC ten minutes before and after hemodialysis between these two groups. Meanwhile, the hemodynamic changes were analyzed in IHD patients with or without symptoms. It was found that there were no difference of change values and absolute values of CI and SVRI in these subgroups.

**Conclusions:** It was found that CI decreased while SVRI increased during hemodialysis. In the mid and later period, the CI decreased much more in patients with IDH. It was suggested that CI might be an indicator of IDH. Funding: Government Support - Non-U.S.

**Dual Relationships of Serum Leptin on Heart Rate Variability in Patients with Stage 5 Chronic Kidney Disease**

**Ningning Wang, Yao Jiang, Jingjing Zhang, Changying Xing. Nephrology. First Affiliated Hospital of Nanjing Medical Univ; Nanjing, China.**

**Background:** Leptin regulates nutrition, bone metabolism and cardiovascular function. Lower heart rate variability (HRV) in chronic kidney disease (CKD) predicts higher risk of cardiovascular disease (CVD). Relationships between leptin and HRV in CKD is obscure.

**Methods:** This study included cross-sectional observation and longitudinal follow-up on parathyroidectomy (PTX) patients.

**Results:** In leptin/BMI showed no difference between stage 5 CKD and controls. However, quartile 2 of leptin/BMI level in CKD patients prone to have higher HRV indices

**Association of Geriatric Nutritional Risk Index and Responsiveness to Erythropoiesis-Stimulating Agent in Mortality of Chronic Hemodialysis Patients**

**Kosaku Nitta, Ken Tsuchiyu. Dept of Medicine, Tokyo Women's Medical Univ; Shinjuku-ku, Tokyo, Japan.**

**Background:** Responsiveness to erythropoiesis-stimulating agent (ESA) may be associated with mortality in hemodialysis (HD) patients. The aim of the present study was to assess the effects of geriatric nutritional risk index (GNRI) and responsiveness to ESA in outcomes in HD patients.

**Methods:** The ESA response index (ERI) was determined as the weekly weight-adjusted dose of ESA divided by hemoglobin concentration. Patients were divided into four groups by quartiles of ERI. Odds ratios were estimated using a Cox proportional model for the association between GNRI and ERI and mortality, adjusting for potential confounders. Patients were divided into four groups by quartiles of ERI.

**Results:** Of the 298 subjects enrolled, 51 died with 31 cardiovascular deaths during the follow-up period of 34.6 ± 6.1 months. The ERI was inversely correlated with the GNRI (r = 0.287; p < 0.0001). Age, gender, serum total cholesterol, phosphorus, ionized calcium concentrations were independent predictors of ERI. Older age, female gender, serum total cholesterol, transferrin saturation and GNRI were independent predictors for ESA hyporesponsiveness. Receiver operating curve analyses indicated the cut off values of GNRI and ERI for mortality were 94.9, 13.5, respectively. When subjects were stratified by ERI and GNRI value into four groups, those who had low GNRI and high ERI were associated with the highest risk of mortality among the four groups (log-rank p < 0.001).

**Conclusions:** High ERI and low GNRI were associated with an increased risk of all-cause mortality.

**PUB337**

**A Multidisciplinary Approach Is Required to Reduce Hospitalizations for Cardiovascular Disease in Maintenance Hemodialysis Patients**

**David L. Epstein, Thomas Parker, Daniel Levine, Jeffrey Silberzweig. 1Medicine, The Rogosin Inst, New York, NY; 2Medicine, Weill Cornell Medical College, New York, NY.**

**Background:** Patients receiving maintenance hemodialysis have hospital admissions rates significantly greater than patients with other chronic diseases. Approximately 40% of the hospital admissions are related to cardiovascular disease including both acute events and pulmonary edema. We sought to assess the contribution of fluid weight gains to hospital admissions.

**Methods:** We compared inter-dialytic weight gains as a percentage of target weight and changes in blood pressure for the approximately 1200 patients receiving maintenance hemodialysis in our seven dialysis clinics in New York City between January and April 2015. We compared these data to total and cardiovascular hospital admissions using t-tests.

**Results:** Greater relative weight gains were significantly associated with pre-treatment systolic blood pressure (2.7 mmHg increase in BP per 1% increase in weight; p < 0.0001) and hospitalizations for cardiovascular complications (p = 0.03). In contrast, neither greater relative weight gain nor pre-treatment systolic blood pressure was significantly associated with all-cause hospitalization (p > 0.5). The clinic with both the greatest relative weight gains and the highest rate of hospitalization for cardiovascular disease was without a full-time dietitian for the months of the study.

**Conclusions:** In our population of maintenance hemodialysis patients, we report a statistically significant association between relative weight gains, hypertension and hospitalization for cardiovascular disease. We suggest that this relationship may be related to the absence of a full-time dietitian leading to a lack of a true multidisciplinary team approach to fluid management in these patients. **Acute Effects of Cinacalcet on Arterial Stiffness and Ventricular Function in Hemodialysis Patients**

**Mohsen Aghazari, Karine Marquis, Catherine Fortier, Sacha A. De Serres, Fabrice Mac-Way. CHU de Quebec Research Center, Hôtel-Dieu de Québec Hospital; Quebec, QC, Canada.**

**Background:** Ionized calcium concentrations are crucial for vascular smooth muscle tone and myocardial contractility. The aim of the present study was to investigate whether a reduction in serum calcium concentration by the calcimimetic cinacalcet can reduce aortic stiffness and improve diastolic dysfunction.

**Methods:** This is a randomized, double blinded, cross-over study comparing the effects of 30 mg/dl of cinacalcet for 7 days to 7 days of placebo. Aortic stiffness was measured by determination of carotid-femoral pulse wave velocity (cf-PWV), central aortic pressure wave form was performed by radial tonometry using generalized transfer function, and cardiac function was evaluated by an echocardiogramme. Linear mixed model with fixed effects including period, treatment and sequence, while a random effect for the patients nested in sequence was used.

**Results:** 21 patients were enrolled. After administration of cinacalcet the total serum calcium decreased (2.28 ± 0.18 versus 2.15 ± 0.14 mmol/L, p < 0.001), with a significant reduction of PTH levels as expected (558 ± 293 to 306 ± 333 ng/L, p < 0.001). There were no significant differences in central pulse wave profile. Taking into account changes in the mean blood pressure, sequence, carryover and treatment effect, there was a small decrease in cf-PWV under cinacalcet that was not statistically significant (0.35, 95% CI -0.13 – 0.83 mmHg).
Kidney Transplantation and Cardiac Repolarization Descriptors

Dimitrios J. Poulikakos, Debashish Banerjee, Marek Malik, Renal, Salford Royal, United Kingdom; St. George’s Univ of London, United Kingdom; Imperial College, London, United Kingdom.

Background: Selected descriptors of cardiac repolarization derived from the computerized analysis of electrocardiogram (ECG) can predict cardiac risk in hemodialysis (HD) patients. Kidney transplantation improves cardiovascular survival. The aim of the study was to investigate the impact of kidney transplantation on these descriptors.

Methods: The study was conducted in two phases. In phase 1, Holter ECGs were obtained during HD sessions and repeated 5 times at 2-week intervals in stable HD patients. The repolarisation descriptors QRS-to-T angle (TCRT) and T wave morphology dispersion (TMD) were calculated in overlapping 10 second ECG segments and averaged over the first hour of recordings. In phase 2, continuous 1-hour ECG recordings were obtained in patients who received a kidney transplant minimum three months after transplantation and if they were stable with EFGFR-30 ml/min/1.73m2. Average values of post transplant repolarisation descriptors were compared with average values over the first hour of HD using Wilcoxon test and t-test was used for baseline comparisons.

Results: In 80 HD patients in phase 1 both descriptors showed intra-subject stability and exhibited extreme values in subjects that suffered major arrhythmic events. During a period of 35.9 ± 3 months 10 eligible transplanted subjects were recorded and although TMD and TCRT improved 7 months following kidney transplantation (see table) the difference did not reach statistical significance (p=0.05). However these subjects had better baseline TCRT and TMD values compared to the study population (TCRT 0.463 vs 0.078 < 0.05 and TMD 17.9 vs 32.4 p<0.05).

Conclusions: In transplant recipients with healthier baseline repolarisation profiles the improvement did not reach statistical significance in the early post transplant period. Larger studies with longer follow up are needed.

PUB340

Prognostic Significance of Cardiopulmonary Exercise Test and 6-Minute Walk Test in Chronic Dialysis Patients

Wioletta Dziubek, K. Bulinska, B. Ochman, U. Kaszak, Kuszela, T. Golebiowski, D. Markowska, A. Zembron-Lacny, M. Mariusz, Kusztal, M. Mariusz, Kusztal, Dept. of Nephrology and Hypertension, Komagome Nogi Hospital, Tokyo, Japan; Physical Education, University of Tokyo, Tokyo, Japan.

Background: The 27 dialysis patients (sixteen diabetics, eleven non-diabetics) are included in this study. Out of them, electrocardiogram, SDB, echocardiography, laboratory tests, plasma BNP level, medications, and clinical conditions. ASV therapy was used in the patients diagnosed with severe SDB and/or central apnea. AIMS: to evaluate the effects of ASV therapy in HD patients.

Methods: Study was performed using an portable sleep test device (SleepTest LS-300, Fukuda Denki Co., Ltd, Japan). We measured the variables of cardiac function by echocardiography. The relation between apnoea index and the echocardiogram indicates was evaluated. We also collected patients' medical data, medications, laboratory tests, plasma BNP level, medications, and clinical conditions. ASV therapy was used in the patients diagnosed with severe SDB and/or central apnea. The cardiac function variables were evaluated in comparison to the previous year.

Results: The 27 dialysis patients (sixteen diabetics, eleven non-diabetics) are included in this study. Out of them, electrocardiogram, SDB, echocardiography, laboratory tests, plasma BNP level, medications, and clinical conditions. ASV therapy was used in the patients diagnosed with severe SDB and/or central apnea. The cardiac function variables were evaluated in comparison to the previous year.

Conclusions: In dialysis patients with uncontrolled office BP (>140/90mmHg despite of two or more agents at maximal tolerated dosages) were recruited into this feasibility study. Office and ambulatory BP monitoring (ABPM) were performed at baseline, one and three months post RDN, along with supine muscle sympathetic nerve activity (MSNA) and tilt testing. The 27 dialysis patients (sixteen diabetics, eleven non-diabetics) are included in this study. Out of them, echocardiogram, SDB, laboratory tests, plasma BNP level, medications, and clinical conditions. ASV therapy was used in the patients diagnosed with severe SDB and/or central apnea. The cardiac function variables were evaluated in comparison to the previous year.

Conclusions: In this study, we demonstrated the efficacy of ASV therapy in hemodialysis patients with SDB. Near future, ASV is possible to be one of attractive devises for HD patients, with aging, several complications, to improve their poor prognosis.

PUB341

Adaptive Servo-Ventilator Therapy Improves the Cardiac Dysfunction in Hemodialysis (HD) Patients with Sleep-Disordered Breathing

Fumiko Fukuchii, Ken Tsuchiya, Kosaku Nitta, Nephrology, Komagome Kyoritsu Clinic, Bunkyo-ku, Tokyo, Japan; Medicine I, Tokyo Women's Medical Univ, Shinjuku-ku, Tokyo, Japan.

Background: Cardiac dysfunction is a very serious problem in HD patients. Sleep Disordered Breathing (SDB) is considered to cause cardiac dysfunction. Dialysis patients have a disordered respiratory center and a high prevalence of central apnea. Adaptive Servo-Ventilator (ASV) is automated modality used to treat heart failure patients with SDB, especially central apnea. The aim of this study is to explore the relationship between sleep apnea and cardiac dysfunction, and to evaluate the effects of ASV therapy in HD patients.

Methods: Sleep study was performed using a portable sleep test device (Sleeptest LS-300, Fukuda Denki Co., Ltd, Japan). We measured the variables of cardiac function by echocardiography. The relation between apnoea index and the echocardiogram indicates was evaluated. We also collected patients' medical data, medications, laboratory tests, plasma BNP level, medications, and clinical conditions. ASV therapy was used in the patients diagnosed with severe SDB and/or central apnea. The cardiac function variables were evaluated in comparison to the previous year.

Results: The 27 dialysis patients (sixteen diabetics, eleven non-diabetics) are included in this study. Out of them, electrocardiogram, SDB, echocardiography, laboratory tests, plasma BNP level, medications, and clinical conditions. ASV therapy was used in the patients diagnosed with severe SDB and/or central apnea. The cardiac function variables were evaluated in comparison to the previous year.

Conclusions: Both cardiopulmonary exercise test and 6-minute walk test were able to differentiate survivors and non-survivors within 3 years. National Science Centre grant 2011/03/B/NZ7/01764.

Funding: Government Support - Non-U.S.

PUB342

Endovascular Renal Denervation: Effects on Dyslipidemia and Vascular Inflammation in Dialysis Patients

Background: Endovascular renal denervation (RDN) reduces arterial and efficient sympathetic nerve activity. Its effects on vascular inflammation and cholesterol levels in dialysis patients are unknown. We hypothesized RDN would reduce sympathetic activity, resulting in improvement in biomarkers of vascular inflammation and dyslipidemia.

Methods: Nine dialysis patients with uncontrolled office BP (>140/90mmHg despite of two or more agents at maximal tolerated dosages) were recruited into this feasibility study. Office and ambulatory BP monitoring (ABPM) were performed at baseline, one and three months post RDN, along with supine muscle sympathetic nerve activity (MSNA) and venulecture. Bilateral RDN was undertaken with an EnligHTN™ catheter.
Results: Similar to previous, office systolic BP reduced and the effect on ABPM was attenuated. MSNA did not change, a novel finding. Despite lack of change in MSNA, total cholesterol: HDL ratio increased along with a falling trend in CRP and rising trend in albumin, all novel findings.

Conclusions: Non survivors were characterized by older age, higher prevalence of diabetes, CAD, lower Hb & Albumin. But dialysis adequacy and UF were comparable. Short duration of follow up may limit the ability to study other factors influencing outcomes.

PUB343

New Anticoagulant Free Strategy for Non Valvular Atrial Fibrillation in Hemodialysis Patients

Methods: An alternative to OAC could be the percutaneous Left Atrial Appendage (LAA) closure. With this technique an implantable component is permanently fixed in the LAA to prevent thrombus embolization. Different studies demonstrated that this procedure is not inferior to systemic anticoagulation with OAC in prevention of thromboembolic risk. We reported our clinical experience with the use of this technique in haemodialysis patients with non valvular AF.

Results: In the last few months seven (7) haemodialysis patients were treated with percutaneous LAA closure. Bleeding and stroke risks were evaluated by HAS-BLED score and CHA2DS2-VASc score: HAS-BLED score was 4.5±0.38 (equal to 9%±1.1% yearly risk of major bleeding) and CHA2DS2-VASc was 4.10±1.1 (equal to 4.47%±1.5 yearly risk of stroke). This procedure was well tolerated by each patient. OAC treatment was interrupted after the procedure and doubled antiplatelet therapy was introduced for a month. At this moment median of 9 months of follow-up was archived [IQR 3-12]; no adverse events has been assessed.

Conclusions: To the best of our knowledge this is the first consecutive series of LAA closures in haemodialysis patients. This procedure represents a real clinical alternative to the use of coumarin derived drugs. Our experience leads the way to the possible routine use of this procedure in CKD-5D patients. As well as this procedure could be used in those patients with contraindications to OAC; even more this treatment should be used in haemodialysis population, in which the use of OAC should be avoided for both increased risk of life-threatening bleeding events and well known negative cardiovascular effects.

PUB345

Management of Subclinical Thyroid Dysfunction Can Reduce Cardiovascular Events in Patients with End-Stage Renal Disease on Hemodialysis

Methods: All hemodialysis patients in Red Cross Hospital within a period of one year were included in the study. Thyroxine-3 (T3), free thyroxine-4 fT4, Thyroid Stimulating Hormone (TSH) and lipid profiles in the serum were estimated and death from all causes and CV events served as outcome variables over a median follow-up period of 12 months. Participants were divided into groups based on the thyroid function. Statistical analysis was carried out by using SPSS.

Results: Among the 92 cases, 28.2% of the patients were having thyroid disorder. In which 21.2% were of hyperthyroid, 13.7% were of subclinical hyperthyroid. We observed negative correlation between T3 & fT4. Total cholesterol was raised in hyperthyroidism in comparison to euthyroid ESRD patients. However, thyroid function didn’t have significant association with lipid profiles. Cardiovascular disease significantly often occurred in subclinical thyroidism patients than other group.

Conclusions: Our results show that the blood thyroid hormone level isn’t affected by dyslipidemia but affected by occurrence of CVD. Therefore, the management of subclinical hypothyroidism in hemodialysis patients should be considered.

Non survivors were significantly older, had lower number of total sessions, lower albumin and no of hospitalizations. All novel findings.

Conclusions: Non survivors were characterized by older age, higher prevalence of diabetes, CAD, lower Hb & Albumin. But dialysis adequacy and UF were comparable. Short duration of follow up may limit the ability to study other factors influencing outcomes.

Effect of Altitude on All-Cause Mortality in End-Stage Kidney Disease Patients Undergoing Hemodialysis in Peru  
*Medicine, Univ of Rochester Medical Center, Rochester, NY; Medicine, Jackson Memorial Hospital, Miami, FL; Instituto de Investigaciones de Altura, Univ Peruana Cayetano Heredia, Lima, Peru; Asociacion Medica de Investigacion y Servicios en Salud, Lima, Peru; Pediatrics, Inst Nacional de Salud del Niño, Lima, Peru.

**Background:** Worldwide, end-stage kidney disease (ESKD) prevalence has tremendously risen. Previous studies suggested that receiving hemodialysis (HD) at high altitude confers mortality benefits; however, this effect has not been proved above 2000 m or in developing countries.

**Methods:** This historical cohort study analyzed medical records from six HD centers of the Peruvian Social Security System. Adult ESKD patients who started HD between 2000 and 2010 were included. Patients were classified into two strata (< 2000 and > 2000 m). The outcome variable was death from any cause. Cox proportional hazards models were built to compare the hazard ratios of death between the strata for different causes of death. The study was conducted to measure the prevalence, incidence and death rate (epidemiology) among the population of Oman and we need to receive data from neighboring countries to compare with.

**Results:** 723 patients were enrolled, including 248 women (32%). The mean age was 52.8 ±16.9 years. 166 patients lived > 2000 m (22%). In first years after follow-up, survival rates were lower in the group > 2000 m, however after 8 years of follow-up this trend reversed. Age and gender were not significantly associated to mortality at altitude levels > 2000 m. Patients with diabetes had higher mortality rates at > 2000 m (p=0.003), independently of age.

**Conclusions:** In Peru, patients receiving HD at high altitude do not experience mortality benefits. In fact, diabetics have higher mortality rates at > 2000 m.

End-Stage Renal Disease in North Region of Oman/Epidemiology, Incidence, and Aetiology 
*Nursing and Health Care, Univ of Glasgow, Glasgow, United Kingdom; Nursing Education, Ministry of Health, Muscat, Sohar, Oman.

**Background:** The epidemiology of renal failure in Oman is scarce. There is a paucity of information on the size and burden of renal failure in Oman. Therefore, our research was conducted to measure the prevalence, incidence and death rate (epidemiology) among patients who have renal failure and undergo dialysis in four dialysis centers in the North of Oman; and to provide a description of the major characteristics of the studied patients.

**Methods:** A cross-sectional study was conducted. A proportional sample was selected from four Renal Dialysis Centers (RDC) who were interviewed face to face or via telephone using a structured questionnaire. Data collection took place between October and November, 2014. The incidence, prevalence and death rates are under collection until the end of December, 2015.

**Results:** Over the period January 1st, 2014 to December 31st, 2014, a total of 96 new patients started dialysis in the four observed RDCs. The overall incidence rate was 13 patients per 100,000. The mortality rate for the same period of time was four patients per 100,000. Demographic data are summarized in table 1.

**Conclusions:** Renal failure is a burden on patients, and the health and social systems of Oman. The expenditure on these 380 patients in 2014 was 6.5 million dollars. However, to determine the size of the burden, we need a comprehensive study covering the whole country of Oman and we need to receive data from neighbouring countries to compare with.

Low Potassium Bath Protocol Experience in Hemodialysis Patients in Qatar 

**Background:** Hyperkalemia is a major problem in hemodialysis (HD) patients affecting there morbidity and mortality. HD patients receiving low potassium (K) bath for hyperkalemia have double the risk of sudden cardiac death. We noticed high rate of use of low K dialysate due to high prevalence of hyperkalemia in our dialysis unit. We are studying this phenomenon.

**Methods:** Our study was done in the biggest out-patient HD facility in Qatar (306 patients). We identified patients who required low K bath (based on an existing rigorous protocol, any K over 5.5 will be started on low K bath 1 mmol/L with checking K level every HD treatment till corrected) in 6 months period from 10/1/2014 to 3/31/2015. We collected background data in these patients and their potassium levels during that period.

**Results:** 62 out of 306 hemodialysis patients required low K bath continuously (5 patients) or intermittently (57 patients). Mean age was 59.9 ±15 years. There were 36 females on low K bath out of total 137 females versus 26 males out of 160 (p Value 0.014). 39 out of 62 were Qataris (62% versus 65% in patients not on low K bath). Table 1 summarize number of patients on low K bath and number of low K bath HD treatments done on monthly base versus average temperature in Doha, Qatar.

**Conclusions:** In a study of using low K bath in a major HD clinic in Qatar we found a statistically significant higher number of female patients who required low K bath than males. This might be attributed to dietary habits based on our dietary experience and vascular access issues but further study is needed to explain these findings. There was a significant decrease in need for low k bath in January and February compared to other months both in the number of patients and HD treatments. We attributed that to combination of cooler weather and seasonal change in dietary habits. Further study again is needed to evaluate that prospectively.
Co-Morbidity Rather Than Clinical Practice Patterns Determines Mortality in an Aged Dialysis Population

Background: Hemodiafiltration (HDF), by adding convective to diffusive transport, is more effective in removing larger uric acid retention solutes than hemodialysis (HD). As these solutes are thought to have a role in the accelerated cardiovascular disease of dialysis patients, HDF might result in lower mortality compared to HD.

Methods: All patients treated with thrice weekly HD (high-flux) or online HDF at 3 Belgian dialysis centers for ≥ six and < 42 months were included in July 2008. Hospitalized patients or patients with access-related problems were excluded. The effect of HDF versus HD on all-cause mortality at 6 years was evaluated. Multivariate analysis taking into account all relevant baseline variables was performed to determine independent predictors of outcome.

Results: 342 patients were included (142 males, mean age 70.9 ± 11.8 years; 84 treated with HD, 158 with HDF). After 6 years, the incidence of all-cause mortality was significantly higher in HD than in HDF: 54% of patients in HD-group (64.3%), 15% of patients in HDF group (57.5%) (P = 0.04). Based on univariate associations with survival (*) and/or significant association with center or HD/HDF variable, following parameters were introduced in multivariate analysis: HD/HDF*, age*, weight, CCP*, use of calcium(Ca)-based and non-Ca-based phosphate (P) binders, dialysis hours/week, Qb, Qd, dialysate Ca concentration*, vascular access*, mean P*, Ca-P product*, hemoglobin, albumin*, interdialytic weight gain and center. The final multivariate model is shown in the table below.

Conclusions: In an aged Western dialysis population, treatment with HDF did not improve all-cause mortality compared to high-flux HD. Mortality seems to be determined by comorbidity rather than by clinical practice patterns.

Depression Is Associated with Frailty and Malnutrition but Not Comorbidity Load in Chinese Peritoneal Dialysis Patients

Background: Depression is common amongst patients with chronic kidney disease and is associated with excessive mortality in dialysis patients. This study determines the prevalence and risk factors of depression in Chinese peritoneal dialysis (PD) patients.

Methods: We studied 178 prevalence PD patients (103 males). Depression was screened by the 15-item self-reported Geriatric Depression Scale (GDS). We also determined patients’ comorbidity load, dialysis adequacy, residual renal function, nutritional status, and degree of frailty.

Results: The mean age was 60.7 ± 11.7 years; vintage of dialysis 42.5 ± 44.1 months. Average GDS score was 4.9 ± 4.4. GDS score is closely associated with the frailty score (r = 0.692, p < 0.0001), malnutrition inflammation score (r = 0.406, p < 0.0001), and subjective global assessment score (r = 0.386, p < 0.0001). GDS score also has a modest but significant correlation with Charlson’s comorbidity index (r = 0.164, p = 0.026) and serum albumin level (r = 0.192, p = 0.019), but not with patient age, vintage of PD, dialysis adequacy, or residual renal function. When defined as a GDS score ≥8, 50 patients (28.1%) had depression.

Conclusions: Depression is common amongst Chinese PD patients. Frailty and malnutrition are the major risk factors of depression in our cohort, while comorbidity load and dialysis adequacy have little effect.

Trends in Anemia Management with Darbepoetin Alfa in Patients on Maintenance Hemodialysis

Methods: We included ~650 adults (age ≥18 years) with 1+ months on HD between 2008-2013 in 18 FSDCs within the UIU Dialysis Program. We summarized quarterly intravenous DA and iron use and dose, Hb, and serum transferrin saturation (TSAT) and ferritin levels.

Results: 70-78% of patients received DA over the study period. Mean Hb levels among patients who received DA fell from 12.2 g/dl in 2008 before leveling around 10.3 g/dl from Q4 2011 to 2013 (Figure). The mean monthly DA dose was 209 mcg in Q1 2008, reached a peak of 256 mcg in Q1 2010, and decreased to ~105 mcg in 2013. Quarterly iron use rose from 52% in 2008 to 67% of patients in 2013. Iron dose also rose from 129 mg in Q4 2008 to 194 mg in Q4 2010, but declined to 163 mg in Q4 2013. Mean serum TSAT levels remained relatively constant at ~30% between 2008-2013 but serum ferritin levels increased from 449 ng/ml in Q1 2008 to 770 ng/ml in Q4 2013.

Conclusions: Trends in anemia management parameters among patients on HD treated with DA within FSDCs in the UIU Dialysis program were consistent with national reports of patients treated with EA.
A Prospective Study of Routine Heparin-Free Hemodialysis (HFD) with Streamline® Bloodlines (SL) in a Large Tertiary Acute Care Inpatient Practice Sami Safavi,1 Mary Ann Ryan,2 Amanda L. Severson,2 Fares Alahbad,3 John J. Dillon,4 Robert C. Albright,1 Amy W. Williams,1 Marie C. Hogan,1 1Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 2Nursing, Mayo Clinic; 3KSP Unit, Mayo Clinic.

Background: Extracorporeal circuit (EC) anticoagulation (AC) with heparin was a key advancement in hemodialysis (HD). However, AC in patients at risk of bleeding remains a frequently encountered problem. SL bloodlines eliminate blood-air contact, and reduce turbulence in HD circuit. Small studies suggest that SL reduces heparin use and improves HD efficiency. We prospectively evaluated EC clotting rates, impact on dialysis efficiency, and associated risk factors in our inpatient practice.

Methods: In this single center, randomized, factorial (2 x 2) study, chronic adult hemodialysis patients were randomized to one of four IDE groups: cycling, resistance, or stretching (an attention control). Exercise was semi-supervised by a kinesiologist. Outcomes focused on a priori feasibility criteria: recruitment, fidelity to the protocol, and participant and staff response to IDE. As a secondary outcome, we evaluated the main effect of cycling and weights each compared with control on quality of life and physical performance at baseline and 12-weeks. To better understand feasibility, we conducted interviews with users.

Results: We exceeded targeted accrual of 28 people over 12 weeks. Of 100 patients screened, 51 were enrolled (36 did not meet inclusion criteria, 33 declined participation); 16% dropped out after randomization. Fidelity to the intervention was high: of 1,039 training sessions offered, 877 were delivered. Participant response to the intervention was favorable: 92% of participants continued exercising after the trial. There were no crossovers and no reported contamination. Dialysis staff were not consistently available to assist with implementation, so study staff were necessary to deliver IDE. Secondary outcomes were not statistically significant.

Conclusions: This pilot study demonstrated feasibility of recruitment, high patient acceptability, and low risk of contamination. However, IDE will not be feasible in the long term unless dialysis staff assist with implementation. This will need to be addressed before executing a definitive trial.

PUB355

A Randomized, Factorial Pilot Study to Evaluate the Feasibility of an Implementation Program to Improve Dialysis Efficiency: The Dialysis-SIZE Study Stephanie E. Thompson,1 Scott Klarenbach,1 Anita Molzahn,1 Mark Haykowski,2 Anita Lloyd,2 Marcello Tonelli,2 1Univ of Alberta, Edmonton, AL, Canada; 2Univ of Calgary, Calgary, AB, Canada.

Background: Intradialytic exercise (IDE) is associated with improved dialysis adequacy and amelioration of dialysis-related symptoms. However, the uptake of IDE is limited by knowledge gaps on efficacy—what type of exercise to prescribe to optimize outcomes, and on feasibility. The results of this pilot will inform the design of a full-scale efficacy study evaluating two types of IDE (aerobic and resistance) and will also provide researchers with practical information on IDE.

Methods: In this single center, randomized, factorial (2 x 2) study, chronic adult hemodialysis patients were randomized to one of four IDE groups: cycling, resistance, cycling and resistance, or stretching (an attention control). Exercise was semi-supervised by a kinesiologist. Outcomes focused on a priori feasibility criteria: recruitment, fidelity to the protocol, and participant and staff response to IDE. As a secondary outcome, we evaluated the main effect of cycling and weights each compared with control on quality of life and physical performance at baseline and 12-weeks. To better understand feasibility, we conducted interviews with users.

Results: We exceeded targeted accrual of 28 people over 12 weeks. Of 100 patients screened, 51 were enrolled (36 did not meet inclusion criteria, 33 declined participation); 16% dropped out after randomization. Fidelity to the intervention was high: of 1,039 training sessions offered, 877 were delivered. Participant response to the intervention was favorable: 92% of participants continued exercising after the trial. There were no crossovers and no reported contamination. Dialysis staff were not consistently available to assist with implementation, so study staff were necessary to deliver IDE. Secondary outcomes were not statistically significant.

Conclusions: This pilot study demonstrated feasibility of recruitment, high patient acceptability, and low risk of contamination. However, IDE will not be feasible in the long term unless dialysis staff assist with implementation. This will need to be addressed before executing a definitive trial.

PUB356

Low Serum Albumin Is a Risk Factor for In-Hospital Mortality Among Hemodialysis Patients Hospitalized with Infectious Diseases: A Multicenter Retrospective Cohort Study in Japan Shun Minatoguchi,1,2 Daiyu Suzuki,1 Fumio Iwase,1,2 Shun Minatoguchi,1 Takashi Matsumoto,3 Hiroshi Watanabe,1,2 Hiroki Nishiwaki,2 Pellegrini, E Celia, R Gelfman, MR Leal, M Torok, A Bednarek Skublewska, J Dulawa, P Stroumza, L Frantzen, D del Castillo, AG Bernat, J Heiglmann, C Wollheim, L Gargano, CP Bots and GFM Strippoli.

Background: Serum albumin is the known marker of nourishment and inflammation. Several studies in the past have shown the relationship between low serum albumin and long-term mortality among dialysis patients. However, there is insufficient data on the
relationship between serum albumin levels and short-term mortality among chronic dialysis patients who are hospitalized with infectious diseases. This multicenter retrospective cohort study in Japan evaluated if serum albumin levels at the occurrence of infection is a risk factor for in-hospital mortality among hemodialysis patients.

Methods: From June 2011 to July 2013, a total of 418 hemodialysis patients who took blood cultures were reviewed retrospectively in five tertiary dialysis units participating in the “TOMEI Nephrology Group for Clinical Research” study. After exclusion of 232 patients diagnosed with non-infectious diseases, 186 patients diagnosed with infections were analyzed. Patients were divided into two groups according to the serum albumin level at hospitalization: low serum albumin (Serum albumin<3.5 g/dL) or not. Outcome measured was in-hospital mortality. For statistical analysis, Cox proportional hazard model was used.

Results: Among 186 patients with infectious diseases, there were 117 patients (62.9%) in low albumin group, and 69 patients (37.1%) in normal albumin group. During hospitalization (median ± interquartile range 10-37), 29 patients (15.5%) died. 25 of 117 (21.4%) in low albumin group, and 4 of 69 (5.8%) in normal albumin group. The cox proportional hazard model verified that low serum albumin and bacteremia were associated with in-hospital mortality. The hazard ratio of in-hospital mortality among low albumin group was 4.293 (95% CI: 1.36–13.55).

Conclusions: Although low serum albumin is a known risk factor for long-term mortality, this study showed that low serum albumin strongly predicts short-term mortality among hemodialysis patients hospitalized with infectious diseases.

PUB357
Usefulness of High-Frequency Wave-Length Ultrasonography as a Diagnostic Tool for Carpal Tunnel Syndrome in Hemodialysis Patients

Tadaaki Yamazaki,1 Tokie Hayasaka,2 Tetsuo Saito,3 Shuichi Tsurowaka,
1Nephrology, Nippon Medical School, Tokyo, Japan; 2Dialysis Unit, Moka Hospital, Moka, Tochigi, Japan.

Background: Carpal tunnel syndrome (CTS) is a common complication in dialysis-induced amyloidosis. In orthopedics, high-frequency wave-length ultrasonography (US) with improved resolution is recently used for diagnosing disorders of the upper extremity. We aimed to determine the value of US for diagnosing CTS in hemodialysis (HD) patients, through a cross-sectional analysis.

Methods: All maintenance HD patients (N = 150) at our hospital were recruited after providing written informed consent. Patients with apparent paralysis or pain in the upper extremities due to causes other than CTS were excluded. Longitudinal scan of the median nerve around the carpal tunnel area was performed with US (Toshiba Viamo TM, 12-MHz probe) during HD, and the compression rate (CR) of the nerve was calculated as 1 - (smallest diameter of the carpal tunnel area)/smallest diameter of the nerve around the carpal tunnel area). The CTS symptoms were evaluated with the visual-analogue scale (VAS) of pain around the index finger area and the quick form of the Disabilities of the Arm, Shoulder and Hand (Quick-DASH) questionnaire. Pinch strength was also measured. Serum C-reactive protein (CRP) and β2-Mg concentrations, and medical histories related to CTS or dialysis-induced amyloidosis were extracted from the patients’ records.

Results: Total 250 wrists from 125 patients (Mean age = 65.6±10.6 years) were studied. The mean CR was 11.8±0.7% and the cut-off values of CR from ROC curve for history of carpal tunnel release was 25.7% (sensitivity 0.80, specificity 0.91). Multivariate analysis confirmed that CR was significantly positively correlated with dialysis care, VAS and Quick-DASH scale, positive Tinel’s sign, and serum CRP and β2-Mg concentrations, whereas it showed a significantly negative correlation with pinch strength. Especially, patients with >4 years of HD and serum β2-Mg concentrations >20 mg/L showed significantly high CRs.

Conclusions: Measurement of CR with US is an easy and reproducible method for diagnosing dialysis-related CTS. The CR significantly correlated with symptoms and factors associated with dialysis-induced CTS.

PUB358
Technique Failure in Korean Incident Dialysis Patients: A National Population-Based Study

Shina Lee1, Hyunwook Kim2, Seung-Jung Kim1, Duk-Hee Kang1,1 Kyu Bok Choi,1 Dong-Ryol Ryu1,21 Dept of Internal Medicine, School of Medicine, Ewha Womans Univ Mokdong Hospital, Seoul, Republic of Korea; 2Dept of Internal Medicine, Wonkwang Univ College of Medicine Sanbon Hospital, Gunpo, Republic of Korea.

Background: Technique failure is an important issue for dialysis patients. In this study, we aimed to analyze a detailed technique failure rate and to determine the predictors for technique failure in Korea.

Methods: We identified all patients who had started dialysis between January 1, 2005 and December 31, 2008 in Korea, using the Korean Health Insurance Review and Assessment Service database. A total of 32,357 eligible patients [24,743 hemodialysis (HD) patients and 7,614 peritoneal dialysis (PD) patients] were included, and the median follow-up was 26.76 ± 4.8 months.

Results: The crude incidence rates of technique failure among HD patients and PD patients were 3.4 and 5.1 per 1000 patient-years, respectively. When comparing technique survival rate between HD and PD in both Kaplan-Meier analysis and competing risks analysis, it was significantly higher in patients on PD. Although the gap of technique failure incidence between HD and PD was exaggerated in Kaplan-Meier analysis compared to competing risks analysis. In multivariate analyses, diabetes mellitus and Medical aid as a crude reflection of low socioeconomic status were independent risk factors in both Cox proportional hazard model and Fine and Gray subdistribution model. In addition, cancer was independently associated with a lower risk of technique failure in Fine and Gray model.

Conclusions: Technique failure in PD is higher than that in HD, and it is major concern in patients initiating dialysis in Korea. The results of our study offer a basis for risk stratification and customized care for technique failure.

PUB359
Frequency of Not Achieving Target Weight in Hemodialysis Patients and the Reasons Behind It

Tomei Kyu Bok Choi,1,2 Frank Modersitzki,1 Lada Beear Lasic,1
1Internal Medicine, Div of Nephrology, New York School of Medicine, New York, NY; 2Internal Medicine, Div of Nephrology, New York Harbor VA Healthcare System, New York, NY.

Background: Volume overload and volume depletion have both been associated with morbidity and mortality in patients with end stage kidney disease (ESKD) on hemodialysis (HD). A recent study demonstrated an increased mortality risk when post HD weight is more than 2kg above or below the prescribed estimated dry weight (EDW) for >30% of HD sessions. Our aim was to determine the frequency of sessions with weight difference (WD)≥2kg, determine the prevalence of patients WD≥2kg for <30% of sessions and identify the possible reasons in our outpatient chronic HD population.

Methods: 32 outpatients on chronic HD at the New York Harbor VA Healthcare System in Manhattan were monitored for 2 months. Data for 631 sessions was obtained. Charts and HD nursing notes were reviewed every 2–4 weeks for: weight, prescribed EDW, ultrafiltration (UF) rate, intradialytic complications (hypotension with systolic BP<90, dizziness, cramping, administration of intravenous fluids). Sessions with a missing documented EDW or post HD weight were excluded. 502 sessions were used in the analysis.

Results: The mean WD for all sessions was 0.67±1.64 kg with a majority (83.7%) of HD sessions ending with post HD weight within 2kg of EDW which is consistent with the literature. 6 out of 31 (19.3%) patients had WD≥2kg for >30% of the evaluated sessions. The inability to achieve post HD weight within 2kg of EDW was most commonly (51.2%) associated with an elevated UF rate (defined as ≥875ml/hour). Possible reasons for not achieving EDW also included cramps (4.9%) and hypotension (2.4%).

Conclusions: Failing to achieve EDW within 2kg range is most commonly associated with high UF rates, indicating high weight gains between treatments. Proposed strategies to continue aiming at achieving EDW while compensating for the constraints of elevated UF include: decreasing intradialytic weight gain, increasing treatment frequency or treatment time. Further studies identifying the best strategies to achieve this goal are needed.

PUB360
Comparative Effectiveness of Dialyzers: A Longitudinal Propensity Score-Matched Study

Scott Bibel1, Abigail Hunt,1 Suzanne Laplante,2 Werner Beck,3 Mary Gellens,4 John Alan Laich,1 Steven M. Brunelli,1 DaVita Clinical Research, Minneapolis, MN; 2Baxter Healthcare Corporation, Deerfield, IL.

Background: Differences in dialyzer design may affect systemic inflammation and extracorporeal blood sequestration and thereby impact anemia management and control. We evaluated the comparative effectiveness of commonly used dialyzers with respect to hospitalization hemoglobin (Hb) levels, and ESA and IV iron utilization.

Methods: Patients included in the analysis received hemodialysis between 01 Jan 2009 and 31 Dec 2013 and were new users of Revaclear, Optiflux 160, or Optiflux 180 dialyzers. Patients were followed for 1 year or until end of study or censoring for dialyzer switch, modality change, or loss to follow up. For each comparison, eligible patients were propensity score-matched 1:1 on a range of demographic, comorbidity history, and baseline laboratory parameters. Outcomes were assessed using generalized linear mixed models including fixed effects for dialyzer type, time, and their interaction term.

Results: Matched patient pairs (31,551 for Revaclear-Optiflux 160 comparison; 21,008 for Revaclear-Optiflux 180 comparison) were assessed. ESA doses evolved differently over time among Revaclear patients versus both Optiflux 160 and Optiflux 180 patients (p interaction<0.001 for both). Differences in ESA dose were significant from month 3 for Revaclear versus Optiflux 160 (range, 173-483 U/treatment) and at all time points for Revaclear versus Optiflux 180 (range, 120-392 U/treatment). Hb levels were equivalent between Revaclear and Optiflux patients at all times. IV iron dosing was lower for Revaclear patients than Optiflux 160 and 180 patients (p<0.001 for each) but differences were small (<1 g/dL in most cases).

Conclusions: Use of Revaclear versus Optiflux dialyzers was associated with lower ESA doses, modestly lower IV iron doses, and equivalent Hb concentrations.

Lack of Leukocytic Response to Infections in End Stage Renal Disease

Deepa Amberker,1 Ritesh J. Rampure,1 Mary C. Naglak,1 Harold D. Stein.1 Internal Medicine, Abington Jefferson Health, Abington, PA; 2Hypertension Nephrology Associates, Abington Jefferson Health, PA.

Background: Patients with end stage renal disease (ESRD) on dialysis are at increased risk of infection resulting from a relatively immunosuppressed state. Dysfunctional immunity may be the result of uremia, dialyzer membrane interactions, poor nutritional status and impaired leukocyte responsiveness. Abnormal leukocytic response in such situations may result in missed diagnosis in the clinical setting as well as increased morbidity and mortality. The nature and magnitude of the leukocytic response to infection in this population has not been well characterized. This study is an attempt to assess the degree of leukocytosis in ESRD patients and compare it with the general population in the presence of an infection.

Methods: This was a retrospective study wherein all patients with ESRD on hemodialysis admitted to our hospital between December 2011 and December 2014 with any kind of infection were taken as the ESRD group and compared to others without ESRD or significant chronic kidney disease. Analysis of total WBC as well as percentage of bands/mcl were compared and analyzed for statistical significance. Patients were excluded if on steroids, less than 18 years of age, presence of cancer, HIV, pregnancy, CKD stages 3-5 or if sent from dialysis unit.

Results: After reviewing the medical records of approximately 600 patients admitted for infection, 201 patients were studied based on selection criteria, of which 100 had ESRD and 101 did not. Pneumonia followed by sepsis were the most common infections in both groups. The variables studied were as shown in following table:

<table>

Conclusions: The results of this study demonstrate impaired leukocytic response in ESRD patients on dialysis with infection. Leukocytic response in this population is not a reliable infectious biomarker and if used clinically may lead to diagnostic error and potentially adverse outcomes.

Funding: Pharmaceutical Company Support - Baxter Healthcare Corporation
of poor functional capacity and other co-morbid conditions from the Medical Evidence Form 2728. We conducted both Kaplan-Meier and Adjusted Cox regression analyses with death as the outcome variable.

**Results:** 56,194 (7.18%) were identified as nursing home residents upon initiation of dialysis. Among NH patients, 50.53% were female, 69.92% were white, and 99.49% were on hemodialysis and the mean age was 71.1 ± 12.1 years. The overall incidence rates of death of NH vs. non-NH patients were 51.8/100 and 17.6/100 patient-years, respectively (p < 0.001). The unadjusted 1-year mortality was 50% in NH patients (vs. 20% in non-NH patients, p < 0.001). Adjusted Cox analysis showed that NH patients were at significantly higher risk of death compared to non-NH patients (adjusted hazard ratio [AHR] 1.37; 95% confidence interval 1.35-1.38). Within this NH cohort, age (AHR 1.02; 95% CI 1.02-1.02), inability to transfer (AHR 1.25; 95% CI 1.22-1.29), inability to ambulate (AHR 1.08; 95% CI 1.05-1.11), cancer (AHR 1.15; 95% CI 1.12-1.19) and other co-morbid conditions were significantly associated with death.

**Conclusions:** NH patients on dialysis have a high mortality rate, even when compared to the broader ESRD population. Further studies on modifiable risk factors of mortality in this particularly high-risk ESRD population are warranted. **Bicarbonate as Nutrition Marker in Hemodialysis Patient Louis-Michael Pellerin, Robert Zoel Bell, Jean-Philippe Lafrance, Vincent Pichette, Michel Vallee. Nephrology, Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.**

**Background:** Protein-energy malnutrition (PEM) is prevalent in the hemodialysis (HD) population and is associated with a high morbidity-mortality burden. Metabolic acidosis and PEM are closely related. Protein intake, which constitutes an acid load, is an important factor of pH regulation in end-stage renal disease patients. Therefore, a high bicarbonate serum level be the result of insufficient protein intake and be a useful marker of malnutrition?

**Methods:** We conducted a retrospective study in our HD service using a computer database with measurements obtained simultaneously for all 342 patients. Correlation between pre-HD session bicarbonate, albumine, prealbumine and normalized protein catabolic rate (nPCR) was assessed by the use of Pearson’s and Spearman’s correlation test. Subgroup analysis were realised for patients with negative C-Reactive Protein (CRP < 5) and patients classified as clinically stable.

**Results:** We found a significant, negative and moderate, correlation between bicarbonate and nPCR, (spearman’s p = -0.27, p<0.001). Subgroup analysis showed similar results, (spearman’s p = -0.28, p<0.001)for198clinically stable patient and (spearman’s p = -0.24, p<0.003) for 144 patients with a negative CRP. There was no association between albumin (spearman’s p = 0.06, p=0.151) or prealbumin (spearman’s p = -0.08, p=0.151) and bicarbonate in any group.

**Conclusions:** A higher serum level of bicarbonate is associated with a lower nPCR, reflecting of poor protein intake, but not with a malnutrition state define by albumin or bicarbonate in any group.

**Scope and Consistency of Outcomes Reported in Randomized Trials of Hemodialysis Gabrielle J. Williams, Allison Tong, Jonathan C. Craig. School of Public Health, Univ of Sydney, Sydney, NSW, Australia.**

**Background:** Inconsistent outcome selection and reporting in clinical trials may limit their capacity to inform evidence-based decision making and the ability to combine findings in systematic reviews. **Aim:** We aimed to assess the scope and consistency of outcome selection and reporting in trials included in systematic reviews of interventions for patients on hemodialysis (HD).

**Methods:** The Cochrane Database of Systematic Reviews was searched from 1999 to January 2015 for published systematic reviews of interventions for patients on chronic HD. The description and frequency of outcomes reported within the source randomized controlled trials were assessed.

**Results:** The 18 systematic reviews included 282 trials that reported over 518 outcomes. There was considerable heterogeneity among the outcomes reported. Across all trials, 320 outcomes occurred only once, and 198 outcomes were identified twice. The five most commonly reported common outcomes were mortality (50 trials, 18%), blood pressure (46 trials, 16%), calcium (44 trials, 16%), parathyroid hormone (41 trials, 15%) and quality of life (39 trials [14 %]). There was considerable variation in how the domains were measured, the time at which they were measured, and the units and threshold changes that defined an outcome. For example, blood pressure was reported as pre-dialysis, post-dialysis, maximum, difference in HD vs post dialysis, maximum, resting, rise, and time to restore.

**Conclusions:** A wide array of outcomes are reported in trials of interventions in HD, with large heterogeneity in timing of measurements, units of measure, and threshold changes that define an outcome. This highlights the need for a well-defined set of standardized core outcomes to improve the comparability of trial findings in meta-analysis and to provide greater confidence around treatment decisions for patients undergoing HD. **Funding:** Government Support - Non-U.S.

**Blood Pressure and Cognitive Decline in Hemodialysis Patients Sarah M. Duncan,1 Hocine Tighiouart,1 David A. Drew,1 Tammy Scott,1,2 Daniel E. Weiner,1 Mark J. Sarnak.1 Tufts Medical Center, Boston, MA; 2Tufts Univ, Boston, MA.**

**Background:** Cognitive impairment is common in hemodialysis (HD) patients; however, the relationship between measures of blood pressure (BP) and longitudinal decline in cognitive function is unknown in this population.

**Methods:** 314 participants in the Cognition and Dialysis Study underwent an annual comprehensive battery of cognitive tests. Using principal components analysis (PCA), we reduced individual test results to two domain scores representing memory and executive function. Adjusted joint mixed models accounting for death, transplant, and drop-out were used to explore the association of blood pressure (systolic [SBP], diastolic [DBP] and pulse pressure [PP]) with change in cognitive function over time.

**Results:** Mean (SD) age was 63 (16) years, 47% were women, 22% were African American, and 44% had cardiovascular disease (CVD). Mean (SD) SBP, DBP, and PP were 141 (21), 73 (12) and 68 (15) mmHg, respectively. Median follow up time was 1.8 years (IQR 1.0-3.4). Mean slopes of PCA memory and executive were 0.03 (95% CI -0.01, 0.07) and -0.11 (95% CI -0.15, -0.06) per year, respectively. Lower DBP and higher PP were associated with decline in measures of both memory and executive function. There was no association between SBP and cognitive decline.

**Conclusions:** Lower DBP and higher PP are associated with faster rate of cognitive decline, in particular that related to executive function. Because impairment in executive function is a manifestation of vascular disease and lower DBP and higher PP are associated with CVD in HD patients, our results suggest that cognitive decline may be mediated by vascular disease in this population. **Funding:** NIDDK Support, Pharmaceutical Company Support - Dialysis Clinic Inc.
Methods: Data were obtained from the 52-wk active control period of the FC pivotal trial. Subjects with a baseline ferritin *1000ng/mL, or TSAT%=50% were excluded from the trial. We randomized 292 subjects to FC and 149 to AC. Any subjects who developed ferritin level *1500ng/mL at any time over 52wks were identified. CV, ID, and dialysis access related adverse events (AE) occurring at any time over the 52-week period were tabulated.

Results: 57 subjects (19.8%) in the FC group and 14 subjects (9.5%) in the AC group had at least a single ferritin*1500ng/mL (p=0.012) during the 52 wks. CV events including MI, CHF, and arrhythmias, occurred in 12.3% of the FC group compared to 21.4% AC. ID AE's occurred in 42.1% FC and 50% AC. Dialysis access related AE occurred in 15.7% FC and 42.2% AC. IV iron administration was statistically significantly lower (p=0.003) in the FC group. (2.95±3.75mg/wk) than the AC group (6.20±3.64mg/wk), consistent with the full FC cohort that saw a significant reduction in IV iron use. Cumulative ESA dosing was 1016±906 Units/wk FC and 1781±1756 Units/wk AC (p=0.256).

In the subjects who developed ferritin *1500ng/mL shows that few subjects experienced a CV, ID, or dialysis access related AE in those receiving FC vs AC. IV iron use was statistically lower and ESA dosing was numerically lower. As previously reported the majority of ferritin*1500ng/mL resolved and 90.1% were adjudicated to be related to IV iron and/or inflammatory AEs. This analysis, although limited by small sample size, supports the conclusion that FC is clinically useful and safe vs traditional binders.

**Association Between Employment Status and KDQOL Scores in Dialysis Patients**

Diana V. Dunn, 1 Deborah S. Evans, 1 Elizabeth J. Jones, 1 Caroline Hann, 2 Rich Mutti, 3 Allen R. Nissenson, 4 Deborah A. Benner. 1 DaVita HealthCare Partners Inc, Denver, CO; 2 Apex Health Innovations, Simi Valley, CA.

**Background:** Studies have shown that unemployment negatively impacts dialysis patients' quality of life (QOL). 2 QOL can be quantified and low scores on the Kidney Disease Quality of Life (KDQOL) survey are associated with poor outcomes. 3 Our study examines employment/unemployment status and KDQOL scores.

**Methods:** We collected employment status data on 122,166 adult patients at a large dialysis organization from Nov 2014-Apr 2015. Patients were grouped as either employed (42.0%) and unemployed (35.2%) categories, followed by the other (n=7936) and unemployed groups (n=98,014) [Table]. A preliminary analysis found employment is positively associated with KDQOL scores.

**Results:** The employed group (n=61,216) had the highest KDQOL scores in all categories (Table 1). Employment status was associated with KDQOL scores (p=0.001) [Table]. A clinically significant difference (6.8) in Physical Component Score was found between the employed (42.0) and unemployed (35.2) groups. This difference was greater (~10 points) between full-time employed and Workers Compensation patients, who scored lowest in all categories.

**Reduction of Pruritus in Hemodialysis Patients by Adjustment of Serum B-Type Natriuretic Peptide**

Yoshio Yamada, 1, 2 Toshiki Kano, 1, 2 Yasuhiko Tomino. 1 Juntendo Univ Hospital, Tokyo, Japan; 2 Juntendo Univ, Tokyo, Japan.

**Background:** Pruritus reduces the quality of life (QOL) and worsens the prognosis in hemodialysis patients. It was reported that the neuropeptide natriuretic polypeptide B (Brain natriuretic peptide) in hemodialysis patients was positively correlated with the expression levels of a-SMA, bFGF, IGF-1 and MMP9. Hyperplasia intima was eccentric and the hyperplasia intima showed obvious inflammatory cells infiltration and vascular degeneration. Immunohistochemical staining showed that compared with the group of chronic glomerulonephritis, hypertensive nephropathy and diabetic nephropathy groups' a-SMA, bFGF, IGF-1 and MMP9 expression levels were significantly increased, expression of VEGF was significantly reduced, MMP2 was no significant change (P<0.05). Univariate regression analysis revealed that the expression levels of all-SMA was positively correlated with bFGF, IGF-1 and MMP9, negatively correlated with the VEGF. AVF intimal hyperplasia mainly dominated by the vascular smooth muscle cells (VSMC) proliferation. The present study is to investigate whether pruritus can be reduced by controlling serum BNP.

**Methods:** Forty-eight patients participated in this study. (Test 1) Serum BNP was measured with common laboratory tests and visual analogue scale (VAS) in a single hemodialysis session. The factors influencing the changes of VAS during the dialysis session were analyzed. (Test 2) The fluid volume was strictly managed to decrease serum BNP level by reporting the weight gain during each dialysis session. Patients who gained weight reduced pruritus in hemodialysis patients but it was difficult to improve long-term QOL.

**Conclusions:** It was suggested that the adjustment of serum BNP by strictly managing the weight reduced pruritus in hemodialysis patients but it was difficult to improve long-term QOL.

**The Mechanisms Study on Neointimal Hyperplasia of Autogenous Arteriovenous Fistula in Maintenance Hemodialysis Patients**

Nanmei Liu, Jumin Hospital of Shanghai.

**Background:** To evaluate the influence and the possible mechanism about neointimal hyperplasia of autogenous internal arteriovenous fistula in hypertensive nephropathy and diabetic nephropathy patients which was going maintenance hemodialysis and provide possible theory about how to prevent from intimal hyperplasia, extend the life of AVF in clinical practice.

**Methods:** Collecting cephalic vein when the hemodialysis patients had the surgery of AVF angioplasty and reconstruction. Vascular tissues were divided into chronic glomerulonephritis group, hypertensive nephropathy group and diabetic nephropathy group. Immunohistochemistry was used to detect the expression of vascular smooth muscle actin (a-SMA). Selecting the control group and fistula vascular tissue which the useful life was 12-18 months, basic fibroblast growth factor (bFGF), insulin-like growth factor 1 (IGF-1), matrix metalloproteinase2 (MMP2) and matrix metalloproteinase9 (MMP9) were used to detect expression change by immunohistochemical staining.

**Results:** Compared with chronic glomerulonephritis group, intima thickness of hypertensive nephropathy and diabetic nephropathy were significantly increased and the increase was more significant in diabetic nephropathy. Hyperplasia intima was eccentric and a-SMA, bFGF, IGF-1 and MMP9 expression levels were significantly increased, expression of VEGF was significantly reduced, MMP2 was no significant change (P<0.05). Univariate regression analysis revealed that the expression levels of all-SMA was positively correlated with bFGF, IGF-1 and MMP9, negatively correlated with the VEGF. AVF intimal hyperplasia mainly dominated by the vascular smooth muscle cells (VSMC) proliferation. Matrix metalloproteinases can be considered as a diagnostic and the possible therapeutic targets for the prevention and treatment on intimal hyperplasia of AVF in dialysis patients.

**Association of Nutritional Status with Depression and Sleep Disorders in Elderly Hemodialysis Patients**

Avsan Ibs. 1 Emre Tutar. 2 Nephrology, Afyonkarahisar State Hospital, Afyonkarahisar, Turkey; 1 Nephrology, Baskent Univ Hospital, Ankara, Turkey.

**Background:** The relationship between depression, sleep quality, and malnutrition in an elderly population in maintenance hemodialysis is very complex and not yet fully understood. We aimed to determine the association of nutritional status with depression and sleep quality in elderly hemodialysis patients. Methods: Seventy three dialysis patients (41 female, 32 male; aged, 72.5±6.0 years) older than 65 years of age, were enrolled in the study. Nutritional status was determined by Subjective Global assessment (SGA). Beck Depression Inventory (BDI) questionnaire was used to measure presence and degree of depression. Quality of sleep was measured using the Pittsburg Sleep Quality Index (PSQI). Demographic and biochemical parameters and Charlson Comorbidity Index and frequency of infection in previous year of all patients were recorded.

**Results:** In our elderly patients 15% (n=20) had sleep disorder and 24% (n=32) had mild to moderate depression and 11% (n=4) had moderate to severe depression. According to SGA 48% (65%) patients were well-nourished and 25% (34%) patients had mild-moderate and severe malnutrition. When the well-nourished and malnourished patients were compared, well-nourished group had higher albumin levels (4.28±0.25 g/dL vs 3.50±0.36 g/dL), lower CRP levels (7.51±4.23 vs 16.02±19.45), better quality of sleep (3.50±0.82 vs 5.56±1.73) and better depression scores (6.82±2.75 vs 16.28±4.54) than malnourished group. By multivariate analysis when factors affecting nutritional status were taken into account BDI (p=0.001; OR=1.79, CI 1.26-2.56) and PSQI (p=0.022; OR=4.43; CI 1.23-15.2) was associated with SGA.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusions: Depression and sleep disorders are important factors influencing the nutritional status and could be an independent risk factors for malnutrition in elderly patients receiving maintenance dialysis. Psychological assessment should be mandatory in the follow up of these patients to identify depression and sleep disturbance because many of them are reversible.

PUB373

Predialysis Hyponatremia and Mortality in Elderly Patients with Incident Maintenance Renal Replacement Seon Ho Baek, Sung Woo Lee, Shin-Young Ahn, Sejoong Kim, Ki Young Na, Dong-Wan Chae, Ho Jun Chin. Internal Medicine, Seoul National Univ Bundang Hospital, Republic of Korea.

Background: Predialysis hyponatremia recently have been reported to be associated with mortality in incident hemodialysis patients. However, little is known about whether predialysis hyponatremia is associated with unfavorable outcomes in elderly patients.

Methods: We retrospectively assessed mortality in 397 (mean age 73.0 year, male female 226/171) patients aged ≥65 years with non-diabetic end-stage renal disease (ESRD) who initiated renal replacement therapy (RRT) at a tertiary university hospital between 2000 and 2010. 1 year and 3 year mortality (ACM) was analyzed in relation to predialysis sodium serum (sNa). We divided subjects into 3 groups according to sNa: Group1, < sNa 125; Group 2, sNa 125-134, Group 3, sNa ≥ 135 mEq/L. Patients with sNa levels >145mEq/L were excluded.

Results: The median value of sNa was 137 mEq/L (interquartile range 133-140 mEq/L). Chronic comorbidities including congestive heart failure (r = -0.215, P=0.001) and liver cirrhosis (r = -0.174, P=0.001), late referral (r = 0.230, P=0.001), use of thiazide (r = -0.160, P=0.001), lower estimated glomerular filtration rate (r = 0.152, P=0.005) and mortality difference was not observed between group 3.

Conclusions: Predialysis hyponatremia was associated with increased 1-year mortality in elderly ESRD patients who initiated RRT. However, the higher mortality was only observed in elderly patients with severe hyponatremia (sNa < 125mEq/L). These findings suggested that compared to adults <65 years, other comorbidities or factors rather than sNa may affect mortality in elderly.

PUB374

Observation of the Correlation Between the Uremic Toxins with Clinical Feature in Uremia Patients Mei Li,1 Qiong-Li Yin,2 Zhenda Zheng,3 Cai-Lian Cheng,3 Xun Liu,1 Cheng-Gang Shi.1 1VIP Healthcare Center, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China; 2Cardiovascular Dept, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China; 3Nephrology Dept, The Third Affiliated Hospital of Sun Yat-sen Univ, Guangzhou, China.

Background: To investigate the correlation between the uremic toxins with age, dialysis duration, and the different blood purification techniques on removal uremic toxins with biochemical analyze, Middle molecular and macromolecular toxins (MMS) with Ultraviolet therapy, blood was sampled for small molecule water soluble toxins BUN with automatic soluble toxins BUN with automatic

Results: A total of 251 patients were included with mean age of 59.0 ± 11.9 years, mean eGFR of 5.4 ± 1.2 mLA/min/1.73 m², 57% were males and 51.4% were Chinese. Majority started hemodialysis. Although improving, maternal and fetal outcomes in those with chronic kidney disease remain variable. Our experience adds to the growing literature on dialysis conversion from intravenous doxercalciferol to oral calcitriol using a conversion algorithm maintains iPTH within KDIGO recommended targets and does not appear to cause hypercalcemia or hyperphosphatemia. The clinical significance of higher iPTH values among those treated with oral calcitriol and sevelamer needs further study. Funding: NIDDK Support, Veterans Administration Support

PUB376

Pregnancy and Chronic Dialysis in Elderly Patients Who Initiated RRT. However, the higher mortality was only observed in elderly patients with severe hyponatremia (sNa < 125mEq/L). These findings suggested that compared to adults <65 years, other comorbidities or factors rather than sNa may affect mortality in elderly.

Conclusions: This small retrospective study suggests that conversion from intravenous doxercalciferol to oral calcitriol using a conversion algorithm maintains iPTH within KDIGO recommended targets and does not appear to cause hypercalcemia or hyperphosphatemia. The clinical significance of higher iPTH values among those treated with oral calcitriol and sevelamer needs further study. Funding: NIDDK Support, Veterans Administration Support

PUB377

When Shall the Advanced Chronic Kidney Disease Patients Start Dialysis? Ling Yeoh Yeo,3 Sir Fairuz baizuri Salif, Bek Choon How, Yan Lun Allen Liu, Milind Nikam. Medicine, Kho Teck Puat Hospital, Singapore.

Background: Recent guidelines suggest dialysis should be initiated when estimated glomerular filtration rate (eGFR) drops below 10-12ml/min. The aim of the present study was to analyse outcomes of those initiating dialysis at very low eGFRs.

Results: Among the patients who received oral calcitriol were 8.8±0.6 mg/dL. Hyperparathyroidism (n=1), hyperphosphatemia. The clinical significance of higher iPTH values among those treated with oral calcitriol and other non-sevelamer binders (-102 ± 294 to 155 mEq/L, P=0.173).

Conclusions: This small retrospective study suggests that conversion from intravenous doxercalciferol to oral calcitriol using a conversion algorithm maintains iPTH within KDIGO recommended targets and does not appear to cause hypercalcemia or hyperphosphatemia. The clinical significance of higher iPTH values among those treated with oral calcitriol and sevelamer needs further study. Funding: NIDDK Support, Veterans Administration Support

PUB377

When Shall the Advanced Chronic Kidney Disease Patients Start Dialysis? Ling Yeoh Yeo,3 Sir Fairuz baizuri Salif, Bek Choon How, Yan Lun Allen Liu, Milind Nikam. Medicine, Kho Teck Puat Hospital, Singapore.

Background: Recent guidelines suggest dialysis should be initiated when estimated glomerular filtration rate (eGFR) drops below 10-12ml/min. The aim of the present study was to analyse outcomes of those initiating dialysis at very low eGFRs.

Methods: A single center, prospective study of new ESRD patients who were initiated on dialysis between 2012 – 2014 and dialysis was performed for >90 days. The patients were categorized into 2 groups according to eGFR ≤ 5 and ≥ 5ml/min upon initiation. The patients with incomplete data, and those who underwent transplantation were excluded. Results: A total of 251 patients were included with mean age of 59.0 ± 11.9 years, mean eGFR of 5.4 ± 2.9ml/min; 57% were males and 51.4% were Chinese. Majority started on hemodialysis (81.7%) and 69.7% were unplanned. The survival rate till May, 31 2015 was 88.4%; 61% were initiated when eGFR ≤ 5 (mean 3.6±1.1 ml/min) and 39% with eGFR > 5 (mean 8.3 ± 2.6 ml/min). Dialysis vintage was shorter in the group with eGFR < 5 (18.2 ± 9.5 vs. 21.7 ± 11.1 months). The patients with eGFR < 5 had lower Charlson Comorbidity Index (4.0 ± 1.3 vs. 4.7 ± 1.2), and hemodialysis was preferred (90.9% vs. 67%). The disease burden was significantly lower in the group with eGFR < 5, including diabetes mellitus (72.1 vs. 88.7%), ischemic heart disease (23.4% vs. 37.1%) and peripheral arterial disease (4.5 vs. 12.4%). However, there were trends showing that these patients were younger, had higher serum albumin and shorter hospitalization for index admission. Underlying diabetes, ischemic heart disease, modality selection and dialysis vintage remained significant after adjusted. Mean survival for both groups were comparable (36.3 months, 95% CI: 34.4-38.2 vs. 34.5 months, 95% CI: 32.0-37.0). Among the patients who survived, 97.7% remained on their initial modality. Conclusions: Our study suggests that the ESRD patients without significant morbidities may be able to delay dialysis initiation without significant short term adverse outcomes. Further studies are required.
The Incidence and Type of Cancer in Patients with End-Stage Renal Disease: A Prospective Cohort Study for End-Stage Renal Disease in Korea

Kyang Don Yoo,1 Hajong Lee,1 Jung Pyo Lee,1 Dong Ki Kim,1 Shin-Wook Kang,2 Chul Woo Yang,1 Yong-Lim Kim,1 Chun Soo Lim,1 Kwon Woo Joo,1 Won Suk Kim,2 Seoul National Univ;1 Yonsei Univ;1 The Catholic Univ;1 Kyungpook National Univ.

Background: In patients with end-stage renal disease, urinary tract kidney cancer is known to be closely related to the general population. However, the incidence and type of cancer is affected by variable factors such as age, gender, ethnic differences. Moreover, the causation of dialysis and cancer incidence in certain type of cancer is still needed to be clarified.

Methods: A total of 5,225 patients in the clinical research center for ESRD cohort were included from Jan 2007 to Aug 2014. The primary outcomes to be compared were cancer incidence rate of ESRD patients with the general population. We obtained cancer incidence data from National Cancer Information Center Registry in healthy counterpart.

Results: A total of 2,200 incident and 3,035 prevalent dialysis patients was included throughout the study. The mean follow-up duration was 25.8 months, and 116(2.2%) patients were diagnosis with cancer during the observation periods. ESRD with cancer group was significantly older, longer dialysis duration and more comorbidity than control group. The incident rate of cancer in prevalent dialysis patients was higher than those in incident dialysis patients (2.5 vs 1.5%, p<0.002). The proportion of primary organ was highest in digestive organ (35.6%) and then followed by urinary tract organ (28.3%). Among 116(2.2%) patients of dialysis patients diagnosis with cancer from dialysis initiation was 58.6 months in digestive cancer, 52.0 months in urinary tract cancer. The standardized incidence ratio (SIR) of overall cancer was 0.94 [95% CI: 0.72 –1.19]. Urinary tract cancer showed the highest SIR [SIR: 4.7, 95% CI: 4.42–8.19] and had reached a level 1.6 higher than the general population (16.1%). In terms of cancer incidence of digestive organ cancer showed no difference in the incidence of cancer compare to the general population [SIR: 0.607, 95% CI: 0.36–0.94].

Conclusions: Further research was needed to compare the organ-specific cancer incidence of ESRD patients with the general population. The screening test could be necessary for digestive and urinary tract cancer.

The Role of Social Support in Hemodialysis Patients

Gun Woong Kang,2
Internal Medicine, Catholic Univ of Daegu School of Medicine, Daegu, Korea.

Background: A number of patients with End-Stage Renal Disease (ESRD) have significant impairment in social support. Especially, the limited function of patients with hemodialysis (HD) prevents them from social activities and even makes them social withdrawal. There are few studies of the factors affecting the social support in HD patients. The aim of the current study was to identify the clinical and psychosocial factors including quality of life related to impaired social support in HD patients.

Methods: The 101 participants on HD from the Daegu Catholic University Medical Center were assessed from September in 2013 to September in 2014. Patients on HD for acute kidney injury were excluded from this study. Multidimensional Scale of Perceived Social Support (MSPSS) was used for evaluating patients' social support. Variables included in the analysis were the MSPSS factors including quality of life, anxiety, depression and sleep disorder were evaluated.

Results: The mean of MSPSS (social support) score was 36.8±4.5. In subgroups of social support, the MSPSS-family, MSPSS-friend, and MSPSS-medical team scores were 14.0±2.4, 14.0±2.4, and 8.4±2.9, respectively. The variables showed significant association with social support were quality of life (r=0.33, p=0.001), depression (r=-0.29, p=0.003), anxiety (r=0.37, p=0.001), and serum creatinine (r=-0.27, p=0.007). Multiple regression showed that quality of life (95% CI, 0.615–19.799, p=0.037) and serum creatinine (95% CI; -1.543–0.319, p=0.003) were independent predictors of impaired social support.

Conclusions: This study explored the determinants of high susceptibility to the impaired social support in HD patients. We found that the impaired social support is associated with the quality of life and serum creatinine. Further study will be needed because of the possibility of different results depending on culture and ethnicity. As well as, we should consider the psychosocial interventions to improve the impaired social support.

Use of Portable Fundoscopic Photography to Screen for Diabetic Retinopathy in the Hemodialysis Unit

Beekie Michael,1 Yasin G. Brahmbhatt,2 Nika Bagheri,2 Laura T. Pizzi,2 Benjamin Leiby,4 Anne P. Murchison.1

1Marlton Nephrology and Hypertension; 2Thomas Jefferson Univ; 3Wills Eye Hospital.

Background: Over 40% of dialysis patients have diabetes, yet only 25% get annual eye exams. Due to the frequency and duration of visits to dialysis centers, patients on dialysis likely have increased barriers to receiving eye exams and other recommended preventive care. This study evaluated the need for ophthalmic care, barriers to care, and prevalence of diabetic retinopathy (DR) in this population.

Methods: Prospective cohort study at two dialysis centers (1 urban, 1 suburban). A total of 101 participants on HD from the Daegu Catholic University Medical Center were assessed from September in 2013 to September in 2014. Patients on HD for acute kidney injury were excluded from this study. Multidimensional Scale of Perceived Social Support (MSPSS) was used for evaluating patients' social support. Psychosocial factors including quality of life, anxiety, depression and sleep disorder were evaluated.

Results: The mean of MSPSS (social support) score was 36.8±4.5. In subgroups of social support, the MSPSS-family, MSPSS-friend, and MSPSS-medical team scores were 14.0±2.4, 14.0±2.4, and 8.4±2.9, respectively. The variables showed significant association with social support were quality of life (r=0.33, p=0.001), depression (r=-0.29, p=0.003), anxiety (r=0.37, p=0.001), and serum creatinine (r=-0.27, p=0.007). Multiple regression showed that quality of life (95% CI, 0.615–19.799, p=0.037) and serum creatinine (95% CI; -1.543–0.319, p=0.003) were independent predictors of impaired social support.

Conclusions: This study explored the determinants of high susceptibility to the impaired social support in HD patients. We found that the impaired social support is associated with the quality of life and serum creatinine. Further study will be needed because of the possibility of different results depending on culture and ethnicity. As well as, we should consider the psychosocial interventions to improve the impaired social support.
Enhancing Patient Engagement in Future Clinical Trials – The Effects of Age and Ethnicity

Territa Santahkumaran, Kieran Mccafferty. Renal, Royal London Hospital, London, United Kingdom.

Background: Increasing patient engagement from ethnic minority populations is crucial to the widespread applicability of research findings, but this represents a challenge in nephrology clinical research. Ethnicity, socio-cultural and language barriers along with a lack of understanding and awareness of clinical trials are potential factors that affect patient involvement in clinical trials.

Methods: We developed a patient survey in English, Urdu and Bengali to represent our ethnically diverse population in East London to explore the attitudes and understanding of clinical research using a 1-7 scoring system to rate various statements about research. The surveys were offered to all patients attending the haemodialysis and renal outpatients department over a 2 week period.

Results: 151 forms were completed, 145 in English, 7 in Bengali and 1 in Urdu. 41% of the respondents were from patients who attended transplant clinic and 31% from patients who attended for haemodialysis. Overall there was a strong message that patients wanted more trials in nephrology and felt that taking part in trials would help them take a more active role in their health. They also felt there was a lack of information on how to access research opportunities. Of those who completed the survey there was no significant ethnicity differences in their attitudes and understanding of clinical research, however transplant patients who identified themselves as White British were significantly more likely to take part in the survey (p<0.02). Patients who identified themselves as Black British were significantly less likely to take part in the survey (p<0.02). In the dialysis cohort, patients who identified themselves as White British were significantly more likely to take part in the survey (p<0.02). Whereas patients who identified themselves as Bangladeshis were significantly less likely to take part in the survey (p<0.04). Age did not appear to have an effect on patients’ perception and understanding of clinical trials.

Conclusions: From our work it is clear that there is a patient led demand for greater engagement in translational research. However, challenges remain in engaging ethnic minority cohorts in clinical research.

Deferred Educational App Personalization Increases Registration Completion

Daniel Schwartz, 1 Chan Kruse. 1 'Faculty of Medicine, Univ of British Columbia, Vancouver, BC, Canada; 2'QxMD, Vancouver, BC, Canada.

Background: ‘Read by QxMD’ (http://qxmd.com/read) is an app that curates the nephrology literature and personalizes reading recommendations based on a clinician’s or researcher’s interests. In order to provide highly accurate recommendations, the app must collect content preferences such as preferred journals and topics. In addition, it must collect email address and personal identifiers in order to complete registration and offer CME. When the registration process is too onerous, mobile app users may not complete registration. If the registration process fails to collect necessary user data, this may negatively impact the educational value of the app. We hypothesized that allowing users to delay providing personal information until after they set their preferences would increase registration completion.

Methods: We randomly assigned all users registering on the Android version of ‘Read to two different registration processes. In version 1, “upfront personalization”, users are asked to provide personal identifiers prior to setting their preferences, while in version 2, “deferred personalization”, users set preferences first and after this has been completed are asked for personal identifiers. The Leanplum SDK was used to implement and automate the randomization of alternate registration pathways. The primary outcome was completion of registration.

Results: Between April 6, 2015 and June 1, 2015, a total of 5660 users who registered using the Android version of ‘Read’ were randomized with 2824 users randomized to upfront personalization and 2836 to deferred personalization. Upfront personalization yielded a 47.4% (95% CI 46.0 to 48.8) registration completion rate versus 50.7% (95% CI 49.0 to 52.4) with deferred personalization (p < .05).

Conclusions: A strategy of deferred collection of personal identifiers yielded slightly higher completion rates. To maximize user registration when onboarding users to educational medical apps, consider deferring the collection of personal information until user preferences have been provided. Further research is required to maximize app registration when data requested is extensive as in ‘Read’.

Patients-Initiated Educational Research in a Digital Age

Chavakrit Krittanawong, 1 Zhen Wang, 2 Sakkarin Chirapongsathorn, 1, 2 Hua Ann Jenny L. U. 3 Div of Cardiovascular Disease, Mayo Clinic, Rochester, MN; 3Dept of Healthcare Policy and Research, Mayo Clinic, Rochester, MN; 3Div of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN; 3Div of Gastroenterology, Dept of Medicine, Phramongkutklao Hospital and College of Medicine, Royal Thai Army, Bangkok, Thailand; 3Div of Nephrology, Massachusetts General Hospital and Harvard Medical School, Boston, MA.

Background: The emergence of web-based technology in the digital age has become popular in the healthcare industry, particularly in the educational research field. A web-based technology can bridge the educational gap between researchers and patients.

Methods: We aimed to develop a user-friendly interface between a virtual community that is driven by patients and researchers and a preliminary knowledge-building activity. Wikiheart is a web research environment that creates a real-time community between researchers and patients without geographical restrictions.

Results: Once patients have registered for free, the system allows these users to write their own articles or to edit other articles, which often leads to thought provoking medical research questions. Wikiheart also demonstrates a novel approach to population science that is based on huge databases with multiple cloud servers that reach the web research community. Nowadays Wikiheart has more than one million visitors, and serves as an educational web technology that provides its users with both a variety of learning methods, and several areas of research focus.

Conclusions: Wikiheart is an innovative web-based program for conducting educational research in the digital community. It is a excellent tool for researchers and patients to generate new hypotheses via the scientific method in an online environment.

Urinary Trefoil Factor 3 Is Significantly Associated with Renal Tissue
Fibrosis in Patients with Tubulointerstitial Nephritis Keiko Tanaka,
Hitoshi Sugiyama, Tosho Yamanari, AY Akiyama, Akifumi Onishi, Masashi
Kitagawa, Hiroshi Morinaga, Yoko Kikumoto, Tatsuyuki Inoue, Jun Wada.
Dept of Medicine and Clinical Science, Okayama Univ Graduate School, Okayama, Japan.

Background: Trefoil factor 3 (TFF3) is a small peptide involved in mucosal protection. TFF3 is widely expressed in multiple tissues including kidney. Previous studies have suggested that serum and urinary TFF3 significantly increases in patients with chronic kidney disease and that urinary TFF3 level decreases in rats with acute kidney injury. However, it is unclear whether serum or urinary TFF3 is associated with human renal tissue injury. The aim of this study is to elucidate the relationship between serum and urinary TFF3 levels and the degree of renal tubulointerstitial injury.

Methods: The total study population included 52 patients (tubulointerstitial nephritis: 31, minor glomerular abnormalities and thin basement membrane disease as controls; 21) who underwent renal biopsy. The serum and urinary TFF3 concentrations were determined by a specific ELISA. The degrees of tubulointerstitial cell infiltration and fibrosis were semiquantitatively graded in biopsy specimens and defined by the inflammation score and the fibrosis score, respectively. An immunohistochemical analysis was performed to reveal tissue localization of the TFF3 protein.

Results: The median serum and urinary TFF3 levels of the disease group were significantly higher than those of the controls (p<0.002 and p<0.008, respectively). A statistically significant positive correlation was observed between the urinary TFF3 levels and the renal fibrosis score in the disease group. However, there was no correlation between the serum or urinary TFF3 level and the renal inflammation score in tissue with disease. TFF3-positive cells were observed in the renal tubular epithelium.

Conclusions: The data indicate that serum and urinary TFF3 levels significantly increased and, in particular, that urinary TFF3 could reflect renal tissue fibrosis in patients with tubulointerstitial nephritis. Further studies are required to elucidate the precise distribution of renal TFF3 protein and mRNA, and the mechanism underlying the contribution of TFF3 to renal fibrosis.

PUB391
Induction of Epithelial-to-Mesenchymal Transition and Fibrosis Signals via AKT and Peroxisome Activator-Receptor Pathway in Renal Tubular Cells Induced by a Plasticizer Di(2-ethylhexyl) Phthalate Shing-Hwa Liu, Li-Chen Huang, Bo-Lin Chen, Chih-Kang Chiang.

The data indicate that DEHP is capable of inducing the EMT process and the renal fibrosis score in the disease group. However, there was no correlation between the serum or urinary TFF3 level and the renal inflammation score in the disease group. TFF3-positive cells were observed in the renal tubular epithelium.

Conclusions: The data indicate that serum and urinary TFF3 levels significantly increased and, in particular, that urinary TFF3 could reflect renal tissue fibrosis in patients with tubulointerstitial nephritis. Further studies are required to elucidate the precise distribution of renal TFF3 protein and mRNA, and the mechanism underlying the contribution of TFF3 to renal fibrosis.

PUB388
Teaching Ethics and EBM in the Medical School: Case Discussion as a Teaching Tool on End-of-Life Issues – Dialysis or Palliative Treatment in a 92 Year Old Patient? Giorgio P. Piccoli, Laura Sacchetti, Laura Verze, Franco Cavallio, Department of Philosophy, Clinical and Biological Sciences, Univ of Torino, Italy; 2Course of EBM and Ethics, Univ of Torino, Italy.

Background: History of Nephrology influences the development of bioethics and offers insights for teaching: the first Ethics Committee (the "God's Committee"), brain death, the sale of organs, the limitation of resources, up to the global needs (as in the 0-25 project). Case discussion within the Medical school may be a useful tool to acquire bioethical skills and analytical tools.

Methods: Discussion of a clinical case: patient in his nineties, high comorbidity, good cognitive status (writer), GFR 10 mL / min. The case raises questions about the choice of dialysis-palliation. 50 medical students of the curricular course of ethics and EBM are tutored for an academic year through the collection of information from databases (PubMed), web, talk with experts, tutors and teachers. The analysis is performed according to the 4 major ethical principles (beneficent, non maleficent, justice, autonomy) to a narrative approach.

Results: The students produces a text, here summarized: from a clinical standpoint, beneficent and non-maleficent suggest to postpone dialysis (intent-to-treat) with the start of palliation: medical treatments other than dialysis, death (favorable context). Distributive justice favors less expensive therapies (diet, palliation); in the context of individual justice, the start of dialysis, if necessary, has a role in life support. The patient, by consulting more doctors, has expressed his desire for autonomy. Considering the chronic disease, the intellectual level, a doctor-patient relationship of "shared decision making" is advisable. Sharing the choice improves results, reduces dropout rate of dialysis, if undertaken. Since the four principles of bioethics take on different priorities depending on the socio-cultural context, the approach to the patient will be modulated in a narrative in his views or religious beliefs.

Conclusions: Nephrology offers suggestions for bioethical discussion. Conversely, bioethics offers analytical tools for the analysis of complex decisions such as dialysis in the "very old".

Ssrc Kinase Is a Potential Therapeutic Target in Renal Fibrosis. Yanni Yan,1,2 Murugavel Ponnusamy,1 Evelyn Tolbert,1 George P. Bayliss,1 Shougang Zhuang,1 1Dept of Emergency Medicine, Shanghai East Hospital, Tongji Univ School of Medicine, Shanghai, China; 2Dept of Medicine, Rhode Island Hospital and Alpert Medical School, Brown Univ, Providence, RI.

Background: Increased activity of Src, a non-receptor tyrosine kinase, has been associated with the pathogenesis of renal tumors and some glomerular diseases, but its role in renal interstitial fibrosis remains elusive.

Methods: In this study, we investigated the effect of Src inhibition on renal interstitial fibroblast activation in vitro and renal fibrogenesis in a murine model of unilateral ureteral obstruction and the mechanisms involved.

Results: Exposure of cultured renal interstitial fibroblasts (NRK-49F) to PP1, a selective inhibitor of Src, resulted in decreased expression of α-smooth muscle actin (α-SMA), and fibronectin and collagen 1 in response to serum- or transforming growth factor-b1 (TGF-b1). Silencing Src with siRNA also inhibited expression of those proteins. Further, pretreatment of NRK-49F with a selective Src inhibitor blocked renal fibroblast proliferation as indicated by a dose-dependent down-regulation of Cyclin D, Cyclin E and PCNA (proliferating cell nuclear antigen), three proteins involved in cell cycle progression and up-regulation of p21 and p27, two major cell cycle inhibitors. In a murine model of renal interstitial fibrosis induced by unilateral ureteral obstruction (UUO), the active form of Src (phospho-Src Tyr416) was upregulated in the fibrotic kidney, and its inactivation with PP1 reduced renal fibroblast activation and attenuated extracellular matrix protein deposition. Src inhibition also suppressed expression of TGF-bR1, activation of Smad3 and STAT3, and phosphorylation of epithelial N-cadherin, a profibrotic marker. Finally, PP1 treatment reduced renal epithelial cells arrested at G2M phase of cell cycle, a phenotype that produces profibrotic genes/factors, cytokines, after UUO injury.

Conclusions: Our results demonstrate the importance of Src in mediating renal interstitial fibroblast activation and renal fibrogenesis and suggest Src as a potential therapeutic target for treatment of chronic renal fibrosis.

Orthostatic Hypotension as the Presenting Feature of Primary Systemic Amyloid Light-Chain (AL) Amyloidosis.

Elnaz Arefi Talakshi,1 Rajiv A. Perinbakekar,2 Gary R. Briefel,1 Moro O. Salifu,1 1Medicine, Renal Div, Downstate Medical Center, Brooklyn, NY; 2Medicine, Renal Div, Kings County Hospital Center, Brooklyn, NY.

Introduction: Orthostatic hypotension is a common disorder among the elderly, often associated with hypovolemia, adrenal insufficiency, and autonomic neuropathies. Primary systemic amyloid light-chain (AL) amyloidosis is a rare acquired plasma cell disorder. Morbidity results from extracellular depositions of amyloid fibrils in vital organs. Deposition of amyloid protein in the nervous system leads to autonomic neuropathy, resulting in orthostatic hypotension, early satiety, erectile dysfunction and intestinal motility dysfunction. We report a case of primary systemic amyloidosis, presenting initially as orthostatic hypotension.

Case Description: A 61-year-old man was admitted for orthostatic hypotension with syncopal episodes and proteinuria. He was well until six months prior to admission, when he began experiencing severe recurrent orthostatic lightheadedness, anorexia, and dysgeusia. He reported weight loss and periumbilical paresthesias. He had been admitted to an outside hospital and underwent extensive evaluation including a chest CT which revealed lung and liver granulomas. Fluidcortisone was started for hypotension. He noted no improvement and stopped fluidcortisone two weeks prior to presentation to our hospital.

Extensive evaluation of his orthostasis, including an adrenocorticotropin hormone stimulation study was normal. Cardiac and endocrine evaluation revealed no abnormalities. Laboratory examination showed serum creatinine of 0.74 mg/dL, Hgb of 10.4 g/dL, MCV of 90.0FL, total protein 6.4 g/dL and albumin 2.5 g/dL. 24-hour urine protein excretion was 5g. Free kappa (436 mg/L) and lambda light chains (6.5 mg/L) with a ratio of 67. A monoclonal spike was noted on serum protein electrophoresis. Additional rheumatological workup was negative. Bone marrow biopsy was consistent with multiple myeloma and congo red stain was positive for amyloidosis.

Discussion: The finding of heavy proteinuria in conjunction with orthostatic hypotension should lead one to consider the diagnosis of primary systemic (AL) amyloidosis in the differential diagnosis.

Refractory Anemia Secondary to B Thalassemia in a Patient with CKD.

Case Report Lilia Maria Rizo Topete, Giovanna Y. Arteaga Muller, Jesus Cruz Valdez, Elisa Maria Guerrero Gonzalez, Concepcion Sanchez Martinez. Nephrology, Univ Autonoma de Nuevo Leon, Monterrey, Nuevo Leon, Mexico.

Introduction: We present a case of a Male patient, 28 years old, Mexican, diagnosed with CKD of unknown etiology.

Case Description: He denies chronic diseases. Mother with SLE, Sd. Evans and DM. The renal sonogram showed small kidneys. Viral panel negative as immunological tests. The patient comes as ERC G5 with uremic syndrome. RRT starts with PD, 3 months after an episode of peritonitis for candida and HD was initiated. He presented hemoglobin of 7.5 g/dL, microcytichypochromic anemia, treated with erythropoetin 12 000 IU a week, oral Iron and folic acid. Months later the patient came up with anemia syndrome and hemoglobin of 6.6 mg/dL, 2 units of blood was transfused. He presented 3 similar episodes of anemia and iron transfusions were reduced. Erythropoietin was exchanged for darbepoetin. Direct Coombs test was negative. He did not respond to treatment, iron test was performed and IV iron therapy was initiated. Hematology reported aspiration and biopsy Bone marrow normal, with megakaryocytes, M:E ratio 2:1; without blasts. Biopsy reported hypocellular. Abdominal US reported normal. Hemoglobin electrophoresis was performed which reported increased A2 hemoglobin.
A Case of IgA Nephropathy in an HIV-Positive Patient

**Introduction:** IgA nephropathy has been described in patients infected with HIV. Though IgA levels are commonly elevated in HIV, these patients may also develop IgA antibodies against specific HIV antigens. Renal lesions may result from HIV antigen-specific immune complexes that are derived from the circulation and in situ complex formation.

**Case Description:** We present a case of a patient with HIV/AIDS, on highly active antiretroviral therapy (HAART), who was evaluated for microscopic hematuria and worsening renal function. The patient’s only complaint was early morning periorbital edema. On examination, BP was 103/72 mm Hg with a BMI 23 kg/m². Labs showed normal electrolytes, serum creatinine 1.7 mg/dL (baseline 0.7 mg/dL), urine protein/creatinine ratio of 2.5 grams/dL. Other serologies were negative. HIV VL was undetectable, and CD4 count was 183. Renal US showed bilateral enlarged, echogenic kidneys.

Renal biopsy revealed sclerosing glomerulopathy with IgA immune type deposits on immunofluorescence. The patient was initiated on an ACE inhibitor and a low salt and protein diet, with resolution of his proteinuria to 0.7 Grams/dL. His renal function stabilized, with a creatinine of 1.6 mg/dL.

**Discussion:** In conclusion, IgA glomerular disease arising in HIV positive patients has clinical and pathologic aspects similar to idiopathic IgA nephropathy. IgA nephropathy should be suspected in patients with HIV presenting with unexplained hematuria, and renal biopsy should be performed as soon as possible for early diagnosis and therapy. Current management recommendations are similar to those with idiopathic IgA, including ACE inhibitors or ARB for control of proteinuria (>1 g/day) or hypertension.

**PUB399**

#### Calcium Channel Blocker Toxicity: Management Strategies and Considerations

**Introduction:** Calcium channel blocker overdose is rare but carries a high mortality due to cardiovascular complications. Generally the management is supportive with use of vasopressors, IV fluids, cardiac pacing, and insulin therapy. There are reports of CVVHDF, hemodialysis or hemofiltration alone and charcoal hemoperfusion for the treatment of CCB overdose. Effective management strategies are needed to improve outcomes.

**Case Description:** Here we describe a patient who presented to the ER after a suicide attempt with ingestion of Norvasc. On arrival to the ER he was awake but later he was intubated. The patient developed acute kidney injury and became anuric. Patient was started on CVVHDF that lasted 48 hours. Unfortunately after two days the patient continued to decompensate and expired.

**Discussion:** Amlodipine is a CCB of the dihydropyridine group acting primarily on vessel walls whereas the non-dihydropyridines act more on cardiac muscle and pacer cells. In our case it was clear Norvasc selectively took its effect on the vasculature with profound hypotension with preserved systolic function and no arrhythmia. The case was complicated with ARDS related to diffusely pulmonary edema, a well known complication with CCB overdose. In our case renal failure was likely related to severe hypoperfusion leading to ischemia. There was development combined respiratory and metabolic acidosis. The metabolic acidosis was attributed to renal failure but it is possible that CCB induced inhibition of insulin secretion leading to ketoacidosis may also have contributed. In terms of management of CCB overdose, if recent ingestion then GI decontamination is reasonable with activated charcoal or whole bowel irrigation. The use of high dose insulin therapy has been tried and its role may include increasing ionized calcium levels, improvement of hyperglycemic acids, and improved myocardial function. Most case reports, though
A Rare Case of IgG1-Heavy Chain Deposition Disease Using Oral Prednisone and Therapeutic Plasmapheresis

Sacha Baldeosinh, Madhu Kandarpa. Internal Medicine, Kettering Medical Center.

Introduction: Heavy chain deposition disease (HCDD) is rare, especially without light chain deposition and when causing non-amyloid tissue deposits.

Case Description: A 75-year-old male with chronic kidney disease (CKD) stage 3 (baseline creatinine 2.3mg/dL) and right single lung transplant for idiopathic pulmonary fibrosis in 2008 presented with extremity edema and decreased urine output. He has no history of diabetes or uncontrolled hypertension. Admission labs showed BUN 77 mg/dL, creatinine 4.37 mg/dL, and subtherapeutic tacrolimus levels at 3.9 ng/mL. Urine protein/creatinine ratio was 6.6. A 24-hr urine protein collection revealed 5822 mg/24hr. Serum protein electrophoresis showed hypalbuminemia, but no monoclonal proteins were identified. Urine protein electrophoresis was negative for Bence Jones proteins or monoclonal proteins. Urine protein concentration was 713 mg/dL, consisting of 57.8% albumin and 42.2% globulins. C3 and C4 complement levels were low at 46.5 mg/dL and 8.92 mg/dL, respectively. Antinuclear antibodies (ANA), anti-streptolysin O (ASO), anti-neutrophil cytoplasmic antibodies (C-ANCA and P-ANCA), and cryoglobulins were negative. Renal ultrasound showed multiple renal cysts without hydronephrosis. Renal biopsy revealed nodular sclerosing glomerulopathies and IgG1-heavy chain deposition disease with significant mesangial and interstitial fibrosis. Neutrophilic infiltrate and negative for multiple myeloma. The patient was placed on oral prednisone and therapeutic plasmapheresis in an effort to prevent further renal damage and delay hemodialysis. The patient underwent eight plasmapheresis treatments, however still required hemodialysis for fluid overload.

Discussion: HCDD is a monoclonal plasma cell proliferative disorder characterized by tissue deposits of heavy chain fragments which can lead to renal disease. In HCDD, deposits do not have a fibrillary structure and do not stain positive with Congo red such as with heavy-chain amyloidosis. The rarity of the disease and limited data on evidence-based guidelines for treatment make HCDD challenging to treat. We describe a rare case of IgG1-Heavy chain deposition disease (HCDD) with no plasma cell dyscrasia. To our knowledge, no cases have been described using oral prednisone and therapeutic plasmapheresis to treat HCDD renal dysfunction.

Cocaine-Induced Vasculitis

David Araujo, Nephrology, Univ of New Mexico, Albuquerque, NM.

Introduction: An increasing number of cases of Cocaine-induced vasculitis are being found among cocaine users in the United States which is due to the use of Levamisole laced cocaine. It is estimated that about 70% of the cocaine used here in the US is contaminated with Levamisole.

Case Description: We describe a 65 year old male, with a 20 year history of cocaine abuse, who presented with a 1 month history of a progressively worsening, non-healing and painful rash on his trunk and extremities. He denied fever, weight loss and myalgias but admitted to itchiness. Examination revealed multiple tender, erythematous and violaceous plaques with central necrosis on the trunk and extremities. These plaques were found to be in different stages of healing with their size ranging from 1cm-7 cms. Lab investigations revealed an elevated creatinine of 2.9 mg/dL, an elevated ESR, a low C3, presence of MPO antibody and perinuclear Anti Neutrophil Cytoplasmic Antibody (p-ANCA), and an absence of ANCA. Antibody (ANA) and Anti-dsDNA. Skin biopsy showed thrombotic vasculopathy with overlying re-epithelialization. Kidney biopsy revealed focal endocapillary proliferative glomerulonephritis with crescents involving 10% of glomeruli and interstitial fibrosis and tubular atrophy involving approximately 70% of the specimen.

Treatment: is mainly abstinence and supportive. •The clinical course of patients is difficult to assess due to the fact that few patients are able to abstain from cocaine use. Our patient was able to abstain from cocaine use for about 30 days, and that almost resulted in clinical resolution after 30 days of being cocaine-free (Fig 3) •Although in the setting of worsening skin lesions and ongoing cocaine use, some patients have been treated with anticoagulation or thrombolytic vasculopathy, immunosuppression and corticosteroids with varying degrees of success, robust evidence lacking.

Discussion: With more than 2 million Americans using cocaine, occurrences of HCDD with no plasma cell dyscrasia. To our knowledge, no cases have been described using oral prednisone and therapeutic plasmapheresis to treat HCDD renal dysfunction.
treated by maintenance hemodialysis since 1973. In 1995, biopsies documented beta 2-microglobulin amyloid deposits in his tongue, consistent with a diagnosis of DRA. Over time, it has progressed to involve his shoulders bilaterally, his hips, knees, wrists and most recently his colon. He has undergone bilateral total hip replacements and carpal tunnel release procedures. Given his extensive disease burden as a result of DRA despite adequate dialysis, we intend to enroll him in a post-approval study using the Lixelle column. Measures of disease burden will include pre- and post-treatment Beta 2-microglobulin levels, presence of bone cysts, and quality of life (QOL) scores.

Discussion: The Lixelle Beta 2-microglobulin apheresis column appears to increase the Beta 2-microglobulin reduction rate in a single dialysis session, and therefore may be an effective treatment option to improve symptoms and quality of life for patients with dialyis related amyloidosis.

PUB406

An Unusual Case of Anticoagulant-Like Nephropathy in a Non-Anticoagulated Patient Elvys Safar, Apurva Khanna. Internal Medicine, Div of Nephrology, SUNY Upstate Medical Univ, Syracuse, NY.

Introduction: Anticoagulant-related nephropathy is a well-known cause for Acute Kidney Injury (AKI), which was first described in Coumadin anti-coagulated patients, usually with excessive anticoagulation (INR >4). It was also reported to be associated with other Anticoagulants such as direct thrombin inhibitor Dabigatran. We report a case of Anticoagulant-related Like Nephropathy in a Non-anticoagulated patient.

Case Description: A 71-year-old male was admitted to the VA medical center for shortness of breath and hemoptysis. Past medical history was significant for Non Small cell Lung Cancer, Cryptogenic liver cirrhosis and COPD. CT chest, showed no pulmonary emboli. He was treated with Vancomycin and Zosyn for Pneumonia. The patient reported gross hematuria initially, which resolved spontaneously. His admission creatinine was 1.1 mg/dl, (baseline 0.6 mg/dl), and went up to 2.4 mg/dl. The patient had another episode of gross hematuria and his creatinine went up to 3.5 mg/dl. The patient remained non-oliguric throughout the course of his AKI. Kidney biopsy showed Tubular epithelial cells injury with red cell casts, but no inflammatory changes and no Immune complexes by Immunofluorescence. The histopathologic pattern shown by the kidney biopsy was consistent with Anticoagulant-related nephropathy. However, the patient was not anticoagulated with Coumadin, Heparin, or any other anticoagulants. His Pro-thrombin time (PT) was 13.1 seconds (normal 9-12 seconds) and INR 1.2. His PTT was 20.1 seconds (normal 25-34 seconds). He had a low platelets count between 55-100K/mm³, due to liver cirrhosis.

The findings in this case, suggest a role for Thrombocytopenia in liver cirrhosis, in causing anticoagulant like intra-glomerular hemorrhage, which may result in an AKI.

Discussion: Thrombocytopenia and likely Platelets dysfunction in Liver cirrhosis can cause intra-glomerular Hemorrhage and results in Anticoagulant-like Nephropathy, even in the absence of excessive anticoagulation as evidenced by a normal PTT & near normal INR. To our knowledge, there has not been a reported case of Anticoagulant-like Nephropathy in Non-Anticoagulated patients.

PUB407

Smoking Related Idiopathic Nodular Glomerulosclerosis with Crescents Taher Zaman,1 Frederic Clayton,2 Josephine Abraham.1 1Nephrology, Univ of Utah, Salt Lake City, UT; 2Pathology, Univ of Utah, Salt Lake City, UT.

Introduction: Idiopathic nodular glomerulosclerosis (ING) is a rare but important cause of nephrotic syndrome. There have been case series reported in the literature regarding the association of ING and smoking.

Case Description: A 37-year-old female with a history of rheumatoid arthritis (RA) presented to the hospital with cough and hemoptysis. Her RA treatment consisted of leflunomide, prednisone and folic acid. Her social history is pertinent for a history of smoking (20 pack-years). Urine analysis was with dysmorphic hematuria and proteinuria (spot protein/creatinine ratio 3.2gms). Serologic workup was unremarkable. Renal biopsy showed lymphocytic glomerulitis with other Anticoagulants such as direct thrombin inhibitor Dabigatran. We report a case of Anticoagulant-related Like Nephropathy in a Non-anticoagulated patient.

Discussion: ING with crescents has not been described in the literature. In a case series reported by Markowitz et al, patients with ING had renal failure with a mean sCr of 2.4 mg/dl and proteinuria. The main clinical predictors of progression included lack of angiotensin II blockade and continued smoking. In retrospect, it is likely the severity of her intra-glomerular pressures which lead to proteinuria was exacerbated with steroid treatment and resolved with discontinuation.

PUB408

Thrombotic Microangiopathy Secondary to Hepatocellular Carcinoma Taher Zaman,1 Frederic Clayton,2 Josephine Abraham.1 1Nephrology, Univ of Utah, Salt Lake City, UT; 2Pathology, Univ of Utah, Salt Lake City, UT.

Introduction: Thrombotic microangiopathy (TMA) is a microvascular occlusive disorder characterized by microangiopathic hemolytic anemia, thrombocytopenia and end organ damage. We report a case of malignancy associated TMA.

Case Description: 65-year-old female presented with diarrhea and was noted to be in acute renal failure with microangiopathic hemolytic anemia and thrombocytopenia. Therapeutic plasma exchange was discontinued after ADAMST 13 activity was normal. Patient underwent colonoscopy and EGD with evidence of microthrombi in bowel wall concerning for TMA.

Serologies were remarkable for negative APS, SLE, ANCA-vasculitis but Ca-125 was 753. Stool Shiga toxin was negative. Patient was treated for atypical hemolytic uremic syndrome (aHUS) with weekly eculizumab. Diagnostic laparoscopy on HD 24 with peritoneal washings were negative for malignancy. The patient died on hospital day 25 from septic shock secondary to bowel perforation. Autopsy revealed 2.5 x 2.0 x 2.0 cm lesion within the liver consistent with hepatocellular carcinoma (HCC). The prognosis is very poor for diabetic hemodialysis (HD) patients with foot lesions. Foot lesions are associated with risk of systemic inflammation and cardiovascular (CV) morbidity. Severe cases of diabetic foot with neuropathic arthropathy, microvascular changes from mediasclerosis, and alteration of foot architecture are known as Charcot Foot Syndrome (CFS). Since diabetic and nondiabetic HD patients may experience changes in calcium and phosphate metabolism and secondary hyperparathyroidism, the question arises whether CFS can occur in HD patients in the absence of diabetes.

Case Description: Presented is a decade-long case study of a male HD patient (DOB 1961) who was treated since Dec 1999 for biopsy-proven nephrotic syndrome due to glomerulosclerosis. The patient began thrice weekly HD in Sept 2005 without prior treatment for diabetes mellitus (A1C 4.9%). In Apr 2012 he presented with a painless inflammatory acute foot syndrome, then presented in Apr 2013 with a planar ulceration. After conservative wound management, prophylactic shoes were prescribed. In clinical examination he showed signs of chronic CFS and arthropathic changes in osa metatarsalia 2 and 3 with osteolysis and luxation of tarsometatarsal joints. Lab results indicate secondary hyperparathyroidism: parathyroid hormone 465 pg/mL, phosphate 6 mg/dL, and calcium 2.2 mg/dL.

Discussion: We believe this is the first description of chronic CFS in a nondiabetic HD patient. Acute CFS diagnosis is important because its symptoms (red warm skin, foot edema) are similar to those of phleghmon and osteomyelitis, and thus may be considered a differential diagnosis. Further investigations are necessary to determine whether this is an authentic entity of a foot syndrome, and if it’s associated with CV morbidity.

Crescentic Glomerulonephritis (GN) in a Lupus Patient with Normal Serum Creatinine – A Treatment Challenge Venkata Buddhurajlu, Rishikesh Morey, Rudrick V. Ledesma, Savneck S. Chugh, Praveen N. Chander.

Introduction: Crescentic GN is usually manifested by features of active glomerular disease in the urine and by progressive rapid loss of significant renal function. SLE can present as predominantly crescentic GN often as Class III or IV lupus nephritis (LN) usually resulting in rapid deterioration of renal function requiring RRT.

Case Description: 18 y/o female recently diagnosed with SLE, on Plaqueulin presented to ER with nausea, vomiting and epigastric pain after consuming “tiny tea” and was found to have serum creatinine (SCr) 4.5 mg/dL, which further increased to 4.74 with 3+ protein (2.5g/day), 3+ blood and RBC casts on urinalysis. Other relevant lab data: ANA 1:600, negative dsDNA, positive RNP, anti-SM Ab and normal complements. She was initiated on IV fluids and SCr normalized within 2 days. Renal biopsy showed Pauci immune Crescentic GN, class IV-S (AC) with minimal IF staining. The clinical course was complicated by seizures; the diagnostic considerations included lupus cerebritis vs. PRESS. She was put on valproate to be started on immunosuppression as outpatient. She was admitted a week later with acute liver failure due to valproate and Tylenol at which time she was paused with IV Solu-Medrol and discharged on oral steroids with a plan to start MMF after normalization of LFTs.

Discussion: Crescentic and focally necrotizing GN can be infrequently present in the spectrum of diffuse proliferative LN. Such cases are generally ANCA negative. Normalization of SCr after hydration in this case suggest pre renal as the likely etiology which poses a treatment dilemma for biopsy proven crescentic GN. While there is much literature available regarding the treatment of lupus with crescentic GN and normal SCr, a retrospective case series reported that even <50% crescents portend a significant much literature available regarding the treatment of lupus with crescentic GN and normal SCr, a retrospective case series reported that even <50% crescents portend a significant morbidly.

PUB411

Anti-Thymocyte Globulin Induced Non Cardiogenic Pulmonary Edema Jaya Kalia, Amit Lahoti. Nephrology, Univ of Texas MD Anderson Cancer Center, Houston, TX.

Introduction: Anti-Thymocyte globulin (ATG) is used in treatment of hematologic malignancies and solid organ transplantation. Immediate local and systemic reactions are known. There has been only one reported case of non cardiogenic pulmonary edema (NCPE) caused by ATG.

Case Description: Our patient was a 59-year-old man with Marginal Zone Lymphoma which had progressed to diffuse large B cell lymphoma. Despite Hyper CVAD and Rituximab his disease continued to progress. He received Matched Unrelated Bone marrow transplantation after conditioning with ATG and rituximab. The next day he was admitted to the ICU with respiratory distress and bilateral lung infiltrates initially thought to be pulmonary edema. He was started on Lasix drip but did not improve. His CVP was 5, and his echocardiogram showed normal ejection fraction. Based on these findings he was diagnosed to have NCPE. Bronchoscopy revealed pulmonary hemorrhage. His condition worsened and he was intubated and started on Continuous Renal replacement therapy. He was given additional doses of steroids but without improvement. His died due to respiratory failure after two days of ICU stay.

Discussion: Non cardiogenic pulmonary edema is a clinical syndrome characterized by presence of severe hypoxemia, bilateral alveolar infiltrates on chest radiograph without evidence of left atrial hypertension, fluid overload or congestive heart failure. Drug related NCPE is usually diagnosed after other causes of pulmonary infiltrates such as gastric aspiration, sepsis and pneumonia are excluded. The presence of normal echocardiogram and pulmonary hemorrhage within a day of administration of ATG, pulmonary infiltrates which did not resolve after intense attempts of volume removal indicated that the patient had NCPE. ATG is known to cause acute respiratory distress syndrome, alveolar hemorrhage and rapidly progressive interstitial fibrosis likely secondary to Cytoxin release syndrome. Providers need to be aware of such complications as even though rare these cause increased morbidity and mortality. It is beneficial to give ATG infusions slowly and accompanied by high dose systemic steroids.

PUB412

Hypomagnesemia After Treatment with Pertuzumab Lilian Saro-Nunez,1 Tiffany A. Traina,2 Karen A. Cadoo,1 Teresa Gilewski,1 Ilya Glezerman.4 1Nephrology, NYP-Well Cornell Medical Center, New York, NY; 2Breast Medicine Service, Memorial Sloan Kettering Cancer Center, New York, NY; 3Gynecologic Oncology Service, Memorial Sloan Kettering Cancer Center, New York, NY; 4Renal Service, Memorial Sloan Kettering Cancer Center, New York, NY.

Introduction: Hypomagnesemia is a known side effect of epidermal growth factor receptor (EGFR) inhibitors such as cetuximab and panitumumab. Pertuzumab blocks HER (human epidermal growth factor receptor) 2 dimerization with HER3 and EGFR, and is used in HER2+ breast cancer. We present two cases of hypomagnesemia with pertuzumab use.

Case Description: Case 1 58 year-old woman with history of breast cancer treated with trastuzumab (T), docetaxel, pertuzumab (two doses of 840mg and one dose of 420mg) and carboplatin (AUC6). Patient developed hypomagnesemia with serum magnesium (Mg2+) level of 0.7 (1.7-2.6) mg/dl and symptomatic hypomagnesemia of 5.9 (8.5-10)mg/dl. Since initiation of chemotherapy she experienced diarrhea controlled with loperamide. Fractional excretion of magnesium (FeMg) was 2%. Parathyroid hormone (PTH) was 309.2 (12-88)pg/ml. Pertuzumab and carboplatin were stopped. Mild hypomagnesemia persisted 6 months later.

Case 2 56 year-old woman with history of breast cancer on treatment with T, paclitaxel and pertuzumab (one dose of 840mg and 2 doses of 420mg) was admitted with Mg2+ of 0.3 (1.4-2.2) mEq/L and corrected calcium of 6.1mg/dl. She complained of chronic diarrhea which improved with loperamide and was receiving proton pump inhibitor (PPI). FeMg was 3%, PTH was 161 (12-88)pg/ml. PPI was stopped but patient received another dose of pertuzumab (840mg). She remained hypomagnesemic and required IV supplementation until her death from progression of disease 22 months later.

Discussion: Although there were other confounding factors that could have caused hypomagnesemia including diarrhea, PPI and carboplatin, hypocalcemia (a manifestation of hypomagnesemia) did not develop until patients were started on pertuzumab. Carboplatin has been associated with hypomagnesemia but not with the degree of hypomagnesemia seen in these two patients. We postulate that pertuzumab may interfere with reabsorption of Mg2+ similar to EGFR inhibitors.

PUB413

Acute Renal Infarction: Case Series Yelda Delignoz bildaci,1 Rumeyza Kazancioglu,2 Nephrology, Bezmialem Vakif Univ, Istanbul, Turkey; 2Nephrology, Bezmialem Vakif Univ, Istanbul, Turkey.

Introduction: Acute renal infarction (ARI) occurs from interruption of kidney’s blood supply either partially or totally. Causes of renal infarction include: thromboembolism (usually from injured or replaced heart valves, congenital heart defects etc.) vasculitis disorders, trauma to the kidneys or hypercoagulable state. We present five cases of ARI with different etiologies.

Case Description: Of the five cases presented: two female, three male, mean age 52 (range 26-72) patients presented to the emergency department between 2013 and 2015 in a university based hospital setting. Presenting complaint was severe flank pain lasting between 2 to 5 days for all of them. At initial examination all patients had costo-vertebral angle tenderness at the effected side. Contrast enhanced abdominal tomography was useful for showing renal artery occlusion and also renal infarction. Trans thoracic echocardiography were all normal and were not adequate in identifying patients having had heart defects, trans esophageal echocardiography was obviously superior in finding cases with possible paradoxical embolism. All patients were treated with enoxaparin therapy. During follow-up there was neither further complication nor kidney damage.
Discussion: ARI usually is a hidden disease, which can easily be missed without any specific suspicion for patients presenting with flank pain. It should be kept in mind that there is no specific biochemical test for ARI and diagnosis process must involve evaluation of cardiac pathologies preferably with trans esophageal echocardiography.

PUB414
Disseminated Cryptococcal Infection in a 24-Year-Old Man with Primary Focal Segmental Glomerulosclerosis

Introduction: Focal segmental glomerulosclerosis (FSGS) is commonly treated with high doses of corticosteroids and calcineurin inhibitors to induce remission of proteinuria, however immunosuppression carries with it the risk of infection. We present here the case of a 24-year-old African American man following seven months of intermittent treatment for biopsy-proven FSGS with high-dose prednisone and cyclosporine.

Case Description: Our patient initially responded to prednisone 80 mg daily with proteinuria reduced to 37 mg/g from 3.5 g/g, but then suffered frequent hospitalizations for infection necessitating interruption of immunosuppression, now with decreased responsiveness to prednisone. Cyclosporine was added but interrupted after he developed Clostridium difficile diarrhea. He was placed on ethacrynic acid and atovaquone because of a sulfa allergy. His albumin remained < 1.5 mg/dL. Renal function worsened, developed non-nephrotic-range proteinuria with preserved renal function which we developed non-nephrotic-range proteinuria with preserved renal function which we.

Discussion: There is no clear evidence of focal segmental glomerulosclerosis to portend a worse prognosis. Her decision to pursue pregnancy prompted further inquiry into the effects of pregnancy on her renal disease. Review of existing literature, limited as it may be, suggested that this could be a result of either cryoglobulinemia may be associated with normal placental growth and development in the context of hormonal changes.

Discussion: Therefore, interpretation of typical parameters, including urinary protein excretion alone, may not be sufficient in determining disease status. This case demonstrates the importance of renal biopsy in defining the underlying pathology in young women with evidence of glomerular disease who wish to become pregnant as it can help guide prognosis.

PUB417
Outcomes of Calcific Uremic Arteriopathy (CUA) Management: An Inner City Tertiary Center Experience

Introduction: CUA is a rare, necrotizing skin condition caused by medial calcification of subcutaneous arterioles leading to tissue ischaemia and eventual necrosis. It predominantly occurs in patients with chronic kidney disease, associated with high morbidity, mortality and variable outcomes-- posing a difficulty in management.

Case Description: We conducted a retrospective chart review from 2010-15. 17 patients were diagnosed and treated for CUA in a tertiary university center. Diagnostic methods and multi-disciplinary treatment included parathyroidectomy, medical management of bone mineral disease, standard wound care, and sodium thiosulfate. We classified outcomes as No Improvement, Stable, and Improvement of Lesions related to the mean Calcium-Phosphate product (CaXPbs). Table 1 shows patient characteristics.

PUB415
A Rare Case of Kidney Amyloidosis Caused by Heroin Abuse

Introduction: Secondary (AA) Amyloidosis nephropathy is a rare manifestation of IVDA, is a condition characterized by deposition of insoluble fibrils in various organs; most commonly the liver and kidneys. Occurs as a result of chronic inflammatory states such as RA, IBD, chronic osteomyelitis, or familial Mediterranean fever. Kidney involvement in amyloidosis is a significant source of morbidity as it can progress to CKD.

Case Description: A 40 y/o AA man with no past medical history just 20 years of IV heroin abuse presented to the ED for seven months of intermittent treatment for biopsy-proven FSGS with high-dose prednisone and cyclosporine.

Discussion: This case demonstrates the infectious risk of high dose immunosuppression in treating resistant focal segmental glomerulosclerosis and the need to balance efficacy of treatment against these risks.

Underline represents presenting author.
He was started on fludrocortisone 0.1 mg daily, which was subsequently increased to achieve a normal morning cortisol level of 13.8 μg/dl but very low renin and aldosterone levels and hypokalemia with aggressive potassium supplementation, orthostatic hypotension and severe orthostatic hypotension (table 1). While hyponatremia improved with hydration was 3 months post-transplant and taking tacrolimus, mycophenolate, and prednisone for fulminant liver failure presented to our institute with nausea, emesis, and fever. He had never taken immunosuppressive drugs. In 68 years old, because urine protein increased to 3g/gCr, the temocapril hydrochloride has been prescribed from 67 years old. He has never taken immunosuppressive therapy is recommended. If the disease is due to secondary causes, obstruction if renal function is compromised. If the cause of the disease is idiopathic, then often idiopathic, but secondary causes should be ruled out. Secondary causes include infection, radiotherapy, and trauma. Patients diagnosed with retroperitoneal fibrosis should undergo thorough evaluation for infectious causes and malignancy.

**Case Description:** A 55 year old male presented to the clinic with a chief complaint of left side flank and groin pain. He had additional symptoms of night sweats, left leg edema, and weight loss. He was referred to our clinic after initially presenting to the emergency department and receiving a CT scan of the abdomen identifying left side hydroureteronephrosis and a retroperitoneal mass. His past medical history included melanoma 4 years prior and cutaneous follicular lymphoma of the right mandible one year prior. Repeat ultrasound prior to initiation of therapy showed new right sided hydroureteronephrosis. The patient was started on monotherapy with prednisone 1 mg/kg/day. Imaging after initiation of therapy showed improvement in fibrosis with resolution of ureteral obstruction. The patient’s serum creatinine improved from 1.93 to 1.2 after initiation of therapy. No secondary causes of retroperitoneal fibrosis was identified.

**Discussion:** Retroperitoneal fibrosis can present as obstruction of the ureters. It is often idiopathic, but secondary causes should be ruled out. Secondary causes include malignancy, infection, and medications. Recommended therapy includes decompression of obstruction if renal function is compromised. If the cause of the disease is idiopathic, then immunosuppressive therapy is recommended. If the disease is due to secondary causes, the underlying cause should be immediately addressed.

### PUB420

**A Case of Hydroureteronephrosis due to Bilateral Retroperitoneal Fibrosis**

Zachary Freestrong, Akram M. Shaaban, Josephine Abraham. *Nephrology, Univ of Utah, Salt Lake City, UT.*

**Introduction:** Retroperitoneal fibrosis is characterized by inflammatory and fibrous retroperitoneal tissue. It is believed to be due to an exaggerated inflammatory reaction to aortic atherosclerosis resulting from an immunologic trigger. Retroperitoneal fibrosis can be classified as primary or secondary. Secondary causes include medications, malignancy, infection, radiotherapy, and trauma. Patients diagnosed with retroperitoneal fibrosis should undergo thorough evaluation for infectious causes and malignancy.

**Case Description:** A 55 year old male presented to the clinic with a chief complaint of left side flank and groin pain. He had additional symptoms of night sweats, left leg edema, and weight loss. He was referred to our clinic after initially presenting to the emergency department and receiving a CT scan of the abdomen identifying left side hydroureteronephrosis and a retroperitoneal mass. she developed new onset BK viruria. One month later, she had a new onset BK viremia and worsening BK viruria up to 3 million and 67.5 billion copies/mL, respectively (Figure 1). Concurrently, she had AKI with a serum creatinine (Scr) of 4 mg/dL from a baseline of 1.4 mg/dL. Ultrasound showed moderate hydronephrosis (Figure 2). Allograft biopsy revealed acute tubular injury with negative SV40. A percutaneous nephrostomy (PCN) tube was placed and anastomosis nephrogram showed high-grade ureteral stricture (Figure 3). A ureteral stent was placed. FK and MPA target levels were decreased to 5-7 ng/mL and 2-4 mg/L, respectively. One week later, a repeat nephrogram showed no obstruction and PCN tube was removed. Scr trended down to 1.2 mg/dL. Ureteral stent was removed 6 weeks later. BK viremia became undetectable 6 months posttransplant (Figure 4). The high-level BK viremia but negative SV40 in the kidney biopsy in the context of ureteric obstruction suggested that there was extensive BK replication within the urethelium leading to ureteral stricture and mechanical obstruction. The obstruction improved with resolution of BK viremia following reduction in immunosuppression.

Discussion: Medical management of BK virus with lowering immunosuppression can be an effective treatment to reverse ureteral obstruction due to BK virus infection, while surgical intervention is used to temporarily relieve obstruction.

responsiveness of intestinal epithelial and immune cells, and altering the immunogenicity of degraded enteric antigens. Given the frequency of the over-the-counter use of probiotics, multiple potential coexisting etiologies for AN in the often indolent nature of this disease, the rarity of this association, and the need for a renal biopsy to establish the diagnosis, the association between probiotics and AN may be under-recognized.

PUB426

Decision-Making for the Critically Ill Un-Befriended Patient 

Aparajita Mattoo, Jennifer S. Scherer. Nephrology, NYU School of Medicine, New York, NY.

Introduction: The “un-befriended” patient is one that lacks decision-making capacity & a surrogate decision-maker (SDM). Nephrologists encounter un-befriended patients often, yet limited literature exists to guide decision-making for these vulnerable patients. This case describes an organized approach to caring for a critically ill un-befriended patient.

Case Description: Mr. S was a 74 year old wheelchair bound nursing home (NH) resident who underwent an urgent right hemicolectomy for a perforated colon. His post-operative course was complicated by septic shock & multi-organ failure including AKI due to ATN. During this time his serum Cr increased from 0.8 to 3.6 mg/dl with a urine output of <50cc/day. Mr. S was obtunded & had diffuse anasarca. He lacked advance directives & any SDM. The primary service believed that dialysis (HD) should be withheld given his overall poor prognosis. The consulting renal service utilized the four-topic approach to ethical decision-making to guide their recommendations. An estranged sister was asked to partake in an inter-disciplinary team (IDT) family meeting with renal, palliative care, bioethics, & the primary service to explore Mr. S’s values. It was established that Mr. S cherished his life in the NH & would have appreciated time there even if on HD. Given this information, the IDT decided that a time-limited trial of HD would be reasonable. Before HD was needed however, Mr. S decompensated due to fungemia. The IDT agreed that death was imminent, even with HD. Under provisions of the NY State Family Health Care Decisions Act (FHCA), it was determined to be ethically appropriate to withhold HD & transition Mr. S to comfort care.

Discussion: Utilizing the four-topic approach to decision-making, established legal policies, & an IDT, nephrologists can manage un-befriended patients within an organized, legally sound, & ethically sensitive framework.

PUB427

Persistent Kidney and Alveolar Damage in Patients with Goodpasture's Disease and Negative Anti-GBM Antibodies 

Giovanna Y. Arteaga Muller, 1 Lilia Maria Rizo Topete, 1 Elisa Maria Guerrero Gonzalez, 2 Concepcion Sanchez Martinez, 1 Jesus Valdez, 1 Gabriela Alarcón Galván, 1 Nephrology, Univ Hospital José E. González UANL, Monterrey, Mexico, 2Anatomic Pathology, Univ Hospital José E. González UANL, Monterrey, Mexico.

Introduction: Goodpasture’s disease is characterized by the presence of baseline membrane antibodies which act against type 4 collagen in the glomerular basement membrane (GBM) and alveoli, it represents 20% of all crescentic glomerulonephritis. CASE DESCRIPTION: A 23 year old woman, with anemic syndrome presenting Hb 4.33g/dl, Cr 0.8mg/dl, receiving a cell red transfusion. Is readmitted 15 days later Hb 2.7g/dl and Cr 1.9 mg/dl, whereby three globular packages were transfused and she was referred to our hospital. On admission, the patient was hypertension, lower limb edema and gross hematuria, Hb 11g/dl, Cr 1.7mg/dl, negative ANAS and ANCAs and positive anti-GBM antibodies. Renal biopsy showed crescentic glomerulonephritis and linear staining deposits of IgG in GBM (4+).

Direct immunofluorescence technique (400X). Linear glomerular basement membrane staining for IgG.

Immunosuppressive therapy begins with methylprednisolone and CYCLOPS protocol. Later hemoptysis which improves with plasmapheresis, negative control anti-GBM antibodies. After presented sudden hypoxemia, bronchoscopy with abundant hemosiderin-laden macrophages, whereby plasmapheresis is performed again together with methylprednisolone, cyclophosphamide and rituximab. Currently the patient is in chronic hemodialysis, with negative anti-GBM antibodies.

Discussion: In patients with positive anti-GBM antibodies renal involvement may occur alone or associated with pulmonary hemorrhage, our patient despite having negative anti-GBM antibodies presented pulmonary hemorrhage. The literature recommends confirm the sustained absence of anti-GBM antibodies and signs of recurrence every 6 months.

PUB428

Gitelman Syndrome: Use of Dual Potassium-Sparing Agents in Refractory Hypokalemia 

Maria Bernadette Yhalla, Sandeep Aggarwal. Div of Nephrology, Drexel Univ, Philadelphia, PA.

Introduction: Hypokalemia is one of the most frequently encountered electrolyte disturbances. Chronic hypokalemia with hypomagnesemia should prompt further investigation to include rare genetic disorders such as Gitelman syndrome. Despite the appropriate diagnosis, treatment can be challenging.

Case Description: We present a case of a 49 year-old non-hypertensive Caucasian female who presented to our outpatient clinic for an evaluation of her polypria, chronic hypokalemia and hypomagnesemia. Her polypria testing revealed two distinct heterozygous missense autosomal recessive mutations of the SLC12A3 gene from Athena Diagnostics: c.2221G>A; p.Gly741Arg and c.1315G>A; p.Gly439Ser. She was continued on spironolactone (100mg/day) and remained hypokalemic. Genetic testing revealed two unique recessive alleles presenting sudden hypoxemia, bronchoscopy with abundant hemosiderin-laden macrophages, whereby plasmapheresis is performed again together with methylprednisolone, cyclophosphamide and rituximab. Currently the patient is in chronic hemodialysis, with negative anti-GBM antibodies.

Discussion: In patients with positive anti-GBM antibodies renal involvement may occur alone or associated with pulmonary hemorrhage, our patient despite having negative anti-GBM antibodies presented pulmonary hemorrhage. The literature recommends confirm the sustained absence of anti-GBM antibodies and signs of recurrence every 6 months.

PUB429

Cerebral Ethylene Glycol Toxicity Despite Prompt Renal Replacement Therapy 

Maria Bernadette Yhalla, Sandeep Aggarwal. Div of Nephrology, Drexel Univ, Philadelphia, PA.

Introduction: Acute cerebral edema is a rare consequence of ethylene glycol toxicity. Despite prompt initiation of therapy with fomepizole and renal replacement therapy, rare case reports of central hypodensities on CT imaging with neurologic abnormalities have been reported.

Case Description: We present a case of a 38 year-old female with PMH of HTN and anxiety who was brought in for agitation. One hour later, the patient became obtunded with significant respiratory distress requiring intubation. Home medications included isupropion. It was unclear if she ingested any toxins but the patient did have a history of marijuana use. On physical examination, the patient was hypertensive 210/114 mm Hg with reactive pupils. She was found to have high anion gap metabolic acidosis with a pH of 6.808, a serum bicarbonate of 4, an osmolal gap of 68, and a lactate acid of 5.6. Levels of ethanol, acetaminophen, phenobarbital, salicylate, and valproic acid levels were undetectable while urine drug screen was only positive for THC. Head CT did not reveal any acute
Encapsulating Peritoneal Sclerosis – Case Reports

Introduction: Encapsulating Peritoneal Sclerosis (EPS) is a rare but serious and potentially lethal complication in peritoneal dialysis (PD), first described in 1980. Intestinal obstruction, serious malnutrition and sepsis are the causes of this death. This uncommon condition is the result of chronic abdominal inflammation of multifactorial origin. High risk patients include PD for more than 8 years and with frequent peritonitis (two-hits theory). The exact incidence is unknown.

Case Description: We described outcomes of 6 cases followed in a referral service between 2010 and 2015.

AM Tolvaptan to Avert Hypointravenous Seizures in a Patient with Primary Polydipsia and New Mildly Impaired Free Water Excretion

Introduction: A former pilot with a history of primary polydipsia PP (past urines >6 l/day) complained of confusion. Plasma (P_un) and urine sodium were 123 and 37 mEq/L, and plasma (P_un) and urine osmolalities, 251 and 207 mOsm/kg-H2O. With cessation of Prozac and advised fluid restriction (FR) P_un corrected. P_un was 286 mOsm/kg and urine SG 1.005. Following multiple surgeries (decompressive laparotomy, subtotal colectomy, ileostomy, feeding gastrostomy, for compartment syndrome/pancreatitis), she was found to have a first hypotonic polyneurologic seizure (HS). No cause for impaired free water excretion (iFWE) was found. Her PP made FR difficult, as she was thirsty at P_un <125 mEq/L, and caused repeat HSs.

Case Description: After her 4th seizure, we replaced FR and salt tablets with AM tolvaptan. This normalized PAs, abolished her recurrent HSs, and was tailored to her new dreadful PP-SIADH combination.

Indeed, since thirst is constant in DI but only diurnal in PP, the AM tolvaptan-induced daytime DIAlow allowed her to quench her thirst without fear of HSs, since if WE were corrected by us, when the drug effect wore off, and her PP abided. She was reluctant giving up this diurnal/nocturnal PP-DESIADH, for fear of seizures.

Discussion: Given the high capacity for FWE, a syndrome of inappropriate antidiuresis (SIAD) or impaired diuresis-aquarexia (SIDA), due to or not to ADH (SIAD/H or SIDA/H) must coexist in PP, for HS to occur; conversely some PP or other source of free H2O must exist in the “SIAD/H – SIDA/H” spectrum of iFWE to cause HS, since FR alone increases the low P_un, and prevents HS during depot ADH in man, or chronic iDAP infusion in rats. This is the first report of successful compassionate offer label use of AM tolvaptan, instead of FR, to prevent HS in a patient where PP is the culprit. However FR instead of vaptans is the first line treatment of low P_un in SIAD, still here ADH is the culprit. Tolvaptan in that PP and SIAD/H (or iFWE state) must coexist to cause HS, and that ADH, as assessed by sensitive assays is rarely totally suppressed, resolves this paradox.

PUB432
Atypical Presentation of Calcium Oxalate Nephropathy Young-Soo Song,1 Joel M. Henderson,2 David J. Salant,3 Sandeep Gha1. 1 Renal Medicine, Boston Univ Medical Center, Boston, MA; 2Pathology and Laboratory Medicine, Boston Univ Medical Center, Boston, MA.

Introduction: Ethylene glycol ingestion can cause multi-organ dysfunction including acute kidney injury (AKI) and death. The diagnosis can be made based on history, a high anion gap metabolic acidosis with an elevated osmolal gap, oxalate crystalluria and an elevated ethylene glycol level. The diagnosis may be challenging with the concurrent use of other substances such as cocaine as it causes vasoconstrictor or anoxia vasculitis. To elucidate the diagnosis, a renal biopsy may be required. Herein, we present a patient with biopsy proven calcium oxalate nephropathy who presented with unexplained AKI likely related to an unusual low dose regular ethylene glycol use. She did not have any symptoms or classic biochemical features of ethylene glycol intoxication.

Case Description: A 57-year-old homeless woman with a history of rheumatoid arthritis, COPD presented with a productive cough and dyspnea and was found to have a Cr of 3.9 mg/dl, elevated from a recent baseline of 0.9 mg/dl. Her anion gap was 17, with no other electrolyte abnormalities. Toxicology was negative for ethanol or salicylates. Her BP was 157/77 mm Hg and physical exam was unremarkable. Her last use of cocaine was 3 days prior to admission. She was initially given normal saline and maintained an adequate urine output, but her Cr continued to rise to 13.0 mg/dl. Urine oxalate showed a few isomorphic RBC’s only. A renal ultrasound revealed normal sized kidneys. Serological tests for autoimmune, post-infectious and dysproteinemic causes of AKI were normal or negative. Renal biopsy revealed acute tubular injury with calcium oxalate deposition. An in depth history did not reveal a high oxalate diet or a medical history predisposing her to hyperoxaluria, however she admitted to the regular ingestion of “juiced” street alcohol.

She did not require dialysis. Her follow-up Cr was 1.8 mg/dl two months later.

Discussion: In conclusion, a thorough history is required when encountering unknown AKI in patients with a history of drug abuse or homelessness, while keeping a high index of suspicion for drug intoxications including ethylene glycol.

PUB433
Thrombotic Microangiopathy (Hemolytic-Uremic Syndrome) Induced Acute Kidney Injury Associated with Brucella Infection

Introduction: Thrombotic microangiopathies (HUS, TTP and DIC) have been associated with a host of infectious agents. Its association with Brucellosis is uncommon. We present a case of a patient who developed TMA associated with a case of Brucellosis.

Case Description: A 52-year-old woman with minimal past medical history presented to the hospital with abdominal pain, fever/chills and general body aches. History was significant for intermittent bloody diarrhea approximately 2 weeks prior to ED presentation. Physical examination revealed epigastric and right upper quadrant tenderness to palpation and patient was started on broad-spectrum, empiric IV antibiotic therapy with...
Vancomycin, Piperacillin/Tazobactam, and Ciprofloxacin. Shortly thereafter, her clinical status began to deteriorate resulting in acute respiratory failure requiring intubation and mechanical ventilation. CBC was notable for a white blood cell count of 27,000, hemoglobin of 7.3 g/dL and a platelet count 80,000. Other labs were notable for total bilirubin 2.3 mg/dL, LDH 509 U/L, lactate dehydrogenase less than 10, lactate acid 5.7 mmol/L and elevated transaminases. Peripheral Smear was notable to be positive for numerous schistocytes. Patient was anemic and Nephrology consulted to begin CRRT in setting of sepsis requiring three vasoressors. Patient had a rapid improvement in symptoms after initiation of sepsis protocol and was weaned off all vasoressors by 72 hours. Initial workup including abdominal imaging and blood cultures were negative for a source of infection. Patient had remarkable spontaneous clinical recovery and was later found to be positive for Brucellosis by immunoglobulin assay.

Discussion: Brucella infection has uncommonly been associated with the development of Hemolytic Uremic Syndrome. In addition, clinical course is widely variable, ranging from spontaneous recovery, as occurred with this patient, to disease requiring long-term renal replacement therapy.

**Patient with Clinical Diagnosis of Scleroderma Presenting with Sjögrens’ Associated Renal Disease:** Aasli Jaberi, Jasvinder S. Bhatia. Nephrology, Boston Medical Center, Boston, MA.

**Introduction:** Overlap rheumatologic syndromes can occur in a substantial number of patients with renal disease. The clinical manifestations often favor one diagnosis over another, which can make diagnosing and treating the renal disease very challenging.

**Case Description:** 69-year-old female with no known history of previous rheumatologic disease presented with cough, fever and AKI and was diagnosed with myopericardial pneumonia. Initial laboratory tests revealed a creatinine level of 2.2mg/dl, and persistent non-anion- gap metabolic acidosis. On further history, she complained of long standing heartburn and Raynaud’s symptoms in her fingers. Her physical exam disclosed telangiectasia on palms and skin thickening of the face and PIP joint. These features were consistent with systemic sclerosis, which prompted a rheumatologic work-up. Serologies were significant for a positive ANA and SSA antibody as well as hypoocomplementemia. Urine sediment revealed many WBCs with no casts and some non-dysmorphic RBCs. A decision was made to proceed with kidney biopsy to identify the cause of her renal disease since the sediment was not supportive of Scleroderma associated renal disease. Kidney pathology showed acute interstitial nephritis with mild chronic changes which, when combined with the serologic tests, was highly suggestive of Sjögrens syndrome-associated renal disease. She was commenced on corticosteroid therapy and two months post-initiation, her renal function has stabilized.

**Discussion:** This case demonstrated the importance of kidney biopsy in elucidating a diagnosis in a challenging case of overlap syndrome. The rapid diagnosis of interstitial nephritis was particularly important in this patient since most cases of renal associated Sjögrens’ go unrecognized until significant renal dysfunction has occurred. It has been proposed to consider kidney biopsy findings of tubulointerstitial disease as additional supportive criteria in the classification of Primary Sjögren’s syndrome, which is a sentiment we also support.

**PUB435**

**Introduction:** Acute post infectious glomerulonephritis (APIGN) most frequently affects children and is relatively uncommon in adults. The incidence has declined sharply in industrialized countries over the last 50 years. Adults with an immune compromised background, especially due to alcoholism and/or diabetes are at higher risk for developing the disease.

**Case Description:** A 61 year old Hispanic male with medical history of uncontrolled diabetes, Hypertension and chronic alcohol abuse presented to the emergency department due to shortness of breath and swelling of his legs since one week. Patient was afibrile, blood pressure 200/102 mm Hg. On exam he had clear signs of fluid overload. Pitting edema was due to shortness of breath and swelling of his legs since one week. Patient was afebrile, blood pressure 200/102 mm Hg. On exam he had clear signs of fluid overload. Pitting edema was due to shortness of breath and swelling of his legs since one week.

**Discussion:** This case demonstrated the importance of kidney biopsy in elucidating a diagnosis in a challenging case of overlap syndrome. The rapid diagnosis of interstitial nephritis was particularly important in this patient since most cases of renal associated Sjögrens’ go unrecognized until significant renal dysfunction has occurred. It has been proposed to consider kidney biopsy findings of tubulointerstitial disease as additional supportive criteria in the classification of Primary Sjögren’s syndrome, which is a sentiment we also support.

Two Cases of Kidney Injury Induced by Anti-VEGF Therapy for Carcinoma Yudai Isozaki, Yosuke Nakagawa, Takuya Isegawa, Masahiro Koizumi, Masafumi Fukagawa. Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan.

**Introduction:** Anti-vascular endothelial growth factor (VEGF) agents have been widely used in the treatment of various types of advanced-stage malignant tumor, including lung carcinoma and renal cell carcinoma. Although these agents are generally well tolerated, there are increasing reports of renal adverse events, especially proteinuria.

**Case Description:** Case 1: A 69 year-old male started chemotherapy including bevacizumab (monoclonal antibody of VEGF) with a diagnosis of advanced lung adenocarcinoma of left upper lobe. The completion of four-course chemotherapy resulted in reduction of tumor volume, and then converted to bevacizumab monotherapy. At one year after the start of therapy, proteinuria with renal insufficiency developed. He was referred to our service for further evaluation and management. Renal biopsy demonstrated microthrombi in the loop wall with duplication of GBM, which was consistent with thrombotic microangiopathy (TMA). Thereafter, with cessation of anti-VEGF agent, proteinuria was gradually ameliorated to less than 1.0 g/day and renal function returned to normal range. Case 2: A 56 year-old male with renal cell carcinoma, who had undergone nephrectomy with nephrotic-range proteinuria with three years before, subsequently proved to have metastatic lesion in lumbar vertebra. He started treatment with sunitinib, a tyrosine kinase inhibitor which blocks the intracellular domain of the VEGF receptor. This patient had baseline renal insufficiency due to nephrectomy and diabetes. After the introduction of therapy, he exhibited progression of kidney disease with nephrotic-range proteinuria in a short time. In addition to the cessation of sunitinib, hemodialysis was initiated because of fluid overload. After several times of dialysis, urine output was gradually increased and renal function returned to the baseline level.

**Discussion:** The renal adverse effects of anti-VEGF agents are supposed to arise from inhibition of podocyte-endothelial VEGF signaling pathway. VEGF signaling pathway plays an essential part in glomerular development and endothelial maintenance. We need to pay attention to renal adverse effects with anti-VEGF therapy.

**PUB437**

Concurrent Development of Eculizumab (ECU) (Anti-C5 Antibody)-Responsive Atypical Hemolytic Uremic Syndrome (aHUS) and Siltuximab (SLT) (Anti-IL-6 Antibody)-Sensitive Multicentric Castleman Disease (MCD): Evidence for the Pathogenic Role of Inflammatory Cytokines Joe Ghata, 1 Abdulmawla Albiniri, 1 Kai Lau. 1, 2 Nephrology, Univ of Oklahoma, Oklahoma City, OK; 1 Medicine, VA Medical Center, Oklahoma City, OK.

**Introduction:** The literature has a few cases on the association of MCD with thrombotic microangiopathy (TMA), but the pathogenesis & therapy are unknown.

**Case Description:** We describe a 29-year-old previously healthy man initially presented with non-specific symptoms of what later proved to be MCD. Diagnosis was delayed due to explosive full-blown systemic & biopsy-proven renal TMA, producing dialysis-dependent ARF, severe thrombocytopenia & transfusion-dependent hemolytic anemia till eculizumab (ECU). The appearance of diffuse lymphadenopathy 8 weeks after acute renal failure (ARF) led to node-biopsy proven MCD diagnosis & therapy with SLT. We postulate MCD was the trigger for TMA & full resolution needs both ECU & SLT directed at the etiology.

10 days before ARF, patient had abdominal pain, treated as cholecystitis by cholecystectomy. Mild splenomegaly & trace ascites were overlooked. Day 7 after ARF, bilateral pleural & pericardial effusion & moderate ascites emerged but overlooked as serum creatinine rose
from 0.9 to 11.3 mg/dL by day 33. At this point, Hgb fell to 6 g%, platelet to 45 k/mm
, LDH peaked at 90, C3 down to 50 & C4 to <0.8. APL was diagnosed by normal ADAMTS13 level, absent Ab & negative Shigatoxin. After 4 doses of ECU, by day 50 all features of TMA improved. Negative were ANA, ANCA, cryo, antiphospholipid Ab, hepatitis profile, SFP, HIIV 6, 8, & HIV. On day 54, diffuse large lymhphadenopathy appeared on CT of chest & abdomen with 13.8 cm spleen & generalized anasarca & polynesitosis. HS-CRP was up 25 x nL [IL-6] & [VEGF] were 2-12 fold nL. Lymphadenopathy regressed 50% after 4 & >75% after 8 doses of SLT. Edema fully resolved after 2 doses.

Discussion: We conclude that intense cytokine activation due to MCD played a pathogenic role in his aHUS, as evidenced by the precedence of sleepiness & anasarca to his TMA & by the dependency of anti-IL-6 Ab for full resolution of his MCD.

PUB438
Severe Hypercalcemia Presenting During Recovery Phase of Ischemic Acute Kidney Injury Buttavitha A. Dinay,1 Fazel Dinay;2 Lavinia A. Negre.1
1Nephrology and Hypertension, Univ Hospitals Case Medical Center, Cleveland, OH; 2Internal Medicine, SIVCM/CWRU, Cleveland, OH.

Introduction: AKI is frequently complicated by multiple electrolyte abnormalities, including hyperkalemia, hyperphosphatemia, and hypo/hypercalcemia. Hypercalcemia is often seen in the recovery phase of rhabdomyolysis associated AKI, can be severe and life-threatening. Several etiologies for delayed hypercalcemia have been proposed, including mobilization of calcium deposits out of the recovering muscles, secondary hyperparathyroidism, increase in calcitriol, and resolution of hyperphosphatemia. In this case, we report a patient who presented with severe symptomatic hypercalcemia. Improved with volume administration, calcitonin, and bisphosphonates are some of the methods used for its prevention.

Case Description: A 31 yo Caucasian male with recently diagnosed Type 1 DM. Admitted for DKA complicated by cardiac arhythmia, cardiac arrest, respiratory failure, septic shock, and oliguric AKI requiring a prolonged period of renal replacement therapy. Ultimately renal function recovered and patient was taken off dialysis. There was no evidence of rhabdomyolysis clinically or biochemically at any time during his hospitalization. It was hypothesized that the oliguric phase of AKI may have been the diuretic phase he developed severe symptomatic hypercalcemia. Improved with volume replacement and administration of calcitonin. Hypercalcemia reached a peak of 14.1 mg/dL, corrected for serum albumin and urine output was as high as 3.5 liters daily. Hypercalcemia lasted for 3 weeks and then calcium returned back to normal levels. Plasma levels of 25-OH and 1-25(OH)2 vitamin D were not elevated, intact parathyroid hormone level suggests the possibility of secondary hyperparathyroidism. Hypercalcemia as well as mobilization of calcium from calcium deposited in various tissues seems to account for hypercalcemia and hypercalciuria in this case.

Discussion: Hypercalcemia is uncommon during the recovery phase of non-rhabdomyolysis associated ATN. Unattended, it can cause severe morbidity. Fluid administration, calcitonin, and bisphosphonates are some of the methods used for its treatment.

PUB439
A Case of Hyponatremia from Adrenal Insufficiency Mimicking Siadh Pradeep Reddy Thodina, Rashid Raja, Siddhesh R. Lotlikar, Imara Dissanayake, Eric J. Bloom. Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA; Nephrology, Albert Einstein Medical Center, Philadelphia, PA.

Introduction: A 40 yr old male with a diagnosis of nasopharyngeal carcinoma was admitted for dysphagia and decreased oral intake. He had severe hyponatremia with serum Na 126 meq/l, other labs including K -4.2, Cr -94, HCO3-26. He was euclidean and normotensive. A urine panel showed Na - 122 meq/l and Uosm of 932 osm/l. He was deemed to have euvolemic hyponatremia from SIADH and started on fluid restriction. There was no improvement in hyponatremia and Una increased to 235 meq/l. He was diagnosed with adrenal insufficiency with a co-syntropin test. Imaging studies did not demonstrate pituitary invasion by nasopharyngeal carcinoma. He was started on high doses of hydrocortisone with rapid improvement of hyponatremia and Una dropped to 35meq/l. Hyponatremia with high Una (280 mg/dL) recurred during hydrocortisone taper. He required prolonged high doses of hydrocortisone to maintain normal serum sodium level. Although there have been many case reports of hyponatremia with adrenal insufficiency, to the best of our knowledge, there has been no reports of hyponatremia with very high Urine sodium (> 200 meq/l).

This case highlights that euclidean hyponatremia can occur with adrenal insufficiency with clinical and biochemical manifestations mimicking SIADH. Adrenal insufficiency should be considered in all cases of hyponatremia especially with very high urine sodium. 

PUB440
Acute Tubulointerstitial Nephritis Preceding the Diagnosis of Multiple Myeloma Alper Alp1, Hakan Akdam2, Aysegul Ormeci,1 Ibrahim Meteoglu,2 Harun Akar,4 Yavuz Yenicieroglu.1 1Nephrology, Van Region Education and Research Hospital, Van, Turkey; 2Nephrology, Adnan Menderes Univ, School of Medicine, Aydin, Turkey; 3Pathology, Adnan Menderes Univ, School of Medicine, Aydin, Turkey; 4Internal Medicine, Nephrology, Tepeck Education and Research Hospital, Izmir, Turkey.

Introduction: Multiple myeloma(MM) is characterized by a neoplastic proliferation of monoclonal plasma cells-usually-originating in the bone marrow. Atypical presentations of MM is not seldom in clinical practice. The hidden signs of the disease may cause late diagnosis and clinicians should be suspicious and aware for this entity. However in some rare cases these signs may really be invisible.

Case Description: A 55 yo woman presented with confusion, oliguria and elevated creatinine level of 18.2 mg/dL. Hemodialysis was started acutely. Renal ultrasonography revealed normal size kidneys without hydronephrosis. Renal biopsy was compatible with acute tubulointerstitial nephritis. 

Kappa and lambda light chain staining was negative. 1 mg/kg metilprednisolone therapy was initiated and given for 1 month. No regression was observed and hemodialysis therapy was continued. After 2 months steroid therapy was reintitated again but there was no clinical and biochemical response. On follow-up, after 7 months from renal biopsy hypercalcemia, anemia, high sedimentation rate, hyperglobulinemia and lytic bone lesions were detected. 16% monoclonal plasma cells were present in bone marrow. With further examinations MM diagnosis was made.

Discussion: Renal biopsies revealing acute tubulointerstitial nephritis pattern which are unresponsive to steroid therapy should always be deeply investigated for alternative diagnoses. MM may have obscure presentations.

PUB441
Sleep Disturbances in an ESRD Patient Soon After Initiation on Hemodialysis: An Atypical Presentation of ESRD-Related Sleep Disorders Desiree Garcia Anton, Franco H. Cabeza Rivera, Alexandre Abreu, Marco A. LadinioAvellaneda. Nephrology, Univ of Miami, Miami, FL.

Introduction: Sleep disorders including obstructive sleep apnea (OSA), restless leg syndrome (RLS) and insomnia are highly prevalent in ESRD patients undergoing dialysis, however, these remain stable or tend to improve after initiation of dialysis. There is scarce evidence of new-onset sleep complaints or disorders after initiation of dialysis.

Case Description: We present a case of a 64 year-old male with HTN, DM, ESRD and no previous sleep problems who developed insomnia, RLS, sleepwalking and other sleep disturbances within a month after initiation of continuous hemodialysis. He presented to the nephrology clinic with secondary complications from uncontrolled diabetes (neuropathy, retinopathy and nephropathy); he had been followed by the nephrology service for 4 years before requiring dialysis for uremia and volume overload. Intermittent HD was well tolerated during first month of treatment, achieving good metabolic clearance and volume control; his KTV was 1.16, phosphorus was controlled at 4.6 mg/dl and his anemia improved to a hemoglobin of 9.6 mg/dL; iron was 36 mcg/dl, ferritin 135 ng/ml and transferrin saturation 15%. Despite clinical and laboratory improvement, disabling sleep symptoms were reported and he was referred to the Sleep clinic for further evaluation. On his initial actigraphy, a bedtime or rise time pattern was unable to be determined as it showed continuous movements and he was referred to the Sleep clinic for further evaluation. On his initial actigraphy, a bedtime or rise time pattern was unable to be determined as it showed continuous movements and he was referred to the Sleep clinic for further evaluation. He was referred to the Sleep clinic for further evaluation. His nocturnal actigraphy revealed a high stage 1 sleep with no stage 2 sleep and low stage 3 sleep.

Discussion: New-onset sleep problems after initiation of dialysis in patients who previously had no sleep complaints are an atypical presentation. The role of RRT on sleep disturbances in the ESRD population is unknown. We propose PSG pre and post dialysis initiation on advanced CKD patients to assess for differences and identify how RRT may affect sleep disturbances.

PUB442
Reduced Serum Anion Gap due to Lithium Overdose Tanmav Sahai,1 Josef Bautista.1 1Internal Medicine, Roger Williams Medical Center, Providence, RI; 2Nephrology, Brown Univ/Rhode Island Hospital, Providence, RI.

Introduction: This case demonstrates the clinical presentation and corresponding laboratory results of lithium overdose as well as further discuss management of overdose with intermittent hemodialysis.
Case Description: A 32-year-old man with a history of bipolar disorder came to the hospital complaining of intense thirst and worsening lethargy. He was subsequently intubated for airway protection. Patient’s lithium level was ~ 20 mmol/L. CT head showed no injury. The rest of the toxicology screen was negative. His basic metabolic panel (including calcium and albumin) was within normal limits however his bicarbonate was 32 mmol/L and his potassium was 4.2 mmol/L. Munin gap was 3 mmol/L and other causes including hyperglycemia, hypercalcaemia, and metabolic acidosis were ruled out. In addition, his osmolality was not measured at time of presentation. Patient was hemodynamically stable. Vigorous hydration with isotonic saline was initiated. Intermittent hemodialysis with high blood pump speed was initiated. Serum lithium level was checked 24 hours later and it fell to 2mmol/L. Munin gap was 1 mmol/L and patient was extubated 48 hours after initial presentation. Low anion gap is a diagnostic clue to lithium intoxication however other causes include hyperkalemia, hypermagnesemia, and monoclonal gammopathies. Although serum osmolality was not measured in our patient, this can also be a helpful indicator noted in previous case reports. Elevated osmolar gaps with low anion gaps are useful in diagnosing lithium overdose. The standard management for lithium overdose is intermittent hemodialysis and maintaining water balance. The theory behind using intermittent hemodialysis versus continuous venovenous hemofiltration is that higher clearance of lithium can be achieved from faster blood flow rates in intermittent hemodialysis if it can be tolerated hemodynamically.

Discussion: The case is very unique as the contrast injury resulted in nephrogenic DI. The patient is also at risk of thirst response and rise in sodium was even more peculiar as the DI was clearly nephrogenic due to lack of response to DDAVP. It is still unclear why the thirst response in this patient was affected. More studies in future will unravel the complex relation between thirst response and osmolality.

PUB445

Frailty Modifies the Association Between Age and Dysnatremia in Community-Dwelling Adults Amanda Jean Miller,1 Susan E. Howlett,2 Kenneth John Rockwood,2 Karthik K. Tennankore.1 1Nephrology, Dalhousie Univ; Halifax, NS, Canada; 2Geriatrics, Dalhousie Univ; Halifax, NS, Canada.

Background: Frailty represents a state of increased risk to adverse health outcomes, reflecting some combination of increased damage and repaired resource processes. Dysnatremia is more common with age and can occur in many settings, suggesting that it may reflect not simply a specific renal problem, but a more general imbalance in damage and repair. The aims of this study were to establish what frailty severity is associated with a higher rate of dysnatremia and to determine whether frailty explains the previously established association between age and dysnatremia.

Methods: The relationship between age, frailty severity and dysnatremia was investigated across the adult life course in 8989 respondents from the 2003-2004 and 2005-2006 cross-sectional National Health and Nutrition Examination Survey (NHANES) datasets. Respondents were assigned a frailty index (FI) and assessed for dysnatremia (a deviation of serum sodium from the 135-144 mmol/L normal range). The coefficient of variation in serum sodium was used as a systems measure of the response repertoire.

Results: In the overall population, there was a significant positive association between increasing frailty severity and the proportion of patients with dysnatremia (chi-square trend p = 0.001). Increasing frailty severity was also associated with more variability in serum sodium. There was a significant association between advancing age and dysnatremia (p < 0.001); however after stratifying by frailty (FI <0.100, 0.100-0.199, 0.200-0.299, 0.300-0.399, >=0.400), the association between increasing age and dysnatremia became non-significant in all categories.

Conclusions: Increasing frailty severity is associated with dysnatremia and greater variability in serum sodium. Furthermore, frailty appears to modify the earlier association between age and dysnatremia.

PUB446

Approach to Hyponatremia in Congestive Heart Failure: A Survey of Canadian Physicians and Trainees Amanda Jean Miller1, Bonnie Kuehl,2 Karthik K. Tennankore.1 1Nephrology, Dalhousie Univ; Halifax, NS, Canada; 2Research, Scientific Insights Consulting Group Inc., Mississauga, ON, Canada.

Background: Hyponatremia is a complication of congestive heart failure (CHF) and is associated with reduced survival, however there are no consensus guidelines for the treatment of hyponatremia in CHF. The aim of this study was to determine the approach to hyponatremia in CHF among Canadian Nephrologists, Cardiologists, Internists and trainees in each of two domains; pathophysiology and management. Management topics included use of diuretic therapy, hypertonic saline, oral urea tablets, vasopressin receptor antagonists (vaptans) and rate of sodium correction. Correct answers were determined by an expert panel of Canadian Nephrologists and Cardiologists.

Methods: Respondents completed 15 multiple-choice style questions surrounding three cases of hyponatremia complicating CHF using an online survey on UKidney.com between December 2012-May 2013. Results were summarized as the proportion of correct/ incorrect responses among Canadian Nephrologists, Cardiologists, Internists and trainees in each of two domains; pathophysiology and management. Management topics included use of diuretic therapy, hypertonic saline, oral urea tablets, vasopressin receptor antagonists (vaptans) and rate of sodium correction. Correct answers were determined by an expert panel of Canadian Nephrologists and Cardiologists.

Results: There were 1097 responses to survey questions among 455 Canadian respondents. Pathophysiology governing hyponatremia in CHF was correctly identified in 68.7% of responses (n = 380). Overall, hyponatremia was managed incorrectly in 33.3% of responses (n = 759). The proportion of incorrect responses among specialists and trainees is depicted in Figure 1. Importantly, an incorrect rate for sodium correction was selected 61.1% of the time (n = 211).
Conclusions: This study highlights knowledge gaps regarding pathophysiology and management of hyponatremia in CHF amongst Canadian specialist physicians and trainees. There is a need for further education to improve the management of hyponatremia in CHF at a national level.

PUB447
Sorafenib Induced Hyponatremia

Elan Gorshein,1 Catherine K. Wei,1 Jasmeet S. Bajaj,1 1Internal Medicine, Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; 2Critical Care Unit, Univ Medical Center of Princeton at Plainsboro, Plainsboro, NJ.

Background: Sorafenib treats unresectable hepatocellular carcinoma (HCC). It is a multi-targeted tyrosine kinase inhibitor (TKI), which prevents tumor cell proliferation. For those with inoperable disease, it prolonged median survival. Nevertheless, adverse reactions may limit its use. Sorafenib has been associated with hyponatremia, which may be related to the syndrome of inappropriate antidiuretic hormone (SIADH) secretion. We present a case of sorafenib induced hyponatremia.

Methods: A 58 year-old female presented with lethargy and edema. Patient was diagnosed with HCC 6 months earlier. She underwent transcatheter arterial chemoembolization and was noted on repeat imaging to have metastatic disease. Patient began sorafenib two weeks prior to admission, with a dose of 200 mg daily. A week later, the dose was increased to 200 mg twice daily. Three days later, the patient increased her dose to 400 mg in the AM and 200 mg in the PM. A day thereafter, patient became lethargic, with generalized swelling. The serum sodium was 106 mmol/L, with a baseline of 134 mmol/L three weeks prior to admission. Urine osmolality was 542 mOsm/kg, and the urine random sodium was less than 25 mEq/L. Patient’s TSH was 6.82, with a normal FT4. AM cortisol was measured at 20.2. Her total protein and lipid profile were normal.

Conclusions: TKI agents have improved median survival in advanced HCC disease. Their use, however, has been limited by adverse events. Hyponatremia has been reported with a rate of up to 11% in patients treated for HCC. The pathophysiology may be related to SIADH. TKI agents may enhance the effects or increase the action of ADH. Time to onset of hyponatremia may be within ten days. Our patient took sorafenib for two weeks. Upon admission, her serum sodium was 106 mmol/L. TKI treatment induces hyperkalemia, saline and fluid restriction, her sodium reached 128. Other etiologies of hyponatremia were excluded. Sorafenib was discontinued, and attempts at patient follow-up have been unsuccessful. However, this report highlights that while sorafenib has had favorable impact on advanced HCC outcomes, clinicians should be mindful of its adverse effects.

PUB448
Current Trends in Etiologic Factors Responsible for the Development of Hyponatremia in Hospitalized Patients

Sander Win,1 Maria V. DeVita,1 Diana Dreyer,1 Samuel J. Wahl,1 Michael F. Michelinis.1 1Nephrology, NSLIJ/Lenox Hill Hospital, New York, NY; 2Pathology, NSLIJ/Lenox Hill Hospital, New York, NY.

Background: Hyponatremia remains the most common electrolyte disorder seen in hospitalized patients. The prevalence has been reported to vary from 3% to 15% and to be as high as 29.6% depending on the hospital setting.

Methods: New data were obtained on 2 separate days to evaluate the prevalence and etiologies of hyponatremia in hospitalized patients in a large metropolitan hospital. Hyponatremia was defined as less than 135mmol/L.

Results: Hyponatremia was recognized in 41 of 879 patients (4.6%). The mean serum sodium level in the hyponatremia group was 132.0 ±3.2 mmol/L. Eighty-five percent of the patients exhibited a serum sodium level of <130 mmol/L. Individuals aged 65 years old or greater made up 58.5% of the patients. Etiologic factors identified in the total number of hyponatremic patients included 9.7% with ESRD, 4.8% post op, 14.6% dehydration, 24.3% with pulmonary disorders, 26.8% with a diagnosis of cancer. The majority of patients were noted, however, to be receiving related drug therapies 63.4%. They were distributed between diuretic therapy (36.6%) and psychiatric drug therapy (26.8%).

Methods: 62-year-old female with history of adenocarcinoma of the lung, developed severe hypomagnesemia secondary to metastatic neuroendocrine tumors with serum magnesium (Mg) levels of 1.8 mg/dL. She had concurrent severe hypocalcemia with serum calcium (Ca) of 5.1 mg/dL. Aggressive repletion was started & further workup was done. Her serum Mg level was reported as 381 mg/L, her fractional excretion of Mg was calculated & it was 9%. She received 3 cycles of carboplatin before hospitalization. She was not on any diuretics, PPIs & Aminoglycosides. She did not receive ceftriaxone as U/m magnesium was less than 150mg, it was thought that she had carboplatin-induced distal nephron Mg wasting . Her serum PTH level was 245.5 pg/mL. Her hypercalcemia was thought to be secondary to presence mediated distal nephron hypomagnesemia. After aggressive repletion her serum Mg & Ca level normalized.

Conclusions: Hypomagnesemia can be due to multiple causes,Initial step in evaluation involves calculating FeMg,if less than 2.5%,it is likelyy secondary to GI loss.If FeMg is<2.5% then we measure 24-hour urine calcium,if its more than 250mg it is likely due to TAL-Mg wasting which can be secondary to loop diuretics,neptrotoxins(Aminoglycosides) or Familial hypomagnesemia with hypercalciuria.If less than 150mg then it is likely due to distal nephron Mg wasting which can be secondary to thiazides & Gitelman’s syndrome.
Our case represents an interesting concurrent presentation of severe hypomagnesimemia and hypocalcemia, which was successfully treated.

PUB455
Effect of Arterial pH and Bicarbonate Level on Survival of Lactic Acidosis Patients Treated with Sodium Bicarbonate
Dongyoul Lee,1 Hansue Kim,2,3 Eun Geun Jeong,2 Su Mi Lee,4 Sung Hyun Son,2 Yong Ki Park,5 Young Ki Son,6 Seong Eun Kim,7 Won Suk An,2 1Internal Medicine, Bong Seng Hospital, Busan, Korea; 2Internal Medicine, Han Seo Hospital, Busan, Korea; 3Internal Medicine, Dong-A Univ, Busan, Korea.

Background: Patients with lactic acidosis have high mortality rate, and higher lactate level is poor prognostic indicator. The correction of lactic acidosis with sodium bicarbonate is potentially harmful when sodium bicarbonate inappropriately was used. Therefore, we evaluated whether starting pH of sodium bicarbonate affect on the survival in lactic acidosis patients treated with sodium bicarbonate.

Methods: We conducted a single center analysis from May 2011 through April 2014. We retrospectively analyzed 230 patients with lactic acidosis treated with sodium bicarbonate. Patients were divided four groups according to starting arterial pH of sodium bicarbonate.

We analyzed arterial blood gas analysis, lactate level about 6, 12, 24, 48 hours after using sodium bicarbonate.

Results: The mean age of patients was 62.8 ± 15.0 years, 174 patients (75.7 %) were male. The non-survivals had lower pH, Na, hemoglobin, and CRP (P < 0.001, P < 0.001, P = 0.003), higher SOFA and APACHE II scores (P < 0.001, P < 0.001), and higher blood lactate level at 6, 24, 48 hours, and maximum after checking the initial lactic acid levels (P < 0.001, P < 0.001, P < 0.001, P < 0.001). Patients with increased second lactate level have higher mortality (84.4 %). The mortality rate was 90% in patients with sustained high lactate level at 48 hours. The mortality rate was not different according to starting point of sodium bicarbonate. In survival group, arterial bicarbonate level was slowly increased without fluctuation. However, arterial bicarbonate level showed fluctuation in non-survival group.

The mortality rate was independently associated with arterial pH at 12 hours after sodium bicarbonate infusion.

Conclusions: Stably increased arterial bicarbonate without fluctuation and recovering arterial pH at 12 hours are important factors in patients treated with sodium bicarbonate. Therefore arterial pH and sodium bicarbonate level should be closely monitored especially till 48 hours, if sodium bicarbonate treatment with lactic acidosis.

PUB456
Evaluation and Management of Hyperkalemia in an Academic Medical Center Jason K. Law,1 Gaurav Ghosh,1 Daniel Edmonston,1 Saif A. Muhsin,2 Yasin Hussain,1 Miriam Chung,1,2 Jeffrey I. Silberzweig,1,2,4 Dept of Medicine, New York-Presbyterian Hospital, New York, NY; Weill Cornell Medical College, New York, NY; 1Weill Cornell Medical College, Qatar, Doha, Qatar; 2Rogosin Inst, New York, NY.

Background: Hyperkalemia (K > 6.0 mmol/L) is common among hospitalized patients but the approach to evaluation and management is highly varied. Patients are not routinely evaluated for clinical effects. Decisions regarding whether and how to treat are often based on individual physician judgments since few evidence-based guidelines exist. Since both hyperkalemia and its treatments can be associated with serious adverse consequences, we sought to evaluate the management in our institution.

Methods: Electronic medical records were reviewed for patients in our institution with potassium levels greater than 6.0 mmol/L between January 1, 2012 and December 31, 2014. Records were extracted for hyperkalemia associated symptoms and ECG findings, as well as interventions and outcomes.

Results: Only 2% of patients had clinical findings consistent with hyperkalemia. Over 98% of patients had ECG changes performed and only 20% of those had findings consistent with hyperkalemia. Of patients with ECG findings consistent with hyperkalemia, only 15% had repeat tracings performed after treatment. At least 50% of patients were treated with insulin and dextrose and/or calcium. One-third of patients were treated with sodium polystyrene sulfonate (SPS), 25% with sodium bicarbonate and 10-15% were treated with lactulose or furosemide. Only 25% of patients had repeat potassium levels measured within six hours of treatment.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

Background: The aim of the study was the analysis of the prevalence of hyponatremia in hospitalized patients, and the effect of total plasma protein (TPP) concentration on plasma sodium levels.

Methods: We registered all biochemical analysis from in-hospital patients during one year. Data from age, sex, and department was recorded. Plasma Na was measured by an indirect ion selective electrode measuring system (Cobas 8000 analyzer, Roche Diagnostics). Hyponatremia was defined when plasma sodium was lower than 135 mmol/L. Hyponatremia was classified based on plasma Na concentration. Mild hyponatremia was defined as 130-134 mmol/L, moderate as 125-129 mmol/L and profound as lower than 125 mmol/L. When TPP was measured, plasma Na concentration was corrected according to: NaTPP = NaTPP + 0.7 x (TPP concentration – 0.7).

Results: Our hospital is a 520 in-hospital beds. Plasma Na was measured in 26,904 biochemical analyses from 6,873 patients. Median age was 67 (IQR 50-79). 55.9% were men. Median plasma Na measurements was 5 (IQR 2.11). Hyponatremia was present in 1,514 patients (22%), mild hyponatremia 1,114 (16.2%), moderate 287 (4.2%) and profound 113 (1.6%). Plasma Na could be corrected to TPP in 3,122 patients, using the first formula hyponatremia was present in 29.4% (mild 19.6%, moderate 6.8% and profound 3%) while using the second one, 27.9% (mild 18.7%, moderate 6.4% and profound 2.8%).

Conclusions: Hyponatremia is present in one fifth of in-hospital patients. Correction of plasma Na concentration according to TPP concentration increase hyponatremia diagnostic up to 25%.

PUB460
An Unusual Cause of Hypokalemia Mohammad A. Hanounah,1 James F. Simon.2 1Internal Medicine, Cleveland Clinic, Cleveland, OH; 2Glickman Urologic and Kidney Inst, Cleveland Clinic, Cleveland, OH.

Methods: A 59 year-old woman presented as a self-referral for a second opinion regarding hypokalemia. She had long-standing resistant hypertension currently treated with benazepril and spironolactone. She was also on aspirin, and alendronate for osteoporosis. Her medical records were reviewed for hyperkalemia treatment and outcomes. Hyperkalemia treatments were made using t-tests. 24 cases of hyponatremia in the bronchiolitis group (18.75% prevalence),8 cases in the asthma exacerbation, and 69 patients with gastroenteritis were available for analysis. There were 24 cases of hyponatremia in the bronchiolitis group (18.75% prevalence),8 cases in the asthma exacerbation, and 69 patients with gastroenteritis. Other diagnoses and patients without serum sodium levels were documented. The aim of this study is to characterize the prevalence of hyponatremia and assess its impact on the course of hospitalization, but this association has not been explored in pediatrics. The analysis was performed between those with hyponatremia and those with normal sodium. The analysis for prevalence and LOS was performed using a two-tailed, unequal t-test with a p <0.05 used for significance.

Conclusions: Management of hyperkalemia in our institution is far from systematic. Most patients receive treatment without evaluation for clinical effects of hyperkalemia. There is no standard treatment regimen and follow up measurements of potassium and ECGs were rarely done.

PUB457
Treatment of Hyperkalemia with Kayexalate in an Academic Medical Center Gaurav Ghosh, Yasin Hussain, Jason K. Law, Daniel Edmonston, Sait A. Muhls, Miriam Chung, Jeffrey L. Silberzweig.1,2,4 1Dept of Medicine, New York-Presbyterian Hospital, New York, NY; 2Weill Cornell Medical College, New York, NY; 3Weill Cornell Medical College, Qatar, Doha, Qatar; 4The Rogosin Inst, New York, NY.

Background: Hyperkalemia (K > 6.0 mmol/L) is a potentially life-threatening condition; standard treatment has included sodium polystyrene sulfonate (Kayexalate) since its introduction in 1958. Recent literature has questioned the benefits of this treatment because of the lack of proven efficacy and the risk of serious adverse effects. We evaluated the effectiveness of Kayexalate for treatment of patients with hyperkalemia in our institution.

Methods: Electronic medical records were reviewed for all patients in our institution with potassium levels > 6.0 mmol/L between January 1, 2012 and December 31, 2014. Records were extracted for hyperkalemia treatment and outcomes. Hyperkalemia treatments included albuterol, diuretics, insulin, lactulose, sodium bicarbonate, and Kayexalate. Comparisons between hyperkalemia treatments with Kayexalate and without Kayexalate were made using t-tests.

Results: One-third of patients diagnosed with hyperkalemia were treated with Kayexalate. Post-treatment potassium values decreased by 14.8% in treatment with Kayexalate, compared to 17.4% reduction in treatment combinations without Kayexalate (p = 0.46). No patients suffered serious adverse effects from Kayexalate treatment.

Conclusions: In our population, treatment of hyperkalemia with Kayexalate was common. While no adverse events of treatment were noted, there was no significant difference in reduction of potassium levels with it. We conclude that there is insufficient evidence to support routine use of Kayexalate in our population.

PUB458
The Impact of Hyponatremia on Children: Prevalence and Consequences During Hospitalization Zachary Sartor, Poonam Thakore, Tetyana L. Vaaylyeva. Pediatrics, Texas Tech Univ Health Sciences Center, Amarillo, TX.

Background: Hyponatremia in adults is associated with increased morbidity and mortality, but this association has not been explored in pediatrics. The aim of this study is to characterize the prevalence of hyponatremia and assess its impact on the course of hospitalization in pediatric patients.

Methods: Patients who were admitted to the TTUHSC pediatric service at Northwest Texas Hospital in Amarillo, TX from January through December 2012 were considered for retrospective chart review. Patients were divided into 3 diagnosis groups: bronchiolitis, asthma exacerbation, and gastroenteritis. Other diagnoses and patients without serum chemistry results were excluded. Age, sex, and serum sodium levels were documented. The number of days admitted were also recorded. Hyponatremia was defined as mild if the sodium was 130-135 mEq/L, moderate if 125-129 mEq/L, or severe if <125 mEq/L. Hyponatremia was classified based on plasma Na concentration. Mild hyponatremia was defined as 130-134 mmol/L, moderate as 125-129 mmol/L and profound as lower than 125 mmol/L.

Results: Overall, 416 patients were admitted to the inpatient service during the study period. After exclusion 128 patients with bronchiolitis, 137 patients with asthma exacerbation, and 69 patients with gastroenteritis were available for analysis. There were 24 cases of hyponatremia in the bronchiolitis group (18.75% prevalence), 8 cases in the asthma exacerbation group (5.84% prevalence), and 18 cases in the gastroenteritis group (26.09% prevalence). There was one case of moderate hyponatremia in the bronchiolitis group, otherwise all other cases involved mild levels of hyponatremia. LOS was increased for patients with hyponatremia (2.33±0.11 days versus 4.26±0.71 days, p=0.01).

Conclusions: Hyponatremia was prevalent at an overall rate of 15% during the study period. Hyponatremia was associated with increased hospitalization at a statistically significant level.
mortality adjusted for patients’ characteristics and co-morbid conditions. We used random effects meta-analysis to derive pooled estimates of effect in medical, surgical and mixed admission settings.

Results: We evaluated 135 full text publications from 2014 reviews, of which 32 studies met the inclusion criteria (19, 13, and 5 reported aOR, proportion and both respectively). Patients with hyponatremia were at increased risk of hospital mortality (OR=2.59, 95% CI 1.5-4.47, P<0.001).

Hyponatremia and studies evaluating the efficacy of early intervention are warranted. With twice the odds of hospital mortality. Protocols towards increasing awareness of ingestion are needed. These findings suggest the need to consider replacing ethylene glycol with alternative and less toxic agents.

Conclusions: Hyponatremia is associated with poor outcomes. Studies show that hospitalized hyponatremic patients seldom get adequate diagnostic workups. This study tests the effects of a CME activity on physician’s behavior in the diagnostic workup of hyponatremia.

Methods: This is a cross sectional analysis of patients admitted to the Internal medicine department at Montefiore Medical center between 05/2014 and 12/01/2014. Demographic and clinical data were collected retrospectively. Patients were included if they were admitted under the service of 24 hospitalist attendings. These attendings were chosen based on their participation in a CME activity (lecture based). This activity was implemented to improve hyponatremia workup as defined by the frequency of the following orders: serum osmolality, urine osmolality, and urine sodium. Hyponatremia was defined as the earliest serum sodium less than 135 mEq/L. There was further subclassification into three groups based on the severity: mild: 130-135 mEq/L, moderate: 125-130 mEq/ L and severe: less than 125 mEq/L. Frequency of the diagnostic orders was stratified to better evaluate the effect of the activity.

Results: There were 358 patients with hyponatremia: 176 hyponatremia admissions occurred before the live lectures and 182 occurred after. Average age was 63yrs±17, average length of stay was 5.2 days ± 2.9. The severity of hyponatremia was 82%, 14% and 3.4% for mild, moderate and severe, respectively. Forty eight percent of all patients who had hyponatremia at admission were discharged with hyponatremia. There was an increase in serum sodium between admission and discharge with a mean difference of 3.06 (95%CI, 1.63-5.5mg/dL), (P<0.0001). The frequency of all 3 orders was 3.2%, 19% and 50% in the cohort; (P value <0.001). One trend was 6% in the pre-activity cohort versus 8% post. More of the severely hyponatremic patients were discharged with hyponatremia than the mild or p<0.005.

Conclusions: Hyponatremia was underinvestigated in our cohort despite a formal educational exercise addressing better diagnostic workup. Further research is warranted to evaluate the effect of CME activity on the treating physician behavior and patient outcomes.

Characteristics and Initial Outcomes of a Multidisciplinary Renal Genetics Clinic (RGC) Andrew John Mallett,1,2,3 Helen G. Healy,1,2,4,5 Julie M. McTaggath,1,2,6 Melissa H. Little,1,2,7,8 Chirag Patel,1,2,9,10,11 Kidney Health Service & Joint Kidney Research Laboratory, Royal Brisbane & Women's Hospital, Brisbane, QLD, Australia; 2School of Medicine, The University of Queensland, Herston, QLD, Australia; 3Austin Health, Melbourne, VIC, Australia; 4Genetic Health Queensland, RBWH, Brisbane, QLD, Australia; 5Murdock Children’s Research Inst, Melbourne, VIC, Australia.

Background: Genetic Renal Disease (GRD) accounts for 10% of adults and 50% of children with end stage kidney disease. Advances in molecular genetic diagnostic testing and multidisciplinary renal clinic models suggest opportunities for clinical redesign. Here we describe the initial characteristics, experience and outcomes of the first Australian genetic renal clinic model.

Methods: A retrospective audit was undertaken of the RBWH Adult Conjoint RGC (1st year of operation; Aug’13-Jul’14). Each encounter involved a nephrologist, clinical geneticist and genetic counselor.

Results: 27/48 patients (56%) encountered had a known GRD, 9/48 (19%) had a suspected GRD and 12/48 (25%) had an unknown GRD with positive family history (FHs). Patients were most commonly referred by nephrologists (66%). The most common GRD category & diagnosis were cystic kidney disease (49%) and Autosomal Dominant Polycystic Kidney Disease (29%). Mutations found in patients associated with GRD were seen in 26/48 (54%). During consultations differential diagnoses were explored (54%), management
advise provided (83%) and genetic counseling undertaken (79%). A genetic test was requested in 58.3%, most commonly being induced by co-morbid diagnostic and genetic counseling reasons (78.6%). Of 12 returned genetic test results, 7 were positive and 1 was a variant of uncertain significance. Two negative results have prompted additional genetic testing. Of 27 patients referred with a known GRD, 6 now have a new suspected GRD. The majority of those referred with either a suspected (69) or unknown GRD diagnosis (10) now have a new suspected or confirmed GRD.

Conclusions: These findings demonstrate the early successful operation of this RGC model including diagnostic and genetic counseling benefit. Future assessment of clinical outcomes and expansion to telehealth and paediatric settings is anticipated.

### PUB466

#### Characteristics and Clinicopathological Analysis of Japanese Nephronophthisis Patients

**Patients** Keisuke Sugimoto,1 Tomoki Miyazawa,1 Takaji Enya,2 Hitomi Nishi,2 Keihe Miyazaki,1 Hidetaka Yanagida,3 Mitsuwa Okada,1 Tsukasa Takenuma,1 1Pediatrics, Kindai Univ Faculty of Medicine, Osaka, Japan; 2Pediatrics, Sakai Hospital, Kindai Univ Faculty of Medicine, Sakai, Osaka, Japan.

**Background:** Nephronophthisis (NPHP) affects 4 to 5% of end-stage renal disease (ESRD) occurring in childhood. Disease subtypes include infantile NPH1, which progresses to ESRD around the age of 5 years, juvenile NPH, which develops from early childhood to school age and usually progresses to ESRD by an age of 13 or 14 years; and adolescent NPH, with development of ESRD at an average age of 19 years. Juvenile NPH is reported to be the most common subtype.

**Methods:** We investigated clinical, histologic, and genetic features in 35 Japanese patients clinically and histologically suspected to have NPHP, aiming to promote early diagnosis. We studied many exons as many as 13 NPHP genes. Since such genetic analysis involves significant cost and time, we also screened biopsy specimens by immunohistologic methods employing antibodies against relevant peptides.

**Results:** NPHP occurred fairly uniformly throughout Japan irrespective of region or gender. In 3 families, NPHP affected siblings. The median age of patients was 12.5 years. Renal abnormalities attributable to NPHP discovered through mass screening, such as urine tests in school. However, NPHP accounted for less than 50% of children with abnormal findings, including incidentally discovered renal dysfunction during evaluation of extrarenal symptoms or during routine check-ups. Typical extrarenal manifestations led to discovery including anemia and delayed physical development. The urine often showed low gravity specific density and low-molecular-weight proteinuria. Frequent renal histologic findings included cystic dilation of tubules, mainly in the medulla, and irregularity of tubular basement membranes. Genetically abnormalities of NPHP1 were not common, with large deletions found in few heterozygotes showing single abnormalities in each of NPHP1, NPHP3, NPHP4 were observed.

**Conclusions:** Our findings resemble those reported in Western populations.

### PUB467

#### The Functional Role of the ARHGAP32 L405V Mutation on Cytoskeleton

**Patients** Guisen Li,1 Li Wang. Nephrology, Sichuan Academy of Medical Sciences & Sichuan Provincial People’s Hospital, Chengdu, China.

**Background:** A site-directed mutagenesis for ARHGAP32 was developed to whether the mutation of ARHGAP32 has the effect on the related factors of cytoskeleton in vitro and to understand the functional role of ARHGAP32 in FSGS.

**Methods:** (1) Blood DNA of 110 FSGS patients proved by renal biopsy were used. DNA was sequenced and screened for the mutation of ARHGAP32. (2) Total exons sequencing was performed in 28 DNA samples to find whether mutation of ARHGAP2 and other genes were existed. (2) site-directed mutagenesis primers of ARHGAP32 was designed and amplified by PCR, constructing the mutations of ARHGAP32 plasmids. (2) Transform the wild type and mutant plasmids of ARHGAP32 into Escherichia Coli respectively, sequenced and screened for the mutation of ARHGAP32. (2) Total exons sequencing was performed to find whether mutation of ARHGAP2 and other genes were existed. (3) Transfected the mutated plasmid of ARHGAP32 into 293T cells and then verified by western blot and realtime RT-PCR. (3) Detected the expression of ARHGAP32 in FSGS, IgAN, MN, minimal change disease and diabetic disease by IHC.

**Results:** (1) No mutation of ARHGAP32 was detected while 6 candidate genes were existed. (2) Detected the expression of CDC42 and β-catenin by realtime RT-PCR and western blot in 293T cells which were transfected with the wild type and mutated plasmids of ARHGAP32. (2) Transform the wild type and mutant plasmids of ARHGAP32 into ESCHERICHIA COLI respectively, sequenced the plasmids to identify whether the site-directed mutagenesis of ARHGAP32 was successfully constructed. (3) Transfected the mutated plasmid of ARHGAP32 into 293T cells and then verified by western blot and real time RT-PCR. (3) Detected the expression of F-actin by immunofluorescence in the wild plasmid of ARHGAP32 and mutant type in COS7 cells. (4) The expression of ARHGAP32 in FSGS, IgAN, MN, minimal change disease and diabetic disease by IHC. (2) Detected the expression of CDC42 and β-catenin by realtime RT-PCR and western blot in 293T cells which were transfected with the wild type and mutant plasmids of ARHGAP32. (2) Transform the wild type and mutant plasmids of ARHGAP32 into ESCHERICHIA COLI respectively, sequenced the plasmids to identify whether the site-directed mutagenesis of ARHGAP32 was successfully constructed. (3) Transfected the mutated plasmid of ARHGAP32 into 293T cells and then verified by western blot and real time RT-PCR. (3) Detected the expression of F-actin by immunofluorescence in the wild plasmid of ARHGAP32 and mutant type in COS7 cells.

**Conclusions:** No mutation was detected in sporadic FSGS currently. The mutation of ARHGAP32 had effect on the distribution of cytoskeletal protein of F-actin.

### PUB468

#### Hyponatraemia and Fractured Neck of Femurs in a Geriatric Population: A Retrospective Analysis

**Patients** Tamer Rezk, Krish Patel, Ashish Karir, Sashinie Tennekoon Jayasundera, Christine Sarah Catley, Abdelgalil Abdellahman Ali, Sunith Abeygunasekara. MEHT, United Kingdom.

**Background:** Hyponatraemia is the commonest electrolyte abnormality found in elderly hospitalized patients defined as a serum sodium concentration <135 mmol/L with a mean prevalence of 5%. (NDT 2003; 18: 2466). It is a risk factor for fractures due to unsteady gait as well as osteoporosis and bone fragility. Fractured necks of femurs (NOF) are a significant cause of morbidity and mortality in the elderly with an estimated 24% mortality at 1 year (JAMA 2001; 285: 2736).

**Methods:** Retrospective analysis of 501 patients from fractured NOF database from 1/1/2004 to 31/12/2014 to identify the incidence and severity of hyponatraemia, Chronic Kidney Disease(CKD) Stage and mortality at 30 days and 1 year.

**Results:** Mean age was 83 years and M:F ratio of 1:3. Mild-moderate hyponatraemia was found in 48% of patients (serum sodium of 126-134mmol/L) with only 3% suffering with severe hyponatraemia (<126mmol/L). 31% of patients had CKD Stage 3, 5% Stage 4 and 2% Stage 5. 30-day and 1-year mortality was 7% and 18% respectively. Patients were separated into 3 groups based on natreemic status.

<table>

Kaplan-Meier survival functions were calculated looking at 1-year mortality.

Those with hyponatraemia at the time of presentation appeared to have a worse 1-year survival. Log-rank test was performed. Using a chi-squared value of 3.521, a p value of 0.172 was obtained (not significant).

**Conclusions:** From our analysis it is clear that nearly half of patients on admission with a fractured NOF have at least mild hyponatraemia with evidence to suggest reduction in 1-year survival. We propose more rigorous investigation of this subtle electrolyte disturbance in primary care which carries with it a significant morbidity and mortality.

### PUB469

#### The Effect of Age on Mitochondrial Protein Levels in Rat Kidney Cortex and Medulla

**Patients** Marianna J Zamauskas-Tucker, Natalya Mezenina, Cameron M. Behringer. Physiology & Health Science, Ball State Univ. Muncie, IN.

**Background:** The present study was undertaken to determine the effect of rat age on total protein levels in mitochondria from kidney cortex and medulla.

**Methods:** Young (3 months of age) and Old (22 months of age) female Lewis rats were used. The kidneys were harvested from anesthetized rats after being perfused with isotonic saline via a catheter in the abdominal aorta. The kidneys were separated into cortical and medullary sections and homogenized in isotonic saline. Differential centrifugation was used to isolate the mitochondrial pellet. The mitochondrial pellet was dissolved in distilled water and spun again at 10,000 rpm to isolate the mitochondrial protein pellet. The mitochondrial protein pellet was dissolved in 1 ml of 0.1 M sodium hydroxide. The protein concentration of the sodium hydroxide solution was measured using the Lowry Protein Assay. The protein concentration was expressed as mg protein/g kidney wet weight. Differences were evaluated using a Student’s t test.

**Results:** A significant decrease in the total mitochondrial protein level was observed in kidney cortex from Old rats. The total mitochondrial protein level in kidney medulla from Old rats was not significantly decreased.

Intradialytic Hemodynamic Stability and Functional Status

Zubin T. Lathara, Aniko Szabo, Alexis Visiotcky, Dawn F. Wolfgang. Nephrology, Medical College of Wisconsin, Milwaukee, WI.

Background: Prior research suggests that functional status in ESRD patients declines after initiation of dialysis, implicating the dialysis process in contributing to functional decline. We evaluated a dialysis-specific risk factor of intradialytic change in blood pressure (BP) in relation to changes in physical performance, a component of functional status.

Methods: We enrolled 29 dialysis patients ≥ 50 years. Participants completed a 4m timed walk to measure gait speed both pre and post dialysis and a Falls Efficacy Survey, a measure of concern for falls. Dialytic variables included BP measurements from pre, post and during dialysis along with ultrafiltration rate. Demographics and comorbid data was collected. Analysis evaluated for association between dialytic BP variables and change in gait speed and score on Falls Survey. Multivariate analysis was done to adjust for age, race, sex, diabetes and congestive heart failure.

Results: 28 participants completed the study. The mean age was 62.7 (12.3) years. The majority were male (70.4%) and hypertensive (86.2%). Diabetes was present in 55.2%. The mean (SD) change in systolic and diastolic BP from pre to post dialysis was -10.6(25.8) mmHg and -4.6(10.5) mmHg, respectively. Participants with diabetes had greater intradialytic (SD) change in systolic and diastolic BP from pre to post dialysis was -10.6(25.8) mmHg and -4.6(10.5) mmHg, respectively. Participants with diabetes had greater intradialytic hemodynamic changes with mean (SD) change of SBP + DBP of -26.9(23.5) and -7.9(11.3) respectively. Univariate analysis showed that every 10mmHg decrease in systolic BP and every 5mmHg decrease in diastolic BP was associated with a change in gait speed of -0.01m/s (p = 0.02) and -0.02m/s (p = 0.01), respectively. This association was no longer significant in multivariate analysis, likely due to correlation of change in BP with diabetes status. There was no association between BP change and Falls Survey score.

Conclusions: Decline in physical performance, as measured by gait speed, can be seen post dialysis and is associated with hemodynamic changes during dialysis. Patients with diabetes may be most susceptible to hemodynamic changes. Improving dialytic hemodynamic stability may be a way to reduce the significant functional impairment that occurs post-dialysis.

PUB471

Sirtuin1 Expression in Kidney Tissue Specimens in Patients with IgA Nephropathy
Serhan Tuglular, Izzet Hakki Arikan, Ceren Oczen, Derya Guler, Serhan Tuglular, Deniz Filinte. 1Internal Medicine, Marmara Univ Hospital, Istanbul, Turkey; 2Nephrology, Marmara Univ Hospital, Istanbul, Turkey; 3Pathology, Marmara Univ Hospital, Istanbul, Turkey.

Background: SIRT1 immunexpression in renal biopsy samples of the patients with IgA nephropathy were evaluated to identify the possible role of SIRT1 in the pathogenesis of SIRT1 in IgA nephropathy.

Methods: Twenty eight patients 28 patients (16 women, mean age 37±13.8 years) were included. Biopsy specimens of the patients were reevaluated according to Oxford Classification. Immunexpression of SIRT1, TNF-α, IL-10 and TGF-β were evaluated on kidney tissue specimens byimmunohistochemical staining.

Results: Older age, and higher serum creatinine and uric acid levelswere the predictors of a greater decline of the kidney function. There was a positive correlation between mesangial hypercellularity and uric acid levels. TGF-β (nuclear) and IL-10 (cytoplasmic) expressions were shown in 20 (%71.4) and 25 (%89.3) of the patients, respectively. Expression of the IL-10 was higher in patients who had a high average mesangial score. Tubular and weak (1+) SIRT1 expression was present only in 7 patients.

Conclusions: A positive correlation was shown between mesangial hypercellularity with any of the cytokines or chemokines tested upon HMGB1 stimulation. The TLR4 antagonists EX 76233 and EX 76824 were tested for the ability to modulate cytokine production induced by LPS stimulation.

Results: In HK-2 cells, LPS from E. coli 0111:B4 induced IL-6 and IL-8 production, whereas, S. minnesota and E. coli K12 did not stimulate cytokine production. In PTEC, IL-6 and IL-8 production increased upon S. typhosa, and S. minnesota stimulation. Other strains of LPS did not stimulate production of IL-6 and IL-8 in PTEC. There was little detectable production of IL-10, TNFα or MCP-1 under the conditions tested in both HK-2 and PTEC cells. HMGB1 induced IL-8 production in PTEC whereas HK-2 cells did not produce any of the cytokines or chemokines tested upon HMGB1 stimulation. The TLR4 antagonists EX 7624 and EX 76233 blocked cytokine production stimulated by S. typhosa in PTEC. EX 76248 inhibited IL-6 and IL-8 production stimulated by E. coli 0111:B4 in HK-2 cells.

Conclusions: Primary PTEC have unique responses to different strains of LPS, and this response profile differs from that of the HK-2 cell line. HMGB1 induced IL-8 production in PTEC, whereas HK-2 cells did not respond to HMGB1 stimulation. These results highlight a limitation of using the HK-2 cell line in lieu of primary PTEC for investigating the role of TLR4 in renal inflammation.

Response of Human Primary Renal Proximal Tubular Epithelial Cells to Different LPS Strains
Hong Wang, Margaret M. O’Neill, Carine Boustaney, Steven S. Pullen. CardioMetabolic Diseases Research, Boehringer Ingelheim Pharmaceuticals, Ridgefield, CT.

Background: Toll-like receptors are expressed on leukocytes and renal tubular epithelial cells where they regulate immune responses. Recent evidence has implicated renal TLR4 signaling in the pro-inflammatory response in diabetic nephropathy. Ligands for TLR4 include lipopolysaccharide (LPS) and HMGB1. We sought to explore the response of renal proximal tubular epithelial cells (PTEC) to different strains of LPS and HMGB1 as well as modulation by TLR4 antagonists.

Methods: The HK-2 human proximal tubular cell line was stimulated with 3 strains of LPS (S. minnesota, E. coli K12, E. coli 0111:B4) and HMGB1. Primary human PTEC were stimulated with 5 strains of LPS (S. minnesota, E. coli 0111:B4, E. coli 055:B5, E. coli K12, S. typhosa)and HMGB1. Supernatants were harvested and IL-1β, IL-6, IL-8, TNFα, and MCP-1 were detected. TLR4 antagonists EX 76233 and EX 76824 were tested for the ability to modulate cytokine production induced by LPS stimulation.

Results: In HK-2 cells, LPS from E. coli 0111:B4 induced IL-6 and IL-8 production, whereas, S. minnesota and E. coli K12 did not stimulate cytokine production. In PTEC, IL-6 and IL-8 production increased upon S. typhosa, and S. minnesota stimulation. Other strains of LPS did not stimulate production of IL-6 and IL-8 in PTEC. There was little detectable production of IL-10, TNFα or MCP-1 under the conditions tested in both PTEC and HK-2 cells. HMGB1 induced IL-8 production in PTEC whereas HK-2 cells did not produce any of the cytokines or chemokines tested upon HMGB1 stimulation. The TLR4 antagonists Ex 7624 and Ex 76233 blocked cytokine production stimulated by S. typhosa in PTEC. Ex 76248 inhibited IL-6 and IL-8 production stimulated by E. coli 0111:B4 in HK-2 cells.

Conclusions: Primary PTEC have unique responses to different strains of LPS, and this response profile differs from that of the HK-2 cell line. HMGB1 induced IL-8 production in PTEC, whereas HK-2 cells did not respond to HMGB1 stimulation. These results highlight a limitation of using the HK-2 cell line in lieu of primary PTEC for investigating the role of TLR4 in renal inflammation.

Assessment of Serum Transforming Growth Factor-Beta 1 in Patients with Diabetic Nephropathy
Om Prakash Kalra,1 Avanish Shukla,1 Ashok Kumar Tripathi,2 Alpana Raizada.3 1Medicine, UCMS & GTB Hospital, Delhi, India; 2Biochemistry, UCMS & GTB Hospital, Delhi, India.

Background: Diabetes mellitus is the leading cause of chronic kidney disease (CKD) worldwide. The pathogenesis and initial molecular events leading to diabetic nephropathy are still elusive. Chronic low grade inflammation plays an important role in pathogenesis of diabetic nephropathy. Ubiquitous cytokines like transforming growth factor-beta1 (TGF-β) function in an autocrine or paracrine fashion to elicit extra cellular matrix (ECM) accumulation and cellular hypertrophy in several cell types. TGF-β may play an important role in the pathogenesis of diabetic nephropathy by influencing ECM accumulation.

Methods: This was a case control, cross sectional study. 75 subjects aged 30–65 years of either sex were recruited and divided into three groups: Group I: healthy controls (n=25), Group II: patients of T2DM without nephropathy (n=25), Group III: patients of T2DM with nephropathy (n=25). Detailed history, complete physical examination, routine investigations, urine albumin creatinine ratio (ACR) estimation was done. Serum levels of hs-CRP and TGF-b1 were estimated by ELISA.

Results: A statistically significant difference in serum TGF-b1 and hs-CRP levels was observed between all the 3 groups (p<0.001), where highest levels were found in group III and lowest in group I. A positive correlation was observed between serum TGF-b1 and duration of diabetes, FBG, PPBS, HbaC levels, serum creatinine, urinary ACR and serum hs-CRP. Similarly serum hs-CRP levels positively correlated with the duration of diabetes, FBG, PPBS, HbaC levels, serum creatinine, and urinary ACR. Serum TGF-b1 and serum hs-CRP showed negative correlation with eGFR.

Conclusions: Overall, TGF-b1 and hs-CRP levels were significantly higher in diabetics as compared to non-diabetic subjects. They were higher in diabetic subjects with nephropathy as compared to those without nephropathy. Serum TGF-b1 and hs-CRP levels in diabetic subjects appear to be dependent on duration of diabetes, glycemic control and degree of renal dysfunction. Thus cytokines like TGF-β may play a role in the etiopathogenesis of diabetic nephropathy.
Daptomycin Antibiotic Lock Therapy for Hemodialysis Patients with Gram-Positive Bloodstream Infections following Use of Tunneled, Cuffed Hemodialysis Catheters. Retrospective Single Center Analysis Hung-Wen Yen, Szu-yuan Li. Dept of Medicine, Div of Nephrology, Dept of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.

Background: Catheter-related blood stream infection (CRBSI) is a major complication in hemodialysis patients. We assessed the efficacy of systemic daptomycin (DPT) plus DPT antibiotic lock therapy (DPT-ALT) for catheter-salvage in patients with Gram-positive CRBSIs.

Methods: Study Design: Retrospective study of hemodialysis patients with tunneled, cuffed hemodialysis catheters. Setting & Participants: All patients were from a single institution in Taipei and received systemic DPT plus DPT-ALT for treatment of Gram-positive CRBSI. Outcome: Successful resolution of CRBSI. Measurements: Resolution of fever within 48 h, negative result of repeated blood cultures after resolution of fever, no clinical evidence of CRBSI relapse, and no need for catheter removal.

Results: Fifteen hemodialysis patients received DPT-ALT for CRBSI, 9 with coagulase-negative Staphylococcus (CONS), 2 with methicillin-resistant Staphylococcus aureus (MRSA), 3 with methicillin-sensitive Staphylococcus aureus (MSSA), and 1 with polymicrobial infections. Systemic DPT plus DPT-ALT cured 11 patients (73.3%). Treatment failed in all 3 MRSA cases (2 with MRSA and 1 with MRSA + polymicrobial infections). Systemic DPT plus DPT-ALT cured 11 patients (73.3%).

Conclusion: The findings of this study suggest that CVC patients need more EPO dose compared with AVF patients within targeted hemoglobin level. It is to further illustrate the importance of priority of AVF.

Trans Radial Access for Percutaneous Treatment of Arteriovenous Fistula Thrombosis – 2 Cases Cinthya Sohel Velay, 1 Enio Zonta Siqueira Junior, 2 Eduardo Ferreira Medronha, 1 Heloísa Maria Chagas Rego, 2 Mauricio Da Silva Telles. 1 Hemodialysis Unit, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil; 2 Intervention Radiology Service, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil.

Background: Arteriovenous Fistula (AVF) is considered to be the preferential access for patients needing hemodialysis. It is called the “line of life” for these patients. Complications may occur even in autologous AVF or grafts (PTFE). Stenosis is the most frequent complication. Therefore thrombosis is highly desirable for high morbidity, mortality, hospitalizations, interruption of the treatment and access loss. The patient must go to angiography study immediately. We want to show that endovascular percutaneous technique with transluminal angioplasty through trans radial access (TRA), results in quick recovery, particularly in AVF thrombosis.

Methods: Case 1: a 62 y.o. man with right medium radial AVF, for 3 y., started having AVF ache and missed the fistula thrill 48 h after dialysis. It took 45min. to realize the exam. Case 2: a 81 y.o. man, with a left brachiocephalic AVF, for 5 m. visited the ER with gastroneteritis, dehydration and loss of fistula femuratis (less than 24 h).

Results: In these cases, TRA were used with implant of a 6Fr with high compliant balloon angioplasty (Conquest,Bard Peripheral Company). The AVF was recovered without early or late complications.

Conclusion: Besides the small number of subjects and a follow-up of 4 months with AVF patency, the TRA technique shows to be a good alternative, promising and very useful for AVF recovery, even without fibrinolysis in south Brazil. Contraindications must be observed like: intra cardiac shunt R/L, pulmonary hypertension, infected access, surgery in the last 30 days. The most traditional technique was the occluded vein, angioplasty or mechanical thrombectomy which demands more time of Rx and contrast exposition, higher costs and hospitalization. This procedure does not need hospitalization. The success is dependent of early diagnosis of AVF thrombosis, by the Nephrology staff. There must be a close relationship between the staffs: Nephrology and Intervention Radiology.

The Association of the Type of Vascular Access and Erythropoietin Dose in Maintenance Hemodialysis Patients with Targeted Hemoglobin Level Fangpin Lu, 1 Nephrology, First Hospital of Tsinghua Univ, Beijing, China; 2 Blood Purification, Beijing Chaoyang Hospital, Beijing, China; 3 Nephrology, The Third Hospital of Beijing Hospital, Beijing, China.

Background: Both patients with central venous catheter(CVC) and higher doses of erythropoietin(EPO) are at increased risk of mortality in hemodialysis patients, but very limited studies involved the relationship. The present retrospective study aimed to investigate the association between the type of vascular access and EPO dose in MHD patients with targeted hemoglobin level.

Methods: We selected sixty-one patients among 711 MHD patients met inclusion criteria from January 2014 to June 2014 from three hospitals in Beijing, China and compared the difference of EPO dose between arteriovenous fistula(AVF) and CVC group. Logistic regression model with MHD treatment for at least 6 months with 3 sessions per week, at least 18 years of age, no malignant disease or obvious infection or active immunological disease, no gastrointestinal bleeding, no severe iron depletion, no blood transfusions within 3 months before inclusion, stable hemoglobin level(100-120g/L) for consecutive 3 times within 6 months with unchanged vascular access and EPO dosage, and unchanged EPO dosage for 6 months.

Results: There were 32 AVF and 29 CVC patients. There were no difference of Kt/V, serum ferritin, albumin, iPTH and CRP level between AVF and CVC patients. The mean total EPO dose (8793.10±2664.31 vs 7039.06±3651.79, iPTH=0.035) and mean EPO dose (IU/kg body weight/week) were significant higher in CVC patients compared with AVF patients (160.30±58.89 vs 118.02±70.60, p=0.013). It had been increased with in total weekly erythropoietin dose by 24.9% in CVC patients.

Conclusion: The findings of this study suggest that CVC patients need more EPO dose compared with AVF patients within targeted hemoglobin level. It is to further illustrate the importance of priority of AVF.

Incidence and Risk Factors for Catheter Related Infections (CRI) and Their Antibiograms in Haemodialysis Patients – A South Indian Study Shitali Gupta, Shikara P. Mallary, 1 Microbiology, SGPGIMS, Lucknow, India; 2 Microbiology, KMC, Mangalore, India.

Background: Bacterial infections particularly Staphylococcus species often complicate the vascular access in dialysis patients. This study aimed to determine the incidence and associated risk factors for catheter related infections in patients on maintenance hemodialysis in a tertiary Hospital in South India.

Methods: Eighty-seven hemodialysis patients (56 M; 31 F) were enrolled in the study. After insertion of dual lumen catheter, patients were followed up till its removal. Nasal swabs were also collected before insertion. At each dialysis session, catheters were examined for any evidence of local infection or sepsis. In case of suspicion, local pus swab, blood culture samples and the catheter tip were sent to microbiology laboratory and patients were subjected to various investigations, particularly in AVF thrombosis.

Results: Fifty–three  catheters (61%) showed colonization(>15 CFU). Twenty four cases (28%) were associated with catheter related infections. The most common organisms isolated in CRI cases were: S. aureus (9, 17%), P. aeruginosa (9, 17%), E. coli (9, 17%), Enterococcus (5, 9%), K. pneumoniae (5, 9%), S. marcescens (3, 6%) and 1 each by A. baumannii, P. aeruginosa, E. coli, Enterobacter, K. pneumoniae, S. aureus, S. pseudintermedius, P. multocida, C. albicans. Bacteriaemia was positive in 18(20.7%) patients and was the organism isolated in 7(38.8%) episodes. Staphylococcal nasal carriage was the organism isolated in 7(38.8%) episodes. Staphylococcal nasal carriage was the most common organism in catheter related infections with clinical and socio demographic risk factors.

Conclusion: Fifty–three catheters (61%) showed colonization (>15 CFU). Twenty four cases (28%) were associated with CRI, Forty-five (45.2%) catheter tips were found to be colonized by S. aureus, 9 (17%) by P. aeruginosa, 5 (9%) by Acinetobacter, 4 (7.5%) by Enterobacter, 3 (5.6%) by Klebsiella, 2 (3.7%) each by E. coli and Citrobacter spp and one (1.9%) each by S. epidermidis, S. maltophilia, S. marcescens and C. albicans. Bacteriaemia was positive in 18(20.7%) patients and P. aeruginosa was the organism isolated in 7(38.8%) episodes. Staphylococcal nasal carriage was seen in 60 (69%) patients, and 36(41.4%) of these isolates were MRSA. Positive Statistically significant factors associated with CRI included history of bacteremia, presence of diabetes mellitus, long duration (>15 days) of catheterization and antibiotic use within 3 months (p < 0.05 for all). However, the age, gender and staphylococcal nasal carriage did not correlate with increased risk of infection.

Conclusions: P. aeruginosa is the most common organism in catheter related bacteremia which may have a bearing on our current antibiotic policy. Also, early initiation of hemodialysis through fistula may help reduce the CRI rate.

Analysis of Risk Factors of Death in Patients of Maintenance Hemodialysis with Tunneled Cuffed Venous Catheter

Background: To analyze the causes of death in patients of maintenance hemodialysis with tunneled cuffed catheter, and explore the risk factors of death.

Methods: All patients of maintenance hemodialysis with tunneled cuffed venous catheter starting hemodialysis from January 1, 2009 to December 31, 2014 in West China hospital were included and observed until June 1, 2015. The patients were divided into observation (death) and control group (survival). Multivariate logistic regression analysis was used.

Results: In total 94 hemodialysis patients who met the inclusion criteria, 24 cases died in the study period. The median age of dead patients was 73.4 years (51.5–96.4). The median time of hemodialysis was 19.20 months (3.17–56.27). Twenty-three cases replaced tunneled cuffed catheter for once. The main primary causes of renal disease were: diabetes mellitus (25.5%), chronic glomerulonephritis (20.0%), chronic pyelonephritis (13.4%), hypertensive renal damage (12.5%), and post-infectious glomerulonephritis (0.0%). Thromboembolism was the main complication. A VG thrombosis occurred in 16 cases, of whom 3 cases were treated using percutaneous interventions. Among the 294 patients of vascular access, of whom thromboembolism was the main complication. A VG thrombosis occurred in 16 cases, of whom 3 cases were treated using percutaneous interventions.

Conclusions: Among the 294 patients of vascular access, of whom thromboembolism was the main complication.

Vascular access is the life line for maintenance hemodialysis patients. More than 60% patients' initial vascular access was tunneled cuffed central venous catheter. The exchange from non-tunneled HD catheter to tunneled one over the guidewire using previous venotomy does not require time for hemostasis for a new tunneled catheter insertion after its removal. It also does not require a new venipuncture so that it can prevent additional vessel wall injury. However, some concerns of the increased risk of infection and bleeding related infection rates in patients undergoing hemodialysis at the Department of Nephrology, Sichuan Provincial People's Hospital, Chengdu, Sichuan, China.

The Exchange Technique Using Previous Venotomy Site Over the Guidewire from Non-Tunneled to Tunneled Hemodialysis Catheter Can Be Performed without Compromising Catheter Long Term Patency

Methods: From March in 2009 to March in 2013, 46 cases where the exchange from non-tunneled to tunneled catheter and 310 cases with de novo catheter placement were respectively assigned to exchange and de novo placement groups and their 2 groups were compared.

Results: Compared with the de novo placement group, the exchange group over the guidewire with higher hemoglobin level (11.6 ± 2.1 g/dl vs. 11.7 ± 2.1 g/dl, p = 0.001), more females (69.6% vs. 48.1%; p = 0.006), more ESRD rather than AKI as a cause of catheter insertion (95.7% vs. 74.8%; p = 0.002). Both immediate complication rate including suturing at exit site for bleeding control (19.6% vs. 8.7%; p = 0.02) and late one including infection and catheter dysfunction were lower in the exchange group. However, the catheter survival rates between two groups were comparable (p = 0.58) and multivariate Cox regression analysis for catheter survival showed the development of late complication was the only risk factor (odds ratio [OR] 1.391, 95% confidence interval [CI]: 1.017–1.901; p = 0.039) rather than the exchange procedure was not a risk factor (OR 0.878, 95% CI: 0.554–1.393; p = 0.582).

Conclusions: The exchange over the guidewire from a previous tunneled catheter to a new one should be positively considered and performed when the new tunneled catheter placement is required.
Utility of Arterio-Venous Fistula Flow and Doppler Ultrasound in the Prevention of Thrombosis of the Vascular Access

Miglenos Fernandez-Lucas, Fernando Caravaca-Fontan, Estefania Yerovi, Maria Delgado yagüle, Saul Enrique Pampa, Jose L. Teruel, Fernando Liano. Nephrology, Hospital Univ Ramon y Cajal, Madrid, Spain.

Background: A Multidisciplinary Unit for attention to the vascular access was established in our hospital in December 2010. The main role of the nephrologist consists in monitoring the functioning of the vascular access by determining the arterio-venous flow (AVF) and undertaking the doppler ultrasound. The objectives for initiating this program were to reduce the thrombosis rate by diagnosis and treatment of a non clinically detected pathology and to decrease the percentage of patients with a tunnelled catheter.

Methods: The prevalence of haemodialysis patients on 31st December 2014 was 65 patients in the Hospital Unit and 90 patients in the Dialysis Center. In the Hospital Unit we supervise the functioning of the vascular access by measuring the AVF flow and we perform a Doppler ultrasound study if the flow is less than 500 ml/min, if there are significant decreases in comparison with previous controls or if there is any clinical dysfunction. The Dialysis Center uses first generation methods for monitoring (increase in venous pressure, pump flow decrease, recirculation) and requests the Hospital Unit to undertake a Doppler ultrasound study whenever there is any type of dysfunction.

Results: We have observed differences in the results between both centers: 1° Incidence of patients with a tunnelled catheter was lower in the Hospital Unit (14 vs 22%). 2° Thrombosis rate was 40% lower in the Hospital Unit (7,9 vs 12/100-patients-year). 3° Doppler ultrasound detected 25 patients with haemodynamically significant stenosis, confirmed by radiologic study, which were successfully treated.

Conclusions: The combined use of AVF flow measuring and doppler ultrasound studies for monitoring the vascular access is an efficient method for reducing the rates of thrombosis and the number of tunnelled catheters due to the early detection of stenosis and its preventive treatment.

Females Have Less Arteriovenous Fistula and More Grafts Compared to Men: Data from the Slovenian Renal Replacement Therapy Registry

Jadranka Buturovic-Ponikvar, Jakob Gubencsek, Vanja Persic, Rafael Ponikvar. Dept of Nephrology, Univ Medical Centre Ljubljana, Ljubljana, Slovenia.

Background: The aim of our study was to compare prevalence of arteriovenous fistula (AVF) and graft in female and male chronic hemodialysis (HD) patients.

Methods: Data on vascular access in prevalent HD patients on December 31, from 2009-2013, were analyzed, in addition to sex, age, dry body weight and blood flow (QB) during HD, from database of the Slovenian Renal Replacement Therapy Registry. The use of preoperative ultrasonographic mapping before AVF and graft construction in standard practice in the country.

The difference between percentage of AVF comparing females and males is persistent and highly significant during the observation period (p<0.001), with females having less AVF. Females had persistently slightly more grafts. Males had higher mean dry body weight (77.1±11.6 kg vs. 64.7±14.7 kg, end of 2013, p<0.001). Although absolute blood flow during HD was higher in males, females had higher blood flow when standardised to body weight (4.41±1.03 vs. 3.83±0.83 ml/min/kg, p<0.001, end of 2013).

Conclusions: Females chronically have significantly less arteriovenous fistula and slightly more grafts compared to males, with the difference being persistent during five years. Blood flow during HD, when standardised to body weight, was significantly higher in females than in males. Potential clinical consequence of higher blood flow during HD in females should be explored. Strategies to increase arteriovenous fistula prevalence in females should be explored, including potential acceptance of AVF providing lower blood flow during HD.

Analysis of Early Arteriovenous Fistula/Graft Management and Coexistence of Dual Hemodialysis Accesses: Etiology and Clinical Implications of Waiting Too Long to Intervene

Background: A number of patients with newly created arteriovenous fistula (AVF) require tunneled dialysis catheter (TDC) for dialysis until their AVF is deemed mature. Although data have emphasized that the AVF maturation period is 4-6 weeks long, providers often wait up to 6 months hoping the AVF will eventually mature. During this maturation period if dialysis is required, patients frequently use TDC and can experience complications associated with these devices. This retrospective study evaluated 43 ESRD patients with a maturing AVF who were dialyzing with a coexisting TDC placed within 3 months of AVF creation. The patient population included: 1) DA<42 days, 2) DA=42-90 days, and 3) DA>90 days. An analysis of DA duration and follow-up visits were performed. All patients had surgical follow up at least once within the first 42 days of AVF placement regardless of DA duration. Additionally, patients whose DA duration greater than 90 days were evaluated consistently by a surgeon during this period suggesting that prolonged DA is not due to lack of surveillance. Despite this, patient with DA period of greater than 42 days had increasing propensity to undergo avoidable exposure to the risks of prolonged TDC use (p<0.01). Specifically patients with DA>42 days, DA=42-90 days, and DA<90 days were unnecessarily exposed to the risks of dual access for an additional 2.5, 11.7, and 46 days, respectively (p<0.01). This discrepancy between regular surveillance and delayed TDC removal raises concerns that there is a lack of timely intervention after assessment. A more thorough documentation of reasons for prolonged TDC use and analysis of such data are required to verify this hypothesis and get a better idea of etiology of delayed TDC removal.

Methods: Retrospective collection of data from outpatient dialysis units on patients who have AVF/Graft and TDC.

Results: The delayed TDC removal in patients with AVF/Graft the risk of infection in these patients with both devices.

Conclusions: TDC should be removed at an appropriate period once AVF/Graft are mature enough to be used.

Gene Methylation Profile of Human Vein Tissues Taken at the Time of Surgery: Correlation with AVF Maturation

Background: Early arteriovenous fistula (AVF) failure remains an important cause of hemodialysis vascular access dysfunction and a major impediment to the Fistula First initiative. Despite the magnitude of the clinical problem, there are currently no effective therapeutic interventions for early AVF failure. In order to better understand the cellular and molecular mechanisms involved in early AVF failure we have evaluated the gene methylation profile of venous segment tissue samples obtained at the time of AVF creation. DNA methylation of CpG islands (regions of the genome that are rich in cytosine and guanine sequences), influences gene expression (turns off the gene). An increasing number of diverse factors are now known to epigenetically regulate genes, including stress, inflammation, nutrition, metabolism, drugs and infection (all of which are prominent in the biological milieu of patients with CKD and ESRD). In this study we compare the overall methylation profiles of non-maturing AVFs at 6 months as compared to AVFs that are able to support dialysis.

Methods: gDNA was isolated from venous segments collected at the time of AVF creation. DNA sequencing technologies were used to identify genes with the greatest differences in methylation between the two groups. Gene networks focused on inflammation, oxidative stress and endothelial dysfunction were evaluated. Standard bioinformatic techniques were used to identify/interrogate both the gene list and the network analyses.

Results: We were able to identify approximately 300 genes that were significantly different in the overall methylation profiles of non-maturing AVFs at 6 months compared to AVFs that were able to support dialysis.

Conclusions: Our results suggest that epigenetic regulation (DNA methylation) could play an important role in AVF maturation, and also in the identification of novel druggable targets. This latter point could result in the development of novel therapies for dialysis vascular access dysfunction as a whole.

Development of a Uremic Pig Model of Arteriovenous Fistula Stenosis (AVF): A Surgical Approach

Begoña Campos, Yang Wang, Carissa Nicole Lester, Krishnanath Gaitonde, Keith Louis Saum, Sanjay Misra, Prabir Roy-Chaudhury. 1 University of Cincinnati; 2 Mayo Clinic; 3 Cincinnati VA Medical Center.

Background: AVF stenosis remains an important cause of hemodialysis vascular access dysfunction for which there are no truly effective therapies. We and others have previously described well characterized large animal models of AVF stenosis. An important flaw in the majority of these prior AVF stenosis models is the lack of unique methods which increasingly had been shown to play an important role in the pathogenesis of AVF stenosis.

Methods: Chronic renal insufficiency was created by initially removing one of the kidneys through a midline incision. Following this the contralateral kidney underwent a dissection of the pelvis in order to expose the primary and secondary branches of the renal vasculature. A selective ligation of the renal vasculature in the pelvis,
which allowed for the viability of less than 20% of the renal mass on one side was then performed (upper figure = a, b and c). Of note the differential blanching/mottling of the kidney following ligation of vessels in the renal pelvis, allows us to perform a real time assessment in terms of the amount of viable renal tissue. BUN and creatinine estiminations were then made biweekly for 6 weeks.

**Results:** The described surgical technique has allowed us to achieve a stable creatinine of 4 mg/dl over a four week period (lower figure = d). This stable period of uremia will allow us test out the impact of "downstream uremic vascular biology" on AVF maturation.

**Conclusions:** We have developed a unique, innovative and surgically created pig model of uremia with potential logistic and financial benefits. The availability of this animal model will put us in a unique position to be able to tease out the relative contributions of hemodynamics and uremia to AVF stenosis both in our experimental pig model and also in CKD and ESRD patients.

Multimedia Education Tools for Dialysis Vascular Access Monitoring Tushar J. Vachharajani,1 Claudia L. Poole,2 Victoria L. Cash,3 Joseph A. Vassalotti.3

1. Nephrology, W. G. (Bill) Hefner VAMC, Salisbury, NC; 2Fistula First Catheter Last Workgroup Coalition, ESRD National Coordinating Center; 3Nephrology, Icahn School of Medicine at Mount Sinai & National Kidney Foundation, NY.

**Background:** From 2005 to 2012, the Fistula First Breakthrough Initiative (FFBI) of the Centers for Medicare & Medicaid Services focused on improving the arteriovenous fistula (AVF) rate in the hemodialysis (HD) patients. Since the transition to Fistula First Catheter Last (FFCL) in 2013, the workgroup has created multimedia tools to help dialysis facilities and clinicians reduce the use of central venous catheters (CVCs) and further increase AVF use. The key focus for FFCL remains access planning, access monitoring (physical examination) and prevention of access infection.

**Multimedia Access Planning Tools to Attain Catheter Freedom**

Tushar J. Vachharajani,1 Claudia L. Poole,2 Victoria L. Cash,3 Joseph A. Vassalotti.3

1. W. G (Bill) Hefner VAMC, Salisbury, NC; 2Fistula First Catheter Last Workgroup Coalition, ESRD National Coordinating Center; 3Icahn School of Medicine at Mount Sinai & National Kidney Foundation, NY.

**Background:** From 2005 to 2012, the Fistula First Breakthrough Initiative (FFBI) of the Centers for Medicare & Medicaid Services focused on improving the arteriovenous fistula (AVF) rate in hemodialysis (HD) patients. Since the transition to Fistula First Catheter Last (FFCL) in 2013, the workgroup has created multimedia tools to help dialysis facilities and clinicians reduce the use of central venous catheters (CVCs) and further increase AVF use. The key focus for FFCL remains access planning, access monitoring (physical examination) and prevention of access infection.

**Methods:** Why the need for change? FFBI Change Concepts over the past decade resulted in an increase in the AVF rate in the prevalent HD population from 23% to 61% of eligible patients. The impact on the incident HD population has remained suboptimal, with >78% HD patients initiating dialysis with a tunneled CVC. Moreover, the percentage of patients in the prevalent HD population with CVCs in use for 90 days or longer has remained stagnant. Access planning tools: FFCL tools are created to educate the patient and the multidisciplinary dialysis care team (DCT) with the ultimate goal of achieving freedom from CVC. Two separate toolkits available on the FFCL website (http://esrdncc.org/ffcl/) highlight patient-level and DCT-level education.

**Results:** The multimedia toolkits are interactive and easily accessible from any mobile device. Conventional handout/poster formats are also available. The impact of these educational tools will be evaluated once these resources are widely utilized in clinical practice. The primary goal is to develop and disseminate tools to educate and create awareness to increase AV fistula utilization to 68% of appropriate patients, decrease the use of long term catheters (<90 days) to <10%. FFCL is currently collecting metrics on professionals that are aware and using these tools.

**Conclusions:** The purpose of this presentation is to achieve wider dissemination of these tools and increase awareness among patients/professionals.

Cardiac Implantable Electronic Device Infection and Ipsilateral Arteriovenous Fistula in End Stage Renal Disease: Avoidance and Management of Complications Stephanie Lanoisele,1 François Babinec,2 Guillemette Serret,1 Helene Loubiere,1,2 Achiour Laradi.1,2

**Background:** Cardiac implantable electronic devices (CIEDs) are frequently utilized for management of cardiac dysrhythmias in patients (pts) with End Stage Renal disease (ESRD) and are associated with central venous stenosis resulting in adverse effects for existing or future arteriovenous fistula (AVF) with an increase risk of infection of both (CIEDs and AVF). We report the case of a pt with ESRD who experienced a potentially life-threatening complication related to his ipsilateral AVF and CIEDs.

**Methods:** We report the case of a 80-years-old male pt who developed a symptomatic unilaterial left arm edema with skin lesions.He has past history of CIEDs four years ago and the ipsilateral implementation of an AVF 2 years after the CIEDS.He experienced 3 angioplasties on his AVF and a repeated surgery with a persistent post-anastomotic anastomosis with flow reduction of 180 ml/min. A left side chest blood collateral circulation was also present.A deep venous thrombosis related to the implantation of CIEDs was investigated and a left subclavian venous thrombosis was confirmed.On the meantime infection of the CIEDs was suspected but non confirmed. An attempt of a venous recanalization was unsuccessful.A closure of AVF with a plug of 14mm diameter leading to a complete occlusion of AVF.

**Results:** After the occlusion of AVF we noticed a complete regression of the huge left arm edema and a total recovery of the skin lesions. The pt underwent antibiotics therapy for life for the CIEDs infection with successful results two years after initiation of treatment.

**Conclusions:** Although the CIEDs can provide life-savings benefits, device associated complications needs careful management and should be placed by the epicardial approach as a first option for pts with ESRD. It remind us that the AVF is still the Achilles’ heel of dialysis.

Weekly Beta 2 Microglobulin (B2M) Kt/V, Residual Renal Function and Middle Molecule Levels in Daily Dialysis Christos Argyropoulos, Maria-Eleni Roumellioti, Mark L. Unruh. Internal Medicine, Div of Nephrology, UNM-HSC, Albuquerque, NM.

**Background:** B2M and residual renal function (RRF) are predictors of cardiovascular morbidity, mortality and LVH in ESRD. Daily dialysis leads to higher B2M removal and has been associated with improvements in LVH and mortality in randomized trials. It is not known whether kinetic measures of middle molecule adequacy are applicable to daily dialysis.

**Methods:** We adopted a population kinetic model (PKM) for the intradividual variability in generation, distribution and extracranial removal of B2M (ASN 2014,5A-P0969). We used the PKM to simulate B2M concentrations in 10000 patients dialyzed with HF membranes. We examined the intervention protocols for Short (SD), Long Daily (LD) and twice weekly HF dialysis utilized in the FFHI trials. Weekly B2M Kt/V was calculated as the sum of the Kt/V in each session. The impact of Kt/V relative to residual renal function (RRF) on B2M was examined across the three dialysis modalities averaging over the intra-individual variability of kinetic parameters and dialysis prescription.

**Results:** B2M was lower in SD and LD relative to HF irrespective of RRF. Given the variability in dialysis prescriptions there was a substantial overlap in the average Kt/V values between HF and SD.
There was a steep relationship between weekly Kt/V and B2M in all three modalities. The steepness of this relationship was similar between HD and SD across RRF values, but differed for RRF=4ml/min in LD. At any given level of Kt/V the B2M level depended on RRF and dialysis modality.

Conclusions: Weekly B2M Kt/V, a simple measure of middle molecule dialysis adequacy, tracks middle molecule exposure in conventional and daily dialysis. The interpretation of a given Kt/V value requires knowledge of RRF in all dialysis modalities. Future studies should determine whether RRF, dialytic Kt/V or both are predictors of survival in daily dialysis.

PUB492
A Test Battery to Establish Changes in Physical Performance and Protein Energy Wasting in Nocturnal Hemodialysis: The DiapriFIT Study
Manouk Dam,1 Floor Neeleman,1 Caroline E Douma,2 Brigit C. van Jaarsveld,2 1Nutrition and Dietetics, UY Univ Medical Center, Amsterdam, Netherlands; 2Nephrology, UY Univ Medical Center, Amsterdam, Netherlands; 1Nephrology, Sparne Gasthuis, Hoofddorp, Netherlands.

Background: Nocturnal hemodialysis (NHD) improves volume control and phosphate and middle molecule removal. Observational data show increases in body weight and protein intake upon switching to NHD. Other aspects of protein energy wasting (PEW) remain underexposed and also little is known about functional outcomes, such as physical performance and muscle strength. Therefore, the aim of this study is to investigate whether physical performance improves and PEW decreases in patients who change from conventional hemodialysis (CHD) to NHD, compared to patients who continue their treatment on CHD.

Methods: The DiapriFIT study plans to include 25 patients on CHD (2-4x/wk, 3-4 hours) and 25 patients on CHD who switch to NHD (3-4x/wk, 8 hours) with 1-year physical performance and PEW as endpoints. They were submitted to a Visual Appetite Score (VAS), Handgrip Strength (HGS), upper arm circumference (UAC), Short Physical Performance Battery (SPPB) and 6 minute walk test (6MWT), baseline results are reported here. As in NHD weight increases, we tested associations of the outcome parameters with dry weight.

Results: At present, 23 patients were included, aged 58.3±16.0 years, 30.4% males, with a dry weight of 87.6±9.8 kg, UAC 31.9±5.6 cm, SPPB 8.0±1.96 and 6MWT 576±328 meters. Only HGS and UAC were correlated with HD dry weight (r=0.43, p<0.05 for HGS, r=0.79, p<0.001 for UAC).

Conclusions: The DiapriFIT Study measures a great variety of parameters regarding physical performance and PEW. As some, but not all parameters correlate with HD dry weight, we expect to differentiate between CHD and NHD during follow-up of the study. Other results of physical performance and PEW, as subjective global assessment, physical activity, sleep, and QOL questionnaires, activity monitoring, body composition measurement, nutritional diary, DEXA and lab tests will provide additional information on these patient-relevant outcomes of NHD.

PUB493
Anti-Thymocyte Serum Nephritis Rats Developed Augmented Circadian Rhythm of the Intrarenal Renin-Angiotensin System
Shinsuke Isogai, Naro Ohashi, Sayaka Ishigaki, Hideo Yasuda. Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan.

Background: We reported the disturbed circadian rhythm of urinary angiotensinogen (AGT) excretion levels might lead to renal damage, hypertension and diurnal BP variation. Our purpose is clarify the circadian rhythm of intrarenal renin-angiotensin system (RAS) components and its contribution to renal damage, hypertension and BP variation and to evaluate whether administration of RAS dependent or independent antihypertensive drug contributes to circadian rhythm of intrarenal RAS components.

Methods: Anti-thymocyte serum (ATS) nephritis rats were made as chronic progressive glomerulonephritis models (A group) and compared with control rats (C group). Other rats with ATS nephritis received olmesartan [angiotensin II (AngII) type 1 receptor (AT1R) blocker] (AO group) or hydralazine (vasodilatory drug) (AH) group, respectively. Rats were sacrificed every 6 hour and the levels of the intrarenal RAS components were evaluated.

Results: The protein expression levels of intrarenal AGT, AngII and AT1R proteins were increased in A group compared with C group and attenuated in AO and AH group (Peak trough ratio of AGT in C: 1.13, A: 1.47, AO: 1.24, AH: 1.17, AngII in C: 1.03, A: 1.26, AO: 1.14, AH: 1.17 and AT1R in C: 1.36, A: 1.51, AO: 1.37, AH: 1.26). However, renal function, proteinuria and augmentation of intrarenal RAS components were attenuated only in AO group. The protein expression levels of intrarenal renin and proteinurin were the same tendency as AGT, AngII and AT1R, thereby fluctuation of them was attenuated in AO group. The protein expression levels and fluctuation of angiotensin converting enzyme and (pro)renin receptor were not different among groups.

Conclusions: Intrarenal AGT, AngII and AT1R proteins were increased and the amplitude of oscillations of these proteins was attenuated in ATS nephritis rats. Furthermore, renal damage may be linked to the activation of the intrarenal RAS independent of amplitude of its oscillation and BP.

PUB494
Do KCNQ1 Channels Contribute to Control of Arterial Vascular Tone?
Dmitry Tsvetkov,1 Ian Chen,2 Mario Kassmann,1 Jean-Yves Tano,3 Johanna Schliebenbaum,1 Jakob Völk,1 Florian C. Lang,1 Yu Huang,4 Maik Gollasch,3 1Experimental and Clinical Research Center (ECRC), a Joint Cooperation between the Charité Medical Faculty and the Max Delbrück Center for Molecular Medicine (MDC), Berlin, Germany; 2Xiamen Zhongshan Hospital, Xiamen Univ, Xiamen, Fujian Province, China; 3Dept of Physiology, Univ of Tübingen, Tübingen, Germany; 4School of Biomedical Sciences, Lo Kwee-Seong Integrated Biomedical Sciences Building, Area 39, Chinese Univ of Hong Kong, Hong Kong, Hong Kong.

Background: Recent data suggest that the KCNQ family of voltage activated K+ (K,7) channels represents a new therapeutic target in cardiovascular disease. We used Kcnq1-/- mice to determine whether Kcnq1 (K,7)1 mice play a role in the regulation of arterial tone.

Methods: Wire-myography, pharmacology approach and patch-clamp techniques were used.

Results: We found that R-L3 produces similar concentration-dependent relaxations (EC50=1.4 µm) in wild-type (Kcnq1+/+), but not in Kcnq1-/- arteries pre-contracted with either phenylephrine or 60 mM KCl. This relaxation was not affected by 10 µm chromanol-293, 10 µm HMR1556, 30 µm E2991 or 500 µM 4-aminopyridine. Chromanol-293 and HMR1556 did not affect the anti-contraction effects of perivasical adipose tissue (PVAT). The anti-contraction effects of PVAT were normal in Kcnq1-/- arteries. Whole-cell recordings showed normal peak K, currents, capacity and their blockade by E2991 in Kcnq1-/- VSMCs. The pan KCNQ2-5 opener retigabine lead to a similar relaxations in Kcnq1-/- and wild-type vessels.

Conclusions: We conclude that Kcnq1 channels are apparently not involved in the control of arterial tone by alpha, adrenergic vasoconstrictors and PVAT. R-L3 is an appropriate pharmacological tool for studying the function of native vascular KCNQ channels in mice.
Soleimani. Collaborative Study Ambulatory Blood Pressure in Chronic Kidney Disease: An International and its inactivation can cause salt appetite, specifically in male animals, and provoke salt genotypes. Male CAII null mice exhibited a remarkable propensity toward salted water 

hypertension (systolic BP of 155 +/- 3.9 in CAII null vs. 138 +/- 3.2 in WT, p<0.003). When given options are provided. In age and gender matched mice (n=4 per each group), daily salted judged by their preference for salted water (140 mM NaCl) over regular water, when both

- characteristics of the cohorts are shown below.
- salt appetite or salt intake in excess of physiological needs is a major health problem and a risk factor in the pathogenesis of hypertension, which consequently can lead to heart disease and stroke. Few genetic factors are implicated in the pathogenesis of salt appetite.

Methods: Wild-type and CAII null mice were given a choice of regular water or 140mM NaCl dissolved in their drinking water. Balance studies were performed and blood pressure was measured via the COBA tail cuff system. Western blots and Northern Hybridizations were performed.

Results: Our results indicate that CAII null mice display significant salt appetite as judged by their preference for salted water (140 mM NaCl) over regular water, when both options are provided. In age and gender matched mice (n=4 per group), daily salted water intake was 2.89 ml in WT vs. 7.51 ml in CAII null mice, while daily regular water intake was 5.05 ml in WT and 3.6 ml in CAII null mice. Kidney renin expression and blood creatinine concentration were comparable in WT and CAII null mice. When given only salted water, CAII null animals showed a robust increase in their daily salt intake (12.21ml in CAII null vs. 7.80ml in WT mice) and urine volume (4.62ml/day in CAII null vs. 2.62ml/day in WT mice). Expression of sodium and water absorbing channels, ENaC and AQP-2, increased by ~100 to 200% in both cortex and medulla in CAII null vs. WT mice in response to salt intake for 10 days. Consequently, CAII null mice developed hypertension (systolic BP of 155 +/- 3.9 in CAII null vs. 136 +/- 3.2 in WT, p<0.003). The protein expression levels of ENaC in taste buds were not different between the two genotypes. Male CAII null mice exhibited a remarkable propensity toward salted water intake vs. regular water intake as compared to female null mice.

Conclusions: We propose that CAII plays an important role in regulating salt intake and its inactivation can cause salt appetite, specifically in male animals, and provoke salt sensitive hypertension.

### Ambulatory Blood Pressure in Chronic Kidney Disease: An International Collaborative Study

#### Background:

In chronic kidney disease (CKD), ambulatory blood pressure (BP) is a better measure of hypertension related risk for cardiovascular disease and ESRD than clinic BP. The International Ambulatory Blood Pressure in Chronic Kidney Disease Collaborative Group is a collaboration among investigators from different countries interested in ambulatory BP in patients with CKD. The main aims of the research facilitated by this collaboration will be to evaluate: 1) the clinical and demographic characteristics associated with elevated ambulatory BP, 2) the prognostic role of ambulatory BP on cardiovascular and renal outcomes, and 3) ethnic and geographic differences in these associations.

#### Methods:

This group will establish a large database derived from individual databases in the various countries to allow for powerful individual participant data meta-analyses of the relationship between clinical and demographic characteristics, CKD severity, ambulatory BP, and clinical outcomes.

#### Results:

Investigators from 5 cohort studies have already agreed to participate. Characteristics of the cohorts are shown below.

**Conclusions:** This multi-national collaboration will provide greater insights than possible from within-country analyses into the etiology and consequences of high risk ambulatory BP profiles. This information will be instrumental in helping us design prospective international large scale multicenter trials aimed at reducing renal and cardiovascular events in patients with CKD.

### Clinical Study of Pregnancy Related Kidney Injury

#### Background:

The diagnosis and treatment of pregnancy related kidney injury is a complicated clinical problem for obstetricians and nephrologists. However, information regarding this topic in China is insufficient.

#### Methods:

- **Totally 18589 women hospitalized between August 2004 and January 2013 from Obstetric and Nephrology Department in Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China;**
- **Obstetrics and Gynecology, Shanghai Jiao Tong Univ Affiliated Sixth People's Hospital, Shanghai, China.**

#### Results:

- The prevalence of pregnancy related kidney injury was 3.1%. The incidence of kidney injury caused by obstetric disease was 3.1%, with the most common reason for pre-eclampsia (88.9%).
- The incidence of chronic kidney disease women pregnancy is 0.74%, with the most common reason for chronic glomerular nephritis (36.2%).

#### Conclusions:

- Prevalence of pregnancy related kidney injury increases due to the foundation of Shanghai First-Aid Center for High-risk Pregnant Women in 2007. Serum creatinine, proteinuria and blood pressure have different indication for maternal condition and pregnancy outcome.

**Funding:** Government Support - Non-U.S.

### A New Vasculo-Renal Marker Enhances Accuracy of Hypertensive Nephropathy Recognition

#### Background:

Latent and slow beginning of chronic kidney disease (CKD) coexisting with well tolerated, usually not recognized previously hypertension makes difficult to recognize hypertensive nephropathy (HN) from CKD of others origins. The aim of the study was to investigate the best marker helpful in differentiating HN from other causes of CKD.

#### Methods:

- Forty patients (4 F; 36 M; age 52.7 ±14.5) with stable CKD (CKD-EPI 53.1 ±7.6 ml/min/1.73m²) and a history of hypertension (26 with HN) were enrolled in the study. Serum Creatinine (Cre), Cystatin C (Cys), NT-pro brain natriuretic peptide (NTproBNP), Troponin 1 (TNI) and urinary albumin to creatinine ratio (UACR) were tested. Renal function was estimated according to Cre and Cys based CKD-EPI formula. Echocardiographic examination, carotid Intima-Media Thickness (IMT), ABI, Renal Resistive Index (RRI) were performed. Vasculo-Renal Index (VRI) was calculated as IMT to UACR ratio.

#### Results:

- Groups with HN and CKD of other origins did not differ in renal function (CKD-EPI 46.2 ±7.1 ml/min/1.73m²), but higher IMT (2630/1804) vs. 1492/1003 (p=0.039), had lower UACR (0.264 ±0.564 mg/mg, p=0.001), but higher IMT (0.858 ±0.217 vs 0.652 ±0.380, p=0.009) and VRI (m. 28.8 ±0.36; 1030.00) vs mn. 0.78 ±0.12 (0.50<0.001). In ROC analysis VRI ≥ 1.91, UACR ≤ 0.199, and IMT ≥ 0.87 could recognize HN with sensitivity of 85%, 73% and 62% respectively, specificity of 79%, 93% and 86%, and accuracy of 82.5%, 80% and 70% (AUC 0.874, 0.849 and 0.749; p<0.05).

#### Conclusions:

- A new Vasculo-Renal Index recognizes HN more accurately, but UACR and IMT are not significantly worse.

Underline represents presenting author.
Contacted by phone three to six weeks after the clinic encounter to assess adherence.

Antihypertensive medications with a focus on the once daily study antihypertensive in the evening. After a nephrology clinic visit, a student pharmacist reviewed participants’ medications. Once daily were randomized to take one once daily antihypertensive in the morning or the evening.

Background: In the evening dosing of antihypertensive medications lowers nighttime blood pressure and, at least in one large randomized trial, reduced risk for cardiovascular outcomes. However, whether evening dosing reduces adverse outcomes in patients with chronic kidney disease (CKD) is unknown. The purpose of this pilot study was to assess the feasibility of a brief pharmacist based intervention on patient adherence to an assigned time of day to take antihypertensive medications and the feasibility of a pragmatic randomized controlled trial. Methods: Patients with moderate to severe CKD taking 1 antihypertensive medication were randomized to take once daily antihypertensive medications: morning or evening. Each morning patient adherence was electronically assessed. Each evening the pharmacy student with each participant was 9.9 (6.1) minutes.

Conclusions: This meta-analysis suggests that the bedtime dosing regimen drug therapy benefits CKD patients in terms of hypertension especially those with non-dipper BP pattern.

Background: The prognosis of kidney disease with hypertensive emergency (malignant glomerulosclerosis) is still worse compared with benign nephrosclerosis. Here, further to assess the reasons of worse prognosis and to reconsider more appropriate therapy for malignant nephrosclerosis, we compared pathological parameters between malignant and benign nephrosclerosis.

Methods: 8 patients diagnosed as hypertensive emergency with acute renal failure were performed renal biopsies from October 2005 to May 2015. We selected all patients with benign nephrosclerosis (n=8) who were performed renal biopsies during same period, as controls. We compared changes in clinical and pathological data using the paired t-test and the Mann-Whitney U-test.

Results: All 8 patients with hypertensive emergency had characteristic pathological changes of malignant hypertension, such as fibronoid necrosis, onion-skin thickening and edematous-appearing matrix in arterioles. These changes were never observed in benign nephrosclerosis. The rates of global sclerosis and segmental sclerosis had no statistical differences between these two groups. Interestingly, when glomerular collapsing rate was counted by GCR (number of glomerular collapse/total number of glomeruli), GCR scores were much higher in hypertensive emergency cases compared with those in benign nephrosclerosis cases (42.9 ± 23.8 v.s. 6.5 ± 7.4 %; p < 0.05). These patient’s clinical characteristics showed a high level of plasma renin activity (PRA) (14.9 ± 5.8 mU/l) and a high level of plasma aldosterone (3.5 ± 2.8 μg/dl). Two of 8 patients reached to end stage kidney disease requiring dialysis.

Conclusions: Glomerular collapse and hyper-renin mean glomerular hyperfusion. Therefore, if therapy accelerate this glomerular hyperfusion, it might affect renal outcome. We should reconsider the way of therapy, such as the selection of anti-hypertensive drugs, and the speed of declining blood pressure and volume control by thinking glomerular hyperfusion.

Background: To investigate whether early treatment with super high dosage ACEI can reverse glomerulosclerosis in SHR.

Methods: 30 SHRs were randomized and divided into three groups( n=10): model control group (M group), 10 mg·kg\(^{-1}\)·d\(^{-1}\) Benazepril treatment (HT group), 50 mg·kg\(^{-1}\)·d\(^{-1}\) Benazepril treatment(SHT group), 10 Wistar-Kyoto rats were studied as normal control group(N group), placebo , 10 mg·kg\(^{-1}\)·d\(^{-1}\) Benazepril and 50 mg·kg\(^{-1}\)·d\(^{-1}\) Benazepril were given through intra gastric administration starting from 0 week of the experiment, rats were killed until 12 week of the experiment. Blood pressure(Bp), 24 hours urinary protein(24hUpr) and serum creatinine(Scr) were detected in the 0, 4, 8, 12 week of the experiment. Renal pathology damage was evaluated with paraffin wax section of kidney tissue through HE, MASSON stain; the protein levels for TGF-b1 and PAI-1 were tested through immunohistochemistry staining method.

Results: Compared with model control group, Bp, 24hUpr of HT and SHT groups decreased obviously (P<0.05), the protein levels for TGF-b1 and PAI-1 in kidney tissue of HT group and SHT group were inhibited(P<0.05), glomerular collagen deposition of HT group and SHT group reduced evidently (P<0.05).
Conclusions: This study shows that high dosage ACEI and super high dosage ACEI all can decrease blood pressure, reduce proteinuria, depress the expressions of TGF-β and PAI-1 protein in SHR, and delay glomerulosclerosis. But super high dosage ACEI cannot reverse glomerulosclerosis in SHR.

PUB505

Background: Scleroderma renal crisis (SRC) is a rare cause of atypical hemolytic uremic syndrome (aHUS) and differentiating it from other causes of thrombotic microangiopathies can be challenging. A 53-year-old Caucasian male, with no past medical history was found unresponsive. BP was elevated to 207/141 mm Hg. Skin examination showed diffuse telangiectasia and edema of his extremities with bilateral sclerodactyly (Figure 1). Fundoscopy revealed bilateral retinal hemorrhage and exudates. Labs showed a hemoglobin=5gm/dl, platelet=25×10^9/dl, creatinine=6mg/dl; LDH=1122U/L, bilirubin=1-6mg/dl, haptoglobin<5%, reticulocyte count=10.4%, and schistocytes. ANA and anti-RNA Polymerase III antibody were positive (C3 and C4, coagulation profile, fibrinogen were normal; Coombs negative). CT head showed severe microvascular changes throughout the white matter of the cerebrum and MRI showed evidence of punctuate chronic micro-hemorrhages in the left thalamus and cerebellar tonsils. The presence of MAH, acute renal failure and thrombocytopenia raised suspicion for possible aHUS/TPP. Serum ADAMTS 13 was ordered. Because of the possibility of SRC, the patient was started on captopril. A dramatic improvement in BP, hemoglobin and platelets count along with the normalization of LDH and schistocytes disappearance was observed. However, there was no improvement in kidney function requiring hemodialysis. ADAMT-13 activity returned at 40% (cut-off for TTP is <5%). Patient did not pursue eculizumab therapy. A significant portion of patients with Scleroderma can develop aHUS. In this case, hypertension might have served as a complement amplifying condition.

Methods: Clinical presentation/course of the patient.
Results: Despite therapy with ACE inhibitors patient ended up on RRT.
Conclusions: Patient presenting with Malignant HTN and MAH was found to be in scleroderma crisis.

PUB506

Background: Only a few studies with a very limited sample size have evaluated the impact of neck irradiation on baroreceptor reflex failure and blood pressure (BP) abnormalities. We investigated 60-patients, with head/neck cancer, who received neck irradiation between 2005 to 2010. IRB approval was obtained. Median for age was 61.5 years (range 24-90 years). We used the same cohort of patients, before the received neck irradiation, as a control for BP. Mean systolic BP before neck irradiation was 129±1.2, 646 mm Hg, 1-months post-neck irradiation was 121.4±1.178 mm Hg (P=0.02), 3-months post-neck irradiation was 121.9±1.2180 mm Hg (P=0.04), 6-months post-neck irradiation was 125.2±2.933 mm Hg (P=0.27), 1-year post-neck irradiation was 123.4±4.087 mm Hg (P=0.32), 2-years post-neck irradiation was 122.7±3.565 mm Hg (P=0.06) and 5-years post-neck irradiation was 124±8.333 mm Hg (P=0.35). Mean diastolic BP before neck irradiation was 76.28±1.802 mm Hg, 1-month post-neck irradiation was 69.881±1.855 mm Hg (P=0.009), 3-months post-neck irradiation was 72.84±1.764 mm Hg (P=0.17), 6-months post-neck irradiation was 71.00±1.957 mm Hg (P=0.07), 1-year post-neck irradiation was 72.22±2.341 mm Hg (P=0.17), 2-years post-neck irradiation was 74.09±1.757 mmHg (P=0.47), 3-years post-neck irradiation was 70.17±2.131 mm Hg (P=0.16). Patients with head/neck cancer did not have clinically significant change in their BP after neck irradiation. These data do not support either acute fulminant hypertensive crisis or a chronic labile hypertension after neck irradiation. The study suggests that carotid baroreceptors might not have been damaged by radiation or baroreceptors in other locations might have been able to control BP.

Methods: Retrospective study of blood pressure in patients with neck radiation for cancer.
Results: Blood pressure before and after radiation showed no increase.

to adequately treat refractory hypertension. Lifestyle modification remains an important approach in managing this syndrome. Buddhist meditation encompasses a variety of meditation techniques that aim to develop mindfulness, concentration, and insight.

**Methods:** We aimed to study whether Buddhist Insight Meditation (IM) Practice, composing of Walking Meditation and Sitting Meditation, could reduce the level of blood pressure in Buddhists. 65 exemplary people were divided into 3 groups according to the schedule they performed IM Practice. Group 1 (n=25) performed 30 minutes of the Walking and 30 minutes of the Sitting Meditation, group 2 (n=20) performed 45 minutes in each Meditation and group 3 (n=20) performed 60 minutes in each Meditation. Their blood pressures (BP), pulse pressures (PP) and pulses (P) were measured before and after Walking and Sitting Meditations.

**Results:** The results clearly showed that systolic BP, PP and P were significantly decreased after the Walking Meditation at 30-45-60 minutes. After IM Practice schedule, an artesianised group has been significantly increased in all 3 groups, PP has been significantly decreased after the Walking Meditation at 30-45-60 minutes. After IM Practice schedule, an arterial pulse has been significantly decreased in all 3 groups, PP has been significantly decreased in group 2 and systolic BP has been significantly reduced in group 3.

**Conclusions:** In conclusion, the Buddhist IM Practice could meaningfully reduce the sympathetic activities including systolic BP, PP and P. Therefore, this Buddhist Practice should be added to be one modality of the standard hypertensive treatments.

**ENA as a Novel Mechanism for Hypertension and Volume Expansion in Type 2 Diabetes**

Mark L. Unruh,1 V. Shane Pankratz,2 Evan C. Ray,2 Rebecca P. Hughey,3 Thomas R. Kleyman.3 1Div of Nephrology, Univ of New Mexico; 2Renal-Electrolyte Div, UPMC.

**Background:** Renal Na retention and extracellular fluid volume expansion are hallmarks of nephrotic syndrome. There is evidence that the ENA inhibitor amiloride would be an effective therapeutic agent in inducing a natriuresis and lowering blood pressure in individuals with macroscopic proteinuria.

**Methods:** We conducted a pilot double-blind randomized cross-over study comparing the effects of daily administration of either oral amiloride (10 (low dose) followed by 20 (high dose) mg/d) or HCTZ (NaCl co-transporter inhibitor) to patients with type 2 diabetes and macroscopic proteinuria. We examined safety and feasibility of amiloride by monitoring kidney function, adherence, blood pressure, weight, urinary Na excretion and serum electrolytes during diuretic administration.

**Results:** 9 subjects were enrolled in the trial. Systolic blood pressure (SBP) decreased in both treatment groups, but there was not a significant difference between HCTZ and amiloride (p=0.53). Amiloride treatment was associated with a 1.1±0.4 kg decline in weight (p=0.02), and a 0.76 ± 0.18 mmol/L greater increase in serum potassium (p=0.002) over the low dose portion of the study. 2 subjects developed acute kidney injury and hyperkalemia when treated with amiloride. 5 subjects had readily detectable levels of urinary amilorin in plasma and 4 did not. Among those receiving amiloride, the low plasma group experienced a change of 1.1±4.6 mmol/L in SBP and the high plasma group experienced a change of 13.9±8.7 mmol/L, although there was insufficient evidence to conclude that there were differential treatment effects by high/low plasma status (p=0.113).

**Conclusions:** Among patients with type 2 diabetes, normal renal function, and proteinuria, there was suggestion of increased naturalness for those treated with amiloride vs. HCTZ. However, acute kidney injury and severe hyperkalemia was a safety concern.

**Serum Phosphorus Control and Reduced Phosphate Binder Pill Burden Among Hemodialysis Patients Who Switched from Sevelamer to Sucroferric Oxyhydroxide**

Vidhya Parameswaran, Lin Ma, Linda H. Ficociello, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. Fresenius Medical Care North America, Waltham, MA.

**Background:** Clinical management of hyperphosphatemia among hemodialysis (HD) patients (pts) can present challenges. A retrospective database analysis was conducted to study the effectiveness of sucroferric oxyhydroxide (SO) among in-center HD pts who switched from sevelamer to SO as part of routine clinical care.

**Methods:** Pts who switched from sevelamer and had ≥1 serum phosphorus (sPhos) measured during SO treatment were included. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and pill burden were assessed at baseline (3-months prior to SO) and at follow-up (3-months during SO treatment).

**Results:** Pts (n=1487) were, on average, 54 years old, with dialysis vintage of 4.4 years and hyperphosphatemia (baseline sPhos=6.94 mg/dl). Figure shows sPhos distribution at baseline and follow-up. Pts who in-range sPhos (3.5-5.5 mg/dl) increased from 12% to 20.1% (68% increase). Mean sPhos decreased from 6.94 to 6.7 mg/dl (p<0.001) and mean sCa decreased from 9.3 to 9.25 mg/dl (p<0.001). There was a significant decrease (74 pills/day, p=0.001) in pill burden (8.5 to 3.7 pills). No significant change in iPTH levels was observed in Baseline (1.6 to 1.03 ng/ml). TSAT and FER significantly increased (p<0.001) from 33.7% to 35.8% and 98.35 to 105.14 ng/ml, respectively. In pts not receiving IV iron (n=149), there were no significant changes in TSAT (36.3% to 35.9%) or FER (1221.5 to 1177.4 ng/ml).

**Conclusions:** Correlations of y-variables with FER ultimately reflect correlations with E/Cr, TR/Cr or both (Clin Nephrol 83:167). As expected, TmGFR was closely associated with TR/Cr. The other y-variables, which depicted comparisons of TmGFR to TR/Cr were inversely related to E/Cr as a specific indicator of P influx and a surrogate for [P] in the CDN. As [P] fell in the CDN, the difference rose between actual and maximal P reabsorption in the proximal nephron. We did not identify an endocrine mediator of this interaction.

Dobrinskikh, Jason R. Stubbs, Niacin Improves Cardiac Function in Alport Mice with Progressive high.

...in the early stages of the disease and consists of disorders in bone metabolism. **Methods:** A descriptive, retrospective observational study was done using patient records at the Institute for Social Security and Services for State Worker’s (ISSST) National Medical Center 20 de Noviembre Nephrology outpatient clinic, located in Mexico City, Mexico. 50 cases of adult patients with advanced chronic kidney disease were reviewed in renal replacement treatment, dportional dialysis and/or hemodialysis who were managed with Cinacalcet for Secondary Hyperparathyroidism, with PTHi > 300 pg/ml. **Results:** The baseline level of serum parathyroid hormone of the 42 patients was 1371.6 pg/ml prior to the use of cinacalcet, with a percentage reduction of 33% per month and 6 months of treatment 55% with a mean of 1133 pg/ml and 615.48 pg/ml respectively. A total of 42 patients; 19 (45%) achieved targets at the end of the 6-month study. 36 patients underwent to scintigraphy of parathyroid gland, because they did not obtain parathyroid hormone decreased over 30% at the 3rd month of treatment; 5 patients showed hyperplasia and 11 parathyroid adenoma. **Conclusion:** Cinacalcet combined with conventional treatment succeeds in reaching goals compared to standard treatment only. Hypocalcemia is a common side effect however when administered together with calcium salts and/or vitamin D or its analogues decrease side effects According to previous studies cinacalcet it increases the achievement of goals in mild hyperparathyroidism. In our study was more important for the response time in the RRT than the severity of hyperparathyroidism. **Funding:** Government Support - Non-U.S.

“Binder Reminders” for Persistent Hyperphosphatemia in Hemodialysis Patients: A Fellow’s Quality Improvement Project Divyak Jammalamadaka, N. Stanley Nahman, John Jason White. Medicine, Georgia Regents Univ, Augusta, GA.

**Background:** Despite regular quality improvement (QI) processes, control of mineral metabolism remains poor. One root cause is patient non-adherence to phosphate (Pho) binders. Evolving data suggest SMS/text reminders improve medication adherence in a wide range of chronic illnesses. Here, we report our initial experience with text reminders on Pho control in HD patients.

**Methods:** 40 patients with Pho > 5.5 mg/dL for 2 of last 3 months, and possessing cell-phones with texting capabilities were studied. We randomly assigned 20 to receive the phrase “Binder Reminder” at mealtimes x 7 days prior to their monthly lab draw. The remaining 20 received usual care. Group assignment and messaging was performed by a nephrology fellow, not part of the multidisciplinary team. Patients were excluded if they declined participation, missed any dialysis sessions during the 7 day period, or if they were unable to obtain their binders. Pho level after intervention was the primary outcome. **Results:** Of 20 after exclusions, 13 patients received the intervention and were compared to 14 controls. Pre-intervention Pho levels were 6.81 +/- 0.88 and 6.60 +/- 0.93 mg/dL (Mean +/- SD) in the control and intervention groups respectively. After intervention, Pho levels declined in the intervention group to 6.00 +/- 0.76 mg/dL. Hence there was no difference between the groups (P = 0.76). Each group had 8 patients with improved Pho levels, and 5 patients at goal. **Conclusion:** Our initial QA project utilizing SMS/text messaging appears to have no effect on short-term Pho control in a group of HD patients with chronic hyperphosphatemia. **Funding:** Clinical Revenue Support

Niacin Improves Cardiac Function in Alport Mice with Progressive Chronic Kidney Disease and Hyperphosphatemia Kelly Ambre, Evgenia Duben, Veronica A. Hogg-Cornejo, Xiaoxian Wang, Jiangsu Zhang, Jason R. Stubbbs, Moshe Levi. 

1 Univ of Colorado Denver. 2 Univ of Kansas Medical Center.

**Background:** Increase in serum phosphate (Pi) level (hyperphosphatemia) is a common clinical problem in chronic kidney disease (CKD). Systemic Pi homeostasis is balanced through three major mechanisms: intestinal uptake, retention or release from bone, and renal reabsorption. Sodium-phosphate co-transporter type 2b (NaPi2b) is a major phosphate transporter in the small intestine. Alport syndrome is a genetic disorder characterized by CKD, hearing loss and cardiac dysfunction. **Methods:** By 9-10 weeks of age Alport mice, which have a mutation in a COL4A3 gene on the SvEv129 background, develop signs of CKD and hyperphosphatemia. **Results:** We have found by western blot that there is an increase in intestinal NaPi-2b protein expression and Everted Sac studies showed increased NaPi transport in the Alport Heem compared to the WT littermate controls. Cardiac echo studies revealed that Alport mice have decreased ejection fraction (EF: 67±2% compared to 75±3% in the WT littermate) and diastolic dysfunction (mitral Doppler flow E/A ratio: 1.20±1 compared to 1.60±1 in the WT littermate, p<0.05), which could be corrected by treatment with Niacin (intestinal phosphate uptake inhibitor). In the treated Alport mice EF increased to 78±2% (p<0.05) and E/A ratio improved to 1.33±0.1 (p<0.05). In addition, there were significant decreases mRNA relative expression in β-MHC (0.08±0.02 in control vs. 2.19±0.34 in Alport, p<0.001, vs. 0.2±0.001 in Alport+Niacin, p<0.005). PAL-I (0.12±0.01 in control vs. 1.05±0.15 in Alport, p<0.05, vs. 0.15±0.05 in Alport+Niacin, p<0.05), and TGF-β (0.03±0.01 in control vs. 0.77±0.23 in Alport, p<0.01, vs. 0.07±0.23 in Alport+Niacin, p<0.01), markers of heart failure and cardiac fibrosis. **Conclusion:** Inhibition of intestinal phosphate transport with Niacin therefore improves systolic and diastolic cardiac dysfunction in CKD.

Establishing Regulatory Networks of Phosphorus Metabolism in HD Patients – A New Path of Treating Hyperphosphatemia Mengjing Wang, Payan Wang,1 Yulin Zhang,2 Li Ni,3 Minmin Zhang,4 Jing Chen.1 Nephrology, Huashan Hospital, Shanghai; 2 MOE Key Laboratory of Contemporary Anthropology, School of Life Sciences, Fudan Univ, Shanghai.

**Background:** The clinical efficiency of current treatment of hyperphosphatemia in HD varies widely on different patients. We assume that it is due to phosphorus regulation in vivo. In physiological conditions, phosphorus is regulated by a biological network consisting of interacting hormones and nutrients. In HD, this network changes dramatically and affect serum phosphorus. This study aims to establish the regulatory networks of phosphorus in HD and identify the key factors that may have a causal effect on circulating concentrations of phosphorus. **Methods:** 50 HD patients were enrolled and divided into three groups (n=10; PTH300 ng/mL; n=10; 300 ng/mL<PTH≤(600 ng/mL; n=10; PTH>600 ng/mL). Pre-dialysis blood samples were obtained on the mid-week dialysis day for detection of PTH, FGF23, 25(OH)D3, Klotho, and Ca every week for 12 weeks every patient. Causal inference, a widely used process of concluding a causal connection, was adopted to establish the regulatory networks of phosphorus metabolism within different PTH levels. **Results:** The networks show that when PTH<600 ng/mL, FGF23 can stimulate the increase of serum Pi, Ca, and PTH, in turn, serum Ca and Pi can also stimulate the increase of FGF23. When PTH>600 ng/mL, FGF23 becomes the stimulator of only serum Ca, and serum Pi has a positive causal effect on PTH, besides, the rise of PTH increases serum Pi level, too. So, serum Pi is affect by FGF23 when PTH<600ng/mL and by PTH when PTH>600 ng/mL. Since FGF23 promotes the increase of PTH when PTH>600 ng/mL, FGF23 becomes the key factor in disorders of phosphate metabolisms. The figures also shows that Klotho and 25(OH)D3 may be not important in the therapy of hyperphosphatemia.

**Conclusion:** Reducing FGF23 levels might contribute to the control of phosphorus.

**PUB517**

Evolution of Renal Calcium Excretion Throughout Chronic Kidney Disease Carmen Gonzalez Corvella, Paula Batalla-Castano, Silvia Ros-Ruiz, Fernandez Valdeco Ibarra, Jose G. Herrera, Mercedes Salgueira Lazo. Nephrology, Hospital Virgen Macarena-Rocio, Sevilla, Spain; Nephrology, Hospital Regional, Malaga, Spain; Nephrology, Hospital Puerto Real, Cadiz, Spain; Nephrology, Universidad, Granada, Spain.

**Background:** Chronic kidney disease(CKD)patients have a normal serum calcium(Ca) concentration until the end of renal disease(ESRD).The decrease of VitaminD levels and that a percentage of patients develops hypocalcemia at ESRD,lead us to think that our patients have a negative Ca balance, which could justify the treatment with Ca supplements. Objective:analyze renal calcium excretion during different stages of CKD and the effect of the treatments. **Methods:** Observational multicenter,retrospective and transversal study,with the participation of Hospitals.63 patients were included,in different stages of CKD,66,7%men,mean age 66years).None on renal replacement therapy. Variables:blood,urine analysis and treatment. The sample was stratified by stage of the disease and urine Ca(>or<100 mg/dl).

**Conclusion:**
Results: Sample:6,3%CKD1,4,8%CKD2,28,6%CKD3,38,1%CKD4 and 22,2%CKD5. Mean serum Ca 2.47 mg/dL(mean serum phosphate(P): 3.77 mg/dL)PTH level 174 pg/mL 27 mg/mL Mean ca excretion:126mg/day. Mean P excretion:47mg/dL.47%was on Ca based binders, 22.2%on calcidol, 12.7%on calcitriol and 28.6%on paricalcitol. 70%of the sample had Ca excretion<100mg/dL. When classifying by stages of the disease, increases the amount of patients with Ca excretion<100 mg/dL: CKD1 25%, CKD2 50%, CKD3 50%, CKD4 80%, CKD5 83%.decreasing the mean Ca excretion. The subgroup of patients with lower Ca excretion had a higher PTH level(155 vs 111pg/dL)=0.05. 94%of patients treated with Ca based binders had a Ca excretion<100 mg/dL with no difference in serum Ca. Patients on calcidol,paricalcitol or calcitriol had lower Ca excretion than those without treatment.

Conclusions: According to our results, patients within CKD show a decrease in renal Ca excretion that become exacerbated as the renal disease progresses. Supplementation with hypercalemic drugs is not balanced out with the expected increase of renal Ca excretion. Therefore, we think that CKD patients are exposed to a chronic Ca overload,sometimes underestimated,with the resulting negative impact in morbidity and mortality.

PUB518

Effect of Parathyroid Hormone on Serum Magnesium Level: The Neglected Relationship in Hemodialysis Patients with Secondary Hyperparathyroidism

Bing Tang, Li Fang, Junwei Yang. Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.

Background: Chronic kidney disease-mineral and bone disorder (CKD-MBD) is an important complication in patients with end-stage kidney disease which is associated with cardiovascular morbidity and mortality. Since recent studies have shown that serum magnesium play an important role in secondary hyperparathyroidism, vascular calcification and cardiovascular mortality, the interest on magnesium (Mg) has grown.

Methods: This cross-sectional study was conducted on 111 patients with end-stage renal disease on maintenance hemodialysis who was hospitalized for secondary hyperparathyroidism. The interventional study was conducted on 23 patients underwent parathyroidectomy. Results: In our study, hypermagnesemia (>2.5 mg/dL) occurs in up to 44% of cases and hypomagnesemia did not present. No significant correlations were found between serum magnesium and parathyroid hormone (r=−0.143, p=0.134). Correlation analysis and logistic regression analysis suggested that the derangement of magnesium homeostasis was correlated with the derangement of calcium/phosphate homeostasis. After parathyroidectomy, serum magnesium levels dropped immediately and reached the lowest level at one day after surgery; however, it gradually restored three days later. The changes of serum magnesium after surgery was positive correlated with the changes of parathyroid hormone (r =−0.143, p = 0.134). Correlation analysis and logistic regression analysis suggested that the derangement of magnesium homeostasis was correlated with the derangement of calcium/phosphate homeostasis.

Conclusions: The effect of PTH on magnesium metabolism could not be neglected, especially in hemodialysis patients with secondary hyperparathyroidism. The role of magnesium metabolism and therapeutic strategies to achieve optimum serum magnesium level in CKD-MBD should be taken into account the varying stages of disease development.

Calciphylaxis in Patient with Chronic Renal Disease Not Dialytic and Multiple Myeloma

Patricia Junqueira Freitas, Aline Lourenco Baptista, Clovis Antonio lopes Pinto, Joubert Araujo Alves, Pedro Caruso, Benedetto Jorge Pereira, Fernanda Lemos Moura, Marina Harume Imanishi, Luis Andre Andrade, Germana Alves Brito. Nephrology, AC CAMARGO, Sao Paulo, Brazil.

Background: Calciphylaxis, also known as calcifying uremic arteriolopathy, is a rare medical condition, which is normally diagnosed in patients with terminal CKD who are already in renal replacement therapy (RRT). Objective:report the presence of calciphylaxis in CKD, in patient with oncologic disease.

Methods: Female patient, 71 years old,caucasian, conducted to AC Camargo Hospital for etiological investigation of injuries in lower limbs associated with renal failure, hypercalcemia, anemia and astenia. Has history of hypertension and obesity. Physical examination: poor general state, dyspneic, respiratory and cardiovascular systems without resistance index and a higher cardiac index, which might be associated with serum phosphorus level.

Results: The patient was transferred to ICU due to septic shock of cutaneous focus, performed antibiotic therapy, hemodialysis (HD) with Calcium (Ca) 2.5, intravenous thiosulfate three times a day and cinacalcet, presenting improvement of the injuries.

Conclusions: The calciphylaxis is a complex clinical entity and pathogenesis not fully elucidated, what makes the treatment still not uniform. It is characterized by dermal ischemic necrosis, of acute and progressive installation. It must be paid attention to its presence even in non dialytic stages of CKD as happened in the described case.

PUB521

Hemodynamic Changes in Maintenance Hemodialysis Patients with Hypotension After Parathyroidectomy

Meijuan Meng, Bing Tong, Hong Ye, Junwei Yang. Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.

Background: Parathyroidectomy (PTX) is applied to treat secondary hyperparathyroidism in hemodialysis patients. Some patients suffered from hypotension after PTX although hypocalcemia was corrected. The aim of this study was to demonstrate the hemodynamic changes in hemodialysis patients after PTX.

Methods: Twelve patients were included in this study. Among them 4 have hypotension after PTX (Group 1) and the other have their blood pressure remained after PTX (Group 2). Before PTX, systolic blood pressures (SBP) of all the 12 patients were above 90 mmHg. Noninvasive hemodynamic evaluation was performed before, during and after dialysis.

Results: Comparing with group 2, cardiac index (CI) was higher (P=0.252) while systemic vascular resistance index (SVRI) was lower (P=0.05) in group 1. The mean thoracic fluid capacity (TFC) of the two groups were similar (P=0.424) before dialysis. Serum Ca, PTH, ALP, ventricular ejection fraction and vascular calcification score of thoracic aorta, abdominal aorta and heart valve before PTX, as well as the weight of the removed parathyroid glands, serum Ca, ALP, hemoglobin after PTX of the patients were determined. No statistical differences were found. However, the phosphorus level was lower in group 1 both before and after PTX. CI, SVRI and TFC were similar in both groups during hemodialysis.

Conclusions: Patients with hypotension after PTX have a lower systemic vascular resistance index and a higher cardiac index, which might be associated with serum phosphorus level.

PUB522

Cost of Medications Used in the Management of Secondary Hyperparathyroidism (SHPT) in Patients with End Stage Renal Disease (ESRD) Mark E. Bensink,1 Leigh Darryl Quarles,2 Vasily Belezeroff,1 Kerry Cooper,1 Jonathan D. Campbell.1 Amgen Inc., Thousand Oaks, CA; 1Univ of Tennessee, Memphis, TN; 2Univ of Colorado, Aurora, CO.

Background: Management of SHPT associated with ESRD is complex, typically requiring combinations of medications. Eighty-two percent of the ESRD population is covered by Medicare with detailed drug expenditures reported annually by the US Renal Data System. For the remaining 18% covered by commercial health plans, drug expenditure information is unknown. The purpose of this study is to estimate the cost of medications used in the management of SHPT in ESRD patients from the US commercial health plan perspective.

Methods: Economic analysis with one-year time horizon to estimate per-member-per-month (PMPM) cost for SHPT related medications: calcium and non-calcium-based phosphate binders, calcitriol or active vitamin D analogs, and calcimimetics. Input parameters include: prevalence of ESRD in commercial health plans (MarketScan®); medication utilization and non-adherence (IMS Health for oral medications and Outcomes Plus for intravenous [IV] medications); and medication wholesale acquisition costs (WAC) (AnalySource.com) with one-way sensitivity analysis

Results: The total PMPM (2014 US Dollars) cost of SHPT-related medications is $0.34: cinacalcet $0.06, phosphate binders $0.16, oral vitamin D $0.02, and IV vitamin D $0.10.

Figure 1. Total PMPM Cost Breakdown

Results are most sensitive to variation in ESRD prevalence and cinacalcet WAC parameters.

Conclusions: Results indicate that the collective cost of medications for the management of SHPT in commercial health plans is substantial with the cost of cinacalcet being lower compared to phosphate binders and IV vitamin D, but higher compared to oral vitamin D.

PUB523

Medullar Compression by Bone Tumor: Case Report Cinhia Sobral Vieira, Nicole D.T. Carvalho. Nephrology Unit-Clinico, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil.

Background: The presentation of vertebral tumors may have different kinds of manifestation. They can mimic neoplastic, inflammatory and congenital diseases. The following report is about a patient with a lytic bone lesion in the thoracic spine causing medullar compression symptoms.

Methods: A 66 years old masculine patient, with chronic renal disease in hemodialysis for 5 years, non-adherent to treatment or diet, had his levels of phosphor, calcium/phosphor, alkaline phosphate and parathyroid hormone (PTH) elevated in the last year. He did not use phosphate binders, calcitriol or active vitamin D, had his levels of phosphor, calcium/phosphor, alkaline phosphate and parathyroid hormone (PTH) elevated in the last year. He did not use phosphate binders, calcitriol or active vitamin D analogs, and calcimimetics. Input parameters include: prevalence of ESRD in commercial health plans (MarketScan®); medication utilization and non-adherence (IMS Health for oral medications and Outcomes Plus for intravenous [IV] medications); and medication wholesale acquisition costs (WAC) (AnalySource.com) with one-way sensitivity analysis

Results indicate that the collective cost of medications for the management of SHPT in commercial health plans is substantial with the cost of cinacalcet being lower compared to phosphate binders and IV vitamin D, but higher compared to oral vitamin D.

Rescue-Therapy with Lanthanum-Carbonate (LC) in Uncontrolled Hyperphosphatemia in Dialysis Nicola Giotto, Angela maria Marino. Dept of Medicine, Nephrology and Dialysis Unit, Cardinal Massaia Hospital, Asti, AT, Italy.

Background: Control of hyperphosphatemia in hemodialysis provides an approach based on changes in diet, dialysis efficiency improvement, and use of phosphate binders. The latter, however, in some patients do not prove effective, conditioning the indirect increase of mortality and morbidity of the subject on dialysis. The objective of this study was to evaluate the difference in efficacy of a regimen of lanthanum carbonate plus standard therapy (LTS) compared to standard therapy alone (TS) in the treatment of patients with persistent hyperphosphatemia, as rescue-therapy.

Methods: We conducted an observational study of data on consecutive patients in hemodialysis who have presented more than four phosphorus values greater than 6 mg/dL in three months. Patients treated with TS, have varied therapeutic scheme introducing LC. Patients treated with sevelamer have outstanding this therapy and were treated with LC. The data analysis has been done considering a retrospective phase (FR) of three months and a prospective phase (FP) of six months, for each subject analyzing the effectiveness of therapy before and after enrollment.

Results: In a cohort of 163 patients on hemodialysis, we have selected for the study, 14 patients who had a mean age of about 65 years and length of dialysis than 6 years. The combination of LC plus TS produced a significant increase in the proportion of patients achieving the therapeutic targets as defined by the K/DOQI Guidelines. Reduction of 2.12 mg/dL (-32.7%) than the average of the P phase prospective (4.55 mg/dL) than the retrospective phase (6.77 mg/dL), was statistically significant (p <0.001), is associated with the reduction of 19.21 mg/dL (-32.9%) of the average value of CaXp in the prospective phase (39.07 mg/dL) compared to the retrospective phase (58.28 mg/dL), also statistically significant (p < 0.001). The patients at the target of the FP accounted for 92.31% for P and 100% for the CaXp, respectively vs. the 7.14% and 50% of FR.

Conclusions: The introduction of the LC-as rescue therapy in the treatment of hemodialysis patients with uncontrolled hyperphosphatemia resulted very effective allowing more easily reach the therapeutic objectives.

PUB525

Glucocorticoid-Induced Osteoporosis in Renal Patients Gabrielle Golde,1 George Greenhall,2 Alan D. Salama,2 Basildon and Thurrock Univ Hospital; 1Royal Free Hospital, London, 2Royal Free Hospital, London.

Background: Glucocorticoid-induced osteoporosis (GIO) is associated with severe morbidity due to fragile fractures as well traumatic fractures and 30-50% of patients on long term steroids are affected by GIO. GIO is relevant in the renal context as steroids are widely used to treat renal disease and as part of immunosuppression in transplant. Also, renal patients are already at higher risk of fractures in association with renal bone disease.

Methods: We designed and undertook an audit to assess screening and management of GIO in nephrology outpatients in a university hospital in London, using national guidelines as a benchmark for our performance. We then presented the results at a local meeting, produced posters and leaflets on GIO to be placed in the outpatient waiting area for patients so as to raise awareness of this issue and provided a simple algorithm to be followed by clinicians in all the clinic rooms. We then re-audited after 6 months.

Results: 100 patients were audited in each audit cycle. Measures audited were a) whether all patients over 65 were treated with bone-sparing agents (BSA); b) whether all patients with documented fragility fracture were treated with BSA; c) whether all patients under 65 without fragility fracture underwent DXA scan; d) whether all patients with T-score below -2.5 were treated with BSA; e) whether all patients with T-score 0 to -1.5 underwent repeat DXA within 3 years; f) whether BSA was prescribed for all patients where indicated; g) whether all patients are managed according to national guideline (cycle 1: 29%; cycle 2: 41%). See table for breakdown of results.

Conclusions: Our intervention has improved performance as measured against national guidelines, though the rate of GIO screening remains low. Many patients could potentially benefit from bone protection, though larger studies would be needed to demonstrate an effect on fracture incidence.

The Kidney Stone and Increased Water Intake Trial in Steel Workers: Results from a Pilot Study
Hakam Gharbi, 1 Yair Lotan, 1 Jodi Antonelli, 2 Immaculada Buendia Jimenez, 3 Allison Ahrens Beaver, 4 Aphril Dennis-Barrie, 5 Dendra K. Von merveldt, 6 Suez Cathy, 7 Adam Baker, 8 John Poindexter, 9 Orson W. Moe, 1, 10 Margaret S. Pearl. 1, 11 Danone Research, Palaiseau, France; 12 Univ. of Texas Southern Medical Center, Dallas, TX; 13 Mineral Metabolism, Univ of Texas Southern Medical Center, Dallas, TX.

Background: Preventing dehydration in subjects at risk may provide a means of primary prevention of kidney stones. The purpose of this pilot study was to assess the hydration status of an at-risk group of steel plant workers based on end-of-shift ("post-shift") spot urine osmolality and 24-hour urinary stone risk parameters.

Methods: 100 volunteers were recruited from Gerdau Midlothian steel mill in Texas on 11/14/14 and 12/5/14. Clinical data was recorded and a post-shift spot urine sample was obtained for measurement of urine osmolality. In addition, participants were invited to submit a 24-hr urine sample within 4 weeks of enrollment.

Results: Mean age was 41 and 95% were men. The majority of subjects were white (75%), followed by 10% Hispanic and 9% Black. Mean body mass index was 30.1 kg/m² and overall 16% had past history of stone disease. Mean post-shift urine spot osmolality was 704.5 mOsm (169-1165 mOsm) and was >800 mOsm and >700 mOsm in 39% and 57%, respectively. Among 59 24-hour urine samples, mean volume was 1.89 ± 0.92 l/day, with 56% <2 liters and 17% <1 liter. Elevated levels of urinary analytes were found in 29% of subjects for calcium (>250mg/TV), 39% for uric acid (>700 mg/TV), 25% for oxalate (>45mg/TV) and 50% for sodium (>200 meq/TV).

Conclusions: The prevalence of stone disease in this population of steel workers is higher than the published prevalence of stone disease in the general population. A significant number of workers had concentrated post-shift and 24-hour urines and elevated levels of urinary analytes.

Chronic Renal Pain in Medullary Sponge Kidney
Giovanni Gambaro, 1 Jackie Hirsch, 2 Rocco Baccaro, 1 Nicole Topilow, 2 Matteo Bargagli, 2 David S. Goldfarb, 3 Pietro Manuel Ferraro. 1 Nephrology, Catholic Univ, Rome, Italy; 2 NY Univ, School of Medicine, New York, NY.

Background: MSK usually occurs with recurrent stones; less frequently it is asymptomatic; very rarely the main manifestation is severe chronic flank pain. Often these pts are accused of seeking pain medications. Because of the rarity of such a presentation it is not known if pain is due to intense lithogenic activity or is independent of it, something like a form of the "loin pain hematuria syndrome". Three Facebook support groups exist for North American patients with MSK and chronic pain. Their cooperation allowed us to investigate chronic pain in MSK patients.

Methods: An ad hoc questionnaire and the Brief Pain Inventory were administered through a dedicated web site; 92 patients (89 females) participated after verification of the diagnosis of MSK (imaging and diagnosis certified by a nephrologist or urologist).

Results: Mean age of patients was 39.8y (range 24-66). Age at onset of manifestations and MSK diagnosis were 23y (4-47) and 31y (7-57), respectively. Manifestations at onset were: flank pain (31%), renal-ureteral colic (RUC) (26%), hematuria (19%), cystitis (14%), pyelonephritis (10%). 71% of pts have daily pain, 76.5% have taken painkillers in the previous week and 69.1% needed them at the time of questionnaire administration; 58% take them >1 time/day. The strong pain (5.4 in a scale from 0 to 10), jeopardizes general activities, mood and sleep. Only 4.6% of pts have RUC like pain; in 52.9% it is non-radiating flank pain with manifestations of possible UTI or stone passage (painful micturition, urgency, frequent urination, hematuria, fever); in 42.5% it is non-radiating lumbar pain without other manifestations (however only in 3 cases the pain was a unilateral flank pain). Pain is frequently associated with stone (67%) or sand passage (46%), hydronephrosis (42%), hematuria (42%).

Conclusions: Although in these MSK pts the chronic pain that dominates the clinical manifestations - is usually associated with some of the typical symptoms of stone passage, in a fraction of pts this is not the case and pain is not associated with lithogenic activity. The etiology of this pain syndrome remains uncertain and merits investigation.

Difference in Vitamin D Level Between Older and Younger Kidney Transplant Recipients
Mohamed Amin Elesnawi, Abdullah Hamad, Fadwa S. Al-Al, Nephrology, Fahd Bin Jasim Kidney Center, Hamad General Hospital, Doha, Qatar.

Background: Vitamin D deficiency is more common in older than younger people. In kidney transplant recipients, vitamin D deficiency has a high prevalence of up to 80% according to recent studies. We compared vitamin D status in older versus younger patients with kidney transplant.

Methods: We reviewed all available record of kidney transplant recipients that came to our clinic at Hamad General Hospital in Qatar between September 1st 2013 and March 1st 2014. We recorded background data and laboratory tests. Patients divided into 2 groups younger and older (below 60 and above 60 years old respectively). All patients were receiving vitamin D supplement.

Results: 102 patients were included. 52 patients in the younger group and 50 patients in the older. Age was 68.1±5.9 years in the older versus 41.9±10.4 years in the younger group. (Table 1) compare laboratory values between the two groups. Vitamin D status was classified (normal above 30, mild 20-29, moderate 10-19 and severe below 10 ng/mL) figure (1).

Conclusions: In a comparative study, we found that older transplant recipient group had more male patients (pValue<0.05), lower alkaline phosphatase and higher intact parathyroid hormone (not statistically significant) but similar vitamin D, calcium and phosphorus level. There was a trend towards milder vitamin D deficiency in the older group that could be due to better compliance with vitamin D supplement. Despite vitamin D supplement protocol and long sunny days in Qatar we still found high rate of vitamin D deficiency in transplant recipients (81.4%).
Parathormone Stability in Hemodialyzed Patients: Comparison on Non-Centrifuged EDTA and Serum Samples with 2nd and 3rd Generation Assays

Marie Dohet, Pierre Delanaye, Etienne Cavalier. Clinical Chemistry, Univ of Liege, CHU Sart-Tilman, Liege, Belgium; Nephrology, Univ of Liege, CHU Sart-Tilman, Liege, Belgium.

Background: PTH stability is of importance. Many studies have shown divergent results between EDTA and serum, mainly linked to differences in protocols or cut-offs used to decipher whether PTH remained stable or not. No studies have yet compared PTH as measured by 2nd and 3rd generation assays on the same samples in hemodialyzed (HD) patients.

Methods: Five pairs of samples (EDTA and gel tubes) were obtained in 10 HD patients before session. One pair was centrifuged and run immediately to establish the “T0”. Two pairs were kept at -4°C and +25°C. They were centrifuged after 4 and 18 hours. Supernatant was kept at -80°C for one week. Then, all samples were measured in a single batch, on Roche Cobas and Diasorin XL 2nd and 3rd generation PTH assays. Samples were considered as stable if 90% of subjects had a decrease lower than a total change limit (TCL) that takes both analytical and biological variability into consideration. All determinations were run in duplicates.

Results: At T0, no difference was observed between plasma and serum for any of the methods. PTH decreased in all samples and degradation was the same with 2nd or 3rd generation assays, whatever the method used. Percentages of decrease were systematically lower in EDTA plasma compared to serum and none of our subjects presented a decrease higher than the TCL with EDTA plasma. In serum, PTH was not considered as stable, but only when kept at 25°C for 18 hours.

Conclusions: PTH stability is of paramount importance for correct interpretation of the results. Many studies have tried to evaluate this stability but are not free from criticisms, mainly due to a poorly defined T0 and questionable acceptance limits. In this study, we used an unfrozen T0 and decision limits based on analytical and biological variations. Moreover, we tested 2nd and 3rd generation PTH on two automated platforms. Our results show that, if PTH is basically more stable in EDTA plasma than in serum, this advantage is only clinically significant when samples are stored for a long period (18h) at +25°C.

Vitamin D Metabolism Is Incompletely Restored After Kidney Transplantation

Thomas F. Hiemstra, Stephen M.S. Ting, Ragada El-Damanawi, Kenneth Lim, Martin Kaufmann, Glenville Jones, Daniel Zehnder. Univ of Warwick, United Kingdom; Univ of Cambridge, United Kingdom; Massachusetts General Hospital, Boston; Queen’s Univ, Kingston, Canada.

Background: Vitamin D deficiency is widely reported in patients with renal impairment and is associated with adverse outcomes. The extent and rate of recovery of vitamin D metabolism after kidney transplantation is uncertain.

Methods: We enrolled 175 dialysis patients (HD) listed for kidney transplantation, and 85 hypertensive but otherwise healthy controls (HTN). We determined blood markers of mineral metabolism including intact FGF23 and vitamin D metabolites at entry (or immediately pre-transplantation), and 2 and 12 months. As a surrogate for vitamin D deficiency, we assessed the 25(OH)D3: 24,25(OH)2D3 ratio (D-ratio, normal 5-25).

Results: Of 175 dialysis patients, 76 were transplanted (TXR) during the study. TXR were younger with a lower BMI than controls. FGF23 was higher in HD patients than HTN at baseline, but normalised after 12 months (p=0.13). At baseline, vitamin D insufficiency (defined as 25(OH)D <30 ng/mL) was present in 82% of subjects and did not differ between groups. However, vitamin D deficiency (defined as 25(OH)D <10 ng/mL) was more common in dialysis (15% versus 4%, p=0.49). The baseline D-ratio was higher in HD (48, IQR 27-67) than in HTN (16, IQR 14-18, p=0.0001) patients. Transplantation resulted in significant reduction in D-ratio after 2 and 12 months compared to HD (p=0.0008 and p=0.005 respectively). The slope of D-ratio vs 25(OH)D3 increased after transplantation, but remained lower than for HTN controls, suggesting reduced expression or activity of the cataboly CYP24A1 (25-OH-D3-24-hydroxylase) in kidney failure.

Conclusions: Vitamin D insufficiency is highly prevalent in patients on dialysis and in hypertensive controls, and only partially resolves after kidney transplantation.
Results: During the observation period, 408 patients were evaluated. There was a significant increase in eGFR and in calcium levels 12 months after the TxR. Compared to the baseline, PTH, AlkP, and P significantly decreased. 25-OH Vit D did not change during the period. Fifteen percent of patients presented both PTH and Ca above the reference levels, while 37% presented isolated high PTH and 8% hypercalcaemia only. Multivariate analysis disclosed that post-TxR hyperparathyroidism was dependent on pre-transplant PTH (OR 1.001; CI 95%: 1.001-1.002) and Ca (OR 1.23; CI 95%: 1.036-1.468).

Conclusions: Monitoring Ca and PTH before and after TxR may be important to detect patients at high risk of persistent hyperparathyroidism, and to identify patients in need of treatment to prevent its complications.

PUB534

Predictors of FGF23 and Soluble Klotho in HIV Infection Rubbin Wang,1 Michael Shlipak,2 Joachim H. Ix,2 Michelle M. Estrella.1 Johns Hopkins Univ: 1UCSF, 2UCSD.

Background: In the general population, FGF23 and its co-receptor, soluble klotho (sKlotho), have been implicated in the aging process. HIV+ individuals are at higher risk of age-related comorbidities compared with HIV- persons. We evaluated whether FGF23 and sKlotho levels differed by HIV status and determined clinical factors associated with each hormone in HIV+ men.

Methods: 384 HIV+ and 225 HIV- men in the Multicenter AIDS Cohort Study (MACS) were randomly selected for FGF23 and sKlotho measurements from samples stored in 2008-2010. We compared FGF23 and sKlotho levels by HIV status, adjusted for age and race. Multivariable linear regression models were used to determine predictors of FGF23 and sKlotho levels among HIV+ men.

Results: Mean age was 53y; 34% were black; and median eGFR was 90mL/min. 99% of HIV+ men were antiretroviral-treated. FGF23 and sKlotho were not significantly correlated (r=0.09). In adjusted analyses, HIV was associated with 11% (p=0.002) higher sKlotho but not FGF23 levels (-1%; p=0.84). Among HIV+ men, diabetes was associated with 34% (95% CI: 3.65%) higher FGF23, whereas HCVR (34%), 95% CI: 14%, -49%, and cumulative tenofovir (TDF) exposure (-4% year; 95% CI: -1%, -7%) were associated with lower FGF23 levels. In contrast, only HCV was associated with higher sKlotho (21%; 95% CI: 7%, 36%). [Figure] Neither CD4 count nor HIV RNA were associated with FGF23 or sKlotho concentrations.

Conclusions: HIV+ individuals had similar FGF23 but higher sKlotho levels compared to HIV- counterparts. Among HIV+ men, clinical predictors associated with FGF23 differed from those associated with sKlotho. Mechanisms by which HIV treatment and co-morbid conditions may impact these hormone levels need further study.

PUB535

Response of Fibrobistal Growth Factor 23 to Sodium Interventions in Diabetic Nephropathy and Arterial Hypertension Jelmer K. Humalda,1 Srinivas Arjun,1 Rajkumar Chinnadurai,2 Gunnar H. Heinc,2 Martin H. De Borst,1 1Nephrology, Univ Medical Center Groningen, Groningen, Netherlands; 2Nephrology and Hypertension, Saarland Univ Medical Center, Homburg, Germany; 2Nephrology, VU Medical Center, for NGrAm, Amsterdam, Netherlands.

Background: Fibroblast growth factor 23 (FGF23) rises progressively in chronic kidney disease (CKD) and is associated with adverse cardiac outcomes. Both CKD patients with diabetic nephropathy (DN) and patients with hypertension are vulnerable to secondary hyperparathyroidism due to hungry bone syndrome with an incidence as high as 51%. Hypocalcaemia can be prevented by effectively preloading patient with Vitamin D supplements and close monitoring of calcium levels post operatively. Currently there is no clear guidance on the preloading dose of one-alphacalcidol in literature. Our current practice is to preload all patients with 2 mcg one-alphacalcidol for 5 days pre operatively. Our aim was to study the management of hypocalcaemia post parathyroidectomy in renal patients and factors influencing length of hospital stay (LOS). To identify if any changes in current practice could improve outcome.

Methods: Retrospective observational study of all renal patients who underwent parathyroidectomy under a single surgeon over 6 years (April 2008 to September 2014). Data was collected from the Electronic Patient Record. Data were analysed using Stats direct and Fisher Exact test was used for testing statistical significance.

Results: 72% of our sample (n= 25) were male with a mean age of 54. Of the 25 there were 13 transplant, 9 haemodialysis and 3 CKD patients. The mean hospital stay was 5 days shorter than quoted in the literature (5.6 Days). 3 of 25 patients were not preloaded. Of our patients needed intravenous calcium replacements which was the main cause for increased LOS (p=0.0002). Haemodialysis patients had longer LOS than CKD and Transplant patients (p=0.0002), this group were more likely to not have received pre-loading. Those undergoing total parathyroidectomy had increased LOS compared to subtotal parathyroidectomy (p=0.0009). There were no surgical complications contributing to a delay in discharge.

Conclusions: Insufficient preloading was identified as a major risk factor for hypocalcaemia, which significantly increased LOS. Further to consensus between renal and surgical teams we have increased the preloading dose of one-alphacalcidol to 5 mcg for 5 days pre operatively. A follow up study is planned in 12 months to observe the outcome of this change.

Links Between Urinary Phosphate Handling, FGF23 and Klotho: An Australian Single-Centre Cross-Sectional Study. Sven-Jean Tan,1 Edward Robert Smith,1 Stephen G. Holt,2 Tim Hewitson,1 Nigel David Toussaint.1

1Nephrology, The Royal Melbourne Hospital, Melbourne, Victoria, Australia; 2Medicine (RMH), The Univ of Melbourne, Melbourne, Victoria, Australia.

Background: Aim: To examine the links between measured phosphate parameters and regulators of phosphate homeostasis (fibroblast growth factor-23 [FGF23] and soluble α-klotho [sKlotho]). Background: FGF23, via the FGF-Receptor/Klotho complex, reduces expression of sodium-phosphate co-transporters thereby inhibiting tubular phosphate reabsorption. Chronic kidney disease (CKD) leads to FGF23 excess and deficiency of sKlotho. Elevated serum phosphate (sPi) results as remaining functioning nephrons are unable to compensate for total phosphate excretion. Complex relationships between these parameters in health and disease, and the impact on phosphate handling, are not fully understood.

Methods: Blood samples and spot and 24-hour urine were collected from patients with CKD (Stages 1-5) and healthy volunteers. Serum and urine biochemistry, intact FGF23 and sKlotho were measured in patients and factors influencing length of hospital stay (LOS). To identify if any changes in current practice could improve outcome.

Results: 116 participants (77 CKD and 39 controls) were recruited. 74 (63.8%) were male. Median (IQR) age of all participants was 61 (49-71) years. FGF23 and sKlotho in current practice were higher, while sPi and TmP were lower, in CKD compared to controls (all p<0.005). Adjusting for eGFR, LnFGF23 correlated with FePi (r=0.22, p=0.026) and LnPi (r=0.268, p=0.005). However, LnKlotho did not correlate with either relation (r=0.038, p=0.636, and r=0.001, p=0.904). There was no association between LnFGF23 and LnKlotho.

Conclusions: Disruption of phosphate regulatory mechanisms is characteristic of CKD. In this small cohort, we established that FGF23 contributes to phosphate excretion. However, sKlotho may provide insight into a greater physiological role of Klotho in regulating TmP at a cellular level. Causal relationships should be explored further in vivo.

Fibroblast Growth Factor 23 Can Predict the Progress of Aortic Artery Calcification in Dialysis Patients
Zhi Chen, Xiaonong Chen, Xiaobo Ma, Bei Ding, Huawei Ling, Nan Chen.
1Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China; 2Radiology, Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China.

Background: To investigate the factors associated with progress of aortic artery calcification in maintenance haemodialysis (MHD) patients and to determine whether plasma FGF23 level is related to progress of aortic artery calcification.

Methods: MHD patients from Ruijin Hospital from July 1st 2011 to July 31th 2011 were involved in our study. Follow up 36 months. Aortic artery calcification (AAC) was detected by a lateral lumbar X-ray plain and read by two radiologists.

Results: 120 MHD patients were enrolled and followed up for 36 months. To July 2014, a total of 67 MHD patients finished the study. Among 67 patients, 32 were male, mean age 53.9±13.1 years old, mean dialysis vintage 44.1±31.8 months, median FGF23 level 4805±2 (11372-35750) µIU/mL, LgFGF23 3.79±0.83. In July 2011, 53.7% of patients had visible calcification in the abdominal aorta and mean involved segment was 1.42 with mean AAC scores (AACS) 3.96. In July 2014, 73.1% had AAC and mean involved segment was 2.34 with mean AACS 10.7. There are significant differences between two AAC involved segments and AACS (both P<0.001). Age, dialysis vintage and FGF23 level had significant difference between AAC progress group and no AAC progress group (P = 0.007, <0.001 and 0.020, separately). Logistic analysis showed that the independent parameters associated with AAC progress were age (OR=1.114, CI:1.045-1.186) and Lg FGF23 (OR=3.848, CI:1.429-10.346) (P<0.001).

Conclusions: The severity of vascular calcification progress yearly in maintain haemodialysis patients. Age and FGF23 are independently associated with the progress of AAC. FGF23 level could predict the progress of AAC in MHD patients.

Funding: Government Support - Non-U.S.

PUB539

Background: Hepcidin is a 25-amino-acid protein synthesized in hepatocytes and macrophages that acts as a post-translationl inhibitor of ferroportin, the only receptor known to export iron from intracellular compartments to systemic circulation. Thus, higher hepcidin levels are associated with greater intracellular sequestration of iron, and increased risk of anemia. Vitamin D is an inhibitor of hepcidin expression; the working hypothesis is that FGF23 could be an “inverse” regulator of iron metabolism in comparison to vitamin D, with a stimulation of hepcidin expression, an increase of intracellular ferritin and an inhibition of ferroportin expression on the cell membrane, leading to a further intracellular sequestration of iron.

Methods: Three different types of liver cells were used: HepG2, HepARG and primary human hepatocytes (PHH). Cells were exposed to FGF23 (1, 10 or 100 ng/mL), at different time points (0h, 24h, 48h). Cultures were performed in triplicates, and qRT-PCR in duplicates (StepOne Plus Real-Time PCR). Western Blots were also performed (Erik and Akt phosphorylation pathways, FGF1, FGF3, ferritin).

Results: In HepG2, even though FGF1-1 expression was found by Western blot analysis, FGF23 did not modify hepcidin expression by qRT-PCR, and Erik/Akt pathways were not activated by FGF23. In HepARG cells, hepcidin expression was modified with FGF23 by qRT-PCR, i.e. increased at 6 hours and decreased at 24 hours.

PUB540

Prevalence of Hyperparathyroidism and Its Correlates in a Large Cohort of Hemodialysis Patients
Pasquale Espositi,1 Fabio Malberti,2 Elena Caramella,3 Marta Calatroni,4 Edoardo La Porta,5 Marina Foramitti,6 Rosanna Coppo,2 Antonio Dal Canton.7 Nephrology, Fondazione IRCCS, Pavia, Italy; 2Nephrology, Istituti Ospitalieri di Cremona, Cremona, Italy; 3Nephrology, Regina Margherita Children’s Hospital, Turin, Italy.

Background: Beyond experimental setting of randomized trials, little is known about the occurrence of mineral bone disorders (MBD) in the real-life clinical practice of hemodialysis (HD). This is the reason why we designed this observational study to define the prevalence of hyperparathyroidism (HPT) and its correlates in a large cohort of HD patients.

Methods: We enrolled HD prevalent patients from 38 Dialysis Units collecting data on: clinical information, dialysis parameters, biochemical and instrumental evaluations and pharmacological therapy. According to the KDIGO guidelines we divided the patients in: patients affected by HPT (i.e. PTH> 9 the upper reference limit of each laboratory) vs patients on target.

Results: Out of 495 patients, 34 (6.8%: 59.9±15.5 years, 53%M) presented HPT with mean PTH of 1064±536 pg/ml, while 461 patients resulted OHT (93.2%: 66.9±13.7 years, 66%, mean PTH 242±151 pg/ml (p<0.001). HPTs were younger than OHT (59.9±15 vs 69.9±13.7 years, p=0.008), with a longer HD history (126±125 vs 64.3±69.4 months, p<0.0003). There were not significant differences in both clinical and dialysis parameters. Similarly, there were not differences in laboratory examination except from serum ALP that resulted higher in HPTs (194.8±142 vs 144.1±108 U/l, p=0.01). Moreover, there were not differences in the use of phosphate binders, whereas a significantly higher percentage of HPTs was taking paracalcitol and calcimetics and the prescribed vitamin D doses (both as calcitriol and paracalcitriol) were significantly higher in HPT patients.

Conclusions: The prevalence of HPT in our population was surprisingly lower, compared to that reported in previous studies. This finding could be due to the general application of KDIGO guidelines, which recommend more permissive PTH levels compared with the previous K-DQOJ2 guidelines, as to the availability of effective drugs, probably used more appropriately than in the past.

PUB541

Effect of Vitamin D Receptor Activators on Glomerular Filtration Rate:
A Meta-Analysis and Systematic Review
Qian Zhang, Jing Chen. Div of Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China.

Background: Vitamin D receptor activators (VDRAs) can protect against mineral bone disease, but they may also elevate serum creatinine and reduce glomerular filtration rate (GFR).

Methods: We conducted a systematic review and meta-analysis of randomized clinical trials (RCTs) to evaluate the effect of VDRAs on kidney function and adverse events. MEDLINE, EMBASE, the Cochrane Controlled Trials Register were searched for RCTs that evaluate vitamin D receptor activators (alfacalcidol, calcitriol, doxercalciferol, falcicalcitriol, maxacalcitol and paricalcitol) up to March 2015.

Results: We included 31 studies, all of which were performed between 1976 and 2015, which enrolled 2621 patients. Patients receiving VDRAs had lower eGFR (weighted mean difference WMD -1.29 mL/min/1.73 m², 95% CI -2.42–0.17) and elevated serum creatinine (WMD 7.03 µmol/L, 95% CI 0.61-13.46) in sensitivity analysis excluding studies with dropout rate more than 30%. The VDRAs and control groups had no significant differences in all-cause mortality (relative risk RR 1.41, 95% CI 0.68-3.80), cardiovascular disease (RR 0.84, 95% CI 0.42–1.71), and severe adverse events (RR 1.15, 95% CI 0.75–1.77). Episodes of hypercalcemia (RR 3.29, 95% CI 2.02-5.38) were more common in the VDRAs group than in the control group.

Conclusions: Although administration of VDRAs slightly reduced the eGFR, all-cause mortality and severe adverse events were comparable between the groups. Future RCTs with larger sample sizes are needed to assess whether the mild reduction of eGFR is of clinical significance.

Fold change of hepcidin mRNA expression in comparison to PBS

* p<0.05; Western blot analyses demonstrated the presence of FGF1R and FGF3R, with an activation of the Erk pathway at 30 and 60 minutes with FGF23. However, there was no modification of ferritin by Western blots analysis with FGF23. In the only batch of PIH that was available, hepcidin expression increased at 6 and 24 hours.

Conclusions: FGF23 does not appear to play a crucial role in iron regulation in liver cells, even though its potential role in PIH deserves further studies.

Funding: Private Foundation Support
Low Dose Cholecalciferol Supplementation on Serum Inflammatory Markers in Hemodialysis Patients with Hypovitaminosis D

The levels of inflammatory markers. 6 months of low dose cholecalciferol supplementation in these patients did not improve serum vitamin D deficiency or insufficiency and safe for hemodialysis patients. However, it was to analyze the association of FGF-23 and reduces inflammatory markers. Moreover, it was also to investigate the effect of cholecalciferol supplementation on the biological variables and inflammatory markers. In addition, the effective factors on the levels of 25(OH)D and 1,25(OH)2D, and other biological variables were measured every 3 months for one year. We investigated the effects of cholecalciferol supplementation on the biological variables and inflammatory markers. Furthermore, the variation of drug prices by ±25% did not change the conclusion of the base-case.

Conclusions: The low dose cholecalciferol supplementation was effective in correcting serum vitamin D deficiency or insufficiency and safe for hemodialysis patients. However, another study was to evaluate serum SOST levels in Tx in whom few data are available. Aim of our study was to evaluate serum SOST levels in Tx in whom few data are available.

Cost-Minimization Analysis of Sucroferric Oxhydroxide and Sevelamer Carbonate in Patients on Dialysis with Secondary Hyperparathyroidism in Germany

Many patients with chronic kidney disease (CKD) on dialysis require vitamin D (ViT.D) agents for managing secondary hyperparathyroidism (SHPT). It has been shown that the concomitant administration of oral phosphate binders (sucreforter oxidroxide, SFOH or sevelamer carbonate, SEV) and ViT.D therapies might impair the therapeutic effect of the ViT.D due to drug-drug interaction. Based on clinical trials (NCT01324128, NCT01461903), this cost-minimization analysis assessed the economic impact of using SFOH compared to SEV treatment with ViT.D agents from a German third-party payer perspective.

Methods: Costs of patients with serum phosphate concentrations ≥6.0 mg/dl receiving either SFOH (1.5g/day [3 tablets/day]) or SEV (6.4g/day [8 tablets/day]) were assessed. Due to lack of interaction, it was assumed that patients on SFOH were treated exclusively with oral ViT.D (calcitriol, 0.25mg/day), whereas SEV patients received inna-venous ViT.D agents (paricalcitol, 1.84mg/day). Costs for the administration of paricalcitol and for adverse events were not included. Drug acquisition costs were calculated on the basis of the German standard pharmacy prices (Rote Liste 2015). Uncertainties were addressed in one-way sensitivity analyses.

Results: Over an observation period of one year, costs for SFOH or SEV resulted in EUR 416 or EUR 3,592, respectively. Annual ViT.D therapy costs yielded in EUR 209 for calcitriol and EUR 3,303 for paricalcitol, respectively. SFOH treatment with calcitriol versus SEV with paricalcitol resulted in an annual cost-saving of EUR 3,273 per patient. The variation of drug prices by ±25% did not change the conclusion of the base-case.

Conclusions: This study provide evidence that SFOH treatment with calcitriol has an economic benefit compared to SEV with paricalcitol to treat German CKD patients with SHPT. Economic savings might be substantial for the German health care system, but real world data will be needed to confirm these findings.

Effect of Intravenous Saccharated Ferric Oxide on FGF23 Metabolism in Dialysis Patients

The ongoing CARE FOR HOMe study recruits chronic kidney disease patients. Underline represents presenting author.

Funding: Government Support - Non-U.S.
Methods: We performed a cross sectional study in 80 Tx (55:10 y.o.:49M/31W) with CKD stage 2-4 (eGFR 47±16 ml/min). 30 healthy subjects (34:12 y.o.:eGFR59±19 ml/min) were the control group. We evaluated in all patients SOST, Ca, P, PTH, FGF23 and Alkaline Phosphatase (AP).

Results: SOST was not different between Tx and controls (27.6±10.2 10±1.8 0±0.7 178.6±5 59±±1 261±6 42±15 47.3±28.8). Serum levels of FGF23 were increased compared to controls (47.3±28.8 vs 30:019.0 pg/ml p<.05). SOST showed a negative correlation with AP (r=−.375 p<.05) and a positive correlation with FGF23 (r=.236 p<.05) and 25(OH)D (r=.238 p<.05). No correlation existed between other parameters.

Conclusions: eGFR does not seem to affect serum levels of SOST in Tx. The negative correlation wht AP indicates that SOST maintains its modulatory role of osteoblastic activity in this population. The correlation with FGF23, which is in agreement with low FGF23 in SOST null mice, suggests modulatory effects of both proteins on osteoblastic direct, through Wnt inhibition, for SOST; indirect, through effects on 1,25D levels, for FGF23. Serum SOST may be an additional marker of bone metabolism, useful to understand metabolic pathways in normal subjects and in CRF.

**Conclusions:**

Serum 25(OH)D levels were observed in both groups. Differences in biochemical pathways in normal subjects and in CRF.

**Background:** Low serum vitamin D concentrations have been reported in chronic kidney disease (CKD). Very few studies concerns vitamin D deficiency (25(OH)D) in Chinese patients. Our aim is to assess the deficiency of serum 25(OH)D concentrations in patients with IgAN, and to explore the possible correlated factors contributing to Vitamin D deficiency.

**Methods:** 283 patients who come from north China and were not receiving vitamin D supplementation were included in this study from February 2013 and April 2014. We collected blood samples to determine levels of Scr, BUN, UA, serum phosphate (P) and calcium (Ca), iPTH, albumin, as well as urinary excretion of creatinine, protein, P and Ca within 24h. Electrohydroxyvitamin.D measurement measured total 25-hydroxyvitamin.D. Vitamin D deficiency should be defined as a 25(OH)D of < 15 ng/ml.

**Results:** All of the 283 patients, 25(OH)D concentration was 10.25±6.94 ng/ml. Only 18.82% of the patients had a circulating 25(OH)D level greater than 15ng/ml. The prevalence of deficiency (<15ng/ml) were 87.2%, 72.9%, 75.0%, 85.45%, 93.1%(P<0.000) at different CKD stages. All the 120 IgAN patients were divided into 4 groups according to eGFR. The prevalence of vitamin D deficiency were higher in CKD stage 1 and 4(5-P<0.000), but there is no difference of average 25(OH) D concentration according to eGFR(P>0.009). The 25(OH)D concentration was higher in TMA IgAN patients than MN and DN patients. But, 24UPR in IgAN patients was lower than MN and DN patients. In different age, gender, season, BMI or iPTH group, 25(OH)D levels were not affected, but 25(OH)D level was lower in >15 and >24 age group.

**Conclusions:** For the IgAN patients in north China, kidney function might be related to vitamin D deficiency, and 24UPR may play a very important role in maintaining 25(OH) D serum concentrations.

**Utility of Whole Exome Sequencing in the Diagnosis of a Family with Apparent Mineralocorticoid Excess**

Using next generation sequencing in the diagnosis of rare inherited diseases. A characterized report of AME from Indian population. Our study underscores the utility of whole exome sequencing in the diagnosis of a family with AME.

**Methods:**

- Three different and amplified exome amplicons, confirming the diagnosis. Both parents were heterozygous for the variation. This is the first genetically demonstrated in the family using whole-exome sequencing. This is the first genetically characterized AME from Indian population.

**Conclusions:**

A homozygous mutation (p.R337C) variation in the 11HSD2 gene was demonstrated in the family using whole-exome sequencing. This is the first genetically characterized report of AME from Indian population. Our study underscores the utility of next generation sequencing in the diagnosis of rare inherited diseases.

**Funding:**

- Government Support - Non-U.S.

**Genetics of Thrombotic Microangiopathies – The Viennese TMA Cohort**

- The variant was further validated using Sanger sequencing of the amplicons, confirming the diagnosis. Both parents were heterozygous for the variation. This variation has been reported to be associated with the similar phenotype in two independent studies on native American populations.

**Conclusions:**

A homozygous mutation (p.R337C) variation in the 11HSD2 gene was demonstrated in the family using whole-exome sequencing. This is the first genetically characterized report of AME from Indian population. Our study underscores the utility of next generation sequencing in the diagnosis of rare inherited diseases.

complement system. This is a result of either genetic alterations within complement factors or regulatory proteins or secondary causes. The aim of this study was to systematically investigate our cohort of patients with TMA regarding genotype and triggers of disease episodes.

Methods: Data were analyzed by means of patient records: Demographic and laboratory data, results of kidney biopsies, results of genetic sequencing of complement regulatory proteins, CFβ, thrombomodulin (THBD) and C3, and medical history for triggering factors were analyzed.

Results: Out of 92 patients with TMA we classified 30 as atypical HUS (aHUS), 1 as typical HUS (tHUS) and 61 as secondary HUS. At onset of disease patients with aHUS had a mean age of 25 years (range: 1-47), 20 were female (65%), and 13 (43%) were kidney transplant recipients. First presentation of 24 patients was AKI, 3 showed hemolysis, 2 had pre-eclampsia and 1 HELLP-syndrome. Distinct triggering factors in 20 patients were diet (n=9), Infection (n=5), hypertension (n=2), surgery, diarrhea and renal transplantation (each n=1). Thirteen and 3 showed a CHF-3 and a MCPδ&aaχ risk haplotype, respectively; potentially disease-causing mutations were identified in 22 patients (7 CHF, 6 CD64, 3 C3, 4 C2, 2 CFβ, 1 THBD; 4 of them with more than 1 mutation); 7 showed wild-types and no data existed for 1 patient.

Conclusions: In our cohort of TMA patients we identified 30 cases of aHUS. In 22 patients (74%) we identified a mutation within genes of the complement regulatory proteins or C3, whereas 7 subjects showed wild-type sequences despite presenting with a classic phenotype of aHUS.

PUB551

Under-Diagnosis of Alport Syndrome in First-Degree Relatives of Affected Individuals Clifford E. Kashdan,1,2 Theresa F. Cassidy,2,2 Michelle N. Rhcauit,1,2 1Pediatrics, Univ of Minnesota, Minneapolis, MN; 2Alport Syndrome Treatments and Outcomes Registry (ASTOR).

Background: Alport syndrome (AS) is an important inherited cause of progressive renal disease. Hematuria, the cardinal feature of AS, is highly penetrant in affected individuals. Urinalysis is a sensitive method for detecting AS in relatives of AS patients. This report describes a cohort of at-risk individuals (first-degree relatives of known AS patients) who underwent a first urinalysis as part of a clinical trial feasibility study.

Methods: For a study entitled “Multi-center Controlled Clinical Trials in Alport Syndrome - A Feasibility Study” (R21 DK19480, Clinicaltrials.gov #NCT01962253) conducted during 2013-14, first morning urine collection kits were sent to 104 people registered with ASTOR who carried a diagnosis of AS or were first-degree relatives of people known to have AS. 45/104 participants (43%) had been classified as unknown under-Diagnosis of Alport Syndrome in First-Degree Relatives of Affected people known to have AS. 45/104 participants (43%) had been classified as unknown under-Diagnosis of Alport Syndrome in First-Degree Relatives of Affected.

Results: 17/43 unknowns did not return the urine kit. Of the 28 who returned a urine kit, 11 had hematuria and 17 had normal urinalyses. Of the 11 who were reclassified from unknown to affected, 6 were siblings of a known affected child, 3 were sons of a known affected mother and 2 were mothers of known affected children. 3/11 had microalbuminuria (urine microalbumin:creatinine ratio > 30 mg/g); none had overt proteinuria.

Conclusions: The results are consistent with the following conclusions: 1) it is not unusual for first-degree relatives of known AS patients to have never been screened by urinalysis; 2) screening of first-degree relatives of known AS patients frequently identifies individuals affected (39% [11/28] of those who returned urine kits) who may benefit from early intervention. Early initiation of ACE-inhibitor therapy appears to slow renal disease progression in AS (Gross et al, Kidney Int 2012). It is recommended that treatment be initiated at an earlier age as soon as they develop overt proteinuria (Kashdan et al, Pediatr Nephrol 2013; Savage et al, JASN 2013). Screening urinalyses should be performed in all first-degree relatives of AS patients in order to identify those who are or may become candidates for treatment.

PUB552 Urinary Biomarkers (UBio) Predict Renal Damage in Primary Hyperoxaluria (PH) Gauri Bhutani,1 Lisa E. Vaughan,2 Felicity T. Enders,1 Samuel Edeh,1 Andrea G. Cogal,1 Nick Vyskoboho,1 Dawn S. Milliner,1 John C. Lieszke,1 Nephrology, Mayo Clinic, Rochester, MN; 2Biostatistics, Mayo Clinic, Rochester, MN.

Background: PH often results in kidney stones and CKD/ESRD. We investigated diverse UBio for correlations with urinary chemistries (UChem) and as predictors of GFR decline.

Methods: UBio (Table 1) were measured in biobanked urine from PH cases and healthy controls. Clinical details and outcomes for PH cases were obtained from the Rare Kidney Stone Consortium Registry, including 24 hour UChem assays (Uox, calcium (UCa), citrate (UCit) and calculated CaOx supersaturation (CaOx SS) and proximal tubular Ox (PTOx= (UOx* serum Cr* 4)/ UCr). Univariate and multivariate models were used to compare UBio with UChem and outcomes.

Results: Urine was available from 30 cases (114 samples) and 47 controls (47 samples). Significant correlations were present between urine and UChem including: U RBP, NGAL, MCP1, L-FABP with U Cq; U MCP1, L-FABP with U CaOx SS; L-FABP, H-FABP with PTOx (all P<0.05). Compared to controls NGAL was increased and OPN decreased in PH cases. Both UBio and OPN independently predicted subsequent eGFR (P<0.001).

Conclusions: In PH, specific UBio correlate with UChem and provide renal prognostic information. These likely reflect ongoing intrarenal pathology.

PUB553 Whole Exome Sequencing Identifies Adillin Mutation as a Novel Single-Gene Cause of Nephrotic Syndrome Jia Rao,1 Shazia Ashraf,1 Svjetlana Lovric,1 Weiizen Tan,1 Merlin Airik,1 Eugen Widmeier,1 Heon Yung Goe,2 Richard P. Lifton,3,4 Friedhelm Hildebrandt,3,4 1Div of Nephrology, Boston Children’s Hospital, Harvard Medical School, Boston, MA; 2Dept of Pediatric Nephrology, Faculty of Medicine Univ of Istanbul, Istanbul, Turkey; 3Dept of Genetics, Yale Univ School of Medicine, New Haven, CT; 4Howard Hughes Medical Inst, Chevy Chase, MD.

Background: Identification of single-gene causes of steroid resistant nephrotic syndrome (SRNS) has furthered the understanding of its pathogenesis. However, many genes and disease mechanisms remain unknown. To identify additional genes that if mutated cause SRNS, we combined homozygosity mapping (HM) and whole human exome sequencing (WES) in a consanguineous families with NS.

Methods: An individual of consanguineous parents from Turkey with SRNS, deafness, cataract, microcephaly, and mental retardation histologically exhibited diffuse mesangial sclerosis. HM yielded >11 segments of homozygosity by descent with cumulative segments of ~200 Mb. We performed WES in this individual to identify the underlying single-gene disease-causing mutation.

Results: We identified a homozygous missense mutation (p.Leu425Met) in the AVIL (adillin) gene in an amino acid residue conserved since Ciona intestinalis. The mutation segregated with the affected status in this family and was absent from >6,500 European controls. By exome sequencing Variant Server, AVIL (adillin) is a member of the gesulin superfamily of actin binding protein. AVIL (adillin) is known to be involved in neurite outgrowth and morphogenesis via interaction with the cytoplasmic domain of the Type F scavenger receptor, SREC-I.

Conclusions: We identified mutation of AVIL (adillin) as a novel single-gene cause of SRNS. Further genetic and functional studies will shed light on the gesulin superfamily of actin binding proteins in the pathogenesis of NS and will provide further understanding of the disease mechanism.

PUB554 Adult-Onset Familial Thrombotic Microangiopathy and Pulmonary Arterial Hypertension Related to Cobalamin C Deficiency Steven Grange,1 Elise Artaud-Macari,1 Soumeya Bekri,1 Arnaud Francois,1 Christophe Girault,2 Fabienne Taman,1 Dominique Guerrot,1 1Intensive Care Unit, Rouen Univ Hospital, France; 2Dept of Metabolic Biochemistry, Rouen Univ Hospital, France; 3Dept of Pathology, Rouen Univ Hospital, France.

Background: Cobalamin C (cbC) deficiency is the most frequent inherited disease of vitamin B12 metabolism, related to mutations in the MMACHC gene. The presentation in adults is dominated by neuro-psychiatric symptoms, and usually constitutes a diagnostic conundrum. We describe a unique presentation of cbC deficiency in 2 brothers, with the association of adult thrombotic microangiopathy (ATMA), atypical glomerulopathy, and pulmonary arterial hypertension (PAH).

Methods: An 18 year-old patient was referred for dyspnea. The investigations revealed stage 5 CKD, nephrotic syndrome, haemolytic anaemia, and PAH. Renal histology showed major microvascular lesions and proliferative myxoid lesions in the interlobular arteries. The glomeruli presented an ischemic appearance, with thickened and ribbon-like glomerular basement membranes. Immunofluorescence showed granular glomerular deposits of IgM, IgG, C3, and C4d.
without IgG or C3. Metabolic analyses showed an elevation of plasma homocysteine, methylenetetrahydrofolate, and propionylcarnitine concentrations. Genetic analyses found a compound heterozygosity in MMACHC gene, with c.271dupA and c.82-9delTTC mutations. The patient’s brother died at the age of 17. Autopsy revealed pulmonary capillary hemangiomatosis, while the kidney histology showed similar lesions to those of his brother.

**Conclusions:** The first report of late-onset TFTA, atypical glomerulopathy, and PAH associated with chBc deficiency. We suggest that the association of TFTMA and/or glomerular proteinuria with PAH in children and young adults should prompt metabolic investigations to identify chBc deficiency, and provide early specific management including hydroxyecobalamin, folic acid, and betaine.

The DS3 Scores and Quality of Life in Japanese Patients with Fabry Disease Nobuhito Hirawa, Keisuke Yatsu, Sanae Saka, Gen Yasuda, Satoshi Umemura. 1Dept of Nephrology and Hypertension, Yokohama City Univ Medical Center, Yokohama, Kanagawa, Japan; 2Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Kanagawa, Japan.

**Background:** Fabry disease (FD) is the lysosomal storage disorder, caused by the deficiency of lysosomal hydrolase alpha-galactosidase A activity. Various symptoms associated with renal disease, heart lesion and cerebrovascular disease occur in Fabry disease patients. Thus, the quality of life (QoL) would be altered with the disease progressed. We evaluated the clinical severity and the QoL in a sample of Japanese patients with Fabry (FD) disease using the Disease Severity Scoring System (DS3) and the SF-36 survey in male and in female.

**Methods:** Observational cross-sectional study. The DS3 and SF-36 survey was administered to the patients of the hospitals, which belong to the research group of Kanagawa enzyme replacement therapy. Participants were treated with agalsidase-alpha or agalsidase-beta. Disease activity was assessed by the Disease Severity Scoring System (DS3). The QoL was measured by Short form-36 (SF-36) and the Kidney Disease Qol. Short form version 1.3 (KDQol).

**Results:** Fifteen patients were included in the study. Mean age was 45 years (M/F=10/5), and all patients were receiving ERT. The mean serum Cr was 2.9 mg/dL. The DS3 scores were follows; mean assessment score: 26.5 +/- 10.1, average domains: 10.5 +/- 0.9. The renal domain and the cardiac domain showed relatively high score compared to PNS and CNS scores. The QoL scores of the FD patients were lower than those of general population, but the scores were better than the previous reports of FD from U.S. or EU. The mental component summaries of women were similar to those of the general population. The physical component summaries of Qol were negatively associated with the age (r= -0.535, p=0.001).

**Conclusions:** Japanese patients with FD receiving ERT had a relatively good QoL beyond anticipation. DS3 score is useful for assessing disease severity, and may predict some components of QoL.

**PUB556**

Two Cases of Fabry Disease in Women with Proteinuria Diagnosed by Molecular Analysis of a-Galactosidase A Gene and Kidney Biopsy Jong Oh Yang. 1Eun-Young Lee. 2Internal Medicine, Soonchunhyang Univ, Cheonan, Chungcheongnam-do, Korea; 2Internal Medicine, Soonchunhyang Univ, Cheonan, Chungcheongnam-do, Korea.

**Background:** Fabry disease is a X-linked lysosomal storage disorder caused by deficiency of a-galactosidase A. This abnormality in enzyme results intracellular accumulation of globotriaosylceramide and leads to severe painful neuropathy with progressive renal, cardiovascular, and cerebrovascular dysfunction and early death. We report 52 and 55 year-old women with proteinuria and hematuria, which were proven to be due to Fabry disease.

**Methods:** A 52 and 55 year-old women were admitted to the hospital due to proteinuria. They had previous histories of hypertension, diabetes mellitus, pulmonary tuberculosis, and hepatitis. Their sister and cousin diagnosed fabry disease. Physical examination revealed nonspecific findings. On admission, blood pressure 110/60 mmHg, heart rate 64/min, respiratory rate 16/min, body temperature 36.5°C. Lungs were clear and heart was normal. The extremities showed no edema, cyanosis or skin rashs. The laboratory data showed the WBC 5650/mm3, HB 13.2 g/dL, Platelet 212,000/mm3, BUN 10.2 mg/dL, serum creatinine 0.7 mg/dL. Urinalysis showed pH 5.0 SG 1.023 protein 2+ RBC 5-9/HPF WBC 5-9/HPF 24-hour urine protein was 533 mg. Abdomen & Pelvic CT and echocardiography were normal.

**Results:** The extremities showed no edema, cyanosis or skin rashs. The laboratory data showed the respiratory rate 16/min, body temperature 36.5°. Lungs were clear and heart was normal.

**Conclusions:** The enzyme activity for a-galactosidase in serum was 0.59 nmol/min/mg protein. The thesm patients received enzyme replacement therapy every other week. They had reduction in proteinuria and normal renal function.

**PUB557**

Intradyalisis Partial Parenteral Nutrition (IDPN) in Hemodialysis Patients (HDP) with Protein Caloric Malnutrition (PCM): Preliminary Results Susana Beatriz Asta. 1 Marcela Fabiana Munizaga. 2 Servicio de Nefrologia, Hospital Nacional de Clínicas, Cordoba, Argentina; 1 Servicio de Nefrologia, Hospital Nacional de Clínicas, Cordoba, Argentina.

**Background:** PCD is high prevalence in HDP and predicts morbi-mortality. NPID is according Espen Guides (March2012) and the SMOFF formula(ojiga,TG,olive oil and fish oil), improve inflammation and lipid status.Our goal is to define the evolution of nutritional parameters in HDP and characterize them for future interventions. OBJECTIVE: To evaluate if severe PCD in HDP, improve malnutrition and inflammation markers such as albumin,Alb),cholesterol (Ch), reactive C protein(RCP).

**Methods:** Prospective and observational study that included 14 patients up this time,both sex,age27-80 years old, in maintenance HD from a University Hospital and Army Hospital.Patients signed informed consent. Patients received each HD session and during six months,SMOF lipids 4 grs/kg/d,IV continuous infusion. We analyzed weight, Hematocrit,Alb,TG,creatinine,RCP and Global Subjective Valoration(GSV) in pre HD blood samples at the beginning,three and six months.Cuantiative demographic variables(age,sex,biochemic parameters)were expressed as medium,SD and applied Student Wilcoxon Test and Chi Test (p=0.01).

**Results:** patients improved weight(63,1+/-3,3vs64,9+/-3,5,p,0,351),alb(gr/ml)(3,4+/-0,4vs3,2+/-0,3,1,p:0,016),TG(mg/dl)(190,1+/-30,8vs179,4+/-30,8,p:0,03)and RCP(mg)(28,9+/-6,7vs10,1+/-2,5,p:0,009).there were not statical significance inHto(gr/dl)(1017,4+/-166,8vs1017,3+/-13,0,p:0,846),creatinine(mg/dl)(163,9+/-12,9vs165,6+/-13,0,p:0,846).There were not significant differenc between the begining and six monthsexcept the RCP.

**Conclusions:**- NPID is a successful tool as partial supplementation in HDP with oral dietary intake.2-In spite of our sample is small,the improvement of Nutritional and inflammatory status, applying Internatinal Guides was observed after three months of treatment.3-Medical awareness about nutritional risks in HDP, is the best tool to prevent alteration of nutritional status 4-We ll expand the sample.

Association of Protein Energy Wasting with Income in Chronic Kidney Disease Stage 3 Patients Anita Saxena, Armit Gupta. Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, Uttar Pradesh, India.

**Background:** Protein energy wasting (PEW) is a major challenge in CKD. Purpose: Assessment of PEW in predialysis patients at first visit to a nephrologist.

**Methods:** Three day dietary intake of 484 CKD stage 3 patients. Patients were divided in to groups based on appetite and BMI.

**Results:** Male and female parameters: Serum albumin 3.7±0.84/3.68±0.81 g/dL, total protein 7.02±1.27/6.49±1.26 g/dL, creatinine 4.68±4.19/3.74/3.36 mg% creatinine clearance 33.22±30.48/37.55±33.87 ml/minute, BMI 22.60±4.29/23.43±4.77 kg/m² energy/kg 16.97±0.65/16.8±0.64, protein g/kg 0.65±0.28/0.64±0.30, carbohydrate g/kg 2.98±1.54/2.38±1.36, fat g/kg 2.96±0.23/2.79±0.22, respectively. As appetite decreased dietary protein and energy intake decreased significantly.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Malnutrition is closely associated with mortality in end-stage renal disease (ESRD) patients. However, little is known whether improvement or deterioration of nutritional status after dialysis initiation affects clinical outcome. This study was aimed to elucidate the association between the changes of subjective global assessment (SGA) after dialysis initiation and mortality in ESRD patients.

**Methods:** Residens over the age of 35 of the Beijing Pinggu District by random sampling method. Laboratory test: take morning ACR, blood samples were taken for blood routine, kidney function. Test body composition after eliminating the by using INBODY-720 machine.Use SPSS 17.0 software for data statistical analysis, count data were analysed by using multivariable linear regression .

**Results:** A total of 126 patients participated in the survey, which 5324 males, age 54.7±10.7 years, 4599 females, age 53.1±11.2 years. Male: 1) Human body mass cell (BCM) and ACR, Cystatin-C, no correlation, was positively correlated with height (B=0.43, P<0.01), and serum creatinine was that positive correlation (B=0.01, P=0.01). 2) Lean body mass (FFM) and ACR, serum creatinine, Cystatin-C, no correlation. 3) Skeletal muscle content and ACR, serum creatinine, Cystatin-C, no correlation. 4) Body fat mass and ACR, no correlation, and Cystatin-C was positively correlated with (B=0.09, P < 0.01). Female: 1) Human body mass cell (BCM) with height and cystatin-C, no correlation, but positively correlated with serum creatinine (B=0.05, P=0.01), and ACR was negative correlation (B=0.95, P<0.05). 2) Lean body mass (FFM) and ACR, Cystatin-C, no correlation, and serum creatinine were positively correlated (B=0.05, P=0.01). 3) Skeletal muscle content and ACR, Cystatin-C, no correlation, and was positively correlated with height (B=0.03, P=0.01), and serum creatinine were positively related (B=0.05, P=0.01). 4) Body fat mass and ACR was negative correlation (B=0.01, P<0.05). Cystatin-C was positively correlated (B=12.3, P=0.01), and age were negatively correlated (B=0.13, P<0.05), and serum creatinine was negative correlation (B=0.092, P<0.01).

**Conclusions:** There was a positive correlation between serum creatinine and the human body mass cell (BCM), lean body mass (FFM) in men, and skeletal muscle content, body fat weight in women, but the correlation is not strong. The blood cystatin-C and body fat weight was positively correlated.

**Worsening Nutritional Status Assessed Is an Independent Predictor of All-Cause Mortality in Incident Dialysis Patients**

Jong Hyun Jhee, Young Eun Kwon, Tae-Hyun Yoo, Shin-Wook Kang. Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.

**Background:** Malnutrition is associated with mortality in end-stage renal disease (ESRD) patients. However, little is known whether improvement or deterioration of nutritional status after dialysis initiation affects clinical outcome. This study was aimed to elucidate the association between the changes of subjective global assessment (SGA) after dialysis initiation and mortality in ESRD patients.

**Methods:** Data were recruited from the Clinical Research Center for ESRD cohort. SGA score was measured by trained investigators at the time of dialysis initiation and after 12 months. Nutritional status was defined as well-nourished (SGA 6-7), mildly to moderately malnourished (SGA 3-5), or severely malnourished (SGA 1-2). Severely malnourished patients (SGA C) were excluded due to small sample size. The patients were divided into four groups according to the change of SGA: group 1; A to A, group 2; A to B, group 3; A to B; and, group 4; B to B. A significant risk factor for mortality (group 3 vs. 1, HR=3.15, CI=1.51-6.54, P=0.002), while baseline nutritional status at dialysis initiation was not (group 1 vs. 2, P=0.063; group 3 vs 4, P=0.107).

**Conclusions:** Improvement of nutritional status after dialysis initiation could be beneficial for patient outcomes regardless of baseline status, suggesting that intervention to improve nutritional status after dialysis initiation might be a strategy to reduce mortality in ESRD patients.

**PUB561**

**Prophylactic Effect of Erythropoietin Injection to Prevent Acute Mountain Sickness: An Open-Label Randomized Controlled Trial**

Joon Bae Kim. Div of Nephrology, Dept of Internal Medicine, Univ of Ulsan, College of Medicine, Asan Medical Center, Seoul, Republic of Korea.

**Background:** This study was performed to evaluate whether increasing hemoglobin before ascent by prophylactic erythropoietin injections prevents acute mountain sickness (AMS). Methods: This open label, randomized, controlled trial involved 39 healthy volunteers with hemoglobin £15.5 g/dL, who were divided randomly into erythropoietin (n = 20) and control (n = 19) groups. Epoetin alpha 10,000 IU injections were given weekly for four consecutive weeks. On day 1, and 7 days after the last injection (day 29), oxygen saturation (SaO2), and hemoglobin were measured. The subjects departed Seoul on day 30 and arrived at Annupu base camp (ABC, 4,130 m) on day 34. AMS was diagnosed when headache and Lake Louise score (LLS) of ≤ 3 were present. Immediate descent criteria followed US Army recommendations. Results: Two groups differ in hemoglobin levels on day 29 (15 ± 1.1 vs 14 ± 1.2 g/dL, P = 0.001). At ABC, erythropoietin group had a significantly lower mean LLS, AMS incidence, and number of subjects who met immediate descent criteria. Multiple logistic regression analysis showed that SaO2 < 87% and control group, but not hemoglobin < 15.0 g/dL, independently predicted satisfaction of immediate descent criteria.

**PUB562**

**Nutritional Assessment for the Chronic Dialysis Patients with/without Sarcopenia**

Mih Suzuki, Yuya Sakai, Ikuto Masakane. Tabuki Hospital.

**Background:** A recent arising problem of chronic dialysis patients is sarcopenia closely related to malnutrition. Muscle loss deteriorates daily activities of dialysis patients and ultimately worsens the QOL and prognosis of the patients. The aim of this study was to clarify the relationship between the nutritional status and sarcopenia and to analyze the status of nutrient intake in these patients.

**Methods:** 90 chronic hemodialysis patients were enrolled to the current study. (age 62.8±5.8 years. Men were 76%, DM 41%).Skeletal muscle mass (SMM) was estimated by biochemical impedance analysis and a low muscle mass was defined by the SMI index (SMI: SMM [kg] / height [m]² > 15g: > men: 7.0kg, women: 5.7kg). Muscle function was estimated by grip strength and walking speed as the Timed up and go test (TUG). A low grip strength was defined as less than 26 kg (men) or 18 kg (women). TUG less than 11 second was diagnosed as a low walking speed. Malnutrition was defined as by the Malnutrition-Inflammation Score (MIS)<36point, GNRI<92 and the criteria of protein energy wasting (PEW). The dietary assessment was performed by the food frequency questionnaire.

**Results:** Sarcopenia was identified in 22% of the subjects. The sensitivity to detect sarcopenia was not sufficient as 35% in MIS, 50% in GNRI and 10% in PEW. In the patients with sarcopenia, the average of total energy intake and protein was significantly lower than those in non-sarcopenia, 1618±122kcal vs 2041±165kcal in energy, 52±4g vs 68±2g in protein. The intake of fishes and meats (110±5g vs 153±8g, beans (31±11g vs 61±6g) ,confectionery, beverages and sugar (126±77g vs 306±41g) were significantly lower in sarcopenia than non-sarcopenia. Conclusion: Malnutrition-related sarcopenia was only 10-50% among sarcopenia. It is important to measure muscle mass and muscle function regularly for dialysis patients because it is not enough to screen sarcopenia only by nutritional measurements. Sufficient protein and energy intake are essential for the prevention of sarcopenia. If patients don’t have appetite,confectionery or a beverage or sugar may be acceptable for the prevention of muscle loss.

STUDY OBJECTIVES

To determine the actual potassium content of a number of products often consumed to control the intake of potassium, and are advised for doctors and dietitians to restrict. Additionally, the study aimed to evaluate the potassium content in food categories and to identify the products that are low in potassium.

METHODOLOGY

1. **Study Design**: Cross-sectional study of 103 patients undergoing chronic hemodialysis in Budapest, Hungary, at a university hospital-based dialysis unit.

2. **Participants**: Patients aged 19 to 85 years, who were on maintenance hemodialysis for at least 6 months. Only those who did not take an acid reducing agent, such as a proton pump inhibitor (PPI) or H2 blocker, were included.

3. **Methods**: The study measured the potassium content of various products consumed by the patients. The potassium content was determined by flame photometry according to the reference source.

4. **Results**: The study found that the potassium content varied significantly among the different food categories. Processed foods, such as baked goods, had higher potassium levels than fresh foods. The study also identified products that were low in potassium, such as powdered juices and processed beverages, and products that were high in potassium, such as tomatoes and tomato sauce.

5. **Conclusions**: The study concluded that the potassium content of food is variable and that patients with chronic kidney disease need to be aware of this variability. The study also highlighted the importance of dietary management for patients with chronic kidney disease.

**Key Points**

- The study highlights the variability in potassium content among food categories.
- Patients with chronic kidney disease need to be aware of this variability for dietary management.
- The study recommends a healthy diet that is low in potassium for patients with chronic kidney disease.

Obese Donors: The Multidisciplinary Approach in Improving Outcomes

Giselle Guerra, 1 Ian Thomas, 1 Panagiots Tryphonopoulos, 2 Linda J. Chen, 2 Gaetano Ciancio. 2

1 Department of Medicine, Miami Transplant Inst, Miami, FL; 2 Department of Surgery, Miami Transplant Inst, Miami, FL.

Background: Living donation appears safe over the years but concerns still exist long-term. Small analyses after unilateral nephrectomies have resulted in proteinuria and slight decrease in renal function (eGFR) if patient tended to be obese; thus raising a concern for accepting living kidney donors (LKD) with body mass index (BMI) greater than 30 but less than 35 Aim: Determine the outcomes of obese LKD with BMI greater than 30 but less than 35.

Methods: A single center retrospective analysis was performed at out transplant center, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil from January 1st, 2009 to November 30, 2014. LKD aged 18-65 were assessed: 1. Study Arm (SA): obese LKD with BMI>30 who were enrolled into a nutritional program and 2. Control arm (CA): non-obese living donor candidates at the time of referral. Weight loss prior to surgery and afterwards, surgical complications, loss of kidney function (eGFR), and proteinuria (spot urine protein/spot urine creatinine ratio) after 6 months from donation were reviewed.

Results: Patient demographics - SA: 15African Americans (AA), 13 Hispanics (H), 7 White, 1 Other, 3 Unknown versus CA: 55 H; 49 Whites; 20 AA, 5 Other [figure1]. In the SA 24/40 had BMI>35 at time of referral and placed in nutritional program; 8/24 dropped BMI to less than 35 prior to surgery and 3/24 pending surgery now; 4/24 ruled out due to medical issues & (8/24) were non-compliant. Surgical complications 1/8: Parasthesia. After donation in SA, blood pressure remained stable, 2/8 gained weight kidney function at 6 months: 47% of obese donors had a decrease in eGFR at 6 months of 40% or greater. The mean decrease in eGFR was 33.9% in the study arm. In the control arm: 55H: Hispanics; 49 Whites; 20 AA; 5 Other. 15% had a decrease in eGFR at 6 months 40% or greater and the mean decrease in eGFR was 28.9.

Conclusions: Obesity in living donors needs careful analysis especially in minority populations since there is a trend to have a greater loss in kidney function after donor nephrectomy. Donation is possible but strict nutritional and guidelines and medical evaluation need to persist for the welfare of these patients long-term.

The Role of Renal Pharmacist in Prescribing Immunosuppressant Medication for Renal Transplant Patients to Improve Safety

Sobral Francisco, Preetham Boddana. Pharmacy Dept, Gloucestershire Hospitals NHS Foundation Trust, Gloucester, Gloucestershire, United Kingdom.

Background: This paper describes the safe and efficient repatriation of renal immunosuppressant prescribing from General Practitioners (GPs) to secondary care using hospital Pharmacist Independent Prescribers (PIPs).

Methods: From March 2015 the UK commissioner NHS England required all renal immunosuppressant medication, which was traditionally prescribed by GPs following nephrologists’ advice, to be prescribed by hospital renal prescribers. Gloucestershire hospitals NHS Foundation Trust decided to use Pharmacist Independent Prescribers to implement this change and provide the ongoing service using commercial Homecare Companies. All Patients were initially sent detailed information about the changes and asked to consent. On receipt of the completed consent form the PIP wrote the initial homecare prescription which was then processed by the pharmacy homecare team. Patients continued to be reviewed at regular intervals by their nephrologist. Details of these consultations were documented using a central renal database which included graft function, drug levels and communication with GPs. The Pharmacist Prescribers subsequently reviewed the renal database prior to generating ongoing homecare prescriptions and, when necessary, contacted the nephrologist for clarification and interventions.

Results: This service reconfiguration has resulted in safe and robust pathway. The use of Pharmacist Independent Prescribers has insured the whole pathway is efficient and closely monitored. Patients are satisfied with the new homecare service and clinicians value the pharmacists’ input. Pharmacist prescribers have made a number of interventions which have included patient compliance issues, changes to doses in response to serum drug levels and appropriate brand changes to improve cost effectiveness.

Conclusions: The use of Pharmacist Independent Prescribers to prescribe and manage the renal immunosuppressant homecare service at Gloucestershire Hospitals NHS Foundation Trust has been shown to be safe and efficient.

Tools for Adverse Events Prevention in a Hemodialysis Facility: A Local Experience

Cinthia Sobral Vieira, 1 Cassiana G. Prates, 2 1 Nephrology Service, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil; 2 Hospital Epidemiology and Manager Risks Service, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil.

Background: After the publication “To err is human” there has been a new approach to prevent risks in health system. According to the International Patient Safety Goals there are six steps to be followed like patient identification, proper communication, right surgery in the right person, right time, right dose, fall prevention, high alert medication and infection prevention. The goal is to show how a hemodialysis unit, for ambulatory and hospitalized patients leads with adverse event prevention.

Methods: This experience happens in a hemodialysis unit with 101 patients, 3 shifts of 4 hours. It is located in a general hospital in Porto Alegre, south Brazil.
Conclusions: Proteinuria and albuminuria were significantly elevated in UO infants who required surgery compared to normal term infants and those with non-surgical UUO. Although both were sensitive markers of renal injury, albuminuria was superior in predicting who required surgery compared to normal term infants and those with non-surgical UUO.

PUB573

High Prevalence of Glomerular Hyperfiltration in Obese Adolescents
Anitha Ezekiel, Jennifer Therese Potonia, Pedro Anis Rahnemaye, Samhar I. Al-Akash. Driscoll Children’s Hospital - Kidney Center; Corpus Christi, TX.

Background: Glomerular hyperfiltration (GHF) has been described in diabetic and obese (O) adults, and usually precedes proteinuria or clinical disease, and may indicate underlying renal damage and chronic kidney disease (CKD). GHF is poorly studied in adolescent children (AC). We hypothesized that GHF is present in AC and that GFR correlates with the BMI.

Methods: We queried the electronic medical records from 6/2010 to 12/2013 to include AC 12-21 years of age with at least one serum creatinine (SCr) and BMI in the same encounter, and excluded pts with CKD, HTN, DM, proteinuria, or renal transplant. Pts were separated into 2 groups; Control (C) - BMI < 30 and O - BMI ≥ 30 kg/m2. We used the original Schwartz formula (OSF) to calculate GFR as our lab uses the Jaffe method to normal serum albumin. Other investigations demonstrated raised lipid profiles but in keeping with nephrotic syndrome. A renal biopsy was performed in view of escalating protein and albumin creatinine ratios.

Results: Demographic data and results are shown in table 1.

Prevalence of GHF (GFR > 150)

- Male | 0% | 28% | 0.0001 (OR 6.2)
- Female | 0% | 28% | 0.0001 |

Conclusions: Using the OSF, we showed a higher prevalence of GHF in obese AC, and a showed that GFR correlated with BMI. Males have a greater risk of GHF. Due to the increased incidence of obesity in AC, special attention needs to be paid to renal function. In the absence of proteinuria or signs of clinical disease, GFR may be the earliest sign of renal disease, and should be assessed in obese AC. The choice of GFR estimation formula specifically in the obese has not been well established. This study provides preliminary data for a prospective trial for comparison of standard GFR measurement with existing GFR estimation formulas to allow the use of the most appropriate formula in obese pts.

PUB574

Familial Lecithin-Cholesterol Acyltransferase Deficiency Masquerading as Membranous Nephropathy in Childhood
Ania B. Koziej, Katrina Soderquest. Experimental Immunobiology, King’s College London, London, United Kingdom.

Background: Familial Lecithin-cholesterol acyltransferase deficiency (LCAT) deficiency is a rare autosomal recessive disorder of lipid metabolism characterised by severely reduced HDL concentrations and impaired esterification of cholesterol. It is characterised clinically by glomerulopathy and mild haemolytic anaemia presenting in adulthood leading to ESRD by the fourth decade of life through the deposition of abnormal lipoproteins in the renal stroma. Paediatric cases are rarely described.

Methods: 2 siblings aged 8 and 11 years presented with asymptomatic non-nephrotic range proteinuria detected on routine testing. There was no family history of renal disease, although parents were consanguineous. Initial screens revealed normal renal function and normal serum albumin. Other investigations demonstrated raised lipid profiles but in keeping with nephrotic syndrome. A renal biopsy was performed in view of escalating protein and albumin creatinine ratios.

Results: Renal biopsy initially demonstrated light microscopic features of membranous nephropathy. However, electron microscopy demonstrated inclusions that were not typical of the adult form of the disease but clearly lipid filled (Figure 1). Confirmation of the diagnosis was by demonstration of significantly reduced HDL-cholesterol, and detection of a novel LCAT gene missense mutation G54V as well as reduced LCAT enzyme activity on assay.

Conclusions: LCAT deficiency may present with mild symptomatic proteinuria in childhood. Although rare, it should be considered in a differential in paediatric membranous nephropathy. The diagnosis was made on characteristic EM appearances, genetics and reduced enzyme activity. A trial of enzyme replacement is planned. Interestingly, the older sibling has higher lipids yet the younger worse renal disease opening up new hypotheses for how LCAT deficiency might cause renal pathology.

PUB575

Umbilical Artery Histomorphometry: Linking the Intrauterine Environment and Nephrogenesis
Marissa J. Defreitas, Deepan Mathur, Wacharee Seerunyong, Shahnaz Duara, Salih Y. Yasin, Maria Matilde Rodriguez, Carolyn L. Abitbol. Pediatric Nephrology, Pediatric Pathology, Neanatolgy, Perinatology, Unv of Miami/Holtz Children’s Hospital, Miami, FL.

Background: An adverse intrauterine environment is linked to the developmental origins of aortic stiffness, nephron deficit, and adult onset cardiovascular and renal disease. We hypothesized that umbilical artery histomorphometry(UAH), a direct extension of the central vascular tree, would provide insight into nephrogenesis across gestational age (GA) groups.

Methods: From 156 newborns enrolled in the Gerber Infant Kidney Study, a subcohort of 32 had umbilical cord specimens evaluated (7 term(T-S), 15 preterm singletons(PT-S) and 10 preterm twins(PT-T)). The umbilical cord was sectioned, stained with Trichrome and digitalized.Muscular (MA) and collagenous areas(CA) of the umbilical arteries were measured in pixels using the ImageJ1.48q software and converted to mm2. The combined total kidney volume(TKV) was measured by ultrasound and factored by the infants’ ponderal indices and BSA's.

Results: TKV/PI of T-S (6.9±1.8) and PT-S (7.5±1.9) were similar; while TKV/PI of PT-T was significantly less than either of the singleton groups (4.5±0.8;p<0.001). Among PT-S, 64(40%) were from pre-eclamptic (PE) mothers. When paired by GA to other PT-T not from PE mothers, they demonstrated stunted TKV/BSA (93±28 versus 122±19mm2/m2;p=0.02). Among twin pairs, there was also a discordance in TKV/BSA (68±10 versus 81±15 mm2/m2;p=0.04). UAH demonstrated a positive correlation with increasing %MA and a negative correlation with increasing %CA.

Conclusions: Using the OSF, we showed a higher prevalence of GHF in obese AC, and a showed that GFR correlated with BMI. Males have a greater risk of GHF. Due to the increased incidence of obesity in AC, special attention needs to be paid to renal function. In the absence of proteinuria or signs of clinical disease, GFR may be the earliest sign of renal disease, and should be assessed in obese AC. The choice of GFR estimation formula specifically in the obese has not been well established. This study provides preliminary data for a prospective trial for comparison of standard GFR measurement with existing GFR estimation formulas to allow the use of the most appropriate formula in obese pts.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

1021A
Conclusions: UAH links an adverse and/or competitive intrauterine environment with nephroptogenesis independent of GA. An enhanced umbilical arterial muscle area reflects an increased renal mass while increased vascular collagen parallels decreased renal mass in discordant twins and singletons of PE mothers.

Insulin-Like Growth Factor/Growth Hormone and Insulin-Like Growth Factor Binding Proteins in Normal Heighted and Short Children with CKD

John D. Mahan,1 Rose M. Ayoob,1 Larry A. Greenbaum,2 Amina Al-Uziri,3 Frederick J. Kaskel,4 Susan L. Furth,4 Bradley Warady,1 Pediatrics, Nationwide Children’s/OSU, Columbus, OH; 2Pediatrics, Emory Univ, Atlanta, GA; 3Pediatrics, Oregon Health & Science Univ, Portland, OR; 4Pediatrics, Albert Einstein COM, New York, NY; 5Pediatrics, Univ of Pennsylvania, Philadelphia, PA; 6Pediatrics, Children’s Mercy Hospital, Kansas City, MO.

Background: Earlier reports indicated that children with chronic kidney disease (CKD) have ‘normal’ Growth Hormone (GH) and Insulin-Like Growth Factor-1 (IGF-1) levels, suggesting that intracellular resistance and increased IGF-1 Binding Proteins (BPs) account for the poor growth seen in 35% of these children. We explored key growth mediators in subjects with CKD enrolled in the Chronic Kidney Disease in Children (CKiD) study with either normal height or short stature to explore potential explanatory differences in this two subsets.

Methods: 232 children in CKiD (206 normal height: 26 short stature; none on GH Rx) were compared. Normal height children were matched by gender, age and GFR. Short stature = Height Standard Deviation Score (SDS) < -1.88. GH, IGF-1, and IGFBP-1 and -3 were determined by chemiluminescent and ELISA.

Results: Normal height CKD children had higher serum IGF-1/GH, higher IGF-1/IGF-1 BP1 and similar IGF-1/IGF-1 BP3 compared to short CKD children.

Background: An enhanced umbilical artery muscle area reflects an increased renal mass while increased vascular collagen parallels decreased renal mass in discordant twins and singletons of PE mothers.

Assessment of Cochlear Sensitivity of the Pediatric Chronic Kidney Disease and Hemodialysis Patients

Rahime Renda,1 Levent Renda,2 Omer Tark Selcuk,3 Antalya Research and Training Hospital Pediatric Nephrology; 2Antalya Research and Training Hospital Otorhinolaryngology Dept.

Background: Abnormalities in auditory system are frequent in patients with chronic renal disease and dialysis. This study was to throw light on the relationship between cochlear sensitivity and chronic kidney disease with or without hemodialysis.

Methods: Children aged 6-18 years were evaluated in three groups; 36 nondiabetic patients with chronic kidney disease, 16 end stage renal disease patients undergoing hemodialysis, and 30 age and sex-matched control subjects. Hearing outcomes were obtained by pure-tone audiometry and distortion product otoacoustic emissions measurements.

Results: No significant difference was found except in the both ears at 500 Hz frequencies between the study group and the control group. The signal/noise ratio levels and distortion product levels were significantly lower in the nondiabetic and dialytics group at all frequencies. Patients with normal hearing were found to have significantly lower signal/noise ratios and distortion product levels than those observed in the healthy controls.

Conclusions: These results showed lower cochlear functions in the nondiabetic group regardless of hearing loss than in the control group. Patients with chronic renal disease with or without hemodialysis should be monitored periodically even if the hearing thresholds seem to be within normal limits.

Funding: Government Support - Non-U.S.

Percutaneous Renal Biopsy at OPD Level

Byoung-Soo Choi,1 Yumi Choi,2 Jin-Soon Sub,1 1TheAll Medical Hub Kidney Center, MIRAE ING Research Inst, Seoul, Republic of Korea; 2Dept of Pediatrics, Gwangmyeong Sung-Ae Hospital, Gwangmyeong-si, Gyeonggi-do, Republic of Korea.

Background: Renal biopsy is a prerequisite procedure for the final diagnosis and to evaluate the treatment effect or to determine the prognosis, however due to serious complication of the procedure, should be done by nephrologist and has been performed at admission state.

Methods: Our center performed percutaneous renal biopsy 3,000 cases without major complications during last 30 years, when patients were admitted for 3days. During last 18 months, we performed percutaneous renal biopsy at OPD level under the ultrasound guide (LOGIQ E9).

Results: The youngest one is 1 year old male and the oldest was 64 years old. Mean age was 26 years old. Male to female ratio was 3:2 Mean glomerular numbers were 31. We used disposable kidney biopsy needle (TSK AECUT). We checked ultrasound 3 times after renal biopsy for checking AV fistula, hematoma formation during 6 hours hospital stay. Of the 100 case cases received follow up biopsies. Among 100 samples renal medulla was not detected. Two patients(2%) among 100 biopsies showed small(less than 1cm) hematomas. No AV fistula were detected. All patients went home within after renal biopsy without any problems. Renal biopsy results showed IgA(23%), Non-specific GN(21%), Diffuse mesangial proliferative GN(17%),JPSN (6.7%), MGN(5.6%), FSGS (5.6%).Others were Alport,Lupus nephritis,DM nephropathy,MPGN type I,Thin GBM nephropathy.

Conclusions: In conclusion, percutaneous renal biopsy under the ultrasound guide at OPD level with 6 hour ABR is safe and effective if performed at renal cortex level.

PUB579

Acute Lymphocytic Leukemia with Bilateral Renal Masses Masquerading as Nephroblastomatosis

Salim Aljabari,1 Poonam Thakore,2 Curtis W. Turner,3 Tetyana L. Vasylyeva.4 Pediatrics, Texas Tech Univ Health Sciences Center, Amarillo, TX.

Background: While leukemia has a wide spectrum of presenting features, relevant involvement at presentation of the disease is rarely seen. We are reporting a child with bilateral renal masses resembling nephroblastoma as the first and the only finding subsequently developing classic features of acute lymphocytic leukemia (ALL).

Methods: A 4 year old boy was presented with low grade fever and abdominal pain for few days. A complete blood count (CBC) and abdominal CT scan were done to rule out appendicitis. WBC of 1.8 K/UL, Hemoglobin of 13.3 g/dl, Platelets of 170 K/UL, neutrophils 22%.Lymphocyte of 68.9% and absolute neutrophil count of 1.8 K/UL. CT scan showed bilateral renal enlargement with multiple hypodense lesions in the cortical and subcortical regions. Blood urea nitrogen of 7 mg/dl and creatinine of 0.38 mg/dl. The patient was diagnosed with viral gastritis and sent home on supportive treatment. CT scan was later interpreted as nephroblastomatosis by pediatric radiologist as an incidental finding advised to follow up with the pediatric nephrologist. After 14 days he again had low grade fever with abdominal pain. CBC showed WBC of 3.4 K/UL, Hemoglobin of 11.1 g/dl, Platelets count of 21 K/UL, neutrophils 62 % and lymphocyte 38 %; absolute neutrophil count was 351 and ESR of 71 mm/hr. The pediatric oncology service was consulted for possible malignancy. Peripheral blood smear showed the presence of abundant immature lymphoid cells representing 90 % of the total white cells. Bone marrow aspirate and biopsy,flow cytometry and cytogenetic studies showed early B cell leukemia. Treatment was initiated following the guidelines of COG AALL0932. After one week of induction therapy, the CT scan showed a complete interval resolution of all renal hypodense lesions.

Conclusions: Renal involvement in leukemia is challenging to diagnose due to its variable presentation on imaging. On CT scan, it may present as enlargement of kidneys (unilateral or bilateral), or a low-attenuation focal parenchymal. These focal lesions can be difficult to distinguish from nephroblastomatosis which has a similar radiological picture on CT scan.

Modality of Treatment of Pediatric Patients with Diarrheal HUS in Acute Renal Failure Does Not Affect Long Term Outcome and Survival
Sonia Solomon, Julia W Tzeng, Pediatrics, Valley Children's Hospital, Madera, CA; Pediatrics, Univ of California, San Francisco - Fresno, Fresno, CA.

Background: Diarrheal HUS is a disease process usually resulting from infection by E. coli H7:O157 and leading to the development of microangiopathic hemolytic anemia, thrombocytopenia, and acute renal failure. Acute renal failure typically follows in five days from the onset of diarrhea, with the majority of the population requiring renal replacement therapy. Studies have demonstrated that these patients are at risk for long term renal insufficiency and end-stage renal disease. Indications to start dialysis and the mode of dialysis vary from institution to institution. There is no current study comparing which mode of dialysis, hemodialysis or peritoneal dialysis, has greater benefit and less complications. The aim of this study is to compare dialysis modalities and determine whether one modality will result in less complications and better outcomes.

Methods: This is single center, retrospective review. We studied a total of 102 patients from HUS starting in 2004. We compared patients with dialysis started on PD or HD. We compared the number of complications and the types of complications from each modality. Long term outcomes were measured by each patient’s CKD staging at least one year after diagnosis.

Results: No statistical significance was found between the mode of dialysis and associated complications (p=0.4). There was also no statistical significance between mode of dialysis and long term outcome (p=0.9). Complications of PD were catheter malfunction (p=0.05), peritonitis (p=0.5), and the need to switch to HD or CVVHDF (p=0.3). Complications of HD included central line infections (p=0.1). Conclusions: PD and HD are equally effective in treating patients with dHUS in renal failure and have comparable long term outcome and risks for complications. An important complication to consider for patients on PD is the potential need to switch to HD or CVVHDF; this exposes the patient to an additional surgical procedure that may result in further complications.

Self-Reported Health Care Transition Readiness Among Mexican Adolescents with Chronic or End-Stage Kidney Disease
Guillermo Cantu,1 Ana Catalina Alvarez-Elias,1 Saul Valverde,2 Maria E. Ferris,3 Mara Medeiros.2 1Univ Panamericana, Mexico, DF, Mexico; 2Univ of North Carolina at Chapel Hill, NC; 3Hospital Infantil de Mexico Federico Gomez, Mexico, DF, Mexico.

Background: 90% of pediatric patients with chronic disease live more than 20 years after being diagnosed. When pediatric patients are transferred to adult-focused health services, generally they do not have the skills and abilities to manage their disease. Adolescents tend to have poor adherence to treatment, and there is a period when there may be complications and increased morbidity-mortality. Performance on self-reported health care transition readiness (HCTR) needs to be assessed in patients with chronic or end-stage kidney disease. The aim of the study was to measure self-reported HCTR using the STARs (Self-management and Transition to Adulthood with Rx=Treatment) Questionnaire1, among adolescents in the Nephrology Service at Hospital Infantil de Mexico Federico Gomez.

Methods: The Spanish version of the STAR, Questionnaire was translated and back translated. Self-reported data collected from adolescents with chronic or end-stage kidney disease attending the outpatient nephrology department over a 9-month period. The 18-question tool diagnoses actions, knowledge, and skills on chronic disease self-management, medications adherence and ability to find new health providers. Age was divided at 16 years. Student’s T-tests were performed and p-values of < 0.05 were considered significant.

Results: We enrolled 68 adolescents (53% males) who had a mean age of 15.75 years (± 1.87). Patients who received hemodialysis in the past were 22 (34%). Females had significantly greater scores than males in the “action” category. Those who received hemodialysis in the past had greater knowledge about the disease (p=0.013).

Conclusions: The self-reported HCTR among Mexican adolescents with chronic or end-stage kidney disease differs by sex and treatment modality.

Italian Survey on Patients on Peritoneal Dialysis Treatment: ATENA
Alessandro Paparatti,1 Anna Maria Costanzo,5 Anna Pippa,3 Flavia Caputo,3 Cesare De Micheli,2 1Dell’Aquila, 2Hospital Infantil de Mexico Federico Gomez, Mexico, DF, Mexico; 3Univ Panamericana, Mexico, DF, Mexico; 4Univ of North Carolina at Chapel Hill, NC; 5Hospital Infantil de Mexico Federico Gomez, Mexico, DF, Mexico.

Background: In Italy, there are few epidemiological data concerning the clinical management of patients on Peritoneal Dialysis(PD) and the impact of PD on clinical outcomes. In Italy, the majority of patients on PD are females, compared to 52% of females in the U.S. The aim of this study was to evaluate the impact of PD on clinical outcomes and how to improve quality of life (QoL). Studies have demonstrated that patients on PD are at risk for long term renal insufficiency and end-stage renal disease. Indications to start dialysis differ by country. There is no current study comparing which mode of dialysis, hemodialysis or peritoneal dialysis, has greater benefit and less complications. The aim of this study is to compare the dialysis modalities and determine whether one modality will result in less complications and better outcomes.

Methods: This is a single center, retrospective review. We studied a total of 102 patients from HUS starting in 2004. We compared patients with dHUS started on PD or HD. We compared the number of complications and the types of complications from each modality. Long term outcomes were measured by each patient’s CKD staging at least one year after diagnosis.

Results: No statistical significance was found between the mode of dialysis and associated complications (p=0.4). There was also no statistical significance between mode of dialysis and long term outcome (p=0.9). Complications of PD were catheter malfunction (p=0.05), peritonitis (p=0.5), and the need to switch to HD or CVVHDF (p=0.3). Complications of HD included central line infections (p=0.1). Conclusions: PD and HD are equally effective in treating patients with dHUS in renal failure and have comparable long term outcome and risks for complications. An important complication to consider for patients on PD is the potential need to switch to HD or CVVHDF; this exposes the patient to an additional surgical procedure that may result in further complications.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author. 1023A
Conclusions: Our single-center experience demonstrated similar PD catheter survival rate and a better 2-year survival for catheters placed by peritoneoscopy. Our predominant use of the curvy PD catheters suggests no significant difference in outcome compared to the straight catheters.

**Improved Serum Phosphorus Control and Decreased Phosphate Binder Pill Burden Amongst African American Peritoneal Dialysis Patients Taking Sucroferric Oxyhydroxide**

Vidhya Parameswaran, Linda H. Ficociello, Daudy Mullon, Franklin W. Maddox, Robert J. Kossmann. Fresenius Medical Care North America, Waltham, MA.

**Background:** This study evaluated the real world effectiveness of sucroferric oxyhydroxide (SO) use among peritoneal dialysis (PD) patients (pts) who self-reported race as Black or African American (AA).

**Methods:** A retrospective database analysis was conducted on a cohort of AA PD pts who were prescribed SO as part of standard care at FMCNA clinics. Pts had 1 serum phosphorus (sP) measured while using SO and had been on sevelamer, calcium-based phosphate binders or had no phosphate binder specified prior to SO treatment. Differences in sP, pill burden (PB), serum calcium (Ca), transferrin, ferritin and intact parathyroid hormone (iPTH) were noted between baseline (BL; 3 months prior to SO) and follow-up (SO-TX; 3 months during SO).

**Results:** 117 AA PD pts (mean age=50 years, dialysis vintage=4.2 years) were included. At BL, 37% were on sevelamer, 31% on calcium-based phosphate binders, 2% on dual therapy and 31% had no phosphate binder specified. Figure shows increase in pts who have in-range sP (20% to 31.6%; 58% increase). Mean sP decreased from 6.55 to 6.38 mg/dl (p=0.06). A significant decrease in PB was observed (4.5 pills/day, p<0.001) between BL (8.8 pills) and SO-TX (4.3 pills). No significant differences were observed between BL and SO-TX for sCa (BL=9.1 mg/dl, SO-TX=9.1 mg/dl), ferritin (BL=861.9 ng/ml, SO-TX=870 ng/ml), TSATs (BL=44.7%, SO-TX=36.8%) and iPTH (BL=729.5 pg/ml, SO-TX=696.4 pg/ml).

**Distribution of serum phosphorus during baseline compared to sucroferric oxyhydroxide (SO)-treated follow-up among African American PD patients (N=117)**

**Conclusions:** In a cohort of African American peritoneal dialysis patients who were prescribed sucroferric oxyhydroxide as part of routine clinical care, there was a 58% increase in the number of patients with serum phosphorus levels in-range (p<0.006). Furthermore, there was a significant reduction in pill burden (4.5 fewer pills, p<0.001).

**Funding:** Pharmaceutical Company Support - Fresenius Medical Care North America

**PUB587**

**Peritoneal Dialysis for Management of Refractory Heart Failure**

**Background:** Refractory heart failure (RHF) is associated with significant morbidity and mortality. There is growing interest in the use of peritoneal dialysis (PD) for management of patients with RHF. In this study, we explored the currently available data on the safety and efficacy of PD in this setting.

**Methods:** A search of PubMed database using key words “peritoneal dialysis” and “refractory heart failure” from 1985 to 2015 was performed by two of the authors independently and found 763 articles, from which those including at least 20 patients who had initiated PD for cardiac indication were selected. Relevant data on efficacy and safety such as changes in the quality of life and cardiac function as well as the rate of hospitalization were extracted and compared.

**Results:** Seven studies (4 prospective and 3 retrospective) met the inclusion criteria with a total of 398 patients and a mean age of 70.4 years. PD was associated with improvement in functional status (1 to 2 NYHA class reductions) in 5 of the 7 studies (not reported in 2) as well as an increase in the ejection fraction in 6 studies. A variety of PD regimens were used that in general showed efficacy in removal of fluid as suggested by notable reduction in patients’ weight in 6 studies by up to 8.3 kg (unavailable in 1). It was also shown to significantly reduce the number of days of hospitalization for acute HF in 6 studies by up to 90%. Five studies reported increase in responsiveness to diuretics as well as perceived improvement in the quality of life. The PD-related complications were found to be minimal in 6 studies while one reported 0.75 episode/patient/year of peritonitis.

**Conclusions:** Currently available evidence suggests that PD is an efficacious option for management of patients with RHF that can result in significant improvement in their functional status, hospitalization rate, and the quality of life. Based on the findings of these studies PD is safe in this population and its related morbidity does not replace HF-
associated morbidity. Larger controlled trials are warranted to explore the potential impact of PD on the mortality of patients with RHF and to define those subgroups most likely to benefit from this therapy.

**PUB588**

**Procalcitonin: Is It a Useful Biomarker for Peritoneal Dialysis Peritonitis?**

Shishan Song, Hyeon-Choel Park, Jae Seok Kim, Jae Won Yang, Byoung Geun Han, Seung-Ok Choi. *Internal Medicine, Yonsei Wonju College of Medicine, Wonju, Korea.

**Background:** Peritonitis is a common complication in peritoneal dialysis (PD). Procalcitonin is a peptide hormone which has been used as a biomarker for the diagnosis of bacterial infection. We aimed to investigate the usefulness of procalcitonin in the patients with PD peritonitis.

**Methods:** This study included 33 episodes of peritonitis in 27 patients for follow-up period of 450 days. In addition, we collected samples of PD effluents from 7 PD patients without peritonitis to compare with those of peritonitis. We investigated clinical characteristics, serum and PD effluent levels of procalcitonin at the time of initial visit and discharge.

**Results:** The mean value of dialysis vintage of patients with peritonitis was 1774 days, incidence of total peritonitis for period of PD maintenance; 4.3 times, interval from symptom onset to visit; 13.6 hours, duration of intraperitoneal antibiotic treatment; 8.2 days, and interval from clinical improvement to recurrence; 80.7 days. Initial serum procalcitonin increased to 0.97 ng/mL with clinical improvement but not significantly (p=0.503), and the PD effluent procalcitonin also increased compared with in the subjects without peritonitis, but not significantly (0.07 ± 0.19 vs. 0.01 ± 0.01 ng/mL, p=0.503). The serum procalcitonin decreased to 0.33 ± 0.54 ng/mL with clinical improvement but not significantly (p=0.308), and the PD effluent procalcitonin also showed the decreased level of 0.03 ± 0.08 ng/mL but not the statistical significance (p=0.360). Pearson’s correlation analysis showed that the serum and PD effluent procalcitonin did not have relationships with existing inflammatory markers such as ESR, CRP. Lastly, procalcitonin could not predict recurrence and mortality of peritonitis.

**Conclusions:** Collectively, procalcitonin showed the tendencies corresponding to the clinical course of PD peritonitis, but not statistical significance. We believe that procalcitonin is not superior biomarker in PD peritonitis compared with other existing markers.

**Epidemiological Survey of Maintenance Peritoneal Dialysis in China**

Xiang-Mei Song, Xueying Cao, Delong Zhao, Guangyuan Cai. *Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases.

**Background:** Peritoneal dialysis (PD) is the most widely used method for maintenance renal replacement therapy in China. The objective of this study was to evaluate the epidemiological characteristics of PD patients in China, had ³1 serum phosphorus (sPhos) measured during SO, and the most recent PB switch from calcium-based binders (CaPB); either calcium acetate (n=95) or calcium carbonate (n=35) to SO.

**Methods:** All pts were prescribed SO as part of routine clinical practice at FMCNA clinics, had ≥1 serum phosphorus (sPhos) measured during SO, and the most recent PB used was a CaPB. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), % transferrin saturation (TSAT), ferritin (FER), and PB pills per day were assessed at baseline and follow-up during SO treatment (follow-up). There was significant change in sCa (8.9 to 8.95 mg/dl, p=0.05) and iPTH (519.2 to 544.4 mg/ml, p=0.04) was observed. There was minimal increase in sFER (708.5 to 788.5 mg/ml, p=0.008, but not TSAT (35.8 to 35.5%, p=0.8) when pts treated with IV iron were included. There was minimal increase in FER (733.6 to 735.0 mg/ml, p=0.98) or TSAT (38.0 to 39.1%, p=0.61) in pts not administered IV iron (n=45).

**Conclusion:** A cohort of PD patients who switch from calcium-based binders to suroferroxyhydroxide as part of regular clinical practice, there was a 78% increase in patients achieving in-range serum phosphorus (p=0.003). Additionally, phosphate binder pill burden was lessened from 3.7 to 3.6 pills per day (3.7 fewer pills, p=0.001).

**PUB590**

**Peritoneal Dialysis Patients Who Switch from Calcium-Based Binders to Suroferoxyhydroxide as Part of Routine Clinical Practice: A Retrospective Database Study**

Linda H. Ficociello, Vidhya Parameswaran, Phaneth Keo, Claudia Mutton, Franklin W. Maddux, Robert J. Kossmann. *Fresenius Medical Care North America (FMCNA), Waltham, MA.

**Background:** A retrospective database study on the real-world effectiveness of suroferoxyhydroxide (SO), an iron-based phosphate binder (PB), was conducted in a cohort of adult peritoneal dialysis (PD) patients (pts). This analysis examines pts who switched from a calcium-based phosphate binder (CaPB); either calcium acetate (n=95) or calcium carbonate (n=35) to SO.

**Methods:** All pts were prescribed SO as part of routine clinical practice at FMCNA clinics, had ≥1 serum phosphorus (sPhos) measured during SO, and the most recent PB used was a CaPB. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), % transferrin saturation (TSAT), ferritin (FER), and PB pills per day were assessed at baseline and follow-up during SO treatment (Figure). There were significant reductions in sPhos (7.1 to 6.8 mg/dl, p=0.004) and PB pills per day (7.4 to 3.6 pills, p<0.001). Minimal change in sCa (8.9 to 8.95 mg/dl, p=0.5) and iPTH (519.2 to 544.4 mg/ml, p=0.04) was observed. There was significant change in FER (708.5 to 788.5 mg/ml, p=0.008, but not TSAT (35.8 to 35.5%, p=0.8) when pts treated with IV iron were included. There was minimal increase in FER (733.6 to 735.0 mg/ml, p=0.98) or TSAT (38.0 to 39.1%, p=0.61) in pts not administered IV iron (n=45).

**Conclusion:** A cohort of PD patients who switch from calcium-based binders to suroferoxyhydroxide as part of regular clinical practice, there was a 78% increase in patients achieving in-range serum phosphorus (p=0.003). Additionally, phosphate binder pill burden was lessened from 3.7 to 3.6 pills per day (3.7 fewer pills, p=0.001).

**Effects of Chlorhexidine-Impregnated Patches on Catheter Exit Site and Tunnel Infections in Peritoneal Dialysis Patients**

Chinki Kawabata, General Internal Medicine, Japanese Red Cross Kamamoto Hospital, Kamamoto, Japan.

**Background:** Exit-site infections and tunnel infections are major causes of catheter loss in peritoneal dialysis (PD) patients. We studied the effects of chlorhexidine-impregnated patches (Biopatch), which are used as central-line dressings or drain site dressings, on PD catheter exit site infection and tunnel infections.

**Methods:** A retrospective review was conducted of 45 patients whose PD catheter exit site was made between January 2007 and December 2014. We compared acute exit site infections, chronic exit site infections, and tunnel infections of the two groups, (the Biopatch Group and the Non-Biopatch Group), 6 months after the exit site was created.

**Results:** The Biopatch was used until the exit site had healed perfectly. The mean time of using the Biopatch was 63±26 days. The two groups had no significant differences in age [49.4±12.0 years vs 52.3±16.3 years], diabetes mellitus co-morbidity or pattern of peritoneal dialysis. There were no statistical differences in acute exit site infections [15.4% vs 6.1% (p=0.27)], chronic exit site infections [0% vs 9.1% (p=0.28)] or tunnel infections [15.4% vs 15.2% (p=0.901)] during the 6 months.

**Conclusion:** Using the Biopatch until the exit site has healed perfectly does not reduce either exit site infections or tunnel infections.
The UK Peritoneal Dialysis Catheter Study (UK Cath): An Ancillary Study to the Peritoneal Dialysis Outcomes and Practice Patterns Study

Martin F. Wilkie,1 Simon J. Davies,2 Mark Lombie,3 Francesca Tentori,4 Jeffrey Perl1,3 1Sheffield Kidney Inst, Sheffield Teaching Hospitals NHS FT, Sheffield, United Kingdom; 2Keele Univ, Keele, United Kingdom; 3Arbor Research Collaborative for Health, Ann Arbor, MI; 4St. Michael’s Hospital, Toronto, ON, Canada.

Background: Delivering high quality peritoneal dialysis (PD) access placement and outcomes is limited by lack of standardization of PD access definitions and events, variable reporting of outcomes, and a paucity of robust evidence regarding optimal PD catheter insertion pathways. The UK Renal Registry PD access audit (2013) demonstrated 82% catheter survival at 1 year, with considerable variation between centres. Moreover, catheter function at 13 months was poorer for a medical (percutaneous) compared to a surgical (open surgical) insertion pathway.

Methods: UK-Cath, a multi-centre prospective cohort study (1350 patients, 45 dialysis centres, 18 month recruitment window) will assess the outcomes associated with different pathways of catheter insertion, dialysis unit-level policy associated with pathway use, and patient-level factors (e.g. case-mix, urgent start). Health economic benefits of these pathways will be determined using the cohort data, enriched by additional information obtained from more long-term follow-up study in a subset of patients using Hospital Episode Summary (HES) data linkage. The study has received funding from the UK NIHR Research for Patient Benefit Programme, NIHR PB-PG-0613-31026. A subset of study 20 centres will contribute to International Peritoneal Dialysis Outcomes & Practice Patterns Study (PDOPPS) with the primary outcome of understanding variations in PD technique failure.

Results: We will present information on study design, instrument development, governance mechanisms, and recruitment plan. We will discuss the impact of patient engagement on study design.

Conclusions: The UK Peritoneal Dialysis Catheter Study will inform dialysis units’ decision to either focus their efforts on improving a single surgical pathway or to practise a mixture of surgical and medical insertions, with the ultimate goal to improve catheter survival, patient experience and optimise health economic efficiency.

Funding: Government Support - Non-U.S.

Preparedness for Telemedicine in Outpatient Peritoneal Dialysis

Background: Peritoneal dialysis (PD) is generally performed daily by patients at home, where questions may arise. Telemedicine has the potential to improve the delivery of healthcare services and outcomes for PD patients. We studied the preparedness of a PD clinic run by a large dialysis organization (LDO) serving an urban under-resourced population.

Methods: Adult PD patients cared for by the clinic were asked about their interest and ability to use VSEE® (HIPPA-compliant tool for video calls) to remotely manage clinical concerns about PD. We compared patient characteristics between interested and non-interested groups. We also assessed the clinic’s ability to implement VSEE®.

Results: Initial barriers encountered were with the LDO. These included a firewall that prevented video products from being loaded onto clinic computers, consent issues, concerns regarding unequal care potentially being provided to patients with and without internet access, and lack of video equipment for on-call nurses. All of these barriers were overcome. We then assessed interest in 56 patients. Their age (mean/standard deviation) was 54.3 ± 15.8 years, 49% were male, 36% were Hispanic and 24% had <12 years of education. We found that 28% of patients were interested in telemedicine (≥ 75) and 35% not interested (≤ 69). These patients were interested in using telemedicine (≥ 75) and 35% not interested (≤ 69). These patients were interested in using telemedicine (≥ 75) and 35% not interested (≤ 69).

Conclusions: Multiple barriers to delivering telemedicine to PD patients exist, both on the clinic and patient side. 61% of patients were telemedicine-ready. Future evaluations will determine the impact on clinically significant outcome, patient satisfaction, and clinic workflow in this population.

When to Remove the Peritoneal Dialysis (PD) Catheter After Renal Transplantation? (RT)

Saul Enrique Pampu,1 Maite Rivera,2 Victor Burguera,3 Fernando Caravaca-Fontan,4 Estefania Yerovi,5 Nuria Rodriguez mendioila,6 Sara Jimenez alvaro,7 Cristina Galeano,8 Fernando Liano.1 1Nephrology, Hospital Univ Ramon y Cajal, Madrid, Spain; 2Urology, Hospital Univ Ramon y Cajal, Madrid, Spain.

Background: There seems to be consensus that the time of removal of the peritoneal catheter after RT may be delayed until renal function and the patient is stabilized, but there are few publications about this.

Methods: We analyzed retrospectively patients on Peritoneal Dialysis Unit (PD) who have received a RT between May 1995 and March 2015 gathering medical history data relating to the peritoneal catheter removal and complications.

Results: 108 patients transplanted from PD, 32 women/76 men with a mean age at the time of transplantation (58-80) +/- 13 years were analyzed. 65 patients (59%) have received RT of living donor and 106 of cadaver. The catheter used in all was a straight Tenckhoff with two cuffs. If renal therapy substitution was needed posttransplantation all patients were treated with hemodialysis. The catheter was removed during surgery in nine patients (8%) due to a tunnel infection by Staphylococcus aureus or Pseudomonas aeruginosa. The withdrawal was delayed in 91 patients (84%) and 8 has not yet been removed. The average withdrawal time was 4.1 +/- 2.7 months. The indication of withdrawn was: stable renal function in 85 (93%), stable pancreatic and renal function in 4 (4%), and exit site infection in 2 (2%). The complication rate at the time of withdrawal was 2.1 [mg/dl +/- 1.8]. 15 (18%) patients suffered complications before withdrawal: 13 exit site infection, one peritonitis associated with urinary fistula and one spontaneous peritonitis.

Conclusions: In our experience the removal of the peritoneal catheter may be delayed until renal graft function were stabilize since the rate of complication is low compared with another studies.

Funding: Other NIH Support - Spanish Public Health Service

Clinical Outcomes by Differences in Therapy Among Peritoneal Dialysis Patients

Hironori Nakamura, AnaYana Mariko, Yasushi Makino, Masaki Nagasawa. Dept of Nephrology, Shinonoi General Hospital, Nagano, Japan.

Background: Studies evaluating the outcomes of peritoneal dialysis (PD) technique and patient survival, including those among patients who switch from PD to hemodialysis (HD), are scarce.

Methods: This retrospective study screened 120 patients in whom PD was initiated between January 1998 and December 2012 at our hospital. Of these, patients who were initiated during a time when PD had not been implemented were excluded. A total of 61 patients (61%) who had not follow-up data were excluded. Fifty-two patients (age, mean ± SD: 69.2 ± 12.6 years) were included to investigate the time of survival based on PD technique and overall survival, including those patients who switched to HD, and to evaluate the correlation between survival time and pharmacotherapy at the initiation of PD.

Results: Time (in months) on PD, HD, and overall survival were 34.3 ± 30.0, 18.5 ± 43.4, and 52.6 ± 53.2, respectively. Comparison between the APD (n = 20) and non-APD patients (n = 28) showed that time on PD was 45.3 ± 34.4 vs. 31.3 ± 26.0 months, time on HD was 39.0 ± 40.6 (n = 8) vs. 91.8 ± 72.5 (n = 8) months, and overall survival time was 69.0 ± 49.9 vs. 54.7 ± 55.4 months, respectively. Comparison between groups with (n = 41) and without use of icodextrin (n = 7) showed time on PD was 10.8 ± 6.0 vs. 41.4 ± 30.1 months, time on HD was 49.6 ± 45.0 (n = 3) vs. 62.9 ± 65.3 (n = 13) months, and the survival time was 32.1 ± 41.7 vs. 61.6 ± 53.6 months. When analyzed by age groups of 60, 61–70, 71–80, and >81 years: time on PD (months): 47.2 ± 38.4 (n = 14), 45.2 ± 23.4 (n = 15), 19.8 ± 27.0 (n = 10), and 21.2 ± 19.2 (n = 13), respectively. Time on HD was 22.8 ± 44.2 (n = 14), 14.6 ± 36.3 (n = 5), 8.7 ± 28.2 (n = 1), 26.3 ± 60.1 (n = 4), respectively; and survival time was 70.1 ± 52.8, 59.2 ± 41.9, 28.5 ± 39.7, and 46.7 ± 67.2 months.

Conclusions: The time on dialysis and survival time may be underestimated because of the exclusion of patients who are currently on dialysis. Compared with non-APD patients, APD patients had longer time on PD and overall survival time. Patients who needed icodextrin when commencing PD had shorter time on PD and overall survival time.

Combined Markers of Protein-Energy Wasting and Inflammation Predict Clinical Outcomes in Incident Peritoneal Dialysis Patients

Chun Ho Kim,1 Jung Tae Park,2 Seung Hyeok Han,3 Tae-Hyun Yoo,1 Shin-Wook Kang. 1Internal Medicine, Catholic Kwandong University College of Medicine, Incheon, Korea; 2Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea.

Background: Protein-energy wasting (PEW) and chronic inflammation are not only common but are known as predictors of adverse clinical outcomes in end stage renal disease (ESRD) patients. Whether the combined values of serum albumin, high sensitivity C-reactive protein (hs-CRP), and body mass index (BMI) have an additive impact on clinical outcomes compared to each variable by itself in incident peritoneal dialysis (PD) patients was evaluated.

Methods: A prospective cohort of 565 incident PD patients from the Clinical Research Center for ESRD in Korea was selected. Patients were divided into two groups based on the baseline levels of albumin (≤ and >3.8 g/dL), hs-CRP (≤ and >0.45 mg/dL), and BMI (≤ and >23 kg/m²). Primary outcome was the composite of all-cause mortality and unplanned hospitalization.

Results: The mean age was 51.4 years and 60.0% were male. During a median follow-up duration of 27 months, 50 patients (8.8%) died and unplanned hospitalization events occurred in 123 patients (21.8%). Univariate analysis revealed an increase in primary outcome risk with lower albumin and elevated hs-CRP compared to higher albumin and lower hs-CRP, respectively. A similar tendency was observed with lower BMI and primary outcome, although without statistical significance. Regarding the combination of these factors, Cox proportional hazards model revealed that patients with any two risk factors and all three risk factors exhibited significantly higher hazard ratios for primary outcome compared to patients without any single risk factor. The combination of these factors retained a significantly higher HR for predicting primary outcome, even after adjusting for other confounders.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusions: The combination of serum albumin, hs-CRP, and BMI at the time of PD commencement was a significant independent risk factor for the composite outcome of all-cause death and unplanned hospitalization in incident PD patients.

Single Center Experience with a Peritoneal Dialysis Cycler with Advanced Patient Interactive Screen: Impact on Patient Training

Lili Chan, Ma shelda Cabus-fojas, Marica A. Duffoo, Catherine Firancak, James A. Sloord, Jaime Uribarri. 1 Mount Sinai; 2 Baxter.

Background: Learning proper device use and clinical concepts of care must be internalized by patients to successfully perform PD at home. With increasingly diverse patients going on PD and increasing adoption of urgent start PD, there is a need for simpler devices. Enhancing the learning environment with methods including visual, graphical and voice will improve the educational experience leaving the patient with better understanding of the procedure.

Methods: Automated PD training was undertaken at a university based home dialysis program using a novel APD device (AMIA). 5 patients were trained on the device in a 1:1 nurse to patient ratio. The cycler provided on screen instructions using a touch screen interface with voice guidance, text instructions and animation. Each patient was trained according to standardized outlines and sequential training progression from CAPD to APD techniques. Training included RN demonstration followed by patient direct interaction with the device. Instructions were displayed on a touch screen. The step by step instructions and graphical cues. Patient training completion required consistency of error free setup.

5 patients aged 30-68 yrs (mean 47), 80% female with a minimum of HS education completed training. Device training ranged from 2-3 days for urgent start patients and 4-5 days for native start patients.

Conclusions: From our experience, training times were similar or reduced using the AMIA cycler and allowed the ability to efficiently train urgent start patients. Observed advantages of the new cycler included: 1) less need for memorization 2) distinction of a beginner vs advanced mode 3) online alarm troubleshooting 4) presence of an air detector in the device. Instruction was displayed on a touch screen. The step by step instructions and graphical cues. Patient training completion required consistency of error free setup.

PUB600

Body Composition and Cardiovascular Outcomes Using Continuous Automated Peritoneal Dialysis – A Prospective Cohort Study

Carlos Alberto Garza, Gabriela Leal, Bernardo Moguel. Dept of Nephrology, National Inst of Cardiology, Mexico City, Federal District, Mexico.

Background: Fluid overload (FO) due to compliance in Continuous Ambulatory Peritoneal Dialysis (CAPD) is common. Efforts to achieve dry weight and avoid cardiovascular outcomes (CO) are lessen from inaccurate body composition (BC) estimations despite best clinical assessment.

Methods: We’ll follow BC, multiple frequency bioelectrical impedance (InBody SI0, InBody Co.) standard laboratories and CO, in all new patients to continuous Automated Peritoneal Dialysis (APD) previously in a CAPD. Measurements at baseline (CAPD), 1 month and every visit to the dialysis clinic thereafter (APD) for a 5 year period.

Results: These are the first data of BODY cohort study. Initial 10 subjects are described, men and 6 women, median age 27 years (17-46), height 159.5cm (146-166), baseline and first follow up variables are in Table 1. Wilcoxon rank test for related samples was performed. We found that PD modality switch to APD, at 1 month, reflected a body composition transition with statistical significance (P<0.05), within the EBW/TBW ratio at expense of trunk compartment. Most likely from improved dialysis adherence

**“not statistically significant**
Conclusions: We consider that APD, on the ground of increased, uninterrupted and rigorously performed therapy, is a appropriate therapy to optimize F0 and aim for dry weight in PD. Further recruitment of patients and follow up of the BODY Cohort study is expected to confirm this hypothesis.

The Changes in Bicarbonate Level and Ionized Ca/ Corrected Ca Ratio of Patients Receiving Peritoneal Dialysis Using Bicarbonate/Lactate-Buffered Solution

Emi Kimoto, Nanae Matsuoe, Masamitsu Morishita, Mami Nakamura, Yukio Maruyama, Yasuyuki Nakada, Masatsugu Nakao, Yudo Tamio, Ichiro Ohkido, Hiroyasu Yamamoto, Keitaro Yokoyama, Takashi Yokoy. Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan.

Background: Recently, PD solution which contains 25mEq/L bicarbonate and 10mEq/L lactate (Bicarbonate/Lactate-buffered peritoneal dialysis solution; B/L solution) is developed in Japan. Because of high concentration of lactate (40mEq/L) of conventional peritoneal dialysis (PD) solution, patients have generally higher serum bicarbonate level than those of patients receiving hemodialysis (HD). The new B/L solution is expected not only its biocompatibility but also improving excess correction of acidosis. Under the metabolic alkalosis environment, we reported that PD patients have lower levels of ionized Ca (iCa) at the same corrected Ca (cCa) levels. Thus, we hypothesized that iCa / cCa ratio increased after switching PD solution from Lactate-buffered to B/L solution.

Methods: We recruited 28 patients (55 ± 13 years, male 82%, PD duration 42 ± 21 months) who switched from Lactate-buffered to B/L solution, and investigated changes in serum bicarbonate, iCa, and cCa levels.

Results: After switching solution, serum bicarbonate decreased (26.7 ± 3.2 vs 24.8 ± 2.5, P<0.01), and cCa did not change (9.3 ± 0.5 vs 9.3 ± 0.5, P=0.63). Neither iCa nor iCa/cCa ratio increased significantly (1.12 ± 0.09 vs 1.11 ± 0.09, P=0.48; 0.12 ± 0.007 vs 0.19 ± 0.0006, P=0.54, respectively).

Conclusions: Conversion to B/L solution from lactate solution was associated with lower serum bicarbonate. Unfortunately, iCa did not change. Further investigations are needed to confirm the utility of the monitoring of iCa for the management of chronic kidney disease - mineral and bone disorder (CKD-MBD) in PD patients.

PUB602

Road to Success: One Academic Medical Center’s Experience Building a Peritoneal Dialysis Clinic

Yazan M. Ali, William A. Schlueter, Erwin E. Morales, Maria A. Gavino, Shubhada N. Ahya, Robin E. Watson. Nephrology, Northwestern Memorial Hospital, Chicago, IL.

Background: Peritoneal Dialysis (PD) is an option for renal replacement therapy. The US Renal Data System 2012 Annual Report states that the annual per-patient HD cost is approximately $87,500 whereas for PD it is $66,750. In addition, studies have demonstrated that some aspects of quality of life are improved in PD patients compared with HD patients. Despite this, PD is underutilized in the US. Northwestern Medicine’s PD Program was initiated in 01/2014 with 4 nephrologists and 10 patients who transferred from a neighboring PD Unit. From 02/2014 to 04/2015, Northwestern’s Peritoneal Dialysis Clinic grew to 50 peritoneal dialysis patients.

Methods: We included all patients who started on PD (or transferred to PD) in PD Clinic between the periods of 2/14 and 4/15. Patients excluded from this analysis stopped PD within this period for the following reasons: switched to HD, expired, recovered kidney function, or underwent transplantation.

Results of dialysate to plasma concentration ratios for creatinine (D/P Cr) and sodium (D/P Na), and dialysate to initial glucose concentration (D/D0 glucose) at the end of each test were compared by analysis of variance (ANOVA), Pearson correlation and Bland-Altman test.

Results: Whereas D/P Cr was not significantly different between PET and mod-PET (p=0.746) there were significant differences between mini-PET and both PET (p=0.001) and mod-PET (p=0.001). D/P Cr for PET correlated with D/P Cr for mod-PET (r=0.387; p=0.009) but not with D/P Cr for mini-PET (r=0.088; p=0.241). Bland-Altman test showed no significant bias of D/P Cr for PET vs mod-PET (-0.029; p=0.201) but a systematic difference (0.206; p<0.001) of D/P Cr for PET vs mini-PET. Whereas measurements of D/D0 glucose and D/P Na were in general not comparable nor significantly correlated, ultrafiltration during PET and mini-PET were weakly correlated (r=0.260; p=0.009).

Conclusions: These results confirm that characterization of transport status based on D/P Cr may not necessarily differ between conventional PET and mod-PET.

PUB604

Low Level of Albumin Is a Risk Factor for Short-Term Mortality of PD Patients

Kenji Harada. Kokura Memorial Hospital; Kokura Memorial Hospital.

Background: Mortality of HD(hemodialysis) patients are reported, but few reports about PD(peritoneal dialysis) patients. This study aims to investigate clinical features of PD patients, their prognostic risk factors, and to establish a prognostic model for predicting their short-term mortality(1-2 years).

Methods: We investigated the mortality about PD patients(n=269, age:65 years old:13.7, male/female 173/96, PD vintage within 2 years, DM:121), and the influence of several parameters from 2009 to 2012. The dead and the transferred HD were excluded within 90 days. Finally 241 patients are remained. The survival rates for one year and two years were 91 % and 72 %. Infection was the most causes of death(53%). We investigated the between death and several parameters(age, sex, blood pressure, albumin, hemoglobin, Ca, P, whole PTH, TC) by univariate analysis with JMP12, SAS. Those physical and laboratory data are measured at one month after PD started. Age and level of albumin were correlated with death. We hypothesized that low albuminuria and malnutrition influenced the rate of death. We divided three categories, from group A(albumin>3.3, n=82) and group B(2.8<Albumin<3.3, n=89), group C(albumin<2.7, n=73). Cox proportional hazards regression model was used to analyse prognostic risk factors and establish prognostic model.
Results: There were significant differences between group B and A (Hazard Ratio: 2.611, p = 0.016, 95%CI: 1.232-6.009) group B and C (Hazard Ratio: 6.031, p = 0.001, 95%CI: 2.975-13.53), group C and A (Hazard Ratio:2.309, p =0.0029, 95%CI: 1.33-4.09). In addition these groups were analysed by adjustment factor such as age, sex, blood pressure, hemoglobin, Ca, P, whole PTH, TC with multivariable analysis. The results proved that there were tended to be correlation between group B and A (Hazard Ratio: 1.963, p = 0.09, 95%CI:0.901-4.61). There were significant differences between group B and C (Hazard Ratio: 4.00, p = 0.003, 95%CI:1.866-9.35), group C and A (Hazard Ratio: 2.037, p = 0.0029, 95%CI:1.165-3.63).

Conclusions: Low level of albumin increases the mortality of PD patients gradually. Therefore we may decrease mortality of PD patients by improving nutritional condition and infection control when PD patients are introduced.

PUB605

The Effect of Neutral pH versus Conventional Peritoneal Dialysis Solutions on Peritoneal Permeability Atushi Ueda, Kei Nagaï, Toshiki Uusi, Joichi Usui, Kunihito Yamagata, Chie Saito. Univ of Tsukuba, Tsukuba, Japan.

Background: Biocompatible peritoneal dialysis (PD) solutions have been anticipated to reduce oxidative stress compared to conventional PD solutions; however, previous reports suggested peritoneal permeability have not been changed. This study was undertaken to investigate the peritoneal transport status from PD initiation, using biocompatible or conventional PD solutions.

Methods: We employed retrospectively 101 patients who started PD and divided into three groups. Acid group was consisted of 76 patients who used only conventional low pH solutions, and neutral pH group was consisted of 19 patients who used only biocompatible neutral pH solutions during the subsequent two years. The rest of six patients used low pH solutions at the initial phase of PD, then switched to neutral pH solutions. The ratios of dialysate to plasma creatinine concentration at 4 hour (D/Pcre) in peritoneal equilibration test were measured at every year. We evaluated D/Pcre levels at the initiation and two years after between acid and neutral pH groups, and also the D/Pcre movements before and after switching PD solutions of the six patients.

Results: There was no significant difference on the D/Pcre values between at the start and two years after in the acid and neutral pH groups respectively. D/Pcre change between at the start and two years after in the acid group was not significant different compared to that of the neutral pH group. However, D/Pcre declined significantly one year after switching PD solutions from acid to neutral pH.

Conclusions: It was not observed obvious beneficial effects of neutral pH solutions on peritoneal permeability within two years PD duration. However, the transient effect in decreasing peritoneal permeability was found, and suggested that biocompatible solutions may preserve peritoneal functions compared to conventional solutions in a long time period.

PUB606

Predictive Power of Serum Cystatin C Assessing Residual Renal Function in Patients on Peritoneal Dialysis: Hong Min Park, Sung Heon Song, Eun Young Seong, Harin Rhee, I hm Soo Kwak, Il Young Kim, Dong Won Lee, Soo Bong Lee, Woo Jin Jung, Su Min Park, Min Jung Kim, Jo Hui Kim. Internal Medicine, Pusan National Univ Hospital, Busan, Republic of Korea; Internal Medicine, Pusan National Univ Yangsan Hospital, Yangsan, Republic of Korea.

Background: Residual renal function (RRF) is of considerable importance for patient survival on peritoneal dialysis. In clinical practice, the RRF is usually measured by assessing the urine concentrations of urea and creatinine and total urine output and the process is cumbersome and time consuming. Cystatin C has proposed to be used in place by assessing the urine concentrations of urea and creatinine and total urine output and the process is cumbersome and time consuming. Cystatin C has proposed to be used in place of RRF measurement. This study aims to investigate the predictive power of cystatin C in peritoneal dialysis patients.

Methods: This study included 54 patients on peritoneal dialysis who had evaluated RRF, serum cystatin C and serum creatinine. RRF was measured using the 24-hour urea-creatinine clearance method and cystatin C based glomerular filtration rate (eGFRcysC) was estimated using the Hoek’s formula. RRF and cystatin C were followed up for 6 months at the start and two years after in the acid and neutral pH groups respectively. D/Pcre change between at the start and two years after in the acid group was not significant different compared to that of the neutral pH group. However, D/Pcre declined significantly one year after switching PD solutions from acid to neutral pH.

Conclusions: Cystatin C was correlated with the rate of RRF decline (γ = 0.616, p <0.01) during follow up. The overall small loss of RRF group had a higher level of serum cystatin C at the point of dialysis initiation (p = 0.017).

Conclusions: Serum cystatin C level might be convenient parameter for estimating the RRF and serum cystatin C at the point of dialysis initiation might be a predictive marker of preservation of RRF. Further studies about the cystatin C based equations are required to replace creatinine/urea clearance measured RRF.

PUB607

Peritoneal Dialysis: A Decade Experience at a Reference Centre in Brazil Patrícia O. Costa, Carla M.V. Melo, Flavia A. Nobrega, Jordiano P. Oliveira, Jandson P. Oliveira, Kleyton Andrade Bastos, Dept of Medicine, Federal Univ of Sergipe, Aracaju, Sergipe, Brazil.

Background: Peritoneal Dialysis (PD) is underutilized in most countries. The Brazilian prevalence is around 9%. This study aims to describe the ten years experience on PD in a dialysis center in Northeast of Brazil (Aracaju-Sergipe). Unlike other national programs, negative selection for DP is not an attribute of this dialysis unit.

Methods: Retrospective cohort study that evaluated the sociodemographic and clinical profiles, comorbidities, peritonitis, hospitalizations and death causes of 565 patients who remained in PD for at least 30 days from 01/01/2003 to 12/31/2012.

Results: Patients were mostly men (53%), living outside Sergipe’s capital (56%), had a mean age of 54 ± 19 years old when started on dialysis, were illiterate or had less than 4 school years (62%) and had a family income less than 5 national minimum wages per month (88%). The etiology of nephropathy was identified in 54% of cases, diabetic nephropathy (46%) and hypertensive nephrosclerosis (22%) were the most prevalent. Hypertension was the most prevalent comorbidity (77%). The prevalence of peritonitis (22%) was higher among patients, mainly as an emergency (58%), and only 9% of patients had undergone predialysis care for at least six months. Patients remained in PD by an average of 710.5 ± 714.2 days, and 61% of them also underwent hemodialysis (HD) at some point during their dialysis treatment. 676 peritoneal catheters were implanted (1.19 patient), 75% by trocar, by nephrologist, mostly Tenchoff (38%). The main cause of dropout was infections complications related to therapy (17%). The peritonitis index was 1 episode every 27.03 months, and S. aureus was the most prevalent etiological agent (22%). There were 1045 hospitalizations during follow up, most frequently due to infections (48%). The cause of death was identified in 64% of cases, mostly from cardiovascular diseases (50%).

Conclusions: In this study, patients had predominantly low socioeconomic status and did not have access to predialysis treatment, however, peritonitis rates and catheter complications are similar to those reported in other international series. HD and PD are shown as complementary techniques.

PUB608

Implementation of Clinical Practice Guidelines on Antimicrobial Prophylaxis in Peritoneal Dialysis Patients Denise Campbell, Fiona Brown, John F. Collins, Jonathan C. Craig, Martin P. Gallagher, David W. Johnson, Geoffrey S. Kirkland, Subramanian K. Kumar, Wai Hon Lim, Dwarakanathan Ranganathan, Walaa W. Saweire, Germaine Wong, David Mudge. School of Public Health, Univ of Sydney, Sydney, New South Wales, Australia; Nephrology, Monash Univ, Clayton, Victoria, Australia; Renal Medicine, Auckland City Hospital, Auckland, New Zealand; Renal and Metabolic Div, George Inst for Global Health, Sydney, New South Wales, Australia; Nephrology, Princess Alexandra Hospital, Woolloongabba, Queensland, Australia; Nephrology, Royal Hobart Hospital, Hobart, Tasmania, Australia; Renal Unit, Gosford Hospital, Gosford, New South Wales, Australia; Renal Medicine, Sir Charles Gairdner Hospital, Perth, Western Australia, Australia; Nephrology, Royal Brisbane & Women’s Hospital, Herston, Queensland, Australia; Renal Unit, Whangarei Hospital, Whangarei, New Zealand, Australia.

Background: Despite the existence of international guidelines, peritoneal dialysis (PD)-related infections vary widely across Australian and New Zealand units, with multiple units reporting suboptimal rates and variable practice.

Methods: The current practice and barriers to guideline uptake were evaluated in eight PD units located in Australia and New Zealand in 2011. A multifaceted intervention was developed which included case report forms, a patient diary, a ‘Preventing Peritonitis Checklists’, an Emergency Department flyer, a letter to the patient’s general practitioner, a medical card, and a poster summarizing ISPD and KHA-CARI guidelines.

Results: At baseline (1 Jan-31 Dec 2011), exit-site infection (ESI) rates ranged from 0.06-0.53 episodes/patient-year; peritonitis from 0.31-0.86 episodes/patient-year; and funga peritonitis from 0.00-0.48 episodes/patient-year. After implementation (9 Dec 2013-8 Dec 2014), the ESI rates were 0.00-0.22 episodes/patient-year; peritonitis was 0.29-0.49 episodes/patient-year; and fungal peritonitis was 0.00-0.14 episodes/patient-year.

Conclusions: Implementing the various tools resulted in improvement in the ESI and peritonitis rates but the difference was not statistically significant (P=0.15 and P=0.08). There was no statistically significant difference in the fungal peritonitis rate (P=0.64).

Funding: Government Support - Non-U.S.
Factors Influence the Baseline Peritoneal Transport Status

Hao Zhang, Bin Yi, Cuiling Hou. The Third Xiangya Hospital, Central South Univ, Changsha, Hunan, China.

Background: Baseline peritoneal solute transport rate(PSTR) is an independent risk factor for total cardiovascular mortality in PD (peritoneal dialysis) patients. The determinants of PSTR in incident PD patients are still under debate. Our objective was to explore the influence factors of baseline PSTR.

Methods: (1) 205 PD patients who had a standard peritoneal equilibration test(PET) within 1-3 months after commencing PD and without peritonitis history were enrolled. Pre-dialysis clinical parameters and biochemical indexes were assessed. 205 individuals were divided into two groups according to the baseline PSTR. High transport group: PET>0.65, Low transport group: PET < 0.65. (2) Pre-dialysis serum advanced oxidation protein products (AOPP) and dialysate AOPP, GPx, hsCRP, IL-1beta, TGF-beta1 of 59 patients among the enrolled 205 individuals were detected.

Results: (1) High baseline PET are more likely to be male (male: 77.3% vs 52.5%, p = 0.001), had lower serum albumin (34.0±4.4 g/L vs 35.9±4.5 g/L, p = 0.005) and TG levels (1.11±0.62 mmol/L vs 1.28±0.57 mmol/L, p = 0.047) compared to the low baseline PET. Gender (r = 0.299, p = 0.299), serum albumin (r = 0.199, p = 0.199) and TG level (r = 0.140, p = 0.140) are correlated with the baseline PET respectively. Multiple stepwise linear regression analysis showed that gender (β = 0.085), serum albumin (β = 0.005, p = 0.005) are associated with baseline PET independently. Multivariate Logistic analysis showed that men (OR = 3.314, p = 0.001), hypoalbuminemia (OR = 2.552, p = 2.552) are independent risk factors for high baseline PET. ROC curve display that when serum albumin < 35.8 g/L, it is likely to have a high baseline PET. (2) High baseline PET had a relatively high level of dialysate TGF-beta1 (1.58±0.34ng/ml vs 1.75±0.30 ng/ml, p = 0.049) than the low transport status. No statistical differences were found in serum AOPP and dialysate AOPP, GPx, hsCRP, IL-1beta between groups. Dialysate TGF-beta1 (r = 0.336, p = 0.049) is independent predictors of fast baseline PSTR. (2) When serum albumin < 35.8 g/L, it is likely to have a high baseline PSTR.

Conclusions: (1) Male, hypoalbuminemia, high dialysate TGF-beta1 level are independent predictors of fast baseline PSTR. (2) When serum albumin < 35.8 g/L, it is likely to have a high baseline PSTR.
follow up and dialysis start. PD patients (p=0.02) received more mobility information than HD (02% vs. 78%) and were mainly under 50 years (p=0.001). Incidence varied according with different studied groups

Conclusions: Despite commitment to offer PD/HD as complementary treatments, PD incidence is still low. Optimal care provision is important to improve outcomes but also to involve patients in their therapy choice.

PUB616 The Adsorption Kinetics Profile of Aminoglycoside Antibiotics During Lixelle S-35 Cartridge Hemoperfusion Marco Sartori,1,2 Angela Casas,3 Silvia De Rosa,3 Mirella Zancato,4 Leopolda Zampieri,5 Davide Giavarrina,1 Claudio Ronco.1 1International Renal Research Inst of Vicenza, St. Bortolo Hospital, Vicenza, Italy; 2Dept of Pharmaceutical and Pharmacological Sciences, Univ of Padua, Padua, Italy.

Background: The bactericidal activity against Gram(-) of Tobramycin(TOB)and Gentamicin(GEN)is concentration-dependent. It is therefore fundamental achieving the maximum drug plasma levels. Lixelle S-35 CARTRIDGE is a sorbent used for dialysis-related amyloidosis which can modify the drug plasma levels. The aim of in vitro study was to evaluate the TOB and GEN adsorption removal by Lixelle S-35.

Methods: We performed mock direct hemoperfusion (DHP; Q=100ml/min;Bellico prototype dialysis machine) for 120 min using Lixelle S-35 cartridge. Human blood was diluted with fresh frozen plasma in order to achieve appropriate rheological characteristics (Hct 30%:650mL each bag:n=6). Blood was separated spiked with TOB (1.00±0.42 mg/L; n=3) and GEN (12.80±0.18 mg/L; n=3) then it was circulated into the system. Samples were taken from arteri(al/venous) lines at 5,10,60 min. Samples were measured by TOBIR and GENT Flex methods(Siemens Healthcare,Newark,NJ,USA) for TOB and GEN, respectively. The adsorption kinetics profiles were calculated.

Results: At the end of DHP TOB and GEN levels were 7.13±0.18 and 7.20±0.90mg/L. Ratio C vein/Cp gave quickly after the first 5 min then reach plateau for both antibiotics as shown Fig.On mass balance analysis, the total mass of antibiotics introduced into the system decreased from 5.12±0.25 to 3.22±0.50 and from 6.10±0.51 to 3.32±0.14mg for TOB and GEN, respectively. The TOB mass adsorption was 37.20% whereas GEN was 46.20%.

Conclusions: Our in vitro study indicates an high adsorption rate for both aminoglycosides. This should be considered when TOB or GEN are used in pts treated with Lixelle S-35 cartridge. A supplemental dose may be needed to maximized efficacy.

PUB616 Analysis of Some Aminoglycoside Antimicrobials in Human Plasma by HILIC-MS/MS Shinya Omura,1,2 Xiaohan Wanchoo,1 Takushi Kumazawa,1 Kiyosato Sato,1 Kiyoko Inui,1 Tomokazu Miyazaki,1 Yoshikazu Inoue,1 Ashio Yoshimura,1 1Dept. of Medicine, Div of Nephrology, Showa Univ Fujigawa Hospital, Kanagawa, Japan; 2Dept of Legal Medicine, Showa Univ School of Medicine, Tokyo, Japan.

Background: Aminoglycoside(AG) antimicrobials(AMBs) have been used for a treatment of bacterial infections, especially by acid-fast bacteria. However, their acute overdose or chronic abuse can cause serious side effects, such as difficulty in hearing, interstitial nephritis resulting in renal failure and even sudden death from anaphylactic shock. In such cases, there is a need to identify and quantify AG AMBs in the blood from patients or cadavers. We earlier reported an analytical procedure for nine AG AMBs

Conclusions: in human serum by capillary HPLC/mass spectrometry(MS). Although this method works well for identification of the drug, it is semi-quantitative unless a suitable isotopic internal standard is used.

Methods: A simple, rapid, sensitive and quantitative method is presented for the analysis of six AG AMBs (streptomycin, ribostamycin, kanamycin, amikacin, dibekacin, arbekacin) in human plasma samples by hydrophilic interaction liquid chromatography tandem MS/MS. A small volume (50μl) of plasma spiked with six drugs was diluted with 350μl of acetonitrile containing 0.1% formic acid. After centrifugation, 100μl of the clear supernatant extract was directly injected into the HILIC-MS/MS, without any solvent evaporation or reconstitution steps. The chromatographic separation of the AG AMBs was achieved on Unison UK-Amino HILIC column (50mm x 3mm i.d., particle size 3μm) with a linear gradient elution system composed of 0.1% formic acid and acetonitrile.

Results: All drugs showed base peaks due to [M+H]+ ions by HILIC-MS with positive ion electrospray ionization, and the product ions were produced from each [M+H]+ ion by MS/MS. Calibration was made by selected reaction monitoring. The data obtained from actual determination of the AG antimicrobials in human plasma after their oral or intramuscular administration are also presented for validation of the methods.

Conclusions: This method would seem to be useful in clinical and forensic medicine because of its ability in both identification and quantification of the drugs.
First Dialysis Prescription and Access Use: A Survey of United States Nephrologists
Mary C. Mallapallil,1 Steven Fishbane,2 Rindah Wanchoo,2 Andrea Roche-Recinos,1 Subodh J. Saggi,1 Moro O. Salifu,1 1Internal Medicine-Renal Div, SUNY Downstate School of Medicine, Brooklyn, NY; 2Div of Nephrology, Hofstra North Shore LIJ School of Medicine, Great Neck, NY.

Background: As there is no standard approach to initiate renal replacement therapy in CKD patients in regard to location of first treatment, access and dialysis prescription we conducted a survey of US nephrologists to better identify current practice patterns.

Methods: We created an anonymous electronic survey with 39 questions that was validated then approved by the IRB. Aggregate data was analyzed using descriptive statistics, avoiding duplicate responses.

Results: 120 US nephrologists replied to the survey, 60% were in nephrology practice for more than 10 years. The first hemodialysis (HD) treatment was as inpatient (22%), outpatient (29%) or either (49.5%). At the first HD, most nephrologists (92%) used a blood flow (BF) <300 mL/min; 65% would use lower than usual diastolic flow rates (DFR) and 47% would use smaller dialyzers. Ninety six percent prescribed less time than usual, even with blood area nitrogen less than 100 mg/dL. About 45% replied that only 10 - 50% of patients meeting criteria for peritoneal dialysis were actually started on this modality (p<0.005). Of the participants 47% noted that only 10 – 50% of patients who were eligible for transplant were listed, and the majority of responders (83%) noted that less than 10% of their patients got a preemptive transplant (p<0.0005). A patient educator was available to 64% of the participants. First dialysis with a permanent access was noted among 30-60% of patients by 43% of responders and in more than 60% of patients by 22% of responders. Of the participants 73% replied that the majority (>60%) of their patients got vein mapping before access creation. The time between vein mapping and access creation was one week to one month (61%) and more than one month (26%), (p<0.005). The number of angioplasties that were acceptable prior to primary access failure was noted as 2, (25%) 3 (25%) or more than 4(24%).

Conclusions: There is variation in practice in several areas in regard to the initial dialysis session in CKD5 which may benefit from guidelines.

How to Dialyze a Patient with Left Ventricular Assist Device in a Chronic Dialysis Unit? A Practical Protocol
Sadiaq Ahmed,1 Debbie Baker,2 1Univ of Kentucky; 2Davita.

Background: To provide chronic HD treatments to ESRD patients with LVAD in a chronic unit in the community is a challenge and a relatively new experience for nephrologists. As LVADs have revolutionized the treatment of advance heart failure there are rising numbers of these patients developing ESRD with need for HD in the community. Development of a practical, simple and safe protocol is needed to dialyse these patients in the chronic units.

Methods: This protocol and safety check list is developed to provide routine HD treatment for patients with LVAD and successfully implemented in a chronic dialysis unit in the community setting. The special policy and procedure relevant to this protocol, safety check list and standing orders for the dialysis nurses was approved by the governing body before dialysis staffs were trained. The VAD coordinator is present during first training.

Results: This protocol is a step by step guidance for the dialysis staff. The whole process has 3 components. 1. A supplemental informed consent signed by the patient to cover for vascular access failure was noted as 2, (25%) 3 (25%) or more than 4(24%).

Conclusions: This protocol to provide Incener HD to patients with LVAD in a chronic unit is simple & safe. It can be implemented in a chronic HD unit.

Association Among Calcium, Phosphorus, and Parathyroid Hormone with Aortic Ring Calcification in a Cohort of Hemodialysis Patients
Arturo Reyes Marin, Nephrology, Hospital Juarez de Mexico, DF, Mexico.

Background: The prevalence of vascular calcification in dialysis therapy is 40-92%, values increased in serum levels of calcium (Ca), phosphorus (P) and parathyroid hormone (PTH) have been associated with high calcification progression and cardiovascular mortality. It has been described association among serum levels of Ca, P, Ca-P product and PTH with aortic ring calcification in patients with chronic renal disease (CRD). We did an observational and descriptive study, in the nephrology department of Hospital Juarez de Mexico, with a cohort of 95 hemodialysis patients, the aim of study was to evaluate the association among aortic ring calcification by torax radiography with the serum levels of Ca, P and PTH.

Methods: Adult patients in hemodialysis were included, patients with severe malnutrition, cancer and mental abnormalities were excluded. We used 2 scales (torax radiography), in order to assess the aortic ring calcification and we did correlation coefficient among Ca, P, PTH and 2 scales. We used Pearson correlation coefficient for analysis and Bland-Altman test for analysis of concordance among Ca, P, PTH and 2 scales.

Results: They were 95 adult patients: 50 (52%) men and 45 (48%) women, average age was 40.7 years old. We found weak negative correlation between Ca and PTH (r = -0.28, p > 0.05), weak positive association was found between P and PTH (r = 0.30, p > 0.05), correlation between PTH and CasP (r = 0.36, p > 0.05), PTH and 2 scales (r = 0.5, p<0.05). In the scales that we used to evaluate vascular calcification (torax radiography) showed high scores, however the intraclass correlation coefficient between scales and PTH, Ca and P (0.33) showed not statistical significance.

Conclusions: Despite that vascular calcification was high by torax radiography, the association among scales (torax radiography) and serum levels of Ca, P and PTH was not statistical significant. There are other important factors that can explain the progression of vascular calcification and the traditional markers for calcification: Ca, P and PTH are not enough for explain it.

β2-Microglobulin Removal: Comparison Between Lixelle S-35 Cartridge Coupled with High-Flux Dialysis versus Online-Hemodiafiltration
Marco Sartori,1 Davide Iengo,2 Sara Samoni,1 Federico Nalesso,1 Alessandra Brendolan,1 Mauro Neri,1 Francesco Garzotto,1 Silvia De Rosa,1 Mirella Zancato,1 Claudio Ronco,1 1International Renal Research Inst of Vicenza, St. Bortolo Hospital, Vicenza, Italy; 2Dept of Pharmaceutical and Pharmacological Sciences, Univ of Padua, Padua, Italy.

Methods: We enrolled 2 pts with β2-MG levels over 1mg/L; treated with OL-HDF. We compared the data obtained in each treatment.

Results: β2-MG levels over 15mg/L, treated with OL-HDF. We collected samples previous and after pre/post-reinfusion OL-HDF (n=3). Then the pt was shifted to HFD+Lixelle S-35 (n=3; Qβ2=500mL/min; ∆BW=2.87±0.42Kg). We collected samples previous and after post-reinfusion OL-HDF (n=3). Then the pt was shifted to HFD+Lixelle S-35 (n=3; Qβ2=500mL/min; ∆BW=2.87±0.42Kg). We collected samples previous and after post-reinfusion OL-HDF (n=3). Then the pt was shifted to HFD+Lixelle S-35 (n=3; Qβ2=500mL/min; ∆BW=2.87±0.42Kg). We collected samples previous and after post-reinfusion OL-HDF (n=3). Then the pt was shifted to HFD+Lixelle S-35 (n=3; Qβ2=500mL/min; ∆BW=2.87±0.42Kg).

Conclusions: Lixelle is a sorbent used to treat dialysis-related amyloidosis due to β2-microglobulin(β2-MG)deposit. The aim of this study was to assess the impact of Lixelle S-35 coupled with High-Flux Dialysis(HFD)vs online Hemodiafiltration(OL-HDF) on β2-MG.

Does Dialysis Influence Treg Cells? A Meta-Analysis
Carlootta Cuprara,1 Gilbert R. Kinsey,2 Wenjun Xin,3 Jennie Z. Ma,3 Valentina Corradi,1 Elisa Scalzotto,1 Francesca K. Martino,1 Mark D. Okusa,4 Mitchell H. Rosner,2 Fiorenza Ferrari,1 Claudio Ronco,1 International Renal Research Inst Vicenza (IRRV), Dept of Nephrology, Dialysis & Transplantation, St. Bortolo Hospital, Vicenza, Italy; 2Medicine, Univ of Virginia, Charlottesville; 3Public Health Sciences, Univ of Virginia, Charlottesville.

Background: The immunological state of patients with ESRD is dysregulated. Regulatory T (Treg) cells comprise a small proportion of the total lymphocyte population yet regulate key immune responses across a variety of disease settings. Contrasting results have been reported about the influence of dialysis on Treg cells. Our aim is to determine whether the available literature support a positive or negative influence of dialysis on Treg cells.

Methods: After screening 84 published studies (PubMed and Web of Science) we included 10 that evaluated Treg cells in ESRD patients. Of these, 5 studies that included comparable healthy controls (HCs) and hemodialysis (HD) patients and used similar criteria for determining the percentage of Treg cells in total CD4 T cells were subjected to a meta-analysis.

Results: A total of 99 HD patients and 88 age-matched HCs were included in these 5 studies. Using the fixed effect model a significant difference in the percentage of Treg cells in total CD4 T between HD and HCs was observed (P<0.001). The mean difference in Treg percentage was -2.34% in HD patients vs. HCs. Several discrepancies were noted between studies that may be due to the lack of consistent criteria for Treg cell identification and use of different type of dialysis membranes which was not specified in all articles.

Conclusions: The available literature comparing Tregs in HD patients and HCs suggested a reduction in Tregs. A limitation is that only a few articles consider uremic patients (ESRD not on dialysis) as a control group for HD. Furthermore, no studies have investigated Treg cells in the same patient before and then after initiating dialysis. This type of study will be critical to understanding the influence of dialysis on Treg cells. Furthermore, the clinical significance of these changes in Treg cell numbers will need to be elucidated.

PUB624
Combination of Insulin Degludec (IDeg) and Lisproglirardina (Lira) Is Potentially Superior to Basal-Bolus Insulin Therapy (BB) in Hemodialysis (HD) Patients with Type 2 Diabetes (T2DM) - An Assessment by Continuous Glucose Monitoring (CGM)
Satoshi Funakoshi,1 1Jyunihiro Hashiguchi,1 Kenji Sawase,1 Osamu Sasaki,2 Hiroshi Ichinose,1 Miwa Shirahama,1 Miki Yano,1 Yutaka Mori,3 Takahisa Uchino,1 Kazunori Usatsumiya,2 Yoko Obata,2 Toomya Nishino,2 Takashi Harada,2 Nagasaki Kidney Center, Japan; 3Dept of Internal Medicine, Nagasaki Univ Graduate School of Medicine, Japan; 1Dept of Diabetology, Jikei Univ, Japan.

Background: During HD, plasma glucose (PG) level drops due to various factors including clearance gap between glucose and insulin, and then rebounds to hyperglycemic state after HD. Therefore, it may be difficult for conventional BB to control these complicated PG changes in HD patients with T2DM. Recently a free combination of any insulin has been approved in Japan.

Methods: Eight adults with T2DM, glycosylated hemoglobin (GA) of >20%, fasting C-peptide of >8 ng/ml and treated with BB including IDeg (5-74 units) + insulin lispro (5-30 units) were evaluated before and after the change to a free combination of IDeg+Lira. IDeg was titrated to achieve an appropriate fasting plasma glucose level. Glycemic control was assessed by CGM and the mean amplitude of glycemic excursions (MAGE) was calculated before and after the conversion.

Conclusions: IDeg+Lira can potentially be superior compared with BB in controlling glycemic fluctuations in HD with T2DM.

PUB625
More Nephrologist Visits Are Associated with Lower Cost of Care for Dialysis Patients
Fresenius Medical Care North America, Waltham, MA.

Background: Medicare patients with end stage renal disease (ESRD) are treated by nephrologists, primary care providers (PCPs), cardiologists and other specialists on a regular basis. We investigated the relationship of visits to these providers and total costs of care.

Methods: Medicare 100% ESRD data for patients with evidence of dialysis at any time during January 1, 2010 through December 31, 2011 were analyzed. Nephrologist, PCP and cardiologist visits were determined by specialty codes of Part B claims (including both in- and out-patient visits). All data was aggregated at the Metropolitan Statistical Area level (MSA). We computed a ratio of nephrologist visits to PCP visits per MSA as well as nephrologist visits to cardiologist visits per MSA during the above period (visits were calculated on a per patient per month basis). Total costs of care (per member per month [PMPM]) were determined by aggregating Medicare Part A and B costs. Comparisons of ratios were performed using t-tests for quartiles of PMPM for two specialty visit ratios.

Results: Claims for 368,711 patients were analyzed. Patients in the lower quartiles of total cost had significantly more nephrologist visits relative to PCPs and cardiologists.

PUB626
Prediction of Non-Adherence to Hemodialysis Treatment Regimens
Yue Jiao,1 Daniel E. Geary,1 Theresa J. Hetzel,1 Sheetal Chaudhuri,1 Mahathi Mothali,1 Terry Ketchersid,1 Dugan Maddux,3 John W. Larkin,1 Peter Kotanko,1,2 Brian Scott Ash,1 Len A. Usvyat,1 Franklin W. Maddux.1 Fresenius Medical Care North America, Waltham, MA; 2Renal Research Inst, New York, NY; 1Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Non-adherence with hemodialysis (HD) treatment regimens is known to be associated with increased morbidity and mortality. The aim of this project was to develop a predictive model (PM) to identify HD patients who will likely have unexcused no shows to routine dialysis treatments within the next week.

Methods: Using data between 1/1/2014 and 12/31/2014 from the Fresenius Medical Care Knowledge Center and 2014 weather data from the National Oceanic and Atmospheric Administration National Centers for Environmental Information, PMs were designed and developed for prediction of unexcused no shows in patients not residing in a nursing home. Various PMs were investigated and included the generalized linear model, partitioning and regression trees, artificial neural networks, and generalized additive model (GAM). In all, 1,554,833 records stratified in weekly intervals on 60 variables from 172,854 patients were utilized. Variables included data on the patient’s history of unexcused no shows, demographics, comorbidities, laboratories, holidays, sporting events, and weather. A multi-tier prediction process was performed with respect to the availability of data. The area under the curve (AUC), sensitivities and specificities were investigated to determine the model with the highest performance.

Results: Best performing model had AUC of 0.87 for the multi-tier PMs utilizing a 30% test dataset. A small pilot test on 860 patients for three weeks utilizing optimal Youden index as the cutoff value to predict the high probability of the unexcused no show events achieved an average sensitivity of 0.57 and specificity of 0.95.
Conclusions: This pilot test of the developed modeling demonstrates that PM can assist identifying patients with a high probability for unexcused missed HD treatments. Additional studies are needed to further analyze the potential of predictions for and interventions associated with reducing unexcused no show events.

PUB627
Factors Influencing Residual Renal Function Decrease in Hemodialysis Treated Patients
Fernando Caravaca-Fontan, Milagros Fernandez-Lucas, Jose L. Tenuel, Saul Enrique Pampa, Estefania Yerovi, Maria Delgado yagüe, Fernando Liano.
Nephrology, Hospital Univ Ramon y Cajal, Madrid, Spain.

Background: We have shown in previous studies that maintenance of residual renal function in hemodialysis treated patients is conditioned by the number of weekly sessions, and is better in patients who start treatment with a twice weekly schedule. The aim of this study is to analyse the influence of other variables in the preservation of residual renal function.

Methods: Of the 174 consecutive patients who started hemodialysis treatment in the hospital, 98 began with 2-weekly sessions (2HD group), and 76 with 3-weekly sessions (3HD group). Residual renal function was measured every two months (mean urea and creatinine clearance).

Results: Decrease in residual renal function was lower in the 2HD group (median 0.19 vs 0.46 ml/min/month, p=0.005). In both groups the residual renal function decrease was higher in the patients from the transplant program than in those from pre-dialysis: 2HD group: median 0.93 vs 0.17 ml/min/month, p=0.003; 3HD group: median 0.76 vs 0.32 ml/min/month, p=0.005. Neither the initial schedule, sex, or etiology of the renal disease influenced the decrease in residual renal function in either of the two groups of patients. Moreover we found no correlation between the decrease in residual renal function with age, the renal mass, total cholesterol, and the Charlson morbidity index. The 98 patients who began with the 2HD schedule, 45 went on to dialysis three times a week when the residual renal function was less than 3 ml/min/1.73m2: these patients had a mean of 10.8 ± 6 months on the 2HD schedule. The length of time on this model was not influenced either by age, sex, etiology of the nephropathy, morbidity index, scheduled start or basal renal function.

Conclusions: The decrease in residual renal function in the patient treated with hemodialysis depends basically on the number of weekly sessions with which the dialysis treatment was started. Of all the variables analysed only the return to dialysis due to graft loss conditioned a higher decrease in residual renal function in both groups of patients.

PUB628
Circadian Blood Pressure Behaviour in Hemodialysis Patients Dimitrios Petras, 1 Kyriakos Dimitriades, 2 Panagioti E. Giannou, 1 Eirini Andrikou, 2 Konstantinos Tsiofis. 2 1Nephrology Dept, Hippokration Hospital, Athens, Greece; 2First Cardiology Clinic, Hippokration Hospital Univ of Athens, Athens, Greece.

Background: Blood pressure (BP) evaluation and management in haemodialysis (HD) patients is often a matter of debate. During HD hypotension as well as a paradoxical rise in BP are frequent findings. Indrivialytic BP is also variable depending mostly from the weight gain between the HD sessions. We investigated circadian BP behavior in the setting of HD.

Methods: We performed an observational trial of this filter in a hospital-based acute dialysis facility in the USA.

Results: There were 23 chronic stable hemodialysis outpatients treated during the 6 month period after the installation of the filters to the preceding 6 months, there was an increase in the mean hemoglobin level of 0.5 g/dl (p=0.010) with a reduction in the mean weekly darbepoetin dose of 14.6 mcg or 40% (P<0.001) translating to a reduction in the ESA resistance index (weekly ESA dose/hemoglobin level) of 1.52 (p<0.001). During this time period, indirect hematological markers showed a reduction in the mean MWC count from 7,000 to 6,600 x 109/L (p=0.008) and an increase in serum albumin from 3.6 to 3.7 (p=0.024). The mean sPctkV was unchanged during the 2 time periods (from 1.609 to 1.607, p=0.30).

Conclusions: In conclusion, the use of the Nephros® DSU filter to further reduce endothelial exposure in chronic hemodialysis patients can result in improved ESA responsiveness and a lower ESA dose.
hemodialysis for at least for one year. 58% had hypertension or coronary pathy. Hemodialysis hemodiafiltration, as described as a reposition volume higher than 22lts, was used for patients undergoing dialysis with high levels of phosphorus. High efficiency on-line Hickson, Control Symetrical Dimethylarginine (SDMA) Is Poorly Cleared by Standard PUB632 and reported patient important outcomes i.e. mortality, important clinical outcomes, >5 dialysis patients over age 18 years and receiving treatment, >6 months follow up, and reported patient important outcomes i.e. mortality, important clinical outcomes, hospitalizations and quality of life. Data was abstracted by reviewer pairs; study quality was assessed using Cleveland and Newcastle On-line tools.

Results: 1841 abstracts were screened, 59 full text articles were reviewed, and 23 studies with 87,281 patients were included for final analysis. The interventions included nutritional (n=4), multidisciplinary care (n=6), satellite programs (n=3), home dialysis (n=3), access monitoring (n=2), physician contact (n=4), and nocturnal dialysis (n=1). Most were observational studies of decent quality with representativeness and incomplete follow up being the main potential sources of bias. Two randomized studies on home dialysis and pharmacist care, had attention as the main risk of bias. Most interventions showed positive effect raising concern of publication bias. Overall, hospitalizations were significantly lower in the intervention group despite large heterogeneity:RR: 0.824, 95% CI 0.781, 0.868,p<0.001, 12-95.6%.

Conclusions: Multiple interventions have the potential to improve the outcomes of dialysis patients but have not been compared in terms of safety and effectiveness. Limited evidence is available to inform dialysis practice redesign to adapt to new payment structures. Further studies are needed to define best delivery models for dialysis care.

PUB632
Symetrical Dimethylarginine (SDMA) Is Poorly Cleared by Standard Hemodialysis Mirela A. Dobre,1 Peter B. De Oro,2 Timothy W. Meyer,3 Thomas H. Hostetter.1 1Case Western Reserve Univ; 2Centers for Dialysis Care, Cleveland; 3Stanford Univ School of Medicine.

Background: High SDMA levels have been associated with an increased risk for cardiovascular disease in patients with normal or reduced renal function. The effect of hemodialysis on SDMA has not been thoroughly studied.

Methods: We measured SDMA levels and its handling by hemodialysis and by the normal kidney in subjects with ESRD on chronic hemodialysis (n = 7) and in normal controls (n=6).

Results: The mean (SD) SDMA levels in ESRD were six times higher than in normal controls, 3.35(0.63) vs 0.53(0.25) µM, p<0.001. For comparison pre-dialysis BUN levels were 44.1(23.1)mg/dl in ESRD, and 14.9(3.2) mg/dl in controls. The fractional reduction was significantly lower in the intervention group despite large heterogeneity:IRR: 0.824, 95% CI 0.781, 0.868,p<0.001, 12-95.6%.

Conclusions: Further studies are needed to define best delivery models for dialysis care.

PUB633
On-Line Hemodiafiltration Filters a Comparative Study Nadia Guimarães-Souza, Adriano Luiz Ammirati, Thais Nemeto Matsui, Maria C.C. Andreoli, Fabiana Dias Carneiro, Ana C M S Ramos, Bento C. Santos. Dialysis Center, Hospital Israelita Albert Einstein, Brazil.

Background: High efficiency on-line hemodiafiltration is the best method for middle molecules and phosphorus remotion. Many studies had demonstrated the efficiency of this method in mortality reduction. The main objective of this study was to compare the three filters available for on-line HDF comparing the ability to remove urea, phosphorus and beta-2-microglobulin.

Methods: Prospective cross-over study including four patients and three available filters for hemodiafiltration. All section of on-line hemodiafiltration was made with high efficiency (23-25h). Filters HDF 100, FX100 and HDF90COR were compared. Urea, phosphorus and beta-2 microglobulin were collected before and after first use of each filter A reduction ratio was calculated to compare both filters.

Results: 76% of patients were man, the middle age (61.3±5), 76% of patients were diabetics and had peripheral neuropathy and 34% had coronaryopathy. FX100 filter showed significantly higher dialysis higher dose compared to FX80COR (p<0.05); the same was observed for urea reduction ratio(p<0.04). Beta-2-microglobulin and phosphorus reduction ratio were similar between all filters.

Conclusions: FX100 and HDF100 filter were similar for urea remotion ratio. There were no differences for other molecules.

PUB635
Satisfaction of Patients on Dialysis Unit Jorge Nicolas Abdala, Nephrology, Militar Hospital, Cordoba, Capital, Argentina.

Background: The assessment of the satisfaction of patients in Dialysis, is a useful tool to meet patient needs; axis on which the care service is based.In turn it allows to identify the deficient areas.

Methods: Objective: 1) To know the views of patients about the service that is offered in each of the areas of focus. 2) To analyze the profile of satisfaction of patients they expressed their overall dissatisfaction. Prospective, descriptive study conducted at the Dialysis Unit of the Military Hospital Córdoba, conducted between 15/11/2014 to 15/12/2014. Patients: All patients attending the service, which received a survey during the year 2014. Results: 95 surveys of the total population comprised 111 patients were taken; of which 85 are for patients undergoing hemodialysis and 10 patients on CAPD. By studying the “General Satisfaction” in all aspect of the service that is offered to the patients responses they were largely positive, 80 % of the sample expressed feeling satisfied, while 20 % responded negatively. The results denote that carriers are those who receive the worst assessment by patients. The ambient temperature for both dialysis room to the waiting room appears as an aspect also of disagreement. The most valued aspect is the power received during treatment, both the quality and quantity as well as the attention of the professionals: technical, medical and social work, in that order.

Conclusions: 1. As a management tool, it should be rated as positive aspects stimulate and work on correcting the negative aspects. 2. The level of dissatisfaction is directly related to dialysis treatment time of the patient, the longer, higher degree of dissatisfaction. 3. It is advisable conduct regular surveys on the degree of patient satisfaction Dialysis, and that will help improve their quality of life.
Results: Of the 60 ESRD patients, 35 (58.3%) were males with a mean age was 39.5±5 years. Cerebrospinal fluid (CSF) was seen in 18 (30%) patients with high pre-dialysis MAP in 8 (44%) and high post-dialysis MAP in 4 (22%) patients respectively. Of 42 (70%) patients with CaXp product below 50 high pre-dialysis MAP was seen in 31 (73%) and high post-dialysis MAP was seen in 29 (69%) patients.

Conclusions: This study showed that high CaXp product (>50) is not correlated with high pre and post-dialysis MAP. The results are not consistent with earlier studies done in developed countries. Larger studies are needed to re-evaluate these findings.

Characterization of T Regulatory Type 1 (Tr1) Cells in Naive and Transplanted Non-Human Primates
Ruihao Yu, Makoto Tonsho, Philip Spencer, Sibylle Bernard-stoecklin, Gilles Benichou, Joren Madsen. Center for Transplantation Sciences, Harvard Medical School, Massachusetts General Hospital, Boston, MA.

Background: T regulatory type 1 (Tr1) cells are peripheral CD4 Foxp3 regulatory T cells expressing CD49b andLAG-3 in mice and humans. Mouse Tr1 cells inhibit antigen-presenting cell (APC) activation via secretion of IL-10 and TGF-β1 and via cell-contact dependent mechanisms mediated through their expression of programmed cell death (PD-1). However, the phenotype and functions of Tr1 cells in non-human primates are still unknown.

Methods: Mononuclear cells were isolated from the peripheral blood of cynomolgus monkeys (PBMcs). First, co-expansion of CD49b and LAG-3 was compared among bona fide CD4 CD25+Foxp3+ Tregs and CD4 CD25 Foxp3+ using flow cytometry. Second, cytokines (IL-10, TGF-β1, INF-γ, IL-4, IL-17 etc.) were processed after polyclonal activation via anti-CD3/CD28 Ab-coated beads. Next, we compared PD-L1 and CD45RO expression trafficking collected from activation via secretion of IL-10 and TGF-β1 and via cell-contact dependent mechanisms mediated through their expression of programmed cell death (PD-1).

Conclusions: While our data show that the surface markers CD49b and LAG-3 can be used to distinguish Tr1 from “classical” Foxp3+ Tregs in cynomolgus monkeys. Tr1 cells are likely to inhibit T cell responses mediated by PD-1/PD-L1 interactions. The contribution of these activated Tr1 cells to induction and maintenance of organ allograft tolerance in non-human primates is under investigation.

Urinary MicroRNA-25 as a Potential Biomarker for Detection of Renal Damage in Rats and Renal Transplant Patients
Kumiko Nishihara,1 Masayuki Kanki,1 Moto Kajiwara,2 Kei Kurihara,3 Takahisa Yano,2 Hidehisa Kitada,1 Satoshi Masuda,1 Akira Unami.1 1Drug Safety Research Laboratories, Astellas Pharma Inc., Osaka, Japan; 2Dept of Pharmacy, Kyushu Univ Hospital, Fukuoka, Japan; 3Dept of Research and Development of Next Generation Medicine, Faculty of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 4Dept of Surgery and Oncology, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.

Background: Circulating microRNAs (miRNAs) were proposed as potential biomarkers of various biological functions and diseases in the kidneys. We have found that some urinary miRNAs were useful for detection of cisplatin-induced proximal tubular injury in rats (Kanki M et al., Toxicology, 324, 158, 2014). In this study, we examined the feasibility of urinary miRNAs for renal damage in Japanese patients receiving kidney transplantation as well as rats.

Methods: Gentamicin (100 mg/kg) (model of tubular injury) was daily given for 7 days and puromycin (50 mg/kg) (model of glomerular injury) was given as a single injection 4 weeks before the rats were killed. Seven days after the treatment, the urinary levels of 15 miRNAs were determined by real-time PCR. The receiver-operator characteristics (ROC) curve analysis for proximal tubular necrosis was performed including previous cisplatin study. Human urine samples were collected from 30 healthy volunteers and 11 renal transplant patients at days 2, 10, and 11 weeks after surgery. The levels of 4 miRNAs were determined.

Results: In gentamicin treated rats, the levels of miR-328, let-7a-1, miR-1839, miR-25, miR-140, and miR-378 were increased more than 2-fold with high values of the area under the ROC curve, which were the same or more than those of BUN and serum creatinine, while they were not changed in rats treated with puromycin. Among these miRNAs, miR-25, miR-140-3p, miR-328 and miR-378 were measured in the human urine samples. In human samples, miR-25 at postoperative day 7 in some patients exhibited higher levels than the highest value of those in the volunteers.

Conclusions: Urinary miRNAs were potential biomarkers for detecting renal damage in the postoperative course of renal transplant patients as well as in the rats with proximal tubular injury.

Methods: PBMCs were isolated from blood of patients with Delay graft function (DGF) n=10 and Early graft function (EGF) n=10 at T0 and T24h from transplant. Gene expression profiles of PBMCs from both groups were assessed by Affymetrix technologies. Results were evaluated by statistical analysis and functional pathway analysis and validated by confocal analysis on a swine model of IR injury. Renal I was induced in pigs by arterial clamping for 30 min and tissues were analyzed at different time points after R (T15’, 30’).

Results: Microarray analysis (FDR<5% and a P<1.5) revealed that the expression of PTX3 and C3 were downregulated in EGF compared to DGF patients. On the contrary, the gene CR1 was upregulated in DGF. Furthermore, in the pig model, confocal laser microscopy demonstrated deposits already at 15 min, localized at peritubular (7.7±1.1; p<0.005) and glomerular (8.2±2.5; p<0.05) capillary levels. We found a significant increase in infiltrating interstitial leukocytes such as CD163+ PTX3+ monocyte-macrophages (6.2±2.1; p<0.05) and SWC3+PTX3+ dendritic cells (3.7±0.5; p<0.05) compared to T0. Finally, we identified tubulointerstitial FSP1+ PTX3+ myofibroblasts (4.1±1.3; p<0.04). Co-localization between C5b-9-PTX3, PTX3/C1g and PTX3/MBl clearly demonstrated the activation of Classical and Lectin Complement pathways in presence of PTX3 deposits.

Conclusions: Our data would suggest a key role of PTX3 synthesized by peripheral blood mononuclear cells (PBMCs) during DGF leading to an early activation of complement in transplant kidney.

PUB642
The Effect of Combined Treatment of Dipeptidyl Peptidase-4 Inhibitor and Metformin in Sriluim-Induced Diabetes Mellitus
Long Jin, Jian Jin, Sun Woo Lim, Byung Ha Chung, Chul Woo Yang.

Background: Optimal treatment of post-transplant diabetes mellitus is still controversial. This study was performed to evaluate whether the combined treatment of DPP IV inhibitor with metformin (MET) is effective in sirolimus (SRL)-induced diabetes mellitus.

Methods: SRL-induced diabetes mellitus was made by treating SRL (0.3 mg/kg) for 3 weeks in rats, and then started to treat DPP IV inhibitor (LC15-0444[LC], 5mg/kg), and/or MET (200 mg/kg) for further 3 weeks. The effect of combined treatment of LC and MET on SRL-induced diabetes mellitus was evaluated by IPGTT and islet size. The oxidative stress was evaluated by measuring 8-OHdG and 4-HHE, MnSOD, and catalase in samples. Insulin secretion capacity was evaluated by glucose-stimulated insulin secretion (GISIS) test using normal isolated rat islets treated with SRL, exendin-4 and/or MET.

Results: SRL treatment for 6 weeks decreased body weight and increased water intake and food intake compared with vehicle group. SRL treatment significantly increased AU/Cg from the values obtained during the IPGTT, but LC or MET treatment recovered the result with SRL treatment. Combined treatment with LC and MET has more significantly decreased blood glucose level than LC or MET treatment alone. Islet size which was significantly decreased in the SRL group was recovered with combined treatment of LC and MET. SRL treatment significantly increased intense nuclear expression and larger positive area for 8-OHdG and 4-HHE, but combined treatment LC and MET has significantly decreased expression of 8-OHdG and 4-HHE. The decreased expression of MnSOD and catalase in the SRL group was recovered with combined treatment of LC and MET. The result of GISIS also showed that combined treatment of LC and MET showed higher insulin level than exendin-4 or MET treatment alone.

Conclusions: Combined treatment with LC and MET exerts better glucose control by decreasing oxidative stress induced by SRL. This study provides the rationale for the combined use of DPP IV inhibitor and MET in SRL-induced diabetes mellitus.

Incidence and Outcomes of Hyperonatremia Early Post Lung Transplantation
Ekamol Tantisattamo,1 Aneesha A. Shetty,1 Bing Ho,1 John J. Friedewald,1 Opas Traitanon,1 Sangeeta Bhorade,1 Alexander Haynes,2 Amber Nieland,2 Lorenzo G. Gallon,1 1Div of Nephrology and Hypertension; 2Pulmonary and Critical Care, Dept of Medicine, Northwestern University Feinberg School of Medicine.

Background: Outcomes of in-hospital hyperonatremia in lung transplant recipients are unclear. The aim of this study is to describe the frequency of hyperonatremia and outcomes associated with hyperonatremia during the early postoperative period.

Methods: We performed a retrospective chart review of all lung transplant recipients at Northwestern Memorial Hospital since the first case performed in July 2014 until May 2015. The severity of hyperonatremia was defined as mild, moderate, and severe with serum Na+ <135, <130, and <125 mEq/L, respectively.

Results: A total of 13 lung transplant recipients were included. Age at the time of transplantation was 61.5±2.2 (SEM) years and 69% was female. The most common indication for transplantation was severe COPD (66%). Serum creatinine at the time of transplant and at hospital discharge was 0.8±0.1 and 1±0.2 mg/dL, respectively. Seven patients (54%) developed hyperonatremia (100% vs. 71%; p=0.151). Among 11 patients with postoperative hyperonatremia, 7 were readmitted (5 with hyperonatremia and 4 with AKI). At the time of transplant, 8% of the patients had hyperonatremia whereas the incidence was up to 46% at the time of discharge (Table1). Almost half of the patients had persistent hyperonatremia during 1 month follow-up.

Conclusions: Lung transplant recipients commonly develop hyperonatremia during the immediate postoperative period and are more likely to be readmitted with hyperonatremia. The incidence of hyperonatremia remains high up to 1 month post transplantation. AKI is also a risk for readmission and predicts longer length of hospital stay.

Degree of serum sodium At transplant 3 days 7 days At discharge 30 days 60 days 90 days 180 days
Normal 12(92%) 6(46%) 9(7%) 7(54%) 7(54%) 7 4
Mild 0 4(33%) 0 5(38%) 6(46%) NA 1

Motivations, Challenges, and Attitudes to Self-Management in Kidney Transplant Recipients: A Systematic Review of Qualitative Studies
Nathan Jamieson,1,2 Camilla Sara Hanson,1,2 Michelle A. Josephson,3 Elisa J. Gordon,4 Jonathan C. Craig,2 Fabian Halleck,4 Klemens Budde,4 Allison Tong,5 1Centre for Kidney Research, The Children’s Hospital at Westmead, Sydney, New South Wales, Australia; 2School of Public Health, Uni of Sydney, Sydney, New South Wales, Australia; 3Dept of Medicine, The Univ of Chicago, Chicago, IL; 5Centre for Healthcare Studies and Comprehensive Transplant Centre, Northwestern Univ Feinberg School of Medicine, Chicago, IL; 2Dept of Nephrology, Charité, Universitätsmedizin Berlin, Berlin, Germany.

Background: Kidney transplantation offers superior life expectancy and quality of life outcomes compared to other renal replacement therapy modalities. However, the complex and ongoing medication and self-management regimes impose a treatment burden on patients, and non-adherence remains a leading cause of graft loss.

Methods: MEDLINE, Embase, PsycINFO, and CINAHL were searched from database inception to October 2014. We used thematic synthesis to analyse the findings.

Results: Fifty studies involving 1238 participants aged from 18 to 82 years across 19 countries were included. We identified five themes: empowerment through autonomy (achieving mastery, tracking against tangible targets, developing bodily intuition, routinising and problem-solving, adaptive coping), prevailing fear of consequences (inescapable rejection anxiety, averision to dialysis, minimising future morbidity, trivialisation and denial, defining acceptable risks), burdensome treatment and responsibilities (frustrating ambiguities, inadvertent forgetfulness, intrusive side-effects, reversing ingrained behaviours, financial hardship), over-medicalising life (dominating focus, evading patienthood, succumbing to burnout), and social accountability and motivation (demonstrating gratitude towards medical team, indebtedness to donor, peer learning).

Conclusions: Self-efficacy and social accountability are motivators for self-management, but ongoing adherence can be mentally and physically taxing. Multi-component interventions that incorporate education, psychosocial support, decision aids, and self-monitoring tools may foster self-management capacity and improve transplant outcomes.

Characteristics of Patients with Vitamin D Deficiency After Kidney Transplantation in Qatar
Mohamed Amin Elesawy,1 Abdullah Hamad,2 Fadwa S. Al-Ali. Nephrology, Fahd Bin Jasim Kidney Center, Hamad General Hospital, Doha, Qatar.

Background: Vitamin D deficiency is common among normal people and in patients with chronic kidney disease including dialysis patients. Vitamin D deficiency continues to be prevalent after kidney transplantation (studies showed prevalence of 50-80%) especially with immunosuppression use and sun protection needed for elevated risk of skin cancer. We studied characteristics of kidney transplant patients with vitamin D deficiency in Qatar.

Methods: We reviewed all available records of kidney transplant patients presented to our clinic at Hamad General Hospital in Doha, Qatar between 1/9/2013 and 1/3/2014 and have vitamin D level less than 30 ng/mL. Background data and laboratory tests of patients were obtained. All patients were receiving vitamin D supplements and prednisone within their immunosuppression per institution protocol.

Results: We studied 83 patients. Mean age was 55.5 ± 16.1 years. There were 55 males (66%) and 28 females (34%). Vitamin D deficiency was severe (level than 10 ng/mL) in 15 patients (18%), moderate in 38 (46%) and mild in 30 patients (29-29 ng/mL). Duration of transplant was 7.9 ± 2.5 years. Glomerular Filtration Rate was 65.5 ± 20.6 ml/min. We found no correlation between vitamin D and PTH levels or between vitamin D and GFR levels. Table 1 summarize bone mineral panel in our patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Conclusions: In a study of kidney transplant patients with vitamin D deficiency in Qatar we found that they were predominantly males, have normal calcium, phosphorus and alkaline phosphatase levels, while they have variable degree of elevated PTH with no correlation to vitamin D level. Most patients have mild to moderate vitamin D deficiency (82%) despite receiving vitamin D supplement although the supplement could have decreased the number of patients with severe vitamin D deficiency (18%). Further study could help to evaluate the role of vitamin D supplement in improving vitamin D level in kidney transplant recipients.

**PUB647**

**Background:** Vitamin D deficiency is common in normal population and in patients with chronic kidney disease including kidney transplant recipients. Elderly patients are vulnerable to vitamin D deficiency with less sun exposure and having multiple medical problems. We compared young versus elderly kidney transplant recipients with vitamin D deficiency in Qatar.

**Methods:** We reviewed all available records of kidney transplant recipients presented to our clinic at Hamad General Hospital in Qatar between 1/9/2013 and 1/3/2014. Background data and laboratory tests of patients were collected. All patients were receiving vitamin D supplements and prednisone per institution protocol.

**Results:** 83 patients were included. 41 patients in the young group (< 60 years old) and 42 in the elderly group (> 60 years old). There were 21 females versus 20 males in the young group and 35 males versus 7 females in the elderly group (pValue=0.05). Time on transplant was 9.1 +/- 4.93 years in the young group versus 8.6+/-.2.7 in the elderly. Table 1 summarizes laboratory values for kidney transplant patients with vitamin D deficiency.

Conclusions: We compared vitamin D deficiency in young versus elderly kidney transplant recipients in Qatar. Although elderly patients have higher vitamin D levels, it was not statistically significant. This could be due to better compliance with vitamin D supplement in the elderly. Although duration on transplant, calcium, phosphorus and intact parathyroid hormone were similar, Glomerular Filtration Rate (GFR) was higher in the elderly. We explain that almost all kidney transplants in Qatar are from live donors which lead to a higher GFR in the elderly as they are receiving kidneys from younger donors. There was statistically significant smaller number of females than males in the elderly group.

The Current Status of Plasmapheresis Before Living Donor Kidney Transplantation in Japan. Norio Hanafusa, 1 Tomoko Usui, 2 Akihiko Matsumoto, 2 Satoko Sakurai, 1 Isei Noiri, 2 Hideo Yasunaga, 2 Masami Nangaku. 3 1 Dept of Hemodialysis and Apheresis, The Univ of Tokyo Hospital, Bunkyo-ku, Tokyo, Japan; 2 Dept of Clinical Epidemiology and Health Economics, School of Public Health, The Univ of Tokyo, Bunkyo-ku, Tokyo, Japan; 3 Dept of Nephrology, Nankai NPH, Bunkyo-ku, Tokyo, Japan.

**Background:** Plasmapheresis (PP) is utilized to remove alloantibodies before the living donor kidney transplantation (LDKT). The detailed practice patterns of PP before LDKT remains unknown. There also are concerns about the depletion of coagulation factors [Transfus Apher Sci 49: 254, 2013] by PP. We investigated the current status of PP before LDKT with use of the nationwide database.

**Methods:** The Japanese Diagnosis Procedure Combination Database includes all the patients discharged from hospitals participating in this program between July 2010 and March 2013. Those who received LDKT and PP before LDKT were included into this study. The modalities of PP, fresh frozen plasma (FFP) use, and albumin use were examined. We also investigated the relationship between modalities selected and outcomes such as the length and total costs of the hospital stay, or the amount of blood transfusion as the proxy of bleeding.

**Results:** In total 775 patients received PP before LDKT during the period. Among them 209 patients were treated only by simple plasma exchange (PE). Remaining 566 patients received double filtration plasmapheresis (DFPP), or cascade filtration. Interestingly, 274 patients treated by DFPP received also PE before transplantation. FFP was used during PP on 109, 180, and 42 patients treated by PE only, DFPP followed by PE, and DFPP only, respectively. Moreover, FFP was infused before the operation on 161 patients who were not used FFP during PP. As a whole 63.5% of total patients received FFP from the start of PP to the day of operation. DFPP followed by PE groups received less amount of blood transfusion (p=0.047), though the length of stay was longer and total costs were higher, compared to DFPP only (p=0.05).

**Conclusions:** Many of the patients received FFP, which suggests concerns about the depletion of coagulation factors during PP. The practice patterns were quite heterogeneous and the standardization of the practice patterns is needed to maximize the benefits of PP.

1038A
A DNI value of 2.7% was selected as cut-off value for AGPN, and renal transplant recipients with a DNI ≥ 2.7% were found to be at a higher risk of infection than those with a DNI < 2.7% (odd ratio [OR] 40.50; 95% CI 8.68-189.08; P < 0.001). In a multivariate logistic regression analysis, DNI was a significant independent factor for predicting AGPN after adjusting age, sex, log WBC count, log neutrophil count, log lymphocyte count, DNI value, CRP concentration and procalcitonin concentration (OR 4.32; 95% CI 1.81-10.34, P = 0.001).

Conclusions: The present study demonstrated that a DNI value above 2.7% was an independent predictive marker for AGPN and an effective marker to differentiate between AGPN and acute graft rejection. Thus, these findings suggest that DNI may be a useful marker in the management of these patients.

PUB652
Effect of Pre-Transplant Dialysis Modality on Outcomes of Living-Donor Kidney Transplantation Recipients Chiaki Kawabata, General Internal Medicine, Japanese Red Cross Kumamoto Hospital, Kumamoto, Japan.

Background: There are few studies on living-donor kidney transplantation that compare the outcomes after pre-transplant dialysis modality. We examined the short-term outcomes of living-donor kidney transplantation recipients after peritoneal dialysis (PD) and hemodialysis (HD), respectively.

Methods: 112 patients have undergone living-donor kidney transplantation procedures in our hospital between January 2001 and May 2014. We studied 40 patients, under 40 years of age, with dialysis durations of less than 5 years. We compared 13 PD patients with 27 HD patients and investigated the short-term outcomes.

Results: These two groups showed no significant differences as regards baseline characteristics including dialysis duration, body mass index, type of calcineurin inhibitor or ABO blood type incompatibility. The PD group was younger than the HD group as regards recipient age and donor age (22.5±8.0 years vs 29.1±6.0 years [p=0.005] : and, 50.7±8.2 years vs 56.9±7.1 years [p=0.02], respectively). There were no differences in early post-transplant complications, such as wound infection, bleeding, thrombosis, delayed graft function, or acute rejection. The PD group was better than the HD group in the estimated glomerular filtration rate (eGFR) at discharge (74.3±27.3 ml/min/1.73 m2 vs 48.3±12.3 ml/min/1.73 m2 [p=0.001]) and eGFR 1 year post-transplantation (68.4±21.8 ml/min/1.73 m2 vs 45.6±13.2 ml/min/1.73 m2 [p=0.003]).

Conclusions: In the case of younger and less than 5 years of dialysis duration, PD and HD demonstrated no differences in early post-operative complications. PD is significantly better than HD as regards eGFR up to 1 year post-transplantation.

PUB653
Bright Field Microscopy of the Unstained Urine Sediment: A Basic Tool to Identify Decoy Cells due to Polyomavirus BK on Kidney Allograft Recipients During Routine Urinalysis José A. Poloni,1,2,3 Gabriel Godinho Pinto,1 Marta Giordani,1,2 Maria De Girolamo,1,2 Alessandro C. Pasqualletto,1,2 Lianne Rotta,1,2 Irmandade da Santa Casa de Misericórdia de Porto Alegre, Porto Alegre, RS, Brazil; 1Univ Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, RS, Brazil; 2Control Lab, Rio de Janeiro, RJ, Brazil.

Background: Polyomavirus BK (BKV) is an important pathogen that can be reactivated in kidney allograft recipients, potentially leading to BKV nephropathy (BKVN), an important cause of graft loss. Decoy cells (DC), urothelial cells or renal tubular epithelial cells modified by the proliferation of BKV, are one of the hallmarks of BKV reactivation and can be identified in the fresh urine sediment.

Methods: A cohort of 102 kidney transplant patients was followed during months 3 and 6 after the transplant procedure. Urine samples were obtained to detect the presence of DC in the fresh and unstained urine sediment under bright field microscopy (BFM) by two experienced analysts, as well as by BKV viruria by qPCR.

Results: DC were found in 15 patients.

Figure 1 – Three decoy cells presented under bright field microscopy (left panel) and under phase contrast microscopy (right panel). Original magnification 400x.

Intravenous Immunoglobulin in the Management of Pneumocystis Pneumonia: A Case Series Musab Ellnaqel, Muhammad Imran, Matthew Edey. Hull Royal Infirmary, Hull, United Kingdom.

Background: Pneumocystis pneumonia (PCP) is a well-recognized complication of renal transplantation. We present 2 cases of severe PCP treated successfully with intravenous immunoglobulin (IVIg), trimethoprim-sulfamethoxazole (TMP-SMX) and withdrawal of immunosuppression. Graft function was maintained despite a high baseline immunosuppressive risk.

Methods: Case A: A 32 year-old woman presented 2 years post-transplant with acute cellular rejection treated with steroids. 2 months later she was admitted with respiratory failure due to PCP. She required intubation and ultimately oscillatory ventilation. CMV DNA was detected at low levels in bronchoalveolar lavage (BAL) fluid. IVIg 30g on alternate days (10 doses) was added, in addition to withdrawal of immunosuppression and hydrocortisone replacement. She made a full recovery, with preservation of transplant function throughout. Case B: A 47 year-old woman received a second kidney transplant. Early post-transplant she developed acute antibody mediated rejection managed with plasma exchange and escalating ventilator requirements. She received IVIg 25g/day for 5 days, replacement hydrocortisone and immunosuppression was withdrawn. Her AKI resolved and later she became ventilator-independent. Graft function was at baseline on discharge. Maintenance immunosuppression was recommended.

Conclusions: It is understood that immunity against Pneumocystis jirovecii is both B- and T-cell mediated. Thus pooled immunoglobulin might be expected to have some anti-Pneumocystis activity. It is also recognized that IVIg has immunomodulatory properties. In both cases the administration of IVIg allowed withdrawal of immunosuppression apart from replacement steroid without graft rejection despite high immunological risk. Both patients survived life-threatening PCP. We suggest adjunctive therapy with IVIg be considered in severe PCP.

**Ethical Issues Related to Kidney Donination/Transplantation: Perspective of Indian Doctors**

Richard S. Fernandes Almeida,1 Nirmala Almeida,2 Karen Almeida,3 Alan F. Almeida.4 *Lifesupporters Inst of Health Sciences; *Human Development, Nirmala Niketan College of Home Science; *Psychology, Mumbai Univ; *Nephrology, PD Hinduja Hospital, Mumbai, India.

**Background:** Dearth of kidneys for transplantation has provoked the need to evaluate new policies and practices. This spurred the current study which addressed the perspective of doctors regarding emerging ethical issues pertaining to kidney donation/transplantation.

**Methods:** The sample consisted of 140 doctors from Mumbai (Age Range:21–80 years, M=38.1, SD=17.95, Males=44.3%, Females=55.7%). A questionnaire, presenting ethical issues related to kidney donation/transplantation, in an agree-disagree format with supporting reasons was employed. The research design was exploratory; data was analyzed quantitatively and qualitatively.

**Conclusions:** This study is relevant in view of the dearth of Indian research. Educating doctors about medico-ethical issues is the need of the hour.

**PUB656**

**Cardiovascular Risk Management of Renal Transplant Patients**

Joseph C. Newton, Thalakunte M. Muniiraju. Dumfries and Galloway Royal Infirmary, Dumfries, United Kingdom.

**Background:** There is a high burden of cardiovascular disease amongst renal transplant recipients, and it is the most common cause of death with a functioning graft. We have assessed the medical management of all transplant patients in our region by comparing regular monitoring of glycaemia, blood pressure and serum lipids, with appropriate prescription of medicines based on their cardiovascular risk.

**Methods:** Using the electronic health record information was collected on cardiovascular comorbidities, all current medications, frequency of clinic monitoring, BP and LDL levels. The recent biochemical results for glycaemia, proteinuria and lipid results for the local transplant cohort of 69 patients. Prescription of statins, antiplatelet agents and aspirin were audited against guidelines from the UK Renal Association (RA) and KDIGO. Cardiovascular risk was calculated using the Joint British Societies Guidelines (JBS2).

**Results:** Amongst hypertensive patients, 2/28 (7.1%) were not on an antihypertensive therapy. Significant proteinuria (aPCR >50) was not common (6/68 = 8.8%), but of these only 2/6 (33.3%) were receiving an ACE inhibitor or ARB. Glycaemic control of diabetic patients was generally good, with 9/12 (75%) achieving target HbA1c <48 mmol/mol. For non-diabetic patients, 11/56 (19.6%) were found to have a random glucose ≥7. Of these 4/11 (36.4%) had Hba1c checks, one of which confirmed new diabetes. The remaining 7 patients (63.6%) have not had a follow up Hba1c. 20/69 (29.0%) of patients were calculated as >20% cardiovascular risk on the basis of comorbidities or using JBS2. Of these only 12/20 (60%) were on statin therapy. Almost all 6/7 (85.7%) of patients with vascular disease were taking regular aspirin.

**Conclusions:** We have identified room for improvement in the management of hypertension and proteinuria. Rates of statin prescription suggest that we often underestimate cardiovascular risk clinically, however, further analysis will need to determine whether valid reasons exist to support decisions to omit statins or renin-angiotensin blockade. These audit results will be discussed with local clinicians, and will be added to the electronic record to highlight where individual management differs from national guidelines.

**Preemptive Transplantation Is Associated with Improved Graft Survival: Results from the French Transplant Database**

Mathilde Revard,1 Christian Combe,1 Jerome Harambat,1 Christian Jacquelin,2 Pierre Merville,1 Lionel Couzi,1 Karen Leffondre,1 INSERM U897, Bordeaux School of Public Health, Bordeaux, France; 1Nephrology and Transplantation, Bordeaux Univ Hospital, Bordeaux, France; 1Agence de la Biomedecine, Paris, France.

**Background:** Kidney transplantation (KT) is the treatment of choice for end-stage renal disease. In France, preemptive kidney transplantation (P KT) is considered because glomerular filtration rate is under 20 ml/min/1.73m² but European reports on the results of P KT are scarce. Our objective was to evaluate the impact of P KT on graft and patient survival.

**Methods:** We analyzed all first kidney-only transplants performed in adults in France between 2002 and 2012. A Cox multivariable model was used to study the impact of P KT on the hazard of graft failure defined as death, return to dialysis, or retransplant, whichever came first.

**Results:** Between 2002 and 2012, 22,288 patients received a first KT, including 3112 (14%) who had a P KT. Mean recipient age at KT was 50.5 ± 13.4 years, 61.9% were men. Mean time of follow-up was 4.7 years. In the first year of surveillance, P KT was associated with a 43% reduction in the hazard of graft failure when compared with patients who were treated by dialysis before KT (HR 0.57, CI 0.59 to 0.64). Reduction in the hazard of graft failure was greater after the first year of transplant (HR during the first year 0.69, CI 0.65 to 0.74; HR after the first year 0.51, CI 0.45 to 0.59) and the impact of P KT was also greater in living than in deceased donor recipients (HR in living donor 0.34, CI 0.29 to 0.40; HR in deceased donor 0.59, CI 0.52 to 0.66). Among the subgroup of patients registered on the waiting list before the initiation of dialysis, P KT was associated with a 29% reduction in the hazard of graft failure (HR 0.71, CI 0.58 to 0.87).

**Conclusions:** In France, P KT is associated with better graft survival than KT performed after the initiation of dialysis. Nephrologists should prepare patients to P KT rather than to dialyze.

**PUB658**

**Novel Potential Theranostic Targets in Individuals with Kidney Allograft Dysfunction**

Roberto Bassi,1,2 Monika A. Nieczcas,2 Stefania Bussolino,3 Valentina De Zan,4 Giuseppe Paolo Segoloni,5 Antonio Sacchi,6 Amil K. Chandraker,7 Luigi Biancone,8 Paolo Fiorina.1,2 1Nephrology, Boston Children’s Hospital, Boston, MA; 2Medicine, San Raffaele Scientif Inst, Milan, Italy; 3Psychology, Boston Children’s Hospital, Boston, MA; 4Transplantation Research Center, Brigham and Women’s Hospital, Boston, MA; 5Internal Medicine, San Giovanni Battista Hospital, Turin, Italy; 6Univ of Torino.

**Background:** The lack of early diagnostic and therapeutic targets for chronic allograft dysfunction (CAD) is among the major determinants of poor long-term graft survival. Metabolic abnormalities in serum and kidney graft parenchyma may worsen allograft function, while alterations of urinary metabolites may be used as diagnostic biomarkers. Novel targets: To explore this hypothesis, we recruited individuals with stable allograft function and performed a comprehensive metabolomic analysis of serum and kidney graft tissue using high-performance liquid chromatography-tandem mass spectrometry (LC/MS-MS). We identified metabolic profiles in serum and in vivo two dimensional correlated spectroscopy (2D-COS) of the kidney graft.

**Results:** LC/MS-MS revealed serum and urinary abnormalities of amino acids, biogenic amines and acylcarnitines in individuals with worse allograft function (T3) compared to conserved graft function (T1). Particularly, CAD was associated with reduction of serum tryptophan and glutamine (T3 vs. T1, p<0.01) and of urinary histidine (T3 vs. T1, p<0.05). Derivatives of dimethylarginine (DMA; symmetric (SDMA): T3 vs. T1, p<0.01; p<0.05) and short-chain acylcarnitines (C4; C12: T3 vs. T1, p<0.01; p<0.05) increased in serum, while dopa and dopamine (T3 vs. T1, p<0.01; p<0.001) together with DMA, SDMA and ADMA (T3 vs. T1, p<0.01; p<0.05) decreased in serum. In vivo 2D-TREE performed on the same patients revealed reduction (p<0.05) of the parenchymal content of choline, creatine, taurine and threonine in individuals with CAD. Notably, taurine was selectively reduced within the graft parenchyma and increased in serum and urine of individuals with CAD.

**Conclusions:** Novel potential theranostics targets have been identified with an unbiased ex vivo and in vivo metabolomic profiling of individuals with CAD.

**Funding:** Government Support - Non-U.S.
Results: As compared with controls, the change of estimated glomerular filtration rate was similar in recipients with dipstick proteinuria after 3-year post-KT (1.5 vs. 7.1 vs. -4.4 ± 7.4 mL/min/1.73 m²/year, P=0.017). In Kaplan-Meier analysis, KT recipients in control group had a better dialysis-free survival as compared with cases (201 vs. 6 vs. 164 ± 10 months; log-rank P=0.0118). In Cox proportional hazard models, trace or more dipstick proteinuria was closely associated with long-term allograft loss (HR=1.964, 95% CI=1.522-3.438), and further adjustment for age and gender did not attenuate this association (HR=1.764, 95% CI=1.050-3.065).

Conclusions: Our results may suggest that presence of small amount protein in urine may be the first sign of deteriorating allograft renal function.

PUB660

Impact of Pre-Transplant Peritoneal Dialysis Compared with Hemodialysis on the Incidence of Delayed Graft Function in Kidney Transplant Recipients with Lupus

Gabriel Contreras, Javier Pagan, Antonio A. Armstrong, Jorge M. Diego, Ian Thomas, Patricia Marie Byers, Alberto J. Sabucedo, Jair Munoz Mendoza, David Roth. Univ of Miami Miller School of Medicine.

Background: Delayed graft function (DGF) increases the risk of allograft failure in recipients of kidney transplants.

Methods: In this study, we assessed the impact of pre-transplant peritoneal dialysis (PD) compared with hemodialysis (HD) on the risk of DGF in patients with lupus using logistic regression models.

Results: Three hundred-fifty three of 2513 (14 %) recipients transplanted between 1979 and 2014, including 88 with diabetic ESRD (DM group) (type 1, n = 8; type 2, n = 80) and 270 with non-diabetic ESRD (NDM group). Mean follow-up was 92 ± 38.9 months.

Results: Mean age was higher in the DM group (52.8 vs 44.6 years; P < 0.001), and there was a significant difference in recipient gender, donor age or donor source. At the end of follow-up, there was no differences between the groups in terms of blood pressure (DBP 139 ± 16.7 in DM and 133 ± 17.6 mmHg in NDM), of lipid profile (LDL 191 ± 57 in DM and 177 ± 48 mmHg in NDM), of glucose (168 ± 36 in DM and 162 ± 34 mmHg in NDM) and of HbA1c (6.2 ± 1.2% in DM and 6.1 ± 1.2% in NDM). Surprisingly, there were no differences between the DM and NDM groups in terms of albuminuria or of proteinuria.

PUB666

Association Between Dipstick Proteinuria and Allograft Outcomes in Living Donor Kidney Transplant Recipients

Joon-sung Lee, Gheun-Ho Kim.

Dept of Internal Medicine, Hanyang Univ College of Medicine, Seoul, Republic of Korea.

Background: Proteinuria is one of the important factors suggestive of kidney function impairment. Previous epidemiological studies had demonstrated that greater than trace amounts of protein on a casual urine dipstick may be an important predictor of long-term clinical outcomes in general population. In kidney transplant (KT) recipients, there were few data concerning it.

Methods: Thus, we retrospectively analyzed 238 living donor KT recipients to investigate impact of dipstick proteinuria on allograft outcomes. All KT recipients were divided into 2 groups according to dipstick proteinuria: control group (n=190), negative; case group (n=48), ≥ trace. Cox’s proportional hazard model with time-dependent covariates was used to adjust for effect of covariates that change over time, including vintage and allograft survival time.

Results: In lupus patients with dipstick proteinuria after 3-year post-KT (1.5 vs. 7.1 vs. -4.4 ± 7.4 mL/min/1.73 m²/year, P=0.017). In Kaplan-Meier analysis, KT recipients in control group had a better dialysis-free survival as compared with cases (201 vs. 6 vs. 164 ± 10 months; log-rank P=0.0118). In Cox proportional hazard models, trace or more dipstick proteinuria was closely associated with long-term allograft loss (HR=1.964, 95% CI=1.522-3.438), and further adjustment for age and gender did not attenuate this association (HR=1.764, 95% CI=1.050-3.065).

Conclusions: Our results may suggest that presence of small amount protein in urine may be the first sign of deteriorating allograft renal function.

PUB666

Cytomegalovirus Exposure Is Associated with Immunological Sensitization in End-Stage Renal Disease

Robert Lam, Rita Suri, Amitabh Singh, Lakshman Gunaratnam.

School of Medicine and Dentistry, Western Univ, London, ON, Canada; Uni of Montreal, Montreal, QC, Canada; Matthew Mailing Center, London Health Sciences, London, ON, Canada.

Background: The presence of antibodies to Human Leukocyte Antigen (HLA) is associated with long transplant wait-times, acute rejection, and poor graft outcomes. While prior transplant, pregnancy, and blood transfusion can trigger HLA antibodies, many sensitized patients have none of these known risk factors. Previous infections have been proposed as a potential cause of “spontaneous” sensitization, but this has not been well studied. Because cytomegalovirus (CMV) is known to modulate the host’s immune defenses to avoid identification and clearance, we hypothesized that prior CMV exposure would be associated with HLA sensitization.

Methods: We conducted a cross-sectional study of 150 patients aged ≥18 years attending a University hospital renal transplant assessment clinic from 10/19-10/18. Patients with prior transplant were excluded. Demographics, comorbidities, viral serology, peak Panel Reactive Antibody (pPRA), blood transusions, and pregnancies were obtained by chart review; sensitizing events were confirmed by patient questionnaire.

Results: Fifty percent were CMV IgG positive and 32% had cPRA>20%. A cPRA>20% was significantly associated with CMV positive IgG (adjusted odds ratio 2.8, 95% CI 1.3-6.6; p=0.012), prior pregnancy (adj OR 4.0, 95%CI 1.7-9.4; p=0.002), and blood transfusion (adj OR 3.9, 95%CI 1.7-8.7; p=0.001), whereas age, sex, hypertension, diabetes, and years on dialysis were not. In the subgroup of 83 patients with no previous pregnancy or blood transfusion, the prevalence of pPRA>20% was 24% in CMV positive patients, versus 12% in CMV negative patients (unadj OR 2.3, 95%CI1.0-7.7; p=0.152).

Conclusions: We identified previous CMV exposure as a novel independent risk factor strongly associated with the presence of HLA antibodies. Whether CMV infection triggers HLA sensitization requires further studies in prospective longitudinal studies.

Successful Treatment of BK Nephropathy with Tacrolimus and mTOR Inhibitors
Nephrology, Hospital Unif 12 de Octubre, Madrid, Spain.

Background: BK nephropathy (BKN) is a relevant cause of graft dysfunction in kidney transplantation. mTOR inhibitors (mTORi) have been suggested as the best immunosuppression in BKN. However Tacrolimus-free therapy could increase risk of rejection. Since 2009 in patients with BKN we conducted a protocol discontinuing Mycophenolate and decreasing Tacrolimus (TAC) dose in association with mTORi, both with target levels of 5 ng/mL.

Methods: From 2007 to 2013 we diagnosed 22 BKN. Patients diagnosed since 2009 (n=14, group 1) were treated beginning mTORi and decreasing TAC dose. The others 8 patients suffered significant reduction of immunosuppression (group 2). We analyze renal function, plasma quantitative BK PCR, antiHLA antibodies, rejections and dialysis or death at final follow-up.

Results: 22 patients were identified. The BKN was diagnosed at 7th month after transplantation (range 2-55). The medium duration of follow-up was 53 months (6-85). Baseline characteristics and evolution are listed in table 1.

Although group 1 had a greater immunologic risk and a higher plasma BK viral load at diagnosis, the renal function during follow-up was more favorable than patients from group 2. No rejection episodes were diagnosis in group 1. Only one patient in each group started chronic dialysis at the end of the follow-up (52 and 85 months after BKN diagnosis).

A Rare Case of Guillain-Barré Syndrome Associated with Cytomegalovirus Disease in a Renal Transplant Patient
Jessica Bian, George P. Bayliss.
Medicine, Rhode Island Hospital, Providence, RI.

Background: While cytomegalovirus (CMV) infection is associated with Guillain-Barré syndrome (GBS) in the general population, there are few reports of GBS associated with CMV disease in the renal transplant patients. We describe the case of a renal transplant recipient who developed GBS after treatment for documented CMV disease.

Methods: The patient is a 62-year-old woman with ESRD from polycystic kidney disease status post deceased donor renal transplant (CMV donor positive/reipient-seronegative) on tacrolimus and prednisone. She completed 6 months of CMV prophylaxis with valganciclovir. Fourteen days after stopping valganciclovir, she presented with fevers, myalgias, and headache. Tacrolimus level was 6.6 ng/mL on admission. She was diagnosed with CMV disease (serum CMV PCR 2200 copies; CSF CMV PCR undetectable) and started on treatment-dose valganciclovir. Ten days later, she returned with numbness of her hands and feet. CSF studies were notable for albuminocytologic dissociation. MRI brain and spine was normal. Electromyography showed diffuse sensory motor polyneuropathy consistent with GBS. She developed ascending motor weakness, sensory loss, and areflexia without progression to respiratory compromise, improving with IVIG therapy. She was discharged to rehabilitation.

Results: She returned 7 days later with compartment syndrome of her right arm due to deep venous thrombosis of her right subclavian, axillary, and brachial veins with associated hematoma requiring emergent fasciotomy and hematoma evacuation. This was attributed to recent IVIG therapy, as thromboses may occur even in the absence of other risk factors (US boxed warning). She was bridged to warfarin prior to discharge. Of note, she maintained excellent alflograft function throughout this complicated course.

Conclusions: This vignette describes a case of CMV-associated GBS after renal transplantation. The case is notable for the development of CMV disease shortly after cessation of valganciclovir prophylaxis in a CMV donor positive/reipient negative renal transplant despite only being only on a two-drug immunosuppressive regimen. This may support a longer course of CMV prophylaxis in donor positive/reipient negative transplants.

A Clinical Significance of Pre-Transplant 25-Hydroxyvitamin D Levels on Post-Transplant Clinical Outcome
Tae Hyun Ban, In-Ge Jang, Bum Soon Choi, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim, Byung Ha Chung, Soon Choi, Cheol Whee Park, Chul Woo Yang, Yong-Soo Kim, Byung Ha Chung.
Internal Medicine, Seoul St. Mary’s Hospital, Seoul, Korea; Transplant Research Center, Seoul St. Mary's Hospital, Seoul, Korea.

Background: It is well known that vitamin D shows immune modulating effects in various immunologic disorders and infectious disease. The aim of this study is to investigate the clinical significance of 25(OH)D levels on acute rejection or infection in kidney transplant recipients.

Methods: We included 174 kidney transplant recipients with low immunologic risk between 2011 and 2013. We measured 25(OH)D levels right before transplantation, and investigated whether the level of 25(OH)D predicts the development of acute rejection or infectious complications.

Results: During the first year after the KT, a total 27 cases of biopsy proven acute rejection was detected. 25(OH)D levels showed significant association with the development of acute rejection within the first year from KT. In the high tertile, the rate of acute rejection was 6.9 % (p=0.012). It was significantly lower incidence toward the high tertile. There was significant distinction between each tertile (low and second, p=0.032; second and high, p=0.002). For the prediction of infectious complications, after the 1 year predictive periods of 25(OH)D levels were dissipated. During the first year after KT, a total of 82 (47.5%) cases of infectious complications were detected. Most common causes were 23 (13.2%) cases of CMV and UTI respectively.25(OH)D levels did not show significant association with either the overall or different types of infectious complications.

Conclusions: Pre-transplant serum 25(OH)D levels are independent predictor of acute rejection in the first year from kidney transplantation. However, they were not associated with infectious episode.

Mammalian Target of Rapamycin Inhibitors Withdrawal in Kidney Transplant Recipients: Risk Factors and Related Transplant Outcomes

Lee-Mooy Lim,1 Mei-Chuan Kuo,2,3 Hung-Tien Kuo,2,3 1Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan; 2Faculty of Renal Care, College of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan.

Background: With its antiproliferative and antineoplastic properties, Mammalian Target of Rapamycin Inhibitors (mTORI) potentially have important long-term therapeutic consideration in kidney transplantation. Treatment cessation frequently occurs following its unique adverse effects. The objective of this study was to investigate the risk factors for mTORI withdrawal and its impacts on transplant outcomes.

Methods: This retrospective observational study consisted of kidney transplant recipients followed up from January 1999 till May 2015. We examined the risk factor for mTORI withdrawal using multivariate logistic regression analysis. The impacts of mTORI withdrawal on transplant outcomes were analyzed using multivariate Cox regression and logistic regression. P<0.05 was considered as statistically significant.

Results: A total of 111 kidney transplant recipients who received mTORI treatments were included, with 46 patients withdrew (41.0%). The risk factors for mTORI withdrawal included initial proteinuria (adjusted OR=4.61, P=0.007), higher initial serum creatinine (per 1mg/dl increment, adjusted OR=2.73, P=0.035), and glomerulonephritis as primary renal disease (adjusted OR=5.00, P=0.035). mTORI withdrawal was associated with an increased risk of graft failure (adjusted HR=3.79, P=0.027), but not with patient survival (adjusted HR=0.61, P=0.595).

Conclusions: mTORI withdrawal is a strong risk factor for renal graft failure. Proteinuria, poor initial graft function and primary renal disease of glomerulonephritis are predictors for mTORI withdrawal. Earlier identification of risk factors may assist physician to decide the best candidate for mTORI conversion in order to optimize transplantation outcomes.

Impact of Donor Age on Longterm Outcomes in Living Donor Kidney Transplants: A Propensity Score Matched Analysis Using Multicenter Cohort

Kyoung Don Yoo,1 Jung Nam An,1 Jung-Hee Cho, 2chain-Duck Kim, 3Su-Kil Park, 2Dong-Wan Chae, 3Yun Kyu Oh, 3Chun Soo Lim, 3Yon Su Kim, 3Young hoon Kim, 3Jung Pyo Lee.1 1Seoul National Univ College of Medicine; 2Immunopathology, Post Graduate Inst of Medical Education and Research, Chandigarh, India; 3Asan Medical Center and Univ of Ulsan College of Medicine.

Background: Recently, kidney transplantation from elderly living donor has been increasing. However, the impact of donor age on outcomes in kidney transplantation recipients has not well established in Asian.

Methods: This multicenter cohort study included 2,595 adult kidney transplant recipients admitted to 5 major tertiary hospitals in Korea between 1997 and 2012. Patient survival, allograft survival, and biopsy-proven acute rejection (BPAR) were compared between the elderly donors (≥ 50 years) and young donors (18–49 years) by the propensity score matched (PSM) analysis.

Results: The proportion of donor with over 50 years was 21.2% (N=553). The mean age in the elderly donor was 54.9 ± 4.3 years old. Despite of difference of donor age, mean recipient age was similar between the groups. Elderly donors were more likely to donate to unrelated recipients. The proportions of recipients with diabetes mellitus (22.8%), serum creatinine and BMI of donor were significantly higher in the elderly donor group than in the young donor-age group. In elderly donor group, recipients’ patient survival was worse than younger age group before PSM (p=0.014). After PSM, donor age did not affect the recipients’ survival (p=0.305) and allograft survival (p=0.077), however, BPAR was frequently occurred in the allograft from elderly donor (p=0.019). In the multivariate Cox regression analysis, elderly donor affected the BPAR-free survival (p=0.01, hazard ratio 1.52, 95% confidence interval 1.07-2.17).

Conclusions: Kidney transplantation from elderly donor needs more meticulous management, because donor age could affect the outcomes of transplantation.

Long-Term Outcome of Randomized Trial Comparing Cyclosporine and Tacrolimus Therapy with Steroid Withdrawal in Living-Donor Renal Transplantation: 10-Year Follow-Up

Jin Hae Kim, Jee Eun Park, Do Hee Kim, Hye Ryoun Jang, Jung Eun Lee, Dae Joong Kim, Yoon-Goo Kim, Ha Young Oh, Woo Seong Huh.1 Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Republic of Korea.

Background: The use of steroid withdrawal protocols after kidney transplantation has been increasing because of well-known adverse effects of steroids and the introduction of new effective immunosuppressants. Long-term efficacy and safety of tacrolimus plus mycophenolate mofetil (TAC group) compared with cyclosporine Aplus MMF (CsA group) for 10 years were analyzed in renal transplantation patients with low immunologic risk who were converted to steroid withdrawal 6 months after transplantation.

Methods: Overall 10-year follow-up data of patients who underwent their first living-donor renal transplantation at Samsung Medical Center between September 2000 and August 2003 were retrospectively analyzed. Patients were randomized to CsA or TAC groups and underwent steroid withdrawal at 6 months after renal transplantation. End points were patient and graft survival, and the incidence of acute rejection and post-transplant de-novo comorbidity such as diabetes mellitus.

Results: A total of 117 patients who successfully discontinued steroid treatment were included (55 in CsA group vs. 62 in TAC group). The 10-year patient survival was 96.2% in the CsA group and 98.4% (61/62) in the TAC group (p=0.495). The 10-year graft survival rate did not differ between groups (81.3% in CsA vs 91.2% in TAC; p=0.412). The cumulative incidence of acute rejection for 10 years after transplantation was 24.5% and 15.6% in the CsA and TAC groups, respectively (p=0.201). The incidence of post-transplantation diabetes mellitus was higher in the TAC group compared to the CsA group (10.0% vs. 23.3%, respectively; p=0.046).

Conclusions: Long-term graft and patient survival, and the incidence of acute rejection were similar between CsA- and TAC-based regimens combined with MMF in low immunologic risk patients who underwent steroid withdrawal 6 months after kidney transplantation.

Dysregulation of Circulating Immunoglobulins in Renal Transplant Recipients

Mukut Minz1, Ravi Dhitla,1 Ranjan Walker Minz,2 Ashish Sharma,1 Ritambhara Nada,1 Deepesh Kenwar,1 Sarbpreet Singh.1 1Transplant Surgery, Post Graduate Inst of Medical Education and Research, Chandigarh, India; 2Immunopathology, Post Graduate Inst of Medical Education and Research, Chandigarh, India; 3Nephrology, Post Graduate institute of Medical Education and Research, Chandigarh, India; 4Histopathology, Post Graduate Inst of Medical Education and Research, Chandigarh, India.

Background: Peripheral levels of serum immunoglobulin reflect humoral immunity. Gross demarcations in the immunoglobulin levels might occur in the post-transplant period.

Methods: Peripheral venous blood was periodically collected from patients before (pre-Tx) and after kidney transplantation at 1Month, 3 Months, 6 Months, 12 Months and at the time of Rejection. Serum was isolated from clotted blood after brief centrifugation at 3000g for 10 minutes. Serum level of IgG, IgA, lgG1, lgG2, lgG3 and lgG4 were quantified by nephelometry (MiniNeph, UK).

Results: This study includes 75 first kidney transplant recipients who were divided into two groups: Rejection group (R, n=35) and Non Rejection group (NR, n=35). Rejection group included (n=25) and non-rejecters (n=35) and were matched (n=39). Thirty five age and sex matched healthy donors were recruited as control. No differences in the levels of lgG, lgA and lgM were noted in the pre-transplant period. Post-transplantation, there is an early decrease in serum lgG and lgA levels in both R and NR groups between 1-3 months and the rate of decrease is higher in patients with rejecting grafts. lgG3 and lgG4 are significantly reduced during rejection (p<0.0001 and 0.006 respectively). lgG3 levels correlated with cellular rejection, while the rate of decrease of lgG2 and lgG4 was higher in antibody mediated rejection.

Conclusions: Post-transplantation, there is a fall in serum levels of IgG, IgA, and its subtypes in both no rejecters and rejecters, more so in the later. Low serum levels of lgG3 and lgG4 could be a pointer to rejection. Significant correlation of lgG3 with cellular rejection abnormalities that lgG subtypes are dysregulated in cell-mediated rejection.

Impact of Donor Age on Longterm Outcomes in Living Donor Kidney Transplants: A Propensity Score Matched Analysis Using Multicenter Cohort

Kyoung Don Yoo,1 Jung Nam An,1 Jung-Hee Cho, 2chain-Duck Kim, 3Su-Kil Park, 2Dong-Wan Chae, 3Yun Kyu Oh, 3Chun Soo Lim, 3Yon Su Kim, 3Young hoon Kim, 3Jung Pyo Lee.1 1Seoul National Univ College of Medicine; 2Immunopathology, Post Graduate Inst of Medical Education and Research, Chandigarh, India; 3Asan Medical Center and Univ of Ulsan College of Medicine.

Impact of Kidney Transplantation on Arterial Stiffness in Patients with ESRD

Hysunsook Kim, Chul Woo Yang, Byung ha Chung, Cheol Whee Park, Yong-Soo Kim, Bom soon Choi. 1Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, The Catholic Univ of Korea, Seoul, Republic of Korea.

Background: Arterial stiffness is closely associated with cardiovascular mortality in end-stage renal disease (ESRD) patients. We investigated whether kidney transplantation (KT) can improve arterial stiffness in patients with ESRD.

Methods: We enrolled 171 KT recipients and we measured brachial-ankle pulse wave velocity (baPWV) and ankle-brachial blood pressure index (ABI) before KT, and post KT baPWV and ABI was assessed in a subgroup of 84 patients. First, we investigated cardiovascular(CV) events risk and established influence factors. Second, these patients divided into improvement and non improve groups based on change of baPWV after KT which was very strong marker of CV disease progression. We also compared risk factors which affect arterial stiffness between two groups.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Results: 10 CV events occurred in the overall group, and 7 events in the post KT batch. Of the 10 events, 6 of the affected CV events of this group were diabetes, high body mass index (BMI) and high baPWV. Overall arterial stiffness measured by baPWV after KT showed significant improvement (1417.5 ± 234.3 cm/s) compared to those of before KT (1503.5 ± 252.2 cm/s) (p=0.05 vs after KT).55 out of 79 patients (69.6%) showed improvement of baPWV after KT, but 24 patients did not. Between two groups, improvement group showed higher pre-transplant baPWV than no-improvement group (1561.0 ± 263.9 vs. 1371.6 ± 177.1), and multivariate analysis revealed that gender and BMI, degree of decrement of calcium level were an independent risk factor of change of baPWV.

Conclusions: We could expect CV event risk in KT recipients by diabetes, BMI and baPWV, and these were very strong prediction marker of CV event. Arterial stiffness in ESRD patients improves after transplantation, and lower BMI, the amount of calcium decreased, gender affected the improvement of baPWV. PUB673

The Correlation of Donor:Recipient Body-Mass Index (BMI) Ratio and 6-Month Post-Transplant Kidney Function in Known End-Stage Renal Disease (ESRD) Patients Joseph Justin Hipolito Regalado, Internal Medicine, Cardinal Santos Medical Centre (CSMC), San Juan, Metro Manila, Philippines.

Background: Kidney Transplant (KT) is the preferred treatment for ESRD. The challenge rests in finding appropriate donors. Donor-recipient size mismatch was shown to correspond to donor-recipient nephron supply mismatch, affecting prognosis. Matching nephron supply to recipient needs was proposed to improve outcomes. Patients with a higher BMI relative to their donors were shown to have poorer post-KT graft function. Determining whether measures such as BMI are valid predictors of outcomes is a legitimate area of study. This research sought to determine the association and correlation between Donor-Recipient BMI Ratio and the 6-month post-KT creatine (crea).

Methods: A review of patients who underwent KT in 2005-2014 at the CSMC was done. Inclusion criteria were Filipinos aged 18 years and above with a graft, coming from a Living Donor, functioning for at least 6 months post-KT (25 Donor-Recipient pairs). Association using Chi-Square and correlation using Multiple Regression Analysis between Donor-Recipient BMI and renal function based on 6 months post-KT crea were determined.

Results: Data showed no statistically significant association (p=0.64) and correlation (p=0.77) between Donor-Recipient BMI ratio and post-KT crea. Statistically significant correlations (p<0.10) were noted between the post-KT crea and the recipient and donor BMI respectively: r=0.78, with a 22.51umol/L increase in post-KT crea per 1 point increase in the donor BMI, and a 13.51umol/L decrease in post-KT crea per 1 point increase in recipient BMI.

Conclusions: The data support two schools of thought on donor-recipient selection in improving outcomes. First, recipients are to lose weight to improve BMI before KT to decrease the increased risk of graft damage from hyperfiltration and lipotoxicity. Second, donors with larger BMI’s are better due to a higher nephron reserve. It could be surmised from the study that the donor and recipient BMI’s influence the 6-month post-KT crea. The appropriate mathematical instrument defining the relationship between these measures predicting KT outcomes more accurately, however, is yet to be universally established.

PUB674

Incidence of Malignancies in Kidney Transplant Patients – Report from Eastern Province of Saudi Arabia Abdulrazak Amir1,2,3 Nephrology, Internal Medicine, Johns Hopkins Aramco Healthcare, Dhahran, Eastern, Saudi Arabia; 1Internal Medicine, Univ of Dammam, Dammam, Eastern, Saudi Arabia.

Background: Renal transplant patients have a higher incidence of malignancies due to the use of immunosuppressive medications and concomitant infections.

Methods: Based on the follow up of a single center in Saudi Arabia, the incidence of malignancies patients who underwent kidney transplantation was analyzed.

Results: During the 15 years study period, a total of 221 patients underwent renal transplantation. Eleven patients developed post-transplant malignancies with an average incidence of 4.9%. Two patients had Kaposi sarcoma (0.9%) and two developed Non-Hodgkin lymphoma (0.9%). One case was reported to have transitional cell carcinoma of urinary bladder (0.4%), one had breast cancer (0.4%), one had cervical cancer (0.4%), one developed angiosarcoma (0.45%), and one had hepatocellular carcinoma (0.45%). In addition, two patients developed renal cell carcinoma, one in the native kidney (0.45%), and the other in the transplanted kidney (0.45%). The duration to cancer development ranged from 6-120 months. Mortality rate in renal transplant patients with cancer was higher (55%) than those who did not develop cancer. Risk factors that determined cancer development included patient age, gender, duration of the transplantation and type of immunosuppression. Type of transplant was not found to be a determining factor of cancer development.

Conclusions: The incidence of malignancies in post renal transplant patients in the Kingdom of Saudi Arabia is evidently comparable to that reported in literature. In addition, the data highlights the importance of long term close follow up of renal transplant patients.

PUB675

Left Ventricular Global Longitudinal Strain as Early Detection of Subclinical Myocardial Dysfunction in Renal Transplant Recipients Secundino Cigarrañ,1 Jose Lomban,2 Ana Maria Sanjurjo Amado,1 Diego Coronel,1 Sheila Casas,3 Juan Latorre,3 M’ Milagros López hernández,2 Jesus Calvino.3 1Nephrology, Hospital Da Costa, Barela, Lugo, Spain; 2Nephrology, Hospital Nuestra Augusti, Lugo, Spain; 3Cardiology, Hospital Da Costa, Barela, Lugo, Spain.

Background: Echocardiographic global longitudinal strain (GLS) is recognised as a technique to detect subtle changes in left ventricular function. As in CKD pts, kidney transplant recipients (TXKR) has an increased mortality risk by CV events. Early detection of CV risk is the utmost importance in the TXKR outcomes. The aim of this cross section study is to assess the grade of myocardial dysfunction in TXKR without previous CV events and normal left ventricular ejection fraction (LVEF).

Methods: 37 TXKR following ≥1 yr were included. 14.4% F, 24.5% DM, age 55.4±12.6 yr, GFR-EPI 51.93 ± 23.2 mL/min/1.73 m², No previous CV events & LVEF≥55%. All of them were stable on treatment with ACE/ARB, CCB, diuretics added to immunosuppressive drugs (TAC, CSA). Echocardiography 2D Vivid 9 (GE Vimed Ultrasound, Horten, Norway), was performed;GLS,LAVI (ml/bsa), E’, E/A, LVEF followings recommendations of American Society of Echocardiography. Body composition analysis were performed by BIVA and serum biomarkers of inflammation,aemia, mineral bone disease, renal function (GFR-EPI) and CV risk markers.Normal GLS (≤-20%) LAVI 24 mL/m² were considered as published for general population Rev Esp Cardiologia 2014;67:651-8.

Results: Mean GLS was -18.6 ± 3.78%, LVEF 70.8 ± 8.7% LAVI 30.16± 20.4 mL/glomerul correlated negatively with GLS (r: -0.33, P=0.016) and LAVI (r: 0.37, p < 0.14). GLS progression was negative as GFR decline (P adjusted 0.025) E’ 13.06±6.48; E/A 0.93±0.28. Multivariat analysis was significant the relationship between GLS with ACR (β = -0.151, p = 0.043) and ejection fraction (β = -0.47, p =0.004). All other correlations were met. LVEF decrease in 60% TXKR ≤-20% and 41.6 % LAVI > 24 mL/m² GLS LAVI echocardiography derived were two valuable measures to assess early subclinical myocardial damage in TXKD. GLS appears more sensitive predictor than LVEF Studies on TXKD pts are required.

Seroenegative Invasive Gastro-Intestinal Cytomegalovirus Disease in Renal Allograft Recipients – A Diagnostic Dilemma! Tissue PCR the Saviour? Shreejitha Harikrishnan,2 Dharmendra Bhaduriah, Narayan Prasad, Anil Gupta, Raj K. Sharan,3 Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, UP, India.

Background: CMV as opportunistic infection affecting the gastrointestinal tract is the most common cause for tissue invasive CMV disease occurring in 10-30% of organ transplant recipients. Gastrointestinal CMV disease can be diagnosed in presence of clinical suspicion along with histopathological findings (CMV inclusions) and presence of macular lesion(s) on endoscopic examination with collaborative evidences via molecular technique.

Methods: Few cases of CMV infection affecting the gastrointestinal tract show no evidences of dissemination despite use of highly sensitive molecular techniques.

Results: We encountered 6 cases where in despite strong clinical suspicion of Gastrointestinal CMV disease there were seronegative and endoscopic negative evidences for CMV,blind tissue biopsy yeilded positive results for CMV disease with excellent improvement with antiviral therapy.

Conclusions: Blind biopsy specimen for tissue PCR could serve as saviour in immunocompromised individuals who has a strong clinical symptomatology for GL-CMV disease in absence of viremia ,normal endoscopy and histopathology ,so that the early therapeutic interventions could help in excellent patient and graft survival.

PUB677

Background: The presence of antibodies to donor human leukocyte antigens (HLA) is a significant barrier to transplantation. High dose intravenous Ig (IVIg) is widely used for desensitization. There is no general consensus on the best approach for desensitization, and different data on efficacy of IVIg are unknown.

Methods: We reviewed kidney transplants done from Jan, 2010 to Dec, 2014 at Tufts. Sensitization was defined as PRA>20% and/or presence of donor specific antibody (DSA). Patients who were desensitized with IVIg were identified as those; those without desensitization served as control group. No attempt was made to desensitize patients awaiting deceased donor kidneys. Baseline characteristics and follow up data were collected at months 3, 6, 12 and 24. A sensitivity analysis was done for patients who received a living donor kidney.

Results: There were 19 patients in the desensitized group and 37 patients in the control group. Mean age at transplant in two groups was 47±12 and 49±12 respectively. In the desensitized group, there were more patients with prior transplant (37% vs 22%), receipt of living donor (95% vs 54%) and positive DSA (89% vs 22%). One patient developed severe side effects from IVIg, requiring discontinuation. Leukopenia and BK viremia were
in the first year after transplantation was 32.3%, mostly urinary tract infection (82%). No episode of malignancy was reported. Graft and patient survival rates were 96.9% and 98.5% respectively.

Conclusions: Our findings support previous studies, with similar incidence of AR episodes during the first year of transplanted patients, accompanied by a similar incidence of infectious and malignant complications, and similar patient and graft survivals at 1 year follow up. We can conclude that basiliximab is associated with excellent graft and patient survival and low rates of AR episodes.

PUB680
Death within the First Year After Kidney Transplantation

Background: A successful kidney transplant improves the quality of life and reduces the risk of death in most patients when compared with staying on dialysis, however, the survival of transplant patients is lower than general population patients of the same age. This study was performed to evaluate mortality and characteristics of the dead patients.

Methods: It was a retrospective observational study that included all kidney transplant patients between January 1, 2010 to April 30, 2014, at HE-CMNO, IMSS, Guadalajara, Jalisco, Mexico. The follow-up time was one year. Mortality was calculated, the causes of death and characteristics of deceased patients were identified.

Results: During this time 1,047 transplants were performed. 30 deaths (2.86%) were recorded during the first year after transplantation. Regarding the type of donor: 12/102 (11.76%) patients with brain death donor died, and 18/945 (1.9%) patients with living donor died. The causes of death were 20 (66.66%) infections, 6 (20%) cardiovascular events, 2 (6.66%) related to graft rejection event and 2 (6.66%) unknown. The average time of transplantation to death was 2 months 27.4 days with a SD of ± 2.2 months 29.1 days; 70% of deaths occurred in the first 3 months after transplantation. The average time in dialysis was 5 years, with a SD ± 3 years 4.4 months; 83.3% of patients had more than two years on dialysis. Most patients who died had thymoglobulin induction, but patients were older, had more comorbidities, more time on dialysis, increased immunological risk and they had a brain death donor. Finally, 76.7% of patients who died had functional graft.

Conclusions: In our hospital, 1 year mortality postkidney transplantation is low, but there are many individual patient factors that contribute to the risk of mortality increases significantly in them and there we could intervene.

PUB681
Granzyme B Level and Acute Kidney Allograft Rejection: Impact on One Year Survival in Mexican Population
Perla Edith Simancas Ruiz, Caridad Aurea Leal, Benjamin Gomez-Navarro. Nephrology and Transplant, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico; Surgical Research, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.

Background: Exposure to insufficient levels or discontinuation of immunosuppressants often increases the risk of rejection. Creatinine is the most useful test to monitor graft function. However, it is a poor predictor of rejection and often raises only after significant damage occurred to the allograft. Granzyme B level is associated with rejection risk, with high specificity and sensitivity in different types of sample and has also enabled the identification of subclinical
rejection. The elevation of both the mRNA and protein has been associated with a worse prognosis. 

Methods: Based on biopsy findings among 242 renal allograft biopsies taken in study 42/17.35% had post-transplant glomerulonephritis. Further the incidence of individual glomerulonephritisand their outcome at the end of one year post diagnosis.

Results: Based on biopsy findings among 242 renal allograft biopsies taken in study 42/17.35% had post-transplant glomerulonephritis. Further the incidence of individual glomerulonephritisand their outcome at the end of one year post diagnosis.

Conclusions: The main causes of ESRD were diabetes (35%) and hypertension (20%). We conclude that post-transplant glomerulonephritis should be the critical focus of post-transplant care.

PUB683

Impact of Hemoglobin Concentration on Mortality After Renal Transplantation

Vitoria C. Vilela, Marco A. Meniconi, J. Medina-Pestana, Miguel Cendoroglo Neto, Miguel A. Goes, Nephrology Div, Federal Univ of Sao Paulo, Sao Paulo, Brazil; Nephrology Div, Hospital Israelita Albert Einstein, Sao Paulo, Brazil.

Background: Kidney transplant recipients have chronic anemia, irrespective of the time from transplantation. Objective: To assess the impact of hemoglobin concentration on kidney transplant survival.

Methods: A total of 233 patients who underwent renal transplantation at one center (Hospital do Rio) were prospectively analyzed. Follow-up time was 6 years, from January 2008 through December 2014. Data on demographics, ESRD etiology, pre-transplant dialysis, transplant characteristics, and immunosuppression regimen. Two-sample t test were used to compare differences between two groups (mortality vs non-mortality groups) and X2 to analyze categorical variables. Linear logistic regression was used to determine the impact of factors on outcome.

Results: The main causes of ESRD were diabetes (35%) and hypertension (20%). Transplants from living donors occurred in 59%. During the entire follow-up period, there were 24 (10%) deaths within 3+1 yr after renal transplantation. 7 (29%) from cardiovascular disease and 17 (71%) died from infection. We observed that mortality group were older (P=0.01) and longer time on dialysis (4.2+2.5 vs 2.5+2.0 yr; P=0.006). Hemoglobin (Hb) concentration was lower in mortality (10.7+2.3) than non-mortality (12.0+2.4; P<0.01) group. Patients who used mycophenolate had lower mortality (P = 0.04). There is no correlation between Age and Hb (r=-0.02; P=0.8). Age (P = 0.01) and Hb concentration (P = 0.02) were independent predictors of mortality.

Conclusions: This study shows that a lower Hb concentration is an independent predictor of mortality in renal transplant patients.

PUB684

Prediction of Recipients Survival in Deceased Donor Kidney Transplant Using Korean Network for Organ Sharing Database

Kyung Don Yoo,1 Junhyung Koh,1 Hajeong Lee,1 Dong Kim,1 Chun Soo Lim,1 Young hoon Kim,1 Yon Su Kim,1 Gunhee Kim,2 Jung Pyo Lee.1 1Seoul National Univ Coll of Medicine; 2Seoul National Univ Coll of Engineering; 3Univ of Ulsan.

Background: The Korean Network for Organ Sharing (KONOS) was founded in 2000 for organ allocation in Korea. It has been allows medical doctors and researchers to fully access the national population-based raw data about KT recipients. We propose a novel prediction approach of recipient survival based on machine learning techniques using KONOS data.

Methods: Our dataset is collected from 2000 to 2014 by the KONOS. We design a novel prediction model that uses all of the follow-up recipients’ data including censored ones, on which estimated death risks are weighted according. We compare this approach with the baseline model that uses only uncensored data by the CART (Classification And Regression Trees) modeling.

Results: We analyze 5,430 recipients’ records with more than one attributes, among whom 4,378 were 15 independent attributes to learn our models. The proposed weighted algorithm leads a better performance when predicting survival rates of transplant recipients within 6 years, but fails to show any significant difference from the baseline for those more than 7 years after transplantation. Using the decision-tree models, we find that the inotropic agent usage of donor management is the most important predictor, which estimates in 51.3% of 10-year mortality. In the age ≥51.5 group, non-diabetes recipients, waiting period < 4years, and donor age < 23.5 years show significant associations with better 10YRS. The results are consistent with our hypothesis that poor donor status, recipients’ longer waiting time and advanced age are associated with poor prognosis.

PUB685

Perforin Expression in Renal Allograft Biopsies

Michele T. Rooney,1 Ping L. Zhang,1 Dilip Samarapungavan,1 Randolph Alexander Henningar,1 1Incyte Diagnostics, Spokane, WA; 2Anatomic Pathology, William Beaumont Hospitals, Royal Oak, MI; 3Nephrology, William Beaumont Hospitals, Royal Oak, MI; 4Nephropathology Associates, Little Rock, AR.

Background: Perforin is a cytotoxic protein in effector lymphocytes that facilitates targeted cell killing and it has an established role in allograft rejection. A diagnostic value has not been delineated. We examined perform expression in renal transplant biopsies by immunohistochemistry (IHC) and found that positive lymphocytes are confined largely to the microvasculature in cases of active cellular rejection (ACR). The goal of this study is to investigate whether perforin IHC is a useful metric in identifying and classifying acute rejection in renal transplant biopsies.

Methods: Renal transplant biopsies accessioned over a one-year period were selected to include cases showing no acute rejection, acute tubular injury, BK nephritis, ACR types 1 and 2, and C4d+ antibody-mediated rejection (AMR), according to the 2013 revised Banff Classification. IHC using a mouse monoclonal anti-perforin antibody was performed on each case. Perforin positive cells/10 high power (400X) fields (hpf) were counted from slides identified by number only.

Results: Most rejection-negative cases had < 10 perforin-positive cells/hpf. Biopsies showing type 1 ACR, excluding one outlier, did not exhibit a significant increase in perforin-positive cells relative to rejection-negative cases. In contrast, cases of type 1B and 2 ACR, and C4d+ AMR displayed significantly increased perforin-positive cells (p = 0.0001) with most showing > 40/ 10 hpf. Cases of AMR contained the highest number of perforin-positive cells (p = 0.0352). Cases of BK nephritis varied widely from < 10 to > 50/ 10 hpf. 2 of 3 cases with > 50 had a recent history of ACR developing BK infection upon increasing immunosuppression, raising the possibility of coexisting BK and rejection.

Conclusions: Further study is needed, but our data suggests that increased numbers of perforin-positive lymphocytes correlate with more aggressive forms of rejection, and that perforn IHC may be a useful ancillary test for acute allograft rejection of type 1B or higher.
PUB686
Is It Safe to Transplant Sensitized Patients? Analysis of 1,002 Consecutive Kidney Transplants Anna Rita Aguirre, Patricia Soares Souza, Fabiana Agena, Daisa R.S. David, Flavio Jota Paula, Elias David-Neto, Maria Cristina R. Castro. Renal Transplant Service, Hospital das Clínicas - Univ of Sao Paulo School of Medicine, Sao Paulo, Brazil.

Background: From 2009-13, 24% of kidney recipients in our center had antiHLA antibodies (aHLA abs). Obj: To compare the risks of rejection, patient and graft survival when transplantations (Tx) were performed with or without aHLA abs and with or without DSAs. To compare mortality between patients transplanted with aHLA abs to mortality in the waiting list.

Methods: Retrospective study, which included all isolated kidney Tx in patients older than 18 years of age performed between 2009 and December 2012. We analyzed the incidence of TCMR and ABMR in the 1st year after Tx. Median follow-up time was 32mo. Graft and patient survival were evaluated by Kaplan Meyer estimates.

Results: In 741 Tx(74%), no aHLA abs were detected(ARP=0) and 26(1.26%) had positive aHLA abs with 4(1.5%) patients who had more than one aHLA Abs. In the 1st year, 77(10.4%) had TCMR and 6(0.81%) had ABMR. Among Tx with PRA=0 without DSAs(139, 129(86.6%) did not have rejection, 16(11%) had TCMR and 7(4.7%) had ABMR. In Tx with PRA>0 with DSA(91), 58(62.4%) did not have rejection, 7(7.5%) had TCMR and 31(33.4%) had ABMR. ABMR was more frequent when there was a DSA(p<0.001).

Graft survival did not differ according to ARP or DSA in groups with no rejection, TCMR and ABMR. There were more graft losses in the whole sample when a DSA was detected(p<0.001) or when RAMA occurred, in comparison to no rejection(p=0.001) and TCMR(p=0.014).

Patient survival: The presence of aHLA abs and DSAs, nor influence of TCMR or ABMR. In recipients with aHLA abs, mortality was 11% in 2mo, or 4.12% per year, smaller than in the waiting list in our state, which was 5.61% in the same period.

Conclusions: There was no difference in patient survival after 3 mo between patients with or without aHLA abs or DSAs, or even between patients with or without ABMR. However, there were more graft losses in recipients with aHLA abs and with ABMR. Mortality after Tx among sensitized patients hasn’t been larger than in the waiting list. We conclude that transplanting the sensitized patient does not increase mortality risk.

PUB687

Background: ABO-incompatible (ABOi) kidney transplantation (KT) is an option for overcoming the shortage of organ donors. Before performing ABOi transplant, it is important to reduce anti-blood group antibodies titers (ABGAT) by desensitization. The aim of our study was to determine: 1) Baseline ABGAT in patients undergoing ABOI KT, 2) Response of ABGAT to desensitization and 3) Behavior of ABGAT after KT.

Methods: Nineteen (13 male and 6 female) ABO-I patients (6-O, 8-A and 5-B blood groups) studied. The IgG and IgM ABGAT were determined using column agglutination technique (CAT). Desensitization was attempted if baseline IgG ABGAT > 1:32. For desensitization, besides rituximab, Plamapheresis (PP) and/or Glycosorb was used. Desensitization considered successful if IgG ABGAT dropped to < 1:32.

Results were found not to be statistically different from non HCV infected renal allograft recipients.

Conclusions: HCV infected end stage renal disease patients may undergo transplantation safely after virological remission and outcome is not different from other renal transplant recipients.

PUB689
The Impact of Hepatitis C Virus Infection on the Clinical Course, Short Term and Long-Term Outcome in Renal Transplant Recipients – A Retrospective Study Pratik Das, Rohit Rungta, Santosh Kumar. Nephrology and Transplantation, Rabindranath Tagore International Inst of Cardiac Sciences, Kolkata, West Bengal, India.

Background: Hepatitis C infection is common in patients of end stage renal disease with increased morbidity and mortality post-transplant. The aim of the study was to find out the impact of HCV infection on graft and patient outcome and compare it with the non-HCV infected post-transplant recipients.

Methods: We retrospectively analysed patient and graft survival of HCV infected (after virological remission) post renal transplant patients from 2008 to 2014 with a median follow up of 24 months and compared them with our HCV negative statistically matched cohort.

Results: Outcome analysis was done at 6, 12, 18 and 24 months in terms of liver dysfunction, acute rejections, infections, hospitalization and death. Results were further tabulated as shown.

PUB690
Patient and Graft Survival in Pediatric Kidney Transplantation: A Single-Center Experience According to Transplant Era Marta Monteverde, Juan Carlos Lopez, Gerardo Nyman, Liliana Briones. 1Nephrology Unit, Hospital JP Garrahan, Buenos Aires, CABA, Argentina; 2Urology Unit, Hospital JP Garrahan, Buenos Aires, CABA, Argentina.

Background: Improvements in the management of kidney transplantation has improved the last 20 years. However the long term results in terms of graft survival and morbidity still require more research.

Methods: We evaluated 744 pediatric renal transplants (RTX), 551 with deceased donor (DD) and 222 with living-related donor (LRD), between 1988-2015. We divided this time in 2 periods: 1988-2000 and 2001-2015. Patient and graft survival were calculated for each period for LD and DD recipient. We analyzed causes of mortality, causes of graft failure and risk factors for graft loss. Mean age at RTX was 3.6 y (r: 0.7-19.5). Median time of follow-up was 54.5 months (IQR: 22.4-90.1) months.

Results: Patient and graft survival for DD have significantly increased in the recent era (p=0.0002; p=0.0013 resp). Chronic rejection was the first cause of graft loss in both eras (93.6% vs 85.11%). Vascular thrombosis decreased (14.9% vs 5.5% p<0.001), and also Death with a Functioning Graft (15.8% vs 8.3% p<0.001). Acute rejection during the first 30 days post RTX + relapse of the original disease increased (0% vs 9.7%). First cause of death in both eras was bacterial infection (77% vs 66%). No death due to PTLD were seen in 2001-2015. Independent Risk factors for graft loss for DD recipients were: FSGS

1047A
as cause of ESRD (HR: 3.1; CI 95%: 2.4-4.8), DGF (HR: 2.8; CI 95%: 2.4-4) and Receiving no induction therapy (HR: 2.1; CI 95%: 1.3-3.5). For recipients: DGF (HR: 5.2; CI 2.9-9.3) and Age at RTX < 12y (2.2; CI 95%: 1.2-3.9).

**Conclusions:** Patient and graft survival has significantly improved for DD in the recent era. Chronic rejection remains a major cause of graft failure. No death from malignancy were observed in the recent era.

**PUB691**

Impact of Rituximab Induction on Short Term Outcome of Kidney Transplant Recipients

**Background:** Acute graft rejection remains a major problem in kidney transplant (KT) recipients. Induction with Thymoglobulin or Basiliximab is a KDIGO recommendation to minimize the risk of acute rejection. However, these induction agents do not eliminate the risk of antibody mediated rejection. Recent studies of ABO incompatible (ABOi) transplant using Rituximab, in addition to standard induction and maintenance immunosuppression (IS) have shown better outcome than ABO compatible (ABO) transplant (Koheh N, Tanabe K Am J Transplant 2010; 10: 1378). The aim of our study was to evaluate efficacy and safety of Rituximab induction in addition to single dose Thymoglobulin induction in living donor (LD) KT patients.

The study included 53 adult LD KT recipients transplanted between 3/14/15 and 2/28/15 and followed for at least 3 months after KT. Of these, 39 were (ABO) recipients and 14 were (ABOi) recipients. Rituximab 200 mg was given within a week before transplant. ABOI recipients received an additional 20 mg Rituximab on the day of transplant. Thymoglobulin 1 mg/kg was used only on the day of transplant. Maintenance immunosuppression included Tacrolimus, MMF, and tapering doses of prednisolone in all. All patients received valganciclovir and cotrimoxazole prophylaxis. The short term outcome of these patients (Ritus group) was compared to that of 53 historic controls (control group) who received only thymoglobulin 1 mg/kg on the day of KT.

There was no difference in characteristics (age, sex, etiology of CKD, donor characteristics, HLA mismatch) of patients in the 2 groups. Six patients in the Ritux group developed acute rejection (5, cellular and 1 antibody mediated). Six patients in the control group developed acute rejection (2 cellular and 4 antibody mediated). The patient and graft survival at 3 months was 100% in Ritux group. The patient survival was 100% in control group. One graft was lost from antibody mediated rejection in control group. Infections within 3 months after KT were similar in both groups.

**Conclusions:** Rituximab induction is safe in KT. It reduces the risk of antibody mediated rejection without increasing infectious complications in the early period after KT.

**PUB692**

Epo Use in Pregnant Renoparenchymal Transplant Patients

Amelia R. Heguilen, Alicia M. Lapidus, Liliana Susana Votto, Ricardo M. Heguilen. Medicine, Hospital Juan A. Fernandez, Buenos Aires, Argentina.

**Background:** Renal disease is the most common in this population. Prenatal counselling addresses potential fatal complications; as well as worsening anaemia, hypertension, preclampsia, gestational diabetes, acute rejection or graft loss. The aim of this study was to evaluate the use of Erythropoietin (rHuEpo) during pregnancy in Tx recipients.

**Methods:** Four out of 21 (20%) cadaveric donor recipients underwent successful pregnancies after a complex medical history of diabetes in their childhood with retinopathy & polyneuropathy, two with hypothyroidism, and end stage renal disease. They were all switched into a pregnancy regimen. Given his long term immunosuppression, low back weight are common in this population probably due to other drug adverse effects.

**PUB693**

Acute Rejection Incidence in Deceased Kidney Transplant Recipients with Delayed Graft Function After Single Dose Thymoglobulin

Igor Gouveia Pietrobon, Laila Almeida Viana, Cinthia Montenegro Teixeira, Andre Caires Alvino Lima, Mayara Ivani de paula, Geovana Basso, Tainá Veras de sandes Freitas, J. Medina-Festana, Helio Tedesco Silva. Hospital do Rim, Federal Univ of Sao Paulo, Sao Paulo, Brazil.

**Background:** Thymoglobulin (rATG) induction has proven efficacy. However, it remains unclear what is the best dosing regimen.

**Methods:** From August 8th, 2014 immunosuppression protocol was changed at our institution to induction with single dose thymoglobulin to all deceased donor kidney transplant recipients. This retrospective study evaluated the incidence of acute rejection (AR) in deceased kidney transplant recipients with delayed donor graft function (DDGF) before and after the adoption of a new induction protocol.

**Results:** Pre-protocol Group 1 - 96 patients transplanted between 12/31/2013 and 08/08/2014; Standard criteria deceased donors (SCD) (without induction, tacrolimus 0.15 mg/kg) and expanded criteria deceased donors (ECD) (induction with thymoglobulin 6mg/kg, tacrolimus 0.05 mg/Kg/dose, prednisone and mycophenolate sodium) versus Group 2 (new protocol), 87 patients transplanted between 08/08/2014 and 03/31/2015, subdivided in the same way, receiving the same maintenance therapy and thymoglobulin induction 3mg/kg single dose. In both groups, the population was overwhelmingly male (63% vs. 55%), young (47 vs. 46 years) and low immunological risk. The incidence of AR in G1 vs. G2, SCD subgroup was 13%, vs. 4% (p = 0.09). When compared ECD recipients, the incidence of rejection was similar between G1 vs. G2 (15% vs. 15%, p = 0.1), respectively.

**Conclusions:** In the SCD kidney transplant recipients, the incidence of AR was numerically lower in the group that received induction with single dose rATG 3mg/kg and induction with a reduced dose of rATG was not inferior in the ECD group.

**PUB694**

Cardiovascular Changes After Kidney Donation

Fernando H. Margulis, Nefrologia y Trasplante Renal, Hospital General de Aguascalientes Argerich, CABA, Buenos Aires, Argentina.

The aim of our study was to investigate the changes in cardiovascular structural and endothelial function after donation in kidney donors.

**Methods:** Four living kidney donors (both genders) without history of kidney disease, diabetes, cardiovascular events or hypertension, who participated in the donor screening protocol with subsequent donation, were included. Office blood pressure (OBP), ambulatory blood pressure monitoring (ABPM), left ventricular mass index (LVMI), arterial stiffness (AS) and endothelial function (EF) were measured before and one year after the donation. AS was assessed from the left index finger using a digital photoplethysmograph (Pulse Trace; Micro Medical), that uses a simplified analysis of the digital volume pulse waveform, to assess endothelial dependent arterial vasodilation, 400 g of salbutamol was given by inhalation. Data were expressed as mean ± SD or median & interquartile range respectively, p<0.05 were considered to be statistically significant.

**Results:** The mean age of the cohort was 47 ± 8 (range, 30 – 56) years. At one year after donation the mean BMI (27.1 ± 2.6, P=0.006), median OBP (89 (86, 92), P=0.0232) were significantly lower compared to baseline. In SCD recipients, the mean LVMI (98.7 ± 25.1, P=0.001) was significantly decreased as compared to baseline (26.4 ± 3; 85 (76, 92) and 0.78 (0.74, 0.97). Respectively. The estimated glomerular filtration rate levels by MDRD 4 formula at 1 year (57.4 ± 12ml/min/1.73 m², P=0.0001) were significantly decreased as compared to baseline (82.2 ± 10ml/min/1.73 m²). We did not find significantly differences in mean 24h ABPM (84.8 ± 5.8 mmHg, P=0.940), mean LVMI (86.6 ± 17.3 mm, P=0.727), mean AS (7.78 ± 2.3 ms, P=0.210) and median EF (5.1% (0.8, 13.3), P=0.374) compared to baseline (85 ± 7 mmHg, 99.8 ± 3.16 g/m²; 9.03 ± 2.3 ms and 10% (-1.6, 34.6), respectively).

**Conclusions:** Our study demonstrated that after an year, reduced nephron mass because of kidney donation was not associated with changes in cardiovascular structure and endothelial function.

**PUB695**

A Rare Case of Chronic Lymphocytic Inflammation with Pontine Perivascular Enhancement Responsive to Steroids (CLIPPERS) After Kidney Transplantation

Maria C. Bermudez, Mayurkumar Gohel, Ali Javed, Michael F. Schultz. Nephrology, Geisinger Medical Center, Danville, PA.

**Background:** Chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids (CLIPPERS) is a recently described inflammatory condition of the central nervous system. To date 50 cases have been reported in the literature, however none have been reported following renal transplantation.

**Methods:** 47 year old Hispanic male, status post deceased donor kidney transplant in 2008, with history of hypertension and diabetes, presented to our clinic with several months of progressive dizziness, unsteadiness and right facial numbness that progressed to diplopia and right facial palsy. An MRI of the brain with gadolinium revealed a 1.3 cm mass with a ring-like target appearance in the right brachium pontis and dorsalpons. MR spectroscopy revealed mild elevation of choline, suggesting demyelinating disease versus lymphoma or other high-grade malignancy. Given his long term immunosuppression, malignancy or an infectious process were considered as the main differential diagnoses.

An extensive evaluation included serial lumbar punctures for cytology and a variety of
viral, fungal and bacterial cultures. Cytologic and serologic studies were unremarkable. Flow-cytometry analysis of the spinal fluid showed no evidence of lymphoma. A brain biopsy was performed revealing non-specific perivascular lymphoplasmocytoid infiltrate with no evidence of lymphoma or infection. Additionally, myelin stain was positive ruling out demyelinating disease. Our patient was started on high-dose steroids with remarkable improvement of his symptoms. Diagnosis of CLIPPERS was made.

Conclusions: CLIPPERS is a rare and poorly recognized CNS inflammatory condition.

To our knowledge, this is the first case reported after renal transplantation. More studies are needed to determine the pathophysiology of CLIPPERS in immunosuppressed patients and whether it could represent a pre-malignant state. Duration of treatment and follow up is yet to be determined. In this case, treatment with steroids has led to symptomatic improvement over a month and close follow-up continues.

PUB696

The Impact of Post-Transplant Hemoglobin and Creatinine Level on Renal Allograft Survival

Luiz Fernando Christiani, Fernanda Paula Feres Rios Da Costa, Ana Flavia Baldoni, Alcina Imada, Kelly Rodrigues, Maria Izabel Neves de Holanda Barbosa, Gessika Marcelo Gomes, Claudia Fagundes. Nephrology, Hospital Federal de Bonsucesso, Rio de Janeiro, Brazil.

Background: Anemia is a common finding after kidney transplantation. The roll and the prevalence of Posttransplantation anemia (PTA) in predicting renal allograft outcomes still vary between different studies. In this study, we aim to assess the prevalence of anemia at one and six months post transplant and its correlation with 1 year renal allograft survival.

Methods: Anemia was defined by an absolute level of hemoglobin less than 11 g/dL. Hemoglobin and creatinine level were assessed at one, six and twelve-month after transplantation.

Results: We included 261 consecutive patients who underwent renal transplant from January/2010 to June/2012. Mean recipient age was 42±10 years and 56% were male. Prevalence of anemia was 42% at 1 month, 15% at 6 months and 9% at 12 months. Hemoglobin and creatinine level at first month of transplantation were 11.2±2 and 1.8±1.0 for patients with functional allograft vs. 9.4±2.1 and 4.8±3.4 for those who return to dialysis within 12 months (p<0.001 for both comparisons). Overall patient and graft survival was 8% and 10%, respectively. On multivariate analysis, creatinine and hemoglobin level were independently associated with poor graft survival at 12 months. The best cut-off selected by receiver operating characteristic curve analysis was 10.8 g/dL for Hemoglobin level, (AUROC 0.74 (0.63-0.86), p=0.001) and 2.25 mg/dL, for serum creatinine (AUROC 0.77 (0.62-0.91), p=0.001). Combining the best points of those two variable could identify patients at risk of graft loss. Patients who met both criteria (Hb<10.8 g/dL and Creatinine ≥ 2.25 mg/dL) had 59% graft survival at 1-year, whereas allograft survival was 98.5% for patients without any criteria (Hb≥10.8 g/dL and Creatinine ≤ 2.25 mg/dL).

Conclusions: Prevalence of anemia was high in the first month after transplant and persisted in a substantial proportion of functioning kidney transplant recipients. Early (1-month) hemoglobin and creatinine level can predict 1-year graft survival.

PUB697

Examining Adverse Weight Gain After Kidney Transplantation

Biru Workneh,1 Linda W. Moore,2 William E. Mitch.3 Medicine/Nephrology, Baylor College of Medicine, Houston, TX; 2Transplant Medicine, Houston Methodist Hospital, Houston, TX.

Background: Between 15,000-17,000 patients with end-stage renal disease (ESRD) receive a kidney transplant in the United States every year. Among the most consequential complications to these patients are adverse weight gain and the development of diabetes, commonly termed New-Onset Diabetes After Transplantation (NODAT) with consequent complications to these patients are adverse weight gain and the development of diabetes, commonly termed New-Onset Diabetes After Transplantation (NODAT) with consequent CV mortality. However, there is no consensus about the exact nature of the weight gain that routinely occurs after kidney transplantation (i.e., relative changes in fat vs. muscle vs. fluid volume) and how this relates to insulin resistance. We wish to test the hypothesis that weight gain is primarily due to an increase in fat mass.

Methods: We are conducting a longitudinal study in ESRD patients anticipating receiving a live donor kidney transplant. We are studying subjects before kidney transplant, at 12 weeks and 1 year after they have received living donor kidney transplant to measure changes body composition and other indices. Body composition was characterized by DEXA as well as total body potassium (a gold standard measure of muscle mass).

Results: Results from 5 subjects who completed baseline assessment and 3 months post-transplant reveals there is significant gain in adipose weight gain in all cases.

Additionally, we discovered there is significant loss in skeletal muscle mass (p=0.032) measured by total body potassium.

Conclusions: We have not studied enough to conclude whether changes in energy expenditure and diet contribute to adipose weight gain and whether there is acute nitrogen (muscle) loss peroperatively. Ultimately, methods to identify patients at high risk for adverse weight gain and related metabolic disorders before transplant are greatly needed.

PUB698

Effect of Mycophenolate Mofetil Dose on BK Virus Infection in Kidney Transplant Recipients

Vedran Pasara,1 Danica Galesic Ljubanovic,2 Mladen Knotek,1 1Dept of Medicine, Renal Div, Univ of Zagreb Medical School, Merkur Hospital, Zagreb, Croatia; Dept of Pathology, Univ of Zagreb Medical School, Dubrava Univ Hospital, Zagreb, Croatia.

Background: Intensity of overall immunosuppression is a risk factor for BK virus infection (BKVI). However, the exact impact of exposure to tacrolimus and mycophenolate mofetil (MMF) to BKVI is unclear. The aim of this study was to determine if BKVI in kidney transplant (KT) recipients is associated with drug exposure to MMF.

Methods: This prospective randomised controlled clinical trial (NCT01860183) included 36 KTR who underwent KT from May 2013 to February 2015 at Clinical Hospital. Immunosuppression consisted of basiliximab induction, with tacrolimus, MMF±steroid maintenance. KTR were randomized in two groups, with respect to MMF dose (2g or 3 g daily). Urine cytology for decoy cells was performed at prespecified time-points posttransplant. KTR were followed up to 12 months post KT. Graft biopsy was performed per protocol at 2, 6 and 12 months, or in case of graft dysfunction. Kaplan-Meier analysis with log-rank test was used to assess graft survival. A Cox regression was used to determine variables associated with graft survival.

Results: 13 (37.1%) KTR had decoy cells in urine, 4 (11.4%) KTR had biopsy-proven BK virus-associated nephropathy (BKVAN). The time to-occurrence was 4.8 months for decoy cells and 4.3 months for BKVAN. Cumulative one-year overall graft survival was 93.5%. Incidence of decoy cells, BKVAN, or acute rejection was similar in the two MMF groups. Rejection was not a risk factor for decoy cell positivity or for BKVAN.

Conclusions: MMF dose may not increase risk for BKVI after kidney transplantation.

Malignancy following Renal Transplantation

Lourdes de la Vara Iniesta,1 Francisco Llamas Fuentes,2 Inmaculada Lorenzo Gonzalez,3 Carmen Gomez Roldan, 2Virgen de la Luz Hospital, Cuenca; 3Univ Hospital of Albacete, Albacete.

Background: There is retrospective experience in many reports about the association between the intensity of immunosuppression and the higher frequency of malignancy. Objective: Analyse and describe our centre’s experience.

Methods: 275 transplant patients were analyzed. A record was made of the frequency, anatomic-pathological diagnostics, location, the mean interval between transplantation and diagnostics (latency time), follow-up time, use of antilymphocyte-antibodies, affection by cytomegalovirus, rejection and immunosuppressive therapy.

Results: Of 273 patients, 9.52%(26) were diagnosed of cancer. The majority, 93.43%(24), corresponded to De novo malignancy. 7.7%(2) were recurrences of pre-existing disease. The mean age at diagnosis was 63.19±7.24years. The latency time was 63.65months (11-114), although there is a notable but unexplained reduction over the last five years (33,50±63,65 months). The average follow-up time was 97.54months. The most frequent malignancies were skin cancers, predominantly Basal-cell and Squamous-cell carcinomas. The incidence of other tumors was similar to the general population. The most common causes of chronic renal failure was the glomerular and interstitial disorders. The risk of neoplasia was 0.36%, 4.36% and 9.52% at one, five and ten years after the kidney transplant. No association was detected with use of antilymphocyte-antibodies, CMV infection, rejection episodes or different immunosuppressive therapy. At the time of analysis, 84.60%(22) of patients had functioning graft, 7.70%(2) had returned to dialysis and 7.70%(2) had died, both due to the cancer.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

1049A
Conclusions: Our experience is similar to what is reported in the literature. The incidence of cancer is higher than expected in the general population and increases according to the duration of the immunosuppression. Skin cancers were the most frequent malignancies. Unlike other studies, there was a low incidence of lymphoproliferative disorder and Kaposi’s sarcoma, and the incidence of other solid malignancies being similar to that of the general population. To reduce the development of malignancies must be one of our objectives.

PUB700
Lipidapheresis in 3 Sisters with Familial Hypercholesterolemia
Chenay Aylan, Yang Wang, Andrea Schlune, Thomas Meissner, Lutz Thorsten Weber;
1Pediatric Nephrology, Univ Hospital of Cologne, Cologne, Germany; 2Dept of Pediatrics, Neontology and Cardiology, Univ Hospital of Duesseldorf, Duesseldorf, Germany.

Background: Familial hypercholesterolemia (FH) is the most common monogenic form of hypercholesterolemia. It carries the risk of premature coronary heart disease. As the atherosclerotic burden is dependent on the degree and duration of exposure to raised LDL-cholesterol levels, early diagnosis and effective treatment are imperative. Statins are the mainstay in the management of these patients. Lipoprotein-apoheresis becomes recently more established in patients with severe dyslipidemia. Together these treatments improve the prognosis of FH. Most children fail to attain targeted lipid goals owing to persistent shortcomings in diagnosis and treatment.

Methods: Three siblings with a LDLR mutation (p.Trp577Arg) being on statins (20 mg/d Atorvastatin) and Ezetimib (10 mg/d) for 12 months with still LDL-C plasma concentrations of above 300-500 mg/dl started once a week a double filtration plasmapheresis (DFPP) with a single plasma volume to be treated.

Results: After each LDL-apheresis LDL-C concentration of 100-150 mg/dl could be reached. (66-70% reduction). After 6 months plasma volume to treat was doubled because of a rebound within 7 days with LDL-C concentration up to 300-350 mg/dl. But though after each session LDL-C concentration decreased to 50-100 mg/dl the rebound was still evident after 7 days of therapy pause. With a treatment regime with twice plasma volume every 3-4 days the children finally attained a stable pre-treatment LDL-C concentration of 120-170 mg/dl. Another 2 months later statin therapy was stopped because of underlying mutation with assumed non receptor function. Neither the effectiveness of each apheresis nor the LDL-C concentration after 4 days showed any change.

Conclusions: In pediatric FH patients with high levels of LDL-cholesterol plasma concentration it might be necessary to treat instead of conservative medication with apopheresis in high frequency and with high plasma volumes to reach a durable decrease in LDL-cholesterol plasma concentration. The use of cholesterol uptake-inhibitors should be considered.

PUB701
Thrombomodulin Up-Regulation in Preeclamptic Nephropathy Is Associated with Parietal Cell Activation
Rosanne Jane Turner; Maria Elisabeth Penning, 1 Malu Zandbergen, 1 Eliyahu V. Khankan, 2 S. Ananthi Karumanchi, 1 Jan A. Brujin, 1 Kitty Bloemenkamp, 1 Hans J. Baelde. 1 Pathology, LUMC, Leiden, Netherlands; 2Howard Hughes Medical Inst and Dept of Medicine, Obstetrics and Gynecology, Beth Israel Deaconess Medical Center, Boston, MA; 3Obstetrics, LUMC, Leiden, Netherlands.

Background: Preeclampsia is a pregnancy-specific syndrome characterized by angiogenic imbalance and endothelial dysfunction. This endothelial dysfunction leads to kidney injury, i.e. glomerular endotheliosis, increased podocyte turnover and proteinuria. Thrombomodulin (TM) facilitates maintenance of glomerular endothelium by inhibiting coagulation, inflammation and apoptosis. In preeclampsia, levels of soluble thrombomodulin in the circulation are increased. We hypothesize that glomerular thrombomodulin expression is increased in preeclampsia and set out to correlate thrombomodulin expression with endothelium and podocyte damage.

Methods: A nationwide, ethics committee-approved search of the Dutch Pathology Registry (PALGA) was conducted; this revealed renal autopsy material from 11 women with preeclampsia disease. Of these, 9 women were biologically active, and had roles in intracellular communication. Especially tumor-derived exosomes has been intensively exploit and proven to be associated with distant metastasis. On the other hand, it is well known that CKD patients are at risk of cardiovascular diseases, but the mechanism of this distant organ crosstalk is not fully understood. Under the hypothesis that exosomes are involved in cardio-renal syndrome (CRS), the aim of this study is to explore the role of exosomes from kidney fibroblasts, which are activated in diseased kidney, on vascular endothelial cells.

Results: Exosomes are small (50-140nm) membrane vesicles of endothelial origin that contain host cell’s proteins, mRNAs, and microRNAs (miRNAs). The body of the exosome is 100nm, and the exosomes have been isolated using ultracentrifugation methods. The exosomes are known to be involved in many physiological and pathological processes. The exosomes containing miRNA form the basis for the identification of the disease. The exosomes are also involved in the communication between cells, and between different tissues.

Conclusions: So far, CRS is supposed to be caused by uric acid, RAS system, chronic inflammation, and so on. From this study, we showed that exosomes from activated kidney fibroblasts have amenable roles in atherosclerosis by modulating the expression of adhesion molecules, metabolic factor, and VEGF system on endothelial cells. Further studies are needed to elucidate the contribution level of exosomes on CRS.

PUB702
Cadmium Induces Matrix Metalloproteinase-9 Expression via NADPH Oxidase/ROS-Dependent EGFR Signals in Human Endothelial Cells
Nam ho Kim. Internal Medicine, Chonnam National Univ Hospital, Gwangju, Korea.

Background: Cadmium, a widespread cumulative pollutant, is a known human carcinogen, associated with inflammation and tumor. Matrix metalloproteinase-9 (MMP-9) plays a pivotal role in inflammatory reaction and tumor metastasis, however, the mechanisms underlying MMP-9 expression induced by cadmium remains obscure in human endothelial cells.

Methods: Here, cadmium elevated MMP-9 expression and enzyme activity, as well as MMP-9 promoter-driven luciferase activity, in a dose and time dependent manner in ECV304 human endothelial cells. Moreover, cadmium activated phosphorylation of EGFR, Akt, Erk1/2, JNK1/2, P38MAPK and promoted NF-κB and AP-1 binding.

Results: Specific inhibition and mutation studies shows that EGFR, Akt, Erk1/2, JNK1/2 and transcription factor NF-κB and AP-1 were related to cadmium-induced MMP-9 expression in ECV304 cells. Akt and MAPKs (Erk1/2 and JNK1/2) functioned as upstream signaling molecules in the activation of NF-κB and AP-1, respectively. Furthermore, Cadmium increased ROS production and the ROS-producing NADPH oxidase. Cadmium translocates p47phox,ayebstonus, to the cell membrane. The exogenous H2O2 increased MMP-9 mRNA expression. And that, inhibition of ROS by ROS scavenger (NAC) or NADPH oxidase inhibitor (DPI) attenuated EGGF, Akt, MAPK(Erk1/2,JNK1/2,p38MAPK) activation, and MMP-9 expression. Likewise, inhibition of EGFR phosphorylation prevented the activation of Akt,MAPK(Erk1/2,P38MAPK).

Finally, ECV304 cells treated with cadmium displayed markedly invasiveness, which was partially abrogated by MMP-9 neutralizing antibodies.

Conclusions: These results demonstrated that cadmium induces MMP-9 expression via NADPH oxidase ROS-dependent EGFR(Akt)/NF-κB band MAPKs(Erk1/2,JNK1/2) signaling pathways and, in turn, stimulates invasiveness in human endothelial ECV304 cells. These findings provide further insight into the molecular mechanisms in the carcinogenesis effect of cadmium.

PUB703
Exosomes from Activated Kidney Fibroblast Have Ambivalent Potential Effect on Atherosclerosis
Fumitoshi Nishio, Noritoshi Kato, Yoshio Funahashi, Takuji Ishimoto, Tomoki Kosugi, Naotake Tsuoi, Shioichi Maruyama, Seichi Matsuo. Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi-Pref, Japan.

Background: Exosomes are small (50-140nm) membrane vesicles of endothelial origin that contain host cell’s proteins, mRNAs, and microRNAs (miRNAs). The body of the exosome is 100nm, and the exosomes have been isolated using ultracentrifugation methods. The exosomes containing miRNA form the basis for the identification of the disease. The exosomes are known to be involved in many physiological and pathological processes. The exosomes containing miRNA form the basis for the identification of the disease. The exosomes are also involved in the communication between cells, and between different tissues.

Methods: Three siblings with a LDLR mutation (p.Trp577Arg) beeing on statins (1050A old) were purchased from George King Biomedical Inc. (Overland Park, KS). Samples

Conclusions: These results demonstrated that cadmium induces MMP-9 expression via NADPH oxidase ROS-dependent EGFR(Akt)/NF-κB band MAPKs(Erk1/2,JNK1/2) signaling pathways and, in turn, stimulates invasiveness in human endothelial ECV304 cells. These findings provide further insight into the molecular mechanisms in the carcinogenesis effect of cadmium.

PUB704
Prevalence of Metabolic Syndrome in Patients with End Stage Renal Disease: Relevance of Biomarkers
Vinod K. Bansal, Jennifer Saluk, Debra Brown, Danayel Syed, Shubhamraz Abros, Jawed Fareed. Nephrology, Loyola Univ Medical Center, Maywood, IL; Pathology, Loyola Univ Medical Center, Maywood, IL.

Background: Since the metabolic syndrome (MetS) and chronic kidney disease (CKD) share many of the same risk factors and similar inflammatory pathogenesis, many studies have suggested a correlation between CKD and MetS, and shown that patients with MetS are more likely to develop CKD. The purpose is to investigate metabolic biomarker levels in ESRD patients to evaluate their relevance to ESRD and to prevent or treat the pathogenic ESRD processes and the development of associated comorbidities.

Methods: Plasma samples were retrospectively collected from 89 ESRD patients prior to maintenance hemodialysis. Normal human plasma samples (female & male, 18-35 years old) were purchased from George King Biomedical Inc. (Overland Park, KS). Samples
were stored at -80°C. Biochips were purchased from RANDOX (Co. Antrim, Northern Ireland) to test C peptide, ferritin, IL-6, resistin, insulin, TNFs, IL-1a, leptin, PAI-1. These biomarkers were tested on 82 ESRD and 17 normal samples.

Results: All biomarkers, except insulin, were significantly elevated in Patients with ESRD compared to normal (p values are 0.05 - .0001). MetS patients with ESRD, as compared to non-MetS Patients with ESRD, had significantly elevated Leptin (P=0.002), and the correlation between MetS and Leptin levels was significant (P=0.0001, r=0.43). All other biomarkers showed no significant difference between ESRD+MetS and ESRD-MetS patients. Furthermore, when leptin levels for Patients with ESRD were broken down into ESRD+MetS and ESRD-MetS, ESRD+MetS vs. normal was significant (P=0.0003), but ESRD-MetS vs. normal was not (P=0.6).

Conclusions: Elevated biomarkers suggest an ongoing inflammatory process in ESRD patients. Insulin levels were not significantly elevated in ESRD patients, possibly attributable to the high Leptin levels, which can interfere with insulin secretion and signaling. ESRD+MetS and ESRD-MetS populations are not statistically different for all other biomarkers. This suggests that biomarker elevation is due to ESRD pathogenesis, rather than due to MetS as a comorbidity.

PUB705
Decreased Mitochondrial Membrane Potential in Monocyte Subsets from Patients with Chronic Kidney Disease Ying Wang,1 Eric Joseph Lai,2 Annie Fesus,1 Yuan Zhang,2 Linda Vernocchi,2 Anjali Ganda,1 1Div of Nephrology, Dept of Medicine, Columbia Univ Medical Center, New York, NY; 2Dept of Biostatistics, Mailman School of Public Health, Columbia Univ, New York, NY.

Background: Particular monocyte subsets are associated with future cardiovascular events in patients with chronic kidney disease (CKD), and the underlying mechanisms require further investigation. Previous studies have suggested impaired mitochondrial function in patients on dialysis, while little is known about mitochondrial functionality in monocyte subsets from non-dialedy patients with CKD. Given that mitochondrial dysfunction has been linked to atherosclerosis, we hypothesized that non-dialedy patients with CKD would have mitochondrial dysfunction in monocyte subsets which could accelerate atherosclerosis in patients with CKD.

Methods: Monocyte subsets from 18 adult CKD patients (eGFR<30 ml/min/1.73 m²) and 26 matched controls (eGFR ≥60 ml/min/1.73 m²) were freshly analyzed by flow cytometry. Mitochondrial membrane potential (ΔΨm), as a measure of mitochondrial functionality, was determined by the mean fluorescence intensity (MFI) of TMRM (tetramethylrhodamine methyl ester).

Results: ΔΨm was significantly reduced by 10% in patients with CKD vs. controls in the intermediate monocyte subset (CD14⁺CD16⁻), which has the highest ΔΨm among all the monocyte subsets and has been shown to predict accelerated atherosclerosis in patients with CKD.

Conclusions: Patients with CKD demonstrate mitochondrial dysfunction in total monocytes and monocyte subsets. Mechanistic and prospective studies are needed to examine the relationship between monocyte mitochondrial dysfunction, atherosclerosis, and future cardiovascular events in CKD patients.

PUB706
Paricalcitol Upregulates Renal Klotho and Restores Uremia-Induced Endothelial Integrity Disruption Marc Vila cuenca,1 Robert H.J. Beelen,1 Marc G. Vervloet.1 1Molecular Cell Biology & Immunology, YU Univ Medical Center, Amsterdam, Netherlands; 2Nephrology, YU Univ Medical Center, Amsterdam, Netherlands.

Background: Klotho deficiency in chronic kidney disease (CKD) is associated with the disruption of the endothelial integrity. Active vitamin D induces klotho expression. Hence, active vitamin D may limit endothelial layer disruption.

Methods: Male wistar rats were assigned into one of four groups: Control; Vitamin D deficiency, induced with Vitamin D deficient diet; Uremic, developed after 6 weeks nephrectomy; Uremic + Vitamin D deficiency. Animals were treated with Paricalcitol or vehicle control during 7 weeks. Serum samples were analyzed for 25D and 1,25D. Evans Blue was injected for estimation of the endothelial thoracic aorta and lung permeability and quantified using spectrophotometry. To determine the levels of Klotho, qPCR and WesternBlot was performed in kidney tissue.

Results: Average 25D levels were 9.83 nmollL while 1,25D levels were below the detection levels (20pmol/L) after the induction Vitamin D deficiency. mRNA and protein levels of Klotho in the kidney were decreased in Vitamin D deficient and uremic rats and restored after Paricalcitol treatment. Aortic Evans blue leakage increased in all uremic rats regardless of vitamin D level, compared with the control group and restored after Paricalcitol treatment (p<0.03). Uremia did not induce pulmonary leakage, but paricalcitol lowered it compared to control and uremic condition (p<0.04). Figure shows uremic with/ without D-deficiency together.

Conclusions: Klotho induces aortic endothelial leakage, while the deficit of vitamin D on its own did not. Paricalcitol completely restored endothelial leakage induced by CKD. In parallel, Klotho expression increased upon this treatment and may mediate the beneficial effect on the endothelium. To explain the difference between aortic and pulmonary tissue, additional studies are required.

PUB707
Altered Intra-Aortic Expression of the Renin-Angiotensin System Is Associated with Arterial Aging in Mice Hye Eun Yoon,1 Eun Nim Kim,2 Min Young Kim,1 Ji Hee Lim,1 Cheol Whee Park,1 Bum Soon Choi.1 1Internal Medicine, The Catholic Univ of Korea, Seoul, Korea; 2Internal Medicine, Incheon St. Mary’s Hospital, Incheon, Korea.

Background: Aging is the major risk factor of cardiovascular diseases and results in progressive decline in physiological function and structural abnormalities of vasculature. The renin-angiotensin system (RAS) is the key player in cardiovascular diseases. This study evaluated whether the change in the RAS is associated with arterial aging.

Methods: Histologic changes and expressions of angiotensin, angiotensin converting enzyme 1 (ACE1), angiotensin II type 1 receptor (AT1R), angiotensin II type 2 receptor (AT2R), and antioxidant enzymes, superoxide dismutase 1 (SOD1) and superoxide dismutase 2 (SOD2), were measured in the thoracic aortas from 2-month-old, 12-month-old, and 24-month-old C57BL/6 mice.

Results: Twenty-four-month-old mice showed significantly increased aortic media thickness compared to 2-month-old mice (1.6-fold). The aortic expression of angiotensin was increased in 12-month-old (1.2-fold) and 24-month-old mice (1.3-fold) compared to 2-month-old mice. Similarly, the expression of ACE1 was increased in 12-month-old (1.2-fold) and 24-month-old mice (3-fold) compared to 2-month-old mice. The AT1R/AT2R ratios were increased in 12-month-old (1.3-fold) and 24-month-old mice (1.5-fold) compared with 2-month-old mice. The expressions of SOD1 and SOD2 were decreased in 12-month-old (0.8-fold and 0.6-fold, respectively) and 24-month-old mice (0.6-fold and 0.5-fold, respectively) compared with 2-month-old mice.

Conclusions: Age-related intra-aortic activation of the RAS was associated with reduced antioxidant enzymes and hypertrophy of the aorta. These results suggest that the altered expression of the RAS contributes to the increased susceptibility to vascular injury in the elderly population.

Funding: Government Support - Non-U.S.

PUB708
Upregulation of Microparticles, Tissue Factor, Adhesion Molecules, Nitric Oxide and Adiponectin in End Stage Renal Disease Vinod K. Bansal,1 Daneyal Syed,2 Debra Hoppensteadt,1 Jawed Faried.1 1Nephrology, Loyola Univ Medical Center, Maywood, IL; 2Pathology, Loyola Univ Medical Center, Maywood, IL.

Background: End stage renal disease (ESRD) represents the final stage of chronic kidney disease characterized by kidney failure (GFR <15 mL/min/1.73 m²). To understand the pathophysiology of ESRD, we measured the circulating levels of microparticles (MP), tissue factor (TF), adhesion molecules, such as p-selectin (P-selectin), soluble ICAM (sICAM), nitric oxide (NO) and adiponectin (AD).

Methods: Plasma samples were collected from 119 ESRD patients undergoing maintenance hemodialysis to profile various inflammatory biomarkers. 100 normal plasma samples were collected from healthy individuals. MP levels were measured using an annexin
binding method (Hyphen Biomedical, Paris, France). NO was measured using a kit from R&D systems (Minneapolis, Minnesota) and ELISA methods for TF, P-Sel, s-ICAM and adiponectin were obtained from R&D systems. A chromogenic substrate method was used to measure heparin.

**Results:** MP levels were elevated in the ESRD group (28.1mm ± 6.1mm vs. the control 8.9mm ±1.3mm). Tissue factor levels were found to be increased in the ESRD group (20.4±1.6ng/ml) vs the control (11.9±2.8ng/ml). The nitric oxide level was markedly higher in the ESRD group (321.1μM) vs the controls (73.3μM). The p-selectin levels were elevated in the ESRD group (46±20ng/ml) vs the control (31±3ng/ml). The soluble ICAM levels were higher in the ESRD group (250±12ng/ml) vs the control (180±19ng/ml). Interestingly, the adiponectin levels were also increased in the ESRD group (19.2±4.1ug/ml) vs the control (11.2±2.0 U/ml) were measured in the ESRD group.

**Conclusions:** These studies suggest that MP, TF, NO, p-selectin and s-ICAM levels are increased in the ESRD patient. It is of interest to note that despite that a significant number of ESRD patients were diabetic; the AD levels were increased. These results also suggest that while ESRD represents a pro-inflammatory/hypercoagulable state, the repeated administration of heparin and other drugs may contribute to the regulation of the hemostatic process and inflammatory balance.

Coronary Artery Calcification and All-Cause Mortality in RRT Patients with Diabetes: 5 Year Survival Analysis  
Ramin Tolouian,1 Sean M. Connery,2 Kyari Sumayin Ngamdu.2 Internal Medicine, Eastern Virginia Medical School, Norfolk, VA; *Internal Medicine, Texas Tech Univ HSC El Paso, El Paso, TX.

**Background:** Vascular calcification is a significant sequel of ESRD. A Coronary Artery Calcification (CAC) Agatston score ≥ 300 has been associated with adverse cardiovascular events & increased mortality. The purpose was to evaluate all-cause mortality rates in ESRD with diabetes.

**Methods:** 113 diabetic pts undergoing RRT had CAC scoring by sub-second gated helical CT standard Agatston scoring system, slice thickness 3mm. Patients were categorized into 3 groups according to their CAC score: 0, 1-299, ≥ 300 (Low, Medium, High Risk). Survival of 3 groups was calculated using Kaplan-Meier curves for all-cause mortality for 5 year period after CAC. Adjusted and risk-factor adjusted for age & length of time on dialysis Cox proportional hazard modeling was used to estimate time to all-cause mortality.

**Results:** 5 year survival was 92%, 60%, 46% for Low, Medium, High Risk CAC groups.

Mean ±SD, p<0.05 *Low vs Medium, **Medium vs High, †Medium vs High ANOVA

There was a statistically significant difference between survival curves, Gehan-Breslow p = 0.031, but no difference between Medium & High Risk groups when pairwise multiple comparison procedures Holm-Sidak method (p=0.1). Adjusting for covariates of age & length of time on dialysis at time of scan did not make a significant difference in survival curves, Age HR = 1.04 (0.99-1.0795% CI), time on dialysis HR = 1.004 (0.99-1.01 95%).

**Conclusions:** There was a statistically significant difference between survival curves, Gehan-Breslow p = 0.031, but no difference between Medium & High Risk groups when pairwise multiple comparison procedures Holm-Sidak method (p=0.1). Adjusting for covariates of age & length of time on HD at time of measurement the log rank statistic for the survival curves is not great enough to exclude the possibility that the difference is due to random sampling variability; there is not a statistically significant difference (P = 0.614).

**Kaplan-Meier Curve Survival Analysis - CACS in ESRD**

Mortality in Medium & High groups was 40% & 50% while only 8% in low group.

**Conclusions:** Any level of CAC, regardless of severity, in HD pts with diabetes has a significant impact on survival. CAC might be useful predicting mortality in this population.

Elevated Toll Like Receptor 4 Expression and Macrophage Infiltration Is Found in High Dose Vitamin D-Induced Non-Uremic Vascular Calcification  
Jianheng Zhou,1,2 Yuan Min Wang,1 Helen Williams,3 Anne M. Durkan,1 Geoff yu Zhang,1 Huiling Wu,3 Andrew Sawyer,7 Stephen I. Alexander,1 David C. Harris,1 Vincent W. S. Lee.1 Centre for Kidney Research, Children's Hospital at Westmead, Sydney, NSW, Australia; 2Centre for Transplantation and Renal Research, Univ of Sydney at Westmead Millennium Inst, Westmead, Sydney, NSW, Australia; 3Vascular Biology Research Centre, Surgery, Univ of Sydney, Westmead Hospital, Sydney, NSW, Australia; 4Transplant Research Group, Royal Prince Alfred Hospital, Sydney, New South Wales, Australia.

**Background:** Vascular calcification is strongly associated with cardiovascular morbidity and mortality. Several studies have suggested that monocytes/macrophages are involved in arterial vascular calcification, while the involvement of the TLR4 pathway in vascular calcification has also been proposed.

**Methods:** Male C57BL/6 mice aged 8 weeks were injected with a high dose of vitamin D (50000IU/kg/day) subcutaneously for 3 days at 0, 24 and 48 hours. All mice were sacrificed 3 days after the final administration of vitamin D. Kidneys were assessed histologically. Whole aortas were dissected. Macrophage infiltration and TLR4 expression was assessed by immunohistochemistry and histology and vascular calcification by Von Kossa staining.

**Results:** High dose vitamin D treatment did not induce kidney fibrosis or injury in C57BL/6 mice within the short time frame, as assessed by GT fibrosis score and PAS tubular damage score. High dose vitamin D treated mice demonstrated significantly higher calcium deposition in the aortic arteries (17.45% of vessel area) compared to controls (1.2% p<0.05). This was accompanied by a greater level of macrophage infiltration and TLR4 expression in these arteries compared to controls.

**Conclusions:** Accelerated vascular calcification was induced in mice with high dose vitamin D treatment. These data also identify a potential role for macrophages and the TLR4 pathway in vascular calcification.

Lack of Correlation of Pyrophosphate Levels with Survival and Coronary Artery Calcification in Hemodialysis Patients  
Ramin Tolouian,1 Sean M. Connery,2 *Internal Medicine, Div of Nephrology, Eastern Virginia Medical School; *Internal Medicine, Texas Tech Univ HSC El Paso.

**Background:** Vascular calcification is an important predictor of cardiovascular mortality in ESRD. Decreased levels of inorganic pyrophosphate (PPI) are thought to increase vascular calcification. The purpose of this study was to evaluate the association of PPI & coronary calcification scores in maintenance HD patients and all-cause mortality over 5 years.

**Methods:** 98 maintenance HD patients were studied (mean ±SD): Age (yr.) 57 ±10.7, HD vintage (month) 36 ±37.6. Platelet free plasma PPI was measured by radiometric, enzymatic method as described by Tolouian. Coronary arterial calcification score (CACS) was measured by sub-second gated helical computed tomography with an Imatron C-150 XL ultra fast CT scanner using a standard protocol for vascular calcification. Patients were categorized into 3 groups according to their CAC score: 0, 1-300, and > 300.

**Results:**

The covariate PPI had no significant effect on the hazard rate, log rank p=0.61. After adjusting for covariates of PPI, age, length of time on HD at time of measurement the log rank statistic for the survival curves is not great enough to exclude the possibility that the difference is due to random sampling variability; there is not a statistically significant difference (P = 0.614).
Conclusions: The difference in 5 year survival rate in dialysis patients based on the severity of vascular calcification is not influenced by pyrophosphate levels. This supports the multi-factorial nature of vascular calcification.

Aortic Artery Calcification and Cardiac Valve Calcification Is Associated with Mortality in Chinese Hemodialysis Patients: A 3.5 Year Follow-Up

Xiaonong Chen, Zijin Chen, Xiaobo Ma, Bei Ding, Huawei Ling, Zhongwei Shi, Nan Chen. Nephrology, Ruijin Hospital Affiliated to Shanghai Jiao Tong Univ, Shanghai, China; Radiology, Ruijin Hospital Affiliated to Shanghai Jiao Tong Univ, Shanghai, China; Cardiology, Ruijin Hospital Affiliated to Shanghai Jiao Tong Univ, Shanghai, China.

Background: Aim to investigate the relationship among aortic artery calcification (AAC), cardiac valve calcification (CVC) and mortality in maintenance hemodialysis (MHD) patients.

Methods: The study included 110 MHD patients. All MHD patients were treated in Shanghai Ruijin Hospital in July 2011. Follow-up these patients for 42 months.

Results: Totally 110 MHD patients were involved in this study. 64 (58.2%) patients were male, and the mean age was 55.2 ± 15.0 years old, the mean dialysis duration was 41.7 ± 38.1 months. 25.5% patients had cardiac valve calcification, while 61.8% had visible calcification. After 42 months follow-up, 26 (22.7%) patients died, including 16 cases death from cardiovascular events, 5 cases respiratory failure, 3 cases tumor metastasis, 1 case deep venous thrombosis and 1 case abandon treatment. Kaplan-Meier analysis showed that patients with AAC or CVC had a significant greater number of all-cause and cardiovascular deaths than those without. In multivariate analyses, the presence of AAC was a significant factor associated with all-cause mortality (HR 3.149, P = 0.025) in addition to lower albumin level and lower 25(OH)D level. The presence of CVC was a significant factor associated with cardiovascular mortality (HR 3.800, P = 0.029) in addition to lower albumin level and lower 25(OH)D level.

Conclusions: The presence of AAC and CVC were independently associated with mortality in MHD patients. Regular follow-up by X-ray and echocardiography could be useful method to stratify mortality risk in MHD patients.

PUB 713

Beneficial Effect of the Vasopressin AV1a and AV2 Receptor Blocker Conivaptan (C) on the Renal Alterations Resulting from Mild Heat-Induced Dehydration (MHID) and Rehydration with a 10% Fructose (F) Beverage

L. Gabriela Sanchez-Lozada, Fernando E. Garcia-arroyo, Monica Gabriela Bias-Marron, Jose Pedraza-chaverri, Cecilia Zazueta, Magdalena Cristobal, Edilia Tapia. Renal Physiopathology, INCICH, Mexico City, DF, Mexico; Biology, UNAM, Mexico City, DF, Mexico; Cardiovasc BioMed, INCICH, Mexico City, DF, Mexico.

Background: The aims of this study were: 1. To define a possible synergistic effect between fructose and vasopressin during MHID, and 2. To evaluate the potential therapeutic benefit of C (3 mg/kg BW) on this condition.

Methods: Six groups of male Wistar rats were MHID (37°C/ 1 h/day) and rehydrated with the selected beverage during 30 days: Water (W)+Veh, W+C, F+Veh, F+C, Stevia (S)+Veh and S+C. A group of normal control (NC) rats was studied as reference. After 30 days plasma and urine parameters were evaluated, renal cortex mitochondria were isolated and respiratory control rate (RCR) was evaluated with malate/glutamate (M/G) and succinate/rotenone (S/R) substrates.

Lack of Aquaretic Effects of the kappa Opioid Agonist Nalbuphine following Multiple Ascending Oral Doses in Healthy Volunteers

Amale Hawi, 
Thomas Sciascia, 
Vandana S. Mathur, 
Havi Consulting, Ridgefield, CT; 
Trevi Therapeutics, New Haven, CT; 
Mathur Consulting, Woodside, CA.

Background: Nalbuphine is a mixed µ-antagonist κ-agonist opioid drug that may suppress itch in hemodialysis patients with pruritus following oral administration of nalbuphine HCl extended release (ER) tablets. However, as a class, kappa opioid agonists have aquaretic effects in both animals and humans, which can be treatment-limiting. In this Phase 1 study, the potential of nalbuphine to induce aquaretic effects was explored.

Methods: Healthy male and female subjects (n=9) were administered oral doses of nalbuphine escalating every 2-3 days from 30 mg QD on Day 1 to 30 mg BID, 60 mg BID, 120 mg BID, and 180 mg BID over a 2-week period. Urine output and vital signs were measured-pre-treatment and at multiple time points on Days 1 through 14.

Results: Repeated measurements of urine volume with progressively higher nalbuphine doses over the 6-fold dose range showed no evidence of increased urine output related to dose or duration of time on nalbuphine. Urine specific gravity remained within the normal range (1.001-1.03) and did not decline in any subject during treatment. None of the subjects developed hypernatremia nor was there a trend of rising serum sodium with all values remaining within the normal range. There were no dose-related reductions in blood pressure and none of the subjects developed hypotension. The mean systolic blood pressure remained consistently in the 108–128 mmHg range. Likewise, heart rate remained normal throughout the study with no HR > 73 beats per minutes.

Conclusions: There was no evidence of an aquaretic effect at nalbuphine oral doses up to 180 mg BID in healthy subjects, the most sensitive population in which such effects may be observed.

PUB715

Urinary Excretion Pattern of Exosomal Aquaporin-2 in Nephronophthisis Patients

Hiroko Sonoda, Nobuyuki Mikoda, Sayaka Oshikawa, Masahiro Ikeda.
Veterinary Nephrology, Univ of Miyazaki, Miyazaki, Japan.

Background: Nephronophthisis (NPH), an inherited disorder, is the most frequent genetic cause of end-stage renal failure in children. So far, twenty responsible genes have been identified, including the NPHP3. The pyc mouse with missense mutation in Nphp3 gene orthologous to human NPHP3 is an animal model of NPH. Recent animal work has shown that urinary exosomes contain renal functional proteins, including AQ2. In this study, we examined whether the level of urinary exosomal AQ2 expression was altered in pyc mice.

Methods: Urine samples were collected for 20 hrs from either pcy or control DBA/2 mice, at 7, 16, and 21 weeks of age, respectively. Urinary exosomes were isolated by differential centrifugation. The levels of urinary exosomal and renal protein were analyzed by immunoblotting.

Results: Although urinary volume in pcy mice was not altered at 7 weeks of age, those were significantly increased at 16 and 21 weeks of age in comparison with age-matched control mice. Urine osmolality was significantly decreased in pcy mice at all ages examined in this study. Urinary exosomal AQ2 protein levels in pcy mice were dramatically increased at 16 weeks of age, whereas those at 7 and 21 weeks of age were not significantly increased. Similarly, a transient increase in urinary excretion of exosomal tumor susceptibility gene 101 protein (TSG101), frequently used as an exosome marker protein, was observed in pcy mice at 16 weeks of age. The levels of renal AQ2 protein in pcy mice at 16 weeks of age or older were significantly higher than those in the control mice.

Conclusions: Urinary exosomal AQ2 protein excretion was transiently increased in pcy mice and this increase appeared to be related to both the number of exosomes excreted into the urine and its renal abundance.

PUB716

Low Osmolar Diet and Adjusted Water Intake for Vasopressin Suppression in ADPKD

Osama W. Amro,1,2 Jessica K. Paulus,1,2 Farzad Noubary,1,2 Ronald D. Perrone,1,2 Nephrology, Tufts Medical Center; 1Tufts Univ School of Medicine.

Background: Autosomal dominant polycystic kidney disease (ADPKD) affects 12.5 million persons worldwide and accounts for 10% of patients with end-stage renal disease in the United States. Vasopressin is a known detrimental factor in disease progression and cyst enlargement.

Methods: This randomized controlled trial examined the effect of a novel approach of combining low osmolar diet and adjusted water intake on vasopressin, measured by change in urinary osmolality, and total daily urinary solute in 34 patients with early ADPKD. Participants were randomized to receive a low osmolar diet (low sodium (1500 mg/day), low protein (0.8 gram/kg body weight) diet) followed by adjusted water intake to achieve a urine osmolality of 280 mosm/kg versus no intervention for two weeks duration, with equal (1:1) allocation. Permutated block randomization was performed within strata of age and sex.

Results: Baseline characteristics of the two groups were similar. Compared with baseline, the mean urine osmolality significantly declined from 426 (±193) to 258 (±110) mosm/kg (P<0.007) but not in the control group. At 2 weeks, levels significantly differed between groups (P=0.04).

Total urinary solute decreased only in the low osmolar diet group and significantly differed between groups at 2 weeks (P<0.03). The two week adherence rate to diet and adjusted water intake was 70% with a mean water prescription of 2.6 liters/daily.

Conclusions: We identified a novel step wise dietary intervention that led to significant reduction in vasopressin as measured by reduction in 24 hour urine osmolality in patients with early ADPKD. Furthermore, this dietary intervention led to significant reduction in water required for vasopressin suppression. Long-term studies are needed to evaluate diet and adjusted water intake adherence, and determine if the reduction in vasopressin slows ADPKD progression.

CRISPR-Cas9-Mediated Deletion of Myosin Light Chain Kinase in Cultured Collecting Duct Cells

Background: Regulation of osmotic water transport in the renal cortical collecting duct by vasopressin is in part dependent on membrane trafficking of aquaporin-2 (AQP2) to the apical plasma membrane of the principal cells. It is known that trafficking of AQP2 is in part dependent on changes in AQP2 phosphorylation. We previously proposed that AQP2 trafficking is dependent on the protein kinase Myosin Light Chain Kinase (MLCK; gene symbol: Mylk). Here, we test the role of MLCK in AQP2 phosphorylation and trafficking, utilizing CRISPR-Cas9-generated mutations in MLCK in cultured mouse mpkCCD cells.

Methods: We used CRISPR-Cas9-genome-editing to mutate the catalytic region of the Mylk gene. Clones were generated with 4 different guide RNAs and were characterized by genomic sequencing and immunoblotting. Effects of the deletions were assessed by immunoblotting and immunofluorescence immunocytochemistry of AQP2.

Results: Multiple clones with mutations in the catalytic domain of MLCK were generated. Western blots showed absence of MLCK protein in MLCK-deleted clones. Controls were clones that express MLCK without mutations in the catalytic domain, but may contain off-target modifications. AQP2 protein abundance varied over a broad range, among all MLCK-deleted (n=4) and control (n=4) lines, but, on average, was not affected by the deletion. Immunocytochemistry showed that vasopressin stimulates redistribution of AQP2 to the apical plasma membrane in both control cells and MLCK-deleted cells. Vasopressin-dependent phosphorylation of AQP2 at Ser256 and Ser269 was not significantly reduced in MLCK-deleted cells.

Conclusions: The results demonstrate the feasibility of CRISPR-Cas9-mediated genome editing in mouse mpkCCD cells. Our experiments in mouse cultured collecting duct cells provide evidence that vasopressin-induced phosphorylation of AQP2 and redistribution of AQP2 to the apical plasma membrane can occur independently of myosin light chain kinase.

The PDZ Domain-Containing Protein Harmonin Is a Binding Partner of Sodium-Coupled Monocarboxylate Transporter 2

Nobuyuki Onizawa,1,2 Naoyuki Otani,1 Promsuk Jutabha,1 Motoshi Ouchi,1 Hajime Hasegawa,2 Naohiko Anzai.1, Dept of Pharmacology and Toxicology, Dokkyo Medical University School of Medicine, Mibu, Tochigi, Japan; 1, Dept of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical Univ, Kawagoe, Saitama, Japan.

Background: Lactate is freely filtered and extensively reabsorbed in the proximal tubule to prevent the loss of this valuable metabolite from the body. Sodium-coupled monocarboxylate transporter SMCT2(SLC5A12) mediates the transport of pyruvate, lactate and nicotinate and lactate (Gopal et al., BBA. 2007). In contrast to its well characterized monocarboxylate transporter SMCT2(SLC5A12) mediates the transport of pyruvate, lactate and nicotinate and lactate (Gopal et al., BBA. 2007). In contrast to its well characterized transport properties, less information is available on the regulatory mechanism of SMCT2. We recently identified Harmonin as the binding partner for SMCT2 (28.17 ng/ml before and after FA respectively. 11 patients experienced more than 25% rise in serum creatinine but not hypouricemia in human unlike SIADH (G Decaux, JASN, 1996).

Results: Moreover, co-immunoprecipitation studies revealed that the SMCT2 interacted with Harmonin in the yeast two-hybrid system. Furthermore, co-immunoprecipitation studies revealed that the SMCT2 interacted with Harmonin in the yeast two-hybrid system. Furthermore, co-immunoprecipitation studies revealed that the SMCT2 interacted with Harmonin in the yeast two-hybrid system. Furthermore, co-immunoprecipitation studies revealed that the SMCT2 interacted with Harmonin in the yeast two-hybrid system.

Conclusions: Harmonin was identified as the binding partner for SMCT2. The elucidation of these interactions may further our understanding of the function and regulation of monocarboxylate (e.g., lactate) transport in the human kidney.

PUB719

Stimulation of V1a Receptor Increases Renal Uric Acid Clearance via ABCG2 Transporter – Insight into Hypouricemia in SIADH

Kei Taniguchi, Yoshifumi Tamura, Shigeru Shibata, Shunyu Uchida. Dept of Internal Medicine, Teikyo Univ School of Medicine, Itabashi, Tokyo, Japan.

Background: Hypouricemia seen in the subjects with syndrome of inappropriate secretion of antidiuretic hormone (SIADH) is pathogenomic but the mechanism of hypouricemia remains to be clarified. V2 receptor agonist ‘desmopressin’ induced hyperuricemia but not hypouricemia in human unlike SIADH (G Decaux, JASN, 1996). Therefore, we hypothesized that V1 receptor but not V2 receptor may play a role in inducing hypouricemia. In the present study, we examined the changes in serum uric acid, urinary uric acid excretion and expression of uric acid transporters in response to V1a receptor agonist ‘terlipressin’.

Methods: Terlipressin was subcutaneously infused by osmotic mini pump to 7-weeks-old male Wistar rats (n = 9). Control rats were infused with normal saline (n = 9). The rats were sacrificed to obtain renal cortical tissues at 3 days.

Results: Serum uric acid significantly decreased and the excretion of urinary uric acid significantly increased in the terlipressin group. Thus, fractional excretion of uric acid increased from 1.20 ± 0.28 % to 3.10 ± 0.56 % (P < 0.001). The expression of ATP-binding cassette transporter, sub-family G, member 2 (ABCG2) significantly increased in the terlipressin group. Other uric acid transporters did not significantly change.

Conclusions: These results suggest that stimulation of V1a receptor increases renal uric acid clearance probably via upregulation of ABCG2, leading to hypouricemia seen in SIADH patients.

PUB720

Fluorescein Angiography and the Kidney: Friend or Foe?

Mohamed E. Elraggaly,1 Ahmed Fathy Elkerai,2 Ahmed M. Abdelhadi,1 Ashraf Nabiel Abdalla.4 Nephrology, Kidney and Urology Center, Alexandria, Egypt; 2Nephrology, Alexandria Univ, Alexandria, Egypt; 1Ophthalmology, Alexandria Univ, Alexandria, Egypt; 4Pharmacology, Umm Al-Qura Univ, Saudi Arabia.

Background: Fluorescein angiography (FA) is an indispensable tool for diagnosis and management of diabetic retinopathy (DR). However, safety of fluorescein sodium on renal functions is not fully understood.

Methods: 100 type 2 diabetic patients presenting to the ophthalmology outpatient clinic at Alexandria main university hospital were included in our study. Serum creatinine and cystatin-C were measured just before and 2 days after FA. Urinary NGAL as a tubular biomarker was measured also before and 4 hours after FA. Renal injury was defined as 25 % increase in serum creatinine or cystatin-C.

Results: The mean of serum creatinine was 0.99 ± 0.36 mg/dl and 1.0 ± 0.36 mg/dl before and after FA respectively with no statistically significant change (P=0.061). Only one patient (out of 100) experienced more than 25% rise in serum creatinine from baseline. Cystatin-C and urinary NGAL increased significantly after FA (P<0.001). Mean of serum Cystatin-C was 0.89 ± 0.34 mg/l and 0.95 ± 0.36 mg/l before and after FA respectively. 11 patients experienced more than 25% rise in serum cystatin-C from baseline. Mean of urinary NGAL was 21.78 ± 23.90 ng/ml and 27.15 ± 28.17 ng/ml before and after FA respectively.

Conclusions: Using ordinary renal biomarkers as serum creatinine, FA was thought to be kidney friendly. Nevertheless, using more sensitive early biomarkers as serum cystatin-C and urinary NGAL, FA is not as innocent as previously thought. A creatinine negative, biomarker positive change may imply a form of subclinical AKI.

Underline represents presenting author.

Hemodialysis was required in 9.3% of cases. The recovered AKI was observed in 75.9% at the time of hospital discharge. The length of hospital stay (9.0±3.7; vs. 7.6±4.3; p<0.05) and mortality (18.5 vs 7.2%; p=0.02) were greater in patients with AKI compared with patients without AKI. Patients with H-AKI had a longer hospital stay (15±12 vs. 8±8; p<0.05) and a statistical trend to higher mortality (36.4% vs 14.7%; p=0.08) in relation to patients with C-AKI.

Conclusions: AKI was a frequent diagnosis on hospital admission or during hospitalization. C-AKI and H-AKI added a negative effect on the prognosis. H-AKI episodes were more severe and were associated with a longer hospital stay and an statistical trend in mortality in comparison with C-AKI.

PUB724

Drug Utilization Patterns and Factors Associated with Acute Kidney Injury in an Intensive Care Unit in a Brazilian Public Hospital: A Prospective Cohort Study

Background: Acute kidney injury (AKI) is associated with a significant increase in morbidity, mortality, and health care costs. In intensive care units (ICU), the cause of AKI is commonly associated with multiple factors, among which the use of potentially nephrotoxic drugs is often neglected as a preventable cause of AKI.

Methods: This is a prospective cohort study that evaluated the AKI as a primary outcome in ICU patients at a teaching hospital in Belo Horizonte, Brazil. Length of stay greater than 24 hours and hospital stay lower or equal to 7 days were evaluated for potential eligibility. To be enrolled, patients should not present kidney dysfunction at the time of ICU admission.

Results: Data collection was performed from October 2014 to February 2015, including 122 patients, mostly originated from the surgical department (46.7%). An average of 22.0±9.4 drugs was prescribed and 2-24 potentially nephrotoxic drugs were used per patient. Mechanical ventilation was required for 67.2% of patients and at least one vasoactive drug was used in 68.0% of cases. An incidence of AKI was observed in 23.8% of patients, among them 34.5% required dialysis, 24.1% reached the third stage of AKI and 31.8% were referred to additional treatment after ICU discharge. Eleven (9%) patients died and 63.6% of them developed AKI. The bivariate analysis showed that p<0.06 and APACHE II score (p=0.001) had a higher median among patients who developed AKI compared to those who did not develop AKI. In the logistic regression, the number of medications (OR: 1.15; 95% CI: 1.05 to 1.26) presented a statistically significant correlation with the development of AKI.

Conclusions: These results demonstrate that the identification of factors associated with AKI in ICU patients is very important for the early identification of renal dysfunction induced by drugs, providing conditions for appropriate prevention and treatment of the extent of kidney damage.
Clinical, Dialytic and Laboratorial Factors Associated with Poor Health Related Quality of Life in Mexicans Hemodialysis Patients

Edgar Dehesa Lopez,1 David Olvera,2 Carlos Gonzalez parra,3 Rafael Baizabal.4
1Dept of Nephrology, Research and Teaching Center in Health Sciences (CIDOCS), Culiacan, Sinaloa, Mexico; 2Dept of Nephrology, Hospital ISSSTE, Ciudad Valles, San Luis Potosi, Mexico; 3Dept of Nephrology, IMSS, Puebla, Mexico; 4Department of Nephrology, Hospital ISSSTE, Xalapa, Veracruz, Mexico.

Background: The evaluation of health related quality of life (HRQOL) in hemodialysis patients has recently gained great importance because it has proven to be an independent predictor of clinical outcomes.

Methods: Cross-sectional study. The validated Mexican version of the KDQOL-SF36 v1.3 questionnaire were applied to 194 adult patients with ESRD on hemodialysis in different regions of Mexico. According to the global score of questionnaire, patients were grouped in: patients with poor HRQOL (global score below the median) and patients with good HRQOL (global score greater than the median). Logistic regression was used to investigate the effects of clinical, dialytic and laboratorial factors on HRQOL.

Results: The average age was 54±16 with 54.6.1% male. Comorbidities were: hypertension in 86.6%, diabetes mellitus 2 in 57.2% and dyslipidemia in 7.2%. The vascular access was a catheter in 55.2% and fistula in 44.8% of the cases. Diabetes mellitus and the use of catheters as vascular access were more frequent in patients with poor quality of life. On the other hand, phosphorus >5.5 mg/dl and albumin >4g/dl were more frequent in patients with good quality of life. There were no differences in age, Kt/V, hemoglobin and calcium between groups. Table 1 shown the clinical, dialytic and laboratorial factors studied in the multivariate logistic analysis.

Table 1-Multivariate logistic regression analysis of clinical, dialytic and laboratorial factors associated with poor HRQOL.

Conclusions: The associated factors with poor HRQOL in Mexicans hemodialysis patients were: the time spent in hemodialysis, serum albumin <4 g/dl and use of catheter for vascular access.

Empagliflozin and Cardiovascular Outcomes in Patients with Type 2 Diabetes and Chronic Kidney Disease

Christopher Wanless, John M. Lachin, David H. Fitchett, Silvio E. Inzucchi, Michaela Mattheus, Odd Erik Johansen, Hans-Juergen Woerle, Uli Christian Broedl, Bernard Zimman, 

*Dept of Medicine, Würzburg Univ Clinic, Würzburg, Germany; †BioImaging Center, The George Washington Univ, Rockville, MD; ‡St Michael’s Hospital, Div of Cardiology, Univ of Toronto, Toronto, Canada; §Section of Endocrinology, Yale Univ School of Medicine, New Haven, CT; †Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; ‡Boehringer Ingelheim Norway KS, Asker, Norway; §Lunenburg-Tanenbaum Research Inst, Mount Sinai Hospital, Toronto, Canada; ‡Div of Endocrinology, Univ of Toronto, Toronto, Canada.

Background: Patients with type 2 diabetes (T2D) and chronic kidney disease (CKD) are at high risk of cardiovascular (CV) events and premature death. Empagliflozin is a sodium-glucose co-transporter (SGLT)-2 inhibitor used in the treatment of T2D.

Methods: In EMPA-REG OUTCOME®, we explored long-term CV outcomes with empagliflozin vs placebo when added to standard of care in 7020 T2D patients with established CV disease. Inclusion criteria included eGFR 30min/ml/1.73m². Patients (mean age 63 years, mean HbA1c 8.1%) were randomized 1:1:1 to empagliflozin 10 mg, or mg, or placebo.

Results: Most patients had impaired kidney function (52.2% stage 2, 17.8% stage 3a, 7.7% stage 3b CKD) while 28.7% and 11.0%, respectively, had moderately (30-300mg/g) and severely (>300mg/g) increased urine albumin to creatinine excretion. After a median follow-up of 3.1 years, the primary outcome (first occurrence of non-fatal myocardial infarction, non-fatal stroke, or CV death) occurred in a lower percentage of patients on empagliflozin (10.5%) than placebo (12.1%) (HR 0.86 [0.74-0.99]; p=0.04). This result was driven by a 38% reduction in CV death vs placebo (HR 0.62 [0.49-0.77]; p=0.001), with no difference in the risk of heart attack or stroke. Empagliflozin reduced hospitalization for heart failure by 35% (HR 0.65 [0.50-0.85]; p=0.0017). Pre-defined subgroup analyses on CV outcomes in patients with T2D and CKD will be presented.

Conclusions: Empagliflozin reduces CV morbidity and mortality in patients with T2D and various degrees of CKD.

High Dose Perioperative Atorvastatin and Acute Kidney Injury Following Cardiac Surgery

Federic Tremaine Billings, Chad E. Wagner, Patty Hendricks, Yaping Shi, Michael R. Petracek, Nancy J. Brown. Vanderbilt Univ, Nashville, TN.

Background: Hydroxy-methylglutaryl-coenzyme A reductase inhibitors (statins) affect several mechanisms underlying acute kidney injury (AKI), a common and dangerous complication after cardiac surgery. We hypothesized that short-term high-dose perioperative atorvastatin would reduce AKI following cardiac surgery.

Methods: We randomized elective cardiac surgery patients, stratified by chronic kidney disease (CKD), to atorvastatin or matching-placebo starting the day prior to surgery until hospital discharge in pre-study statin-naive subjects or until the day after surgery in pre-study statin-using subjects. Our primary endpoint was AKI by AKIN criteria.

Results: The study was stopped on recommendations of the DSMB after 653 of 820 subjects completed the study due to futility and an increased incidence of AKI among statin-naive patients randomized to atorvastatin versus placebo (P=0.075). Among statin-naive subjects (n=199), however, AKI occurred in 21.6% randomized to atorvastatin versus 13.4% randomized to placebo (p=0.14), and 52.9% vs. 15.5%, P=0.05, in patients with CKD (n=36). Serum creatinine concentrations increased a median of 0.11 (0.11 – 0.56) versus 0.05 (0.12 – 0.33) mg/dl in statin-naive patients randomized to atorvastatin versus placebo (P=0.007), and this effect was magnified among those with CKD, whereas serum creatinine concentrations increased by 0.26 (0.22 – 0.94) versus -0.06 mg/dl (-0.16 – 0.41), P=0.04.

Conclusions: High-dose perioperative atorvastatin treatment does not reduce AKI following cardiac surgery and may increase risk in patients with CKD who are naive to statin treatment. Perioperative continuation or short-term withdrawal of statin treatment in statin-using patients does not affect AKI.

HI-OR03

Effect of Methylprednisolone on Acute Kidney Injury in Patients Undergoing Cardiopulmonary Bypass

Background: Acute kidney injury is a common complication of the 20 million cardiac surgeries performed worldwide each year. We conducted a substudy of the Steroids In Cardiac surgery (SIRS) trial to determine whether methylprednisolone alters the risk of acute kidney injury in patients undergoing cardiac surgery with cardiopulmonary bypass [substudy protocol BMJ Open 2014 Mar 5;4(3): e004842].

Methods: This was a randomized clinical trial of 7,286 high-risk patients undergoing cardiac surgery with cardiopulmonary bypass from 79 centres in 18 countries between June 2007 and December 2013. Patients were assigned to take intravenous methylprednisolone (250 mg at anesthetic induction and 250 mg at initiation of cardiopulmonary bypass) or placebo. Patients, care givers and outcome-assessors were blinded to allocation. Acute kidney injury was defined as ≥250 mg or ≥ 25.5 mmol (≥ 0.3 mg/dl) increase in the postoperative serum creatinine concentration from the preoperative concentration in the 14 days following surgery, or new dialysis in the 30 days following surgery.

Results: Methylprednisolone (n=3,647) versus placebo (n=3,639) did not alter the risk of AKI (40.9% versus 39.5%, respectively; relative risk 1.03 [95% CI, 0.96 to 1.11]). Results were consistent with multiple alternate continuous and categorical definitions of acute kidney injury, and in the subgroup with baseline chronic kidney disease.

Conclusions: Amongst patients undergoing cardiac surgery with cardiopulmonary bypass, the use of corticosteroids during the perioperative period did not alter the risk of acute kidney injury. Trial Registration: NCT00427388

The NEFIGNAT Trial: NEFECON, a Novel Targeted Release Formulation of Budesonide, Reduces Proteinuria and Stabilizes eGFR in IgA Nephropathy Patients at Risk of ESRD

Benct C. Fellsrom, 1 Rosanna Coppo, 2 John Feehally, Jürgen Floege, Johan W. De Fijter, Alan G. Jardine, Francesco Locatelli, 3 Bart D. Maes, Alex Mercier, Fernando Ortiz, 4 Manuel Praga, 5 Soren Schwartz Sorensen, 5 Vladimir Tesar, 5 Uppsala Univ Hospital, 6Univ Turin, 7Univ Leicest; RWTH Univ Aachen; 7Leiden Univ Medical Center; 8Univ Glasgow; 'Ospedale A Manzoni, Lecco; 'AZ Delta Roeselaar; 'Pharmalink; 'Helsinki Univ Hospital; 'Hospital 12 de Octubre, Madrid; 'Rigshospitalet, Copenhagen; 'Charles Univ, Prague.

Background: IgA nephropathy (IgAN) is the most prevalent primary chronic glomerular disease. Despite RAS blockade, >25% of patients progress to ESRD within 20 years. This study evaluated a novel budesonide formulation (NEFECON) targeted for release in the distal ileum, where Peyer’s patches reside, in patients at risk of ESRD despite optimized RAS blockade.

Methods: Double-blind, placebo-controlled study in 150 patients (62 sites, 10 EU countries) with primary IgA glomerulonephritis (UPCR > 0.5 g/GR urine protein > 0.75 g/d) and eGFR > 60 mL/min/1.73m² randomized to placebo (n=75) or NEFECON 8 mg/d and 16 mg/d (n=75) for NEFECON 8 and 16 mg/d, respectively; difference in mean percentage change in eGFR achieved statistical significance for 8 mg/d (p=0.006) and 16 mg/d (p=0.003). Adverse event rates were higher in NEFECON groups (88–94%) than placebo (84%). Two serious adverse events were assessed as possibly related to NEFECON: deteriorated renal function (in follow-up) and deep vein thrombosis.

Conclusions: NEFECON reduced UPCR and maintained eGFR in patients with primary IgAN at risk of progression to ESRD despite optimized RAS blockade. Treatment was generally well-tolerated.

HI-OR05

Randomized Trial on Efficacy of Mycophenolate Mofetil versus Tacrolimus in Maintaining Remission in Children with Steroid Resistant Nephrotic Syndrome

Aditi Sinha, Arvind Bagga. All India Inst of Medical Sciences, New Delhi, India.

Background: Since prolonged therapy with tacrolimus (Tac) causes nephrotoxicity, this RCT examined non-inferiority of mycophenolate mofetil (MMF) to Tac in maintaining remission in patients with steroid resistant nephrotic syndrome (SRNS).

Methods: Following approvals, 84 patients with SRNS (1-18 yr; minimal change 48, FSGS 36) & eGFR >60 ml/min/1.73m² received Tac (0.15 mg/kg/d; trough 4-8 mg/ml) for 6-months. Stratifying for histology & type of response, patients with complete (Up/Uc <0.2 mg/mg) or partial remission (Up/Uc 0.2-2, albumin >2.5 g/dl) were randomized to continue Tac or receive MMF (0.75-1 g/m²/d), prednisone & enalapril. Primary outcome, at 12-mo, was proportion with remission or infrequent relapses. Therapy failure was recurrent SRNS, frequent relapses or >1 SAE. Enrolment was closed after interim intention-to-treat 12-mo, was proportion with remission or infrequent relapses. Therapy failure was recurrent SRNS, frequent relapses or >1 SAE. Enrolment was closed after interim intention-to-treat analysis of outcome in 1/2 sample.

Results: Baseline features were similar. Therapy with MMF led to significantly higher treatment failure, prednisone dose & SAE; cGFR change was similar. On multivariate regression, hazards of treatment failure were high with MMF (HR 9.7, adjusted for histology, type of resistance & remission; P<0.0001).

Conclusions: Therapy with MMF is inferior to Tac in maintaining Tac induced remission in patients with SRNS.

HI-OR06

Prevention of Bone Mineral Density Loss in De Novo Kidney Transplant Recipients with Twice-Yearly Denosumab: A Randomized Controlled Trial

ClinicalTrials.gov number NCT01377467

Rudolph P. Wuthrich,1 Diana P. Frey,2 Jens Gunther Brockmann,3 Thomas Feih,2 Thomas F. Mueller,2 Lanja Saleh,4 Arnold Von Eckardstein,1 Nicole Graf,5 Marco Bonanni.1

1 Div of Nephrology, 2Div of Visceral and Transplantation Surgery, 3Inst of Clinical Chemistry, Univ Hospital, Zurich, Switzerland; 4Graf Biostatistics, Winterthur, Switzerland.

Background: Kidney transplantation is associated with bone loss and an increased risk of fracture. Since current therapeutic options to prevent bone loss are limited we assessed the efficacy and safety of Receptor Activator of Nuclear Factor kB Ligand (RANKL) inhibition with denosumab to improve bone mineralization in the first year after kidney transplantation.

Methods: We enrolled 108 kidney transplant recipients and randomized 90 patients two weeks after surgery in a 1:1 ratio to receive denosumab (subcutaneous injections of 60 mg denosumab at baseline and after 6 months) or no treatment. The primary endpoint was the percentage change in bone mineral density (BMD) measured by DXA at the lumbar spine at 12 months.

Results: After 12 months, the primary outcome of total lumbar spine BMD increased by 4.6% (95% CI 3.3-5.9%) in 46 patients in the denosumab group and decreased by -0.5% (95% CI -1.8-0.3%) in 44 patients in the control group (between-group difference 5.1%, 95% CI 1.7-8.0; p=0.001). Denosumab also significantly increased BMD at the total hip by 1.9% (95% CI 1.0 to 3.7%; p=0.035) over that in the control group at 12 months. HR-pQCT in a subgroup of 24 patients showed that denosumab also significantly increased BMD and cortical thickness at the distal tibia and radius (p=0.05). Biomarkers of bone resorption (p-CTX, urine deoxypyridinolone) and bone formation (P1NP, BSAP) markedly decreased with denosumab (p<0.0001). Episodes of cystitis and asymptomatic hypocalcaemia occurred more often with denosumab, whereas graft function, rate of rejections and incidence of opportunistic infections were similar.

Conclusions: Antagonizing RANKL with denosumab effectively increased BMD in de novo kidney transplant recipients, but was associated with more frequent episodes of urinary tract infection and decreased calcemia.

Randomized, Double-Blind, Placebo-Controlled, Parallel, 3-Arm Study of Safety and Anti-Pruritic Efficacy of Nalbuphine HCl ER Tablets in Hemodialysis Patients with Uremic Pruritus

Vandana S. Mathur,1 Jayant Kumar,2 Paul W. Crawford,3 Howard Halt,4 Thomas Sciascia.3

1Mathur Consulting; 2Trevi Therapeutics; 3Research by Design; 4Edenridge Consulting; 5Renal Medical Associates.

Background: Uremic pruritus (UP) is associated with decrements in quality of life and sleep and higher mortality. UP pathogenesis may involve endogenous α/μ opioid ligand ratio imbalance. Nalbuphine ER tablets (NAL) are a κ-opioid agonist/μ-opioid antagonist being developed for chronic pruritic conditions.

Methods: 373 hemodialysis patients (HD/P) with mean baseline numerical rating scale score (NRS) ≥ 4.5 for worst itching (0 [no itch] -10 [worst possible itching]) were randomized 1:1:1 to NAL 60 mg (n = 128), NAL 120 mg (n=120), or placebo (n = 125) and treated for 8 weeks.

Results: Demographics, dialysis adequacy and vintage, phosphorus, parathyroid hormone, proteinuria, duration, and antihistamine use were similar in the 3 arms at baseline. The primary efficacy endpoint was the change from Baseline to the Evaluation Period (Weeks 7 and 8) in the NRS for each dose of NAL, with pre-specified hierarchical ordering – the most common adverse events were nausea, vomiting, and constipation. A statistically significant mean reduction for NAL 120 compared to placebo was observed as early as one week following titration. The most common adverse events were nausea, vomiting, and constipation. A statistically significant mean reduction for NAL 120 compared to placebo was observed as early as one week following titration. The mean NRS in the NAL 60 mg group declined from 6.87 (1.40) to 4.95 (2.10), with an LS mean decline vs. placebo = -0.24 (0.31), p = 0.432. A statistically significant mean reduction for NAL 120 compared to placebo was observed as early as one week following titration. The mean NRS in the NAL 60 mg group declined from 6.87 (1.40) to 4.95 (2.10), with an LS mean decline vs. placebo = -0.24 (0.31), p = 0.432. A statistically significant mean reduction for NAL 120 compared to placebo was observed as early as one week following titration.

Conclusions: Nalbuphine ER tablets at a dose of 120 mg BID were safe and significantly reduced itching intensity.

The Omega-3 Fatty Acids (Fish Oils) and Aspirin in Vascular Access Outcomes in Renal Disease (FA VOURED) Study: A Randomised Placebo-Controlled Trial

Ashley B. Irish,1 2Nephrology, Fiona Stanley Hospital, Perth, Western Australia, Australia; 3Australian Kidney Trials Network, Univ of Queensland, Brisbane, Queensland, Australia.

Background: Increasing the use of arteriovenous fistulae (AVF) to improve haemodialysis access is limited by early thrombosis and maturation failure. Omega-3 polyunsaturated fatty acids (ω3FA) may prevent these complications by inhibition of platelet aggregation, vasocostriction, intercellular hyperplasia and inflammation.

Results: Baseline features were similar. Therapy with MMF led to significantly higher treatment failure, prednisone dose & SAE; cGFR change was similar. On multivariate regression, hazards of treatment failure were high with MMF (HR 9.7, adjusted for histology, type of resistance & remission; P<0.0001).

Conclusions: Therapy with MMF is inferior to Tac in maintaining Tac induced remission in patients with SRNS.
Methods: This international, randomised, double-blind, placebo-controlled trial examined whether 3 months therapy with w3FA (4g/d) reduced primary AVF failure at 12 months after AVF creation. AVF failure was defined as AVF thrombosis and/or abandonment and/or cannulation failure. A subset of patients received aspirin (100mg/day) or matching placebo in addition to w3FA or placebo in a factorial design (n=388).

Results: The 567 randomised participants had a mean age of 55 years, 63% were male and 46% diabetic. AVF failure occurred in 128 (27%) participants assigned to w3FA compared with 125 (26%) assigned to placebo (relative risk for aspirin use [RR] 1.03, 95% confidence interval [CI] 0.86-1.23, p = 0.78). Regarding each component of AVF failure, w3FA did not reduce the risk of thrombosis (22% vs 23%, RR 0.98, 95% CI 0.72-1.34, p = 0.90), AVF abandonment (19% vs 22%, RR 0.87, CI 0.62-1.22, p=0.43) or cannulation failure (40% vs 39%, RR 1.03, 0.83-1.26, p=0.81). A subgroup difference was observed for diabetes mellitus (interaction p = 0.038; RR 1.30 vs 0.78; diabetics vs non-diabetics) but not for age, gender, AVF site, dialysis modality or cardiovascular disease. There was no difference in any serious adverse event (AE) (9.2% vs 13.0%, p=0.14; bleeding, 8.1% vs 10.9% p=0.26, or gastrointestinal AE, 4.9% vs 5.4%, p=0.86. The risk of AVF failure was similar (45% vs 45%, RR 1.01, 95% CI 0.95-1.07) in the subset of participants randomised to aspirin or placebo-aspirin as part of the factorial design.

Conclusions: Three months of w3FA intake was ineffective in reducing primary AVF failure at 12 months. Aspirin may be similarly ineffective. There was no increased risk of bleeding. Neither w3FA nor aspirin increased the proportion of useable de novo AVF.

SA-PO1091
The Remote Ischemic Preconditioning in Cardiac Surgery Trial (Remote IMPACT) Michael Walsh, 1,2 McMaster Univ; 3Population Health Research Instit.

Background: Cardiac surgery is frequently complicated by ischemia-reperfusion injury which can lead to kidney and myocardial injury. Preoperative Remote Ischemic Preconditioning (RIPC), cycles of brief ischemia to a limb alternating with reperfusion, may reduce the frequency or severity of organ injury after cardiac surgery.

Methods: We randomly allocated 258 patients at high risk for death after cardiac surgery to receive either RIPC or a sham procedure immediately after induction of anesthesia. RIPC consisted of 3 cycles of thigh tourniquet inflation to 300 mmHg for 5 minutes followed by 5 minutes reperfusion. The sham group tourniquets were inflated to 15 mmHg. Patients and care providers were blinded. The main clinical outcomes were change in creatinine and estimated glomerular filtration rate ≥60 mL/min/1.73 m².

Results: We randomized 128 patients to RIPC and 130 to sham. No patients were lost to follow-up. There was no significant between group differences in postoperative change in creatinine (p=0.79) or peak CK-MB (p=0.18) (Figure 1). We found no significant differences in the frequency of acute kidney injury (34% vs 31%), myocardial injury (24% vs 19%), stroke (4% vs 3%) or mortality (6% vs 5%) at 30 days.

Figure 1. Mean and 95% confidence intervals of creatinine over time for the RIPC (green diamonds) and sham (blue circles) groups.

Conclusions: In this trial RIPC did not affect markers of kidney and myocardial injury. These results fail to provide proof-of-concept that RIPC may impact clinically important outcomes in the cardiac surgery setting.

SA-PO1092
Nephrotoxicity of Invasive and Noninvasive Coronary Angiography: Randomized Controlled Study of Intracoronary and Intravenous Contrast Agent Administration Eva Schönenberger, 1 Patricia D. Bady, 2 Peter Martus, 1 Elke Zimmermann, 2 Michael Laule, 1 Marc Dewey, 1 Anesthesiology, Charité, Berlin, Germany; 1Radiology, Charité, Berlin, Germany; 1Inst for Clinical Epidemiology and Applied Biostatistics, Eberhard Karls Univ, Tübingen, Germany; 1Cardiology, Charité, Berlin, Germany.

Background: Ionised contrast agents can have nephrotoxic effects. It is unknown whether nephrotoxicity is more likely following intracoronary or intravenous contrast agent administration.

Methods: We randomly assigned patients with suspected coronary disease to either intracoronary contrast agent for invasive coronary angiography (ICA) or intravenous administration for coronary computed tomography angiography (CTA). The same low-osmolal nonionic contrast agent with a concentration of 350 mg iodine per milliliter was used for ICA and CTA. Blood samples were taken before and at two time points after ICA and CTA (18 to 24 hours and 46 to 50 hours) to identify contrast-induced acute kidney injury (AKI) defined according to the most commonly used definition as an increase in creatinine of at least 0.5 mg per deciliter or 25%.

Results: We enrolled 340 patients of whom 10 and 4 dropped out from the ICA and CTA group, respectively, leaving 161 and 165 patients who underwent ICA and CTA until September 8, 2015. Baseline creatinine levels in the ICA (0.85±0.19) and the CTA group (0.87±0.21 mg per deciliter) were similar (P=0.34). Follow-up creatinine was not available in 3 and 5 patients in the ICA and CTA group, respectively. Twenty-one of the 158 patients in the ICA group (13%) had an increase in creatinine of at least 0.5 mg per deciliter or 25%, as compared with 9 of the 160 patients in the CTA group (6%; P=0.05). 3 patients without coronary disease on ICA or CTA, such a creatine increase was found in 17 of the 134 patients in the ICA group (13%) and 6 of the 139 patients in the CTA group (4%; P=0.05). No patient without coronary disease in the CTA group had an increase in creatinine according to the KDIGO definition of at least 0.5 mg per deciliter or 25%, but 6 of the 134 patients in the ICA group (4%; P=0.05).

Conclusions: Nephrotoxicity may be more likely after intracoronary than after intravenous contrast agent administration.

SA-PO1093
Efficacy and Safety of Bosutinib in Autosomal Dominant Polycystic Kidney Disease: A Phase 2, Randomized, Double-Blind, Placebo-Controlled Study Eva E. Kucharzewska, 1,2,3 Jovan Godovic, 4,1,2,3 Vladimir Tesar, 1,2,3 York P. Pei, 1,2,3 Megan Shannon, 1,2 Rui Feng Li, 1,2 Jason Williams, 1,2 Matteo Levitski, 1,2 Steven Arkin, 1,2 Andreas L. Serra, 1,2 Pomeranian Medical Univ, Szczecin, Poland; 1Charles Univ, Prague, Czech Republic; 1Univ Health Network, Toronto, Ontario, Canada; 1Icahn School of Medicine at Mount Sinai, New York, NY; 1Pfizer Inc, San Diego, CA; 1Pfizer Inc, Cambridge, MA; 3Sanofi US, Bridgewater, NJ; 2Roche Pharma Research and Development, Basel, Switzerland; 1Inst for Allgemeine Innere Medizin und Nephrologie, Swiss ADPKD Hirslanden, Zurich, Switzerland.

Background: Src overactivation has been linked to the pathogenesis of autosomal dominant polycystic kidney disease (ADPKD). We assessed efficacy and safety of bosutinib (BOS), an oral dual Src/Abl tyrosine kinase inhibitor, in ADPKD patients (pts).

Methods: In this phase 2, multicenter study (NCT01233869), ADPKD pts with estimated glomerular filtration rate ≥60 mL/min/1.73 m² and magnetic resonance image confirmed total kidney volume (TKV) ≥750 cc were randomized 1:1:1 to placebo or 50, 100, or 200 mg/d oral BOS for 24 weeks. The primary endpoint was unannounced TKV % change. Pts treated for ≥2 wk who had an MRI after a 30-d washout period were in the modified intent-to-treat (mITT) analysis.

Results: 169 of 172 enrolled pts received ≥1 dose of treatment. 24 pts who initially received 400 mg/d BOS were later reduced to 200 mg/d BOS per protocol. 88 pts (52%) were in the mITT population (200 mg/d, n=27; 400 mg/d, n=7; 400 to 200 mg/d, n=21; PBO, n=33) after discontinuations (unrelated to study drug, 27%; study drug-related adverse events, 17%, consent withdrawal, 14%). Annual rate of kidney enlargement was significantly reduced for pooled BOS vs PBO (0.84% vs 4.74%, respectively, 95% CI for difference in annualized rates [2.02-5.74; p<0.0001) and was 65.2% lower for BOS 200 mg/d vs PBO (1.63% vs 4.74%, respectively, 95% CI [0.93 to 5.23]; p=0.005). Total gastrointestinal (GI) effects were dose-dependent for BOS, the overall safety profile, including GI toxicities, was consistent with the known profile of BOS.

Conclusions: BOS reduced the annual rate of kidney enlargement vs PBO in ADPKD pts, and the safety profile was consistent with the BOS label.

Low Osmolar Diet and Adjusted Water Intake for Vasopressin Suppression in ADPKD: A Randomized Controlled Trial Osama W. Amro, 1,2 Jessica K. Paulus, 1 Farzad Noirbary, 1 Ronald D. Perrone. 1,2 Nephrology, Tufts Medical Center, Boston, MA; 1Tufts Univ School of Medicine.

Background: Autosomal dominant polycystic kidney disease (ADPKD) affects 12.5 million people worldwide. Vasopressin promotes disease progression.

Methods: This randomized trial examined the effect of combining a low osmolar diet and adjusted water intake on vasopressin as measured by change in plasma copeptin, and

Underline represents presenting author/disclosure.
urinary osmolality in 34 ADPKD patients. Participants were randomized to receive a low osmolar diet (low sodium (1500 mg/day), low protein (0.8 gram/kg body weight) diet) followed by adjusted water intake to achieve a urine osmolality of 820 mOsm/L versus no intervention for two weeks.

Results: Change from baseline to two weeks between intervention and control groups was statistically significant for the primary outcome of copeptin and urine osmolality (-0.36 ±1.3 pmole/L versus +0.39 ±1.2 pmole/L (p=0.009) and -167±264 mOsm/L versus +20.80 mOsm/L (0.007) respectively). Mean plasma copeptin and urine osmolality declined from 6.2 ±3.05 to 5.3 ±2.5 pmole/L (p=0.3) and from 426 ±193 to 258 ±117 mOsm/L (p=0.003) respectively in the intervention group compared to a non-significant increase from 4.7 ±3.6 to 5.07 ±5.4 pmole/L (p=0.7) and from 329 ±159 to 349 ±139 mOsm/L (p=0.6) in the control group.

Total urinary solute decreased only in the intervention group and significantly differed between groups at week one (p=0.03) reducing mean water prescription from 3.2 to 2.6 liter/day.

Conclusions: we developed a step wise dietary intervention that led to significant reduction in vasopressin in ADPKD patients. Furthermore, this intervention led to reduction in water required for vasopressin suppression. Long-term studies are needed to determine if vasopressin suppression slows ADPKD progression.

Funding: Other NIH Support - Dr. Amro is supported by NIH 5T32DK007777 institutional training grant. This project was performed and Dr. Perrone were supported in part by the National Center for Advancing Translational Sciences (NCATS), National Institutes of Health (NIH), Grant Number UL1 TR001064.

SA-PO1095

A Phase 2, Double-Blind, Randomized Study of Fresolimumab or Placebo in Patients with Steroid-Resistant Primary Focal Segmental Glomerulosclerosis James A. Tumlin,1 Flavio Vincenti,2 Fernando C. Fervenza,3 Kirk N. Campbell,4 Montserrat M. Diaz Encarnacion,1 Manuel Praga,5 Denyse Théobald-Brown,6 Francisco Verissimo Veronez,7 Beverly Accamando,8 Sara Enstrup,9 Steven R. Ledbetter,10 Julie Lin,11 John F. Neylan.12 1 UT Coll. of Med., Chattanooga, TN; 2 UCSF, San Francisco, CA; 3 Mayo Clinic, Rochester, MN; 4 Icahn Sch. of Med. at Mt. Sinai, New York, NY; 5 Fundación Puigvert, Barcelona, Spain; 6 Hosp. Univ 12 de Oct., Madrid, Spain; 7 Univ of Alabama at Birmingham, AL; 8 Hosp. de Clinicas de Porto Alegre, Brazil; 9 Sanofi, Cambridge, MA; 10 Formerly Genzyme, Sanofi.

Background: Steroid-resistant primary FSGS confers substantial risk of morbidity & progressive kidney failure. Fresolimumab (freso), a neutralizing mAb to all 3 isoforms of TGF-β, is a potential new treatment.

Methods: 36 pts with biopsy-proven nephrotic-range FSGS randomized to freso 1mg/kg (n=14) v 4 mg/kg (n=12) v placebo (PL) (n=10) for D112, allowed immunosuppressives after D112 & followed up double-blind for D252. 1st outcome: proteinuria remission; 2nd outcomes included changes in Up/c & eGFR.

Results: Pts: 53% male; median age 41 y; 17% Black, 31% Hisp. Baseline (BL) median Up/c: 6.19 mg/kg; eGFR, 63 ml/min/1.73 m². 72% pts received prior CNL. Durable partial remission (-50% Up/c decline from BL to <3 mg/kg); 3 pts, 1 mg/kg; 2 pts, 4 mg/kg; 1 pt, PL; 1 additional pt on 1 mg/kg had steep & consistent Up/c decline from 17–4 mg/kg. All 7 freso responders were Black/Hispanic. Mean Up/c changes at D112: -18.5% (1mg/kg,P<0.008), +10.5% (4mg/kg,P=0.52), +9.0% (PL,P=0.91). eGFR showed nonsignificant trend for stability in freso v decline in PL. Freso was generally well tolerated with no significant difference in AEs in low v high doses.

Conclusions: In steroid-resistant FSGS, freso may be associated with proteinuria remission. Black & Hisp pts may have higher response rates. Freso merits continued evaluation in FSGS.

SA-PO1096

Effects of Sustained-Release Beraprost Sodium in Patients with Primary Glomerular Disease or Nephrosclerosis: The CASSIOPEIR Study Toshiro Fujita,1 Xueqing Yu,2 Suhyungwon Kim,3 Hideki Origasa,4 Hajimu Kurumatani,4 Takashi Kiriyama.5 1 The Univ of Tokyo, Tokyo, Japan; 2 The First Affiliated Hospital, Sun Yat-sen Univ, Guangzhou, Guangdong, China; 3 Seoul National Univ Hospital, Seoul, Korea; 4 Saitama Medical Univ, Saitama, Japan; 5 The Univ of Toyama, Toyama, Japan; 6 Toray Industries, Inc., Tokyo, Japan; 7 Astellas Pharma Inc., Tokyo, Japan.

Background: No single treatment, except RAS inhibitors, can delay progression of CKD. TRK-100STP, a sustained-release tablet of an orally-active prostacyclin analogue, beraprost sodium, is suggested to suppress worsening of renal filtration function. We aimed to demonstrate superiority of TRK-100STP over placebo in patients with CKD, either as primary glomerular disease or nephrosclerosis; determine the recommended dose of TRK-100STP; and evaluate its safety profile.

Methods: We performed a randomized, double-blind, placebo-controlled, parallel-group comparative study at 160 sites in seven Asian-Pacific countries and regions (CASSIOPEIR: CRF Asian Study with Oral PGI; Derivative for Evaluating Improvement of Renal Function). Patients entered a run-in period with oral administration of placebo twice daily for two to eight weeks. Patients meeting the inclusion/exclusion criteria at the end of the run-in period (n=892) were randomized to TRK-100STP 120 mg, TRK-100STP 240 mg, or placebo for a treatment period of two to four years. The primary efficacy endpoint was the time to first occurrence of a renal composite endpoint: doubling of SCr or occurrence of end-stage renal disease. ClinicalTrials.gov identifier : NCT01090037.

Results: No significant differences were evident observed in renal composite endpoints between TRK-100STP and placebo (±2-sided 5% significance level, P=0.5674). The overall incidence of adverse events and adverse drug reactions was comparable between the treatment arms.

Conclusions: TRK-100STP did not demonstrate superiority over placebo, and the recommended therapeutic dose for patients with CKD either primary glomerular disease or nephrosclerosis was not determined. However, no findings raised safety concerns in the comparison between TRK-100STP and placebo.

SA-PO1097

Corticosteroid Monotherapy versus Combined Immunosuppression in IgA Nephropathy: Insights from the STOP-IgAN Trial Jürgen Floege,1 Thomas Rauen,1 Frank Eitner,2 Christina Fitzner,2 Ralf-Dieter Hilgers.2 1 Nephrology, RWTH Aachen Univ, Aachen, Germany; 2 Biostatistics, RWTH Aachen Univ, Aachen, Germany; 3 Bayer AG, Wuppertal, Germany; 4 For the STOP-IgAN Investigators.

Background: In high-risk IgA nephropathy (IgAN) the value of immunosuppression in IgA nephropathy (IgAN) the value of immunosuppression is controversial.

Methods: We recently reported a randomized, controlled trial in IgAN patients (STOP-IgAN trial). Following 6 months of optimized supportive treatment 162 trial participants, who still displayed a proteinuria >0.75 g/d, entered a 3 year study phase and were randomized to continue on supportive therapy (SUP) or to receive additional immunosuppression (IMM). IMM-patients with an eGFR <60 ml/min/1.73 m² received a 6-month corticosteroid monotherapy (“Pozzi-protocol”). Patients with an eGFR of 30 to

Underline represents presenting author/disclosure.

B4
59 ml/min/1.73m² received cyclophosphamide for 3 months, followed by azathioprine, plus oral prednisolone (“Ballardie protocol”). Primary endpoints were (i) full clinical remission (proteinuria < 0.2 g/g and eGFR loss of < 5 ml/min) and (ii) eGFR loss >15 ml/min from baseline to trial end.

Results: Here we report a secondary analysis of the two IMM subgroups versus corresponding SUP patients matched for eGFR. The intention-to-treat (ITT) analysis assuming a worst-case scenario at 3 years is shown in the table.

<table>
<thead>
<tr>
<th>Endpoint</th>
<th>GFR &gt;60 ml/min/1.73m²</th>
<th>GFR 30-59 ml/min/1.73m²</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMM vs. SUP (n = 55 vs. 54)</td>
<td>OR 5.23 (95%-CI 1.29-21.15), p=0.020</td>
<td>OR 2.77 (95%-CI 0.38-22.29), p=0.319</td>
</tr>
<tr>
<td>IMM vs. SUP (n = 27 vs. 26)</td>
<td>OR 0.65 (95%-CI 0.27-1.56), p=0.333</td>
<td>OR 1.62 (95%-CI 0.49-5.61), p=0.428</td>
</tr>
</tbody>
</table>

eGFR loss >15 ml/min

Patients treated with the Pozzi protocol had a transient decrease in proteinuria after 12 months and significantly less microhematuria at trial end compared to matched SUP patients. In the group with the low eGFR range, there were no significant differences between both arms. Compared to supportive care, more patients receiving immunosuppression developed severe infections, impaired glucose tolerance and weight gain in year one.

Conclusions: Our secondary analyses provide little evidence for a stabilization of renal function with immunosuppression in the group with an eGFR >60 ml/min and no evidence for a benefit in patients with a lower eGFR.

Funding: Government Support - Non-U.S.

SA-PO1098

A Randomized Trial of Rituximab in Advanced IgA Nephropathy

Richard A. Lafayette,1 Pietro A. Canetta,2 Brad H. Rovin,3 Gerald B. Appel,4 Marie C. Hogan,5 Stephen B. Erickson,6 Fernando C. Fervenza,7 Stanford Univ, Stanford, CA;7 Columbia Univ, New York, NY;7 Ohio State Univ; Columbus, OH;7 Mayo Clinic, Rochester, NY.

Background: IgA nephropathy (IgAN) frequently leads to progressive renal dysfunction. Present immunosuppressive treatment remains uncertain in terms of benefit and risks side effects. B cells are an attractive target in IgAN so we performed a pilot trial of rituximab in subjects at high risk of progression.

Methods: Patients with biopsy proven IgAN, more than 1 g/d of proteinuria despite RAAS (or >0.5 g/d if on dual RAAS), well controlled blood pressure (BP) and eGFR <90ml/ min were randomized to 1 year of rituximab therapy (4g total) vs ongoing BP control, fish oil and use of RAAS. They were followed for B cell depletion, effects on proteinuria and changes in eGFR. Safety signals were also followed.

Results: 34 patients were randomized. Baseline serum creatinine was 1.5±0.5 mg/dl and proteinuria was 2.1, 0.6-5.5 g/d. There was no change in BP during the study. Treatment with rituximab resulted in significant B cell depletion and was generally well tolerated. There was no change in renal function during the study in either group. Rituximab treatment had no significant effect on proteinuria compared to baseline or control patients, and 3/17 patients in each group experienced a ≥ 50% reduction in proteinuria during the study.

Conclusions: In this small study, rituximab therapy had no influence on renal function or proteinuria in subjects with advanced disease due to IgA nephropathy. There were numerically greater reductions in proteinuria, but this did not reach significance. Few patients had substantial responses in either group. These results do not support the use of rituximab as treatment for patients with IgA nephropathy.

Establishing Endpoints for Lupus Nephritis Clinical Trials: Progress by the Kidney Health Initiative/Lupus Nephritis Trials Network Collaboration

Brad H. Rovin,1 Meggan Mackay,2 Joanna Stein,3 Maria Dall’Era,4 Kenneth Kalunian,5 Martin L. Lesser,6 Melissa West7 (Ohio State Univ; Feinstein Inst; Univ Calif San Diego; Univ Calif San Francisco; American Society of Nephrology).

Background: There are no universally accepted endpoints for lupus nephritis (LN) clinical drug trials. To obtain approval of new therapies a uniform endpoint that can be applied to future LN trials is needed. The optimal endpoint is a short-term measurement that accurately reflects long-term kidney survival. The present work was undertaken to define LN trial endpoints.

Methods: Clinical data at LN flare (baseline) and during serial follow-up (minimum 22 months) from 751 patients were analyzed. Clinical variables at baseline and after 6 and 12 months were tested as predictors of adverse long-term renal outcomes, in this case time to new chronic kidney disease (CKD), defined as a sustained increase in serum creatinine (SCr) ≥30%. Multivariable Cox regression analysis was used to model time to CKD.

Results: After accounting for missing data 507 patients were included in the final analysis. This cohort was 89% female, 56% White, 20% Asian and 14% Black. The average baseline eGFR was 61±17 ml/min, proteinuria was 4±1.8 g/d, and eGFR by CKD® was 81±35 ml/min. Median follow-up was 42 months (range: 22-147 months). By univariate analysis urine RBCs, race, complement C3, SCR, eGFR and proteinuria were potential significant predictors of time to CKD. By multivariate modeling the significant predictors were: SCR at 12 months (p=0.0005, Hazard Ratio (HR) 1.8 (95%-CI:1.3-2.5)); proteinuria at 12 months (p=0.0001; HR 1.6 (1.3-1.8-3.8)); and an increase in eGFR≥10% from baseline to 12 months compared to no change in eGFR (p=0.0001; HR 0.4 (0.3-0.6)).

Conclusions: We have identified 3 highly significant predictors of time to CKD in LN patients that can be measured during the first 12 months of treatment for LN. These can be developed into a composite endpoint for future LN therapeutic trials. Unexpectedly, small improvements in eGFR appear to predict renal survival. Also, because urine RBCs do not appear to predict time to CKD, it may be possible to exclude urinalysis as an endpoint component in future clinical trials.

Grazoprevir (GZR)/Elbasvir (EBR) Treatment of Hepatitis C Virus (HCV) Infection in Patients with Chronic Kidney Disease Stage 4/5: Final Results of the C-SURFER Phase 3 Study

David Roth,1 Annette Bruchfeld,2 Paul Martin,3 David R. Nelson,4 Marcelo Silva,5 Howard Monsour,1 Laurent Alric,7 Shuyan Wan,1 Beth Jackson,1 Bach-Yen Nguyen,1 Janice Wahl,1 Ellie Barr,2 Wayne L. Greaves,2 Univ of Miami, Miami, FL; Karolinska Inst, Stockholm, Sweden;1 Univ of Florida, Gainesville, FL; Hospital Univ Austral, Pilar, Buenos Aires, Argentina;2 Houston Methodist Hospital, Houston, TX;7 Hôpital de Purpan, Toulouse, France;1 Merck & Co, Inc., Kenilworth, NJ.

Background: Limited options are available for treating HCV infection in patients with advanced kidney disease. C-SURFER is the first randomized, placebo-controlled phase 3 study to evaluate an all-oral, ribavirin-free regimen in CKD 4/5 patients.

Methods: 224 patients with HCV genotype (G1) and CKD 4/5 ≥ hemodialysis (HD) were randomized to GZR/EBR 100/50mg (Immediate Treatment Group, ITG; n=113) or placebo for 12 weeks. Placebo subjects (deferred treatment group, DTG; n=113) were randomized to GZR/EBR 100/50mg (Immediate Treatment Group, ITG; n=111) or placebo for 12 weeks. Placebo subjects (deferred treatment group, DTG; n=113) were randomized to GZR/EBR after placebo therapy. 11 additional subjects received GZR/EBR with intensive pharmacokinetic (PK) sampling. The primary safety comparison was GZR/EBR vs. placebo. The primary efficacy endpoint, sustained virologic response (SVR) 12 weeks post-therapy in the ITG+PK group, was reported previously. Here we report the final results, including data from subjects who received GZR/EBR after placebo.

Results: In the placebo-controlled phase, serious adverse events (AEs) occurred in 16 (14%) GZR/EBR and 17 (15%) placebo subjects; discontinuation due to an AE in GZR/EBR and placebo subjects was 0% and 4% and SVR12 in all subjects who received GZR/EBR was 94.6% (ITG+PK; 94.3% [95%CI:91.5-96.2]). GZR/EBR after placebo. 11 additional subjects received GZR/EBR with intensive pharmacokinetic (PK) sampling. The primary safety comparison was GZR/EBR vs. placebo. The primary efficacy endpoint, sustained virologic response (SVR) 12 weeks post-therapy in the ITG+PK group, was reported previously. Here we report the final results, including data from subjects who received GZR/EBR after placebo.

Results: In the placebo-controlled phase, serious adverse events (AEs) occurred in 16 (14%) GZR/EBR and 17 (15%) placebo subjects; discontinuation due to an AE in GZR/EBR and placebo subjects was 0% and 4% and SVR12 in all subjects who received GZR/EBR was 94.6% (ITG+PK; 94.3% [95%CI:91.5-96.2]).

Conclusions: Once-daily GZR/EBR for 12 weeks was highly effective with a low rate of adverse events in patients with advanced kidney disease and HCV G1 infection.

Long-Term (52-Week) Efficacy and Safety of ZS-9 in the Treatment of Hyperkalemia: Interim Results From a Phase 3 Open-Label, Multi-Center, Multi-Dose Maintenance Study
James A. Tumlin,1 Mikhail Kosiborod,2 Pablo E. Pergola,3 Wajeeh Y. Qunibi,4 David K. Packham,5 Simon D. Roger,6 Edgar V. Lerman,7 Steven Fishbane,8 Henrik S. Rasmussen,9 Bruce S. Spinowitz.10 1U of Texas Health Science Center, TX; 2Mayo Clinic, Rochester, MN; 3American Heart Inst., MO; 4Renal Associates PA, TX; 5U of Texas Health Science Center, TX; 6Melbourne Renal Research Group, Australia; 7Renal Research, Gosford, Australia; 8U of Illinois, IL; 9North Shore U. Hospital, NY; 10ZS Pharma, Inc., TX; 11Well Medical College, NY.

Background: Hyperkalemia (HK) is a common and potentially lethal electrolyte disorder, often induced with the use of renin-angiotensin-aldosterone inhibitors (RAASi). Currently, the use of RAASi is prevented by HK and thus the potential for cardiac and renal protective effects of these agents is limited. In previous studies, ZS-9 (sodium zirconium cyclosilicate), a selective K+ ion trap, significantly lowered serum K+ and maintained normokalemia (NK) for up to 28 days. We present the results to date of the largest ever phase 3 trial examining the efficacy of ZS-9 in treating HK patients for up to 52wks.

Methods: ZS-005 (target N=750) is a multicenter, ongoing, open-label study evaluating ZS-9 treatment for 52wks in ambulatory pts with HK (K+ 5.1 mEq/L) with or without concurrent RAASi therapy. In the acute phase (AP), pts with HK received 10g ZS-9 TID over a 24-72hr period untilNK (K+ 5.5 mEq/L) was achieved. Pts achieving NK were enrolled in a 52wk maintenance phase (MP) starting with 5g ZS-9 QD. There were no restrictions on diet and ZS-9 could be titrated to maintain NK. Primary outcomes were proportion of pts with mean K+ ≤5.1 mEq/L during MP and safety of ZS-9.

Results: To date, 583 pts with a mean baseline K+ of 5.6 mEq/L (15% >6.0 mEq/L) entered the study. Overall, 575 (99%) normalized K+ in AP and transitioned to the MP. To date, K+ was maintained at ≤5.1 and <5.5 mEq/L in 87% and 99% of patients, respectively. The incidence and severity of adverse events were similar to that of previous studies.

Conclusions: ZS-9 acutely reduced K+ levels in pts with HK and maintained NK for up to 52wks irrespective of RAASi use. ZS-9 may control HK, both emergent and long-term, while allowing continued use of cardio- and renoprotective RAASi.

Interleukin-1 Inhibition and Vascular Function in Patients with Chronic Kidney Disease (CKD): A Randomized Controlled Trial
Kristen I. Nowak,1 Michel Chonchol,1 Talat Alp Ikizler,2 Heather Farmer,3 Natjalie Salas,2 Rafia I. Chaudhry,2 Wei Wang,1 Gerard John Smits,1 Adriana Hung,4.5 Univ of Colorado Denver; 2Vanderbilt Univ; 3VA Tennessee Valley Healthcare System.

Background: Vascular endothelial dysfunction and increased arterial stiffness contribute to increased cardiovascular risk in CKD patients who exhibit chronic systemic inflammation. As chronic inflammation is a key mechanism contributing to vascular dysfunction, blocking inflammation may reduce cardiovascular risk in CKD.

Methods: In a two-site, double-blind trial, n=42 patients with stage 3-4 CKD were randomized to receive either the interleukin-1 (IL-1) trap rilonacept (subcutaneous injection; loading dose of 320 mg followed by 160 mg/wk) or placebo for 12 weeks. All patients were receiving optimal treatment of hypertension, diabetes, and/or hypercholesterolemia, with 64% and 62% receiving a statin and an ACE inhibitor or ARB, respectively. The co-primary endpoints were change in brachial artery flow-mediated dilation (FMD(ba)) and aortic pulse-wave velocity (aPWV) after 4, 8 and 12 weeks using mixed effects models. Secondary endpoints were change in high-sensitivity C-reactive protein (hsCRP), ∆FMD, and vascular endothelial cell protein expression of NADPH oxidase (n=13).

Results: Participants were 63±12 (mean±s.d.) years of age, 24% female and 24% Black, with eGFR 38±13 ml/min/1.73m2. Rilonacept improved FMD(ba) (baseline: 3.8±3.1%, 12 wks: 4.9±3.2%) compared to placebo (baseline: 3.4±2.1%, 12 wks: 2.5±2.3%; p<0.01), without changing aPWV (p=0.92). Rilonacept also reduced hsCRP levels (baseline: 4.6 (1.9, 8.22) [median (interquartile range)]; 12 wks: 2.16 (0.96, 7.38) mg/L; p<0.01), and endothelial cell NADPH oxidase expression (p<0.05). Acute infusion of ascorbic acid tended to improve FMD(ba) in the placebo (p=0.07) but not the rilonacept group (p=0.56), indicating reduced vascular oxidative stress. Overall, rilonacept was well tolerated.

Conclusions: 12 weeks of treatment with an IL-1 trap improved FMD(ba) without changing aPWV in patients with stage 3-4 CKD. This was associated with a reduction in systemic inflammation and vascular oxidative stress.

Impact of Vitamin D Supplementation on Endothelial and Vascular Function in Patients with Chronic Kidney Disease: A Randomized, Double Blind, Placebo-Controlled Trial
Vivek Kumar,1 Ashok Kumar Yadav,2 Vinod Sharma,3 Manphool Singhal,4 Anupam Lal,5 Debasish Banerjee,6 Vivekanand Jha.7 Nephrology, Postgraduate Inst of Medical Education and Research, Chandigarh, Chandigarh, India; 2Radiodiagnosis, Postgraduate Inst of Medical Education and Research, Chandigarh, Chandigarh, India; 3Nephrology, St. George’s Univ Hospitals NHS Foundation Trust, London, London, United Kingdom.

Background: Vitamin D deficiency is associated with mortality and morbidity in CKD patients. We investigated the effect of Vitamin D supplementation on endothelial and vascular function in patients with non-diabetic CKD stage 3-4.

Methods: In a prospective, randomized, double blind, placebo-controlled trial, 120 patients with non-diabetic CKD stage 3-4 and vitamin D deficiency [serum 25(OH)D <20ng/ml] aged 18-70 years were randomized (1:1) to receive either two directly observed oral doses of 300 IU of cholecalciferol at 0 and 8 weeks or matching placebo. The pre-specified primary outcome was 40% change in endothelium dependent brachial artery flow mediated dilation (FMD) at 16 weeks. Secondary outcome measures included changes in pulse wave velocity (PWV), augmentation index (AI), and serum biomarkers.

Results: Baseline FMD was identical in both arms (7.6±2.24% vs 7.8±2.34%)

Conclusions: Twenty-four week therapy with cholecalciferol or calcitriol did not improve vascular endothelial function or reduce inflammation in patients with non-diabetic CKD stage 3-4.

Vitamin D Receptor Activation and Dietary Sodium Restriction to Reduce Residual Albuminuria in Chronic Kidney Disease

Martin H. De Borst,1 Charlotte A. Keyzer,1 Fenna van Breda,2 Marc G. Vervoet,2 Gozewijn Dirk Laverman,3 Marc H. Hemmelder,1 Wilbert M. Janssen,1 Hiddo Jan Lambers Heerink,3 Stephen J.L. Bakker,4 Gerjan Nasis,1 1UMC Groningen; 2VUMc Amsterdam; 3ZGT Almelo; 4MC Leeuwarden; 5Martini Hospital Groningen; Netherlands.

Background: Reduction of residual albuminuria during single-agent RAAS-blockade is associated with improved cardiovascular outcomes in CKD. Both vitamin D receptor activators (VDRA) and dietary sodium restriction reduce residual albuminuria. Previous data suggested that sodium restriction is not required for optimal albuminuria reduction by VDRA. We studied the individual and combined effects of paricalcitol and sodium restriction on residual albuminuria during optimally dosed ACEi in CKD.

Methods: In a multi-center, randomized, placebo-controlled cross-over trial, 10 patients with non-diabetic CKD stage 1-3 and residual albuminuria ≥300 mg/24h despite ramipril 10 mg/d and BP <140/90 mmHg were treated during four 8-week periods with paricalcitol (PARI, 2 µg/day) or placebo (PLAC), each combined with a low (LS, 2.5 gr Na+/d) or regular sodium (RS, 4 gr Na+/d) diet, in random order. Linear mixed-effect models for repeated measurements were used to determine treatment effect.

Results: In the intention-to-treat analysis, albuminuria was 1,060 [778 to 1,443] (geometric mean [95% CI]) mg/24h during RS+PLAC. During RS+PARI, albuminuria was 990 [755 to 1,299] mg/24h (-12.5% [-26.0% to 26.3%] vs. RS+PLAC, P=0.2). LS+PLAC reduced albuminuria to 717 [512 to 1,005] mg/24h (-25.4% [-52.6% to -2.3%] vs. RS+PLAC, P=0.001). LS+PARI provided the strongest reduction of albuminuria to 683 [502 to 929] mg/24h (-31.7% [-55.0% to -0.9%], P<0.001 vs. RS+PARI), although the additional reduction by PARI beyond the effect of LS was non-significant (P=0.6). However, in a per protocol analysis (<95% compliance, N=34) PARI did reduce residual albuminuria beyond the effect of LS (P=0.04).

Conclusions: The combination of paricalcitol and moderate dietary sodium restriction provided the strongest reduction of residual albuminuria during optimal ACEi; the effect was mainly driven by sodium restriction. Our findings underline the relevance of sodium restriction, possibly combined with paricalcitol, to optimise albuminuria reduction.

SA-PO1107

Vascular Function and Uric Acid Lowering via Allopurinol in Stage III CKD: Results of a Double-Blinded Randomized Placebo-Controlled Study

Diana I. Jalal,1 Emily Decker,1 Loni J. Perrenoud,1 Nina Bispham,2 Tapan Mehta,3 Gerard John Smits,1 Richard J. Johnson,1 1Medicine/Renal Div, UC AMC, Aurora, CO; 2Integrative Physiology, UC Boulder, Boulder, CO.

Background: Observational studies suggest that asymptomatic hyperuricemia associates with vascular disease in chronic kidney disease (CKD). A recent study suggested that lowering serum urate with allopurinol improves endothelial function in elderly adults with stage III CKD. It remains unknown if lowering serum urate with allopurinol improves endothelial function in elderly adults with stage III CKD. It remains unknown if lowering serum urate improves endothelial function in adult subjects with stage III CKD.

Methods: 80 adult subjects (18-70) years of age with stage III CKD and asymptomatic hyperuricemia (>7 mg/dL in men and >6 mg/dL in women) were randomized to receive placebo or allopurinol (100 mg) tablets for 12 weeks. The study was double-blinded and subjects were instructed to take 1 tablet for 1 week, 2 tablets for another week, and 3 tablets thereafter. Changes (from baseline) between both groups were compared by Wilcoxon rank-sum test.

Results: No significant differences existed between both groups at baseline. After 12 weeks, allopurinol lowered serum urate significantly. FMD increased in the allopurinol group compared to placebo; but this was not statistically significant. NMD increased with allopurinol but decreased with placebo; p value = 0.14. These data are shown in Table 1. There were no significant differences between allopurinol and placebo for systolic or diastolic blood pressure, markers of inflammation, or markers of oxidative stress. 10 subjects withdrew from the study. A few adverse events were noted in both groups including 1 gout attack in each group. 1 subject died during the study due to cardiac event.

Conclusions: Allopurinol effectively and safely lowered serum urate in adults with stage III CKD and asymptomatic hyperuricemia but this did not improve endothelial function significantly. There was tendency towards improved NMD suggesting that hyperuricemia may negatively impact vascular smooth muscle function in stage III CKD.

Podocyteuria Is an Earlier and Superior Predictor of Cardiovascular Outcomes Than Is Albuminuria

Assaad Antoine Eid,1 Robert Habib,1 Kamal F Badr.1 1Anatomy, Cell Biology and Physiological Sciences, American Univ of Beirut - Faculty of Medicine, Beirut, Beirut, Lebanon; Internal Medicine, American Univ of Beirut - Faculty of Medicine, Beirut, Beirut, Lebanon.

Background: Increased urinary albumin excretion rate (AER), a predictor of cardiovascular events, results from abnormally increased albumin filtration accompanying injury to glomerular endothelial and epithelial cells (“podocytes”). Since AER is modified by renal proximal tubule albumin retrieval, we hypothesized that urinary podocyte shedding, podocyteuria, would be a more relevant and earlier biomarker of endothelial injury (and CVD) than moderate albuminuria.

Methods: 106 Type II diabetic subjects (mean age: 46/60 men/women) with normal AER [<2.26 mg/mmol [20 mg/g creatinine]] and free of overt cardiovascular disease (CVD) were enrolled. AER and podocyte-specific proteins (podocin and nephrin) mRNA were measured at baseline (visit 1), 3-4 years later (visit 2) and at 7 years (visit 3). Development of cardiovascular diseases VD - defined as coronary disease, cerebrovascular disease and/or peripheral vascular disease (can be removed to fit words counting) - was collected as outcome. 7-year Kaplan-Meier time-to-event (log rank) data were compared in baseline biomarker tercile groups (low, intermediate, high).

Results: Allopurinol reduced microalbuminuria significantly between visits (P<0.001). AER/excreta exhibited similar time to CVD (p<0.127), which was in contrast with the step-wise and substantial increase in CVD events with increasing podocin and nephrin levels (P<0.001).

Conclusions: Compared to traditional AER/podocyturia prediction models, more accurately and earlier predicted the presence of silent systemic vascular injury, that manifests as overt cardiovascular events.

Empagliflozin Reduces Microalbuminuria and Macroalbuminuria in Patients with Type 2 Diabetes

David Cherney,1 Soren Sogaard Lund,1 Bruce A. Perkins,1 Per-Henrik Groop,2,6 Mark E. Cooper,3 Stefan Kaspers,3 Susanne Crowe,4 Hans-Juergen Woerle,5 Maximilian von Eynatten,1 1Toronto General Hospital, Univ of Toronto, Canada; 2Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; 3Mount Sinai Hospital, Univ of Toronto, Canada; 4Univ of Helsinki and Helsinki Univ Hospital, Folkhalsan Research Center, Helsinki, Finland; 5Baker IDI Heart and Diabetes Inst, Melbourne, Australia.

Background: Reductions in HbA1c, systolic blood pressure (SBP), and weight with the highly selective SGLT2 inhibitor empagliflozin in patients with type 2 diabetes (T2D) may favorably impact albuminuria.

Methods: Using data pooled from 5 Phase III, randomized clinical trials, we assessed the effect of empagliflozin 10 or 25 mg for 24 weeks on urine albumin to creatinine ratio (UACR) in patients with T2D and prevalent microalbuminuria (UACR 30–300 mg/g; n=636) or macroalbuminuria (UACR >300 mg/g; n=215) at baseline.

Results: Empagliflozin reduced UACR vs placebo in patients with T2D and microalbuminuria (-32%; p<0.001) or macroalbuminuria (-41%; p<0.001) after controlling for baseline log (UACR), HbA1c, SBP, estimated glomerular filtration rate (MDRD), region, study and treatment (Figure). Adjusted mean (SE) changes in HbA1c, weight, SBP and diastolic BP with empagliflozin vs placebo were -0.50 (0.07) %, -1.6 (0.2) kg, -4.4 (1.1) mmHg and -2.3 (0.6) mmHg, respectively, in patients with microalbuminuria (all p<0.001), and -0.53 (0.13) %, -1.8 (0.4) kg, -6.3 (2.0) mmHg and -2.2 (1.1) mmHg, respectively, in patients with macroalbuminuria (all p<0.05). Linear regression analyses showed that changes in HbA1c, weight and SBP accounted for a maximum of half the UACR-lowering effect.

Variable | Placebo | Allopurinol | P value
--- | --- | --- | ---
Serum Urate (mg/dL) | 0.65 (1.54) | -3.24 (1.35) | <0.0001
FMD (% change) | 0.16 (4.05) | 0.93 (6.05) | 0.47
NMD (% change) | -1.29 (5.33) | 0.93 (6.05) | 0.14

Conclusions: Allopurinol effectively and safely lowered serum urate in adults with stage III CKD and asymptomatic hyperuricemia but this did not improve endothelial function significantly. There was tendency towards improved NMD suggesting that hyperuricemia may negatively impact vascular smooth muscle function in stage III CKD.

Vadadustat, a Novel Oral Treatment for Anemia of Chronic Kidney Disease, Maintains Stable Hemoglobin Levels in Dialysis Patients Converting from Erythropoiesis-Stimulating Agents

**Background:** Vadadustat is a novel, oral agent that stimulates erythropoiesis by stabilizing hypoxia-inducible factor (HIF). Prior studies in patients with Non-Dialysis Dependent Chronic Kidney Disease (NDD-CKD) have shown that vadadustat results in controlled, dose-dependent increases in hemoglobin (Hb) and enhances iron mobilization and utilization. Here we present data from a Phase 2 trial of vadadustat in hemodialysis patients.

**Methods:** A multi-center, open-label, 16-week trial was designed to assess Hb response, safety, and tolerability of vadadustat. The trial enrolled 94 hemodialysis patients (Hb 9 - 12 g/dL), who were maintained on erythropoiesis-stimulating agents (ESAs) prior to study entry. Patients were converted from ESA to vadadustat, and assigned to 1 of 3 dose cohorts: 300 mg once daily (QD); 450 mg QD; or 450 mg three times weekly (TIW). The primary endpoint was to evaluate mean Hb changes from baseline at weeks 7/8, and weeks 15/16.

**Results:** Vadadustat maintained stable Hb levels in all 3 dose cohorts during the 16 week treatment period following conversion from ESA.

SA-PO1111
Autologous Erythropoietin Production by the TARGT Gene Therapy Platform Maintains Stable Hb for 6-12 Month in ESRD Patients without the Need for ESA Administration

**Background:** Recombinant human erythropoietin (rHuEPO) administration to iron replete patients corrects anemia in most patients with ESRD, but doses result in supra-physiological peak serum concentration (C_{max}) of EPO that may cause thromboembolic complications. The Transduced Autologous Restorative Gene Therapy system (TARGT™) is an ex-ovo gene therapy, providing autologous, continuous protein therapies at physiological ranges that was used encoding for the human erythropoietin gene (TARGT_{EPO}) for these studies. Patient dermal tissue biopsies (MOS) are transduced with a Helper-Dependent Adenoviral Vector containing the EPO gene and then re-implemented subcutaneously to deliver the required EPO dose.

**Methods:** We present initial data from 3 opening open label ascending dose studies of TARGT_{EPO} in patients with anemia due to CKD undergoing either Hemo or Peritoneal Dialysis.

**Results:** Thus far 14 patients were enrolled in all protocols. Follow up is ongoing with the first implanted patient being followed with stable EPO secretion and stable Hb for over 14 months from a single implantation without the need for rHuEPO or blood transfusion. Results obtained suggest that treatment with TARGT_{EPO} stabilize serum EPO levels at the physiological range of 20 mU/ml resulting in Hb levels between 9-12 g/dL. Comparative analysis of serum EPO levels revealed significantly lower C_{max} with TARGT_{EPO} compared to rHuEPO and an order of magnitude less overall EPO exposure as calculated by Area Under the Curve which may confer significant clinical benefit. No treatment related serious adverse events have been reported.

**Conclusions:** TARGT_{EPO} is a promising novel therapy for the treatment of anemia of CKD and potentially for other protein deficient diseases.

Monitoring in Dialysis (Mid) Study: Exploring the Timeline and Etiology of Increased Arrhythmias in Hemodialysis (HD) Patients

**Background:** Sudden cardiac death (SCD), likely due to cardiac arrhythmias (CA) is the most important cause of mortality in the HD population. We herein present data on the timeline and potential etiology of CA in HD patients (pts).

**Methods:** The MID study (n=66) characterized the type and frequency of CA in 36 wk HD pts over 6 mths, using an implanted loop recorder (Medtronic Reveal). Reviewer confirmed arrhythmias (RCA;all documented CA) and clinically significant arrhythmias (CSA;brady,asytole,YT / symtomatic), were linked to the dialysis cycle, pt wt and pre- post-session electrolytes, using negative binomial mixed effects regression analyses.

**Conclusions:** Mean age 56.3±12.2; 64% diabetic; 70% male; HD vintage 4.3±5.1 yrs. 97% and 67% of pts had a RCA/CSA. Most CA occurred during the intradialytic period of the first weekly HD and then decreased in subsequent sessions. Univariate analyses identified increased pre and post wt, high pre HD potassium (K) and drop in K as risk factors for RCA. Multivariate analyses (adjusted for DM, yrs on HD, pre-wt), identified higher pre HD K levels as a predictor for increased RCA. The highest risk of arrhythmia occurred in pts with high K drops AND substantial volume removal (p=0.03).
Conclusions: These data establish linkages between intra-dialytic CSA and the long interdialytic period, and also identify a unique interaction between fluid removal and $K^+$ in the generation of RCA. This suggests for the first time, that fluid data driving target of these parameters might reduce $K^+$ and possibly SCD in HD pts. **Funding:** Pharmaceutical Company Support - Medtronic

SA-PO1113

The Occurrence of Cardiac Arrhythmias in Hemodialysis Patients is Linked to the Hemodialysis Procedure and to Electrolyte Abnormalities as Recorded by Implantable Loop Recorders **Christian Combe,**1,2 Antoine Benard,3,4 Hélène Savel,5,6 F. Sacher,3,4 **CHU & Univ. Bordeaux, Bordeaux, France; **Rythmodial Study Group.

Background: Sudden cardiac death (SCD) is the most common mode of death among hemodialysis (HD) patients (pts). Little is known about the terminal arrhythmic events in these pts. Our objective was to identify the mechanisms which may lead to SCD in HD pts using an implantable loop recorder (ILR, Reveal XT®, Medtronic).

Methods: Pts from 9 HD centers have been included in the study. Continuous monitoring of the cardiac rhythm has been performed using the remote monitoring capability of the ILR device (Carelink®). Clinical, biological, and technical HD parameters and medications have been recorded for at least 1 year. General joint frailty model for recurrent event data were used to analyze associations between these parameters and the occurrence of cardiac rhythm events.

Results: 72 pts (65±1.8 yr, 52M) have been included. Causes of ESRD were diabetes (n=32) and hypertension (n=19). 22 pts had an ischemic cardiomyopathy. In M. Spiegel,1,2 Benard,3,4 Louis, MO; 

SA-PO1116

Background: Current stationary dialysis machines hinder mobility and limit activities of daily life during dialysis treatments. There is a critical need for new technologies to increase patient autonomy, enhance quality of life, and allow for increased patient rehabilitation.

Methods: This is the first FDA-approved human trial of the WAK, a miniaturized, wearable hemodialysis machine based on dialysate-regenerating sorbent technology (NCT02280005). We aimed to determine the safety and efficacy of the WAK in maintaining euolemia and achieving solute clearance and electrolyte homeostasis over 24 hours.

Results: All patients remained hemodynamically stable, and there were no serious adverse events. Serum electrolytes and hemoglobin remained stable over the treatment period for all subjects. Six out of seven patients ambulated while receiving WAK treatment. Fluid removal was consistent with prescribed ultrafiltration rates. Mean blood flow was 42±24 and dialysate flow was 43±20 ml/min with no laboratory evidence of hemolysis. Mean BUN, creatinine, and phosphorus clearances were 21±13, 20±11, and 22±12 ml/min respectively during the first hour of treatment. In one subject, treatment was discontinued due to clotting after 4 hours. In a second subject, treatment was discontinued due to discoloration of dialysate observed after 10 hours. The trial was stopped after the 7th subject due to device-related malfunctions. These included excessive CO2 bubbles in the dialysate, variable blood and dialysate flows, and tubing leaks during the priming phase. Redesign and re-manufacturing of the WAK prototype will be required prior to additional human studies.

Conclusions: Treatment with the WAK was well tolerated, resulted in effective uremic solute clearance and maintenance of electrolyte and fluid homeostasis. These results serve as proof-of-concept of the WAK as a viable novel dialysis technology. **Funding:** Private Foundation Support

SA-PO1117

CR845, a Novel Kappa Opioid Receptor Agonist Reduces Moderate-to-Severe Pruritus and Improves Quality of Life in Chronic Kidney Disease Patients Undergoing Hemodialysis **Robert Spencer,**1 Vandana S. Mathur,2 James A. Tumlin,3 Joseph W. Staufler,4 Frederique Menzaghi,5 **Cara Therapeutics, Inc., Shelton, CT; Mathur Consulting, San Francisco, CA; **Univ of Tennessee, Chattanooga, TN.

Background: Approximately 40% of US hemodialysis (HD) patients experience moderate-to-severe pruritus, which negatively affect their mental and physical health (e.g., sleep loss, depression, higher antibiotic and erythropoietin use and increased mortality). The etiology of this condition is likely multi-factorial, including immune system dysfunction and imbalance of mu/kappa endogenous opioids. CR845 is a novel and well-tolerated kappa opioid receptor (KOR) agonist with limited central nervous system entry, thereby preferentially activating KOR on peripheral neurons and immune cells.

Methods: In this Phase 2 double-blind, randomized (1:1), placebo-controlled clinical study, 65 prevalent US HD patients with persistent (~5 years) moderate-to-severe pruritus (baseline VAS ~68 mm, 0=no itch; 100 mm =worst itch) were treated with 1 mcg/kg intravenous CR845 or placebo following each HD session for 2 weeks. Antihistamines (baseline VAS ~68 mm, 0=no itch; 100 mm =worst itch) were treated with 1 mcg/kg intravenous CR845 or placebo following each HD session for 2 weeks. Antihistamines were discontinued 1 week prior to the study.

Results: The primary endpoint was met (VAS change in worst itch intensity from Baseline to Day 12-15), with a significant difference in itch intensity between placebo and CR845-treated patients (p<0.006). CR845-treated patients had a 50% mean reduction in itch intensity from baseline. The 1st secondary endpoint was also met with a significant improvement in Skinindex-10, a validated patient-reported outcome measure of pruritus-related quality of life (p =<0.003). Furthermore, a trend for a sleep improvement was observed (SLEP).

Conclusions: Short-term treatment with CR845 significantly reduced itch intensity and improved quality of life in HD patients with moderate-to-severe pruritus. Thus, CR845 appears to have substantial potential to alleviate the symptoms and consequences of this frequently incapacitating condition for which existing treatments have often provided little or no relief. These data also support the opioid/immune etiology of this condition. **Funding:** Pharmaceutical Company Support - Cara Therapeutics, Inc.

The ASsERTed Study: Feasibility Randomised Controlled Trial of Drug Treatment for Depression in Patients on Haemodialysis

Aymun Guirgis,1,2,3 Michael K. Almond,4 Joseph Chilcott,4 Andrew Davenport,5 Clara Day,8 Naomi Fineberg,2,3 Karin Friedli,6 Benjamin Spencer,7 David Wellsted,7 Ken Farrington,1,2 1East & North Hertfordshire NHS Trust, United Kingdom; 2Univ of Hertfordshire, United Kingdom; 3Hertfordshire Partnership University NHS Trust, United Kingdom; 4Southend Univ Hospitals NHS Trust, United Kingdom; 5King’s College London, United Kingdom; 6Royal free london NHS Trust, United Kingdom; 7Univ Hospitals Birmingham NHS Trust, United Kingdom.

Background: Major Depressive Disorder (MDD) is common in patients on Haemodialysis (HD) but there is little evidence of benefit from antidepressants. Hence we undertook a multicentre feasibility Randomised Controlled Trial (RCT) of sertraline versus placebo.

Methods: A screening phase identified patients with Beck Depression Inventory (BDI-II) ≥18. Those meeting eligibility criteria, underwent psychiatric assessment (Mini International Neuropsychiatric Interview). Consenting patients with mild to moderate MDD and Montgomery-Åsberg Depression Rating Scale (MADRS) score ≥18 were randomised to sertraline or placebo. Follow-up by study psychiatrist/week 2, month 2, 4 and 6 monthly by study nurses. Initial dose was 50 mg with titration to 100 mg if required.

Results: Of 1355 patients approached, 715 consented for screening. BDI-II ≥18 was present in 231 (32.3%), 58 (25.1%) were ineligible due to current treatment for MDD. Sixty-three underwent psychiatric assessment. MDD was diagnosed in 37; 30 consented to the RCT (mean age 61 ± 15, 71% male; 60% white). Twenty-one (70%) completed the trial. (p=0.016 and 0.006 respectively). Multiple pairwise comparison showed a significant difference between G1 and G3 in PP analysis (p-value=0.010) but not in the ITT analysis. (p=0.016 and 0.006 respectively). Baseline characteristics were similar in both groups. The median [IQR] total volume of fluid administered was 6446mL [8087,8075] for NS and 7776mL [5140,9008] for PL (p<0.3). The incidence of hyperkalemia in the first 48 hours postoperatively was higher in the NS group: 20 patients (80%) vs. 12 patients (50%) in the PL group (p<0.04). Sixteen patients (64%) in the NS group required treatment for hyperkalemia compared to 5 patients (21%) in the PL group (p=0.003). The peak serum potassium in the 48 h postoperative period was higher in the NS group: (6±1.0 vs. 5±0.9 mEq/L, p=0.009). Patients receiving NS were more acidotic (pH: 7.32 ±0.06, vs. 7.39 ±0.05, p=0.001) and had higher serum chloride (107 mEq/L vs. 101 mEq/L, p<0.001) at the end of surgery. There were no significant differences in delayed graft function or hospital length of stay.

Conclusions: Deceased donor renal transplant patients that received NS developed hyperchloremic metabolic acidosis with an increased incidence of hyperkalemia when compared to PL. This study supports the use of acid buffered crystallloid solutions for perioperative fluid management in patients undergoing deceased donor renal transplantation.

Abstract Withdrawn

SA-PO1122

D. Clogt,1 G. Russ,2 Lionel Rostaing,3 Christophe M. Legendre,4 Steven J. Chadban,1 J. Grinyo,1 Nizam Mamode,1 Gunnar Tuveson,1 Lionel Couzi,1 P. Riggoti,1 Y. Lebranche,1 S. Sandrini,1 W. Marks,2 Hôpital Saint-Louis, Paris, France; 3Metropolitan; 4A’lexion Pharmaceuticals, Inc., Cheshire, CT; 1The International Eculizumab Transplant Study Group.

Background: Complement activation by preformed DSA is the major mechanism of acute antibody-mediated rejection (aAMR) in sensitized, kidney transplant recipients (SKTR). In a previous interim study report, the CS inhibitor eculizumab (Ecl) appeared effective in preventing aAMR in deceased donor (DD) SKTR compared to historical controls. We now report 12-mo efficacy and safety data from a Sept 2015 update of this ongoing, open-label, single-centre, RCT.

Methods: SKTR defined as current DSA >3000MFI detected by SAB; or B- or T-cell flow cytometric crossmatch ≥300 and ≤500 mean channel shift; or historical positive complement-dependent cytotoxicity crossmatch to donor HLA. All recipients received Ecl 1200mg postoperative day (POD) 0 prior to reperfusion. 900mg on POD 1, 7, 14, and 28, and 1200mg at wks 5, 7, and 9. Recipients received Rabbit ATG for induction and corticosteroids, tacrolimus, and mycophenolate for maintenance immunosuppression. Plasmapheresis was not allowed through Post-transplant week 9. The primary composite endpoint was clinically significant, biopsy-proven aAMR grade IUH (Banff 2007, based on centrally read bx), graft loss, death, or loss to follow-up at 9wks. Graft and patient (pt) survival were estimated by K-M.

Results: 80 pts were transplanted (48 F, 32 M); median age 52y (range: 24–70); 7 of 80 SKTR had aAMR (8.8%) compared to 30% expected for historical controls. 11/80 SKTR met the 9wk composite primary endpoint based on local bx (13.8% [95% CI 7.1–23.3]). Graft survival at 6 and 12mo was 93.7% and 88.7%, respectively; pt survival at 6 and 12mo was 97.4%. SCR levels (mg/dL) at baseline, 1 and 2mo were 7.43 (±2.51), n=79; 1.66 (±1.07), n=79; and 1.54 (±0.75), n=57, respectively.

Conclusions: Ecl appeared to be effective in reducing aAMR in SKTR. Pt and graft survival and kidney function at 12mo were similar to those expected for non-sensitized KTR. Ecl was well tolerated.

Impact of De Novo Donor Specific Antibodies on Graft Outcomes in Kidney Transplant Recipients Following Early Switch from Calcineurin Inhibitor to an mTOR Inhibitor: Analysis of the ELEVATE Trial

Johan W. De Fijter,1,2,3,5 Hallvard Holdaas,1 Patricia M. Lopez,4 Peter Bernhardt,5 Zailong Wang,5 Frans Claas,6 Wolfgang Arns,4 Josep M. Cruzado,1 Markus van der Giet.1 For the ELEVATE Study Group.

Background: Development of de novo donor specific HLA-antibodies (dnDSA) after kidney transplantation (KTx) is associated with an increased risk of antibody-mediated rejection (AMR) and graft failure. The ELEVATE study evaluated the impact of early conversion from CNIs to everolimus (EVR) after KTxs and prospectively explored the status and development of dNSAs.

Methods: In this 24-month (M), multicentre study KTxs recipients were randomized at 10–14 weeks post-Tx to convert from CNI to EVR (n=360: C0 6–10 ng/mL) or continue CNI (n=357; C0, tacrolimus 5–10 ng/mL, cyclosporine 100–250 ng/mL). All received enteric-coated mycophenolate sodium (MPS) + corticosteroids. Blood samples were collected at

Underline represents presenting author/disclosure.
baseline, randomization (RND), M12 and M24 or at time of rejection episodes and analysed
by Luminex/SAB assay in one central lab. dnDSA was defined by a MFI value ≥500 any

time post-RND in patients with MFI <500 at RND.

Results: Baseline characteristics were comparable between groups. Incidence of
preformed DSA (MFI ≥500 at baseline) against HLA class-I or -II was low (table A).
Overall, incidence of dnDSA HLA class-I was higher with EVR/MPS treatment vs CNI/
MPS at M12 and M24. The incidence of dnHLA Class-II antibodies was dominated by
anti-DQ in the CsA/MPS [lrm] group (table B). No association between de novo (either
HLA class-I or -II) antibodies and a diagnosis of AMR or tBPAR was evident in this
population up to M24 (table C, D).

Conclusions: Early conversion to EVR at 3M post-Tx did not increase the risk of
dnDSA formation vs CNI continuation. Moreover, no association was observed between
development of dnDSA and AMR or tBPAR, even with the lowest detection thresholds.

Donor-Derived Cell-Free DNA in Plasma Increases with Rejection and Decreases after Treatment in Kidney Transplant Recipients

Marica Grskovic,1 Brian Christie,1 David Hiller,1 Robert Woodward,1 Jim Yee, Flavio Vincenti.2
1CareDx, Inc., Brisbane, CA; 2UCSF, San Francisco, CA.

Background: Donor-derived cell-free DNA (dd-cfDNA) is an emerging biomarker
of acute cellular rejection in organ transplant recipients. The utility of determining plasma
levels of dd-cfDNA aimed at diagnosing rejection and evaluating treatment response was
assessed in kidney transplant recipients in a longitudinal observational trial.

Methods: Clinical status, biopsy grade (performed in response to elevated serum
creatinine) and plasma were collected at 326 routine surveillance visits from 101 patients.
Samples from nine patients assigned a biopsy grade I, II or III (NIH criteria) were classified
as rejection (R). Samples from seventeen patients assigned a biopsy grade 0 were classified
as quiescent (Q). cfDNA extracted from plasma was amplified at targeted SNPs and analyzed
using a sensitive and accurate Next Generation Sequencing assay to quantify dd-cfDNA
levels without the need to separately genotype the donor. Standard statistical measures of
significance were used.

Results: dd-cfDNA levels were significantly higher (p=0.029) in patients with biopsy-
confirmed rejection (R, mean 4.23%) compared to quiescent patients (Q, mean 0.96%).
Creatinine levels were not significantly different between R and Q patients (p=0.69; mean
4 and 3.1 mg/dL, respectively). Longitudinal sample analysis from 15 patients showed
increased dd-cfDNA levels following transplant (mean 2.8%) with reduction to levels below
1% by two weeks post transplantation. In 3 cases with clinically treated biopsy-confirmed
rejection and 2 serial samples following the rejection, levels of dd-cfDNA decreased
following rejection treatment.

Conclusions: dd-cfDNA shows promise as a biomarker of rejection that may be
used for non-invasive surveillance of kidney allograft status and treatment response.
The ongoing measurement of cfDNA may allow clinicians to better personalize care and
improve patient outcomes.
