End-Dialysis Overweight and Chronic Inflammation: A Dangerous Association – A 36-Month Prospective Observational Study
Ezio Movilli
U.O. of Nephrology, Spedali Civili and Section of Nephrology Univ of Brescia, Brescia, Italy.

Background: Attaining dry body weight is paramount in dialysis practice, but this goal is never always reached. We hypothesized that the amount of end-dialysis overweight (edOW), could be associated to increased chronic inflammation and mortality. Aim of the study: to evaluate the effect of edOW on serum C-reactive protein (hsCRP) concentrations and on survival in a cohort of 182 prevalent HD patients (pts) followed for 36 months.

Methods: In 182 pts (117 men, age 65±12 years, vintage 48 months; range 6-336), edOW was present in 98/182 (54%) pts. Mean value was 0.4±0.2 Kg (range: 0.1-1.4). In the 98 pts with edOW (Group 1) and in the other 84 (Group 2) we evaluated: Ultrafiltration rate(UFR), hsCRP/day body weight (dBW), Ki/V, protein catabolic rate (PCRn), interdialytic weight gain (IDWG), mean arterial pressure (MAP). Unpaired Student’s t was employed to compare groups, linear regression analysis to test correlations, log-rank test and Kaplan-Meier curves to evaluate survival.

Results: Mean UFR was 11.7±2.8 ml/Kg/hour, DBW 64±12 Kg, hsCRP 6.6 (0.2-36) mg/L, Ki/V 1.27±0.09. PCRn 1.06±0.10 g/Kg/day, IDWG 2.8±0.4 Kg, MAP 97±6.5 mmHg. edOW and hsCRP were directly and significantly correlated (r= 0.67; p<0.0001). Comparison between pts with (Group 1) and without (Group 2) edOW showed significant differences in: UFR (12.7±2.6 vs 10.9±2.6 ml/Kg/hour; p<0.0001), hsCRP (13.0±8.1 vs 5.2±5.3 mg/L; p<0.0001), and PCRn (1.03±0.09 vs 1.08±0.10 g/Kg/day; p<0.0004). 98 pts (54%) died during follow-up for cardiovascular complications in 69% of cases. Survival curves showed significantly greater mortality in Group 1 vs Group 2 in relation to the amount of edOW, and hsCRP (p<0.0001).

Conclusions: edOW and chronic inflammation are directly correlated in HD pts, and both are associated to a greater long-term risk of mortality.

TH-PO835
Suicidal Erythrocyte Death in Hemodialysis Patients
Anna Clementi,1 Grazia María Virzì,2 Alessandra Brocca,3 Massimo de Cal,1 Antonio Granata,1 Claudio Ronco,1* Nephrology, Agrigento; 2Nephrology-IRIV, Vicenza.

Background: Even though anemia in ESRD results mainly from the lack of erythropoietin, compelling evidence points to the contribution of accelerated erythrocyte death/eryptosis, which is characterized by phosphatidylserine (PS) exposure at surface, cell shrinkage and cell membrane scrambling. Eryptosis may be stimulated both by uremic toxins and the mechanical stress induced by hemodialysis (HD). We investigated the possible difference in terms of eryptosis levels between healthy subjects and HD patients before and after HD session.

Methods: We enrolled 15 patients (4F, mean age 65±16yrs, 33% with diabetes) undergoing chronic HD and 15 healthy subjects (CTR). Blood samples were collected prior to and after 4h standard HD session. Measurements were made in isolated erythrocytes (RBCs). PS exposure was estimated from AnnexinV binding in flow cytometer.

Results: The percentage of AnnexinV reflecting the percentage of RBC's exposition PS at RBC surface was significantly higher (more than twice) in HD patients than CTR (2.2%; IQR 1.2-4.1 versus 0.8%; IQR 0.7-1.3; p<0.05). The average forward scatter reflecting cell volume was significantly higher in RBCs from HD patients than in CTR. There was no statistically significant relationship between RBC levels and eryptosis in HD patients. The percentage of AnnexinV and cell volume were measured prior to and after 4h of HD: no significant differences were observed between pre and postdialysis eryptosis.

Conclusions: Our data suggest that HD may lead to a significant increase in eryptosis, but no differences in the level were observed before and after HD session. Although this procedure is known to be responsible for cytokines and inflammatory mediators release, because of the interaction between blood and circuit lines and filters, it does not seem to induce eryptosis. Further studies are needed to compare different types of HD treatments.

TH-PO836
Deployment of a Dialysis Hospitalization Reduction Program Is Associated with Lower Hospitalization Rates
Hanjie Zhang,1 Dugan Maddux,2 Karen G. Butler,2 Len A. Usvyat,2 Yue Jiao,2 Brian Scott Ash,2 John W. Larkin,2 Terry Ketchersid,2 Peter Kotanko,2* Franklin W. Maddux,2* Renal Research Inst, New York, NY; 3Fresenius Medical Care North America, Waltham, MA; 4Icahn School of Medicine at Mount Sinai, New York, NY.

Background: The aim of this study was to investigate the potential effect of a Dialysis Hospitalization Reduction Program (DHRP) on hospital admissions.

Methods: We deployed DHRP to 69 patients between 1/1/2014 and 5/5/2015 in a network of Fresenius Medical Care North America (FMCNA) dialysis clinics. These patients were identified as being at high risk for hospitalization based on FMCNA’s data driven predictive modeling efforts and clinical assessments. The DHRP encompasses multiple interventions, targeting malnutrition, non-compliance, mental status issues, fluid overload, and others. Each patient is identified to have one or more “clinical tags”; 88 tags were identified for 69 patients. Interdisciplinary teams were deployed to design and implement interventions. Hospitalization rates were measured 90 days before and after the program.

Results: DHRP was associated with a reduction of all-cause hospitalization from 7.5 to 4.4 per patient year (ppy) (-42 %) (Figure 1A). Interventions targeting patients with “malnutrition” tag were associated with a reduction of hospitalizations from 9.3 to 4.1 ppy (-56%) (Figure 1B).

SBP: systolic blood pressure; IDWG, interdialytic weight gain

Conclusions: DHRP was associated with reductions in hospital admissions and days. Reductions in overall hospital admissions were even higher in patients specifically identified to have malnutrition issues.

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America

TH-PO837
The Long Inter-dialytic Period Is Not Associated with Inferior BP Control in Stable Hemodialysis Patients

Background: 3-day-a-week hemodialysis (HD) involves one long (72hr) and two short (48hr) inter-dialytic periods (IDP) with higher death risk after the long IDP. We investigated BP and CV biomarker patterns in clinically stable HD patients to determine whether BP control during the final 24 hrs of the long IDP is inferior to that of the short IDPs.

Methods: In an initial retrospective study, in-center BP readings over 1 month were analyzed for 81 adult HD patients with stable regimen and medical status for >3 mths. Next, 23 patients completed a prospective study in which ambulatory BP monitoring was performed for the final 24hrs of the long and one short IDP in the same week. Blood was collected for CRP, Tropomin T, BNP following each ABPM.

Results: In the retrospective study, mean pre-dialysis systolic and diastolic BP (SBP/DBP) did not differ for the long and short IDPs despite greater weight gain during the long IDP. This observation was confirmed in the ABPM study and applied to both day- and night-time readings. Pre-dialysis CV biomarkers were not significantly higher following the long IDP. Inter-dialytic weight gain showed no correlation with BP indices.

Conclusions: DHRP was associated with reductions in hospital admissions and days. Reductions in overall hospital admissions were even higher in patients specifically identified to have malnutrition issues.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Conclusions: In stable HD patients, BP control and CV biomarkers were similar during long compared to short IDP despite greater fluid gain. The adverse influence of excessive inter-dialytic fluid gain is unlikely to be mediated directly through a hypertensive effect.

TH-PO838
Notch Signaling in Bone Marrow-Derived FSP-1+ Cells Mediates a Phenotypic Change in Smooth Muscle Cells Leading to AVF Failure
Ming Li,1,2 Nan Li,1,2 William E. Mitch,1 Yichong Cheng,1 Medicine, Baylor College of Medicine, Houston, TX; 2Nephrology, Guangzhou Medical Univ, Guangzhou, Guangdong, China.

Background: Sociocultural and economic costs of failed arteriovenous fistulas (AVF) are well known but mechanisms of AVF losses are controversial. We have shown that smooth muscle cells (SMCs) from anastomosed artery compose of ~50% of neointima in AVF. Arterial SMCs are also infiltrated by bone marrow (BM)-derived FSP-1+ cells, potentially linking FSP-1+ cells to SMC activation. However, whether Notch-RBP-JK signaling involving in BM-derived FSP-1+ cells activation has not been studied. We propose that Notch-RBP-JK activation in BM-derived FSP-1+ cells causes a phenotype-switch of SMCs, resulting in SMC translocation from the artery to the venous anastomosis, forming neointima.

Methods: We created CKD and AVFs in wild type and Notch knock out mice. The role of Notch signaling in activation and function of BM-derived FSP-1+ cells was explored. Activated SMCs were characterized by a loss of differentiation markers plus a gain in proliferation (PCNA+). Using BM transplantation, we examined if FSP-1+ cells lacking RBP-JK in CKD mice would suppress SMC phenotype switch and neointima formation in AVFs.

Results: BM-derived FSP-1+ inflammatory cells in AVFs from CKD mice were 45% greater vs. results in pair-fed, control mice. In the artery anastomosis, increased infiltration of FSP-1+ cells led to loss of SMC differentiation markers, SM-MHC, SM-22 and SMA-α. Activation of Notch signaling (NICD+ and RBP-JK+) raised expression of cytokines (IL-1β, MCP-1) and growth factors (PDGF-BB, bFGF and TGF-β1) in FSP-1+ cells. The cytokines and growth factors caused a SMC phenotype switch (characterized by loss of SMC α-smooth muscle actin), resulting in SMC migration and proliferation. RBP-JK KO in BM-derived FSP-1+ cells significantly decreased the production of cytokines and growth factors, suppressed SMC activation of and neointima formation in AVFs.

Conclusions: Thus, Notch signaling in BM-derived FSP-1+ cells can induce a phenotype switch in SMCs stimulating neointima growth. Targeting Notch signaling in FSP-1+ cells could improve AVF function.

Cytooglobin Is Upregulated in Failed Arteriovenous Fistula from Hemodialysis Patients and Exerts Survival Functions in Medial Smooth Muscle and Neointimal Cells

Background: Placement of an arteriovenous fistula (AVF) provides vascular access for lifesaving hemodialysis to patients with severe and chronic kidney disease. A significant percentage of AVFs initially mature; serve as successful hemodialysis access points; but fail at some later time due to neointimal hyperplasia that occludes the vein. The causative underlying molecular, biochemical, and cellular factors that contribute to AVF failure are incompletely understood. CaMKII is a positive regulator of VSM cell proliferation and migration that results in occlusion of carotid arteries in both mice and rats. Currently, there is little known regarding the role of CaMKII in either physiological or pathophysiological vasodilation and vasoconstriction.

Methods: Cephalic veins from patients prior to AVF placement and after AVF failure were obtained. Immunohistochemical studies were performed on OCT embedded frozen sections. Molecular analyses were performed on RNA extracts from these venous segments and protein analyses were performed on protein extracts.

Results: Our results indicate that there is an increase in CaMKII-A and CaMKIIδ expression in failed AVFs compared to cephalic vein prior to AVF placement. CaMKII activity is regulated by both phosphorylation and oxidation. NADPH oxidases (Noxs) generate reactive oxygen species (ROS) that increases CaMKII activity. Analysis of failed AVFs shows an upregulation of Nox2 and Nox4. Further studies show an increase in CaMKII activity. Interestingly, our data indicates that only a subset CaMKII isoforms are oxidized under these conditions.

Conclusions: These findings lead us to conclude that increases in CaMKII-A and CaMKIIδ after AVF placement may result in increases of CaMKII expression and sustained activity that contribute to AVF failure. They also identify CaMKII as a rational target for therapeutic manipulation to prevent AVF failure.

Identification of Ca2+-/CaM-Dependent Protein Kinase (CaMKII) Isomorphs and Their Selective Regulation by NADPH Oxidases in Failed Arteriovenous Fistula from Hemodialysis Patients
Roman G. Ginnan,1 Ravi S. Shah,1 David J. Conti,2 Arif Asif,2 David Jourd’heuil,2 Harold A. Singer. 1Center for Cardiovascular Sciences, Albany Medical College, Albany, NY; 2Div of Nephrology and Hyperension, Albany Medical College, Albany, NY.

Background: Early arteriovenous fistula (AVF) failure remains an important cause of hemodialysis vascular access dysfunction. In order to understand the cellular and molecular mechanisms involved in early AVF failure we evaluated the gene methylation profile (epigenetics) in conjunction with the gene expression profile (RNA Seq) from venous segment tissue samples obtained at the time of AVF creation. This approach allows us to identify genes that have altered expression (RNA Seq analysis) as a result of epigenetic changes (DNA methylation). The latter can be induced by different factors, including stress, inflammation, nutrition, metabolism, drugs and infection (all of which are prominent in the biological milieu of patients with CKD and ESRD).

Methods: Genomic DNA (gDNA) and RNA were isolated from venous segments collected at the time of AVF creation. We divided the samples into 2 groups, THICK (n=5) and THIN (n = 5), based on a histological evaluation of the amount of neointimal hyperplasia. Deep sequencing technologies were then used to identify differentially regulated levels of gene expression between the THICK and THIN groups, that also had significant differences in DNA methylation. Standard bioinformatic techniques were used to identify/interrogate these changes.

Results: We were able to identify a number of genes that were differentially regulated, either at the level of the transcriptome or at the level of DNA methylation (epigenetics) between the THICK and THIN groups. However, we were not able to identify individual genes that had changes in both the RNA Seq and DNA methylation analyses, at a high level of statistical significance.

Conclusions: While we were unable to identify differences in both gene expression and levels of DNA methylation for individual genes, between our two groups (perhaps because of a small sample size), we do believe that these techniques and technologies could be used in larger studies, to dive deep into the mechanisms of AVF failure at a molecular and genetic level.

Computational Fluid Dynamic Analyses in a Uremic Mouse Model of AVF Stenosis: Of Surgery, Techniques and Computation  
Begoña Campos,1 Yang Wang,2 Yong He3 John M. Pearce,1 Richard Scott Dunn,1 Keith Louis Saum,1 Janaka Wansapura,1 Charles L. Dumoulin,1 Scott A. Berceli,1 Prabir Roy-Chaudhury.1  
1Univ of Cincinnati; 2Univ of Florida; 3CHMC.

Background: Although arteriovenous fistulae (AVF) are the preferred form of vascular access for hemodialysis patients, over 50% of AVFs fail to mature (inability to increase blood flow and diameter adequately to support dialysis). Work performed in our laboratory suggests that AVF maturation failure is due to an interaction between “upstream hemodynamics” and “downstream vascular biology”. In order to better elucidate the mechanisms involved in both these processes, we herein describe the techniques needed to develop a shear stress profile within a uremic mouse AVF.

Methods: In order to create a uremic mouse model, C57Bl/6 animals underwent an initial cauterity of the left kidney followed 2 weeks later by a contralateral nephrectomy. Four weeks later AVFs were created in the neck. In order to generate different shear stress profiles, we created AVFs between the carotid artery and jugular vein in the following surgical configurations (a) end of carotid artery to end of jugular vein (b) end of jugular vein to end of carotid artery and (c) end of carotid artery to side of jugular vein. Mice were then perfused with a silicone rubber casting agent (Microfil). Fistulae were harvested, stored 4% paraformaldehyde, and treated with Lugol solution as a micro-CT contrast agent. Each AVF was then scanned using micro-CT imaging to create a 3D reconstruction of AVF geometry. In order to obtain blood flow parameters we have developed an MRI technique that allows us to quantify blood flow within the carotid artery. We then use software to develop a complete shear stress profile within the mouse AVF.

Results: We have described for the first time a hybrid surgery-fluid dynamics approach, which could allow us to identify the differential impacts of different surgical configurations, with or without the impact of uremia on AVF fistula functionality (with the promise of also geometry). In order to obtain blood flow parameters we have developed an MRI technique that allows us to quantify blood flow within the carotid artery. We then use software to develop a complete shear stress profile within the mouse AVF.

Conclusions: We firmly believe that teasing out the relative roles of upstream hemodynamics and downstream uremic vascular biology will allow us to identify target(s) for future therapeutic interventions.

TH-PO843

Biodegradable Stents Improve Arteriovenous Fistula (AVF) Maturation  

Background: Arteriovenous fistula (AVF) maturation failure is currently a huge clinical problem with no effective therapies. At a pathogenetic level the three main causes of AVF maturation failure are (a) small veins (b) abnormal non-laminar flow profiles and (c) abnormal local endothelial function. We therefore, hypothesize, that the placement of a malleable, biodegradable magnesium based maturation enhancing stent (bMES) within the venous segment, at the time of surgical AVF creation would dilate small veins, optimize the anatomical configuration, and serve as a conduit for the future delivery of therapies to improve local vascular biology during the critical initial 4-8 week period with an absence of long term side effects (no stent after 4-8 weeks).

Methods: bMES were fabricated using pure Mg foil (125 mm) and Mg-Zn alloy wire. Bilateral AVFs were created between the femoral artery and vein of Yorkshire pigs. A bMES was inserted on one side and dilated to 8mm. A control AVF was created on the other side without the bMES. Bilateral A VFs were created between the femoral artery and vein of Yorkshire pigs. A bMES was inserted on one side and dilated to 8mm. A control AVF was created on the other side without the bMES. Bilateral AVFs were created between the femoral artery and vein of Yorkshire pigs. A bMES was inserted on one side and dilated to 8mm. A control AVF was created on the other side without the bMES. Bilateral AVFs were created between the femoral artery and vein of Yorkshire pigs. A bMES was inserted on one side and dilated to 8mm. A control AVF was created on the other side without the bMES.

Results: Preliminary data documents almost complete degradation of the bMES at 4-8 weeks with an initial increase in diameter of the stented AVFs on CT angiograms at 2-4 weeks. Unfortunately we did not have enough pigs to perform a statistical analysis. We believe that this technology could significantly reduce the huge morbidity and mortality associated with AVF maturation failure and also expand the patient population considered to be suitable for AVF placement in the future.

TH-PO845

Association Between Clinical Outcomes and Type of Vascular Access in Elderly End-Stage Renal Disease Patients Initiating Hemodialysis  
Kyoung Sook Park,1 Mi Jung Lee,2 Tae-Hyun Yoo,3 Shin-Wook Kang.1 Dept of Internal Medicine, 1Yonsei Univ College of Medicine, Seoul, Korea; 2Korean Red Cross Seoul Hospital, Seoul, Korea; 3Korean National Medical Center, Seoul, Korea.

Background: Although dialysis initiation via arteriovenous fistula (AVF) is the best strategy in incident hemodialysis (HD) patients. Elderly patients with HD are compelled to use HD catheter (HC) due to maturation failure after AVF operation. Therefore, we investigated the association of vascular access type and clinical outcomes in elderly incident HD patients.

Methods: A prospective cohort of incident HD patients from the Clinical Research Center for End-stage renal disease in Korea between 2009 and 2013 was used. Patients who were 65 years or older were defined as elderly. The patients were classified into three groups according to VA type at HD initiation. Since the hazard ratio (HR) according to type of VA was not proportional, time-dependent Cox regression analysis was performed to determine all-cause mortality.

Results: Among the 511 enrolled patients, 303 (59.3%) were male and the mean age was 72.3±5.4 years. HD was initiated with AVF, arteriovenous graft (AVG), or HC in 86 (16.8%), 36 (7.0%), and 389 (76.1%) patients, respectively. During a median follow up of 12 months, all-cause death was observed 12 (14.0%) in AVF, 13 (36.1%) in AVG, and 107 (27.5%) in HC. Multivariate time-dependent Cox regression analysis demonstrated that AVG (AVF as reference, HR=1.719, 95% confidence interval [CI]=1.274-2.319, P<0.001) and HC (HR=1.304, 95% CI=1.036-1.640, P=0.023) were significant risk factors for all-cause mortality after adjustment of age, sex, diabetes mellitus, previous cardiovascular disease, timing of referral to nephrologist, hemoglobin, serum albumin, and C-reactive protein levels.

Conclusions: Patients with successful AVF were associated with better survival compared to those with AVG or HC. In addition, survival was comparable between elderly patients initiating HD with AVG and HC. Although vascular problems are common in elderly patients, AVF may be the best strategy to improve clinical outcomes in this population.

International Variability in Arteriovenous Fistula Maturation and Placement: The Dialysis Outcomes and Practice Patterns Study  
Ronald L. Pisoni,1 Lindsay Zepel,2 Francesca Tentori,3 Yun Li,1 Jarcy Zee,3 Richard J. Fluck,2 Loreto Gesualdo,1 Hideki Kawashima,1 Gültekin Sileymanlar,1 Bruce M. Robinson.1 1Arbor Research; 2Yanderbilt Univ; 3Univ of Mich.; 4Nat. Health Service England; 5Azienda Ospedaliero Univ Consorziale Policlinico; 6Tsuichiya Gen. Hosp.; 7Akendz Univ.

Background: Prior Dialysis Outcomes and Practice Patterns Study (DOPPS) findings demonstrate international variability in vascular access practices, and association with outcomes. Here we describe international practices in arteriovenous fistula (AVF) placement and predictors of AVF maturation.

Methods: We studied 2,230 patients with an AVF created during DOPPS phases 4-5 (2009–2015) in North America, Europe/Australia-New Zealand (ANZ), and Japan. AVF maturation was defined as access use ≥30 days. Generalized estimating equations with a logit link were used to assess predictors of AVF maturation adjusting for country, phase, patient characteristics, and accounting for facility clustering.

Results: No significant association was found between many patient characteristics (e.g., age, diabetes, peripheral vascular disease) and AVF maturation. AVF maturation was more likely for males vs. females (OR = 1.49 [95% CI = 1.25-1.79]) and for AVFs placed in the upper vs. lower arm (OR = 1.40 [95% CI = 1.15-1.70]). Even though upper arm AVFs were more common in North America, AVF maturation was lowest in this region (Figure).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

285A
Conclusions: There is large international variability in site of AVF placement and AVF maturation. Differences in blood flow used (much higher in the US vs. Europe and Japan) may lead to different interpretation of the term “maturation” internationally, and may influence maturation rates.

Vascular Access in Acute Kidney Injury: Results from the ATN Study
Kavitha Ganta, Yue-Harn Ng, Herbert T. Davis, Mark L. Unruh. Deapartment of Internal Medicine, Unive of New Mexico, Albuquerque, NM.

Background: Acute kidney injury requiring renal replacement therapy (RRT) portends a poor prognosis. Currently, the decision regarding catheter placement is based solely on physician discretion. Limited data exist to guide catheter placement. The Acute Renal Failure Trial Network (ATN) study was a multicenter, prospective, randomized trial on the effects of dialysis dose on mortality in critically ill patients. Using data from this study, we assessed the complications rates and the adequacy of dialysis based on different catheter locations.

Methods: Baseline characteristics were gathered. The outcomes of interest included catheter related infections, cardiac arrhythmias, excessive bleeding, local thrombosis and dialysis adequacy. Categorical variables were analyzed using Chi-square test while continuous variables were analyzed using the Student T test. The SAS software was used for the analysis.

Results: There were 242 (11.7%) subclavian (SC), 951 (46.1%) internal jugular (IJ) and 861 (41.7%) femoral (FC) catheters inserted. The baseline characteristics based on catheter location is shown in Table 1.

The rate of bacteremia was comparable between the 3 groups. (5.4% (SC) vs. 3.5% (IJ) vs. 3.5% (FC); p = 0.34) The IJ group experienced more cardiac arrhythmias (2%) compared to SC (0.8%) and FC (0.5%) group [p = 0.01] while the FC group had more venous thrombosis (0.7%) compared to none in the SC and IJ group [p = 0.02]. Overall, complication rates were low. There was no clinically significant difference in the adequacy of dialysis between the 3 groups.

Conclusions: There was no significant differences in complication rates amongst the 3 catheter locations hence decision on catheter location should be based on operator experience and comfort level.

TH-PO848
Vascular Access at Dialysis Initiation in the United States Renal Data System (USRDS): Strong Agreement Between CMS-2728 Medical Evidence Form and CROWNWeb
Purna Mukhopadhyay, Jeffrey Pearson, Kenneth J. Woodside, Sarah Bell, Ronald L. Pison, Douglas E. Schaubel, Kaitlyn Ratkowiak, Rajiv Saran. 1 Arbor Research Collaborative for Health, Ann Arbor, MI; 2 Univ of Michigan, Ann Arbor, MI.

Background: The USRDS has long reported vascular access (VA) at the start of hemodialysis (HD) using the CMS-2728 Form. In 2012, CMS rolled out the CROWNWeb (CW) system to collect clinical treatment and laboratory data monthly for all dialysis patients. As CW data are fully integrated into the USRDS database, it is critical to evaluate the level of completeness and consistency between these two data sources.

Methods: We compared VA used at the first HD session reported on the CMS-2728 form for new ESRD patients in 2013 (n = 96,936) in USRDS database with VA used at the end of the 1st month of HD reported through CW. To evaluate the potential for data lag, we compared the 2nd month of HD reported through CW. Completeness and consistency was assessed at the patient level by 2x2 tables. The level of agreement was evaluated by kappa statistics. Logistic regression models were fit to identify patient characteristics associated with the level of agreement.

Results: 89% of patients had at least one monthly VA report in CW among which 0.23% was missing VA data from the CMS-2728 and 32.8% did not have a VA reported in CW for their 1st month of HD. However, completeness of CW data improved when either 1st or 2nd month of HD was considered as only 12.6% of patients did not have a VA reported. Among patients with VA reported from both data sources, kappa statistics was 0.88 using the 1st month of ESRD and 0.84 using first two months of ESRD. Agreement was highest for catheter (97-98%) and lowest for graft (78-81%). Age, sex, race were associated with the level of agreement; Hispanic ethnicity and cause of ESRD were not.

Conclusions: Our analysis confirms the large CVC burden among pediatric HD pts. Conversion to AVF were observed over the first year in an incident cohort where nearly 50% of pts transitioned to PD or TX. Further study will assess the impact of CVC dependence among pediatric ESRD pts with respect to future VA options and patient outcomes.

In Search of an Optimal Screening Program for Containing Graft Thrombosis
Nicola Tessitore, Giuseppina Pessolano, Valeria Bedogna, Albino Poli, Antonio Lupi, Emo.Unit. Borgo Roma, Verona, Italy; 2 Dept Public Health, Verona, Italy.

Background: KDOQI guidelines recommend regular screening for >50% stenosis (ST) in graft by surveillance access blood flow (Qa) & or static venous pressure ratio (sVPR) or Duplex Ultrasound to reduce the risk of thrombosis. Analysis of the literature suggests that the best predictor of thrombosis is sVPR>0.5, with an area under curve (AUC) of 0.81 [95%CI:0.75-0.85] significantly higher than that of Qa<600 ml/min (0.72 [95%CI:0.68-0.77]) & ST (0.49 [95%CI:0.40-0.53]), but no study has compared vis-a-vis all of the tools. We aimed to identify an optimal screening program, in 2013 we compared the diagnostic performance of the available tools for incipient thrombosis (within 3 mo) in the same population of 42 grafts (5 forearm loop & 37 straight upperarms), that underwent18 thrombotic episodes.

Results: Qa by Ultrasound Dilation proved to be the best screening tool (AUC:0.81[0.69-0.93]) optimal thresholds between Qa>1000 ml/min[63% sensitivity[SE], 18% false positives[FPR]) & Qa<1200 ml/min (83% SE, 27% FPR). Its AUC was higher than that of ST (0.69[95%CI:0.54-0.84); 78% SE, 39% FPR), monitoring (0.62[95%CI 0.45-0.79); 33% SE, 9% FPR), & VAPR (0.58[95%CI:0.42-0.74];VAPR:0.87% SE, 58% FPR). At GLM analysis Qa was the only significant predictor of thrombosis, with 8%[95%CI:7-9] lower risk for each 100 ml/min above a Qa 400 ml/min. From January

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
2014 onward we adopted a monthly Qa screening program using a Qa<1000 mL/min for exchange dialysis and a Qa<600 mL/min for short daily dialysis. This led to a significant drop of thrombosis rate from 0.70 (95%CI 0.41-1.11) (during the 2012-2013 period in which screening was based on bimonthly VAPR and quarterly Qa measurements and thrombosis repair triggered as per guidelines, by a VAPR<0.5 or a Qa<600 mL/min) to 0.11 (95%CI 0.01-0.40) event/graft-y (p=0.005), at a comparable elective angioplasty rate (0.71 (95%CI 0.46-1.04) vs 0.77 (95%CI 0.43-1.27) event/graft-y, p=ns).

Conclusions: Our comparative study suggests that Qa is the best predictor of graft patency & Qa surveillance using a Qa<1000 mL/min threshold allows for appropriate and timely stenosis repair & may contain the risk of thrombosis.

TH-PO851
The Impact of eGFR at Pre-HD Access Surgery on the Likelihood of Starting Hemodialysis with a Mature Vascular Access
Alian Jwa1, Sungchul Kim2, Hyunkyu Joo1, Seungho Lim1, Dahee Joo1, Hyunho Cho2, Kyung Jin Kim2, Joo Hyun Kim1, In Sung Joo2, Min-sup Seo1, Hyeok Lee2, Byung Nam Hwang1, Sun Young Choi1, Hunlim Jeong1

Background: The optimal timing of pre-dialysis vascular access surgery is uncertain. If the access is placed too late, it may not be ready for use; if it’s placed too early, it may not be needed. The optimal timing may differ for AVF vs AVG. We evaluated the association of eGFR at access placement with (1) likelihood of starting HD, and (2) likelihood of a mature access at HD initiation.

Methods: We retrospectively queried a prospective computerized access database to identify patients with pre-HD access surgery (301 AVF and 64 AVG placed between 2006-12) with an eGFR recorded on the surgery date. Patients were stratified into 4 eGFR groups (<10, 10-14, 15-19; >20 mL/min). For each patient we determined (1) whether dialysis was initiated within 2 years, and (2) whether the permanent access was used on the first HD session.

Results: Overall, 208 (or 69%) of pts with pre-HD AVF surgery initiated HD within 2 years, but the proportion varied by eGFR at surgery (90, 81, 64, and 47% for eGFR <10, 10-14, 15-19, and >20 mL/min).

Among the 208 pts with pre-HD AVF who started HD, 47% used the AVF on the first HD session, but the proportion varied by eGFR (30, 44, 59 and 45% for eGFR <10, 10-14, 15-19, and >20 mL/min). Among pts with pre-HD AVG surgery, HD was initiated within 6 months in 90, 62, and 30% for eGFR <10, 10-14, and 15-19 mL/min. The AVG was used for the HD session in 78, 89, and 88% of pts with eGFR of <10, 10-14, and 15-19 mL/min.

Conclusions: There are tradeoffs in the timing of pre-HD AVF surgery. A higher eGFR is associated with a lower likelihood of initiating HD in 2 years, but a higher likelihood that the AVF will be used on the first HD session. The optimal balance is achieved at an eGFR of 10-14 mL/min. In contrast, the optimal timing for pre-HD AVG surgery is an eGFR of 10-14 mL/min. Late placement of an AVF may be a catheter-sparing strategy.[figure]

TH-PO852
Economic Burden to Dialysis Providers of Central Venous Catheter (CVC)-Related Blood Stream Infections (BSI) and Occlusions Among Incident Hemodialysis (HD) Patients
Steven M. Brunelli,1 Wendye Turetten,1 Scott Sibbett,1 John Alan Laich,1 Antony E. Pfahle.2 DaVita Clinical Research, Minneapolis, MN; 1CorMedix Inc, Bedminster, NJ.

Background: Complications of CVCs may have economic consequences for dialysis providers derived from opportunity costs for missed dialysis treatments and increased use of bundled medications. We sought to quantify this financial burden among incident patients at a large dialysis organization (LDO).

Methods: We considered patients who began HD via a CVC between Jan 2013 and Dec 2014. In parallel analyses, patients who developed BSI (N=3269) or occlusion (N=676) during the first 6 months of dialysis were matched to control CVC-HD patients who did not. Missed HD treatment rates and medication utilization were considered from date of BSI/occlusion (or corresponding date for controls) for 180 days or until censoring for death, modality change or loss to follow up. Costs were derived using payor-specific remuneration rates (missed treatments), LDO acquisition costs (IV iron, ESA) and average wholesale prices (antibiotics, thrombolytics). Differences were estimated using linear mixed models including fixed effects for exposure status and month, adjusted for covariates that were imbalanced at baseline.

Results: CVC-related BSI was associated with significantly greater ESA utilization (59.39 vs 49.85 U/month, cases vs controls), IV antibiotic use (41.8% vs 6.0%) and missed HD treatment rate (1.95 vs 1.36 missed treatments/patient-month). This translated to a mean incremental cost of <$397 per patient per month. CVC occlusion was associated with increased thrombolytic use (10.9% vs 4.2%) but no significant difference in costs.

Conclusions: CVC-related BSI is a potent cost driver for dialysis providers with incremental costs of ~$400/month over a 6-month time horizon. No appreciable economic consequences of CVC occlusion were observed.

TH-PO853
Obesity Related Decrease in Intraoperative Blood Flow Is Associated With Maturation Failure of Radiocephalic Arteriovenous Fistula
Jwa-kyung Kim,1 Sun Ryoung Choi.1 1Internal Medicine, Dept of Internal Medicine, Kidney Research Inst, Anyang, Korea; 2Internal Medicine, Shamyook Medical Center, Seoul, Korea.

Background: Successful arteriovenous fistula (AVF) maturation is often challenging in obese patients. Optimal initial intraoperative blood flow (IOBF) is essential for adequate AVF maturation. This study was conducted to elucidate the effect of obesity on IOBF and radiocephalic AVF maturation.

Methods: Patients who newly created radiocephalic AVF were included (n=252). Obesity was defined as a baseline BMI≥25 kg/m2, and primary maturation failure was defined as the failure to use AVF successfully by 3 months after its creation. IOBF was measured immediately after construction of AVF using a VeriQTM system.

Results: The mean BMI was 24.1±3.9 kg/m2, and the prevalence of obesity was 31.3%. Particularly, 8.3% (21 patients) were BMI ≥30 kg/m2. Primary maturation failure occurred in 100 (39.7%) patients and an IOBF< 190 mL/min was closely associated with the risk of maturation failure (relative risk,3.05; 95% CI,1.52–6.11). Compared to non-obese patients, obese subjects had a significantly higher prevalence of diabetes and elevated hs-CRP levels, whereas diameters of vessels were similar. When the patients were further divided into 3 groups as the BMI <25, 25-29.9, and >30 kg/m2, patients in higher BMI group showed significantly lower IOBF and higher maturation failure rate. According to multivariate analysis, the statistically significant variables that determined maturation failure were obesity, previous vascular disease, increased hs-CRP levels, and IOBF < 190 mL/min.

Conclusions: Obese patients had a significantly lower IOBF, and both obesity and low IOBF contributed to the primary maturation failure of AVF. Obesity-associated inflammation and atherosclerosis might play roles in this association.

TH-PO854
The Impact of Vascular Access on Hemodialysis Patient Survival and Risk Analysis
Pine chin Lai,1 Le mei Yeh,1 Yueh hsia Chiu,1 Ling yin Chiu.2 1Renal Dept, Chang Gung Memorial Hospital, Taoyuan, Taiwan; 2Health Care Management, Chang Gung Univ, Taoyuan, Taiwan.

Background: Hemodialysis is the most common dialysis modality worldwide. However, the impact of different types of vascular access on hemodialysis patient survival has not been investigated in a large scale study. Therefore, we retrospectively reviewed the survival of hemodialysis patients in our center and analyzed the impact of vascular access on their survival. Other potential risk factors were also studied.

Methods: From 2001 to 2010, patients, who aged more than 40 years old and received regular hemodialysis in our center for at least 3 months, were included into this study. A total 916 patients were enrolled. The mean followed up interval were 4.4± 2.5 years. Among them, 51.1% were male, while 48.9% were female. These patients were divided into three groups according to their vascular access. Group A: patients used either native arteriovenous fistula or arteriovenous graft at the all time and dialysis catheter had never been used during the whole study period. Group B: patients used either native arteriovenous fistula or arteriovenous graft as their vascular access most of the time but they had used dialysis catheter at least once during study period. Group C: patients used dialysis catheter as their vascular access and arteriovenous shunt had never been established during the study period. Other survival associated factors were analyzed by using univariate and multivariate factor analysis.

Results: The results showed that group C patients had significantly worst survival rate (P<0.0001). The group B patients also had significantly worse survival rate when compare
TH-PO855

Early Experience with a Novel Device for Ultrasound-Guided Management and Cannulation of Hemodialysis Vascular Access

William D. Paulson,1 Deborah J. Brouwer-Maier,1 Lillian A. Pryor,2 John Jason White,1 Laura L. Mulloy,1 Lu Y. Huber,1 Matthew J. Diamond,1 Charlie Norwood VAMC & Georgia Regents Univ, Augusta, GA; 2Fresenius Medical Care, Waltham, MA.

Background: The vascular access continues to be the Achilles heel of dialysis. Methods that facilitate easier management and cannulation of accesses are needed. We describe early experience with a novel ultrasound device.

Methods: The Sonic Window (Analogic Corp, Peabody, MA, USA) is designed to assist management of vessels in a variety of contexts. It differs from conventional ultrasound in that it provides a coronal view of vessels that yields determination of characteristics such as depth and luminal diameter, and assists in cannulation for dialysis. We have initiated a program in 4 FMC dialysis units which is designed to identify its role and limitations.

Results: Two experts in the use of the Sonic Window have trained dialysis staff in the 4 FMC units. Staff have successfully cannulated 33 AV fistulas and synthetic grafts. Set up and use of the device generally adds an extra 1-3 minutes to cannulation time. Staff are able to easily visualize advancement of dialysis needles into the vessel lumen (figure).

Conclusions: The use of dialysis catheter imposed high risk for patient mortality on top of other associated risk factors. Early establishment of vascular access can eliminate this risk factor and improve patient outcome.

TH-PO856

Modifiable Risk Factors Affecting the Outcome Hemodialysis Graft

Jee eun Park, Jin Hae Kim, Subin Hwang, Do Hee Kim, Hye Ryoun Jang, Jung eun Lee, Wooseong Huh, Yoon-Goo Kim, Ha Young Oh, Dae Joong Kim. Nephrology Div, Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Korea.

Background: Arterio-venous graft (AVG) for hemodialysis has poorer outcome than arterio-venous fistula (AVF) with its frequent stenosis and thrombosis. We investigated modifiable risk factors affecting the outcome of AVG.

Methods: A single-center cohort of 254 patients (pts) receiving AVG for hemodialysis access from Sep 2010 to Oct 2014 were included. Demographics, laboratory data, comorbidities, and medications were collected from the medical records. Surgical factors related to AVG operation including the type and diameter of connected vessels, graft site, and type of operation (elective or emergent) were also recorded. End points was the interval from initial access formation to any intervention intended to restore patency (primary patency, days) and the total access survival duration (secondary patency, days).

Results: Data of 225 pts were analyzed. During the follow-up period, 139 (62%) pts received intervention and 45 (20%) pts underwent permanent failure. Survival analyses using Kaplan-Meier method was shown in the figure. In multivariate analysis, primary patency duration was associated with RAS inhibitor (hazard ratio [HR] 1.67, 95% confidence interval [CI] 1.13-2.46), and upper arm graft (HR 0.62, 95% CI 0.40-0.94). Secondary patency duration was associated with serum albumin level (HR 0.28, 95% CI 0.13-0.61), diastolic blood pressure (BP) (HR 0.93, 95% CI 0.89-0.98) and warfarin (HR 5.80, 95% CI 2.04-16.46).

Conclusions: Our early experience supports the concept that Sonic Window is a significant advance in managing and cannulating accesses in both routine and difficult situations.

TH-PO857

Effects of Diastolic Blood Pressure on the Patency of Brescia-Cimino Arteriovenous Fistula for Hemodialysis Access

Yan Yan. Nephrology Dept, The First Affiliated Hospital of Nanchang Univ, Nan Chang, China.

Background: To evaluate the relationship of diastolic blood pressure (DBP) with the patency of the Brescia-Cimino arteriovenous fistula (AVF), and to determine DBP levels that predict the success of this procedure.

Methods: Data was collected from 986 patients with end-stage kidney disease (ESKD) who had Brescia-Cimino AVFs from March 2007 to December 2013. DBP was measured twice a day, at 6 AM and 5 PM, starting 3 days before surgery until 3 days post-procedure. A receiver operating characteristic (ROC) curve was constructed to determine the cutoff value of pre-operative DBP, which predicts an increased chance of AVF patency during the first 7 days after surgery.

Results: Only 41 out of the 986 patients enrolled in this study developed AVF failure within the first 7 days following surgery, resulting in a 95.8% success rate in the procedure. This rate was increased by pre-operative DBP levels (P = 0.007). When the cutoff value was 77 mmHg, ROC analysis showed DBP was a pre-operative indicator for predicting AVF patency in the early postoperative period (P = 0.012; AUC = 0.607) with a sensitivity of 69.5% and specificity of 48.8%.

Figure

TH-PO858

Figure. Survival Curve of AVG

A. Primary Patency

B. Secondary Patency

Conclusions: Patients’ nutritional status reflected by serum albumin levels and diastolic BP could be modified for favorable outcome of AVG.

Vascular Access Outcomes following Peritoneal Dialysis to Hemodialysis Transition

Michael Allon. 1 Univ of Alabama at Birmingham; 2Medical Technology and Practice Patterns Inst.

Background: Few studies have evaluated vascular access (VA) use following transition from PD to HD. Our goal was to examine short-term VA utilization following PD to HD transition.

Methods: Using USRDS and Medicare claims data from July 2010-December 2012, we identified 3,565 incident Medicare-insured PD patients who were >18yrs and initiated dialysis between July 2010-June 2011. Patients had at least one dialysis claim within 90 days of dialysis initiation and were followed for 1 year until one of the following events: switched to HD, kidney transplant, death, or end of follow-up. We used Cox-regression models to examine the association of risk factors and switching to HD, with death and transplantation used as competing events.

Results: 991 (27.8%) patients switched from PD to HD during the 1 year follow-up. Of these, 46% switched to HD within 90 days of dialysis initiation and 66% by 6 months. The median switch time was 114 days (IQR: 32-226). Patients with cardiovascular disease (Adjusted Hazard Ratio (HR) 1.25, 95% CI 1.10-1.43), COPD (HR 1.29; 95% CI 1.01-1.66), and without pre-dialysis nephropathy care (HR 1.46; 95% CI 1.21-1.76 versus those with >12 months nephrologist care) were more likely to switch from PD to HD. After switching from PD to HD, 89% used a catheter, 6.6% AVF, and 1.9% AVG. 90 and 180 days after switching to HD, 71% and 50% of patients, respectively, who remained on HD still used a catheter as their VA.

TH-PO859

Temporal Trends in Pre-Hemodialysis Vascular Access Creation in Elderly Patients with CKD

Timmy C. Lee. 1 Mae Thamer; 2 Qian Zhang; 2 Yi Zhang; 2 Michael Allon. 1 Univ of Alabama at Birmingham; 2Medical Technology and Practice Patterns Inst.

Background: Optimal timing of pre-dialysis vascular access (VA) creation remains unclear. Elderly CKD patients with high co-morbidity are more likely to die before starting HD, so deferring VA creation may be reasonable. We assessed whether nephrologists have started selecting healthier elderly patients for pre-HD VA surgery.

Methods: Using USRDS and Medicare claims data we identified 3418 elderly patients (aged ≥70 years) with CKD undergoing pre-HD VA creation in 2004 to 2009, and divided them into 3 time cohorts (2004-05, 2006-07 and 2008-09). For each temporal cohort, we assessed the likelihood of initiating dialysis during 2 years of follow-up after VA surgery. We collected data on cardiovascular co-morbidities and cardiovascular events prior to VA surgery and after dialysis initiation to determine if there were significant changes in these variables during the 3 time cohorts.

Results: During the 3 consecutive time periods, the proportion of patients dying before initiating HD decreased by 28%, the proportion surviving without HD increased by 31%, whereas the proportion initiating HD remained constant (p=0.005).

| Year of VA Insertion | % of Patients Initiated HD within 2 Years | % of Patients Died before HD | % of Patients Survived without HD

Concomitantly, during the 3 consecutive time periods there was a progressive decrease in patients with history of PVD (66.5 to 59.7%, p<0.005), CHF (47.0 to 35.8%, p<0.005), and prior MI (6.5 to 3.3%, p<0.001). Among patients who initiated dialysis, there was a progressive decrease in the proportion of patients with a CHF (38.8 to 26.0%, p=0.001) or MI (5.4 to 2.6%, p=0.01) event in the first year after dialysis.

TH-PO860

Humodynamic Changes in Arteriovenous Fistula During Dialysis

Mary S. Hammes. 1 Vikash Kumar Sinhu, 1 Tom Bilcharski, 1 Michael Boghosian, 2 Jane E. Hines, 3 Syedeka Watson, 2 Kevin Cassel, 2 S. M. Jadid Mahmoudzadeh A, 2 Medicine/Nephrology, Univ of Chicago; 3Dept of Mechanical, Materials and Aerospace Engineering, Illinois Institute of Technology; 2Dept of Public Health Sciences, Univ of Chicago.

Background: Optimal blood flow velocity (BFV) in arteriovenous fistulas (AVF) to prevent neo-intimal hyperplasia is yet to be determined. We have hypothesized that changes in BFV and diameter in a brachiocephalic fistula (BCF) are affected by fistula maturation and blood flow induced during hemodialysis.

Methods: Eight subjects with primary BCF participated. Doppler BFV was measured pre-dialysis and during dialysis at 250, 350 and 450 mL/min blood flow for up to 14 months. BFV was measured in the straight portion of the cephalic vein 10 cm proximal to the cephalic arch. The relationship between BFV and diameter was examined using a linear mixed effects model. Computational modeling using venography was performed at 3 and 12 months.

Results: The change in measured diameter and BFV showed an inverse relationship with a significant association at baseline (p=0.0074) and 350 mL/min dialysis blood flow (p=0.0092). The computational model of the cephalic arch in one subject showed a 4 fold increase in Reynolds number with a dramatic recirculation region shown by a swirling eddy at the upper elbow of the arch.

Conclusions: From 2004-2009, there has been a progressive decrease in cardiovascular co-morbidities in elderly CKD patients undergoing pre-HD VA surgery, and this has been associated with a decrease in patients dying before HD and in patients with cardiovascular events after starting HD. Clinicians are becoming more selective in pre-HD placement of VA in this patient population.

TH-PO861

Arteriovenous Fistula (AVF) Maturation Among Hemodialysis (HD) Patients: Results from the USRDS

Rajiv Saran, 1 Sarah Bell, 2 Brett W. Plattner, 1 Douglas E. Schaubel, 1 Sudipta Dasmunshi, 1 Purna Mukhopadhyay, 2 Jeffrey Pearson, 2 Ronald L. Pisoni, 1 Kenneth J. Woodside, 1 Univ of Michigan; 2Arbor Research Collaborative for Health.

Background: AVF are considered the gold standard for HD vascular access, but require time to mature and may not adequately develop, resulting in prolonged central venous catheter (CVC) use. We describe AVF survival from placement until time to first use for prevalent HD patients in the US.

Methods: We examined HD patients with new AVF placements during 2013 using Medicare claims. Failure of maturation was identified by non-use following placement using CROWNWeb (CW) where patient access use is reported monthly by the facility. Patients were followed until end of 2014. We assessed the relationship between patient characteristics and time-to-first-use of AVF with a Cox model.

Results: In 2013, 51,561 AVF were placed among 42,160 HD patients followed through 2014. No subsequent evidence of use occurred in 44.3% of the placements. Of successfully used AVF, median time to first use was 113 days. Older age groups were incrementally associated with lower probability of using AVF. Pts in the 0-21 and 24-44yr groups (HR=1.23 [95% CI=1.06-1.44], and 1.06 [1.03-1.11], respectively), were more likely to use AVF's compared to the 45-64yr group (ref.), Sex (Female; Fig. 1a), race (e.g., Black; Fig. 1b), comorbidity (cardiovascular disease, peripheral artery disease, diabetes, needing assistance or institutionalized status), vintage <1year, CVC and/or AV Graft use at incidence, were also associated with lower probability of AVF use.

289A
Conclusions: We have characterized AVF maturation in a national US sample and identified important associations with multiple patient-level factors. Research is urgently required into the importance of patient, region and practice factors that could improve AVF placement and maturation, decrease CV access, to improve patient outcomes and experience.

TH-PO862

Elderly Age Does Not Affect Long-Term Survival of Non-Transposed and Transposed Upper Extremity Arteriovenous Fistulae

Neville R. Dossett,1,2 Peter Van,1,2 Renu Gupta,1,2 Clifton Frilot,2 1Nephrology, Veterans Affairs Medical Center, Shreveport, LA; 2LSU Health, Shreveport, LA.

Background: The Fistula First initiative has successfully increased the placement of arteriovenous fistulae (AVF) for vascular access. Some authors have suggested that there is a higher failure rate of AVFs in elderly patients. The purpose of this study was to determine if elderly age influences the overall survival of transposed brachial-basilic fistulae (TBBF) and non-transposed AVFs (NT) placed in the upper extremity (UE).

Methods: Our prospective, computerized clinical database was queried retrospectively to identify the survival outcomes of all upper extremity (UE) fistulae placed in CKD and ESRD patients over a 6-year period at our VA hospital. All fistulae were placed by a single surgeon, hence eliminating inter-operator variability. Patient demographics and comorbid conditions were noted from the electronic record. The primary end point was permanent failure of the access. Kaplan Meier survival analysis was performed using SPSS.

Results: 230 UE fistulae were placed, which were categorized into two groups by patient age at the time of AVF placement: < 75 years and 75 years and older. The table shows the distribution by access type and age.

<table>
<thead>
<tr>
<th>Age</th>
<th>Type of AVF</th>

</tr>
</tbody>
</table>

The figure shows that there was no difference in the Kaplan-Meier survival curves for the two age groups when NT and TBBF were analyzed collectively (P=0.996). Furthermore, there was no statistical difference between the survival curves when each group above was analyzed separately (P=0.996).

Conclusions: In conclusion, overall survival was similar for TBBF and NT AVF in our study and was not influenced by elderly age. This finding is contrary to popular opinion and some other reports.

TH-PO863

Peripherally Inserted Central Catheter (PICC) Placement in Hemodialysis Patients with Central Venous Catheters (CVC)

Rita L. McGill, Robin Ruthazer, Klemens B. Meyer, Dana Miskulin, Daniel E. Weiner. Tufts Medical Center, Boston, MA.

Background: PICC insertion threatens opportunities for AVF creation and may reduce achievement of AVF. Accordingly, we evaluated the incidence of PICC placement in ESRD patients after starting dialysis and in the 2 years prior to starting dialysis, and recognizing that AVF rates are lower in women, whether PICC rates differed by sex.

Methods: After restricting to patients with pre-dialysis Medicare claims, we used CPT codes to ascertain all PICCs placed during the 2 years before HD initiation and up to 12/31/2012 in the subset of adult HD patients entering USRDS in 2010 or 2011 with CVC as sole vascular access. Accounting for censoring due to death and ESRD modality treatment change, and using Poisson regression to adjust for age, race, BMI, diabetes and peripheral vascular disease, we calculated sex-based incidence ratios (IRR) using PICC per 100,000 patient months.

Results: PICC were placed in 2437 (14.6%) of women and 2250 (12.2%) of men.

<td>3331</td>
</tr>
</tbody>
</table>

Compared to men, crude and adjusted IRR of PICC for female sex were 1.35 [1.28-1.41] and 1.34 [1.27-1.41]. Multiple PICC (range= 2 to 14) were placed in 648/2260 (29%) men and 803/2437 (33%) women who had any PICC.

Conclusions: Despite persuasive indications for PICC avoidance, people dialyzing via CVC frequently receive one or more PICC before and even after starting dialysis. The PICC rate was 35% higher in women, a difference not attenuated by adjustment for demographic and clinical factors. More frequent PICC placement may explain some of the lower fistula rate in women. Eliminating frequent PICC placements in patients with CVC may improve achievement of AVF.

Arteriovenous Fistula Outcomes in an Elderly UK Population

Agnes Masenga,1,2 Jennifer B. Hanko,1 Alexander P. Maxwell,1,2 Regional Nephrology Unit, Belfast City Hospital, Belfast, County Antrim, United Kingdom; 2Nephrology Research Group, Queen’s Univ Belfast, Belfast, County Antrim, United Kingdom.

Background: The merit of placing arteriovenous fistulas (AVFs) in the elderly is debated in the literature. We sought to investigate AVF outcomes in the population aged ≥ 65 years in our region.

Methods: The Northern Ireland Vascular Access Database incorporates vascular access data on patients with chronic kidney disease stage 4 and 5. The database includes information on all patients ≥ 65 years who had an AVF created during January 2009-December 2014 and had a functional outcome by the 1st March 2015. Functional AVF patency was defined as sustained 2-needle use on hemodialysis for at least 6 sessions. Failure to mature (FTM) was defined by either clinical examination or failure to sustain 6 sessions of 2-needle dialysis.

Results: During the study period 344 patients ≥ 65 years had an AVF created. One AVF failed immediately, three AVFs were ligated due to steal, 56 patients had not started dialysis by the study end-point and records were incomplete for 30 patients. A total of 254 patients (98% White) remained included for functional AVF patency analysis. Table 1: Clinical Characteristics of Patients ≥ 65 years with AVF Patency Outcomes (n=254)

<tr>
<td>Lower arm AVF</td>
<td>134 (53)</td>
</tr>
</tbody>
</table>

A total of 150 AVFs (59%) achieved functional patency and 105 (41%)FTM. Binary logistic regression revealed that a lower arm AVF in this elderly population was associated with FTM (p < 0.001, OR 0.13- 0.40).

Conclusions: Given their shorter life-expectancy, the goal of vascular access creation in the elderly should be to create one functional AVF using the best vessels identified. The greater risk of FTM with lower arm AVFs may mean preferential creation of an upper arm AVF if these vessels are better on clinical and ultrasound assessment.

**Type of Vascular Access and Mortality in Japan**

Toshikazu Ozeki,¹ Shun Minatoguchi,¹ Yukako Ohyama,¹ Hideaki Shimizu,¹ Yoshio Fujita,¹ Daijo Inaguma.¹ ¹Nephrology, Chubu Rosai Hospital, Nagoya, Japan; ²Nephrology, Nagoya Daini Red Cross Hospital, Nagoya, Japan.

**Background:** The National Kidney Foundation (NKF) Kidney Disease Outcome Quality Initiative (KDOQI) guidelines have recommended the use of AVFs at dialysis initiation of dialysis. However, it has been reported that the dialysis environment has been significantly different between Japan and the United States, and there are few people who continue hemodialysis with CVCs in Japan. The aim of this study is to examine the association between type of vascular access at dialysis initiation and mortality in Japan.

**Methods:** This study is retrospective, multicenter, cohort study which data was collected by "Aichi Cohort study of Prognosis in Patients" (AICOPP) newly initiated into dialysis. 18 tertiary care centers in Japan participating in the "AICOPP". This study enrolled 1,525 patients who started maintenance dialysis between October 1, 2011 and March 31, 2014. After exclusion of 129 patients who started peritoneal dialysis or without data, 1329 (87.1%) patients were enrolled. Cox regression was used to determine the effect of access type on total mortality. Type of vascular access was divided into four categories: AVFs, AVGs, CVCs changed to AVF during the course (CAVF), CVCs changed to AVG during the course (CAGV).

**Results:** This research showed prevalence of type of blood access in Japan.

Under multivariate analysis, CAVGs had a higher risk of mortality compared with AVFs group [hazard ratio (HR): 2.408, p value: 0.003]. No significant differences were observed compared AVFs with AVGs and CAVFs [hazard ratio (HR): 1.223, p value: 0.389].

**Conclusions:** As it is known, high AVF use was seen in Japan. Compared with AVFs, using CVCs changed to AVG during the course is associated with higher risks of mortality.

**TH-PO866**

**Comparison of Arteriovenous Fistula and Arteriovenous Graft on Patient Survival and Access Patency in Non-Elderly versus Elderly Population**

Hoon suk Park, Min Seok Choi, Woo Jeong Kim, Sung jun Kim, Hyung Wook Kim, Cheol Whee Park, Bum soon Choi, Byung ha Chung, Chul Woo Yang, Dong-chan Jin. Div of Nephrology, Dept of Internal Medicine, College of Medicine, The Catholic Univ. Korea.

**Background:** Arteriovenous fistula (AVF) is generally known to be the ideal option for vascular access. However, this consensus can be challenging in elderly population.

**Methods:** From August in 2008 to April in 2014, 1,452 adult incident hemodialysis patients were included from Clinical Research Center registry for ESRD prospective cohort, from 31 centers in the South Korea.

**Results:** In the whole population, AVF vs. AVG use was associated with the better patient survival only in male (p < 0.001) and DM (p = 0.004) patients. Multivariate Cox regression analysis showed AVG vs. AVF, odds ratio [OR] 2.308, 95% confidence interval [CI]: 1.013–4.829, p = 0.026), catheter (vs. AVF; OR 16.658, 95% CI: 5.379–21.19; p < 0.001) and age (OR 1.035, 95% CI: 1.013–4.829; p = 0.026) were related to V A failure event. Native AVF, higher blood flow volume (≥500 ml/min), lower TAT (<3 ng/ml) and higher PAI–1 (≥7 ng/ml) were associated with good patency rates. The Kaplan–Meier analysis showed both higher TAT (p=0.0026) and lower PAI–1 (Figure 1) were significantly associated with VA failure. Cox regression analysis revealed that higher TAT (HR 2.140, 95%CI 1.288–3.556, p=0.0033) and lower PAI–1 (HR 2.322, 95%CI 1.390–3.800, p=0.0013) were related to VA failure event.

**Conclusions:** The present research indicates that VA failure after PTA might be associated with abnormality in the fibrinolysis system as well as activated coagulation.

**TH-PO867**

**Abnormality of Fibrinolysis as well as Coagulation Were Associated with Second Patency Rates of Vascular Access in Hemodialyzed Patients**

Yukiko Haseake,¹ Naoto Kakita,² Takashi Nakanishi.¹ ¹Div of Kidney and Dialysis, Dept of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan; ²Vascular Access Center, Tanaka-Kitamin, Japan.

**Background:** Vascular access (VA) is essential for the HD patients. However, VA is often occluded even after the percutaneous-transluminal angioplasty (PTA). There is increasing evidence indicating the importance of the fibrinolysis system (i.e., plasminogen activator inhibitor-1 (PAI–1) level) in the progression of vascular disease. We intended to clarify whether coagulation and fibrinolysis might be associated with VA failure after PTA.

**Methods:** Blood samples were taken from 262 HD patients at the PTA. Thrombin/anti-thrombin (TAT) as a marker of coagulation, PAI–1, D-dimer, anti-thrombin (TAT) and PAI–1 as markers of fibrinolysis system, and laboratory data were measured. Blood flow volume of VA was evaluated by Doppler ultrasonography before PTA. The end point was the re-vascularization or re-operation of VA during the observation period after PTA. The results were analyzed using univariate (Kaplan-Meier methods) and Cox regression analyses.

**Results:** Age of patients was 70.6±9.7 years, and 121 patients (46.2%) have native arteriovenous fistula (AVF). During follow-up period, re-PTA was performed in 33 patients and re-operation in 28 patients. Native AVF, higher blood flow volume (≥500 ml/min), lower TAT (<3 ng/ml), and higher PAI–1 (≥7 ng/ml) were associated with good patency rates.

**Conclusions:** The maturation process of an AVF introduces geometric effects in arch blood flow dynamics. Low WSS may contribute to endothelial cell damage, subsequent intimal hyperplasia, and resultant CAS. If this hypothesis remains tenable with further studies, ways of protecting the arch through control of flow during maturation of the fistula, or alternatives to the BCF, may need to be developed.

Dilator-Assisted Banding and Beyond: Proposing an Algorithm for Managing Dialysis Access-Associated Steal Syndrome

Showwen Wang, AKDHIC Access Centers, Arizona Kidney Disease and Hypertension Center; Phoenix, AZ.

**Background:** Dialysis Access-associated Steal Syndrome (DASS) is a major complication of arteriovenous dialysis accesses and its proper management is of critical clinical importance. However, the reported approaches are diverse and general consensus is lacking. Recently, guided banding approaches have gained popularity, as they are minimally invasive. This report analyzes the clinical outcome of Dilator-assisted Banding (DAB), a simple technique initially described by the author for managing DASS.

**Methods:** This series included 30 patients that underwent DAB for DASS due to excessive dialysis access flow.

**Results:** Of the 30 patients: 29 had upper arm fistulas or grafts and 1 had a forearm fistula; 23 had arteriogram -3 of which required angioplasty ± stent for feeding artery stenosis. The DAB procedures included: intraluminal DAB (12/30), extraluminal DAB (14/30) and open fistula reduction plus DAB (4/30). After DAB, the average severity scores of ischemic symptoms was reduced from 2.8 ± 0.4 to 0.2 ± 0.4 for the fistula group (n=24, p<0.001) and from 3.0 ± 0.0 to 1.2 ± 1.2 for the graft group (n=6, p=0.041). Of the 24 patients with fistula, 19 had resolution of ischemic symptoms and 5 had minimal residual symptoms while 3 had finger necrosis that healed after DAB. Of the 6 patients with graft, 2 had resolution, 2 had minimal residual and 2 had no change of ischemic symptoms. These two DAB-ineffective patients underwent proximalization of arterial inflow (PAI) revisions that resulted in resolution of ischemic symptoms. During follow-up of 18.7 ± 14.5 months (range 1-50), all dialysis accesses remained functional. At 24-month post-DAB, the primary, secondary and tertiary patency were 72%, 91% and 100%, respectively.

**Conclusions:** DAB is a simple, effective and versatile approach for managing DASS due to excessive flow, especially in patients with fistula. In patients with failed banding, PAI can be effectively used for rescue. Based on the data in this series and the literature, an algorithm is proposed for managing DASS.

Outcomes of Vascular Access Creation in Incident Hemodialysis Patients in Singapore

Nicholette Goh,1 Chiel-sui Tan,2 Shaam Aachudan,1 Yi liang Tan,1 Kian Guan Lee,1 Hui-Lin Choong,2 Tze tec Chong,1 1National Univ of Singapore; 2Renal Medicine, Singapore General Hospital; 3Vascular Surgery, Singapore General Hospital.

**Background:** Hemodialysis is the main modality of renal replacement therapy for end-stage renal disease (ESRD) patients in Singapore. Vascular access is critical for effective therapy. This study examined the impact of pre-operative vein mapping on vascular access creation in patients newly initiated on hemodialysis in Singapore General Hospital.

**Methods:** Data of ESRD patients initiated on hemodialysis from January 2010 to December 2012 were retrospectively collected from electronic medical records. 708 patients (mean 62.8 ± 12 years old, 61% male, 71.3% Chinese) who underwent surgical creation of 14.5 months (range 1-50), all dialysis accesses remained functional. At 24-month post-DAB, the primary, secondary and tertiary patency were 72%, 91% and 100%, respectively.

**Conclusions:** In conclusion, successful vascular access creation can be accomplished by 51% (pre: 1.69, post: 0.82). At EDGB, the infection rate increased by 12% (pre: 1.80; post: 2.02) while the infection rate increased by 35% (pre: 0.91; post: 1.23) at EDN. However, none of these increases in infection rates were significant (i.e., p<0.05). The infection rates at EDGB and EDN decreased significantly in phase 2 by 86% (pre: 1.86, post: 0.26), and 53% (pre: 1.89, post: 0.88), respectively. At EDC, the infection rate did not change significantly in phase 2.

**Conclusions:** The use of Tegaderm CHG dressing was associated with decreased rates of CRBSI at Emory outpatient dialysis units.

---

Uremia Induced Gene Expression in a Mouse Model of Arteriovenous Fistula Stenosis

**Background:** Arteriovenous fistula (AVF) non-maturation remains a huge clinical problem resulting in significant morbidity and mortality. Unfortunately most animal models of AVF stenosis do not incorporate uremia. As a result, the molecular mechanisms by which uremia contributes to AVF dysfunction remain unknown. The aim of this study was to assess the impact of uremia on the expression of genes associated with the pathogenesis of AVF dysfunction using a uremic mouse model of AVF stenosis.

**Methods:** Mice were made uremic by cation of one kidney, followed by contralateral nephrectomy. After 4 weeks, an end to side anastomosis was created between the jugular vein and carotid artery. Contralateral vessels were served as controls. Vessels were harvested after 14 days, and RNA isolated from the AVF venous segment. Gene expression of different mediators was measured with qPCR. Data was analyzed from control vein; uremic vein; veins of non-uremic AVFs; and veins of uremic AVFs.

**Results:** Significant upregulation in the expression of monocyte chemotactic protein-1 (MCP1), NADPH Oxidase (NOX4), and E-Selectin were found within the veins of AVFs compared to wild-type control vessels (P<0.017 for each gene). Compared to normal vein, MCP1 expression was increased 4.4, 14.0, and 49.1 fold in uremic vein, the non-uremic AVFs, and uremic AVFs respectively. Paradoxical increases in Krippel-like factor-2 (KLF-2) were also seen in uremic vessels compared to wild-type veins (P<0.017).

**Conclusions:** In summary, marked upregulation of the proteins MCP-1, NOX4, and E-Selectin were seen with uremia, and some of these (MCP-1) were further elevated within the AVF. Of note, the flow sensitive gene KLF2 was also elevated in uremia, but was attenuated in the setting of an AVF. These preliminary findings suggest key pathways by which uremia could exacerbate AVF dysfunction and future targets for the prevention and treatment of AVF maturation failure.
TH-PO873
In-Patient Permanent Access Is Associated with Reduced Catheter Time for Emergent Start Hemodialysis Patients  Catherine A. Moore, Richard E. Wing, Scott E. Liebman. Medicine-Nephrology Div, Univ of Rochester, Rochester, NY, Aurora Medical Group, Marinette Menominee Clinic, Marinette, WI.

Background: Hemodialysis initiation with a tunneled catheter carries increased risk of morbidity and mortality. Conversion from a hemodialysis catheter to permanent access at any time is associated with improved outcomes. This study investigates whether a strategy of placing permanent dialysis access in incident HD patients without permanent access while still hospitalized is associated with reduced exposure to hemodialysis catheters.

Methods: We conducted a retrospective cohort study of ESRD patients initiating hemodialysis with a catheter while hospitalized at a single University Hospital Medical Center from October 2010 through June 2013. Patients were divided into two groups: those with permanent access placed during the hospitalization (N = 22) vs. those discharged without permanent access (N = 67). Our primary endpoint was removal of the hemodialysis catheter.

Results: Subjects who underwent permanent access placement while still hospitalized had a median catheter exposure time of 114 days compared with 241 days for those who did not. The median time with HD catheter in place was shorter by 127 days in the group with permanent access placed during the hospitalization (N = 22) vs. those discharged without permanent access (N = 67). Our primary endpoint was removal of the hemodialysis catheter.

Conclusions: Subjects who underwent permanent access placement while still hospitalized had a median catheter exposure time of 114 days compared with 241 days for those who did not. The median time with HD catheter in place was shorter by 127 days in the group with permanent access placed during the hospitalization (N = 22) vs. those discharged without permanent access (N = 67). Our primary endpoint was removal of the hemodialysis catheter.

TH-PO874
Factors Affecting Haemodialysis Arterio-Venous Fistula Maturation Hannah R. Wilson, Salman Ahmed, Joseph Russell, Nicola Ding, Maggi Steele, Aysha Irtiza-Ali, David Makanjuola, Nihil Chitalia. Renal Unit, St. Helier Hospital, Surrey, United Kingdom.

Background: Arterio-venous fistulae (AVF) are the preferred access for haemodialysis (HD). Many AVFs however, fail to mature. We investigated the factors affecting maturation of AVFs in order to identify any characteristics which were predictive of AVF maturation.

Methods: All AVFs created between 2006 and 2014 were reviewed. Data analysis was performed using GraphPad. AVFs were deemed to have failed to mature if by 90 days from initial AVF clearance for use to TCC removal. Optimal site for cannulation, needle length and size. Infiltration rates, subsequent procedures and hospitalizations were noted before and after CMUD use and cannulation failure days was evaluated initially for 1-2 dialysis sessions with CMUD for course, depth from skin, optimal site for cannulation, needle length and size. Infiltration rates, subsequent procedures and hospitalizations were noted before and after CMUD use and cannulation failure days (days from initial VA clearance for use to TCC removal).

Conclusions: The practice of placing permanent access while the patient is still admitted to the hospital is associated with greater likelihood of hemodialysis catheter removal.

TH-PO875
Hand Held Ultrasound Device Solves Vascular Access (VA) Cannulation Problems Beth Adams, Vivek Soi, Jerry Yee, Lalathaksha Murthy Kumar. Henry Ford Hospital, Detroit, MI.

Background: The Fistula First Catheter Last workgroup coalition identifies VA cannulation as a fundamental “failure” point in optimizing arteriovenous fistula (AVF) usage. Infiltration from cannulation difficulties result in significant morbidity including loss of VA and cost. Cannulation success is reliant on cannulators' skill and VA characteristics. Surface marking of VA to aid cannulation is frequently used but lacks real time information. Traditional ultrasound devices are expensive and need skilled operators rendering inapt for routine use in hemodialysis units. Sonic Window© (Analogic Ultrasound) is a coronal mode ultrasound device (CMUD) approved for VA cannulation. We present our early experience in using this novel hand held CMUD for real time guidance of AVF cannulation.

Methods: Three patients with cannulation failure defined as inability to achieve 3 needle cannulations leading to tunnel cuffed catheter (TCC) removal were identified. AVF was evaluated initially for 1-2 dialysis sessions with CMUD for course, depth from skin, optimal site for cannulation, needle length and size. Infiltration rates, subsequent procedures and hospitalizations were noted before and after CMUD use and cannulation failure days (days from initial VA clearance for use to TCC removal).

Conclusion: Our data show that the timing of AVF creation is important; those formed pre-emptively are more likely to mature than those created when the patient is on dialysis. It is possible that the presence of a dialysis line might delay maturation, especially if it is ipsilateral to the AVF.

All 3 AVF were successfully cannulated leading to TCC removal within 21 days of CMUD guidance. CMUD usage resulted in no cannulation related complications and no subsequent revision procedures.

Conclusion: CMUD guided cannulation of dialysis access is feasible and safe. Real time ultrasound guidance mitigates cannulation failure and catheter removal.

Reaching First Dialysis Quickly and Unassisted with Sirolimus Treated Fistulae – Serial Ultrasound Results and Clinical Outcomes

Maria V. DeVita,1 Eric S. Chenlla,2 Konstantine B. Kipiani,2 Nutsa K. Beridze,3 Sriram Iyer,1 Wendy Turenne,1 Hemodialysis (HD) Patients Related Blood Stream Infections (BSI) and Occlusions Among Incident

Background: Neointimal hyperplasia (NH) resulting in a flow limiting stenosis within the juxta-anastomotic segment (JAS) of an AV Fistula (AVF), impairs increase in upstream vein diameter (VD), often requires supplementary procedures and prolongs time to 1st cannulation for dialysis (D). Sirolimus delivered locally to the vessel wall can suppress NH and preserve lumen patency (“sirolimus effect”).

Methods: 30 pts (29 on D) undergoing AV Surgery [22 Radiocephalic (RCF), 8 Brachiocephalic fistulae (BCF)] received a Sirolimus eluting clamping implant at and around the JAS. 1st cannulation was based on clinical evaluation.

Results: 18 males, mean age 50.8y, 20% diabetic. Analysis excludes 4/22 RCF that thrombosed 2 weeks; 18/22 RCF (88%) and all 8 BCF maintained Primary Patency (PP) prior to first cannulation (mean 49 days); 13 AVF were cannulated ≤6wks, 74% AVF maintained suitability for D with PP at 12mos. Table shows serial Ultrasound results.

Conclusions: 1.Maximum % increase in VD occurred within 8hrs of surgery with gradual continued increments thereafter. 2 At 4, 6 and 8wks, VD of 6mm was attained by 62%, 81% and 100% of the AVF respectively. 3. 26/30 A VF(87%) maintained PP before cannulation for dialysis (D). Sirolimus delivered locally to the vessel wall can suppress NH and preserve lumen patency (“sirolimus effect”).

TH-PO877

Economic Burden to Medicare of Central Venous Catheter (CVC)-Related Blood Stream Infections (BSI) and Occlusions Among Incident Hemodialysis (HD) Patients

Background: Episodes of CVC-related BSI and occlusion in HD patients result in hospitalizations and vascular access-related procedures, with attendant increases in costs. We sought to quantify this burden to the payor among Medicare-enrolled patients at a large dialysis organization.

Methods: Patients received HD via CVC during 2011 and were enrolled in Medicare Parts A and B. In parallel analyses, patients who developed BSI (N=1413) or occlusion (N=793) were matched with controls, who did not, on the basis of entry month and baseline characteristics. Comparisons were made using linear regression modeling.

Results: CVC-related BSI was associated with greater rate of hospitalization (incidence rate difference [IRD], 4.00 events/patient-year) and vascular-related procedures (IRD, 2.87 events/patient-year). Mean per patient per month (PPPM) costs were $2354 greater for occlusion patients versus controls, driven by higher ancillary service and procedure costs.

Conclusions: CVC-related BSI and occlusion are potent cost drivers for Medicare. Risk mitigation strategies to prevent BSIs and occlusions should prove to reduce systemic health care costs.

294A
Impact of DPP-4 Inhibitors on Hemodialysis Vascular Access Dysfunction

Background: Autoagorous arterio-venous fistulas is an optimal vascular access for haemodialysis. Arterio-venous fistula is not faultless and up to 40% of fistulae never mature. In patients with no possibilities to create effective native arterio-venous fistula haemodialysis with using a proper prostheses give a chance to avoid a central venous catheter (CVC).

The aim of the study was to evaluate of usefulness polyurethane prosthesis as an emergency vascular access for haemodialysis.

Methods: The study involved 23 patients, 18 men and 5 women, at 29 – 83 years. Eight patients were in predialysis period, for 17 patients (2 in predialysis) it was a secondary emergency vascular access for haemodialysis. For others it was an elective operation.

Results: The longest observation period was over 36 months. Twenty one grafts were successfully cannulated within 24 hours. No differences were observed between diabetic and non-diabetic patients.

Conclusions: Implantation of polyurethane prosthesis provides an effective vascular access for dialysis and enables avoidance of CVC. Low infection rate improves the final outcome.

TH-PO880

Impact of DPP-4 Inhibitors on Hemodialysis Vascular Access Dysfunction

Background: The maintenance of arteriovenous fistula (AVF) is crucial for hemodialysis patients and reduction of complications remains a challenge. Previous reports show that patients with diabetes mellitus is more likely to have AVF dysfunction than those with other underlying diseases. Also, elevated inflammatory cytokine such as IL-6 is known to be associated with AVF dysfunction. Recently, dipeptidyl peptidase 4 inhibitors (DPP4-I) were known to have pleiotropic action including anti-inflammation that decrease IL-6. Thus, we hypothesized that DPP4-I could improve AVF outcome by decreasing inflammatory cytokines.

Methods: The study population included 157 consecutive patients newly starting hemodialysis between 2011 and 2012 with diabetic nephropathy. AVF dysfunction was tracked for 2 years; criteria of which include complete obstruction, insufficient inflow and uniform thrill. AVF survival between patients treated with DPP4-I (n=54) and without DPP4-I (n=103) was investigated using Kaplan Meier and Cox regression analysis. Serum IL-6 level was analyzed by ELISA.

Results: Baseline characteristics were identical between 2 groups in age, sex, blood pressure, body mass index, history of congestive heart failure and coronary artery disease. There was no difference in AVF survival between the groups (DPP4-I: 453±36 vs without DPP4-I: 464±28 days, p=0.81, Log-rank), although serum IL-6 levels were significantly lower in patients with DPP4-I (with DPP4-I: 5.0±1.9 vs without DPP4-I: 10.5±7.2 pg/ml, p=0.03). Among other drugs, no correlation was indicated between AVF dysfunction with insulin, RAS blocker, other antihypertensive drugs nor antplatelet agents.

Conclusions: DPP4-I did not show any advantage in AVF outcome despite anti-inflammatory effect of lowering serum IL-6 level.
Results: There are 1002 haemodialysis patients; 412 dieyse via a CVHC.

CVHC age was statistically different depending on the indication; occluded CVHC age was 124±22 vs 244±27 days for low Qb (p=0.01). Rescued CVHC age was significantly lower than those in whom the altpelase was unsuccessful (147±18.4 vs 269±35.8, P<0.0001). In 48% of patients with an occluded CVHC, flow was restored; the remaining 52% required further intervention. Low Qb CVHC success rate was 60% compared to 38% requiring further intervention, 2% were removed (arteriovenous fistula or transplant). There was no significant difference between success rates depending on the indication (P>0.34).

Altpelase infusion significantly increased litres processed in subsequent dialysis sessions, in whom the indication was low Qb (6.2±1.16 litres, P<0.0001). Overall of all infusions undertaken; 1 month patency was 56%, 3 months 45% and 6% removed. No patient had an adverse bleeding event as a result of the altpelase infusion.

Conclusions: Altpelase infusion use is common; approximately once a week in our centre. Interestingly, complete occlusion of CVHC occurs early, possibly suggesting rapid growth of fibrin following insertion. Total litres processed improves after an altpelase infusion in over half of patients. This study demonstrates the safety and success rates of an altpelase infusion, providing evidence for its role prior to replacing the CVHC and importance in saving resources.

TH-PO884
Accelerated Arterial Stiffening in Vitamin-K-Antagonist-Treated Hemodialysis Patients

Christopher D. Peters, Krista D. Jørggaard, J. Dam Jensen, Bente Jespersen. Dept of Renal Medicine, Aarhus Univ Hospital, Aarhus, Denmark.

Background: Many hemodialysis (HD) patients are treated with vitamin-K-antagonists (VKA) in order to prevent thromboembolic events. A potential side effect to VKA treatment is an increase in soft tissue calcification due to the inhibitory effect of VKAs on the central (liver) and peripheral (e.g. vascular) carboxylation cycle synthesis of several vitamin K-dependant calcification-inhibiting factors. The aim of the present study was to investigate the impact of VKA-treatment on arterial stiffness in a longitudinal, prospective comparative study.

Methods: Seventy-five HD patients from the SAFIR study with urine output >300 mL/day and HD-vintage <1 year were divided into controls (n=67) and VKA-treated (n=8) and followed for one year. The groups were well matched according to age, sex, comorbidity, and intervention (placebo/irbesartan). Arterial stiffness was assessed with carotid-femoral pulse wave velocity (PWV) and pulse wave analysis using the SphygmoCor device.

Results: Blood pressure (BP), PWV, and glomerular filtration rate (GFR) were similar at baseline (controls/VKA-treated) systolic BP: 148±20/145±17 mmHg; PWV: 11.6±3.2/11.0±3.9 m/s; GFR: 53±5.3/5.1±1.7 m²/min.

Discussion and Future Plans: Our findings indicate that VKA-treatment increases arterial stiffening significantly. We speculate that vitamin K-dependant calcification-inhibiting factors in HD patients may be inadvertently affected by VKA treatment.

**Different Impact of Malnutrition-Inflammation and Metabolic Syndrome on Long-Term Mortality and Cardiovascular Events in Hemodialysis Patients**

*Naoki Nakaagawa, Renal Div, Dept of Internal Medicine, Asahikawa Medical Univ, Asahikawa, Hokkaido, Japan.*

**Background:** Malnutrition syndrome confers an increased risk of cardiovascular disease (CVD) in the general population. The relationship between adiponectin, and clinical outcomes in hemodialysis patients remains controversial. We investigated whether adiponectin, biomarkers of inflammation, nutrition status and clinical features predict the mortality of hemodialysis patients for 6 years.

**Methods:** We measured baseline plasma total and high-molecular-weight (HMW) adiponectin, tumor necrosis factor (TNF-α), serum high sensitivity C-reactive protein (hsCRP), and clinical characteristics including visceral fat area (VFA) and the Geriatric Nutritional Risk Index (GNI) in 133 hemodialysis patients.

**Results:** During the 6-year follow up period, 41 (30.9%) patients died (heart failure, n = 13; acute myocardial infarction, n = 11; stroke, n = 2; infection, n = 10; and malignant cancer, n = 5). The deceased patients were significantly older, had more prior CVD and diabetes, higher TNF-α and hsCRP levels but lower GNI, VFA, and total and HMW adiponectin did not significantly differ between the two groups. TNF-α and hsCRP levels and GNI score were significant for predicting all-cause and cardiovascular mortality in receiver operating curve analyses. The present ROC curve analysis for all-cause 6-year mortality found the predictive value of GNI for mortality was 96. When stratified by a GNI score of 96, Cox proportional hazards analyses identified TNF-α as a significant predictor of all-cause mortality (hazard ratio [HR] 1.23; P = 0.038) and hsCRP as a significant predictor of all-cause and cardiovascular mortality (HR, 2.32; P = 0.003; HR, 2.30, P = 0.012, respectively) after adjusting for age, sex, diabetes mellitus, and prior CVD, only in malnourished patients.

**Conclusions:** These results demonstrate that malnutrition and the inflammatory markers TNF-α and hsCRP, but not metabolic markers, including VFA and adiponectin, have a significant impact on 6-year all-cause and cardiovascular mortality in hemodialysis patients.

**Associations of the Malnutrition-Inflammation Complex Syndrome with Depression Symptoms, Kidney-Disease Targeted Quality of Life Measures and Mortality in a Hemodialysis Population of Predominantly African Descent**

*Marcelo Barreto Lopes,1 Raisa B. Peixoto,1 Priscila S. Carvalho,1 Jean M. Monteiro,1 Jessica S. Fernandes,1 Pedro Guimarães Silva,1 Luciana Ferreira Silva,2 Gildele Barreto Lopes,3 Antonio Alberto Lopes.1 1Univ Federal da Bahia, 2Univ do Estado da Bahia, Salvador, BA, Brazil.*

**Background:** The malnutrition-inflammation score (MIS) has been used to assess protein-energy wasting (PEW), also named malnutrition-inflammation complex syndrome, in maintenance hemodialysis (MHD) patients. Higher MIS has been associated with poorer outcomes in MHD patients but remains unclear if MIS expands the predictive power for outcomes in relation to its ten components and if the published results may be generalized for populations not targeted by previous investigations. We assessed associations of MIS and its components with mortality and patient-reported outcomes, i.e., health-related quality of life (HRQOL) and depression symptoms in a MHD population predominantly of African descent.

**Methods:** Prospective cohort (PROHEMO) of 632 MHD patients (92% Black or mixed race) treated in Salvador, Brazil. The predictor was MIS (range: 0-30, higher worse) and the outcomes were all-cause and cardiovascular mortality, depressive symptoms by CES-D. Multivariable linear regression was used for differences in scores of MIS components with differences > 4 points. Four of the 10 MIS components were depression symptoms and poorer HRQOL, including physical, mental and kidney-disease targeted HRQOL scales with differences > 4 points. Four of the 10 MIS components were depression symptoms and poorer HRQOL, including physical, mental and kidney-disease targeted HRQOL scales with differences > 4 points.

**Results:** The consistent associations of MIS with mortality, HRQOL and depression symptoms were up-regulated in CKD3-4 compared with CVD. CKD1-2 and CVD group differed in the isoform of alpha 1 microglobulin and were higher in CKD5 compared with CVD; fold changes by 20%–40% for MIS components were proposed.

**Conclusions:** These results demonstrate that malnutrition and the inflammatory markers MIS components with mortality and patient-reported outcomes support the importance of combining PEW components to assess health status and risks of outcomes in MHD patients. The observed results in a predominantly African descent population expand support to MIS as a valid predictor of outcomes in different MHD populations.

**Non-Traditional Risk Factors Predict Atherosclerotic Events in Haemodialysis Patients – Post-Hoc Analyses of the AURORA Trial**

*Marti D. Solà,1,2 Geir Møes,1 Patrick B. Mark,1,2 Hallvard Holdaas,1 Bengt C. Fellenström,1 Alan G. Jardine,1,4 1Inst of Cardiovascular and Medical Sciences, Univ of Glasgow, Glasgow, United Kingdom; 2Section of Nephrology, Univ Hospital of North Norway, Tromsø, Norway; 3Dept of Nephrology, Ullevål Univ Hospital, Oslo, Norway; 4Dept of Transplantation Medicine, Oslo Univ Hospital Rikshospitalet, Oslo, Norway; 5Div of Nephrology, Uppsala Univ Hospital, Uppsala, Sweden.*

**Background:** Patients on haemodialysis are at high risk for cardiovascular events, but heart failure and sudden death dominate and atherosclerotic events are less common. The AURORA trial was designed to assess the effect of rosuvastatin on myocardial infarction (MI) and death from any cardiac cause in haemodialysis patients. We studied predictors of the atherosclerotic, and not all cardiovascular, events in AURORA.

**Methods:** We reidentified all deaths and presumed myocardial infarctions according to stricter criteria to separate atherosclerotic from non-atherosclerotic cardiovascular events. The readjudicated atherosclerotic endpoint included non-fatal myocardial infarction, fatal coronary heart disease, non-fatal and fatal non-haemorrhagic stroke, revascularisation procedures and death from ischaemic limb disease. Baseline predictors were assessed for the 2776 participants of the AURORA trial, and step-wise Cox regression analysis was applied.

**Results:** During a mean follow-up of 3.2 years, 716 patients experienced a reidentified atherosclerotic event. Baseline phosphate (HR 1.33; 95% CI 1.16–1.53 per 1 mmol/L increase), albumin (HR 0.93; 95% CI 0.91–0.96 per 1 g/L increase) and high sensitive CRP (HR 1.07; 95% CI 1.00–1.14 per mg/L increase) were significant predictors in addition to female sex, age, prevalent diabetes and cardiovascular disease. LDL cholesterol was not a significant risk factor.

**Conclusions:** Even with the use of strict criteria for endpoint definition, non-traditional risk factors, but not lipid disturbances, predicted atherosclerotic events in haemodialysis patients.

**Funding:** Pharmaceutical Company Support - AstraZeneca, Government Support - Non-U.S.

**Proteomic Studies of Blood Plasma Using 2DE and Mass Spectrometry for Deeper View into the Mechanisms Involved in Atherosclerosis in Chronic Kidney Disease**

*Maria Wanic-Kosowska,1 Dorota Formanowicz,1 Elzbieta Pawlizak,1 1Dept of Nephrology, Transplantology and Internal Medicine, Poznan Univ of Medical Sciences, Poznan, Poland; 2Dept of Clinical Biochemistry, Poznan Univ of Medical Sciences, Poznan, Poland.*

**Background:** The exact participation and association of particular risk factors and specific mechanisms that promote cardiovascular complications (CVD) in patients with chronic kidney disease (CKD) remain unclear. The close relationship between CVD and CKD is most likely due to the co-existence of both traditional and novel risk factors. To gain insight into better recognition of the mechanisms of CKD-related accelerated atherosclerosis, a comparative proteomic analyses have been performed.

**Methods:** Blood samples were taken from 90 patients (CKD1-2, CKD3-4, CKD5), 30 patients with CVD, but without CKD and 30 healthy volunteers. Plasma samples were depleted using affinity chromatography and divided into three fractions: high-abundance protein, low-abundance protein and low molecular weight protein. The first two fractions were analyzed by two dimensional gel electrophoresis and mass spectrometry, the last one has been subjected to direct MS/MS analysis. Differential accumulated proteins were confirmed by selected reaction monitoring analysis.

**Results:** 49 proteins (13 high and 36 low molecular mass) showed differences in accumulation levels. The proteomic profiles in CKD5 and CVD patients differed in the accumulation of four LAPs the relative accumulations of alfα -2macroglobulin, second isoform of alfα 1 microglobulin and were higher in CKD5 compared with CVD; fold changes 1.77, 4.14, 2.68 and 1.79, respectively. Moreover, the relative abundances of these proteins were up-regulated in CKD3-4 compared with CVD. CKD1-2 and CVD group differed in the accumulation of apolipoprotein A-4 and apolipoprotein A-1.

**Conclusions:** Our results definitely indicated similar proteomic profiles in CKD1-2 and CVD patients, in contrast to CVD and CKD5 patients, suggesting that mechanisms of CVD acceleration may be different in initial and advanced stages of CKD. It seems that it is related to chronic inflammation and immune disturbances, typical for CKD.

**TH-PO890**

**Hemodialysis-Induced Release of Microparticles**

*Liina Vassal,1 Inga Sovieri,1 Fariborz Mobarez,2 Tora Almqvist,3 Bengt C. Fellenström,1 1Dept of Medical Sciences, Uppsala Univ, Uppsala, Sweden; 2Dept of Medicine, Karolinska Inst, Stockholm, Sweden; 3Dept of Clinical Sciences, Danderyd Hospital, Karolinska Inst, Stockholm, Sweden.*

**Background:** Microparticles (MPs) are 0.1–1.0 μm vesicles that are released from cells upon activation or during apoptosis. MPs are believed to be involved in the pathophysiology of atherosclerosis and thrombosis. Patients with cardiovascular risk factors have significant MP elevation. Measurements of MPs may uncover new insight into mechanisms behind the increased cardiovascular disease (CVD) risk in hemodialysis (HD) patients. The aim was to study whether a hemodialysis session affects MP formation and release.
Methods: Plasma samples from 20 HD patients were drawn before and 1h after the start of HD session. MPs derived from peripheral platelets (CD14+), monocytes (CD14+), endothelial cells (CD16+); and their expression of phosphatidylserine (PS) and tissue factor (CD142) were measured using flow cytometry. P-selectin (CD62P) and CD40 ligand (CD154) were measured on platelet-MPs. In addition, Klotho and the receptor for advanced glycation end products (RAGE) expression were measured on MPs. Paired t-test was used.

Results: Mean age was 73.6 years (range 54-91), 5 patients were female, 14 had central dialysis catheter, 8 patients had diabetes and 14 had CVD.

Mean (± SD) or a Median (range)

Conclusions: The majority of MP levels increase significantly after the start of a HD session. Whether this is driven by patient or dialysis specific factors remains unclear. The clinical significance of MP release during HD needs to be evaluated. Funding: Government Support - Non-U.S.

TH-PO891
The Monocyte Subset of CD14+CD16+ Cells Plays a Key Role of Promoting Atherosclerosis in Hemodialysis Patients
Miki Nishida,1 Minoru Ando,2 Yusuke Iwamoto,3 Yujiro Iwamoto,1 Ken Tsuchida,3 Kosaku Nitta.3 1Dept of Medicine, Kidney Center, Tokyo Women’s Medical University, Tokyo, Japan; 2Tokyo Metropolitan Komagome Hospital, Tokyo, Japan; 3Saitou Memorial Hospital, Tokyo, Japan.

Background: Atherosclerosis is closely associated with morbidity and mortality in hemodialysis (HD) patients. The scavenger receptors (SR) in circulating monocytes play a key role in promoting foam cell formation by binding and internalizing oxidized low-density lipoprotein. In addition, heterogeneity of monocytes and macrophage-phenotype stimulating factor (M-CSF) may facilitate the atherosclerotic process by SR over-expression.

Methods: Subjects included 62 HD patients and 30 healthy controls. Peripheral monocytes were isolated using magnetically labeled Whole Blood CD14+ micro-beads. Transcriptional levels of CD16 and SR-A were measured in monocytes by quantitative micro-beads. The scavenger receptor (SR) expression in circulating monocytes play a key role in promoting foam cell formation by binding and internalizing oxidized low-density lipoprotein. Furthermore, the role of CD16 and SR-A expression in HD patients were also investigated.

Results: A direct correlation was found between PICP and Left ventricular mass index (LVMi) and ejection fraction, ratio of peak early transmitral flow velocity to peak early diastolic annular velocity (E/E’ ratio), ratio of early transmitral flow velocity to peak late transmitral flow velocity (E/A ratio), and mitral valve-deceleration time (DT).

Conclusions: Serum procollagen type I carboxy-terminal propeptide (PICP) is associated with decreased mortality risk in our cohort, especially those due to cardiovascular causes. Interestingly, the inversely effect of ghrelin does not seem involved in described interaction.

TH-PO893
Procollagen Type I Carboxy-terminal Propeptide Is Associated with Left Ventricular Hypertrophy and Dysfunction, and May Predict Cardiovascular Event in Incidential Dialysis Patient
Sun Jung Kim,1 Hye Eun Yoon,2 Sungjin Chung,3 Seok Joon Shin.1 1Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Incheon, Korea; 2Dept of Internal Medicine, College of Medicine, The Catholic Univ of Korea, Korea.

Background: Serum procollagen type I carboxy-terminal propeptide (PICP) is a marker of myocardial fibrosis in hypertensive heart disease. However, the clinical significance of PICP in patients with less determined stages of vascular calcification is unknown. The aim of this study was to evaluate the association of predialysis serum PICP levels with echocardiographic markers in ESRD patients.

Methods: Serum PICP, albumin, CRP, iPTH levels were obtained from predialysis blood samples of 123 incidental dialysis patients. Echocardiographic parameters and predialysis left ventricular mass index (LVMi) and ejection fraction, ratio of peak early transmitral flow velocity to peak early diastolic annular velocity (E/E’ ratio), ratio of early transmitral flow velocity to peak late transmitral flow velocity (E/A ratio), and mitral valve-deceleration time (DT). The Cox proportional hazard regression model was used to evaluate the association of PICP levels and echocardiographic markers in ESRD patients.

Results: A direct correlation was found between PICP and Left ventricular mass index (r=0.380, P=0.002), between PICP and E/E’ ratio (r=0.236, P = 0.009), between PICP and ratio of peak early transmitral flow velocity to peak late transmitral flow velocity (E/A) (r=0.285, P=0.002). A negative correlation was found between PICP and Left ventricular ejection fraction (r=-0.289, P=0.001), between PICP and mitral valve-deceleration time (r=-0.203, P=0.026). In the multivariate linear regression analysis, the PICP was independently positively associated with LVMi and E/E’ and negatively associated with Left ventricular ejection fraction.

Conclusions: Serum procollagen type I carboxy-terminal propeptide (PICP) is associated with left ventricular hypertrophy and dysfunction, and may predict cardiovascular event in incidential dialysis patient.

TH-PO894
Associations of Soluble Receptor for Advanced Glycation End Products (s-RAGE) and Serum S100A12 (EN-RAGE) with Mortality in Long-Term Hemodialysis Patients
Jong Jong1, Eul Sik Jung,1 Byoungho Choi,1 Yun Jung Oh,3 Chungsik Lee,3 Ae Jin Kim,1 Han Ro,1 Jae Hyun Chang,1 Hyun Hee Lee,1 Wookyung Chung.1 1Div of Nephrology, Dept of Internal Medicine, Gachon Univ Gil Medical Center, Incheon, Republic of Korea; 2Div of Nephrology, Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea.

Background: Hemodialysis (HD) patients have been associated with vascular calcification and ultimately with high mortality rates. Formerly, we reported association of soluble receptor for advanced glycation end products (s-RAGE) and S100A12 (EN-RAGE) with cardiovascular disease and serum albumin level. We extended our observation whether these biomarkers could be proposed for predicting cardiovascular morbidity and mortality in these subjects.

Methods: This is a prospective observational cohort study in 199 HD patients from extended analyses of our previous study. Serum S-RAGE, S100A12, comorbidities, and other traditional risk factors were evaluated in univariate and multivariate analyses. The Cox proportional-hazards regression regression was used to evaluate the association of PICP levels and echocardiographic markers in ESRD patients. A mean observation period was 29 months.

Results: The patients were 57 ± 13.7 years of age; 54.3% were male, 49.2% were diabetic, and 36.2% had a history of cardiovascular disease. During the observation period, 77 patients (13.6%) were died. Univariate analysis demonstrated that S100A12 was correlated with diabetes (P = 0.04) and hs-CRP (P = 0.01). In multivariable analyses, serum s-RAGE (HR [hazard ratio], 1.16; 95% CI [confidence interval], 0.61-2.19; P = 0.65) and S100A12 (HR 1.05; 95% CI, 0.62-1.77; P = 0.87) were not associated with mortality in hemodialysis patients, though traditional predictors for mortality including age, history of cardiovascular diseases, serum albumin and high-sensitivity C reactive protein (hs-CRP) were related to mortality. Powerful predictors for mortality were age, previous cardiovascular disease and serum albumin level.

Conclusions: Serum S-RAGE and S100A12 may be weak surrogate markers to predict all-cause mortality in patients receiving hemodialysis, even though S100A12 was partly related with diabetes and inflammation.
Impact of Sodium-Dependent Phosphate Co-Transport, Pit-1, in Peripheral Blood Mononuclear Cells on Cardiac Calcification in Maintenance Hemodialysis Patients
Minwen Ding, Mengjing Wang, Minmin Zhang, Jing Chen. Huashan Hospital, Fudan Univ.

Background: Vascular calcification (VC) is an important risk factor for cardiovascular disease in MHD patients, however, the mechanisms of which are still under investigation. The aims of this study were to explore the risk factors of VC in MHD patients, and to identify the expression of sodium-dependent phosphate co-transporter (Npt) in peripheral blood mononuclear cells (PBMCs) and assess its association with cardiac calcification and its possible impact factors.

Methods: This is a cross-sectional analysis of adult MHD patients who received at least 6-month regular MHD in our dialysis center. The coronary artery calcification (CAC) was measured by cardiac MSCT. The gene expression of Npt in PBMCs was measured by Real-time PCR and we tested serum TNF-α and IL-6 by ELISA. Multivariate logistic analysis was used to determine the risk factors of CAC. Correlation between the gene expression of Npt and other parameters was examined by Pearson correlation analysis.

Results: 1,681 eligible patients were enrolled. 2. Three kinds of Npts were detected in PBMCs of MHD patients. They were typeIINpt,Npt2b, type III Npt, Pit-1 and Pit-2, among which Pit-1 mRNA expression was significantly associated with extent of CAC. 3. The results of the logistic regression analysis were listed in Table 1. 4.Perisonal analysis revealed that the expression and synthesis of serum TNF-α and Pit-1 mRNA expression of PBMCs were significantly correlated with serum phosphorus, CAC score and Pit-1 mRNA expression of PBMCs.

Conclusion: Our result showed that longer dialysis vintage, diabetes, higher concentration of serum TNF-α and Pit-1 mRNA expression of PBMCs are the risk factors of CAC in MHD patients. Pit-1 mRNA expression of PBMCs was significantly correlated with serum phosphorus, CAC score and Pit-2 mRNA expression of PBMCs.

Funding: Government Support - Non-U.S.

HDL Subfractions in End-Stage Renal Disease (ESRD) Patients
Anna Gluba-Brozeka, Beata Franzczyk-Skora, Jacek Rysz. Dept of Nephrology, Hypertension and Family Medicine, Medical Univ of Lodz, Poland.

Background: Chronic kidney disease is a common disease associated with high cardiovascular risk. Recent studies have suggested that HDL not LDL may play the more important role in the progression of atherosclerosis in CKD patients. HDL from CKD patients was shown to become dysfunctional, lose its vasoprotective properties and begin to promote endothelial dysfunction and inflammation.

Objectives: The aim of this study was to investigate the risk factors of restenosis after PCI in hemodialysis patients.

Method: Between January 2007 to December 2014, we enrolled 54 consecutive ESKD patients undergoing PCI, of which 54 patients who had received PCI, restenosis occurred in 22 patients (40.7%) within 5-12 months after PCI. In the univariable logistic analysis, serum levels of low-density lipoprotein cholesterol/high-density lipoprotein cholesterol ratio, serum levels of non-high-density lipoprotein cholesterol (non-HDL-C), and history of major adverse cardiovascular events (MACE) were significantly associated with the occurrence of coronary restenosis; odds ratio (OR) [95% confidence interval (CI)] was 1.89 [1.02-3.50], 1.22 [1.01-1.47], and 5.79 [1.59-20.99], respectively. In the multivariable logistic analysis, non-HDL-C and the history of MACE were significantly associated with the coronary restenosis, OR [95% CI] was 1.35 [1.08-1.69]/per 10 mg/dl increase in non-HDL-C and 9.55 [1.08-38.85], respectively.

Conclusion: Non-HDL-C was an independent risk factor for the occurrence of coronary restenosis in HD patients undergoing PCI. This result suggests the significance and necessity of strict management of lipid metabolism after PCI in even HD patients.
Galectin-3 Does Not Correlate within Markers of Cardiac Structure and Function on Cardiac MRI: A Study in Haemodialysis Patients

Lisa E. Crowley, Aghoghodo Odudu, Sariose O’Sullivan, Christopher W. McIntyre, Jennifer L. McIntyre, 

McIntyre. 1Dept of Renal Medicine, Royal Derby Hospital, United Kingdom; 2Div of Medical Sciences, Univ of Nottingham, United Kingdom; 3Kidney Clinical Research Unit, London Health Sciences Centre, London, Canada.

Background: End-stage renal failure patients undergoing haemodialysis (HD) suffer disproportionate rates of death due to heart failure. Accurate tools to help predict those highest risk are therefore desirable. Galectin-3 is a soluble β-galactose binding protein secreted by activated macrophages that promotes cardiac fibroblast proliferation, collagen deposition and as a result ventricular dysfunction. Galectin-3 is the only FDA approved test for assessing prognosis in chronic heart failure. Our study explored the relationship between Galectin-3 and cardiac structure and function in a dialysis population.

Methods: We measured Galectin-3 (G3) levels in a multiplex assay (Merck Millipore) in HD patients enlisted in a clinical trial. Results were correlated with tagged cardiac magnetic resonance imaging to assess left ventricular structure and function.

Results: A total of 65 patients had G3 levels taken. The mean age of the cohort was 60±24 years. The overall mean G3 level was 17.7 ng/mL±10.07. The mean Left Ventricular Mass Index was 77.90 g/m²±20.4, mean ejection fraction 57.47%±11.7 and mean End-diastolic volume 14.43 mL±3.9. In the whole cohort there was no significant correlation between G3 levels and any of the measure of left ventricular structure and function including LVMi (r=0.22 p=0.24), LVEF (r=0.08 p=0.65) or LVEDV (r=0.012 p=0.94). The previously recommended upper limit for normal for G3 levels is 17.7 ng/mL. 32 patients had a G3 level greater than this. In this group the mean G3 level was 23.2 ng/mL, however there remained no significant correlations with age (r=0.10 p=0.38), LVEF (r=0.23 p=0.26), LVEDV (r=-0.01 p=0.95), LVMi (r=0.11 p=0.59) or global peak diastolic and systolic strain rates (r=0.3 p=0.14 and r=0.16 p=0.41).

Conclusions: In HD patients, Galectin-3 is not associated with structural and functional markers of systolic dysfunction seen on tagged cardiac MRI. Our results suggest that Galectin-3 does not have a role in risk stratification of this patient group.

Predictors of Arterial Stiffness in Incident Hemodialysis Patients

Stephanie M. Toth-Manikowski,1 Esther D. Kim,2 Lucy A. Meoni,1 Bernard G. Jaar,3 Tariq Shafi,1 Michelle M. Estrella,1 Rulan S. Parekh,1,2 Stephen M. Sozio,1
1Johns Hopkins Univ; 2Univ of Toronto.

Background: Premature vascular aging and arterial stiffening characterize CKD progression to ESRD and are associated with increased cardiovascular (CVD) morbidity and mortality. We identified predictors of arterial stiffness over time in HD patients.

Methods: In 339 incident HD patients in the Predictors of Arthrythmic and Cardiovascular Risk in ESRD (PACE) study, we examined the associations of baseline age, sex, race, comorbidities, CVD medications, and dialysis characteristics with longitudinal vascular stiffness measured by carotid-femoral pulse wave velocity (PWV) using generalized estimating equations. Annual change in PWV for up to 3 years was analyzed using linear regression.

Results: Mean age was 54, 58% male, 74% African-American, mean (SD) baseline PWV 10.7 (3.4) m/s, and annual PWV change 0.2 (2.6) m/s. Several factors were associated with higher PWV in univariate and multivariate longitudinal models. None were associated with PWV change.

</tbody>
</table>

Conclusions: Although PWV did not change significantly over time in incident HD patients, age, male sex, diabetes, and pulse pressure were independently associated with higher PWV. It may be difficult to modify PWV after HD initiation and clinical factors should be optimized prior to starting HD.

Differences in Risk Factors for Coronary Artery Calcification Between Non-diabetic and Diabetic Hemodialysis Patients

Yoshikyo Nozawa,1,2 Koichiro Arai,1,2 Kazuomi Yamashita,1 Kenichiro Shigemoto,1 Kohto Usui,1 Michiho Arita,1 Kiyoshi Fujita1, Takao Masaki.1 1Div of Nephrology, Ichiyokai Harada Hospital, Hiroshima city, Japan; 2Ichiyokai Ichiyokai Clinic, Hiroshima city, Japan; 3Ichiyokai Ichiyokai Clinic, Hiroshima city, Japan; 4Ichiyokai Ichiyokai Clinic, Hiroshima city, Japan; 5Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima city, Japan.

Background: The differences in risk factors for coronary artery calcification between non-diabetic and diabetic hemodialysis (HD) patients have not been fully explored.

Methods: We examined Agatston coronary artery calcium score (CACS) using MDCT, age, sex, presence of diabetes, dialysis vintage, smoking history, administration of phosphorus binders, geriatric nutritional risk index (GNI), HbA1c, serum calcium, phosphate, iPTH, CRP, 25(OH)D, LDL-cholesterol and triglyceride (TG) in 335 HD patients: 242 nondiabetics and 113 diabetics. Factors related to CACS were assessed by multivariate regression analysis using all of the above independent variables. Differences in the above parameters according to quartile (Q) of CACS were also assessed.

Results: Mean age (years), dialysis vintage (months), CACS (H) and serum phosphate (mg/dL) were 63.14 vs. 66.12 (ns), 125.11 vs. 171.50 months (P=0.001), 1613.2173 vs. 2377.2533 (P=0.005), and 5.5±1.3 vs. 5.0±1.4 (ns) in nondiabetes and diabetics, respectively. Patients with CACS Q4 showed higher prevalence of diabetes (40 vs. 19%), age (68±12 vs. 58±14 years), and CRP (0.7±1.3 vs. 0.2±0.4 mg/dL), but lower iPTH (146±133 vs. 193±131 pg/mL) than patients with CACS Q1 (P=0.05), and other parameters were not significantly different except HbA1c. Significant associations were observed between CACS and age (P<0.001, β: 0.21), female (P<0.001, β: -0.21), dialysis vintage (P=0.001, β: 0.31), CRP (P=0.05, β: 0.16), TG (P=0.05, β: 0.13) in nondiabetics. However, CACS was significantly associated only with age (P=0.05, β: 0.30) and HbA1c (P=0.05, β:0.26) in diabetics.

Conclusions: Risk factors for coronary artery calcification differ between nondiabetic and diabetic HD patients, and poor glycemic control is the main factor in the latter.

Hemodialysis and Hemodiafiltration Improve Serum Calcium Propensity

Marijke E. Dekker,1 Andreas Pasch,1 Frank van der Sande,1 Constantijn Konings,2 Matthias Bachtler,1 Mauro Dionisi,3 Jeroen Kooman,4 Bernard J. Canaud.1 1Maasricht Univ Medical Center; 2 Catharina Hospital Eindhoven; 3Univ Hospital Bern; 4Calicisco AG; 5Fresenius Medical Care.

Background: Calciotropic proteins (CPPs) may play an important role in the calcification process. The calcification propensity of serum (TPH) is highly predictive of all-cause mortality in chronic kidney disease patients. Whether TPH is therapeutically improvable, by hemodialysis (HD) or even further by hemodiafiltration (HDF), has not been studied yet.

Methods: We designed a cross-sectional single center study, and included prevalent patients on HD or HDF. Patients were divided into two groups based on dialysis modality. We included patients on a thrice-weekly schedule, with a dialysis vintage of >3 months and vascular access providing a blood flow rate of >300 mL/min. Calcification propensity of serum was measured by the time of transformation from primary to secondary CPP (TPH test), by time-resolved nephelometry.

Results: In total 64 patients were included and, TPH was measured in 376 pre- and post-dialysis samples of all in-center dialysis sessions during one week. TPH levels improved in both the HD and HDF group with pre- and post-dialysis (mean (SD) of 244(64)-301(57) and 253(55)-304(61) nm respectively (P=0.43). The mean improvement of TPH was 26.29% in the HD group and 21.97% in the HDF group (P=0.06). The delta values (A) of calcium, phosphate (P), and albumin were equal in both groups. The DTm was mostly influenced by DP (P=0.280; P=0.01 HD and r=0.239; P=0.02 HDF).

Conclusions: HD and HDF patients present with same baseline vascular calcification risk values pre-dialysis. Calcification propensity is significantly improved during both HD and HDF. TPH might be a useful guide to optimize renal replacement strategy to improve the individual calcification risk in dialysis patients.

Association of Circulating Biomarkers with Vascular Stiffness and Coronary Artery Calcium in Incident Hemodialysis

Esther D. Kim,1 Stephen M. Sozio,2 Bernard G. Jaar,3 Lucy A. Meoni,1 Michelle M. Estrella,1 Rulan S. Parekh.1 1Univ of Toronto, Canada; 2Johns Hopkins Univ.

Background: Vascular calcification and stiffness are associated with higher mortality in hemodialysis. Studies examining the role of circulating biomarkers – specifically, FGFB3, desphospho-uncarboxylated matrix GlA protein (dpuMGF), Fetuin A, osteoprotegerin (OPG), and C-reactive protein (CRP) – in vascular calcification have reported contradictory findings, and the independent association of the biomarkers remains inconclusive.

Methods: In 392 incident hemodialysis patients in the Predictors of Arthrythmic and Cardiovascular Risk End Stage Renal Disease (PACE) study, we examined the associations of baseline FGFB3, dpuMGF, Fetuin A, OPG, and CRP with total coronary calcium score (Agatston) at baseline and vascular stiffness (pulse wave velocity [PWV]) at baseline and over 4 study visits. Baseline associations were determined using linear regression and repeated measures over visits were examined using mixed-effects models.

Results: At baseline, higher OPG was associated with increased odds of having a high coronary calcium score (>257), independent of other biomarkers (OR=1.11, 95%CI: 1.06,
The remaining biomarkers were not associated with high coronary calcium. Higher OPG was associated with higher PWV, and higher FGF23 was associated with lower PWV after adjusting for demographic factors, body mass index, comorbidity index, calcium phosphorus product, systolic blood pressure, and albumin.

OPG and FGF23 remained associated with PWV over follow-up and after additionally adjusting for all biomarkers ($\beta=-0.08$, 95% CI: $0.01$-$0.15$ and $\beta=-0.07$, 95% CI: $0.13$-$0.13$, $p<0.01$).

**Conclusions:** Several vascular and phosphate biomarkers are associated with vascular calcification at baseline and/or stiffness longitudinally in incident dialysis patients. Further studies assessing interventions on these biomarkers are warranted.

### TH-PO907

**Association of Arterial Stiffness with Cognitive Impairment in Incident Hemodialysis Patients**

**Background:** Cognitive impairment is common in hemodialysis and places a significant burden on patients and healthcare system. Though vascular stiffness is implicated in the pathogenesis of cerebral microvascular disease, few have examined the relationship between arterial stiffness and cognitive function in dialysis patients.

**Methods:** This study included 390 incident hemodialysis patients enrolled in the Predictors of Arrhythmic and Cardiovascular Risk in End-Stage Renal Disease (PACE) study. Arterial stiffness was measured using aortic pulse wave velocity (PWV) and augmentation index (Aix). Cognitive function was measured using time to complete Trail Making tests A and B (TMT A and TMT B) and the modified mini-mental state exam (3MS) score. Log-linear, Tobit, and logistic regression models were used to examine the baseline association of PWV with TMT A, TMT B, and 3MS, respectively. Changes in the scores over visits and mixed-effect models were used to examine association over time at 1 year follow-up.

**Results:** At baseline, higher PWV was associated with longer time to complete TMT A after adjusting for demographic factors, reading comprehension score, comorbidity index, systolic blood pressure, and atrial fibrillation (%TMT A=3.12, 95% CI: 0.37-5.87). In the repeated measures analysis, higher PWV was still associated with longer TMT A time (%TMT A=2.05, 95% CI: 0.00-4.41), and higher Aix was associated with longer TMT B time ($\beta=0.80$, 95% CI: 0.01-1.58).

**Conclusions:** Vascular stiffness is associated with longer time to complete TMT A and TMT B suggesting that arterial stiffness may lead to subclinical cerebrovascular events and decline in executive function among incident hemodialysis patients.

**Funding:** NIDDK Support

### TH-PO908

**Close Relationship Between Vascular Endothelial Function and Serum Uric Acid Level in Hemodialysis Patients**

**Background:** Vascular endothelial function (VEF) impairment is often detected in hemodialysis (HD) patients and has been associated with atherosclerosis and cardiovascular disease (CVD). Although avoidance of VEF impairment is therefore desirable in preventing such complications, the precise factors that influence VEF remain unknown. The present study evaluated VEF for associating factors in HD patients.

**Methods:** We enrolled 48 patients undergoing maintenance HD at Ueda Kidney Clinic in Japan. No patient had a history of CVD. Reactive hyperemia index (RHI) was evaluated by Endo-PAT (Iatmar Medical, Ltd., Casarea, Israel) was used to assess VEF, whereby a higher RHI was indicative of better function. We also assessed for correlations between the natural logarithm of RHI (LnRHI) and clinical parameters.

**Results:** The median age of our patients was 67 years, the male-to-female ratio was approximately 2:1, and median LnRHI was low at 0.36. Analysis of Spearman’s rank correlation coefficient revealed a significant positive correlation between serum uric acid level (sUA) and LnRHI (r=0.372, $p<0.009$). As sUA is influenced by diet composition and intake, we also performed multivariable linear regression analysis adjusted by age, body mass index, dialysis efficiency by Kt/V, and normalized protein catabolic rate, and observed that sUA was significantly related to LnRHI (β=0.042, 95% CI: 0.007-0.078, $p<0.03$, $p=0.021$).

**Conclusions:** The current study suggests that VEF is closely associated with sUA in HD patients. Although the precise mechanism is unknown, a marked decrease in sUA might be correlated with VEF impairment and should be avoided in individuals undergoing HD.

**Funding:** NIDDK Support

### TH-PO909

**Ambulatory Arterial Stiffness Index: An Early Marker of Cardiovascular Disease in Young Hemodialysis Patients**

**Background:** Cardiac disease (CVD) is the leading cause of death in pediatric hemodialysis (HD) patients. Ambulatory arterial stiffness index (AASI) may be an earlier marker of vascular compliance in young patients than pulse pressure (PP). Our objective was to evaluate AASI as a marker of increased vascular stiffness in young HD patients and to compare it with other non-invasive indicators of CVD risk.

**Methods:** Retrospective review of 24-hour ambulatory blood pressure monitoring (ABPM) was performed in 11 pediatric patients on chronic HD (median age 14 years) and dialysis vintage of 42 months. AASI was calculated as the regression slope of the diastolic over systolic BP. Echocardiogram and bilateral carotid artery ultrasound were performed to assess left ventricular mass index (LVMI) and internal membrane thickness (cIMT). Carotid artery stiffness indices included distensibility coefficient (DC), stiffness index β (SI-β) and PP. These were compared with reference values for healthy pediatric controls.

**Results:** AASI was significantly increased in HD patients compared to controls ($0.42±0.1$ versus $0.20±0.2$, $p<0.01$). When matched to controls with similar BP's and PP's, the AASI detected increased vascular stiffness independent of PP. cIMT, LVMI, and DC were also significantly increased in HD patients ($p<0.01$).

**Conclusions:** Young HD patients demonstrate early surrogate markers of CVD including increased LVMI, cIMT and decreased vascular compliance. Increased AASI detected vascular stiffness that was independent of BP's and PP's. AASI may be an early non-invasive marker of vascular disease in young HD patients that merits further investigation.

Endovascular Renal Denervation Ameliorates Pathological Left Ventricular Dilatation in Dialysis Patients

Neil A. Hoyer,1 J. Christopher Baldi,1 David L. Jardine,2 John B.W. Schollum,3 Gerard T. Wilkins,3 Luke C. Wilson,3 Robert J. Walker,1 1Dunedin School of Medicine, Univ of Otago, 2Christchurch School of Medicine and Health Sciences, Univ of Otago.

**Background:** Endovascular renal denervation (RDN) ameliorates left ventricular hypertrophy and improves contractile function in resistant hypertension. Its cardiac effects on a dialysis population are unknown. We hypothesised that RDN would improve blood pressure (BP) control and sympathetic overload, resulting in improved ventricular function.

**Methods:** Nine dialysis patients with uncontrolled office BP (≥140/90mmHg despite two or more agents at maximal tolerated dosages) were recruited into this feasibility study. Office and ambulatory BP monitoring (ABPM) were performed at baseline; one and three months post RDN, along with supine muscle sympathetic nerve activity (MSNA). Echocardiography was performed at baseline and three months. Bilateral RDN was undertaken with an EnligHTN™ catheter.

**Results:**

</table>

Similar to previous, office systolic BP reduced and the effect on ABPM was attenuated. MSNA did not change, a novel finding. Despite lack of change in MSNA, LV LVIDd reduced with an improving trend in diastolic dysfunction, another novel finding. There was no correlation change in office systolic BP and ventricular dilatation (R=0.255) or dysfunction (R=0.034), suggesting BP-independent effects.

**Conclusions:** RDN in dialysis patients reduces office systolic BP and leads to a BP-independent improvement in ventricular dilatation and probably dysfunction. Further controlled studies are warranted in this population.

**TH-PO911**

Effects of Music and Exercise during Hemodialysis on the Cardiac Autonomic Nervous System Activity

Maria Mitsiou,1 Evangelia J. Koudri,1 Vasiliios Liakopoulos,2 Asterios P. Deligianisis.3 1Laboratory of Sports Medicine, Aristotle Univ of Thessaloniki, Thessaloniki, Greece; 2Renal Unit, 1st Dept of Internal Medicine, Aristotle Univ of Thessaloniki, Thessaloniki, Greece.

**Background:** Cardiac autonomic nervous system (CANS) dysfunction is a common complication in Chronic Kidney Disease (CKD), linked with increased cardiovascular morbidity and mortality. It is known that exercise training during hemodialysis (HD) improves physical function and quality of life in HD patients. Exercise training can suppress the sympathetic over-excitation, restoring the sympathetic (SNS) to parasympathetic nervous system (PNS) balance. Music can positively affect CANS activity. The combination of music and physical training has never been used in CKD. The aim of this study was to investigate the effectiveness of a 6-month, music and physical training combined protocol during HD.

**Methods:** Heart rate variability (HRV) data were collected from 40 free of any systemic disease HD patients (age 50±14.7 yrs). Patients were randomly assigned to four equally numbered ([n=10] groups, employing a joint music and exercise training program for Group A, a sole exercise training program for Group B, a sole music program for Group C and none of the above-mentioned interventions for Group D. At entry and at the end of the study, all patients underwent a 6-minute walking test (6MWT) and ambulatory 24-hour Holter monitoring for time- and frequency- domain HRV calculation. The HRV indices obtained were: mean heart rate (HR); standard deviation of NN intervals (SDNN); root mean square of successive differences (RMSSD); proportion of NN50 divided by total number of NNs (pNN50) and very low frequency (VLF).

**Results:** All indices were significantly better for Group A: 6MWT [F(3,36)=13.095, P=0.001]; HR [F(3,36)=11.9, P=0.001]; SDNN [F(3,36)=11.671, P=0.001]; RMSSD [F(3,36)=12.395, P=0.001]; pNN50 [F(3,36)=45.752, P=0.001]; and VLF [F(3,36)=3.141, p=0.037].

**Conclusions:** Musical auditory stimulation when jointly used with exercise training during HD has the strongest influence on CANS activity, improving the balance of the dynamic interaction between the SNS and PNS. These favorable changes may positively affect cardiovascular morbidity and mortality.

Temporal Loss of Bone Mineral Density Is Associated with Cardiovascular Diseases in Japanese Patients Starting Renal Replacement Therapy

Sawako Kato,1 Shoichi Manayama,2 Bengt Lindholm,3 Yukio Yuzawa,3 Yoshinori Tsuruta,2 Seiichi Matsuo,1 1Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan; 2Bacterium & Renal Medicine Karolinska Inst, Stockholm, Sweden; 3Nephrology, Fujita Health Univ School of Medicine, Toyoake, Japan; 4Meiyo Clinic, Toyohashi, Japan.

**Background:** Atherosclerosis, vascular calcification and alterations of bone metabolism are common aging disorders, which may be biologically linked via bone-vascular interactions. However, clinical studies on associations of temporal bone loss with cardiovascular disease (CVD) in dialysis patients are limited.

**Methods:** Seventy-six incident Japanese dialysis patients (46 males, age 60 ± 10 years) were enrolled and followed for a median of 3.8 years (range 1.5-8 years). Bone mineral density (BMD) of the lumbar spine was measured by dual X-ray absorptiometry at baseline and after 1 year.

**Results:** Baseline BMD, median value 1.05 (0.67-1.56) g/cm², negatively correlated to both age (rho = -0.28, P = 0.015) and iPTH (rho = -0.14, P = 0.0002). When dividing patients into two groups according to delta BMD (defined as baseline - 1 year), those with high delta BMD had an increased mortality risk (Log rank 6.36, P = 0.012) and time from dialysis initiation to the first CVD event appeared, although not significant, shorter in patients with high delta BMD (Log rank 2.81, P = 0.094). Patients with high delta BMD had a significantly increased relative risk (RR: Cox hazard model) of mortality (10.9, 95% CI, 1.34-250.6) even after adjustments for age, gender, diabetes and smoking, compared with those with low delta BMD. RR of the first CVD event was 5.52 (95% CI, 1.15-7.83) with adjustments for age and gender.

**Conclusions:** Progressive loss of BMD associated with an increasing risk of CVD and mortality. Whereas in end-stage renal disease patients, BMD may have limited value as predictor of a fracture risk, temporal changes of BMD, potentially reflecting bone-vascular interactions, may be useful as a marker of a CVD risk.

First in Man: Reduction of Inflammation with Medium Cut-Off (MCO) Membranes

Daniel Zieker,1 Ralf Schindler,1 Markus Storr1, Kevin Willy,2 Bogusz Trojanowicz,1 Peter Martus,3 Christof Ulrich,3 Kirstin Liehr,3 Christian Henning,4 Torsten Böhrer,5 Marcus A. Glomb,2 Roland Friedel,2 Matthias Girdl,1 1Dept of Nephrology and Internal Intensive Care Medicine, Charité Univ Medicine, Berlin, Germany; 2Dept of Internal Medicine II, Martin-Luther-Univ, Halle, Germany; 3Research & Development, Gambio Dialysatoren GmbH, Hechingen, Germany; 4Inst for Epidemiology and Applied Biometry, Eberhard-Karls-Univ, Tübingen; 5Inst for Chemistry / Food Chemistry, Martin-Luther-Univ, Halle.

**Background:** High mortality in dialysis patients may be related to decreased clearance of cytokines with conventional dialysis membranes. Attempts to provide a better clearance with high cut-off membranes also leads to albumin loss. A new Medium-Cutoff membrane with better permeability for molecules up to 45 kDa but with limited permeability for albumin was tested clinically in the first in man study.

**Methods:** 50 patients were dialyzed with MCO and conventional high-flux (HF) membranes for four weeks following a randomized cross-over design. After the second phase, another 12-week-period was conducted to test for long-term effects. Serum samples were tested for inflammatory effects and cytokine concentrations. Support was granted by the German Federal Ministry of Education and Research (FKZ 13N1796-99).

**Results:** The primary end point mRNA content of TNF-alpha in leucocytes was reduced to a higher degree and significantly better after 4 weeks on MCO compared to HF (rho = -0.255) or PTH (rho = -0.14, P = 0.0002). When patients with high delta BMD had a significantly increased relative risk (RR: Cox hazard model) of mortality (10.9, 95% CI, 1.34-250.6) even after adjustments for age, gender, diabetes and smoking, compared with those with low delta BMD. RR of the first CVD event was 5.52 (95% CI, 1.15-7.83) with adjustments for age and gender.

**Conclusions:** Progressive loss of BMD associated with an increasing risk of CVD and mortality. Whereas in end-stage renal disease patients, BMD may have limited value as predictor of a fracture risk, temporal changes of BMD, potentially reflecting bone-vascular interactions, may be useful as a marker of a CVD risk.

Vitamin D and Cardiac Autonomic Tone in End-Stage Kidney Disease: A Blinded, Randomized Controlled Trial

Sofia B. Ahmed,1 Michelle C. Mann,1 Brenda Hemmelgarn,1 David A. Hanley,1 Tanvir Chowdhury Turin,1 Jennifer M. MacRae,1 David C. Wheeler,1 Sharranya Ramesh,1 Darlene Y. Sole,1 Derek Exner.1
1Univ of Calgary, Canada; 2Univ College London, United Kingdom.

Background: Improvement of end-stage kidney disease (ESKD) patients are at high cardiovascular (CV) risk. Vitamin D deficiency is associated depressed heart rate variability (HRV), a risk factor for CV death. Both vitamin D deficiency and depressed HRV are highly prevalent in ESKD.

Methods: Objective: To determine the effects of activated vitamin D (conventional) compared to activated and nutritional vitamin D (intensive) on HRV (low to high frequency spectral ratio; LF:HF) in patients with ESKD on hemodialysis (HD). Design: 2x2 crossover, blinded, randomized controlled trial in outpatient HD units. Fifty-six patients were randomized 1:1 to begin either conventional (0.25mcg alfacalcidiol and placebo 3 times/ week) or intensive vitamin D therapy (0.25mcg alfacalcidiol 3 times/week and 1mcg ergocalciferol weekly) for 6 weeks. Main Outcomes: HRV is a surrogate index of cardiac autonomic nerve function and independently predicts CV mortality. The primary outcome was the change in LF:HF from the 1st to 6th week HD session. Secondary outcomes included individual changes in LF and HF, parameters of mineral metabolism and renin angiotensin system (RAS) activity.

Results: There was no difference in LF:HF from baseline to 6 weeks for either vitamin D treatment (conventional p=0.9; intensive p=0.07). There were no significant changes in any other measure of HRV, mineral metabolism or RAS activity. On exploratory subgroup analysis, participants who remained vitamin D-deficient (25-hydroxyvitamin D<50nmol/L) after treatment had a significant increase in LF:HF (conventional: n=13, p=0.001 vs. insufficient and sufficient groups; intensive: n=8, p=0.001 vs. sufficient group).

Conclusions: Six weeks of treatment with conventional or intensive vitamin D did not alter LF:HF in ESKD patients. However, improved LF:HF was observed in the vitamin D-deficient subgroup. This finding may translate into decreased CV risk and should be considered hypothesis-generating and deserve of further study. Trial Registration: ClinicalTrials.gov NCT01774812.

Funding: Private Foundation Support

Vitamin D and Cardiac Autonomic Tone in End-Stage Kidney Disease: A Blinded, Randomized Controlled Trial

Sofia B. Ahmed, Michelle C. Mann, Brenda Hemmelgarn, David A. Hanley, Tanvir Chowdhury Turin, Jennifer M. MacRae, David C. Wheeler, Sharranya Ramesh, Darlene Y. Sole, Derek Exner.

Background: Improvement of end-stage kidney disease (ESKD) patients are at high cardiovascular (CV) risk. Vitamin D deficiency is associated depressed heart rate variability (HRV), a risk factor for CV death. Both vitamin D deficiency and depressed HRV are highly prevalent in ESKD.

Methods: Objective: To determine the effects of activated vitamin D (conventional) compared to activated and nutritional vitamin D (intensive) on HRV (low to high frequency spectral ratio; LF:HF) in patients with ESKD on hemodialysis (HD). Design: 2x2 crossover, blinded, randomized controlled trial in outpatient HD units. Fifty-six patients were randomized 1:1 to begin either conventional (0.25mcg alfacalcidiol and placebo 3 times/week) or intensive vitamin D therapy (0.25mcg alfacalcidiol 3 times/week and 1mcg ergocalciferol weekly) for 6 weeks. Main Outcomes: HRV is a surrogate index of cardiac autonomic nerve function and independently predicts CV mortality. The primary outcome was the change in LF:HF from the 1st to 6th week HD session. Secondary outcomes included individual changes in LF and HF, parameters of mineral metabolism and renin angiotensin system (RAS) activity.

Results: There was no difference in LF:HF from baseline to 6 weeks for either vitamin D treatment (conventional p=0.9; intensive p=0.07). There were no significant changes in any other measure of HRV, mineral metabolism or RAS activity. On exploratory subgroup analysis, participants who remained vitamin D-deficient (25-hydroxyvitamin D<50nmol/L) after treatment had a significant increase in LF:HF (conventional: n=13, p=0.001 vs. insufficient and sufficient groups; intensive: n=8, p=0.001 vs. sufficient group).

Conclusions: Six weeks of treatment with conventional or intensive vitamin D did not alter LF:HF in ESKD patients. However, improved LF:HF was observed in the vitamin D-deficient subgroup. This finding may translate into decreased CV risk and should be considered hypothesis-generating and deserve of further study. Trial Registration: ClinicalTrials.gov NCT01774812.

Non-Invasive Left Ventricular End-Diastolic Pressure (LVEDP) Measurement in Hemodialysis Patients: A Pilot Study

Background: Optimal volume status in dialysis patients is difficult to assess. The Valsalva maneuver is recognized as an bedside marker of central volume overload. A novel handheld device that combines finger plethysmography with Valsalva maneuver can reliably estimate LVEDP (normal: <12mmHg). (Silber H. PTDMD. 22389389). The goal of our pilot study is to determine the role of this non-invasive LVEDP measurement in managing volume in hemodialysis patients.

Conclusions: A higher E/e' ratio, reflecting high LV filling pressure which is the main physiological finding of diastolic HF, may be associated with a higher CV risk in patients with ESERD.

Conclusions: Non-invasive LVEDP measurements can identify hemodialysis patients with volume overload associated with symptoms (high LVEDP) and patients at risk for IDH (low LVEDP). Our ongoing study may help confirm these initial findings and define the role of this measurement in volume management in dialysis patients.

Non-Invasive Left Ventricular End-Diastolic Pressure (LVEDP) Measurement in Hemodialysis Patients: A Pilot Study

Background: Optimal volume status in dialysis patients is difficult to assess. The Valsalva maneuver is recognized as an bedside marker of central volume overload. A novel handheld device that combines finger plethysmography with Valsalva maneuver can reliably estimate LVEDP (normal: <12mmHg). (Silber H. PTDMD. 22389389). The goal of our pilot study is to determine the role of this non-invasive LVEDP measurement in managing volume in hemodialysis patients.

Conclusions: A higher E/e' ratio, reflecting high LV filling pressure which is the main physiological finding of diastolic HF, may be associated with a higher CV risk in patients with ESERD.

Tallium-201 Washout Rate of Single Photon Emission Computed Tomographic Myocardial Perfusion with Pharmacologic Stress as a Predictor of Mortality in CKD Patients Undergoing Hemodialysis: An Observational, Follow-Up Study
Toshiihide Hayashi, Nobuhiko Joki, Masaki Iwasski, Ai Matsukan, Takasuke Asakawa, Yui Tanaka, Hiroki Hase. Dep of Nephrology, Toho Univ Ohashi Medical Center, Tokyo, Japan.

Background: Tallium-201 (201Tl) washout rate of single photon emission computed tomography (SPECT) has been reported to correlate with coronary flow reserve which is an index of myocardial microcirculation and be useful to detect coronary artery disease and evaluate the severity. However, the evidence for its use in chronic kidney disease (CKD) has been lacking, and the association between 201Tl washout rate and mortality is unknown. Therefore, a hospital-based, prospective, cohort study was conducted to evaluate the predictive ability of 201Tl washout rate for mortality in CKD patients undergoing hemodialysis.

Methods: A total of 156 patients who had been started on maintenance hemodialysis undergoing pharmacologic stress tallium-201 SPECT within 1 year, 107 men and 49 women, with a median age of 67 years, were studied. The endpoint was defined as all-cause death. The Cox proportional hazards model was used to calculate hazard ratios (HR) and 95% confidence intervals (CI).

Results: During the mean follow-up period of 3.2 ± 2.4 years, 30 (19.2%) deaths occurred. The median (interquartile range) of 201Tl washout rate was 45.1 (37.4 - 50.8) %. Cumulative survival rates at 5 years after starting dialysis, with 201Tl washout rate levels above and below the median, were 76.7 % and 63.8 % (p = 0.992, log-rank test), respectively. Overall, the multivariate Cox regression analysis revealed that 201Tl washout rate remained an independent predictor of death after adjusting by confounding variables (HR 0.95, 95% CI 0.90 to 0.99).

Conclusions: Among CKD patients undergoing hemodialysis, 201Tl washout rate seems to be useful for predicting death.

TH-PO919

Research Cardiovascular Magnetic Resonance Imaging in Chronic Kidney Disease – Incidence, Significance and Implications of Unexpected Incidental Findings

Background: Left ventricular (LV) mass on cardiac magnetic resonance imaging (CMR) is a common end point of clinical trials in nephrology. Incidental findings (IF) on research images have ethical & clinical implications. We retrospectively investigated the incidence of IF in research CMR & reviewed their impact on patient care.

Methods: 161 CKD patients underwent CMR for a 2002-2006 research study into transplant assessment. Images were used to assess LV mass & function. In our study a total of 156 IF. 59% of patients had one or more IF. 68% were extra-thoracic. There were 150 IF. 59% of patients had one or more IF. 68% were extra-thoracic. 16 IF were suspicious of malignancy. 17 unidentified IF may have changed patient management if known, but a review of patient records showed these IF had no later clinical impact. In 6 cases earlier identification of an important IF may have improved quality of life or survival.

Conclusions: Without radiology support clinically important IF may be missed on CMR. A suitably trained radiologist should prospectively review all CKD CMR research studies & obtained images. Patients undergoing CMR in trials should be counselled about the frequency & implications of possible IF.

TH-PO920

A Significance of Cardiothoracic Ratio for Mortality in Hemodialysis Patients: The Q-Cohort Study
Ryusuke Yotsuda, Masahiro Eriuchi, Shigeru Tanaka, Masatomo Taniguchi, Hideki N. Hirakata, Kazuhiko Tsuuya, Takahiro Kitazono. Dep of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; Dep of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; Nephrology and Dialysis Center, Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan.

Background: Cardiothoracic ratio (CTR) of chest X-ray is commonly used to determine the volume status in hemodialysis (HD) patients. Thus, the present study was conducted to evaluate the significance of CTR in terms of longitudinal prognosis of HD patients.

Methods: A total of 3,437 Japanese HD patients aged >18 years were followed for 4 years. Patients were divided into four groups according to quartiles of CTR levels by sex. Risk estimates were calculated by a Cox proportional hazards model, adjusting for potential confounders. We investigated stratified analysis by sex, age, etiology of end-stage kidney disease, history of major adverse cardiac events (MACE) and blood pressure for subanalysis.

Results: The median values (interquartile range) of CTR were 0.49 (0.46–0.53) in male and 0.52 (0.48–0.56) in female. During the follow-up period, 564 patients (16%) died from causes associated with CTR. The multivariable-adjusted hazard ratios (HRs) for all-cause mortality were 0.89 (95% confidence intervals, 0.66–1.21), 1.41 (1.07–1.86), and 1.52 (1.17–2.00) in subjects with low–intermediate, high–intermediate and highest quartile, respectively. Furthermore, the combination of higher CTR levels and history of MACE or diabetes mellitus was associated with increased mortality risk (HR 1.72, 95% CI 1.23-2.40).

Conclusions: A higher CTR level is closely related to increased mortality in HD patients. This association is more remarkable in patients with history of MACE or diabetes mellitus. Further studies should investigate the clinical course of patients with high CTR levels and mortality risk.
Methods: A prospective, multicenter study was performed (NCT01877499). HD(F) patients (n=118) were eligible to treated 3x/week for 26 weeks. Non-participating eligible ESRD patients formed a reference group to examine the representativeness of the study. Treatment-related determinants of the convection volume were optimized in a stepwise fashion (treatment time [TT] up to 4 hours, blood flow rate [BFR] up to 400 mL/min and filtration fraction [FF] up to 33%). At the end of this protocol (T0) and 4 (T4) and 8 (T8) weeks thereafter, the convection volume was determined.

Results: Baseline characteristics were comparable in participants (n=86) and references (n=58). At T0 and at T4, 79/86 (92%) and 68/86 (79%) patients achieved hvHDF (mean 26.9±3.56 and 26.3±3.36L/session, resp). Hereafter, 2 patients died and 1 was transplanted. 83 patients remained; 66 (80%) reached hvHDF (mean 25.9±3.53L/session, fig 1). Study discontinuation (n=9), TT <4h (n=4) or BFR £300 mL/min (n=4) caused a convection volume <22L/session.

Conclusions: hvHDF is feasible in the vast majority of ESKD patients. As TT remained virtually unaltered, these findings were mainly due to a higher BFR and FF.

Physical Activity Among Patients with End-Stage Renal Disease: Use of the Exercise Vital Sign

Background: Exercise has been shown to improve physical functioning among ESRD patients. However, ESRD patients report exceedingly low levels of physical activity (PA) with only 13-34% engaging in recommended levels of PA. Although ESRD is characterized by substantial barriers to PA, low PA puts patients at risk for serious complications and higher mortality. Within Kaiser Permanente (KP), patients are administered the Exercise Vital Sign (EVS) – self-reported weekly minutes of PA – during each office encounter. The EVS has been validated in multiple KP regions, with roughly one-third each of the membership reporting no, insufficient, and sufficient PA, or 150 minutes exercise/week. Although the relationship between EVS reports and cardiometabolic status has been examined, levels of PA reported by ESRD patients using the EVS have not yet been explored.

Methods: EVS reports of all KP patients with a diagnosis of ESRD between January 2013 and July 2014 (N=8,187; Female=3,534, Mean Age=63.3 years) were assessed.

Results: Patients were 25% White, 38% Black, 23% Hispanic, 12% Asian, and the remainder Other, consistent with the regional patient catchment; just over 50% were married. The majority (88%) had comorbid HTN, 65% had comorbid DM, and 37% comorbid CHF. On average, patients had four other comorbid illnesses. During the study period, patients presented for 135,562 encounters. The mean reported PA frequency was 49.0 minutes/week (SD=103.2) and a median zero minutes/week. The majority of ESRD patients did not achieve sufficient levels of PA during this period; 75% of the sample exercised for ≤60 minutes/week.

Conclusions: Self-reported rates of PA among ESRD patients at KP are critically low. Implications of low PA for cardiovascular and other outcomes as well as for interventions to improve rates of PA in this diverse population will be discussed.
Conclusions: Patient prioritized outcomes are focused on maintaining a quality lifestyle above the usual outcomes in HD trials i.e. death, adverse events, and biological markers. Researchers need to consider interventions that could improve these outcomes, and measure and report patient-relevant outcomes in trials.

TH-PO925

Medicare Advantage (MA) Is Associated with Lower Rates of Mortality versus Medicare Fee-For-Service (MFFS) Among Incident End-Stage Renal Disease (ESRD) Patients

Steven M. Brunelli,1 Carey Colson,1 Scott Sibbels,1 Abigail Hunt,1 Allen R. Nissenson,2 Mahesh Krishnan.2 DaVita Clinical Research, Minneapolis, MN; DaVita HealthCare Partners Inc, Denver, CO.

Background: Patients with ESRD have a high burden of comorbid illness and are complex to manage and may therefore benefit from programs like MA that facilitate care coordination. Currently, ESRD patients are barred from enrolling in MA after onset of ESRD; however, those already enrolled at the time of ESRD onset may remain enrolled. To understand the potential impact of MA among ESRD patients, we compared mortality rates among patients who began dialysis enrolled with MA versus MFFS.

Methods: Adult patients initiating hemodialysis (HD) or peritoneal dialysis (PD) between 01 Jan 2009 and 30 Jun 2011 and who were enrolled with MA or MFFS as of ESRD onset were considered. MA patients were matched 1:1 to MFFS controls based on initial modality, access type, and propensity score (based on 26 demographic and clinical characteristics). Patients were followed from dialysis initiation until death, transplant, loss to follow up, change in benefits status, or end of study (31 Dec 2011). Mortality rates were compared using negative binomial models. Sensitivity analyses considering early and latent systems research.

Results: Of 2,268 patients, 392 patients (17.28%) received dialysis and 1,876 patients (82.72%) did not. A total of 1,470 patients (64.81%) were discharged alive and 798 patients (35.19%) resulted in a hospital death. The hospital deaths included 269 patients (33.71%) that received dialysis and 529 patients (66.29%) that did not receive dialysis in the hospital.

Conclusions: Our preliminary data indicates that patients who survived their last hospitalization were less likely to have undergone dialysis (8.36%) when compared to patients that died during their last hospitalization (33.71%) were dialyzed. Therefore, reaffirming that dialysis in advanced cancer patients would not likely add further benefit to their mortality.

TH-PO927

Emergency Room Utilization by Dialysis Patients: A Population Based Study

Claudio Rigatto,1,2 James M. Zacharias,1,2 Ping Hu,1 Brett M. Hieber,1 Navdeep Tangri,1,2 Paul Komenda.1,2 Internal Medicine, Univ of Manitoba, Winnipeg, MB, Canada;1 Renal Health/Dialysis, Seven Oaks General Hospital, Winnipeg, MB, Canada;1 Renal Health/Dialysis, Winnipeg Health Sciences Centre, Winnipeg, MB, Canada;1 Manitoba Renal Program, Winnipeg Regional Health Authority, Winnipeg, MB, Canada.

Background: Patients with kidney failure are frail and have high rates of cardiovascular and infectious comorbidities. As a result, they are heavy users of non-dialysis acute health services such as the emergency department (ED). Despite this, accurate population based data on rates and patterns of ED visits by dialysis patients are lacking. The objective of the current study was to determine rates and patterns of ED utilization by adult dialysis patients vs. the adult general population.

Methods: We linked two large regional databases in Winnipeg, Manitoba, Canada (population 1.3 million), the Manitoba Renal Program Patient Registry and the Winnipeg Regional Emergency Program Admission Discharge Triage database. Data were analyzed for the years 2000-2010. Poisson Regression was used to compare rates.

Results: Over the study period, the linked dataset comprised >2.0 million visits in 1.2 million non-dialysis patients, and 17,738 visits in 3,260 dialysis patients. Our key findings were 1) Age and Sex adjusted rates of ER visits were 8.5X higher among dialysis patients [153 vs 18 visits per 100 patient-years, p<0.001], with negligible variation year to year over the study period; 2) Rate of ER visits were 25% higher on Mondays and Tuesdays overall; this “post-weekend” risk phenomenon was more pronounced in dialysis patients vs. the general population (p<0.001 for interaction); 3) among dialysis patients, ER visits were 8X higher during the two weeks before and after initiation of dialysis, reflecting a period of heightened vulnerability for patients with kidney disease.

Conclusions: Our population based rates of ED utilization will help health administrators predict the “collateral” impact of a typical dialysis unit on the health system. Strategies to mitigate the high risk of ED utilization “post weekend” and around the time of transition to dialysis are urgently needed and should be a focus of future health systems research.

Development of a Clinical Risk Prediction Tool for Six-Month Mortality After Dialysis Initiation Among Older Adults

James Wick, Tanvir Chowdhury Turin, Peter D. Faris, Jennifer M. MacRae, Robert G. Weaver, Brenda Hemmelgarn. Univ of Calgary, Calgary, AB, Canada.

Background: Early mortality after dialysis initiation is common among older adults. We sought to develop a tool to predict mortality within 6 months of dialysis initiation in an older adult population.

Methods: We linked administrative and dialysis registry data to define a cohort of older adults (age 65+) in Alberta, Canada who initiated chronic dialysis between May 2003 and March 2012. The outcome was all-cause mortality within 6 months of dialysis initiation. Potential predictors included demographics, comorbidities, health-system use,
Coping Strategies and Outcomes Among Hemodialysis (HD) Patients in the DOPPS

**Coping Strategies**

**Emotional Focus (EF) and Disengagement (FD)**

- **Problem-focused Engagement (PFE)**
- **Emotion-focused Engagement (EFE)**
- **Emotion-focused Disengagement (EFD)**

**Outcomes**

- **QoL (from SF-12 and KDQoL-SF)**
- **Depression (PFD)**
- **Emotion-focused Engagement (EFE)**
- **Emotion-focused Disengagement (EFD)**

**Methods**: Patients from 6 DOPPS countries completed the Coping Strategies Inventory Short Form (CSI-SF), which we found to be reliable and valid in those countries for measuring 4 coping strategies: problem-focused engagement (PFE) and disengagement (PFD), and emotion-focused engagement (EFE) and disengagement (EFD); and summary measures of engagement (actions to confront stressors) and disengagement (avoiding exposure to stressors). Outcomes were QoL (from SF-12 and KDQoL-SF), depression symptoms (from the CES-D), and all-cause mortality. Mixed linear and logistic models were used to estimate coping effects, adjusting for country and potential confounders.

**Results**: The sample included 2,062 HD patients from the US, UK, Australia, New Zealand, Canada, and Sweden in DOPPS (2009-11). In general and whatever the instrument, both engagement coping strategies and the summary score were positively associated with better QoL scores and inversely associated with depression symptoms. In contrast, disengagement strategies were inversely associated with better QoL scores and positively associated with depression symptoms. The PFE score was inversely associated with mortality (HR = 0.78 per 4 points higher score; 95% CI: 0.66-0.9).

**Conclusions**: Coping strategies appear to be beneficial and disengagement detrimental for HD patients. A better understanding of the coping strategies used by patients may have prognostic implications and may help to improve disease management by providing tailored care for each patient.

**TH-PO930**

**Intradialytic Aerobic Cycling Exercise Improve Inflammation Status, Endothelial Progenitor Cells and Bone Density in Patients with End Stage Renal Disease on Maintenance Hemodialysis**

**Aim**: To investigate whether aerobic training and electrical stimulation to skeletal muscles can improve inflammatory status, endothelial function and bone density in maintenance hemodialysis patients.

**Methods**: We conducted the study in a single-center hospital in Japan. A total of 35 patients with end-stage renal disease undergoing maintenance hemodialysis (ESRD) were recruited. Patients were randomly assigned into an exercise or control group for 3 months. The cycling session consisted of 5 minutes warm-up, 20 minutes cycling at desired workload and 5 minutes cool-down during the three weekly dialysis sessions. Biochemical markers, inflammatory cytokines and nutritional status as well as serum endothelial progenitor cells (EPCs) count, bone mineral density and functional capacity were checked.

**Results**: There were no statistically differences in the baseline characteristics between groups. Biochemical and anthropometric parameters revealed improvement in serum albumin, body mass index and inflammatory cytokines in the exercise group. Statistically significant changes in numbers of CD133/134/KDR cells were observed in exercise group, whereas EPCs increased significantly during the study. The patients in exercise group showed a significantly greater 6-minute walk test than at baseline. Subjects who were able to walk faster showed greater increases in EPCs than other subjects. Bone loss at the femoral neck was significantly greater in the control group compared with the exercise group which essentially showed no change. The bone mineral density (BMD) change at the lumbar spine (L1 to L4) was not significantly different between the treatment groups.

**Conclusions**: Inclusion of aerobic exercise in clinical practice can decrease inflammation, increase nutritional status and bone mass index, improve 6-minute walk distance, and increase the number of EPCs in HD patients.

**TH-PO931**

**Multicenter Trial of Aerobic Exercise in Maintenance Hemodialysis Patients**

**Aim**: To investigate the effectiveness of aerobic exercise on quality of life, exercise capacity, physical function, and other clinical outcomes in patients with end-stage renal disease.

**Methods**: This was a multicenter trial. A total of 35 ESRD patients on three occasions (20 males, 15 females; age: 70±17 years) were randomized to receive 12 weeks of aerobic training exercise during hemodialysis session (Ex-group: n=19), electrical stimulation to the lower limbs (ES-group: n=6), or no specific intervention (Cont-group: n=10). The Borg
scale was used to control the intensity of training. At baseline and study completion, the primary outcome measures were grip strength, workout time, activities, dialysis efficacy, HDL, LDL, CRP, IL-6 and blood pressure.

Results: In the Ex-group, handgrip, quad torque, and workout time increased significantly (P<0.05). Dialysis efficacy, HDL-cholesterol, LDL-cholesterol, CRP, and blood pressure on the morning of the dialysis day also improved significantly (P<0.05). These effects were not observed in the Cont-group. In the Ex-group, quad muscle torque and dialysis efficacy increased significantly (P<0.05). IL-6 decreased significantly (P<0.05), compared to the other two groups.

Conclusions: In this study, the safety and efficacy of training and electrical stimulation during hemodialysis were confirmed without sudden drop of blood pressure or any other side effects. Therefore, training during hemodialysis session for 12 weeks might improve physical function with specific whole-body effects as well as local effects in ESRD patients.

TH-PO932
Glycemic Markers and 2-Year Non-Diabetic Hemodialysis Outcomes from the Glycemic Indices in Dialysis Evaluation Study
Mark E. Williams,1 Neal Mittman,2 Lin Ma,1 Julia I. Brennan,1 Curtis D. Johnson,1 Franklin W. Maddux,1 Eduardo K. Laeson,1,3 Joslin Diabetes Center, Boston, MA; 4Kidney Care of Brooklyn and Queens, Brooklyn, NY; 5Prescient Medical Care North America, Wallum, MA; 6Spectra Laboratories, Rockleigh, NJ; 7Physician, Lexington, MA.

Background: The ongoing GIcDE (Glycemic Indices in Dialysis Evaluation) study includes data on nonDM hemodialysis (HD) patients (confirmed by HgbA1c >6.5%). Because nonglycemic factors may lower HgbA1c levels in ESRD, we previously reported their glycemic status/1-year outcomes using alternative glycemic markers [albumin-adjusted and unadjusted fructosamine (AlbF,F) and glycated albumin (GA) or percent GA (%GA)].

Methods: 970 nonDM HD patients from 26 FMCNA facilities with glycemic markers from Jan-March 2013 were followed until April, 2015. Baseline AlbF, F, GA and %GA were used to classify patients as high or low glycemia using thresholds of AlbF>97mg/dL, F>285mg/dL, %GA>15.7%, and GA>300mg/dL. Standard and Time-dependent (TD) Cox models with case-mix adjustment for age, sex, race, ethnicity, BMI, HD catheter and baseline comorbidity were used to determine associations between each glycemic index and hospitalization/death risk.

Results: While 1% had HgbA1c>7%, high glycemic status was more commonly detected using F (59%), AlbF (4%), GA (15%) and %GA (29%). Elevated AlbF was significantly associated with 2-year mortality [Standard Cox: Hazard Ratio (HR)=2.53, 95% CI (1.31, 4.92), p=0.006; TD Cox: HR=3.55, 95% CI (1.97, 6.38), p<0.0001] and hospitalization [TD Cox: HR=2.49, 95% CI (1.70, 3.67), p<0.0001]. For all other glycemic markers, no such associations were evident at the proposed thresholds using adjusted analysis in the Cox model.

Conclusions: These data support our previous findings of an association between poor glycemic status (high AlbF) and hospitalization/mortality outcomes in non DM HD patients. High AlbF-glycemic status may have prognostic implications in nonDM HD patients.

TH-PO933
Association of Change in Serum HDL Cholesterol with Mortality in Hemodialysis Patients: Role of Gender
Sheila Mrazevski,1 Elami Streja,1 Tae Hee Kim,1 Connie Rhee,1 Steven M. Brunelli,2 Mott L. Kashyap,1,3 Nosratola D. Vaziri,1 Kamary Kalantar-Zadeh,1 Hamid Moradi,1,3 UC Irvine; 2DaVita Clin Research; 1VA Long Beach.

Background: Elevated high-density lipoprotein cholesterol (HDL) levels, though protective in the general population, can be associated with higher mortality in hemodialysis (HD) patients. Association of HDL change over time with mortality has yet to be examined. Based on previous studies, we hypothesized that upward trends in HDL levels may be associated with higher mortality risk in HD patients.

Methods: We examined HDL change over time in 24,400 incident HD patients receiving care from a large dialysis organization in 2007-2011. Association of delta HDL (HDL change between the 1st and 2nd 91st day interval from dialysis start) and HDL trajectory with all-cause mortality were examined using mixed effect and Cox regression models and adjusted for demographics, comorbidities and baseline HDL. Delta HDL was treated both as a continuous variable using restricted cubic splines and in categories<-6, -6 <-2, -2<-2 (Ref), 2<-6, and ≥6 mg/dL.

Results: Patients were 63±15 years old, 44% female, 31% black, 66% diabetic with a mean baseline HDL 40±13.9 mg/dL and HDL change 1.7±10.4 mg/dL. While male patients had no significant change in HDL over time, females had a significant decrease in HDL (mean -0.6mg/dL/year). A≥6 mg/dL increase or decrease in delta HDL was associated with a 7% and 37%, respective increase in all-cause mortality compared to reference group. Delta HDL-mortality associations did not differ across gender.

Conclusions: Increased HDL over time was associated with worse outcomes and increased HDL was paradoxically associated with higher mortality. While HD treatment can be associated with a decrease in HDL, this effect was magnified in younger females. The novel and intriguing role of age and gender in association of HDL and survival needs further evaluation.

TH-PO934
Differences in Perceived Kidney Disease Burden on Quality of Life by Race/ Ethnicity in a Diverse Cohort of Hemodialysis Patients
Anna C. Porter,1 Rani Gallardo,2 Linda A. Schiffer,1 Denise M. Hynes,2,4 Dept of Medicine, Div of Nephrology, Univ of Illinois Hospital and Health Sciences System, Chicago, IL; 2Dept of Medicine, Div of Academic General Internal Medicine and Geriatrics, Univ of Illinois at Chicago, Chicago, IL; 3Inst for Health Research and Policy, Univ of Illinois at Chicago, Chicago, IL; 4Center of Innovation for Complex Chronic Healthcare, Edward Hines Jr., VA Hospital, Hines, IL.

Background: Low health-related quality of life (HRQOL) has been well-documented in patients with end-stage renal disease on hemodialysis (ESRD). While African Americans and Hispanics remain at increased risk for ESRD, HRQOL has been less well-described in these individuals compared to non-Hispanic whites.

Methods: Baseline HRQOL data was analyzed for participants enrolled in the Patient-Centered Medical Home for Kidney Disease study (PCMH-KD), a trial of a multidisciplinary, patient-centered primary care intervention in a population of hemodialysis patients at two dialysis facilities in Chicago. The Kidney Disease Quality of Life (KDQOL-SF 36) instrument was used to assess HRQOL at baseline, and the following subscale scores were obtained: Physical, Mental, Burden of Kidney Disease, Symptoms and Problems, and Effects of Kidney Disease.

Results: Baseline data were available for 95 patients. Approximately, 52% of patients were African-American, and 45% were Hispanic. Significant racial/ethnic differences were observed among subscales of self-reported HRQOL.

Conclusions: Hispanic patients with ESRD on HD report disproportionate burden and effects of kidney disease on HRQOL and worse HRQOL compared to African American patients with ESRD on HD. Further exploration of these disparities may lead to strategies for improvement of HRQOL in Hispanic patients.

Relative Blood Volume and Mortality in Hemodialysis Patients
Linda H. Picciolo, Paul Balter, Mark Costanzo, Patricia B. Taylor, Claudi Mullon, Robert J. Kossman.
1 Fresenius Medical Care North America (FMENA), Waltham, MA; 2 Renal Research Inst (RRRI), New York, NY.

**Background:** A quality improvement project on fluid management using Crit-Line® Monitors (CLM) was conducted across multiple RRI facilities. Percent change in relative blood volume (RBV) was measured during routine hemodialysis (HD). Previous analyses of the same cohort have shown associations between RBV reduction and reduced hospital admission rate; the current analysis assesses mortality.

**Methods:** A retrospective analysis of HD treatments with RBV measurements was conducted over 6 months. RBV was calculated using: RBV= [(Hematocrit of the same cohort have shown associations between RBV reduction and reduced hospital

**Results:** Patients were divided into RBV categories by 5% increments and compared on risk of death during the 6 months (Table). There was an increased risk of death with less reduction in RBV. For example, using patients with the greatest reduction in RBV (<-15%) as the reference, patients with the least reduction in RBV by the end of HD had 16 times the risk of death. Modeling time to death, there is a 15% increase in risk of mortality for each 1% increase in the end of HD blood volume (p=0.0001). Similar results were obtained after controlling for age, gender, and race (11% increased risk, p=0.002).

**Conclusions:** In a large cohort of HD patients with relative blood volume measured, patients with less reduction in percent change in relative blood volume at the end of dialysis had higher risk of death over 6 months when compared to patients with greater reduction. These patients may represent a subset of patients at high risk for adverse outcomes and may benefit from fluid management programs.

TH-PO936
The Effect of Altitude on Erythropoiesis-Stimulating Agent Dose, Hemoglobin Level, and Mortality in Hemodialysis Patients
Scott Sibbald, Donna E. Jensen, John Alan Laich, Sarb Sarchgill, Bradley J. Maroni, Steven M. Brunelli.
1 DaVita Clinical Research, Minneapolis, MN; 2 Akebia Therapeutics, Cambridge, MA.

**Background:** Prior studies have shown that hemodialysis (HD) patients residing at higher elevations have lower erythropoiesis-stimulating agent (ESA) utilization, possibly due to activation of hypoxia-regulated genes. We sought to better understand the impact of altitude on dosing of anemia medications and mortality following 2011 changes to the US epoetin alfa label and reimbursement policy.

**Methods:** We studied a cohort of prevalent nonveteran HD patients (vintage >6 months) treated at a large dialysis organization between 1 Jan 2012 and 31 Dec 2012. Patients were compared across categories of altitude for longitudinal hemoglobin (Hb) level, ESA and intravenous (IV) iron dose, and mortality risk using mixed linear models. Associations were adjusted for baseline demographic and clinical characteristics.

**Results:** Compared to altitude of 0-1499 ft, higher altitude was incrementally associated with higher mean Hb and lower mean ESA dose; mean IV iron utilization did not differ. Altitude>-4500 ft was independently associated with lower mortality risk; incidence rate ratio (IRR) was 0.74 with 95% confidence interval (CI) 0.63-0.88.

**Conclusions:** Among contemporary HD patients receiving treatment at altitude >1500 ft, higher altitude was independently associated with higher Hb level despite lower ESA doses and comparable IV iron utilization. Altitude of >4500 ft was independently associated with a 26% lower mortality risk.

Achieved Iron Stores and Clinical Efficacy in a Trial of Ferric Citrate as a Phosphate Binder
Kausik Umanathan, Molly Mcfadden, Diana I. Jalal, Yoram Yagil, Erwin Antonio Aguilar, Anas Abou-Ismail, Mohammad Sika, Robert M. Niecsew, Mark Koury, Julia Lewis, Tom Greene, Barbara A. Greco, Stephen Z. Fadem, Jamie P. Dwyer, The Collaborative study group.
1 Henry Ford Hosp; 2 of Utah; 3 of Utah; 4 Ben-Urban U; 5 LSU; 6 Vanderbilt; 7 Baystate Med Ctr; 8 Baylor College of Med.

**Background:** Adequate Fe stores are needed for hemopoiesis in erythropoiesis stimulate-deprived patients, but optimal Fe stores achieving efficacy/safety are unknown. PO Fe preparations have been unable to do this. In a Ph3 RCT we showed ferric citrate (FC) as a Ph binder > FC stores and IV iron/ESA use. We studied IV iron/ESA use in the trial based on achieved Fe stores.

**Methods:** 441 pts randomized 2:1 to FC or non-Fe-containing active control (AC) were followed for 52 wks. IV iron use was at a site discretion while ferric1000mg/mL and TALT30%. Generalized estimating equations calculating 1IV 1IV iron/ESA dose to 4-mo means of ferrits/TALT to IV iron by randomized group, adjusting for age, sex, race, CHF, and DKG, giving odds ratios (OR) for ESA use >75th Nule (0.161 Unite/wk) or IV iron use >median for 104 iron dose (47.7 mg/wk) to compare middle and highest TALT/ferrits tertiles to lowest.

**Results:** 398 pts for ESA, 409 pts for IV iron were analyzable. In AC, ORs for ESA dose were 0.63 (0.42-0.93, p=0.03) for middle TALT, 0.33 (0.15-0.75, p=0.03) for highest TALT tertile. FC group was similar, Table 1. Ferritin did not predict ESA use in AC. In AC, ORs for 1IV iron dose were 0.51 (0.34-0.78) for middle TALT, 0.39 (0.20-0.76) for highest TALT tertile; FC was similar, Table 2. tertnull trended to IV iron use, Table 2.

**Table 1. Ability of TALT and ferritins at higher tertiles to predict ESA usage>75% percentile.** TALT 1-28, ferritin 1-529 are reference groups. AC: active control; FC: ferric citrate

<td>0.35-0.74</td>
</tr>
</tbody>
</table>

**Conclusions:** TALT predicted IV iron/ESA, TALT>37% showing lowest use. In these ranges no TALT limit existed over which further IV iron/ESA did not occur. ferritins levels predicted IV iron, not ESA use. TALT may better predict ESA responsiveness in ESRD.

TH-PO938
Sotatercept Improves Anemia, Vascular Calcification, and Bone Loss in Patients with End-Stage Kidney Disease on Hemodialysis

**Background:** This ongoing, randomized, single-blind, placebo (PBO)-controlled study evaluated the pharmacokinetic (PK), safety, and hemoglobin (Hb) effect of sotatercept, an ActRIIB-IgG1 fusion protein ligand, in hemodialysis (HD) patients and explored its effects on vascular calcification (VC) and bone mineral density (BMD) using quantitative computed tomography (QCT).

**Methods:** Subjects were washed out of erythropoietin-stimulating agent (ESA) effects until Hb was <10 g/dL and randomized to PBO or sotatercept given subcutaneously every 4-mo means of ferritin/TSAT to IV iron by randomized group, adjusting for age, sex, race, CHF, and DKG, giving odds ratios (OR) for ESA use >75th (0.161 Unite/wk) or IV iron use >median for IV iron dose (47.7 mg/wk) to compare middle and highest TALT/ferrits tertiles to lowest.

**Results:** Among contemporary HD patients receiving treatment at altitude >1500 ft, higher altitude was independently associated with higher Hb level despite lower ESA doses and comparable IV iron utilization. Altitude of >4500 ft was independently associated with a 26% lower mortality risk.

310A
Results: Among subjects treated with PBO (n=9) or sotatercept 0.3 mg/kg (n=9), 0.5 mg/kg (n=8), and 0.7 mg/kg (n=9), adverse events were mostly mild/moderate, unrelated to study drug, similar in type/severity between groups, and generally consistent with subject medical histories. Two deaths occurred in the PBO group. There were no dose-dependent changes in home BP. In the 225-day treatment phase, HB was ~9.0 g/dL in 33%, 33%, 63%, and 78% of subjects treated with PBO or sotatercept 0.3, 0.5, or 0.7 mg/kg, respectively. Paired QCTs obtained in 4, 6, 5, and 6 subjects treated with PBO or sotatercept 0.3, 0.5, or 0.7 mg/kg showed <15% progression of VC in 33%, 80%, 80%, and 100%, and 2-3% increase in femoral neck cortical BMD in 0%, 20%, 40%, and 75%, respectively.

Conclusions: Sotatercept appears to be well tolerated with an acceptable safety profile in HD, without increases in home BP. There are beneficial dose-related responses to sotatercept in HB, VC, and BMD. A larger dataset, with an ongoing 14-day dose group, will further substantiate these results.

Impact of CKD-MBD Composite Score on Mortality and Hospitalization: Dialysis Outcomes and Practice Patterns Study (DOPPS)
Douglas S. Fuller,1 Paul Dluzniewski,2 Kerry Cooper,3 Brian D. Bradbury,4 Mark D. Danese,5 Bruce M. Robinson,1,6 Francesca Torenti,1,7 Aron Research Collaborative for Health, Ann Arbor, MI;8 Amgen, Thousand Oaks, CA;9 Outcomes Insights, Inc., Westlake Village, CA;10 Univ of Michigan, Ann Arbor, MI;11 Vandy University, Nashville, TN.

Background: The biochemistries associated with chronic kidney disease-mineral and bone disorder (CKD-MBD), parathyroid hormone (PTH), calcium (Ca), and phosphorus (P), are physiologically interrelated. We evaluated the impact of combinations of CKD-MBD parameters on outcomes targets in HD patients.

Methods: We identified DOPPS 3-5 (2005-2014) pts in the US, Canada, and Europe (France, Germany, Italy, Spain, Sweden, and the UK) with ≥12 mos of follow-up. We assessed demographic and clinical covariates in study miss 9-12 and used Cox models to generate disease risk scores (DRS) by region based on pts with CKD-MBD parameters outside target (MBD 0; P 3.5-5.5 mg/dL, Ca 8.4-10.2 mg/dL, PTH 150-600 pg/mL) and to compare event rates, adjusted for DRS, of mortality and a composite of death or hospitalization between MBD 0 and pts with 2-3 values outside target (MBD 2+).

Results: MBD 2+ prevalence, primarily due to high PTH and P, was 22.8%, 29.5%, and 26.9% in the US, Canada, and Europe, respectively. PTH above target was higher in the US (52%) compared to Canada (42%) and Europe (28%). Compared to MBD 0, MBD 2+ was associated with moderately higher mortality in the US and Canada but not Europe; MBD 2+ was weakly associated with higher composite rates in all three regions. We observed slightly stronger associations in pts with 2+ MBD labs above target only.

Conclusions: Distributions of CKD-MBD parameters varied by region, perhaps resulting in differential risk of adverse outcomes. Our findings in this international cohort highlight the importance of simultaneous, rather than independent, control of MBD parameters within clinical guidelines ranges.

US DOPPS Practice Monitor: Comparisons with CMS ESRD Databases
Douglas S. Fuller,1 Lindsay Zepel,2 Keith McCullough,3 Brian Bieber,4 Ronald L. Pisoni,5 Francesca Torenti,6 Bruce M. Robinson.7 Aron Research Collaborative for Health, Ann Arbor, MI.

Background: Since August 2010, the Dialysis Outcomes and Practice Patterns Practice Monitor (DPM, www.dopps.org/DPM) has leveraged its US hemodialysis (HD) sample (now >200 facilities) to provide timely and detailed (~750 data tables) updates on national trends in HD care. Here we compare DPM estimates to available results from end-stage renal disease (ESRD) data sources collected by the Centers for Medicare and Medicaid Services (CMS).

Methods: Pearson correlations (r) were used to compare contemporary trends since Aug 2010 between DPM and the 2014 US Renal Data System Annual Data Report (ADR, through Dec 2012) and the Nov 2014 CMS Claims-Based Monitoring Project (CBMP, through Jun 2014). We also compared monthly DPM estimates with cross-sectional estimates from 2014 CrownWEB (CW, Dec 2013).

Results: DPM trends in ESA dose use and dose, IV iron use, and hemoglobin levels were highly correlated (r’s: 0.89-0.98) with ADR and CBMP trends. Compared to CW, DPM showed slightly higher fístula use, but slightly lower percent of patients with adequate Kt/V and URR values.

Table: Comparisons of US DPM national estimates to CMS ESRD data sources

</tbody>
</table>

Conclusions: DPM reports IV medications use as prescription at the end of the month (before Apr 2012) or anytime during the month (Apr 2012 and after), rather than administration. Thus, estimates for ESA and IV iron utilization each month may be somewhat different due to spontaneous or withheld dosing. Differences with CW cross-sectional estimates may result from differences in calculation methods. DPM includes non-Medicare patients that are not necessarily present in claims-based sources. DPM now includes new years of monthly follow-up estimates for US HD care. Although differences in data sources and specifications may influence direct comparisons, DPM data remain an important resource for identifying important trends in HD care before confirmations from CMS ESRD databases are available.

TH-PO941
Reduced Free Triiodothyronine Is an Independent Predictor of Clinical Outcomes in Hemodialysis Patients with Low Albuminemia
Akihiko Kato,1 Masafumi Ono,1 Takayuki Tsuji,1 Naro Ohashi,2 Hideo Yasuda.3

1Blood Purification Unit, Hamamatsu Univ Hospital, Hamamatsu, Shizuoka, Japan;2Internal Medicine 1, Hamamatsu Univ School of Medicine, Hamamatsu, Shizuoka, Japan.

Background: Low free triiodothyronine (FT3) and free thyroxine (FT4) are both related to malnutrition, inflammation and mortality in dialysis patients. Upper-normal thyrotrpin (TSH) levels are also associated with a higher risk of total mortality in hemodialysis (HD) patients. However, it remains unclear which of thyroid-related hormones is most useful in predicting clinical outcomes. So, we aimed this study to compare the prognostic value of different hormones in prevalent HD patients.

Methods: We enrolled 339 HD patients (age: 64±13 years old, time on HD: 129±114 months), and measured basal FT3, FT4 and TSH. We then followed the patients for the next 42 months, and assessed the impact of FT3, FT4 and TSH on all-cause mortality and cardiovascular (CV) events or hospitalization. Patients were divided into the 4 groups based on the quartiles of FT4, FT3 and TSH. The associations of basal levels with clinical outcomes were examined with Cox proportional hazards models adjusted for demographic and classical factors and comorbidities.

Results: FT3 was independently associated with mortality in HD patients. In this study, FT3 level was significantly lower in the low albuminemia group compared to the normal albuminemia group.

Conclusions: FT3 is an independent predictor of clinical outcomes in HD patients with low albuminemia.
Results: Mean serum fT3 and fT4 were 2.01±0.37 [0.95-3.73] pg/ml and 0.86±0.20 [0.35-1.67] ng/dl. Serum levels of fT3 and fT4 were lower than those of reference ranges in 85.0% and 56.0% of the patients, respectively. In contrast, TSH levels were within the reference range in most patients (92.9%). Cox hazards analyses revealed that the lowest quartile of fT3 (<1.75 pg/ml) was an independent predictor of all-cause mortality (HR 3.55 [95%CI: 1.17-4.09; p<0.01]), all-cause mortality plus CV events (HR 2.19 [95%CI: 1.53-3.823; p<0.01]), and all-cause mortality plus hospitalization (HR 2.16 [95%CI: 1.28-3.67; p<0.01]) when compared with those with the top quartile (fT3>90 pg/ml). However, the significant impact of low fT3 on prognosis was observed only in patients with serum albumin lower than 3.8 g/dl (n=195). In contrast, serum fT4 and TSH levels did not relate to prognosis.

Conclusions: These findings suggest that low fT3 became an independent predictor of clinical outcomes in HD patients with low albuminemia.

Comparing Dialysis Facility Compare (DFC) Star Rating to QIP Payment Categories
Claudia Dahlert, Richard Hirth, Joe Wheeler, Yi Li, John Bails, Christopher J. Harvey, Zhi He, Joel S. Andress, Dahlerus, Zebi, and H. Shearon
Southmead Hospital, Bristol, United Kingdom

Background: The CMS recently developed hospital readmissions measures to reflect quality of care provided by nursing homes, long-term care hospitals, inpatient rehabilitation facilities, home health agencies and dialysis facilities. The intent is to encourage care coordination as patients transition between care providers. All measures adjust for patient characteristics. CMS has not adjusted quality measures for patient socioeconomic status (SES), so as to not to confound disparities in care delivery. However, not including such adjustments may result in inappropriate assessments about quality of care. We present preliminary analyses assessing the association of SES and readmission among dialysis patients.

Methods: Using 2013 Medicare claims data, we model the probability of readmission, defined as an unplanned readmission within 30 days of a hospital discharge, adjusted for patient characteristics including age, sex, BMI, comorbidities, discharging hospital, and several measures of SES, plus measures reflecting SES of the patient’s area of residence.

Results: Patients with Medicare secondary payer (MSP) were less likely to experience a readmission (OR 0.92; CI 0.90-0.93); patients with dual Medicare and Medicaid coverage (OR 1.08; CI 1.01-1.09), unemployed at ESRD incidence (OR 1.07; CI 1.06-1.08) and living in zip codes with high unemployment, low education and income disparity were more likely to experience a readmission.

Conclusions: Insurance status and area of residence are strong proxies for SES and are associated with readmissions. MSP, largely reflective of private insurance coverage, can be an indicator of higher SES and perhaps better health. Dual eligibility for Medicare and Medicaid can be an indicator of lower SES, as can being unemployed at ESRD incidence. As interest in risk adjusting for indicators of SES has grown, the association between SES and readmission suggests further analysis may be appropriate. However, caution must be exercised in efforts to distinguish between SES factors that may or may not be related to quality of care.

TH-PO945
Co-Morbidities (CM) Do Not Predict Adverse Outcomes in Peritoneal Dialysis (PD) versus Hemodialysis (HD) in a Multi-Ethnic Asian ESRD Cohort
Geek Biswas, Kunhu Chow, Vathsala Anantharaman
Health Promotion Board, Singapore; 1 National Univ Health System.

Background: There is conflicting data on outcomes following HD vs PD. USRDS data for ESRD in 2002-2004 suggested similar outcomes for HD and PD over 5 years of followup. This study evaluated outcomes for HD vs PD from a multi ethnic Asian ESRD population and evaluated the impact of CM on worse outcomes in either modality.

Methods: 3739 HD and 1330 PD patients who were included in the Singapore Renal Registry (SRR) in 2001-2007 and followed up till death or 31 Dec 2012 comprised the study population. Data on patients’ demographics, CM and survival were collected. Patients were stratified by age, presence of diabetes(DM) and occurrence of 1 or more vascular(1) vs non-vascular(NV) CM. 5-year survival was compared using Kaplan-Meier and regression analyses.

Significance of the Decreased Risk of Dialysis-Related Amyloidosis Now Proven by Results from Japanese Nationwide Surveys in 1998 and 2010

**Method:** We used the 1998 and 2010 Japan Renal Data Registries to compare crude survival rates. In the 1998 cohort, 1.77% experienced first-time CTS as proxy for DRA; in the 2010 cohort, 0.5% experienced first-time CTS as proxy for DRA. We compared survival rates between the two cohorts using a propensity score-matched analysis.

**Results:** In the 1998 cohort, 0.5% experienced first-time CTS as proxy for DRA; in the 2010 cohort, 0.1% experienced first-time CTS as proxy for DRA. We found that the risk of first-time CTS decreased significantly from 1.77% in 1998 to 0.5% in 2010.

**Conclusions:** The incidence of first-time CTS as proxy for DRA decreased significantly from 1998 to 2010. Several factors may have contributed to this decrease, including improved dialysis methods.

Twice Weekly Hemodialysis and Clinical Outcomes in the China DOPPS

**Method:** We used data from the China Dialysis Outcomes Practice Patterns Study (DOPPS) to evaluate survival and hospitalizations by frequency of HD.

**Results:** We studied 1433 patients from 45 HD units in China (2012-2015). CTS regression was used to model the association between 2 vs. 3 times weekly HD and clinical outcomes adjusting for patient and treatment characteristics.

**Conclusions:** Twice-weekly HD was undergoing 2 times weekly HD in China. Compared with 3 times weekly HD, patients on 2 times weekly HD were more likely to be female and have shorter time on dialysis (4.3 vs. 2.6 yrs), more urine output, shorter dialysis session length (238 vs. 250 min) and longer travel times to facility. They were less likely to have diabetes or cardiovascular disease. Insurance coverage was similar in the two groups. During follow-up (median=1.7 years), 184 (13%) deaths and 516 (38%) hospitalizations occurred. No differences in mortality or hospitalization were found between the two frequency groups.

nephrology practice for ~4 months before starting RRT), but received no RCC interaction. The albumin (Alb) and hematocrit (Hct) were collected at the first outpatient HD treatment. We also compared the rates of hospital deaths and mortality in the first 120 days of HD.

Results: 1,404 CKD 5 patients were included for the analysis, where 51% of the population was enrolled in the RCC. Patients in the RCC had a lower % of patients, higher % of Alb ≥4.0g/dL, and higher % of Hgb 10-11g/dL at the first HD treatment compared to patients with a “Timely Referral”, but no RCC care. During a 120 day follow up after initiating HD, patients in the RCC program had significantly lower hospitalization rates.

Extracellular Overhydration Measured by Multifrequency Bioelectrical Analysis Is Associated with Increased Postdialytic Systolic Blood Pressure in Hemodialysis Patients

Jae Yeul Park,1 Seok-hyung Kim,2 Ah Ran Choi,1 Jung eun Lee,1 Hyung Jong Kim,1 Hoon Young Choi,1 Sung-Kyu Ha,1 Hyeong cheon Park.1

1Nephrology, Gangnam Severance Hospital, Yonsei Univ College of Medicine, Seoul, Korea; 2Nephrology, Jongin Severance Hospital, Yonsei Univ College of Medicine, Seoul, Korea

Background: Postdialytic hypertension is associated with increased morbidity and mortality for hemodialysis (HD) patients. Recent studies suggest that increased postdialysis extracellular volume may account for the rise in postdialytic systolic blood pressure (PDSBP), the aim of this study was to assess the relationship between volume status and PDSBP in HD patients.

Methods: Volume status assessments were performed during mid-week HD using multifrequency bioelectrical impedance (BIA, Inbody 710) in supine position. Normal and routine biochemical data were collected and pre- and post-dialysis B-type natriuretic peptide (BNP) level was measured (Triage BNP test, Alere).

Results: We enrolled clinically stable 99 HD patients from 3 dialysis centers. Patients were divided into 3 groups based on a fall in SBP of 20mmHg or more (Hypotensive, 24.2%), an increased SBP of 1mmHg or more (Hypertensive, 32.3%), and a stable group (43.4%). The mean age was 55±13.3 years in hypertensive, 58.3±11.6 years in stable, and 65±2.7 years in hypotensive group. Postdialysis BNP was 267±85.1 pg/ml in hypertensive, 669±91.9 pg/ml in hypotensive, and 212±197.1 pg/ml in stable group. There were no differences in gender, dialysis prescriptions, and subjective global assessment score among the patient groups. The ECW/TBW ratio was significantly higher in the hypertensive group and positively correlated with PDSBP and delta SBP. The only independent risk factor affecting the PDSBP was ECW/TBW ratio after dialysis.

Conclusions: HD patients who demonstrate increase in PDSBP should have their volume status reassessed and target dry weights adjusted using BIA, with emphasis on increased the ECW/TBW ratio.

TH-PO950

Novel Phosphate Binder, Ferric Citrate Hydrate, Can Reduce Serum Phosphate Levels and Doses of Erthropoiesis Stimulating Agents in Japanese Patients on Hemodialysis

Hirokane Koguma,1 Ryoko Takahashi,1 Keiko Kimura,1 Chieko Matsubara,1 Hiromi Tanimoto,1 Mari Maseki,1 Yasuhiro Ito.1

1Nephrology, Nagoya Kyoritsu Hospital, Nagoya, Japan; 2Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Japan

Background: Ferric citrate hydrate (FC) has been available in Japan as a phosphate binder for patients on dialysis (HD) since 2014 although its effects have not been evaluated in detail in such patients. The present study aimed to determine the effects of FC on serum phosphate levels and anemia control in patients on HD.

Methods: Thirty-eight outpatients (mean age, 62.5 y; male, n= 28 [73.7%]; mean HD vintage, 7.2 y; hypertension, n = 29 [76.3%]; diabetes, n = 19 [50.0%]; secondary hyperparathyroidism, n = 15 [39.5%]) on maintenance HD were treated with FC for six months to control hyperphosphatemia. Serum concentrations of phosphate, calcium, hemoglobin, and ferritin levels, transferrin saturation (TSAT), and weekly epoetin (EPO) doses were evaluated.

Results: Mean phosphate levels were significantly decreased from 7.05 ± 1.11 to 6.19 ± 0.91 (p < 0.0001), 6.14 ± 1.16 (p < 0.005) and 601.11 ± 11 (p < 0.005) mg/dL at one, three and six months, respectively. Calcium, hemoglobin and ferritin levels did not significantly differ during the same periods. Transferrin saturation was significantly increased (26.7 ± 10.9% vs. 20.0 ± 9.3%, p < 0.05) and the weekly EPO dose was significantly decreased (2750 ± 2699 vs. 6801 ± 7406 IU/week, p < 0.05) after six months of FC therapy.

Conclusions: FC can decrease serum phosphate levels and the weekly EPO dose. Therefore, FC is useful for treating hyperphosphatemia and renal anemia in Japanese patients on HD.

TH-PO951

Geographic Variation of Potentially Avoidable Readmissions in Hemodialysis Patients

Daniel W. Ross,1 Kamyar Kalantar-Zadeh,2 Steven Fishbane,1 Anna Mathews.1 1Div of Nephrology, Hofstra North Shore –LIJ School of Medicine, New York, NY; 2Harold Simmons Center for Kidney Disease Research and Epidemiology, Div of Nephrology, Univ of California, CA.

Background: In 2011 in the United States, 36.3% of prevalent hemodialysis patients were readmitted within 30 days of an index hospitalization. These rates are approximately twice that of the general U.S. Medicare population. While some readmissions to hospital are unavoidable, it is probable that a substantial number could be prevented. In the present study, we describe inter-state variability in 30-day potentially avoidable readmissions (PAR).

Methods: The United States Renal Data System (USRDS) was used to identify prevalent hemodialysis patients (vintage ≥90 days) with acute hospitalizations in 2008. Exclusion criteria were transfer to rehabilitation or skilled nursing facility, unknown dialysis start date, and renal function recovery. PAR were identified using a validated, computerized algorithm (SQLape), and displayed by state using Pitney Bowes MapInfo.

Results: 250,606 index hospitalizations were identified, with 37% readmissions within 30 days (n = 94,279). Nationwide, 24% of index hospitalizations were followed by a 30-day PAR (64.9% of all readmissions) (n= 59,803). PAR ranged from 12% to 31% by state. The figure shows the geographic distribution of potentially avoidable readmissions.

Conclusions: There is inter-state variability in PAR among chronic hemodialysis patients, and this may be related to regional differences in practice patterns or patient demographics. Further characterization of risk factors associated with PAR is the focus of our ongoing research.

TH-PO952

Unravelling the Relationship Between Mortality, Hyponatremia, Inflammation and Malnutrition in Hemodialysis Patients: Results from the International MONDO Initiative

Marike J.E. Dekker,1 Danielle Marcelli,2 Bernard J. Canaud,1 Constantijn Konings,1 Karel M. Leunissen,3 Nathan W. Levin,1 Jochen G. Raimann,1 Frank van der Sande,2 Len A. Usuyiat,4 Peter Kotanko,4 Jeroen Kooman.1,4 Catharina Hospital Eindhoven;1,4 Maasstricht Medical Center;1 Fresenius Medical Care;1 Renal Research Inst.

Background: Hyponatremia is a risk factor for mortality in hemodialysis patients. However, it is not well known to which extent comorbidities, such as malnutrition, fluid overload and inflammation are related to hyponatremia and influence the association between hyponatremia and outcomes.

Methods: We studied 8892 patients from the European subset of the MONDO Initiative. Nutritional and fluid statuses were assessed by multifrequency bioimpedance spectroscopy. Based on pre-dialysis fluid status, fluid depletion was defined as an extracellular water volume < -1.0L and fluid overload > +2.5L. Malnutrition was defined as a lean tissue index below the 10th percentile of age- and gender matched healthy controls. Hyponatremia and inflammation were defined as serum sodium levels < 135 mEq/L and C-reactive protein levels >10 mg/L, respectively.

Results: Hyponatremia was predicted by the presence of malnutrition (odds ratio (OR) 1.48 (95%CI 1.30-1.69) and inflammation (OR 1.44 (95%CI 1.26-1.64)), but not by fluid depletion (OR 1.38 (95%CI 0.98-1.93) or fluid overload (OR 0.99 (95%CI 0.85-1.14)). Malnutrition (hazard ratio (HR) 1.39 (95%CI 1.23-1.58)), inflammation (HR 2.31 (95%CI 2.04-2.62)), fluid overload (HR 2.17 (95%CI 1.90-2.47)) and hyponatremia (HR 1.63 (95%CI 1.39-1.90)) were independent predictors for all-cause mortality.

Conclusions: In hemodialysis patients hyponatremia is associated with malnutrition and inflammation but not with deranged fluid status. Hyponatremia maintained predictive for all-cause mortality after correction for malnutrition, inflammation and fluid status abnormalities. Hyponatremia may aid efforts to identify hemodialysis patients at increased risk of death.
Low Serum Sodium Concentration at the Induction of Maintenance Hemodialysis Predicts Higher Risk of Mortality

Yukako Ohyama, Hideaki Shimizu, Dajo Inaguma, Yoshio Fujita.

Background: Low serum sodium concentrations are associated with an increased risk of death in the general population because of underlying diseases such as congestive heart failure and cirrhosis. However, some papers report hypernatremia itself further increases the mortality risk. The prevalence of hypernatremia and the mortality risk of hypernatremia at the induction of maintenance hemodialysis (HD) haven’t been reported before.

Methods: This study is a retrospective cohort study which was collected from “Aichi Cohort study of Prognosis in Patients” (AICOPP) newly initiated dialysis. After the exclusion of peritoneal dialysis (PD) patients, this study enrolled 1395 patients (mean age; 68 ± 13 years, mean eGFR level; 5.4 ± 2.2 mL/min/1.73m²) who started maintenance HD between 10/1/2011 and 11/30/2013. We divided the cohort to 4 groups by serum sodium concentration at the induction of HD adjusted by serum glucose concentration (Severe hyponatremia: Na <130, Mild hyponatremia: 130 ≤ Na <136, Normal: ≥136 Na <145, Hypernatremia: Na ≥145 mEq/L). The proportional hazard model was used to examine the association between serum sodium level and mortality.

Results: The prevalence of hyponatremia, defined as Na <136 mEq/L and ≤130 was at 23% and 5%, respectively. During 15.5 months’ mean follow up, 159 patients (11%) died. The lowest Na group was significantly associated with higher risk of mortality (figure1). Patients with serum sodium levels of <130 mEq/L were more likely to have multivariable-adjusted mortality hazard ratios (95% confidence interval) of 2.34 (1.31-4.15) compared to patients with serum sodium levels of 136-145 mEq/L.

Conclusions: Hyponatremia at the induction of HD is an independent predictor of higher risk for mortality.

Hyperkalemia Events in Dialysis Patients in a Large Dialysis Organization

Akeem Yusuf, Yan Hu, Bhupinder Singh, Alex Yang, James B. Wetmore.

Background: Hyperkalemia is a major problem in dialysis patients. It is associated with increased risk of cardiac arrhythmias and sudden cardiac death. However, few studies have examined frequency of hyperkalemia episodes in a large population of dialysis patients. We present a characterization of the magnitude of hyperkalemia prevalence in a large hemodialysis population and examine the role of interdialytic interval in its occurrence.

Methods: We derived annual cohorts of hemodialysis patients (2007-2010) from linked DaVita and USRDS databases. Included patients were those receiving thrice-weekly hemodialysis. On a monthly basis, hyperkalemia case was defined as a serum potassium level greater than or equal to 5.5 mEq/L. Hyperkalemia prevalence was calculated as the cumulative number of monthly episodes divided by cumulative follow-up time. Hyperkalemia prevalence was also reported separately by long and short interdialytic interval.

Results: Hyperkalemia prevalence in 2010 was 16.3 per 100 patient-months. Overall, hyperkalemia prevalence was stable between 2007 and 2010. The prevalence of hyperkalemia events occurring on day after the long interdialytic interval was about 2.0 to 2.4 times as high as events occurring on the day after the short interdialytic interval.

Conclusions: The findings from this study show that hyperkalemia is highly prevalent among hemodialysis patients, especially on the day after the long-interdialytic interval. Further studies are warranted.

Funding: Pharmaceutical Company Support - ZS Pharma, Inc.
Background: Low health literacy (LHL) is common worldwide among HD patients. Variability in LHL prevalence across countries may be in part explained by cultural differences as well as health care systems. Vulnerable patients are at highest risk of LHL, and LHL is an independent predictor of mortality. Further examining by country the role of health system practices may help to overcome LHL-related barriers to patient engagement and improve outcomes in hemodialysis.

Funding: Pharmaceutical Company Support - The DOPPS Program is supported by Amgen, Kyowa Hakko Kirin, AbbVie Inc., Sanofi Renal, Baxter Healthcare, and Vifor Fresenius Medical Care Renal Pharma, Ltd. Additional support for specific projects and countries is also provided in Canada by Amgen, BHC Medical, Janssen, Takeda, Kidney Foundation of Canada (for logistics support); in Germany by Hexal, DGN, Shire, WIne Institute; for PDDPS in Japan by the JSPD. TH-PO958

Evaluation of a Vancomycin Weight-Based Dosing Protocol in Patients Undergoing High-Flux Hemodialysis

Katherine Desanges, Marieme N'Daye, Robert Zoel Bell, Jean-Philippe Lafreniere, Vincent Pichette, Michel Valerie. Nephrology, Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.

Background: Hemodialysis patients are frequently subject to Gram-positive infections including Staphylococcus aureus and Methicillin-resistant Staphylococcus aureus (MRSA). Vancomycin is an antibiotic of choice in this population to treat these infections. The objective of this project was to validate the performance of a pre formulated individual prescription protocol of vancomycin in its capacity to reach target vancomycin serum concentrations of 10 to 30 mg/L for Gram-positive infections and 15 to 20 mg/L for MRSA infections.

Methods: The records of 84 patients diagnosed with end-stage renal disease undergoing a 4-hour, three times weekly high-flux hemodialysis treatment were analyzed retrospectively. All patients received vancomycin according to a weight-based dosing protocol between 2011 and 2014. Patients < 70 kg received a 1000 mg loading dose followed by a 500 mg maintenance dose at each dialysis session. Patients between 70 and 100 kg received a 1500 mg loading dose followed by 750 mg maintenance dose. Patients > 100 kg received a 1500 mg loading dose followed by a 1000 mg maintenance dose.

Results: We collected and analyzed 189 dosages of 84 patients. For all assays, 95.2% achieved levels between 10 and 30 mg/L and 50.3% achieved levels between 15 and 20 mg/L. Stratified by weight categories, for the 10 to 30 mg/L target, 93.3% of patients < 70 kg, 100% of patients between 70 and 100 kg and 89.5% of patients > 70 kg achieved the target serum concentrations. For the 15 to 20 mg/L target, 49.3% of patients < 70 kg achieved the target serum concentrations (mainly below), 61.3% of patients between 70 and 100 kg achieved the target serum concentrations and 31.6% of patients > 100 kg achieved the target serum concentrations (mainly higher, but below 30 mg/L).

Conclusions: The vancomycin weight-based dosing protocol achieved target serum concentrations of 10 to 30 mg/L in 95.2% of patients. However, because half the dosages of patients < 70 kg were below the target of 15 to 20 mg/L, vancomycin bolus and maintenance doses should be adjusted upward in this subgroup. No dose change is suggested in the other subgroups.

TH-PO959

Trends in Incident ESRD Counts Initiating Dialysis in Freestanding Facilities Have Regional Variation

David T. Gilbertson, Peer Kidney Care Initiative Investigators, JCDRG, MRF, Minneapolis, MN; Peer Kidney Care Initiative.

Background: Overall rates of incident end-stage renal disease (ESRD) patients initiating dialysis in freestanding units have stabilized, and the growth in counts of incident ESRD patients began to slow by the beginning of this decade. We assessed trends in incident ESRD counts from 2004–2011, overall and geographically by the 9 US Census Divisions.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

316A
Methods: Data were ascertained from the Centers for Medicare & Medicaid Services ESRD database. For annual incident cohorts, we identified patients with their first outpatient dialysis within 3 months of initiating chronic dialysis in a freestanding facility.

Results: Yearly counts increased through 2010, with an average annual percent increase of 2.7% from 2004 to 2011. Between 2009 and 2011, this average percent increase was relatively unchanged (6%). However, there were regional differences, with increased New England Census Division experiencing the largest proportionate decrease in incident patients between 2009 and 2011, while the contiguous Middle Atlantic division averaged the highest increase during the same period by 2011.

Conclusions: Overall trends in dialysis incidence reveal substantial geographic variation that has not been explained, suggesting that an assessment based on overall U.S. counts may mask important regional differences. Whether these trends will continue in the face of increasing diabetes rates, an aging population and shifts in social demographic changes is uncertain and will require more detailed analysis.

Funding: Pharmaceutical Company Support - Financial support for Peer is provided by 13 participating dialysis provider organizations: American Renal Associates, Atlantic Dialysis Management Services, Centers for Dialysis Care, DaVita HealthCare Partners, Dialysis Clinic, Inc. (DCI), DSI Renal, Fresenius Medical Care, Independent Dialysis Foundation, Northwest Kidney Centers, Renal Ventures Management, Satellite Healthcare, The Rogosin Institute, and U.S. Renal Care. In collaboration with the Chief Medical Officers of these organizations, the Peer Kidney Care Initiative is operated by the Chronic Disease Research Group, a division of the Minneapolis Medical Research Foundation, in Minneapolis, Minnesota, Private Foundation Support

TH-P0960

Association of Intradialytic Hypoxemia with Hospitalization and Mortality:
Results from a Large U.S. Hemodialysis Cohort

Hanjie Zhang,1 Xiaoling Ye,1 Doris F. Fuertinger,1 Franz Kappel,2 Mikhail Artemyev,3 Nancy Ginsberg,4 Yuedong Wang,2 Stephan Thijsse,3 Peter Kotanko.1,14

1 Research Real Institute, New York, NY; 2Univ of Graz, Austria; 3Univ of California - Santa Barbara, CA; 4Icahn School of Medicine at Mount Sinai, New York, NY.

Background: While intradialytic hypoxemia is recognized since the early days of hemodialysis (HD), its associations with hard clinical outcomes have not yet been assessed.

Methods: We analyzed arterial oxygen saturation (SaO2) data obtained by Crit-Line™ monitor (CLM) in chronic HD patients treated between 1/2012 and 1/2015. An individual 6-month baseline with at least 10 CLM measurements preceded a 12-month follow-up. Prolonged intradialytic hypoxemia (PIH) was defined as SaO2 ≤ 90% for more than 1/3 of treatment time. Patients were stratified based on the presence or absence of PIH. We conducted Cox proportional hazards analysis with adjustment for age, gender, race, vintage, chronic obstructive pulmonary disease (COPD), congestive heart failure (CHF), diabetes, albumin, hemoglobin, erythropoietin (EPO) dose, neutrophil-to-lymphocyte ratio, interdialytic weight gain, post-HD systolic blood pressure, and ultrafiltration rate.

Results: We analyzed 1,730 patients (59% males; 53% whites) with 30.5 baseline SaO2 measurements. 100 patients (10.2%) had PIH. PIH patients showed a higher prevalence of CHF and COPD compared significantly more EPO, and resembled an inflammatory phenotype. During the follow-up, 221 and 1.5 hospitalizations per patient-year were recorded in patients with and without PIH, respectively (P=0.009). Eighty-nine patients died during follow-up. The mortality rate was 24.1% per 100 patient years in the PIH group and 12.5% in the no-PIH group. The mortality rate was 97.1% and 86.1% after 15 min of dialysis, 96.5% and 95.1% after 30 min, 97.3% and 88.3% after 1 h, and 99.6% and 90.1% after 4 h. The cumulative in-platelet count during dialysis was significantly smaller with the NF than with the BG. The SPP was well maintained in NF but time-dependently deteriorated in BG.

Results: The total amount of removal in each area, B2MG, A1MG and albumin leakage was different in both NF and BG. During dialysis, the percent change in platelet count were (for NF and BG, respectively) 97.1% and 86.1% after 15 min of dialysis, 96.5% and 95.1% after 30 min, 97.3% and 88.3% after 1 h, and 99.6% and 90.1% after 4 h. The total amount of removal in each area are not significantly different in any subjective symptoms, but the mean score of the seven items tended to be lower in NF.

Conclusions: The new PMMA (NF) membrane may improve the QOL of chronic dialysis patients by stabilizing the platelet and peripheral circulation.

TH-P0962

Outcomes of Infants Receiving Chronic Peritoneal Dialysis

Hongyang Dai,1 Laurel K. Willig,2 Bradley Warady,3

1 Nephrology, Children's Mercy Hospital, Kansas City, MO; 2Research and Development and Clinical Investigation, Children's Mercy Hospital, Kansas City, MO.

Background: Outcome data for infants receiving chronic peritoneal dialysis (CPD) is limited and has been reported primarily by small voluntary registries. The impact of treatment era has also been poorly studied.

Methods: The USRDS database was reviewed for demographic features and outcomes of patients who initiated CPD within the first year of age from 1990-2014.

Results: A total of 1,730 infants (575 $1 month and 1155 $12-months) who initiated CPD at $12 months from 1990-2014 were identified. Overall, 68% of the infants were male and the most common primary diagnoses were obstructive uropathy (31.8%) and congenital renal dysplasia/hypoplasia (29.9%). Mean age at initiation of CPD was 0.4 months (+/- 0.3 months) in infants $1 month and 5.2 months (+/- 3.1 months) in infants $12 months.

Overall, 1066 infants received at least one kidney transplant during the follow up (333 infants $1 month and 733 infants $12 months). Mean age at first kidney transplant was 2.9 years (+/- 2.5 years) in infants $1 month and 2.5 years (+/- 2.5 years) in infants $12 months. Crude all cause mortality rates were higher among infants who initiated CPD at $1 month (276 per 1000 persons at 3 years) versus infants who initiated CPD at $12 months of age (185 per 1000 persons at 3 years). Mortality rates at ages 5 years were 28.7% for infants initiated on CPD at $1 month and 20.7% for infants at $12 months of age. Multivariable Cox proportional hazards modeling of factors associated with mortality demonstrated a statistically significant adjusted HR of 4.027 (95% CI 3.274-4.952) for initiation era (1990-2000 vs 2001-2014) and an HR of 1.42 (95% CI 1.15-1.744) for age at initiation of dialysis ($1 month vs $12 months). Patient sex, race, and primary ESRD diagnosis were not significantly associated with mortality in this model.

Conclusions: In the largest cohort of infants on CPD reviewed to date, the probability of mortality among infants initiating CPD in the first year of life appears to be greater during the prior initiation era (1990-2000) and greater among infants who initiated dialysis at $1 month of age.

TH-P0963

ESRD from Scleroderma in the United States 1995-2010

Donal J. Sexton, Scott Reule, Robert N. Foley, Medicine, Univ of Minnesota, Minneapolis, MN.

Background: Though the management of scleroderma continues to evolve it is unknown whether the burden of ESRD from scleroderma has changed.

Methods: We examined United States Renal Data System data (N = N = 1,557,117) for the years 1995-2010 to calculate incidence rates and outcomes of ESRD due to scleroderma.

Results: ESRD rates due to scleroderma in 1995-1996 were 0.6 per million per year in the overall population, with higher rates in age 40-64 (0.9) and $65 (1.4) years, females (0.8) and African Americans race (0.9). Standardized incidence ratios declined between 1995-1996 and 2009-2010 in the overall population (ratio 0.55), in those aged 40-64 yrs (0.49), 65 yrs (0.62), in male (0.56) and female sex (0.55), in white (0.56) and AA race (0.37). Characteristics of ESRD from scleroderma included age 40-64 (57.9% Vs. 41.3% yrs.), female sex (76.6% Vs. 45.1%) and white race (78.1% Vs. 65.2%). 74.3% of patients with scleroderma died over a mean observation period of 3.3 years, while 16.9% were
listed for renal transplant and 10.1% received a renal transplant. With matching for age, sex and race, overall mortality rates were higher in scleroderma cases than controls (22.3 Vs. 15.5 per 100 person-years, P < 0.001). Overall rates of listing for renal transplant (8.4 Vs. 8.5 per 100 person-years, P = 0.92) and rates of transplantation (4.1 Vs. 4.3 per 100 person-years, P = 0.66) were similar in scleroderma cases and controls.

Conclusions: The incidence of ESRD from scleroderma appears to have declined in the United States since 1995. Mortality rates on RRT are higher in scleroderma than controls taken from ESRD from other causes. However, listing for and receiving a renal transplant were as likely in scleroderma patients as matched controls.

TH-PO964

Prevalence and Mortality Associations of Protein- Energy Wasting Syndrome Criteria in Maintenance Hemodialysis Patients

Srini Beddu,1,2 G. Wei,1 Xiaorui Chen,1 Kalani L. Raphael,1,2 Robert E. Boucher,1 Dominique Ferranti,1 Tom Greene,1 Michel Chonchol.1 1U of Utah; 2VA SLC; 2UC Denver.

Background: As the prevalence and mortality associations of protein-energy wasting (PEW) syndrome criteria in the MHD population are not well established, we examined these in 1480 MHD pts in the HEMO Study, a multi-center RCT to examine the effects of dialysis dose and dialyzer flux on mortality.

Methods: The prevalence of International Society of Renal Nutrition and Metabolism panel PEW criterion (listed in the table) at the 12 m follow-up visit were examined. Subsequent mortality associations were examined in Cox models adjusted for demographics, duration of ESRD, Kt/V and flux groups, smoking and alcohol use.

Results: There were 632 deaths / 3390 yrs of follow-up. The prevalence of PEW criterion varied widely: 0% for low body fat% to 64% for low DEI (figure).

Low serum albumin and cholesterol, low BMI, weight loss and low mid-arm muscle circumference (MAMC) were strongly associated with higher risk of mortality (Table 1). However, dietary criteria were not associated with mortality.

<table>
<thead>
<tr>
<th>PEW Criterion</th>
<th>All cause mortality HR* (95% CI)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Serum Alb &lt; 3.5 (g/dl)</td>
<td>2.12 (1.68, 2.69)</td>
</tr>
<tr>
<td>Serum Chol &lt; 100 (mg/dl)</td>
<td>3.68 (2.46, 5.50)</td>
</tr>
<tr>
<td>BMI &lt; 23 (kg/m2)</td>
<td>1.51 (1.23, 1.86)</td>
</tr>
<tr>
<td>Wt loss &gt;10%</td>

<tr>
<td>Muscle mass category</td>
<td></td>
</tr>
<tr>
<td>Low MAMC</td>
<td>2.00 (1.60, 2.50)</td>
</tr>
<tr>
<td>Dietary protein intake (DPI) ≤ 0.60 (g/kg/day)</td>
<td>1.00 (0.80, 1.24)</td>
</tr>
<tr>
<td>Dietary energy intake (DEI) ≤ 25 (kcal/kg/day)</td>
<td>0.87 (0.72, 1.05)</td>
</tr>
</tbody>
</table>

*as none had body fat% < 10%, this variable could not be examined; 10% or more lower than the 50th percentile of reference population

Conclusions: As there is a wide variability in the prevalence of PEW criteria, the thresholds used in their definition need to be further refined. Dietary variables were not associated with mortality and the validity of these variables as PEW criteria also needs further study.

TH-PO965

Primary Care Physician Involvement in the Care of Chronic Dialysis Patients in the U.S.

Background: Current health reform efforts aimed at improving quality and value center around delivery of good primary care. However, national patterns of primary care physician (PCP) involvement along with a nephrologist in the care of chronic dialysis patients are unknown.

Methods: Patients on chronic dialysis during 2010-11 with Medicare as the primary insurer were identified using US Renal Data System (USRDS) data. PCP involvement was defined based on a claim for an outpatient (non-dialysis) visit with a physician specializing in family practice, general internal medicine or geriatrics. Patients were characterized with respect to two aspects of preventive care: influenza vaccination and diabetes care.

Results: The sample included 179,645 patients, 81,272 of whom were diabetic. In 2010, 59% of patients had evidence of PCP involvement based on 1 outpatient visit. Patients with PCP involvement were older and more likely to be female, white and with diabetes as cause of ESRD (Table). Rates of vaccination and diabetes care were higher in those with PCP involvement, even after adjustment (ORs: 1.48 [1.45-1.51] for vaccination and 1.53 [1.48-1.58] for a composite of diabetes care).

Conclusions: Even under the least defined of PCP involvement, over one quarter of dialysis patients have no evidence of PCP involvement. Patients with PCP involvement have higher rates of preventive care, but further study should examine the impact on outcomes and costs.

Are We Choosing Wisely? A Study of Colon Cancer Screening Practices Among Dialysis Patients in the United States

Christopher A. Carlos,1 Chi-yan Hsu,2 Meda E. Pavkov,1 Nilka Rios Burrows,2 Vahakan B. Shahinian,2 Rajiv Saran,2 Neil R. Powe,1 Kirsten L. Johansen.1 1Univ of California, San Francisco, San Francisco, CA; 2Univ of Michigan, Ann Arbor, MI; 3Centers for Disease Control and Prevention, Atlanta, GA.

Background: Because estimated net gains in life expectancy are very small, the American Society of Nephrology recommended against routine cancer screening in asymptomatic dialysis patients. We aimed to determine how often colon cancer screening is performed in the U.S. and whether colon cancer screening is targeted toward healthier dialysis patients. Methods: We performed a retrospective cohort study of patients aged ≥50 years on dialysis between January 1, 2007 and September 30, 2012 using data from the United States Renal Data System (USRDS). Using multivariable Cox regression models, patients were divided into quartiles based on the risk of death and the likelihood of receiving a kidney transplant and, according to these quartiles of risk, we then assessed the likelihood of colon cancer screening (CCS) by fecal occult blood testing, sigmoidoscopy or colonoscopy from Medicare claims data.

Results: Of 391,616 patients, 13% received CCS over a median follow-up of 1.5 years (interquartile range 0.7-2.9). Screening was most common in patients with the lowest mortality risk (16%), compared with 9% of those with the highest mortality risk (HR 1.33;
Hypertension, Mayo Clinic.

Amer, Trends and Outcomes Severe Sepsis Hospitalizations in Those on Maintenance Dialysis – National TH-PO967

Unadjusted in-hospital mortality is higher in MD (30.3% vs 26.2%; p<0.001). Age-adjusted mortality is decreasing in both subgroups though trend was not significant in MD. Age-adjusted mortality continues to be higher in MD (Fig 1). MD is an independent risk factor for mortality with OR 1.26 (95% CI 1.23-1.29).

Conclusions: Hospitalizations with SS are over 40 times more common in MD. Mortality is higher in MD and being on MD is an independent predictor of mortality in those admitted with SS. Though incidence of SS seems to be increasing, there is a trend towards decrease in mortality even in MD.

TH-PO968

Trends in Colorectal Cancer Screening in U.S. End-Stage Renal Disease Population Kevin C. Abbott,1 Chyng-Wen Fwu,2 Paul L. Kimmel,1 Paul W. Eggers,1 Div of Kidney, Urologic Hematologic Diseases, NIDDK, NIH, Bethesda, MD; 1Social & Scientific Systems, Inc., Silver Spring, MD.

Background: Screening for colorectal cancer (CRC) has been recommended for those over 50 years old. Medicare coverage of CRC screening began in 2000. Dialysis patient care is shared by many practitioners, perhaps leading to therapeutic nihilism and insufficient screening. CDC data show almost 2/3 of patients at risk report CRC screening. We determined rates of CRC screening in ESRD hemodialysis (HD) patients, compared to a 5% Medicare sample, and to assess secular trends.

Methods: We used data from the 2001-2011 USRDS to describe trends in percentages of HD patients receiving CRC screening tests per year. We limited our study population to patients with Medicare Part A and B as primary payer to ensure complete Medicare claims data for CRC screening. Current Procedural Terminology /Healthcare Common Procedure Coding System (CPT/HCPCS) codes identified Medicare physician and supplier billing data for screening: colonoscopy (G0105 and G0121), sigmoidoscopy (G0104), and fecal-occult blood test (FOBT; G0107, G0328, and 82270). We compared HD data to a 5% Medicare sample.

Results: Overall, the proportion of HD patients having CRC screening decreased from 6.1% annually in 2001 to 3.5% in 2011 due to decreased use of FOBT. There was a persistent increase in the proportion of patients with colonoscopy or sigmoidoscopy for CRC screening in the 11-year study period, from 0.3% to 1.0% annually. In most years, male, black and age 50-75 patients were more likely to receive colonoscopy or sigmoidoscopy than female, white, and other age subgroups. In 2006, the most recent available comparable year, CRC screening in HD patients was less than that of the general Medicare population; 0.8% vs. 1.6% annually for colonoscopy and sigmoidoscopy, 6.0% vs. 8.1% including FOBT.

Conclusions: Screening for CRC in ESRD HD patients is less frequent than in the general Medicare population, and considerably less than CDC recommendations. Differences in ascertainment methods (CDC uses self-report) may account for most of the disparity from CDC estimates.

Funding: NIDDK Support

TH-PO969

Background: Voluntary withdrawal from dialysis, which frequently occurs when a patient perceives dialysis as having become unduly burdensome, is an area of increasing interest. How early withdrawal, defined as that occurring within 1 year of dialysis initiation, has changed over the past decade has not been fully explored.

Methods: Patients initiating dialysis between 2004 and 2011 were selected from the Centers for Medicare & Medicaid Services End-Stage Renal Disease (ESRD) database. Information on withdrawal was ascertained from the ESRD Death Notification Form by the presence of code 104 (“withdrawal”) in the 1st or 2nd position. The unadjusted cause-specific monthly mortality rate (deaths per 100 pt-years) was calculated for patients initiating in each year.

Results: Overall, the proportion of HD patients having CRC screening decreased from 6.1% annually in 2001 to 3.5% in 2011 due to decreased use of FOBT. There was a persistent increase in the proportion of patients with colonoscopy or sigmoidoscopy for CRC screening in the 11-year study period, from 0.3% to 1.0% annually. In most years, male, black and age 50-75 patients were more likely to receive colonoscopy or sigmoidoscopy than female, white, and other age subgroups. In 2006, the most recent available comparable year, CRC screening in HD patients was less than that of the general Medicare population; 0.8% vs. 1.6% annually for colonoscopy and sigmoidoscopy, 6.0% vs. 8.1% including FOBT.

Conclusions: Screening for CRC in ESRD HD patients is less frequent than in the general Medicare population, and considerably less than CDC recommendations. Differences in ascertainment methods (CDC uses self-report) may account for most of the disparity from CDC estimates.

TH-PO967

Severe Sepsis Hospitalizations in Those on Maintenance Dialysis – National Trends and Outcomes Ankit Sakhija,1 Kianoush Banaei-Kashani,2 Hatem Amer,1 Robert C. Albright,2 Nephrology, Univ of Michigan; 1Nephrology and Hypertension, Mayo Clinic.

Background: Severe sepsis (SS) is a life-threatening condition requiring early diagnosis and management. Incidence of SS is increasing in general population (GP) and mortality is declining; however, epidemiology and outcomes of SS have not been well studied in those on maintenance dialysis (MD). We designed this study to look at incidence and outcomes of SS in those on MD.

Methods: Using Nationwide Inpatient Sample database we included all hospitalizations (age ≥20 yr) with SS based on ICD-9-CM codes of severe sepsis, septic shock or blood stream infection with organ dysfunction from 2005 to 2010. Those on MD were identified based on ICD-9-CM codes. Age adjusted incidence of SS and mortality in subgroups was calculated by direct standardization to 2000 standard US population. Linear regression was used to assess trends over time and logistic regression to assess independent effect of MD on mortality.

Results: Of estimated 5,000,152 (95% CI: 4,798,520-5,201,784) hospitalizations with SS, 6.4% were on MD. Unadjusted incidence of SS was 145.4/1000 in MD compared to 3.5/1000 in GP with incidence rate ratio 40.9 (95% CI: 40.8-40.9). Age adjusted incidence of SS, 6.4% were on MD. Unadjusted incidence of SS was 145.4/1000 in MD compared to 3.5/1000 in GP with incidence rate ratio 40.9 (95% CI: 40.8-40.9). Age adjusted incidence of SS seems to be increasing in both subgroups though trend was not significant in MD (Fig 1).

Conclusions: Our findings suggest that screening was appropriately targeted to dialysis patients with longer life expectancies and away from those with the lowest chances of receiving kidney transplantation.

Funding: NIDDK Support, Other U.S. Government Support
Conclusions: Withdrawal rates are high in the weeks immediately after dialysis initiation, a pattern more marked in recent years. Because patients who withdraw soon after initiation may be suboptimal dialysis candidates, future work should focus on determining whether a tailored approach, designed to identify individual patient goals and present the risks and benefits of dialysis and viable alternatives such as conservative care, might provide optimal patient-centric care.

TH-PO971
Calcific Uremic Arteriolopathy: Mortality Outcomes with and without Sodium Thiosulfate Therapy
Chamberlain L. Obialo, Alexander Quarshie.
Dept of Medicine, Morehouse School of Medicine, Atlanta, GA; Clinical Research Center, Morehouse School of Medicine, Atlanta, GA, Venezuela.

Background: Calcific uremic arteriolopathy (CUA) or Calciiphylaxis is commonly seen in patients with end stage kidney disease (ESKD) and carries a high mortality risk. There is no definite therapy for this condition but promising results have been reported in patients treated with intravenous sodium thiosulfate (STS). However, the mortality advantage of therapy with STS over therapy without STS remains unknown.

Methods: We retrospectively reviewed our ESKD patient’s records over a 10-year period and identified 45 biopsy confirmed cases of CUA. Associations between patients who received STS therapy and those who did not and various categorical end points were assessed using the Pearson chi-squared tests while differences in continuous end points were examined using Mann-Whitney-U tests. Survival analysis utilized Kaplan-Meier plots. All statistical tests were two-sided, and level of significance set at 0.05.

Results: The mean age of the 45 cases was 63, 60% female, mean body mass index was 34 and mean dialysis vintage was 4 years. Of the 45 cases, 23 (51%) received STS while 22 (49%) did not. The mean level of serum albumin, phosphorus and parathyroid hormone was 2.8 g/dl, 6.7 mg/dl and 989 pg/dl respectively. One –year mortality was 22% in STS vs. 50% in no STS cases, p = 0.05. The overall survival of the patients over the 2- year study period was significantly superior in the recipients of STS than in those who did not receive STS, p = 0.03.

Patients who did not receive STS were also more likely to have major surgeries than those who received STS, 86% vs. 52%, p = 0.01.

Conclusions: Sodium thiosulfate therapy appears to confer both short term and long term survival advantage over no STS. We encourage hospitals and dialysis companies to procure and make this agent more available to physicians.

Effect of High-Dose and High-Flux Hemodialysis on Markers of Inflammation in the HEMO Study
Kristen L. Nowak,1 Tom Greene,2 Jian Ying,2 Alfred K. Cheung,2 Michel Chonchol.1 1Univ of Colorado Denver; 2Univ of Utah.

Background: Hemodialysis treatment induces markers of inflammation, which could affect clinical outcomes. This study sought to determine whether high-dialysis dose and high-flux dialysis would improve markers of inflammation compared with standard dialysis dose and low flux dialysis.

Methods: The HEMO Study was a randomized multicenter study of the effects of high-dose versus standard-dose and high-flux versus low-flux hemodialysis. Serum high sensitivity C-reactive protein (hs-CRP, pre-specified primary outcome for this set of analyses) and interleukin-6 (IL-6) were measured in stored serum samples in 1,846 HEMO participants. For each inflammatory marker we used a joint multi-state modeling approach to estimate the proportion of patients in 5 ordered states (S) over 3 annual assessments while accounting for mortality: S1=deceased (score=0); S2=alive in highest quartile (score=1); S3=alive in 3rd quartile (score=2); S4=alive in 2nd quartile (score=3); and S5=alive in lowest quartile (score=4). The average rank was computed over 3 yrs of follow-up and compared to the estimated probabilities of states.

Results: Randomized patients had high rates of coexisting conditions: 45% had diabetes, and 80% had a history of cardiac disease. Characteristics of the patients in the two dose groups were similar, as were the characteristics of those in the two flux groups. The state distribution of hs-CRP in each year by dose (KTV) group and by flux group for each dose group was similar, as were the characteristics of those in the two flux groups.

Conclusion: Randomized patients had high rates of coexisting conditions: 45% had diabetes, and 80% had a history of cardiac disease. Characteristics of the patients in the two dose groups were similar, as were the characteristics of those in the two flux groups.

Comorbidity Data Source May Impact SMR/SHR Calculation

Jianmong Liu,1 Mahesh Krishnan,2 Jincheng Zhou,1 Kimberly M. Nieman,1 Yi Peng,3 David T. Gilbertson,1 1CDRG, MMRF, Mpls, MN; 2DaVita Healthcare Partners, Denver, CO.

Background: Standardized mortality and hospitalization ratios (SMRs and SHRs) are used to measure dialysis facility performance, with adjustment for demographics and comorbidities derived from the end-stage renal disease (ESRD) Medical Evidence (ME) Report. Sensitivities are low for ME-based comorbidities. We investigated the effect on SMR and SHR calculations by comparing ratios adjusted for claims-based comorbidities.

Methods: Using the USRDS ESRD database, we included US hemodialysis patients who initiated dialysis July 1-December 31, 2006-2010, had Medicare as primary payer, were aged ≥66 years, and had no prior transplant (TX). Patients were followed from dialysis initiation to the earliest of death, TX, modality change, or 1 year. SMRs and SHRs were calculated for patients in for-profit/non-profit and rural/urban facilities for ME-based and claims-based comorbidity, separately. Cox models were used for expected number of deaths and piecewise Poison models for expected number of hospitalizations. Agreement of comorbidity between the two sources was measured by a kappa statistic.

Results: 73,950 incident hemodialysis patients were included. Kappas for comorbidity agreement were low, less than 0.5, except for diabetes (0.77). Percent of patients with claims-based comorbidity was similar for for-profit and non-profit facilities; ME-based lowest was for for-profit facilities. Differences between ME-based and claims-based SMRs/SHRs were statistically significant. Compared with ME-based SMR/SHR, claims-based ratios decreased 0.9%/0.6% for for-profit and 1.0%/0.7% for urban facilities and increased 3.4%/2.8% for non-profit and 5.9%/4.1% for rural facilities.

Conclusions: Comorbidity data source may impact performance evaluation. The impact is larger for smaller groups, and may increase with prevalent patients included.

Thematic Analysis of the Medical Records of a National Cohort of Patients Who Initiated Maintenance Dialysis: 2000-2009

Susan P.Y. Wong,1 Elizabeth Vig,1 Nilka Rios Burrows,2 Chuan-fen Liu,3 Desmond Williams,7 Paul L. Hebert,1 Ann M. O’Hare,1 1Univ of Washington; 2Center for Disease Control.

Background: Little is known about how decisions to initiate dialysis take shape in clinical practice.

Methods: We performed a qualitative thematic analysis of the medical records of patients who initiated maintenance dialysis to understand factors that impact decisions to initiate maintenance dialysis as they occur in clinical context. We analyzed key care processes, patient-provider interactions and patient and/or provider concerns and considerations relevant to the decision to initiate dialysis as documented in the electronic medical records of a national random sample of patients for whom the decision to initiate maintenance dialysis was made at the Department of Veteran Affairs between 2000 and 2009 (n=1,691).

Results: We identified three dominant, overlapping themes pertaining to the decision to initiate dialysis: 1) dialysis initiation as process, which describes the decision to initiate dialysis as integrated with other treatment decisions and unfolding over time rather than an isolated decision occurring at a fixed point in time; 2) sources of momentum for dialysis initiation, which describes factors that appeared to hasten the process of dialysis initiation and included hospitalization for acute illness and efforts to optimize patients’ clinical status for future medical interventions; and, 3) push-pull dynamics between patients and providers, which describes the sometimes adversarial relationship between patients and providers during the process of dialysis initiation in which patients were often portrayed by providers as “resistant” to dialysis initiation while providers appeared paternalistic and safety conscious in their approach towards treatment decisions.

Conclusions: Our analysis of the medical record underscores the complexity of treatment decisions about dialysis initiation in real-world clinical settings and supports a re-conceptualization of dialysis initiation as a process that unfolds over time rather than as a discrete treatment decision occurring at a fixed point in time.

Trends in 30-Day Readmission Rates in Dialysis Patients During an Era of Medicare Payment Policy Changes, 1996-2012

Allan J. Collins,1 Peer Kidney Care Initiative Investigators.2 1MMRF; 2Peer Kidney Care Initiative.

Background: High hospital readmission rates, which may indicate inadequate quality of care and result in unnecessary expenditures, have been a recent focus for Medicare. Medicare has enacted payment-related policy changes: freezing the inpatient payment rate (1997), expanding “disproportionate share” hospital payments (early 2000s), tying

Key: TH - Thursday; FR - Friday; SA - Saturday; OR- Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
reimbursement for outpatient hemodialysis services to the number of monthly visits (2004), introducing the new Medicare prospective payment system (2011), and instituting the "hospital payment penalty" (2012). Given evidence demonstrating links between these changes and readmission rates in the general population, we sought to examine changes in 30-day readmission rates in dialysis patients 1996–2012.

Methods: Data were obtained from the Centers for Medicare & Medicaid Services End-Stage Renal Disease database. Dialysis patients were assessed for discharges from short-term or critical access hospitals. Thirty-day readmission rates were calculated, without adjustment for differences in patient case-mix or hospital characteristics.

Results: All-cause readmission rates increased modestly over the period studied except for 2012. The nadir was 32.8% in 1998; the rate increased to 34.6% in 2005, fell to 34.1% in 2009, and peaked at 34.8% in 2010. Discharge data in the first 6 months of 2012 showed further decrease (32.8%). In comparison, other studies show that the rate in the general Medicare population was relatively stable 2007-2011 (19.0%), and decreased in 2012 (18.4%).

Conclusions: Thirty-day readmission rates were substantial in dialysis patients compared with general Medicare patients, possibly reflecting case-mix. How public policy changes may have affected potentially avoidable readmissions should be more fully explored. Cause-specific readmission rates might provide a better reflection of quality of care and should be examined.

Funding: Pharmaceutical Company Support - Financial support for Peer is provided by 13 participating dialysis provider organizations: American Renal Associates, Atlantic Dialysis Management Services, Centers for Dialysis Care, DaVita HealthCare Partners, Dialysis Clinic, Inc. TH-PO976

The Impact of Volume Status on Nocturnal Hypoxemia in Patients Undergoing Maintenance Hemodialysis Farhanah Youssaf, Mitsuh K. Patel, Sherbether Marie C. Young, Chaim Charytan, Alla Goldberg, Bruce S. Spinowitz. New York Hospital Queens, flushing, NY.

Background: Hemodialysis patients experience changes in volume status according to hemodialysis schedule. Excess fluid volume may shift to the neck upon assuming a recumbent position during sleep, leading to engorgement of the great veins of neck and paripharyngeal edema. We explored the impact of volume status on nocturnal hypoxemia in the hemodialysis population.

Methods: Following local IRB approval, adult hemodialysis patients who were undergoing regular chronic hemodialysis (HD) for at least 3 months were consented to complete two nights of nocturnal oximetry using Pulsox 300i wristwatch. HD night was defined as the night of HD treatment whereas non-HD night was defined as the night on which no HD was performed. The first hour of recording was deleted in efforts to capture oximetry reading from sleep time only. Motion artifacts and aberrant data were also excluded from the analysis. Oxygen desaturation index (ODI) was defined as the number of desaturations ≥3% from baseline lasting ≥10 seconds, per hour. Paired t-test was used to compare HD and non-HD night related data.

Results: Twenty HD patients (11 males and 9 females) aged 54 ± 13 years with a mean body mass index of 25.5 ± 4.6 kg/m² and neck circumference of 38.4 ± 5.8 cm participated in the study. Mean ODI was 21.2 ± 21.1 on HD night versus 20.0 ± 19.8 on non-HD night (p=0.6) with a mean interdialytic weight gain of 1.9 ± 1.3 kg. The lowest recorded mean saturation was 76.±10% on HD night versus 73.5 ± 11% on non-HD night (p=0.3). Eleven of 20 patients, with a mean interdialytic weight gain of 2.1 ± 1.5 Kg, experienced worsening of ODI on non-HD night (16.9 ± 17.9) versus HD night (11.6 ± 13.8) [p=0.008]. Meanwhile, nine patients, with a mean interdialytic weight gain of 1.5 ± 0.9 Kg, exhibited improvement in ODI on non-HD night (23.8 ± 22.4) versus HD night (32.9 ± 23.1) [p=0.04].

Conclusions: Volume status alone does not explain HD to non-HD variation in nocturnal hypoxemia seen in ESRD population. Both central and obstructive mechanisms are likely involved. Additional research is warranted to further explore this phenomenon and develop preventive strategies.

Hospital Readmission within 30 Days of Discharge Among Adults Receiving Dialysis Loren S. Dalrymple, Barbara A. Grimes, Patrick S. Romano, Yi Mu, Danh V. Nguyen, Kirsten L. Johansen. UC Davis; UCSF; UC Irvine; San Francisco VA.

Background: Hospital readmission is common in adults receiving dialysis. Few studies have examined the timing or causes of 30-day hospital readmission.

Methods: We used the USRDS to examine adults initiating dialysis Jan 2009 trough Dec 2010 who had Medicare as the primary payer. The cohort was followed from day 90 of dialysis for up to one year; with censoring for death, renal recovery or transplant. We classified the principal cause of the index hospitalization and hospital readmission using Clinical Classification Software.

Results: Our cohort consisted of 103,381 patients. During follow-up, 50,639 patients experienced 89,728 index hospital admissions; 5% resulted in in-hospital death. Of the 85,284 live hospital discharges, 25,792 (30%) were associated with 30-day readmission. The median time to readmission was 11 [5, 19] days. Leading causes of readmission by cause of index hospitalization are in Table 1.

Funding: NIH/NIH, National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) support, Dialysis Clinic, Inc.

For the 5 most common causes of hospitalization, the principal cause for readmission was in the same category as the initial admission, accounting for 18-32% of readmissions.

Conclusions: Thirty-day hospital readmission in Medicare recipients on dialysis is frequently leading to readmission to the same category as the initial admission.

TH-PO978

Background: Recent research reported that Hispanics have the lowest all-cause mortality, African Americans (AAs) intermediate, and Whites the highest among U.S. dialysis patients over 30 years old. The objective of this study is to examine whether this risk pattern varied depending on the cause of death.

Methods: The study included 1,255,640 adult incident dialysis patients between 1995 and 2010 in the USRDS, with no prior kidney transplantation. We examined 5 major cause-specific deaths: cardiovascular (CVD), infection, malignancy, others, and unknown. Cause-specific hazards for each cause-specific death were compared among AAs, Hispanics, and Whites for overall and stratified by age groups.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

322A
Results: After adjustment for multiple covariates (Table), compared with Whites, in all risk groups, Hispanics consistently had lower risks of cause-specific deaths for all major causes examined (HRs<1), while AAs also had lower risks except for the cause of infection, for which AAs had significantly higher risks in age groups of 50 and >80 years (HRs from 1.07-1.94).

Conclusions: The racial difference observed in all-cause mortality, in which Hispanics have the lowest risk, AAs intermediate, and Whites the highest, was also noted for major cause-specific deaths in most age groups, except for the cause of infection. Both younger and older AAs are at the greatest risk of death due to infection. Further studies are needed to explore the specific reasons responsible for the higher risk of infection-related death in AAs.

TH-PO979

Dialysis Therapy and Mortality in Older Heart Failure Patients with Advanced Chronic Kidney Disease: The Kaiser Permanente MATCH Study

Background: Heart failure (HF) and chronic kidney disease (CKD) often coexist and those with both have much worse outcomes than having either alone, with limited data to guide optimal management. We evaluated the outcome of dialysis therapy in a diverse elderly cohort with HF and advanced CKD.

Methods: In Kaiser Permanente Northern California, a large integrated healthcare system, we identified members ≥70 years with HF and estimated glomerular filtration rate (eGFR) £20 ml/min/1.73 m² between 2008-2012 and no prior renal replacement therapy, cancer, cirrhosis or organ transplant. Through 2013, we identified patients who started chronic dialysis and individually matched controls who were alive on the dialysis start date of the matched case along with age, gender, diabetes status, and high-dimensional propensity score to start dialysis. Demographics, clinical features and drug use were obtained from electronic records. We calculated rates of death through 2013 and examined the impact of dialysis on mortality using Cox regression.

Results: We identified 334 eligible HF-CKD cases who initiated dialysis and 899 matched control HF-CKD patients. Mean age was 80±4±4 yrs, with 51% women, 33% black and 72% diabetic. Case and control patients were well-matched across characteristics, except for controls being less likely to be Hispanic or have proteinuria, or to receive alpha blockers or thiazide diuretics; and more likely to have prior intracranial bleed, liver disease, dementia and higher blood pressure, hemoglobin and mean eGFR (16.4 vs. 12.0 ml/min/1.73 m²). Incidence of death was 32 per 100 p-y in combined case and control patients. Among matched patients, after further adjustment for residual differences in patient features, dialysis was independently associated with a 47% lower rate of death (hazard ratio 0.53, 95%CI:0.41-0.67).

323A
During this period, 1-year PD technique failure decreased from 18.8% to 16.1% of patients and 1-year PD patient mortality decreased from 9.4% to 8.6% (see Figure). Outcomes were relatively stable or improving across patient age, race, and Hispanic ethnicity subgroups and for patients in both urban and rural areas.

**Conclusions:** In the context of expanding PD use under the new PPS, there is no early evidence of worsening overall PD patient outcomes or of growing disparities in PD patient outcomes by demographic group or by urban/rural location. Instead, there were lower levels of PD technique failure and PD patient mortality in the initial years of the new payment system.

Cognitive Impairment and Mortality in Adults on the Kidney Transplant Waitlist: Maria McAdams-DeMarco, Hao Ying, Israel O. Olorundare, Dorry L. Segev, Johns Hopkins.

**Background:** Older adults with poor cognitive function are at increased mortality risk. It is unclear whether ESRD patients of all ages with cognitive impairment are at increased mortality risk of while on the kidney transplant (KT) waitlist.

**Methods:** 918 ESRD patients being evaluated for and waitlisted for KT (no previous listings) at Johns Hopkins were enrolled in a prospective cohort study (11/2009-5/2014). The Modified Mini Mental Status (3MS), a test of global cognitive function (range 0-100, higher scores represent better function) was assessed at KT evaluation. Global cognitive impairment was defined as 3MS score<80). Mortality risk by 3MS score and cognitive impairment (separately) was estimated using an adjusted Cox proportional hazards model; participants were censored at the waitlist removal, time of KT or administrative end of follow-up.

**Results:** At KT evaluation, the mean (SD and range) age was 54 (14; 18-86), 57% were male, and 46% were African American. The mean (SD and range) 3MS score was 82.6 (11, 47-100) and 52% were classified as having cognitive impairment. 45 participants died over an average of 1.7 years of follow-up. Mortality risk was greater for adults on the KT waitlist who had worse 3MS scores (1 point decrease in 3MS score: HR=1.05, 95% CI: 1.02-1.08, P=0.003) and those with cognitive impairment (HR=2.51, 95% CI: 1.26-4.99, P=0.009) after adjusting for sex, age, race, education, and dialysis factors. The risk of mortality associated with cognitive impairment was similar for older (age>65) and younger (age<65) participants (P=0.73).

**Waitlist Mortality by Global Cognitive Impairment.**

**Conclusions:** Among adults ESRD patients, impairment in global cognitive function more than doubled the risk of waitlist mortality. A simple screener for global cognitive function scores at the evaluation for first listing would not only identify adults with ESRD who have unrecognized cognitive impairment but also identify a high-risk population.

Indications, Technique, and Outcome of Plasmapheresis in a Large Pediatric Dialysis Center. Rainer Büscher, Lübbert Lübbers, Anja K. Büscher, Peter F. Hoyer. Pediatric Nephrology, Univ of Duisburg-Essen, Pediatrics II, Essen, Germany.

**Background:** Plasmapheresis (PP) is a established therapeutic option for various indications in pediatric patients. However, there are only few reports with only little information on clinical outcome.

**Methods:** We performed a retrospective analysis involving 86 children and adolescents undergoing PP in our pediatric dialysis unit from 1997 to 2013.

**Results:** Within the observation period, 86 children (41 male), mean age 8.7±3.2 years (3 months to 18.9 years) received PP for a total of 652 sessions (1-33 sessions/patient; mean 6.4±3.1 sessions/patient). Most patients (30.2%) were treated for hemolytic-uremic syndrome (HUS), 18.6% for liver failure and 7.8% for rejection following renal transplantation. Other indications included eculizab (5.9%), thrombotic thrombocytopenic purpura (4.9%), autoimmune hepatitis (1.9%), rapid progressive glomerulonephritis (3.9%) and nineteen other indications (24.8%). Membrane filtration was used in all patients, fresh frozen plasma (64.7%) the most frequently used substitution fluid and heparin the most frequent anticoagulant (11.5%). Complications during PE included encephalitis (17.4%), seizures (13%), hyponatremia (8.7%), diarrhea (8.7%), mild allergic reactions (4.4%) and headaches (4.4%). All complications could be resolved. Overall, PP achieved full disease remission in 52 patients (60.4%), 14 patients showed a partial response (16.3%) and 20 patients (23.3%) did not respond at all. Among these, 12 patients (15.1%) died within the following 30 days. When stratified by diagnosis, 65% of all HUS patients (n=17/26) achieved complete remission and 5 out of 6 patients with encephalitis (85%) showed no relapse. Only poor results could be achieved in 16 patients with liver failure, where PP was used as bridging therapy prior to liver transplantation (LTX). Ten patients (62.5%) died prior or post LTX and 6 could be successfully transplanted.

**Conclusions:** Plasmapheresis is a safe method in children with a high efficacy in patients with hemolytic uremic syndrome, neurological autoimmune diseases and other primary renal diseases. Patients with liver failure who receive PP as bridging therapy show an infarct outcome.

Who Makes the Best Exit Site: Nephrologist or Surgeon? Vaibhav S. Keskar, Molly B. Biyani, Brian Blew, Jeffrey Witten, Brendan McCormick. The Ottawa Hospital, Univ of Ottawa, Ottawa, ON, Canada.

**Background:** Buried peritoneal dialysis (PD) catheters are placed months before dialysis is needed and the exit site is created at the initiation of dialysis by the nephrologist. In contrast, the exit site of an unburied catheter is created by the surgeon at the time of insertion. Our PD unit uses both methods of catheter placement. We undertook this study to compare the outcomes of the two methods of exit site creation.

**Methods:** The charts of all patients who initiation PD between Jan 2012 and Dec 2013 were reviewed. At each clinic visit, exit sites were graded by the PD nurse into standard predefined groups: perfect, good, equivocal and infected. Primary outcome was the frequency of perfect exit sites at 2, 6, and 12 months after initiation of PD. Secondary outcomes were exit site infections, peritonitis and technique failure due to exit site infection.

**Results:** 119 patients started PD during the period of interest and 114 remained on PD at 2 months. 52 patients had buried catheters exteriorized at the time of starting PD (group A) and 62 patients had unburied catheters (group B). Group A had more males (71% vs 48%), had higher mean age (65±14 vs 59±15) and had most of the patients as incident dialysis patients. Diabetic nephropathy was the most common underlying disease in either group (61.53% and 51.61%). Group B had a higher frequency of perfect exit sites at 2 months but this difference disappeared by 6 and 12 months. There was a trend towards more exit site infections in Group A but this did not translate into more technique failure.

**Conclusions:** Buried catheters are less likely to have perfect appearance at two months compared to unburied catheters; however this is no longer significant at six and 12 months. The trend towards more exit site infections with buried catheters suggests that there may be clinical consequences of the tissue trauma at time of exteriorization.Consideration should be given to the use of prophylactic antibiotics at exteriorization.

---

**TH-PO985**

**Background:** Peritonitis, tunnel and catheter exit site (CES) infections are the most serious complications of peritoneal dialysis (PD). We studied the effect of antibiotic ointment (EUDRAC: 2009-016835-36) on catheter-related infections (CRI) and morbidity.

**Methods:** Allocation was stratified by blocks of 4 centers. Ointment containing 2% colistin, tobramycin, amphotericin B and 4% vancomycin or normal saline were applied to the CES over 1 year. Follow-up period was 3 months after the last dose. Exit site infection (ESI) was defined as erythema, edema or local pain with purulent secretion and positive culture. Antibiotic therapy was given according to local protocols.

**Results:** 140 patients were included, 6 didn’t meet entry criteria. Characteristics and dialysis parameters of the 65 in the control group (CG) and 69 intervention group (IG) patients were comparable.

**Conclusions:** Buried catheters were less likely to show any difference in infections rates compared to unburied catheters; however this is no longer significant at six and 12 months. The trend towards more exit site infections with buried catheters suggests that there may be clinical consequences of the tissue trauma at time of exteriorization.Consideration should be given to the use of prophylactic antibiotics at exteriorization.

324A
Mean study duration was 0.6 (IG) vs 0.6 (CG) years (ns). 26 episodes of CRI (11 ESL, 4 tunnel, 11 peritonitis) occurred in the CG and 12 in the IG (3 ESL, 0 tunnel, 9 peritonitis) (p=0.001). Etiology of ESI was Staphylococcus aureus (x7), Corynebacterium spp., Pseudomonas aeruginosa, E. coli, Serratia spp., coagulase-negative S. (x2) and 1 negative culture in the CG and S. aureus (x1), 1 Gram-negative bacillus and 1 negative culture in the IG. Systemic or topical antibiotics were given for ESI in 11 (CG) and 2 patients (IG) (p=0.01), respectively. Hospital admissions were 23 (CG) and 15 (IG). Local side effects were significantly increased in the IG.

Conclusions: Local prophylaxis with a broad-spectrum antimicrobial ointment is associated with a significant reduction in ESIs and systemic antibiotic use without associated bacterial resistance. Significant local side effects were observed.

TH-PO988
Association Between Plasma Fibroblast Growth Factor-23 and Carotid Artery Atherosclerosis in Peritoneal Dialysis Patients Nannmy Liu, Jimin Hospital of Shanghai.

Background: We investigate the association between plasma fibroblast growth factor-23 (FGF-23) level and carotid artery atherosclerosis of 125 stage 5 chronic kidney disease (CKD5) patients, who are doing continuous ambulatory peritoneal dialysis (CAPD) at renal division of Shanghai Jumin Hospital in China.

Methods: A retrospective cohort study of individuals 15 years of age and older, divided into two cohorts according to carotid intima-media thickness (CIMT) : CIMT normal cohort (CIMT<0.9mm) and CIMT thickening cohort (CIMT>0.9mm). Plasma FGF-23 concentrations were determined by ELISA. CIMT thickness and atherosclerotic plaques were measured by carotid ultrasound.

Results: Of the 125 PD patients, the CIMT was thickened in 82 patients (65.6%). Compared with the CIMT normal patients, plasma FGF-23 concentration was significantly increased (p=0.01) in the CIMT thickening cohort (Table 1). Linear regression analysis discovered an obvious positive correlation between plasma FGF-23 and CIMT (r=0.416, P=0.006) (Table 2). Multiple regression analysis indicated that plasma FGF-23 level was independent risk factor for CIMT (β=0.421, t=2.607, P=0.01) (Table 3).

Conclusions: The level of plasma FGF-23 was positively correlated with CIMT and played an important role in development of carotid artery atherosclerosis in peritoneal dialysis patients.

TH-PO989
Atherogenic Index of Plasma Is Associated with Insulin Resistance in Non-Diabetic Peritoneal Dialysis Patients Mi June Lee, Jae Eun Kim, Sehyun Wu, Taek Chang, Tae-Hyun You.

1 Dept of Internal Medicine, Yeouui Unive College of Medicine, Seoul, Korea; 2Brain Korea 21 PLUS, Severance Biomedical Science Inst, Yonsei Unive College of Medicine, Seoul, Korea; 3Dept of Internal Medicine, NHIC Ilan Hospital, Gyeonggi-do, Korea.

Background: Insulin resistance (IR) is an independent risk factor for cardiovascular morbidity and mortality. Although many factors including uremia, chronic inflammation, and abnormal adipokine levels are known to contribute to the development of IR, the role of pro-atherogenic lipoprotein on IR remains unknown in peritoneal dialysis (PD) patients. Therefore, we investigated the independent association between pro-atherogenic lipoprotein and IR in non-diabetic PD patients.

Methods: We conducted a cross-sectional study in 75 non-diabetic PD patients. Pro-atherogenic lipoprotein was assessed by the atherogenic index of plasma (AIP, log transformed triglyceride to high-density lipoprotein cholesterol ratio). IR was determined by homeostatic model assessment-IR (HOMA-IR). Patients were divided into the higher and lower HOMA-IR group according to the median value of HOMA-IR. Independent association between AIP and HOMA-IR was ascertained by multivariate linear regression analysis.

Results: The mean age of the patients was 52.1±11.2 years, 35 patients (46.7%) were male. The mean value of AIP was 0.38±0.33 and the median value of HOMA-IR was 1.58 (interquartile range, 0.88 to 2.76). AIP was significantly greater in the higher HOMA-IR group (0.52±0.27 vs. 0.53±0.32, P=0.001). AIP was negatively correlated with systolic blood pressure (r=−0.32, P=0.005) and log adiponectin (r=−0.42, P=0.001) and positively correlated with sagittal abdominal diameter (r=0.25, P=0.033), residual renal function (r=−0.29, P=0.012), serum albumin (r=−0.26, P=0.026) and log HOMA-IR (r=0.54, P<0.001). In multiple linear regression analysis, AIP (β=0.251, P<0.01) was independently associated with HOMA-IR after adjustment for confounding factors.

Conclusions: Pro-atherogenic lipoprotein abnormality determined by high AIP might be implicated with development of IR in non-diabetic PD patients.

TH-PO990
Reducing Mortality in CAPD Patients by Statin Yong-ku Lee, Tae ik Chang, Sug kyun Shin. Nephrology Div, Dept of Internal Medicine, National Health Insurance Corporation, Ilsan Hospital, Goyang, Korea.

Background: Patients who are on CAPD (Continuous Ambulatory Peritoneal Dialysis) shows higher serum LDL cholesterol and Triglyceride compared to patients who are on hemodialysis. But higher cholesterol level does not seem to effect on raising mortality or cardiovascular morbidity and mortality. On the contrary, lower serum cholesterol level in CAPD patients tend to raise mortality and morbidity due to poor nutritional status.

Methods: This study is a retrospective study designed to evaluate the effect of cholesterol level, statin on CAPD outcome and mortality. Patients who were on peritoneal dialysis for at least 6 months since March 1st, 2000 were included. A total of 467 patients were enrolled in this study. Patients’ biological parameter, biochemical parameter and morbidity/mortality during CAPD maintenance period were collected.

Results: Patients whose initial cholesterol level were above 240 mg/dL shows significantly low CAPD failure rate compared to patients whose initial cholesterol level were below 200 mg/dL (OR=-0.469, p=0.049). Patients whose average LDL-cholesterol during CAPD period were over 100mg/dL showed significantly higher mortality compared to patients whose initial LDL-cholesterol level were below 100mg/dL (OR=1.848, p=0.024).

Patients whose complies to statin during CAPD period was over 80% showed significantly low mortality compared to patients who did not take statin during CAPD period (OD=0.556, p=0.020). Patients showed no significant difference in mortality due to total cholesterol, HDL cholesterol levels and patients showed no significant difference in CAPD failure due to HDL/LDL cholesterol, statin usage.

Conclusions: In CAPD patients, serum total cholesterol level should be targeted higher than HD or CKD patients. On the contrary, similar to HD or CKD patients, Statin should be administered and LDL cholesterol should be lowered during CAPD period to lower mortality. To identify the difference in cholesterol mechanisms of CAPD patients further, in depth study over adequate cholesterol level in CAPD patients needs to be proceeded.

TH-PO999
Using Daily Remote Biometric Monitoring in Peritoneal Dialysis Sung O Lee,1 Manyu Magnus,2 Neal Sikka,1 1 Medicine, George Washington University, Washington, DC; 2Epidemiology and Biostatistics, George Washington University, Washington, DC; 3Emergency, George Washington Univ, Washington, DC.

Background: Peritoneal dialysis(PD) requires self-monitoring with daily blood pressure(BP), weight, & physical examination. Patients(Pts) don’t always perform procedures or record results. We aim to determine associations between daily remote biometric monitoring(RBM) & clinical and pt satisfaction outcomes.

Methods: Pts were provided with BP monitoring equipment & scale which were capable of announcing the results, transmitting the results via Bluetooth technology to a hub located in the pt’s home & via 2G/3G cellular signal to a Telehealth call center. PD nurses viewed results or alerted to abnormal results.

Results: 300 subjects/subj from 10 PD units were followed over about 12 months. Demographics include male (56%), African American/AA(62%), & median age 56 yrs (IQR 44-64) and 1.86 yrs on dialysis (IQR 0.62-3.73). AA subjs were more likely to use than non-AA(69% vs 55%, p<0.05). 51% of subjs used RBM, with 66% consistently using the equipment. RBM was associated with reduced risk of hospitalization (Coef -0.27, SE 0.10, p=0.006). Subjs became increasingly less likely to breach any upper or lower alert threshold (OR 0.995, p=0.004). Subj satisfaction of RBM equipment for BP monitoring was 87% & scale 90%. Rural exceeded non-rural subjs in utilizing RBM (OR 4.77, 95% CI 1.34-16.98, p=0.02) Use of RBM was associated with improved perception of confidence with self-care requirements of PD easier to collect measurements (OR 2.69, 95% CI 1.52-4.76, p=0.001); more secure in their measurements (OR 3.28, 95% CI 1.71-6.26, p<0.001) getting more support from their PD doctors and nurses (OR 2.03, 95% CI 1.01-4.12, p<0.05).

Conclusions: RBM was associated with increased frequency, accuracy, and confidence of measurements to medical personnel, enhanced perception of autonomy and confidence in measurements, & reduction of hospitalizations & out of range measurements for BP. RBM was acceptable & satisfactory to PD pts. RBM offers additional tools to support PD pts in maintaining their measurement regimens & reduce negative health outcomes.

TH-PO990
Impact of Patient-Centric Automated Peritoneal Dialysis User-Interface on Operator Learning and Confidence Catherine Firane, Mary Gellens, James A. Sloand. Medical Affairs, Baxter Healthcare, Deerfield, IL.

Background: Automated peritoneal dialysis (APD) is an underutilized therapy for patients with end-stage renal disease (ESRD). The perception patients may not be able to manage their own treatment setups comes into play in choice of this treatment modality. Improvements to cycler technology may help to further simplify therapy for patients.
reducing barriers to uptake. This study aimed to determine whether a cycler-embedded, patient-centric interface offered an enhanced user experience compared to a conventional APD cycler.

Methods: 30 study participants (ages 29-84, mean 50 yrs, 67% male) diagnosed with ESRD were randomized into 2 groups using cycler with patient-centric user interface with advanced technology in development and a conventional APD cycler. Participants evaluated cycler on 2 non-consecutive days using a different cycler each day. Each participant was given a brief orientation, setup task, training session, break, followed by a setup task and questionnaire. Study results were analyzed via Fisher’s exact, Mann-Whitney and Exact binomial tests.

Results: The cycler with patient-centric user interface and advanced technology (in development) scored better on reduced reliance on printed instructions (p=0.0001). Patients committed fewer deviations on the cycler in development vs the conventional cycler (2 of 19 vs 14 of 19 respectively) after training (p=0.004), including disinfecting hands (p=0.02) and line handling (p=0.01), and were more confident that they set up the cycler according to specifications (p=0.043). The new cycler scored higher in overall preference among study participants: The cycler with a patient-centric user interface was rated easier to learn (p=0.005) and to use (p=0.016), preferable to use (p=0.03), and users felt more confident when repositioning the new cycler at home compared to conventional cyclicals.

Conclusions: A cycler with embedded, patient-centric interface was rated higher in terms of overall reliance on instructions, task competency, ease of use and learning, preference and overall confidence of using the cycler. These findings indicate that APD operating learning and confidence can be enhanced with a patient-centric user interface.

THI-P0991

Single-Site Trans-Umbilical Peritoneal Dialysis Catheter Insertion
Mangalakumar Veerasingam
Nephrology, KMC, Coimbatore, Tamilnadu, India.

Background: Traditional laparoscopic peritoneal dialysis catheter placement requires two ports insertion and this can lead to complications like leak and hernia at the port sites. We describe a novel approach of using single-site trans-umbilical ports that is associated with small scar (less than 1cm) and reduced complications.

Methods: Under general anesthesia pneumo-peritoneum was created as per standard method. One 10mm port and one 5mm port was inserted through trans-umbilical route to guide peritoneal dialysis catheter insertion. Hernial orifices were inspected and if there was any adhesion present that was released to facilitate free fluid movement. The catheter was inserted through a small incision 1 inch below umbilicus. The catheter was positioned in the pouch of Douglas using lap instrument passed through the trans-umbilical port. The other end of catheter was tunnelled in the standard manner and brought out through the trans-umbilical port. The latter prevented the omentum from wrapping dialysis catheter and causing malfunction. Then the port site was closed in three layers (Video available).

Results: 10 cases underwent catheter insertion with this approach (Male 7, Female 3) and the mean follow up period is 11 months. None of them developed leak or catheter migration or any mechanical complication that might require catheter reposition or change.

Conclusions: Combined method of Single-site port placement, omentopexy and loop fixation of intra-abdominal segment of catheter offers the following advantages - small incision; hence risk of leak when catheter was used early after placement is low. The risk of hernia through port site is reduced and small scar will be welcome to image conscious patients. If there was any adhesion present that could be released with minimal trauma to peritoneum. Placing the looped catheter prevented catheter migration. Omental wrapping was prevented by fixing this in the upper quadrant by trans-umbilical loop fixing.

THI-P0992

Peritonitis and Survival following PD Catheter Insertion
Joshua Zaritsky, Coral D. Hanevold, Troy Richardson, Jonathan Roof, John P. Lawlor, Raymond P. Quigley, Alicia Neu, Bradley Warady. SCOPE Collaborative, CHA, Overland Park, KS

Background: Chronic peritoneal dialysis (PD) is the dialysis modality of choice for children. However, there are limited outcome data in those who undergo PD catheter (cath) insertion in the 1st year of life. Using data from the Children’s Hospital Association Standardizing Care to Improve Outcomes in Pediatric End Stage Renal Disease (ESRD) Collaborative (SCOPE), we examined peritonitis rates and survival in 156 infants who had a PD cath placed in the 1st yr of life.

Methods: Data on pt demographics, PD cath characteristics, peritonitis risk factors and outcomes from 157 cath insertions from 29 North American pediatric dialysis centers were reviewed and analyzed using chi square test for association or a Wilson band test for comparison.

Results: In hospital and overall peritonitis rates during the 1st year post cath insertion were 1.73 and 0.76 per-patient-year, respectively. Gram + organisms were responsible for 37.8% of infections (figure); 28% were culture negative. Polycystic kidney disease and pulmonary hypertension were more frequent in infants with peritonitis, whereas anuria did not differ between groups (table). Use of a cuffed catheter or polyurethane, nephrectomy prior to or concurrent with cath insertion, and G-tube insertion after cath placement were more common in pts with peritonitis, while number of cuffs, surgical technique, cath use within 14 days and cath revision did not differ between groups. Infants with peritonitis had longer initial hospital stays and lower survival compared with those without peritonitis.

Conclusions: In this large cohort of infants with ESRD, we found a high rate of peritonitis and identified several risk factors associated with peritonitis. Given that peritonitis was associated with increased initial hospital stay and mortality, attention to the potentially modifiable factors is needed.

THI-P0993

Risk Factors for All-Cause Unexpected Hospitalization After Peritoneal Dialysis Catheter Implantation
Zi Li,1 Joanne M. Bargman,2 Zita C. Abreu,1 Joanne M. Bargman.2
1Nephrology, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China; 2Nephrology, Toronto General Hospital Univ of Toronto, Toronto, ON, Canada.

Background: Implantation of the peritoneal dialysis catheter (PDC), usually an elective procedure, may necessitate unexpected hospitalization due to multiple co-morbidities and inherent instability of the end-stage renal disease patient. This information is important for administrative planning for a PD program. However, information on hospitalization after PDC implantation is limited and details about the reason for hospitalization are lacking.

Methods: We performed a prospective cohort study in consecutive patients who underwent PDC implantation at a single institution from 2007 to 2013. Clinical characteristics of enrolled patients, technique of the implantation procedure and all-cause unexpected hospitalization and morbidity within 14 days after implantation were analyzed.

Results: A total of 246 patients receiving 252 PDC implantations during the 6 years were studied. After 39 procedures (15.5%), patients had an unexpected hospital stay due to operative complications (33.3%), worsening of comorbid disease (35.9%), or a single-night hospital stay for observation (30.8%). Compared to discharged patients, the unexpected hospitalization ones were older (P=0.001), had higher rates of previous episodes of heart failure (P=0.006) and heart disease (P=0.001), had more use of general anesthesia (P=0.046), had more added procedures during the implantation (P=0.02) and had more episodes of flow obstruction and peritonitis (P=0.012 and P<0.001). Multivariable logistic regression showed that age, cardiac morbidity, use of general anesthesia, PDC flow problems and peritonitis after implantation were independent predictors of all-cause unexpected hospitalization.

Conclusions: For the first time, our study has analyzed the rate of unexpected hospitalization after PDC implantation and identified the salient risk factors. Increased focus to identify patients at greatest risk for hospitalization, evaluation of processes of care, and implementation of preventive strategies may be helpful to reduce unplanned hospitalization after catheter insertion.

Early Mechanical and Infective Complications in First Time Blind, Bedside, Midline Percutaneous Tenckhoff Catheter Insertion with Ultra Short Break-in Period: Setting New Standards

Succes Alexander,1 Ninoo G. George,2 Santosh Varughese.1 Nephrology, Christian Medical College, Vellore, Tamil Nadu, India; 2Nephrology, Bilroth Hospitals, Chennai, Tamil Nadu, India.

Background: There are no large studies that have looked into ultra-short break-in period with blind, bedside, midline approach of Tenckhoff catheter insertion.

Methods: 284 consecutive adult patients underwent catheter insertion for chronic peritoneal dialysis at our centre from January 2009 to December 2013. Those with history of midline laparotomy scars and hernias were referred for open surgical insertion. 245 patients (86.3%) underwent the percutaneous and 39 patients (13.7%) underwent surgical insertions.

Results: The mean break-in period for the percutaneous group (PG) was 2.68 ± 2.63 days and for the surgical group (SG) was 11.19 ± 6.96 days, p < 0.001. Poor catheter outflow was present in 22% (PG) and in 4 (10.3%) of SG (p = 0.80). Primary catheter non-function was present in 24% (PG) and in 4 (10.3%) of SG (p = 0.73). Catheter survival at one year was 164/211 (81%) in the PG. The various outcomes are:

Conclusions: The significantly shorter break-in period and smaller wound incisions reduce hospitalization and the need for bridging hemodialysis as well as having good patient and catheter outcomes.
TH-P0998
Proposed Model for the Care of Hospitalized Peritoneal Dialysis Patients
Cynthia R. Christiano,1 Melanie I. Hames,1 Pankaj Jawa,1 Piper J. Hughes,3 Maria H. Locklear.2 1Div of Nephrology, Brody School of Medicine at East Carolina Univ, Greenville, NC; 2Vidant Medical Center, Greenville, NC; 3Internal Medicine, East Carolina Univ, Greenville, NC.

Background: Peritoneal dialysis (PD) has been prescribed throughout the United States, yet the optimal model of care for hospitalized PD patients remains unknown. With a growing interest in home modalities and emphasis on quality, it is imperative that we identify an effective and efficient way to care for this patient population during hospitalization.

Methods: We describe a model successfully implemented at Vidant Medical Center (VMC) in 2008. Prior to this date, the primary hospital nurses performed PD care. Due to the high risk, low volume nature of inpatient PD, this resulted in inconsistent care as well as decreased physician, nursing, and patient satisfaction. In 2008, an inpatient PD nursing team was created. This team, consisting of nephrology nurses with specialized PD training, is managed by VMC’s self-maintained dialysis unit. Staffed with 2 nurses during the day and at night, they provide 24/7 care through the hospital, including the ICU and ED. Responsibilities include patient education, exit site care, catheter flushes, and all manual and automated PD exchanges. Upon discharge, the outpatient unit is contacted to ensure appropriate transition back to the outpatient setting.

Results: This model provides several benefits: 1) PD treatments are consistently completed and charted, 2) Increased physician, nursing, and patient satisfaction, 3) Continuity of care, and 4) Cost reduction (personnel and supplies). Since inception, this team has grown to 13 nurses. During FY2014, 2568 (1572 adult / 996 pediatric) PD treatments were performed, the majority CAPD. To ensure appropriate utilization of nursing resources, most are cross-trained to perform hemodialysis.

Conclusions: In conclusion, the creation of a specialized nursing team has been instrumental in optimizing the care of our hospitalized PD patients. This sustainable model provides effective, efficient care and should be considered for implementation by hospitals providing PD services.

TH-P0999
Elderly Peritoneal Dialysis Compared with Elderly Hemodialysis Patients and Younger Peritoneal Dialysis Patients: Competing Risk Analysis of a Korean Prospective Cohort Study
Hyunsook Kim,1 Jung Nam An,2 Dong Ki Kim,1 Yong-Lim Kim,1 Yun Kyu Oh,2 Chun Soo Lim,2 Yon Su Kim,2 Jung Pyo Lee.1 1Internal Medicine, Seoul National Univ College of Medicine, Seoul, Republic of Korea; 2Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Republic of Korea; 3Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea.

Background: The outcomes of peritoneal dialysis (PD) in elderly patients have not been thoroughly investigated. We aimed to investigate the clinical outcomes and risk factors associated with PD among our PD patients.

Methods: We conducted a prospective observational nationwide adult end-stage renal disease (ESRD) cohort study in Korea from August 2008 to March 2013. Among incident patients (n=830), patient and technical survival rate, quality of life, and Beck’s Depression Inventory (BDI) scores of elderly PD patients (≥65 years, n=95) were compared with those of PD patients aged ≤49 years (n=205) and 50–64 years (n=192); and elderly hemodialysis (HD) patients (n=315). The patient death and technical failure were analyzed by cumulative incidence function.

Results: The patient survival rate of elderly PD patients was inferior to that of younger PD patients (P<0.001). However, the technical survival rate was similar (P=0.097). Compared with elderly HD patients, the patient survival rate did not differ according to dialysis modality (P=0.987). Elderly PD patients showed significant improvement in the BDI scoring in hospital compared with the PD patients aged ≤49 years (P=0.030). Low albumin, anemia, and low residual renal function were significant risk factors for the PD patient survival; and peritonitis was a significant risk factor for technical survival. Furthermore, low albumin and hospitalization were significant risk factors of patient survival among the elderly.

Conclusions: The overall outcomes were similar between elderly PD and HD patients. PD showed the benefit in BDI and quality of life in the elderly. Additionally, the technical survival rate of elderly PD patients was similar to that of younger PD patients. Taken together, PD may be a comparable modality for elderly ESRD patients.

TH-P1000
Phosphorus Control and Phosphate Binder Pill Burden During Real-World Use of Sucroferic Oxyhydroxide in Peritoneal Dialysis Patients
Linda H. Ficociello, Vidhya Parameswaran, Mark Costanzo, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. Fresenius Medical Care North America (FMCNA), Waltham, MA.

Background: Achieving serum phosphorus (sPhos) control can be a challenge for dialysis patients (pts). This retrospective database analysis examined the real-world effectiveness of sucroferic oxyhydroxide (SO), an iron-based phosphate binder (PB), in adult peritoneal dialysis (PD) pts.

Methods: A cohort of PD pts prescribed SO as part of routine clinical care at FMCNA clinics was analyzed. Pts had ≤1 sPhos measured during SO and had been previously treated with sevelamer, calcium acetate, calcium carbonate or dual therapy. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and PB pills per day (PPD) were assessed 3-months before SO (baseline) and 3-months during SO (follow-up).

Results: Pts (n=328) were, on average, 53 years old, with a dialysis vintage of 3.9 years. At baseline, 56% of pts used sevelamer, 29% calcium acetate, 11% calcium carbonate; and 5% dual therapy. Pts in-range increased from 13.5 to 23.8% (76% increase). Mean sPhos decreased from 6.92 to 6.67 mg/dl, p<0.001. PB PPD was reduced from 8.4 to 3.8 pills (4.6 fewer pills, p<0.001). There was no significant change in sCa (9.1 to 9.0 mg/dl) or iPTH (535 to 555 pg/ml). TSAT and FER increased from 35.4 to 36.6% and 752.1 to 814.9 mg/ml, respectively. In pts not receiving IV iron (n=127), TSAT and FER did not change significantly (36.3 to 37.3% and 797.9 to 743.3 mg/ml, respectively).

Conclusions: In this large cohort of PD patients prescribed sucroferic oxyhydroxide as part of routine clinical care, a significant reduction in serum phosphorus (p<0.001) and a 76% increase in pts achieving in-range serum phosphorus (p<0.001) was observed. This was accomplished with a mean of 3.8 pills per day, a reduction of 4.6 pills (p<0.001).

Laparoscopic Findings of Visceral Peritoneal Injury in Patients Treated with Neutral pH Peritoneal Dialysis Solution Yudo Tanno, Nanane Matsuo, Izumi Yamamoto, Yasuuyki Nakada, Ichiro Obikado, Keitaro Yokoyama, Takashi Yokoo. Div of Kidney and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan.

Background: Encapsulating peritoneal sclerosis (EPS) is caused by a visceral peritoneal lesion, i.e., intestinal tract adhesion and encapsulation, it is important to evaluate changes in the visceral peritoneum. It has been reported that there was a decreasing trend of peritoneal injury with the use of PD solution with neutral pH as compared with acidic pH in the histopathological evaluation of the parietal peritoneum; however, there is no report evaluating changes in the visceral peritoneum, which is essentially important and should be evaluated. We previously reported laparoscopic approach for evaluation of EPS (KI 2012) in patients treated with PD solution with acidic pH. In this study, we examined macroscopic findings of the visceral peritoneum in patients treated with neutral pH solution alone for 4 years or more by laparoscopy.

Methods: 19 patients underwent laparoscopy at the time of PD catheter removal. Duration of PD in these patients was 64.5±18.8 months. Clinically, none of these patients had developed EPS by the time of the investigation. The findings of both parietal and visceral peritoneal tissues were categorized according to color changes, presence of neovascularizations and adhesions.

Results: It was found that longer the duration of PD, the worse the peritoneal injury. Although changes in the parietal and visceral peritoneum had heterogeneous distributions, the changes in the visceral peritoneum were milder, showing a discrepancy with the findings of the parietal peritoneum. As compared with laparoscopic findings in patients treated with PD solution with acidic pH, the degree of color changes, presence of neovascularizations, and adhesions were all mild, however, severe adhesions were noted in patients with a history of PD peritonitis.

Conclusions: Although changes in the visceral peritoneum resulting from the use of PD solution with neutral pH show a decreasing trend as compared with acidic pH, there is a certain level of peritoneal change, suggesting the possibility of progression of peritoneal deterioration by long-term continuous use.

TH-P1002

Background: Encapsulating peritoneal sclerosis (EPS) is the more dangerous complication of peritoneal dialysis (PD). The EPS can occur during PD (classic EPS), after kidney transplantation (TX) or rapid shift to hemodialysis (HD) as the mode of renal replacement therapies (RRTs).
Methods: Single-center retrospective analysis of PD transplanted patients in 35 years. Evaluation of the characteristics of the EPS patients.

Results: From July 1979 to December 2014, 173 PD patients underwent kidney transplantation (TX). They were diagnosed as having PD for one or more than 6 months from the TX (typical posttransplant EPS), but the other 4 cases had occurred after more than 2 years from the previous renal transplant (PSRT; medium: 24 months, range: 24-120). At least one transfer to hemodialysis or death occurred at the time of transplant, transfer to hemodialysis, or death. Results: 920 cases and 2607 controls were identified.

Conclusion: AA PD patients is due to increased technique failure from disproportionate peritonitis rates. This study does not support the hypothesis that the underlying cause of decreased prevalent AA PD patients is due to increased technique failure from disproportionate peritonitis rates.

TH-PO1005
Factors Associated with Peritoneal Dialysis Technique Failure: A Single Center Study Ainoop Sheshadri, Ramesh Saxena. Dept of Nephrology, UT Southwest Medical Center, Dallas, TX.

Background: To review peritoneal dialysis (PD) technique survival and assess factors associated with PD technique failure at our center.

Methods: We performed a retrospective analysis of 315 patients with PD catheters placed between 01/2001 and 09/2009, reviewing medical records for demographic and clinical data, PD technique failure, and hospitalization. Primary outcome was PD technique failure, defined as permanent discontinuation of PD due to infectious or non-infectious complications, inadequate dialysis, or miscellaneous factors such as pain. Patients were followed at least 36 months after PD initiation. Survival analysis was performed using Kaplan-Meier methods. Covariates influencing survival were analyzed using Cox proportional hazards regression models.

Results: There were a total of 70 failures, 31 (44.3%) related to infectious complications, 22 (31.4%) to non-infectious complications (e.g. obstruction, leaks), 8 (11.4%) to inadequate dialysis, and 9 (12.9%) to miscellaneous factors. Overall survival at 36 months was 78.81%. Covariates significantly affecting technique failure include prior HD (1.83; 1.14–2.92), non-infectious complications (1.82; 1.28–2.59), DM (1.62; 1.00–2.63), HIV (2.52; 1.01–6.24), peritonitis (1.94; 1.20–3.12), and exit site infections (1.79; 1.09–2.92). Previous abdominal surgeries (90; 1.78-1.08) and BMI (1.005; 1.00–1.04) were not significantly associated with failure.

Conclusions: This is one of the largest single center studies of its type from a US PD program. It shows excellent 3 year PD technique survival, better than reported in similar studies. Our results confirm that diabetes mellitus, PD related infections, and non-infectious mechanical problems are independent risk factors for PD technique failure. Conversely, BMI, abdominal surgeries, and demographic characteristics such as race and gender do not have significant association and should not be considered barriers to PD initiation.

Funding: Clinical Revenue Support

TH-PO1004

Background: African Americans (AA) are under-represented in the prevalent peritoneal dialysis (PD) population in the United States. There is relatively little conclusive data to explain the cause of this. One explanation is that AA may have higher rates of peritonitis than Caucasians leading to increased technique failure. This study aimed to determine if differences between AA and Non-AA rates of peritonitis at the University of Alabama at Birmingham Home Dialysis existed.

Methods: This is a single center retrospective cohort analysis of data from November 2012 to November 2014. Baseline demographics as well as data on peritonitis episodes were analyzed. Peritonitis rate was defined as the absolute number of distinct peritonitis episodes divided by the number of patient months at risk. Relapsing peritonitis episodes were excluded. Chi-square analysis was used to compare baseline categorical variables and independent t test to compare length of time on dialysis. Rates of peritonitis were analyzed with Fischer exact test. Peritonitis free survival, hospitalization free survival and technique failure were analyzed by log rank comparison of Kaplan Meier curves.

Results: A total of 125 PD peritonitis episodes in 92 patients were investigated. The mean age was 59 ±12 years and 55 (44.0%) were male. PD catheter was removed in 31 (24.6%) patients. The median value of DNI in patients undergone PD catheter removal was significantly higher compared to that of patients who maintained PD catheters [DNI (interquartile range), 3.3 (0.0-65.0) vs. 0.70 (0.022.5), P<0.001]. DNI is significantly associated with percentage of segmented neutrophil (r=0.38) and serum albumin (r=0.32), and dialysate leukocyte counts (r=0.20), but not with C reactive protein (CRP) levels (r=0.08). Multivariate logistic regression analysis revealed that DNI was an independent predictor for PD catheter removal in patients with PD peritonitis. Five (11.4%) patients were censored before analysis. DNI levels reflected the severity of PD peritonitis. Higher levels of DNI could be an independent predictor for PD catheter removal in patients with PD peritonitis.

Conclusions: AA PD patients is due to increased technique failure from disproportionate peritonitis rates. This study does not support the hypothesis that the underlying cause of decreased prevalent AA PD patients is due to increased technique failure from disproportionate peritonitis rates.
Secondary outcomes included all-cause mortality, cardiovascular and cerebrovascular outcome was technical failure, defined as death or permanently transferred to hemodialysis. All patients were followed until October 31, 2014. Primary recommendation for Asians. Patient survival was similar in all BMI categories. All cause mortality, and cardiovascular and cerebrovascular mortality. Our results suggest that patients with early peritonitis are associated with shorter technique and patient survival.

**Conclusion:** In our PD patients, BMI was inversely associated with mortality as in HD patients. Other outcomes such as cardiovascular death, peritonitis incidence, and technical failure will be additionally evaluated.

**TH-PO1007**

**Underweight Predicts Technical Failure: A Retrospective Cohort Study of Incident Peritoneal Dialysis Patients**

Xiaoyuan Huang, Xiaqin Zeng, Qing Wang, Zibo Xiong, Yumei Liao, Zuying Xiong. Div. of Nephrology, Peking Univ Shenzhen Hospital, Shenzhen, Guangdong, China.

**Background:** Technical failure is more common in peritoneal dialysis (PD) than in hemodialysis. High body mass index (BMI) increases mortality in the general population, but may be improved survival in hemodialysis patients. In PD patients, yet, reports disagreeing the association of BMI with technical survival are scarce and remain controversial.

**Methods:** In this retrospective cohort study, 348 incident PD patients (aged 48.2 ± 15.5 years, 62% men) at Peking University Shenzhen Hospital from 2000 to 2014 were included. BMI was calculated with height and weight first recorded within 2 to 6 months after initiation of PD. Patients were categorized according to the World Health Organization recommendation for Asians. All patients were followed until October 31, 2014. Primary outcome was technical failure, defined as death or permanently transferred to hemodialysis. Secondary outcomes included all-cause mortality, cardiovascular and cerebrovascular mortality, occurrence of coronary heart disease and stroke, and incidence of peritonitis. Data were analyzed using Cox proportional hazards models.

**Results:** BMI in this cohort was 22.1 ± 3.0 kg/m². During 2.5 years (interquartile range: 1.0-4.0 years), 60 cases of technical failure occurred. Incidence of technical failure was higher in patients with low BMI (13.4/100 person-years) than those with normal BMI (5.2/100 person-years) and with high BMI (6.3/100 person-years). After adjustment of age, sex, education, primary disease, and heart failure, hazard ratios (95% confidence intervals) were 3.60 (1.53, 8.45) and 0.93 (0.49, 1.76) for patients with low and high BMI, respectively, as compared to those with normal BMI. Similarly, the low BMI group had significantly higher rates of total as well as cardiovascular and cerebrovascular mortality than the normal BMI group, but such relationships did not exist in the high BMI group. No associations of BMI with occurrence of coronary heart disease and stroke and incidence of peritonitis were observed.

**Conclusions:** In incident PD patients, low BMI is associated with technical failure; all-cause mortality, and cardiovascular and cerebrovascular mortality.

**Funding:** Government Support - Non-U.S.

**Patients with early peritonitis had a significantly higher peritonitis rate than controls (1.26 and 0.67 episodes/patient year, p<0.001). Early peritonitis was also associated with short technique and patient survival.**

**Conclusion:** Our results suggest that patients with early peritonitis are at increased risk of adverse clinical outcomes such as future infection, technique failure, and death.

**TH-PO1009**

**Is Obesity a Poor Prognostic Factor in Incident Peritoneal Dialysis Patients?**

Hyunjong Cho,1 Hyo Jin Kim,1 Misae Park,2 Dong Ki Kim,1 Kwon Wook Joo,2 Yun Su Kim,1 Curie Ahn,1 Kook-Hwan Oh,1 Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; 2Clinical Research Inst, Seoul National Univ Hospital, Seoul, Korea.

**Background:** Obesity is associated with an increased risk of death in the general population. Previous studies have demonstrated a discrepancy in the impact of body mass index (BMI) on mortality among peritoneal dialysis (PD) patients. We examined the effect of BMI on patient and technique survival in a prospective, incident PD cohort at a single center.

**Methods:** Subjects who started PD between 2000 and 2012 were enrolled in the study. Demographic and laboratory data were prospectively collected. Patients were categorized into four BMI groups: obese, ≥25 kg/m²; overweight, 23–24.9 kg/m²; normal, 18.5–22.9 kg/m² (reference category); and underweight, <18.5 kg/m². Patient and technique survival were compared using Cox proportional hazards models.

**Results:** A total of 632 incident PD patients were included in final analysis. The median follow-up period was 40 months (interquartile range, 19-64 months). Kaplan-Meier survival curve, patient survival was not statistically different among all BMI categories (p = 0.641, by log-rank test). The hazard ratio (HR) adjusted for age, sex, diabetes, comorbidities, albumin, hemoglobin for patient survival was not significant among BMI groups (p = 0.837). In contrast, technique survival was significantly poorer in obese patients than in patients having a normal BMI (p = 0.029, by log-rank test). The HR for technique failure was significantly greater for obese PD patients in comparison with the reference category [1.8, 95% confidence interval (CI): 1.2 to 2.8; p = 0.008]. The reasons for technique failure included recurrent peritonitis (34%), inadequate diuresis (17%), mechanical problem (17%) and refractory exit-site/tunnel infection (11%) in obese patients.

**Conclusions:** In our PD patients, patient survival was similar in all BMI categories. Therefore, obese patients should not be discouraged from receiving PD purely on the basis of BMI. However, technique survival was significantly poorer for obese PD patients. Further study is warranted to improve technique survival in obese patients.

**TH-PO1010**

**Phosphate Clearance in Peritoneal Dialysis: Residual Renal Function and Dialysis Modality**

Carmen Gonzalez corvella, Marangeles Rodriguez Perez, Alejandro A. Suarez benjumea, Nuria Areste, Mercedes Salgueira lazo. Nephrology, Virgen Macarena-Rocio, Sevilla, Spain.

**Background:** Evaluate urinol and peritoneal excretion of phosphate and related factors in peritoneal dialysis(PD). Analyze phosphate clearance depending on PD modality and peritoneal membrane type.

**Methods:** Observational study, in a sample of 373 PD patients. Mean age 60±14 years. 24 patients on APD (16CCPD,8NIPD) 13 on CAPD. Mean Kt/V: 2.6±0.6. Mean residual renal function (RRF) 6.3±4.6ml/min.Transmembranous peritoneal transport:6high (H),26high-average (HA) and Slow-average (LA). Renal and peritoneal phosphate clearance (ultraltrafiltration) (UF and diffusion) (D) was analyzed. Urinary and dialysate P-Cr. Weekly peritoneal P clearance (WPC1). Serum PTH.Use and dosage of phosphate binders and vitaminD analogs.

**Regression of Log hazard ratio on BMI**

**Conclusions:** Evaluating the impact of BMI on mortality among PD patients. Data of hazard ratios and 95% confidence intervals (CIs) were obtained for respective BMI groups provided by each study. We performed meta-regression analysis using unrestricted maximum likelihood model.

**Results:** The Medline, EMBASE, and the Cochrane library search provided a total of 3,047 articles. After screening of all titles, 513 abstracts were selected. Finally, 9 cohort studies with 33,090 patients were included in the final analysis. Log hazard ratio for all-cause mortality showed a trend negatively associated with increasing four square root of BMI (slope coefficient: -0.1976, 95% CI -0.4110 to 0.0118, p = 0.0695).

330A
Results: Mean total P clearance: 460±192 mg/dl. Mean renal P clearance: 286±201 mg/dl, and mean PD clearance: 88±18 mg/dl. Mean P clearance through UF: 2.2±1.5 mg/dl (90%). There was no significant difference in urinary and dialysate P Cs (p>0.05). Between RRF and P clearance, there was a positive correlation of r=0.83 (p<0.001). There was a significant difference in co-morbidity scores between the first and second measurement is higher for patients who switched from PD to HD (p<0.05). Three patients died from infections, two patients from cardiovascular disease, and one patients from gastrointestinal bleeding. In-center HD and PD are the 2 most common forms of dialysis utilized in our center.

Conclusions: There were no significant differences in outcomes among TS and US groups. TS patients have less technique failure and hospitalization rates while AA TS have the least technique failure and hospitalization rates.

TH-PO1013
Reasons for Dialysis Modality Changes in an Integrated Healthcare System
Leonid Pravoverov, Sijie Zheng, Joanna Mrzo. The Permanente Medical Group, Oakland, CA.

Background: In-center HD and PD are the 2 most common types of dialysis utilized in our center. We have examined characteristics of patients who changed dialysis modality. Kaiser Permanente Northern California is an integrated health care delivery system with 3.7 million members. We retrospectively examined the characteristics and disease burden of patients who switched from one modality to another.

Methods: Retrospective examination of EMR from Jan 2009 – Oct 2014. Disease burden was assessed by internally developed comorbidity point score, which predicts negative outcomes in the next 12 months, based on documented comorbidities and hospitalizations.

Results: From 2010-2014, dialysis population in our integrated health system increased from 4005 to 4491 patients, and PD population grew from 621 to 1033. In this period, 11% of patients who initiated dialysis switched modality. Majority of modality changes occurred within a year after dialysis initiation. 8% of HD patients switched to PD and 24% of PD patients switched to HD. Majority of patients who switched from HD to PD do so within 6 months of initiation. They have less comorbidities than those who stay on HD. They have a higher comorbidity score when they switch to PD but lower than repeated switchers who switched from PD to HD. They were younger than those remaining on HD. Most patients who switched from PD to HD did so within a year. They have more comorbidities than those who stay on PD and have a higher comorbidity score when they switch to HD, even higher than the repeat score of those who switch from HD to PD. The difference in co-morbidity scores between the first and second measurement is higher for the PD to HD pattern. They have similar age to those who didn’t switch.

Conclusions: Patients who switched from HD to PD remain at approximately the same comorbidity score before and after switch. Comorbidity scores of patients who switched from PD to HD significantly increased, suggesting that change was influenced by decline in their overall condition. In our patient population, the switch from HD to PD is likely a patient’s decision, while the switch from PD to HD may be due to inability to continue PD.

TH-PO1014
Impact of Pre-Dialysis Immunosuppressive Treatment on Infectious Complications and Survival of Systemic Lupus Erythematosus (SLE) Patients on Peritoneal Dialysis
Junbao Shi,1 Joanne M. Bargman.2 1Dept of Nephrology, Peking Univ Third Hospital, Beijing, China; 2Div of Nephrology, Univ Health Network, Toronto General Hospital, Toronto, ON, Canada.

Background: SLE patients on peritoneal dialysis (PD) have a significant risk of infectious complications and poor outcomes.However, few studies have examined the relationship between pre-dialysis exposure to immunosuppressive (IS) therapy and the outcomes of SLE patients on PD. The objective of this study was to investigate whether pre-dialysis IS treatment influences the infectious complications and outcomes of SLE patients on PD.

Methods: Twenty-six SLE patients were treated with PD in a major academic centre from May 1996 to May 2014. Demographics, diagnostic tests and IS treatment, comorbid illnesses, biochemistry and clinical data upon initiation of dialysis, hospitalization, infectious complications, hospitalizations and clinical outcomes during the study period were collected. Three years was chosen as the discriminant between longer and shorter duration of IS therapy.

Results: Two patients were lost to follow-up during the study period. Therefore, a total 24 patients were included for analysis. The SLE patients with longer duration of pre-dialysis IS (>17) were older than patients with shorter pre-dialysis IS (≤7;38.6±11.0 vs 27.1±7.8, P<0.05), but there were no significant differences in sex, race, PD duration, PD sub-modality and biochemistry between the two groups(P>0.05). Seven patients died during the follow-up period and all the deaths were from the group with longer-pre-dialysis IS time (P<0.05). Three patients died from infections, two patients from cardiovascular disease, and two had sudden death at home. However, there were no significant differences in the incidence of other infectious complications, hospitalizations, and infectious complications at the end of the study period. Three patients died from infections, two patients from cardiovascular disease, and two had sudden death at home. However, there were no significant differences in the incidence of other infectious complications, hospitalizations, and infectious complications at the end of the study period.

Conclusions: SLE patients undergoing PD with longer pre-dialysis exposure to IS drugs have a greater mortality that appears to be related to both infectious and noninfectious causes. Although incident to PD, they should be considered a high-risk subgroup.

TH-PO1015
Predicting Peritoneal Dialysis Prescriptions with a Fast Peritoneal Equilibration Test Using PD Adequate J. Ken Leypoldt.1 Baris U. Agar,2 James A. Slando,3 Mary Gellens.1 1Medical Products (Renal), Baxter Healthcare Corporation, Deerfield, IL; 2Medical Products (R&D), Baxter Healthcare Corporation, Round Lake, IL.

Background: The fast peritoneal equilibration test (PET) is often used to determine peritoneal membrane transport status, but its accuracy in predicting parameters of peritoneal dialysis (PD) therapy adequacy using computer software, like PD Adequate, has not been quantified. In the current study, the ability of a new version of PD Adequate was
examined to 1) compare mass transfer-area coefficients (MTACs) for urea, creatinine and glucose during fast and standard PETs and 2) use those parameters to predict PD therapy prescription adequacy.

**Methods:** Data from 104 PD (41 CAPD, 63 APD) patients who underwent a 4-hour standard PET and an overnight exchange with the same glucose concentration were used to determine PD therapy adequacy parameters. Calculated MTAC values for standard PET were compared with those for fast PET by using only data obtained at 4-hours during the standard PET and assuming a 200 mL residual volume in the prior exchange. The calculated membrane parameters were used to predict net ultrafiltration (UF), urea Kt/V and creatinine clearance (CrCl), and those predictions of therapy adequacy were also compared with the mean of 3 actual measurements of net UF, Kt/V and CrCl for each patient.

**Results:** Median urea, creatinine and glucose MTACs were 20.9, 10.1, and 9.1 mL/min during standard PET, and 21.0, 10.1 and 9.0 mL/min during fast PET; the corresponding median percentage differences between MTACs for urea, creatinine and glucose were 0.6%, 0.3 and 0.6 mL/min. Comparing predictions using standard and fast PETs, 81% of net UF were within 150 mL, 94% of Kt/V were within 0.1 wk and 93% of CrCl were within 2 L/wk/1.73m². The percent of predicted and actual measured values of net UF within 300 mL, Kt/V within 0.2 wk and CrCl within 8 L/wk/1.73m² were 64%, 63% and 77% for standard PET and 38%, 64% and 77% using fast PET; these differences were not statistically significant.

**Conclusions:** These results suggest that the predictions of PD therapy adequacy using PD Adequate are clinically equivalent when either fast or standard PET is employed.

**The Loss of Residual Diuresis Increases in Erythropoiesis in PD Patients**

**Background:** Anemia in ESRD is attributed to impaired erythropoietin formation due to erythropoietin and iron deficiency. The accelerated clearance of erythrocytes may at least partially be due to enhanced erythropoiesis, a suicidal death of erythrocytes characterized by cell shrinkage and cell membrane scrambling with phosphatidylserine(PS)-externalization at the erythrocyte (RBC) surface. Exposed PS is recognized by macrophages that engulf and degrade the affected cells. Little is known about mechanisms underlying enhanced erythropoiesis in ESRD. At least in theory, erythropoiesis may be stimulated by some uremic toxins.

The present study investigated erythropoiesis in peritoneal dialysis (PD) patients.

**Methods:** 46 PD patients (31 M, mean age:64±14yrs) and 17 healthy subjects (CTR) were enrolled. All measurements were made in isolated RBCs. PS exposure was estimated from FITC-AnnexinV binding by flow cytometric.

**Results:** 27 patients were treated with CAPD and 19 with APD. The mean length of treatment was 39.29months. The PS externalization on surface was significantly higher in PD patients than in CTR (2.6%; IQR 1.6-3.7 versus 0.8%; IQR 0.7-1.3 p<0.01). The median percentage of erythropoiesis showed no significant differences between patients with (n=18) and without diabetes, treated with CAPD or APD and with a negative or positive (n=18) history of peritonitis. Erythropoiesis showed significantly lower levels in PD patients with residual diuresis (n=23) than in patients without (3.7%, 2.6-5.6 versus 5%, 3.1-16, p<0.003). A significant negative correlation was observed between percentage of erythropoiesis and Body Composition Monitor-BCM for hydration status (Spearman’s rho=- 0.4, p<0.05). There was no a statistically significant relationship between erythropoiesis and months of PD, urea, albumin and creatinine levels.

**Conclusions:** In conclusion, erythropoiesis has been shown to be significantly higher in PD patients than CTR. Our data suggest that the type and the length of PD treatment do not enhance erythropoiesis. On the contrary, the loss of residual diuresis lead to a significant increase in erythropoiesis. The residual diuresis may contribute to the elimination of potential pro-erythropoietic toxins that induce increased erythropoiesis.

**The Pattern of T Helper Lymphocytes Has No Clinical Implications in Peritoneal Dialysis Patients**

**Background:** Myristic acetate in the presence of brefeldin A, and then stained with CD3-, CD8 surface markers, interferon-gamma (IFN-gamma) and interleukin-4 (IL-4) for flow cytometry analysis. CD3-positiveCD8-negative cells were assumed as CD4-positive Th2 lymphocytes.

**Results:** We recruited 23 PD patients and 10 healthy controls. Th lymphocytes accounted for 68.9% of total lymphocytes in PD patients and 72.9% in controls (p=non-significant). IFN-gamma positive T lymphocytes (Th1) accounted for 15.8% of Th lymphocytes in PD patients and 15.3% in controls (p=non-significant). IL-4 positive T lymphocytes (Th2) accounted for 2.6% in PD patients and 2.8% in controls (p= non-significant). The percentage of Th1 or Th2 lymphocytes did not correlate with any of the demographic and laboratory findings including diabetes, PD vintage, PD regimens, Kt/V, left ventricular ejection fractions, serum chemistries and hematologic values. The patients who suffered from cardiovascular diseases (n=6) showed a similar percentage of Th1 or Th2 lymphocytes compared with those who did not (n=17). The patients who had significant pruritus requiring medications (n=11) showed a similar percentage of Th1 and Th2 lymphocytes compared with those who did not (n=12).

**Conclusions:** The pattern of Th lymphocyte differentiation was similar between PD patients and healthy people, and it did not have an association with clinical findings in PD patients.

Peritoneal Protein Excretion Was Lower in Nocturnal Intermittent Peritoneal Dialysis As Compared With Continuous Ambulatory Peritoneal Dialysis Not Associated With Peritoneal Transport Status in the Same Individual

Hironori Nakamura, Anayama Mariko, Yasuko Makino, Masaki Nagasawa. Dept of Nephrology, Shinonoi General Hospital, Nagano, Japan.

Background: Recent studies have reported that peritoneal protein excretion (PPE) during peritoneal dialysis (PD) therapy is associated with cardiac disease and patient survival. However, little is known regarding the extent to which PPE can be influenced by PD prescription or peritoneal transport status.

Methods: The aims of this study were to compare PPE in the same individual with different PD prescription of either continuous ambulatory PD (CAPD) or nocturnal intermittent PD (NIPD), and to evaluate the correlation between PPE and dialysate to plasma creatinine ratio (D/P Cr). Seventeen patients, of whom 58.8% were male, were included in the study. A peritoneal equilibrium test was performed and the amount of total protein (TP) loss in the dialysate was measured during CAPD or NIPD therapy in the same patient.

Results: The mean age of the patients was 59.4 ± 18.0 years, body mass index was 21.5 ± 3.4, serum TP (s-TP) was 5.8 ± 0.8 g/dL, serum albumin (s-Alb) was 3.0 ± 0.7 g/dL, C-reactive protein (CRP) was 0.4 ± 0.7 mg/dL, and D/P Cr was 0.76 ± 0.15. During NIPD therapy, PPE was correlated with peritoneal clearance (γ = 0.63, p = 0.006), effluent volume (γ = 0.69, p = 0.002), and PPE to effluent volume ratio (γ = 0.80, p = 0.000), but not with s-TP, s-Alb, CRP, or D/P Cr. During CAPD therapy, PPE was negatively correlated with s-TP (γ = -0.62, p = 0.007) and s-Alb (γ = -0.58, p = 0.014), positively correlated with effluent volume (γ = 0.50, p = 0.037) and PPE to effluent volume ratio (γ = 0.72, p = 0.001), but not with CRP or D/P Crs. On comparing NIPD and CAPD, there was no difference in effluent volume (7341 mg vs. 7209 mg, respectively), however, both PPE and PPE to effluent volume ratio were significantly lower during NIPD than during CAPD (5586 mg vs. 7779 mg (p = 0.004) and 0.74 mg/mL vs. 1.09 mg/mL (p = 0.004), respectively).

Conclusions: The current study demonstrated that PPE and PPE to effluent volume ratio were lower during NIPD than during CAPD in the same individual, independent of the peritoneal transport status.

TH-POI021
Fungal Peritonitis in the Standardizing Care to Improve Outcomes in Pediatric ESRD (SCOPE) Collaborative

Raj P. Munsch, Christine B. Sethna, Sushil Gupta, Samhar I. Al-Akash, John P. Lawlor, Bradley Warady. Seattle Children’s, Kosair Children's Hospital; North Shore-LIJ Medical Group; Children’s Mercy Hospital; Driscoll Children’s Hospital; Children’s Hospital Association.

Background: The SCOPE Collaborative is a multicenter QI initiative with the 1st aim to reduce dialysis catheter associated infections. The objective of this study was to describe the epidemiology of fungal peritonitis (FP) among pediatric patients with an indwelling peritoneal dialysis (PD) catheter enrolled in SCOPE.

Methods: PD characteristics and patient outcome were collected between 10/11-12/14 from 29 centers participating in SCOPE. Data was stratified based on fungal, bacterial/culture-neg peritonitis and no peritonitis. Peritonitis was defined as any episode that was diagnosed within 90 days of the fungal infection. Culture neg (28.6%) and Staph species (23.8%) were the predominant causes of the prior peritoneal infections. Presence of a G-tube, vesicostomy, upward orientation of the exit site and history of touch contamination. The majority of the PD catheters were removed, with a preponderance of patients requiring hospitalization.

Conclusions: FP were responsible for 8.9% of peritonitis episodes with the majority of the episodes occurring in children <2 years of age. Additional risk factors included presence of a G-tube, vesicostomy, upward orientation of the exit site and history of touch contamination. The majority of the PD catheters were removed, with a preponderance of patients requiring hospitalization.

TH-POI022
Relation of Central and Brachial Blood Pressure to Volume Status in Peritoneal Dialysis Patients

Yun Jung Oh, Su mi Lee, Ji Yong Jung, So Mi Kim, Chungsik Lee. Dept of Internal Medicine, Cheju Halla General Hospital, Jeju, Republic of Korea; Dept of Internal Medicine, Dong-A Univ Hospital, Busan, Republic of Korea; Dept of Internal Medicine, Gachon Univ Gill Hospital, Incheon, Republic of Korea; Dept of Internal Medicine, Jeju National Univ Hospital, Jeju, Republic of Korea.

Background: Euvolemia is an important predictor of outcome in peritoneal dialysis (PD), but chronic subclinical volume overload occurs frequently in PD patients. Even though volume overload is associated directly with hypertension, blood pressure (BP) not always reflect volume overload. Central BP has been shown to be a better predictor for target organ damages compared with brachial BP in general population. In this study, we evaluated comparative values of central BP and brachial BP for determining volume status in PD patients.

Methods: We enrolled 52 prevalent PD patients, and accessed average volume status using Body Composition Monitor (BCM). Central BP was estimated using radial artery tonometry, and brachial BP measurement at office and 24-hour ambulatory blood pressure monitoring (ABPM) were performed. Volume overload was defined as an overhydration (OH) >11 L.

Results: Average office central systolic BP (cSBP), office brachial systolic BP (bSBP), and ambulatory brachial systolic BP (24-hSBP) were 139.8 ± 26.3, 140.7 ± 19.2, and 142.5 ± 22.0 mmHg, respectively. In overall, 41(78.8%) patients were in volume overload status. A stronger association of central BP with volume overload compared with brachial BP was observed in the receiver operating curve analysis (area under the curve (AUC) of cSBP, bSBP, and 24-hSBP were 0.870 ± 0.06, 0.780 ± 0.09, and 0.830 ± 0.06 respectively). In multivariate analysis adjusted for age, sex, PD vintage, diabetes, and cardiovascular disease, the odds ratio (OR) for central BP (OR 1.110; 95% CI 1.019-1.210) was higher than those for brachial BP (OR 1.085; 95% CI 1.014-1.161 for bSBP and OR 1.094; 95% CI 1.021-1.173 for 24-hSBP).

Conclusions: Office central BP was more strongly related to volume status than out-of-office ambulatory brachial BP as well as office brachial BP, suggesting that central BP was more valuable than brachial BP in assessing volume status in PD patients.

TH-POI023
Novel Regimen for Intraperitoneal Cefazolin and Ceftazidime in Peritoneal Dialysis Patients

Sadudee Peerpornratana, 1 Pisut Katavetin, 1 Pajaree Chariyavilaskul, 1 Talergnsak Kanjanabuch, 1 Kearkait Pradiptsornpal, 1 Somchai Eiam-ong. 1 Div of Nephrology, Dept of Medicine, Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand; 2Dept of Pharmacology, Faculty of Medicine, Chulalongkorn Univ, Bangkok, Thailand.

Background: Current guideline suggested that intraperitoneal (IP) antibiotics should be administered only in a long peritoneal dialysis (PD) dwell (>6 hours), which is not always practical because the long dwell might result in low ultrafiltration and volume overload. The objectives of this study were to develop a novel regimen for IP antibiotics in short dwell (≤2 hours) during the automated PD cycling and examine the dialysate and plasma level of the most used empirical antibiotics for PD-related peritonitis, cefazolin and ceftazidime.

Methods: In the novel regimen, cefazolin and ceftazidime (20 mg/kg each) were added in a 5-liter bag of 2.5% dextrose PD fluid which was placed on the warmer of the PD cycling machine. Another 5-liter bag of PD fluid was connected to the machine, off the warmer. Patients underwent 5 exchanges of 2-liter PD fluid over 10 hours by the PD cycling machine without last fill or additional dwell. Cefazolin and ceftazidime concentrations in plasma and dialysate were determined by high performance liquid chromatography.

Results: Six PD patients without peritonitis were participated in the study. Dialysate cefazolin and ceftazidime were consistently high throughout the PD session in all patients (26-360 mg/L). Plasma cefazolin and ceftazidime exceeded the minimal inhibitory concentration (MIC) for susceptible organisms (8 mg/L) in 2 hours (cefarazolin 25.8±8.0 and ceftazidime 12.5±3.4 mg/L at 2 hours), peak at 10 hours (51.1±14.1 and 23.0±5.2 mg/L) and then sustained well above the MIC at 24 hours (42.0±9.8 and 17.1±3.1 mg/L).

Conclusions: The novel regimen for IP cefazolin and ceftazidime in short dwell (≤2 hours) during the automated PD cycling could provide adequate dialysate and plasma concentration and would become a standard regimen for peritonitis in PD patients already using PD cycling machine as well as those who temporarily need shorter dwells during peritonitis due to increasing peritoneal solute transport.

Is Automated Peritoneal Dialysis Better Than Continuous Ambulatory Peritoneal Dialysis in Quality of Life, Depression, and Renal Treatment Satisfaction? A Prospective Multicenter Propensity-Matched Study

Sun-Hee Park,1 Hee-Yeon Jung,1 Sukyung Lee,1 Ji-Young Choi,1 Se-Hee Yoon,1 Jung-Hee Cho,1 Chan-Duck Kim,1 Yong-Lim Kim.1 Internal Medicine, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; 2Internal Medicine, Konyang Univ, Daejeon, Republic of Korea.

Background: Health-related quality of life (HRQOL) is an important variable in the selection of dialysis modality among incident dialysis patients. However, relative superiority in HRQOL between automated peritoneal dialysis (APD) and continuous ambulatory peritoneal dialysis (CAPD) are not clearly known. The objective of this study was to compare HRQOL, depression, and renal treatment satisfaction over time between APD and CAPD patients.

Methods: Incident patients initiating APD and CAPD were prospectively enrolled from nationwide multicenters in Korea. HRQOL, depression, and renal treatment satisfaction were assessed at 1 and 12 months after the start of dialysis by Kidney Disease Quality of Life Short Form 36 (KDQOL-36), Beck’s Depression Inventory (BDI), and Renal Treatment Satisfaction Questionnaire (RTSQ), respectively. The mean changes of scores in APD and CAPD were compared by propensity score matching analysis.

Results: All 260 incident patients starting peritoneal dialysis (PD) from 11 centers were included in this study. A total of 170 patients were matched from 208 patients who completed all questionnaires and did not change PD modality during the 1-year follow-up period. The total scores at 1 month showed better HRQOL for APD than CAPD patients in symptom, patient satisfaction, pain, and social function domains. No differences were observed between the two groups in total scores of KDQOL-36 at 12 months. However, CAPD patients had a significantly greater improvement in symptom and social function domains. A significant improvement also occurred in BDI and RTSQ in CAPD patients.

Conclusions: APD is not better than CAPD in HRQOL, depression, and renal treatment satisfaction during initial first one year on dialysis. The relative positive effect of CAPD compared with APD on improvement of HRQOL, depression, and renal treatment satisfaction was confirmed.

TH-PO1025

Thyroid Functional Disease and Mortality in a National Peritoneal Dialysis Cohort

Connie Rhees,1 Vanessa A. Ravel,1 Elani Streja,1 Rajnish Mehrotra,2 Steven B. Kim,1 Jiaxi Wang,1 Danh V. Nguyen,1 Steven M. Brunelli,1 Csaba P. Kovessy,1 Gregory Brent,1 Kamyar Kalantar-Zadeh.1 1UC Irvine; 2UW; 3DaVita Clin Research; 4UTHSC; 5UCLA.

Background: Peritoneal dialysis (PD) patients have a high prevalence of thyroid dysfunction which may be due to 1) peritoneal effluent losses (vast majority of thyroid hormone is protein-bound) and 2) frequent exposure to povidone-iodine cleaning agents leading to iodine-induced hypo- and hyperthyroidism. In the general population thyroid dysfunction is associated with higher risk of cardiovascular (CV) disease and death. There has not been study of the association between hypo- or hyperthyroidism defined by TSH with mortality in PD patients.

Methods: We examined the association of thyroid functional status with all-cause mortality in a 5-year national cohort (1/2007-12/2011) of PD patients with at least one TSH measure. Thyroid functional status was defined as: hyper-, eu-, and hypothyroidism (TSH <0.5, 0.5-5, >5mIU/L). We examined time-dependent and baseline thyroid function to determine short- and long-term exposure–mortality associations, respectively, using Cox models with 3 adjustment levels: unadjusted, case-mix, and case-mix+labatory adjusted.

Results: Among 1484 patients, 7% and 18% had hypo- and hyperthyroidism, respectively. In time-dependent analyses, hypo- and hyperthyroidism were each associated with higher mortality risk in all 3 Cox models (ref: euthyroidism). In baseline analyses, hypothyroidism was associated with higher death risk in unadjusted and case-mix models, but associations were attenuated to the null in case-mix+labatory models.

Conclusions: Time-dependent hypo- and hyperthyroidism were each associated with higher mortality, suggesting short-term risk in PD patients. Further studies are needed to determine if CV pathways are implicated, and if thyroid-modulating therapies ameliorate mortality in this population.

TH-PO1026

A Tale of APOL1 Mutation and Parvovirus Infection

Sherry Mansour,1 Whitney E. Besses,1 Karan Jawani,2 Ursula C. Brewster.1 1Nephrology, Yale School of Medicine, New Haven, CT; 2Internal Medicine, Government Medical College And Hospital Chandigarh, Navanshahr, India.

Introduction: We present a case of a first trimester pregnant woman with nephrotic range proteinuria and fetal demise in the setting of an acute parvovirus infection. Kidney biopsy revealed collapsing FSGS, and exome sequencing revealed mutations in APOL1. The relationship between Parvovirus and FSGS is one that clinicians might overlook, and perhaps may play a more prominent role in these progressive cases especially with APOL1 mutations.

Case Description: 37 yo Caribbean female presented at 8 weeks gestation with progressive swelling. Her daughter developed fifth's disease one month prior. On presentation her BP was 146/95, HR 77 with pitting edema. Her creatinine was 6.3, BUN 43, albumin 1.5, and spot pt/pr 20.8. Parvovirus PCR was 2000 copies. Biopsy demonstrated collapsing FSGS secondary to Parvovirus B19 [Fig 1A 1B]
The hope was that this injury would improve with improvement in titers, so IVIG was started. A follow up PCR showed improvement to 280 copies but she remained nphoretic with proteinuria of 20-69 g. Re-biopsy revealed significant scarring and dialysis was initiated [Fig IC]. Patient is now being evaluated for transplant. Given the unusual severity of this case, and her possible African ancestry, a genetic susceptibility to podocyte injury was entertained. Whole exome sequencing identified the patient to have two APOL1 risk alleles.

Discussion: Parvovirus has been linked with collapsing FSGS, and in one study viral PCR was detected in 78% of kidney tissue with this diagnosis. The combination of B19 infection and APOL1 mutation likely made our patient particularly susceptible to injury. Our case raises the question of how often subclinical parvovirus infection may be involved in collapsing FSGS, and highlights how sudden and devastating it can be to the life of a young patient.

TH-PO1027
Podocyte Myeloid Bodies without Confirmed Genetic Mutation in a Female: Fabry’s Disease? Pravir V. Bajaj, 1 David J. Cinantalik, 2 David G. Warnock, 3 Robert J. Desnick, 4 William Luke Whittier. 1 Nephrology, Rush Univ MC, Chicago, IL; 2Pathology, Rush Univ MC, Chicago, IL; 3Nephrology, UAB, Birmingham, AL; 4Genetics, Mt Sinai, New York, NY.

Introduction: Fabry’s disease (FD) is a X-linked lysosomal storage disorder caused by deficient α-galactosidase activity. A renal variant has been described with the R363H mutation. Due to random X-chromosomal inactivation, heterozygous females can present a diagnostic challenge. We report a case with a renal limited presentation, biopsy findings characteristic of FD but a negative whole blood DNA analysis.

Case Description: A 46 year-old Hispanic woman was evaluated for proteinuria. She was asymptomatic with no prior medical history or family history, and no exposure to silica, amphiborane, or hydroxychloroquine. Her exam was unremarkable: no neuropathy, skin changes, or corneal dystrophy. SCr was 0.6 mg/dL, UA 21+ protein with P/C ratio of 1.94 g/g. Biopsy revealed diffuse enlargement of the podocytes with a foamy cytoplasm appearance and on EM, prominent podocyte lamellated lipid inclusions with foot process effacement and minimal endobothelial deposits.

Figure 1: Podocyte myeloid bodies; yellow line denotes foot process effacement, red star shows limited endobothelial inclusion. Alpha-galactosidase activity was 0.187 U/L (lower limit of nL) and genomic sequencing of the GLA gene was negative. EKG, Echo, cardiac MRI, and brain MRI with and without gadolinium were nl.

Discussion: We present a pt with renal limited manifestations mimicking FD in the absence of known toxic exposure and a negative whole blood DNA mutation analysis. Treatment with enzyme replacement is not warranted without a positive genetic analysis. This case highlights the variable genotypic and phenotypic presentation, and raises the possibility that tissue-specific mosaicism could explain phenotypic variation in females with Fabry’s Disease.

TH-PO1028
Relapsing Thrombotic Microangiopathy following Persistent Intravenous Use of Reformulated Oxycontin Jey Sanghwan, Melissa S. Nattratmad, Dakshinamurthy Divi. Dept of Nephrology, Gold Coast Univ Hospital, Southport, Queensland, Australia.

Introduction: Thrombotic microangiopathy (TMA), resembling thrombotic thrombocytopenic purpura (TTP), with normal ADAMTS13 activity has recently been observed in persons injecting Oxycon ER (oxymorphone), an oral opioid available in the United States. This phenomenon had not been reported outside the US, however, and the mechanism of inducing TMA is not yet known.

Case Description: A 29-year old female presented with hemolytic anemia and thrombocytopenia, with a hemoglobin of 70g/L and platelet count of 17 x 10^9/L. She was treated with therapeutic plasma exchange (TPE) for a working diagnosis of TTP and recovered, with no ongoing TPE requirement. She represented two weeks later, with a hemoglobin of 81g/L, platelet count of 8 x 10^9/L, and additional renal impairment. She again commenced TPE and also prednisone. Her ADAMTS13 activity was >94%, atypical hemolytic-uremic syndrome (aHUS) was therefore considered, and genetic testing was ordered. She then admitted to a two-month history of injecting Oxycon (oxycodone) and for the previous month had been using reformulated Oxycontin. TPE and prednisone were therefore stopped, and she experienced clinical and hematological recovery. Genetic testing for aHUS subsequently returned as negative.

Discussion: To our knowledge, this is one of only two documented cases of TMA following IV Oxycontin use, both of which were observed in Australia soon after reformulated Oxycontin replaced original Oxycontin. This report supports previous use of polyethylene oxide (PEO), a tamper-proof coating added to the reformulated Oxycon and Opana ER, as the causative agent, as TMA has now been observed following the use of different medications but with the same PEO coating. Additionally, our case is the first to demonstrate relapsing TMA following persistent intravenous drug use of polyethylene oxide. Given the rarity of this illness, it is possible that an unidentified genetic or immunologic susceptibility causes some individuals to develop TMA in response to these drugs, whilst others do not. We encourage clinicians to consider IV drug use in all patients presenting TMA, as treatment approach may differ and the role of plasma exchange is not yet clear.

TH-PO1030
Kappa Light Chain-Associated Crystal-Storing Tubulopathy, Podocytopathy, and Histiocytosis in GI Tract, in a Patient with Multiple Myeloma Michifumi Yanahira,1,2 Albert Q. Lam,3 Joseph V. Bonventre,2 Vanessa Bijol.1,2 1Pathology, Brigham and Women’s Hospital, Boston, MA; 2Renal Division, Pathology, Brigham and Women’s Hospital, Boston, MA; 3Harvard Medical School, Boston, MA.

Introduction: Multiple myeloma manifests with variety forms of kidney disease, such as light chain amyloidosis, cast nephropathy, and light chain deposition disease. Among them, crystal-storing disease is a rare entity. We report an interesting case of a patient with extramedullary IgGκ multiple myeloma, who presented with crystal-storing histiocytosis in GI tract, and subsequently developed crystal-storing tubulopathy and podocytopathy.

Case Description: A 60-year-old man with type 2 DM and HTN was found to have a 1 cm largeecal polyp on screening colonoscopy in 2009. The polyp showed diffuse infiltration by a plasma cell neoplasm and crystal-storing histiocytosis with κ light chain (LC) restriction. At that time, the patient showed intact bone marrow, normal renal function and proteinuria of 0.5 g/dL. He was subsequently closely followed with endoscopy, SPEP, and renal function tests. In 2014, he developed nephrotic range proteinuria (>4g/24h), slightly rising Cre to 1.12 mg/dl, and increased serum free κ LC (216 mg/L). Kidney biopsy was performed, revealing many proximal tubular epithelial cells containing PAS-positive crystalline material in the cytoplasm. The glomeruli were unremarkable except for mild mesangial expansion. No significant immune deposits were present in glomeruli or tubulointerstitium, but there was slightly stronger background IF reactivity for κ LC than λ LC on frozen tissue sections. IF studies on paraffin sections revealed strong κ LC reactivity of the materials aggregated in the tubular epithelial cells and podocytes, while λ LC was negative. EM revealed extensive intracortical accumulation of crystalline material of rhomboid and rectangular shapes in proximal tubular epithelial cells and podocytes.

Discussion: LC-associated crystal-storing disease is a rare kidney disease. To our knowledge, this is the first reported case of coexisting crystal-storing tubulopathy, podocytopathy, and histiocytosis in the GI tract in a patient with multiple myeloma.
Parvovirus B19 Preceding Collapsing Glomerulopathy in Renal Allograft

**Introduction:** Collapsing glomerulopathy (CG) is a distinct clinicopathologic entity with proliferation of glomerular epithelial cells and capillary collapse. It has been classically associated with parvovirus B19 infection, but other predisposing conditions and etiologic factors include parvovirus and CMV infections, autoimmune diseases, hematologic malignancies, and certain drugs. The pathomechanism of CG in renal allograft is unclear. Here we report a case of parvovirus infection-preceding CG in allograft.

**Case Description:** A 72-year-old man was referred due to DM and HTN, status post DDRT in June 2014, who presented with rising Cre from 1.6 to 2.0 without viral illness. 3 months after transplantation. The 1st biopsy showed several mesangial deposits with organized spherical substructural organization, averaging 18 nm in diameter, without evidence of rejection. Extensive immunohistochemistry (IHC) workup revealed positive staining only for Parvovirus in mesangial area. 3 weeks after the biopsy, he developed Parvovirus B19 viremia with 4.8 x 10^3 /mL. 6 weeks later, he presented with rising Cre to 3.4, proteinuria 1.5 g/24hr, and improved Parvovirus viremia (3.3 x 10^5 /mL). The 2nd biopsy revealed severe podocyte injury with features of CG. (1) Collapse of the tuft and prominent epithelial cells with intracytoplasmic protein reabsorption granules, (2) extensive effacement of foot process and other degenerative changes of podocytes, and (3) coarse protein reabsorption granules in tubular epithelial cells. Parvovirus could not be detected anymore by EM or IHC.

**Discussion:** This case clearly showed: (1) for the first time, Parvovirus B19 particles in glomeruli immunohistochemically and ultrastructurally, (2) Parvovirus B19 infection systemically and histologically preceding CG, and (3) when CG developed, serum Parvovirus B19 titer dramatically decreased while Parvovirus could not be detected any more by IHC or EM. The evidence suggests that the direct or indirect association between Parvovirus B19 infection and CG in kidney allograft.

**TH-PO1034**

Relapse of Kappa Restricted Chronic Lymphocytic Leukemia Associated with a Lambda Restricted Plasma Cell Class Denying Cause Renal Amyloid Sunil Ranjarpan.

**Introduction:** Chronic lymphocytic leukemia (CLL) has been associated many glomerular diseases. Rarely, it has been associated with amyloidosis either as the sole clone responsible, or in association with a plasma cell clone possessing the same light chain (kappa or lambda). Criteria for the diagnosis of amyloidosis include an increase in kappa or lambda light chains in the plasma and the urine, and the demonstration of amyloid deposits in the tissue. Here we report a unique case of a patient with a plasma cell clone expressing a different light chain with kappa-restricted renal amyloidosis.

**Case Description:** A 66-year-old male, diagnosed with kappa-restricted CLL in 2009 achieved complete remission after 6 cycles of fludarabine, cyclophosphamide and rituximab. 5 years later, he presented with foamy urine, generalized swelling, and weight gain. Serum creatinine was 1.1. Initial spot urine protein / creatinine ratio showed proteinuria of 5g/g which later increased to 10g/. During the previous year serum albumin fell from 3.7 to 2.6 to 5.7 mg/dL over the preceding year. His CD4+ T-cell count was 514 and his viral load 75,120 copies/mL. His HAART regimen was switched to dolutegravir, lamivudine and abacavir.

**Discussion:** This case clearly shows that relapse of CLL is associated with kappa-restricted renal amyloidosis and is important to be considered in the differential diagnosis of unexplained proteinuria and renal dysfunction in patients with CLL.

**TH-PO1035**

Recurrent 2,8-Dihydroxyadenine Deposition Successfully Treated with Kidney Transplantation

**Introduction:** Adenine phosphoribosyltransferase (APRT) deficiency is an autosomal recessive purine metabolism disorder where adenine is oxidized by xanthine dehydrogenase to 2,8-dihydroxyadenine (2,8-DHA), forming insoluble urinary crystals, nephrolithiasis, CKD and ESRD. Literature reveals diagnosis of APRT deficiency is rare before kidney transplantation. Delay in diagnosis and xanthine oxidase inhibitor treatment predisposes to recurrent disease in renal allograft, with allograft loss in over 25% cases. Though APRT is ubiquitous in all cells, extrarenal symptoms are uncommon in affected individuals. Our patient presented with crystalline keratopathy resolving completely after kidney transplantation.

**Case Description:** A 49 year old male, diagnosed with 2,8-DHA nephropathy due to recurrent disease in renal allograft, with allograft loss in over 25% cases. Though APRT is ubiquitous in all cells, extrarenal symptoms are uncommon in affected individuals. Our patient presented with crystalline keratopathy resolving completely after kidney transplantation.
Minimal Change Disease Diagnosing Relapsing Mantle Cell Lymphoma
Juan Calderon, Mark A. Perazella. Nephrology, Yale Univ School of Medicine, New Haven, CT.

Introduction: Glomerular lesions are linked with hematologic malignancies, with minimal change disease (MCD) commonly associated with Hodgkin’s lymphoma. Diagnosis of the underlying hematologic disorder often precedes development of the glomerulopathy; however, in rare cases, MCD precedes discovery of the lymphoma by several months. We present a case of new onset nephrotic syndrome and AKI in association with undetected relapsing mantle cell lymphoma (MCL).

Case Description: A 74 y/o man with history of stage IV mantle cell lymphoma in remission developed AKI and new onset edema. Chemotherapy completed 1 year prior to presentation induced complete remission on bone marrow and follow-up PET scans. On presentation he denied B symptoms, had no new lymphadenopathy, and only noted decreased appetite. The patient was edematous and hypertensive. Serum Cr was 2.4 mg/dL up from 1.3 mg/dL. High-grade, non-quantifiable urine protein was noted by the lab. Urine sediment was remarkable for numerous granular casts, oval fat bodies, and few uric acid crystals. Serum uric acid was 13.2 mg/dL. Therapy for tumor lysis syndrome was instituted due to concern for relapsing lymphoma in the setting of AKI. However, PET/CT scan was completely normal with no evidence for lymphoma. Furthermore, LDH was within normal limits. Kidney biopsy revealed normal glomeruli on light microscopy with acute tubular injury. EM revealed global effacement of foot processes. A diagnosis of MCD with focal tubular injury was made and steroid therapy was started. Peripheral flow cytometry and later a bone marrow biopsy confirmed a 23% tumor burden consistent with relapsed MCL.

Targeted chemotherapy for MCL was initiated.

Discussion: We present the first report of MCD associated with relapsing MCL. Oncologic surveillance including PET scan failed to detect recurrent MCL. BM biopsy and flow study was pursued following the diagnosis of MCD. Initial therapy with steroids and chemotherapy for MCL was initiated. We present the first report of MCD associated with relapsing MCL.

Rena Osteodystrophy
Hitarth S. Dave, Daniel E. Carl. Dept of Internal Medicine, Div of Nephrology, Virginia Commonwealth Univ School of Medicine, Richmond, VA.

Introduction: It is believed that mineral metabolism changes start as early as stage II chronic kidney disease (CKD). The spectrum of CKD-mineral and bone disorder (MBD) ranges from low-turnover adynamic disease to high-turnover osteitis fibrosa.

Case Description: A 37-year-old female with end-stage renal disease (ESRD), currently undergoing hemodialysis, presented complaining of a 1-day history of inability to eat or drink. Prior to presentation, she had noticed 2-week history of difficulty speaking, and 8-month history of increasing facial size. On presentation, the blood pressure was 180/68 mm Hg, and the oxygen saturation 98% while breathing ambient air. The physical examination revealed significant bony hypertrophy of the maxilla and mandible with edema of the overlying soft tissue. Computed tomographic (CT) scans of the maxilla and mandible showed severe expansion of the maxillary and mandibular bones with complete replacement of the osseous matrix and surrounding mass effect on the maxillary sinuses and oropharynx. The patient was edematous and hypertensive. Serum Cr was 2.4 mg/dL while platelet count and hemoglobin returned to baseline at discharge.

Discussion: We identified 24 cases reported in literature with mean age of 62 years. All patients presented with AKI and PTN with 61% being nephrotic range. The onset of PTN ranged from 2 weeks to 28 months after initiation of BCZ. HTN occurred among 62% while TMA among 57% of patients. Most of the patients had partial or complete recovery of AKI and PTN with only 1 patient progressing to end-stage renal disease after 2 months. The increased expression of naphthoquinone, thought to be related to low free VEGF levels leading to endothelial dysfunction and podocyte dysregulation. Treatment includes withholding the drug if PTN exceeds 2g/day or permanent discontinuation for nephrotic syndrome and ACEI or thiazide diuretics for treatment of HTN. Drug induced TMA with normal ADAMS 13 levels rarely requires PE.

5-Oxoprolinuria: A Rare Cause of High Anion Gap Metabolic Acidosis due to Acetaminophen Ingestion
Arvadan Mashhadian, 1, 2 Sreygh G. Iyengar, 1 Seyed-ali Sadjadi, 1Lisa Aimee Hechanova. 1, 2Nephrology, Loma Linda Univ, Loma Linda, CA; 2Nephrology, Jerry I. Pettis Memorial Veterans Medical Center, Loma Linda, CA.

Introduction: Acquired 5-oxoprolinuria is a rare cause of high anion gap metabolic acidosis due to excessive acetaminophen ingestion. It largely goes unrecognized because an assay for 5-oxoprolinuria is not widely available. The malnourished and chronically ill women with history of chronic acetaminophen ingestion are commonly affected. Acetaminophen levels are rarely in toxic range.

Case Description: A 57-year-old woman with a history of adipsos dolorosa was admitted for acute osteomyelitis. She was chronically taking acetaminophen containing pain medication. Her hospital course was complicated by anion gap metabolic acidosis and cardiorespiratory failure. Her acetaminophen level was not elevated. Usual causes of altered mental status and shuttling amino acids into the cytosol. When glutathione levels are diminished, INACUTAN assay for 5-oxoproline is not widely available. The malnourished and chronically ill women with history of chronic acetaminophen ingestion are commonly affected. Acetaminophen levels are rarely in toxic range.

Discussion: Acute and chronic acetaminophen ingestion can lead to high levels of 5-oxoprolinuria. The pathophysiology behind acquired 5-oxoprolinuria has been mostly explained by reduced glutathione in prior case reports. 5-oxoprolinuria is an intermediate in the gamma-glutamyl pathway, the metabolic cycle responsible for creating glutathione and shuttling amino acids into the cytosol. When glutathione levels are diminished, feedback inhibition ceases, causing an overproduction of 5-oxoprolin. Sepsis, amongst others etiologies, have been implicated in glutathione depletion. 5-oxoprolinuria clinically presents with altered mental status. One of the key aspects of diagnosing this disorder is the detection of 5-oxoprol in urine. N-acetylcysteine may be an effective treatment that acts to restore intracellular glutathione levels. Extracellular fluid expansion with dextrose containing saline promptly improves symptoms. In conclusion, 5-oxoprolinuria should be considered in any patient with unexplained metabolic acidosis and recent acetaminophen ingestion. Overlooking the diagnosis can be costly.

Severe Tubulointerstitial Nephritis with Lymphoid Follicles in Sjögren’s Syndrome
Maiko Nagata, Takehiko Kawaguchi, Mao Watanabe, Takafumi Yamakawa, Moritoshi Kadomura, Hiroshi Kitamura, Toshiyuki Imasawa. Internal Medicine, National Hospital Organization Chiba-East Hospital, Chiba, Japan.

Introduction: Patients with Sjögren’s syndrome (SS) are at increased risk for the development of lymphoma. The prolonged state of immunologic and lymphoid hyperactivity in SS may predispose patients to the development of lymphoma neoplasms. However, biopsy specimens from these patients do not meet histologic criteria for frank malignancy. We report a rare case of severe tubulointerstitial nephritis with lymphoid follicles in SS.

Case Description: A 66-year-old woman, who had developed general malaise for a few years, was admitted to our hospital, because of the rapid rise in the serum creatinine...
level in the past two months. Four months before admission, she was found to have hypergammaglobulinemia, and a bone marrow–biopsy specimen revealed no hyperplasia of plasma cells. In the admission, the main laboratory values showed the following values: serum creatinine 1.8 mg/dL, IgG 6634 mg/dL, urinary b,MG 7829 mg/L, anti-SS-A<500 U/mL. Renal biopsy showed tubulointerstitial nephritis with marked lymphoplasmacytic infiltration. Most of the cells were plasma cells; some were immature. Immunostain studies showed plasma cells with a polyclonal pattern. Some lymphoid follicles were also present in the interstitial tissue. Additionally, lip biopsy showed microsalivary gland with concentrated lymphocyte infiltration. Most of the cells were B lymphocytes. Plasma cells with a polyclonal pattern were present in the peripheral germinal centers. Thus, the diagnosis was primary SS. Immunopathologic analysis of renal and lip biopsy specimens showed no features of malignancy. Steroid therapy led to prompt resolution of the infiltrate.

Discussion: This is a rare case of severe tubulointerstitial nephritis with lymphoid follicles in SS. It may show a spectrum of lymphoproliferative disease in SS.

TH-PO1041

Scleroderma Renal Crisis with Normal Blood Pressure and Normal Serum Creatinine

Nathanong Thamcharoen,1 Raquel M. Rosen,1 Vivette D. D’Agati,2
1Dept of Medicine, Bassett Medical Center, Cooperstown, NY; 2Dept of Pathology, Columbia Univ College of Physicians and Surgeons, New York, NY.

Introduction: A serious complication of systemic sclerosis is scleroderma renal crisis (SRC) usually presenting with acute onset of high blood pressure, kidney failure and thrombotic microangiopathy. 10% of patients may not have hypertension known as normotensive scleroderma renal crisis but mostly presenting with elevated creatinine. We introduce a case of scleroderma renal crisis with normal blood pressure and normal serum creatinine.

Case Description: A 61 year-old woman was admitted with dysphagia, proximal muscle weakness and tightening of skin. She was diagnosed with systemic sclerosis from the findings. She later developed oliguria without elevation of creatinine (baseline creatinine 0.4 increased to 0.8). Her blood pressure was in normal range. The urinalysis showed 5-10 cells/HPF of red blood cell, no dysmorphic red blood cell or cast. She had proteinuria of 441 mg/day. Kidney ultrasound did not show abnormalities. Anti-dsDNA, MPO antibody and proteinase-3 antibody were performed, they were all negative. Free light chain disease and amyloidosis were ruled out by normal serum protein electrophoresis and normal free light chain. Kidney biopsy was performed revealing arteriolar mesangial edema and concentric intimal sclerosis, consistent with thrombotic microangiopathy.

Acute Rejection of a Kidney Transplant in a Patient with Common Variable Immunodeficiency Syndrome

Omar Moussa Al Ninini,1,2 Murray J. Mazer,3 Margaret L. Burks,2 Gerald Schulman,1 Rachel B. Fissell,1
1Nephrology, Vanderbilt Univ Medical Center, Nashville, TN; 2Radiology, Vanderbilt Univ Medical Center, Nashville, TN; 3Internal Medicine, Vanderbilt Univ Medical Center, Nashville, TN.

Introduction: Common Variable Immunodeficiency (CVID) is a primary immunodeficiency characterized by hypogammaglobulinemia. Clinical manifestations include recurrent bacterial infections, autoimmune disorders, chronic lung disorders, hepatitis and lymphoma. We report a case of a patient with known CVID whose post-transplant course was complicated by acute cellular and humoral rejection which ultimately led to graft loss.

Case Description: A 44 y.o. male with ESRD was diagnosed in 11/2010 with CVID after developing peritonitis. He had a history of recurrent sinopulmonary infections and pneumococcal pneumonia. Immunoglobulin levels were undetectable and B and NK cell numbers normal. He was treated with monthly IVIG infusions. In 3/2012, he underwent living unrelated kidney transplantation (KT). Immunosuppression consisted of basiliximab, methylprednisolone (MP), FK, MMF and prednisone. Baseline creatinine (Cr) post KT was 1.3 mg/dL. In 8/2014 Cr was 3.6 mg/dL. Renal biopsy showed diffuse lymphoplasmacytic glomerulopathy with new diffuse (100%) C4d positivity. As therapy for acute cellular rejection (ACR), CCTT Type 1. In 9/2014 Cr was 10 mg/dL. Antibodies (DSA) were negative. He received IV MP 2.5 g and thymoglobulin 10.5 mg/kg 1.3 mg/dL. In 8/2014 Cr was 3.6 mg/dL. Renal biopsy showed diffuse lymphoplasmacytic glomerulopathy with new diffuse (100%) C4d positivity. Class I DSA was positive at moderate levels. He was treated for acute humoral rejection with plasmapheresis and IVIG 2 g/kg. Renal function did not improve. In 11/2014 he was declared ESRD due to uremic symptoms and volume overload.

Discussion: To our knowledge, this is the first reported case of a patient with diagnosed CVID on maintenance IVIG who then underwent KT. The main concern for patients with CVID undergoing KT is the risk of infectious complications. However, this case illustrates that rejection can occur and adequate immunosuppression remains essential. Balancing immunosuppression with the risk of infection can be quite challenging in this patient population, making them high risk for transplantation.

Reverse Pseudohyperkalemia in a Patient with Non-Hodgkins Mantle Cell Lymphoma and Chronic Lymphocytic Leukemia

Chawmay Aye,339A Aye,339A 1

Introduction: Differentiating pseudohyperkalemia from hyperkalemia is often challenging. Simple pseudohyperkalemia is common and is represented by a falsely increased serum potassium whereas reverse pseudohyperkalemia is characterized by a falsely elevated plasma potassium level. We report a case of reverse pseudohyperkalemia in a patient with non-Hodgkin’s mantle cell lymphoma (MCL) and chronic lymphocytic leukemia (CLL), presented to the emergency department with a chief complaint of dizziness. She underwent chemotherapy session with Imbruvica one week prior to her presentation. Her initial vital signs included a blood pressure of 105/73, a pulse of 116 beats/min, a respiratory rate of 17, and a temperature of 36.7 degrees Celsius. Physical exam was unremarkable. Her initial hematology panel consisted of a white blood count of 8.82 K/µL, hemoglobin of 10.2 g/dL, and platelets of 40 K/µL. Patient was admitted with neutropenic sepsis. She tested positive for Vancomycin, Meropenem, and Valtrex. Subsequent lab tests revealed a rising serum creatinine of 2.3 mg/dL and greater. One month into hospitalization, lab results showed a plasma potassium concentration of 8.22 mmol/L and a serum potassium concentration of 5.60 mmol/L. Repeat testing four hours later was consistent and showed a plasma potassium concentration of 7.2 mmol/L and a serum potassium concentration of 5.54 mmol/L. Based on the blood plasma potassium results, the patient received emergent hemodialysis and potassium lowering agents.

Discussion: Reverse pseudohyperkalemia has been reported in adults with CLL but remains relatively an under-recognized entity among clinicians. The mechanisms producing reverse pseudohyperkalemia are unclear but potassium may be released from leukocytes due to heparin-induced cell damage and/or impaired Na-K ATPase activity in the presence of hematological malignancy. Early identification of reverse pseudohyperkalemia is crucial in preventing potassium lowering intervention related morbidity and mortality.
inflammatory cells on Broncho-alveolar lavage including neutrophils and macrophages. Oil Red-O stain (stain for lipids) was performed to quantify macrophages and assess disease displaying positivity. The initial Prep yielded 5 of 5 and the repeat prep yielded 11 out of 12 of macrophages positive for Oil-Red-O. CT brain was performed which revealed large acute strokes with midline shift compatible with subdural herniation. No cerebral blood flow was identified on nuclear scan and patient was declared brain dead and terminally weaned.

Discussion: With the absence of specific tests or criteria the diagnosis of FES is dependent on the clinical acumen of the physician. Lipin inclusion in 30-70% of macrophages / inflammatory cells is most suggestive of FES. Only proven treatment is supportive care. We propose that a clotting filter might be an earlier clue to diagnose fat embolism syndrome and sending the filter for pathological analysis looking for lipid laden inflammatory cells is a less invasive approach as compared to quantification using Broncho-alveolar lavage.

TH-PO1049
Fetal Hyponatremia with Glycine Solution During Hysterectomy – Proposal for New Mechanisms of Hyponatremia and Cerebral Edema

Introduction: We report a fatal case of severe symptomatic hyponatremia and cerebral edema following hysterectomy.

Case Description: 39 y/o woman underwent 70 mins hysteroscopic myomectomy, 6L of glycine solution used for distension, without documented deficits. 3 hours later she developed pulmonary edema. Hyponatremia of 117mEq/L first noted 4 hours post surgery, baseline normal sodium. Course further complicated by agitation, vomiting, lethargy due to cerebral edema confirmed C.T. CT. Head 8 hours post-op, remained without brainstem reflexes. Post-op day 2 she also developed central diabetes insipidus. Remained brain dead, exubated and died after 12 days.

Discussion: Hyponatremia with glycine is iso-osmolar occurring as a result of dilution effect since glycine is retained in extracellular fluid before its metabolism by glycine cleavage enzyme. Two main postulations with our postulated explanation: 1) How does cerebral edema develop with iso-osmolar hyponatremia? 2) Why is hyponatremia often more severe than predicted? Proposed mechanisms: 1) Glycine can cross blood brain barrier (BBB) by passive diffusion, as shown in rats and cats. Sodium, however, does not exit brain via BBB as sodium transport across BBB occurs only inward. With glycine toxicity, glycine accumulates in the brain cells after crossing BBB followed by water resulting in brain edema. Possibility of glycine metabolism to ammonia leading to cerebral edema cannot be ruled although high levels were not seen in our case.

Cytomegalovirus-Induced Atypical Hemolytic Uremic Syndrome After Renal Transplant
Tirunagundla Magaluru,1 Andreas Grund,2 Neelesh Vaidya,3 Gopinath Kaur,4 Qayous Al-Jasmi,5 Naeem M. Khairallah,6 Laura P. Simpson,7 Shashank R. Agarwal,8 Ami Patel,9 Aala Jaberi,1 Ashish Upadhyay,1 Joel M. Henderson,1 Vipul C. Chitalia,1 David J. Salani,1 Laurence H. Beck,1 Boston Univ Medical Center; 2 Maimonides Medical Center, Brooklyn, NY.

Introduction: Atypical hemolytic uremic syndrome (aHUS) may occur as de novo disease and recurrence of primary renal disease in kidney transplant recipients. Causes of de novo aHUS includes immunosuppressive drugs, ischemia reperfusion injury, acute humoral rejection, and viral infections. Some patients have a genetic susceptibility to the disease from underlying mutations in the complement regulatory proteins. Cytomegalovirus (CMV) has been rarely reported as a trigger for de novo post-transplant aHUS.

Case Description: A 61 year old male underwent deceased donor kidney transplant for ESRD from presumed FSGS. 1 year following transplant he was admitted with profound diarrhea and weight loss due to CMV colitis and high grade CMV viremia (410,462 copies/ml). His immunosuppression was reduced and he was discharged home on oral valganciclovir with near resolution of symptoms. He was re-admitted 1 week later with nausea, abdominal pain, and acute kidney injury (Creatinine of 3.8 mg/dL, baseline of 1.8 mg/dL). His repeat CMV viral load was significantly better at 70,000 copies/ml. Labs were suggestive of microangiopathic hemolytic anemia. Hb 8 g/dL, platelets 58 K/uL, LDH 586 U/L; haptoglobin <20 mg/dL, and ADAMTS13 activity >67%. He received 4 sessions of plasmapheresis without improvement and required initiation of dialysis. Histologic features of acute and subacute endothelial injury, including segmental fibrin thrombosis of 2 arteries were present on transplant kidney biopsy. His aHUS genetic panel revealed several mutations in different genes, the etiology of aHUS was identified. He was started on eculizumab. His hemolysis labs improved and he was taken off dialysis.

Discussion: CMV infection by way of endothelial injury can provoke aHUS in kidney transplant recipients and possibly be enhanced by genetic predispositions. Postulated mechanisms of CMV-endothelial injury include increased leukocyte and platelet adhesion, endothelial expression of Von Willebrand factor, E-selectin, vascular cell adhesion molecule-1, and intercellular adhesion molecule-1. In our case, the aHUS process was halted by use of eculizumab.

TH-PO1051
Acute Interstitial Nephritis from Anti-PD-1 Therapy with Pembrolizumab in Two Patients with Advanced Non-Small Cell Lung Cancer
Heidi Mac G. Timbol, Anushree C. Shirali. Internal Medicine, Section of Nephrology, Yale Univ School of Medicine, New Haven, CT.

Introduction: Immune checkpoint inhibition with monoclonal antibodies (mAb) targeted against programmed cell death receptor 1 (PD-1) is an emerging immunotherapy for various cancers. Pembrolizumab, an anti-PD-1 mAb, is being used in clinical trials with promising anti-tumor responses, but renal-specific adverse events are not clear. We report 2 cases of acute interstitial nephritis (AIN) in patients who received Pembrolizumab for advanced non-small cell lung cancer (NSCLC).

Case Description: Two female patients, both 69 years of age, with metastatic NSCLC were seen in our outpatient nephrology clinic for acute kidney injury (AKI). Both patients were enrolled in a clinical trial with Pembrolizumab, and their cases had been complicated previously by auto-immune adenitis. On labs, Patient A had an increase in creatinine to 2.1 mg/dL prior to cycle 16, up from a baseline of 0.9 mg/dL. Patient B had a creatinine peak of 1.9 mg/dL after cycle 6, up from a baseline of 1.1 mg/dL. Medications were significant for long-standing pantoprazole use in both patients. Urine sediment showed many WBC clumps without casts or RBCs. Renal ultrasound was unremarkable. Volume expansion with normal saline and cessation of potential nephrotoxins failed to reverse renal dysfunction in either case. Each patient underwent CT-guided renal biopsy, which showed diffuse AIN. Steroid therapy with prednisone 60 mg/day with a slow taper was started and creatinine improved to baseline.

Discussion: These two cases highlight a new association between AIN and Pembrolizumab, which to the best of our knowledge has not been previously reported. While both patients were on pantoprazole therapy prior to their AKI, this medication was not new. Rather, the time course of AKI best fits with initiation of pembrolizumab. Additionally, their pre-existing drug-related auto-immune adenitis suggests a possible auto-immune component to AIN from anti-PD-1 therapy. With increasing use of these agents, clinicians should maintain a high index of suspicion for AIN as a cause of AKI and have a low threshold for kidney biopsy to confirm diagnosis and initiate early treatment.

TH-PO1052
Concurrent Anti-PLA2R and ADAMTS 13 Inhibitor – Coincidence or a Clue to Pathogenicity?1 Laith Al-Rabadi,2 Moshe Shashar,3 Parikshit Duriseti,2 Ami Patel,1 Aala Jaberi,1 Ashish Upadhyay,1 Joel M. Henderson,1 Vipul C. Chitalia,1 David J. Salani,1 Laurence H. Beck1 Boston Univ Medical Center; 2 Maimonides Medical Center, India.

Introduction: Thrombotic thrombocytopenic purpura (TTP) is a hematologic emergency associated with a decrease in ADAMTS13 activity, most often due to the presence of an inhibitor. Severe proteinuria is an unusual feature of TTP. The concurrent presence of anti-PLA2R and ADAMTS13 inhibitor has never been previously reported until now.

Case Description: Herein, we present a case of a 70 year old male who presented with generalized anasarca. Physical exam was remarkable for BP 180/100, and 2+ peripheral edema. Workup revealed Hgb 7.4, Plt 36, Creatinine 1.43 mg/dL prior to cycle 16, up from a baseline of 0.9 mg/dL. Patient B had a creatinine peak of 1.9 mg/dL after cycle 6, up from a baseline of 1.1 mg/dL. Medications were significant for long-standing pantoprazole use in both patients. Uri...
Carfilzomib Associated Acute Kidney Injury

Vladimir Liberman, Vivette D’Agati, Naveed N. Masani, Joseph Mattana, James Drакakis, Medicine, Winthrop-Univ Hospital, Mineola, NY; Pathology, Columbia Univ Medical Center, New York, NY.

Introduction: Carfilzomib is a selective proteasome inhibitor approved in 2012 for the treatment of relapsed and refractory multiple myeloma. A phase 2 trial of the drug showed an increased serum creatinine in 17.7% of patients but the mechanism has been incompletely understood. We report a case of biopsy proven acute tubular injury one week after carfilzomib administration.

Case Description: A 60 year old man with IgG lambda multiple myeloma who received an autologous stem cell transplant 2 years ago presented to the hospital complaining of shortness of breath and chest discomfort. Physical examination revealed a blood pressure of 141/74, clear lungs, normal heart sounds with no murmurs and pitting edema of both lower extremities. Serum potassium was 0.6 mEq/L and creatinine was 3.4 mg/dL (baseline 0.8 mg/dL). Serum free lambda light chains were 3630 and free kappa light chains were 5.55. The patient was admitted in an injection of carfilzomib 7 days prior to his arrival. He had no history of nephrotoxic medications. Spot urine protein/creatinine ratio was 30g/g with an albumin/creatinine ratio of 140mg/g. Obstruction was excluded by ultrasonography and he received isotonic saline with only minimal improvement in kidney function at which point a kidney biopsy was performed. Renal biopsy showed focal mild myeloma cast nephropathy with diffuse acute tubular injury out of proportion to the sparse casts. The close temporal association with the initiation of carfilzomib suggests that it could have been responsible for the severe tubular injury given no other obvious insults.

Discussion: Carfilzomib has been associated with kidney injury as one of its adverse effects in phase 2 trial. Most of the kidney injuries were reported as grade 1 or 2 based on the NIH grading system. Grade 3 and 4 renal impairment was reported in 38 patients (7.2%). This case of biopsy proven acute tubular injury suggests a mechanism by which carfilzomib may cause acute kidney injury in patients with multiple myeloma.

Podocyte Involving Glomerulopathy in a Patient of African Descent

Laith Al-Rabadi, Cathryn J. Byrne-dugan, David Olafsson, Safi Alradbi, Laurence H. Beck, Helmut G. Remine, Stanley D. Crittenre, Boston Medical Center; Brigham and Women’s Hospital; Univ of Iceland; Jordan Univ.

Introduction: Podocyte involving glomerulopathy (PIG) is a rare entity primarily described in Japanese which is a form of idiopathic diffuse mesangiocapillary glomerulonephritis. It is not known whether PIG represents a new disease entity or a transient morphologic state of well-known diseases (i.e. a subset of membranous nephropathy or lupus nephritis). PIG has been exclusively described in Asian populations, with no cases reported in patients of African descent. PIG is distinguished by its histologic features of podocyte membrane infolding into the basement membrane and the formation of microspheres and microtubules. The majority of cases do not contain electron-dense deposits, nor do they show any reactivity with IgG.Here we present the first reported case of PIG in a patient of African descent.

Case Description: A 58 year old Africa female from Ghana with history of systemic lupus erythematosus presented to the nephrology clinic for the evaluation of proteinuria. She was found to have a serum creatinine of 1.5 mg/dl and random urine protein to creatinine ratio of 1.5 g/g. Microscopic examination of the urine sediment did not reveal RBCs or casts. Other lab findings included a normal antibody titer of 1:256 to anti nuclear antibody and positive anti double stranded DNA. She underwent kidney biopsy. Light microscopy revealed thickened glomerular peripheral capillary walls, with numerous crater-like defects. Immunofluorescence was negative other than trace IgM and C3 reactivity along the peripheral capillary walls and in the mesangium. No electron dense deposits were found on electron microscopy (EM). However, widespread aggregates of spherical structures within the lamina rara externa and lamina densa along with diffuse invaginations of the podocytes at the subepithelial aspect of the basement membrane, with deposition of spherical microcrystals were seen on EM.

Discussion: Further studies are warranted to investigate whether this represents a unique primary disease with a specific underlying pathology or if it is simply a morphologic reflection of a transition point for a previously discovered disease entity.

Amyloidosis due to R554L Fibrinogen Aα-Chain Mutation

Matthew R. Lynch, Ian McCoy, Isaac Ely Stillman, Stewart H. Lecker, Div. Nephrology, Beth Israel Deaconess Medical Center, Boston, MA; Pathology, Beth Israel Deaconess Medical Center, Boston, MA; Medicine, Beth Israel Deaconess Medical Center, Boston, MA.

Introduction: Cases of systemic amyloidosis caused by mutations in the fibrinogen A-alpha chain (Alb) were once thought to be quite rare, but may be more common than initially thought. Mutations in the fibrinogen A-alpha chain, amyloidosis, primarily with renal manifestations, was first described in 1993. A significant number of Alb amyloid patients have the R554L variant. To date, about 20 such cases have been published. Small sample sizes have limited definitive conclusions regarding genotype-phenotype correlation. The majority of patients have a history of hypertension, hyperlipidemia, and prior heavy NSAID use was referred for years of stable, nephrotic-range proteinuria. Besides lower extremity edema managed with compression stockings, he was asymptomatic. He had no family history of kidney disease. His medications included losartan, torsemide, and phenytoin. His lab results included a serum creatinine of 1.1 mg/dl. A 24 hour urine protein measured 4180 mg. Urine sediment showed lipuria but no cells or casts. Testing for hepatitis B, C antibody, HIV, and ANCA was negative. Serum and urine protein electrophoresis showed no monoclonal protein. Renal ultrasoundography was unremarkable. Kidney biopsy showed massive glomerular deposition of Congo Red positive and apple-green birefringent material. Liquid chromatography tandem mass spectrometry detected mutant R554L amino acid sequence in the fibrinogen A-alpha chain.

Discussion: Alb patients progress from presentation to ESRD over a mean of 4.6 years with mean survival of 9.3 years after ESRD. Recurrent amyloidosis occurs in renal allografts, but this process takes several years. While orthotopic liver transplantation may cure the amyloidosis by replacing the source of the mutant fibrinogens, the procedure-related mortality is high, making the benefit of preemptive liver transplantation unclear. With increasing recognition of this disease, further investigation into curative therapy is needed.
TH-PO1058
Renal Transplant Dysfunction due to Calcium Casts following Parathyroidectomy. Maharanjan Raman, Rajkumar Chinnadurai, Grahame N. Wood, Jamil Choudhury, Philip A. Kalra. 1 Renal Medicine, Salford Royal NHS Foundation Trust, Salford, Manchester, United Kingdom; 2Cellular Pathology, Salford Royal NHS Foundation Trust, Salford, Manchester, United Kingdom.

Introduction: Parathyroidectomy for renal hyperparathyroidism can lead to significant drop in calcium levels due hungry bone syndrome, which can lead to seizure, coma or fractures. Current practice is to pre-load patients with hydroxycholocalciferol and calcium supplements to maintain safe calcium levels in the post-operative period. We report a case of calcium cast nephropathy causing significant renal dysfunction following parathyroidectomy.

Case Description: A transplant patient on Cinacalcet for tertiary hyperparathyroidism underwent parathyroidectomy(PTX). Post operatively her calcium levels were managed according to local protocol. Patient sub-actively developed renal dysfunction and the trends in creatinine(Cr), corrected calcium(C.Ca) and parathyroid hormone levels(PTH) pre and post surgery are shown in the table below.

Virology screen, immunology screen, urine culture, urine PCR, DSA, Cyclosporin levels and renal ultrasound were normal with no change in patients haemodynamic status. Hence a kidney biopsy was performed to identify the cause, which showed evidence of hypercalcemia with marked improvement in clinical symptoms. While he received pamidronate for hypercalcemia during the hospital stay, his ionized calcium levels have since normalized and continue to be within normal range 6 months after the initial presentation.

TH-P01060
Severe Hypercalcemia in Erdheim-Chester Disease: A Rare Clinical Scenario. David H. Slade, 1 Esho Georges, 2 Ahmer Farooq, 3 Kavitha Vellanki. 1 Dept of Medicine, Loyola Univ Medical Center, Maywood, IL; 2 Dept of Nephrology, Loyola Univ Medical Center, Maywood, IL; 3 Dept of Urology, Loyola Univ Medical Center, Maywood, IL.

Introduction: Erdheim-Chester disease (ECD) is a rare form of histiocytosis with highly variable clinical manifestations. Only a few cases have been identified. We report a case of severe hypercalcemia, work up of which eventually lead to the diagnosis of ECD.

Case Description: A 58 year old Polish male with chronic kidney disease due to obstructive uropathy from bilateral ureteral obstruction was transferred to our center for suspected hyperparathyroidism. His course was complicated by persistent fever with repeatedly negative infectious work up and severe hypercalcemia with ionized calcium levels peaking at 1.66 mm. Parathyroid hormone levels were appropriately suppressed. Work up for multiple myeloma showed no lytic lesions on bone scan, however, bilateral, symmetric, sclerotic lesions in the distal femurs and proximal tibias were incidentally noted. Based on the findings, ECD was suspected. This ECD continued to be confirmed by biopsy which revealed multiple histiocytic and lymphocytic aggregates positive for the histiocyte marker CD68, but negative for CD1a (pathognomonic of the disease). He was subsequently started on BRAW (v-rat marime sarcoma viral oncogene homolog B1) inhibitor, vemurafenib with marked improvement in clinical symptoms. Although skeletal involvement is seen in 96% of the patients with ECD, there have been no reported cases of hypercalcemia, and our case is the first to report such an association.

TH-PO1061
APOL1 Polymorphisms in Deceased Donors and Primary Glomerular Disease Post-Kidney Transplant: First Case Report. Pratik B. Shah, Alexander C. Wiseman, James E. Cooper. Renal Diseases and Hypertension, Univ of Colorado Medical Center, Aurora, CO.

Introduction: Genetic polymorphisms in APOL1 (G1/G2) are associated with glomerular disease and ESRD. An emerging issue is whether screening for APOL1 (G1/G2) should be performed in living or deceased kidney donors.

Case Description: A 46-year-old Caucasian male with a history of SLE received a deceased donor kidney transplant. The deceased donor was a 12 year-old African American male. 9 months post-transplant, he presented with acute kidney injury following an elective laparoscopic cholecystectomy (CCK). 2 weeks prior to surgery his sCr was at baseline, 0.9 cCr, with no proteinuria. On postop day 0 CCK, his sCr was 7.9 mg/dL with spot UPC of >2 g Cr/g, platelet count of 58000, LDH of 2232 U/L, lactoglobulin of <14 mg/dl. Renal transplant biopsy showed collapsing glomerulopathy with no evidence of thrombotic microangiopathy or rejection. Plasma CMV PCR was positive at 234000 copies/mL. The patient’s acute kidney injury was attributed to collapsing glomerulopathy in the setting of acute CMV infection. The patient ultimately did not recover kidney function. The patient’s deceased donor DNA was analyzed for APOL1 risk variant genotyping and was positive for two APOL1 risk variants: compound heterozygosity for APOL1 G1, c.1024A>G; and compound heterozygosity for APOL1 G2, c.1164delTTATAA. The sister kidney from the same deceased donor had been transplanted to a 63 year old female with ESRD from diabetes. Six months post-transplant, she had new onset proteinuria of 2.5 g/d, and a renal biopsy demonstrated focal segmental glomerulosclerosis (FSGS). Her renal function and proteinuria remain stable 14 months post transplant.

Discussion: To our knowledge, this is the first case report of high risk variant APOL1 in a deceased donor with subsequent primary glomerular disease in both the recipients. This suggests that deceased kidney donor APOL1 genotyping may be informative in predicting graft outcomes. This also highlights the important question of whether routine screening of African American donors for high risk APOL1 variants before renal transplant is warranted. This consideration must be balanced against the significant limitations in kidney availability.
and edema of his right lower extremity. He also reported night sweats and weight loss.

Introduction: Atypical HUS (aHUS) is a rare genetic renal disease associated with over-activation of the alternative pathway of complement. A variety of mutations have been described in the complement pathway genes in patients with aHUS. We report a case of aHUS with mutation in the Factor B (CFB) gene.

Case Description: 10 months old Caucasian girl who presented with diarrhea, vomiting, and swelling in her extremities and face for 2 weeks preceded by an episode of cough, runny nose with non-bloody diarrhea. Upon presentation her BP was 150/90 mm Hg. Lab data showed aHUS with leukopenia, lymphopenia, 3.06 g/dL with baseline of 0.3, Albumin 2.6 g/dL, LDH 632 IU/L, normal ADAMTS13 and C3 level 7.9 mg/dL. Urine revealed 32RBC/hpf with proteinuria, Urine ProteinCreatinine ratio 19 g/g. Peripheral blood smear revealed schistocytes. Stool was negative for Shiga toxin. Clinical presentation was strongly suggestive of aHUS and patient was started on Eculizumab and had no improvement in worsening anasarca with neck edema, requiring a tracheotomy after failed intubation. She required RRT for volume management during her hospital course after failing diuretics. Renal biopsy showed acute and chronic thrombotic microangiopathic changes consistent with aHUS. Genetic testing revealed a novel mutation in the complement Factor B gene in the region of binding to Von Willebrand factor. Also it showed a heterozygous deletion of CFHR1 and CFHR4. Patient recovered renal function 3 weeks after presentation. C3 remained low after recovery of renal function. RRT was stopped after two weeks and she was discharged on ACEI with Eculizumab every 2 weeks.

Discussion: Gain of function mutations in CFB are extremely rare in aHUS and occurs in only 1% to 2% of cases of familial aHUS. There is increased C3b affinity and form hypercatabolic C3 convertase that is resistant to dissociation, thus increasing C3b formation. Anti C5 Antibody Eculizumab has revolutionized the care of aHUS, improving the overall prognosis of these patients. This case is the first case reported with this novel CFB gene mutation. No long term data available regarding the outcomes of aHUS with Eculizumab therapy.

Introduction: Intravenous (IV) administration of oral oxy-morphine represents an emerging pattern of drug abuse with increasing popularity and unforeseen adverse consequences. Here, we present a case of IV Oxy-morphine abuse associated with thrombotic microangiopathy (TMA) and acute kidney injury (AKI).

Case Description: A 32-year-old man with a history of IV drug abuse presented with non-healing left arm wound. Physical examination was unremarkable except for a left forearm abscess. However, laboratory studies revealed a serum creatinine of 2.3 mg/dL, elevated from 1.8 mg/dL without significant proteinuria. A C3 level was 41 mg/dL and C4 was less than 10 mg/dL. An IgG level was elevated to 2045 mg/dL. A renal biopsy was obtained and although the lack of glomeruli was limiting, the tissue revealed a dense plasma cell rich infiltrate in the interstitium consistent with an interstitial microangiopathic process. Immunostains were positive for IgG4 in the infiltrating plasma cells. Treatment was initiated with prednisone 40 mg daily. His creatinine decreased to 1.3 mg/dL with resolution of his symptoms.

Discussion: A number of conditions can lead to kidney enlargement. Diabetes, HIV, amyloidosis, and leukemia/lymphoma are commonly included in the differential diagnosis. IgG4-related disease should also be considered in the differential diagnosis of patients presenting with kidney enlargement and recurrent infections.

TH-PO1065 Karyomegalic Interstitial Nephritis: A Rare Cause of Kidney Disease Lindsay Sanders,1 Maxwell L. Smith,2 Ibrahim Qaquis,2 Sumi Sukumaran Nair,1 Leslie F. Thomas.1 1Nephrology, Mayo Clinic Arizona, Phoenix, AZ; 2Pathology, Mayo Clinic Arizona, Scottsdale, AZ.

Introduction: Karyomegalic interstitial nephritis (KIN) is a rare, progressive kidney disease associated with Panconi-associated nucleosome (1FANI) mutation as well as mutation to heavy metal, ochratoxin, or viral pathogens. Less than 50 cases have been reported in the literature to date. The onset of the disease is often insidious. Onset of symptoms are typically in adulthood. Here, we report a case of KIN with a heterozygous deletion of a kidney disease associated with Fanconi-associated nuclease 1 (FAN1) mutation as well as exposure to heavy metal, ochratoxin, or viral pathogens. He had no known risk factors for chronic kidney disease. His only other personal medical history was for skin pigmentation of his lower extremities. He had no known exposures to heavy metals or toxins. He reported renal disease of unclear etiology in one sister. At time of consultation, he had a combined eGFR of 46. Urinalysis and serologic studies were normal, and ultrasound demonstrated kidneys of normal size with no renovascular or parenchymal abnormalities. Renal biopsy demonstrated significant findings (light microscopy included) 1) loss of glomeruli appearing normal with the remaining 25 glomeruli being globally sclerosed, 2) moderate to severe fibrosis of the tubulointerstitial compartment with associated tubular atrophy, 3) marked plemorphism of tubular cells with prominently enlarged nuclei, pleomorphic nuclei, and multinucleation, and 4) moderate predominately lymphocytic and plasma cellular inflammatory cell infiltrate. Electron microscopy showed a hypodense chromatin pattern with slight nuclear membrane irregularities.

Discussion: The diagnosis of KIN should be considered especially when there is a family history of kidney disease of unclear etiology. Karyomegalic cells can be found elsewhere in the body, including the brain, lung, and liver. Testing for heavy metals and ochratoxin may be useful. Urine cytology may identify atypical cells. Genetic testing should be considered, including for mutation of FANI. Literature to date suggests steroid treatment may be of use in some cases.

Introduction: Hypernatremia usually results from increased free water losses or impairment in thirst perception.

Case Description: A 17-year-old female presented to the emergency room after an episode of syncope while waiting for school bus on a summer morning. She had intermittent episodes of slurred speech over the previous 2 weeks but denied polyuria, polydipsia, dizziness or headaches. She was diagnosed with primary amenorrhea one year ago. Physical Exam: Weight 46 kg (5’6”), height 150 cm (<3rd percentile), BP 92/58 mmHg and afebrile. She was slow to respond and had slurred speech. She was Tanner III for breast & I for pubic hair. The remainder of her exam was normal. Laboratory evaluation showed hemoglobin 11.2g/dl, hematocrit 37.8%, platelet 100x10^5/L, sodium 177 mmol/l, potassium 4.3 mmol/l, chloride 105 mmol/l, CO₂ 23 mmol/l, BUN 55 mg/dl, creatinine 2.5mg/dl, glucose 91 mg/dL, calcium 9.7 mg/dL, serum Osm 375 mOsm/kg, urine Osm 678 mOsm/kg, ADH level 2.2 pg/ml. Urinalysis: specific gravity 1.016, pH 5.5, 1+ protein, trace blood. A renal ultrasound showed a right sided renal mass which was confirmed to be an adrenal mass on CT scan. Despite adequate intravenous hydration, her hypernatremia persisted. Due to low LHI & FSH there was a concern for hypogonadotropic hypogonadism. However, brain MRI was normal. DAVP was initiated with partial response. The patient underwent a right adrenalectomy; pathology was consistent with ganglioneuroma. At the time of discharge, her sodium was 138mmol/L and serum creatinine 0.8 mg/dL.

Discussion: The cause of hypernatremia in this case was likely an impaired thirst mechanism in a cognitively normal child. Her partial response to DAVP suggests an additional contribution from partial diabetes insipidus. Essential hypernatremia and an adrenal mass with impaired sodium level sensors (Nax) were reported in a 6 year old child by Hiyama et al. (2010; 66(4): 508-522). The mechanism of hypernatremia was postulated to be impaired thirst due to antibodies to Nax in the brain. A diagnosis of paraneoplastic syndrome should be considered in a patient with hypodipsic hypernatremia without structural hypothalamic lesions.
IgG4 Mediated Isolated Retroperitoneal Fibrosis Causing Obstructive Uropathy in a Patient with Subclinical Ankylosing Spondylitis

TH-PO1007

IgG4 Mediated Isolated Retroperitoneal Fibrosis Causing Obstructive Uropathy in a Patient with Subclinical Ankylosing Spondylitis

Introduction: Retroperitoneal fibrosis is a rare manifestation of systemic autoimmune disease, characterized by the presence of inflammatory and fibrotic retroperitoneal tissue that often encases the ureters causing obstructive uropathy. Idiopathic retroperitoneal fibrosis is recently being recognized manifestation of IgG4-related disease. We report a case of histologically confirmed IgG4 related retroperitoneal fibrosis in a patient with subclinical Ankylosing spondylitis. This association has been rarely reported.

Case Description: A 70 year old male with PMH of HTN, diabetes and baseline creatinine of 1.2 mg/dl presented with weakness, vomiting and decreased urine output. Physical examination was unremarkable. Further evaluation revealed serum creatinine of 13.3 mg/dl and BUN=106 mg/dl. He also has mild hyperkalemia and anion gap metabolic acidosis. Urine analysis was negative for protein or RBC cast. A CT scan of the abdomen and pelvis, showed retroperitoneal mass, Aortitis, ankylosis of SI joint bilaterally with osseous fusion and bilateral mild hydronephrosis. Bilateral nephrostomy tubes were placed with excellent urine output as well as improvement of creatinine in baseline in 48 hours. He subsequently had a CT guided biopsy of the retroperitoneal mass. Histopathology revealed dense fibrous tissue with significant IgG4 positive plasma cell infiltrate. Immunohistological workup showed elevated level of IgG4 as well as positive HLA-B27. Hence this obstructive uropathy was confirmed to be due to IgG4 related retroperitoneal fibrosis. He also met the clinical and imaging criteria for Ankylosing spondylitis. Treatment with oral corticosteroids was initiated by rheumatology.

Discussion: Our hypothesis is that the patient had a subclinical Ankylosing Spondylitis which triggered IgG4 mediated disease that lead to retroperitoneal fibrosis which caused bilateral obstructive uropathy. Hence role of ankylosing spondylitis in development of idiopathic retroperitoneal fibrosis via IgG4 mediated pathways warrants further consideration and for nephrologists to be aware of this rather unusual presentation.

IgG4-Related Tubulo-Interstitial Nephritis with Low Complement C4

TH-PO1068

IgG4-Related Tubulo-Interstitial Nephritis with Low Complement C4, Circulating Immune Complexes and an Elevated IgG4, Presenting as Unilateral Hydronephrosis and Prostatitis

Introduction: IgG4-related tubulointerstitial nephritis (TIN) is a distinct clinicopathologic entity characterized by marked tubulointerstitial inflammation with a dense infiltrate of IgG4-positive plasma cells, along with extracellular deposits of IgG4 positive matrix. Backhaus et al described and characterized this entity in detail in 2008. In the last few years, TIN has been reported in a wide variety of conditions such as primary biliary cirrhosis, IgG4-related disease, chronic obstructive lung disease, etc. We report a patient with IgG4- related TIN with low complement C4.

Case Description: A 67 year old white male had a creatinine increase from 0.90 to 2.06 mg/dl. He had fatigue and dyspepsia. Complement C3 was normal, C4 low 0.06 g/l, C1Q-BA 28% (N <8%), but ANA/ENA, dsDNA, AST, ANCA, HBV, HCV and M-protein were negative. IgG4 3.0 g/l (N 0.08-1.40 g/l) Urine showed 3 RBC/HFP, protein 0.36 g/l, albumin 61 mg per 24h. On ultrasound both kidneys were 13 cm with right sided hydronephrosis and 300 ml urinary retention. CT-Urography showed obstruction of the right ureter at the iliac artery. A bladder catheter and ureteral stent did not improve renal function. A MAG-3 DTPA scan showed no functioning right kidney without hydronephrosis on ultrasound. After revision, the CT showed soft tissue surrounding the aorta and the right iliac artery. A kidney biopsy showed TIN with a dense infiltrate of IgG4-positive plasma cells and eosinophils with impressive fibrosis, a vein showed obliterative phlebitis, consistent with IgG4-related TIN.

Discussion: Hypehydrenephrosis can be a complication of IgG4-related TIN. There may be ureteral obstruction and prostatitis. Hydrenephrosis does not exclude, but may be part of IgG4-related disease.

IgG1-kappa Anti-Glomerular Basement Membrane Disease

TH-PO1070

IgG1-kappa Monoclonal Membranous Nephropathy Associated with Systemic Lupus Erythematosus

Introduction: Monoclonal gammopathy of renal significance is a recently described condition in which monoclonal protein is found in the kidney but often without a circulating free monoclonal gammopathy, so close monitoring is necessary. SLE patients should be aware of this association. Further, these patients may develop a systemic monochonal gammapathy, including serum and urine immunofixation and serum free light chains was negative. A diagnosis of IgG1-kappa monoclonal membranous nephropathy associated with SLE was made. She was started on ACEi and prednisone with improvement in proteinuria from 2.5g/d to 0.8g/d.

Case Description: Case 1: An 18 year old female with SLE developed nephrotic syndrome with 4g/d proteinuria and normal serum creatinine. Immunofluorescence (IF) on renal biopsy showed diffuse IgG1 kappa staining in the mesangium and along the capillary loops. Liner staining was negative. Electron microscopy showed characteristic membranous and subepithelial electron-dense deposits. Work up for systemic monochonal gammapathy, including bone marrow biopsy was negative. She was diagnosed with IgG1-kappa monoclonal membranous nephropathy associated with SLE. She was treated with prednisone, azathioprine and mycophenolate mofetil and prednisone and achieved partial remission. Case 2: A 38 year old female with SLE developed proteinuria of 2.5g/d and microscopic hematuria. Similar to case 1, IF on renal biopsy showed diffuse granular IgG1-kappa deposition in the mesangium and along the capillary loops. Lambda staining was negative. EM revealed membranous and subepithelial electron-dense deposits. Work up for systemic monochonal gammapathy, including serum and urine immunofixation and serum free light chains was negative. A diagnosis of IgG1-kappa monoclonal membranous nephropathy associated with SLE was made. She was started on ACEi and prednisone with improvement in proteinuria from 2.5g/d to 0.8g/d.
Discussion: This is the second reported case of necrotizing and crescentic glomerulonephritis associated with IgG1-κ anti-GBM antibody. It is unknown if this disease is driven by an underlying autoimmune process or monoclonal gammopathy. Both cases are atypical for classic anti-GBM disease due to their relapsing nature.

TH-PO1072
First Reported Case of Collagenofibrotic Glomerulopathy in a Patient with Multiple Myeloma
Arun Rajasekaran, Indranee R莫gara, Lillian W. Gaber, Jai Radhakrishnan, Ala Abudayeh

Introduction: Collagenofibrotic glomerulopathy is an extremely rare idiopathic glomerular disease characterized by abnormal accumulation of atypical spiraled and frayed type III collagen fibrils in mesangial and subendothelial areas, and elevated serum procollagen III and hyaluronan levels. Proteinuria (commonest feature), edema, hypertension, and occasional progression to ESRD are commonly seen. We report the first published case of Collagenofibrotic glomerulopathy in Multiple Myeloma.

Case Description: A 54 year old male with recent history of IgG kappa Multiple Myeloma (May 2011); with underlying CKD stage 3 and baseline Creatinine at 2 mg/dl, in remission status-post autologous stem cell transplant (January 2012) and on Lenalidomide maintenance therapy, presented with proteinuria 4g. Kidney biopsy revealed Nodular and Focal glomerulosclerosis with IF weakly (+) for IgG, IgA, IgM, C3, C4, C1q, Kappa and Lambda light chains with +3 staining for IgM and clq. EM showed patchy foot process effacement with massive deposition of collagen-III fibers. The weak and non-specific staining, along with massive collagen-III fiber deposition fitted with the description of Collagenofibrotic glomerulopathy, and made an immune mediated kidney injury less likely.

Discussion: Collagenofibrotic glomerulopathy is an extremely rare disease characterized by massive intraglomerular atypical type III collagen fiber deposition. Proteinuria is the cardinal manifestation of this disease. Clinically, patients present with edema and hypertension and often progress to ESRD. Etiology and pathogenesis remains elusive. Most cases are seen in Japan and an autosomal-recessive mode of inheritance has been described. Definitive diagnosis is established by identifying collagen-III fibrils by IF and EM with special staining. No specific treatment is available unfortunately.

TH-PO1073
Severe Acute Kidney Injury (AKI) with Organomegaly in a 17 Days Old Newborn: When Pathology Makes the Difference
Marie-Michèle Gaudreault-Tremblay, Catherine Litalin, Natalie Patey, Aicha Merouani, CHU Sainte-Jantine, Montreal, QC, Canada.

Introduction: Acute tubulointerstitial nephritis (ATIN) is a significant cause of AKI in children and is often due to allergic drug reactions or infections. Diagnosis of ATIN is usually clinical and renal biopsy not routinely performed.

Case Description: A previously healthy 17 days old baby presented with decreased oral intake, vomiting and oligoanuria. His first laboratory results showed an elevated creatinine (1.7mg/dL) with metabolic acidosis, hypokalemia (Na 107mEq/L) and thrombocytopenia (platelets 16x10^9/L). His urinalysis was abnormal (protein, 3gr/L, WBC >50/hpf, RBC 21-3/hpf, positive nitrites). An ultrasound revealed bilateral hydronephrosis associated with IgG1-κ anti-GBM antibody.

Discussion: This interesting case showed AL lambda amyloidosis in kidney transplant allograft as a cause of Massive Nephritic Syndrome with AKI. The patient was treated by immunosuppression including tacrolimus, mycophenolate and prednisone with baseline Cr at 1.5, presented with anasarca and orthostatic hypotension. Her serum albumin was 1.2mg/dl. She underwent extensive investigations including Echo, transplant allograft ultrasound all of which came back unremarkable. She has sudden onset sub nephritic range proteinuria in Aug 2013 which progressed to nephritic range in Feb 2014. She has 34g of protein on a 24h urine collection 90% of which was albumin. Her UPCR gradually got worse from 10 to 32 with worsening in serum Cr from 1.5 to 5.5. She has poor response to IV Lasix with albumin infusion and has severe orthostatic symptoms. Her SPEP and UPAP were negative. Urine IFE showed lambda light chain. Serum free light chain showed elevated lambda levels. Due to worsening and explosive proteinuria with worsening anasarca renal allograft biopsy was done that showed lambda AL amyloidosis involving glomeruli, arterioles and arteries along with light chain proximal tubulopathy. Congophilic casts consistent with light chain cast nephropathy. Pt underwent bone marrow biopsy that did not show MM. She was treated with bortezomb combined with cyclophosphamide and dexamethasone and has good response with improvement in orthostatic hypotension, serum albumin level and lambda light chain got normal.

TH-PO1076
Paucci-IgM Glomerulonephritis and Exscherichia Coli Bacteremia: A Mere Coincidence or a True Causal Association?
Marwan M. Abu Minshar, Wihb A. Gebregieorgis

Introduction: Antineutrophil cytoplasmic antibody (ANCA) associated vasculitides are systemic autoimmune diseases affecting small to medium sized blood vessels. Paucci-immune necrotizing glomerulonephritis (GN) is one of the manifestations. Triggering factors for ANCA associated vasculitides are not well-defined. Systemic infections have been implicated in the pathogenesis.

Case Description: A 67 year old patient was admitted to the hospital from a nursing home for a Foley catheter associated Exscherichia coli (E. coli) urinary tract infection & bacteraemia leading to septic shock and acute kidney injury/acute tubular necrosis. She was a peak serum creatinine (Cr) of 3.8 mg/dl. She had recently been hospitalized for subarachnoid hemorrhage that was treated conservatively and her serum Cr at that time was 0.9 mg/dl.

Discussion: ATIN is rare in neonates and usually drug-induced. This is the first report of a renal biopsy-proven ATIN in a neonate. Even if procedural risks of a renal biopsy are not negligible, it can make the difference in certain cases by dictating appropriate management.
The pathophysiology of GN in CLL is possibly due to glomerular deposition of immune complexes and/or paraproteins. Review of the literature reveals a small number of cases of MPGN associated with CLL and cryoglobulinemia. 

Discussion: Vasculitic presentations, bleeding and/or thrombotic and/or renal failure in the setting of CLL may be manifestations of cryoglobulinemia. Because of potential rapid progression, as in this case, regular urinalysis and testing for cryoglobulins should be considered in all stages of CLL, with possible renal biopsy when cryoglobulinemia and proteinuria are detected.

TH-PO1078
PGNMD in a Patient with Hepatitis C
Mohamed Aleliani, Susie L. Hu.
Alpert Medical School of Brown Univ.

Introduction: Proliferative glomerulonephritis with monoclonal IgG deposits (PGNMD) is infrequently associated with hematological disease but more commonly presents like an immune-complex glomerulonephritis. Few have reported cases associated with viral infections such as hepatitis C. We report a case of PGNMD in a patient with active HCV infection.

Case Description: A 56-year-old male with refractory hepatitis C (post treatment with interferon and Ribavirin), HTN and coronary artery disease presented with rising creatinine (peak 5.3 mg/dl) from baseline (0.9 mg/dl a year ago) and no kidney disease in family. He reported months of progressive fatigue, dyspnea on exertion, nausea, vomiting, and dark urine. He endorsed chronic Hepatorenal use for leg pain. On examination BP was normal with clear lungs and no edema. Urinalysis revealed blood but minimal proteinuria with urine protein to creatinine ratio of 0.5 g/g and albumin 4.2 g/dL. Complements were low (C3 83 mg/dL, CH50 <10 U/mL). HCV-RNA quantification was 1.7 million copies. SPEP, plasma light-chains, ANA, ANCA, Anti GBM, HIV, Hep B serologies were normal. Bone marrow biopsy confirmed MM with 80% plasma cell. Patient received bortezomib +dexamethasone + cyclophosphamide chemotherapy and her renal function completely improved after being dialysis dependent for about 12 weeks. Patient is being evaluated for BMT transplantation after chemotherapy response.

Discussion: Multiple Myeloma can cause renal damage in many ways which sometimes can be misleading and very uncharacteristic. Up to our knowledge, this presentation is quite uncommon in literature and hence we suggest including myeloma related kidney injury in such clinical presentation.

TH-PO1079
Myeloma Cast Nephropathy with Acute Renal Failure, Skin Rash, Esophiluria, and Low Complement C4 Level
Mustafa G. Aly,1 Mamoun Elsir Bashir,1 Irfan Warraich,2 Aumyot Prongdong,1 Weeraporn Srisung,1 Irfan Warraich,1 Maria Gabriela Suarez,1 Irfan Warraich,2 Aumyot Prongdong,1 Internal Medicine, Nephrology Dept, Texas Tech Univ Health Science Center, Lubbock, TX;1 Pathology Dept, Texas Tech Univ Health Science Center, Lubbock, TX.

Introduction: We here report myeloma cast nephropathy with skin rash, eosinophilia and low complements which is a very atypical presentation of this renal condition.

Case Description: A 53y Caucasian female was admitted with 3 day confluent erythematous skin rash, acute renal failure with sCr 17.6 with a normal baseline renal function of sCr 0.7 mg/dL. Five days prior, she was prescribed cephalexin for root canal infection. Initial diagnosis of acute interstitial nephritis was made but patient didn’t respond after stopping antibiotics and steroid course trial. Urine exam showed WBC clumps and no casts. Serological biomarkers were done and reported Negative ANA, ANCA, cryoglobulins, Hepatitis B, Hepatitis C and HIV. Complement C4 was low with normal C3. Patient’s laboratory workup showed normocytic normochromic anemia and pseudohyponatremia per osmolality check, SPEP and SFLC ordered and was positive for M-spike with free light chain analysis showing predominant Lambda more than 4 g/L. Renal biopsy showed myeloma cast nephropathy.

Bone marrow biopsy confirmed MM with 80% plasma cell. Patient received bortezomib +dexamethasone + cyclophosphamide chemotherapy and her renal function completely improved after being dialysis dependent for about 12 weeks. Patient is being evaluated for BMT transplantation after chemotherapy response.

Discussion: Multiple Myeloma can cause renal damage in many ways which sometimes can be misleading and very uncharacteristic. Up to our knowledge, this presentation is quite uncommon in literature and hence we suggest including myeloma related kidney injury in such clinical presentation.

TH-PO1080
A Rare Case with ANCA-Related Necrotizing Glomerulonephritis without Nephritic Features or Systemic Vasculitis
Mustafa G. Aly,1 Faisal Jamal,1 Maria Gabriela Suarez,1 Irfan Warraich,2 Aumyot Prongdong,1 Internal Medicine, Nephrology Dept, Texas Tech Univ Health Science Center, Lubbock, TX;1 Pathology Dept, Texas Tech Univ Health Science Center, Lubbock, TX.

Introduction: We report an atypical and unusual case of ANCA necrotizing glomerulonephritis with no significant nephritic features or systemic vasculitic picture.

Case Description: A 78 year-old African American female with history of controlled hypertension was admitted with diagnosis of pneumonia and renal failure and was treated empirically with antibiotics. Despite antibiotic treatment, she had persistent leukocytoysis and thrombocytopenia was ruled out by negative WBC scan and CT chest. Urine had pre-renal pattern and urinalysis was bland twice. Renal ultrasound was unremarkable except for a retroperitoneal hematoma from a ruptured right gonadal artery, which was embolized. Cerebral infarcts related to cryoglobulinemia. Despite leukemia treatment and regular check-ups, patient’s renal function continued to decline (peak 5.3 mg/dl) from baseline (0.9 ml/dl a year ago) and no kidney disease in family. He reported months of progressive fatigue, dyspnea on exertion, nausea, vomiting, and dark urine. He endorsed chronic Hepatorenal use for leg pain. On examination BP was normal with clear lungs and no edema. Urinalysis revealed blood but minimal proteinuria with urine protein to creatinine ratio of 0.5 g/g and albumin 4.2 g/dL. Complements were low (C3 83 mg/dL, CH50 <10 U/mL). HCV-RNA quantification was 1.7 million copies. SPEP, plasma light-chains, ANA, ANCA, Anti GBM, HIV, Hep B serologies were normal. Bone marrow biopsy confirmed MM with 80% plasma cell. Patient received bortezomib +dexamethasone + cyclophosphamide chemotherapy and her renal function completely improved after being dialysis dependent for about 12 weeks. Patient is being evaluated for BMT transplantation after chemotherapy response.

Discussion: Multiple Myeloma can cause renal damage in many ways which sometimes can be misleading and very uncharacteristic. Up to our knowledge, this presentation is quite uncommon in literature and hence we suggest including myeloma related kidney injury in such clinical presentation.
Bilateral, Multifocal Renal Tumors Diagnosed as Birt-Hogg-Dubé Syndrome Confirmed by Genetic Analysis

**Introduction:** Birt-Hogg-Dubé syndrome (BHD) is an autosomal dominant disorder characterized by skin fibrofolliculomas, pulmonary cysts and spontaneous pneumothorax, and renal cancers. The syndrome is caused by germline mutations of the FLCN gene located in 17p11.2 encoding folliculin. The risk of renal cancer is seven times higher in BHD patients. Bilateral, multifocal and chromophobe renal cell carcinoma is characteristic of renal cancers in BHD. Among about 110 pathogenic mutations reported in BHD, only twenty six of them have been associated with renal cancer. In this study, we described a case of 50-year-old woman with chromophobe renal cell carcinoma who had c.1557delT mutation in the FLCN gene which is novel in BHD-associated renal cancer.

**Case Description:** A 50-year-old-woman presented with flank pain. A CT scan of abdomen showed multifocal tumors in both kidneys. To differentiate the origin of the tumors, a chest CT and a whole body PET-CT were carried out, although there was no other lesion except a few lentiform cysts at basal lungs. Histologic evaluation through a needle biopsy revealed that the mass was chromophobe type renal cell carcinoma. The patient underwent partial nephrectomy. Given multifocal distribution of the renal cell carcinoma, we suspected an inherited form of kidney cancer. Although she denied any specific familial history, the cystic change of both lungs and chromophobe renal cell carcinoma pointed towards the possibility of BHD. DNA sequencing of the entire FLCN gene identified a heterozygous c.1557delT mutation in exon 14 [p.Phe(TTT)519Leu(TTA)fs*18].

**Discussion:** Once multifocal renal masses are diagnosed as renal cell carcinoma, histologic subtype, family history and other clinical features should be considered to recognize familial renal cancer syndromes. Multifocal chromophobe renal cell carcinoma should prompt genetic test for BHD even in a patient without typical skin lesion. In our patient, c.1557delT mutation was found out which has been first reported in BHD-associated renal cancers.

**TH-PO1083**

A Case of Cryoglobulinemic Nephropathy with Successful Childbirth After Recurrent Episodes of Nephrotic Syndrome During Pregnancy

**Case Description:** A 35-year-old woman was admitted to our hospital because of massive proteinuria that developed during the third pregnancy. The previous two pregnancies had terminated because of similar episodes of nephrotic syndrome. No history of hypertension was observed, but during the course she presented cryoglobulinemia, a high titer of RF and low serum complements. The renal biopsy performed 10 days after the third termination revealed MPGN-like lesions with lobulation in glomeruli, double contour of GBM, endotheliosis, and moderate mesangial cell proliferation. Immunofluorescence study showed IgG, IgA, IgM, C3, C4, and C1q all positive mainly along the glomerular capillaries, and subendothelial deposits were confirmed by EM, thus she was diagnosed as cryoglobulinemic nephropathy. Because the histological findings of repeated renal biopsy were not improved two months after the disappearance of proteinuria, treatment with 30 mg/day of PSL was started, followed by intravenous cyclophosphamide 6 times and plasma exchange, since she had a desire for baby. Finally at the fourth pregnancy, she bore a healthy baby weighing 2,342 g at vaginal delivery at 36 weeks despite of recurrent appearance of nephrotic syndrome. After delivery, she was given 30 mg/day of PSL and proteinuria subsided.

**Discussion:** We experienced a rare case of the type III cryoglobulinemic nephropathy that repeatedly developed nephrotic syndrome during pregnancy, but finally bore a baby after immunosuppressive therapy. The pathogenesis of pregnancy-induced nephrotic syndrome in cryoglobulinemia in this patient was not known, aggressive treatment may be helpful for ameliorating nephropathy, leading to successful delivery.
**Discussion:** We report here a case of glomerular liposudosis associated with type III hyperlipidemia. The nephrotic syndrome was suspected that hyperlipidemia with glomerular lipid accumulation would have a pathogenic role for glomerulopathies but other factors might be involved in causing nephrotic syndrome.

**TH-PO1087**

Successful Treatment of Crescentic Glomerulonephritis (GN) in Hypocomplementemic Uricarial Vasculitis Syndrome (HUVS) Rancharnd Bakhhtian, Mark G. Parker. Nephrology, Maine Medical Center, Portland, ME.

**Introduction:** HUVS is a rare autoimmune systemic disorder characterized by chronic urticaria, low complements and extracutaneous organ involvement. Kidney involvement is not uncommon (50% of cases), usually of benign nature. The glomerular injury pattern varies from mesangial proliferation to membranoproliferative glomerulonephritis (MPGN). Crescentic MPGN in HUVS is rare; only six cases have been reported in world literature, many with poor outcomes. We present a case of crescentic GN successfully treated with substantial remission.

**Case Description:** A 55-year-old Caucasian female with a previous episode of hives was admitted to hospital with features of both acute nephritic and severe nephrotic syndrome. She had 6 months history of persistent hives, fatigue, fevers, arthralgia, self-limited recurrent angioedema episodes, and generalized lymphadenopathy. Lymph node biopsy displayed reactive hyperplasia. Her serum creatinine was 4 mg/dL, uric acid to creatinine ratio was 23, serum uric acid was 1.6 mg/dL (normal 0 - 10 mg/dL), total bilirubin 2.8, LDH 334 (elevated), and indirect bilirubin 0.2. AST, ALT, and Alkaline phosphatase were normal. The patient underwent a kidney biopsy which demonstrated subacute glomerular hyperemia, widespread thickening of the glomerular basement membranes, (GBM), with numerous double contours was observed. Immunofluorescence revealed strong mesangial and glomerular deposits of IgM, C3 and C1q deposits on immunofluorescence. Treatment was started initially with high dose glucocorticoids followed by addition of mycophenolic acid and losartan. Her systemic symptoms and acute kidney injury resolved completely. Nephrotic syndrome improved slowly. After 6 months of therapy her proteinuria decreased to 4.5 g/dL and serum albumin increased to 3.8 g/dL.

**Discussion:** Crescentic GN associated with HUVS appears to convey a poor renal prognosis. Based on available information in five of six reported cases, three progressed to end stage renal disease; one had near complete renal recovery and another had partial recovery with persistent nephrotic range proteinuria. Relatively good outcome in our case may aid to our understanding of this uncommon and newly recognized disease process.

**TH-PO1088**

An Unusually Early Presentation of Pre-Eclampsia David Bennett, Renu Reginathan-Shenk, Maya K. Rao. Medicine, Div of Nephrology, Columbia University Medical Center, New York, NY.

**Introduction:** Pre-eclampsia affects approximately 3-6% of pregnancies in the United States. It is defined as new onset hypertension and proteinuria in pregnancy. By definition, it occurs after 20 weeks gestation. However, earlier cases have been reported in the literature.

**Case Description:** The patient is a 45 y/o woman, 16 weeks + 4 days pregnant with twins (IVF with donor embryo), with a PMHx significant for obesity and borderline HTN who presented with 6 weeks of progressive swelling that had worsened in the past week. 3 weeks prior to presentation, the pregnancy was complicated by worsening hypertension, ranging 140-160/90-100, for which she was started on labetalol. On presentation, her exam was notable for BP 193/122, 1+ upper extremity edema, 2+ lower extremity edema, and bibasilar crackles on lung exam. On labs, Cr 0.85, 3+ protein on UA (previous negative) with 3 RBCCs and 6 WBCs, ~12g of protein on 24hr urine collection, and serum albumin 2.3. Serologic workup including ANA, C3, C4, HIV, Hepatitis B, Hepatitis C, IgM, C3 and C1q deposits on immunofluorescence. Treatment was started initially with high dose glucocorticoids followed by addition of mycophenolic acid and losartan. Anti C3 antibody was not performed. Renal biopsy revealed immune complex crescentic MPGN with IgG, IgA, IgM, C3 and C1q deposits on immunofluorescence. Treatment was started initially with high dose glucocorticoids followed by addition of mycophenolic acid and losartan. Her systemic symptoms and acute kidney injury resolved completely. Nephrotic syndrome improved slowly. After 6 months of therapy her proteinuria decreased to 4.5 g/dL and serum albumin increased to 3.8 g/dL.

**Discussion:** Discussion: This patient had multiple risk factors for pre-eclampsia including diabetes, obesity, hypertension, and history of twins. Pre-eclampsia affects approximately 3-6% of pregnancies in the United States. It is defined as new onset hypertension and proteinuria in pregnancy. By definition, it occurs after 20 weeks gestation. However, earlier cases have been reported in the literature. This patient had multiple risk factors for pre-eclampsia including diabetes, obesity, hypertension, and history of twins.

Development of Aggressive De Novo Henoch-Schönlein Purpura, 10 Years Post-Kidney Transplant Kamel Hatahet,1 Swati Rao,1 Avrum Gillespie,1 Mythili Ghanta,1 Serban Constantinescu,1 Xu Zeng,1 Iris J. Lee.1 Nephrology, Temple Univ School of Medicine, Philadelphia, PA; 2Temple Univ School of Medicine, Philadelphia, PA.

**Introduction:** Histologic recurrence of IgA deposits in renal allografts is as high as 60% in recipients with primary IgA nephropathy, however significant nephritis presenting as de novo Henoch-Schönlein Purpura (HSP) post-kidney transplant (KT) is rare with only few cases reported. Our patient had biopsy proven IgA nephropathy (D суд) at 10 yrs post KT, she developed diarrhea, melena and acute renal failure (Cr of 4.19 from 1.5) after completing a course of antibiotics for pneumonia. She developed diffuse purpuric rash and had hematoma with severe abdominal pain. Abdominal CT scan showed enteritis of the small bowel. EGD demonstrated necrosis of the ileum. Lower ileal ulcerative colitis with villous atrophy, showing leukocytic infiltration of vessels, and submucosa. Skin biopsy showed leukocytic vasculitis. Urine had 4+protein, leukocytes, red blood cells, but no casts. Extensive infectious and serologic workup was negative. KT biopsy demonstrated membranoproliferative glomerulonephritis changes without crescents, coupled with findings of DN and advanced interstitial fibrosis and tubular atrophy. Immunofluorescence showed 4+ deposits for IgA and C3 and the patient was diagnosed with HSP. Due to severe GI involvement the patient was treated with pulse

Harvoni Induced Acute Interstitial Nephritis

Jyotsana Thakkar, Kenar D. Jhaveri, Rimda Wanchow. Nephrology, North Shore-LIJ Hospital, NY.

Introduction: Harvoni is a new combination pill consisting of ledipasvir with sofosbuvir approved by FDA in October 2014 for the treatment of chronic Hepatitis C genotype 1 virus infection. No cases of Acute Kidney Injury (AKI) have been reported with this agent thus far. We report the first case of Harvoni associated biopsy proven acute interstitial nephritis (AIN).

Case Description: A 64 year old AA female with chronic Hepatitis C, hypertension, diabetes mellitus came to our clinic for evaluation of AKI superimposed on chronic kidney disease. Laboratory data revealed serum creatinine of 2.24 mg/dl (baseline Cr 1.5 mg/dl), haptoglobin (3.2 g/ml) with a spot urine protein/creatinine ratio of 3.3 (baseline of 1). Her AKI coincided with peripheral eosinophilia. Home medications included hydralazine, lansoprazole and simvastatin. She had recently completed eight weeks of treatment for Hepatitis C with Harvoni and her most recent viral load was undetectable. She denied using any NSAID, antibiotics, PPI or herbal supplements. Physical exam was normal. AKI workup revealed negative ANCA, normal complement, normal serum free immunoglobulin light chain ratio and negative ANA panel.

Patient underwent kidney biopsy. Light microscopy showed 11 glomeruli, 3 were globally sclerosed, 3 had cellular crescents with mesangial nodular matrix expansion and moderate tubular atrophy. Interstitium showed moderate fibrosis with severe lymphocytic inflammation. Immunofluorescent microscopy was normal and electron microscopy showed diffusely thickened glomerular membrane and moderately effaced foot processes. A final diagnosis of acute interstitial nephritis with chronic diabetic nephropathy was made. Her clinical picture, pathology findings and time course of renal impairment coincided with Harvoni use and is suggestive of Harvoni induced AKI. She was initiated on steroid therapy and advised to stop further use of Harvoni. Her renal function is stable with no further deterioration after stopping offending agent.

Discussion: Harvoni has a cure rate of up to 94-100% in patients with Hepatitis C genotype 1. We report first case of biopsy proven AKI with Harvoni. Hematologists and nephrologists need to be aware of the potential side effect of this novel agent.

Thrombotic Microangiopathy Secondary to Smoldering Myeloma: A Form of MGRS

Jyotsana Thakkar, Rimda Wanchow, Kenar D. Jhaveri. Nephrology, North Shore-LIJ Hospital, NY.

Introduction: Thrombotic microangiopathy syndrome (TMA) is not a usual presentation of paraproteinemic diseases. We report a case of TMA secondary to smoldering myeloma presenting as monoclonal gammopathy of renal significance (MGRS).

Case Description: A 69 year old male with past history of hypertension, diabetes mellitus, prostate cancer, Chronic kidney disease (CKD) (baseline creatinine 1.3-1.5 mg/dl), chronic back pain was referred to our clinic for evaluation of CKD. Home medications included enalapril, humalog, pioglitazone and acetaminophen as needed. Physical exam was normal except for elevated BP of 160/80 mmHg. Workup showed serum creatinine 1.5 mg/dl, Spot urine protein/creatinine ratio of 0.2, Hb 15.5 g/dl and platelets 113K/UL. Serum free light chain ratio was suggestive of elevated IgA kappa light chain and elevated K/L ratio. Bone marrow biopsy showed mild plasmacytosis (10% plasma cell). Skeletal survey was negative for lytic lesion. Patient was diagnosed with smoldering myeloma. Kidney biopsy was done to rule out MGRS.

Light microscopy showed 24 glomeruli, 11 of which were sclerotic. Immunofluorescence was negative. On Electron microscopy, extensive glomerular basement membrane (GBM) duplication with sub endothelial widening was seen. Between the duplicated GBM, two types of electron dense deposits were seen, consisting of short fibrils and well demarcated dense material giving bubbly appearance consistent with thrombotic microangiopathy. Serological workup for secondary causes of TMA including HIV, Hepatitis, CMV PCR, Parvovirus B19 PCR, antiphospholipid antibody, cryoglobulin, complement (C3, C4) , HTLV, HIV were negative. Beta 2 glycoprotein IgA Ab were negative. Given the smoldering nature of MM and the finding of TMA on kidney biopsy with no secondary cause, patient was considered to have MGRS presenting as renal limited TMA and is currently being treated with anti plasma cell agents.

Discussion: Case series of cancer related microangiopathic hemolytic anemia and TTP as initial presentation of multiple myeloma has been described before but not biopsy proven chronic renal limited TMA secondary to smoldering myeloma. We report first case of biopsy proven TMA likely secondary to smoldering myeloma.

TH-PO1092

A Case of Leukocyte Chemotactic Factor 2 Associated Amyloidosis

Nada Badeg, Saeed Kamran Shaffi. Nephrology, Univ of New Mexico.

Introduction: Leukocyte chemotactic factor 2-associated amyloidosis (ALCET2) is a newly described form of nonhereditary amyloidosis. The disease usually presents with chronic kidney disease and bland urinary sediment with variable degrees of proteinuria. We describe a case of a young Hispanic female who presented with nephrotic syndrome without renal insufficiency.

Case Description: A 40 year old Hispanic female with history significant for uncontrolled type 2 diabetes, hypertension and rheumatoid arthritis, was referred to renal clinic for evaluation of nephrotic syndrome. Physical examination revealed peribulbar and bilateral lower limb edema. Pertinent diagnostic data are shown in figure 1.

Figure 1: Diagnostic Data

| Urinalysis | 3+ protein |
| Spot urine protein/creatinine (g/g) | 20 |
| Serum creatinine (mg/dl) | 0.5 |
| Serum albumin (g/dl) | 1.4 |
| SLEP | No M component |
| Serum Kappa/Lambda | Normal |
| Hepatitis panel | Non-reactive |
| ANA | Non-reactive |
| Renal ultrasound | Normal kidney size with mild echogenicity |

Renal biopsy showed extensive amyloidosis involving the glomeruli, interstitium and arterioles. Immunofluorescence was negative for immunoglobulins and amyloid associated protein. Proteomic typing of the amyloid revealed ALECT2 associated amyloidosis. The patient was started on lisinopril and spironolactone, but her proteinuria failed to improve and she had progressive deterioration of renal function. Two years later, she developed ascites and elevated liver enzymes. Her presentation was concerning for hepatic amyloidosis; therefore, she was transferred to a liver transplant center for further evaluation.

Discussion: Based on two large renal biopsy series, ALECT2 accounts for 2.5-2.7% of all cases of renal amyloidosis. In a multicenter study involving 72 patients with renal ALECT2, 92% were Hispanic, 2.8% were below the age of 50 and 91.4% had a serum creatinine > 1.2mg/dl. One third had nephrotic range proteinuria, but only 10% of all patients presented with nephrotic syndrome. Pathogenesis is not clear. It is postulated that inflammatory processes lead to excessive production of an amyloidogenic variant of ALECT2. Accurate identification of the amyloid protein is essential as disease modifying treatments are available for certain types of amyloidosis.

TH-PO1093

Complement Polymorphisms in Patients with Thrombotic Microangiopathy Associated with Intravenous Abuse of Oral Formulation of Extended-Release Oxyphormone (OPANA-ER) 

Joe Ghana, Lukas Haragissm, Satish Kumar. Nephrology, Univ of Oklahoma Health Science Center, Oklahoma City, OK.

Introduction: In 2012, the CDC reported 15 cases of unexplained renal failure and thrombotic microangiopathy (TMA) in which all patients reported dissolving and intravenously injecting an oral preparation of oxyphormone (OPANA ER) prior to presentation. Since then, 30 additional cases have been reported in the U.S. The mechanism of IV Opana-associated TMA is unclear. ADAMTS13 levels were normal. We report two patients with genetic polymorphisms of complement system proteins as a possible mechanism for Opana-associated TMA.

Case Description: Two patients, a 26 yo WM (Pt 1) and a 38 yo WM (Pt 2) presented with unexplained renal failure (serum creatinine 8.2 and 4.6 mg/dl respectively) in the setting of IV Opana Abuse. Both displayed a hematological constellation of microangiopathic hemolytic anemia, thrombocytopenia, consumed haptoglobin and elevated LDH. Both patients had normal INR/PT/PTT, ADAMTS13 (both > 55%) and fibrinogen levels. ANA, HV, and hepatits profiles were negative. Renal biopsy showed intermediate sized vessels with vessel TMA in both patients. Both received plasmapheresis for 5 days. Hematological microangiopathy resolved in Pt 2 but persisted in Pt 1. Both remained dependent dialysis.

Genetic studies for complement-mediated HUS demonstrated both to be positive for a heterozygous polymorphism (IVSP-78 G>A) within an intron of the membrane cofactor protein (MCP/CD 46) and for a homozygous polymorphism (p.His602Ty) in the complement factor H (CFH). In addition, both patients had an additional CFH polymorphism (p.Val621Le; Pt 1 homozygous, Pt 2 heterozygous).

Discussion: Our patients suggest a 2 bit mechanism for IV Opana-associated TMA. Bivalent polymorphisms in complement system proteins MCP and CFH with a potential predisposition for complement-mediated HUS. The MCP/CD 46 polymorphism has been shown to be enriched in patients with complement-mediated HUS. Polymorphisms in complement system proteins could cause hyperactivation and dysregulation of the complement system and provide a genetic predisposition for thrombotic microangiopathy, with IV Opana abuse acting as a trigger.
TH-PO1094
Acute Kidney Injury due to an Excessive Dose of Rivaroxaban
Sandar Win, Kevin G. Lazo, Jordan L. Rosenstock, 1 1Nephrology, NSU/Lenox Hill Hospital, New York, NY; 2Internal Medicine, .

Introduction: Recently, over-anticoagulation with warfarin has been recognized as a cause of acute kidney injury (AKI) and has been termed warfarin related nephropathy (WRN). We report a patient who developed AKI and gross hematuria while taking the new oral direct thrombin inhibitor, rivaroxaban.

Case Description: A 45 y/o man presented to his physician’s office with abdominal pain. Computed tomography (CT) of the abdomen was done and thrombosis of the portal, splenic, and mesenteric vein was identified. He was admitted to the hospital and discharged on warfarin 10 mg daily. He was given a prescription for rivaroxaban 20 mg tab and told to take 1 tablet daily. He mistakenly took 2 tablets daily. After 5 days, he noticed painless gross hematuria for several days. He reported to his physician’s office and his serum creatinine had increased to 2.7 mg/dL from a baseline of 1.5. He had a previous history of splenic vein thrombosis of unclear cause 2 years previously (treated with warfarin), hypertension, and diabetes. His medications included metformin, glipizide, gemfibrozil, valsartan, sitaglipitin, and rivaroxaban. His vital signs were normal. Physical examination showed splenomegaly but was otherwise unremarkable. Urinalysis revealed many red blood cells with trace proteinuria. The urine protein to creatinine ratio was 257 mg. Serologies were negative and there was no evidence of intravascular hemolysis. Antiphospholipid antibodies were negative as was a hypercoagulable work-up. A bone marrow biopsy was unremarkable and paroxysmal nocturnal hemoglobinuria was ruled out. Renal dopplers were negative for renal vein thrombosis. Renal function remains stable after 3 months. Renal biopsy was not performed in the setting of the required anticoagulation and likely diagnosis of anticoagulant related AKI.

Discussion: WRN is a newly recognized form of AKI in the setting of excessive anticoagulation with warfarin. This appears to be the first reported case of a WRN-like AKI due to the NOAC rivaroxaban, and was likely caused by inadvertent doubling of the patient’s dose. WRN can often be irreversible and in this patient no well renal recovery was evident at 3 months.

TH-PO1095
Irreversible Acute Kidney Injury due to Oxalate Nephropathy from Intravenous Vitamin C
Tarvinder S. Mathan, Satish Kumar. Nephrology, Univ of Oklahoma Health Science Center, Oklahoma City, OK.

Introduction: High doses of vitamin C are widely used in alternative medicine for treatment of cancer, viral illness and fatigue. Vitamin C is metabolized to oxalic acid in the body. High doses of vitamin C have the potential to cause hyperoxaluria, nephrolithiasis and oxalate nephropathy. We report a patient who developed severe, irreversible, acute kidney injury due to acute oxalate nephropathy from high dose intravenous vitamin C.

Case Description: 75 yo male with a history of hypertension, hypothyroidism, and mild pancytopenia, presented to a wellness clinic with fatigue and weight loss. He had a normal metabolic profile except hypercalcemia (corrected Ca, 12 mg/dl). He received IV vitamin C 30 g/d for 7 days. Serum creatinine was 1.3 mg/dl prior to Vitamin C administration. One month following treatment, he was admitted to our hospital with serum Cr 9.1, Na 110, K 27, CO2 16, BUN 152, Glucose 131, Ca 8.4, Uric Acid 12.1, CPK 175, Phos 11.9, and WBCs 5.6. Urinalysis showed many red and white blood cells, proteinuria, and glucose. A renal ultrasound revealed normal sized, echogenic kidneys with bilateral diffuse parenchymal calcification. Renal function remains stable 5 months following treatment. He was discharged with prednisone 40 mg daily.

Discussion: It is important to recognize that vitamin C can cause AKI. Vitamin C is metabolized by the enzyme oxaloacetate decarboxylase to oxalic acid. An estimated 90% of ingested vitamin C is metabolized to oxalic acid. The oxalic acid is then either excreted or reabsorbed in the proximal tubule. However, if the amount of oxalate exceeded the tubular capacity, it can be deposited in the kidneys, causing acute oxalate nephropathy. In severe cases, renal failure can result. This case describes a severe case of AKI due to oxalate nephropathy from high dose vitamin C.

TH-PO1096
Atypical Hemolytic Uremic Syndrome (aHUS) due to a Novel Sequence Variation of Diacylglycerol Kinase Epsilon (DGKE)
Magdi Y. Youssef, Tarvinder S. Mathan, Armand Achaintre, Jaleel H. Hakime, Sally Self, Milos N. Budisavljevic. Nephrology, MUSC, Charleston, SC.

Introduction: Atypical Hemolytic Uremic Syndrome (aHUS) is a rare disease characterized by the triad of microangiopathic hemolytic anemia, thrombocytopenia, and renal failure. Recent advances in the understanding of ADAMTS13 c.3287G>A, p.R1096H, associated with decreased ADAMTS13 function and is heterozygous for CFHR5. Subsequently, a younger sister presented with hypertension, hematuria and nephrotic range proteinuria. The symmetric sister is also homozygous for membrane DGKE and is heterozygous for CFHR5, but lacks the ADAMTS13 variant. Parents and siblings with heterozygous DGKE variants are healthy.

Discussion: This is the first reported case of a kinase accessory domain of DGKE associated with aHUS. Additional studies are needed to determine the impact of DGKE mutations on the clinical course of patients with aHUS and their appropriate management.

TH-PO1097
Membranoproliferative Glomerulonephritis with Mixed Cryoglobulinemia in Patients with Autoimmune Hepatitis
Jalar El, Hakime, Sally Self, Milos N. Budisavljevic. Nephrology, MUSC, Charleston, SC.

Introduction: Autoimmune hepatitis (AIH) is frequently associated with extrahepatic manifestations; however, glomerulonephritis is rarely seen. We describe two patients with biopsy proven AIH who developed membranoproliferative glomerulonephritis (MPGN) despite treatment with prednisone and azathioprine. Screening for hepatitis B and C virus was negative and neither patient had SLE.

Case Description: Case 1: A 56 yo female presented with microscopic hematuria (6-10 RBC), proteinuria (6.9 g) and acute kidney injury (creatinine 1.5 mg/dL). Her renal function deteriorated requiring hemodialysis treatment. Serum IgG was elevated and a hypercoaguable work-up was negative. A bone marrow biopsy revealed many red blood cells with trace proteinuria. The urine protein to creatinine ratio was 1:640. Anti-dsDNA was negative as was a hypercoaguable work-up. A renal ultrasound revealed a normal sized, echogenic kidney with bilateral diffuse parenchymal calcification. Renal function remains stable 4 months following treatment. She was discharged with prednisone 40 mg daily.

Case 2: 18 year old female presented with proteinuria (1.7 g), hematuria (44 RBC) and renal failure. Her renal function deteriorated requiring hemodialysis treatment. Serum IgG was elevated and a hypercoaguable work-up was negative. A renal ultrasound revealed a normal sized, echogenic kidney with bilateral diffuse parenchymal calcification. Renal function remains stable after 4 months following treatment. She was discharged with prednisone 40 mg daily.

Discussion: Patients with AIH should be monitored for proteinuria and active urinary sediment due to the risk of glomerulonephritis, despite treatment with prednisone and azathioprine. MPGN is a rare, but important, complication of AIH. Prompt diagnosis by kidney biopsy and aggressive treatment of AIH associated MPGN with rituximab and/or cyclophosphamide may result in a favorable renal outcome.

TH-PO1098
Complicated by Bladder Cancer
Melin Joe Narayan, Bahar Bastani. Dept of Nephrology, St. Louis Univ, St. Louis, MO.

Introduction: A Chinese herb (aristolochic acid) nephropathy is a rapidly progressive interstitial nephritis leading to tubulo-interstitial fibrosis. It is linked with high frequency of urothelial malignancy.

Case Description: We report a 59 year old white female who had received Chinese herbs for one and half years before she developed progressive renal insufficiency that over a six month period lead to ESRD requiring hemodialysis. A renal biopsy showed tubular atrophy and interstitial fibrosis. She presented with proteinuria and hematuria. Her history included exposure to a Chinese herb with herbal ingredients containing aristolochic acid which is linked to urothelial malignancy.

Discussion: Despite the occurrence of urothelial malignancy, with incidence as high as 70-80%, patients with aHUS should be closely monitored for the development of AKI. Renal function remains stable after 4 months following treatment. She was discharged with prednisone 40 mg daily.

TH-PO1100
A Case of Chinese Herb (Aristolochic Acid) Nephropathy Leading to ESRD Complicated by Bladder Cancer
Melin Joe Narayan, Bahar Bastani. Dept of Nephrology, St. Louis Univ, St. Louis, MO.

Introduction: Chinese herb (aristolochic acid) nephropathy is a rapidly progressive interstitial nephritis leading to tubulo-interstitial fibrosis. It is linked with high frequency of urothelial malignancy.

Case Description: We report a 59 year old white female who had received Chinese herbs for one and half years before she developed progressive renal insufficiency that over a six month period lead to ESRD requiring hemodialysis. A renal biopsy showed tubular atrophy and interstitial fibrosis. She presented with proteinuria and hematuria. Her history included exposure to a Chinese herb with herbal ingredients containing aristolochic acid which is linked to urothelial malignancy.
Discussion: There has been a high risk of urorheal malignancies associated with Chinese herb-aristolochic acid exposure with 40 - 45% of these patients developing multifocal high grade transitional cell carcinoma leading to a suggestions for either prophylactic bilateral native nephrectomy and urothectomy at the time of renal transplantation or screening cystoscopies every 6 months to identify early stage urothelial carcinoma. Our patient is a classic example of aristolochic acid associated nephropathy complicated with urorheal cancer.

TH-PO1099

Anti-Tumor Necrosis Factor Therapy – A Trigger for Anti-Glomerular Basement Membrane Disease

Carlos Antonio Cottes Sanchez, Hector R. Cordova, Krystahl Z. Andujar. Medical Service, VA Caribbean Healthcare System, San Juan, PR.

Introduction: Tumor necrosis factor (TNF) has a key pathological role in diseases such as rheumatoid arthritis (RA). Vasculitis and other autoimmune diseases have been associated with the use of anti-TNF agents such as Adalimumab.

Case Description: A 73-year-old man with of RA, Hypertension, Diabetes Mellitus type 2 and Non-Hodgkin’s Lymphoma in remission for 3 years complained of decreased urine output, dark urine, poor appetite, weight loss and peripheral edema for three weeks. He was on chronic low dose Prednisone and Adalimumab intermittently during the previous 21 months. Physical exam revealed bilateral lower extremity pitting edema but no skin lesions. Laboratories showed a serum creatinine of 9.5mg/dl (baseline of 1.3mg/dl). Urinalysis exhibited many RBCs, proteinuria (2+) and pyuria without casts. The clinical picture suggested acute glomerulonephritis. Hemodialysis (HD) was started.

SeroLOGY tests were compatible with Anti-Glomerular Basement Membrane Disease. Alveolar hemorrage was not present. Plasmapheresis therapy decreased anti-GM titers but there was no recovery of renal function. The patient continued using Adalimumab after discharge. He later returned with hemoptysis due to alveolar hemorrage, which resolved after the discontinuation of Adalimumab. The patient remained HD-dependent.

Discussion: The temporal association of the illness with anti-TNF therapy and worsening of symptoms upon reexposure suggest an etiologic role of Adalimumab in the development of Anti-GM Disease in our patient. Patients receiving anti-TNF therapy should have renal function closely monitored to allow early detection of this infrequent but life-threatening side effect.

TH-PO1100

Severe Pauci Immune Crescentic Glomerulonephritis Mimicking ANCA Related Vasculitis Caused by Clinically Silent Dental Abscess Leading to Bacterial Endocarditis

Anil K. Chunduri, Maria Saleeen Khan, Anthony Alvarado, Tibor Nadasdy, Lee A. Hebert. Nephrology, OSUMC, Columbus, OH.

Introduction: Severe crescentic GN is usually categorized based on the cause if it is Anti GBM or IC mediated disease. However, it is not widely appreciated that some instances of pauci immune GN are actually the result of severe occult systemic infections. We present a case of severe pauci immune crescentic GN whose initial assessment for infection was negative. The patient was assumed to have idiopathic AAV and was treated with high dose steroids. Despite no obvious signs of infection, bacteria was on our differential due to pancytopenia. These findings are rarely common, if ever, associated with AAV.

Case Description: 55 year old male with PMH of CAD presented to an outside hospital with fatigue. Initial labs revealed Hb: 7.6g/dL, WBC: 2.8 K/µL, Pt: 44 K/µL, Plt: 2.26 mg/dL. Infectious work up was negative. Autonomic workup revealed: ANA positive (1:40), Anti GM (<0.2), Anti PR3 (0.6), ANCA and Anti MPO: negative. C3: 77mg/dL, C4: 16.9 mg/dL (wml). Cryoglobulin (<5), Urine PCR ratio was 1.2. Further workup included a bone marrow biopsy and kidney biopsy, which was suggestive of pauci-immune crescentic and necrotizing GN. He received treatment with steroids and was discharged on steroid taper. His creatinine upon discharge was 1.5 mg/dL. On follow up his creatinine was elevated to 3.5 mg/dL. He was transferred to our institution. Repeat Infectious work up revealed streptococcus viridans bacteremia, tricuspid and aortic valve endocarditis. A panoramic radiograph of his teeth showed periapical abscess. He was subsequently diagnosed with infection related acute pauci-immune crescentic necrotizing GN. Unfortunately this patient remained dialysis dependent at the time of discharge.

Discussion: It is well established but not widely appreciated that severe pauci-immune crescentic GN can be the direct result of infection. Thorough investigation is warranted even if the initial infectious workup is negative, if the patient does not have a positive response to conventional therapy to improve morbidity and mortality.

TH-PO1101

POEMS syndrome with Cast Nephropathy

Amanda K. Hall, Josephine Abraham, Monica Patricia Reavelo Penafiel, Frederic Clayton. ‘Div of Nephrology and Hypertension, Univ of Utah, Salt Lake City, UT; ’Div of Pathology, Univ of Utah, Salt Lake City, UT.

Introduction: POEMS syndrome(Polynephropathy, Organomegaly, Endocrinopathy, Monoclonal protein, Skin changes) is a plasma cell disorder with peripheral neuropathy and any of the following features osteosclerotic bone, Castleman’s disease, increased levels of serum vascular endothelial growth factor(VEGF), organomegaly, endocrinopathy, edema or skin changes. We report a case of POEMS presenting with acute renal failure due to cast nephropathy.

Case Description: A 63-year-old Caucasian female presented with a 3 month history of increasing weakness and was diagnosed with chronic inflammatory demyelinating polyneuropathy. She was also noted to have new onset diabetes mellitus and hypothyroidism. She was treated with intravenous immunoglobulin(IgIV) with minimal response. She was admitted with acute renal failure initially thought to be secondary to IVIG, progressive weakness, and shortness of breath. Serum beta 2 microglobulin was elevated and kappa/lambda ratio was abnormal with Bence-Jones proteinuria. Renal biopsy was deferred as the patient developed respiratory failure, subarachnoid hemorrhage, and a left middle cerebral artery stroke. Comfort measures were initiated. Bone marrow biopsy confirmed multiple myeloma with 20% clonal plasma cells. Patient subsequently developed uncontrolled hepatomegaly, splenomegaly, and peripheral nerve demyelination with active axonal loss. Renal examination showed cast nephropathy with monoclonal kappa light chains.

These features are characteristic of POEMS given the multiple myeloma with neuropathy, organomegaly, rash and new onset diabetes mellitus and hypothyroidism.

Discussion: POEMS is a paraneoplastic syndrome associated with plasma cell dyscrasia. Polynephropathy with plasma cell disorder should prompt evaluation for POEMS as outcomes have been excellent with diagnosis and treatment.

TH-PO1102

Acute Interstitial Nephritis Associated with a New Breast Cancer Chemotherapy Regimen

Cory Handelsman, Michael T. Tanoue, Amy Kwon, Steven Salvatore, Jeffrey I. Silberzweig. ‘Div of Nephrology, Weill Cornell Medical College; ’Dept of Medicine, Weill Cornell Medical College; ’Dept of Pathology, Weill Cornell Medical College, New York, NY; ’The Rogosin Inst, New York, NY.

Introduction: Acute interstitial nephritis (AIN) as a direct consequence of chemotherapy is infrequently described. A recent review implicated ifosfamide, tyrosine kinase inhibitors, and pemetrexed as culprits in this process. We describe a case of AIN related to the recently approved chemotherapy regimen of pertuzumab, trastuzumab, and docetaxel for HER-2 positive metastatic breast cancer. While diarrhea, rash, and pruritis are well-known side effects, this report is the first to show AIN as a consequence of this chemotherapy regimen.

Case Description: A 69-year-old woman recently diagnosed with HER-2 positive breast cancer and treated with six cycles of neoadjuvant pertuzumab, trastuzumab, and docetaxel was hospitalized for acute kidney injury after two days of diarrhea and vomiting. Admission labs demonstrated leukocytosis to 26,000/µL, serum creatinine of 5.9 mg/dL (baseline of 1.55 mg/dL), and elevated union gap metabolic acidosis with a lactic acid of 4.5 mmol/L. Urinalysis showed pyuria with occasional granular casts. Fractional excretion of sodium was 1.88%. Renal sonogram showed normal resistive indices with no evidence of hydropnephrosis or calculus. Infectious workup, including blood, urine, and stool studies, was unrevealing. Despite aggressive hydration and resolution of diarrhea and vomiting within 48 hours, her renal function worsened; her creatinine peaked at 9.0 mg/dL on hospital day 3. She was non-oliguric throughout the admission. A renal biopsy revealed moderate, diffuse acute and subacute, interstitial inflammation characterized by lymphocytic infiltration with moderate eosinophilia and diffuse tubular injury. Some endothelial injury
was present as well. The patient was diagnosed with AIN secondary to chemotherapy and treated with prednisone. At this time, her symptoms had fully resolved and her serum creatinine had returned to baseline.

Discussion: This is the first documented case of AIN related to combination chemotherapy with docetaxel, pertuzumab, and trastuzumab.

TH-PO1103

Sarcoidosis-Lymphoma Syndrome Presenting with Severe Refractory Acute Interstitial Nephritis

Gianni Goris,1 Giacomo Davilla,2 Deepak Nandikanti,1 *Nephrology Div, UTHSC, Memphis, TN; 2Nephrology Section, VAMC, Memphis, TN.

Introduction: Sarcoidosis-lymphoma syndrome (SLS) is rare. Sarcoidosis (S) usually precedes lymphoma (L) by many months. Constitutional symptoms and hilar lymphadenopathy high on the differential initial manifest. We report a SLS case presenting with severe acute hypercalcemia and acute kidney injury (AKI).

Case Report: A 70 yr-old Caucasian male was hospitalized with symptoms of generalized weakness, poor oral intake, and altered mental status. Examination was significant for dry mucous membranes, depressed mentation, evidence of bilateral pleural effusions, mild ascites, and 2cm well-delineated hyperpigmented erythematous plaques on anterior chest wall. Laboratory findings included a corrected serum Ca 19.4mg/dL (2 months prior- 9.3mg/dL), ionized Ca 2.3 mmol/L, BUN 56mg/dL, serum creatinine 2.5mg/dL (baseline 1.4 mg/dL) and mild anemia. Further work up revealed suppurated PT (0.2mg/L), normal LFT, PT/INR, serum uric acid, electrolytes, creatinine electrophoresis, calciol, calciol, ACE, CEA, PSA, and TSH. A working diagnosis of hypercalcemia of malignancy was made. Intralesional fluids, calcitinin, prednisone, and low dose pamidronate were initiated; however, hypercalcemia remained poorly responsive to conservatory management and hemodialysis was required. Skin biopsy of chest wall lesion demonstrated non-caseating granulomatous dermatitis consistent with sarcoidosis. Thoracentesis was performed and pleural fluid cytology showed occasional plasmacytoid lymphoid cell and polyclonal T-cells on flow cytometry. However, flow cytometry of ascitic fluid was positive for monoclonal B cells. Computed tomography (CT) demonstrated diffuse soft tissue lung masses and abdominal carcinomatosis. Oursese sequence was normal. CT-guided omental mass biopsy showed dense fibrous tissue with lymphoplasmacytic infiltrate. The diagnosis of SLS with associated B-cell lymphoma was made. Given poor functional status and widespread disease, the patient and his family opted for hospice care.

Discussion: Severe refractory hypercalcemia leading to AKI is unusual for sarcoidosis and should prompt investigation for concomitant lymphoma.

TH-PO1104

End Stage Renal Disease Secondary to Oxalate Nephropathy in a Patient with Undiagnosed Chronic Pancreatitis

Kalyani Chandra,1 Buri R. Don. Div of Nephrology, UC Davis Medical Center, Sacramento, CA.

Introduction: Oxalate nephropathy is a rare, underdiagnosed, devastating disease characterized by excessive oxalate deposition, acute kidney injury and rapid progression to end stage renal disease (ESRD). Secondary hyperoxaluria occurs in enteric disorders associated with increased intestinal oxalate absorption and renal tubular injury. Chronic pancreatitis is a rare cause of oxalate nephropathy.

Case Description: A 66 year-old white man with history of diabetes mellitus, hypertension and recurrent kidney stones, was noted on routine labs to have an elevated serum calcium level (11.7mg/dL; baseline 9.9mg/dL, 6 months prior). He reported having chronic diarrhea, fatigue, loss of appetite and weight loss over the past 6 months. Workup revealed pancreatic calcifications consistent with chronic pancreatitis. Urinalysis and renal ultrasound were normal. Renal biopsy revealed acute tubular necrosis with extensive oxalate deposition. A 24 hr urine collection noted increased oxalate and reduced citrate excretion. Despite a 6 month course of a low oxalate diet, pancreatic enzymes, calcium supplementation, and sodium citrate to alkalinize the urine, the patient’s renal function failed to improve, and he is preparing for home hemodialysis.

Discussion: Enteric hyperoxaluria can lead to acute oxalate nephropathy. It has been described in patients with post-gastric bypass surgery and inflammatory bowel disease. There are rare reports noting the association between chronic pancreatitis and oxalate nephropathy leading to chronic kidney disease (CKD) and rarely ESRD. The pathogenesis of hyperoxaluria in chronic pancreatitis remains uncertain, but it is postulated that fat malabsorption may increase oxalate production and fatty acids that inhibit the formation of calcium oxalate in the GI tract, combined with increased colonic mucosal permeability, leading to hyperoxalemia, hyperoxaluria and oxalate crystalization in the kidney. Treatment remains largely empiric, aiming at decreasing oxalate burden to the kidney as was done leading to hyperoxalemia, hyperoxaluria and oxalate crystalization in the kidney. Treatment remains largely empiric, aiming at decreasing oxalate burden to the kidney as was done

TH-PO1105

mRNA Expression of Proinflammatory Mediators in Common Variable Immunodeficiency with Granulomatous Interstitial Nephritis: Case Report

Giacomo Cappelli,1 Nilson Faria de Andrade,2 Bruno Barbas,3 Alexandre Bittencourt,1 Ana Paula Tavares,4 Jonas Antunes,1 Elke Abat,1 Fabio Cappelli,1 *Univ Hospital - Modena.

Introduction: Common Variable Immunodeficiency (CVID) impact on kidney function is poorly understood. We present a case of a woman, 39 years old, affected by CVID, expressing hypergammaglobulinemia, anemia and chronic kidney failure secondary to granulomatous interstitial nephritis (IN).

Case Description: In 2013 serum creatinine(s-cr) rose from 0.8 to 2.6mg/dL without urinalysis. A kidney biopsy showing AIN was performed. The patient was treated with intravenous immune globulin (IVIG) and prednisone. In 2015 s-cr was 3.5mg/dL, blood cell count 18.7, hemoglobin 4.9 g/dL, normal basic metabolic panel and calcium 8.8mg/dL. He was transfused blood products and given antibiotic therapy. Bone biopsy demonstrated invasive squamous cell carcinoma. His calcium increased to 14.1mg/dL with elevated PTH (208 pg/mL). He was diagnosed with hyperparathyroidism secondary to cancer Paget’s disease with intravenous normal saline and pamidronate 90mg. His calcium initially reduced to 11mg/dL, but rose again to 13.4mg/dL. He received a second dose of pamidronate, but his calcium decreased to 9.32 mg/dL over the next four days. The response was sustained without additional need for administration over the next two months before the patient expired due to complications related to his decubitus ulcer.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

352A
Discussion: This case illustrates the potential effectiveness of denosumab for the treatment of hypercalcemia refractory to bisphosphonates. Denosumab is a human monoclonal antibody against RANK-Ligand (RANKL) whose use has previously been described for management of hypercalcemia, but required multiple infusions. Recognition of this additional treatment, with effectiveness from a single infusion, is critical in managing refractory hypercalcemia, as the only other known option is hemodialysis. Increasing availability of options for management of refractory hypercalcemia may allow patients to avoid complications associated with hemodialysis.

TH-PO1108
Collapsing and NOS Focal Segmental Glomerulosclerosis (FSGS): Progression Along a Spectrum or Different Diseases? Suzanne L. Katsanos, Patrick H. Nachman, JulieAnne G. McGregor, Volker Nieckelet. UNC Kidney Center, Chapel Hill, NC.

Introduction: Minimal change disease (MCD) and some variants of FSGS (tip lesion and not otherwise specified NOS) are thought to represent a histologic spectrum of a similar autoimmune pathogenic process (Habib, R. Proceedings XIXth Int Cong of Neph). This contention has not been proven, however. Some cases of MCD are thought to be “unsampled” FSGS. A “transition” from MCD to FSGS is common in steroid-resistant forms (Tejani, A. Nephron 39). It has been proposed that collapsing FSGS is pathogenically and clinically distinct from other FSGS variants based on morphology, demographics, severity of nephrotic syndrome, and renal prognosis. The etiology has not been identified but viral agents, drugs, and cyclosporine toxicity have all been proposed.

Case Description: We present the case of a 37-year-old African American male with a complicated course of nephrotic syndrome. He was diagnosed with biopsy-proven MCD when 9 years old. He was treated with steroids followed by chlorambucil and then cyclophosphamide over the next several years. He was in complete remission off therapy for about 2 years until he re-presented with increased edema, proteinuria (3.8 g/d), hypoalbuminemia, and acute kidney injury (AKI). A repeat biopsy (23 glomeruli) showed FSGS NOS. He was treated with steroids followed by mycophenolate mofetil and cyclosporine, resulting in complete remission. 7 years later, he developed edema, proteinuria (21 g/d) and AKI. Repeat biopsy showed 25 glomeruli demonstrating segmental tuft collapse, activation of endothelial cells, and segmented marked activation and crowding of podocytes consistent with collapsing FSGS. HIV, hepatitis B, and hepatitis C were negative.

Discussion: The transition from MCD to FSGS NOS is common in the literature. However, the transition from FSGS NOS to collapsing FSGS is rarely reported. This patient’s case raises questions about this transition from NOS to collapsing variant. Glomerular undersampling is unlikely given 25 glomeruli were examined each time. This could represent a progressive, patient-related pathogenic process versus a de novo lesion (either related to a viral infection or medication, for example).

TH-PO1109
Lymphoma Associated Monoclonal Cryoglobulinemia in a Patient with Hepatitis C: Sangeeta Mutnuri,1 Marjan Afrozian,2 Hania Kassem.1 1Dept of Nephrology, UTMB, Galveston, TX; 2Dept of Pathology, UTMB, Galveston, TX.

Introduction: We present a case of type I cryoglobulinemia and membroanoproliferative glomerulonephritis (MPGN) in a patient with hepatitis C infection (HCV), leading to the diagnosis of a marginal zone lymphoma.

Case Description: A 47 year old male with HCV and hypertension presented with two month duration of shortness of breath and decreased urine output. On examination he was hypertensive (blood pressure: 183/111 mm of Hg), had lung crackles, lower extremity edema and hepatosplenomegaly. Laboratory tests were significant for anemia of chronic disease (Hgb: 7.3 g/dL), elevated cricsyl (21 g/dL), hypoalbuminemia, and acute kidney injury (AKI). A repeat biopsy (23 glomeruli) showed FSGS NOS. He was treated with steroids followed by mycophenolate mofetil and cyclosporine, resulting in complete remission. 7 years later, he developed edema, proteinuria (21 g/d) and AKI. Repeat biopsy showed 25 glomeruli demonstrating segmental tuft collapse, activation of endothelial cells, and segmented marked activation and crowding of podocytes consistent with collapsing FSGS. HIV, hepatitis B, and hepatitis C were negative.

Discussion: The transition from MCD to FSGS NOS is common in the literature. However, the transition from FSGS NOS to collapsing FSGS is rarely reported. This patient’s case raises questions about this transition from NOS to collapsing variant. Glomerular undersampling is unlikely given 25 glomeruli were examined each time. This could represent a progressive, patient-related pathogenic process versus a de novo lesion (either related to a viral infection or medication, for example).

TH-PO1110

Introduction: IgG4-related kidney disease (IgG4-RKD) usually presents as tubulointerstitial nephritis with IgG4-positive plasma cell (PC) infiltration and serum IgG elevation. IgG4-RKD has characteristic histological findings called storiform fibrosis and radiological findings showing a low-density lesion on computed tomography. Recently, Hara et al. reported a case of IgG4-negative IgG4-RD (Mod Reumatol, 2014) which had a condition closely mimicking IgG4-RD despite the absence of serum IgG4 elevation and IgG4-positive PC infiltration. Here we report a patient diagnosed with lupus nephritis (LN) with IgG4-negative IgG4-RD.

Case Description: A 59-year-old Japanese man was referred to our hospital with chest pain and mild proteinuria. Thoracic biopsy was performed for abnormal lung shadow and interstitial pneumonia was diagnosed. Although ANA titer was elevated to 2560-fold, anti-DNA, anti-Sm, and anti-SS-A-B antibodies were all negative. Serum C3 and C4 levels and complement activity were decreased. Serum IgG and IgE levels were elevated, but serum IgG4 level was within normal limits. On contrast-enhanced CT, multiple low-density lesions were observed in kidney. Renal biopsy findings revealed lymphoplasmacytic infiltration with storiform fibrosis and small numbers of eosinophils. Immunostainings revealed CD138- or IgG4-positive PC infiltration without IgG4-positive PC. Immunofluorescence microscopy showed granular mesangial positivity for a “full-house” pattern. Electron microscopy disclosed mesangial and subendothelial dense deposition accompanied with virus-like particles. We diagnosed this patient with IgG4-negative IgG4-RD and LN (ISN/RPS II). After administration of 20 mg prednisolone, laboratory data was drastically improved.

Discussion: To our knowledge, this is the first report of a patient with LN and IgG4-negative IgG4-RD. IgG4-negative IgG4-RD may be a chronic burnout phase of IgG4-RD.

Further studies gathering similar cases would need to clarify whether or not IgG4-negative IgG4-RD is included in a category of IgG4-RD.

TH-PO1111
A Case of Acute Phosphate Nephropathy in a Kidney Transplant Recipient: Hetal Shah, M. Lee Sanders, Kelly A. Birdwell, Anthony J. Langone, Paisit Pauksakon, Beatrice P. Concepcion. Vanderbilt Univ Medical Center, Nashville, TN.

Introduction: Acute phosphate nephropathy has been described after large doses of phosphate, typically in laxatives and bowel cleansing preparations. We present a case of acute phosphate nephropathy in a kidney transplant recipient who was taking oral phosphorus supplementation for hypophosphatemia.

Case Description: A 26 year-old man with a living related donor kidney transplant in 2011 complicated by recurrent IgA nephropathy with a baseline creatinine of 1.9 mg/dL presented with nausea, vomiting, diarrhea, fatigue and elevated creatinine. Two weeks prior to presentation, he had been started on K-Phos-Neutral 500 mg three times a day for a suspected diagnosis of hyperparathyroidism (iPTH) was 58 pg/mL. He soon after developed diarrhea and ten days later developed nausea and vomiting. He was found to have a creatinine of 10.4 mg/dL, phosphorus 9.7 mg/dL, calcium 9.6 mg/dL and iPTH 761 pg/mL. Urinalysis had a urine pH of 5, no red blood cells and trace protein. Renal biopsy was performed, and pathology revealed 30% of intratubular calcium phosphate crystals with associated acute tubular injury involving 30-40% of tubular profiles, along with known recurrence of IgA nephropathy. The patient underwent acute hemodialysis for oliguric acute kidney injury. Given the high serum phosphorus, he was dialyzed for four consecutive days until phosphorus level was less than 4 mg/dL and did not rebound. Patient was discharged requiring intermittent hemodialysis for an additional three weeks until he demonstrated renal recovery. His new baseline creatinine is 2.2 mg/dL and he has remained off hemodialysis.

Discussion: Hypophosphatemia is common in kidney transplant recipients. Although rare, acute phosphate nephropathy can occur in the setting of phosphorus repletion. This patient also had multiple risk factors, including baseline renal dysfunction, volume depletion and angiotensin receptor blocker use. Acute phosphate nephropathy can potentially lead to irreversible loss of renal function. While no specific treatment exists, in this case, aggressive hemodialysis to decrease serum phosphorus may have played a role in this patient’s eventual renal recovery.

TH-PO1112
Unusual Membranous Nephropathy in a Patient with Lupus: Imanyichukuw Ou, Julia Lewis, Agnes B. Fogo. Nephrology, Vanderbilt Univ Medical Center, Nashville, TN.

Introduction: Membranous nephropathy (MN) is an immunologically mediated glomerular disease. Distinguishing between primary and secondary MN is important in guiding diagnosis and treatment. We present a case of a patient with systemic lupus with pathologic features in a repeat biopsy suggestive of primary MN.
**Case Description:** A 32 year old African American woman presented in 1998 with nephrotic range proteinuria (4g), edema and serum creatinine 0.6. She had negative work up for secondary causes including lupus. Renal biopsy showed mild matrix expansion, diffuse global basement membrane (GBM) spikes, preserved tubulointerstitial compartment; fine granular IgG3(3+), C3(1+) IgM(trace), C1q(trace), IgA(negative) capillary loop staining with focal mesangial IgG and IgA staining; numerous subepithelial deposits, 90% foot process effacement, and unremarkable endothelial cells. She was started on an angiotensin receptor blocker but was lost to follow up. In 2011 she was diagnosed with Lupus and in July 2014, had proteinuria (1.9g). Repeat renal biopsy showed persistent MN with features concerning for lupus, with reticular aggregates, mildly increased mesangial matrix and cellularity, and 20% interstitial fibrosis. After referral to our clinic, additional testing on the 1998 biopsy (fig 1.2) showed diffuse global capillary wall IgG1(<2+), IgG2(2+), IgG3(negative), IgG4(3+), PLA2R(negative); and the 2014 biopsy (figs 3,4) showed diffuse granular capillary granular wall IgG1(+), IgG2(2+), IgG3(negative), IgG4(3+) and PLA2R near global(1+) granular capillary loop staining.

**Discussion:** The PLA2R staining and the dominance of IgG4 currently are consistent with primary MN. The negative PLA2R in 1998 may indicate early disease or epitope change. The mesangial deposits are nonspecific and could possibly represent a low grade lupus-related nephropathy. The presence of reticular aggregates is a marker of high interferon 

**TH-PO1115**

**Pheochromocytoma:** An Unusual Cause of Thrombotic Microangiopathy

**Case Description:** A 32 year-old woman with acquired immunodeficiency syndrome (AIDS) who had been on Stridil for two months presented to the ED with acute kidney injury with a serum creatinine of 2.93 mg/dL and Ca of 15.2 mg/dL. Her CD4 count was 145 /μl and viral load 35 copies/mL. Four months prior, she was treated with amphotericin B for cryptococcal lung infection and Cryptococcemia. One month prior, a right lower lobe mass, elevated at 1223 pg/ml suggestive of pheochromoctoma. BP was stabilized with four drugs and surgical resection of the tumor was done. A wedge kidney biopsy showed thrombotic microangiopathy (TMA). The tumor histopathology confirmed pheochromocytoma, positive for chromogranin and synaptophysin staining. Post operative, her creatinine stabilized at 1.45 mg/dL and glycemic status returned to normal.

**Discussion:** Pheochromocytoma in pregnancy is an extreme rarity with a frequency of 0.0002%. It is often mistaken for other hypertensive disorders of pregnancy. This is the first case report of a patient with acute kidney injury in pregnancy from TMA secondary to pheochromocytoma. Patient made good renal recovery after resection of the tumor.

**TH-PO1116**

**Immune Reconstitution Inflammatory Syndrome in Nephropathy with Acute Kidney Injury Followed by Prophylactic Bortezomib Therapy**

**Introduction:** Immune reconstitution inflammatory syndrome (IRIS) is an inflammatory disorder with paradoxical worsening of preexisting infections processes following HAART in HIV-infected individuals. We describe a case of IRIS following Stridil (eltegravir, cobicistat, emtricitabine, tenofovir) resulting in hypercalemia.

**Case Description:** A 33 year-old woman with acquired immunodeficiency syndrome (AIDS) who had been on Stridil for two months presented to the ED with acute kidney injury with a serum creatinine of 2.93 mg/dL and Ca of 15.2 mg/dL. Her CD4 count was 145 /μl and viral load 35 copies/mL. Four months prior, she was treated with amphotericin B for cryptococcal lung infection and Cryptococcemia. One month prior, a right lower lobe mass histology had revealed necrotic tissue with inflammatory cells. On examination, she was alert, in no acute distress, with unremarkable physical examination. Her temperature was 36.7 degrees Celsius, heart rate 72/minute, BP 108/64 mm Hg, respiratory rate 16/minute, and oxygen saturation 100% on room air. Chest X-ray showed an interval decrease in the right lower lobe mass. Serum intact PTH was 9.7 pg/mL, PTHr peptide, SPEP and UPEP were negative. Serum 25 (OH) D was 37 ng/mL, 1,25 (OH), D3 was 17 pg/mL, and 24 hour urine Ca was 270 mg. Urine fractional excretion phosphorus was 28% with no glucosuria. She was diagnosed with IRIS and Stridil was discontinued. She was treated with IV fluids and calcium with an improvement in her renal function and normalization of her serum calcium over a period of 4 weeks. Lab data summarized.

**Key:** TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

**Underline represents presenting author.**
Discussion: IRIS is thought to be due to increased T-lymphocyte proliferation after HAART in AIDS patients. IRIS typically manifests as a granulomatous inflammation. Corticosteroids are treatment of choice in IRIS in the setting of excess 1.25(OH) vitamin D3. In our case, serum 1.25(OH) D3 was low suggesting possible other mechanisms.

TH-POI117
IgA-Dominant Postinfectious Glomerulonephritis: A Case Series
Pranjali Sharma,1 Anitha Vijayan,2 Tingting Li.1 1Dept of Internal Medicine, Renal Div, Washington Univ in St. Louis, St. Louis, MO; 2Dept of Internal Medicine, Renal Div, Washington Univ in St. Louis, St. Louis, MO

Introduction: IgA dominant post-infectious glomerulonephritis (PIGN) is a distinct clinicopatho-logic entity that typically occurs in diabetic patients and in association with a recent or active staphylococcal infection. Patients usually present with hematuria, proteinuria, and creatinemia. Renal pathology shows an immunecomplex glomerulonephritis with various histologic patterns and IgA-dominance or co-dominance with IgG on immunofluorescence. Here we report the clinical characteristics and outcomes of 10 patients with IgA dominant PIGN.

Case Description: After obtaining approval from the local IRB, retrospective, single-center review of data was performed and 10 patients with IgA dominant PIGN were identified.

Majority was white males, and 6/10 were diabetic. Eight patients had a Staphylococcal infection and one had active Hep C infection. Only 3/10 had low complements. 6/10 required RRT and 4 developed ESRD, of which 2 died at 2 and 5 months after initiation of RRT. Five were left with varying degree of CKD and one was lost to follow up. Three patients were treated with immunosuppression in addition to antibiotics—all had significant improvement in renal function; one patient who was initially RRT-dependent was able to come off dialysis.

Hematuria in a Young Female: This Was a Hard Nut to Crack
Sharma K.,1,2 Saha S.,1,2,3 Jain RS.1 1Dept of Internal Medicine, Mayo Clinic, Jacksonville, FL; 2Dept of Medicine, Division of Internal Medicine, Mayo Clinic, Jacksonville, FL; 3Dept of Medicine, Div of Nephrology, Mayo Clinic, Jacksonville, FL

Discussion: Pauci-immune CnG is associated with either microscopic polyangitis or granulomatosis with polyangiitis. These can present as RGN and have either a positive MPO or PR3 ANCA but have no deposits on immunofluorescence and EM. CnGn in patients with malignancy is an immune complex disease, has distinct immune deposits on glomerular capillaries and fibrillar and tubular structures on EM. Our case was an unusual combination of 2 different pathologically and pathogenically distinct disease entities. To our knowledge this is the first reported case with these unusual manifestations.

TH-POI118
Hematuria in a Young Female: This Was a Hard Nut to Crack

Introduction: Flank pain with hematuria usually indicates urolithiasis but in its absence, renal vascular abnormalities should be considered.

Case Description: A 27-year old female with history of sickle cell trait, was admitted for hematuria. She had flank pain at the end of her urine stream but denied associated fever, chills or dysuria. She was treated with ciprofloxacin for presumed UTI but due to weakness she presented to our hospital. Her vital signs were stable and had a normal physical exam. Her hemoglobin was 5 g/dl and urinalysis was significant for 3 plus proteinuria with >25 RBC/hpf and >30WBC/hpf. Her total protein to creatinine ratio was 2 and had a negative urine culture. She had normal complement, ANA screen and negative serology work up for autoimmune disease. Renal ultrasound (US) showed 10 cm (right) X 9.5 cm (left) kidneys. Her non-contrast CT abdomen and pelvis (NCCTAP) were significant for a 4 cm left renal mass with Doppler which showed narrowing of the left renal vein at the level of the superior mesenteric artery (SMA) with a peak velocity gradient greater than 10:1, consistent with left renal vein (LRV) stenosis or “vein-tractor” syndrome (NCS). She subsequently underwent exploratory laparotomy with evidence of aortic and SMA sacs compressing resection of renal vein at its confluence with inferior vena cava (IVC). The IVC and left renal vein were mobilized and the compression was relieved. Patient continued to have hematuria with persistent proteinuria for few months postoperatively but eventually had resolution of both hematuria and resolution of proteinuria and hematuria.

Discussion: NCS refers to compression of left renal vein by abdominal aorta and SMA in fork-like fashion resulting in renal and pelvic venous congestion. The usual manifestations are microcytic, normochromic anemia, left flank pain and hepatomegaly. Hematuria results from the rupture of thin blood vessels into the collecting system due to elevated renal venous pressure. Symptomatic patients usually need surgical repair, LRV transposition and renal auto-transplantation in rare cases. NCS is an important etiologic in patient with hematuria and flank pain in young patient.

TH-POII19
ANCA Negative Pauci-Immune Necrotizing Crescentic Glomerulonephritis in a Patient with Non Hepatitis C Mixed Essential Cryoglobulinemia
Victor Nevazan,1 Ji ac Yoon,1 Balhinder S. Brar.1 1Medicine, Mercy St Vincent Medical Center, Toledo, OH; 2Nephrology, Univ of Toledo, Toledo, OH; 3Nephrology, Mercy St Vincent Medical Center, Toledo, OH.

Introduction: Mixed essential cryoglobulinemia (MC) is associated with a hepatitis C infection in 70-90% of patients and presents as membranoproliferative glomerulonephritis or rapidly progressive glomerulonephritis (RPGN) with or without crescents. We report an unusual presentation of type II MC without hepatitis C infection presenting as ANCA negative, crescentic glomerulonephritis with various histologic patterns and IgA-dominance or co-dominance with IgG on immunofluorescence. Here we report the clinical characteristics and outcomes of 10 patients with IgA dominant PIGN.

Case Description: A 64 year old male presented with AKI (creatinine of 5.4 from a baseline of 0.8 mg/dl, 2 weeks earlier), 12-18 month history of arthralgias, fatigue, joint pains, petechial and purpuric spots on his extremities. His symptoms were exacerbated in the winter months. Labs tests revealed elevated cryoglobulin level (1380mg/dL), low C4 (5 mg/dl), positive rheumatoid factor, IgG monoclonal gammapathy (0.37g/dl). MPO ANCA, PR3 ANCA, ANA, hepatitis B and C and HIV serologies were negative. Urinalysis showed 20-50 RBCs, no casts and proteinuria of 2.5 g. Bone marrow biopsy showed > 5% plasma cells and no T cell aberrancy or B cell monoclonality. A kidney biopsy revealed pauci-immune necrotizing CnGn. Electron microscopy (EM) showed no deposits or fibrillar or tubular structures in the glomeruli. The patient was treated with hemodialysis (HD), 5 sessions of plasmapheresis and oral cyclophosphamide for 3 months. He responded to treatment with near complete resolutions of his symptoms and near normalization of kidney function.

Introduction: Pauci-immune CnGn is an immune complex disease, has unique clinical and pathologic features that distinguish it from other diseases. Pauci-immune CnGn is characterized by the presence of circulating immune complexes (CIC) and a paucity of granulomatous or fibrillar deposits on EM. However, histologic features that are seen in other disease entities can be seen in rare cases of Pauci-immune CnGn. In such cases, clinical and laboratory features that are seen in other disease entities can be seen. Here, we present a case of a patient with treated CLL whose relapse was identified by the new diagnosis of ANCA-associated pauci-immune glomerulonephritis.

Animal studies have shown that brief postprandial elevation of glucose may trigger renal diagnosis of diabetes. A causal relationship can be established between IGT and DN; nodular diabetes after 15yrs in Type I and variable in Type 2. Our patient did not have a prior albumin, c3 and C1q. E/M; no deposits in glomerular capillary walls or mesangium. I/F: negative staining for IgM, IgG, IgA, lambda, kappa, 13/12cm, increased echogenicity. Biopsy-glomeruli; 25% globally sclerosed, moderate 2.4mg/Dl, Total protein- 4.6g/dl, Cholesterol- 278mg/dl, LDL 191mg/Dl. Hepatitis B, no cast. UPCR- 6G/G. (FPG)-118mg/Dl; Bun - 42mg/Dl, Creatinine 3.9mg/dl, Albumin No gestational diabetes, tobacco, etoh and drug use history. BP -164/77mmgh, Pulse 70/min Madison, WI.

Nephrotic Syndrome, Nodular Glomerulosclerosis and Impaired

TH-PO1123

Nephrotic Syndrome, Nodular Glomerulosclerosis and Impaired Glucose Tolerance (IGT) – A Case Report

Daniel Taiwo Adeneye, Mary C. Mallappallil, Gary R. Briefel. Nephrology, Down State Medical Center, Brooklyn, NY.

Introduction: Diabetic nodular glomerulosclerosis is a recognized complication of overt diabetes but is hardly diagnosed in patients with IGT. Diabetic nephropathy(DN) without overt hyperglycemia vindicates other etiological factors. Pathogenesis of DN is poorly understood but the trigger is still hyperglycemia. Advanced DN without overt diabetes is rare and 3 case reports have been published. This is a 48 yr old AA woman who presented with nephrotic syndrome, renal failure, IGT and renal biopsy with nodular glomerulosclerosis.

Case History: 48 yr old AA woman referred for elevated creatinine and proteinuria. No gestational diabetes, tobacco, etoh and drug use history. BP: 164/77mmgh, Pulse 70/min with pedal edema. BMI-28; fundoscopy not done. Urine protein 3+ and normal sediments, no casts. UPCR- 66G/G (FPG)-11mg/dl, Bun- 42mg/dl, Creatinine 3.5mg/dl,Albumin 2.4mg/Dl, Total protein- 4.6g/dl. Cholesterol-278mg/dl, LDL 191mg/dl. Hyperlipidemia B 2, C, HIV, ANA, C3, C4, SSA, ANCA, Cryoglobulin, SLE, negative; US; kidneys 13/12cm, increased echogenicity, biopsy-glomeruli; 25% globally sclerosed, moderate interstitial fibrosis and tubular atrophy. No IgM, IgA, lambda, kappa, albumin, c3 and c1q. E/M; no deposits in glomerular capillary walls or mesangium. GBM diffuse thickening, focal podocyte effacement and nodular mesangial matrix.

Discussion: Nodular glomerulosclerosis is usually seen in advanced DN with overt diabetes, but the female patient in Type 2. Our patient did not have a prior diagnosis of diabetes. A causal relationship can be established between IGT and DN; nodular glomerulosclerosis found on renal biopsy is usually seen in overt diabetes of long duration. Animal studies have shown that brief postprandial elevation of glucose may trigger renal injury via TGFβ that results in DN. The CKD was advanced and biopsy was undertaken at her insistence even after she was told it may not impact outcome or treatment.

TH-PO1124

A Case of Cataractogenic Antipilosporopilpoid Syndrome Treated with Plasma Exchange

Takayuki Takahara, Fumihiko Furuya, Tetsuhiro Oku, Kenichiro Kitamura. Third Dept of Internal Medicine, Univ of Yamanashi.

Introduction: Cataractogenic antipilosporopilpoid syndrome (CAPS) is characterized by diffuse vascular lesion, leading to multiple organ failure within a few days and resulting to poor prognosis. Antipilosporopilpoid syndrome (APS) is an autoimmune thrombotic syndrome with recurrent thrombosis and occurs in both artery and vein, and from large to micro vessels. CAPS is also defined as a fetal variant of APS and develop thrombosis of three different organ systems with histopathologic evidence of multiple small vessel occlusions and high titters of antipilosporopilpoid antibodies. Treatment for CAPS has not been established, and intensive anticoagulation or immunosuppressive therapy is carried out.

Case Description: A 68- year-old female who had been diagnosed as lupus erythematosus and APS complicated with multiple cerebral infarctions and treated with 5 mg of oral prednisolone. After her admission, she developed de novo cerebral infarction and colonic perforation with ischemic enteritis. Following a partial colecotomy, she developed gram-negative bacteremia, subsequently, multiple strokes, -ST elevation myocardial infarction, renal failure, and pathological findings with multiple thrombi. These clinical findings indicated that patient’s features were consistent with CAPS. She was maintained with anti-bacterial agent, anticoagulant, and prednisolone. However, since renal failure and anuria had continued, she was treated with plasma exchange (PE) and hemodialysis. Thereafter the volume of urine output was gradually increased and her renal function was recovered.

Discussion: We report a case of CAPS with multiple organ failure and successfully treated with anticoagulant, prednisolone, and PE. The clinical manifestation of CAPS depends on the release of inflammatory cytokines from the affected organs by thrombosis and small vessel occlusion. Our patient’s successful course could be attributed to beneficial role of PE through the removal of excessive inflammatory cytokines.

TH-PO1125

Acute HIVAN in a HIV-Naive Patient During Primary HIV Infection and High Viral Load

Amrit N. Shah, Adam G. Winkler, Claude Bassil, Donald E. Wheeler, Jacques A. Durr. Div of Nephrology, Univ of South Florida, Tampa, FL.

Introduction: A hitherto healthy 42 yo AA male felt chillyedly 6 days earlier. He took a NyQuil and skipped next day’s shift for body aches/GI cramps. He improved but again felt bad by HS, 48h later. Next AM in a local ER, his UA showed WBC/RBC, 3+ protein, and a SG of 1.030. Physical exam, chest X-ray, contrast abdominal CT, and eGFR, were normal. His WBC improved and worked full capacity again, but got admitted 48h later after a brief syncope.

Case Description: Vital signs: T 103 °F, BP 100/60 mm Hg, and HR 76 bpm. He had transient mild diarrhea. Serum albumin (Alb) was 2.1 g/dl, creatinine (cr) 2 mg/dl, and WBC 303/ml. UA had WBC/RBC and -05 g protein. UA was 21 mmol/l. His urine protein was ~12 g/24h. CRP was -2 (-0.5 mg/dl), and ESR 50 mm/h. CKP was 8717/U and > 1/1 hr. Hep B C, and HIV-1/2 Ab screens were (-), but (+) for HIV p24 Ag. He had >3+106 HIV copies/ml, and 213 CD4+ cells/ml. US showed normal-sized kidneys, no obstruction, but some cortical echogenicity.

His cr improved for 72h, but then rose to ~8 mg/dl in 1w. Dialysis and HAART were initiated. By then he had edema and Alb was 1.2 g/dl. Renal biopsy showed collapsing GN, podocyte hypertrophy/hyperplasia, microcystic tubular dilations, 3+ acute tubular injury, 2+ patchy (mostly lymphocytic) infiltrate with focal tubulitis, and no signs of chronicity. Prednisone was added. He seroconverted (HIV-1) 2w after his first crs.

Discussion: Of the cases reported of primary renal HIV infection only 2 had biopsy-proven HIVAN. One was HIV Ab (+) but by IFA but not by Western blot, and had 70,000 HIV copies/ml (Szabo S et al. 2002). Both had advanced RA and already other infections. Our patient had normal eGFR until his acute HIV infection. The high HIV Ag load alone, not replication, is the sole likely cause for HIVAN, consistent with the view that a direct toxic effect of the HIV gene products or podocyte dedifferentiation, since viral particle endocytosis readily occurs in podocytes (as their normal filter cleaning role?), but lack of HIV entry receptors precludes local replication (Khattar AK et al. 2010).
FR-PO001

A Case of Hypercalcemia with Renal Failure: Renal Sarcoid?

Introduction: Sarcoidosis is a multisystem granulomatous disease of unknown etiology characterized by noncaseating granulomas in involved organs. Renal involvement occurs in 35-50%, manifested by hypercalcuria, hypercalcemia, nephrocalcinosis, and nephrolithiasis. Granulomatous interstitial nephritis is the most typical histological finding, usually in the setting of systemic disease and rarely in the absence of extrarenal sarcoid.

Case Description: A 54 y/o male presented with AKI superimposed on CKD and severe hypercalcemia (Calcium 13.5mg/dl, Cai-1.7mmol/L, creatinine=7.5mg/dl). Six months prior he had a kidney stone removed at which time his creatinine was 2.4mg/dl with Cai=11 but no further work up was performed. He was taking no medications and complained of back pain. Physical exam was unremarkable. A CT scan was negative for nephroliithiasis or hydronephrosis, chest X-ray revealed no abnormality. He was aggressively treated with IV NS and then Lasix with minimal improvement in the creatinine or the serum calcium. Work up for hypercalcemia included normal serum and urine immunofixation, negative PPD, normal PSA and normal skeletal survey. 25 Hydroxyvitamin D 27.8ng/ml (30-95ng/ml). FTH suppressed at <3pg/ml total 1, 25 Hydroxy Vitamin D 79pg/ml (18-72pg/ml), and Angiotensin Converting enzyme 82 (9-67U/L). A formal ophthalmologic exam and PFTs were normal. A diagnostic kidney biopsy was performed.

Discussion: The diagnosis of sarcoid interstitial nephritis was strongly suggested by the renal biopsy given that other causes of granulomatosis were ruled out. The patient was started on prednisone 60mg/d with rapid resolution of the hypercalcemia and slow improvement in renal function (Creatinine 2.9mg/dl). A slow steroid taper over 1 year is planned.

FR-PO002

Pediatric Chronic Refractory SIADH: Use of Tolvaptan

Cristin Kaspar, Nianzhou Xiao, Timothy E. Bunchman, Megan L. Lo. Pediatric Nephrology, Children’s Hospital of Richmond at Virginia Commonwealth Univ, Richmond, VA.

Introduction: The syndrome of inappropriate antidiuretic hormone (SIADH) is the most common cause of euvolemic hyponatremia in hospitalized patients, and standard therapies can be limited in their effectiveness. Arginine vasopressin receptor antagonists (AVR-A) oral tolvaptan and intravenous conivaptan have been FDA approved in adults, but reports on long-term use in pediatrics are lacking. We report on the dosing and safety of chronic AVR-A treatment in two patients with chronic SIADH. Dosing regimen was extrapolated from current pediatric and adult literature.

Case Description: Case A is a 13 year old, 43.5 kg female with a 12-year history of AI progression of atherosclerotic changes impaired the blood flow of SHA and then decreased hormones reach pituitary through the superior hypophyseal artery (SHA), the nutrient artery if partially, although hypophyseal portal vessel snaps apart. This is because hypothalamic embryology. In PSIS patients, the functions of pituitary are sometimes maintained even indicating PSIS.

Brain MRI visualized severely pressed 2-mm thick pituitary, but not the pituitary stalk, of CRH/TRH/GHRH/LHRH stimulation test disclosed hypothalamic panhypopituitarism. revealed anorchism. He was not mentally retarded. Serum hormonal analyses showed AI, hypothryoidism, growth hormone deficiency, hypogonadism and hyperprolactinemia. A set of CTR/H/TRH/GH/IRI/LHRH stimulation test disclosed hypothalamic panhypopituitarism. Brain MRI visualized severely pressed 2-mm thick pituitary, but not the pituitary stalk, indicating PSIS.

Discussion: We concluded that his PSIS was not an acquired but a congenital anomaly based on his episode of intrauterine growth retardation and anorchism in the light of embryology. In PSIS patients, the functions of pituitary are sometimes maintained even if partially, although hypophysial portal vessel snaps apart. This is because hypothalamic hypopituitarism, growth hormone deficiency, hypogonadism and hyperprolactinemia. A set of CTR/H/TRH/GH/IRI/LHRH stimulation test disclosed hypothalamic panhypopituitarism. Brain MRI visualized severely pressed 2-mm thick pituitary, but not the pituitary stalk, indicating PSIS.

FR-PO003

Methylmalonic Acidemia: An Unexpected Consult for an Adult Nephrologist

Yoshia Lakhera, Hirotsugu Iwatani. Nephrology, JL Pettis VA Medical Center, Loma Linda Univ School of Medicine, Loma Linda, CA.

Introduction: Organic acidemias are caused by deficiencies of enzymes involved in the breakdown pathways of amino acids, fatty acids and carbohydrate metabolism. Methylmalonic academia (MMA) is a heterogeneous group of disorders of impaired metabolism of methylmalonic acid. We present a patient with MMA who was admitted with severe metabolic acidosis.

Case Description: A 21 year old male with past medical history of end stage renal disease on peritoneal dialysis, chronic pancreatitis, diabetes mellitus and coeliac disease presented to emergency room with diarrhea. He denied fever, abdominal pain and vomiting. He was hypotensive with MAP 65, HR 100, RR 16. He was hypoxemic with SaO2 75%. Laboratory tests showed metabolic acidosis with anion gap of 33 mMol/L and absence of leukocytosis. Arterial blood gas result was, pH:7.38, pCO2:18 mmHg, paO2: 108 mmHg and HCO3: 10 mMol/L. Patient was kept NPO and acidosis worsened the next day.

Initial treatment included fluid boluses with NS, bicarbonate drip and broad-spectrum antibiotics for suspected sepsis. Further history revealed that patient had MMA and then iv fluid was changed to D20NS with insulin drip. He was started on special formula feed with MMA enriched formula and oral tolvaptan. Despite this he remained acidic with arterial blood gas showing pH:7.35, pCO2:16 mmHg, PaO2: 100 mmHg and HCO3: 11 mMol/L. Abdominal ultrasound revealed multiple small pseudocysts in the liver and pancreas. It was decided to change to oral tolvaptan as an outpatient setting for chronic hyponatremia due to salt wasting.

FR-PO004

Congenital Pituitary Stalk Interruption Syndrome (PSIS) Newly Diagnosed in Case of Hyponatremia in the Elderly

Keni Kajitani, Takahito Ito, Kaori Takakari, Yoko Tomiyama, Ikue Nagayama, Masafumi Yamato, Akira Wada, Hirotsumu Iwatani. Nephrology, Osaka National Hospital, Osaka, Japan.

Introduction: There are many diseases that cause hyponatremia. Among them, adenoma of the macroadenoma of the pituitary gland is a common pituitary tumor that can result in hyponatremia. About 1% of pituitary tumors are diagnosed as macroadenomas. Hyponatremia is a common manifestation of pituitary adenomas. In the elderly, hyponatremia may be seen due to a variety of factors, including medications, dehydration, and endocrine disorders. It is important to identify the underlying cause of hyponatremia to provide appropriate treatment.

Case Description: A 76-year-old man was admitted to the hospital with a history of diabetes mellitus, hypertension, and chronic obstructive pulmonary disease. He presented to the emergency department with symptoms of confusion, dizziness, and blurred vision. On physical examination, he was found to have a blood pressure of 140/90 mmHg and a heart rate of 90 beats per minute. His mental status was impaired and his speech was slurred. Laboratory tests showed hyponatremia (Na+ 116 mEq/L) accompanied by metabolic alkalosis (pH 7.48, pCO2 29 mmHg, HCO3 28 mEq/L). The patient was admitted to the intensive care unit for further evaluation.

Discussion: We performed a thorough evaluation to identify the underlying cause of hyponatremia. The patient was found to have a pituitary macroadenoma with stalk interruption syndrome (PSIS). PSIS is a rare condition that results from interruption of the pituitary stalk, leading to pituitary dysfunction. The diagnosis was confirmed by magnetic resonance imaging (MRI) of the brain. The patient was treated with oral tolvaptan (Vaptan), a nonpeptide V2 receptor antagonist, to correct hyponatremia. The patient responded well to treatment, and his symptoms improved. The pituitary macroadenoma was also treated with surgical resection.

A Family Case of Hypoparathyroidism, Deafness, and Renal Dysplasia Syndrome with a Novel Mutation of GATA3
Tomoo Yabuuchi, Shoichiro Kanda, 1 Naoya Morisada, 1 Keiichi Takizawa, 1 Yuji Tomii, 1 Naoto Kaneko, 1 Hirota Kama, 1 Eiji Nakano, 1 Norimasa Tada, 1 Kiyonobu Ishizuka, 1 Hiroko Chiba, 1 Yuko Yoshida, 1 Kazuomi Ujiima, 2 Motoshi Hattori.

1 Department of Pediatric Nephrology, Tokyo Women’s Medical Univ, Shinjuku-Ku, Tokyo, Japan; 2 Dept of Pediatrics, Kobe Univ Graduate School of Medicine, Chuo-ku, Kobe, Japan.

Introduction: Congenital anomalies of the kidney and urinary tract (CAKUT), a major cause of end-stage renal disease in children, often present as a systemic disorder with extrarenal symptoms. Extrarenal symptoms and family history are helpful in the genetic diagnosis of CAKUT. We report here a family case of hypoparathyroidism, deafness, and renal dysplasia (HDR) syndrome with a novel mutation of GATA3.

Case Description: Soon after birth, a female patient was diagnosed as having bilateral cystic dysplastic kidneys by renal ultrasonography. She also had hearing impairment at the infancy. She received peritoneal dialysis at the age of 3 years and received a cadaveric kidney transplant at the age of 10 years. When she was 14 years old, she visited the emergency department because of acute abdomen. Detailed examinations showed hematometra associated with vaginal atresia. Branchio-oto-renal syndrome was considered as her diagnosis based on her hearing impairment, bilateral cystic dysplastic kidneys, and normocellulocytica. However, we suspected that she had an HDR syndrome because we found that her mother had hypoparathyroidism after determining a detailed family history. Genetic analysis was approved by the central ethics board of Tokyo Women’s Medical University and Kobe University. This analysis showed a novel mutation, c. 1013G>T (C338F) of GATA3, the causative gene for HDR syndrome.

Discussion: Our patient did not show any symptoms of hypoparathyroidism. However, based on the family history, we performed a genetic analysis and found a novel mutation of GATA3. She was then diagnosed with atypical HDR syndrome. Therefore, determining a detailed family history is important in the precise diagnosis of CAKUT patients.

FR-PO006

Hypocomplementemic Urticarial Vasculitis Syndrome Resistant to Corticosteroid and Plasma Exchange Therapy
Yasuhiko Kawai,1 Kenji Ueki,2 Yuta Matsuzaka,2 Hirota Hiyamuta,2 Akhiro Tsuchimoto,1 Kiichiro Fujisaki,1 Kumi Tokisu,1 Kosuke Masutani,1 Kazuhiro Tsuura,2 Takanari Kitazono.1 1 Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka City, Japan; 2 Dept of Integrated Therapy for Chronic Kidney Disease, Kyushu Univ, Fukuoka City, Japan.

Introduction: We present a case of HUVS resistant to corticosteroid and plasma exchange.

Case Description: A 36-year-old Japanese man with the history of diffuse panbronchiolitis, nephrotic syndrome, sarcoidosis, and kidney dysfunction. Percutaneous kidney biopsy was performed at the other hospital, and the diagnosis was non-IgA mesangial proliferative glomerulonephritis. In spite of the administration of angiotensin II receptor blocker, progressive kidney dysfunction was evident. Then he was transferred to our hospital 4 months later. He also had a history of urticarial rash on his leg and pigmentation was evident at the time of transfer. Urine analysis revealed 3+ proteinuria and 3+ hematuria, and urinary sediment showed red blood cells of 50-99/high power field. Urine protein/creatinine (Cr) ratio was 2.9 g/gCr. Blood tests revealed a serum Cr level was 3.2 mg/dL. A urinalysis showed 3+ proteinuria and 50 red blood cells per HPF. Urine sediment had no dysmorphic cells or casts. A 24-hour urine collection revealed 8.8 grams of protein. Chyluria screen was positive for chylomicrons and triglycerides. Midnight blood smears were negative for filarial parasites. Urine culture was negative for mycobacteria or chlamydia. Serologic studies including IgG western blot for cytotoxicus and IgG ELISA for filariasis were negative. The rapid plasma reagin (RPR) was also negative. Imaging for a lymphatic leak by lymphoscintigraphy was unrevealing. The patient was managed conservatively and underwent spontaneous remission with disappearance of chyluria several months of her initial diagnosis.

Discussion: The most common cause of chyluria is parasitic infection with granulomatous tissues or structural etiologies less frequently encountered. Sclerotherapy of the renal pelvis is the definitive treatment. Idiopathic chyluria as shown in this case is rare. Conservative management of idiopathic disease may be warranted due to the possibility of spontaneous remission.

FR-PO007

Acquired Fanconi Syndrome in a Patient with Acetaminophen Overdose
Deepuk Jasuja, Jay B. Wish. Div of Nephrology, Indiana Univ, Indianapolis, IN.

Introduction: Acquired Fanconi syndrome is described in patients receiving antiretrovirals, aminoglycosides, platinum compounds and with proximal tubulopathies due to light chain disease/paraproteinemia. We describe a case of acetaminophen induced acute tubular necrosis (ATN) presenting as Fanconi syndrome with hypophosphatemia, normoglycemic-glucosuria, aminoaciduria, and uric acid, potassium and bicarbonate wasting.

FR-PO008

Spontaneous Remission of Non-Parasitic Chyluria
Hiilel Sternlicht,1 Lakshmi V. Ramathan,2 Martin Fleisher,2 Edgar A. Jaimes,1 Ilya Gleizerman.2 1 Div of Nephrology and Hypertension, Weill Cornell Medical Center, New York, NY; 2 Renal Service, Memorial Sloan Kettering Cancer Center, New York, NY.

Introduction: Chyluria is a medical condition characterized by the presence of chyle in the urine. The disease is most prevalent in South East Asian countries mostly caused by parasitic (Wuchereria bancrofti) infections. Chyluria presents as a cloudy milk-colored urine accompanied by systemic symptoms such as weight loss, fatigue, and rarely, flank pain from retained clots.

Case Description: A 72 year-old woman presented to Nephrology clinic complaining of milky urine (Figure 1) and painless hematuria with clots for two months as well as twenty-pound weight loss. Physical exam was unremarkable. Cystoscopy and urine cytology were unremarkable. Serum albumin was 3.2 g/dL. A urinalysis showed 3+ protein and 50 red blood cells per HPF. Urine sediment had no dysmorphic cells or casts. A 24-hour urine collection revealed 8.8 grams of protein. Chyluria screen was positive for chylomicrons and triglycerides. Midnight blood smears were negative for filarial parasites. Urine culture was negative for mycobacteria or chlamydia. Serologic studies including IgG western blot for cytotoxicus and IgG ELISA for filariasis were negative. The rapid plasma reagin (RPR) was also negative. Imaging for a lymphatic leak by lymphoscintigraphy was unrevealing. The patient was managed conservatively and underwent spontaneous remission with disappearance of chyluria several months of her initial diagnosis.
hypokalemia, following the discontinuation of the medication, especially after prolonged use. Return of literature is rare knowledge, seems to be the case report demonstrating the association between HTN, hypokalemia and drospirenone.

Case Description: A 54 year-old Indian woman, previously normotensive, noted a new rise in home BP to 200/100 mm Hg and presented to the emergency department, where she was also noted to have mild hypokalemia to 3.1 mg/dL. Given the rather new onset of severe HTN and hypokalemia, work-up for secondary causes of HTN was done, which revealed normal aldosterone level (9 ng/dL), low plasma renin activity (PRA) (0.15 ng/mL/hr) and high aldosterone/PRA ratio (60). Looking back into her history, it was noted that, the timing of the symptoms was closely related to discontinuing Yasmin® (3 mg estradiol and 3 mg drospirenone), which she was taking for over 6 yrs. She was thought to have rebound effect with relatively excess mineralocorticoid activity, precipitated by the abrupt discontinuation of drospirenone. With the introduction of low dose spironolactone, her symptoms significantly improved.

Discussion: Drospirenone (an analogue of spironolactone), which has antimineralocorticoid and antiandrogenic activities similar to endogenous progesterone, counteracts the estrogen-mediated stimulation of the renin-angiotensin-aldosterone system (RAAS). Due to these effects, it has the potential to decrease blood pressure and also cause hyperkalemia. At a dosage of 3 mg/day, drospirenone induces mild natriuresis, which is followed by compensatory stimulation of the RAAS (comparable to a low sodium diet). When the prolonged ongoing suppression for the RAAS is removed, there might be a potential rebound effect (with relatively) high aldosterone state, resulting in sodium retention, leading to HTN. Spironolactone appears to be useful in this situation.

FR-PO010

Acthar Induced Hypokalemic Metabolic Alkalosis
Imran Quyyum, Neil W. Lyman.
Dept of Nephrology, St. Barnabas Medical Center, Livingston, NJ.

Introduction: Acthar, an ACTH formulation from porcine pituitary gland, is an effective therapy for Membranous Nephropathy (MN). A rare adverse effect of hypokalemic alkalosis has been noted with infrequent only. We present a case report of an 80 yrs to Caesarian female who developed severe hypokalemia and metabolic alkalosis with Acthar therapy, and concomitant diuretic use.

Case Description: The patient presented with severe bilateral leg edema. Lower extremity doppler was negative for DVT. Echo revealed normal EF. UA showed 4+ protein. Her labs showed serum sodium 141mmol/L, chloride 104mmol/L, creatinine at baseline and his ultrasound revealed normal sized kidneys with severe hypokalemia since childhood presenting as bilateral lower extremity weakness necessitating home dialysis.

Discussion: ACTH increases endogenous steroid production via MelanoCortin 1 receptor and can induce potassium wasting. The patient was being treated with furosemide and spironolactone. A thorough evaluation ruled out Addison’s disease and polycythemia vera. Her aldosterone was suppressed at 0.2ng/ml/H and his serum aldosterone was raised at 534.4pmol/L. The patient continued on Eculizumab, and after 4 months she recovered renal function and was liberated from dialysis.

FR-PO011

Polycthemia in a Patient with Barter’s Syndrome and Medullary Nephrocalcinosis
Girlie Merdegia.
Dept of Pathology, The Ohio State Univ, Columbus, OH; Dept of Pathology, The Ohio State Univ, Columbus, OH.

Introduction: Barter’s syndrome is a tubular salt wasting disorder presenting with severe hypokalemic alkalosis, hyperphosphatemia, and hyperreninemia with normal blood pressure. Medullary nephrocalcinosis in this disorder is an infrequent finding and is still poorly understood. Polycthemia is an unusual presentation in patients with renal diseases, but has been described in literature among patients with nephrotic syndrome and distal tubular alkalosis. It is noteworthy, however, that reports on secondary erythropoietin in patients with Barter’s syndrome is lacking. The exact mechanism for the polycthemia is unclear, although it may be explained by the increased erythropoietin levels in patients with nephrocalcinosis causes stimulation of oxygen receptors thus increasing erythropoietin secretion, and stimulation of prostaglandin production may be contributory.

Case Description: A 27 year old Filipino male with recurrent bouts of severe hypokalemic alkalosis since childhood presenting as bilateral lower extremity weakness necessitating recurrent hospital admissions was diagnosed with Barter’s syndrome based on metabolic alkalosis, hypokalemia, hyperphosphatemia, slight hypernatremia with normal serum calcium and magnesium levels. He had normal blood pressure and no frank hypercalcemia. His creatinine was elevated and his ultrasound revealed normal sized kidneys with bilateral nephrocalcinosis. He has elevated hemoglobin of 190 g/L, slight leukocytosis with no thrombocytopenia. JAK2 mutation was negative and a bone marrow biopsy revealed mildly hypercellular marrow with trilineage hematopoesis, masymplastic hyperplasia for which polycythemia vera was ruled out. Findings were said to be consistent with a reactive marrow.

His labs showed serum sodium 139mmol/L, chloride 103mmol/L, creatinine 83mmol/L. His arterial blood pH was 7.37 with bicarbonate 21. His plasma renin activity was suppressed at 0.2ng/ml/H and his serum aldosterone was raised at 534.4pmol/L. The transuterinal potassium gradient was 3.87. Genetic analysis of the patient and affected family members revealed a missense mutation affecting exon 13 of the gene KHLH3 (c.1492C>T p.Gln497Ser) affecting a residue located in the 5’ helix motif of the protein . The patient was treated with dietary salt restriction and a thiazide diuretic.

Discussion: This man illustrates classic findings in familial hyperkalemia hypertension including hypertension, hyperkalemia, metabolic acidosis and positive family history. Cases such as this give us further insight into the molecular pathophysiology of blood pressure control. KHLH3 gene products play a key regulatory role in distal nephron Na reabsorption and may have potential as anti-hydroprene drug targets.

FR-PO012

Homoygous Deletion of CFHR3-CFHR1 as a Cause for Atypical Hemolytic Uremic Syndrome in a Patient with Systemic Lupus Erythematosus
Salem Almaal,1 Tibor Nadassy,2 Samir Parikh.1 1Div of Nephrology, The Ohio State Univ, Columbus, OH; 2Dept of Pathology, The Ohio State Univ, Columbus, OH.

Introduction: Thrombotic microangiopathy (TMA) is a rare but devastating condition associated with systemic lupus erythematosus (SLE). In SLE, renal TMA is typically associated with the anti-phospholipid syndrome (APS) or TTP. Here we report a case of atypical hemolytic uremic syndrome (aHUS) associated with SLE that was confirmed by complement genetic studies and treated successfully with Eculizumab.

Case Description: A 21 year old African American female with a history of SLE and class II-V lupus nephritis was hospitalized after presenting with AKI, thrombocytopenia (TCP), and a microangiopathic hemolytic anemia (MAHA). Initial lab values revealed a serum creatinine of 3.5 mg/dL, platelet count of 58, hemoglobin of 7.3, and LDH of 1484. Plasminogen and IV solutedium was started empirically for presumed TTP and SLE flare. ADAMTS13 enzyme activity was normal and APS antibodies were negative. There was no improvement and the patient was started on dialysis. The patient required multiple blood transfusions as TCP and MAHA persisted. A kidney biopsy was performed and findings were consistent with severe TMA. The patient was empirically started on Eculizumab and after the first dose, TCP improved rapidly, with a platelet counts increase from 27K to 170K. Complement mutation studies were obtained and revealed a homoygous deletion of CFHR3-CFHR1 genes. The patient continued on Eculizumab, and after 4 months she recovered renal function and was liberated from dialysis.

Discussion: This is the first report of aHUS associated with SLE in a patient with an identified complement mutation. Our patient had a homogygous deletion of CFHR3-CFHR1, which has previously been linked to aHUS. CFHR3-CFHR1-deficient plasma is thought to contribute to defective regulation of complement activation on the cell surface and occurs despite the presence of normal factor H and L levels. Treatment with Eculizumab is effective and should be started promptly so disease can be halted and chronic damage limited.

A Novel Mutation in KHLH3 Gene Causes Familial Hyperkalemic Hypertension
Mohb Raddz Rodzlan Akih,1 Dearbhhla Kelly,1 Xavier Jeunemaitre,2 Catherine A. Wall.1 1Nephrology, Adelaide & Meath Hospital, Dublin, Ireland; 2Département de Genétique et Centre de Maladies Vasculaire Rares Hôpital Européen Georges Pompidou, Paris, France.

Introduction: Familial hyperkalemic hypertension is an autosomal dominant disorder where mutations in the thiazide-sensitive NaCl co-transporter (NCC) cause salt-dependent hypertension. Implicated genes include WNK1, WNK4, KHLH3 and CUL3. These lead to increased activity of the NCC in the distal neprhon, excessive chloride and sodium reabsorption, and volume expansion. We describe a novel disease-causing variant in KHLH3 not previously reported in the literature.

Case Description: An 18 year-old man with no prior medical history presented with an incidental finding of serum potassium of 7.3mmol/L. He was hypertensive with blood pressure 150/90mmHg. His mother, maternal uncle and grandmother also had a history of early onset hypertension and unexplained hyperkalemia.

Discussion: The association of Barter’s syndrome with medullary calcium is and secondary erythrocytosis and hypokalemia has been described in literature among patients with Barter’s syndrome remains uncertain. Clinicians should be aware of potential complications of this disorder so as to institute appropriate management.

Renal Failure Run A-FUOwl: Disseminated Histoplasmosis Eileen Smith, Rajeev Raghavan, Sreedhar A. Mandayam. Baylor College of Medicine, Houston, TX.

Introduction: In patients with fever of unknown origin (FUO) and glomerulonephritis, Histoplasma capsulatum should be considered.

Case Description: A 37-year-old man presented to the hospital with 3 weeks of fatigue, 15-pound weight loss, intermittent chest pain, dysnea on exertion and 3 day history of erythematous pruritic rash on his neck. PMH included congenital aortic stenosis with AVR, complicated by endocarditis requiring repeat AVR. Physical exam found splenomegally and a lacy erythematous rash on the neck and torso. On admission, creatinine was 3.15 mg/dL (baseline was 1.02 mg/dL last year) with gross hematuria, and new pancytopenia. Initial work-up for glomerular disease was non-diagnostic. He developed persistent cyclical fevers to 102°F during his hospital stay. Blood cultures, tagged WBC scan and TEE were negative. Kidney biopsy showed numerous electron-dense deposits suggestive of Membrano-Proliferative Glomerulonephritis. As part of further histological evaluation, team realized that patient regularly cleaned a chicken coop. An infectious work-up found the patient to be strongly positive for the Histoplasma capsulatum urinary antigen. With itraconazole for histoplasmosis and concomitant steroid therapy for glomerulonephritis, he defervesced and his creatinine improved to 1.4 mg/dL.

Discussion: Infection Related Glomerulonephritis (IRGN) is an immune-mediated disease caused by non-renal pathogens. The incidence is higher in developing countries: for example, per 100,000 individuals, the incidence of cases per year is 39 in India and 0.78 in the United States. It is believed that sub-clinical IRGN is common and underdiagnosed. In the current case, 10/12 kidney biopsies, 10% had evidence of disease, such as subepithelial humps. Hematuria is present in >80% of cases, and patients usually present with Nephritic Syndrome. Endemic mycoses as a cause of glomerular disease in humans are rare. An infection due to H. capsulatum can result from inhalation of aerosolized spores after disruption of chicken droppings harboring the fungus. We suspected endocarditis given his cardiac history, and kidney biopsy findings also supported infection. However, the splanomegaly, FUO, and exposure to fowls (FUOwls) established the diagnosis.

FR-PO015
Next Generation Sequencer Driven Exome Analyses Identified a MCKD1 Family with New Mutation Before VNTR Of MUC1 DNA Sequence, Satoke Yamamoto, Jun-Ya Kaimori, Masaki Hatanaka, Naotsugu Ichimura, Shirou Takahara, Hiromi Rakugi, Yoshitaka Isaka. Dept of Advanced Technology of Transplantation, Osaka University Graduate School of Medicine, Osaka, Japan; Dept of Genetics & Nephrology, Osaka Univ Graduate School of Medicine, Suita, Osaka, Japan.

Introduction: Hereditary tubulo-interstitial nephritis (h-TIN) is characterized by family history, bland urine, normal size kidney, hyperuricemia, renal fibrosis and gradual renal function loss. MCKD1 type h-TIN is also recognized by the difficulty to identify mutant sequence by conventional Sanger Sequencer or next generation sequencer, because the cytosine insertion mutation located in the GC rich valuable number tandem repeat (VNTR) region. The mutant MUC1 DNA sequence is supposed to produce truncated type cysts. The patients are suffering from mucosal dysfunctions including GI ulcer, sinusitis, renal transplant recipients, one is under dialysis, and the other was CKD. The CKD was 8.2 mEq/L and confirmed with repeat of 360A

FR-PO017
A CuriousSLE Tangled Case: Systemic Lupus Erythematosus as the Unifying Diagnosis for Fibriillary Glomerulonephropathy and Toxic Endocardial Necrosis Kawan A. Swain, Hao Liu, Volker Nickelette, Patrick H. Nachman. Nephrology, Univ of North Carolina at Chapel Hill, Chapel Hill, NC.

Introduction: Fibriillary glomerulopathy is a rare cause of glomerular disease. Most cases are idiopathic but can be associated with autoimmune diseases.

Case Description: 58 yo Caucasian male with a past history of hypertension presented a week after developing an acute erythematous rash associated with fever, encephalopathy, and CKD. He was preceded by a month history of intermittent night sweats, fever, and joint pain. The desquamating rash encompassed >30% BSA with mucosal involvement. Skin biopsy revealed acute vascular interface deramitosis consistent with toxic epidermal necrolysis (TEN). Labs showed pancytopenia without evidence of hemolysis. Serum Cr was 2.14 mg/dl (recently 0.9) and urine Protein/Cr was 1.lg. Urine microscopy showed numerous acanthocytes and a few RBC casts. Serologies revealed low C3 and C4, positive ANA 1:640 and ENA screen, but negative ANCA, cryoglobulins, infectious work up and antibodies to ds-DNA, Sm, RNP, Ro/SSA, La/SSB, Jo1 and Scl70. Akindey biopsy showed acute tubular injury and mild mesangial and endothelial proliferation without crescents or tubular necrosis. Immunofluorescence revealed diffuse IgG, IgA, IgM, C3, C1q, kappa and lambda in the mesangium and capillary walls. Electron microscopy showed mesangial and capillary deposits with 20nm non-branching fibrils. Congo red stain was negative and IgG subclass stain did not reveal monosclerol. The findings were classified as a fibriillary glomerulonephritis. After initial methylprednisolone pulse, treatment with oral prednison and mycophenolate Moffet resulted in resolution of rash, encephalopathy, and recovery of renal function and cell counts. The unifying diagnosis is now onset SLE, with TEN (possibly precipitated by naproxen) and fibriillary glomerulopathy.

Discussion: This case illustrates an uncommon presentation of an immune complex mediated fibriillary glomerulopathy consistent with SLE in an older male patient who presented with TEN. SLE has been rarely implicated as a cause of SJS/TEN when associated with initial photodistribution, absence of genital involvement, and a prolonged course.

FR-PO018
An Unusual Case of Renal Failure in an Adult: “Prune Belly Syndrome” Antonio Medaura, Jeffrey D. Wallach, Sudhanshu Jain. Nephrology, Harlem Hospital Center, New York, NY.

Introduction: Prune Belly Syndrome is a rare congenital disease characterized by hypoplastic abdominal wall musculature, severe urinary tract dilatation and bilateral undescended testes. The complete syndrome is seen only in males affecting 3.8 per 100,000 live births. While the cause is unknown several aspects suggest an influence of genetic factors. Very few patients survive adulthood and all of them progress to ESRD.

Case Description: A 25-year-old male from Burma Faso presented with a 10-year history of fever, rigors and right-sided flank pain. On exam he was found to have an empty scrotum and a distended bladder. He reported history of several urinary tract infections and urological surgeries during childhood. He was found to have azotemia (Sr. creatinine 10.8 mg/dl and BUN 82 mg/dl) and an eGFR of 8 ml/ min/ 1.73m2. Urinary culture grew E. coli. No other significant laboratory abnormalities were noted. On exam, he had a distended bladder with diffuse wall thickening and calcification, severe bilateral hydronephrosis, mild left urethral hypospadias, right renal atrophy.
We report a case of SIADH associated with acute motor and sensory axonal neuropathy (AMSAN), a variant of GBS. We have identified a 76-year-old woman with AMSAN and SIADH. She presented with fever, dysuria, and left CVA tenderness. Despite clinical and laboratory improvement with sensitive antibiotics against Klebsiella pneumonia for 14 days, the size of the infected renal cyst paradoxically enlarged (8.9 cm) on follow-up US. Thus, percutaneous catheter was inserted for drainage and after 1 wk, tubogram showed no evidence of dye leakage (Figure 4A). Following complete clinical recovery, absolute ethanol sclerotherapy was performed to prevent further recurrent cyst infection. However, she complained of severe burning pain in low abdomen at the beginning of the procedure. Tubogram dye was shown in pelvocalyceal system and ureter (Figure 1B). Sclerotherapy was immediately stopped and saline irrigation was followed. Then, percutaneous catheter was reinserted into the cyst for further drainage; and double-J catheter was inserted at ureteropelvic junction to prevent a ureteral stricture. Then, she underwent uneventful hospital course, and discharged on hospital day 42.

Pelvocalycal Leakage on Ethanol Sclerotherapy for Recurrent Infected Renal Cyst in ADPKD

Eunyoung Lee, Joo-Hark Yi, Sang-Woong Han, Ho-Jung Kim. Division of Nephrology, Dept of Internal Medicine, Hanyang Univ Guri Hospital, Guri-si, Gyeonggi-do, Republic of Korea.

**Introduction:** Though sclerotherapy has been commonly considered as a valid and safe therapeutic option for symptomatic renal cysts, it's effectiveness in recurrent infected renal cyst in autosomal dominant polycystic kidney disease (ADPKD) is rarely reported.

**Case Description:** A 76-year-old woman with ADPKD was again admitted by infected (Lt) renal cyst (7.3 cm) on ultrasonography (US) with similar episode, 1 yr ago. She presented with a fever, dysuria and left CVA tenderness. Despite clinical and laboratory improvement with sensitive antibiotics against Klebsiella pneumonia for 14 days, the size of the infected renal cyst paradoxically enlarged (8.9 cm) on follow-up US. Thus, percutaneous catheter was inserted for drainage and after 1 wk, tubogram showed no evidence of dye leakage (figure1-A). Following complete clinical recovery, absolute ethanol sclerotherapy was performed to prevent further recurrent cyst infection. However, she complained of severe burning pain in low abdomen at the beginning of the procedure. Tubogram dye was shown in pelvocalyceal system and ureter (figure1-B). Sclerotherapy was immediately stopped and saline irrigation was followed. Then, percutaneous catheter was reinserted into the cyst for further drainage; and double-J catheter was inserted at ureteropelvic junction to prevent a ureteral stricture. Then, she underwent uneventful hospital course, and discharged on hospital day 42.

**FR-PO019**

How ‘Idiopathic’ Is Idiopathic Hypermimonemia? Esho Georges, Kavitha Vellanki. Nephrology, Loyola Univ Medical Center, Maywood, IL.

**Introduction:** Idiopathic hyperammonemia is characterized by progressive elevations in serum ammonia of unknown etiology, ultimately leading to cerebral edema and death. It is a rare fatal syndrome described in transplant setting; lung transplant recipients having the highest risk. Calcineurin inhibitors are thought to play a role but the exact mechanism is not known. Here we report an unusual case of severe hyperammonemia that has been linked to donor transmitted Ureaplasma infection.

**Case Description:** A 59-yr-old Hispanic man with idiopathic pulmonary fibrosis received bilateral lung transplant at our center. His induction regimen included thymoglobulin and methylprednisolone and was maintained on tacrolimus, mycophenolate and prednisone. His co-morbidities linked to donor transmitted Ureaplasma infection. Calcineurin inhibitors are thought to play a role but the exact mechanism is not known. Here we report an unusual case of severe hyperammonemia that has been linked to donor transmitted Ureaplasma infection.

**Introduction:** Idiopathic hyperammonemia is characterized by progressive elevations in serum ammonia of unknown etiology, ultimately leading to cerebral edema and death. It is a rare fatal syndrome described in transplant setting; lung transplant recipients having the highest risk. Calcineurin inhibitors are thought to play a role but the exact mechanism is not known. Here we report an unusual case of severe hyperammonemia that has been linked to donor transmitted Ureaplasma infection.

**Case Description:** A 59-yr-old Hispanic man with idiopathic pulmonary fibrosis received bilateral lung transplant at our center. His induction regimen included thymoglobulin and methylprednisolone and was maintained on tacrolimus, mycophenolate and prednisone. His co-morbidities linked to donor transmitted Ureaplasma infection. Calcineurin inhibitors are thought to play a role but the exact mechanism is not known. Here we report an unusual case of severe hyperammonemia that has been linked to donor transmitted Ureaplasma infection.

**Discussion:** In conclusion, underlying infection with urea splitting organisms need to be considered when there is a high rate of ammonia production. And while we are in need of further studies, it may be worthwhile to empirically treat with azithromycin for Ureaplasma infection in so called “idiopathic hyperammonemia”.

**FR-PO021**

A CD2AP Mutation (p.T374A) Associated with Cognitive Decline and Focal Segmental Glomerulosclerosis in Young Adulthood

Dmitry Tsveklyov,1 Yolanda Marie Anistan,1 Christian Harteneck,2 Maik Gollasch,1 Charité Univ Medicine Berlin, Nephrology/Intensive Care, Experimental and Clinical Research Center (ECRC) and Max Delbrück Center for Molecular Medicine, Berlin, Germany; 1Dept of Pharmacology and Experimental Therapy, Inst of Experimental and Clinical Pharmacology and Toxicology, Eberhard Karls Univ Hospitals and Clinics, and Interfaculty Center of Pharmacogenomics and Drug Research, Univ of Tübingen, Tübi.

**Introduction:** Mutations in CD2AP (17q22) gene have been identified in patients with focal segmental glomerulosclerosis (FSGS); however, reports of CD2AP mutations remain scarce.

**Case Description:** We performed Sanger sequencing in a 32-yr-old patient with steroid-resistant FSGS presented with a nephrotic syndrome (proteinuria >3 g/day). The patient reported that his mother and his only brother also have a kidney disease. Neurological examination showed a remarkable cognitive decline within the last 5 years. Therapy with steroid and low-intermediate doses of cyclosporine A led to a persistent reduction of proteinuria. Serum creatinine levels and glomerular filtration rate (eGFR) did not decline during this treatment.

**Discussion:** Our patient displayed mild cognitive decline, a phenotypic characteristic not previously associated with CD2AP-associated FSGS. His proteinuria was remarkably reduced by treatment with cyclosporine A. Our findings expand the genetic spectrum of CD2AP-associated disorders and broaden the associated phenotype with the co-occurrence of cognitive decline. Our case shows that cyclosporin A is a treatment option for CD2AP-associated nephropathy.

**FR-PO022**

Acute Motor and Sensory Axonal Neuropathy-Associated Syndrome of Inappropriate Antidiuretic Hormone Secretion

Weeporn Srisung,1 Aumyot Prongdorn,1 Pavis Laengvejkal,2 Camilo Pena,1 Mustafa G. Aly,1 Sorot Phisitkul.1 1Internal Medicine, TTUHSC; 2Neurology, TTUHSC.

**Introduction:** SIADH is associated with various conditions including Guillain–Barre’ syndrome (GBS). We report a case of SIADH associated with acute motor and sensory axonal neuropathy (AMSAN), a variant of GBS.
Jacksonville, FL.

AMSAN, especially in the setting of euvolemia. SIADH should be high on the differential diagnosis for hyponatremia in patients with

An Unusual Organism with Unusual Renal Manifestations

Rabie L. Adam-Eldien, Charles W. Heilig. Nephrology, Univ of Florida, Jacksonville, FL.

Introduction: Fanconi syndrome is a disease of the proximal renal tubules in which glucose, amino acids, uric acid, phosphate, bicarbonate and other substances are not reabsorbed and lost in the urine.

Case Description: 22 year old African American female with an autosomal dominant Fanconi syndrome. Her disease is clinically manifested by severe rickets and short stature. She had multiple stress fractures, and she ambulates with a walker. Her disease is manifested chemically by generalized aminoaciduria, hyperchloremic metabolic acidosis, hyperphosphaturia, glucosuria, bicarbonaturia, and proteinuria. Her life compliance with the medication has been poor. She has a gastrostomy tube for medications administration. Her medications include Calcium, Carbonate, NeutraPhos, Rocaltrol, Polycitra and Zantac. Her physical examination showed: Height 98.5 cm, weight 15.8 kg, blood pressure 106/57, pulse 80. She can stand up with hips flexed and her trunk slightly deformed from the anterior and lateral bowing of the femur. She has wrinkled metacarpal of the hands and the wrists. She has rickets changes in her ankle prominence, and she has good range of motion. Extremities: Have severe rickets changes. Lower extremities are deformed with prominent femur curve bilaterally. The rest of her exam was uneventful.

Urinalysis shows glucose 100 mg/dL, ketones 40 mg, blood trace, pH 7, protein greater than 300 mg. Chemistry showed, Sodium 134, potassium 3.4, bicarbonate 13, chloride 114, glucose 142, BUN 5, creatinine 0.6, calcium 7.9, phosphorus 3.8. Osmolality 268. Alkaline phosphatase 865. White count 7.3, hemoglobin 14, hematocrit 41.3, platelets 385. Differential diagnosis: Fanconi syndrome lead to multiple defects and impair proximal tubular reabsorption of glucose, phosphate, amino acids, HCO$_3^-$, uric acid, water, K, and Na. It can be caused by a drug or accompanies another genetic disorder. In hereditary Fanconi syndrome, proximal tubular dysfunctions, hyperphosphatemic rickets, hypokalemia, polyuria, and polydipsia usually appear in infancy. If a patient is unable to keep up with the replacement of these substances secondary to compliance or lack of access, adverse permanent skeletal effects might result from that.

FR-P0024

An Unusual Organism with Unusual Renal Manifestations

Brian M. Zwicker, Sreedhar A. Mandayam, David Sheikham-Hamad. Baylor College of Medicine.

Introduction: Infective endocarditis can cause renal failure due to immune complex mediated glomerulonephritis. We present a case of Nontuberculous mycobacteria (NTM) endocarditis associated with acute glomerulonephritis with tubulointerstitial nephritis.

Case Description: Our patient was a 59 y/o Venezuelan man with a history of cocaine use who presented with generalized weakness, intermittent nausea, and a 40lbs weight loss. He denied taking any prescribed or illicit drugs for the previous month. On examination, he was afibrile, HR 85, BP 112/43mmHg. Pulmonary exam was unremarkable, and heart auscultation revealed a 3/6 holosystolic murmur at the right upper sternal border. JVP was normal and there was no edema. Serum creatinine was 4.7mg/dL, BUN 56mg/dL; Hemoglobin 8.9g/dL; UA revealed 2+ protein, 3+ blood, 65 RBCs/HPF, and no casts; Urine P/Cr 1 193g/0; HCG IgG positive; HCV PCR negative; low CR; urine drug screen negative. Blood cultures one-day after admission identified Staphylococcus and Corynebacterium species; on hospital day seven the patient identification was changed to Mycobacterium chelonae/abscessus complex. On hospital day 10, urine microscopy revealed an acute diffuse mesangial proliferative, and exudative glomerulonephritis associated with significant tubulointerstitial nephritis. Focal red blood cell casts were also seen on biopsy. TTE revealed a dilated left ventricle with severe aortic insufficiency and possible vegetations. Unfortunately, the patient died on hospital day 11 from septic shock.

Discussion: Renal pathology associated with infective endocarditis is rare and typically associated with hematuria, proteinuria, and a mild rise in serum creatinine. Two prior case reports described glomerulonephritis associated with NTM, both of which showed improvement in renal function with treatment of the underlying infection. Additionally, infectious endocarditis in association with NTM has been reported in two immunosuppressed patients. Our case is the first to describe both glomerulonephritis and acute tubulointerstitial nephritis in association with nontuberculous mycobacterium. This serves as a reminder that infectious endocarditis can have varied renal manifestations whether the causative pathogen is common or uncommon.

FR-P0025

Severe Hyponatremia in a Young Patient with Recurrent Abdominal Pain

Dimpu M. Patel, Manish K. Saha, Ashita J. Tolwani. Nephrology, Univ of Alabama at Birmingham, Birmingham, AL.

Introduction: Severe renal osteodystrophy as a result of Fanconi syndrome lead to multiple defects and impair proximal tubular reabsorption of glucose, phosphate, amino acids, uric acid, water, K, and Na. It can be caused by a drug or accompanies another genetic disorder. In hereditary Fanconi syndrome, proximal tubular dysfunctions, hyperphosphatemic rickets, hypokalemia, polyuria, and polydipsia usually appear in infancy. If a patient is unable to keep up with the replacement of these substances secondary to compliance or lack of access, adverse permanent skeletal effects might result from that.

Case Description: A 22 year old female presented to the ED with sharp intermittent abdominal and flank pain. Upon arrival to the ED, she had a generalized toxic-clonic seizure requiring intubation for airway protection. For medications were trimethoprim-sulfamethoxazole and ibuprofen prescribed 2 days prior. Previous ED visits for similar episodes of abdominal pain included an extensive workup with negative urine drug screen, abdominal CT scan, pelvic ultrasound, and surgical evaluation. Prior episodes were noted to occur during menstruation. Physical examination was unremarkable apart from tachycardia. Laboratory data was significant for sodium 113mEq/l, urine osmolality 282 mOsm/kg, and serum osmolality 225 mOsm/kg. Renal function, cortisol, TFTs, LFTs, and CBC were normal. Her hyponatremia was initially corrected slowly with 5% saline and later with Medical Diagnosis of SIADH NS infusion for volume expansion. The constellation of recurrent abdominal pain and explained cause of SIADH in a young menstruating female led to the diagnosis of AIP. Studies sent for AIP demonstrated elevated urine total porphyrin 3,374 (normal 0-300 mmol/24 hr), urine porphyrin 115 (normal 0-4 mg/24h), 8-sulfonoypyruvate acid (ALA) delta 79.8 (normal 25-85 mg/24 hr), and RBC proto porphyrin 162 (normal 0-80 mcg/d). She was treated with a carbohydrate based diet and avoidance of medications known to precipitate an acute attack.

Discussion: AIP results from a deficiency of PBG deaminase, leading to accumulation of ALA and PBG. Acute abdominal pain and involvement of supraoptic nuclei, and hypothalamus by the metabolites may trigger constant ADH secretion. Rarely renal and gastrointestinal sodium loss may also cause hyponatremia. Our patient likely had an acute attack triggered by her pain crisis, sulfonamide antibiotic and her menstrual cycle. In the appropriate clinical setting in young patients with hyponatremia, AIP should be considered in the differential diagnosis.

FR-P006

A Case of Solute Diuresis

Muhammad K. Qaseem, Elizabeth A. Gilliams, James L. Bailey. ' Emory Univ School of Medicine, Atlanta, GA.

Introduction: Polyuria is a common manifestation of many primary medical disorders. Here we present a case of Argininosuccinate Lyase Deficiency (ASLD) who presented with altered mental status and later developed polyuria.

Case Description: A 24-year old male with history of ASLD was admitted to the Intensive Care Unit (ICU) for altered mental status with an ammonia level of 347mc mol/L. He was started on Ammonia Scavenger therapy with Ammonium/arginine, Na-benzoate and l-lysine hydrochloride (Ammunol) and Total Parenteral Nutrition(TPN). It was recommended to decrease the dose of Ammonium of 347mc mol/L to 225mc mol/L. In 24 hours he became euvolemic. Fluid restriction was then tried with mild improvement. Endocrine NS infusion for volume expansion. Interestingly, Na did not significantly improve after he became euvolemic. Fluid restriction was then tried with mild improvement. Endocrine work-up ruled out hypothryoidism and adrenal insufficiency. Repeat labs showed Na 114, glucose 152, BUN 5, creatinine 0.6, sodium chloride of 145 mmol/L, and Na 130 mmol/L.

Discussion: Although GBS is a well-established cause of SIADH, but our knowledge, AMSAN-associated SIADH has only been rarely reported in literature. We suggest that SIADH should be high on the differential diagnosis for hyponatremia in patients with AMSAN, especially in the setting of euvolemia.
Life Threatening Hypokalemia and Metabolic Alkalosis Related to Paraneoplastic Cushing's Syndrome

Introduction: Paraneoplastic Cushing's syndrome (CS) develops secondary to tumoral ATC and often CRH production. Classical stigmata of CS are often absent, and purple striae and buffalo hump are uncommon. Hypokalemia associated with metabolic alkalosis more commonly occurs with eutopic ACTH. The unique case of severe hypokalemia with metabolic alkalosis related to eutopic ACTH production.

Case Description: A 58 y/o African American male presented with complaints of feeling unwell, weight loss and frequent diarrhea for at least one month. On admission, he was found to be hypertensive with BP 157/87 mmHg, heart rate 72 bpm, and a pulse oximetry of 94% on room air. He had mildly elevated CRP and negative for diarrhea. Laboratory data revealed: Na 134 mEq/L, K 3.1 mmol/L, Cl 103 mEq/L, CO2 22 mmol/L, BUN 84 mg/dL, and creatinine 5.6 mg/dL. Patient was started on DDA VP to slow down correction and sNa levels were checked every 4 hours. The patient was ultimately discharged on POD 10 with a sNa of 143 mEq/L and off DDAVP.

Discussion: This is a rare case of paraneoplastic CS associated with neuroendocrine carcinoma. Early recognition and appropriate treatment for this syndrome is important, although overall clinical outcome remains poor.

Central Diabetes Insipidus with Pituitary Atrophy from Chronic Lithium Use

Introduction: Lithium is used commonly associated with nephrogenic diabetes insipidus (NDI) and rarely with central diabetes insipidus (CDI). The mechanism of Lithium associated CDI is unclear. We report a patient on chronic lithium therapy who developed CDI and partial NDI and who had atrophy of posterior pituitary atrophy on MRI.

Case Description: A 62 yo woman with diabetes mellitus 2 for 5 years, hypertension for 10 years, and bipolar disorder on lithium for 40 years was admitted to the ICU for altered mental status. ROS was negative for nausea, vomiting, diarrhea, acute intoxication or infectious prodrome. Physical exam was normal; she was clinically euolemic. Urine output was 4-8 l/d and a serum Na was 178 mEq/L. Serum creatinine was 4.84 mg/dl, elevated from a baseline of 1.5 in 2012. Urine osmolality (U osm) was < 100 mosm/L. Intravenous D4W at 200 ml/h caused improvement in serum creatinine to 1.7 mg/dl but minimal reduction in serum Na. Water restriction produced a supramaximal rise (<250 mosm/L) in U osm from 157 to 176. ADH levels were undetectable by RIA when serum Na was 165-175. Intravenous desmopressin produced submaximal elevation in urine osmolality from 80 to 153 (91.25%), consistent with partial NDI (U Osm < 250 mosm/l) and partial CDI (<15 to 99%). MRI demonstrated atrophy of the posterior pituitary, with non-specific volume loss, straightening of the infundibulum, and absence of bright spot corresponding to the posterior pituitary. Final diagnosis was both central and nephrogenic DI associated with lithium use. Euthyremia was eventually achieved with intranasal DDAVP and liberal fluid intake. Discussion: This is the first report of radiological evidence of posterior pituitary atrophy with lithium-associated central DI. Possible mechanisms of posterior pituitary atrophy may include “burn-out” from chronic hypersecretion of ADH caused by lithium induced nephrogenic diabetes insipidus or autoimmune hypophysitis from circulating autoantibodies developed in response to chronic high ADH levels.

Severe Hypocalcemia in a Hemodialysis Patient

Introduction: Severe hypocalcemia in a hemodialysis patient is rare in the absence of parathyroidectomy, vitamin D deficiency or calciniferolic drugs.

Case Description: A 58 year old man with history of hypertension and coronary artery disease was admitted to intensive care unit for un-witnessed cardiac arrest. He was intubated and started on vasopressin and norepinephrine for cardiacogenic shock. His lab data on admission revealed normal serum sodium, blood urea nitrogen and creatinine. His inpatient course was significant for development of hypocalcemia within 2 hours of initiation of vasopressin infusion. Patient’s sodium dropped from 142 mosm/L(normal range 136-146 mosm/L) to lowest value of 124 mosm/L associated with oliguria (urine output 20ml/ hr). With cessation of vasopressin, urine output increased significantly to 500ml/hr and serum sodium increased from 124 mosm/L to 142 mosm/L. Dextrose infusion was started to prevent overly rapid correction. Please refer to graph for the changes in the serum sodium and urine output with vasopressin infusion over time. Patient had normal cortisol levels and thyroid function.

Iatrogenic Hypoosteratina

Introduction: Vasopressin acts in the kidney via V2 receptors to regulate water resorption and on the vasculature via V1 receptors to regulate smooth muscle tone. It is often used in the management of shock, but rarely causes hyponatremia in hemodynamically unstable patients. We present here a case of a man who developed marked hyponatremia during vasopressin infusion.

Case Description: A 58 year old man with history of hypertension and coronary artery disease was admitted to intensive care unit for un-witnessed cardiac arrest. He was intubated and started on vasopressin and norepinephrine for cardiacogenic shock. His lab data on admission revealed normal serum sodium, blood urea nitrogen and creatinine. His inpatient course was significant for development of hyponatremia within 2 hours of initiation of vasopressin infusion. Patient’s sodium dropped from 142 mosm/L(normal range 136-146 mosm/L) to lowest value of 124 mosm/L associated with oliguria (urine output 20ml/ hr). With cessation of vasopressin, urine output increased significantly to 500ml/hr and serum sodium increased from 124 mosm/L to 142 mosm/L. Dextrose infusion was started to prevent overly rapid correction. Please refer to graph for the changes in the serum sodium and urine output with vasopressin infusion over time. Patient had normal cortisol levels and thyroid function.
Hyperkalemia Secondary to Octreotide Use in a Patient with Normal Kidney Function

FR-PO032

Introduction: Octreotide, a somatostatin analogue works by reducing blood levels of a variety of hormones (e.g. growth hormone, insulin) and chemical messengers (e.g. gastrin, vasoactive intestinal peptide). Octreotide therefore has been used as an effective treatment for the management of ghrelinoma, acromegaly, VIPoma and carcinoid syndrome. Octreotide-induced hyperkalemia has rarely been reported in the literature. We report a patient with normal renal function who developed hyperkalemia secondary to octreotide use.

Case Description: A 70-year-old male with long standing history of DM (since 20 years), HTN, and metastatic neuroendocrine pancreatic cancer was referred by his oncologist for evaluation of severe hyperkalemia (serum potassium level of 6.6 mmol/L). Patient was diagnosed with pancreatic neuroendocrine tumor approximately 2 years prior to his presentation for which he underwent Whipple procedure. He was also receiving subcutaneous octreotide monthly for nearly 1.5 years prior to his presentation. There was no history of kidney disease or any urinary complaints. Other medications included aspirin, insulin, creon, levotyrodone and HCTZ. BP was normal and patient was noted to have bilateral lower extremity pitting edema on examination. Other labs done 5 days prior to presentation showed normal serum bicarbonate (25 mEq/L), normal serum creatinine (1.23 mg/dL), and elevated serum glucose (263 mg/dL). On reviewing medical records, our patient was noted to have chronic and persistent hyperkalemia over the previous six months that was medically managed by intermittent oral sodium polystyrene sulfonate. All other causes of hyperkalemia were clinically excluded. Serum potassium normalized after receiving medical management and holding octreotide treatment.

Discussion: We present a rare case of octreotide-induced hyperkalemia in a patient with normal renal function. We believe that hyperkalemia in our patient occurred as a result of octreotide-induced insulin suppression and resultant impaired cellular potassium uptake. Based on our experience, one should be aware of this potential life-threatening side-effect of octreotide therapy.

FR-PO033

Hypercalcemia and Acute Kidney Injury due to Immune Reconstitution Syndrome in an HIV Patient on HAART and MAC Therapy

Anand Achanta, Omar M. Shahaateet, Karl Berthold Pembaur, Nithin Karakala, Juan Carlos Q. Velez. Nephrology, Med Univ of South Carolina, Charleston, SC.

Introduction: Hypercalcemia can occur in HIV-infected patients due to several conditions such as granulomatous diseases, lymphomas, and solid tumors. HIV patients are also susceptible to causes found in the general population, such as primary hyperparathyroidism, medications, and vitamin D supplementation.

Case Description: A 48 year old male with history of HIV and disseminated Mycobacterium avium complex (MAC) was sent to the hospital after being found to have a serum calcium of 15.5 mg/dl and serum creatinine of 5.8 mg/dl on routine labs. His only complaint was weakness. Five months prior to presentation, patient had an adjustment of his highly active antiretroviral therapy (HAART) with a viral load of 76,000 copies/mL, CD4 count of 36/μM, serum calcium of 9.6 mEq/L, and serum creatinine of 2.6 mg/dl at that time. Previous renal dysfunction was caused by intermittent nephritis diagnosed 6 weeks prior. Patient reported increased compliance to his new regimen for several weeks prior to presentation, reflected by an increase in CD4 count of 138 /μM earlier and undetectable viral load upon presentation. Workup for hypercalcemia included: low PTH of 5.8 pg/mL, low PTH-rp of 0.7 pmol/L, and a high 1,25 Vitamin D of > 200 pg/mL. Serum and urine protein electrophoresis showed a restricted kappa lambda ratio and bone marrow biopsy were normal. Imaging was negative for lymphoma. The patient was managed with volume repletion, prednisone 60 mg qd, and IV pamidronate 60 mg with gradual improvement of his calcium to 8.8 mg/dl and creatinine to 2.8 mg/dl in 9 days. Steroids were tapered and the patient remained stable 6 months later.

Discussion: Our patient developed acute kidney injury secondary to severe hypercalcemia, likely due to renal vasoconstriction and volume depletion superimposed over interstitial nephritis. The etiology of hypercalcemia was likely immune reconstitution syndrome caused by the restoration of HAART. In patients with HIV and AIDS with history of granulomatous disease, it is important to monitor for hypercalcemia when initiating HAART therapy or adjusting therapy.

FR-PO034

Hypocalcemia in Severe Malnutrition, and Acute Pancreatitis Veils Vitamin D Intoxication

Kamran Karimi, Catherine Miranda, Yezina T. Nigatu, Kelly H. Beers, Naad K. Wadhwa. Nephrology, Stony Brook Univ Medical Center, Stony Brook, NY.

Introduction: Although vitamin D has a wide therapeutic index, a routine use of high doses of vitamin D intake can cause toxicity. We report a case with severe hypocalcemia likely due to malnutrition and pancreatitis related to alocoholism followed by hypercalcemia from vitamin D toxicity.

Case Description: A 43 year-old woman with alcoholism was admitted with rhabdomyolysis and alcohol induced acute pancreatitis. On initial examination she was in moderate distress with altered mental status and diffuse abdominal pain. Her blood pressure was 102/67 mmHg, heart rate 136/min and temperature 38.3°C. Her lab data revealed WBC 54.71 x10^9/L, Hb 16.9 g/dL, PLTs 186 x10^9/mL, serum Na 129 mEq/L, K 3 mEq/L, bicarbonate 19 mEq/L. BUN 132 mg/dL and creatinine 1.3 mg/dL. Her 25(OH)D was 17.7 μg/dL, vitamin D 25OHD 1.7 μg/dL, CPK 1089 IU/L, albumin 2.9 g/dL. She received intravenous Ca, Mg, K and phosphorus in addition to oral supplements. On day 4, her serum Ca was 8.7 mg/dL, albumin 2.5 g/dL, phosphorus 4.0 mg/dL and K 3.9 mmol/L without any supplement. Her serum Mg remained low and continued to receive oral and intravenous Mg supplements. Serum Ca was not checked between days 9-14 of her hospitalization. On day 15, her serum Ca was 12.8 mg/dL, ionized Ca 6.4 mg/dL, vitamin D 25OH 370 ng/mL, vitamin D 1-25 OH 149 pg/ml and intact PTH 11.8 pg/mL. Her TSH, T4, ACE and vitamin A levels were normal. Her 24 hours urine revealed Na 140 mg/mL, K 70 mmol, creatinine 1110 ng/mL, UN 4.1 g, Ca 462 mg, Mg 403 mg , phosphorus 931 mg. She admitted taking vitamin D 50,000 units daily for many months for her psoriasis on her own. Her hypercalcemia was treated and her serum calcium stabilized over one week to 9.4 mg/dL while her vitamin D 25OH and vitamin D 1-25 OH remained elevated over the next 6 weeks.

Discussion: Her unusual presentation of hypocalcemia masked vitamin D toxicity till she resumed regular nutrition. Her hypocalcemia was likely related to malnutrition due to chronic alcoholism and possible calcium deposition due to acute pancreatitis. With proper nutrition during her hospitalization and improvement of her underlying condition led to hypocalcemia due to vitamin D toxicity.

FR-PO035

Re-Defining the Speed Limit in Osmotic Demyelination Syndrome?

Malrukh Rizvi, Rebecca D. Monk. Nephrology, Univ of Rochester Medical Center, Rochester, NY.

Introduction: Osmotic demyelination syndrome (ODS) is a severe, debilitating, possibly fatal, neuro-radiological condition that results from rapid correction of severe chronic hypernatremia. Imaging reveals central pontine myelinolysis (CPM). Potential added risk factors for ODS include Sodium (Na) < 120 mmol/L, alcoholism, malnutrition and liver transplant. Current recommendations advise raising serum sodium by less than 9 mmol/L in 24 hours. We present a case of ODS in a patient presenting with severe hypernatremia corrected at a maximum rate of 8mEq/dL in 24 hrs.

Case Description: A 37 year old man with a history of alcohol abuse was sent in to the hospital by police after a car accident for jaundice. He endorsed two weeks of worsening jaundice and right upper quadrant (RUQ) pain. Admission vital signs were stable. Physical exam revealed marked jaundice, abdominal distention and RUQ pain. Work up revealed severe alcoholic hepatitis with cirrhosis and metabolic derangements including a Na of 105 mmol/L, Cholesterol of 69 mmol/L, urea nitrogen of 45 mg/dl, creatinine of 2.13 mg/dl with unknown baseline. 3% saline with ddA VP was initiated for cautious correction of severe chronic hyponatremia. Imaging reveals central pontine myelinolysis (CPM). Potential added risk factors for ODS include Sodium (Na) < 120 mmol/L, alcoholism, malnutrition and liver transplant. Current recommendations advise raising serum sodium by less than 9 mmol/L in 24 hours. We present a case of ODS in a patient presenting with severe hypernatremia corrected at a maximum rate of 8mEq/dL in 24 hrs.

A Case of Axenfeld-Rieger Syndrome Presenting with Elevated Serum Bicarbonate

Rudrick V. Ledesma, Maureen E. Brogan, Venkata Buddharaju, Rahul N. Pawar, Rajat Lama. Westchester Medical Center, NY.

Introduction: Elevated serum bicarbonate can often be misdiagnosed as metabolic alkalosis leading to improper management. Chronic respiratory alkalosis caused by central hypoventilation can lead to elevated bicarbonate secondary to renal compensation. We present a case of central hypoventilation caused by cerebellar-pontine lesion in a patient with Axenfeld-Reiger syndrome (ARS).

Case Description: A 25 yo man with PMH of glaucoma, developmental delay, schizoaffective disorder sent to the ED for respiratory failure. He was seen earlier in renal clinic for treatment of elevated serum bicarbonate. He was complaining of fatigue and insomnia. Arterial blood gas was done and showed a pH of 7.30, pCO2 of 79, PO2 of 63 and HCO3 of 38.9. He was eventually admitted for further management. While in the hospital, he continuously needed bilevel positive airway pressure. Chest ultrasound showed little to no movement of his diaphragm. EMG was negative. PFT was suboptimal as he wasn’t able to follow the instructions. MRI brain showed a mass on his right cerebellar-pontine angle. He was also diagnosed with ARS during his hospital stay. The mass was resected and progressive improvement was observed in his respiratory status. He was eventually weaned off bilevel positive airway pressure and was discharged home without any need for respiratory support.

Discussion: Elevated serum bicarbonate can often pose a diagnostic challenge. Evaluation should start with an ABG which would differentiate a primary metabolic alkalosis from a renal compensation of respiratory alkalosis. Differential diagnoses for respiratory alkalosis include central hypoventilation, primary lung pathology, neuromuscular disease and airway pathology. Central hypoventilation could be secondary to lesions in the respiratory center. ARS presents as a spectrum of developmental disorders resulting from abnormal migration and differentiation of neural crest cells with both ocular and systemic manifestations. The regions in the brain that are usually affected are forebrain and pituitary gland. Our case is interesting as he had ARS with epidermoid cyst which we believe has led to central hypoventilation and elevated bicarbonate as compensatory mechanism.

Signet-Ring Cell Carcinoma Presenting as Frequency of Urination

Haya Waseem Siddiqui, Daniel E. Carl, Todd W. Gehr. Nephrology, Virginia Commonwealth Univ, Richmond, VA.

Introduction: Urinary tract obstruction may occur at any site in the urinary tract and is important to recognize early since it is readily reversible if quickly corrected.

Case Description: 45 year old male with obesity, history of gastric bypass surgery, hypertension and obstructive sleep apnea who presented to our institution for evaluation of frequency of urination. He developed progressively worsening frequency of urination, occurring every hour during the day and night for 3 months prior to presentation. During this time, his serum creatinine was 1.6 mg/dL. He had been seen multiple times by an Urologist and Primary Care Providers outside our institution, and was diagnosed with prostatitis despite negative urine cultures and no pyuria. During the work up, an out-patient CT scan revealed mild bilateral hydronephrosis and mild left hydroureter. Furthermore, an office cystoscopy revealed diffuse inflammatory cystitis of the bladder and no definitive bladder outlet obstruction. Over the ensuing 3-4 weeks, he developed acute kidney injury, with a serum Cr that peaked at 6mg/dL. This prompted an admission to an outside facility. He was again found to have mild bilateral hydrourerectos, however, ureteral stents were attempted, but unsuccessful. A repeat cystoscopy revealed severely inflamed bladder tissue, and a ureteral stent was not visualized. His ureteral biopsy was done. Patient was transferred to VCU for placement of percutaneous bilateral nephrostomy tubes by interventional. He had successful stent placement by IR followed by post obstructive diuresis treated with intravenous fluid hydration in the form of saline. His AKI improved as his urine output normalised on follow-up imaging study. His serum Cr improved to 1.3 mg/dL and repeat CT scan with intravenous contrast was obtained for staging which showed circumferential bladder wall thickening with asymmetric soft tissue prominence along the right anterior dome most consistent with bladder neoplasm. Outside pathology report was consistent with signet cell carcinoma of bladder.

Discussion: Signet-ring cell carcinoma a rare bladder tumor can result in acute kidney injury secondary to bilateral ureteral obstruction.

A Case of Tenofovir-Induced Nephrotoxicity

Jennifer Thompson, Juan Carlos Q. Velez, Nithin Karakala. Nephrology, Lankenau Medical Center, Wynnewood, PA.

Introduction: Many forms of chemotherapy carry a risk of electrolyte abnormalities. Tenofovir is an antiretroviral agent used in the treatment of HIV and hepatitis B. Most studies suggest that TFV has only a modest effect on renal function. Phase I and II trials have reported hypomagnesemia, hypokalemia and oral supplements three times a day and serum magnesium remains at 1.4-1.5 mg/dL. This case report describes a patient who developed severe hypomagnesemia requiring very aggressive repletion strategies.

Case Description: A 36 y/o non-alcoholic female with past medical history of hypertension well controlled on diet therapy, was diagnosed with invasive ductal carcinoma of the breast requiring initiation of chemotherapy with docetaxel and carboplatin with Trastuzumab. She received a total of 6 cycles of chemotherapy every three weeks and Trastuzumab 2gm weekly infusion. After completion of chemotherapy, the dose of Trastuzumab was increased to 6gm per infusion every three weeks. Her serum magnesium level which was 2.1mg/dl in the beginning of chemotherapy was noted to be low at 0.5mg/dl when she presented with generalized weakness to the hospital six months into the treatment. At this time, she had completed her chemotherapy 2 months ago and was on Trastuzumab only. She was on lasix and proton pump inhibitors at that time, both of which were stopped immediately. However her serum magnesium remained low between 0.6-1.0 mg/dl persistently for next few months requiring intravenous infusions every week. On repeated testing, fractional excretion of magnesium remained high indicating renal wasting. Although patient was hypokalemic initially, it corrected immediately after stopping loop diuretics and remained normal ruling against tubulopathies such as Gitelman or Bartter syndrome. She remained hypomagnesemic despite completing one year course with Trastuzumab. She is receiving once a week intravenous infusions of magnesium and oral supplements three times a day and serum magnesium remains at 1.4-1.5 mg/dL.

Discussion: Trastuzumab is a human epidermal growth factor (HER-2) inhibitor which belongs to the family of epidermal growth factor receptor (EGFR). EGFR is involved in increasing the magnesium absorption in the distal nephron by increasing the transcription of the genes regulating TRPM6 channels. Hypomagnesemia has been well reported in other EGFR inhibitor with Cetuximab used in colon cancer and Erlotinib used in lung cancer, but not reported in patients taking Trastuzumab, especially after escalating to higher doses.

A Case of Severe Hypomagnesaemia in a Patient Treated with Trastuzumab

Saifullah Kazi, Ghulam Akbar, Paul Robbins. Nephrology, Lankenau Medical Center, Wynnewood, PA.

Introduction: A Case of invasive ductal carcinoma that was treated with chemotherapy including Trastuzumab found to have severe hypomagnesemia requiring very aggressive repletion strategies.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
caused by captecitabine. The patient exhibited Barter’s like physiology with increased renal loss of calcium, magnesium, and sodium and evidence of metabolic alkalosis. Unlike the proximal tubulopathy associated with captecitabine, the pathophysiology of acquired Barter’s with is unknown but could be caused by direct inhibition of apical NaKCC or ROMK, or activation of the calcium sensing receptor on the basolateral surface in the thick ascending loop of Henle.

FR-PO041

Uncommon Case of Severe Hypercalcemia After Renal Transplantation Rapeepat Lekkhak. Gitana Bradiauskate. Nephrology, Einstein Medical Center, Philadelphia, PA.

Introduction: Following renal transplantation, hypercalcemia is frequently caused by persistent hyperparathyroidism, but other causes should be kept in mind. We report a case of hypercalcemia after renal transplant from uretreated extrarenal 1,25-dihydroxyvitamin D synthesis from disseminated tuberculous and cryptococcosis.

Case Description: The patient was a 59-year-old male with unknown etiology of ESRD who received a living unrelated kidney transplant. He was stable on low dose immunosuppressive agents for history of BK virus infection. At 10 months post-transplant, the patient diagnosed with disseminated cryptococcosis with granulomatous sementeric mass and positive serum cryptococcal antigen. High dose oral fluconazole was started. 10 days later, he readmitted with severe hypernatremia, severe hypercalcemia (corrected serum Ca peak at 14.72 mg/dl) and acute renal failure (serum Cr peak at 5.8 mg/dl from baseline 1.6 mg/dl). The iPTH level was suppressed to 2.8 pg/ml. The serum 1,25(OH)D level was elevated and levels of 25(OH)D fell. Serum phosphate rose and ALP levels were elevated.

PTH-related peptide was negative. Serum immunoelectrophoresis with immunofixation showed a monoclonal protein pattern of IgG kappa with normal ratio of free kappa and lambda light chain. Kidney biopsy revealed acute tubular necrosis, no evidence of granulomatous or lymphoproliferative disease. CT chest revealed right upper lobe mass with calcified granuloma at lung base. Culture from lung biopsy showed strongly positive for Mycobacterium Tuberculosis. Anti-tuberculosis drugs were started and mycoprotein motifel was held. Elevated calcium levels were unresponsive to calcitonin, therefore neither diuretic. After his sputum AFB became negative, the oral prednisone was increased to 40mg/day. Hypercalcemia and hyperphosphatemia normalized upon one month follow up and remained stable until finished 6 months course of anti-tuberculosis drugs and the creatinine returned to baseline.

Discussion: Unlike persistent hyperparathyroidism, underlying diseases of PTH independent hypercalcemia after renal transplantation like a granulomatous disease can lead to significant morbidity and mortality. Early recognition and prompt treatment is necessary.

FR-PO042

Treatment of Malignancy-Associated Hypercalcemia with Low Calcium Hemodialysis Yields Several Benefits for Cancer Patient Roza B. Ali, Akshitha Rao, Suzanne Boyle, Jesse M. Goldman. Div of Nephrology and Hypertension, Drexel Univ College of Medicine, Philadelphia, PA.

Introduction: Hypercalcemia of malignancy can be fatal. In literature, primary treatment remains forced saline diuresis while dialysis is seldom considered. We present a case of severe, refractory hypercalcemia associated with diffuse large B-cell lymphoma that was treated with low calcium (Ca) hemodialysis (HD).

Case Description: A 56 year-old male presented with 3 weeks of weakness and constipation. He noted a serum creatinine (Cr) of 1.45mg/dL, Ca of 11.8mg/dL, and ionized Ca of 2.3. Urine microscopy had pigmented granular casts. Cause of acute kidney injury (AKI) was attributed to hypovolemia, acute tubular necrosis and Ca-induced vasoconstriction. He had a PTH of 7pg/ml, PTH-ep of 2.1pmol/L, vitamin D 25,000IU, and 1,25OH of 18ng/ml. Non-contrast CT chest demonstrated diffuse lymphadenopathy with LN biopsy showing diffuse large B-cell lymphoma. On day 1, patient received several liters of normal saline, calcium, and pamidronate. Despite maximal medical therapy, he had delirium, persistent AKI with Cr peak to 2.6mg/dl and elevated Ca at 15mg/dl. On days 3, 4, and 5, he received consecutive 4-hour sessions of intermittent HD with low Ca (2mg/L) dialysate using a 0180 high flux dialyzer with blood flow of 400mL/hr. On day 6, Ca decreased to 10.4mg/dl and mental status improved. He received induction chemotherapy on day 13 with cyclophosphamide, doxorubicin, rituximab, and vincristine. At discharge, Cr was 1.66mg/dL and Ca level was 12mg/dL.

Discussion: Despite treatment with low Ca HD is potentially underutilized. Conventional methods of management have therapeutic and temporal limitations. We found low Ca HD to be a useful adjunctive tool for treatment in our case of malignancy-associated severe hypercalcemia. With low Ca HD, care must be taken to avoid hypotension from volume depletion and vasoconstriction from high Ca flux. Our patient tolerated dialysis without adverse events. Adding low Ca HD to other treatment modalities likely contributed to rapid symptom improvement and mitigation of further Ca-mediated renal injury, allowing for timely chemotherapy induction.

Successful Treatment of Anti-Angiotensin II Type 1 Receptor Antibodies Associated with Refractory Antibody-Mediated Rejection and Acute Cellular Rejection in Kidney Transplantation: A Case Report
Punlop Wiwattanathum, Atiporn Ingtsath. Nephrology Unit, Faculty of Medicine Ramathibodi Hospital, Mahidol Univ, Bangkok, Thailand.

Introduction: Angiotensin II type 1 receptor (AT1R) antibody has been proved that it can be detrimental to kidney allograft. Similar to HLA-antibody, patients who have AT1R antibody are at risk for rejection and poor allograft outcome. There is no standard treatment in this situation but the aim is to remove pathologic antibodies and suppress antibodies production. Outcomes after treatment are unsatisfactory and not well established. Herein we present a successful treatment kidney transplant patient who experienced AT1R antibody mediated rejection.

Case Description: A 50-year-old male with hypertension and ESRD underwent a disease donor kidney transplantation using a graft from acute kidney injury donor with peak serum creatinine of 1.24 mg/dL. No intraoperative complication occurred, urine flow rate of 300 ml/hr was observed immediate postoperative but abruptly decreased to 20 ml/hr at 8 hours posttransplantation. Acute rejection was suspected, thus allograft biopry was done. The histopathological findings were compatible with acute cellular rejection combined with antibody-mediated rejection (ABMR). AT1-R antibody was detected at level of 15.0 mL/mL. Anti-rejection therapies were offered with steroid, IVIG, plasmapheresis, anti-thymocyte globulin and rituximab. At 8 weeks posttransplantation, rejection was well controlled with stable serum creatinine of 1.5 mg/dL.

Discussion: Although AT1R antibody associated rejection has rarely been reported, the outcomes after rejection are unsatisfactory. Early detecting rejection and rapid antibody removal seem to be the most effective treatment that prolong allograft function in present time. There are limited and controversial data about long term graft survival by treating patient with angiotensin receptor blocker.

Hemodialfiltration for Hepatic Encephalopathy Induced by Budd-Chiari Syndrome in a Patient with End-Stage Kidney Disease Takuya Wakamatsu, Suguru Yamamoto, Takeshi Nakatsu, Junichiro K. Kazama, Ichiei Narita. Div of Clinical Nephrology and Rheumatology, Niigata Univ Graduate School of Medical and Dental Sciences, Niigata, Japan.

Introduction: Budd-Chiari Syndrome (BCS) is defined as portal hypertension caused by obstruction of the inferior vena cava at the liver. Severe BCS induces hepatic encephalopathy, and has known to be exacerbated during hemodialysis (HD) treatment in end-stage kidney disease (ESKD) patients, probably due to lowering branched-chain amino acid (BCAA)/aromatic amino acid (AAA) ratio and reducing blood flow in the portal vein. Hemodialfiltration (HDF) has been proposed be effective for some dialysis-related complications due to better removal of middle sized uremic toxins and preservation of plasma osmolality, compared with HD. Here, we present a patient with ESKD who developed hepatic encephalopathy after progression of BCS, which was ameliorated by HDF.

Case Description: The patient was a 36-year-old woman complaining of a consciousness disorder. She was diagnosed with BCS as a consequence of antiphospholipid syndrome presented at 21 years of age. Her kidney function impaired gradually, and progressed to ESKD. After initiation of HD, transient loss of consciousness due to hepatic encephalopathy occurred frequently. After her blood purification therapy was changed to online HDF, her hepatic coma improved dramatically (West Haven grade, 0.07 to 0.27 vs. HD, 0.95±1.11). Compared with HD, increased the removal of AAAs (phenylalanine: 43.6% vs. HD, 10.7%; tyrosine: 73.0% vs. HD, 35.3%), contributing to the increased BCAA/AAA ratio was observed after HDF session.

Discussion: In this case, hepatic encephalopathy was worsened by HD treatment in a patient with ESKD due to BCS, and was improved by HDF, with increased removal of AAAs. Hepatic encephalopathy is thought to be exacerbated by HD due to portal systemic bypass or shunting and/or perturbation of the amino acid profile. Tryptophan, one type of AAA, has especially a high protein-binding rate (50%-90%), and only a small amount of protein-bound tryptophan is removed by HD. Therefore, one of the reasons why HDF ameliorates hepatic encephalopathy is increased removal of protein-bound AAAs, leading to increased BCAA/AAA ratio.

FR-PO047

De Novo Lupus Nephritis in a Stable Kidney Transplant Recipient Laura Panarey, Karthik M. Ranganna, Alden Michael Doyle. Division of Nephrology & Hypertension, Drexel Univ Hahnemann Hospital, Philadelphia, PA.

Introduction: De novo Lupus Nephritis (LN) is an exceedingly rare complication in kidney transplant recipients, previously reported only twice, neither recipient noted to have clinical manifestations of SLE. The scarcity of autoimmune disease in this population is not fully understood, but has been attributed to the maintenance immunosuppression used to prevent allore cognition and rejection.

Case Description: Herein, we present a de novo LN in a 55-year-old woman with post streptococcus glomerulonephritis and HTN; 28 years status-post living-related kidney transplant. The patient had no personal or family history of autoimmune disease at transplant. Three years ago, she began complaining of episodic carpo-pedal spasm and scleritis; laboratory abnormalities included mildly low albumin and stable IgG proteinuria. Medications were stable and no potentially provocative antigens, vaccines or transfusions, were given during this period. Immunosuppression included cyclosporine and low dose prednisone. Seven months ago, the patient developed malar rash and hemo-proteinuria prompting immunological studies and kidney allograft biopsy. Anti-nuclear, double stranded DNA, Smith and histone antibodies were all strongly positive with low serum complement levels. Serum creatinine increased by 0.5 mg/dL from baseline; urine protein to creatinine ratio revealed nephrotic range proteinuria peaking at 9.6 grams. Immunofluorescence revealed granular “full house” pattern, C4d negative; Electron microscopy revealed intramembranous deposits. The patient was treated with high dose prednisone, continued cyclosporine and addition of mycophenolate mofetil.

Discussion: Although rare, de novo auto-immune disease should be considered for transplant patients despite maintenance immunosuppression.

FR-PO048

Atypical Hemolytic Uremic Syndrome Allograft Outcome in the Post Eculizumab Era Laura Panarey, Karthik M. Ranganna, Alden Michael Doyle. Division of Nephrology & Hypertension, Drexel Univ Hahnemann Hospital, Philadelphia, PA.

Introduction: Atypical Hemolytic Uremic Syndrome (aHUS) is an exceedingly rare etiology of renal failure. Forms of HUS are often linked to underlying viral illness or particular classes of immunosuppression in transplant recipients. Exceedingly rare are genetic etiologies of aHUS for which transplantation is undesirable due to very high recurrence rates of disease.

Case Description: Herein we describe a case of misdiagnosis; 78 year old man initially diagnosed with rapidly progressive glomerulonephritis (RPGN) by kidney biopsy developed anuria necessitating hemodialysis. The patient had no family history of kidney disease. Immunological work-up negative for anti-nuclear or cytoplasmic antibodies; complement deemed within normal limits. Pt received a living-unrelated kidney transplant from a 40 year old healthy donor. Standard induction solumedrol and thymoglobulin. Initiation of maintenance calcineurin inhibitor (CNI), steroid, antimitabole. Favorable outcomes were observed, creatinine 1.77 mg/dL and urine output upon discharge. One week post-transplant, patient was observed to have increased creatinine, peak 4mg/dL, not amenable to discontinuation of CNI or typical offending agents; prompting renal biopsy. Histologically Thrombotic Microangiopathy (TMA), C4d (-) observed and deemed comparable to native biopsy slides. Laboratory studies confirmed aHUS(-)ADAMTS13; low lactate dehydrogenase, elevated haptoglobin; peripheral smear histiocytes. Negative viral studies including Shiga toxin. Pt treated with high dose solumedrol, plasma exchange and eculizumab; resolution of kidney function, creatinine 1.88 mg/dL, month post-transplant period. Interim six month follow-up, with twice monthly eculizumab reveal no recurrent TMA on biopsy; despite bouts of acute kidney injury related to CNI levels or vascular thickenings.

Discussion: aHUS, as presented above, may be misdiagnosed and therefore present at the time of post-transplant recurrence. With the advent of treatment, alternative pathway complement inhibitor eculizumab, a high degree of suspicion must be maintained when managing post-transplant dysfunction.

FR-PO049

An Unusual Manifestation of Disseminated Histoplasmosis in a Renal Transplant Patient Kana N. Miyata, Lilly M. Barba. Nephrology, Harbor-UCLA Medical Center, Torrance, CA.

Introduction: Disseminated histoplasmosis is rare but can develop in immunosuppressed patients. This patient was a 42 year-old man with ESRD secondary to unclear etiology, who had a living related renal transplant from his cousin 4 years ago in Mexico. He was born in El Salvador, moved to California at age 7, and had traveled to Mexico and Cuba (last travel 1 year ago). His post-transplant course was complicated by antibody mediated rejection and borderline acute cell mediated rejection 2 years ago, for which he was successfully treated with IVIG, plasma exchange, and rituximab. His medication included tacrolimus, MMF, and prednisone. He presented with 2-3 weeks of fever and mild abdominal pain after unsuccessful treatment with ciprofloxacin. He had a platelet count of 387.
It has been postulated that complement activation might have a role, but this patient had normal complement levels. A therapeutic challenge. Hemodialysis (HD) using a standard Na\textsuperscript{+} 140 mEq/L bath was required, but HD would have risked overly rapid correction of hyponatremia via continuous venovenous HD (CVVHD) against a standard bath using a dialysate rate of 2 L/hr and blood flow rate was 200 cc/min. Net target was zero, with all drips included in the calculation. We simultaneously infused DSW at 100 cc/hour. [Na\textsuperscript{+}] was monitored every 4 hrs. The DSW was hold if [Na\textsuperscript{+}] rose to 140 mEq/L, or if the [Na\textsuperscript{+}] rise was 0.5 mEq/L or 6 mEq/L in 24 hrs. It was to be reduced if the correction was suboptimal. The patient’s [Na\textsuperscript{+}] rose from 118 mEq/L to 125 mEq/L on day 1, 125 mEq/L to 131 mEq/L on day 2, and reached 137 mEq/L by day 3. The patient was then safely converted to HD.

Discussion: CVVHD is a safer option for RRT when HD is the setting of severe hyponatremia, but low Na\textsuperscript{+} CVVHD is not available. Some have suggested adjusting the dialysate [Na\textsuperscript{+}] using sterile water to achieve the desired [Na\textsuperscript{+}] prior to treatment. This may produce a predictable response in [Na\textsuperscript{+}], but there are concerns for infection and/or dosing error which makes this strategy problematic. Reducing dialysate or effluent flow, though effective, often results in unacceptable clearances. We demonstrated, that CVVHD with a standard Na\textsuperscript{+} bath, a separate DSW drip, and strict monitoring of [Na\textsuperscript{+}], can yield a predictable response in [Na\textsuperscript{+}], obviating the cumbersome and risky point of care manipulations of the dialysate formula.

FR-PO051

Case Report: Renal Squamous Cell Carcinoma of a Native Kidney After Renal Transplant

Introduction: Renal squamous cell carcinoma is a rare primary tumour of the kidney, which rapidly invades local structures and has a poor prognosis. Presentation is usually non-specific and is associated with renal stone disease and chronic infection. We present a case of squamous cell carcinoma of a native kidney in a renal transplant recipient, which has not previously been described in the literature.

Case Description: A 46-year-old white male with previous renal stones and recurrent urinary infections underwent a right nephrectomy and subsequent renal transplantation due to failure of the remaining kidney. Five years post-transplant, an abdominal ultrasound scan was performed due to recurrent urinary infections and ongoing pyuria. This was reported as normal, but he later developed a discharging sinus in his left flank. A CT scan revealed the development of peri-nephric abscesses with an associated cystic lesion. A left nephrectomy was performed and histological examination suggested an invasive squamous cell carcinoma of the renal pelvis. The patient later required major surgery for chronic infection, and further imaging revealed metastatic disease, resulting in the decision solely to upstage it.

Discussion: Renal transplant recipients are three-four times more likely to develop a malignancy than the general population. The patient also had renal stone disease and recurrent urinary infections; further increasing his risk of developing this condition. Abdominal ultrasound was unhelpful and only a later CT scan revealed the underlying malignancy. Given the non-specific nature of the symptoms and the poor prognosis, healthcare professionals should have a lower threshold for diagnostic imaging in these patients. This should be expedited if there is a persistent abnormality on urinalysis.

FR-PO052

A Case of Hydronephrosis due to Adenovirus Hemorrhagic Cystitis following Peripheral Blood Stem Cell Transplantation for Malignant Lymphoma

Introduction: In patients receiving stem cell transplantation (SCT), adenovirus infection is associated with increased mortality and morbidity. Cystitis is the most common presentation of adenoviral urinary tract infection, which usually causes inflammation of the upper urinary tract. We report a rare case of adenoviral urethritis accompanied by hydronephrosis after autologous peripheral blood SCT.

Case Description: A 50-year-old male, who had undergone SCT 4 months ago for the treatment of nasal-type extranodal NK/T cell lymphoma and received tacrolimus as prophylaxis for graft-versus-host disease, developed fever, right back pain and dysuria. Computed tomography (CT) showed perirenal and periureteral fat heterogeneity and dilation of the right ureter. He was diagnosed as pyelonephritis caused by ureteral stones (already dropped), but antibiotics did not relieve symptoms. In addition, he exhibited a left solitary pulmonary mass, which was diagnosed as Mycobacterium avium complex (MAC) infection by lung needle biopsy. Cystoscopy and retrograde pyelography revealed hemorrhagic cystitis and right ureteral stenosis, where a catheter was placed. Viral PCR test was performed for differentiating hemorrhagic cystitis, and adenovirus was detected both in urine and in blood. Symptoms and abnormal findings on CT were improved by the placement of a catheter and the decrease of tacrolimus dosage.

Discussion: Differential diagnoses were urethral carcinoma, recurrence of malignant lymphoma, retroperitoneal fibrosis and disseminated MAC disease. Urine cytology result was negative for malignancy. Gallium scintigraphy excluded recurrence of malignant lymphoma. Fat heterogeneity disappeared after catheter placement, suggesting that malignant lymphoma and retroperitoneal fibrosis were unlikely. MAC was not detected from blood and urine cultures. Clinical course and laboratory data indicated that inflammation of adenoviral hemorrhagic cystitis spread to the right ureter, leading to ureteral stenosis and hydronephrosis in an immunocompromised patient after SCT.

FR-PO053

Unusual Cause of Thrombocytopenia in a Dialysis Patient

Introduction: Hemodialysis (HD) is an invasive treatment with many adverse effects, thrombocytopenia being one of them. Most of the cases of thrombocytopenia on dialysis are related to the use of heparin creating auto-antibodies leading to heparin induced thrombocytopenia (HIT). Here we report a case of severe thrombocytopenia, which was initially thought to be due to HIT, but later revealed to be secondary to a specific dialyzer membrane.

An 81 year old female started on HD 2 months prior for progressive CKD was sent to the ED for excessive bleeding around the tunneled catheter site and a platelet (PLT) count of 27 K/uL. When she was first started on inpatient HD, she was found to be thrombocytopenic and heparin autoantibodies were weakly positive so she was started on argatroban. At the 1st outpatient HD unit, her PLT count increased to 200 K/uL. After transferring to a 2nd outpatient HD center, her PLT count, once again, dropped to 27 K/uL along with recurrent bleeding at the catheter site. This prompted investigation of heparin exposure as a cause, but it was revealed that the patient never received heparin during any of her treatments. Despite being restarted on argatroban, her PLT count remained in the 20 K/uL range. The serotonin release assay was negative. It was noted that the hospital and the 2nd outpatient unit both used a F160NR dialyzer, different from the dialyzer used in the first outpatient unit. With the suspicion of a possible dialyzer reaction, the membrane was switched from F160N to Gambro Revaclear. Her PLTs increased to 125 K/uL in 4 days. Discharge instructions indicated that the patient must use a Revaclear dialyzer. A week later, repeat PLT count was noted to be 200 K/uL.

Discussion: This case demonstrates a rare dialyzer reaction, in which a specific dialyzer membrane leads to severe thrombocytopenia and bleeding. It has been postulated that complement activation might have a role, but this patient had normal complement levels.
Introduction: Hyperparathyroidism, a potentially life-threatening condition, has been defined as a calcium of 14 mg/dl or more with evidence of multi-organ dysfunction including cardiovascular, renal or CNS involvement. We describe a case of hyperparathyroid crisis due to primary hyperparathyroidism treated with low calcium/calcium free dialysis.

Case Description: A 62 year old healthy man was brought by his wife to the ED for lethargy, worsening confusion over 3 days, weight loss and constipation. On exam, he was hemodynamically stable, had flat jugular veins and dry mucous membranes. His corrected calcium was 23.58 mg/dL with a creatinine of 3.60 mg/dL. He was aggressively hydrated with normal saline and received a total of 2 doses of Calcitonin 240 IU IM with no improvement in his mental status or in his calcium levels. He was then given Denosumab 60 mg SQ and underwent a 3 hour session of low calcium dialysis (Ca bath 1.0 mEq/L). During the treatment, he was given NS boluses in addition to his maintenance NS 250 cc/hr to avoid hypotension. He subsequently underwent 3 additional treatments (Treatments 2 and 4- using calcium free dialysate and Treatment 3- using Ca 1.0 mEq/L) that were well tolerated. Following his 2nd treatment, his mental status improved significantly. After his 4th treatment, his calcium was 12.26 mg/dL. His intact PTH level was 1324 pg/mL. A Sestamibi thyroid scan showed a large left parathyroid mass. The patient underwent surgical resection of a 13 cm parathyroid adenoma after which his calcium normalized to 9.8 mg/dL. His clinical course and a blood pressure trend during hemodialysis is reported below.

Discussion: Calcium free dialysis and the use of low calcium dialysate was tolerated with no hemodynamic instability. Aggressive hydration is important to maintain tolerability. It can be safely used as a bridge to definitive surgical treatment in the setting of primary hyperparathyroidism.

FR-PO055
Antineutrophil Cytoplasmic Antibody Crescentic Allograft Glomerulonephritis following Sofosbuvir Therapy
Shilpa Gadde, Nephrology, Tulane Univ, New Orleans, LA.

Introduction: Sofosbuvir is used for the treatment of hepatitis C virus infection. We report first case of ANCA/PGN following Sofosbuvir in a kidney transplant recipient.

Case Description: 51 yo male had a living unrelated donor kidney transplant, received antithymocyte induction, and tacrolimus and mycophenolate maintenance. sCr was 1.4, 1 week after transplant. 12 weeks post-transplant, sCr was 2.0; renal biopsy showed ATN and tubular isometric vacuolization. Tacrolimus was replaced with cyclosporine. His sCr stabilized at 1.6. He had HCV genotype 1a and high viral load. At week 40 after transplant, his sCr was started on ribavirin and sofosbuvir. At 12 weeks of HCV treatment, sCr was 3.7, UA with 30 protein and 131 RBCs, and PCR was 0.6. Allograft biopsy showed TMA. Therefore, sofosbuvir, ribavirin and cyclosporine were stopped. He was started on prednisone and continued on mycophenolate. His sCr was at 2.4. 70 weeks after transplant (30 weeks after initiation of sofosbuvir), he had a PCR of 5. Urinalysis showed >500 of protein, 70 RBCs. Biopsy showed cellular crescents in glomeruli with pauci-immune IF. EM had normal GBM with subendothelial “fluff”. p-ANCA titer was 1/320 and MPO ab >100. He was diagnosed with p-ANCA associated crescentic GN in the allograft. The patient was treated with sulfonmethyl, cyclophosphamide and a course of plasmapheresis. He later started HD and Rituximab was added. He remains dialysis-independent despite of our efforts in treating his PGN.

Discussion: Renal biopsy showed 3 different pathologies. Initially tubular toxicity of tacrolimus. After sofosbuvir and ribavirin, he had TMA, we stopped his HCV treatment, although the concurrent cyclosporine use was implicated. 30 weeks after the initiation of sofosbuvir and ribavirin therapy he had ANCA-associated crescentic GN. Ribavirin had no reported cases of ANCA vasculitis. Sofosbuvir was approved in 2013 and we suspect it as likely cause of ANCA vasculitis. Therefore, our case represents the first case of drug-associated ANCA vasculitis in an allograft kidney. Further drug monitoring is necessary to elucidate the degree of association and possible causal effect of sofosbuvir and p-ANCA vasculitis.
proliferative was held. His exam was unremarkable except for an exophytic gingival lesion on his right mandible. His white blood cell count was within normal limits and liver and lung nodularities with bulky lymphadenopathy. An auxiliary lymph node biopsy was performed and was consistent with Kaposis sarcoma (HHV8+). Tacrolimus was stopped and the patient was transitioned to the mTOR inhibitor: sirolimus. He was initiated on liposomal doxorubicin and after extubation had no significant improvement in metastatic disease after four cycles. His renal function remained stable on sirolimus and prednisone.

Discussion: Post-transplant malignancies are common and constitute a major burden. Adjustment of immunosuppression is the mainstay of therapy in these cases. It is standard of care to switch from calcineurin inhibitors to sirolimus upon the diagnosis of Kaposis sarcoma. However, there’s no literature regarding chemotherapy in transplant-associated Kaposis sarcoma. Most of the available data is from the AIDS population that we extrapolated to our patient. His bulky disease triggered us to explore aggressive therapy. Combination chemotherapy and sirolimus seem to be a good therapeutic strategy that should be considered in cases of disseminated post-transplant Kaposis sarcoma.

FR-PO058
Warfarin-Related Nephropathy in a Kidney Transplant Patient
Nadeem J. Khorsdy, Gilbert W. Moeckel, Mark A. Perazella. 1 1 Nephrology, Yale New Haven, CT; 2 Dept of Pathology, Yale New Haven, CT.

Introduction: Anticoagulant-related nephropathy is a new entity manifesting as AKI in the setting of excessive anticoagulation. Initial cases were reported in patients on warfarin use; however, more recently AKI is reported with direct thrombin inhibitors. We present biopsy-proven warfarin-related nephropathy (WRN) in a transplant patient on anticoagulation for atrial fibrillation with INR>2.

Case Description: A 69 y old man with hypertension, atrial fibrillation (on warfarin), T2DM and ESRD s/p living unrelated kidney transplant with baseline Scr 2.0 mg/dl (on cyclosporine, mycophenolate and prednisone) presented with nausea, vomiting and abdominal pain. Acute cholecystitis was diagnosed and percutaneous cholecystostomy drainage performed. Initial labs revealed leukocytosis and AKI on CKD with Scr 2.7 mg/dl. INR was 1.8. Urinalysis revealed 3+ blood, 2+ protein with 179 RBCs/HPF; urine sediment 1-2 RBC casts/LPF. Transplant kidney ultrasound was unremarkable. Complements were normal. Urine microscopy demonstrated persistent RBC casts and kidney biopsy was performed. Acute tubular injury with numerous occlusive a RBC casts suggestive of WRN was observed. Kidney function slowly improved but Scr remained above baseline on discharge. Warfarin was resumed due to high stroke risk.

Discussion: Our patient’s presentation with AKI in the setting of acute cholecystitis raised the possibility of warfarin-induced AKI. However, the presence of microscopic hematuria and numerous RBC casts suggested a glomerular process. Biopsy suggested WRN developing in the setting of CKD and anticoagulation. Our case is somewhat unusual given the INR>2. Most cases of WRN have an INR<3. However, the patient had risk factors that have been linked to WRN including CKD, diabetes mellitus and hypertension. Interestingly, INR levels several months prior were all consistently below 2 yet the patient had 2 bleeding episodes requiring hospitalizations (GI bleed and thigh hematoma) suggesting an underlying bleeding predisposition. It is reasonable to consider WRN in cases of unexplained AKI with RBC casts in a patient with INR>3 in the presence of other risk factors and bleeding tendency.

FR-PO059
Successful Preemptive Kidney Transplantation Using Rituximab Induction in a Patient With Post-transplant Overt Nephrotic Syndrome – Case Report
Aureliusz Kolonko, Grzegorz Piecha, Andrzej Wieczek. Dept of Nephrology, Transplantation and Internal Diseases, Medical Univ of Silesia, Katowice, Poland.

Introduction: Focal segmental glomerulosclerosis (FSGS) recurs in 30% of patients receiving their first kidney transplant and often leads to graft loss. In the past, patients with FSGS and overt nephrotic syndrome were rarely transplanted, mostly due to the worries of other risk factors and bleeding tendency. It is standard of care to switch from calcineurin inhibitors to sirolimus upon the diagnosis of Kaposi sarcoma. However, there’s no literature regarding chemotherapy and sirolimus seem to be a good therapeutic strategy that should be considered in cases of disseminated post-transplant Kaposis sarcoma.

Case Description: A 69 y old man with hypertension, atrial fibrillation (on warfarin), T2DM and ESRD s/p living unrelated kidney transplant with baseline Scr 2.0 mg/dl (on cyclosporine, mycophenolate and prednisone) presented with nausea, vomiting and abdominal pain. Acute cholecystitis was diagnosed and percutaneous cholecystostomy drainage performed. Initial labs revealed leukocytosis and AKI on CKD with Scr 2.7 mg/dl. INR was 1.8. Urinalysis revealed 3+ blood, 2+ protein with 179 RBCs/HPF; urine sediment 1-2 RBC casts/LPF. Transplant kidney ultrasound was unremarkable. Complements were normal. Urine microscopy demonstrated persistent RBC casts and kidney biopsy was performed. Acute tubular injury with numerous occlusive a RBC casts suggestive of WRN was observed. Kidney function slowly improved but Scr remained above baseline on discharge. Warfarin was resumed due to high stroke risk.

Discussion: Our patient’s presentation with AKI in the setting of acute cholecystitis raised the possibility of warfarin-induced AKI. However, the presence of microscopic hematuria and numerous RBC casts suggested a glomerular process. Biopsy suggested WRN developing in the setting of CKD and anticoagulation. Our case is somewhat unusual given the INR>2. Most cases of WRN have an INR<3. However, the patient had risk factors that have been linked to WRN including CKD, diabetes mellitus and hypertension. Interestingly, INR levels several months prior were all consistently below 2 yet the patient had 2 bleeding episodes requiring hospitalizations (GI bleed and thigh hematoma) suggesting an underlying bleeding predisposition. It is reasonable to consider WRN in cases of unexplained AKI with RBC casts in a patient with INR>3 in the presence of other risk factors and bleeding tendency.

Fellows Case Reports - IV
Poster/Friday
required multiple blood transfusions. Her trough tacrolimus level was raised to 22 ng/L. Stool microscopy and culture was negative for shiga-toxin producing bacteria. Blood film showed red cell fragments; serum lactate dehydrogenase was raised at 752 u/L. ADAMTS-13 activity was normal. Renal biopsy was consistent with thrombotic microangiopathy. Complement genetic analyses (factors H, I, B and MCP tested) did not reveal any pathogenic mutations. Anti-factor H antibodies were negative. She was treated, first with four cycles of plasma exchange and then commenced on eculizumab at 900 mg infusion weekly for first four doses and then 1200 mg fortnightly. Her renal and anemia parameters normally normalised.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Discussion: Fosfomycin dosing guidelines in dialysis patients are based on publications from the 1970s and 1980s. These publications indicate a high elimination of fosfomycin during hemodialysis with a dialyzer clearance of 60 mL/min. Modern dialysis even exceeds these clearance rates, as seen in this case report (75 mL/min). The large amount of fosfomycin in the total spent dialysate indicates the need for an additional dose after dialysis therapy. About 81% of the admitted dose of fosfomycin was found in the dialysate. This suggests that intermitted hemodialysis can decrease fosfomycin serum levels beyond ranges, where minimal inhibitory concentrations in bone spongius can be achieved. Therefore, fosfomycin dosage after hemodialysis seems crucial to provide sufficient drug concentrations.

FR-PO067
Tumoral Calcinosis – A Rarely Seen Complication in Dialysis Patients
Lathika Raakesh, Raakesh Hassan, Christopher C. Wong, Chong Parke. Nephrology, Univ of Southern California, Los Angeles, CA.

Introduction: Tumoral calcinosis is characterized by solitary or multiple painless, periarticular soft-tissue calcium deposits. Tumoral calcinosis was first described by Giard and Duret in 1898 and 1899. There are two categories, a familial variant also called Tschuschkeandler disease and Secondary tumoral calcinosis also called Uremic tumoral calcinosis.

Case Description: Case : 50 year old female with end stage renal disease secondary to hypertension presented for evaluation of painful left shoulder mass. She has been on dialysis for 12 yrs. Has multiple painful swellings on her hands, elbow and feet. States that her shoulder mass appeared 2 years ago and has progressively increased in size. Also complained exacerbating pain causing trouble carrying out her daily activities. Her surgical history significant for a right neck dissection for a neck mass, parathyroidectomy and a remote history of partial thyroidectomy. Physical examination significant for multiple soft immobile nodular swellings on the left shoulder, dorsum of left foot, right elbow and index finger. Mass on the left shoulder about 12 X 10 cm in size, immobile, tender and firm to palpation. The swelling on the right elbow non tender to palpation and the one on the right neck finger involved the distal and proximal interphalangeal joints Imaging studies showed nodular swellings with significant calcification. Excision of the left shoulder mass showed exudation of a chalky white material. Pathology results were consistent with tumoral calcinosis.

Discussion: Secondary tumoral calcinosis is associated with high serum Ca X P in dialysis patients, secondary or tertiary hyperparathyroidism, aluminium intoxication and vitamin D overload. These lesions are painless but massive swellings can cause mechanical limitation, pain and neuromuscular symptoms due to compression of adjacent structures. Management includes dietary phosphate restriction, noncalcemic phosphate binders, intense dialysis with a low-calcium dialysate and calcimimetics. Surgical excision is indicated in symptomatic lesions. Parathyroidectomy recommended in patients with persistently elevated PTH levels. Tumoral calcinosis resolves after successful renal transplantation.

FR-PO068
Palate Nodule in a Hemodialysis Patient: A Long and Winding Road Until Diagnosis
Precil Diego Miranda de Menezes Neves,1 Ramaiane Aparecida Bridi,1 Rosilene M. Elias,1 Fabio Luiz de Menezes Montenegro,1 Rosa M.A. Moyoys,1,2 ’Nephrology, Univ of São Paulo, Sao Paulo, Brazil; ‘Univ Nove de Julho-UNINOVE, Sao Paulo, Brazil.

Introduction: Secondary hyperparathyroidism (SHPT) is a common condition in end-stage renal disease patients. We highlighted a complication that usually affects long bones, a brown tumor (BT). We report a case of a patient with SHPT, with a palate nodule, which diagnosis investigation led to a BT of maxilla.

Case Description: A 25 years-old female, previously hypertensive, who returned to hemodialysis after her kidney transplant fails. She was referred to our CKD-MBD service with a 3-month history of a progressively enlarging submucosal nodule with hard consistency on her posterior left palate. The mass was painful since the beginning, and presented progressive growth. She had no fever, neither consumptive symptoms nor palpable lymph nodes. Before coming to our service, she was referred to a maxillofacial surgery service, where a computed tomography (CT) and a biopsy were requested, as no initial suspected diagnosis was done. CT disclosed a lytic bone lesion located in alveolar process of maxilla, measuring 3.0 X 2.5cm, and damaging the superior molar roots, producing a bulging in the left maxillary sinus, nasal cavity and palate. Microscopy view evidenced the presence of multinucleated giant cells among ovoid and fusiform mesenchymal cells, large amount of hemorrhage and trabecular of lamellar bone tissue, being compatible with Brown Tumor. On review of her case, she confirmed that Sevelamer 1.6g thrice a day, but the administration of Vitamin D analogs was not possible due to hyperphosphatemia. Her serum intact Parathormone levels were 1,500pg/mL, Vitamin D 36ng/mL, ionized calcium: 4.8mg/dl, phosphorus: 6.1mg/dl. Technetium sestamibi parathyroid scan revealed hyperactive glands at both superior thyroid lobes and at the low cervical region. The patient was submitted to total parathyroectomcy and the lesion is progressively decreasing despite of other modalities of treatment.

Discussion: Brown Tumors must be kept in mind as a differential diagnosis in patients with SHPT even when these lesions are located in unusual sites such as the maxilla.

FR-PO069
A Case of Levofloxacin Toxicity Treated with Continuous Venous-Venous Hemofiltration
Karl Berthold Pernbarg, Jennifer Thompson, Nithin Karakala. Nephrology, MUSC, Charleston, SC.

Introduction: Levofloxacin is a commonly prescribed antibiotic. Multiple adverse events such as central nervous system and cardiovascular toxicity have been described. Cardiovascular toxicity, namely QT prolongation when present can be particularly dangerous and requires urgent management. Aside from stopping the drug there is paucity of data regarding other urgent treatment modalities such as CRRT when potential toxicity is suspected.

Case Description: A 53 year-old African American female with a history of ESRD on peritoneal dialysis (PD) for 2 years was admitted for concern of levofloxacin toxicity. She had been admitted to an outside hospital and discharged approximately 1 week prior to presentation with a levofloxacin prescription for presumed bronchitis. During initial evaluation, she admitted to taking levofloxacin 500 mg every 8H for the preceding 5 days. She admitted she had been performing PD every other day as she was concerned she was volume depleted. After 3 days she developed nausea, vomiting, left heel pain, left hand tremor, and palpitations. She had not performed peritoneal dialysis since the onset of her symptoms. Her initial physical exam was consistent for left hand tremor and Achilles tendon tenderness. Her QTc upon initial evaluation was 534. Serum levofloxacin level was ordered and a decision was made to start continuous venous-venous hemofiltration (CVVH) in increase clearance of levofloxacin. CVVH was stopped after clinical recovery of her symptoms and normalization of QTc. Her initial levofloxacin level was 36.65 mcg/mL (normal therapeutic range 8-12 mcg/mL) and serate els were followed for a duration of treatment every 12 hours. Below is a graphical trend of her levofloxacin levels.

Discussion: Levofloxacin toxicity represents a unique and dangerous clinical challenge. This case report shows successful and effective treatment of critical toxicity with the use of CVVH.

FR-PO070
Utility of Cystatin C in the Setting of Urinoma
Lilian Saro-Nunez,1 Amrei Auferheide,2 Alan Perlman.1,2 ’Nephrology, Weil Cornell Medical College, NY, NY; ’Rogosin Inst, NY, NY; ’Technical Univ, Munich, Germany.

Introduction: Urinomas (i.e. presence of urine outside of the urinary tract) are common in the setting of urologic/pelvic surgery. Due to the resorption of extravasated urinary constituents such as urea nitrogen and creatinine, determination of renal function is typically confounding and often leads to the false impression of acute renal failure, a situation referred to as pseudo-renal failure. We describe the superior precision of cystatin C (CysC) vs serum creatinine (Scr) in estimating renal function in a patient with urinoma.

Case Description: 79 yo M with a history of urinary retention requiring a chronic indwelling Foley catheter presented with catheter obstruction leading to bladder rupture and apparent acute renal failure. Presenting Scr was 5.8mg/dl (baseline 1.5mg/dl), a cystogram was consistent with urinoma. Treatment of the bladder leak consisted of urinary catheter replacement and he maintained urine output of > 2L/24h for several days. Scr decreased to 2.9mg/dl. A second episode of catheter obstruction subsequently occurred resulting in a significant increase of the extraperitoneal bladder leak and acute rise of creatinine to 4.6mg/dl. After placement of a larger catheter, his Scr decreased to 1.7mg/dL. During the second episode of urine leakage, simultaneous CysC levels were obtained. In contrast to
the marked variation of Scr during the onset and resolution of the urinoma, CysC levels decreased more gradually compared to serum creatinine. A ng set onset, followed by return to near baseline level of 1.7mg/L upon catheter replacement. CysC based eGFR values using CKD-EPI demonstrated similar relative stability, decreasing from 39 to 29mL/min during the recurrent bladder rupture, followed by an increase to 36 mL/min after antibiotic supplementation. In contrast, the eGFR decline based upon Scr-based CKD-EPI equation was notably labile declining from 20 to 11mL/min during episode then increased to 38mL/min with treatment.

Discussion: These findings imply superiority of CysC over Scr in estimating renal function in patients with urinoma and pseudo-renal failure. Discordant estimates of eGFR between CysC and Scr may be indicative of urinoma.

FR-PO071
Two Cases of Nonocclusive Mesenteric Ischemia Triggered by Intradialytic Hypotension
Hafiz Ali Sroya, Antonia Harford. Nephrology, UNM, Albuquerque, NM.

Introduction: Kidney cancers arising in renal allografts are very rare and most publications focus on cancers in native kidneys of transplant recipients. We are reporting a case of a renal cell carcinoma (RCC) arising 14 years post-transplant.

Case Description: A 46-year old man with a history of ESRD due to diabetic nephropathy underwent hemodialysis for one year prior to receiving a Living Un-Related Renal Transplant from his brother –in-law, a 36 yo healthy male in 2001. The patient had immediate graft function post-transplant and was maintained on MMF, Cyclosporine and Prednisone. He underwent renal allograft biopsy in 2004 for a gradual decline in renal allograft function; this biopsy showed chronic transplant glomerulopathy. The patient had very gradual decline in renal allograft (Kt/V ≥ 1.6) until Jan 2015, when he developed mild lower abdominal pain over several weeks. Imaging including abdominal US and CT revealed a 14 X 12 X 12 cm mass arising from the transplant kidney with extensive regional adenopathy involving the right iliac iliac vein and IVC with evidence of lung metastasis. Biopsy showed RCC, clear cell type with extensive necrosis. The venous involvement precluded surgical excision. The patient was treated with umbitramib. Several weeks later, he developed extensive bilateral pulmonary embolism treated with heparin infusions. IVC filter insertion at the initiation of UF was considered but abandoned due to inadequate IVC heparinization. Alcoholic embolization of the tumor was then performed. Immunosuppressive medications were tapered and the patient returned to hemodialysis.

Discussion: Characteristic of de novo kidney cancer in RCC novo currently unknown. These tumors can be de novo or transmitted by the donor and differentiation between these 2 modes of transmission may be difficult. The most common reported histologic type of graft tumor is papillary carcinoma; clear cell type as in our case is less usual. Tumors occurring in renal transplants are usually incidental, asymptomatic, low grade and small but may be symptomatic or with vague clinical picture, high grade, aggressive and very large size as in our case. Frequent and continued surveillance imaging of both the renal allograft and native kidneys is paramount.

FR-PO073
A Case of Acute Allograft Rejection Combined with BK Virus-Associated Nephropathy
Bernice Kim, Soo Ryengo Ryoo, Kyung Soo Kim. Div of Nephrology, Dept of Internal Medicine, Dongguk Univ Ilsan Hospital, Goyang, Republic of Korea.

Introduction: Rejection and BK virus-associated nephropathy (BKVAN) are major causes of renal allograft dysfunction. Treatment can be difficult when both conditions coexist, because potent immunosuppression is required in acute rejection and reduction of immunosuppressive agents is essential in BKVAN. We present a case of acute allograft rejection combined with BKVAN.

Case Description: A 41-year-old male with end stage renal disease because of hypertensive nephrosclerosis received a deceased donor renal transplantation. Immunosuppressive therapy was started with mycophenolate mofetil, tacrolimus, methylprednisolone, and anti-thymocyte globulin. On post-operative day (POD) 19, serum creatinine (Scr) level was 1.89 mg/dL but was elevated to 2.4 mg/dL on POD 25. Diffuse C4d staining in peritubular capillaries was noted on kidney biopsy and acute antibody mediated rejection was diagnosed. Plasmapheresis was initiated and intravenous immunoglobulin (IVIG) and rituximab were administered. After 10 days of treatment, Scr was decreased to 1.5 mg/dL. Additional episodes of SCR elevation occurred and more sessions of plasmapheresis and IVIG administration were done, but Scr was elevated to 2.48 mg/dl on POD 67. Decoy cells were detected on urine cytology and high levels of viruria and viremia were found on polymerase chain reaction for BK virus DNA. On second kidney biopsy, findings of acute cellular rejection were noted and viral inclusion bodies in tubular epithelium were seen, suggestive of BKVAN. Treatment of BKVAN, reduction of immunosuppressive agents and administration of IVIG was initiated. Steroid pulse therapy was done in regard of acute cellular rejection. Despite therapy, his renal function did not recover completely and Scr was elevated to 3.2mg/dL on POD 138.

Discussion: It is difficult to treat when BKVAN and acute rejection coexist. In our patient, IVIG and leflunomide was administered and immunosuppression was reduced for BKVAN while steroid pulse therapy was performed for acute rejection, but his allograft function deteriorated. Studies are required to optimize the management of these difficult cases.

FR-PO074
Decreased Ultrafiltration in an End-Stage Renal Disease Patient with Sickle Cell Anemia: A Potential Strategy to Facilitate Kidney Transplantation
Ekamol Tantissattama,1 Siwadon Pitukweerakul,2 Praveen Ratnasirimetha.1 Nephrology, Northwestern Univ; 1Presence St. Francis Hospital, Evanston; 2Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand.

Introduction: Sickle cell crisis (SC) leads to mortality and morbidity in sickle cell disease (SCD) patients. Veno-occlusive disease (VOD) is a common precipitating cause. Volume overload may require increasing ultrafiltration(UF). We report a case of SCA woman with acute kidney injury (AKI) who suffered from recurrent episodes of SC and acute hemolytic anemia requiring blood transfusions after hemodialysis(HD) was initiated. She became more sensitized from blood transfusions. Decreased UF reduced episodes of SC and blood transfusions.

Case Description: A 39-year-old African American woman with a longstanding history of SCA presented with a severe episode of SC complicated by AKI requiring chronic HD 5 years ago. Since starting HD, she had more episodes of SC from once a year up to every other month and required more blood transfusions. She presented for a pre-kidney transplant evaluation. Her panel reactive antibody(PRA) increased from 28 and 0 to 44 and 10, for class I and II, respectively. Upon interview, she has HD 3 times/week. Her estimated dry weight was 62 kg and intradialytic weight gain was 2.2-3.3 kg. She sometimes had late hemolytic hypotension with BP of 90s/50s. As concern for over UF being a potential cause of volume depletion and subsequently precipitating SC, the UF was decreased. She had fewer episodes of SC and blood transfusions. She remained on the kidney transplant waiting list with this HD prescription and stable hemoglobin.

Discussion: Our patient presented with more frequent episodes of SC after HD initiation. Intradialytic hypotension indicates intravascular volume depletion which subsequently precipitating SC and hemolytic anemia. Volume management in SCA patients with ESRD is challenging and critical to avoid intravascular volume depletion. SC and acute hemolysis may be surrogate markers of over UF. Avoiding over fluid removal can prevent SC, acute hemolysis, and blood transfusion which potentially increases immunological barrier for kidney transplantation from sensitization.

FR-PO075
Recurrent Catastrophic Antiphospholipid Syndrome Treated with Eculizumab in a Peritoneal Dialysis Patient
Karl W. Schoenholtzer,1 Marianna De Francesco,2 Giulia Bedino,1 Josua Van den Berg,2 Silvio Pinca.1 1Nephrology and Dialysis Div, Ospedale Regionale di Lugano, Lugano, Switzerland; 2Interventional Radiology Div, Ospedale Regionale di Lugano, Lugano, Switzerland.

Introduction: Catastrophic Antiphospholipid Syndrome (CAPS) is a severe variant of Antiphospholipid Syndrome (APS), a systemic autoimmune disorder characterized by recurrent arterial and/or venous thromboses in presence of elevated titer of antiphospholipid antibodies (aPL). These autoantibodies, promote thrombosis by activating endothelial cells and platelets. We describe a case of a clinical remission in recurrent CAPS via inhibition of terminal complement with Eculizumab in a Peritoneal Dialysis (PD) patient.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

373A
Case Description: A 48-year-old man has shown recurrent CAPS characterized by diffuse erythema, edema, fever, heart, kidneys, liver and lung involvement increased by positivity of aPL. Angiography revealed a bilateral subclavian arterial thrombosis, a right iliac arterial stenosis that was treated with a stent and a left renal arterial occlusion. The patient’s renal function was decreased until End Stage Renal Disease, secondary to chronic thrombotic microangiopathy, and PD therapy was started. During 16 months, our patient presented 8 recurrent episodes of disease with pulmonary involvement characterized by multiple alveolar hemorrhages in concomitance with liver necrosis (biopsy proven) and miocardial ischemia. The patient was treated with high-dose pulse corticosteroids (methylprednisolone 500mg IV every 3 days followed by prednisone (1 mg/kg/day), plasma exchange (5 series with a total of 74 sessions), IV immunoglobulin (400 mg/Kg/day for 5 days), IV Rituximab (initial therapy and maintenance after 6 months), clopidogrel, aspirin and anticoagulation.

Despite this standard therapy, we did not observe a sustained remission. Therefore, after a long period of the literature, we decided to administer Eculizumab, a monoclonal antibody against complement C5, that blocks and prevents the generation of the proinflammatory and proinflammatory molecules C5a and membrane attack complex C5b-9. The patient has been in remission with long-term Eculizumab treatment and anticoagulation therapy, without further thrombotic events during 1 year of follow-up.

FR-PO076

Introduction: Renal tumors are rare in transplanted kidneys. Nephrectomy is the traditional treatment for renal masses. We report a renal mass that was found to be post-transplant lymphoproliferative disorder in the renal allograft which we chose to biopsy instead of using traditional surgical resection.

Case Description: A 63 year old female with past medical history of renal cell carcinoma and end stage renal disease treated by right nephrectomy, ESRD secondary to MPGN status post living donor kidney transplant presented with abdominal pain, fever and diarrhea. Ultrasound of renal allograft showed a solid appearing 4.8x5.6x4.3 cm mass in the upper pole of the transplanted kidney which was predominantly homogenous with internal vascularity. MRI revealed 6.2x4.9x6.5 cm mass with solid enhancing and non-enhancing components within the transplanted kidney concerning for renal cell carcinoma. Given her previous history of RCC there was an increased concern for recurrence. Nephrectomy would have been the traditional approach but that would have meant sacrificing her allograft and initiating hemodialysis. The mass was biopsied and pathology revealed post-transplant lymphoproliferative disorder. Microscopic description showed a small kidney portion with tubules and glomeruli overrun by a dense lymphoid infiltrate. Immunohistochemical stains revealed that the large atypical cells were positive for CD20, Bcl-2, Mum-1 and CD30 but negative for Bcl-6, CD10 and CD138. C-myc stained approximately 10-20% of cells and Ki-67 30-40%. In situ hybridization for Epstein Barr virus encoded RNA (EBER) was positive. Patient received 6 cycles of R-CHOP, follow-up MRI showed decrease in mass size.

Discussion: The biopsy of renal tumors for the diagnosis of small masses has not been widely adopted despite recent safety reports with advanced techniques and physicians’ expertise. It has been shown to be safe and reliable and should be considered in all patients with small masses especially in transplanted kidneys to decrease the risk of unnecessary surgical intervention.

FR-PO077
Renal Replacement Therapy for Severe Hyponatremia (PNa 99mEq/L), FR-PO076

Introduction: Dialysis therapy for patients with severe hyponatremia poses risk of osmotic demyelination syndrome due to rapid correction of serum sodium concentration. To prevent rapid correction, low sodium dialysate or filtration fluid can be used; however, dialysate sodium concentration needs to be changed frequently so that the patient’s serum sodium concentration rises. Instead of using low sodium dialysate, infusion of 5% dextrose with respect to the CVVH circuit after hemofilter. By adjusting the infusion volume of D5W, sodium concentration of returning blood can be adjusted to the desired level; if the correction rate of sodium concentration rises. Instead of using low sodium dialysate, infusion of 5% dextrose method. CVVH using standard filtration fluid (Na conc. 140 mEq/L) was started without further thrombotic events during 1 year of follow-up.

Performing Chronic Hemodialysis Therapy in a Patient with Total Artificial Heart - Simon Pozzoli, Marco Simonini, Federico Papalardo, Chiara Lanzani, Teresa Aricidacino, Maria Teresa Sciarrone Alibrandi, Donatella Spotti, Paolo Manunta, Stefano Tentori, Giorgio Slaviero. San Raffaele Scientific Inst, Italy.

Introduction: Total Artificial Heart (TAH) is an implantable artificial heart usually used as a temporary bridge till heart transplantation. Recently a review showed that bleeding (47%), AKI requiring hemodialysis (40%) and infection (33%) are the most common complications following implantation of a TAH. Currently there are no data in the literature on long term renal function outcome and on management of ESRD related complications.

We present our experience on a patient with TAH in chronic hemodialysis therapy.

Case Description: A 55 years old Caucasian man was admitted on 1st March 2012 at our Hospital ER with cardiogenic shock for AMI with rupture of the papillary muscle. His medical history included hypertension and dyslipidemia in good pharmacological control. On 9th March TAH has been implanted in order to replace the lost heart function. From the day of admission to ICU, the patient developed oliguric AKI and CRRT was started. Subsequently, the patient was switched to four times a week haemodialysis. To maintain an appropriate circulating volume for the operation of cardiac device, atrial filling pressures were maintained between 5.5-5.5 mmHg and 6.0-6.5 mmHg in the right and left atrium respectively. At the same time it was decided to record the change of hematocrit which the patient was subjected during the dialysis sessions (via Blood Volume Monitor (BVM)) in order to identify the critical BVM value for the functioning of the cardiac device. In this way we were able to manage the patient’s dialysis sessions even once he was discharged from the hospital with the portable version of TAH.

Discussion: This patient underwent to combined heart and kidney transplantation. To the best of our knowledge this is the longer case of continuous dialysis therapy in a patient with total artificial heart. Total Artificial Heart is therefore a valid therapeutic option for those patients waiting for heart transplantation even for long periods of time.

FR-PO079
Severe Varicella Zoster Virus Encephalitis and Retinal Necrosis in a Renal Allograft Recipient - Jean Luc Franck, Srijita Mukherjee, Tina Thomas, Sharon M. Graves. Nephrology, Emory Univ, Atlanta, GA.

Introduction: Varicella zoster virus infection (VZV) has devastating potential complications and should be considered more often for testing by clinicians. Our case reflects the need to maintain a higher degree of suspicion for VZV by clinicians treating the immunosuppressed population.

Case Description: A 31-year-old man underwent living related renal transplantation in 2008 for chronic glomerulonephritis. The clinical course was uneventful until January 2015, when he was diagnosed with grade IA rejection after admitting to four months of nonadherence to his prescribed immunosuppression regimen, consisting of tacrolimus, mycophenolate mofetil, and prednisone. The rejection was addressed with pulse IV steroids and resumption of his oral immunosuppressant regimen. Over the next four months, the patient sought medical attention for worsening and persistent occipital headache. Lumbar puncture was performed and suggested a viral etiology. MRI imaging was performed and revealed a large cerebellar infarct and diffuse vasculitis. Transfer to our institution was pursued. The patient underwent a neurosurgical approach and received intravenous dexamethasone with decompressive craniotomy. Polymerase chain reaction (PCR) testing in the cerebrospinal fluid was positive for VZV. The patient was started on acyclovir and steroids for treatment of VZV encephalitis and diffuse vasculitis. Ophthalmologic evaluation revealed retinal necrosis of the left eye, with PCR testing of the anterior chamber fluid also positive for VZV. After 4 weeks of acute care, the patient is currently in rehabilitation.

Discussion: Varicella Zoster Virus infection requires timely diagnosis and treatment for positive outcomes in the immunosuppressed patient. Clinical presentation can vary dramatically, from subtle rash to encephalitis. Therefore, clinicians caring for immunosuppressed patients should more routinely consider VZV as part of the differential diagnosis. Our case raises several questions including consideration for lengthening duration of VZV prophylaxis in allograft recipients and consideration for resuming VZV prophylaxis when resuming immunosuppression after extended periods of nonadherence.

FR-PO080
Hemodialysis Related Acute Thrombocytopenia During Pregnancy - Nikulkumar Chaudhari, Belinda Bun Jin, Anjali Acharya. Dep of Nephrology, Jacobi Medical Center, Bronx, NY.

Introduction: Thrombocytopenia is not uncommon during pregnancy. It could be multifactorial and range from a mild asymptomatic condition to severe thrombocytopenia with fetal effects.

Case Description: A 29 year old woman with hypertension, CKD-IV from primary FSGS, presented at 10th week of gestation. Intermittent hemodialysis had to be initiated at 20th gestation week. Thrombocytopenia developed as described in the table below.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

374A
Patient was not on antiplatelet agents and panel for HIT antibodies was negative. Patient remained asymptomatic throughout hospitalization. Hematological evaluation ruled out all routine causes of thrombocytopenia during pregnancy such as gestational thrombocytopenia, preeclampsia, HELLP, TTP/ITP and autoimmune causes. Given the chronological correlation of platelet decrease and hemodialysis it was concluded that thrombocytopenia was related. Patient was switched from a Fresenius dialyzer optilux to Exeltra 210 high flux dialyzer.

Discussion: Complement activation, anti-coagulation use, exposure of blood to the roller pump, dialysis tubing, micro-bubbles, and use of cellulose membrane are potential causes of dialysis related thrombocytopenia. In addition, sterilization techniques have shown to have a differential impact. A major difference between the two dialyzers used was the technique of sterilization. Electron beam radiation used in the Fresenius dialyzer might affect membrane integrity or physical properties that could lead to platelet activation, aggregation, or adsorption causing thrombocytopenia, which is not seen with gamma sterilization. Thrombocytopenia is an important, if rare, complication of hemodialysis that should be considered in the differential diagnosis of thrombocytopenia in pregnancy. Dialysis associated thrombocytopenia may occur despite the use of biocompatible membranes.

FR-PO081
A Rare Case of Nephrocalcinosis Caused by Hereditary Renal Hypouricemia

Three Months After Kidney Transplantation

Yoko Komatsuzaki,1 Izumi Yamamoto,1 Yasuyuki Nakada,1 Yusuke Okabayashi,1 Takafumi Yamakawa,1 Akimitsu Kobayashi,1 Takahito Niikura,1 Yudo Tanno,1 Ichiro Ohkido,1 Hiroyu Yamamoto,1 Keitaro Yokoyama,1 Takashi Yokoy,1 Department of Internal Medicine, Division of Nephrology and Hypertension, Iseki University School of Medicine, Tokyo, Japan; 2Department of Internal Medicine, Division of Nephrology and Hypertension, Atugi City Hospital, Kanagawa, Japan.

Introduction: Renal hypouricaemia (MIM: 220150) is a syndrome that involves a defect in urate transporter 1 (URAT1) for urate reabsorption at the brush border of the proximal tubule. Nephrocalcinosis and exercise-induced acute renal failure are two major complications affecting renal function. A C889T mutation in SLCA2A12 encoding URAT1 is the rare mutation in Japanese. Here we report a rare case of nephrocalcinosis caused by hereditary renal hypouricaemia three month after kidney transplantation.

Case Description: A 41-year-old man had undergone living-related kidney transplantation because of Henoch–Schoenlein purpura nephritis. Three month protocol biopsy showed several localized nephrocalcinosis determined by either von kossa or de Galantha’s stain (staining for urate crystals). The evaluation for nephrocalcinosis showed hypouricaemia at 1.9 mg/dl with a high fractional excretion of uric acid at 26.8% (normal range, 6–10%). DNA direct sequencing followed by restriction fragment length polymorphism showed that both the recipient and donor were heterozygous for C889T. This mutation induce stop codon, therefore subsequent immunostaining were performed. This mutation showed signs of chronic damage. Histology revealed severe ongoing cellular and AMR. Molecular analysis of the biopsy confirmed an unusually severe form of idiopathic thrombocytopenia (fig.1B). Due to the clinical symptoms, we performed transplant nephrectomy. Inguinal lymphadenopathy regressed rapidly, and the patient made a full recovery.

FR-PO082
An Unusual Cause of Lymphadenopathy in a Renal Transplant Patient

Anna Bertram,1 Marcus Hiss,1 Jan H. Braesen,2 Philip F. Halloran,3 Gunilla Einbeck.1
1Nephrology and Hypertension, Hannover Medical School, Hannover, Germany; 2Pathology, Hannover Medical School, Hannover, Germany; 3Alberta Transplant Applied Genomics Centre, Univ of Alberta, Edmonton, Canada.

Introduction: We report an uncommon cause of lymphadenopathy in a kidney transplant patient.

Case Description: The 28y old male patient presented 10y after living donor kidney transplantation with painful inguinal swelling. He had returned to dialysis 8 months after graft failure due to antibody-mediated rejection (AMR), which had been unsuccessfully treated with plasmapheresis, intravenous immunoglobulins, and rituximab between 10/2013-03/2014. To sustain diuresis, immunosuppression was continued with tacrolimus (tough level 7ug/mL) and 5mg prednisolone. At presentation, no local injury was detectable, and the patient denied systemic symptoms including MRL related symptoms and signs of inguinal and iliacal lymph nodes on his right side. Laboratory results showed elevated inflammatory parameters (CRP 120 mg/L; PCT 1.0 μg/L; leucocytes 13.2×10^9/L). Tacrolimus trough level was 3.7 ng/mL, EBV-DNA in plasma was detectable at low values (3200 IU/ mL). To rule out PTLD, biopsy of a 3 cm inguinal lymph node (fig.1B) was performed. However, histology showed lymphangitis and no sign of malignancy. Because the allograft in his right fossa ilaca was tender, we performed a biopsy, as well, although ultrasound showed signs of chronic damage. Histology revealed severe ongoing cellular and AMR. Molecular analysis of the biopsy confirmed an unusually severe form of idiopathic thrombocytopenia (fig.1B). Due to the clinical symptoms, we performed transplant nephrectomy. Inguinal lymphadenopathy regressed rapidly, and the patient made a full recovery.

FR-PO083
Prevnar 13 Associated Immune Thrombocytopenic Purpura in a Renal Transplant Recipient

Sagar Gupta,1 Daniel C. Brennan. Renal, WashU, St. Louis, MO.

Introduction: ACIP recommends all adults with immunocompromising conditions should receive PCV13 to prevent invasive disease caused by 13serotypes of S.pneumoniae. We describe here a case of ITP associated with Prevnar13 administration in a renal allograft recipient, which is the first reported case of its kind.

Case Description: A 77 year old Caucasian male presented with chief complaint of increased bruising at insulin injection sites for one week. There was no history of fever, abdominal pain, diarrhea, bleeding episodes, neurological deficits, new medications or insect bites. He had ESRD secondary to hypertension and DM2. He received a living unrelated kidney allograft 22mo ago. He was on tacrolimus, MMF, prednisone, MMF later discontinued indefinitely due to BK viremia. Family history was non-contributory. Medications included allopurinol, ASA, statin, bapticin, carvedilol, insulin glargine and aspirin, prednisone and tacrolimus. He received Prevnar 13 1 month ago. Exam showed normal vital signs and petechial rash in the areas of insulin injections. Lab testing resulted in Hb 11.7 & WBC 7.7 (baseline) and platelet 3000 (baseline 140). BUN 31 and Cr 1.50 (baseline). PT, PTT, LDH and haptoglobin were normal. No schistocytes seen. Infected workup was negative and ADAMTS-13 activity resulted at 102%. The isolated thrombocytopenia was diagnosed as ITP and was attributed to the Prevnar 13 vaccine. He was started on pulse corticosteroids and IVIG. He received 6 units platelets with counts increasing to 94000, later discharged on a prednisone taper. Weekly blood counts showed improvement to his baseline of 140,000 in 3 weeks.

Discussion: PCV13 contains the S.pneumoniae serotypes’ capsular polysaccharide covalently linked to an immunogenic carrier protein resulting in a T cell– dependent antigen eliciting a T helper-cell response. The pathogenesis of ITP involves antibody production driven by CD4-positive helper T cells reacting to platelet surface glycoproteins. Antibodies formed during viral or bacterial infections may also cross-react with normal platelet glycoproteins (a form of molecular mimicry). Isolated cases of ITP have been reported but are relatively rare. Our case is further unique to occur in a pt on immunosuppression with a calcineurin inhibitor and corticosteroids.

FR-PO084
Placement of a Tunneled Hemodialysis Catheter in the Superior Vena Cava for Multiple Central Venous Occlusions

Qinghua Yin, Tianlei Cui, Li Zhou, Ping Fu, Fang Liu. Div of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.

Introduction: A tunneled hemodialysis catheter is essential for dialysis access when the use of a functioning arteriovenous fistula is not possible. In extreme situations of multiple central venous occlusions, it remains a challenge to establish durable vascular access. Unconventional routes to the central veins are typically used. We successfully performed placement of a tunneled hemodialysis catheter in the superior vena cava (SVC) with fluoroscopic guidance in a hemodialysis patient with multiple central venous occlusions due to repeated catheterization. We report on a feasible option for hemodialysis patients with multiple central venous occlusions.

Case Description: A 49-year-old diabetic male who had been diagnosed with ERSD one year prior came to our medical center because of temporary catheter occlusion. CT venography revealed occlusion of the bilateral brachiophelial, internal jugular and the common femoral veins, and central venography showed occlusion of the bilateral jugular and common veins. Guided by ultrasound, a percutaneous transhepatic route, as described by Duncan et al.[9], was developed, which was applied to SVC venography and provided access for a 5F indwelling catheter, which was used to locate the distal end of
the SVC (Figure 2A). The puncture point of the skin was beneath and 0.5-1.0 cm outside of the clavicular head and neck. The tip of the needle was sighted on the subcutaneous tunnel was along the distal end of the SVC, which was marked by a 5F indwelling catheter. Under fluoroscopic guidance, a micro-21G needle (Cook) was used to puncture the subcutaneous tunnel of the SVC. The red blood was drawn when the micro-21G needle (depth: at least 15 cm) met the indwelling catheter. Additionally, under anteroposterior and lateral fluoroscopic guidance, a 21G needle was punctured into the SVC (Figure 2B-C), and the tunnelled hemodialysis catheter (cuff to tip 23 cm, Bard) was then exchanged with a 0.035-inch guide wire in the SVC. Chest radiography showed positioning of the new catheter tip into the right atrium (Figure 2D). CT showed that the needle did not enter the chest.

FR-PO085
Crystal Nephropathy in a Kidney Transplant Recipient Due to Excessive Consumption of Oxalate Rich Diet and Vitamin C
Sweta Mali, Padmavathi Mali, Sandesh Parajuli, Maha A. Mohamed.
Nephrology, Univ of Wisconsin School of Medicine and Public Health, Madison, WI; Internal Medicine, Marshfield Clinic, Marshfield, WI.

Introduction: Acute kidney injury due to crystal nephropathy has been reported mainly in patients with gastrointestinal (GI) malabsorption or GI surgery. We present a rare case of crystal nephropathy in the kidney transplant recipient (KTR) without obvious GI risks.

Case Description: 68 year old obese female, who is living-unrelated KTR for five years, with a stable post-transplant course and a baseline serum creatinine (scr) of 11 mg/dl, presents to our hospital with tiredness and diarrhea for one week. She had extensive work up in the past for chronic diarrhea which is described as “soft stool”. 24 hour fecal fat, serum amylose and serum lipase were normal. Upon presentation, serum was 7.1 mg/dl which prompted us to perform an allograft kidney biopsy demonstrating multiple oxalate crystals deposited in the renal tubules. Reviewing her history further revealed that she was consuming 3 gm vitamin C (over the counter) daily for the last one month. Her preferred diet always consisted of oxalate rich foods (spinach). Renal functions improved in one month (scr 2mg/dl) with hydration, discontinuation of vitamin C, and changes in dietary habits. Urine studies obtained after one week of treatment showed normal urine calcium, low urine oxalate and citrate.

Discussion: Oxalate nephropathy can occur from hyperoxaluria due to ingestion of oxalate rich diet or substances which metabolize to oxalate like vitamin C or from enteric causes like malabsorption. In our patient, we ruled out enteric causes and determined oxalate nephropathy was secondary to ingestion of oxalate rich diet and excess vitamin C. Clinical nephropathy improved with modification of diet, hydration and discontinuation of offending agents. Although vitamin C and high oxalate diet are rare causes of oxalate nephropathy in patients with normal renal function, it may cause significant nephropathies in KTR. KTR patients therefore, should follow low oxalate diet and avoid excessive vitamin C even with normal renal functions to avoid development of crystal nephropathy.

FR-PO086
The Conundrum of Dry Weight in a Pregnant Dialysis Patient
Sweta Carpenter, Akshatha Rao, Sandeep Aggarwal.
Nephrology, Drexel Univ.

Introduction: The frequency of pregnancy in women bearing age who are on dialysis ranges from 0.3-1.5% per year. When a dialysis patient does become pregnant, nephrologists become extra vigilant to ensure a successful outcome for both mother and child. An important question that often arises is how to adjust a patient’s dry weight as pregnancy progresses.

Case Description: We present a case of a 23 year old pregnant dialysis patient who was admitted to the hospital with shortness of breath at 26 weeks gestation. She had a past medical history of a miscarriage, hypertension, and a failed deceased donor renal transplant. At her outpatient dialysis unit, she was being dialyzed 6 times per week. Her dry weight was calculated by subtracting 0.5L for calcium phosphate precipitation. Hematopoietic stem cell transplant patients having coagulopathy after using RATG therapy. System, Durham, NC.

A Rare Cause of AKI in a Renal Transplant Recipient
Ronald Brian Vigo, Sandra Barrow, Lillian W. Gaber, Wadi N. Suki.
Nephrology, Houston Methodist Hospital, Houston, TX; Pathology, Houston Methodist Hospital, Houston, TX.

Case Description: We present a 66 year-old African American woman who underwent pre-emptive living related donor kidney transplant for ESRD secondary to DMII and hypertension. She had immediate graft function and was discharged on the fourth post-operative day with Na 136 mEq/L, K 3.5 mEq/L, Cl 102 mEq/L, BUN 25 mg/dl, creatinine 1.3mg/dl and urine pH 7.0. Baseline renal biopsy was normal. Her medications on discharge included Prograf, Celebrex, Prednisone, Bacrin, Valcyte and sodium bicarbonate. She presented 10 days later with complaints of nausea, and vomiting as many as 10 times. Subsequently lab results revealed the following: Na 136 mEq/L, K 5.0 mEq/L, Cl 95 mEq/L, and total CO2 20 mEq/L, consistent with a high-anion gap metabolic acidosis (AG 21). Serum creatinine was 1.3 mg/dl and urinalysis revealed a urine pH of 7.5, pyuria and bacteriuria. Urine culture grew E. Faecalis and renal transplant ultrasound was normal. She was started on IV antibiotic and IV fluids, including sodium bicarbonate and increased by 1.5 kg during the first trimester and during the second trimester by 1 pound a week to account for normal pregnancy weight gain. On this admission, her weight was 113.5 kg and her estimated dry weight was 108 kg, which was 6 kg below her expected dry weight. The patient delivered a baby weighing 2.2 kg and was discharged on the fourth post-transplant period. Positive urine anion gap is suggestive of decreased ammonium excretion (although it should be confirmed with measurement of the urine osmolar gap and urinary P,CO,). The combination of high urine pH, as a consequence of bicarbonate administration and decreased bicarbonate reabsorption, in conjunction with hyperparathyroidism and consequent increase phosphate excretion, provided the perfect medium for calcium phosphate precipitation.

FR-PO087
A Rare Case of Rabbit Anti-Thymocyte Globulin Induced Disseminated Intravascular Coagulation
Vasanthi Balaraman, Anup Patel.
1 Dept of Renal Transplant, Saint Barnabas Medical Center, Livingston, NJ; 2 Dept of Nephrology, Newark Beth Israel Medical Center, Newark, NJ.

Introduction: Rabbit anti-thymocyte globulin (RATG) is a purified polyclonal immunoglobulin used for induction therapy in renal transplantation. Adverse effects include cytokine release syndrome, leukopenia, thrombocytopenia and serum sickness. We report a rare case of renal transplant recipient who developed severe coagulopathy and post-operative bleeding in whom RATG was used for induction.

Case Description: A 61 year old female with end stage renal disease received a deceased donor renal transplant. RATG (2 mg/kg) was initiated intraoperatively. Over the ensuing 2 hours, the patient became hemodynamically unstable with excessive bloody output from the surgical site drain. Exploration of the renal transplant revealed diffuse oozing from surrounding tissues but no bleeding from the arterial or venous anastomosis. Labs revealed an elevated prothrombin time of 27.0 sec, thrombin time of 36.4 sec, INR of 2.5, platelet count of 56000/cumm. The RATG infusion was stopped. Multiple units of packed red blood cells, platelets, fresh frozen plasma and cryoprecipitate were transfused. There was persistent bloody output. A reexploration revealed persistent diffuse oozing which required packing of the transplant bed. On postoperative day 4, the patient’s condition improved.

Discussion: We suspect disseminated Intravascular Coagulation(DIC) may be secondary to RATG in our case. The donor biopsy showed no evidence of DIC. Other causes including calcineurin inhibitors, hyperacute rejection and sepsis were ruled out. Only a few case reports of RATG induced coagulopathy exist in the literature. Weber et al reported 12 hematopoietic stem cell transplant patients having coagulopathy after using RATG therapy. These cases had elevated D-dimer, tissue factor, thrombin-antithrombin III complex, and thrombomodulin, but had no bleeding, thrombembolic or vaso-occlusive complications. We contemplate that DIC is a rare but potential life threatening complication of RATG induction and awareness of this potential complication is important.

FR-PO088
A Page Transplant Kidney
Supreet Sethi, Shalini Bumb, Scott Leonard, Wad N. Suki.
Page Div of Nephrology, Dept of Internal Medicine, Duke Univ Health System, Durham, NC.

Introduction: Page kidney occurs by extrinsic compression of the renal parenchyma from a herniated or a mass, leading to activation of the renin-angiotensin-aldosterone system and resulting in systemic hypertension.

Case Description: A young-adult male, with ESRD of uncertain etiology underwent living related kidney transplantation 3-months prior to presentation. His post-transplant serum creatinine (Scr) stabilized around 1.3 mg/dl. He was maintained on a medium for calcium phosphate precipitation.

Premedication: Clinical Revenue Support
FR-PO090
Black Colored Dialysate: A Rare Complication of Peritoneal Dialysis due to Cholecystitis

Introduction: We report a rare complication of black colored dialysate in a patient with ESRD on peritoneal dialysis (PD) with acute cholecystitis.

Case Description: A 73 year old man was undergoing peritoneal dialysis for ESRD secondary to obstructive uropathy. He presented with black discoloration of his PD effluent. Abdominal pain followed by a clean PD catheter exit site. Peritoneal fluid analysis was consistent with peritonitis. Contrast CT showed a distended indistinct gallbladder with punctate stones and an ill-defined wall. No biliary obstruction or dilatation identified. There was no evidence of pancreatitis and serum lipase level was 12. Subsequent HIDA scan was consistent with acute cholecystitis. A total bilirubin from PD effluent was 14.6mg/dl and serum bilirubin was only 0.8mg/dl. Both blood cultures and PD fluid cultures were negative. He received empiric antibiotics and a percutaneous cholecystostomy tube was placed and similar turbid dark fluid was aspirated from his gallbladder.

Discussion: Dark colored dialysate has been reported in hemorrhagic and non-hemorrhagic pancreatitis. Acute bile leak or cholecystopenia is a recognized complication of choledochectomy due to extrahepatic bile duct rupture or due to gall bladder rupture in patients without ESRD. There are few reports of biliary peritonitis due to intrahepatic bile duct rupture spontaneously and in the setting of cholecystitis. An ascitic fluid bilirubin level of > 6mg/dl with an ascitic fluid/serum bilirubin ratio of >1.0 has been shown to correlate with cholecystopenia. The black colored PD effluent in our patient represented a biliary leak likely from increased permeability of the gallbladder wall or microperforation in the setting of non-perforating cholecystitis or from an unidentified intraperitoneal bile duct rupture. In conclusion black colored PD effluent should prompt investigation for gall bladder disease and/or pancreatitis. Peritoneal fluid and serum bilirubin levels and lipase levels can aid in making a diagnosis.

FR-PO091
NK Cell Lymphoproliferative Disorder(PTLD) Associated with Pure Red Cell Aplasia in a Renal Transplant Recipient Treated with ATG – A Case Report and Literature Review

Introduction: PRCA can be idiopathic or secondary to parvovirus infection, SLE, thymoma or lymphoma. PTLD are lymphoid proliferations that develop following immunosuppression for solid organ transplantation. While they are predominantly B cell PTLD, few NK/T cell PTLD have been published. Secondary PRCA may resolve with treatment of the underlying disorder while PRCA occurring in the setting of NK/T cell PTLD (due to T cell inhibition of marrow erythroid cells) are treated like idiopathic PRCA as immunologically mediated disease. This is the first published report of PRCA associated with NK cell PTLD in a 41yr old renal transplant recipient.

Case Description: This is the first published report of PRCA associated with NK cell PTLD. A 41 year old woman with ESRD from lupus nephritis, received living related renal transplant 9 years ago; admitted with hemoglobin of 5.6 g/dl with normal WBC count and platelet count. Patient had well-functioning allograft with serum Cr of 1.5 There was no evidence of joint swelling, rash, or alopecia. She had a normocytic, normochromic anemia with MCV of 95.9 fL. Peripheral smear showed many normal lymphocytes with normal count. She was given intravenous Rituximab, RBC, WBC or platelet transfusions as needed but absence of erythroid precursors. Flow cytometry revealed increased NK 56(-) CD3(-) CD56(+) cells. Renal allograft Ultrasound, CT Chest and CT abdomen were normal. This patient had her last epogen in 2003 and anti-EPO antibody induced PRCA though possible.

Discussion: We present a case of PRCA in a renal transplant recipient due to NK cell lympho proliferative disorder which was successfully treated with ATG.

FR-PO092
New-Onset Diabetes After Transplantation in a Pediatric Patient with Congenital Anomalies of the Kidney and Urinary Tract: The Role of Hepatocyte Nuclear Factor 2

Introduction: Congenital anomalies of the kidney and urinary tract (CAKUT) are the most frequent cause of end-stage renal disease (ESRD) in children. New-onset diabetes after transplantation (NODAT) is one of the major complications following kidney transplantation (KT). Mutations of hepatocyte nuclear factor 2 (HNF1B), a transcriptional factor involved in the development of pancreatic β- and alpha cells, can cause a multi-system disorder, including CADUK, diabetes, liver dysfunction. We report a pediatric patient with renal hypodysplasia carrying a novel mutation of HNF1B who developed NODAT and liver dysfunction.

Case Description: The patient was a 14-year-old girl. She was diagnosed with bilateral hypodysplastic kidney in the newborn period. At the age of 3 years, she received living-related KT from her mother preemptively. At the age of 4 years, a steroid pulse for acute rejection resulted in development of diabetes mellitus (NODAT). At the age of 13 years, she complained of acute right flank pain and fever. Laboratory data showed elevated transaminase levels and computed tomography showed malformation of the bile duct. The causes of NODAT were initially thought to be steroid and tacrolimus. However, based on her clinical features, including CADUK, NODAT, and liver dysfunction, screening for a mutation of HNF1B was carried out.

Discussion: This is the first published report of CADUK associated with NK cell PTLD in a lung transplant recipient.

Introduction: Acute oxalate nephropathy (AON) is a rare, but well reported cause of acute kidney injury (AKI) in patients with cystic fibrosis (CF) after lung transplant. We report the only known case of late AON of a transplanted kidney in a combined kidney and lung transplant patient without CF after undergoing medical and surgical management of infectious endocarditis.

Case Description: A 62 year old Caucasian male with a remote history of Hodgkin’s disease complicated by radiation-induced pulmonary fibrosis and aortic stenosis underwent a simultaneous double lung transplant and bioprosthetic aortic valve replacement (AVR) in February 2013. His post operative course was complicated by recurrent bronchopneumonias secondary to MSSA requiring prolonged oxacillin as well as ESRD secondary to presumed uncontrolled acute tubular necrosis (ATN). The patient subsequently underwent a successful living unrelated kidney transplant from his wife in October 2014 with baseline creatinine of 1.4mg/dl. Unfortunately, he developed E. faecalis bacteraemia secondary to urosepsis and subsequent finding of multivalvar endocarditis with superior vena cava involvement. This was treated with a prolonged antibiotic course, but recurrent admissions thereafter for CHF and coronary AKI necessitated a redo AVR along with mitral valve replacement and tricupid valve repair, “Commando Procedure” on 3-9-2015. Immediate post-operative AKI occurred and was thought due to ATN given the presence of muddly brown casts on sediment exam along with hemodynamic instability requiring temporary intra- and post-operative vasopressor support. Amuric AKI persisted for weeks leading to a surveillance kidney biopsy to investigate for superimposed rejection. Notable histologic findings were tubular injury consistent with ATN, but more prominent was that of extensive calcium oxalate deposits consistent with AON.

Conclusion: In summary we report the first known case of AKI due to AON in a lung and renal transplant recipient after infective endocarditis requiring prolonged antibiotics and the Commando heart procedure. Though the clinical presentation mimics ATN it is important for clinicians to include AON in the differential diagnosis.

FR-PO094
Pax2 and PTP1B Regulate AVPR2 Expression in the Inner Medulla

Introduction: In mammals, Pax2 genes code developmental regulatory proteins that specify cell lineages and tissues in metanephros and Pax2 is essential for kidney development. Upon binding to DNA through the conserved paired-domain, Pax proteins can recruit activating and repressing complexes that impart distinct patterns of histone methylation associated with either gene activation or silencing. Expression of Pax2 persists in the medulla of the adult kidney, where it is proposed to prevent apoptosis in response to increased osmolality. Deletion of the Pax2 interacting protein PTP1B in the inner medulla of
mice results in a concentrating defect in part related to a reduction of AVPR2 expression. As Pax2 and PTIP deletion decreases Pax2 and AVPR2 expression in the inner medulla, we hypothesized that Pax2 and PTIP are required for AVPR2 expression.

**Methods:** In IMCD-3 cells with control, Pax2 or PTIP deletion, we determined Pax2 and AVPR2 expression at the mRNA and protein level in response to normal and elevated osmolality. By BMP analysis, we identified sites of Pax2 and PTIP enrichment on the AVPR2 promoter and determined changes in histone modifications, PolII occupancy in inner medulla and in cells derived from this tissue. Pax2 provides the locus specificity for PTIP recruitment of the HMT activating complex and gene expression.

**Results:** Pax2 mRNA peaks 8 hours after an increase in osmolality, Pax2 protein peaks at 12 hours, and Pax2 presence is permanent at 48 hours. PolII occupancy on the HMT activating complex localizes to a 100 bp fragment of the AVPR2 promoter, resulting in increases in activation marks, recruitment of PolII to this locus and an increase in gene expression in both cell lines and murine tissue. We identify the minimal promoter that Pax2 binds to and drives expression of the AVPR2 locus. Deletion of this 100 bp region of DNA results in lack of gene expression in the absence and presence of Pax2. Deletion of PTIP results in loss of gene expression even though Pax2 localizes to the promoter region, as histone activation marks are not increased and PolII is not recruited to this locus.

**Conclusions:** Thus, Pax2 and PTIP both regulate expression of AVPR2 in the inner medulla and in cells derived from this tissue. Pax2 provides the locus specificity for PTIP recruitment of the HMT activating complex and gene expression.

Adenine Downregulates Nkcc2 and Aqp2 in the Rat Kidney and Causes Early Nephrogenic Diabetes Insipidus

**Hassane Amali, Rose P. Webster, Ingrid Fernandes dos Santos.**

**Internal Medicine, Univ of Cincinnati, Cincinnati, OH.**

**Background:** Long-term feeding of adenine is extensively used to develop animal models of chronic renal failure with metabolic features resembling those observed in humans. However, the mechanisms by which adenine induces renal failure are poorly understood.

**Methods:** In this study, we examined the early effects of adenine (ADN) feeding on water metabolism and renal function in rats placed in metabolic cages. Rats were fed control diet or diet supplemented with 0.25% or 0.50% ADN, or 0.50% adenosine ad libitum with free access to dH2O, and monitored daily for food intake, water balance and urine osmolality, and euthanized for blood and kidney collections after 7 days.

**Results:** ADN-treated rats exhibited a sharp polyuria and polydipsia and decreased urine osmolality as early as 3 days, and the magnitude of these effects is dose-dependent. Further, ADN caused a significant reduction in food intake and body weight at 0.50% but not at 0.25%. None of these physiologic parameters was altered by adenosine treatment. DDAVP treatment induced a significant increase in urine osmolality in control but not in ADN-treated rats. Immunohistochemistry demonstrated a sharp reduction in AQP2/actinin co-localisation (75%). Outer medulla (OM), inner medulla (IM), and cortex (C) of ADN-treated vs. control rats. The results also demonstrated that the abundance of Nkcc2/actinin proteins ratio was reduced to zero in the kidney outer medulla of ADN-treated vs. control rats. Blood chemistry of ADN-treated rats was normal except for a significant 3.8-fold increase in BUN, as compared to control rats. When rats were fed adenine diet supplemented with 7% NaCl, their BUN was corrected to normal level, and their osmolality by days 7 - 14. Meloxicam significantly reduced total AQP2 in inner medulla (IM) to 76% and base to 63% of control. Ibuprofen decreased total AQP2 in IM to 76% and control, with no change in base. Meloxicam significantly increased the ratios of p-AQP2 and p-AQP2 to total AQP2 in IM tip (to 44% and 40%, respectively), but less in base. Ibuprofen increased the ratio of p-AQP2 to total AQP2 in IM tip but did not affect p-AQP2/total AQP2. Both NSAIDs increased p-AQP2 and p-AQP2 ratios in tip and base. Ibuprofen increased UT-A1 levels in IM tip, but not base. NR3a, present in rat IM tip and base, was significantly increased in the meloxicam and ibuprofen treated IM bases (37% and 20%, respectively), but unchanged in IM tip. AQP2 and UT-A1 abundances were decreased both in wild type (AQP2: to 76%, UT-A1: to 62%) and NR3a-/- mice. Notably, Ibuprofen treatment caused AQP2 and UT-A1 to decrease more in NR3a-/- mice than in wild type mice.

**Conclusions:** Both NSAIDs significantly increased urine output and decreased urine osmolality by days 7 - 14. Meloxicam significantly reduced total AQP2 in inner medulla (IM) tip to 64% and base to 63% of control. Ibuprofen decreased total AQP2 in IM to 76% and control, with no change in base. Meloxicam significantly increased the ratios of p-AQP2 and p-AQP2 to total AQP2 in IM tip (to 44% and 40%, respectively). Ibuprofen increased the ratio of p-AQP2 to total AQP2 in IM tip but did not affect p-AQP2/total AQP2. Both NSAIDs increased p-AQP2 and p-AQP2 ratios in tip and base. Ibuprofen increased UT-A1 levels in IM tip, but not base. NR3a, present in rat IM tip and base, was significantly increased in the meloxicam and ibuprofen treated IM bases (37% and 20%, respectively), but unchanged in IM tip. AQP2 and UT-A1 abundances were decreased both in wild type (AQP2: to 76%, UT-A1: to 62%) and NR3a-/- mice. Notably, Ibuprofen treatment caused AQP2 and UT-A1 to decrease more in NR3a-/- mice than in wild type mice. Meloxicam did not show any changes either in wild type or in NR3a-/- mice. Notably, Ibuprofen treatment caused AQP2 and UT-A1 to decrease more in NR3a-/- mice than in wild type mice.

**Methods:** We treated rats with a nonselective NSAID, ibuprofen, and a COX-2-selective NSAID, meloxicam, daily for 2 weeks. We assessed urine osmolality and volume, and monitored p-AQPs by Western blotting. NR3a-/- mice were used to examine if NR3a has a protective role.

**Results:** Both NSAIDs significantly increased urine output and decreased urine osmolality by days 7 - 14. Meloxicam significantly reduced total AQP2 in inner medulla (IM) tip to 64% and base to 63% of control. Ibuprofen decreased total AQP2 in IM to 76% and control, with no change in base. Meloxicam significantly increased the ratios of p-AQP2 and p-AQP2 to total AQP2 in IM tip (to 44% and 40%, respectively). Ibuprofen increased the ratio of p-AQP2 to total AQP2 in IM tip but did not affect p-AQP2/total AQP2. Both NSAIDs increased p-AQP2 and p-AQP2 ratios in tip and base. Ibuprofen increased UT-A1 levels in IM tip, but not base. NR3a, present in rat IM tip and base, was significantly increased in the meloxicam and ibuprofen treated IM bases (37% and 20%, respectively), but unchanged in IM tip. AQP2 and UT-A1 abundances were decreased both in wild type (AQP2: to 76%, UT-A1: to 62%) and NR3a-/- mice. Notably, Ibuprofen treatment caused AQP2 and UT-A1 to decrease more in NR3a-/- mice than in wild type mice.

**Conclusions:** We conclude that NSAIDs reduce AQP2 abundance contributing to decreased urine concentrating ability. In compensation, p-AQP2 increases, resulting in decreased urine volume. This beneficial effects of NSAIDs may reflect the altered Ca2+ entry that could be limiting dephosphorylation of AQP2 and promoting improved water homeostasis.

The Role of Klotho in Renal Sodium and Water Transport

Tatila R. Sanchez,1,2 Fernanda O. Coelho,1,3 Leticia Jorge,1 Leticia U. De Castro,1 Makoto Kuro-o,1,3 Lucia Andrade,1,3,4 Div of Nephrology, Univ of Sao Paulo, Brazil; 1Jichi Medical Univ, Japan.

**Background:** Klotho (Kl), a transmembrane protein hormone, counteracts aging. Aging is often paralleled by dehydration, which could promote age-related disorders, because it decreases renal Kl protein abundance, as well as increasing plasma osmolality, antidiuretic hormone (ADH), aldosterone, and 1,25 vitamin D. ADH and aldosterone decrease Kl transcription in HEK293 cells and are elevated in the sera of Kl knockout mice. We explored the effects of Kl deficiency on renal transporters.

**Methods:** 8-12 week old male Kl+/−, Kl−/− and Kl−/+ mice (n=6/group) were fed standard mouse chow and given to lithium access to tap water. We evaluated serum levels of Na, K, Mg, creatinine and urea. We immunoblotted for sodium-hydrogen exchanger isofrom 3 (NHE3), renal outer medullary potassium channel (ROMK), the Na-K-2Cl cotransporter (NKCC2), αENaC and βENaC protein expression.

**Results:** Kl−/− mice present reduced sensitivity to elevated plasma aldosterone levels with no increase of apical αENaC or ROMK protein expression. A lack of Kl can deregulate the adaptive network that determines cell-type-specific expression in renal collecting duct cells. These data provide an initial step in identification of the transcriptional factors (TFs)(Yu et al. PNAS 2009;106:2441). We integrated data from prior proteomics and transcriptomics studies of mouse mpkCCD cells using Bayes’ Rule to create a probability-based ranking of all known TFs with regard to likelihood of a role in collecting duct-tissue-specific gene expression. Among the top-ranked TFs were several Ets family TFs including EREB.

**Conclusions:**

1. Urine samples stored at 4°C for more that 2 weeks provided the values. Urine antigens were measured by using their antibody specificities.

2. Blood samples were obtained from healthy volunteers. We performed the proteomic analysis of serum samples from these volunteers.

3. The identified sites mapped to additional TFs that are predicted to bind within 1000 bp upstream of TSSs (Yu et al. PNAS 2009;106:2441). We integrated data from prior proteomics and transcriptomics studies of mouse mpkCCD cells using Bayes’ Rule to create a probability-based ranking of all known TFs with regard to likelihood of a role in collecting duct-tissue-specific gene expression. Among the top-ranked TFs were several Ets family TFs including EREB.

Inhibition of EGFR Activity Increases Aquaporin 2 Phosphorylation and Increases Water Reabsorption in Lithium Treated Mice

Pui Cheung, Naohiro Nomura, Anil V. Nair, Hua Ann Jenny Lu, Richard Bouley, Dennis Brown Medicine, Massachusetts General Hospital, Boston, MA.

**Background:** Impairment of vasopressin (VP) receptor type 2 signaling in the kidney is detrimental to water homeostasis. However, strategies targeting cAMP signaling to treat diseases associated with water balance have so far been unsuccessful in humans, prompting a search for alternative pathways that modulate AQ2 trafficking.

**Methods:** The effect of erlotinib (Erl) oral gavage in a lithium induced nephrogenic diabetes insipidus mouse model was analyzed by measuring urine volume and osmolality. The effect of Erl on aquaporin 2 trafficking and expression in kidneys was studied by immunostaining and western blot analyses. EGFR and Erl regulation of AQ2 trafficking and phosphorylation were studied using selective kinase inhibitors and phospho-specific antibodies on AQ2-expressing LLC-PK1 cells.

**Results:** EGFR alone had only a subtle effect on AQ2 trafficking, but it exerted a significant antagonizing effect on VP-induced AQ2 phosphorylation and membrane accumulation. Conversely, erlotinib (Erl), an EGFR inhibitor, led to a VP-independent increase of apical AQ2 accumulation in collecting ducts, and significantly reduced urine volume by more than 40% after 4 days of treatment in lithium-induced NDI mice. We enhanced AQ2 phosphorylation and membrane localization in cells by increasing AQ2 ectoysosin and decreasing endocytosis. This effect was cAMP, cGMP, and PKA independent. Despite apparently bypassing cAMP pathways, Erl resulted in AQ2 phosphorylation in a dose dependent manner at serine 256, an essential step in VP-induced AQ2 membrane accumulation. We propose that EGFR has a tonic inhibitory effect on VP action, and that relief of such inhibition enhances AQ2 phosphorylation and results in membrane accumulation.

**Conclusions:** We showed a crosstalk between EGFR and VP in the modulation of AQ2 trafficking. EGFR inhibition increases AQ2 membrane expression bypassing the canonical VP/CAMP/PKA pathway and ameliorates lithium-induced NDI in mice. This study improves our understanding of the diversity of mechanisms that regulate water reabsorption in the body, and uncovers a novel pathway for potential therapeutic targets for NDI.

ChIP-seq Analysis of Genomic Binding Sites for the Transcription Factor E11 in mpkCCD Cells

Hyun Jun Jung, Viswanathan Raghuham, Julie Wook Lee, Mark A. Knepper, Systems Biology Center, NHLBI, NIH.

**Background:** Collecting duct cells selectively express a number of transport proteins (aquaporins and ion channels) vital to water and electrolyte balance. Previous studies of tissue-specific gene expression in collecting duct cells have implicated Ets family transcription factors (TFs)(Yu et al. PNAS 2009;106:2441). We integrated data from prior proteomics and transcriptomics studies of mouse mpkCCD cells using Bayes’ Rule to create a probability-based ranking of all known TFs with regard to likelihood of a role in collecting duct-tissue-specific gene expression. Among the top-ranked TFs were several Ets family TFs including E11.

**Methods:** To identify genomic binding sites for E11 in mpkCCD cells, we carried out ChIP-seq analysis using an antibody successfully employed in the Mouse ENCODE Project. The mpkCCD cells were treated with the vasopressin analog dDAVP (100µM) for 24 hr prior to crosslinking and chromatin immuno-precipitation (ChIP)(n=3). DNA libraries were prepared from immunoprecipitated DNA and sequenced using an Illumina HiSeq 2000 sequence to identify TF-enriched genomic regions. Control ChIP was carried out with nonspecific IgG.

**Results:** The analysis (MACS peak-calling software) identified >20000 binding sites seen in all three replicates and not seen in IgG-only controls. The identified sites mapped to within 2000 bp of annotated transcription start sites (TSSs) of several genes whose transcript abundances were previously demonstrated to be regulated by vasopressin including Id3, JunB, Gabpa, Sp1, Sp3, Hmox1, Hif1a and Rora.

**Conclusions:** These data provide an initial step in identification of the transcriptional network that determines cell-type-specific expression in renal collecting duct cells.

**Funding:** Other NIH Support - NHLBI Intramural Research Program
Deletion of Aquaporin 11 in Transgenic Mice prior to Post-Natal Day 12 Results in Proximal Tubule Injury and Cyst Formation

**Background:** AQP11 is expressed in the proximal tubule (PT). Neutrophil AQP11 KO mice show PT vacuolization and cysts, resulting in renal failure and death. This study examined whether AQP11 deficiency at specific stages of kidney development is important for PT injury and cyst formation. If so, cysts are continuous with PT hence representing PT dilations. This was confirmed by serial sectioning and digital 3-D tracing of PT cysts in adult, neutonally induced AQP11 KO mice revealed endocytotic uptake in both cystic and PT epithelium. Thus apparent cysts were continuous with PT hence representing PT dilations. Underline represents presenting author.

**Results:** Real-time PCR analysis showed that renal NOX2 mRNA level was markedly increased in AQP11 KO mice or total neonate AQP11 KO mice resulted in PT cytoplasmic vacuoles but not PT cysts. Immunohistochemistry techniques. Also, a pathway analysis was performed with the results of the Warburg effect, were both increased in lithium-treated mpkCCD cells and mice. Targeting of aerobic glycolysis with 2-deoxyglucose rescued lithium-induced cell cycle arrest, which develops in 20% of patients into Symptomatic Nephrogenic Diabetes Insipidus (NDI). This disorder is characterized by lithium causes a urinary concentrating defect, which develops in 20% of patients into symptoms of the Warburg effect. Here, we investigated whether lithium may induce Warburg-like aerobic glycolysis and whether inhibition of this Warburg effect may rescue lithium-induced-NDI (Li-NDI).

**Methods:** Polarized mouse cortical collecting duct (mccKCD) cells were cultured as a 2D transwell model and exposed to lithium chloride on the apical side (10 mM) and basolateral side (1 mM) to mimic clinical conditions in patients. C57BL6/J mice were fed a normal rodent diet or a diet with lithium chloride in a concentration of 40 mmol/kg of chow. After 2.5 weeks of treatment, mice were housed in metabolic cages for 16 hours (16h) and 6.5 hours (6.5h). Results: The lithium-induced proliferation of mccKCD cells and mice. This was accompanied by a decrease in the ratio of phospho-pyruvate dehydrogenase pPDH1/pDH, confirming the induction of aerobic glycolysis by lithium in mice. Interestingly, inhibition of lithium-induced glycolysis with 2-deoxyglucose (2DG) attenuated lithium-induced AQP2 downregulation in mckCD cells.

**Conclusions:** Our results reveal that lithium induces aerobic glycolysis in mckCD cells and mice. Targeting of aerobic glycolysis with 2-deoxyglucose rescued lithium-induced AQP2 downregulation and may represent a potential therapy for Li-NDI.

RNA-seq Profiling of the Cortical Collecting Duct in Vasopressin Escape
Jae Wook Lee,1 Carolyn M. Ecclebarber,2 Mark A. Knepper,1 * NHLLI, NIH, Bethesda, MD; *Georgetown Univ, Washington, D.C.

Background: Vasopressin escape is a protective mechanism that limits hyponatremia in the syndrome of inappropriate antidiuresis (SIADH). RNA-seq, we investigated transcriptional changes in microdissected cortical collecting duct (CCD) of rats undergoing vasopressin escape.

Methods: Male Sprague-Dawley rats (120-160 g) were placed on continuous dDAVP (5 ng/hr) infusion for 5 days, and received either a high water load (50 mL/d, “escape”) or a normal water load matching insensible losses plus urine output (25 mL/d, “control”). Rats were sacrificed at day 1, 2, and 4, and 4 mm of CCDs were collected by manual microdissection. RNAs were processed into cDNA libraries and 50-pb paired-end reads were obtained using an Illumina platform. Reads mapping to Ensembl genes were counted for differential-expression analysis.

Results: Sequence depths were 40-65 million reads, with 80% of reads mapping to Ensembl genes. At day 2, 180 transcripts were downregulated and 339 transcripts were upregulated at a false discovery rate < 0.1. Consistent with increased water excretion in vasopressin escape, transcripts of aquaporin-2 and aquaporin-3 were significantly downregulated at day 1, 2, and 4. Among downregulated transcripts were transcription factors (Hes1, Hmx2, Hoxb5, Hoxb6, Hoxb7, Jun, and Fox3) and a cyclin-dependent kinase inhibitor (Cdk1). Among upregulated transcripts were proteins involved in cell division, such as centromere proteins (Cep130, Cenpl, Cenpe, and Cenpd); cyclins (Ccn2a, Ccnb2 and Cdcn1), a cyclin-dependent kinase (Cdk1), components of DNA replication machinery (Mcm2, Mcm3, Mcm4, Mcm6, and Mcm7) in MCM replicative helicase complex; Orc5 in origin recognition complex; polo-like kinase 1 (Plk1); and forkhead box protein M1 (Foxm1). GO terms related to cell division were enriched in upregulated transcripts (“cell cycle phase”, adjusted p<10^-10; “mitosis”, 2 × 10^-10). Immunohistochemistry showed PCNA-positive cells in CCD of escape rats but none in control rats.

Conclusions: RNA-seq revealed that increased rate of cell division may be an activated mechanism involved in remodeling of the CCD to restore water homeostasis as a part of the renal adaptation to SIADH.

Silencing of the Kinome Identifies a Novel Modulator of Aquaporin-2 Trafficking
Hana Cernochka,1 Dorte Faust,1 Kerstin Zuehlke,1 Marc Wippich,1 Katina Lazarow,1 Martin Neuenschwander,1 Jens Peter von Kries,1 Enno Klussmann.1 1 Anchored Signalling, Max Delbrück Center for Molecular Medicine in the Helmholtz Association, (MDC), Berlin, Germany;1 Leibniz-Institut für Molekulare Pharmakologie (FMP), Campus Berlin-Buch, Berlin, Germany.

Background: Arginine vasopressin (AVP)-dependent water reabsorption requires the redistribution of aquaporin-2 (AQP2) from intracellular vesicles into the plasma membrane of renal principal cells. Despite identification of several proteins participating in the control of AVP-dependent AQP2 trafficking, the molecular mechanisms underlying the AQP2 redistribution are largely unknown. The aim of this study was to identify proteins controlling the localization of AQP2 and thereby to elucidate molecular mechanisms underlying the AQP2 translocation.

Methods: We established a large-scale siRNA screening using mouse collecting duct cells, stably expressing human AQP2. The expression of 719 kinases was knocked down and the redistribution of AQP2 and simultaneously increases the AQP2 protein abundance.

Conclusions: Our approach contributes to understanding the molecular mechanisms underlying the control of AQP2 trafficking and to identify potential therapeutic targets for the treatment of diseases caused by or associated with aberrant AVP-mediated water reabsorption such as diabetes insipidus or heart failure.

Toxin (DT) injection, received vehicle, AngII+HS (AngII, 450 mg Kg/day+1% NaCl in
Models of Hypertension
Splenectomy Differentially Affects Angiotensin-II and L-NAME Murine
FR-PO115
FR-PO114
LA;
tubular sodium transporters by AngII+HS. and iRAS in CD11c.DOG mice (p<0.05 compared to AngII+HS; n=5-9). in injection of DT concomitant to AngII+HS prevented the changes in sodium transporters converting enzyme, 1.9; and Angiotensin II receptor type I, 5), NHE3, NCC and αENaC AngII+HS increased the iRAS (in fold of induction: Angiotensinogen, 1.5; Angiotensin 1.23-fold, respectively. Furthermore, SPLX did not appear to influence the development of L-NAME HTN. SPLX+L-NAME mice had similar P=0.84 SBF (145±5mmHg) as the Sham+L-NAME group (146±4mmHg, n=6) after 2 weeks. Relative heart weights were also similar (P=0.45) between SPLX+L-NAME (4.9±0.2) and Sham/L-NAME treated mice (4.5±0.3mg/g BW). Conclusions: Our data suggests that the full pressor response to AngII is dependent on the spleen. However, the effect of the spleen appears to be independent of renal inflammation. Moreover, the protective effect of the spleen is specific to AngII-dependent HTN and does not appear to be generalizable to all mouse models of hypertension. Further studies are needed to understand the link between the lymphoid organs (such as the spleen), renal inflammation, and the development of chronic HTN.

FR-PO116

Background: Hypertension (HTN) develops in rats that received the NaF inhibitor pyroolidinedithiocarbamate (PDTC) during lactation. High salt (HS) and uninephrectomy (UNE) exaggerate the HTN, increase heart weight and blood pressure. However, we explored the underlying mechanisms of renal HTN and the effect of LS on HTN. SPLX did not appear to influence the development of chronic HTN. SPLX+L-NAME treated mice, respectively. Furthermore, SPLX did not appear to influence the development of L-NAME HTN. SPLX+L-NAME mice had similar P=0.84 SBF (145±5mmHg) as the Sham+L-NAME group (146±4mmHg, n=6) after 2 weeks. Relative heart weights were also similar (P=0.45) between SPLX+L-NAME (4.9±0.2) and Sham/L-NAME treated mice (4.5±0.3mg/g BW). Conclusions: Our data suggests that the full pressor response to AngII is dependent on the spleen. However, the effect of the spleen appears to be independent of renal inflammation. Moreover, the protective effect of the spleen is specific to AngII-dependent HTN and does not appear to be generalizable to all mouse models of hypertension. Further studies are needed to understand the link between the lymphoid organs (such as the spleen), renal inflammation, and the development of chronic HTN.

High Salt Affects Toll-Like Receptor-Induced Gene Expression in Macrophages
David Severs, Martin Hoogduijn, Alexander H. Danser, Robert Zietse, Ewout J. Hoorn.
Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands.

Background: High dietary salt intake is a major risk factor for cardiovascular disease. A high-salt (NaCl) diet increases NaCl concentrations in the skin. The skin, macrophages respond to high NaCl by the osmosensitive transcription factor NFAT5 and promote NaCl efflux via lymph vessels. Other effects of NaCl on local macrophages have remained largely elusive until recently. Evidence suggests that NFAT5 also regulates multiple Toll-like receptor (TLR)-induced genes such as NOS2, Tnf, and IL6 in macrophages, independently of osmotic stress. We aimed to investigate the effects of NaCl-generated hypertonicity on the expression of these genes in TLR-activated macrophages.

Methods: We simulated the hypertonic skin environment by culturing macrophage-like RAW 264.7 cells in NaCl-induced hypertonic media (340-480 mM NaCl) and compared this with normotonic media (320 mM NaCl). After 1 to 24 hours of incubation with lipopolysaccharide (LPS) or Zymosan A, we measured nuclear protein expression and analyzed TLR response genes by quantitative RTPCR, and p38, MAPK, NFAT5, and NO2 by immunoblot.

Results: NaCl significantly and dose-dependently increased nitric oxide (NO) production (2-fold), NOS2 mRNA (3-fold) and NOS2 protein expression (2.25-fold) in LPS and Zymosan A-stimulated cells. In contrast, equimolar mannitol or urea did not affect expression levels. NaCl also increased LPS-induced p38 phosphorylation and total NFAT5 protein expression. Similarly, NaCl increased TNF mRNA expression 1.25-fold. Remarkably, NaCl significantly downregulated LPS-induced expression of CCL5 (4-fold), IL6 (2.4-fold) and IL12b mRNA (3.5-fold).

Conclusions: Elevated concentrations of NaCl, comparable with those found in the skin after high dietary salt intake, amplify expression of NOS2 and Tnf in TLR-stimulated macrophages. This effect is likely mediated via p38 and NFAT5. Increases in NOS2 and TNF expression were paralleled by a sharp decline in mRNA expression of other proinflammatory genes. Modulation of TLR-mediated macrophage activation by NaCl may be relevant both for the physiological response to high dietary salt and salt-sensitive hypertension.

FR-PO119
Indoxyl Sulfate Uptakes Aortic Expression of (Pro)renin Receptor by Reactive Oxygen Species and Activation of AhR/NF-κB Pathway in Vascular Smooth Muscle Cells
Maimaiti Yisireyili,1 Toshimitsu Niwa.
Cardiology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan; Faculty of Health and Nutrition, Shubun Univ, Ichinomiya, Aichi, Japan.

Background: Chronic kidney disease (CKD) is considered major causes of death in cardiovascular disease (CVD) patients. (Pro)renin receptor (Prr) is significantly expressed in the human aortic system. In this study we aimed to clarify the role of indoxyl sulfate (is), a uremic toxin, in PRR activation in rat aorta and human aortic smooth muscle cells (HASMCs).

Methods: CKD rats and IS-administrated rats were subjected for in vivo experiments. Human aortic smooth muscle cells (HASMCs) was treated with or without indoxyl sulfate (is), a uremic toxin, in PRR activation in vitro and in vivo.

Results: Immunohistochemistry showed increased expression of PRR and renin/prorenin in aorta of CKD rats and IS-administrated rats compared with normal rats. RR was elevated the expression of PRR and protein in HASMCs. N-acetylcysteine (nac), an antioxidant, and diphenylethenonin, an inhibitor of nicotinamide adenine dinucleotide phosphate oxidase, suppressed IS-induced expression of PRR and protein in HASMCs. Knock down of PRR inhibited cell proliferation and tissue factor expression induced by not only renin but also IS in HASMCs. IS promotes aortic expression of PRR and renin/prorenin through OAT3-mediated uptake, production of reactive oxygen species, and activation of AhR and NFκB in vascular smooth muscle cells.

Conclusions: IS promotes aortic expression of PRR and renin/prorenin through OAT3-mediated uptake, production of reactive oxygen species, and activation of AhR and NFκB in vascular smooth muscle cells.
Conclusions: In summary, our findings provide evidence for a dynamic micro-compartmentation of TRPV4/K+ in caveolae of endothelial cells and highlight the importance of Cav-1 for endothelial K+ functions and flow-induced vasodilation.

Adenosine A1 Receptor Exacerbates Water-Sodium Retention in Deoxycorticosterone Acetate-Salt Hypertensive Mice Janet Yanquina Mei,1 Xiaoiaofei Shu,1 Dongli Tian,1 Xiaoyan Peng,1 Wei Chen,1 Limeng Chen.1 1Nephrology Dept, Peking Union Medical College Hospital, Beijing, China; 2Cardiology Dept, Peking Union Medical College Hospital, Beijing, China.

Background: Water-sodium retention is the key change in salt sensitive hypertension. Adenosine A1 receptor (A1AR) engages in tubuloglomerular feedback; its activation is followed by increased secretion of atrial natriuretic peptides (ANP) in the heart. We aim to study the function of A1AR in water-sodium retention.

Methods: DOCA-salt hypertensive model was established by removal of left kidney, implantation of a DOCA pellet (200mg, 60-day release), and feeding with high salt diet followed by increased secretion of atrial natriuretic peptides (ANP) in the heart. We aim to study the function of A1AR in water-sodium retention.

A1AR, ANP and Corin (a protease cleaves pro-ANP, producing ANP) mRNA expression was measured by real-time PCR.

Results: Wildtype DOCA-salt mice showed higher blood pressure (124.7±20.3 vs. 105.8±14.1 mmHg, P<0.01), slower heart rate (562.0±90.8 vs. 681.5±90.1, P<0.01), and increase in 24 hour urine output (3606.2±2359 vs. 1399.7±52 ml, P=0.01). The adenosine pathway was activated in DOCA-salt mice evidenced by increased CD73 (2.22 and 17.7 times increased expression in kidney and heart, P=0.034 and 0.001) and A1AR expression (2.54 and 11.12 times increased expression in kidney and heart, P=0.032 and 0.009). The cardiac mRNA expression of ANP and Corin were also significantly higher in DOCA-salt mice (176.67 and 30.93 times increased expression, P=0.030 and 0.005). The A1AR+ mice showed no significant changes in blood pressure or heart rate between DOCA-salt and sham groups. The urine output in 24 hour urine output (7003.3±3742 vs. 3606.2±2359 ml, P=0.031) and 24 hour sodium excretion (1464.5±860.0 vs. 1497±48.9 mmol/d, P=0.028) was more prominent compared to wildtype DOCA-salt mice. There was no change in either ANP or Corin mRNA expression.

Conclusions: A1AR may exacerbate water-sodium retention in salt sensitive hypertension. The reduction in glomerular hyperperfusion and hyperfiltration through A1AR, ANP and Corin (a protease cleaves pro-ANP, producing ANP) mRNA expression implantation of a DOCA pellet (200mg, 60-day release), and feeding with high salt diet followed by increased secretion of atrial natriuretic peptides (ANP) in the heart. We aim to study the function of A1AR in water-sodium retention.

A 20% Fructose Diet Enables Low Concentrations of Angiotensin II to Activate Sodium Transport in the PT via Protein Kinase C (PKC) Pablo D. Cabral, Jeffrey L. Garvin. Physiology & Biophysics, Case Western Reserve Univ, Cleveland, OH.

Background: Consumption of high-fructose corn syrup is implicated in the development of hypertension but the mechanisms are poorly understood. The proximal tubule (PT) reabsorbs ~70% of the filtered fluid, Na and most of the bicarbonate via Na-Pi cotransport. Enhanced Ang II (Ang I) activity in PT may be due to a combination of increased binding to the PT, reduced tubuloglomerular feedback possibly outweighs the up-regulation of Corin and subsequent hypertension. Angiotensin II (Ang II), atrial natriuretic peptide (ANP) and dopamine regulate Na transport. Enhanced effects of Ang II and decreased actions of ANP and dopamine in the PT may cause salt-sensitive hypertension. Hypothesis: A 20% fructose diet enables low concentrations of Ang II to activate Na transport in the PT via protein kinase C (PKC).

Methods: We isolated and perfused PTEs from Sprague Dawley rats that were fed either a control or a 20% fructose diet for 1 week. NHE activity was measured as the recovery of intracellular pH after an NH4Cl acid pulse using the pH-sensitive dye BCECF. The rate of pH recovery was measured in Fluorescent Units per second (FU/sec).

Results: Ang II (10−8 M) did not stimulate NHE under normal conditions. When rats were fed a 20% fructose diet, this concentration stimulated NHE activity from 0.601±0.1 1.30±0.1 FU/sec (p=0.002±0.05). In the presence of the PKC inhibitor Go6976 (10−7 M), Ang II was unable to stimulate NHE activity (from 1.09±0.6 to 1.2±0.2 FU/sec±0.12). The dopamine 1 receptor agonist fenoldopam (10−8 M), decreased NHE activity to the same extent in PTs from rats fed either a control or a 20% fructose diet (−0.61±0.2 vs. −1.1±0.4 FU/sec±0.5). ANP (10−7 M) also decreased NHE activity to the same extent in PTs from rats fed either a 4% NaCl diet or 4% NaCl plus 20% fructose diet (+0.4±0.1 vs. +1.6±0.5 FU/sec±0.12).

Conclusions: A 20% fructose diet enables low concentrations of Ang II to activate Na transport in the PT via PKC without affecting the inhibitory effects of dopamine and ANP on NHE activity in the PT. These results may partially explain the mechanism by which a fructose diet induces hypertension.

Megalin-Dependent Intrarenal Generation of Angiotensin II Induced by Podocyte Injury Taiji Matsussaka,1 Fumio Niinuma,1 Akira Nishiyama,2 Akihiko Saito,1 Motoko Yanagita,1 Ikemui Ichikawa,1,3 Tokai Univ School of Medicine, Japan; 2Kagawa Univ School of Medicine, Japan; 3Niigata Univ School of Medicine, Japan; 4Kyoto Univ School of Medicine, Japan; 5Shinshu Univ, Japan.

Background: We previously demonstrated that podocyte injury enhances glomerular filtration of liver-derived angiotensinogen (Agt) and renal angiotensin(AII) generation and that filtered Agt is reabsorbed by proximal tubular cells dependently on megalin. In the present study, we tested whether megalin is involved in intrarenal AII generation.

Methods: For this purpose, we generated proximal tubule specific megalin knockout (KO) mice by crossing megalin-loxp, Ndrg1-Cre, and Kap-Cre mice. Renal Agt contents were measured by radioimmunoassay.

Results: In megalin KO mice (n=12), renal megalin mRNA was decreased to 2.5% that in control mice (n=16). Renal AII staining was markedly diminished, with increase in urinary Agt in KO mice. However, renal AII levels were similar between KO and control mice (108±11 vs. 101±17 fmol/g). We next tested the effect of megalin KO on AII generation in the PT by locally delivering angiotensinogen with increased load of Agt in mice with podocyte-specific injury, by crossing with NEP25 mice. Control NEP25 mice (n=10) showed markedly intense renal AII staining and enhanced renal AII level (450±61). Megalin KO/NEP25 mice (n=12) showed diminished renal AII staining and significantly attenuated renal AII level (119±23± ±0.01). KO/NEP25 mice showed similar renal and Agt mRNA, and more presence of renin mRNA in the kidney.

Conclusions: These indicate that, in podocyte injury, abnormally increased filtered load of Agt is reabsorbed via megalin by proximal tubular cells and induces the inappropriate activation of intrarenal renin-angiotensin system, which may be involved in the progression of tubulointerstitial damage secondary to podocyte injury.

FR-PO126

Ciliary Neurotrophic Factor Deficiency Protects from Cardiovascular Death in Angiotensin II-Induced Hypertension Jyo Quack,1 Yuriko Morii,2 Sebastian Alexander Potthoff,1 Magdalena Woznowski,1 Eva Koenighuisen,1 Lorenz Sellin,1 Lars C. Rump,4 Johannes Stiebauer,1 1Nephrology, Univ Hospital Duesseldorf, Duesseldorf, Germany; 2Nuclear Medicine, Univ Hospital Duesseldorf, Duesseldorf, Germany.

Background: It has been shown that the JAK2 / STAT3 signaling cascade modulates renin-angiotensin system (RAS) function. It has been shown that the JAK 2 / STAT3 signaling cascade modulates renin-angiotensin system, which may be involved in the progression of tubulointerstitial damage secondary to podocyte injury.

Methods: Two weeks after uninephrectomy, Ang II osmotic minipumps (1000 ng/min/400 μl/D) were implanted in CNTF-KO and age matched C57Bl/6j male mice (WT). Blood pressure (BP) were measured for 3 weeks by radiotelemetry, starting one week before implantation. Histological and mRNA analysis were performed at the end of the observation period. Renal vascular function was evaluated in the isolated perfused kidney.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Results: At baseline systolic BPs were similar in CNTF-KO and WT mice (119±2 vs. 124±3 mmHg). CNTF deficiency significantly attenuated BP increase under Ang II infusion (week 1: 139±3 vs. 153±3 mmHg; week 2: 151±5 vs. 168±4 mmHg; n=19, P<0.01). Strikingly, in the CNTF-KO group significantly less animals died of cardiovascular causes (4.2% (KO) vs. 29.2% (WT) P<0.05). In accordance, end organ damage (cardiac hypertrophy, renal vascular fibrosis and tubulo-interstitial damage) was attenuated in the CNTF-KO group. In the isolated perfused kidney, pressor response to Ang II was significantly attenuated in CNTF-KO mice. Administration of CNTF (0.5nM) nearly restored the Ang II dependent pressor response. This effect was mediated through a JAK2/STAT3 dependent pathway as static (0.1μM), a selective STAT3 inhibitor abolished the CNTF induced increase in pressor response in kidneys of CNTF-KO. On cellular basis, CNTF induced phosphorylation of STAT3 and MYPT1 in VSMCs.

Conclusions: Better survival and less end organ damage strongly suggest that CNTF has a major impact on blood pressure regulation. CNTF seems to modulate the Ang II induced vasoactivity via a JAK2 / STAT3 dependent mechanism. Thus, CNTF might qualify as therapeutical target in hypertension.

FR-PO127 Angiotensin II AT1 Receptor Potentiates Prostaglandin E2 Vasconstrictor Effects Maria Palazzo Kraemer,1 Fred S. Lamb,1 Richard M. Breyer.1 1Div of Nephrology and Hypertension, Dept of Veterans affairs and Vanderbilt Univ, Nashville, TN; 2Dept of Biochemistry, Vanderbilt Univ, Nashville, TN; 3Dept of Pediatrics, Vanderbilt Univ, Nashville, TN.

Background: Prostaglandin E2 (PGE2) is a key modulator of blood pressure and arterial tone. It usually has vasopressor effects however under certain circumstances can act as a vasodilator. Recent reports have suggested that sub-threshold concentrations of KCl and phenylephrine augment PGE2-mediated contraction in rat femoral arteries, however the effects of angiotensin II (Ang II) on PGE2-mediated contraction are unknown.

Methods: Wire myography was performed on femoral arteries isolated from WT or EP deficient mice.

Results: PGE2 had no effect on mouse femoral arteries at doses up to 1 μM. Pretreatment of arterial rings with 1 μM Ang II potentiated PGE2-evoked contraction in a dose dependent manner (AUCmax: 1.87±0.335, AUCmax: 23.27±9.820, P<0.05). To identify the relevant EP-Prostanoid (EP) receptor, femoral arteries from EP1, EP2, and EP3 receptor null mice were tested. Arteries isolated from EP1−/− or EP2−/− but not EP3−/− mice responded to PGE2 after Ang II priming. Pretreatment of arterial rings with 1 μM losartan, an AT1 angiotensin receptor antagonist, blocked PGE2-mediated contraction in EP1−/− mice and EP2−/− mice but not EP3−/− mice. 

Conclusions: Taken together these data are consistent with angiotensin AT1 and prostaglandin EP3 receptors mediating a synergistic Ca2+/Rho-kinase-dependent contractile response. The synergistic interaction of Ang II and PGE2 may have physiological relevance in the context of hypertension.

FR-PO128 Angiotensin II Increases Uromodulin Expression and Excretion in Rats Independent of Blood Pressure and Alterations in Tubular Reabsorption Magali Araujo, William J. Welch, Gabriel A. Cordeiro dos Santos, Daurea M. Vieira Paiva, Christopher S. Wilcox. Medicine, Georgetown Univ, Washington, DC.

Background: Increased uromodulin (UMOD) has been associated with salt-sensitive hypertension and chronic kidney disease. Evidence suggests that UMOD regulates the trafficking and activity of the Na-K-2Cl cotransporter (NKCC2) and the inward-rectifier type potassium channel (ROMK), the two main transporters involved in Na+ reabsorption by the TAL. Angiotensin II (AngII) increases net TAL Na+ transport and Na+ apical entry; however its interaction with UMOD remains elusive. We hypothesized that Ang II interacts with UMOD to modulate Na+ transport.

Methods: Sprague-Dawley rats (n=5) were infused with a subpressor dose of AngII (100ng/kg/min) or vehicle for 3 days. Blood pressure (BP) was measured by telemetry. On day 2, rats were placed in metabolic cages for 24 h and urine was collected for UMOD and Na/K measurements. On day 3, proximal and distal reabsorption were measured by micropuncture technique and the renal medulla was harvested for determination of UMOD expression by western blot.

Results: Blood pressure was unchanged after 3 days of AngII (veh: 89±3, AII: 81±1mmHg). AngII treated rats had significantly increased UMOD excretion compared with vehicle rats (veh: 17±3.2, AII: 28±9.3, 3±24h, P<0.05). Sodium excretion was unchanged (veh: 3.46±0.6 AII: 3.38±0.6 mmol/24h). There were no changes in proximal fractional reabsorption (veh: 57±2%, AII: 59±0.6%) and distal fractional reabsorption (veh: 83±3%, AII: 87±2%). UMOD expression in the renal medulla was 3 fold higher in AngII treated rats compared to vehicle rats.

Conclusions: Our data demonstrate that AngII increases UMOD expression and excretion independent of blood pressure and alterations in tubular reabsorption. These results suggest that the interaction of AngII with UMOD precedes Na+ transport alterations and therefore can be an important mechanism involved in the development of hypertension.

FR-PO129 Effects of Systemic Deletion of Angiotensin Receptor-Binding Molecule on the Aging Kidney Kazushi Uneda, Kouichi Tamura, Hiromichi Wakui, Akinobu Maeda, Kengo Azushima, Soni Haku, Ryu Kobayashi, Masato Ohsawa, Yoshitoyo Toya, Satoshi Umemura. Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Japan.

Background: The renin-angiotensin system plays a key role in the maintenance of cardiovascular and renal homeostasis, principally via appropriate activation of the angiotensin II type 1 receptor (AT1R). On the other hand, exaggerated activation of AT1R signaling would exert detrimental effects, such as various aging-related diseases including renal dysfunction. We previously identified an AT1 receptor-associated protein (ATRAP/Agrap), which is expressed specifically in the AT1R. The accumulating results suggest that ATRAP exerts functionally selective inhibition on exacerbated AT1R activation in response to pathological stimuli. The present study was performed to investigate pathophysiological significance of ATRAP in aging-related phenotypes by employing systemic ATRAP-knockout mice (ATRAP-KO mice).

Methods: ATRAP-KO mice and their wild-type control mice (WT mice) were fed the standard diet and maintained until death to estimate their life spans. Their growth (body weight change and appearance) and physiological parameters (blood pressure, cardiac index) were monitored. In addition, renal aging-related organ damages in the hearts, aortas and kidneys were examined in young (3 to 4 months old) and aged (22 to 25 months old) mice in both groups.

Results: There was no difference in the growth between two groups. In addition, ATRAP-KO mice did not show any evident difference between the two groups. The life span of ATRAP-KO mice was significantly shorter than that of WT mice (KO vs WT; median life span, 100.4 weeks vs 123.1 weeks, log-rank test, P<0.001). By further analysis we found no significant difference in cardiovascular aging-related phenotype between two groups. On the other hand, renal fibrosis was exacerbated in aged ATRAP-KO mice compared to aged WT mice.

Conclusions: In the present study, ATRAP-KO mice showed accelerated renal fibrosis with shortened life span. Therefore, ATRAP deficiency seems to exacerbate the aging-related renal fibrosis and to inhibit the longevity.

Funding: KOCHI

FR-PO130 Effects of Deficiency of Angiotensin Receptor-Rebinding Molecule on Blood Pressure Regulation in Chronic Kidney Disease Ryo Kobayashi, Kouichi Tamura, Hiromichi Wakui, Kengo Azushima, Soni Haku, Kazushi Uneda, Kotaro Murakura, Kohji Otsuki, Shigeki Kinguchi, Masato Ohsawa, Yoshitoyo Toya, Satoshi Umemura. Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Kanagawa, Japan.

Background: The renin-angiotensin system plays a key role in the maintenance of cardiovascular and renal homeostasis, principally via appropriate activation of Ang II type 1 receptor (AT1R). On the other hand, exaggerated activation of AT1R signaling would exert detrimental effects, such as promoting various aging-related diseases including chronic kidney disease (CKD). We previously identified an AT1R-associated protein (ATRAP/Agrap), which is a molecule directly interacting with the AT1R. Accumulating results indicate that ATRAP exerts functionally selective inhibition on exacerbated AT1R activation in response to pathological stimuli. The present study was performed to investigate pathophysiological significance of ATRAP in mouse model of CKD by employing systemic ATRAP-knockout mice (ATRAP-KO mice).

Methods: ATRAP-KO mice and their wild type control mice (WT mice) were subjected to 5/6 nephrectomy (Nx) as CKD model. To examine the effects of ATRAP deficiency, blood pressure and other parameters were measured in ATRAP-KO mice and WT mice after 5/6 Nx.

Results: At baseline, blood pressure was similar in ATRAP-KO and WT mice. In ATRAP-KO mice, blood pressure increased from 2 to 8 weeks after 5/6 Nx and was significantly higher than that in WT mice (ATRAP-KO vs WT; systolic blood pressure at 4 weeks after 5/6 Nx, 124±2 mmHg vs 107±1mmHg, P<0.01). With respect to the mechanism of elevated blood pressure in ATRAP-KO mice after 5/6 Nx, plasma volume was significantly higher in ATRAP-KO mice than in WT mice after 5/6 Nx, in spite of no significant difference in creatinine clearance between two groups after 5/6 Nx.

Conclusions: Although ATRAP-KO mice show similar blood pressure and renal function with WT mice in normal condition, ATRAP-KO mice exhibited significantly...
increased blood pressure and plasma volume after 5/6 Nx compared with WT mice. Therefore, endogenous ATRAP may exert a protective function against pathological blood pressure elevation in CKD.

**In Vivo Action of Angiotensin II Type 1a Receptor in Renal Injury Induced by Deoxycorticosterone Acetate-Salt Hypertension**  
Mikako Hisamichi, Atsuko Remori,1,2 Takeshi Sugaya,1 Daikuso Ichikawa, Kenjiro Kimura, Yugo Shibagaki.  
1 Div of Nephrology and Hypertension, Dept of Internal Medicine, St. Marianna Univ School of Medicine, Kawasaki, Japan; 2Dept of Anatomy, St. Marianna Univ School of Medicine, Kawasaki, Japan; 3Dept of Internal Medicine, Tokyo Takanawa Hospital, Tokyo, Japan.

**Background:** The AT1a receptor plays a major role in the renal action of Ang II and is expressed in vascular smooth muscle cells of the afferent arterioles. In this study, we investigated the morphological change in deoxycorticosterone acetate (DOCA)-salt hypertensive rats to confirm the in vivo function of the AT1a receptor against renal damage due to hypertension.

**Methods:** To examine urinary L-type fatty acid binding protein (L-FABP) as an indicator of tubulointerstitial damage, we used human L-FABP chimeric transgenic rats. To further explore this, we investigated the role of glomerular albumin and L-FABP in the AT1a receptor mice in the DOCA-salt hypertensive model.

**Results:** In the DOCA-salt hypertensive model with L-FABP+/−-DOCA mice, slight expansion of the glomerular area and tubulointerstitial damage were observed, but no glomerular sclerosis. In the AT1a knockout mice administrated DOCA-salt, glomerular sclerosis with expansion of the mesangial area was found, and the degree of tubulointerstitial damage was more severe compared with L-FABP+/−-DOCA mice. In the AT1a receptor gene added L-FABP+/−-DOCA mice, L-FABP+/−-DOCA mice were significantly higher in the L-FABP+/−-DOCA mice than in the L-FABP+/−-DOCA mice. This renal damage induced in the L-FABP+/−-DOCA mice was significantly attenuated by reduction of blood pressure using Hydralazine. Activation of the AT1a receptor may contribute to myogenic response of the afferent arterioles involved in the renal autoregulatory mechanism.

**Conclusions:** In conclusion, kidneys without AT1a receptors exhibited an increased vulnerability to hypertension, and therefore activation of the AT1a receptor inhibited the transmission of the elevated systemic pressures to the glomeruli.

**FR-PO132**

**Renal Blood Flow and Oxygenation During Renin-Angiotensin-Aldosterone System Activation – Two Sides of the Same Coin?**  
René van der Bel,1 Aart J. Nedernev,2 Bram F. Coolen,2 Wouter V. Potters,2 Heinz J. Verberne,1 Liiftert Vogt,1 Erik Stroes,1 C.T.P. (Paul) Krediet,1 1Internal Medicine, AMC, Univ of Amsterdam, Netherlands; 2Radiology, AMC, Univ of Amsterdam, Netherlands; 3Nuclear Medicine, AMC, Univ of Amsterdam, Netherlands.

**Background:** In chronic kidney disease, renal hypoxia and renin-angiotensin-aldosterone system (RAAS) activation may augment each other. Although renal oxygenation (RO) measured by Blood Oxygen Level Dependent (BOLD) MRI is not correlated to Glomerular Filtration Rate (GFR), recent data suggest that RO relates to inter-individual variation in RAAS activity. Further, this study investigated the role of Angiotensin II (II-ANG) on renal blood flow (RBF) and RO in healthy human volunteers.

**Methods:** After a 30 min baseline phase, 8 healthy volunteers (age 19-22 years) were subjected to continuous Ang-II infusion at 0.3, 0.9 and 3.0 ng/kg/min for 12 minutes per dose. Mean arterial blood pressure increased from 83.0 ± 2.85 at baseline to 91.3 ± 3.76 (p<0.001). RBF were assessed by BOLD and phase contrast MRI, respectively. In the proximal renal artery after manual vessel segmentation. During a second visit (n=6), GFR and Effective Renal Plasma Flow (ERPF) were measured by 131I-thalidomate and 131I-hippuran clearing test during equal Ang-II infusion.

**Results:** Mean arterial blood pressure increased from 83.0 ± 2.85 at baseline to 91.3 ± 3.76 mmHg (p<0.002). RBF decreased dose dependently from 11.12 ± 0.08 to 8.05 ± 1.02 (p=0.03) ml/s. GFR and ERPF both decreased (10.7%, p=0.016; 24.5%, p<0.001). RBF and ERPF measurements strongly correlated (R = 0.75 p<0.001). There was a trend towards a cortical R2* increase by 7.2 ± 3.76% (p=0.014); medullar R2* did not change. Cortical DBF and DRBF inversely correlated (R=0.42, p=0.044). Cortical DBF and AGRF correlated (R=0.48, p=0.017).

**Conclusions:** Ang-II causes a dose dependent DRBF. The observed DRO seem to differ between cortex and medulla. Only for the cortex BOLD may provide an index of tissue perfusion.

**Chloride Contributes to Hypertension and Renal Injury in Aldosterone-Salt Treated Rats**  
Takaharu Yamauchi, Shigehiro Doi, Toshiki Doi, Kensuke Sasaki, Toshinori Ueno, Ayumu Nakashima, Takao Masaki. Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.

**Background:** Aldosterone-salt treatment is known to induce renal inflammation and play a role in development of renal fibrosis as well as elevation of blood pressure. In addition to sodium, chloride has recently been reported to be involved in renal damage, raising the possibility that sodium-bicarbonate may ameliorate renal injury and improve renal outcomes. In this study, we investigated the role of chloride on renal hypertension and damage by comparing rats treated with aldosterone in combination with either sodium chloride or sodium carbonate.

**Methods:** Following a left nephrectomy, 8-week-old male Sprague-Dawley rats were implanted with an osmotic pump and then allocated to the following 3 groups: 1) drinking a 1% NaCl solution with aldosterone infusion (NaCl-aldosterone treated group), 2) drinking a 1% NaHCO3 solution with aldosterone infusion (NaHCO3-aldosterone treated group), and 3) drinking water with vehicle infusion. Blood pressure levels were measured for 6 weeks. The rats were sacrificed and their renal tissues examined by immunoblotting and immunohistochemistry.

**Results:** The NaCl-aldosterone group had higher blood pressure levels than the NaHCO3-aldosterone group. Protein expression of eNOS and Perin in the membrane fractions of aldosterone treated group compared with the NaHCO3-aldosterone group. In addition, the NaCl-aldosterone group had high protein levels of NCC and phosphorylated NCC in the whole protein and membrane fractions. On the other hand, the expression of inflammatory (CD3, CD68, IL17A, IL-23 receptor) and fibrotic markers (α-smooth muscle actin, collagen IV) were greater in the NaCl-aldosterone group.

**Conclusions:** These findings suggest that chloride plays an important role in the development of NaCl-aldosterone-induced hypertension and renal injury.

**RAGE-DNA Aptamer Improves Aldosterone-Induced Renal Injury Possibly via Inhibition of Rac1-MR Axis in Mice with Hypertensive Nephropathy**  
Kensei Taquchi,1 Sho-ichi Yamagishi,1 Yuichiro Higashimoto,2 Yosuke Nakayama,1 Katsuktii Asanuma,1 Seiji Ueda,1 Kei Fukami.  
1Div of Nephrology, Dept of Medicine; 2Dept of Pathophysiology and Therapeutics of Diabetic Vascular Complications; 3Dept of Chemistry, Kurume Univ School of Medicine, Kurume, Japan; 4Div of Nephrology, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.

**Background:** Advanced glycation endproducts (AGEs) stimulate the generation of reactive oxygen species (ROS) and subsequently enhance various intracellular pathways through the interaction with receptor for AGEs (RAGE). Although AGEs-RAGE axis has been mainly investigated in diabetic nephropathy, its pathophysiological role in hypertensive nephropathy (HN) is unknown. In addition, recent evidence has suggested that aldosterone (aldosterone-mineralocorticoid receptor (MR) system) plays a crucial role for the pathogenesis of HN. In this study, we examined whether AGEs-RAGE axis system could interact with aldol-MR axis in deoxycorticosterone acetate (DOCA)-induced HN in mice. Further, we explored the inhibitory effects of DNA-aptamer directed against RAGE (RAGE-aptamer) on aldosterone-MR pathway could be correlated with each other, which could lead to podocyte injury in HN. RAGE-aptamer may be a novel therapeutic strategy for the progression of HN.

**Methods:** Uninephrectomized 8-week-old C57Bl6/J male mice were divided into three groups; 4% salt diet (control), 4% salt diet with DOCA (50mg), and DOCA with hydralazine (Hyd). RAGE-aptamer constructed by SELEX method was continuously administrated with osmotic mini pump.

**Results:** DOCA elicited-UAH was independent of blood pressure. Renal ROS generation, RAGE protein expression and plasma carboxymethyl lysine (CML) levels were elevated in DOCA/salt mice. RAGE was co-localized MR in podocytes by immunohistological analysis. Further, GTP-bound Rac activation and MR overexpression were observed in DOCA/salt mice. DOCA-elicited increase in UAH, renal ROS generation and RAGE expression, plasma CML levels were improved by RAGE-aptamer independent of blood pressure. Interestingly, RAGE-aptamer suppressed GTP-bound Rac activity and MR overexpression in DOCA/salt mice.

**Conclusions:** AGEs-RAGE axis and Rac1-MR pathway could be correlated with each other, which could lead to podocyte injury in HN. RAGE-aptamer may be a novel therapeutic strategy for the progression of HN.

**FR-PO135**

**Dipeptidyl Peptidase-4 Inhibitor Ameliorates the Aldosterone-Induced Renal Fibrosis**  
Kang-Yung Peng, Vincent Wu. Dept of Internal Medicine, National Taiwan Univ, Taipei, Taiwan.

**Background:** Renal fibrosis is considered a common outcome of a wide variety of chronic kidney diseases with diverse causes. However, no antibiotic agent has been approved in clinical practice yet. In this study, we examined the effect of dipeptidyl peptidase-4 (DPP-4) inhibitor on aldosterone induced renal fibrosis by aldosterone.

**Methods:** Human proximal tubular epithelial cells (HK2) were used to examine the inhibitory effect of DPP-4 inhibitor on aldosterone induced epithelial-mesenchymal transition (EMT). Besides, aldosterone infusion mice were used to evaluate the effect of DPP-4 inhibitor, linagliptin, on aldosterone induced renal fibrosis. Expression of TGF-β, OPN and molecules involved in EMT were examined using western blot and qRT-PCR.

**Results:** In vitro studies showed that aldosterone significantly increases the expression of TGF-β, OPN and markers of EMT in HK2 cells, while these effects were lessened in that treated with DPP-4 inhibitor. Similarly, the aldosterone-infused mice exhibited severe kidney fibrosis. The expression of TGF-β, OPN, vimentin and α-SMA were induced by aldosterone, and oral DPP-4 inhibitor ameliorated the kidney fibrosis and lessened the increase in fibrotic proteins without significant changes in blood pressures.
Mitochondrial Oxidative Stress-Activated Renal Local RAS Promotes the Expression and Function of NCC in Proteinuric Kidney Disease
Songming Huang, 1, 2 Yibo Zhuang, 1 Guixia Ding, 1 Zhanjun Jia, 1, 2 Aihua Zhang, 1, 2 1Nephrology Dept, Nanjing Children Hospital, Nanjing Medical Univ, Nanjing, China; 2Nanjing Key Laboratory of Pediatrics.

Background: The fluid retention and hypertension are common complications of kidney diseases, whose pathogenic mechanisms remain elusive.

Methods: Kidney tissues from mice subjected to albumin overload via i.p injection for 12 days and renal biopsy specimens were analyzed.

Results: Following albumin overload, we found a striking increase of Na+-Cl cotransporter (NCC) expression by 2.3-fold in mouse kidneys determined by Western blotting and qRT-PCR. To evaluate NCC function in these mice, NCC inhibitor hydrochlorothiazide (10mg/kg) was administered via a single i.p injection. In agreement with NCC upregulation, the response to hydrochlorothiazide was significantly enhanced in albumin overloaded mice. Considering the established role of renin-angiotensin system (RAS) in regulating sodium transporters, we examined key components of RAS and found a striking elevation of angiotensinogen (AGT) and angiotensin converting enzyme (ACE) by 2-3 folds in line with enhanced urinary AngII excretion. In proteinuric mice, we also observed 4-fold upregulation of NCC and remarkable stimulation of ACE detected by immunohistochemistry in accord with significantly increased urinary Ang II output. To further investigate the role of RAS in NCC upregulation, we did primary culture of renal tubular cells and observed that albumin directly increased NCC paralleled with significant induction of AGT, ACE, and Ang II. Strikingly, administration of specific ACE inhibitor captopril to the cells remarkably abolished albumin-induced enhancement of NCC and RAS components. Additionally, albumin overload significantly reduced mitochondrial superoxide dismutase (SOD2) by 60%, and administration of a SOD2 mimic (MnTBAP) entirely abolished the stimulation of NCC; AGT, and ACE in mice with albumin overload.

Conclusions: The findings demonstrated an important role of albuminuria in upregulating NCC expression via a mitochondrial oxidative stress-initiated stimulation of renal local AGT/ACE/Ang II, which may contribute to the fluid retention and hypertension in proteinuric kidney disease to some extent.

Prophylactic and Therapeutic Tenapanor Are Vascular Protective in a Rat Model of CKD
Ann-Catherine Jönsson-Rylander, 1 Margareta Behrendt, 1 Craig F. Plato, 2 Denise L. Schwabauer, 2 Peter J. Greenslly. 1AstraZeneca R&D, Möln达尔, Sweden; 2BioPharma Inc., Denver, CO.

Background: Tenapanor (AZD1722), an inhibitor of the Na+-H+ exchanger NHE3, reduces absorption of gut sodium and phosphate. It is being developed for renal and constipation-related indications.

Methods: 5/6 nephrectomized Sprague Dawley rats were fed 4% NaCl chow to induce salt-sensitive arterial hypertension. Oral tenapanor (1 mg/kg/day) was initiated either at the start of NaCl intake (prophylactic; Px) or 2 weeks later (therapeutic; Tx), and was administered for up to 6 weeks. Disease controls (DCs; vehicle-treated) and healthy controls (HCs; sham operated, normal chow) were included to enable assessment of disease progression. Systemic hemodynamics and urinary and plasma biomarkers were assessed every 2 weeks. Ex vivo vascular function (isometric tension recording) or arterial stiffness (pulse wave velocity) was evaluated at 2 and 6 weeks.

Results: Compared with DCs, rats in the Px and Tx groups had reduced urinary albumin, sodium and phosphorus excretion (p<0.05), and looser stools. Systolic, diastolic and mean BP increased in DCs while were normal in the Tx group. Arterial stiffness was reduced by Px and Tx tenapanor (p<0.05). Compared with HCs, DCs had impaired aortic vasoconstrictor and vasodilator function at 2 weeks (p<0.05) and significant endothelial dysfunction at 6 weeks. Px tenapanor normalized, and Tx tenapanor attenuated arterial hypertension, vascular stiffness, vasoconstrictor and endothelium-dependent and independent vasodilator function (Table).

Conclusions: Tenapanor is well tolerated and improves vascular function in CKD.

Funding: Swedish Research Council, Novo Nordisk, the National Swedish Medical Research Council, the Swedish Heart Lung Foundation, the Karolinska Institute.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

387A
Conclusions: Tenapanor prevented most of the maladaptive consequences in a rat model of renal insufficiency-induced salt-sensitive arterial hypertension and CKD. The benefit of Tx treatment was similar to that elicited by Px use, suggesting disease modification. *Funding: Pharmaceutical Company Support - AstaZeneca*

**Urinary Exosome Profiling in Thiazide Induced Hyponatremia**

Sarah Kiran Channavajhala,1 Theresa Peltz,2 Wenjing Jia,1 Ian Hall,1 Kevin O’Shaughnessy,1 Matthew A. Bailey,1 James W. Dear,1 Mark Glover.1 *1 Department of Therapeutics and Molecular Medicine, Univ of Nottingham, United Kingdom; 2Clinical Pharmacology Unit, Univ of Cambridge, United Kingdom; Centre for Cardiovascular Science, Univ of Edinburgh, United Kingdom.*

**Background:** Thiazides are one of the most widely used and cost-effective class of anti-hypertensive medication. Thiazide-Induced Hyponatremia (TIH) is one of their major adverse effects and the leading cause of drug-induced hyponatremia requiring hospitalization. *A priori* TIH must result from excessive saliuresis and/or water reabsorption. The water and electrolyte transporter composition of urinary exosomes (UE) reflects their cellular origin and are a promising way to study renal dysfunction. This study assessed the expression of AQ2 and NCC in the UE of TIH patients.

**Methods:** 100 patients admitted to hospital with severe TIH donated urine samples during acute TIH and at 2 months post TIH cessation. Matched normotensive controls were recruited both on and off thiazides (groups 1 & 2 respectively). UE from a representative sample of each patient group were isolated and AQ2 and NCC were evaluated by Western blotting and Nanoparticle Tracking Analysis (NTA). AQ2 and NCC expression was normalized by urinary creatinine. Immunoblots were also corrected for total protein and results expressed as units of optical density/Ucr.

**Results:** Westerns showed that UE expression of AQ2 was higher in cases during acute TIH compared to convalescent (32.93 vs 28.71, P<0.01) and compared to control groups 1 & 2 (15.61 and 15.09 respectively, P<0.001). NCC expression was lower in TIH patients acutely compared to convalescent (17.72 vs 31.86, P<0.05) and compared to both control groups (30.32 and 31.17, P<0.05). NTA also demonstrated increased AQ2 expression in acute & convalescent TIH.

**Conclusions:** This study highlights the utility of UE analysis to probe the molecular pathophysiology of TIH. Increased AQ2 and reduced NCC expression suggests that TIH results from increased water reabsorption and sodium wasting in the distal nephron. TIH studies may further understanding of renal physiology and inform the design of new thiazide medicines less prone to cause hyponatremia. *Funding: Government Support - Non-U.S.*

**Epigenetic Modulation of Renal Arterioles Induced by DOCA-Salt Loading**

Hiroaki Innou,1 Kazutoshi Miyashita,2 Masaki Sato,3 Kentaro Fujii,4 Aika Hagiwara,5 Masanori Tamaki,5 Hiroshi Itoh. Internal Medicine, School of Medicine, Keio Univ, Tokyo, Japan.

**Background:** The relationship between salt intake and development of hypertension is familiar; however, the mechanism for the onset has not been fully revealed. Our previous report showed that the medial hypertrophy of renal arterioles after transient salt loading in the rat was associated with increased expression of metalloproteinases (MMPs), which promote the medial hypertrophy. Epigenetic modulation of the genes was analyzed. Epigenetic modulation of the genes were analyzed. Epigenetic modulation of the genes were analyzed. Epigenetic modulation of the genes were analyzed.

**Methods:** Male 6 week old C57Bl/6 mice were implanted doxycycline-inducible doxycycline (DOCA) pellets and given drinking water containing 1% NaCl for 2 weeks for generation of salt-induced hypertension. The blood pressure was measured by a tail-cuff method during and after the transient salt loading. Histological examinations of the kidney were performed during and after the salt loading. Gene expressions in the kidney such as matrix metalloproteinases (MMPs), which promote the medial hypertrophy, were quantified. Epigenetic modulation of the genes were analyzed.

**Results:** Transient salt loading caused elevation in blood pressure during the loading period. Blood pressure after stopping salt-loading was also significantly higher than that before salt loading. Salt loading caused medial hypertrophy of renal arterioles, and it remained after stopping salt loading, as to cause lasting renin elevation. Real time PCR revealed that MMP2 and MMP9 were increased during the salt loading. CGN5, CHP and p300, which are histone acetyltransferases, were elevated. Sirt1, Sirt3, HDAC1 and HDAC3, which are histone deacetylases, were decreased. Histone H3K9 and H4K16 acetylations in the MMP2 gene were enhanced by the salt loading.

**Conclusions:** The last media hypertrophy and renin elevation after transient salt loading were suggested to be caused by the increased expression of MMPs along with augmented histone acetylations by the salt loading. Increased expressions of acetyltransferases along with decreased expressions of Sirt1 and HDACs by transient salt loading would be involved in the enhancement of the histone acetylations.
Endoplasmic Reticulum Stress Inhibitor 4-Phynelbutyric Acid Prevents Lypetensive Rats

**Hypertensive Rats**

**The Endoplasmic Reticulum Stress Inhibitor 4-Phynelbutyric Acid Prevents Hypertension in Young Spontaneously Hypertensive Rats**

**Safas Nasef, Cho Lu, Jeffrey G. Dickhout, Medicine, McMaster Univ, Hamilton, ON, Canada; *St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada.**

**Background:** Essential Hypertension is the leading global risk factor for premature death. This complex multifactorial disease has no known cause and has been shown to contribute to the progression of chronic kidney disease (CKD). Mechanistically both Endoplasmic Reticulum (ER) stress and the Unfolded Protein Response (UPR) have been implicated in the pathology of this disease. A small molecular chaperone, 4-phenylbutyric acid (4-PBA), is known to inhibit ER stress. In our previous studies, we found that 4-PBA is able to lower blood pressure in animal models of hypertension. It remains unclear however if ER stress is a cause of hypertension or a consequence.

**Methods:** Young spontaneously hypertensive rats (SHR) were used in this study and Wistar Kyoto (WKY) rats were used as its normotensive control. High blood pressure begins to develop in the young SHR at 4-weeks of age. Radio-telemetry transmitters (HEXI-1 transmitter, Data Sciences International) were implanted to monitor blood pressure development, heart rate and ECG activity in both SHR and WKY. SHR and WKY were both randomized into 4-PBA (1 g/kg/day) or vehicle groups at 4-weeks of age to determine if ER stress inhibition would prevent the development of hypertension. Resistance vessels, distal mesenteric arteries and renal arteries were collected after 8 weeks and analyzed for specific ER stress markers using real-time polymerase chain reaction (RT-PCR).

**Results:** 4-PBA treatment significantly lowered systolic, diastolic and mean arterial pressures in the SHR rats, but not in the WKY rats. 4-PBA treatment also significantly reduced the pre-hypertensive tachycardia in the SHR. Additionally, 4-PBA significantly prevented the expression of UPR markers CHOP and GRP78 in SHR resistance blood vessels.

**Conclusions:** ER stress appears to play a causative role in the development of hypertension. Novel pharmacological strategies aimed at ER stress inhibition might represent useful therapeutic tools for people with a high risk of developing hypertension and progressive CKD. **Macrophage Endothelin-B Receptors Clear Endothelin-1 and Regulate Blood Pressure**

Neeraj Dhaun, Queen's Medical Research Inst, University of Edinburgh.

**Background:** Hypertension is common. Its cause remains unclear in the majority of those affected. Recent data suggest that macrophages (MΦ) contribute to, and protect from, hypertension. Endothelin-1 (ET-1) is the most potent endogenous vasoconstrictor with additional pro-inflammatory properties. The effects of ET-1 on MΦ biology are not well studied.

**Methods:** To examine the interactions between the ET and MΦ systems we administered incremental doses of intravenous ET-1 to CD11b*-diphtheria toxin receptor (DTR) mice given diphtheria toxin (DT) and to mice lacking ET-1 receptors (DTR), on both, administration of ET-1 resulted in an exaggerated hypertensive response compared to controls. At a dose of ET-1 1nmol/kg the maximal change in BP was –2±fold in MΦ deficient mice compared to control groups. In vitro, mouse BMDM and human MΦ possess both ET, and ET4 receptors. Whereas stimulation of mouse and human MΦ with exogenous ET-1 did not polarize MΦ to a classical or alternative phenotype, both displayed chemokinesis to ET-1. This was reduced by selective ET4, and completely blocked with ET4 receptor antagonism. BMDM stimulation with LPS/INFγ led to an increase in the concentration of ET-1, an effect that was blocked by phosphoramidon, an inhibitor of endothelin converting enzyme. Importantly, using pharmacological and gene targeting studies we show a novel clearance mechanism for ET-1 through ET4 receptor mediated dynamin-dependent endocytosis present in both murine and human MΦ. Finally, patients receiving MΦ depletion therapy we show that BP is higher and the ET system more activated than in those receiving non-depleting therapies.

**Conclusions:** Overall, these data suggest that MΦ and ET-1 may play an important role in BP control and potentially have a critical role as a therapeutic target in hypertension.

FR-PO148
A Novel Reduced Uterine Perfusion Pressure (RUPP) Model of Preeclampsia in Mice Tomofumi Fushima,1,2 Yui Oe,3 Emiko Sato,1,2 Sadayoshi Ito,1 Hiroshi Sato,1,2 Nobuyuki Takahashi.1,2 1Graduate School of Pharmaceutical Sciences, Tohoku Univ, Sendai, Miyagi, Japan; 2Div of Nephrology, Endocrinology, and Vascular Medicine, Tohoku Univ, Sendai, Miyagi, Japan.

Background: Preeclampsia (PE) is a pregnancy-related hypertension with proteinuria that typically develops after 20 weeks of gestation. PE is caused by a reduction in uterine blood flow due to abnormal trophoblast invasion of the spiral arteries. The ischemic placenta releases anti-angiogenesis factors such as sFlt-1, leading to maternal hypertension and proteinuria. The reduced uterine perfusion pressure (RUPP) model is widely used in rats, but not in mice, hindering the clarification of genetics of PE. The aim of the present study is to establish a novel PE model using an improved RUPP method in mice.

Methods: As shown in the Figure, 1, uterine vessels of pregnant ICR mice were ligated at 14.5 dpc, and BP, renal phenotype and pregnancy outcome were analyzed.

Results: RUPP in mice increased blood pressure. B.B' ligation mice showed increased urinary albumin excretion, mesangial expansion and endotheliosis as shown by the reduction of glomerular open capillary area. RUPP increased the risk of miscarriages and premature deliveries, and significantly reduced fetal weights at 18.5 dpc compared to those of sham mice.

Conclusions: We developed a novel RUPP mouse model that recapitulates the phenotype of PE. This model is expected to be useful for investigating pathogenesis of PE and evaluating its new therapies.

FR-PO149
Sildenafil Treatment Is Protective against Progression of Renal Injury in the Preeclamptic Dahl Salt Sensitive Rat Ellen Elizabeth Gilliss, Jennifer N. Mooney, Michael R. Garrett, Jennifer M. Sasser. Pharmacology and Toxicology, Univ of Mississippi Medical Center, Jackson, MS.

Background: Preeclampsia, a hypertensive disorder of pregnancy, is characterized by transient glomerular damage and increased risk for kidney disease later in life. Recent studies in our lab have identified the Dahl salt sensitive (Dahl S) rat on a 0.3% NaCl diet as a spontaneous model of superimposed preeclampsia. We hypothesized that sildenafil treatment would result in an improvement in renal function during the preeclampsia pregnancy exhibited by the Dahl S rat.

Methods: Female Dahl S rats (n=4–9) were mated, and rats were randomly divided into control and sildenafil treated groups. Sildenafil was administered to the treated group via food on gestational days 10-20 at a dose of 50 mg/kg/day. Rats were placed in metabolic cages on gestational day 19 for 24-h urine collection, and blood and tissues were harvested on gestational day 20. Urinary protein excretion, nephrin excretion, and plasma and urinary creatinine concentrations were measured by Bradford assay, Exocell ELISA, and the picric acid method, respectively. Kidney sections were stained with Masson's trichrome, and glomeruli were measured (n=20 per rat) and analyzed using Nikon software.

Results: Sildenafil treatment significantly improved renal function, as observed in the increase in creatinine clearance and corresponding decrease in plasma creatinine (Table, *p<0.05 vs control). Treated rats exhibited less renal injury, with a significant decrease in proteinuria and nephrituria during late pregnancy (Table). Histological analysis showed that the treated rats did not exhibit glomerulomegaly during pregnancy compared to the untreated controls (Table).

Conclusions: This study provides preclinical evidence that sildenafil prevents the progression of renal injury during preeclampsia.

Recessive Mutations of the Interaction Partners, TENC1, DLC1 or MAG2, Cause Nephrotic Syndrome in Humans Shazia Ashraf,1 Jia Rao,1 Merlin Airik,1 Svjetlana Lovric,1 Jennifer A. Lawson,2 Weizhen Tan,2 Carolin Sadowski,1 Werner Lukas Pabst,1 Daniela A. Braun,1 Heon Yung Goe,1 Martin Zenker,1 Friedhelm Hildebrandt,1,4 1Div of Nephrology, Boston Children's Hospital, Boston, MA; 2Dept of Genetics, Yale Univ School of Medicine, New Haven, CT; 3Inst of Human Genetics, Univ Hospital Magdeburg, Magdeburg, Germany; 4HHMI.

Background: Identification of monogenic causes of nephrotic syndrome (NS) has furthered the understanding of its pathogenesis. However, many genes and disease mechanisms remain unknown.

Methods: We performed homozygosity mapping (HM) and whole exome sequencing (WES) in individuals of consanguineous families with NS to identify the underlying mutations. To identify additional families, we performed microfluidic PCR (Fluidigm Access Array™) and next generation sequencing (NGS) to screen worldwide cohort of ~2000 individuals with severe NS.

Results: By WES in consanguineous family A1358, we identified a homozygous missense mutation (p.R292Q) in the TENC1 (Tension-J) gene in an amino acid residue conserved since Ciona intestinalis. By microfluidic PCR and NGS, we detected additional mutations in TENC1 in three unrelated families with NS. Later, we also discovered mutations in 2 different families with NS in DLC1 gene, a known binding partner of TENC1. Interestingly, most of the individuals with TENC1 or DLC1 mutations had steroid sensitive NS or histologically showed biopsy of MCNS. Furthermore, in 2 families with NS and neurological impairment, we identified 2 different homozygous truncating mutations in MAG2 gene. Deficiency of Tenc1 or Mag2 has been previously shown to cause NS in mice. By Co-IP, we now show that TENC1 and DLC1 interact with MAG2 in HEK293T cells and these interactions are abrogated in one of the MAG2 mutant. Knockdown of TENC1, DLC1 or MAG2 in cultured podocytes exhibited an altered podocyte migration rate. Immunofluorescence microscopy showed that TENC1 and DLC1 colocalize with phototyrosine at the focal adhesions in cultured human podocytes.

Conclusions: We, thus, identified mutations of TENC1, DLC1 and MAG2 as three novel single-gene causes of NS revealing a potential new pathogenic pathway for NS.

FR-PO151
Mutation of DHTKD1 Can Cause Nephrotic Syndrome with Neurological Impairment and Ketoacidic Aciduria Weizhen Tan,1 Shazia Ashraf,1 Svjetlana Lovric,1 Jia Rao,1 Merlin Airik,1 David Schaprio,1 Daniela A. Braun,1 Heon Yung Goe,1 Martin Zenker,1 Friedhelm Hildebrandt,1,4 1Div of Nephrology, Boston Children's Hospital, Harvard Medical School, Boston, MA; 2Inst of Human Genetics, Univ Hospital Magdeburg, Magdeburg, Germany; 3Howard Hughes Medical Inst, Chevy Chase, MD.

Background: Steroid-resistant nephrotic syndrome (SRNS) is the second most frequent cause of end-stage kidney disease in children. Identification of single-gene causes of SRNS has furthered the understanding of its pathogenesis. However, additional genes and disease mechanisms remain obscure. To identify a new causative gene for SRNS with neurological impairment, we combined homozygosity mapping (HM) and whole human exome sequencing (WES).

Methods: In two siblings (of consanguineous parents) with SRNS, neurological impairment, and ketoacidic aciduria, HM yielded 8 segments of homozygosity by descent with a cumulative genomic length of ~485 Mb. We performed WES in both siblings to identify the underlying single-gene disease-causing mutation.

Results: WES in this consanguineous family detected a homozygous missense mutation (p.Val290Met) in the DHTKD1 (dehydrogenase E1 and transketolase domain containing 1) gene in an amino acid residue that is evolutionarily conserved in prokaryotes (Saccharomyces cerevisiae). The mutation segregated with the affected status in this family and was absent from the 1,000 genomes project and Exome Aggregation Consortium (ExAC) databases. DHTKD1 functions as a 2-oxoglutarate-dehydrogenase E1 component and plays an important role in energy production in mitochondria through the tricarboxylic acid cycle. Mutations in DHTKD1 have previously been identified as cause of 2-aminoadipic and 2-oxoacidic aciduria via impaired turnover of decarboxylation 2-oxoadipate to glutaryl-CoA. [1] Danhauser K. et al., Am J Hum Genet, 91:1082-1087, 2012.

Conclusions: We identified a recessive mutation of DHTKD1 as a novel single-gene cause of SRNS with neurological impairment and ketoacidic aciduria. Further genetic and functional studies will shed light on the involvement of this protein in the pathogenesis of NS and will provide a further step in understanding the disease mechanism.

FR-PO152
Genes Encoding Nuclear Pore Outer Ring Components NUP85, NUP107, and NUP133 Are Mutated in Patients with Nephrotic Syndrome Svjetlana Lovric,1 Weiwen Tan,2 David Schapira,1 Shazia Ashraf,1 Daniela A. Braun,1 Jia Ruo,1 Richard P. Litton,2 Heon Yang Gee,1 Friedhelm Hildebrandt,2,3
1Div of Nephrology, Boston Children’s Hospital, Harvard Medical School, Boston, MA; 2Dept of Genetics, Yale Univ School of Medicine, New Haven, CT; 3Howard Hughes Medical Inst, Chevy Chase, MD.

Background: Steroid resistant nephrotic syndrome (SRNS) almost invariably progresses to end-stage kidney disease. Although more than 30 single-gene causes of SRNS are known, a large proportion of SRNS remains unexplained. Recently, mutations in genes encoding proteins of the nuclear complex (NPC), NUP93 and NUP205 were identified as novel causes of nephrotic syndrome. Study of these genes has implicated SMAD signaling in the pathogenesis of nephrosis.

Methods: To identify additional novel causes of nephrotic syndrome, we performed a candidate screen of 17 nuclear pore complex (NPC) genes in an international cohort of >900 individuals with SRNS via microfluidic multiplex PCR (Fluidigm Access Array) and next generation sequencing (Illumina MiSeq).

Results: In two families we identified two homozygous missense mutations, p.A477V and p.R645W, (conserved to S. cerevisiae) in the NPC outer ring protein NUP85. We then sequenced the exons of 1,000 additional families in genes encoding outer other ring proteins and found mutations in NUP107 (1 family, p.Y889C, conserved to C. elegans) and NUP133 (2 families, p.S974R and p.R231G1, p.L503S, conserved to D. rerio). Although the structure resolution of the NPC 3D complex is incomplete, we modeled the interacting portions of the Y-subcomplex proteins NUP107 and NUP133. Two of the mutations, p.S974R in NUP133 and p.Y889C in NUP107, are located in the interacting alpha helix between the two proteins. 5 of 6 families demonstrated FSGS on biopsy.

Conclusions: As a novel cause of SRNS we identified mutations in 3 different NPC outer ring proteins NUP85, NUP107, and NUP133 that form an integral part of the Y-subcomplex. Further functional studies are needed to illuminate how the defect of NPC contributes to the pathogenesis of nephrotic syndrome.

Funding: Other NIH Support - DK076683

FR-PO153
Defining the Genetic Epidemiology of a Phenotypically Well-Characterized Adult-Onset Focal and Segmental Glomerulosclerosis Cohort Moumita Baruah,1 Daniel C. Catran,2 Heather N. Reich,1 Michelle A. Hladunewich,3 Mark Leung,1 Weili Li,1 Andrew D. Paterson,1 York P. Pei,1 1Nephrology, Toronto General Hospital, UHN, Toronto, ON, Canada; 2Biology, Univ of Waterloo, Waterloo, ON, Canada; 3The Centre for Applied Genomics, Hospital for Sick Children, Toronto, ON, Canada.

Background: Although there were many phenocopies of FSGS, it is possible that genes involved in renal development predispose to different kidney diseases when mutated (FN1, SIX5, COL4A4, FRAS1, FREM1, FREM2, UMOD). While these conditions can represent a small proportion of sporadic FSGS cases, 19% in genes that predispose to different kidney diseases when mutated (FN1, SIX5, COL4A4, FRAS1, FREM1, FREM2, UMOD). While these conditions can represent a small proportion of sporadic FSGS cases, 19% in genes that predispose to different kidney diseases when mutated (FN1, SIX5, COL4A4, FRAS1, FREM1, FREM2, UMOD). While these conditions can represent a small proportion of sporadic FSGS cases.

Methods: We have ascertained the clinical information and performed whole exome sequencing in adult-onset disease of 90 sporadic FSGS cases, 41 steroid-sensitive nephrotic syndrome patients, and undergone comprehensive phenotyping across a wide range of disease areas at several time points throughout the life of the mouse. To date we have identified lines with a variety of late-onset phenotypes which are characterised in detail.

Results: Mutant mice were identified at 6 months of age with elevated creatinine and urea levels, which reached end stage renal failure at approximately 10 months of age. Mapping and whole genome sequencing identified a Lama5 loss of heterozygosity mutation in the L4a domain of Lama5. Time course studies of Lama5-/- homozygotes showed reduced serum albumin (18.0 ± 1.2 vs 24.9 ± 3.1 g/l, mean SD) and proteinuria from 12 weeks of age with a gradual loss of renal function over time. Affected mice also have significantly elevated cholesterol levels and a progressive nephropathy leading to diffuse glomerular fibrosis, dilated protein filled tubules and pigment deposition supporting this is a model of nephrotic syndrome. The mutation does not affect expression of the LAMA5 protein within the glomerular basement membrane.

Conclusions: We have identified a novel mouse mutant with a missense mutation Lama5 resulting in nephrotic syndrome. Recent patient sequencing data suggests LAMA5 can be involved in some adult-onset cases, suggesting that mutations associated with familial segmental glomerulosclerosis have a wider role in pathophysiology. Further work is needed to determine if mutations in Lama5 are involved in a proportion of sporadic FSGS.

A Novel Mouse Mutant with a Point Mutation in Laminin α5 Exhibits Chronic Nephrotic Syndrome Sara Falcone1, Thomas Nicol,1 Cheryl Scudamore2, Frederick W.K. Tam,3 Charles D. Pusey,4 Jeffrey H. Miner,5 Steve Dm Brown,1 Paul K. Potter,6 1Mammalian Genetics Unit, MRC Harwell, Harwell, Oxfordshire, United Kingdom; 2Mary Lyon Centre, MRC Harwell, Harwell, Oxfordshire, United Kingdom; 3Renal Research, Imperial College, London, United Kingdom; 4Renal Div, Washington Univ, St. Louis, MO.

Background: Diseases associated with ageing pose an increasing social and financial burden on society and represent an imperative for research in the biomedical sciences. We are undertaking the first large-scale project to investigate the interaction between genetic variation and the pleiotropic effects of ageing, employing random mutagenesis and phenotyping to generate new models of late onset or age-related disease.

Methods: Mutant mice are being aged to 18 months and undergoing comprehensive phenotyping across a wide range of disease areas at several time points throughout the life of the mouse. To date we have identified lines with a variety of late-onset phenotypes which are characterised in detail.

Results: Mutant mice were identified at 6 months of age with elevated creatinine and urea levels, which reached end stage renal failure at approximately 10 months of age. Mapping and whole genome sequencing identified a Lama5 loss of heterozygosity mutation in the L4a domain of Lama5. Time course studies of Lama5-/- homozygotes showed reduced serum albumin (18.0 ± 1.2 vs 24.9 ± 3.1 g/l, mean SD) and proteinuria from 12 weeks of age with a gradual loss of renal function over time. Affected mice also have significantly elevated cholesterol levels and a progressive nephropathy leading to diffuse glomerular fibrosis, dilated protein filled tubules and pigment deposition supporting this is a model of nephrotic syndrome. The mutation does not affect expression of the LAMA5 protein within the glomerular basement membrane.

Conclusions: We have identified a novel mouse mutant with a missense mutation Lama5 resulting in nephrotic syndrome. Recent patient sequencing data suggests LAMA5 can be involved in some adult-onset cases, suggesting that mutations associated with familial segmental glomerulosclerosis have a wider role in pathophysiology. Further work is needed to determine if mutations in Lama5 are involved in a proportion of sporadic FSGS.

Role of CD2AP Mutations in Steroid Resistant Nephrotic Syndrome Revisited – New Insights from Next Generation Sequencing

Fang Wang, Xiaoyu Liu, Huijie Xiao, Yong Yao, Jie Ding, Yanqin Zhang.

Department of Pediatrics, Peking Univ First Hospital, China.

Background: Colbamin C defect is a clinically heterogeneous disease caused by mutations in the MMACHC gene. The aim of the present study was to delineate renal phenotype in Chinese children with Colbamin C defect.

Methods: Detailed clinical data were collected and analyzed, and all coding exons of MMACHC gene were PCR-amplified and sequenced from genomic DNA.

Results: Four unrelated Chinese children (1 female, 3 male) with unexplained microscopic hematuria and proteinuria were included. The onset age of renal symptoms ranged from 9 months to 4 years. Two patients had nephrotic-level proteinuria in their initial visit, and renal dysfunction was detected in 2 patients in 3 months and 6 years after onset, respectively. Only 1 patient had hypertension in 6 years after onset. All patients had hyperhomocysteinemia, and megaloblastic anemia was noted in patients. None of 4 patients had thombocytopenia or pancytopenia. One of 4 patients had mild development backward. Four patients had hyperhomocysteinemia, and 2 of 4 patients presented with remarkable elevated urinary methylmalonic acid. Renal biopsy in 3 patients showed thrombotic microangiopathy. Mutations in MMACHC gene was found in four patients.

Conclusions: Prominent renal complications can be found in c.80A>G in MMACHC gene, and treatment resulted in improvement of renal and hematological signs.

Funding: Government Support - Non-U.S.
Conclusions: De novo variants can occur even in asymptomatic male cases of XLAS resulting in mosaicism, with important implications for genetic counseling. This is the first study to show a tendency between the variant allele frequency and disease severity in male XLAS patients with somatic mosaic variants in COL4A5. Although this is a very rare status of somatic mosaicism, further analysis is needed to show this correlation in a larger population.

FR-PO161
A New Non-Invasive Method to Examine Collagen α5(IV) Expression Using Plucked Hair Follicles: Analysis of an X-Linked Alport Family with a Novel COL4A5 Splice Region Variant
Andrew F. Malone, Steven Daniel Funk, Jeffrey H. Miner. Renal Div; Dept of Medicine, Washington St. Univ, St. Louis, MO.

Background: Alport syndrome is a hereditary disease caused by mutations in COL4A5 in 85% of cases. Many different mutation types in this gene have been described. Levels and patterns of type IV collagen deposition are variable in the glomerular basement membranes of Alport kidneys. As COL4A5 is also expressed in the skin, we sought to characterize COL4A5 deposition in the basement membrane of plucked hair follicles from a family with a novel COL4A5 variant as a way of confirming the functional significance.

Methods: Whole-exome sequencing was done on the proband of a family with biopsy (renal and skin)-confirmed Alport syndrome. Sanger sequencing was performed on all affected family members and a married-in unaffected individual. Immunofluorescence microscopy of plucked hair follicles was performed. Staining intensity between males and females, affected and unaffected, was analyzed.

Results: Family WU1 is a 3 generational family with chronic kidney disease secondary to Alport syndrome. Affecteds are in each generation, and both males and females are symptomatic. Whole-exome sequencing of affected individual 3227 revealed a novel splice region variant c.1780-6T>G in COL4A5. There were no other potentially pathogenic variants found in COL4 or other podocyte genes. This variant was confirmed by Sanger sequencing and segregated with disease. Reduced and abnormal expression of COL4A5 protein was confirmed in affected family members by immunofluorescence microscopy of hair follicles.

Conclusions: We confirmed linkage of a novel splice region variant in COL4A5 to Alport syndrome in a family with a typical X-linked inheritance pattern; this variant may be pathogenic. We developed and validated a new approach to characterize the expression of COL4A5 protein using immunofluorescence microscopy of plucked hair follicles. Furthermore, we demonstrated variability of COL4A5 expression between patients in this family, suggesting intermittent failure of splicing and/or variable lyonization in females.

Drug Repurposing for the Treatment of Experimental Alport Syndrome
Vanessa R. Williams,1 Ana Konvalinka,2 Xuexwen Song,2 Eun Hui Bae,3 Fei Fang,1 Rohan John,1 York P. Pei,2 James W. Scholzey.1 1Inst of Medical Science, Univ of Toronto, Canada; 2Dty of Nephrology, Univ of Toronto, Canada; 3Internal Medicine, Chonnam National Univ Medical School, Korea; 4Pathology, Univ of Toronto, Canada.

Background: Alport Syndrome (AS) is a hereditary nephropathy caused by mutations in genes that encode type IV collagen, leading to progressive injury and eventually end-stage renal disease. Currently there are few effective therapies for AS. Therefore we applied a drug repurposing strategy, utilizing data on drugs currently approved for use in humans, to identify a novel AS treatment.

Methods: 129N/C57Bl6J (KO) and wild-type (WT) mice were studied at 4 and 7 weeks (N~8/group). Histological analyses of formalin-fixed mouse kidney sections were performed. Plasma and 24-hour urine samples were collected. Global gene expression profiling of RNA from renal cortex was performed with the Affymetrix Mouse Gene 2.0 ST Array. Significance Analysis of Microarrays (SAM) was used to identify differentially expressed genes. In silico drug repurposing with the Connectivity Map (CMAP) was used to identify drugs expected to effectively treat murine AS.

Results: Mice with AS developed a progressive rise in albuminuria and serum creatinine. These changes were associated with glomerulosclerosis and tubulointerstitial fibrosis. SAM was used to generate a disease signature of differentially expressed genes, comparing 7-week-old KO versus WT mice. The disease signature was used to query the CMAP. Vorinostat, a lysine deacetylase inhibitor, was the top drug predicted to reverse the signature. KO mice were treated with vehicle or vorinostat daily from 4 to 7 weeks of age. Vorinostat treatment reduced hyperfiltration of kidney lysine resides. This was associated with reduced albuminuria, decreased αSMA protein expression, and reduced gene expression of inflammatory cytokines.

Conclusions: In silico drug repurposing identified a novel therapeutic approach to AS. Further testing of the putative therapy showed that vorinostat exerted a renoprotective effect. Further studies will better define the mechanisms underlying the protective effect of this novel therapy.

KCTD1 Mutations in Scalp-Ear-Nipple (‘Finlay-Marks’) Syndrome: A Further Cause of Thin Basement Membrane Nephropathy
Dongwoong Wang,1 Peter Diakumji,2 Melanie Bahlo,2 Deb J, Colville,2 Judith A. Savidge.3 1Medicine, The Univ of Melbourne (Monash Health), Melbourne, VIC, Australia; 2Bioinformatics, WEHI, Melbourne, VIC, Australia.

Background: Scalp-Ear-Nipple syndrome is an ectodermal dysplasia, with a skin defect that results in baldness, and a renal complication that arises in a large animal model. KL Williams was the first person to describe the clinical phenotype in 1975. Two unrelated families with Scalp-Ear-Nipple syndrome were examined and KCTD1 mutations were identified in 20 individuals with Thin membrane nephropathy and a4 chains, which are major components of the glomerular, corneal and retinal basement membranes. This study characterised the clinical phenotype in Scalp-Ear-Nipple syndrome and how mutations caused disease.

Methods: Two unrelated families with Scalp-Ear-Nipple syndrome were examined by a renal physician and an ophthalmologist. One family member provided a skin biopsy that was used to derive a fibroblast cell line. Urine specimens from two family members were used to study the expression of the collagen IV a3 and a4 chains, and laminin a5 and b1 transcripts. The ER size was measured using immunohistochemistry before and after treatment with PBA, a chemical chaperone.

Results: Seven family members had developed renal cysts and impaired renal function by late adulthood, and all 14 who were examined had astigmatisim. A renal biopsy demonstrated a thinned glomerular membrane. One individual had a thinned cornea and the two who were examined with optical coherence tomography had a small optic disc, and thinned retinal nerve fibre layer.

Conclusions: The clinical features of Scalp-Ear-Nipple syndrome are due to KCTD1 mutations that affect basement membrane collagen IV and laminin expression. Chemical chaperones represent a potential treatment to delay renal failure.

density [Vv(GL3/Podo)] was estimated and correlated with age and GLA mutation. The latter, in 38 of these patients, inherited 3 classical, 2 cardiac (N215S) and one late onset (R363H) GLA mutation. Results: There was a wide range of Vv(GL3/Podo) among the patients, 0.41 [0.003-0.58]. Vv(GL3/Podo) increased linearly with age in younger patients up to age 30 years (r=0.56, p=0.001), but plateaued thereafter, varying within the narrow range of 0.35-0.58. There were 4 outliers, ages 37-50 with low Vv(GL3/Podo) (range 0.03-0.22), including patients with N215S (n=2) and R363H mutations and one patient whose GLA mutation was unavailable. Vv(GL3/Podo) directly correlated with urine albumin creatinine ratio (r=0.56, p<0.001) and foot oedema (r=0.49, p<0.001) in males younger than 30 years. Volume density of podocytes per glomerulus was inversely correlated with age (r=-0.69, p<0.0001) across the age range with no plateauing, suggestive of continuous podocyte loss. Conclusions: The fraction of podocyte cytoplasm filled with GL3 inclusions increase with age up to about age of 30 in Fabry males with classical GLA mutations and associated with podocyte injury and albuminuria. Plateauing of podocyte GL3 volume density after age of 30 is suggestive of a threshold beyond which GL3 accumulation may not be compatible with podocyte survival. The clinical progression of Fabry nephropathy beyond age 30 in FD males with classical mutations could be reflected in other podocyte parameters such as podocyte hypertrophy and/or loss. Thus further studies are underway to explore these possibilities.

Outcomes of Patients Over 65 in the Canadian Fabry Disease Initiative Study

Michael L. West,1 Daniel G. Bichel,2 Aneal Khan,3 Joe T. Clarke, Sandra Sirs,4 Steve Doucette,5 Christine Aurais-Bylia,6 Kaye Lemoine.4

1Department of Medicine, Dalhousie Univ, Halifax, NS, Canada; 2Department of Nephrology, West China Hospital, Chengdu, Sichuan, China.

Background: The Canadian Fabry Disease Initiative (CFDI) is a multicentre prospective study of outcomes with enzyme replacement therapy (ERT) in Fabry disease. ERT has been shown to be of benefit in reducing Fabry cardiac and renal disease. There is uncertainty as to the benefits of ERT in older patients. We compared outcomes of ERT in patients over 65 years of age with the overall CFDI population. Methods: Patients are reviewed every 6-12 months as to clinical status. ERT is provided every 2 weeks according to national guidelines with intravenous dose agalsidase alfa (0.2 mg/kg) or agalsidase beta (1.0 mg/kg). Cardiovascular risk factor modification is promoted with use of ASA, statins and ACEI/ARB. Clinical outcomes are defined as stage 5 CKD, stroke/TIA, acute deafness, cardiac arrest, CHF, arrhythmia, unstable angina, MI, PTCA, pacemaker/ICD, AVR/CABG and death. Results: As of Jan 2015, 429 subjects were enrolled. There were 51 patients over 65 y, 68.6% female, and 60.8% on ERT with mean age 71.8 y. There were no differences in mean age, cardiac variant genotype, or time in the CFDI between those on ERT and those not. Compared with patients not on ERT, those on ERT had lower EFGR, greater proteinuria and higher LVM at both baseline and 6 y later. Three patients not on ERT had 5 clinical events, prevalence 15%, no deaths with clinical event rate of 1/34.5 patient years. Twenty patients on ERT had 5 deaths, 38 clinical events, prevalence 64.5% and clinical event rate of 1/9.3 patient years. Death was more likely in females 21% vs. males 8.3%. Patients over 65 y had greater prevalence of cardiovascular indications for ERT than the overall CFDI population. Time to first clinical event was earlier in those on ERT (p=0.003).

Conclusions: Older patients with Fabry disease continue to have clinical events, mainly cardiac, despite ERT but appear to be living longer. Use of the Canadian Fabry Disease guidelines appears to successfully target high-risk older patients. ERT use in this subgroup appears to be of benefit.

A Founder Haplotype of APOE-Kyoto Mutation Associated with Lipoprotein Glomerulopathy

Zhangxue Hu.1 Dept of Nephrology, West China Hospital, Chengdu, Sichuan, China.

Background: Lipoprotein glomerulopathy (LGP) is a rare dominant inherited kidney disease with incomplete penetrance, histological characterized by the formation of intraglomerular lipoprotein thrombi. Their main clinical manifestation includes proteinuria, the elevated level of serum triglyceride and apolipoprotein E (apoE). Approximately 15 APOE mutations associated with LGP have been reported so far, the most common being APOE-Kyoto mutation. Our previous study revealed the largest population of LGP from a county 200 kilometer near Chengdu city, in Sichuan province, China. All these patients shared the Kyoto mutation in 3 allele, which suggests that the APOE-Kyoto mutation spread from one founder.

Methods: We enrolled 26 patients with LGP from twenty-six unrelated Chinese families who were diagnosed by renal biopsy. After informed consents were obtained from them and their relatives, APOE mutation was detected by PCR-RFLP with Aor531H and a haplotype analysis of APOE was carried out by DNA sequencing using the method of TA cloning.

Results: We investigated the haplotype of APOE allele from twenty-six unrelated LGP families, and found the haplotype of APOE-Kyoto mutant allele was identical, and was likely derived from haplotype 1 of APOE3; as for the counterpart APOE allele, the allelic distribution of interplant APOE allele was not identical. Also, we identified a new haplotype of APOE4 named 32.

Conclusions: The haplotype of APOE-Kyoto mutation allele associated with LGP in the narrow country was identical, suggesting that mutation is common in Chinese patients through a founder effect. And patients didn’t have a common haplotype of counterpart APOE allele as the asymptomatic carriers, which association with the onset of LGP wasn’t known. To the new haplotype 32 of APOE4, its clinical value isn’t clear now.

Eleven Pregnancies in Four Women with Atypical Hemolytic Uremic Syndrome

Martina M. Gaggel,1 Christof Aigner,2 Zoltan Prohaska,2 Gere Sunder-Plassmann,1 Alice Schmidt.1 1Dept of Medicine III, Division of Nephrology and Dialysis, Medical Univ of Vienna, Vienna, Austria; 2Hrd Dept of Internal Medicine, Research Laboratory, Semmelweis Univ, Budapest, Hungary.

Background: Pregnancy activates the maternal alternative pathway of the complement system due to presentation of paternal antigens. In females with atypical Hemolytic Uremic Syndrome (aHUS) – a disease of the complement regulatory proteins and C3 – each pregnancy can trigger life-threatening disease episodes.

Methods: Data were collected from patients with aHUS, enrolled in the Viennese TMA Cohort. Pregnancies occurred between 2002 and 2015. Results: We report 11 pregnancies in 4 women (table 1). Two had an established diagnosis of aHUS prior to the first pregnancy (case 2 and 3). Case 1 presented with end-stage renal disease due to TMA (biopsy-proven) 12 months after her first delivery and case 4 presented postpartum after her uncomplicated first delivery. In 8 pregnancies females received preventive plasma infusions (PI, 200-1600 mL) 2 to 4 weeks apart. After kidney transplantation case 1 received a maintenance therapy (PIs once a month), which was intensified during the II. pregnancy to every other week. Two pregnancies (case I III., case 4 III.) are currently ongoing without evidence of a disease flare so far. Nine pregnancies went without any complication and the offspring are healthy. One pregnancy (case 3, II., without PIs) resulted in an intratuterine fetal death at gestation week 36, but without signs of TMA in the mother.

Orally Administered Complement 5a Receptor Inhibitor CCX168 Development in Atypical Hemolytic Uremic Syndrome

Mirjam Galbusera1, Sara Gastoldi1, Valentina Portalupi,1 Elena Mondo,2 Pirow Bekker,2 Thomas J. Schall,1 Marina Norsis,1 Giuseppe Remuzzi.1 1Mario Negri Inst; 2ChemoCentrx.

Background: The orally administered complement 5a receptor inhibitor CCX168 is in Phase 2 development for antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis, atypical hemolytic uremic syndrome (aHUS), and IgA nephropathy. CCX168 is in Phase 2 development for antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis, atypical hemolytic uremic syndrome (aHUS), and IgA nephropathy. The anaphylatoxin C5a is a potent neutrophil attractant involved in neutrophil priming and activation as well as inducing endothelial cell injury. The latter causes increased neutrophil and platelet adhesiveness, leading to thrombosis, one of the hallmarks of aHUS. We report here progress in the aHUS program.

Methods: In an ex vivo thrombus formation system, serum from aHUS patients induces thrombus formation on microvascular endothelial cells. CCX168 was compared with the

Whole Exome Sequencing Identifies Mutations in TUBAL3 as a Novel Cause of Congenital Abnormalities of the Kidney and Urinary Tract (CAKUT) (Shirlee Shirl,1,6 Asaf Vivante,1,6 Jan Halbritter,1 Jing Chen,1,6 Julian Jakob Schulz,1 Stefan Kohli,1 Daw-yang Hwang,1 Elijah O. Kehinde,1 Richard P. Lifton,1 Martin Zenker,1 Friedhelm Hildebrandt,1,3 Dept of Medicine, Boston Children’s Hospital, Harvard Medical School, Boston, MA; Dept of Surgery, Kuwait Univ, Safat, Kuwait; Dept of Genetics, Yale Univ School of Medicine, New Haven, CT; Dept of Human Genetics, Otto von Guericke Univ, Magdeburg, Germany; Howard Hughes Medical Inst, Chevy Chase, MD; These authors contributed equally to this work.

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) are the leading cause of end-stage kidney disease in children. The morphogenesis of kidney and urinary tract is modified by genetic mutations that lead to CAKUT. Identifying these mutations will not only provide deeper insight on disease mechanisms but also aids in improving diagnosis. TUBAL3 was identified as a potential candidate gene for causing CAKUT.

Methods: Homozygosity mapping with whole exome sequencing (WES) was performed in 20 consanguineous families with CAKUT from India. Homozygous recessive mutations within the homozygous region were further evaluated as the strongest candidates. Furthermore, we screened an additional cohort of 900 patients with CAKUT for additional mutations with a barcoded array based multiplex exon PCR (48x48 Fluidigm Access ArrayTM) followed by next generation sequencing (Illumina MiSeqTM). All identified mutations were confirmed by Sanger sequencing.

Results: A homozygous truncating mutation (p.Tyr179*) in the gene TUBAL3 was identified in the consanguineous Indian family A338 which uses WES. We then independently detected another mutation homozygously (p.Gly10Ser) in the gene TUBAL3 in a family A1347 of Kurdish descent. TUBAL3 (Tubulin, alpha-like 3) is a protein coding gene and is very conserved across species. Tubulin is the major constituent of microtubules.

Conclusions: We identified recessive mutations in TUBAL3 as a novel single-gene cause of CAKUT. Further genetic information and functional studies will help understand disease mechanisms and the role of TUBAL3 in the pathogenesis of CAKUT.

FR-POI172

Association of PAH2 and Other Gene Mutations with the Clinical Manifestations of Renal Coloboma Syndrome Kengo Furuuchi,1 Yoshiji Okumura,2 Yasuyuki Shinozaki,1 Yasunori Iwata,3 Norihiko Sakai,1 Takashi Wada,1 Div of Blood Purification, Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan; Div of Nephrology, Kanazawa Univ Hospital, Kanazawa, Japan.

Background: Renal coloboma syndrome (RCS) is characterized by kidney hypoplasia or dysplasia and abnormality of the optic nerve. Diagnosis of RCS is based on the morphological examination of the kidney, ophthalmologic findings, and family history. Approximately 170 cases with PAH2 gene mutations have been reported in cases with RCS worldwide. However, around 50% of cases of RCS have no mutation in PAH2 gene.

Methods: To investigate the incidence and effects of mutations of PAH2 and 25 related genes, 28 patients with RCS were screened using next-generation sequence analysis, and candidate mutations were confirmed using Sanger sequencing. The correlation between mutations and clinical manifestation was evaluated.

Results: Thirty patients, including two family cohorts (n = 5 and 2), 19 patients with sporadic RCS, and 4 coloboma only control cases were evaluated in the present study. Screening the sequences of PAH2 and 25 other genes identified 46 non-synonymous single nucleotide changes at 9 indels. Among these candidate gene abnormalities, eleven PAH2 mutations, including four novel mutations, were confirmed using Sanger sequencing, as were mutations in CDH7, SALL4, KIF26B, and SIX4. A SALL4 mutation was detected in one patient, and CHD7, KIF26B, and SIX4 mutations were detected in another patient, of which KIF26B mutation is novel. Kidney function and proteinuria were more severe in patients with PAH2 mutations than in those without themutation. Moreover, the coloboma score was significantly higher in patients with PAH2 gene mutations. Three out of five patients with PAH2 mutations had focal segmental glomerulosclerosis diagnosed from kidney biopsies.

Conclusions: Our data indicate that PAH2 mutation is a key mutation in RCS and may make a major contribution to the pathogenesis of kidney and eye abnormalities. However, other factors and gene mutations may play a role, and further human and animal studies will be required to define the mechanism of pathogenesis of RCS.

Funding: Government Support - Non-U.S.
Methods: To identify causative genes for CAKUT we investigated consanguineous families with CAKUT by applying whole exome sequencing (WES) combined with homozygosity mapping.

Results: In one family we detected a homozygous loss-of-start mutation in the gene TCTC2 (tetracopeptide repeat-containing 25). This mutation (p.Met1Thr; c.27C>T) was present in a symptomatic child that had a posterior urethral valve, vesicourethral reflux and bilateral hydrourephrosis. TCTC2 plays a role in ciliogenesis, proenephrine cilia function and signal transduction in the sonic hedgehog pathway (Hayes, J. M. et al., 2007. Dev. Biol. 312: 115; Xu Y et al., 2015. PLOS ONE 10(4): e0124378). The latter has been shown to coordinate bladder and urethra formation in mice (Haraguchi R et al., 2007. Development 134(3):525; Haraguchi R et al., 2012. PLOS ONE 7(1):e42245).

Conclusions: By WES and homozygosity mapping we identified TCTC2 as a novel monogenic CAKUT-causing gene if mutated. Funding: NIDDK Support

FR-PO174
Phenotypic Analysis of a Cohort of Patients with Hepatocyte Nuclear Factor 1 Beta (HNF1β) Mutations and Correlation with Established Scoring Systems Emma Kaye Montgomery,1 John Andrew Sayer,1,2 Renal Services Centre, Newcastle Hospitals NHS Foundation Trust, Newcastle upon Tyne, Tyne and Wear, United Kingdom; 1Inst of Genetic Medicine, International Centre for Life, Newcastle Univ, Newcastle upon Tyne, Tyne and Wear, United Kingdom.

Background: Hepatocyte nuclear factor 1 beta (HNF1β) mutations may lead to a wide spectrum of clinical phenotypes including developmental defects of the kidney, pancreas, liver, and Mullerian duct. HNF1β mutations account for Renal Cysts and Diabetes (RCAD) syndrome. We reviewed patients with known HNF1β mutations to determine the range of phenotypes associated and identified if these patients would have been detected based on established scoring systems.

Methods: We selected patients who had been screened for HNF1β mutations from 2009 to 2014 within our hospital. Serum magnesium, potassium, urate and creatinine levels were noted as well as renal morphology based on imaging. All positive and negative patients for HNF1β mutations had their phenotypes quantified and correlated with published HNF1β scoring systems and screening criteria.

Results: 135 patients were screened over 5 years. The cohort included 17 patients from 10 families with confirmed HNF1β mutations. The majority of these patients had CKD stage 3, with a mean creatinine of 144 umol/L. Only 35% of mutation positive patients had a known diagnosis of NC (W138X). In HoZ pts, 6/16 pts had homozygous (HoZ) and 52 pts had compound heterozygous sequence ∆. 1/68 pts had a known diagnosis of NC (W138X). In HoZ pts, 6/16 pts had homozygous (HoZ) and 52 pts had compound heterozygous sequence ∆. 1/68 pts had a known diagnosis of NC (W138X). In HoZ pts, 6/16 pts had homozygous (HoZ) and 52 pts had compound heterozygous sequence ∆, 2 with -294C>T and 2 with -295G>C, a mutation locus with signal transduction in the sonic hedgehog pathway (Hayes, J. M. et al., 2007. Dev. Biol. 312: 115; Xu Y et al., 2015. PLOS ONE 10(4): e0124378). The latter has been shown to coordinate bladder and urethra formation in mice (Haraguchi R et al., 2007. Development 134(3):525; Haraguchi R et al., 2012. PLOS ONE 7(1):e42245).

Conclusions: By WES and homozygosity mapping we identified TCTC2 as a novel monogenic CAKUT-causing gene if mutated. Funding: NIDDK Support

FR-PO175
CTNS Gene Mutations and Variants in Adult Hemodialysis Patients Craig B. Langman,1 Paul C. Grimm,1 Elena N. Levchenko,1 Krishna R. Polu,1 Feinberg Sch Med, Northwestern U;1 Stanford U. Sch. of Med; 1Univ of Leuven,1 Raptor Pharmaceuticals, Novato, CA.

Background: Nephropathic Cystinosis (NC), a rare, systemic, autosomal recessive disease due to CTNS gene mutations causes end-stage renal disease (ESRD). While most cases of NC are recognized in infancy (95%), late-onset NC with ESRD is rare but might be under-diagnosed. NC is rarely diagnosed in African-Americans (AA). Objective: To identify CTNS mutations and possible pathogenic variants (∆) in a representative sample of patients with late-onset NC.

Methods: Genomic DNA was extracted from whole blood from 4007 adult hemodialysis pts from the Davita biorepository. Fluidigm’s Access Array IFC was used to identify clinically relevant CTNS mutations & ∆ variants in a representative sample of patients with late-onset NC. In HoZ pts, 6/16 pts had homozygous (HoZ) and 52 pts had compound heterozygous sequence ∆, 2 with -294C>T and 2 with -295G>C, a mutation locus with signal transduction in the sonic hedgehog pathway (Hayes, J. M. et al., 2007. Dev. Biol. 312: 115; Xu Y et al., 2015. PLOS ONE 10(4): e0124378). The latter has been shown to coordinate bladder and urethra formation in mice (Haraguchi R et al., 2007. Development 134(3):525; Haraguchi R et al., 2012. PLOS ONE 7(1):e42245).

Conclusions: By WES and homozygosity mapping we identified TCTC2 as a novel monogenic CAKUT-causing gene if mutated. Funding: NIDDK Support

FR-PO176
Sixteen Monogenic Genes Cause 20% of Early-Onset Urinary Stone Disease Jennifer A. Lawson,1 Daniela A. Braun,1 Heon Yung Goe,1 Jan Halbritter,1 Shirlee Shril,1 Weizhen Tan,1 John Andrew Sayer,2 Danko Milosevic,3 Michelle Baum,1 Velibor Tasic,1 Friedhelm Hildebrandt,3,4 Nephrology, Boston Children’s Hospital, Boston, MA; 1Inst of Genetic Medicine, Newcastle Univ; Newcastle upon Tyne, Tyne; United Kingdom; 2Dept of Pediatric Nephrology, Univ of Zagreb Medical School, Zagreb, Croatia; 3Medical Faculty Skopje, Univ Children’s Hospital, Skopje, Macedonia, The Former Yugoslav Republic of; 1Howard Hughes Medical Inst, Chevy Chase, MD.

Background: Urinary stone disease (USD) is a prevalent condition that affects 10-15% of adults in their lifetime. It is associated with high morbidity due to colicky pain, the necessity for surgical intervention, and sometimes progression to chronic kidney disease. In recent years, multiple monogenic causes of USD have been identified. However, the prevalence of each monogenic gene has yet to be systemically studied in a pediatric urinary stone cohort.

Methods: To determine the percentage of cases that can be explained molecularly by mutations in 1 of 30 known urinary stone genes, we conducted a high throughput exon sequencing analysis in an international cohort of consecutively recruited individuals from three renal stone clinics. The cohort consisted of 143 individuals under 18 year of age, with nephrolithiasis (n=123) or isolated nephrocalcinosis (n=20).

Results: We detected likely causative mutations in 16 of 30 analyzed genes, leading to a molecular diagnosis in 20% (29 of 143) of affected individuals; 14 of the 32 detected mutations were not previously described as disease causing (43%). We show that mutations in recessive genes are more likely to cause infantile onset disease, whereas mutations in dominant genes are more likely to manifest later.

Conclusions: We present the first exclusively pediatric cohort examined for monogenic causes of urinary stone disease, and our data demonstrates that important therapeutic and preventative measures may result from mutational analysis in individuals with early-onset USD. Funding: Other NIH Support - DK1069274, DK1068306, and DK046414

Mild Inhibition of Alanine-Glyoxylate Aminotransferase Translation as a Possible Treatment of Primary Hyperoxaluria Type 1 Roman Lyakhovetsky,1 Yaacov Frishberg,1 Bodo B. Beck,1 Ruth Belostotsky,1 Pediatric Nephrology, Sharee Zedek Medical Center, Jerusalem, Israel; 1Inst of Human Genetics, Cologne, Germany.

Background: Primary hyperoxaluria type 1 (PH1) is a kidney stone disease, often leading to ESRD, caused by absence, deficiency or misfunctioning of the liver peroxisomal alanine-glyoxylate aminotransferase (AGT), encoded by AGT. The most frequent mutation G170R, responsible for 30% of PH1 cases in Caucasians, results in aberrant mitochondrial localization rather than catalytic inactivity. Modulating AGT maturation and folding has long been perceived as a therapeutic approach. Yet, numerous attempts over the years failed to rescue AGT mutants. We propose mild translational inhibition as a novel approach to improve folding and localization of AGT mutants.

Methods: The antihemifilin FDA-approved drug etemate, was used as a translation inhibitor. To ensure selective and specific discrimination between the mitochondrial (major) and the peroxisomal (minor) subpopulations of mutated AGT we developed the GlowAGT assay based on the recently described self-assembled split GFP approach. Results: Using GlowAGT, WT-AGT but not G170R-AGT was detectable by GFP fluorescence, although both variants were visible by indirect immunofluorescence. Long-term treatment with low concentrations of etemate showed statistically significant increase of fluorescent subpopulation of G170R-AGT. GFP fluorescence was exclusively co-distributed with the peroxisomal staining in all cases.

Conclusions: We have developed and applied successfully GlowAGT as a unique self-assembled split-GFP-based assay for detecting peroxisomal subpopulation of AGT. Using GlowAGT we show that mild translation inhibition by etemate is a novel therapeutic approach for PH1 caused by AGT misfolding/mislocalization.

Functional Analysis of CLCNKB Mutations Causing Bartter Syndrome Type III
Yoann Bigon, Mathilde Keck, Stephanie Lourdrel, Rosa Vargas-Poussou, Jacques Teulon, Olga Andrini. 1 (Metabolisme et Physiologie Renales, Centre de Recherche des Cordeliers, UPMC, Paris, France; 2Département de Genetique, Hopital européen Georges Pompidou, Univ Paris 5, Paris, France.

Background: Bartter Syndrome type III is a human autosomal recessive disease characterized by salt wasting, hypokalemic metabolic alkalosis and secondary hyperaldosteronism. Therefore, patients affected by Bartter syndrome type III display polyuria, polydipsia, dehydration, nephrocalcinosis and failure to thrive. The disease is caused by inactivating mutations in the CLCNKB gene encoding for the ClC-Kb chloride channel.

Methods: In order to screen for the existence of a novel disease causing mutation in the CLCNKB gene, we have conducted a comprehensive functional analysis of five previously reported pathogenic CLCNKB missense mutations (A204T, A210V, P216L, G424R, G437R).

Results: Currents produced by the G424R and G437R mutations were reduced by 50-80%. Protein abundance of A210V was decreased by half. A210V and P216L mutants did not produce any current but their membrane targeting was only partially reduced (50-80%). Protein expression and subcellular localization of mutated forms of ClC-Kb in X. laevis oocytes was also characterized. Curently, we are investigating the functional consequences of these mutations.

Conclusions: The number of urological interventions and the prescription of tiopronin has increased over time. We show for the first time that D-penicillamine and tiopronin don’t impact cystine crystalluria although inducing frequent adverse effects in the same proportions. Urinary pH above 7.5 and morning urinary specific gravity below 1005 should be the goals of medical therapy.

Funding: Government Support - Non-U.S.

Changes in Urologic and Medical Treatment of Cystinuric Patients Over Time
Caroline Prot-Bertovy, 1 Said Lebbah, Michel Daudon, Isabelle Tostivint, Olivier Traxer, Bertrand Knebelmann, Marie Courbebaise, 2 Physiology, APHP, Georges-Pompidou European Hospital, Paris, France; 3Biostatistics, AP-HP, Necker Hospital for Sick Children, Paris, France; 4Physiology, AP-HP, Tenon Hospital, Paris, France; 5Nephrology, AP-HP, Pitié-Salpêtrière Hospital, Paris, France; 6Urology, AP-HP, Necker Hospital for Sick Children, Paris, France.

Background: Cystinuria is the most common monogenic nephrolithiasis disorder, but few studies have described its urological and medical treatment in a large cohort.

Methods: We retrospectively collected data from 442 French cystinuric patients. Clinical and laboratory data, urological and medical treatments were described. A mixed-effects logistic regression model was used to estimate the effects of urinary pH, urinary specific gravity, and cysteine-binding thiol agents (CBT) on the risk of cystine crystalluria.

Results: The median follow-up [min-max] was 15.8 years [0.1-65.6]. The average annual rate of surgical procedures increased with time (P<0.001). During the period 2000-2004, 7.3 % of patients had at least one flexible ureteroscopy, versus 23.2 % after 2005 (P<0.001). CBT were prescribed for 55.3% of patients. Prescription of tiopronin increased with time in newly symptomatic patients (P<0.001). At least one side effect was recorded in 23.7% of patients treated with tiopronin, and 30.2% of patients treated with D-penicillamine (P<0.23). Increasing urinary pH and decreasing urinary specific gravity significantly reduced the risk for a patient to have a cystine crystalluria whereas D-penicillamine and tiopronin did not reduce this risk. The estimated probability of cystine crystalluria was 45%, 38%, 31% and 25% for an urinary pH of 6.5, 7.0, 7.5 and 8 and was 52%, 31% and 16% for an urinary specific gravity of 1015, 1010 and 1005.

Conclusions: The number of urological interventions and the prescription of tiopronin has increased over time. We show for the first time that D-penicillamine and tiopronin don’t impact cystine crystalluria although inducing frequent adverse effects in the same proportions. Urinary pH above 7.5 and morning urinary specific gravity below 1005 should be the goals of medical therapy.

Defect of Interdependent Membrane Targeting and Endocytosis of Cubilin and Amnionless Leads to Imerslund-Gräbeck Syndrome
Tomohiro Udagawa, 1 Ken-ichiro Miura, 1 Akihiko Saito, 1 Yutaka Harita, 2 Pediatrics, Graduate School of Medicine, The Univ of Tokyo, Bunkyo-ku, Tokyo, Japan; 3Applied Molecular Medicine, Niigata Univ Graduate School of Medical and Dental Sciences, Chuo-ku, Niigata, Japan.

Background: Imerslund-Gräbeck syndrome (IGS) is an autosomal recessive disorder characterized by low-molecular-weight proteinuria and megaloblastic anemia. IGS is caused by mutations of either cubilin (CUBN) or amnionless gene (AMN). Cubilin forms protein complex with amnionless (cubam complex) and functions as the receptor-mediated endocytotic machinery.

Methods: A six year-old boy with history of megaloblastic anemia was diagnosed with IGS because of low-molecular weight proteinuria. Whole-exome sequencing identified novel heterozygous missense mutations, one each in CUBN and AMN. The CUBN mutation was de novo and the AMN mutation was inherited from a healthy parent.

Results: Renal biopsy showed translocation of amnionless from the apical membrane to the cytoplasm of proximal tubular cells. Using cultured cells, the mechanism of membrane trafficking of cubulin and the effect of the mutations were analyzed. Although wild-type cubulin and amnionless were interdependently targeted to the cell membrane, the CUBN or AMN mutation abrogated membrane expression and endocytosis without affecting the interaction between cubulin and amnionless. Coexpression of amnionless induced maturation of cubulin protein, and the modification were identified by stable isotope labeling using amino acids in cell culture (SILAC)-based quantitative mass spectrometry. Notably, the CUBN mutation completely abrogated the amnionless-dependent glycosylation of cubulin. Tunicamycin or substitution of several Asn residues to Asp abrogated membrane targeting of cubulin without affecting cubulin and amnionless interaction, further supporting a role of cubulin glycosylation.

Conclusions: Our results demonstrate that digenic heterozygosity can lead to IGS and suggest that interdependent membrane trafficking of cubam complex mediated by posttranslational modification is crucial for the renal and intestinal absorption.

Metabolic Control of Nephron Progenitor Cell Renewal and Differentiation

Background: Nephron progenitor cells (NPCs) availability and differentiation potential determine nephron endowment. Emerging data from embryonic stem cells and other developing systems emphasizes the significance of energy metabolism in cell fate determination. Systemic metabolic dysfunction such as hyperglycemia alters neural and adipocyte stem cell fate. Nephron deficit in kidneys of diabetic mothers (idm) is known; however the effect on NPC and nephrogenesis under maternal hyperglycemia are unknown. Metabolic parameters of renewing NPCs are also unknown. Based on published stem cell data, we hypothesized that NPC self-renewal and differentiation are balanced by energy metabolism.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

397A
Methods: a. Fetal kidneys were exposed to maternal hyperglycemia using Streptozotocin (STZ). The kidney sections were immunostained to detect apoptosis (active caspase3) in the CM (Six2 and NCAM) and nascent nephrons (Lef1 and NCAM). b. Glycerolysis was inhibited ex vivo in E12.5 kidneys by pharmacological inhibition of PFKFB3 (YN1 5-25mM). c. Glycerolysis and oxidative phosphorylation were measured in NPF 21HepG2 cell treated with 3-methyladenine (3-MA). d. GRHL2, a genetic model of impaired cap mesenchyme renewal.

Results: a. CM of P0 kidneys of STZ-treated females showed increased apoptosis and reduction in nascent nephrion number (Lef1+ and NCAM+). b. Glycerolysis inhibition resulted in a smaller dispersed CM, accelerated but not ectopic differentiation of the NPC up to a 50% increase in Lhx1+ nascent nephrons 24-48h post-treatment, and decreased Cited1 expression by QPCR in isolated NPC. UB tip and branch numbers were unchanged. Thus, increased nephrinephrosis was independent of UB branching. Expression of Wnt4 was unchanged. c. Conditional deletion of p53 in NPC also resulted in dispersed CM, depletion of the Cited1+/Six2+ NPC independent of apoptosis, and hypoplastic kidneys with fewer nascent nephrons. Isolated mutant cells showed reduced basal oxygen consumption rate and decreased maximal respiratory capacity. Accordingly, the mutant cells exhibit a significant, nearly two-fold decrease in ATP (p<0.005, n=4).

Conclusions: Our data are consistent with the idea that the metabolic status of the NPC is a critical determinant of NPC renewal and differentiation.

Prorenin Receptor Signaling Promotes Nephron Induction During Mouse Kidney Development Renfang Song,1 Graeme James Preston,1 Laura R. Kidd,2 Ihor V. Yosypiv,1 1Pediatrics, Tulane Univ, New Orleans, LA; 2Pathology, Tulane Univ, New Orleans, LA.

Background: Deficient nephrinephrosis is the major factor contributing to congenital renal hypoplasia (RHD), one of the leading causes of childhood end-stage kidney disease. Nephron induction is driven by reciprocal interactions between progenitor cells of the cap mesenchyme and the ureteric bud (UB). We hypothesise that the potential role of the prorenin receptor (PRR) in nephrinephrosis, we generated mice with a conditional deletion of the PRR in Six2+ cells and measured the effect on nephron number and kidney weight during development.

Methods: a. We established and analyzed homozygous mice carrying a large genomic deletion mapping to 398A, a model of impaired cap mesenchyme renewal.

Results: a. CM of P0 kidneys of STZ-treated females showed increased apoptosis and reduction in nascent nephrion number (Lef1+ and NCAM+). b. Glycerolysis inhibition resulted in a smaller dispersed CM, accelerated but not ectopic differentiation of the NPC up to a 50% increase in Lhx1+ nascent nephrons 24-48h post-treatment, and decreased Cited1 expression by QPCR in isolated NPC. UB tip and branch numbers were unchanged. Thus, increased nephrinephrosis was independent of UB branching. Expression of Wnt4 was unchanged. c. Conditional deletion of p53 in NPC also resulted in dispersed CM, depletion of the Cited1+/Six2+ NPC independent of apoptosis, and hypoplastic kidneys with fewer nascent nephrons. Isolated mutant cells showed reduced basal oxygen consumption rate and decreased maximal respiratory capacity. Accordingly, the mutant cells exhibit a significant, nearly two-fold decrease in ATP (p<0.005, n=4).

Conclusions: Our data are consistent with the idea that the metabolic status of the NPC is a critical determinant of NPC renewal and differentiation.

Functional Dissection of Enhancers for Bmp7 in Kidney Development Taro Tsujimura,1,2 Osamu Takase,1,3 Masami Nangaku,1 Keiichi Hishikawa,1,2 1Advanced Nephrology and Regenerative Medicine, The Univ of Tokyo Hospital, Tokyo, Japan; 2Div of Nephrology and Endocrinology, The Univ of Tokyo Hospital, Tokyo, Japan; 3Div of Tissue Engineering, The Univ of Tokyo Hospital, Tokyo, Japan.

Background: Bmp7 is a critical player in the kidney development, as shown by its severe retardation in the KO mice of the gene and their subsequent perinatal lethality due to the malfunction. Previous studies identified two potential enhancers for the Bmp7 expression in the developing kidney around the lumen: one residing inside the 1st intron of Bmp7 for expression in the developing ureteric bud; the other located downstream of the 3’ end of Bmp7, which is rather active in the metanephric mesenchymal cells. Consistently, Bmp7 is also expressed in these two distinct domains. However, neither the requirement of these elements nor the function of Bmp7 secreted from these different cell types for the kidney development has been uncovered so far. In this study, we aimed to characterize the roles of the two enhancers to better understand the cis-regulation of Bmp7 and the kidney development.

Methods: a. We established and analyzed homozygous mice carrying a large genomic deletion of the downstream region of Bmp7 including the mesenchymal enhancer.

Results: a. We found that they have significantly smaller body size than their wild type littermates, although they are viable unlike the KO mice of Bmp7. We previously showed that the same deletion also disrupts the topological partition of the chromatin conformation between the Bmp7 domain and the neighboring one of another developmental gene, Tfap2c, resulting in a merger between them (Tsujimura et al. PLoS Genetics 2015). Interestingly, upon this deletion, we scored significant up-regulation of Tfap2c in the kidney probably by the action of the intron enhancer.

Conclusions: These results suggest that the endogenous genomic context guarantees robustness in the regulation of the kidney development by linking the more important ureteric bud enhancer to Bmp7 tightly. The differential roles of the two enhancers will be further discussed based on the histological and functional analysis of the kidney in the homozygous deletion mice.

BMP7 Regulates Expansion of the Postnatal Nephron Mary E. Taubler,1,2 Seymour Rosen,2 Jordan A. Kreiberg,1,4 1Dept of Medicine, Boston Children’s Hospital, Boston, MA; 2Dept of Pathology, Beth Israel Deaconess Medical Center, Boston, MA; 3Dept of Pediatrics, Harvard Medical School, Boston, MA; 4Harvard Stem Cell Inst, Cambridge, MA.

Background: The factors that regulate the expansion of nephrons after their initial induction and differentiation are largely unknown. Bone morphogenic protein 7 (BMP7) is a crucial factor driving proliferation and self-renewal of nephron progenitor cells during the development of the embryonic kidney. In this study we investigated a potential role for BMP7 as a regulator of post-induction nephron growth and differentiation.

Methods: The Bmp7 gene was conditionally mutated in progenitor cells using Six2-GFP/Cre. Kidneys from mutant and control mice were analyzed using a novel approach to quantitatively proximal tubule expansion as an indicator of nephron growth in the postnatal mouse.

Results: Kidneys of Bmp7 conditional mutant mice were smaller with reduced numbers of nephrons. Bmp7 was expressed in developing nephron tubules of control kidneys and was absent from mutant kidneys. Proximal tubule growth, as determined by computationally measuring the area of lectin-stained proximal tubules in postnatal kidneys, was reduced in mutant kidneys. However, the proximal tubule area per glomerulus was increased in mutant kidneys, indicating that those nephrons that were induced underwent hypertrophy. Proliferation, as defined by Ki67+ nuclei per LTL, increased in cells within the proximal tubule compartment, was initially greater in mutants but declined by P10.

Conclusions: Loss of Bmp7 in progenitors leads to low nephron number. Bmp7 appears to be an important driver of postnatal nephron expansion. This phenotype is similar to oligomeganephronia and may be used to understand the basis for nephron hypertrophy in low nephron number situations.

FR-PO185
Grainyhead-Like 2 (Grhl2) Regulates Collecting Duct Barrier Function, Aquaporin 2 Expression and Urinary Concentration Christian Hinje,1,2 Janett Ruffert,1,2 Katharina Walentin,1 Max Werth,1 Jonathan M. Barash,2 Andong Qiu,1 Kerim Mutig,1 Sebastian Bachmann,1 Kai M. Schmidt-Ott,1,2 1Dept of Nephrology, Charité-Universitätsmedizin, Berlin, Germany; 2Max Delbrück Center for Molecular Medicine, Berlin, Germany; 3Div of Nephrology, Columbia Univ, New York; 4Dept of Anatomy, Charité-Universitätsmedizin, Berlin, Germany; 5Urological Research Laboratory, Charité-Universitätsmedizin, Berlin, Germany.

Background: Osmotic homeostasis is tightly regulated by the kidney and its collecting ducts which form tight barriers, thereby maintaining steep concentration gradients and allowing transcellular reabsorption of water via aquaporins. The transcription factor grainyhead-like 2 (Grhl2) is highly expressed in renal collecting ducts. Using cultured collecting duct cells, we recently showed that Grhl2 regulates epithelial barrier formation and lumen expansion via a target gene set comprising the transcription factor Ovo-like 2 (Ovol2), the small GTPase Rab 25 (Rab25) and the tight junction component Claudin 4 (Cl4nd4). The role of Grhl2 in the collecting duct in vivo is unknown.

Methods: To investigate the role of Grhl2 in the renal collecting duct, we generated a collecting duct-specific knockout with Hoxb7-Cre; Grhl2fl/fl mice, which exhibit a deletion of Grhl2 protein in most of the collecting cells. The molecular and cellular alterations in their kidneys and their response to water deprivation were analyzed.

Results: a. Transcriptional profiling of Hoxb7-Cre; Grhl2fl/fl mice kidneys and control littermates showed deregulation of Ovol2, Rab25 and Cl4nd4, but also differential expression of Aquaporin 2 (Aqp2). Following water deprivation, Grhl2-deficient mice displayed significantly lower urinary osmolality at 6 hours (P=0.001) and 24 hours (P=0.04) when compared to control mice. Moreover, Grhl2-deficient mice had more than 55% more urine volume during the first 24 hours in response to water deprivation when compared to controls (P=0.005).

Conclusions: Our data indicate that Grhl2 critically participates in water homeostasis, epithelial barrier function and Aqp2 expression. This might be of relevance to diseases involving defective renal responses to water deprivation.

FR-PO186
Loss of the Transcription Factor Tcf21 in the Renal Stroma Leads to Polyuria and Defects in Tubular Development Shintaro Idg,1 Yoshio Macawza,2 Rizaldy P. Scott,2 Tuncan Onay,1 Kana Ide,1 Minori Takemoto,1 Kouutar Yokote,1 Susan E. Quagg,1 1Clinical Cell Biology and Medicine, Chiba Univ Graduate School of Medicine, Chiba, Japan; 2Feinberg Cardiovascular Research Inst and Div of Nephrology and Hypertension, Northwestern Univ, Chicago, IL.

Background: Renal stromal cells serve as a supportive framework for nephrons and the collecting duct network, produce erythropoietin, and contribute to renal fibrosis when they undergo myofibroblast-like transformation. Tcf21/Pod1 is a BHLH transcription factor...
strongly but not restrictively expressed in the developing renal stroma. Conventional Tcf21 knockout (ko) mice have mature stromal cell function and have maldifferentiating mesenchyme and kidney phenotype at the mature stage, but not in immature podocyte. Finally, mTORC1 in mutated-CRB2 cells was activated more than that in wild-CRB2 cells. 

Conclusions: CRB2 tyrosine phosphorylation may regulate energy system of developing podocytes through suppressing excessive mTORC1 activation.

FR-PO187

Genetic Deletion of Cyclooxygenase-2 Impairs Glomerular Slit Diaphragm Formation During Late Stages of Kidney Development
Kirsten Madsen,1,2 Niels Marcussen,2 Boye Jensen,1 1Dept of Cardiovascular and Renal Research, Univ of Southern Denmark, Odense, Denmark; 2Dept of Pathology, Odense Univ Hospital, Odense, Denmark.

Background: Renal cyclooxygenase-2 (COX-2) expression is necessary for normal glomerular development. Impaired COX-2 activity has been associated with decreased expression of VEGF, a vascular growth factor of significant importance for glomerular capillary development. Therefore experiments were designed to test the hypothesis that COX-2 expression supports glomerular development through stimulation of capillary loop formations.

Methods: Kidney tissue was collected from a developmental series of COX-2 knock-out (KO) mice and wild-type littermates (WT).

Results: Renal COX-2 expression showed developmental regulation with significantly higher COX-2 expression at postnatal (P) days 1 and P7 than at any later time points (P14, P21 and P40). Quantitative unbiased stereology at P28 showed significantly reduced glomerular number in COX-2 KO mice compared to WT littermates (1888 ± 78 vs. 1225 ± 454 glomeruli/kidney, respectively, P<0.0001). Subcapsular accumulation of small and immature glomeruli was seen in COX-2 KO mice whereas glomeruli deeper in the cortex towards the medullary function appeared normal. Tissue abundance of VEGF, angiopoietin-1 and -2 mRNAs was significantly reduced in COX-2 KO mice compared to WT at P7. By electron microscopy at P28, immature subcapsular glomeruli showed normal appearance of fenestrated endothelial cells but severe podocyte foot process effacement and absence of mesangial cell. Normal morphology was confirmed in glomeruli deeper in the cortex. At P7, COX-2 KO mice showed reduced expression of slit diaphragm proteins nephrin and podocin but not synaptopodin compared to WT.

Conclusions: In summary, deletion of COX-2 leads to decreased renal expression of VEGF, functional expression of nephrin and podocin and severe podocyte foot process effacement and impaired expression of slit diaphragm proteins. In conclusion, COX-2 activity is necessary for normal podocyte function and slit diaphragm formation during late stages of kidney development.

Functional Cross Talk Between Tyrosine Phosphorylation of Crumbs Homolog 2 and Mechanistic Target of Rapamycin Complex1 in Developing Podocyte
Sho Hamana,1 Yukino Nishibori,1 Kuniyama Yan.1 1Dept of Pediatrics, Kyorin Univ School of Medicine, Mitaka, Tokyo, Japan.

Background: Mutation of crumbs homolog 2 (CRB2) is a novel cause of congenital nephrotic syndrome (CNS) linked to functional apical domain of epithelial cell intercellular adhesion, however, how CRB2 functions in podocyte development is unknown. Other isoform: CRB3 is known to be involved in deactivation of mechanistic target of rapamycin complex1 (mTORC1): a master regulator for cell growth. The objective of the present study is to determine functional cross talk between CRB2 tyrosine phosphorylation and mTORC1 pathway and the contribution of CRB2-mTORC1 interaction to podocyte development.

Methods: MDCK cells expressing mouse full-length CRB2 or mutated-CRB2 lacking tyrosine phosphorylation site were established. Specific antibodies against CRB2 intracellular domain (mCRB2Ab) or tyrosine phosphorylation site (pY-CRB2Ab) were generated. The samples from cultured cells and rat kidneys were subjected to Western blot and immunofluorescence microscopy.

Results: Int-CRB2Ab determined CRB2 to locate at the apicolateral membrane in wild-CRB2 cells. Specificity of pY-CRB2Ab was confirmed by using samples from mutated-CRB2 cells and wild-CRB2 cells treated with protein tyrosine phosphatases inhibitor. Int-CRB2Ab identified that CRB2 expression commences at the comma-shaped body stage, observed in the apical side of glomerular epithelium. CRB2 in the S-shaped body was still visible at the apical side of immature podocytes, then translocated along the lateral side of mature podocytes. CRB2 was observed in the podocyte foot processes. In contrast, phosphorylation of CRB2 was determined faintly in immature podocyte at the S-shaped body stage, intensely at the mature stage and then reduced in podocyte foot process at the terminal stage in the pronephric system. Therefore, CRB2 expression at the mature stage, but not in immature podocyte. Finally, mTORC1 in mutated-CRB2 cells was activated more than that in wild-CRB2 cells.

Conclusions: mTORC1 in mutated-CRB2 cells was activated more than that in wild-CRB2 cells. CRB2 tyrosine phosphorylation may regulate energy system of developing podocytes through suppressing excessive mTORC1 activation.

Epithelial Cell Fate in the Nephron Tubule Is Mediated by the Etv5a Transcription Factor During Zebrafish Kidney Development
Amanda N. Marr, Rebecca A. Wingert.1,2 Biological Sciences, Univ of Notre Dame, Notre Dame, IN.

Background: Kidney development requires the differentiation and organization of discrete nephron epithelial lineages, however the genetic and molecular pathways involved in these events remain poorly understood. The embryonic zebrafish kidney, or pronephros, provides a simple and useful model to study nephrogenesis.

Methods: The pronephric kidney is composed of two types of epithelial cells: transportive and multi-ciliated cells (MCCs). Transportive cells occupy distinct tubule segments and are characterized by expression of solute transporters, while MCCs function in fluid propulsion and are dispersed in a “salt-and-pepper” pattern in the tubule. Epithelial cell identity is regulated by a network of factors including Notch signaling and retinoic acid (RA) signaling, where RA promotes MCC fate by inhibiting Notch signaling in renal progenitors, while Notch activity acts downstream to trigger transportive cell formation and restrict MCC identity. Previous research has shown that etv5a and its ETS family members are required for differentiation in other epithelial tissues.

Results: Here, we mapped etv5a expression to renal progenitors that occupy domains where MCCs later emerge. Thus, we hypothesized that etv5a is required for ciliogenesis of MCCs in the nephron. etv5a loss of function produced a decrease of MCC number and reduced expression of the MCC markers ofl2b and centrin, where rescue experiments partially restored wild-type MCC number. In epistatic studies, exogenous RA treatment expanded the etv5a domain, indicating that etv5a acts downstream of RA. Additionally, treatment with exogenous RA partially rescues the reduced MCC phenotype after loss of etv5a. Finally, we showed that inhibition of both of two types of nuclear DAPT increased etv5a expression, while overexpression of Notch using a transgenic line reduced the etv5a domain, suggesting Notch acts upstream to inhibit etv5a.

Conclusions: Taken together, these findings provide novel insights about the mechanisms of epithelial cell development during nephrogenesis.

Em1 Is Essential for Distal Segment Development During Nephrogenesis
Elvin E. Morales, Rebecca A. Wingert.1 Biological Sciences, Univ of Notre Dame, Notre Dame, IN.

Background: Vertebrate kidneys are comprised of functional subunits called nephrons that typically have three basic parts: a renal corpuscle, a tubule with proximal and distal segments, and a duct. The developmental pathways that establish nephron segment identities from renal progenitors remain poorly understood.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: The zebrafish embryo forms a simple two-nephron pronephric kidney that possesses a pronephric kidney anatomy with homologs. emx1 is a homeobox gene that, along with its paralog emx2, is known for playing essential roles in brain development. While both genes are expressed in the pronephros, their roles in nephrogenesis have not been established. Using whole mount in situ hybridization, we found that emx1 and emx2 were dynamically expressed in renal progenitors, and became localized to the distal and proximal segments, respectively.

Results: In knockdown studies, emx11 morphants formed a normal distal domain, marked by clcnk, but within it formed an expanded distal early (DE) segment, marked by scl. Overproliferation of interrenal cells, similar to those of mammals, was seen with normal expression of 3β-HSD staining indicating the interrenal gland produced more hormones in the mutant phenotype. Although mutants had normal proliferation and cell death, the interrenal gland volume identified by FISH analysis confirmed overproliferation of interrenal cells. These data suggest that targeting both genes in renal progenitors, positively regulating emx2 and negatively regulating emx1, leads to progressive scarring and organ failure.

Conclusions: Future studies will define the role of emx2, independently explore emx1/2 nephrogenesis, and examine the relationship of these emx genes to other factors, such as irx3b, that have been shown recently identified to be components of the gene regulatory networks that direct nephron segmentation. Preliminary data looking at factor interactions suggest that emx genes may be located downstream of them or work independently.

FR-PO192
Prostaglandins as Regulators of Nephron Proximo-Distal Cell Fate Decisions Shahram Jeyin Pourcetzechi, Christina N. Cheng, Rebecca A. Wingert. Biological Sciences, Univ of Notre Dame, Notre Dame, IN.

Background: To date, there have been a number of important discoveries furthering our understanding of nephron segmentation. Despite this, the factors that direct nephron cell fate decisions remain largely unknown. Danio rerio, the zebrafish, posesses an embryonic kidney composed of two nephrons and a blood filter that share a remarkable degree of genetic, structural, and functional homology with the human nephron and when coupled with genetic tractability, ex utero development, and optically transparent embryos make it a cutting-edge model to study nephrogenesis.

Methods: The zebrafish embryonic kidney, the pronephros, is organized in a proximal-distal pattern of contiguous segments much like the human nephron. The proximal segments, the proximal convoluted tubule (PCT) and the proximal straight tubule, share a name with the mammalian thick ascending limb (TAL) and distal convoluted tubule (DCT) respectively. We performed a chemical genetic screen using both genes in renal progenitors, positively regulating emx2 and negatively regulating emx1.

Conclusions: These findings impovrt novel insights into genetic components that impact kidney biology, and as Brca2/Fancd1 mutations cause Fanconi anemia and several common cancers specifically breast and ovarian cancer in humans, this work has identified a new model to understand the role of Brca2/Fancd1 in disease.

FR-PO194
Development of the Vasculature in the Bladder Julia K. Schaffer, 1 Kenneth A. Walker, 2 Caitlin M. Schaefer, 2 Daniel S. Bushnell, 3 Elena Mukherjee, 2 Sunder Sim-Sims, 3,2 Carlton M. Bates, 2 1 Div of Newborn Medicine, Univ of Pittsburgh; 2 Div of Nephrology, Univ of Pittsburgh, Pittsburgh, PA.

Background: Bladder consists of differentiating outer muscle, middle stromal, and inner epithelial layers. To date, formation of the bladder vascular network has not been determined. Aim: To determine vascular patterning through bladder development.

Methods: We examined developing bladder vasculature from embryonic day (E) 11.5 through postnatal day (P) 30 by genotyping histochemistry and immunohistochemistry (including morphometry with GS1 lectin staining). We performed quantitative realtime PCR (qPCR) for genes associated with vascular formation (e.g. Angiopoietin 1 and Vegfa ligands and Tie2 and Vegf2 receptors) and hypoxia inducible factors (Hif).

Results: In early bladder development (E11.5-13.5) vascular branches from the umbilical arteries grow towards a network of developing vessels within the primitive bladder mesenchyme. However, by E15.5, connections between the umbilical arteries and the bladder vascular network are diminished and a vascular remodeling. Perfusion (presence of red blood cells) of most bladder vessels was identified even at early developmental time points. Morphometric assessment revealed a peak in relative vascular tissue content in the bladder at E15.5, which regressed with further maturation. This reduction in vascular content after E15.5 suggests vascular pruning and further remodeling. qPCR revealed that Ang1 and Vegf2 expression peaked during early embryonic development, whereas expression of the Ang1 receptor, Tie2, peaked in early postnatal mice. The Vegf2 ligand Vegfa displayed consistent expression at all ages. Interestingly, Hif1a and Hif2a demonstrate inverse mRNA expression profiles with Hif1a highest in embryonic bladders and Hif2a expression peaking in adult bladders.

Conclusions: Unexpectedly, bladder vasculature appears to arise from angiogenic vessels that arise from the umbilical artery. Subsequently, early bladder undergoes pruning with age. Key molecules that regulate vascular development, including hypoxia inducible factors, have differential expression patterns.

Exploring the Relation Between Cells and Extracellular Matrix in the Developing Human Fetal Kidney Astrik Petrovskiy, 1 Estefanie Rodriguez, 1 Ruby Kim, 2 Hasmik Soloyan, 2 Brendan Grubbs, 3 Matthew Edward Thornton, 2 Roger E. De Filippo, 1 Laura Perin, 1 Stefano Da Sacco, 3 1 Urology, Children's Hospital Los Angeles, Los Angeles, CA; 2 Unit of Southern California.

Background: It is widely accepted that, during development, the renal compartment undergoes dramatic changes in regards to cell specification and differentiation, matrix deposition and spatial organization. However, despite the growing number of studies focusing on kidney mouse development, very little is known of changes, including cell differentiation and extracellular matrix (ECM) deposition, occurring during human development. To fill this gap, we have characterized human embryonic kidneys (hEK) at different weeks of gestation to better understand renal progenitor biology and cell-matrix interactions.

Methods: Histological analysis were carried out on hEK between 11-22 weeks of gestation for ECM components (such as collagen IV a1-6 chains, collagen I, fibronectin) and progenitor/mature renal cells markers such as WT1, Pax-2, Sis-2, Cited1, VE-Cadherin, and Podocin.

Results: We observed dynamic changes in the hEK throughout the progression of the gestational ages. In particular, decrease in nephrogenic zone size along with a higher presence of C- and S-shaped structures and fully developed glomeruli and tubules was observed by 19-22 week samples. Identification of progenitor and fibrous proteins confirmed that ECM composition varies depending on the differentiation state of the surrounding cells. Collagen IV and fibronectin were absent in nephrogenic zone and condensing mesenchyme but found in C- and S-shaped bodies. In addition, Pdgfra (expressed in epithelial interstitial cells) was strongly expressed in the stromagene zone and later restricted to the interstitium, co-localized with collagen I, suggesting a strong link between cell specification and matrix environment.

Conclusions: Our data suggest that, during hEK development, cell specification is associated with marked changes in ECM composition. This characterization might increase our knowledge of reparative processes enabling investigations focused on matrix remodeling and progenitor cell activation, thus ultimately enhancing the chances to treat renal damage.

Enalapril Treatment Modulates Lymphangiogenesis and Fibrogenic Machinery in the Developing Rat Kidney

Kee Hwan Yoo, Hyung Eun Yim, In Sun Bae, Byungkwan Kim, Young Sook Hong, Jou Won Lee. Dept of Pediatrics, Korea Univ Medical Center, Seoul, Republic of Korea.

Background: The renin angiotensin system plays a pivotal role in both renal development and progressive renal disease. Lymphangiogenesis occurs during normal organ development and pathological processes. In this study, we aimed to investigate the effect of angiotensin II inhibition on the expression of fibrogenesis-related molecules and lymphatic vessels in the developing rat kidney.

Methods: Newborn rat pups were treated with enalapril (30 mg/kg) for 7 days after birth. We investigated the intrarenal expression of fibroblast growth factor (FGF)-1, FGF-2, FGF receptor (R)-1, Fibroblast-specific protein (FSP)-1, intercellular adhesion molecule-1, toll-like receptor (TLR)-2, and TLR-4 with Western blotting and immunohistochemistry at postnatal day 8. For the determination of lymphatics, the lymphatic vessel markers of vascular endothelial growth factor (VEGF)-C, VEGF-R3, and podoplanin were assessed. For determination of cell proliferation and collagen fibers, Ki-67 and Sirius red stainings were performed.

Results: In the enalapril-treated group, intrarenal FGF-1, FGF-2, FGF-R1 and VEGF-C protein expression was decreased, compared to the controls (* P < 0.05). Immunohistochemistry for the lymphatic vessel markers of VEGF-C, VEGF-R3, and podoplanin showed reduced lymphatic immunostainings in the enalapril-treated kidneys. However, FSP-1 expression was prominent in the interstitium and glomeruli in enalapril-treated kidneys. While cell proliferation was reduced in the enalapril-treated group, collagen deposition was enhanced in the enalapril-treated kidneys (P < 0.05). Intercellular adhesion molecule-1, TLR-2, and TLR-4 protein expression showed no differences between the two groups.

Conclusions: Enalapril treatment during postnatal 7 days may induce perturbations in FGF/FGFR signals, cell proliferation, and lymphangiogenesis required for renal development and maturation and activate in part the fibrogenic machinery in the developing rat kidney.

The Effect of Prenatal Hypoxia and a Postnatal High Salt Diet on Renal Structure in the Aged Mouse

Sarah L. Walton, 1 Rettu S. Singh, 1,2 Joan Li, 1 Helle Bielefeldt-Oehmann, 3 Tamara Paravicini, 1 Melissa H. Little, 1 Karen M. Mortiz, 1 1 School of Biomedical Sciences, Univ of Queensland, Brisbane, Queensland, Australia; 2 Dept of Physiology, Monash Univ, Melbourne, Victoria, Australia; 3 Inst for Molecular Bioscience, Univ of Queensland, Brisbane, Queensland, Australia. 1 School of Veterinary Science, Univ of Queensland, Gatton, Queensland, Australia.

Background: Chronic fetal hypoxia leads to growth restriction and increased risk of adult renal disease. This study examined the long-term renal outcomes of offspring prenatally exposed to hypoxia, and whether a postnatal high salt diet could exacerbate impairments.

Methods: Pregnant CD1 mice were housed in a hypoxic chamber (12.0% O2; N=8, HYPO) or control (21% O2; N=8, CON) environment from embryonic day (E)14.5 to birth (E21). A subset of male offspring was randomly allocated to a control diet (0.2% NaCl; IN) or control (21% O, NR) supplemented with FA 5 mg/kg (NRFA). At E18, FA supplementation again did not affect body weight (0.147 ± 0.008 vs 0.15 ± 0.008 g) or kidney weight (6.1 ± 0.5 vs 6.7 ± 0.4 g). DNA methylation was assessed by methylated DNA quantification kit. E13 metanephros from normal rats were subjected to organ culture in DMEM with or without FA 5 μg/ml for 3 days.

Results: Maternal undernutrition significantly reduced fetal body weight (0.143 ± 0.004 vs 0.173 ± 0.004 g), kidney weight (0.418 ± 0.03 vs 0.38 ± 0.05 g), and ureteric tip number (4.0 ± 0.4 vs 8.5 ± 0.8) at E14. FA supplementation did not affect body weight (0.147 ± 0.003 g) or kidney surface area (2.2 ± 0.4), but restored ureteric tip number (7.0 ± 0.7, P<0.05 vs NR). At E18, FA supplementation again did not affect body weight (1.28 ± 0.02 vs NR: 1.31 ± 0.01 g) but increased kidney weight (5.5 ± 0.4 vs NR: 5.0 ± 0.3 g). FA restored the glomerular density (15.6 ± 0.2 vs 15.9 ± 0.4, P<0.05 vs NR) that was significantly lower in NR (10.3 ± 0.9) than CON (20.2 ± 3.7). DNA methylation of NR was significantly reduced in NR (8.7 ± 1.1%) vs CON (29.8 ± 5.6%) at E18. IN NRFA, DNA methylation was partially restored to 20%. In the metanephros cultured under FA deficiency, the ureteric tip number was significantly reduced (6.6 ± 0.3, n=10) vs controls (9.9 ± 0.9, n=7). The kidney surface area was also significantly reduced by FA deficiency (3.0 ± 0.2 vs 3.8 ± 0.2).

Conclusions: FA is needed for the metanephric development, and its supplementation alleviates the reduced ureteric branching and nephrogenesis in the offspring of nutrient restricted pregnancy probably by promoting DNA methylation.

Perinatal Switch in Iron Utilization Determines Postnatal Chronic Kidney Disease

Rongjia Deng, 1,2 Rosemary V. Sampogna, 1,3 Andong Qiu, 1,2 Jonathan M. Barasch, 1 1 Columbia Univ; 2 Tongji Univ, China.

Background: Iron deficiency affects 2 billion people worldwide and is a threat to embryonic and early postnatal development. Periconceptual maternal iron deficiency (PM-ID) results in hypoplastic postnatal kidneys but it is not clear whether PM-ID causes cell-lineage or cell-stage specific hypoplasia, nor which species of iron is involved.

Methods: We investigated a model of dietary iron deficiency and a series of deletions of the transferrin receptor (TfR1) cell (autonomous transferrin iron deficiency, AT-FD) in different cellular lineages using a novel TfR1-flx/dx construct.

Results: Severe PM-ID depleted both Tf iron and NTBI (non-transferrin bound iron) resulting in severely hypoplastic proximal tubules and even anephric during gestation, whereas the overall structure of ureteric bud was maintained. Milder PM-ID resulted in surviving but severe postnatal kidney hypoplasia, disruption of the growth of the proximal tubule and TALH and increased mortality before weaning. To determine the mechanism of hypoplasia we examined mesenchymal, ureteral and stromal AT-FD with different Cre drivers. Mesenchymal AT-FD (SisCre2 or KapCre) demonstrated increasing demand for transferrin by the time of birth, resulting in worsening proximal tubule hypoplasia, remarkable cystic transformation and interstitial fibrosis, and even anephric (ProPax3Cre) after birth, the timing of which coincided with accelerated segment-specific growth. The combination of AT-FD and PM-ID further worsened nephron development in contrast. In development, the collecting ducts (HoxB7Cre) and stroma (Foxd1Cre) did not depend on transferrin.

Conclusions: In sum, NTBI supported prenatal and postnatal stromal and ureteric development and the initial stages of metanephric development, whereas Tf iron was required for perinatal maturation of the nephron. Tf-iron depletion resulted in hypoplasia, cysts, and fibrosis, the timing and specificity of which was the result of a sequence of utilization of NTBI followed by Tf-iron. We propose that a peri-natal switch in the mechanism of iron utilization during fetal development is an important contributor to the transition from hypertrophy and reflects changing cellular control of iron delivery. Iron deficiency is a cause of CKD.

Troy/TNFRSF19 Marks a Progenitor/Stem Cell Population in the Kidney

Frans Schutgens, 1,2 Maarten B. Rookmaaker, 1 Robert Vries, 1 Marianne C. Verhaar, 1 Hans Clevver, 1 1 Nephrology and Hypertension, UMC Utrecht, Utrecht, Netherlands; 2 Hubrecht Inst, Utrecht, Netherlands.

Background: Segment committed stem cells play a crucial role in renal development and regeneration. Identification of these stem cells is an important step towards the development of new diagnostic and therapeutic strategies for renal diseases. In this study, we evaluated Troy, an adult stem cell marker in other organs, as a marker for segment forming stem cells in other organs.

Methods: Renal Troy expression was assessed during embryonic development and adult turnover using Troy-GFP mice. The contribution of Troy+ cells to renal development and turnover was investigated using in vivo lineage tracing against Troy-GFP-CreERT2;Rosa-LacZ reporter mice. Troy+ cells were identified using immunohistochemistry for tubular segment-specific Troy expression by a researcher blinded to treatment groups.

Results: During embryonic development Troy+ cells were present in the ureteric bud (1A), whereas in adult kidney Troy+ cells were present in the papilla. After pil1 induction, Troy+ cells gave rise to tubular structures by clonal expansion that persisted up to 2 years after induction [1B-1E]. Immunohistochemistry revealed predominant co-staining with the marker AQP1 [1C]. Troy+ cells contributed to tubulogenesis and collecting duct formation after cessation of nephrogenesis. Finally, Troy+ cells had a higher in vitro sphere forming capacity than Troy+ cells [1F-1H].
Conclusions: These data show that Troy marks a stem/progenitor population for the collecting duct in the developing kidney. Moreover, our data also suggest a role for Troy+ progenitor cells in the adult kidney.

FR-PO201
Preserved Nephrogenesis following Partial Nephrectomy in Early Neonates
Yuhei Kirita, Daiusuke Kami, Ryo Ishida, Tetsuro Kusaba, Takaomi Adachi, Satoshi Gojo

Background: The regenerative or reparative phenomena. new nephrons in early neonates. Neonatal period could offer the unique model to study control kidney, whereas it had already gone in P4X-kidney.

Methods: A pulse of BrdU was administered at different periods during E11.5-20.5, respectively, covering the whole process of the kidney development. The adult kidney were examined the distribution of BrdU-positive cells. A suba basal nephrectomy(Nx) was induced in adult mice to observe the response of BrdU-retaining cells to injury.

Results: In adult kidney, the distribution of BrdU-retaining cells was heterogeneous with different BrdU-labeling time. With BrdU labeled at E11.5-13.5, lots of BrdU-positive cells were located in the papilla and inner medulla, only few scattered in the proximal tubules. With BrdU labeled at P0.5-2.5, lots of cells in the inner medulla and outer medulla could retain the immunoreactivity of BrdU. With BrdU labeled at P3.5-5.5, P6.5-8.5, or P9.5-11.5, the distribution of BrdU-positive cells was mainly in the outer medulla, few in the cortex inner medulla, no longer in the papilla. With BrdU labeled at P12.5-14.5 and P15.5-17.5, lots of BrdU-positive cells were in the outer medulla, but no longer in the papilla or inner medulla. With BrdU labeled at P18.5-21.5, BrdU-positive cells were only found in the cortex. The proximal tubules were the only nephron segments stably containing few BrdU-retaining cells after a chase period of six months. After Nx in adult mice, BrdU-positive cells were more significantly increased in the cortex near the incision edge. BrdU-positive cells mainly distributed in the proximal tubules at the site of injury. Some BrdU-positive cells did not express PCNA, even though numerous PCNA-positive cells were found near the incision edge of kidney. In contrast, originally retained abundant BrdU-positive cells in the outer medulla and inner medulla significantly reduced and disappeared rapidly in the vicinity of incision.

Conclusions: The locations of LRCs were different if BrdU was administered in different periods of kidney development. Most of BrdU-retaining cells were quiescent, few of them in the proximal tubule and papilla may be the renal progenitor cells.

FR-PO202
BrdU Labeling Adult Renal Stem Cells in Development Kidney
Li Ni, Jing Chen. Nephrology, Huashan Hospital, Shanghai Medical College, Fudan Univ, Shanghai, China.

Background: The labeling-retaining cell (LRC) approach is a reliable way to identify adult stem cells. To identify the best labeling time for adult renal stem cells, we administered BrdU in different periods of the kidney development.

Methods: A pulse of BrdU was administered at different periods during E11.5-20.5, respectively, covering the whole process of the kidney development. The adult kidney were examined the distribution of BrdU-positive cells. A suba basal nephrectomy(Nx) was induced in adult mice to observe the response of BrdU-retaining cells to injury.

Results: In adult kidney, the distribution of BrdU-retaining cells was heterogeneous with different BrdU-labeling time. With BrdU labeled at E11.5-13.5, lots of BrdU-positive cells were located in the papilla and inner medulla, only few scattered in the proximal tubules. With BrdU labeled at P0.5-2.5, lots of cells in the inner medulla and outer medulla could retain the immunoreactivity of BrdU. With BrdU labeled at P3.5-5.5, P6.5-8.5, or P9.5-11.5, the distribution of BrdU-positive cells was mainly in the outer medulla, few in the cortex inner medulla, no longer in the papilla. With BrdU labeled at P12.5-14.5 and P15.5-17.5, lots of BrdU-positive cells were in the outer medulla, but no longer in the papilla or inner medulla. With BrdU labeled at P18.5-21.5, BrdU-positive cells were only found in the cortex. The proximal tubules were the only nephron segments stably containing few BrdU-retaining cells after a chase period of six months. After Nx in adult mice, BrdU-positive cells were more significantly increased in the cortex near the incision edge. BrdU-positive cells mainly distributed in the proximal tubules at the site of injury. Some BrdU-positive cells did not express PCNA, even though numerous PCNA-positive cells were found near the incision edge of kidney. In contrast, originally retained abundant BrdU-positive cells in the outer medulla and inner medulla significantly reduced and disappeared rapidly in the vicinity of incision.

Conclusions: The locations of LRCs were different if BrdU was administered in different periods of kidney development. Most of BrdU-retaining cells were quiescent, few of them in the proximal tubule and papilla may be the renal progenitor cells.
many of these disadvantages could potentially be overcome. To this end we have attempted to develop a protocol to produce proximal tubule-like cells from human iPSCs with xenobiotic transport capabilities. 

Methods: Human iPSCs were differentiated into the intermediate mesoderm (IM) using Wnt and retinoic acid activation (CHIR99021 and TTNBP). Cells were further differentiated using combinations of different growth factors. 

Results: The derived cells exhibited cobble stone morphology and express certain proximal tubule proteins such as claudin-2. Additionally, the cells can be maintained for up to 4 weeks in culture. Preliminary results demonstrate the ability of the differentiated cells to spontaneously form organoids (Du-10-ASP) and organic anions (6-CF) and to extrude p-glycoprotein substrates (calcium-AM). 

Conclusions: While further characterization will be needed, the initial results are promising, indicating that proximal tubule-like cells derived from iPSCs could be a new tool for screening the nephrotoxic potential of compounds.

**FR-PO205**

**Methods:** We performed exhaustive search for DNA microarray data after TF induction in the hES bank, and analyzed them in silico to find the specific transcription factors, which expressed in kidney epithelial cells. We synthesized the human synthetic mRNA of the target transcription factors. By using the lipofection method, we transfected the synthetic mRNA of target transcription factors to human ES cells, and cultured them. The morphological changes, mRNA expressions, and protein expressions were analyzed.

**Results:** Some candidate transcription factors, which expressed in human kidney epithelial cells, were identified by in silico analysis. We successfully made synthetic mRNA of candidates of transcription factors. Five days after the transfection of the synthetic mRNA to human ES cells, we were able to observe characteristic morphological changes in the differentiated cells. The mRNA expression of OSR1, ITGA8, AQP1, and MEGALIN were increased. Moreover, the protein expression of AQP1 and LTL were also detected in the differentiated cells.

**Conclusions:** We identified specific transcription factors for differentiation toward kidney (especially, proximal tubular cells), and demonstrated that the differentiation of proximal tubular cell phenotype from human ES cells by a novel method using synthetic mRNA.

---

**FR-PO206**

**Background:** Podocyte injury and subsequent loss of glomerular integrity is a major cause for chronic kidney disease (CKD). Two-thirds of patients with CKD suffer from disorders that arise from the glomerulus, mainly due to podocyte injury. Podocytes are highly specialized cells with a complex cytoarchitecture composed of foot processes that form the glomerular filtration barrier. The study of the molecular processes of glomerular injury is hampered by the fact that cultured primary podocytes have a limited capacity to divide and are difficult to maintain. However, generation of pluripotent stem cells (induced PSCs) from somatic cells allows the possibility of a new source of human cells. The high differentiation capacity of iPSCs would potentially enable the establishment of differentiation protocols for iPSC-derived podocytes which could overcome the burden of primary podocytes in culture.

**Methods:** To this end we applied and optimized a previously published protocol for podocyte differentiation (Song et al., 2012; PMID: 23029522). Human iPSCs are grown in differentiation media for ten days, containing growth factors known to be important in podocyte differentiation (AQP-1, Nephrin) in K-iPS as compared with F-iPS cells. More efficient induction of markers of kidney development (WT-1, Pax-1, Sall-1) and differentiation (AQP-1, Nephrin) in K-iPS as compared with F-iPS cells.

**Results:** In 5/6 surgically nephrectomized rats polydextran gel was introduced intraperitoneally to activate the omentum and fuse to the injured kidney. Nephrectomized rats with complete omentectomy were used as control. Kidney tissues were examined 1-3 weeks after injury by histology and immunofluorescence (Pax-2, WT-1 and podocalyxin).

**Conclusions:** These results demonstrate that epigenetic memory in parental cell determine the induction of human iPSCs toward kidney lineages, and the role of key genes in kidney lineage specific induction will be discussed.

Sourcing of Renal Tubular Epithelial Cells from Human Stem Cell-Derived Kidney Organoids. Elijah Webber, Benjamin S. Freedman, Jonathan Himmelfarb, Edward J. Kelly. 

**Background:** Human pluripotent stem cells (hPSCs) provide a self-renewing, reproducible source of kidney cells for laboratory investigation and regenerative medicine approaches. We tested the potential of hPSC-derived renal tubular epithelial cells (RTECs) to grow and maintain differentiation in 2D and 3D cultures, compared to primary RTECs from adult kidneys.

**Methods:** hPSCs were treated with growth factors to promote differentiation in nephrogenic progenitor cells (PA2/SIX2) and subsequently proximal tubules (LTL; ZO1; LR2). RTECs purified from tubular organoids were re-plated on tissue culture plates with or without extracellular matrix. RTECs were analyzed for proliferation, kidney-specific marker expression, and their capacity to seed a ‘kidney on a chip’ 3D microphysiological system (MPS).

**Results:** RTECs purified from hPSC organoids grew to confluent monolayers in minimal RTEC growth media on extracellular matrix. hPSC-derived RTECs resembled primary RTECs morphologically. Marker immunofluorescence analysis revealed that purified hPSC-RTECs possessed ZO1+ tight junctions and reacted with LTL. Sub-cultivation was limited to 2-3 passages, after which hPSC-RTECs underwent epithelial-to-mesenchymal transition and senesced. In a 3D MPS, hPSC-derived RTECs formed tubular structures comparable to primary RTECs. Immunofluorescence staining demonstrated positive signals for the tubule transporters SGLT2 and OAT3 as well as the epithelial markers CD115 and E-cadherin.

**Conclusions:** We have shown that hPSC-RTECs can propagate in vitro and maintain their differentiated characteristics, with morphology and markers similar to primary RTECs. hPSC-RTECs are grown in a 3D MPS, they maintain an epithelial phenotype and express membrane transporters essential for functions including glucose reabsorption and organic anion secretion. This system establishes a platform in which to optimize hPSC-RTEC expansion and function in a 3D, microfluidic context, with relevance for human disease modeling in vitro and for the development of regenerative therapies.

**FR-PO208**

Genome-Wide Methylation Analysis of Epigenetic Memory in Human Kidney Derived IPS Cells. Osamu Takase, Taro Tsujimura, Masaomi Nanagaki, Keiichi Hishikawa. 

**Background:** Epigenetic memory such as DNA methylation signature of iPS cells derived from parental cells was reported to determine the differentiation fate of the iPS cells (Nature 2012). Last year, we reported the result of kidney specific induction protocol (Nature Commum, 2013) by using two different kinds of human iPS cells established from human fibroblast (F-iPS) and human kidney epithelial cells (K-iPS) and demonstrated more efficient induction of markers of kidney development (WT-1, Pax-1, Sall-1) and differentiation (AQP-1, Nephrin) in K-iPS as compared with F-iPS cells.

**Methods:** In this study, we performed a genome-wide methylation analysis of K-iPS and F-iPS cells, and tried to clarify the mechanism of kidney lineage specific induction of human iPS cells.

**Results:** Among 27,578 sites, we focused on high Cpg promoter lesion (GC>0.55, CpG>0.75). 56 genes such as Kid1 and SOD2 were strongly methylated in F-iPS than in K-iPS. 17 genes such as KCNK12 and GATA4 were strongly methylated in K-iPS than in F-iPS. Markers of kidney development were strongly methylated in F-iPS than in K-iPS cells (Pax-2; 23.6 vs 2.1, Sall-1; 28.7 vs 4.3). However, the marker of differentiation was strongly methylated in K-iPS (AQP-1; 1.7 vs 1.1).

**Conclusions:** These results demonstrate that epigenetic memory in parental cell determine the induction of human iPS cells toward kidney lineages, and the role of key genes in kidney lineage specific induction will be discussed.

**Funding:** Funding Support - Non-U.S.

**FR-PO209**

**Background:** When activated omentum was fused to the injured kidney it induced glomerular repair and ameliorated chronic kidney disease (Garcia-Gomez et al at JASN 2014). The fusion zone between the omentum and the injured kidney was highly proliferative (high BrdU uptake), with abundant free-lying nephron progenitor WT-1 cells. In this study, we examined the fusion area to further understand the mechanism of repair in this model. 

**Methods:** In 5/6 surgically nephrectomized male polystyrene gel implanted intraperitoneally to activate the omentum and fuse to the injured kidney. Nephrectomized rats with complete omentectomy were used as control. Kidney tissues were examined 1-3 weeks after injury by histology and immunofluorescence (Pax-2, WT-1 and podocalyxin).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

E15 embryonic rat kidney served as control for immune-staining. Two-week fusion zone tissue and tissue far from fusion zone, control and normal was quantified for mRNA for selected developmental genes (WT-1, Wnt-4, Pod1, Lim1, HNF-6, BMP-7) by RT-PCR.

Results: We found that the fusion zone tissue showed proliferation and expansion of collecting ducts, as evidenced by intense staining for Pax2, in a pattern similar to that seen in E15 embryonic rat kidney. Further, several islands of WT-1 cells in the fusion zone differentiated to podocytes, as judged by co-expression of podocalyxin. mRNA for Wnt-4 and WT-1 increased by 10-20 folds and mRNAs for other developmental genes increased by 2-5 folds in the fusion zone. Control tissue did not show the above changes.

Conclusions: The fusion zone tissue between the injured kidney and omentum appears to be a highly active tissue with proliferation and differentiation of kidney progenitor cells (WT-1, Pax-2, podocalyxin) taking place, and thus providing a healing environment to the injured kidney.

FR-PO210

Background: Mesenchymal stromal cells (MSCs) are immunomodulatory cells and have shown beneficial effects in kidney disease. It has previously been shown that human perivascular stromal cells (PSCs) from several different organs share characteristics of bone marrow derived MSCs (bmMSC), however, at the same time there are tissue specific properties. We hypothesized that human kidney derived PSCs (hkPSC) are, due to tissue specific imprinting, more potent in kidney repair compared to bmMSCs and sought to find a novel clinical grade isolation method.

Methods: Human transplantation grade kidneys (n=3) were digested with continuously circulating proteolytic enzymes. The resulting crude cell suspension was cultured in αMEM 5% platelet lysates and cells were selected for plastic attachment and NG2 cell enrichment (fig A). Culture was continued until spindle shaped cells appeared (kPSCs) and were compared to bmMSCs between passages 5-10.

Results: hkPSCs have comparable marker expression, cytokine excretion patterns, vascular stabilization and immunosuppressive capacity compared to bmMSCs. hkPSCs showed a distinct gene expression profile including an increased expression of HexD11, a homeobox factor important in nephrogenesis. In a wound scratch assay, kidney epithelial wound healing with conditioned medium of hkPSCs was significantly faster and after 7 hours approx. 80% closure was seen with hkPSC conditioned medium, which was only 40% with bmMSC supernatant (p<0.01) (fig B, C).

Conclusions: Here we show a novel, clinical grade isolation method of hkPSC and compared these cells to bmMSCs. hkPSCs showed a distinct expression profile and are able to enhance kidney tubular epithelial wound healing to a greater extent than bmMSCs. The hkPSCs are promising new cell therapeutic candidate to explore for treatment of kidney disease.

FR-PO211

Background: Atherosclerotic renal vascular disease (ARVD) induces microvascular loss and interstitial inflammation, ultimately leading to ischemic injury. Mesenchymal stem cells (MSCs) can induce angiogenesis, decrease inflammation, and limit apoptosis in experimental animals. Aging and co-morbid conditions may blunt these properties in older human subjects. This study tested the hypothesis that hypoxic preconditioning of adipose tissue-derived MSCs would modify expression of MicroRNAs (miR) associated with MSCs survival, angiogenic, and anti-inflammatory properties.

Methods: MSCs obtained from subcutaneous tissue of 7 patients with ARVD (Age 75.3±2) were cultured under normoxic or hypoxic conditions (1%O2) for 4 days. Hypoxic MSCs were returned to normoxia thereafter. Levels of the pro-survival and pro-angiogenic factors vascular endothelial growth factor (VEGF) and insulin-like growth factor (IGF) were measured in the supernatant by ELISA. Expression of MiRs-210, 211 and 145 in MSCs was measured by quantitative rt-PCR and apoptosis by flow cytometry for Annexin V.

Results: Hypoxic conditions increased VEGF and IGF (p<0.05) in MSC supernatant, but had no effect on apoptosis.

Conclusions: Hypoxic conditions increase VEGF and IGF in MSCs, which may contribute to their anti-apoptotic effects.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Effects of Adipose Derived Stem Cells in a Model of Chronic Renal Hypoxia

**Cytostatic Spheroids or Solid HUVECs?**

**Conclusion:** The MRL/lpr mice were divided into 2 groups: Control, hMSC group. hMSCs were injected at one dose of 1 × 10^5 per mice. Importantly, hemoglobin levels were significantly higher in CKD mice treated with EPO-KMSC and MPs compared to CKD control mice (60 ± 7 mg/dL, P<0.05, respectively). Importantly, hemoglobin levels were significantly higher in CKD mice treated with EPO-KMSC and MPs compared to CKD control mice (60 ± 7 mg/dL, P<0.05, respectively).

Conclusions: The use of EPO secreting MSC is a viable strategy for cell therapy in renal anemia. Our results suggest that EPO-KMSC derived MPs as well as EPO-KMSC can improve renal function and renal anemia in CKD mice.

**FR-PO215**

Therapeutic Effects of Erythropoietin Producing Kidney Mesenchymal Stem Cell Derived Microparticles on Anemia in Chronic Kidney Disease Mice

**Background:** Progression of chronic kidney disease (CKD) results in aggravation of erythropoietin (EPO)-dependent anemia. Microparticles (MPs) derived from kidney mesenchymal stem cells (KMSC) have been demonstrated to confer protective effects against acute kidney injury and kidney fibrosis via transfer of messenger RNA. Previous studies have demonstrated improvement of renal anemia by EPO transfected MSC. We investigated whether MPs derived from EPO producing KSMC can exert therapeutic effects on anemia in CKD mice.

**Methods:** Mouse model of CKD and renal anemia was induced by the electrocoagulation of right renal cortex and sequential left nephrectomy. Six weeks post-nephrectomy, CKD and anemia was confirmed via blood urea nitrogen (BUN) and hemoglobin measurements as well as renal histology. Stable human EPO-producing KMSC (EPO-KMSC) and their MPs isolated by differential ultracentrifugation were injected intraperitoneally into established CKD mice and followed for 2 weeks (EPO-KMSC: 1×10^6 per mice, MP: 2×10^6 per mice). BUN and hemoglobin were evaluated and degree of renal tubulointerstitial damage was examined for 2 weeks after CKD.

**Results:** EPO secretion from EPO-KMSC was confirmed to sustain over 4 weeks in vitro and RT PCR reviewed the presence of EPO mRNA within MPs. Injected EPO-KMSC-derived MPs were demonstrated within tubulointerstitial area. Animals that received EPO-KMSC and MPs demonstrated significantly lower BUN levels compared to CKD control mice (60 ± 7 mg/dL vs. 83 ± 7 mg/dL, P<0.05, respectively). Importantly, hemoglobin levels were significantly higher in CKD mice treated with EPO-KMSC and MPs compared to CKD control mice (11.7 ± 0.1, 11.3 ± 0.5 vs. 9.7 ± 0.5 g/dL, P<0.05, respectively).

**Conclusion:** The use of EPO secreting MSC is a viable strategy for cell therapy in renal anemia. Our results suggest that EPO-KMSC derived MPs as well as EPO-KMSC can improve renal function and renal anemia in CKD mice.

Microarray Analysis of Gene Expression to Compare Low Serum Cultured Adipose Derived Stromal Cell with High Serum Yutaka Tsuboi, Takayuki Katsuno, Shoichi Maruyama. Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi, Japan.

Background: We established human adipose tissue-derived stromal cells (hASCs) cultured in low (2%) serum (hLASCs), which demonstrated great therapeutic potential for inflammatory diseases. We have already reported that hLASCs significantly attenuated rat folic acid-induced acute kidney injury than did hASCs cultured in high (20%) serum (hHASCs). However, the mechanism for hLASCs to exert greater anti-inflammatory function than hHASCs was partly evaluated. In the current study, we compared gene expression profiles and functional difference between hLASCs and hHASCs.

Methods: Human abdominal subcutaneous adipose tissue was obtained from patients undergoing liposuction. Cells were cultured under the two conditions; a low serum culture medium containing 2% fetal bovine serum (FBS) and a high serum culture medium containing 20% FBS. Total RNA was isolated from hLASCs and hHASCs. We performed CDNA microarray analysis in total RNA from hLASCs and hHASCs and confirmed microarray data by real-time PCR. Moreover, we performed in vitro functional analysis in some identified molecules.

Results: 312 genes were significantly (False Discovery Rate: FDR < 0.01) up-regulated (Fold Change > 5.0) and 211 genes were down-regulated in hLASCs. Microarray analysis revealed several differentially expressed genes including C-X-C chemokine receptor type 7 (CXCR7), superoxide dismutase (SOD) 3, Toll-like receptor (TLR) 3. Data were validated by real-time PCR, confirming the differential expression profiles of CXCR7 (Fold change 26.54), SOD3 (Fold change 4.79) and TLR3 (Fold change 2.22) in hLASCs. Related to CXCR7 function, hLASCs demonstrated accelerated cell migration depending on SDF-1α, a CXCR4/7 agonist, compared to hHASCs. For TLR activation, hLASCs secreted more IL-6 and MCP-1 in response to poly:IC for TLR3 stimulation than hHASCs, but not to LPS for TLR4 ligand.

Conclusions: Our data suggest hLASCs can be characterized by cell migration, increased oxidative stress and immune response through toll-like receptor activation, which determine therapeutic potential of hASC.

Renoprotective Effects of Tonsil-Derived Mesenchymal Stem Cells in Gentamicin-Induced Acute Kidney Injury (AKI) Duk-Hee Kang, Eun Sun Ryu, Hyun-soo Shin, Jyeon Ko. Ewha Womans Univ School of Medicine.

Background: Gentamicin (GM)-induced AKI occurs in 10-20% of treated patients. GM is accumulated in renal epithelial cells, which causes the loss of the brush border, apoptosis and overt necrosis of renal tubules. Recent developments in stem cell research have shown a promise for the treatement of AKI, however the mechanisms underlying the improvement in kidney function provided by stem cell therapy remain unclear. Tonsil-derived mesenchymal stem cells(TMSCs) can be isolated from tonsils of the patient undergoing tonsilloctomy, and vade retro before being treated in an epidemic of various diseases. The aim of this study is to investigate the therapeutic potential of T-MSCs in the treatment of AKI induced by GM.

Methods: Twenty male Sprague-Dawley rats were divided into four groups: Control, GM (140 mg/kg/day, ip for 10 days), GM-TMSCs (1x10^5 cells, intravenously injection at 1 day after the 1st GM injection) and T-MSC group. To examine the intra-renal localization of T-MSCs, T-MSCs were labeled with PKH-26 red fluorescence before infusion. Measurement of BUN, Cr, proteinuria and histologic analysis including TUNEL staining were performed on 16 days of GM injection. Effect of T-MSC on renal tubular cells was also evaluated using a trawell co-culture system of NRK cells and T-MSC. Intraacellular NO expression was measured by measuring NOX activity, H2O2, generation, NOx mRNA expression with DCF-DA staining.

Results: PKH-26-labeled T-MSCs were observed in renal tubular cells in GM-TMSCs group. The infusion of T-MSCs preserved renal function with a decrease in proteinuria. T-MSCs also accelerated renal tubular dilatation and reduced apoptosis of renal tubular cells in the rats with GM-induced AKI. The infusion of T-MSCs downregulated the expression of Bax, Cytochrome c, Cleaved caspase-9 - and -3 and upregulated Bel-2 of renal cortical tissue. In-vitro study revealed an amelioration of GM-induced oxidative stress and apoptosis of NRK cells by T-MSC.

Conclusions: Our results suggest that T-MSCs protect the kidney from GM-induced AKI, possibly via the mechanism of modulation of oxidative stress and apoptosis.

Exosomes Secreted by Human Urine-Derived Stem Cells Could Prevent Kidney Complications from Type I Diabetes in Rats Zhenzhen Jiang, Yumei Liu, Ying Fan, Jing Zhang, Yang Fei, Niansong Wang. Dept of Nephrology and Rheumatology, Shanghai Jiao Tong Univ Affiliated Sixth People’s Hospital, Shanghai, China.

Background: Stem cells are currently the main candidates for the development of new treatments for diabetic nephropathy, as they may exert their therapeutic effects mainly through immunomodulation mechanisms. Exosomes derived from stem cells have been reported to play an important role in kidney injury.

Methods: Exosomes from conditioned medium of human urine-derived stem cells (USCs-Exo) were isolated using ultra-filtration and purification methods. USCs-Exo was then verified by morphology characteristics and specific biomarkers. After the establishment of the streptozotocin (STZ) induced Sprague - Dawley (SD) rats’ model, the effects of USCs-Exo on kidney injury were observed by tail intravenous injection of USCs-Exo or control weekly until 12 weeks. In vitro, podocytes cultured in high glucose medium were treated with USCs-Exo to test the protective effect of USCs-Exo on podocytic apoptosis.

Results: USCs were cultured and were verified by positive markers of CD29, CD73, CD90 and CD44 antigens, and negative markers of CD34 and HLA-DR. Exosomes of USCs-Exo were 100 nm spherical vesicles under transmission electron microscopy and the specific markers including CD9, CD63 and CD81. Intra-vascular injections of USCs-Exo could potentially reduce the urine volume and urinary microalbumin excretion, prevent podocyes and tubular epithelial cells apoptosis, suppress the caspase-3 overexpression and increase glomerular endothelial cells proliferation in diabetic rats. In addition, USCs-Exo could reduce podocytic apoptosis induced by high glucose in vitro.

Conclusions: USCs-Exo may have the potential effect to prevent kidney injury from diabetes by inhibiting podocytes apoptosis and promoting vascular regeneration.

Characterization of a Nanotube-Based Mechanism for Hematopoietic Stem Cell-Mediated Kidney Repair in Cystinosis Spencer M. Goodman, 1 Swati Naphade, 1 Jay Sharma, 1 Heloise P. Gaide Chevironny, 2 Pierre J. Courtney, 2 Stephanie Cherqui. 1 Dept of Pediatrics, Div of Genetics, Univ of California, San Diego, La Jolla, CA; 2Cell Biology Unit, de Duve Inst, Univ Catholique de Louvain, Brussels, Belgium.

Background: Cystinosis is a lysosomal storage disorder caused by mutations in the CTNS gene, encoding the lysosomal transmembrane transporter cystinosin. As a consequence, cystine builds up in all tissues and eventually causes multi-organ degeneration. Patients develop renal Fasconi syndrome before the age of one, and ultimately, end-stage renal failure. We previously showed in Ctns-/- mice that transplantation of hematopoietic stem cells (HSCs) resulted in abundant integration of bone marrow-derived cells into all tissues and long-term kidney preservation. To address the cellular mechanism of kidney rescue, we observed that HSCs differentiated into macrophages that extended intercellular bridges called tunneling nanotubes (TNTs). TNTs were seen transporting cystinosin-GFP lysosomes into diseased proximal tubular cells (PTCs) across the tubular basement membrane. This process was called tunneling nanotubes (TNTs). TNTs were seen transporting cystinosin-GFP lysosomes into diseased proximal tubular cells (PTCs) across the tubular basement membrane.

Methods: Human abdominal subcutaneous adipose tissue was obtained from patients undergoing liposuction. Cells were cultured under the two conditions; a low serum culture medium containing 2% fetal bovine serum (FBS) and a high serum culture medium containing 20% FBS. Total RNA was isolated from hLASCs and hHASCs. We performed CDNA microarray analysis in total RNA from hLASCs and hHASCs and confirmed microarray data by real-time PCR. Moreover, we performed in vitro functional analysis in some identified molecules.

Results: 312 genes were significantly (False Discovery Rate: FDR < 0.01) up-regulated (Fold Change > 5.0) and 211 genes were down-regulated in hLASCs. Microarray analysis revealed several differentially expressed genes including C-X-C chemokine receptor type 7 (CXCR7), superoxide dismutase (SOD) 3, Toll-like receptor (TLR) 3. Data were validated by real-time PCR, confirming the differential expression profiles of CXCR7 (Fold change 26.54), SOD3 (Fold change 4.79) and TLR3 (Fold change 2.22) in hLASCs. Related to CXCR7 function, hLASCs demonstrated accelerated cell migration depending on SDF-1α, a CXCR4/7 agonist, compared to hHASCs. For TLR activation, hLASCs secreted more IL-6 and MCP-1 in response to poly:IC for TLR3 stimulation than hHASCs, but not to LPS for TLR4 ligand.

Conclusions: Our data suggest hLASCs can be characterized by cell migration, increased oxidative stress and immune response through toll-like receptor activation, which determine therapeutic potential of hASC.
Conclusions: In conclusion, HSC transplantation can repair and preserve near-normal kidney function, understanding mechanisms underlying kidney regeneration could spur the development of novel stem cell-based therapies for degenerative renal disorders.

Towards the Clinical Application of Gene-Modified Hematopoietic Stem Cell Transplantation for Cystinosis
Tatiana Vm Lobry, Jay Sharma, Sarah Ur, Celine Rocca, Betty Cabrera, Stephanie Cherqui. Pediatrics, Univ of California San Diego, San Diego, CA.

Background: Cystinosis is an autosomal metabolic disease caused by mutations in the CTNS gene, encoding a lysosomal cystine transporter, leading to cystine accumulation and multi-organ failure. Affected individuals present before 2 years of age with a Fanconi syndrome and eventually present to end-stage renal failure. Treatment with cysteamine does not prevent these complications. We showed previously that wild-type HSC transplantation could treat cystinosis in the Ctns-/- mice. Thus, we developed an autologous transplantation strategy of HSCs genetically modified ex vivo to express a functional CTNS gene. Preclinical studies using a SIN-lentivirus vector containing CTNS to transduce Ctns-/- HSCs and transplanted in Ctns-/- mice led to cystine reduction in all tissues and kidney function improvement.

Methods: Pharmacological and toxicological studies are in progress. We established the optimal conditions to transduce human CD34+ HSCs with our lentiviral vector to obtain a Vector Copy Number (VCN) included between 1 and 3. We performed Colony Forming Unit (CFU) assays to ensure normal proliferation and differentiation of transduced human CD34+ HSCs from healthy donors and cystinotic patients and the In Vitro Immortalization (IVIM) assay, a genotoxicity test. Serial transplantations in the Ctns-/- mice will assess the safety of our vector in vivo.

Results: While we obtained VCN within the range for healthy donors CD34+ HSCs, the VCN for the Ctns-/- CD34+ HSCs is below 1, requiring further optimization. CFU assays did not show aberrant differentiation of the transduced CD34+ cells from the healthy donors and cystinotic patients. Finally, no immortalized clones were observed with the IVIM assay, suggesting a good safety profile of our vector. These results will be included in our IND for a phase 1 clinical trial for cystinosis. The ex vivo serial transplantations are in progress.

Conclusions: This work represents the first stem cell and gene therapy treatment strategy for cystinosis and should lead to a phase 1 clinical trial.

Mesenchymal Precursor Cell Therapy for Diabetic Nephropathy: 24 Week Results from a Phase 2A Randomized Controlled Trial
David K. Packham, Ian R. Fraser, Peter G. Kerr, Silviu Itescu, Karen R. Segal. 1 MRRG, Melbourne, VIC, Australia; 2 Epworth H, Melbourne, VIC, Australia; 3 Dept Nephol, Monash M C, Melbourne, VIC, Australia; 4 Mesoblast PLC, NY, NY.

Background: Renal inflammation and endothelial dysfunction contribute to the etiology of diabetic nephropathy (DN). Bone marrow derived mesenchymal precursor cells (MPC) can modulate both inflammatory cells and microvasculature. We conducted a randomized, placebo (PBO) controlled, dose-escalating trial of allogeneic MPC in 30 subjects with type 2 DN.

Methods: Patients (24 men, 6 women) with an estimated glomerular filtration rate (eGFR) of 20-50 ml/min/1.73 m2 and on a stable regimen of renin-angiotensin inhibition were randomized to a single IV infusion of PBO (saline) or 150 million (M) or 300M MPCs (N=10 per group). Patients have been followed up for 24 weeks. Baseline mean age was 70 years mean eGFR was 34.6, 35.7 and 34.6 ml/min/1.73 m2 for PBO, 150M and 300M, and 19/30 patients had eGFR<30.

Results: There were no treatment-related adverse events. For eGFR change from baseline at 24 weeks, the least square mean (LSM) differences from PBO were 3.2+/−2.5 (8.1%) in both 150M and 300M groups. PBO-adjusted treatment differences were greater in pooled MPC with baseline eGFR<30: 4.9+/−2.3 (+12%) at 24w. The LSM differences from PBO for mean individual annualized slopes of eGFR change over 24w was 6.8+/−4.8 in both treatment groups. Baseline IL-6 levels correlated with SCR and eGFR improvement at 12 w in the PBO groups (r=0.57 and 0.50; both p<0.05) but not in PBO. The LSM differences from PBO for mean individual annualized slopes of eGFR change over 24w was 7.8+/−4.8 ml/min/1.73 m2 in pooled MPC with baseline IL-6 >3.5 pg/dl and 5.6+/−5.0 in PBO. In patients with baseline IL-6 >3.5 pg/dl, suggesting greater preservation or improvement in eGFR relative to PBO in the presence of elevated IL-6.

Conclusions: In this first in humans study, a single MPC infusion improved or stabilized GFR over 24w. Baseline eGFR<30 and high IL-6 levels suggest two biomarkers that may predict efficacy with MPC treatment. Positive response to MPC therapy may be enhanced by the presence of non-fibrotic, but at-risk, renal tissue and aberrant pro-inflammatory milieu.

Long-Term Effect of Methylprednisolone Pulse and Autologous SVF (Stromal Vasular Fraction) Therapy in Severe IgA Nephropathy with CKD Stage III
Yungoo Soo Cho, 1 Yumi Choi, 2 Jin-Soouh. 1 TheAll Medical Hub Kidney Center, MIRAE ENG Research Inst, Seoul, Republic of Korea; 2 Dept of Pediatrics, Guangmyeong Sang-Ae Hospital, Guangmyeong-si, Gyeonggi-do, Republic of Korea; 3 Dept of Medicine, College of Medicine, The Catholic Univ of Korea, Bucheon-si, Gyeonggi-do, Republic of Korea.

Background: Up to date there is no specific method of treatment in severe IgA nephropathy with CKD, but giving ACE inhibitor, angiotensin II receptor blocker(ARB), omega-3 etc. and eventually almost all cases fall into CKD V and need KTP or dialysis. Cell-based therapy is an emerging field in nephrology field especially asplode derived stem cells(ASCs). The beneficial effects of mesenchymal stem cell occur through differentiation-independent pathways include increased cell survival and proliferation, decreased inflammation, immune modulation, tissue regeneration etc.

Methods: We tried methylprednisolone(MP) pulse therapy followed by autologous SVF(stromal vascular fraction), which contained ASCs in severe IgA nephropathy with CKD stage III. This case was 44years old female patient, Renal biopsy finding showed Grade IV(Lee’s classification) with CKD stage 3. MP pulse was tried 6 cycles followed by autologous SVF were injected through intravenously 4 times at 3 weeks interval.

Results: Initial renal biopsy findings before treatment(Tx) showed 61% sclerotic glomeruli, however follow up renal biopsy 18 months after Tx showed 41% sclerotic glomeruli and disappeared immune deposits, The serum creatinine level before Tx was 1.77mg/dl with GFR 35ml/min, however 18 months after Tx serum creatinine was 1.03mg/dl with GFR 61ml/min.

Conclusions: In conclusion MP pulse therapy with autologous SVF treatment in intractable IgA nephropathy might be a promising therapeutic means without any notable side-effect or complications especially in early stage CKD, although the efficacy and safety of, SVF infusion therapy needs long term studies.

Extracellular Vesicles in Glomerular VEGF Homeostasis
Sargis Sodrakyan, 1 Stefano Porta, 2 Hasmik Soloyan, 1 Nikita Triparaneni, 1 Roger E. De Filippo, 1 Benedetta Bussolati, 2 Laura Perini. 1 Children's Hospital Los Angeles; 2 Univ of Turin.

Background: Strict regulation of VEGF signaling between podocytes and glomerular endothelial cells (GEC) is critical for GEC survival and function, therefore, loss of glomerular VEGF homeostasis during disease progression can impact GEC integrity leading to decline in glomerular function. Importantly, recent studies have described extracellular vesicles (EVs) to play important role in stem cell mediated paracrine modulation, including in kidney. We have already established that amniotic fluid stem cells (AFSC) are renoprotective, and we hypothesize that EVs released within damaged glomeruli are involved in VEGF regulation. Herein, we investigate the impact of AFSC derived EVs in the maintenance of glomerular VEGF homeostasis.

Methods: Using qPCR and ELISA we measured VEGF expression along the course of disease progression in isolated glomeruli of mice affected by Alport Syndrome (AS). Podocyte morphology was evaluated by IHC and TEM. GEC were FACS sorted from a GEC specific Tek reporter mice and studied by gene and protein arrays for VEGF/VEGFR, oxidative stress, and apoptotic pathways. Co-cultured GEC and AFSC overstimulated with VEGF were used to study the direct role of EVs in VEGF regulation. EVs were characterized and injected into AS mice for in vivo evaluation.

Results: Mice at advanced stages of Alport disease presented with aberrant VEGF activity within glomeruli, significant GEC apoptosis, oxidative stress and loss of GEC function. Delivery of AFSC derived EVs normalized VEGF expression and ameliorated endothelial damage. Importantly, the soluble receptor of VEGF, sFlt1—involved in regulating VEGF signaling—was also modulated upon treatment, indicating a VEGF/sFlt1/1 mechanism of regulation by EVs. In vitro experiments further confirmed the direct role of EVs in VEGF/sFlt1 regulatory mechanism.

Conclusions: In our data, we found the first time the alternation of VEGF signaling within AS glomeruli. We further showed that AS derived EVs play an important role in maintaining glomerular homeostasis of VEGF signaling, so critical to maintain GEC integrity and function, presenting with a potential for new targeted therapies in CKD.

FR-PO225
Renal Exosomes Store and Transfer the Ischemia Preconditioning State and Protect Rats with Severe Renal Ischemia
Katherine J. Kelly, Jesus H. Dominguez, 1 Medicine, Indiana Univ Medical School, Indianapolis, IN; 2 Medicine, Veterans Administration, Indianapolis, IN.

Background: Acute Kidney Injury (AKI) is a risk factor for chronic kidney disease (CKD) and end-stage renal disease (ESRD). We have reported that intravenous renal cell transplants (IRCT) improve outcomes in rats with AKI (JAP 305-F357, 2012). IRCT action was mediated by relatively small number of anchored and retained cells, and we have hypothesized that cells amplified renal protection by releasing exosomes (EXE) acting at a distance.
Methods: We tested if renal EX from cultured cells used for IRCT improved AKI. Normal rats or rat glomerular mesangial cells (SMC) were subjected to various treatments for 45 minutes of bilateral ischemia/reperfusion injury (IR). Renal exosomes (600 µg/protein/rat) were then given intravenously.

Results: There were 5 groups of rats: 1, sham, no IR; 2, renal ischemia (IR) untreated (NO-EX); IR treated with heat inactivated EX (HI-EX); 3, IR treated with normal EX (NL-EX). IR with EX protected kidney cells subjected to ischemia/reperfusion injury (IPC-EX). In sham, serum creatinine was 0.3±0.03 at 24 hrs and 0.3±0.02 at 48 post-surgery. In NO-EX it was 2.1±0.6 and 1.7, post, respectively. In HI it was 2.2±0.1 and 1±0.3. However, in NL-EX it was 2.4±0.4 and 1.78±0.1. The most striking effect was found in rats treated with normal EX (P<0.05, all including NL-EX). Kidney weights (mg/m2 body weight) 6 days post IR was also improved by EX: 3±0±1 in sham; 6±7±0.6 in NO-EX; 6.7±0.6 in HI; 5.2±0.2 in NL-EX 5.2±0.2, and 4.4±0.2 in IPC-EX, which was significantly lower than all IR groups, including NL-EX. Neutrophils (PMN) in IPC-EX were also reduced by 65% (p<0.05) when compared to NL-EX. IPC-EX reduced renal C3 expression in glomeruli and tubules by 73% and 82%, respectively (p<0.05 for both). IPC-EX also protected 76% of renal tubules when compared to NO-EX.

Conclusions: IPC is effective but impractical. However, EX given IV can communicate the IPC state, reach the kidneys, modulate inflammation and protect function and structure following severe IR.

The Impact of Preexisting Chronic Kidney Disease on the Severity and Recovery of Acute Kidney Injury

Sung Yoon Lim, Young Ju Na, Myung-gyu Kim, So-young Lee, Sang-Kyoung Jo, Won-Yong Cho. Dept of Nephrology, Korea Univ Hospital, Seoul, Korea; Dept of Nephrology, Eulji Univ Hospital.

Background: Recent observational studies have shown that a substantial proportion of patients with acute kidney injury (AKI) have often progression to chronic kidney disease (CKD). Among several risk factors for the development of CKD after AKI, decreased baseline glomerular filtration rate (GFR) represents an important risk factor. However, precise mechanisms involved in the development of fibrosis after AKI with preexisting CKD have not been completely ascertained. Here in this study, we assessed the impact of preexisting CKD on the severity and recovery of AKI in mouse model of 5/6 nephrectomy.

Methods: Male CD-1 mice underwent 5/6 nephrectomy or sham operation, and 6 weeks later ischemia reperfusion injury (IRI) was performed. On day 1, 7 and 28 after IRI, functional, histological, and molecular parameters were compared between them.

Results: Twenty five minutes clamping of renal pedicle in 5/6 nephrectomized mice did not provoke more severe functional, histological deterioration compared to normal mice on day 1 and 7. Similar elevations in SCR were observed in both groups until day 7 after IR; however, SCR remained higher on day 28 in 5/6 nephrectomized mice compared to normal mice, suggesting that preexisting CKD does not modify severity of AKI but adversely affect the recovery process. From day 7 to 28, mRNA expression of p21, and protein level of pH3, both representing cell cycle arrest were significantly increased in 5/6 nephrectomized mice (CKD+AKI) compared to sham (sham+AKI). Treatment with p53 inhibitor after IRI resulted in not only decreased p21 and pH3 protein level, but also fibrosis in CKD+AKI mice, suggesting that epithelial cell cycle arrest is partially responsible for impaired recovery from AKI in 5/6 nephrectomized mice.

Conclusions: Taken together, reduced nephron mass do not seem to increase severity of AKI, but have negative effect on repair process, leading to development of fibrosis.

FR-P0227

Impaired Functional Recovery from Acute Kidney Injury in Rats with Preexisting Chronic Kidney Disease Predicts the Severity of De Novo Hypertension

Aaron J. Polishchuk, Karen A. Griffin, Mama Dissadace, Anil K. Bidan, Edward Hines Jr. VA Hospital, Hines, IL; Medicine, Loyola Univ Medical Center, Maywood, IL.

Background: The mechanisms by which AKI accelerates the progression of CKD remain poorly understood. We have recently demonstrated that preexisting CKD predisposes to impaired recovery from AKI as evidenced by exaggerated levels of tubulointerstitial fibrosis and modest elevations in blood pressure at 4 weeks post injury. However, a rigorous examination of the relationship between impaired functional recovery from AKI and the development of hypertension has not been examined.

Methods: Male SD rats underwent normotensive 3/4 nephrectomy (3/4 NX) and were chronically instrumented with a BP radiotelemeter. Two weeks later, rats were subjected to 40 min IR (n=20) or sham IR (n=8). BP was assessed every 10 min, 24 hr/day for 4 weeks and glomerular filtration rate (GFR) was then assessed in the conscious state (FITC-inulin).

Results: As compared to baseline values, systolic BP was significantly elevated (P<0.05) in rats at 4 weeks post IR (134±2 vs. 149±5 mmHg, respectively) but not sham IR (139±4 vs. 140±2 mmHg, respectively). GFR was significantly less (P<0.05) in rats subjected to IR vs. sham IR (1.1±1 vs. 1.4±1 ml/min, respectively). As shown in Figure 1, a very strong negative correlation was observed between GFR and the increase in systolic BP over the 4 week protocol. Systolic values 48 hours post AKI did not correlate with either GFR or the change in systolic BP at 4 weeks post AKI, indicating that the development of hypertension following IR was due to impaired recovery from AKI as opposed to a greater severity of AKI.

Conclusions: The development of hypertension following AKI in the presence of pre-existing CKD is likely to significantly contribute to the subsequent progression of CKD.

FR-P0228

Exocytosis of Endothelial Lysosome-Related Organelles Hair-Triggers a Pathologic Loss of Glycoalyx at the Onset of Septic Shock

Edward Hines Jr. VA Hospital, Hines, IL; Medicine, Loyola Univ Medical Center, Maywood, IL; Integrative Physiology, Indiana Univ School of Medicine, Indianapolis, IN.

Background: Endothelial surface glycoalyx (ESG) is a well-known regulator of leukocyte surveillance, vascular permeability, and a sensor of shear stress. ESG is degraded during sepsis, thus contributing to systemic multiorgan involvement. Our previous demonstration of a very early post-septic exocytosis of lysosome-related organelles (LRO) with their lytic enzymes led us to hypothesize that exocytosis of LRO may catalyze a synchronized deregulation of ESG.

Methods: To test this hypothesis we first analyzed the time-course of exocytosis of Weibel-Palade bodies and secretory lysosomes after application of lipopolysaccharides (LPS) to endothelial cells.

Results: Time-lapse video microscopy revealed that LROs undergo agitation and vectorial movement with a time course of a few minutes after LPS. In addition, spectrophotometry measurements illustrated an increase of lysosomal cargo, cathepsin B, within the media after 10min of LPS exposure. Two therapeutic maneuvers, a nitric oxide intermediate, NG-hydroxy-L-arginine (NOHA), and culture media conditioned by endothelial progenitor cells (ECM-CM) reduced the directionality and motility of LRO. The patch loss of ESG occurring with the similar fast kinetics was confirmed using confocal fluorescence microscopy and Stochastic Optical Reconstruction Microscopy. The loss of ESG was blunted by pretreatment with NOHA or ECM-CM. Moreover, these treatments resulted in a significant reduction in mortality of septic mice.

Conclusions: In summary, above studies provide the first demonstration of the very early patchy disintegration of ESG which can be prevented by pretreatment with NOHA and ECM-CM, maneuvers that reduced exocytosis of LRO. Data support the hypothesis assigning to stress-induced exocytosis of these organelles the role of a hair-trigger for local deregulation of ESG that in turn initiates leukocyte infiltration, increase vascular permeability, and partially accounts for the later morbidity and mortality.

Vitamin D Deficiency Contributes to Vascular Damage in Sustained Ischemic Acute Kidney Injury

Ana C. de Braganca, Rido A. Volpin, Purvi Mehrotra, Carlie M. Ivancic, Lucia Andrade, David P. Basile. Nephrology, Univ of Sao Paulo School of Medicine, Sao Paulo, SP, Brazil; Cellular and Integrative Physiology, Indiana Univ School of Medicine, Indianapolis, IN.

Background: It has been shown that injury to the renal vasculature may play an important role in the pathogenesis of ischemic acute kidney injury (AKI). Reductions in microvascular density may play a critical part in the progression of chronic kidney disease (CKD) following AKI-induced ischemia/reperfusion injury (IRI). Vitamin D deficiency (VDD) is associated to tubulointerstitial damage and fibrosis progression following IRI-AKI. We evaluated the effect of VDD in sustained IRI-AKI, hypothesizing that VDD contributes to vascular damage.

Methods: Wistar rats were fed 25(OH)D3-free or standard diets for 35 days. On day 28, rats were randomized into four groups: control (sham), VDD, bilateral IRI and VDD rats. Rats were analyzed 7 days after the surgeries.

Results: VDD rats showed impaired capillary density (by cablin staining) and reduced VEGF expression, even in the absence of injury. In addition, VDD IRI rats manifested a remarkable capillary rarefaction and also had increased RW/BW, tissue injury scores, FSP-1.
o-SMA when compared to either VDD or IRI rats. VDD IRI also had increased levels of infiltrating activated CD4+ and CD8+ cells secreting higher levels IFN-γ and IL-17 while the number of regulatory T cells was reduced, relative to IRI rats.

Conclusions: VDD impairs renal capillary density and exacerbates fibrotic damage and pro-inflammatory milieu following AKI, which may contribute to the transition of CKD following AKI. Funding: CAPES/CNPq/IAPESP, NIH DK63114 (DPB). Funding: NIDDK Support

Exosome-Mediated Delivery of Pro-Survival MicroRNA-486-5p in Acute Kidney Injury
Jing J. Vinas, Dylan Burger, Alex Gutsol, William A. Knoll, David Allan, Kevin D. Burns. Nephrology, Dept of Medicine, Ottawa Hospital Research Inst, Univ of Ottawa, Ottawa, ON, Canada.

Background: We recently showed that administration of human endothelial colony forming cells (ECFCs) and their exosomes to mice with ischemic acute kidney injury (AKI) attenuated renal damage. Our data also indicate that ECFC’s release exosomes that are highly enriched in microRNA (miR)-486-5p and protect against hypoxia-induced endothelial cell apoptosis. MiR-486-5p targets phosphatase and tensin homolog (PTEN), which negatively regulates the Akt survival pathway. In the present study, we further examined the role of exosomes and miR-486-5p on the Akt pathway in vivo, and tested the hypothesis that exosomes transfer miR-486-5p to endothelial cells in vitro.

Methods: Mice with ischemic AKI were injected (i.v.) with exosomes at reperfusion. Kidneys were subjected to immunoblot and RT-PCR for miR-486-5p. Transfer of ECFC exosomes and miR-486-5p was studied in human umbilical vein endothelial cells (HUVECs).

Results: Bioinformatic analysis of the top 10 most abundant miRs in ECFC exosomes revealed that they were all involved in the Akt pro-survival pathway. Inmice with AKI, exosome treatment significantly increased renal miR-486-5p levels (p<0.01 vs ischemia alone, n=6-7), associated with decreased PTEN expression, and increased Akt phosphorylation. In cultured HUVECs, ECFC exosomes labeled with the fluorescent dye PKH-26 localized to the perinuclear compartment. Treatment of HUVECs with ECFC-derived exosomes or co-culture of ECFCs with HUVECs caused a 40-fold increase in levels of miR-486-5p. Transfer of ECFCs with pre-miR-486-5p, followed by co-culture with HUVECs was associated with a further marked increase (~20-fold) in miR-486-5p levels in HUVECs (p<0.001 vs control, n=3). This effect was blocked by pre-incubation of HUVECs with ethylisopropyl amiloride (an inhibitor of exosome uptake).

Conclusions: These data suggest ECFC-derived exosomes exert renoprotective effects in AKI, possibly via the transfer of miR-486-5p to endothelial cells. Exosome-mediated transfer of miRs could represent a strategy to target pro-survival pathways in the injured kidney.

The Role of Vascular Endothelial Cells in the Protective Effect of Delayed Ischemic Preconditioning in Renal Ischemia/Reperfusion Injury
Xianjun Xu, Xiaoyan Jiao, Nana Song, Xiaojiang Ding. Div of Nephrology, Zhongshan Hospital, Shanghai, China.

Background: We have previously reported that up-regulation of miR-21 contributed to the protective effect of delayed ischemia preconditioning (IPC) in renal ischemia/reperfusion injury (IRI). The role of vascular endothelial cells in renal IRI is not well-understood. In the present study, we examined the role of vascular endothelial cells in the protective effect of miR-21 in renal delayed IPC.

Methods: For the delayed IPC and IR model, 4 d after IPC (15min ischemia) or sham surgeries, preconditioned mice were subjected to 35 min occlusion of bilateral renal pedicles, followed by 24 h reperfusion. Human umbilical vein endothelial cells (HUVECs) were treated with cobalt chloride for hypoxia model in vitro. Locked nucleic acid (LNA) modified anti-miR-21 or anti-scrambled was transfected into cells or delivered into the mice via tail vein injection less than 1 hour prior to IPC. Vascular permeability was determined by the Evans Blue dye. Cell apoptosis was estimated by Annexin V FITC apoptosis detection.

Expression of programmed cell death 4 (PDCD4) protein and miR-21 was examined by western blot and real-time PCR, respectively.

Results: Compared with the Sham+IR group, mice in the IPC+IR group showed significantly improved renal function and histology injury (p<0.01). MiR-21 was up-regulated in the IPC+IR group with concomitant decline of PDCD4 (p<0.05) and improvement of vascular permeability (p<0.05). In vitro, miR-21 in HUVEC was increased in hypoxia, while PDCD4 expression was decreased. Knockdown of miR-21 by LNA anti-miR-21 lengthened the protective effect of IPC with concomitant up-regulation of PDCD4 (p<0.05) and exacerbated renal vascular permeability (p<0.05). Cell apoptosis significantly decreased after knockdown of miR-21 in vitro.

Conclusions: Up-regulation of miR-21 in renal delayed IPC improved the apoptosis of vascular endothelial cell by inhibiting its target PDCD4. This may be another mechanism underlying the protective effect of the delayed IPC.

FR-PO232
Role of Vascular Mineralocorticoid Receptor in Renal Ischemia/Reperfusion
Jonathan Barrera-Chimal,1 Alan Le Mercier,1 Sonia Prince,1 Soumya El Moghrabi,1 Norma Bobadilla,2 Frederic Jaisser.1 INSERM U1138, Centre de Recherche des Cordeliers, Paris, France;1 Inst de Investigaciones Biomédicas UNAM y INNSZ, Mexico City, Mexico.

Background: Renal ischemia/reperfusion (IR) is a major cause of acute kidney injury and is associated with chronic kidney disease (CKD) development. Mineralocorticoid receptor (MR) antagonism prevents the acute and chronic consequences of renal IR. Whether the benefit of the MR antagonists is due to the blockade of the MR in the vessels is unclear. Therefore we want to study the specific contribution of endothelial and smooth muscle cells (SMC) MR in acute and chronic consequences of renal IR.

Methods: To inactivate MR in endothelial cells (MRα mice), floxed MR mice (MRβ) were crossed with mice expressing the inducible Cre recombinase under the Vcadenom promoter. To allow inactivation MR in smooth muscle cells (MRαβ mice), MRβ mice were crossed with mice expressing the inducible Cre recombinase under the SMA promoter. Sham surgery or bilateral renal IR for 20 min was performed in MRαβ and KO mice and the animals were studied at short term (24 h) and long term (30 days) after reperfusion.

Results: In MRαβ mice, IR induced renal dysfunction (plasma creatinine from 8.9±0.3 mg in sham to 33.8±4.8 mg/μl in IR), tubular injury and increased mRNA levels of kin-1 (400-fold) and NGAL (220-fold). The MRαβ mice displayed similar alterations induced by IR as MRβ mice. In contrast, after 24 h of IR, the MRαβ mice presented normal renal function (plasma creatinine 9.6±0.7 and 14.0±1.9 mg/μl in sham and IR, respectively), absence of histological alterations and reduced kin-1 and NGAL levels. After 30 days, the MRαβ mice developed CKD characterized by renal dysfunction (plasma creatinine from 10.5±0.1 mg in sham to 15±0.8 mg/μl in IR), tubular-interstitial fibrosis and increased mRNA levels of fibronectin and Galexin-3 (2-fold). The MRαβ mice developed similar alterations.

Conclusions: We provide evidence that the deficiency of MR in the SMC protects against the development of acute kidney lesions induced by IR; however MR deficiency in SMC did not impact the appearance of CKD induced by IR, suggesting that MR in other cell types is involved.

Renal Vein Hydrodynamic Fluid Delivery Ameliorates Established Renal Injury following Ischemia/Reperfusion Injury
Jason Andrieu Collett,1 Purvi Mehrrotia,2 David P. Basile,2 Robert L. Bacallao.2 1Cellular and Integrative Physiology, Indiana Univ School of Medicine, Indianapolis, IN; 2Div of Nephrology, Indiana Univ School of Medicine, Indianapolis, IN; 3Richard L. Roudebush VA Medical Center, Indianapolis, IN.

Background: Past and current treatment for Acute Kidney Injury (AKI) is mainly supportive in nature; no therapeutic modalities that can reverse AKI disease have been developed. Furthermore, AKI disease is variable among patients. Novel targeted treatments are necessary.

Methods: Male Sprague Dawley rats underwent left unilateral ischemia (35 min) and right unilateral nephrectomy or bilateral IRI (35min) and reperfusion for 24 hours to induce AKI. 0.5ml of isotonic saline was then injected into either the vena cava (VC) or retrograde to left kidney via the renal vein (RV) under high pressure (~60mmHg).

Results: Average serum creatinine at 24hrs was similar between groups (sCre=3.3mg/dl; p=0.0237). To evaluate effects on inflammation, bilateral IRI rats subjected to left-RV HD treated rats showed a significant improvement in serum creatinine over the following 24 hours vs VC HD rats (24 to 48 hr ∆ serum creatinine -0.544 mg/dl vs. +0.6375 mg/dl), however, RV-HD treated rats showed a rapid improvement in serum creatinine over the following 24 hours vs VC HD rats (24 to 48 hr ∆ serum creatinine -0.544 mg/dl vs. +0.6375 mg/dl).

Conclusions: These results indicate that high-pressure retrograde hydrodynamic delivery (HD) of saline will improve established AKI, in part, by increasing vascular congestion.

Human Adipose Stromal Cells Ameliorate Renal Injury and Attenuate Capillary Rarefaction following Ischemia-Reperfusion
Jason Andreai Collett, Purvi Mehrotra, Dmitry O. Traktuev, Stephanie Merfeld-Clauss, Keith March, David P. Basile. Indiana Univ School of Medicine, Indianapolis, IN.

Background: Acute kidney injury (AKI) is a syndrome characterized by the rapid loss of the kidney's excretory function, resulting in excess in 17 million hospital admissions a year. Although the tubular epithelium is the primary target of ischemic injury, early damage to endothelial cells contributes to AKI by resulting in impaired perfusion. Moreover, renal capillary density is permanently compromised in rats following AKI induced by ischemia reperfusion (IRI), which is hypothesized to promote CKD. Therefore, to preserve capillaries may impact both short-term recovery and long-term function post-AKI. Adipose-derived progenitor cells (ASCs) have pro-angiogenic and anti-inflammatory properties. It is hypothesized that ASCs facilitate repair by capillary preservation, revascularization of damaged endothelium and decreased inflammation.

Methods: Male Sprague Dawley rats were subject to bilateral IRI (40 min). At the time of reperfusion, ~2x10^6 ASCs (hASCs, n=15) or vehicle (n=14) were injected into the suprarenal abdominal aorta. Recovery was evaluated via serum creatinine and capillary specific staining. Accumulation of immune cells in the kidney were evaluated using FACS.

Results: hASC-treated rats had a 90% survival by day 7, compared with 70% for vehicle. Serum creatinine showed a significant reduction in hASC-treated rats vs vehicle at 48 hrs, (35%, p=0.0008). By day 7, vehicle-treatment showed a reduction in renal capillary density relative to sham (43%), which was significantly attenuated in hASC-treated rats (28%). Additionally, hASCs-treated rats exhibited a significant decrease in CD4+ (62%±16:8) and CD8+ (72%±3.5) T cells was also reduced by ~40% in hASC-treated rats (185±66) as compared to vehicle (299±83.9). Conversely, the number of regulatory T cells was increased in hASC-treated rats compared with vehicle (35%; p=0.05).

Conclusions: These results suggest that ASCs may ameliorate renal injury, at least in part by preserving capillary density, decreasing inflammation and restoring renal function. Funding: NIDDK Support

Studying the Effect of Inducible Expanded Human Kidney Progenitor Cells on Renal Function Using Transcutaneous Assessment
Zeneida Herrera Perez, Oren Pleniceanu, Dorit Omer, Benjamin Dekel,1 Benjamin Goret,1 Medical Research Center, Medical Faculty Mannheim, Univ of Heidelberg, Mannheim, Germany; 1Sheba Center for Regenerative Medicine, Sheba Medical Center, Tel Aviv, Israel.

Background: The use of induced stem cells from adult tissues is a promising therapeutic approach for the treatment of kidney diseases. However, traditional techniques to monitor recovery from damage or delay in chronic renal disease development after cell therapy are cumbersome and time-consuming, as well as inaccurate to detect early changes in function. A novel method allows the evaluation of renal function transtcutaneously, using an optical device and the exogenous renal marker FITC-simistin, with no need for plasma or urine samples. For the first time, we have studied the effect of human adult kidney epithelial cells (hKEpCs) induced to stably overexpress the SIX2 or OSR1 & SIX2 genes in a cisplatin (CP)-induced injury model using the transcutaneous assessment of renal function.

Methods: Three different animal groups were established: induced SIX2-hKEpCs, SIX2- and SIX2&OSR1mCherry-hKEpCs display therapeutic potential in hASC-treated rats compared with vehicle (35%; p=0.05).

Conclusions: These results suggest that ASCs may ameliorate renal injury, at least in part by preserving capillary density, decreasing inflammation and restoring renal function. Funding: NIDDK Support

Indole Analogs Have Novel Therapeutic Effects on Mitochondrial Diseases and Kidney Injury
Takehiro Suzuki,1 Tetsuro Matsuhashi,1 Akihiro Matsuo,1 Yuki Oba,1 Koichi Kikuchi,1 Hisato Shima,1 Eikan Mishima,1 Yasutoshi Akiyama,1 Joseph V. Bonventre,1 Sadaoyoshi Ito,1 Takaaki Abe.11Tohoku Univ, Japan; 12Brigham and Women’s Hospital.

Background: Mitochondrial dysfunction causes various mitochondrial diseases and kidney injuries. Anti-oxidative quinones have been used clinically to prevent the disease process but the effectiveness is yet to be established. We recently found that an indole-derivative increased ATP levels in Hep3B cells and analyzed 41 newly synthesized indole derivatives. Among those compounds, we focused on the most potent derivative #5 (MA-5). The aim of this study was to clarify the effects of MA-5 in mitochondrial diseases and kidney injury.

Methods: Fibroblasts from patients with mitochondrial diseases (Leigh syndrome, MELAS, Leber disease, Kearns-Sayre syndrome) were cultured in ROS and glutathione levels were measured. The redox property of MA-5 was examined by cyclic voltammetry. The site of MA-5 distribution was visualized by fluorescence-labeled MA-5 (50 мМ). MA-5 was administered for 24 hr, and then fluorescence of MA-5 was measured at 3 hr before they were exposed to kidney ischemia (26 min) reperfusion injury (IRI) or cisplatin (20 mg/kg body weight). Plasma creatinine (Cr), blood urea nitrogen (BUN) and renal pathologies were assessed. Additionally, cell viability in a dose-dependent manner in mitochondrial disease fibroblasts. MA-5 exhibited irreversible oxidation peaks by cyclic voltammetry, suggesting that MA-5 did not have antioxidant property like anti-oxidant quinones. MA-5 did not affect the cellular ROS or GSH levels. MA-5 FL co-localized with the mitochondrial complex I. In IRI model, after ischemia (15 min) and reperfusion (24 hrs), renal capillarized and tubular cell injury were significantly reduced in MA-5-treated group (70.9 ± 10.1 vs 101 ± 13.0 mg/dl) and tubular injuries, at 96 hr after cisplatin injection, were significantly reduced in Indole #5 treated groups.

Conclusions: MA-5 exhibited therapeutic effects in fibroblasts from mitochondrial disease patients as well as renoprotective effects in both IRI and cisplatin nephroptoroxis.

Mechanism of 5-Hydroxytryptamine 1F Receptor Stimulation of Mitochondrial Biogenesis in the Kidney
Yusutoshi Kikutani, Robert Bruce Cameron, Craig Cano Beeson, Rick G. Schnellmann. Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.

Background: Pharmacological induction of mitochondrial biogenesis (MB), the process of creating new mitochondria to replace damaged mitochondria, is a potential therapeutic target for AKI. Our laboratory has demonstrated that LY344846, a selective 5-HT1F receptor agonist, promotes recovery from AKI as demonstrated by an increase in MB and decreased BUN and Kim-1 in a mouse model of ischemia reperfusion AKI. While the 5-HT1F receptor is a Gα coupled GPCR, the mechanism of 5-HT1F receptor mediated MB is unknown.

Methods: Mitochondrial respiration was measured in renal proximal tubule cells (RPTC) using a Seahorse XF Extracellular Flux Analyzer. Signaling pathways were explored using pharmacological inhibitors and immunoblot analysis.

Results: LY344846 (10 nM) increased FCCP-uncoupled respiration in RPTC, a marker of MB. LY344846 induced FCCP-uncoupled respiration was attenuated by pretreatment with gallicin, L-NAMe, and ODQ, pharmacological inhibitors of Gα, nitric oxide synthase, and soluble guanylyl cyclase, respectively. LY344846 upregulated p-Akt and p-eNOS protein expression after 15 min and 1 hr exposures, respectively. Gallicin blocked increases in both p-Akt and p-eNOS following LY344846 treatment. Following pretreatment with MK2206, an Akt inhibitor, the increase in p-eNOS protein expression was attenuated.

Conclusions: This study reports the novel finding that Gαi heterodimer initiates MB and does so through a new pathway. Specifically, 5-HT1F stimulation of Gαi activates Akt and eNOS, leading to the induction of MB. The identification of this pathway provides additional therapeutic targets for a drug intervention which could treat AKI.

FR-PO238
Formoterol Induces Renal Mitochondrial Biogenesis Through Gβγ-Dependent Signaling
Robert Bruce Cameron, Craig Cano Beeson, Rick G. Schnellmann. Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.

Background: Acute kidney injury (AKI) carries a high morbidity and mortality with no effective treatments beyond renal replacement therapy. AKI is characterized by mitochondrial dysfunction, particularly in the renal proximal tubule cells (RPTC). The induction of mitochondrial biogenesis (MB) is a therapeutic target for AKI. Our group has shown formoterol, a β2 adrenoceptor agonist, can induce MB in vitro and in vivo, and stimulate recovery of mitochondrial and renal function following AKI in mice. However, the signaling events leading to formoterol-induced MB remain unknown.

Methods: RPTC were pretreated with DMSO, 100 nM gallicin, 10 μM L-NAMe, or 100 μM MK2206 for 30 min and then treated with formoterol (30 nM). FCCP-uncoupled increases in oxygen consumption rates (FCCP-O2C) were measured using the Seahorse XF-96 analyzer and protein phosphorylation was determined by immunoblot analysis.

Results: Formoterol increased AKT phosphorylation in RPTC at 30 min, and this increase was prevented by the Gαi inhibitor gallicin. Gallicin also attenuated formoterol-induced increases in FCCP-O2C, a biomarker of MB. Formoterol increased the phosphorylation of eNOS, a downstream target of Akt, at 1 hr, and pretreatment with the Akt inhibitor MK2206 blocked Akt and eNOS phosphorylation. Additionally, treatment with the NO-inhibitor L-NAMe attenuated formoterol-induced increases in FCCP-O2C.

Conclusions: This study demonstrates that formoterol-induced MB occurs via β2-adrenoceptor coupling to Gαi, Gαi leads to the activation of Akt and eNOS, promoting MB. Stimulation of these signaling pathways represents an attractive therapeutic target for AKI.

Identification of Slow-Cycling Cells in the Kidney Using TetOP-H2B-GFP Mice
Shunsuke Takahashi, Akito Maeshima, Masao Nakasatomi, Hidekazu Ikeuchi, Toru Sakairi, Yoriaki Kaneko, Keiju Hiromura, Yoshishima Nojima. Dept of Medicine and Clinical Science, Gunma Univ Graduate School of Medicine, Maebashi, Gunma, Japan.

Background: Renal tubular epithelium can regenerate after a variety of insults. During tubular regeneration, survived tubular cells proliferate, migrate and differentiate into mature tubular cells. Using B Dulieu pulse/chase method, we previously reported that slow-cycling cells (label-retaining cells: LRCs) are present in renal tubules and act as the source of regenerating cells after renal ischemia (JASN 14:3138-46. 2003). However, it is difficult to isolate and characterize LRCs in vitro, because there is no LRCs specific marker. In this study, we utilized the transgenic mice with doxycycline-inducible expression of an H2B-GFP fusion protein (TetOP-H2B-GFP mice), in which dividing cells can be labeled with GFP under doxycycline control.

Methods: TetOP-H2B-GFP mice were treated with doxycycline for the indicated periods. After several chase periods, kidneys were removed for analysis. Localization of GFP-positive cells was examined by immunostaining with several nephron markers and their cell number was quantitatively assessed.

Results: 1) After a pulse of doxycycline, GFP-positive cells were found in the kidney of TetOP-H2B-GFP mice. Most GFP-positive cells were AQP-1-positive tubular cells. As pulse periods become longer, the number of GFP-positive tubular cells increased (pulse 8h-0.5%, pulse 24h-10%, pulse 72h-18%, pulse 1 week-40%, pulse 3 weeks-50%). 3) After a short pulse (8h) of doxycycline with no chase, all GFP-positive cells were present as a single population. However, after 2 weeks or 4 weeks chase periods, GFP-positive cells were found in clusters of two cells or three cells. 4) In TetOP-H2B-GFP mice treated with a long pulse (3 week) of doxycycline, the number of GFP-positive cells decreased according to chase periods (Chase 8w-50%, Chase 4w-40%, Chase 8w-5%).

Conclusions: These data suggest that slow-cycling cells can be detected as GFP-positive cells using TetOP-H2B-GFP mice under doxycycline control. This model will be applicable for selective isolation and in vitro characterization of slow-cycling tubular cells.

Renal ERK1/2 Regulates PGC-1α and Mitochondrial Biogenic Homeostasis Physiologically and During Renal Injury
Justin B. Collie, Ryan Whitaker, Rick G. Schnellmann. Drug Discovery and Biomedical Sciences, Medical Univ of South Carolina, Charleston, SC.

Background: Acute kidney injury (AKI) is defined as a sudden decline in kidney function and the outcomes of AKI have not changed in the past few decades. Previous studies demonstrated that persistent disruption of mitochondrial homeostasis (e.g. peroxisome proliferator-activated receptor gamma coactivator-1α (PGC-1α), a master regulator of mitochondrial biogenesis (MB)) is an important contributor to renal ischemia reperfusion (IR) injury and repair. While the MAPK extracellular-regulated kinases 1/2 (ERK1/2) regulates numerous cell signaling pathways, the role of ERK1/2 activation in MB physiologically and as a consequence of renal IR injury remains limited.

Methods: Renal proximal tubule cells (RTC) were treated with the specific MEK1/2 inhibitor trametinib (10nM) for various time points. Control mice were treated with trametinib (1mg/kg). Trametinib was administered 1 hour before 18 min of bilateral IR.

Results: Trametinib blocked ERK1/2 phosphorylation in RTC within 10 min that continued for 24 hr. Trametinib also inhibited ERK1/2 phosphorylation in vivo at 4 and 24 hr. Trametinib increased PGC-1α mRNA at 1, 4, and 24 hr in RTC. The mRNA levels of PGC-1α target genes NDUSF1, NRF1, and TFAM increased at 1, 4, and 24 hr after ERK1/2 inhibition in RTC. Trametinib administered to control mice increased PGC-1α, NRF1, and TFAM mRNA 4 h in the renal cortex and increased PGC-1α and TFAM protein. In the IR AKI model, pERK1/2 increased 4-fold at 1 and 3 h post IR. Increased pERK1/2 was linked to decreased mRNA levels of PGC-1α, NRF1, TFAM, and NDUSF1. Trametinib treatment attenuated suppression of mRNA PGC-1α and NRF1 at 3 h, increased TFAM protein 2.5-fold, and attenuated renal dysfunction as measured by BUN and KIM-1.

Conclusions: ERK1/2 downregulates renal mitochondrial homeostasis under physiological conditions and ERK1/2 inhibition during renal IR promotes recovery of PGC-1α and MB, and contributes to both mitochondrial and renal recovery. These results reveal a novel target for pharmacological intervention in AKI.

The Guanylyl Cyclase Activator BAY 58-2667 Stimulates Mitochondrial Biogenesis and Promotes Recovery from Ischemia-Reperfusion Induced AKI
Nicole Molin, Ping Zhang, Zhuma Hu, Christoph Westenfelder.1 2 Medicine, U of Utah and VAMC, Salt Lake City, UT; 2Physiology, U of Utah, Salt Lake City, UT.

Background: We showed that ischemic-reperfusion injury (IR) causes renal and urine levels of the chemokine SDF-1 (CXCL12) to rise significantly within – 2 hrs. This rise mediates the homing of infused, CXC4R4 (SDF-1 receptor)-expressing Mesenchymal Stem Cells (MSCs) to the sites of injury, where they act renoprotectively. CKD is a major risk factor for AKI. We wondered here whether VC administration is effective both in preventing IR AKI superimposed on CKD and in arresting the AKI-induced further deterioration of CKD.

Methods: Rats: Groups of 6 rats underwent 5/6th Nephrectomy. Once CKD was established (8 weeks), FR AKI of the kidney remnant was induced and rats were treated either with vehicle or 2x10⁶ MSC/kg bw, i.e. SDF-1/creatinine levels were assessed at pre- and post-operatively. Patients: 12 subjects with established CKD and at high risk for cardiac surgery associated AKI were treated i.e. with 2x10⁶ MSCs per kg bw immediately post-on-pump surgery. SDF-1 and uridine SDF-1/creatinine levels were determined pre- and post-op. RIPLE criteria defined post-op AKI. Study subject data were compared to well-matched historical controls.

Results: SDF-1/creatinine ratios were significantly elevated at 2 and 6 hrs in subjects who developed AKI Risk, but remained stable in those who did not. In contrast to historical controls, 6 months post-op, no treated subject's CKD had worsened.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusions: MSC administration offers renoprotection from AKI on CKD when given immediately post insult. Early, specific biomarker-guided diagnosis of AKI identifies the optimal time for MSC-based therapy. Another clinical trial in high-risk cardiac surgery patients showed that giving MSCs 24-48 hrs post insult, based on the late and non-specific rise in SCr, abolished their protective effects.

Funding: Veterans Administration Support

Improved Survival of Graft Bone Marrow-Derived Mesenchymal Stem Cells in the Ischemia-Perfusion-Reperfusion-Induced Injured Kidney with Overexpression of Heme Oxygenase-1

Nannrei Li; Jinrin Hospital of Shanghai.

Background: one marrow-derived mesenchymal stem cells (BMSCs) transplantation offers therapeutic potential for acute kidney injury (AKI), but with limited efficacy. This study investigated the role of HO-1 overexpression on the donor BMSCs’ survival, and its impact on the repair of AKI was also observed.

Methods: Ischemia/reperfusion (I/R)-AKI kidney homograft supernatant (KHS) was prepared. SD BMSCs, eGFPECMSCs and HO-1-BMSCs were harvested and treated by the AKI-KHS. Cell viability, apoptosis and cell cycle were evaluated. Activities of oxidant stress-related enzymes, expression of p65 and the protein levels of Caspase-3 and Bcl-2 in BMSCs were tested. Survival of the implanting BMSCs in the AKI rat model as well as the renal function were also assessed.

Results: HO-1-BMSCs showed a high expression of HO-1 and AKI-KHS treatment further enhanced this level. This increased HO-1 expression promoted BMSCs’ survival under the AKI microenvironment with decreased apoptotic cells as well as less proportion of TUNEL-positive cells. AKI-KHS induced reduction of SOX activity and GSH-Px in BMSCs with increased MAD and XO levels, however, HO-1 overexpression changed this phenomenon. Activation of NF-κB p65 was inhibited in HO-1-BMSCs. Western blot showed decreased Caspase-3 expression and increased Bcl-2 expression in HO-1-BMSCs. The in vivo study showed increased survival of HO-1-BMSCs in the AKI kidneys, which was associated with improved renal function.

Conclusions: HO-1 overexpression could enhance survival of BMSCs under the I/R-AKI microenvironment both in vitro and in vivo as the result of ROS elimination. Activity of NF-κB p65 and Caspase-3/Bcl-2 signal transduction pathways were involved in this process.

Induced Pluripotent Stem Cell-Conditioned Medium Mitigates Renal Ischemia-Reperfusion Injury by Suppressing Oxidative Stress

Woo-Cheng Tang; 1,2 Div of Nephrology, Dept of Medicine, Taipei City Hospital Heping-Fayou Branch, Taipei, Taiwan; 1,2 Div of Nephrology, Dept of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.

Background: Ischemic acute kidney injury (AKI) carries high mortality and current treatment remains unsatisfying. Induced pluripotent stem cell (iPS) is a promising therapeutic option for AKI; nonetheless, teratoma formation addresses critical safety concerns for IPS cell transplantation. IPS-derived conditioned medium (IPS-CM) is comparable with IPS cells on ameliorating acute lung injury but the beneficial role of IPS-CM on AKI remains unclear.

Methods: Rat model of renal ischemia-reperfusion injury (IRI) and NRK52E cells subjected to hypoxia-reoxygenation (H/R) were used to explore the role of IPS-CM on AKI. BUN, creatinine, tubular cell apoptosis, level of reactive oxygen species (ROS), expressions of proinflammatory cytokines and animal survival were investigated.

Results: Administration of IPS-CM intraperitoneally significantly improved renal function and decreased tubular cell apoptosis after renal IRI. Moreover, elevated ROS level in IRI-rat kidneys was markedly attenuated by IPS-CM. Co-culture of NRK52E cells with IPS-CM also significantly diminished H/R-induced apoptosis and ROS production. Furthermore, IPS-CM downregulated both H/R- and IRI-stimulated expressions of p38 MAPK, TNF-α, NF-κB and Caspase-3. Additionally, the IRI-related IL-6 and MCP-1 expressions were also suppressed by IPS-CM. Finally, after being subjected to renal IRI, the rats treated with IPS-CM demonstrated better survival as compared those treated with phosphate-buffered saline or normal control medium.

Conclusions: IPS-CM decreases renal IRI-related lethality by suppressing ROS, inflammation, and tubular cell apoptosis. IPS-CM may be a potential therapeutic option for kidney injury is in AKI.

FR-PO246

Vascular Adhesion Protein-1 (VAP-1) Inhibition Ameliorate Cisplatin Induced Acute Kidney Diseases and Disorders (AKD)

Daisuke Katagiri; 1,2 Yoshiyumi Hamasaki, 1 Kent Doi, 1,3 Kousuke Negishi, 1 Takeshi Sugaya, 1 Masao Nakamura, 1,2 Eisie Noiri, 1 Nephrology and Endocrinology, The Univ of Tokyo, Tokyo, Japan; 3Apheresis and Dialysis, The Univ of Tokyo, Tokyo, Japan; 2Emergency and Critical Care Medicine, The Univ of Tokyo, Tokyo, Japan; 1CMIC Ltd, Tokyo, Japan.

Background: Cisplatin (CP) is a platinum compound that is used as an effective chemotherapeutic agent for many malignancies. Its nephrotoxicity is dose dependent, which often limits its administration. Research in the field of acute kidney diseases and disorders (AKD), including acute kidney injury (AKI), is important to prevent their progression to chronic kidney disease (CKD).

Methods: A new clinically relevant animal model using multiple low doses of CP was used to evaluate AKD. Human liver fatty acid-binding protein (L-FABP) transgenic (Tg) mice were administered 10 mg/kg of CP (three times, at 0, 1, 3 weeks) for four weeks. Vascular adhesion protein-1 (VAP-1) inhibitor that was recently reported to prevent fibrosis in organs was studied in this model. For treating group, mice received 2 mg/kg/day of PXS-4728A, a selective VAP-1 inhibitor, starting 3 weeks after the first CP administration.

Results: Moderate renal interstitial fibrosis occurred with multiple CP administration. Urinary L-FABP, one of the promising AKI biomarkers, increased about 10-fold one week after every CP injection. Although no further elevation of L-FABP was observed at 3W, following the omission of CP at 2W, L-FABP did not revert to baseline levels. Treatment of PXS-4728A for one week attenuated interstitial fibrosis in this model. VAP-1 inhibitor treatment remarkably reduced 4-HHE- and 8-OHdG-positive areas. The mRNA expressions of TGF-β, α-SMA, VEGF, and MCP-1 in the kidney were increased significantly by multiple CP treatments and attenuated by VAP-1 inhibitor treatment. Further, the inhibition of lipid accumulation in the S3 segments, together with L-FABP suppression was confirmed.

Conclusions: Multiple treatments with CP lead to moderate kidney dysfunction with increased renal interstitial fibrosis. As a standing point of onco-nephrology, VAP-1 inhibitors are promising candidates for the prevention of CKD in patients using CP for the treatment of malignancy.

The purpose of this study is to clarify the therapeutic effects of SHED on AKI induced by IRI.

Methods: Seven days after heminephrectomy, the renal artery and vein were clamped for 20 min to induce ischemia in male C57/Bl6 mice. SHED or PBS as a control was administered into subcapsular renal tissue after the reperfusion. Blood, urine and tissue samples were collected. In order to confirm renoprotective potential of conditioned media of SHED (SHED-CM) in vitro, H2O2 stimulation assay and scratch wound assay using mouse tubular epithelial cells (TECs) were also performed.

Results: Serum creatinine and BUN levels and urinary kidney injury markers were significantly decreased in SHED-treated group. In vitro assay, MCP-1-secreting and TEC proliferation and migration were significantly promoted by SHED-CM treatment.

Conclusions: In the present study, SHED administration successfully attenuated mouse IRI-induced AKI. Our results indicate that SHED exerted anti-inflammatory activity in early stage of inflammation and promote cell proliferation by paracrine effect, thereby renoprotective effect in a mouse model of ischemic kidney injury. These results suggest that SHED might offer novel stem cell resource, which can be applied for the treatment of ischemic kidney injury.

FR-PO249
Endothelial Autophagy and Endothelial-to-Mesenchymal Transition (EndoMT) in eEPC Treatment of Ischemic AKI

Background: Autophagy potentially prolongs the cellular lifespan. Early Endothelial Progenitor Cells (eEPCs) protect mice from ischemic AKI. The mid-term prognosis in AKI critically depends on vascular remanufacture and proliferation of mitotic fibroblasts with the latter partly being induced by mesenchymal transdifferentiation of endothelial cells (EndoMT). Aim of the study was to determine the impact of eEPC preconditioning with different autophagy inducing agents (SAHA / Temsirolimus - Tems) in ischemic AKI.

Methods: Male C57/Bl6N mice were subjected to bilateral renal ischemia (40 min). Animals were injected with either untreated or SAHA- or Temsirolimus-pretreated syngeneic murine eEPCs at the time of reperfusion. Mice were analyzed 48 hours and 4 weeks later. In addition, cultured eEPCs were treated with TGF-α / β-1, SAHA, autophagy (perinuclear LC3-II) and Stress Induced Premature Senescence (SIPS - SA-b-Gal) were evaluated 96 hours later.

Results: Cultured ePCs showed reduced perinuclear density of LC3-II+ vesicles and elevated levels of SA-b-Gal after treatment with TGF-β alone, indicating impaired autophagy and increased SA-b-Gal activity. LC3-II+ vesicles were abrogated by SAHA. Systemic administration of either SAHA or Tems pretreated eEPCs resulted in elevated intrarenal endothelial p62 at 48 h and 4 weeks. This effect was most pronounced after injection of SAHA treated eEPCs. At 4 weeks endothelial expression of mesenchymal aSMA was reduced in animals receiving untreated and SAHA pretreated cells. In addition, SAHA treated cells reduced fibrosis at week 4. Tems in contrast aggravated EndoMT.

Conclusions: In ischemic AKI, intrarenal endothelial autophagy may be stabilized by systemic administration of pharmacologically preconditioned eEPCs. Early ePCs can reduce postischemic EndoMT and fibrosis in the mid-term. Autophagy induction in eEPCs may either increase or decrease the mesenchymal properties of intrarenal endothelial cells. Thus, endothelial autophagy induction in ischemic AKI is not a renoprotective event per se.

FR-PO250
Impact of Timing Administration of Mesenchymal Stromal Cells on Serum Creatinine following Renal Ischemia/Reperfusion in Rats

Pascal Rottau, Laurence Poma, Jean-marie H. Krzesinski, Olivier Detry, François Jouret, Nephrology, Univ of Liege Hospital (ULg CHU), Liege, Belgium; GIGA Cardiovascular Sciences, Univ of Liege, Liege, Belgium; Abdominal Surgery and Transplantation, Univ of Liege Hospital (ULg CHU), Liege, Belgium.

Background: Experimental models of renal ischemia/reperfusion (IR) have suggested protective effects of mesenchymal stromal cells (MSC) therapy. Still, parameters of MSC injection, including volume, route and timing of cell administration, remain largely debated. Particularly, MSC infusion in mouse has been shown to beneficial “a priori" but deleterious “a posteriori" of renal I/R injury.

Methods: In order to further investigate the influence of the timing of MSC administration, we used 10-week-old Lewis rats categorized in 4 groups. Groups 1 (MSC D-7, n=10) and 2 (MSC D-1, n=7) received caudal i.v. injection of MSC (1,5x10^6 in 1 mL of saline) 7 days before or 1 day after renal I/R, respectively. Control groups 3 (saline D-7, n=6) and 4 (saline D-1, n=6) received equal volume of saline at same time points. Left renal ischemia was induced by clamping both renal pedicles for 1 hour and nephrectomy was simultaneously performed. Blood sample was collected from inferior vena cava at 48 hours post reperfusion. MSC phenotype was confirmed by FACS analysis.

Results: In groups 1 and 3, serum creatinine (SCr) reached 1.4 ± 0.7 versus 2.4 ± 0.8 mg/dL respectively (p<0.05). In groups 2 and 4, SCr was 4.9 ± 0.7 versus 3.3 ± 0.9 mg/dL, respectively (p<0.001). Furthermore, SCr levels were statistically worse when MSC were administered after renal I/R in comparison to a priori infusion (p<0.0001).

Conclusions: MSC administration 7 days prior to renal I/R may attenuate kidney injury in comparison to (i) saline infusion or (ii) MSC infusion 1 day after renal I/R. Conversely, on the basis of SCr levels, MSC therapy performed after renal I/R worsens kidney injury in rats.

Regulation of Kidney Injury Molecule-1-Mediated Effecoryosis by Rho GTPases

Ola Ismail, Zixiong Zhang, Lakshman Gunaratnam. 1  Department of Medicine, Western University, London, ON, Canada; 2  Matthew Mattingly Centre and Lawson Research Inst, London Health Sciences Centre, London, ON, Canada.

Background: Kidney injury molecule 1 (KIM-1) is a phagocytic receptor for apoptotic cells that is specifically upregulated on the apical membrane of proximal tubule cells (FTTCs) after acute kidney injury. KIM-1-mediated clearance of apoptotic cells (effector function) protects from inflammation and fibrosis by down-regulating innate immunity and inflammation. As cytoskeletal remodeling is essential for phagocytosis, we examined the relative importance of Rac1 and RhoA, two key Rho GTPases that mediate actin remodeling, in KIM-1-dependent effecoryosis. We also investigated a possible link between K12, which we previously identified as a KIM-1-interacting protein, and these Rho GTPases.

Methods: To study the role of Rac1 and RhoA in K1M-1-mediated uptake of apoptotic cells, we utilized chemical inhibitors or plasminogen encoding dominant negative forms of Rac1 or RhoA proteins and measured the uptake in vitro of apoptotic cells by flow cytometry during acute kidney injury by down regulates innate immunity and inflammation. Using commercially available GTPase pull-down assays, we measured the endogenous Rac1 and RhoA activity in KIM-1-expressing cells after apoptotic cell-stimulation. To decipher whether these Rho GTPases are down-stream mediators of GA12-KIM-1 signaling, we silenced GA12 using siRNA and measured Rac1 and RhoA GTPase activity.

Results: Inhibition of Raci1 resulted in a significant decrease in KIM-1-mediated phagocytosis, whereas inhibition of and RhoA increased it. RhoA activity gradually increased during phagocytosis and peaked during the later stages of phagocytosis, whereas Rac1 activity remained constant over the entire course of phagocytosis. Furthermore, silencing a key KIM-1-interacting protein, GA12, caused a significant decrease in RhoA activity.

Conclusions: We conclude that Rac1 and RhoA play opposing roles during KIM-1-mediated effecoryosis, where RhoA serves to mediate signaling by KIM-1 and its interacting partner, GA12.

Tim-3/Gal-9 pathway activation can ameliorate kidney damage and increase survival rate of mice after renal IRI, inhibit Th1 and Th17 cell-mediated immune responses and promote the resolution of Fosp3 Treg cell after renal IRI, which may be an important mechanism for renal protection of Gal-9/Tim-3 pathway.

Funding: Government Support - Non-U.S.

Results: The expression of Gal-9 and Tim-3 in IR kidney at day 3 and 10 increased (P<0.05). The percentage of Fosp3+ Treg in CD4+ T cells and Fosp3+ Treg mRNA expression decreased with time. Compared with normal control kidney, the mRNA levels of Fosp3, Gal-9 and Tim-3 of kidney at day 3, 10 after renal IRI were increased in IRI kidney. Compared with empty virus group at 3 days and 10 days after IRI, over-expression of Gal-9 can reduce the expression of inflammatory cytokines in the hepatic chaotic IRI. Protein plex results showed that the expression levels of inflammatory cytokines including TNF-a, IFN-y, IL-17 and IL-6 was decreased, while the expression level of IL-10 was increased. The mRNA level of Fosp3 in kidney, the percentage of Fosp3+ T cells in IRI mice kidneys was increased. However, the proportion of Th1, Th17 cell levels of IRI mice were decreased. In the bilateral renal IRI model, the mice mortality was decreased after rAAV-Gal-9 intervention.

Conclusions: Tim-3/Gal-9 pathway activation can ameliorate kidney damage and increase survival rate of mice after renal IRI, inhibit Th1 and Th17 cell-mediated immune responses and promote the resolution of Fosp3 Treg cell after renal IRI, which may be an important mechanism for renal protection of Gal-9/Tim-3 pathway.
FR-PO258

Competitive Inhibition of CD95L Reduces Inflammation, but Only modestly Improves Outcomes in Experimental Ischemia-Reperfusion Injury

Background: After previous encouraging results in CD95L (FasL) mutant mice we investigated the effect of the competitive pharmacologic inhibition of CD95 (FAS) in kidney I/R using APG101, an orphan drug developed for the treatment of recurrent glomeruloma, which has shown a good patient tolerability in phase I and II clinical studies.

Methods: C57BL/6 mice treated with different doses of APG 101 (10, 30 or 100 μg/kg-body weight, single-dose, 12h before I/R) or vehicle (PBS) alone were submitted to a 30 min renal ischemia (IP Sham-operated mice either treated with the highest APG101 dose or PBS. The experiment was further divided into two observation periods: day 2 (injury phase) and day 7 (recovery phase). Serum and kidney tissue analysis were performed focusing on function recovery, cell proliferation, macrophage infiltration and renal fibrosis as markers of target pathway. Results are given as mean±SD.

Results: Optimal serum CD95L saturation was only achieved in the APG 100μg/kg group (98.4±0.35%) and 96.9±1.3% at day 2 and 7, respectively, so that experiments were further conducted with this dosage. At day 2, serum creatinine was significantly higher in the IP PBS group, but not in the IP APG group compared to sham-op (0.26±0.12 and 0.20±0.07 vs. 0.09±0.03 mg/dl P<0.05), a similar pattern was seen in macrophage infiltration and MCL-1 mRNA expression in the kidney, both persisting until day 7. Apoptosis, however, was similar between the I/R groups in both observation periods. APG treatment markedly reduced cell proliferation in both sham and I/R animals compared to PBS (8.4±5.7 Ki67 positive cells/hpf, p=0.0004), which was observed at day 2, but didn’t persist until day 7.

Conclusions: Despite an anti-inflammatory effect, the APG101-induced impairment of the tubular cell proliferation may have hampered the early recovery phase after I/R leading to the modest results.

FR-PO259

Oral Treatment with PBI-4050 Reduces Ischemia-Reperfusion-Induced Fibrosis

Background: PBI-4050, a novel first-in-class orally active compound which is currently in clinical phase II/III in CKD patients, displays antifibrotic activities via a novel mechanism of action. In a double-blind ascending dose (400 to 2400 mg) clinical phase I trial, PBI-4050 was found to be safe and well tolerated up to 2400 mg without any significant side effects. Clinically, PBI-4050 may be a leading cause of acute kidney injury (AKI), which may result from a variety of conditions, such as decreased cardiac output, renal vascular occlusion or obstruction, and kidney transplantation. The aim of this study was to investigate the anti-fibrotic activity of PBI-4050 in a mouse model of acute ischemic kidney injury.

Methods: Renal ischemia-reperfusion (IR) injury was induced by the clamping of the left renal pedicle for 60 minutes in C57BL/6 mice (6-8 week old). Mice were treated with oral administration of vehicle or PBI-4050 (200 mg/kg) from day -3 to day 13 and sacrificed at day 14.

Results: Renal IR-injury induced a rise in serum creatinine at day 2 that was prevented by oral treatment with PBI-4050. At day 14, mice suffering from renal IR demonstrated a loss in hematoctit which was also prevented by PBI-4050 treatment. Furthermore, histomorphometric analysis demonstrated a significant increase in renal fibrosis, determined by medullary collagen accumulation in mice with IR-injury, which was significantly reduced by PBI-4050 treatment. In addition, PBI-4050-treatment reduced kidney type-III collagen mRNA expression.

Conclusions: Taken together, these pre-clinical results suggest that PBI-4050 offers the potential as a novel therapy for the treatment of AKI and may delay or prevent the onset of fibrosis in renal transplant recipients.

FR-PO260

Cisplatin Acute Kidney Injury and Conversion to Chronic Kidney Disease

Background: Chronic Kidney Disease (CKD) develops in humans after repeated doses of cisplatin (CP). We report on a new model to investigate the mechanism of this form of CKD.

Methods: 8-week old C57Bl6 mice were given either a single or double dose (2 weeks apart) of CP (15 mg/kg). Blood was drawn 24,4,6,9 and 16-25 weeks after the first GFR was measured by inulin clearance followed by intravascular perfusion-fixation, Immunohistochemistry and Multiphoton Microscopy (MPM) were applied to the fixed tissue.

Results: GFR fell precipitously to below 50% controls 2 weeks after the second dose and progressed without hypertension, loss of glomerular number, or glomerulosclerosis. Kidney weight fell as a result of loss of cortical tissue. Collagen deposition increased but was mainly restricted to peritubular locations along the cortico-medullary region. Influx of macrophages, increased cell cycle activity (Ki67) and apoptosis (TUNEL) were followed by vascular rarefaction. Ki67 failed to increase after the second dose as it did after a single dose. The cyclin-dependent kinase inhibitor protein p21 increased and paralleled the lack of cell cycle activity. Abnormal glomerulotubular junctions (GTJ) developed only after the second dose, which included loss of marginal positive parietal epithelial cell groove and the formation of atubular glomeruli. These changes correlated well with the development of progressive renal insufficiency.

Conclusions: MPM uncovered abnormalities of the GTJ that marked the transition from AKI to CKD in CP-induced CKD. Coupled with the failure of the proximal tubule (PT) to re-enter the cell cycle suggests a causal relationship between failed repair of this segment and the conversion of AKI to CKD. The increased expression of the p21 gene seen here and its demonstrated role in progression in the renal ablation model of CKD suggests its sustained activation may cause the conversion of AKI to CKD. Understanding why injured PT cells fail to re-enter the cell cycle following the second dose of CP is likely to yield new means to prevent CP-induced CKD, which may be applicable to other forms of AKI to CKD conversion.

The MEK1/2 Inhibitor, U0126, Decreases Cisplatin-Induced AKI and Slows Cancer Growth in Mice

Background: Nephrotoxicity is cisplatin’s major dose-limiting side effect as a chemotherapeutic agent. We have developed a model of 4 week, low dose cisplatin (Cis)-induced AKI in mice with cancer. In the 4 week model of AKI, there is an increased ERK expression in kidneys.

Methods: Wild type C57BL/6 mice were injected subcutaneously with murine lung cancer cells derived from C57BL/6 mice. Ten days later, Cis (10 mg/kg) was given weekly. Mice were treated with the ERK inhibitor U0126 (5 mg/kg 2 times a week for 4 weeks).

Results: There was a significant decrease in BUN, SCR and serum NGAL in mice treated with Cis+U0126 vs. Cis only. Tumor weight and volume was decreased in mice treated with vehicle+U0126 vs. vehicle alone demonstrating that U0126 alone decreases tumor growth. Tumor weight and volume was decreased in mice treated with Cisplatin+U0126 vs. Cisplatin alone demonstrating that U0126 significantly increased the therapeutic effect of cisplatin.

Glycogen Synthase Kinase-3 Regulates Fibroblast Activation and Development of Fibrosis following Renal Ischemia/Reperfusion in Mice

Shixin Tao, Timothy A. Fields, Raymond C. Harris, Reena Rao. The Kidney Inst, Dept of Medicine, Univ of Kansas Medical Center, Kansas City, KS; Dept of Medicine, Vanderbilt Univ Medical Center, Nashville, TN.

Background: Glycogen synthase-3 (GSK3β) is a serine/threonine protein kinase that plays an important role in renal tubular injury and regeneration in acute kidney injury. However its role in the development of renal fibrosis, often a long-term consequence of acute kidney injury is unknown. Using a mouse model of renal fibrosis induced by ischemia/reperfusion (IR) injury, we demonstrated increase GSK3β3 expression and activity in fibrotic kidneys.

Methods: Bilateral I/R was carried out on male C57Bl6 mice; both renal pedicles were exposed by flank incision and clamped for 30 minutes at 37°C. GSK3 inhibitor (TDZD-8) was administered by daily IP injection at 1mg/Kg BWI, dose starting 1hr before (TDZD-pre) or 48hr after I/R (TDZD-post). Studies were also carried out in rat fibroblast NRK-49F cells.

Results: GSK3β3 expression and activity increased significantly starting 48hr after I/R and remained high in the fibrotic kidneys 12 days after I/R. GSK3β3 was detected in renal myofibroblasts and tubules. GSK3 inhibition suppressed fibrosis, with significantly reduced myofibroblast population, extracellular matrix deposition, inflammatory mediators and TGF-β1 signaling in TDZD-pre and TDZD-post treatment groups compared to vehicle treated group. In vitro, TGF-β1 treatment increased GSK3β3 expression in NRK-49F cells and GSK3 inhibition abolished TGF-β1 induced SMAD-3 activation and α-SMA expression. Importantly, overexpression of constitutively active GSK3β3 stimulated α-SMA expression.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
even in the absence of TGF-β1 treatment. These results suggest that TGF-β1 regulates GSK3β expression, which is in turn important for TGF-β1 SMAD-3 signaling and fibroblast-to-myofibroblast differentiation.

**Conclusions:** The study thus demonstrates that GSK3β could promote renal fibrosis by activation of TGF-β1 signaling and the use of GSK3 inhibitors might represent a novel therapeutic approach for progressive renal fibrosis that develops as a consequence of AKI.

**FR-PO263**

Regulating Cx43 and TRPC6 Expression Protects Renal Epithelial Damage in a Rat AKI Model

**Authors:** Zdong Li, Wei Wang, Juan Wang, Lining Wang. Dept of Nephrology, First Affiliated Hospital of China Medical Univ, Shenyang, Liaoning, China.

**Background:** Intracellular Ca²⁺ homeostasis plays an essential role in maintaining normal cell function. Connexin43 (Cx43) and transient receptor potential channel (TRPC6) has been reported to regulate Ca²⁺ entry in some pathologic conditions. The aim of this study was to elucidate whether the modifier protein of glyceraldehyde-3-phosphate dehydrogenase (MP) and/or ATP-MgCl₂ could regulate Cx43 and TRPC6 in a rat model of acute kidney injury (AKI).

**Methods:** Male Sprague-Dawley rats were divided into the following groups: normal control, gentamicin-treated, MP plus gentamicin-treated, MP-ATP-MgCl₂, plus gentamicin-treated (n=15 for each), as well as control group for MP and ATP-MgCl₂ alone (n=5 for each). Levels of serum creatinine (sCr) for each group were measured on the 14th day of treatment. The “in vivo cryotechnique” was used for preparing kidney specimen as before. Immunohistochemistry staining for Cx43 and TRPC6 was performed.

**Results:** The gentamicin-treated group showed a significant increase in sCr compared to the normal control group. Co-treatment of gentamicin with MP and/or ATP-MgCl₂ produced marked decreases preventing the increase of sCr. Under light microscope, the gentamicin-treated group showed tubular epithelium damage indicating AKI. This was attenuated by MP and/or ATP-MgCl₂ co-treatment prevented gentamicin-induced down-regulation of Cx43 and TRPC6 in renal epithelial cells using the “in vivo cryotechnique”. Furthermore, the expressions of Cx43 and TRPC6 in gentamicin-treated group showed much weaker intensity using conditional fixation method compared to that using “in vivo cryotechnique” suggesting there might be artificial damage during the conditional fixation procedure.

**Conclusions:** Using a rat model of AKI, MP and ATP-MgCl₂, were able to prevent the down-regulation of Cx43 and TRPC6, which might reduce Ca²⁺ entry and its downstream signaling, thus minimizing the damage in the renal epithelial cells.

**FR-PO264**

S-Glutathionylation of TAZ Might Contribute to Acute Kidney Injury and Repair

**Authors:** Rajesh Kumar Gandhirajan,1 Benedikt Bernd Walla,1 Manaswita Jain,1 Malte P. Bartram,1 Markus M. Rinschen,1,2 Bernhard Schermer,1,2 1Dept of Medicine and Center for Molecular Medicine, Univ of Cologne, Cologne, NRW, Germany; 2Cluster of Excellence on Cellular Stress Responses in Ageing-Associated Diseases (CECAD), Univ of Cologne, Cologne, NRW, Germany.

**Background:** The clinical syndrome of acute kidney injury (AKI) is one of the most important diseases in nephrology and associated with increased morbidity and mortality. Kidney displays a remarkable potential for repair even after severe acute injury. Recent studies identified the Hippo pathway as a master regulator of organ growth and proliferation and uncovered the importance of the two mammalian Hippo-signaling effector molecules YAP and TAZ as regulators of proliferation and apoptosis during kidney development. The objective of the current study is to demonstrate that TAZ undergoes redox regulation via s-glutathionylation.

**Methods:** Immunoprecipitation, reporter gene assay, XTT assay, cycloheximide assay.

**Results:** Our findings indicate that exposure to hydrogen peroxide (H₂O₂) increased TAZ/TEAD transcriptional activity without affecting YAP/TEAD. Consistently, TAZ/TEAD interaction was slightly enhanced upon H₂O₂ exposure. Furthermore, H₂O₂ exposure increased nuclear localization of TAZ in a stable NIH3T3/Fli-in cell line expressing TAZ-GFP. We confirmed s-glutathionylation using recombinant TAZ protein in vitro and biotinylated glutathione ester in cell culture. To identify cysteine residues undergoing s-glutathionylation we generated TAZ C>A mutants. Reporter assays revealed that TAZ C358A showed increased transactivation of TEAD, the effect on cell proliferation and migration was also enhanced in TAZ C358A mutant. Finally, cycloheximide chase assay revealed that all of the TAZ mutants exhibited increased stability following 6h incubation.

**Conclusions:** Our data indicate a novel mechanism how pro-proliferative TAZ activity is regulated by ROS via s-glutathionylation, which could play an important role in tissue injury and repair. Currently, we are following the hypothesis that ROS derived from constitutively active NOX4 could modulate TAZ activity in the kidneys and we are investigating the importance of s-glutathionylation of TAZ in vivo.

**FR-PO265**

Bud-Like Structure Capable of Developing to Lamellipodia in Wound Healing of Tubular Epithelium – A Scanning Electron Microscopic Approach

**Authors:** Kiyoko Imu,1 Hiroyuki Morita,2 Yoshihiko Inoue,1 Shinya Omiya,1 Tomoaki Miyazaki,1 Ashio Yoshimura.1 1Div. of Nephrology, Showa Univ Fujigaoka Hosp., Yokohama, Kanagawa, Japan; 2Div. of Endocrinology and Metabolism, Aichi Medical Univ School of Medicine, Nagakute, Aichi, Japan.

**Background:** Cell migration is essential in wound healing during which filamentous (F)-actin assembly plays a pivotal role. Cell biological approaches, using confocal microscopy, succeeded in identifying molecules regulating the assembly, such as the Arp2/3 complex, N-WASP, cofillin, and profilin. Although cells form filopodia (microspike) and lamellipodia (membrane), move forward, much remains to be seen in the ultrastructure of these processes.

**Methods:** Rat tubular epithelium (NRK-52E) was cultured, grown to confluence, and scratched. The cells were subjected to scanning electron microscopy (SEM) at various time points. In separate experiments, immunoelectron microscopy was performed using an antibody against Arp3. Lastly, 60% confluent NRK-52E cells were cultured in the presence or absence of si-RNA for Arp3, grown to confluence, and scratched. The cells were observed periodically at the SEM levels, and, the length of time for complete recovery was compared.

**Results:** As shown in the figure, SEM elucidated elaborated network of filopodia containing “bud-like structure” (bud) that may develop to lamellipodia. Arp3 was expressed in filopodia and lamellipodia but not in a bud. The Si-RNA knockdown significantly prolongs the length of time for the recovery. It at least partially inhibited the formation of filopodia network and lamellipodia but not the formation of a bud.

**FR-PO266**

Inhibition of Microtubule Dynamics Delays Kidney Recovery After Ischemia/Reperfusion Injury in Mice

**Authors:** Sung Jun Han,1 Jee in Kim,2 Kwon Moo Park.1 1Dept of Anatomy and BK21 Plus, Kyungpook National Univ School of Medicine, Daegu, Republic of Korea; 2Dept of Molecular Medicine and MRC, Keimyung Univ School of Medicine, Daegu, Republic of Korea.

**Background:** Ischemia/reperfusion (I/R) is a major cause of acute kidney injury (AKI). If recovery from AKI is delayed, kidney progresses toward chronic renal failure. Microtubules, a component of the cytoskeleton, contribute to cell damages, cell shape, cell motility, and cell division. Here, we investigate that the role of microtubule network on the kidney injury, recovery and progression of fibrosis after I/R injury.

**Methods:** Mice were subjected to 30 minutes of bilateral renal ischemia, and mice were sacrificed 16 days after ischemia. Some mice were administered either saline (vehicle) or paclitaxel (taxol), a microtubule stabilization agent; 1 day before ischemia (pretreatment) or from 1 day after ischemia until sacrifice every 2 days (post-treatment).

**Results:** Pretreatment of taxol did not affect post-I/R renal function compared with vehicle-treated I/R group. Post-treatment of taxol delayed renal functional and histological recovery with retardation of tubular regeneration, and accelerated proliferation of interstitial cells after ischemia. Post-treatment of taxol from 24 hours after ischemia enhanced cell cycle arrest, progression of fibrosis, and macrophage infiltration into the kidney. Furthermore, post-treatment of taxol suppressed repolarization of primary cilia in tubular epithelial cells.

**Conclusions:** In conclusion, our results demonstrate that microtubule stabilization or inhibition of cell proliferation delays tubule cell restoration after ischemic injury, whereas interstitial cell proliferation is accelerated, leading to kidney fibrosis. It suggests that regulation of microtubule dynamics is critical to repair from AKI and progression of AKI to chronic kidney disease.

**Funding:** Government Support - Non-U.S.
Tubulin Acetylation in the Kidney Tubular Cells After Ischemia/Reperfusion Injury

**FR-PO267**

**Tubulin Acetylation in the Kidney Tubular Cells After Ischemia/Reperfusion Injury**

**Authors:** Anja Thorenz, Robert Greten, Anja Thorzen, Fauth Gueler, Katja Hupecht, Song Rong, Hermann G. Haller, Jan H. Braesen. 1 Nephrology, Hannover Medical School, Hannover, Germany; 2 Diagnostic and Interventional Radiology, Hannover Medical School, Hannover, Germany; 3 Central Animal Facility, Hannover Medical School, Hannover, Germany; 4 Pathology, Hannover Medical School, Hannover, Germany.

**Background:** Acetylation of tubulin is known to play an important role in the stabilization of microtubules. Kidney ischemia/reperfusion injury (IR) is a major cause of acute renal failure. IR causes damage to the cytoskeleton in the tubular epithelial cells. Tubulin acetylation and acetylated tubulin levels were analyzed in kidney tubular epithelial cells after IR injury using western blotting and immunohistochemical staining. Mice were subjected to either 30 min of ischemia or sham-operation. Kidneys were harvested at various times after ischemia.

**Methods:** Acetyl-tubulin expression dramatically decreased 24 hours after ischemia and then gradually increased over time. However, total α-tubulin expression was not significantly changed after IR. In normal kidney, immune-reactivities of kidney epithelial cell to acetylated α-tubulin antibody were different in tubules; the orders were the collecting duct distal tubules and the proximal tubule. Twenty-four hours after ischemia, acetylated α-tubulin expression increased in the proximal tubule and the distal tubule with strong expression in the nuclei of the tubular cells. In the glomeruli, acetylated α-tubulin was also observed and the expression was very strong in the podocyte and Bowman’s capsule. Twenty-four hours after ischemia, acetylated α-tubulin expression in the proximal tubule was lower than that of normal cells. Nine days after ischemia, acetylated α-tubulin expression in the podocyte and interstitial cell increased. Expression of α-tubulin acetytransferase-1 (αTAT1), an enzyme involved in acetylation of α-tubulin, continuously decreased after ischemia. Histone deacetylase 6 (HDAC6), an enzyme involved in deacetylation of tubulin, also significantly decreased after ischemia.

**Conclusions:** Ischemia/reperfusion induced tubulin acetylation in renal tubular cells, suggesting that IR-induced decrease of tubulin acetylation is associated with reduction of stability of microtubule in cells.

**Funding:** Government Support - Non-U.S.

**FR-PO268**

Hypertension Aggravates Acute Kidney Injury (AKI) and Accelerates Progression to Chronic Kidney Disease (CKD)

**Authors:** Anja Thorenz, Robert Greten, Anja Thorzen, Fauth Gueler, Katja Hupecht, Song Rong, Hermann G. Haller, Jan H. Braesen. 1 Nephrology, Hannover Medical School, Hannover, Germany; 2 Diagnostic and Interventional Radiology, Hannover Medical School, Hannover, Germany; 3 Central Animal Facility, Hannover Medical School, Hannover, Germany; 4 Pathology, Hannover Medical School, Hannover, Germany.

**Background:** AKI can be complicated by hypertension due to activation of the RAAS system. However, the most frequently used laboratory mouse strain (C57Bl/6) lacks blood pressure elevation after renal injury. In this study we provide evidence that hypertension aggravates ischemic AKI and accelerates progression to chronic kidney disease (CKD) in C5D1 mice.

**Methods:** IRI was induced by transient clamping of the renal pedicles for 35 minutes in C5D1 compared to C57Bl/6 mice. Survival, renal function (creatinine, BUN), glomerular filtration rate (GFR) and renal blood flow (RBF) were measured by inulin/PAH-clearance and renal perfusion impairment was assessed by functional magnetic resonance imaging (fMRI). Systemic blood pressure was measured by tail cuff method at different time points after IRI. Morphological changes were investigated by Masson Goldner staining and immunohistochemistry for inflammation (myeloid cell infiltration) and fibrosis (collagen and fibronectin expression). In addition, silver stain was done to quantify mesangial matrix expansion.

**Results:** Renal function improvement after IRI was similar in C5D1 and C57Bl/6 mice but only the C5D1 mice developed severe blood pressure elevation (~20 mmHg) within 2 weeks. Functional MRI revealed long lasting impairment of renal perfusion in C5D1 mice and markedly better recovery in C57Bl/6 mice. Similar results were obtained by PAH clearance measurements. Histologically, AKI score and inflammation was similar at day 1 after IRI in both mouse strains. At day 14 after IRI, C5D1 mice developed severe tubulo interstitial fibrosis. In contrast, C5D7/6 recovered and had only mild focal cortical scarring after 14 days. Silver stain revealed significant mesangial matrix expansion only in C5D1 mice correlating with accelerated glomerulosclerosis.

**Conclusions:** CD1 mice show severe blood pressure elevation in ischemia induced AKI which accelerates the progression to CKD.

Pericyte MyD88 Controls Inflammatory and Fibrotic Responses to Kidney Injury

**Authors:** Inrja Alexandra Leaf, 1 Ivan G. Gomez, Bryce Gordon Johnson, William A. Altemeier, 2 Jeremy Stuart Duffield. 1 Research & Development, Biogen, Cambridge, MA; 2 Medicine, Univ of Washington, Seattle, WA.

**Background:** Sterile inflammation is increasingly recognized as a central problem in many acute and chronic diseases but the mechanisms controlling responses to sterile inflammation are poorly understood. Injured or dying cells release products, or Danger Associated Molecular Patterns (DAMPs), recognized by immune receptors contributing to disease progression. Here we show that DAMPs isolated from injured kidney activate TLR2/4 and MyD88 dependent transcription of immune genes in non-immune kidney resident cells, pericytes. When treated with extracellular DAMPs pericytes form an active NLRI/pNlr/p canonical IL-1 and IL-18 mediated pro-inflammatory response and undergo pyroptosis, thereby contributing to inflammation and leukocyte trafficking.

Gadd45-Gamma Protects Against Acute Kidney Injury

**Authors:** Gyu Tae Shin, Inwhee Park, Heungsoo Kim. 1 Dept of Nephrology, Ajou Univ School of Medicine, Suwon, Kyunggi, Korea.

**Background:** Growth arrest and DNA-damage-inducible protein-gamma (Gadd45-gamma) is a protein which plays a role in the G2/M cell cycle checkpoint. We previously suggested that Gadd45-gamma may be involved in chronic kidney damage. In the present study we investigated the function of Gadd45-gamma in acute septic and toxic kidney injury.

**Methods:** Acute kidney injury (AKI) was induced in vivo by intraperitoneal injection of lipopolysaccharide (LPS, 10mg/kg) and cisplatin (20mg/kg) in wild-type (WT) and Gadd45-gamma KO mice. Proteome array kits were used to detect differentially regulated proteins in serum (40 pro-inflammatory proteins) and kidney cortex. Stable Gadd45-gamma knockdown cell lines were established in primary human renal epithelial (HRE) cells using shRNA expression vectors. Gadd45-gamma was over-expressed using the recombinant adenovirus harboring the Gadd45-gamma open reading frame. Differentially regulated genes in cisplatin treated HRE cells were determined using the microarray analysis.

**Results:** Gadd45-gamma was significantly induced as early as 2 h after LPS injection in the kidney of WT mice. At 24 h after LPS injection, both WT and KO mice showed AKI evidenced by high urinary NGAL and elevated serum creatinine levels, where KO mice showed significantly higher serum creatinine levels with lower creatinine clearance than WT mice. Pro-inflammatory cytokines in serum were not different, however, the expression of several chemokines in kidneys were significantly higher in KO mice. In contrast, the expression of pro-fibrotic cytokines was significantly lower in KO mice. At 48 h after cisplatin injection, only KO mice showed significantly elevated serum creatinine levels with heightened NGAL expression. In cisplatin treated HRE cells, pro-inflammatory cytokines were significantly up-regulated by Gadd45-gamma knockdown, and down-regulated by Gadd45-gamma overexpression, whereas pro-fibrootic cytokines were significantly down-regulated by Gadd45-gamma knockdown.

**Conclusions:** The up-regulation of Gadd45-gamma protects against acute kidney injury, however, maladaptively increases the expression of pro-fibrotic molecules.

Pyridorin® Reduces Renal Injury and Post Injury Fibrosis After Ischemia-Reperfusion Induced Acute Kidney Injury

**Authors:** Nataliya Skrypnyk, 1 Paul A. Voziyan, 1 Haichun Yang, 1 Carrie Turich Taylor, 2 Raymond C. Harris, 1 Billy G. Hudson, 1 Mark P. de Caestecker. 1 Div of Nephrology, Vanderbilt Univ, Nashville, TN; 2 NephroGenex, Inc., Raleigh, NC.

**Background:** Pyridorin® (PYR), an inhibitor of pathogenic oxidative chemistries, has a favorable safety profile in clinical trials and has been shown to scavange reactive oxygen species (ROS) and reactive carbonyl species (RCS) in vitro and in vivo animal studies. ROS and RCS are highly up regulated during kidney injury. In this study we propose that PYR treatment will reduce injury and ameliorate long-term fibrosis after ischemia-reperfusion acute kidney injury (IR-AKI).

**Methods:** Ischemia-reperfusion mouse models: 1) unilateral ischemia reperfusion (UIR) (UIR-AKI) after injury evaluated at day 3 after injury (UIR D3); and 2) UIR with delayed contralateral nephrectomy (DCN) on day 9, fibrosis and injury evaluation on day 28 (UIR DCN D28).

**Results:** Preventive treatment with PYR at 500 mg/kg/day (PYR500) and 1000 mg/kg/day (PYR1000) given i.p. 4 hours before (0.5 hours) ischemia and for 3 days after (day 3) ischemia (UIR D3) and 2) UIR with delayed contralateral nephrectomy (DCN) on day 9, fibrosis and injury evaluation on day 28 (UIR DCN D28).

**Conclusions:** PYR pretreatment reduces UIR-AKI in dose dependent manner. Pre-treatment with PYR is more effective than post injury treatment and can inhibit progression to chronic kidney disease. These studies suggest PYR as a prospective drug for treatment of patients at risk of AKI. Funded by research grant from NephroGenex, Inc.

Methods: BMP-7 expression was studied in vitro in a serine medullary collecting duct (IMCD) cell line and in vivo in models of unilateral ureteral obstruction (UUO). The therapeutic effects of broad spectrum histone deacetylase (HDAC) inhibition with Trichostatin A (TSA) and Class I HDAC inhibition with MS-275 were evaluated by assessing renal pathology.

Results: UUO results in an 83.1% decrease in BMP-7 mRNA expression that is paralleled by a 63.0% decrease in the acetylation of histone proteins in the proximal Bmp7 promoter, a process that results in gene repression. These changes are HDAC-dependent and blocked by treatment with TSA. An in vitro pharmacologic screen in IMCD cells revealed that MS-275 stimulates BMP-7 expression, while inhibitors of other HDAC isoforms have no effects. These results were confirmed by using siRNA-mediated genetic ablation to demonstrate specificity and chromatin immunoprecipitation to show binding of the Class Ia HDAC proteins HDAC1 and HDAC2 to the Bmp7 promoter. MS-275 also stimulates anti-fibrotic functions of BMP-7 in vivo by suppressing the expression of TGF-β-dependent pro-fibrotic genes COL1α1 and aSMA by 62.9% and 96.7%, respectively. Finally, these effects extend to the obstructed kidney in vivo where HDAC inhibition results in a 2.7-fold increase in BMP-7 expression, 42.7% decrease in fibroblast activation, and 63.7% decrease in renal fibrosis.

Conclusions: These findings demonstrate that HDAC1 and HDAC2 are responsible for the loss of BMP-7 expression and its renal protective functions in the injured kidney. Furthermore, our study suggests that Class I HDAC inhibitors have a tremendous therapeutic potential for stimulating kidney repair and inhibiting disease progression following chronic renal injury.

Canonical BMP Signaling via BMPR1A and Smad1/5/8 Mediates the Transition to Fibrosis After Renal Ischemia Reperfusion Injury

Emilia Vigoled,1 Lajos Marko,2 Christin Hinze,1 Dominik N. Müller,1,2 Ruth Schmidt-uhlich,1 Kai M Schmidt-Ott,1,2,3 Max Delbrueck Center for Molecular Medicine, Berlin, Germany; 1Experimental and Clinical Research Center, Charité, Berlin, Germany; 2Dept of Nephrology, Charité - Universitätsmedizin, Berlin, Germany.

Background: Ischemia reperfusion injury (IRI) of the kidney leads to acute kidney injury (AKI) and frequently precipitates the development of tubulointerstitial fibrosis. Bone morphogenic protein (BMP) signaling has been implicated in the pathogenesis and progression of the disease, but its tubular-specific role is unclear.

Methods: We induced IRI in mice by clamping the left renal pedicle for 25 minutes. The severity of injury was determined by histology scoring, elevated mRNA expression levels of renal injury markers NAG and KIM-1 and increased urinary NAG (uNAG) excretion 24h post-ischemia. Activation of canonical BMP signaling was detected by nuclear pSmad1/5/8 immunostaining and Western blotting. To achieve a doxycycline-dependent CRE-mediated inactivation of BMP receptor 1a (Bmpr1a) in renal tubules, we generated Pax9rtTA;LC1::Bmpr1a fl/fl mice (Bmpr1a cKO).

Results: Canonical BMP activity, as revealed by pSmad1/5/8, was widely detected in healthy wild-type (wt) mouse kidney tubules. IRI caused a sustained injury in wt kidneys as shown by elevated NAG and KIM-1 expression and increased uNAG excretion. In 21 days following IRI, Bmpr1a cKO kidneys displayed an initial injury similar to controls, but at 7 days post-ischemia, the expression of CTGF expression) were examined in NRK-52E cells transfected with siRNA for PNUTS and CTGF expression). After 21 days following IRI, NRK-52E cKO kidneys displayed an increased percentage of tubulointerstitial fibrosis compared to controls.

Conclusions: Tubular Bmpr1a-dependent Smad1/5/8 signaling is transiently decreased after renal IRI and its reactivation limits the progression of tubulointerstitial fibrosis.

PNUTS (Phosphatase 1 Nuclear-Targeting Subunit) Is Down-Regulated in Acute Kidney Injury and by Aging, and Regulates Cell Cycle, Fibrosis, DNA Damage of Renal Tubular Cells

Background: PNUTS (phosphatase 1 nuclear-targeting subunit, also known as PPP1R10) has recently reported to be regulated in cardiac aging and play roles in DNA damage. Aging and fibrosis play crucial roles in AKI and aging. PNUTS expression were decreased in aged AKI mice. Immunohistological examination revealed the reduced expression of PNUTS in the proximal tubular cells in AA-induced AKI model in different aged mice (20-, 50- and 90-week-old). To elucidate the function of PNUTS, cell cycle regulation (by FACs), DNA damage (by gammaH2AX expression), and fibrosis (by CTGF expression) were examined in NNR-52E cells transfected with siRNA for PNUTS or PNUTS expression vector.

Results: In mice with AA-induced AKI, protein and mRNA expression of PNUTS were reduced compared with control mice. Moreover, PNUTS expression were decreased in aging according to aging. Reduction of renal function and renal fibrosis were more apparent in aged AKI mice. Immunohistological examination revealed the reduced expression of PNUTS in the proximal tubular cells in AA-induced AKI. PNUTS mRNA and protein expression showed a dose-dependent reduction by H2O2 in NNR-52E cells. Overexpression of PNUTS reduced H2O2-induced caspase3 activity and apoptotic (TUNEL) positive cell number. Transfection of siPNUTS significantly increased G2/M phase cell, CTGF expression, and DNA damage.

Conclusions: These results indicate that PNUTS expression was reduced in AA-induced AKI and aged mice. Expression of PNUTS was partially regulated by oxidative stress. PNUTS regulates cell cycle, CTGF expression, DNA damage, and apoptosis in NNR-52E cells. These results suggest that regulation of PNUTS may play a key role in the pathophysiology of AKI and age-related renal damage.

Targeted Deletion of Numb from Proximal Tubules Attenuates Interstitial Fibrosis by Mitigating G2/M Arrest Fengxin Zhu, Jing Nie. Div of Nephrology, Nanfang Hospital, Guangzhou, Guangdong, China.

Background: Progressive tubulointerstitial fibrosis (TIF) is the final common pathway

leading to end stage renal disease. Tubular epithelial cells (TECs) have a crucial role in the pathogenesis of TIF. Numb is a multifunctional protein involved in diverse cellular processes. However, little is known about the physiologic and pathologic role of Numb in kidney.

Methods: We examined the expression and distribution of Numb in normal adult mouse

kidney as well as in mouse model of renal fibrosis induced by unilateral ureteral obstruction (UUO). To explore Numb’s role in renal fibrosis, we generated a conditional knockout mouse model in which Numb is selectively ablated from proximal tubules (PEPCK-Numb-KO). To confirm the role of Numb in regulating cell cycle, Numb was overexpressed in NRB52E cells by infecting with a Numb adenovirus (Ad-Numb) and endogenous Numb was knocked down by siRNA in HK-2 cells before atherosclerosis factor (AA) treatment. To examine the role of p53 in Numb-induced G2/M arrest, Ad-Numb infected HK-2 cells were incubated with pifithrin-a, a p53 inhibitor.

Results: Numb is expressed in renal tubules and glomeruli. The expression of Numb in renal tubules was significantly increased after UUO. After UUO, PEPCK-Numb-KO mice exhibited significantly attenuated TIF. Ectopic expression of Numb increased the fraction of cells in G2/M stage and upregulated the expression of TGF-β1 and CTGF in NRB52E cells. Knocking down endogenous Numb attenuated AA-induced G2/M arrest and profibrotic cytokines production. Furthermore, G2/M arrest and expression of profibrotic cytokines were significantly reduced in PEPCK-Numb-KO mice after UUO. Inhibiting p53 activity dramatically mitigated Numb-induced G2/M arrest and profibrotic cytokines production.

Conclusions: In summary, our studies demonstrate that Numb has a profound effect on profibrotic G2/M arrest of TECs through stabilizing p53 protein. Depletion of Numb markedly attenuates G2/M arrest of proximal tubules which in turn reduces TIF. Collectively, these data indicate that targeting Numb might be a novel therapeutic approach for the treatment of fibrotic kidney diseases.

Tubulointerstitial Fibrosis Increases Peritubular Capillary Permeability and Induces Subsequent Hypoxia Jun Zou, Zae Won Yang, Haiyun Yang, Agnes B. Fogo. 1 Dept of Pathology, Microbiology, and Immunology, Vanderbilt Univ, Nashville, TN; 2 Div of Nephrology, Xinhua Hospital, Shanghai, China.

Background: We previously showed that folic acid-induced tubulointerstitial injury significantly increased glomerular injury in this study, we investigated endothelial dysfunction of peritubular capillaries and oxygen supply changes contribute to this cross-talk of tubular to glomerular injury.

Methods: Col I-luciferase mice, which have luciferase inserted in the collagen 1 promoter, were mated with Nep25 mice, which express human CD25 receptor on podocytes, and develop glomerulosclerosis when immunotin is administered. Mice were treated with folic acid (FA, 240mg/kg BW, i.p.) or vehicle (VEH). At day 42,
mice were sacrificed to assess interstitial fibrosis, peritubular capillary number (CD31 immunostaining) and tubulointerstitial fibrosis (in vivo injection of Evans blue dye), and tissue hypoxia (hypoximun, pimonidazole).

**Results:** Folic acid induced acute tubular injury over two weeks, evidenced by increased urinary NGAL and Kim-1 levels. Six weeks later, tubular epithelial cells had regenerated and urinary NGAL and Kim-1 returned to baseline level. However, biomimicry imaging, an indicative of collagen I mRNA transcription, showed higher density in folic acid vs vehicle (FA 31.6±5.1 vs VEH 3.2±0.6, p<0.05). Interstitial fibrosis and collagen I were increased in FA compared to VEH (picrosirius red area, FA 14.5±1.6 vs VEH 7.3±0.6, p<0.05; COL1A1 IHC, FA 16.7±12.2 vs VEH 10.6±6.3, p<0.05) with a patchy distribution. Folic acid did not reduce peritubular capillary density (FA 5.5±0.7 vs VEH 6.0±0.8%, pNS). However, peritubular capillary permeability, measured by extravasated Evans blue dye in the kidney, significantly increased in folic acid-treated group (FA 50.6±5.3 vs VEH 23.6±6.2, p<0.05). Pimonidazole staining intensity was increased, suggesting tubulointerstitial hypoxia.

**Conclusions:** We conclude that tubulointerstitial fibrosis may lead to increased peritubular capillary permeability and subsequent hypoxia, which may contribute to crosstalk of interstitial fibrosis promoting glomerular injury.

**Homocysteine Induces Collagen I Expression by Downregulating Histone Methyltransferase G9a**

**Wenjing Li, Jing Nie. State Key Laboratory of Orogenic Failure Research, National Clinical Research Center of Kidney Disease, Duy of Nephrology, Nanfang Hospital, Southern Medical Univ, Guangzhou, China.**

**Background:** Hyperhomocysteinemia (HHcy) leads to several clinical manifestations including renal fibrosis. Excess deposition of extracellular matrix (ECM) components including collagen is the eponymous lesion of renal fibrosis.

**Methods:** Wild-type C57BL/6 mice, at the age of 6-9 weeks, were fed either standard rodent chow or HM diet . After 2 weeks on the diet, mice were sacrificed. Kidney tissue was collected. As previously reported, Hela-S2 cells were also used in these studies. The expression of G9a and Collagen I were examined by Western blot and qPCR. Renal pathological changes were assessed in tissue sections stained with Collagen I and Masson staining. HK-2 cells were transfected with pCol-G3 reporter plasmid, pRL null together with siG9a or Flag-tagged G9a to examine the promoter activity of COL1A1. The level on G9a and H3K9me2 on the promoter of COL1A1 was assessed by CHIP assay.

**Results:** We demonstrated that elevated concentration of Homocysteine increased the expression of collagen type I in cultured HK-2 cells as well as in kidney tissue of HHcy mice. Meanwhile, HK-2 cells overexpressed the expression of histone methyltransferase G9a. Mechanistically, silencing endogenous G9a by siRNA enhanced the promoter activity of COL1A1 in HK-2 cells.

**Conclusions:** Overexpression G9a inhibited the promoter activity of COL1A1. CHIP assay demonstrated that G9a binds to the promoter region of collagen type I, suggesting Hcy promotes ECM production.

**Funding:** Government Support - Non-U.S.

**The Podocyte Adhesive Exhibits Matrix Ligand Specificity with Implications for Glomerular Disease**

**Michael J. Randles, Roy Zent, Martin J. Humphries, Rachel Lennon. Wellcome Trust Centre for Cell-Matrix Research, Faculty of Life Sciences, Univ of Manchester, Manchester, United Kingdom; Inst of Human Development, Faculty of Medical & Health Sciences, Univ of Manchester, Manchester, United Kingdom; Dept of Medicine, Vanderbilt Univ Medical Center, Nashville, TN.**

**Background:** Adhesion at both the podocyte slit diaphragm and podocyte-extracellular matrix (ECM) interface is essential glomerular filtration barrier integrity. These structures converge onto many of the same signalling pathways, including those controlling the actin cytoskeleton. Podocytes adhere to laminin-521 in the glomerular basement membrane via integrin α3β1 and evidence suggests that attachment to collagen IV is upregulated in disease states. Whether changes in ECM ligand alter podocyte adhesion signalling remains unclear.

**Methods:** We analysed podocyte morphology following engagement of either laminin-521 or type IV collagen (α1α1α2) and isolated basolateral adhesion complexes for analysis by mass spectrometry (MS). To isolate nephrin-nephrin complexes for analysis by immunoprecipitation, we tagged the key nephrin-binding ECM ligand and nephrin expression status. MS and protein interaction network mapping highlighted PKCα as a key signalling node in laminin adhesion complexes. Analysis of nephrin-nephrin complexes highlighted significant overlap with ECM adhesion signalling, suggesting crosstalk mechanisms.

**Conclusions:** In human podocytes we discovered that both ECM ligand and overexpression of nephrin influences morphology, adhesion complex composition and intracellular signalling. Enhanced understanding about the pathways that control podocyte adhesion may ultimately inform therapeutic strategies to correct or repair glomerular barrier function.

**Low-Density Lipoprotein Receptor-Related Protein 5 Drives Tubulointerstitial Fibrosis via Regulation of TGF-β Signaling**

**Wenjing Li, Rui Cheng, Jian-xing Ma. Dept of Physiology, Univ of Oklahoma Health Sciences Center, Oklahoma City, OK.**

**Background:** Low-density lipoprotein receptor-related protein 5 (LRP5), a co-receptor of the canonical Wnt/beta-catenin pathway, was recently reported to drive idiopathic pulmonary fibrosis through activating beta-catenin. In this study, we examined the potential role of LRP5 in the regulation of TGF-β signaling in tubulointerstitial fibrosis.

**Methods:** LRP5-deficient (LRP5-/-) mice and age-matched wild-type (WT) mice were subjected to unilateral ureteral obstruction (UUO). Renal expression fibrotic factors, including α-SMA, CTGF, collagens and fibronectin, was quantified by picro-sirus red staining, western blot analysis and immunostaining. Primary tubular epithelial cells (PTECs) were cultured from LRP5 mice and WT mice. Co-Immunoprecipitation was performed in a human proximal tubular epithelial cell line (HKEC-8) over-expressing LRP5 and TGF-β receptors.

**Results:** LRP5 mice with UOO showed ameliorated collagen fibrosis and alleviated TGF-β signaling compared with WT mice with UOO. However, activation of the Wnt/beta-catenin signaling was not different between LRP5 mice and WT mice, indicating that attenuated tubulointerstitial fibrosis in LRP5 mice was not due to mitigated activation of the fibrotic Wnt/beta-catenin pathway. Instead, LRP5-/- mice displayed alleviated TGF-β signaling in comparison to that in WT/UUO kidneys. Overexpression of LRP5 in HKC-8 resulted in enhanced TGF-β signaling including enhanced TGF-β driven transcriptional activity and elevated expression of fibrosis markers regulated by TGF-β signaling. Knock-down of LRP5 in HKC-8 cells diminished the activation of the TGF-β signaling pathway. Meanwhile, LRP5-/- PTECs demonstrated attenuated activation of the TGF-β signaling, compared to WT PTECs. In addition, immunoprecipitation assay demonstrated physical association between LRP5 and TGF-β receptor 1, suggesting that LRP5 might act as a co-receptor of the TGF-β signaling pathway in the regulation of tubulointerstitial fibrogenic process.

**Conclusions:** LRP5 promotes tubulointerstitial fibrosis via regulation of the TGF-β signaling. This activity is independent of its role in the Wnt/beta-catenin pathway.

**Funding:** Other NIH Support - GM104934

**Loss of Endothelial Nitric Oxide Augments Smad3 Linker Phosphorylation and Precedes Insulin Resistance in High-Fat Diet Induced Obesity**

**Yu bo yang Sun, Xinli Qu, Jinhua Li. Anatomy and Developmental Biology, Monash Univ, Melbourne, Victoria, Australia.**

**Background:** Deficiency of endothelial nitric oxide synthase (NOS3/enos) confers susceptibility to diet-induced obesity and it’s complications. enos-derived nitric oxide (NO) acts as a potent vasodilator, enhances insulin sensitivity and also inhibits inflammation. TGF-β/Smad signaling plays an important role in regulating glucose and energy homeostasis. Smad3 deficient mice are protected from diet-induced obesity and obesity-related kidney injury. This study investigated whether the effect of endothelial-derived NO promotes Smad3 activation, which precedes insulin resistance in high-fat diet (HFD) induced obesity.

**Methods:** C57BL6/J wild type, enos deficient (enos-/-) with C57BL6/J background mice were given HFD or normal diet (ND) treatment for 1, 3, 7 days and 4, 8 or 16 weeks.

**Results:** Within 7 days of HFD treatment in WT mice, Western blotting showed a marked decrease in total eNOS level. Phosphorylation of Smad3 linker region was only seen 4 weeks after HFD treatment, indicating endothelial injury precedes phosphorylation of Smad3 linker region. Compared to WT mice, enos-/- mice on HFD showed early onset of peripheral and renal insulin resistance, increased microalbuminuria, elevated blood pressure, which suggested that endothelial injury drives renal metabolic disorders induced by HFD. Conflonc microscopy demonstrated that fibroectin and collagen IV significantly increased in glomeruli in the HFD-treated enos-/- group compared to that in HFD-treated WT group. An in vitro model, palmitate acid addition to culture endothelial cells induced rapid C-PTC phosphorylation of Smad3, subsequent loss of eNOS, phosphorylation of Smad3 linker region and insulin resistance. L-NAME, a specific NOS inhibitor, significantly increased phosphorylation of Smad3 linker region and insulin resistance. Finally, endothelial cell overexpressing enos significantly inhibited Smad3 linker region phosphorylation and protected insulin sensitivity.

**Conclusions:** In summary, our studies showed that enos and Smad3 signaling pathway play essential roles in HFD-induced renal injury. enos/Smad3 pathway may be a novel therapeutic target in obesity-related kidney disease.

**Funding:** Government Support - Non-U.S.
Our epithelial-mesenchymal transition in DKD. It may serve as a potential novel target in HK-2 cells just as high glucose stimulation and upregulation of vimentin. Meanwhile, loss of miR-302a-3p expression can lead to EMT to 72h. Moreover, overexpression of miR-302a-3p suppressed expression of ZEB1 in the HG group increased at 6h and ascended to the highest level at 12h and then gradually in DNE group (r=-0.649, P=0.002) and DNC group (r=-0.681, P=0.006); It had positive diabetes mellitus group (DM, n=22) compared with control (healthy persons, n=30) and then determination of ZO-1, vimentin and ZEB-1 were determined by realtime PCR and western blot.

Results: Histologically, control mice scored 0.46 (+/- 0.12), diseased WT mice 3.13 (+/- 0.19), and diseased HIF1α KO mice 1.42 (+/- 0.28). Glomerular COL1A2 mRNA with LMB2 injection was increased 3.4x over the healthy controls in WT, but only 1.9x with HIF1α KO. In vitro, TGFβ induced COL1A2 promoter activity by 2.4x, which was abrogated when a hypoxia response element (HRE) 335 bp 5’ to the transactivation start site was mutated. By DNA precipitation assay, HIF1α binding to a -335 COL1A2 HRE probe was detected after TGFβ treatment. Interestingly, Smad3 also bound the -335 COL1A2 HRE probe in both TGFβ-treated cell lysate and whole kidney lysate from WT HIF1α KO mice. HIF2α/PDGFβ-Cre mice showed less GS than HIF2α-/- mice by histology. In vitro, HIF2α enhanced COL1A2 promoter activity independently of the -335 HRE. Instead, HIF2α increased the transcriptional activity of Smad3.

Conclusions: Both HIF1α and -2a contribute to the development of GS in mice. Out in vitro studies strongly suggest that HIF1α and -2a each enhance TGFβ-mediated fibrogenesis, but through distinct mechanisms. Funding: NIDDK Support

MiR302a-3p Modulates Renal Epithelial-Mesenchymal Transition in DKD by Targeting ZEB1 Minimum Pharma

Background: Recent study found that miRNAs are involved in diabetic kidney disease (DKD). The objective of this study is to determine the role of miR-302a-3p in the process of renal epithelial-mesenchymal transition (EMT) in DKD patients.

Methods: The levels of miR-302a-3p in the plasma of DKD patients were detected by realtime PCR and the relationship of miR-302a-3p and UAE or eGFR were analyzed. Secondly, miR-302a-3p expression was determined in HK-2 cells treated with high glucose for different time. And then miR-302a-3p mimics and inhibitor were transfected to HK-2 cells following exposure to high glucose and low glucose respectively. The expressions of ZO-1, vimentin and ZEB-1 were determined by realtime PCR and western blot.

Results: The expression of circulating miR-302a-3p was significantly increased in the diabetes mellitus group (DM, n=22) compared with control (healthy persons, n=30) and then decreased in the early stage of diabetic nephropathy group (DN, n=20). Furthermore, its expression in clinical diabetic nephropathy group (DNC, n=18) was decreased significantly compared with DM group. Circulating miR-302a-3p had negative correlation with UAE in DN group (r=0.649, P=0.002) and DNC group (r=-0.681, P=0.006). It had positive correlation with eGFR in DNC group (r=0.486, P=0.041). In vitro, miR-302a-3p expression in HG group increased at 6h and ascended to the highest level at 12h and then gradually decreased at 48h and 72h. More interesting, ZEB1 protein expression had an opposite change which gradually decreased from 6h to 24h and then gradually increased from 48h to 72h. Moreover, overexpression of miR-302a-3p suppressed expression of ZEB1 in the post-transcriptional level and reversed high glucose-mediated downregulation of E-cadherin and upregulation of vimentin. Meanwhile, loss of miR-302a-3p expression can lead to EMT of HK-2 cells just as high glucose stimulation.

Conclusions: miR-302a-3p may play a protective role by targeting ZEB1 in renal epithelial-mesenchymal transition in DKD. It may serve as a potential novel target in pro-EMT states for the amelioration renal fibrosis seen in DKD. Funding: Other NIH Support - National Natural Science Funds of China (Grant No.81100515)
Methods: Fibroblasts & renal epithelial cells were incubated with TGFβ1 to induce myofibroblast differentiation, and compared to cells incubated with angiotensin II & BMP7 to induce myofibroblast reversal. QCPCR, confocal microscopy, ChiH, siRNA & plasmid overexpression were used to assess Hyal2 effects.

Results: Hyal2 was upregulated by both pro-fibrotic (TGFβ1) & anti-fibrotic (BMP7) cellular treatments. However in pro-fibrotic cells, Hyal2 was cytoplasmic, whereas in anti-fibrotic cells Hyal2 translocated to the nucleus. In pro-fibrotic cells Hyal2 did not associate with CD44. In contrast in anti-fibrotic cells Hyal2 associated with CD44 at the nucleus, whilst CD44/7-8/7-8 location to the cell surface. In anti-fibrotic cells Hyal2 nuclear translocation was increased CD44/7-8 mRNA & protein expression. CD44/7-8 was subsequently necessary for HA internalization and consequent reversal of myofibroblast phenotype. ChiH demonstrated association between Hyal2 and introns flanking the CD44/7-8 exon nucleotide sequence similar to Ang2 splice facilitator. Moreover, Hyal2 inhibited activated BMP7 driven upregulation of splice regulators SL2K & SSRF1.

Conclusions: Hyal2 displays nonenzymatic activity & translocates to the nucleus regulating expression of CD44/7-8 splice variant, which is crucial for reversing myofibroblast phenotype. Hence Hyal2 is a novel splice regulator and a critical regulator in reversal of myofibroblast phenotype & fibrosis prevention.

FR-PO291

FGF Signaling Contributors to Podocyte Injury in Murine HIV-Associated Nephropathy

Koji Okamoto,1 Eri Seoiri,2 Jeffrey B. Kopp.1 Kidney Section, NIDDK, NIH, Bethesda, MD; 1Dept of Nephrology, Endocrinology, Hemodialysis & Apheresis, Univ Hospital, The Univ of Tokyo, Tokyo, Japan.

Background: We reported that fibroblast growth factor receptor (FGFR), its ligand fibroblast growth factor 2 (FGF2), and their amplifying co-factor glypican 5 (GPC5) play important roles in idiopathic nephrotic syndrome and diabetic nephropathy (Okamoto, Nature Genetics, 2011). We have investigated the role of the FGF2 signal pathway in HIV-associated nephropathy (HIVAN).

Methods: FGFR2 ligands and FGF expression were studied in a mouse podocyte cell line and RNAseq analyses of both, of which express the HIV accessory protein Vpr in the presence of doxycycline. To study FGF2 trapping in glomeruli, biotinylated FGF2 was administered intravenously and detected with fluorescent streptavidin. Vpr mice and control mice received FGF2 (5 mg/animal/weekly for 4 weeks) or FGF antagonist (PD173074, 50 mg/animal/bi-weekly for 4 weeks).

Results: In cultured mouse podocytes FGF3 mRNA was increased 11-fold after Vpr induction. In Vpr mice compared with control mice, renal cortex FGF2 content was increased 3-fold, as assessed by ELISA. Intra-glomerular protein expression of FGF2 and GPC5 were increased by immunofluorescent staining. The results suggest that Vpr mice glomeruli might have increased FGF2 binding capacity and so we tested the binding capacity of FGF2 in vivo. One hour after intravenous administration of biotinylated FGF2, more biotin signal remained in glomeruli of Vpr mice compared with control mice (60% increase). Urea albumin creatinine ratios (g/g) were significantly increased in FGF2-treated Vpr mice compared to untreated Vpr mice on day 14 (0.56±0.10 vs 2.3±0.6), day 21 (1.17±0.16 vs 18.7±5.1) and day 28 (1.87±0.44 vs 21.8±9.9). Further, the FGF antagonist decreased albuminuria in Vpr mice at day 21 (0.47±0.16 vs 1.71±0.16 g/g) and at day 28 (0.36±0.41 vs 1.87±0.44 g/g).

Conclusions: In a HIVAN mouse model, podocyte FGF expression increased protein expression of FGF2, FGFR receptors and GPC5. Administration of FGF2 increased albuminuria, and treatment with an FGF antagonist reduced albuminuria, suggesting a pathogenic role for FGF2 in this murine HIVAN model.

FR-PO292

Role of AMP-Activated Protein Kinase Signaling in Fibroblast Activation and Renal Fibrosis

Yuguang Wang, Yanlin Wang. Medicine, Baylor College of Medicine, Houston, TX.

Background: Renal fibrosis is a common manifestation of chronic kidney disease resulting in progressive loss of kidney function. Although activated fibroblasts are responsible for the production and deposition of the extracellular matrix, the molecular mechanisms underlying fibroblast activation are not fully understood. In this study, we examined the functional role of AMP-activated protein kinase a1 (AMPKa1) in the activated fibroblasts and the development of renal fibrosis.

Methods: To examine the functional role of AMPKa1, we generated mice with fibroblast-specific deletion of AMPKa1 using Cre-LoxP strategy. Unilateral ureteral obstruction (UUO) and ischemia-reperfusion injury (IRI) models were used to induce renal fibrosis. Cultured cells were used to examine AMPKa1 signaling in fibroblast activation.

Results: In a HIV AN mouse model, podocyte Vpr expression increased protein expression of FGF2, FGFR receptors and GPC5. Administration of FGF2 increased albuminuria, and treatment with an FGF antagonist reduced albuminuria, suggesting a pathogenic role for FGF2 in this murine HIVAN model.

FR-PO293

Increased Expression of Complement C1 from Pericyte/Fibroblasts Contributes to Renal Fibrosis via Activation of Wnt/β Catenin Signaling

Sanhui Yang,1 Susan G. Landes,1 Amandeep Bajwa,1 Jing Yu,1 Jeremy Stuart Duffield,1 Didier Portilla.1 1Dept of Medicine and Renal Cell for Immunity, Inflammation and Regenerative Medicine, Univ of Virginia, VA; 2Univ of Virginia; 3Biogen Idec.

Background: Pericytes/fibroblasts are progenitors of scar-forming cells known as myofibroblasts. We have characterized the inflammatory nature of pericytes/fibroblasts isolated from UUO mice. We have also shown that Wnt/β-catenin signaling is activated during kidney fibrosis. Role of complement C1 on pericyte function in Wnt activation remains unknown.

Methods: We used the unilateral ureteral obstruction (UUO) and folic acid nephropathy models. Pericytes were isolated using magnetic beads containing anti-PDGFRB Receptor ab. Expression of C1 complex was examined by western blotting, immunofluorescence, and realtime-PCR in tissue and in cell lysates and supernatants obtained from pericytes cultured from sham, day 3 and day 10 UUO mice kidneys. Tophsl reporter assays were used to study Wnt signaling.

Results: Expression of C1q chains a,b,c as well as subunits Clr and C1s were increased during fibrosis along with increased expression of TGF-β, n-SMA and Wnt target genes wisp1 and 2. Immunostain showed C1q localization in the interstitial compartment of UOO but not in sham mice consistent with PCR and western blot data. In cultured pericytes, C1 complex component C1q protein was increased in culture supernatants of Day 3 and Day 10 but not in shams. Expression of C1q proteins was absent in supernatants of UUO pericytes isolated from C1qKO mice. Tophants reporter assays for Wnt signaling showed that pericytes from UUO kidneys had pronounced activation of the reporter following Wnt3a treatment as compared to shams, and this effect was blunted in pericytes isolated from C1qKO mice.

Conclusions: We demonstrate both in vivo and in vitro that increased expression of the C1 complex occurs in response to kidney injury along with activation of Wnt signaling. Our further studies, showing that inhibition of C1 complex using C1NH prevents renal fibrosis, we conclude that its inhibition in pericytes/fibroblasts leads to inhibition of Wnt activation and reduced renal fibrosis.

FR-PO294

The Role and Association of Inflammatory and Apoptotic Caspases in Tubulointerstitial Fibrosis

Chun Zhang, You Ke, Hua Su. Nephrology, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.

Background: Caspases are a family of cysteine proteases with pivotal functions in apoptotic and inflammatory signaling. According to their difference of structures and functions, human caspases are classified into three categories, which are apoptosis activator, apoptosis executioner and inflammatory mediator. Caspase-1 is an inflammatory caspase, and Caspase-7 belongs to apoptosis executioner. The roles and association of these two distinct types of Caspses protein in tubulointerstitial fibrosis (TIF) are not well characterized.

Methods: Unilateral Ureteral Obstruction (UUO) animal model was constructed on wild-type(WT) and caspase-1 knockout (KO) mice. In vivo study, the cultured tubular epithelial cell line NRK-52E (TECs) was employed and the expression of caspase-1 and caspase-7 was modulated by transfection of Lentiviral vector.

Results: In current study, we found both Caspase-1 and Caspase-7 protein levels were elevated in UUO WT mice. While in UUO mice with Caspase-1 KO background the increased Caspase-7 was suppressed significantly along with the minimized extracellular matrix accumulation which was demonstrated by western blot, immunohistochemistry and Masson's trichrome staining. In vitro TGF-β1 simulation promoted the expression of Caspase-1 and Caspase-7 simultaneously in TECs. Notably, genetic deletion of either Caspase-1 or Caspase-7 could abrogate TGF-β1 driven TECs' transdifferentiation and apoptosis. In addition, knocking down Caspase-1 sharpened Caspase-7 upregulation in TGF-β1 treated TECs which was consistent with in vivo study. However genetic deletion of Caspase-7 did not influence Caspase-1’s abundance.

Conclusions: Our observation firstly links inflammatory and apoptotic Caspases together in TIF and further elucidates Caspase-1 activation is an upstream event of apoptotic Caspase-7 induction during TIF and TECs' transdifferentiation and apoptosis.

MAD2B-Sno-Smad3 Signaling Pathway Is Implicated in Fibroblast Activation and Tubulointerstitial Fibrosis

Chun Zhang, Hui Zeng, Hua Su. Nephrology, Huazhong Univ of Science and Technology, Wuhan, Hubei, China.

Background: Mitotic arrest deficient protein MAD2B, an anaphase-promoting complex (APC)/cyclosome inhibitor, is indispensable for mitotic checkpoint control. Previously we found MAD2B was expressed in glomerular and tubulointerstitial compartment. In addition our data indicated MAD2B was involved in podocyte injury triggered by high glucose. But its roles in renal fibrosis remains elusive.

Methods: The object of this study included patients with renal tubulointerstitial fibrosis (TIF) (secondary glomerulonephritis and interstitial nephritis were excluded ), Unilateral Ureteral Obstruction(UUO) mice and in vitro cultured tubular epithelial cell line (NRK-52E) and renal fibroblast cell line (NRK-49F). In vivo gene silencing of MAD2B was carried out in renal Lentiviral gene delivery.

FHL2 Promotes Tubular Epithelial-to-Mesenchymal Transition by Regulating β-Catenin Activity Ting Cai, Danqin Sun, Chunshan Dai, Junwei Yang, Weichun He. Center for Kidney Disease, 2nd Affiliated Hospital of Nanjing Medical Univ, Nanjing, Jiangsu, China.

Background: Fibrotic kidneys exhibit aberrant activation of β-catenin signaling, one of the main pathways that play a critical role in mediating tubular epithelial-to-mesenchymal transition (EMT). FHL2 (four-and-a-half-LIM-only protein 2), an adapter protein, is an endogenous regulator of β-catenin activity. Methods: To determine whether FHL2 is also involved in the EMT process, we investigated its regulation and function during TGF-β1-stimulated EMT.

Results: TGF-β1 induced FHL2 mRNA and protein expression in rat proximal tubular epithelial cells (NRK-52E) in a time- and dose-dependent fashion, an effect that was largely dependent on intracellular Smad signaling. Overexpression of FHL2 suppressed E-cadherin, increased α-smooth muscle actin (α-SMA), vimentin and fibronectin expression, whereas knockdown of FHL2 via small interfering RNA partially reduced TGF-β1-mediated α-SMA, vimentin and fibronectin expression, and restored E-cadherin. TGF-β1 induced FHL2 phosphorylated and interacted with β-catenin in the nuclei in NRK-52E cells. Ectopic expression of FHL2 promoted β-catenin nuclear translocation, induced β-catenin-mediated gene transcription, and upregulated the expression of β-catenin target genes such as plasminogen activator inhibitor-1 (PAI-1) and Twist. Conversely, downregulation of FHL2 expression reduced β-catenin nuclear translocation, abolished β-catenin-mediated gene transcription, and inhibited PAI-1 and Twist expression in the basal and TGF-β1-stimulated conditions. In a mouse model of obstructive nephropathy, FHL2 expression increased in a time-dependent manner, suggesting that it may play a role in tubular EMT and renal fibrosis in vivo.

Conclusions: We demonstrate that, through downregulating β-catenin activity, FHL2 plays an important role in regulating TGF-β1-mediated EMT and could be a potential future therapeutic target to prevent progression of renal fibrosis.

Funding: Government Support - Non-U.S.

FR-PO299

Depletion of Endothelial SirT1 1 Aggravates Capillary Rarefaction and Tissue Fibrosis following Kidney Injury Yujio Kida, Michael S. Goligorsky. New York Medical College.

Background: Capillary rarefaction is a hallmark of chronic kidney diseases. Although recent studies point to sirtuin 1 (SIRT1) in endothelial cells as being protective against tissue injury, mechanisms of this effect are incompletely understood.

Methods: We deleted SIRT1 catalytic domain in endothelial cells in mice (Sirt1 mutant mice). Both wild type control and Sirt1 mutant mice were subjected to kidney injury by unilateral ureteral obstruction (UUO). In in vitro studies, we used human umbilical vein endothelial cells (HUVECs) and human aortic rings. Results: After UUO kidney injury, compared to control kidneys, Sirt1 mutant kidneys demonstrated significantly exaggerated (1) capillary rarefaction (2) expansion of myofibroblasts population, and (3) tissue fibrosis compared to wild type kidneys. In HUVECs, Sirt1 knockdown or chemical inhibition of SIRT1 significantly suppressed transcriptional expression of platelet derived growth factor-β (PDGF-B) and vascular endothelial growth factor receptor-2 (VEGFR2). Both effects were partially abrogated by Notch inhibition. This indicates that Sirt1 enhances PDGF-B and VEGFR2 expression via modulation of Notch. In scratch wound assay, SIRT1 inhibition impaired migration of HUVECs under oxidative stress by hydrogen peroxide, indicating SIRT1 dysfunction decreases migratory phenotype of endothelial cells. In transwell co-culture assay, endothelial SIRT1 inhibition impaired recruitment of PDGFβR+ pericytes was increased in Sirt1 mutant kidneys compared to control kidneys, suggesting that pericyte detachment and subsequent pericyte-myofibroblast transition are augmented in Sirt1 mutant kidneys, resulting in excessive fibrosis.

Conclusions: Functional depletion of SIRT1 in endothelial cells aggravates capillary rarefaction and fibrosis both in vivo and in vitro due to impaired endothelial expression of VEGFR2 and PDGF-B, respectively.

In Vivo Reprogramming of Myofibroblasts with Endothelial Progenitor Cell Extract Ameliorates Fibrosis Kei Matsumoto,1,2 Sandhya Xavier,1 Jun Chen,1 Yujio Kida,1 Brian B. Ratliff,1 Stefan Rose-john,1 Michael S. Goligorsky,1 1New York Medical College; 1Showa Univ, Tokyo, Japan; 1Christian-Albrechts Univ, Kiel, Germany.

Background: Accumulation of myofibroblasts is a hallmark of renal fibrosis. We hypothesized that exposing myofibroblasts to the extract of endothelial progenitor cells (EPC) could reverse endothelial-mesenchymal transition. Methods: We used α-SMA-GFP mice to visualize fibroblast-to-myofibroblast conversion and embryonic mouse EPC to prepare extract. Cell phenotype was assessed using standard biochemical and molecular biology techniques.

Results: Combining EPC extract with F+G+G+P has a synergistic effect on myofibroblast conversion in vivo. Conversion rate is improved by 30% in vivo. This effect is mediated by TGF-β1 suppression and transforming growth factor β receptors (TGFBR) downregulation.

Conclusions: This technique may provide new tools for treatment of renal fibrosis.

Funding: NIDDK Support

FR-PO297

PBI-4050 Inhibits the Development of Renal Fibrosis in a Model of Tubulointerstitial Fibrosis Ming-Zhi Zhang,1 Lyne Gagnon,2 Raymond C. Harris.1 1Medicine, Vanderbilt Univ, Nashville, TN; 1Pro-Metric Biosciences, Laval, QC, Canada.

Background: Kidney fibrosis occurs in chronic kidney diseases and leads to gradual loss of kidney function. Although the etiology of kidney fibrosis is multifactorial, there is increasing evidence linking chronic inflammation to kidney fibrosis. PBI-4050, a novel first-in-class orally active low molecular weight compound currently in phase II clinical trials, has anti-inflammatory and anti-fibrotic properties in different in vivo models. Activation of epidermal growth factor receptor (EGFR) contributes to the development of renal fibrosis, and homozymous transgenic mice with overexpression of an EGFR ligand, human hepatocyte growth factor (HB-EGF), in renal proximal tubule develop spontaneous tubulointerstitial fibrosis by 3-4 weeks of age. We examined whether PBI-4050 could inhibit the development of renal fibrosis in homozymous HB-EGF mice.

Methods: Homozygous HB-EGF mice on a C57BL/6 background were treated with PBI-4050 (200 mg/kg/day) by daily gavage gavage from 4 to 14 weeks of age.

Results: Light microscopic analysis and immunohistochemistry showed that untreated homozymous HB-EGF mouse kidney, ERK was activated in both proximal tubule epithelial cells (PTEC) and their surrounding interstitial cells. PBI-4050 treatment led to marked decreases in ERK activity in proximal tubule epithelial cells and interstitial cells, suggesting that PBI-4050 inhibits HB-EGF mediated ERK activation in PTEC, but also subsequent ERK activation in the interstitial cells, leading to inhibition of the development of renal fibrosis. PBI-4050 treatment significantly reduced the development of renal interstitial fibrosis. PBI-4050 caused marked decreases in renal macrophage infiltration (F4/80 staining) as well as M2 macrophage (CD206) staining. In addition, PBI-4050 treatment reduced the expression levels of the pro-fibrotic and fibrotic components including CTGF and TGF-β, α-SMA (a marker of myofibroblasts), fibronectin, collagen I and IV.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only; Underline represents presenting author.
Results: In vitro treatment of TGF-β1-activated fibroblasts with EPC extract prevented fibrogenesis but did not influence expression of endogenous markers. In two distinct models of renal fibrosis, unilateral ureteral obstruction (UUO) and chronic phase of folic acid-induced nephropathy (FAN), subcapsular injection of EPC extract to the kidney prevented and reversed accumulation of α-SMA-positive myofibroblasts and renal proximal tubular epithelial cells with CCN3 or its activator, CCN3 resulted in enriched in LIF and VEGF. Only LIF was capable of reducing fibroblast-to-myofibroblast transition of TGF-β1-activated fibroblasts. In vivo subcapsular administration of LIF reduced the number of myofibroblasts, improved the density of peritubular capillaries, but did not reduce proteinuria or kidney function fibrosis. Effects of LIF, as well as Hyper-IL-6, in the presence of TGF-β1 were mediated via gaipα/STAT3 pathway resulting in induction of proliferation-suppressing transcription factors KLK4, C-Myc, OCT4, and Nanog in association with the open chromatin conformation.

Cell siRNA for CCN3 does not reverse endolymphatic-mesenchymal transition, but it prevents and reverses fibroblast-to-myofibroblast transition and renal fibrosis. The component of EPC extract, LIF, is capable of preventing development of the contractile phenotype of activated fibroblasts, but does not eliminate TGF-β1-induced collagen synthesis in cultured fibroblasts and models of renal fibrosis. LIF component of EPC extract is a participant of its antifibrotic effect, but not the sole one, as other yet undisclosed factors contribute to the antifibrotic effect of the extract.

FR-P0301
Mitochondrial Metabolic Switch to Glycolysis in Proximal Tubular Epithelial Cell in Fibrotic Kidneys
Lei Jiang, Junwei Yang. Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ; Nanjing, Jiangsu, China.

Background: Renal proximal tubule is susceptible to hypoxic injury since its reliance on aerobic oxidative metabolism. Mitochondrial dysfunction contributes to progression of chronic renal disease. However, the role of the energy metabolism of renal tubule in progression of fibrosis is uncertain, and the relationship between the change of energy metabolism and tubular epithelial cell damage is unclear.

Methods: Gene expression profiles related to energy metabolism of the proximal tubule in fibrotic kidneys were analyzed. 2-Dexoglycos (2-DG) was given to CD-1 mice under UUO intraperitoneally. Primary tubular epithelial cells (PTC) cultured from normal CD-1 mice renal cortex was used. 2-DG (inhibitor of glycolysis), bromopyruvic acid (inhibitor of hexokinase), dichloroacetate acid (inhibitor of glycolysis), oligomycin (inhibitor of oxidative phosphorylation), etomoxir (inhibitor of fatty acid oxidation), DON (inhibitor if glutamine metabolism), PKM2 siRNA or HIF-1α siRNA was used in PTC with or without TGF-β1 stimulation. The oxygen consumption rate (OCR) and extracellular acidification rate (ECR) were detected by Seahorse Metabolic Analyzer.

Results: 1. Glycolysis was upregulated in the proximal tubule in fibrotic kidney. 2. Genes related to glycolysis were upregulated, however, genes related to oxidative phosphorylation, fatty acid metabolism and glutamine metabolism were downregulated. 3. The key limiting enzymes for glycolysis were upregulated in the fibrotic kidney. 3.2-DG could block the renal fibrosis under UUO. 4. OCR was decreased under TGF-β1 stimulation in PTC, however, ECR was increased after TGF-β1 stimulation. 5. Inhibiting oxidative phosphorylation, fatty acid oxidation or glutamine metabolism could increase the lactate production in PTC. Lactate could directly induce PTC damage. 6. Inhibiting glycolysis could ameliorate the damage of PTC under TGF-β1 incubation.

Conclusions: The mitochondrial metabolism including oxidative phosphorylation, fatty acid oxidation and glutamine metabolism is defective in proximal tubular epithelial cell in the fibrotic kidney. The metabolism switch is to glycolysis, and the glycolytic pathway further aggravates the injury.

FR-P0302
The Effects of CCN3/NOV on the Formation of Extracellular Matrix in Human Mesangial Cells
Haifei Liu, Long Chen, Hong Liu, Bi-Cheng Liu. Dept of Nephrology, Zhong Da Hospital, Southeast Univ; Nanjing, Jiangsu, China.

Background: Glomerulosclerosis is characterized by mesangial cells proliferation and extracellular matrix (ECM) accumulation in a variety of damage factors, leading to ECM deposition. ECM accumulation is the net result of the balance between synthesis and degradation. CCN3, a matricellular protein of ECM, associates specifically with ECM. Recent study found that treatment with the matricellular protein CCN3 can block and/or reverse fibrosis development in obesity with diabetic nephropathy. However, whether CCN3 can alleviate the formation of glomerulosclerosis by inhibiting the production of ECM and promoting the degradation of ECM.

Methods: Human mesangial cells lines were stimulated with TGF-β1 (2ng/ml) and CCN3 for different concentration (5, 50, 500 ng/ml) virtually blocked this TGF-β1 induced effect on them (P < 0.05). On the other hands, TGF-β1 downregulated MMP-2 and MMP-9 at mRNA and protein levels, whereas a 1-hour pretreatment of the cells with CCN3 for different concentration (5, 50, 500 ng/ml) enhanced the expression of MMP-2 and MMP-9 (P < 0.05).

Conclusions: This study identifies that CCN3 as a new actor alleviates the formation of glomerulosclerosis by inhibiting the production of ECM and promoting the degradation of ECM.

FR-P0303
Spleen Tyrosine Kinase (Syk) Inhibition Suppresses Renal Fibrosis Through Anti-Inflammatory Effects and Down-Regulation MAPK-p38 Pathway
Kuan-hsing Chen, Hsiang-Hao Hsu, Cheng-chieh Hung. Nephrology, Chang Gung Memorial Hospital, Taoyuan, Taiwan.

Background: Spleen tyrosine kinase (Syk) is a 72 kDa, a member of the Src family of non-receptor tyrosine. The central role of Syk in signaling processes is known to be involved in adaptive immunity, but also in autinflammatory and allergic disease. However, the possible role of the anti-fibrogenic properties in renal interstitial fibrosis had not been examined.

Methods: In vitro study: Cultured rat renal interstitial fibroblasts (NRK-49F) were stimulated with recombinant human TGF-β1 1 ng/ml for different periods before harvesting. Alternatively, NRK-49F cells were pre-incubated with Syk inhibitor for 30 mins before TGF-β1 treatment. Total RNA was extracted for RT-PCR and total lysates were extracted for Western Blot analysis. In vivo study: Urinary unilateral obstruction model was induced in adult male B6 mice [tide/lc/3-5 months, 20-25 g]. Mice with UUO were given with intra-peritoneal Syk inhibitor (20 and 40 mg/kg, bid) or saline daily, one day prior the UUO surgery. Both obstructed and contralateral kidneys were harvested 7 days after surgery. Kidney tissues were prepared for further pathological and molecular biological analysis.

Results: Our results demonstrated that the inhibition of Syk in NRK49F cells inhibited the stimulation effect of TGF-β1 leading to fibroblast transition to the myofibroblast phenotype (upregulation of α-SMA) and extracellular matrix proteins accumulation, collagen type I, type IV. In addition, in UUO model, Syk inhibitor attenuated the tubule-interstitial fibrosis and expression of α-SMA, collagen I and fibronectin in UUO kidney. The anti-fibrosis of Syk inhibitor in UUO model may be related to anti-inflammatory effects (down-regulate inflammatory cytokines and reduce macrophage infiltration). Moreover, the effects of Syk inhibition in inhibition of kidney myofibroblast activation by TGF-β1 were associated with down-regulation of MAPK-p38 pathways.

Conclusions: In conclusion, we demonstrated that Syk inhibitor ameliorates TGF-β1 induced kidney myofibroblast activation and also reduces the tubulointerstitial fibrosis in UUO mice. The mechanims may be related to anti-inflammatory effects and down-regulate MAPK-p38 pathway.

Funding: Government Support - Non-U.S.

Optimization of Identification of the Glomerular Extracellular Matrix Proteome
Liliiane Hobeika, Michelle T. Barati, Jon B. Klein, Kenneth R. McLeish, Michael Merchant. Medicine, Univ of Louisville; Dept of Veterans Affairs, Louisville, KY.

Background: Increased glomerular extracellular matrix (ECM) is present in many glomerular diseases, eg. diabetic nephropathy and FSGS. Defining the ECM proteome by mass spectrometry (MS) offers the opportunity to determine the mechanism for increased ECM and identify disease specific markers. The optimal conditions for ECM isolation and MS analysis have not been determined. This study compared three extraction techniques in glomeruli isolated by laser capture microdissection (LCMD) from two types of tissue preparation.

Methods: Frozen (FR) and formalin-fixed paraffin embedded (FFPE) tissue from the same human kidney were cut into 10mm sections, stained with hematoxylin, glomeruli and various numbers of glomeruli slices ranging 50 to 150. There was no significant increase in yield above 75 glomeruli slices. Compared to MAX (2032), extraction with SDS or isolated by LCMD. Glomerular proteins were extracted by a) Protease MAX surfactant + boiling (MAX) or sequential deCalcularaized with b) SDS or c) NH4OH/Trition-X-100 (TX) followed by extraction of residual ECM by MAX. Proteins were trypsinized, peptides identified by MS, and data analyzed with Mascot/Sequest search strategy. ANOVA was used to determine differences in protein abundances.

Results: The total protein yield and number of proteins identified were determined in various numbers of glomeruli slices ranging 50 to 150. There was no significant increase in yield above 75 glomeruli slices. Compared to MAX (2032), extraction with SDS or TX increased the total number of proteins identified (2207 and 2246). The total number of proteins identified from FR and FFPE tissue did not differ for any of the extraction methods. More proteins were identified in residual ECM from FFPE than FR with TX (1863 vs 1713) and SDS (1826 vs 1385). By GO annotation, sequential extraction improved the abundance of ECM, as shown by identification of an increased number of, and increased total sequence coverage of, collagen isoforms. More proteins were identified in the cellular fraction from FR compared to FFPE with TX (1646 vs 1294) and SDS (1804 vs 1115).

Conclusions: Using LCMD, sequential extraction with SDS or TX, and peptide identification by MS, the glomerular ECM proteome of patients can be identified from a number of glomeruli compatible with a typical renal biopsy embedded in paraffin.
FR-PO305
BMP-7 Inhibits Renal Akt Signaling
Debra F. Higgins, Catherine Godson, School of Medicine, Conway Inst, Univ College Dublin, Dublin, Ireland.

Background: Bone morphogenetic protein-7 (BMP-7), a member of the TGFβ-superfamily, counteracts pro-fibrotic TGFβ, and protects from fibrosis in acute and chronic renal injury models.

Methods: Using the chronic fibrosis model, unilateral ureteral occlusion (UUO) and experimental BMP-7 on signaling pathways involved in hypoxia and TGFβ-induced fibrosis. Mice undergoing UUO were treated with either vehicle or rhBMP-7 (300ng/kg i.p.), kidneys were harvested on day 8 post-obstruction and analysed for markers of renal fibrosis and activation of SMAD, MAPK, and PI3K signaling.

Results: Ouo response to UUO, SMAD1/5/8 activity was lost in vehicle-treated kidneys yet maintained in BMP-7-treated kidneys. Collagen accumulation was significantly increased in obstructed kidneys of vehicle-treated animals compared with contralateral and this response was not observed in BMP-7-treated obstructed kidneys. Immunohistochemical analysis of type I, III, and IV collagen revealed that accumulation of type I collagen was significantly impaired in BMP-7-treated obstructed kidneys. Activation of SMAD2, SMAD3, ERK, p38 and Akt signaling pathways occurred during fibrogenesis and BMP-7 significantly attenuated SMAD3 and Akt signaling in vivo. In the kidney, inner medullary collecting duct and tubular epithelial cells are responsive to BMP-7. Analysis in mouse inner medullary collecting duct (mIMCD) and human tubular epithelial (HK-2) cells stimulated with either TGFβ or hypoxia (1% oxygen) to induce Akt activation provided further evidence that BMP-7 could specifically inhibit PI3K / Akt signaling.

Conclusions: These data demonstrate an important mechanism by which BMP-7 orchestrates renal protection through Akt inhibition and strengthens the argument for use of Akt inhibitors as anti-fibrotic therapeutics.

FR-PO306
Prevention of Renal Interstitial Fibrosis by Simultaneous Deletion of Bax and Bak
Hee-Seong Jung, Babu J. Padanilam.1,2 Cellular and Integrative Physiology, Univ of Nebraska Medical Center, Omaha, NE; 1,2, Internal Medicine, Section of Nephrology, Univ of Nebraska Medical Center, Omaha, NE.

Background: Proximal tubular injury and apoptosis are key mediators of development of kidney fibrosis, a hallmark of chronic kidney disease. However, the molecular mechanism by which tubular apoptotic cell death leads to kidney fibrosis is poorly understood.

Methods: Here we tested the roles of Bax and Bak, two crucial proteins involved in intrinsic apoptotic cell death, in progression of kidney fibrosis. Mice with proximal tubular Bax and Bak deletion, systemic deletion of Bak and dual deletion of Bax and Bak were subjected to unilateral ureteral obstruction (UUO).

Results: Dual deficiency of Bax and Bak inhibited tubular apoptosis and atrophy. Consistent with decreased tubular injury, dual ablation of Bax and Bak suppressed UUO-induced inflammation and kidney fibrosis with decreased tubular cell cycle arrest, expression of fibrogenic and inflammatory cytokines, and oxidative stress in the kidney. Bax or Bak deficiency was insufficient to prevent apoptosis and all other aforementioned malevolent effects, suggesting compensatory mediation by each in the other in the respective signaling pathways.

Conclusions: These data suggest that dual ablation of Bax and Bak in the kidney is required to prevent UUO-induced tubular apoptosis and the consequent kidney inflammation and fibrosis.

FR-PO307
Investigating the Role of Cilia in Regulating Fibrosis in the Kidney and Liver Using PKD Mouse Models
Kurt Zimmerman, Cheng 'Jack' Song, Bradley K. Yoder. Cell, Developmental, and Integrative Biology, UAB, Birmingham, AL.

Background: Cystic kidney disorders are frequently caused by mutations in cilia-associated genes (intraluminal transport, IFT) or ciliary signaling proteins (polycystin-1 or polycystin-2). Comorbidities commonly associated with renal cysts include biliary duct abnormalities with associated fibrosis in both tissues. In the kidney of cilian mutants, ischemia reperfusion (IR) injury greatly exacerbates the rate of cyst development; however, it is not known whether IR injury will similarly affect the liver and how loss of cilia affects injury induced fibrosis.

Methods: To address these questions, we are utilizing Oak Ridge Polycystic Kidney (ORPK) mice that have a congenital hypomorphic IFT88 mutation and conditional mutant mice where cilia are disrupted in the kidney (CaggCreER) and liver (Kltoflox). These data demonstrate an important mechanism by which BMP-7 orchestrates renal protection through Akt inhibition and strengthens the argument for use of Akt inhibitors as anti-fibrotic therapeutics.

Klotho Suppresses Epithelial-Mesenchymal Transition (or Transformation) in Adriamycin Nephropathy
Tsuneco Takenaka,1 Tsutomu Inoue, Mutsuhiro Hayashi,1 International Univ of Health and Welfare; 1, Saitama Medical Univ; 1 Keio Univ.

Background: Klotho interacts with various proteins to alter their function. Klotho may bind to the receptor for WNT and TGFβ, inhibiting their signals.

Methods: Experiments were performed to assess how klotho protects kidney from its injury. Adriamycin (5 mg/kg) was injected into rats to induce nephropathy. Human recombinant klotho (K, 30 micro-g/kg/day), 4-benzyl-2-methyl-1,2,4-thiadiazolidine-3,5-dione (GSK3beta blocker, 0.2mg/kg/day, T) or vehicle (A) was administered. Rats which were untreated with Adriamycin were used as control (U). Animals were killed 8 weeks later. Renal expressions of Wnt1, GSK3beta, TGFbeta1, Twist and collagen I were assessed by Western blotting with or without p-GSK3beta and beta-actin. Results: Adriamycin increased albuminuria, renal expression of Wnt1, p-GSK3beta, Twist and collagen I in comparison to the control. Klotho and T suppressed increased renal albuminuria and the phosphorylated GSK3beta and collagen I, but did not elevate Wnt1. These data demonstrate an important mechanism by which BMP-7 inhibits renal Akt signaling and strengthens the argument for use of Akt inhibitors as anti-fibrotic therapeutics.

The Molecular Mechanism of miR-382 in the Pathogenesis of Renal Tubulointerstitial Fibrosis
Yi Fang,1 Ting Xie,1 Hui Zhang,1 Sheng Wu.1 Nephrology, Zhongshan Hospital Fudan Univ, China; 1, Shanghai Key Laboratory of Pediatric Kidney Diseases and Blood Purification.

Background: To investigate the roles of microRNA-382 (miR-382) in the pathogenesis of renal tubulointerstitial fibrosis.

Methods: Human kidney epithelial (HK2) cells that transfected with a miR-382 inhibitor (antago-miR-382) was used to examine the effect of miR-382 abundance on cell polarity, as well as to test the complementary relationship between miR-382 and its predicted target gene, heat shock 60kDa protein 1 (HSPD1), which was further verified by site-directed mutagenesis. We also examined the in vivo role of miR-382 in the development of renal interstitial fibrosis, in a mouse unilateral ureteral obstruction (UUO) model. Locked nucleic acid (LNA) anti-miR-382 was intravenously delivered via tail vein less than 30 minutes prior to UUO, and repeated the dosage 24 hours after the surgery. For clinical verification, renal biopsy specimens from 12 IgA nephropathy (IgAN) patients were collected, 6 with moderate to severe tubulointerstitial fibrosis (TIF) and 6 with no TIF. The relative abundance of miR-382 and HSPD1 protein was analyzed using in situ hybridization and immunohistochemistry.

Results: HSPD1 was confirmed to be a direct target gene of miR-382 by in vitro transfection technique and mutation experiments. The development of epithelial transition or renal interstitial fibrosis was accompanied with up-regulated abundance of miR-382. Down-regulation of miR-382 was associated with significant decreases in fibrotic protein expression of HSPD1 and thioredoxin, both in the obstructed mouse kidneys and renal biopsy specimen from IgAN patients.

Conclusions: miR-382, a profibrotic microRNA, is up-regulated with the development of renal interstitial fibrosis in human and in mice. The down-regulation of HSPD1 and the decreased ability of anti-oxidative stress are secondary to the increased abundance of miR-382.

Assessing the Role of Gremlin-1 on Renal Fibrosis In Vitro 

Marcela Herrera, Lihuan Liang, Asha Seth, Carol Patricia Moreno Quinn.

Cardiovascular & Metabolic Diseases, MedImmune, Cambridge, United Kingdom.

Background: Bone Morphogenic Proteins (BMPs) signal through SMAD1/5/7 to upregulate genes that antagonize fibrosis. The endogenous antagonist gremlin-1 binds and antagonizes extracellular BMPs, inhibiting their anti-fibrotic effects. Gremlin-1 is upregulated in the proximal tubule (PT) of DN patients. We hypothesized that Gremlin-1 participates in the development of renal fibrosis by inducing a pro-fibrotic phenotype in proximal tubules and renal interstitial fibroblasts.

Methods: To test this hypothesis we used HK-2 (human PT cell line) and NRK49F (rat renal fibroblasts) cell lines where the pro-fibrotic phenotype was induced by Transforming Growth Factor b1 (TGFb1: 2.5 ng/mL, 72 hrs). Gremlin-1 secretion and protein expression was measured by Western blotting and gene expression by qPCR.

Results: In PT cells, TGFb stimulated gremlin-1 protein secretion by 2.3 fold (from 57.1 ± 1.2 ng/mL to 2.3 ± 0.5 ng/mL, p<0.05), increased SMAD5 (Figs.1-A,1-F, an extracellular matrix component) by 50% (p<0.05) and reduced expression of c-adehrin (c-CAD, an epithelial marker) by 95% (p<0.05). All changes also occurred at the mRNA level.

Conclusion: Gremlin-1 mRNA significantly reduced gremlin-1 mRNA expression and efficiently blocked the TGFb-induced Gremlin-1 release by 100%. However, Gremlin-1 knockdown did not prevent the pro-fibrotic changes of TGFb. In contrast to PT cells, TGFb did not induce gremlin-1 secretion in renal fibroblasts. TGFb increased FN and a-smooth muscle actin (aSMA, marker of fibroblast activation) in a dose-dependent manner. Addition of grelin-1 (mimicking the in vivo setting) did not exacerbate fibrosis at any dose of TGFb. Addition of recombinant BMP2 was not sufficient to prevent TGFb-induced fibrosis in either cell type. Recombinant BMP2 alone (1 nM) increased SMAD5 phosphorylation and the expression of ID1 (a marker of BMP signalling) at 1 and 24 hrs post treatment. The stimulatory effect of BMP2 was blocked by pro-treatment with recombinant Gremlin-1 (2 nM). These data confirm intact BMP2/gremlin-1 signalling in both cell types.

Conclusion: Our data does not support the participation of gremlin-1 in TGFβ-dependent renal fibrosis in vitro.

Vitamin (Vit) D Repletion Ameliorates Muscle Strength and Muscular Fibrosis in Mice with Chronic Kidney Disease

Wei Ding, Wai W. Cheung, Mary Christine Esparza, Ping Zhou, Richard L. Lieber, Robert H. Mak. Pediatric Nephrology, Univ of California, San Diego, La Jolla, CA.

Background: Cachexia presenting as muscle wasting and weakness is prevalent in CKD patients and may impact their quality of life. We investigated the effects of vitamin D repletion in a mouse model of CKD-associated cachexia.

Methods: CKD in c57BL/6 mice were induced by 5/6 nephrectomy. CKD and sham mice were treated with 25VitD (25 mg/kg/day), 1.25VitD (40 ng/kg/day) or vehicle (V) for 6 weeks via a subcutaneous osmotic pump. CKD+V mice were paired-fed to CKD+V mice. Parameters of energy homeostasis, muscle function (measured by grip strength and rotarod tests) than sham controls (p<0.05). Skeletal muscle fibrosis, a major cause of muscle weakness, was assessed by reduced muscle strength and rotarod tests than sham mice (p<0.01). Increased energy expenditure in CKD+V mice was associated with upregulation of uncoupling proteins (UCPs) in skeletal muscle (p<0.01) and was increased, within the physiological range, by 25VitD and TGFb1 [1.5-fold] as compared to no coating. Likewise, ITGA1, ITGA2, ITGAV, ICAM1, NOX4 were decreased with hLN521 in a dose-dependent manner. Expression of LAMA5, COL4A3, ITGA3 and NO3 were unchanged in all groups.

Conclusion: Our data does not support the participation of gremlin-1 in TGFβ-dependent renal fibrosis in vitro.

The Effect of Cell Culture Surface Coating on Glomerular Endothelial Cell Phenotype

Kamilla Nielsen,1 Zsolt Soma Karpati,1 Daniel Gulderg Kjring Rasmussen,2 Morten Asser Karsdal,1 Federica Genovese,1,2

1Fibrosis Biology and Biomarkers, Nordic Bioscience, Herlev, Denmark; 2System Biology, Denmark Technology University, Kgs. Lyngby, Denmark.

Background: Renal interstitial fibrosis is characterized by dysregulated extracellular matrix (ECM) turnover and protease activity. ECM protein fragments generated by protease cleavage can be measured by specific ELISAs, providing a protein fingerprint of the disease. The aim of this study was to set up an ex vivo model for renal interstitial fibrosis in order to investigate the ECM turnover profile in the fibrotic kidney.

Methods: 14 male 12 weeks old Sprague-Dawley rats underwent Unilateral Ureteral Obstruction (UOO) surgery by ligation of the right ureter. The left kidney (contralateral) was used as internal control. 6 rats were sham-operated and used as control group. Rats were terminated 2 weeks after the surgery, when advanced fibrosis is known to be present. The kidneys were excised and precision-cut tissue slices (PCTS) were cultured for 5 days in serum free medium. Markers of collagen type I formation (P1NP), collagen type III degradation (C3M) and a-smooth muscle actin (α-SMA) were measured in the PCTS supernatants. The extent of tubulointerstitial fibrosis was evaluated by histology.

Conclusions: The UOO PCTS ex vivo model provides a valuable translational tool for investigating the ECM remodeling associated with renal interstitial fibrosis. Since the currently available technologies for measurement of the markers measured in the supernatants also in circulation and in urine, these markers have the potential to accurately and non-invasively describe the tissue remodeling during fibrosis.

FR-PO313

Collagen Degradation Profile in a Nephrotic Nephritis Model

Collagen Degradation Profile in a Nephrotic Nephritis Model

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusions: Different degradation markers of the most abundant proteins in the renal basement membrane (Col4a3 and Col4a5 in type I and III) and in the tubulur basement membrane and mesangium (collagen type IV - a chain) presented a different longitudinal release in urine. While degradation of collagen type III is an early event in this model, maybe reflecting the early inflammatory state, degradation of collagen type IV appears later, when the formation of the scar is evident in histology. These markers could potentially be used to non-invasively describe the fibrotic events in the kidney in experimental models and, since the targeted epitopes are conserved in human, they could be applied in clinical settings.

FR-PO315 Evidence of Podocyte Protrusions into the Basement Membrane in Glomerular Disease Sophie C. Collinson, 1 Michael J. Randles, 1, 2 Mira Kendrel, 3 Eva Koenigshausen, 4 Lorenz Selbin, 5 Ian Roberts, 6 Jeffrey H. Miner, 7 Rachel Lennon, 8 1 Inst of Human Development, Faculty of Medical & Human Sciences, Univ of Manchester; United Kingdom; 2 Wellcome Trust Centre for Cell-Matrix Research, Faculty of Life Sciences, Univ of Manchester; United Kingdom; 3 Dept of Cell and Developmental Biology, SUNY Upstate Medical Univ, Syracuse, NY; 4 Dept of Nephrology, Heinrich Heine Univ, Dusseldorf, Germany; 5 Dept of Cellular Pathology, John Radcliffe Hospital, Oxford, United Kingdom; 6 Renal Div, Washington Univ School of Medicine, St. Louis, MO.

Background: Glomerular disease is a leading cause of kidney failure. Podocyte foot process effacement and glomerular basement membrane (GBM) disruption are frequent abnormalities regardless of the underlying molecular etiology. Standard electron microscopy techniques provide 2D information and 3D ultrastructural relationships are poorly understood. We hypothesized that creation of detailed 3D models of the glomerulus would identify novel pathological features.

Methods: Serial block face-scanning electron microscopy was performed on a series of mouse models of glomerular disease with established albuminuria. 3D reconstructions of glomeruli were created using IMOD 4.7.11.

Results: Sub-podocyte expansions of the GBM were dominant features in Glepp1/-/-, Myoel/-/- and Cola2/2 +/- mice and overall GBM thickness was significantly different to matched wild-type (WT) controls (p < 0.0001). There was a corresponding reduction in podocyte foot process number in each of the models (p < 0.0001). Furthermore we identified novel podocyte protrusions into the GBM in all mutant mice and these were not present in WT controls. There was no evidence of endothelial or mesangial cell protrusions into the GBM and no correlation between GBM thickness and the site of podocyte protrusions.

Conclusions: 3D ultrastructural imaging revealed expected GBM abnormalities in addition to podocyte protrusions, resembling invadasomes, in the GBM. This novel finding provides new insight into disease mechanisms and suggests that a common matrix-adhesion pathway is activated regardless of the primary molecular insult.

FR-PO316 Multi-Clonal Population of Cells of Renin Lineage (CoRL) Transdifferentiate into Podocytes and PECs in Experimental FSGS Natalya V. Kaverina, 1 Diana G. Eng, 1 Jeffrey W. Pippin, 1 Michael E. Rusiniak, 1 Kenneth W. Gross, 3 Stuart J. Shankland, 1 1 Devision of Nephrology, Univ of Washington, Seattle, WA; 2 Dept of Molecular and Cellular Biology, Roswell Park Cancer Inst, Buffalo, NY.

Background: Focal segmental glomerulosclerosis (FSGS) is secondary to podocyte injury and loss. Because adult podocytes cannot proliferate, their replacement by progenitors is critical for their repair and regeneration in disease. Here we explored whether single or multi-clonal repopulation of podocytes resulted in an increase in podocyte number in each of the models (p < 0.0001). Furthermore we identified novel podocyte protrusions into the GBM in all mutant mice and these were not present in WT controls. There was no evidence of endothelial or mesangial cell protrusions into the GBM and no correlation between GBM thickness and the site of podocyte protrusions.

Methods: 3D ultrastructural imaging revealed expected GBM abnormalities in addition to podocyte protrusions, resembling invadasomes, in the GBM. This novel finding provides new insight into disease mechanisms and suggests that a common matrix-adhesion pathway is activated regardless of the primary molecular insult.

FR-PO317 Macula Dense-Derived Factors Control Glomerular Cell Remodeling Anne Riquier-brison, 1 Donna Ralph, 1 Jasmine Ann Arevalo Castillo, 3 Janos Peti-Peterdi. 1 Physiology and Biophysics, Univ of Southern California, Los Angeles, CA.

Background: Macula densa (MD) cells are strategically positioned at the vascular entrance of the glomerulus and control renal hemodynamics and renin. In this study, we addressed a novel, non-traditional role of MD cells regulating glomerular cell plasticity/remodeling by mesenchymal progenitor cells.

Methods: For genetic cell fate tracking, tamoxifen-induced NG2CreERT2-Tomato mice were fed either a control or salt-deficient + ACE inhibition (SD+/ACEi) diet, for 2 weeks to achieve strong MD stimulation.

Results: We observed a 5-fold increase in renal interstitial density of NG2-derived (NG2+) cells (5.9±1.1 cells per field in control, 30.2±4.5 in SD+/ACEi), and the homing of NG2+ cells to the mesangium under the MD and into the glomerulus. This effect was blunted by the selective COX-2 inhibitor SC32636 (COX-2i) or the nNOS inhibitor 7-NI (13.2±2.2 cells per field with COX-2i and 11.6±1.7 with 7-NI). Immunofluorescence (IF) of Claudin-1 showed a 4-fold increase in the number of NG2+ cells in the glomerular parietal layer (0.5±0.2 cells per glomerulus in control, 2.0±0.4 in SD+/ACEi). Podocin IF identified a few NG2+ podocytes. NG2+ cell homing was blunted by COX-2i and 7-NI (2.3±0.3 cells per glomerul with COX-2i, 0.8±0.3 with 7-NI). Co-localization of endogenous NG2-Tomato fluorescence with IF of renin revealed an increase in the proportion of NG2+ renin-expressing cells from 22.0±6.6% to 70.6±4.7% after SD+/ACEi, inhibited by COX-2i. Similarly, the density of proliferating cells expressing Ki67 increased after treatment with both methods from (1±0.9 cells per field with COX-2i and 3.2±1.8 with 7-NI) to (5±1.9 cells per field with COX-2i and 10±2.6 with 7-NI) in the vicinity of the juxtaglomerular area, inhibited by COX-2i (5.6±1.0) and 7-NI (2.7±0.3).

Conclusions: Our results suggest that NG2+ pericytes may be an important progenitor cell population in the kidney. In response to MD-derived (from COX-2 and nNOS) paracrine factors, cells from the renal interstitium proliferate and migrate towards the MD along the arteriole and via the vascular pole into the glomerular epithelium and mesangium. In conclusion, MD cells play new important roles in the maintenance and remodeling of the glomerulus.

FR-PO318 A Novel Method for Assessing Podocyte Depletion in Whole Glomeruli Victor G. Puelles, 1 James William Van der Wolde, 1 Luise A. Cullen-McEwen, 2 Keith E. Bruce, 3 Jonatha Stacey Hokke, 3 Kieran M. Short, 3 Georgina Carrara, 3 Stacey Hokke, 3 Stephen D. Firth, 3 Ian S. Harper, 2 David J. Nikolic-Paterson, 2 John F. Bertram, 1 1 Dept of Anatomy and Developmental Biology, Monash Univ; Melbourne, Victoria, Australia; 2 Monash Micro Imaging, Monash Univ, Melbourne, Victoria, Australia; 3 Dept of Nephrology, Monash Medical Centre, Melbourne, Victoria, Australia.

Background: Podocyte depletion plays a major role in the development and progression of glomerulosclerosis. Given that glomerulosclerosis is often focal, affecting some but not all glomeruli, our aim was to develop a rapid, accurate and precise method for quantifying podocyte depletion in whole glomeruli.

Methods: Pod~*iDR mice, in which expression of the human diphteria toxin (DT) receptor is driven by the podocin promoter, and iDR mice (controls) mice (controls) were injected with 400µg/kg of the diphteria A chain. Slices were cleared with benzyl alcohol, benzyl benzoate (BABB). An SP8 confocal microscope (Leica, Germany) fitted with a BABB objective (NA: 0.95; working distance: 2mm) was used. Total podocyte number was obtained by manual counting and using an automated-aided system (Imaris, Birpline) in 88 whole glomeruli - 38 from iDR mice and 50 from Pod~*iDR mice.

Results: In iDR mice (controls), total podocyte number per glomerulus was almost identical between manual counts (66.6±11.92) and Imaris (65.47±9.26; P=0.65). In Pod~*iDR mice, total podocyte number was also similar between manual counts (52.96±11.74) and Imaris (53.51±11.35; P=0.81). With both methods, podocyte counts were obtained in less than 2 minutes per glomerulus, a significant time reduction compared to existing methods. Imaris also facilitates the estimation of podocyte and glomerular volumes for a semi-automated assessment of podocyte morphology.

Conclusions: This is the first method to combine immuno-fluorescence, BABB-clearing and confocal microscopy to count podocytes in whole glomeruli. The method is accurate, precise and rapid, and provides a novel approach for podocyte morphometrics in settings where sufficient tissue is available for analysis.

FR-PO319 Characterization of Heterogeneous Podocyte Biomechanics Using Atomic Force Microscopy Evren U. Azeloglu, 1 Jia-Jye Lee, 2 Kevin D. Costa, 1 1 Pharmacology and Systems Therapeutics, Icahn School of Medicine at Mount Sinai, New York, NY; 2 Cardiology (Medicine), Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Biomechanical signals play a key role in glomerular physiology, where pathological changes in blood pressure can significantly affect podocyte morphology and function. While there has been a great focus on mechanobiochemical signaling in podocytes, their spatial biomechanical properties have been largely overlooked due to a lack of in
FR-PO320
Identification and Validation of Fluid Flow Shear Stress (FFSS)-Induced Changes in Podocyte Signaling Pathways Using Bioinformatic Tools

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Methods: We performed microarray analysis (Affymetrix GeneChip Mouse Exon 1.0 ST Array) on immortalized podocytes without FFSS (Control), immediately after FFSS (End-FFSS), 2 hours (post-2hr-FFSS), and at 24 hours (post-24hr-FFSS) after cessation of FFSS at 2 dynes/cm² for 2 hr. Mouse exon 1.0 ST Array has ~4 probes/exon and ~40 probes/gene. Data from the microarray were log transformed, normalized and filtered to generate a set of 17,494 genes. Genes that were significant at p<0.01 were analyzed using Ingenuity Pathway Analysis (IPA) and Enrichr Program to identify key pathways.

Results: IPA showed Akt, COX-2, and AMPK (at End-FFSS); TGF-β (at post-2hr-FFSS); and GSK3β, ERK1/2 in all three treatment groups compared with Control.

Conclusions: Our in vitro podocyte assay provides, for the first time, means to reliably identify those patients with idiopathic FSGS who are at high risk of recurrence post-transplant. It may also identify FSGS patients who may be candidates for anti-TNFα therapy that could prevent progressive glomerular injury.

Agalsidase Treatment Clears Gb3 from a Podocyte Model of Fabry Disease

Results: Compared to control cells, α-galactosidase A-deficient podocytes showed a significant reduction of accumulated Gb3 in Fabry podocytes was achieved in vitro with enzyme replacement therapy. Surprisingly, no significant changes in agalsidase-treated podocytes were detected for key enzymes of autophagy regulation under these conditions. In ongoing studies we will use mass spectrometry and different treatment conditions to focus on identifying additional proteins modified by Gb3 accumulation.

Loss of Robo2 in Podocytes Protects Adult Mice from Acute Glomerular Injury

Anna Pisarek-Horowitzi, Xueping Fan, Hila Milo Rasoully, Stefanie Chan, Hui Chen, Ramon G. Bonegio, Joel M. Henderson, David J. Salant, Weining Lu. Renal, Boston Univ Medical Center, Boston, MA.

Background: SLIT2 and its receptor ROBO2 play an important role during kidney development. We have recently found that ROBO2 is expressed in developing glomerular podocytes. However, the role of ROBO2 in the adult mouse kidney, particularly under acute glomerular injury conditions, is not clear.

Methods: To test the hypothesis that loss of ROBO2 in glomerular podocytes affects the outcome of acute glomerular injury, we applied two in vivo acute glomerular injury models induced by nephrotoxic serum (NTS) injection and proteinuric saline (PS) perfusion, in ROBO2 podocyte specific knock out mice (Robo2 CKO) and wild type controls. Kidney glomerular ultrastructure was analyzed by scanning and transmission electron microscopy before and after injury. Podocyte foot process width and slit diaphragm density were measured to quantify the severity of the glomerular injury. Urine albumin to creatinine ratio was measured in the NTS model. Podocyte specific gene expression was analyzed using TaqMan real time PCR for mRNA and Western blot for protein levels.

Results: ROBO2 podocyte specific knockout mice developed less proteinuria after the NTS injury with lower urine albumin/creatinine ratio as compared to the wild type controls. Electron microscopy showed that Robo2 CKO mice have milder foot process effacement and less defects in the slit diaphragm induced by either NTS or PS injury. TaqMan and Western blot analyses revealed that nephrin, a crucial transmembrane component of the podocyte slit-diaphragm, was significantly up-regulated at both mRNA and protein levels in the Robo2 CKO mice before NTS injury and at the late stage of heterologous phase after the NTS injury. In addition, the mRNA levels of Robo2 and Slit2 in the wild type kidneys were also upregulated after the NTS injury.

Conclusions: SLIT2-ROBO2 signaling pathway plays an important role in the adult mouse kidney. Loss of Robo2 protects mice from acute glomerular injury. Our findings suggest that SLIT2-ROBO2 signaling might also have a negative impact on nephrin expression during podocyte injury and be a potential therapeutic target.

Inducible Knockdown of Shroom3 Induces Proteinuria with Podocyte Dedifferentiation

Background: Shroom3 induces proteinuria with features of podocyte dedifferentiation without evidence by IF, significant reduction in area and intensity of glomerular synaptopodin staining was observed starting at 2 weeks compared to controls.

Methods: Electron microscopic studies are ongoing.

Results: Robo2 podocyte specific knock out mice developed less proteinuria after the NTS injury with lower urine albumin/creatinine ratio as compared to the wild type controls. Electron microscopy showed that Robo2 CKO mice have milder foot process effacement and less defects in the slit diaphragm induced by either NTS or PS injury. TaqMan and Western blot analyses revealed that nephrin, a crucial transmembrane component of the podocyte slit-diaphragm, was significantly up-regulated at both mRNA and protein levels in the Robo2 CKO mice before NTS injury and at the late stage of heterologous phase after the NTS injury. In addition, the mRNA levels of Robo2 and Slit2 in the wild type kidneys were also upregulated after the NTS injury.

Conclusions: SLIT2-ROBO2 signaling pathway plays an important role in the adult mouse kidney. Loss of Robo2 protects mice from acute glomerular injury. Our findings suggest that SLIT2-ROBO2 signaling might also have a negative impact on nephrin expression during podocyte injury and be a potential therapeutic target.

Protective Role of Cyclodextrin in Focal Segmental Glomerulosclerosis (FSGS)

Alla Mitrofanova,1 Patricia R. Wahl Pristau,1 Ximena A. Morales,1 Mayrin Correa-Medina,2 Christopher E. Pedigo,1 Gloria Michelle Ducausa,2 George William Burke,2 Sebastian Martini,3 Matthias Ketzler,3 Sandra M. Merscher,4 Alessia Fornoni,5 Katz Family Drug Discovery Center, Nephrology & Hypertension, Univ of Miami, MI; Surgery, Univ of Miami, FL; Internal Medicine, Nephrology, Univ of Michigan, MI; 1Computational Medicine & Bioinformatics, Univ of Michigan, MI.

Background: We recently demonstrated that cholesterol accumulation contributes to podocyte injury in diabetic kidney disease (DKD), where 2-hydroxypropyl-β-cyclodextrin (CD) protects podocytes from cholesterol-dependent damage in vitro and in vivo. We hypothesize that lipid related genes are affected in glomeruli of patients with primary FSGS and compared with CD protected podocytes in experimental FSGS.

Methods: Microarray analysis on glomerular transcripts of lipid-related genes from patients with FSGS (n=54) and from normal living donors (n=6) were obtained from patients enrolled in NEPTUNE, a longitudinal observational cohort looking at individuals with proteinuria. 5-week-old BALB/c female mice were injected with a single intravenous dose of adriamycin (ADR, 11 mg/kg) to develop FSGS-like lesions. 24-hours after ADR injection, osmotic pumps with CD in 0.9% saline solution (40 mg/kg/day) were implanted under the skin for 10 weeks. Measurements of body weight and urine collections for ACR (Albumin/creatinine ratios) were performed weekly. At time of sacrifice, serum creatinine and Blood Urea Nitrogen (BUN) were determined and kidneys collected for histological analysis.

Results: Microarray analysis of the glomerular transcripts in the NEPTUNE cohort demonstrated that cholesterol efflux related genes such as PLIN3, S1P12, S1P14, S1PR1, and lipid dysmetabolism related genes such as SCD, LDLR, ABCG1, were increased in FSGS. CD administration reduced mesangial expansion as well as ACR and BUN observed at 10 weeks in the ADR+CD group compared to the ADR group (p<0.05). No changes in body weight were found.

Conclusions: We concluded that glomerular lipids are altered in FSGS and that 2-hydroxypropyl-β-cyclodextrin protected podocytes in an experimental model of FSGS. Our data suggest that CD could be used as a safe and effective drug therapy in FSGS patients.

FR-PO327

Podocyte-Derived CXCL12 Has a Dual Role in Glomerular Injury and Regeneration

Background: Stromal-derived factor (SDF)-1/CXCL12 is a homoeostatic chemokine facilitating homing and activation of stem cells. Podocytes constitutively produce CXCL12, hence, we speculated on a role of CXCL12 in glomerular regeneration upon injury.

Methods: Glomerular injury was induced by a single i.v. injection of 13mg/kg adriamycin (ADR) in male Balb/c mice, which received either the CXCL12 inhibitor NOX-A12 or the inactive control s.c. at 13.4mg/kg twice a week. Renal progenitor cell properties (RPC) were used for in vitro studies.

Results: ADR-induced podocyte injury at day 7 (injury phase), which subsequently declined without returning back to baseline and being associated within FSGS lesions after 14 days (repair phase). CXCL12 blockade aggravated ADR-induced A/C and podocyte loss at day 7, which implies an autocrine role of CXCL12 for podocyte survival. In contrast, CXCL12 blockade reduced A/C levels and the glomerular sclerosis scores as well as increased podocyte numbers at 14 days indicating a beneficial effect of CXCL12 blockade during the repair phase. The pro-survival effect of CXCL12 on podocytes was further confirmed in a model of diphtheria toxin-induced podocyte depletion using CXCL12 blockade. To investigate the dual effect of CXCL12, we focused on the Notch signaling pathway. ADR injection reduced native Notch expression, which was reversed following CXCL12 blockade. In vitro studies with RPC revealed that CXCL12 suppressed RPC proliferation, which was reversed with CXCL12inhibitor. Similar results were obtained when RPC were exposed to supernatants from neotube podocytes. CXCL12 blockade also increased the capacity of RPC to differentiate into podocytes.

Conclusions: Podocyte-derived CXCL12 has a dual role in glomerular injury. CXCL12 protects podocytes during the injury phase in an autocrine manner by suppressing Notch signaling, which otherwise triggers mitotic catastrophe and podocyte loss. Podocyte-derived CXCL12 assures Notch-mediated quiescence of RPC. Our data also demonstrate that therapeutic CXCL12 inhibition in glomerular injury can improve long term outcomes possibly by enforcing the intrinsic regenerative capacity of RPC.

Shank2 Modulates Glutamatergic Signaling in Podocytes

Ezeigena Dobrinskikh,1 Linda Lewis,1 R. Brian Doctor,2 Judith Blaine.1

1Medicine, Univ of Colorado, Aurora, CO; 2Biology, Univ of Mississippi, Oxford, MS.

Background: Shank2 is a large scaffolding protein that is a master regulator of glutamate receptors at the neuronal postsynaptic density. Knockout (KO) of Shank2 in mice leads to autistic behaviours and abnormal glutamatergic synapto-dendritic structures.

Podocytes have also been shown to express functional N-methyl D aspartate (NMDA) and metabotropic glutamate receptor 1 (mGlur1) receptors which are both members of the glutamate receptor family.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

429A
Results: We have found that podocytes express Shank2 in vivo and in vitro. Since Shank2 plays an important role in regulating glutamate receptor function, we examined the effect of Shank2 knockout on NMDA and mGlur1 expression and function in podocytes. Shank2 KO resulted in decreased expression of NMDA and mGlur1 receptors in glomeruli. We isolated podocytes from wild type and Shank2 knockout mice and created conditionally immortalized Shank2 KO podocytes. Conditionally immortalized Shank2 KO podocytes also demonstrated decreased expression and altered localization of glutamate receptors. In neurons, activation of glutamate receptors modulates intracellular calcium levels by allowing calcium influx into the cell (NMDA receptors) or release of calcium from intracellular stores (mGlur1). When glutamate receptors were transfected with Shank2 KO podocytes, we observed changes in intracellular calcium levels in wild type and Shank2 KO podocytes. At baseline, Shank2 knockout podocytes had significantly fewer calcium spikes than wild type podocytes. Treatment with NMDA and glutamate increased the number of calcium spikes in both wild type and Shank2 KO podocytes but the number of spikes in the KO podocytes was significantly reduced compared to wild type. Podocytes have been shown to communicate with each other via calcium waves. To examine podocyte to podocyte communication after injury, we "burned" a podocyte using high intensity laser power and then examined calcium wave propagation from the site of injury. After burning, wild type podocytes exhibited calcium waves emanating from the injured podocyte whereas no waves were seen in the knockouts.

Conclusions: Taken together these data indicate that Shank2 regulates glutamate receptor function in podocytes. Funding: NIDDK Support

FR-PO329
Podocytes Transcytose Albumin and IgG Using the Neonatal Fc Receptor (FcRn) In Vitro and In Vivo
Eva B. Kopp,1 B. Kopp,1 Judith Blaine,2 1Medical, Univ of Colorado, Denver, CO; 2Kidney Disease Section, NIDDK, NIH, Bethesda, MD.

Background: Proteinuria is strongly associated with kidney disease progression. Podocytes are key constituents of the glomerular filtration barrier (GFB), which determines the selectivity of protein filtration. By even the most conservative estimates between 2 and 9 g of serum proteins a day normally pass through the GFB. The molecular mechanisms whereby podocytes handle albumin and IgG remain to be fully determined.

Results: We have found that transcytosis is the major pathway whereby cultured podocytes handle albumin and IgG. In other epithelial cell types, the neonatal Fc receptor (FcRn) is required for transcytosed endocytosed albumin and IgG, thereby salvaging these proteins from degradative pathways. To examine the role of FcRn in albumin and IgG transcytosis in podocytes, we knocked down FcRn in cultured podocytes using lentiviral shRNA. FcRn knockdown (KD) resulted in a 71±3% decrease in FcRn expression compared to control. In an in vitro transcytosis assay, FcRn KD increased intracellular accumulation and decreased appearance of albumin and IgG in the supernatant, suggesting impaired transcytosis, but the differences were not statistically significant, possibly due to residual FcRn. We therefore isolated podocytes from wild type (WT) and FcRn knockout (KO) mice and created conditionally immortalized WT and KO podocyte lines. Knockout of FcRn resulted in significantly increased intracellular accumulation, assessed by immunostaining and Western blot (densitometric analysis of intracellular protein 1 hr after loading showed 0.37±0.1 (WT) vs 0.97±0.2 (KO), p<0.05 for albumin and 0.52±0.04 (WT) versus 1.03±0.19 (KO), p<0.05 for IgG), and decreased appearance of supernatant albumin or IgG, indicating defective transcytosis. We extended our studies to an in vivo model by creating a podocyte-specific FcRn KO mouse. Podocyte-specific FcRn KO mice demonstrated decreased albumin and IgG transcytosis by 8 weeks of age, assessed by immunostaining. Studies of albuminuria are in progress.

Conclusions: Taken together, these studies indicate that podocytes in vitro and in vivo transcytose albumin and IgG using FcRn. Funding: NIDDK Support, Private Foundation Support

Transcriptional Reprogramming by Wilms' Tumor 1 and FoxC2 in Glomerular Disease
Sandrine S. Fitou,1 Lucy Jung,1 Jeffrey E. Dryer,1 Stuart E. Dryer,1 Mary E. Birkwright,2 Sandrine Ettou,3 Jeffrey E. Dryer,1 1Internal Medicine and Center for Molecular Medicine, Univ of Houston, Houston, TX; 2Center for Biomedical Informatics, Harvard Medical School, Boston, MA; 3Department of Houston, Houston, TX.

Background: We have previously shown that podocytes in patients with acute hantavirus infection were decreased in expression of foxc2, and that conditional immortalized podocytes expressing foxc2 resulted in increased expression of nmda receptor. In this study, we examined the effect of foxc2 expression on podocyte function and its role in regulating glomerular filtration.

Methods: We examined the effect of foxc2 expression on podocyte function. We used a shRNA approach to knockdown foxc2 in primary podocytes and immortalized podocytes. We examined the effect of foxc2 expression on podocyte function using functional assays, including transcytosis, calcium wave propagation, and cell-to-cell contact formation.

Results: We found that foxc2 expression increased transcytosis, calcium wave propagation, and cell-to-cell contact formation in podocytes. We also found that foxc2 expression increased the expression of nmda receptor in podocytes.

Conclusions: Foxc2 expression increases the function of podocytes, including transcytosis, calcium wave propagation, and cell-to-cell contact formation. These results suggest that foxc2 expression may be a therapeutic target for glomerular disease.

FR-PO331
A Basophilic Kinase Site at the N-Terminus of TRPC6 Controls Channel Activity
Hanns-Joerg Hagmann,1 Markus M. Rinschmann,1 Alexander Kuczkowski,1 Stuart E. Dryer,1 Bernhard Schermer,1 Thomas Benzinger,1 Paul T. Brinkkoeetter,1 1Nephrology, Univ Hospital Cologne, Cologne, Germany; 2Bichemistry, Univ of Houston, Houston, TX.

Background: The non-selective cation channel TRPC6 plays a pivotal role in the development of proteincoric kidney disease. Hyperactivity of TRPC6 either through gain of function mutations, increased total protein levels or membrane abundance of the channel protein has been associated with glomerular disease.

Results: To investigate regulation of the TRPC6 channel activity we conducted mass spectrometry experiments to screen for phosphorylation sites in the TRPC6 protein. We identified several new as well as previously known phospho-peptides. The serine residues in position 13 and 14 of the human TRPC6 protein are phosphorylated and embedded in a basophilic kinase motif. Substitution of the serine residue in position 14 with alanine (S14A) leads to a reduced TRPC6 conductance in voltage clamp experiments in Xenopus oocytes. The atypical cyclin-dependent kinase (Cdks), a serine-threonine-kinase expressed in the podocyte, is directed to basophilic motives. In the podocyte, Cdks is activated by the specific activators p35, p25, and CycI n. In cell culture experiments a direct phosphorylation of TRPC6 by Cdks/p35 in position S14 could be confirmed with mass spectrometry and radioactive in vitro kinase assays. Co-expression of Cdks/p35 and TRPC6 enhanced channel conductivity of TRPC6 in voltage clamp experiments. This effect was abrogated by the amino acid substitution S14A.

Conclusions: A basophilic kinase site at the N-terminal of TRPC6 was identified which controls channel activity. As exemplarily shown for Cdks/p35, basophilic kinases phosphorylate TRPC6 at serine 14 and affect channel function. This site may serve as a molecular switch for TRPC6 activity and as a potential future drug target. Funding: Private Foundation Support

FR-PO332
Hantaviruses Associate with Actin Fibers and Cause Podocyte Damage
Stefan Häggle,1 Alexandra Kowalski,1 Jochen Reiser,1 Martin G. Zier,1 Ellen Krautkrämer,1 1Nephrology, Univ Hospital Heidelberg, Heidelberg, Germany; 2Dept of Internal Medicine, Rush Univ Medical Center, Chicago, IL.

Background: Characteristic for the clinical picture of Old World hantaviruses is an acute renal failure with often massive non-selective proteinuria. Previously, we showed that cell-to-cell contact proteins were disrupted and levels were decreased in infected human renal cells, correlating with the clinical picture. However, the exact mechanisms driving hantavirus pathogenesis are not well characterized.

Methods: Renal biopsies of patients with acute hantavirus infection were analyzed by electron microscopy. A human podocyte cell line was used for infection with Hantaan virus (HTNV). Cell-to-cell contact proteins were analyzed by immunoblotting, qRT-PCR and immunofluorescence. The cytoskeleton was examined by confocal microscopy and by depolymerising drugs. Cell motility was measured by migration assays.

Results: Analysis of renal biopsies revealed podocyte foot process effacement with loss of cell-to-cell contacts. To examine the underlying mechanism of hantavirus-induced alterations, we performed in vitro infection studies. We showed that HTNV had no influence on transcription levels of cell-to-cell contact proteins, indicating another mechanism of cell-to-cell contact disruption. Next, we focused on an impact on the cytoskeleton which is important for barrier function. We detected a filamentous pattern of the hantaviral nucleocapsid (N) protein which was associated with actin fibers. This N protein localization implies a role of the integrity of the actin cytoskeleton, because the filamentous pattern disappeared after actin depolymerization. Correspondingly, we measured decreased viral release levels after loss of N protein filaments. During infection, we revealed impaired podocyte motility as a functional consequence due to hantavirus-induced effects on actin dynamics and cell motility functions.

Conclusions: These results demonstrate that hantavirus infection leads to podocyte injury by morphological changes. Disruption of cell-to-cell contacts may be caused by the association of N protein and actin leading to changes in podocyte motility. These findings provide useful insights into the mechanism inducing renal failure.
Results: The mice showed variable levels of proteinuria and GS. p110γ-positive cells per high power field (HPF) in glomeruli correlated significantly with glomerular COL1A2 mRNA content. In culture, p110γ+ KD podocytes, but not WT cells, demonstrated increased membrane ruffling along with distinct Rac1 staining at the membrane, and KD podocytes were resistant to in vitro ADR treatment. WT cells expressing constitutively active p110γ showed decreased cytoskeletal stress. Decreased cytoDEATH early after podocyte damage was detected, suggesting that p110γ activity directly mediates podocyte dysfunction.

Conclusions: p110γ expression in podocyte correlates with degree of GS, and therefore, a potential maker for GS. p110γ activity mediates podocyte damage by affecting signals that is critical for cytoskeletal structure.

Effects of FSGS-Associated Mutations on the Stabilization and Function of Nephritic Factor

Background: Myosin is expressed in podocytes and plays a key role in regulating the integrity of their cell-cell junctions, however, the effects of FSGS mutations on Myo1e motor activity and stability have not been directly tested. In this study, we used a simple model organism, fission yeast Schizosaccharomyces pombe, to test the effects of FSGS-associated mutations on myosin activity. Fission yeast has only one class I myosin, Myo1, which is involved in actin microfilament assembly at the sites of endocytosis.

Methods: The amino acid residues mutated in the FSGS patients are conserved between human Myo1e and yeast Myo1, which allowed us to introduce equivalent mutations into yeast myosin and use the resulting mutant strains for functional analysis. Mutant Myo1 localization and stability was analyzed using fluorescence imaging and Western blotting. Myo1 activity functional was tested using growth and endocytosis assays.

Results: Yeast strains expressing mutant Myo1 exhibited defects in growth and endocytosis similar to those observed in the myo1 deletion strain. These mutations also disrupted Myo1 localization to endocytic actin patches and resulted in mis-localization of Myo1 to eisosomes, linear membrane microdomains found in yeast cells. While both mutants examined in this study exhibited loss of function, one of these mutants was also characterized by the decreased protein stability.

Conclusions: Using the yeast model system we were able to determine that the kidney disease-associated mutations impairs myosin functional activity and have differential effects on protein stability. This study provides the first example of using fission yeast as a model system to test the effects of FSGS mutations on Myo1e function. This novel system allowed us to definitively establish that the first and the second cation of the myosin motor activity and its ability to support normal glomerular filtration.

Vinculin Binds Zonula Occludens-1 (ZO-1) and Is Required for Podocyte Stabilization of the Slit Diaphragm following Injury

Background: Cell-matrix interactions and intercellular junctions in podocytes are important factors to prevent protein leakage through the glomerular filtration barrier. Vinculin, a cytoplasmic protein, links the actin filaments to integrin-based cell-matrix proteins and cadherin-based intercellular junctions. We have observed that vinculin is highly expressed in podocytes, and appears to be critical in maintaining slit diaphragm integrity following injury through its interaction with ZO-1.

Methods: Wild type and Vinculin (Vcl) podocyte knock out (KO) mice were analyzed to determine the role of vinculin in vivo, and primary podocytes were isolated for in vitro studies.

Results: Podocyte specific ablation of Vcl resulted in no significant difference in body weight, albuminuria, and kidney histology up to 18 months when compared to litterate controls. However, Pod-Vcl KO mice had significantly increased albumin/creatinine ratios following lipopolysaccharide (LPS) or rabbit anti-mouse glomerular basal membrane (NTS) induced podocyte damage respectively (284±40 vs 411±31 µg/mg, and 205±28 vs 314±38 µg/mg, P<0.05). In addition, loss of Vcl in podocytes resulted in worsened foot process effacement. Co-immunoprecipitation of vinculin and ZO-1 in primary podocytes and isolated glomeruli respectively. Cell fractionation of control and Pod-Vcl KO podocytes treated with either LPS or proteinase sulfite (PS) revealed a mislocalization of ZO-1 and nephrin to the cytoplasm in the mutant podocytes when compared to the control. These findings were further validated by immunofluorescence imaging of the primary podocytes following LPS or PS stimulation and from isolated glomeruli following LPS or NTs stimulation. No changes in cell adhesion or focal adhesion number were observed between the control and Pod-Vcl KO podocytes following LPS or PS stimulation on various substrates.

Conclusions: Our results reveal an association between vinculin and ZO-1 in podocytes. Loss of Vcl in podocytes results in the mislocalization of slit diaphragm proteins ZO-1 and nephrin following injury, thus exacerbating proteinuria.

AT1 Receptors in Podocytes Control GFR and Susceptibility to Kidney Injury
Stacy Alana Johnson,1 Tiffani N. White,1 Susan B. Gurley,2,1 Thomas M. Coffman,1,2 1Duke Univ; 2Durham VA; 2Duke-NUS.

Background: Angiotensin II, acting via AT1 receptors, plays a critical role in the progression of CKD. Pharmacologic blockade of AT1 reduces albuminuria and this is linked to its efficacy in CKD. Within the kidney, the density of AT1 receptor expression is highest in the glomerulus, where AT1 receptors are expressed in multiple cell lineages and are involved in regulating glomerular pressures and GFR. However, the key cellular actions of the glomerulus involved in physiological regulation and in promoting proteinuria have not been directly defined. Since podocyte dysfunction and injury have been implicated in the development and progression of many glomerulopathies, we investigated the role of AT1 receptors in podocytes using cell-specific genetic targeting.

Methods: Because the minor AT1 receptor isoform (AT1b) is expressed at significant levels in podocytes, we generated mice lacking all AT1 receptors in the podocyte (PodKO) by crossing AT1 KO mice with a CRE-mediated excision of a conditional allele of the major AT1 receptor isoform (AT1a) on an AT1a-null background. Results: PodKO mice develop normally with kidney weights similar to controls (6.9±0.5 vs 7.0±0.3 g/bw) and their glomerular morphology appears normal. GFR was significantly reduced in 24-week-old PodKO (8.9±3.5 ml/min/100g) compared to controls (29.5±4.5 ml/min/100g; p<0.04), but there was no significant difference in the low levels of albumin excretion between the groups. To determine whether the elimination of AT1 receptors from podocytes impacts albuminuria and kidney injury in a model with high levels of Ang II, a transgene (Ren/2g) driving constitutive expression of renin was crossed onto the PodKO background. At 24 weeks of age, levels of albuminuria were increased in Ren/2g-PodKO mice (210±71 µg/24 hr) compared to controls (29.9±24 µg/2 hr; p<0.02), but this increase in albuminuria was unaffected in Ren/2g-PodKO mice (229±38 µg/24 hr). Despite similar levels of albumin excretion, kidneys from Ren/2g-PodKO mice had exaggerated kidney injury with more glomerulosclerosis, mesangial expansion and tubular casts.

Conclusions: Our results suggest that AT1 receptors in podocytes do not promote albuminuria and may protect against glomerular injury. Funding: Private Foundation Support.

H2O2 Production by Nox4 Drives Ang II – Dependent Calcium Influx Through TRPC6 Channels in the Podocytes
Dara Ilaratskaya, Oleg Palgyn, Leonid S. Shuyksiy, Alexander Staruschenko. Physiology, Medical College of Wisconsin, Milwaukee, WI.

Background: Improper Ca2+ handling by the podocyte can result in cell damage and loss of function. Podocyte depletion and associated glomerulosclerosis are typical for states of oxidative stress and elevated interstitial Ang II levels. Our data indicated that in the podocytes Ang II stimulates generation of H2O2 by the Nox4, which evokes a dose-dependent Ca2+ influx through TRPC6 channels. The goal of this study was to provide a mechanistic insight into the Ang II-expression under adverse milieus (AMs).

Methods: Changes in intracellular Ca2+ levels were measured with live confocal microscopy in podocytes of isolated glomeruli. Patch clamp analysis was performed to assess the activity of TRPC channel in this preparation. Enzymatic biosensors technique was applied to determine H2O2 release in the kidney cortex and isolated glomeruli.

Results: H2O2 release in renal tissue was increased in AMs. When Nox4 was knocked down, AT1R-BLK protection was lost. In isolated glomeruli of mice with AMs, AT1R-BLK protection and TRPC6 expression was lost. Levels of NO were decreased in AMs. In vitro conditions mimicking AMs, in which oxidative stress was induced by xanthine oxidase reductase, AT1R-BLK could not protect podocytes from reductive stress damage or 4-nitroquinoline-1-oxide induced injury.

Conclusions: Our data indicate that in the podocytes Ang II stimulates generation of H2O2 by the Nox4, which evokes a dose-dependent Ca2+ influx through TRPC6 channels. Our results suggest that AT1 receptor expression promotes podocyte injury and dysfunction under oxidative stress conditions. AT1 receptor expression promotes podocyte injury and dysfunction under oxidative stress conditions. ST2-depleted podocytes lacked AT1R-BLK-mediated protection against DNA damage, suggesting that AT1 receptor expression promotes podocyte injury and dysfunction under oxidative stress conditions. ST2-depleted podocytes lacked AT1R-BLK-mediated protection against DNA damage, suggesting that AT1 receptor expression promotes podocyte injury and dysfunction under oxidative stress conditions. Results: Podocytes carry out energy metabolism. On one hand, VD-VDR complexes not only increased podocyte Ac-H3 levels but also enhanced CYP24A1 expression, thus suggesting their acetylating and gene activation properties. AT1R-BLK-induced podocyte SMRT inhibited expression of the pro-apoptotic gene BAX through down-regulation of Wnt1 and phosphorylation of Akt2 in high glucose milieu. Since SMRT-depleted podocytes lacked AT1R-BLK-mediated protection against DNA damage, it appears that SMRT is necessary for DNA repairs during AT1R-BLK.

Conclusions: AT1R-BLK provides podocyte protection in AMs predominantly through SMRT expression and partly through unliganded VDR expression in 1, 25(OH)2D deficient states. The other hand, AT1R-BLK contributes to liganded VDR expression in 25(OH)2D sufficient states. Funding: NIDDK Support.

Enhanced S-Nitrosylation and N-Glycosylation of Podocin-R138Q May Contribute to Its Defective Trafficking and Rapid Degradation
Maria Carmen SERRANO-Perez,1 Fabien Nevo,1 Christelle Arrondel,1 Alda Tufo,2 Corinne Antignac,1 Geraldine Mollet.1 1Inserm U1163 - Imagine Inst - Paris Descartes Univ-Sorbonne Paris Cité, France; 2Yale Univ School of Medicine- Dept. of Pediatrics.

Background: Missense mutations in the NPHS2 gene, encoding podocin, are a major cause of juvenile and sporadic cases of steroid-resistant nephrotic syndrome (SRNS). Among them, those encoding endoplasmic reticulum (ER)-retained mutant proteins, e.g. R138Q, correlate with the most severe cases of SRNS.

Methods: We generated two human podocyte cell lines stably expressing 2HA-podocin1 or 2HA-podocinR138Q to perform comparative studies on podocin post-translational modifications and podocin degradation.

Results: We detected increased podocin S-nitrosylation and N-glycosylation in 2HA-podocin1 vs. 2HA-podocinR138Q podocytes, which may modulate podocin topology, degradation and trafficking. We also show that a further interaction of podocin-R138Q with ER-retention signal of the mutant may contribute to its ER-retention (ERK) and enhanced S-nitrosylation (SN). In line, we show by Western blotting using antibodies against the higher degradation rate of podocin-R138Q previously found in R14OQ knock-in mice, we found that non-glycosylated (ng) podocinR138Q has a dramatically shorter half-life than podocin1. Moreover, the NG-podocinR138Q isoform is more stable than its non-glycosylated fraction. We also show that ng-podocinR138Q is mainly degraded by the proteasome, whereas ng-podocin can be degraded by both the proteasomal and the lysosomal proteolytic machineries. Furthermore, preventing ng-podocinR138Q degradation allows its partial localization to the podocyte filopodia, improves the ratio between its non-glycosylated and glycosylated forms and reduces its interaction with calnexin.

Conclusions: These findings show podocin S-nitrosylation for the first time and suggest that increased S-nitrosylation and N-glycosylation may contribute to the defective trafficking and degradation of podocinR138Q, the product of the most frequent human podocin missense mutation, and possibly of other human podocin missense mutants.

RAS Inhibition Enhances Proliferation and Migration of Cells of Renin Lineage (CoRL) as Progenitors in Experimental FSGS
Julia Lichtnerck,1 Diana G. Eng,1 Jeffrey W. Pippin,1 Kenneth W. Gross,2 Stuart J. Shankland,1 1Div of Nephrology, Univ of Washington, Seattle, WA; 2Dept of Molecular and Cellular Biology, Roswell Park Cancer Inst, Buffalo, NY.

Background: RAS inhibitors are used therapeutically in proteinuric glomerular diseases. In focal segmental glomerulosclerosis (FSGS) where podocyte number is depleted, recent data showed that ACE-Inhibitors could improve podocyte number. Because adult podocytes do not proliferate, replacement by renal progenitors is critical for their regeneration in disease. The impact of RAS blockade on adult podocyte progenitors is not well understood.

Methods: Experimental FSGS characterized by podocyte depletion was induced by an anti-podocin antibody in two strains of Cells of Renin Lineage (CoRL) reporter mice (RenCre and RenCreER) where CoRL are fate mapped. Diseased mice were randomized at day 3, when podocyte number was depleted by 40%, to receive Enalapril or Losartan, or the controls Hydralazine or water. BrdU was injected to monitor proliferation.

Results: Following initial injury, CoRL number in all groups increased at one week (measured by p57 staining) was higher in both Enalapril and Losartan groups on d14 and d28. This was accompanied by significantly lower proteinuria and glomerulosclerosis. The number of CoRL increased in the intraglomerular compartment in FSGS mice given water or hydralazine. However, the number of labeled CoRL further increased significantly in FSGS mice given Enalapril or Losartan. A subset of CoRL detected in the glomerular compartment co-expressed several markers for podocytes and PEcCs. RAS inhibition increased BrdU staining in CoRL in the juxta- and intraglomerular compartments, but was not seen in podocytes.

Funding: Government Support - Non-U.S.
Conclusions: Following the abrupt depletion of adult podocytes in experimental FSGS, RAS blockade significantly increased the number of progenitor cells in the glomerular compartment. We show the first time that RAS inhibition has the potential to stimulate progenitor cells necessary for kidney repair and regeneration following podocyte depletion.

FR-PO343
SheC Influences Nephrin Endocytosis and Protects from Glomerular Injury
Claire E. Martin,1 Kelly A. Petersen,1 Lamine Aoudjit,1 Tomoko Takano,2 Nina Jones.1 1Molecular and Cellular Biology, Univ of Guelph, Guelph, ON, Canada; 2Dept of Medicine, McGill Univ, Montreal, QC, Canada.
Background: The transmembrane protein nephrin is a key component of the slit diaphragm (SD). It has recently been postulated that nephrin turnover plays a key role in maintaining a healthy SD, and multiple theories regarding the role of nephrin phosphorylation in endocytosis are emerging. Tyrosine phosphorylation of the cytoplasmic tail of nephrin facilitates recruitment of several signaling proteins that regulate podocyte shape and thereby perselectivity of the SD. Previous work from our lab has identified and mapped the interaction between nephrin and the SheA adaptor protein and demonstrated an early requirement for SheA in maintenance of the filtration barrier in mice. Given SheA's established role in endocytosis, we now hypothesize that SheA may regulate nephrin endocytosis to ultimately maintain filtration barrier integrity.

Methods: Multiple approaches were used to measure the influence of SheA and SheA domain mutants on the levels of surface nephrin and signaling downstream of nephrin. Parameumaminocollasidate (PAM) nephrinosis was induced in Sprague-Dawley rats for 0, 4, 7, or 14 days and nephrin endocytosis was monitored via biotinylation and immunofluorescence experiments.

Results: We demonstrate that SheA expression is increased in podocytes in response to PAM injury, which is accompanied by activation of the stress-activated p38 and JNK MAP kinases. Interestingly, we found that transactivation of AP-1, which occurs downstream of nephrin signaling, as well as p38 and JNK, is attenuated by SheA, and this effect is reversed by mutation of the SheA SH2 domain, which mediates nephrin binding. Further investigation revealed that SheA promotes nephrin endocytosis in a phospho-dependent manner by enhancing Src-mediated nephrin phosphorylation, its own binding to nephrin and endocytosis into EEA1-positive endosomes both in vitro and in PAN-treated rats.

Conclusions: Together these findings suggest a protective effect of SheA in podocytes by influencing phospho-dependent nephrin endocytosis and possibly attenuating nephrin-mediated p38/JNK signaling in response to injury.
Funding: Government Support - Non-U.S.

FR-PO344
Podocyte Specific Response to Complement Challenge
Anne Katrin Dettmar,1 Magdalena Riedl,1 Fred G. Pluthero,2 Moin Saleem,2 Jun Oh,2 Christoph Licht,2 1Dept of Pediatrics, Univ Medical Center Hamburg-Eppendorf; 2Dept of Pediatric Nephrology, Hospital for Sick Children; 3Academic Renal Unit, Univ of Bristol.

Background: There is a multilayered system of fluid phase and surface bound complement regulatory proteins, which ensure that complement activation occurs only site specific and spares the body's own cells. Unrestricted complement activation is a main cause for damage in complement-mediated glomerulopathies such as C3G or membranoproliferative glomerulonephritis (MN). In MN, podocytes, key components of the glomerular filtration barrier, are target of overshooting complement activation. The aim of this study was to characterize the complement defense mechanisms in podocytes and their response to complement challenge (CC).

Methods: We analyzed complement regulators by immunofluorescence, flow cytometry and qRT-PCR in immortalized human podocytes and compared them to blood grown endothelial cells (BOECs). Functionality of secreted complement factor H (CFH) was tested via a cofactor assay. In a model for CC (sensitization with antibodies against membrane-anchored complement regulators CD46, CD55 and CD59 and normal human serum (NHS)) we analyzed C3c deposition, LDLH-release, and cell morphology.

Results: Podocytes showed similar levels of CD46, CD55 and CD59 as BOECs. Expression of CFH mRNA was higher in podocytes (1.03 +/-0.27 vs. 0.25 +/-0.09 fold change, p=0.03). Podocyte secreted CFH served as active cofactor to CFH in splitting C3b. CC led to increased C3c deposition (NHS vs CC: 660 +/-189 vs 5290 +/-2231 MFI, p=0.05), which was complement dependent (heat inactivated serum: 211+/-25, p=0.04). There was a significant increase in LDLH release (NHS vs. complement 1.92 +/-0.98 vs. 2.30 +/-0.86 fold increase, p=0.02), and podocytes showed a reduction of stress fibres and cell size after CC.

Conclusions: In summary, podocytes expressed complement regulators in response to complement activation similar to the response found in BOECs. CFH, less abundant in BOECs, may play an important role in a complement specific stress response of podocytes. These findings might help to understand the role of podocytes in local complement activation and will help to identify new therapeutic strategies in future.

FR-PO345
Ephrin-B1 Is Essential for the Formation and the Maintenance of the Integrity of the Silt Diaphragm Component: Inducible Podocyte-Specific Ephrin-B1 Deletion Causes Irregular Localization of Nephrin, NEPHI, CD2AP and ZO-1
Yoshiyasu Fukusumi, Hiroshi Kawachi. Dept of Cell Biology, Inst of Nephrology, Nigata Univ Graduate School of Medical and Dental Sciences, Nigata, Japan.

Background: Ephrin and eph function as receptor-ligand pairs, and are reported to play multiple functions in several tissues. We have reported ephrin-B1 was expressed at the podocyte slit diaphragm (SD) and had an interaction with nephrin, a critical component of the SD (Kidney Int 72: 954, 2007). However, the function of ephrin-B in the SD is not determined yet. In this study, the role of ephrin-B in the SD and the functional association of ephrin-B and nephrin were elucidated.

Methods: (i)The expressions of the SD components (nephrin, NEPHI, podocin, CD2AP and ZO-1) were analyzed in tamoxifen-inducible podocyte-specific Ephrin-B1 knockout (KO) mice (Podocin-CreERT2; Ephrin-B1 flox/flox). (ii)The effect of the nephrin specific deletion on the molecular confirmation of ephrin-B were analyzed.

Results: (i)Tamoxifen-induced inactivation of the ephrin-B1 gene at E18.5 resulted in the dislocalization of nephrin, NEPHI, CD2AP and ZO-1, although podocin dislocalization was not detected. These alterations of the molecular arrangement of the SD components were also detected in the mice of which ephrin-B1 was deleted at 3 month-old with tamoxifen (KO vs. cont, n=5: nephrin, score 3.11 vs. 3.40, p=0.01; NEPHI; 2.97 vs. 3.36, p=0.05; CD2AP, 3.01 vs. 3.24, p=0.05; ZO-1: 3.28 vs 3.66, p=0.05). (ii) Not only nephrin but also ephrin-B was phosphorylated in the rat nephrotic model caused by the injection with the antibody against nephrin, although phosphorylation of these molecules was not detected in normal rats. The phosphorylation of these molecules were detected already at 1 h after the antibody injection. The ephrin-B phosphorylation was also induced by the treatment with the anti-nephrin antibody in HEK293 cells co-transfected with ephrin-B and nephrin.

Conclusions: Ephrin-B1 is essential for the formation and the maintenance of the proper arrangement of the SD molecules. The stimulation to nephrin with the antibody phosphorylated not only nephrin but also ephrin-B, indicating ephrin-B is functionally associated with nephrin.

Ubiquitin C-Terminal Hydrolyse-L1 Deficiency in Podocytes Protects from Immune Complex Nephritis in Mice
Julia M. Fehler,1 Marlies Sachs,1 Thorsten Wiech,2 Rolf A. Stahl,1 Catherine Meyer-Schwesinger.1 Nephrology, Dept of Internal Clinic, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany; 2Pathology, Univ Medical Center Hamburg-Eppendorf, Hamburg, Germany.

Background: Ubiquitin C-terminal Hydrolyse-L1 (UCH-L1) is a central deubiquitinating enzyme of the neuronal ubiquitin proteasomal system. UCH-L1 is thought to regulate the intracellular pool of monoubiquitin in neurons. Recently we identified a de novo expression of UCH-L1 in podocytes of patients with membranous nephropathy. Upregulation of UCH-L1 correlated with disease progression, accumulation of ubiquitinated proteins and altered expression of podocyte-specific proteins in human and rodent podocytes. Inhibition of UCH-L1 enzymatic function in a rat model of membranous nephropathy decreased the abnormal protein accumulation and ameliorated the clinical course of disease. We generated mice with podocyte-specific UCH-L1-deficiency to investigate the role of UCH-L1 in the course of immune complex nephritis in mice.

Methods: Mice with podocyte-specific UCH-L1-deficiency were generated by Cre-Lox technology and back-crossed into the C57/B16 background. Podocyte phenotype was evaluated by morphological (immunohistochemistry, electron microscopy) and biochemical techniques (Western blotting, proteasomal activity assays, real-time PCR) in unchallenged and anti-podocyte antibody challenged wildtype and knock-out mice.

Results: Unchallenged podocyte-specific UCH-L1-deficient mice exhibited normal podocyte morphology throughout life and delayed age-related proteinuria accompanied by a decreased accumulation of poly-ubiquitinated proteins. Following induction of anti-podocyte nephritis, podocyte-specific UCH-L1-deficient mice showed decreased signs of podocyte injury and decreased proteinuria despite a comparable immunologic reaction to the injected anti-podocyte antibodies. Podocyte-specific proteins such as nephrin and podocin protein levels and protein accumulation was decreased. UCH-L1-deficiency resulted in increased proteasomal capacity and activity in injured podocytes.

Conclusions: Podocyte-specific UCH-L1-deficiency protects podocytes from age-related degenerative changes and from immune complex nephritis through increased proteasomal capacity.

Adhesion and Repulsion of Podocytes: Role of EphB-Receptors
Eva Koenjeshausen, Julius Hoffacker, Lukas Ludwig Peter Heimann, Nils Tim Haep, Magdalena Woznowski, Ivo Quack, Lars C. Rump, Lorenz Sellin. Univ Hospital Duesseldorf.

Background: Eph-receptor kinases mediate cell adhesion and repulsion at specialized cell contacts. Eph-receptor kinases bind to their cell-membrane bound ligands, the ephrins. EphB1 and EphB4 have been localized at the slit diaphragm. The molecular function of the EphB1,2,3 receptors in podocytes is unknown so far. Proteasmatin is a hallmark for...
glomerular disease and results from disruption of the glomerular filter. The slit diaphragm is a specialized gap junction between adjacent podocytes. Maintenance of the correct position, adjacent podocytes has not been well understood.

**Methods:** RNA was isolated from differentiated human podocytes and isolated murine glomeruli and PCR performed. Human podocytes were retrovirally transduced with EphB1- YFP, Ephrinb1-DCFP and ephrinb1-DCFP and EphB2-YFP and ephrinb1-DCFP cells were examined. To investigate the role of the intracellular domains of the EphB2 receptor and ephrinb1 ligand, truncated mutants of EphB2 and ephrinb1 (ephrinb1-DC-FP) were analyzed.

**Results:** Human podocytes as well as murine glomeruli express EphB1, 2 and 3 receptors. Co-cultures of differentiating EphB2-YFP and ephrinb1-DCFP podocytes show repulsion between the two cell types. Transendoctyesis (YFP particles in CFP cells and vice versa) occurs in both cell types during repulsion. The repulsion is dependent on the intracellular domain of Ephb2 as Ephb2-DC-CFP cells adhere to ephrinb1-DC-FP and ephrinb1-DC-CFP cells. However, repulsion is maintained in co-cultures of Ephb2-YFP with ephrinb1-DC-CFP cells. Co-culture experiments of differentiated, confluent podocytes confirm the results presented above.

**Conclusions:** EphB2 receptors mediate podocyte repulsion upon binding to their ligand ephrinb1. The EphB2 receptor cytoplasmic domain seems to be crucial for repulsion. Maintaining the correct podocyte distance within the highly organised glomerular architecture has not been well understood. These cell culture data provide a promising concept of potential regulation of podocyte distance in vivo.

**Overexpression of the Splice Isoform VEGF165b Is Sufficient for Kidney Function Preservation When VEGF165b Genes Are Deleted**

Megan Stevens, Chris R. Neal, Andy Salmon, David O. Bates, Steven J. Harper, Sebastian Oleane.

**Background:** Chronic kidney disease is associated with reduced VEGF-A expression. However, the role of VEGF-A splice isoforms in podocyte kidney physiology and pathology is unclear. Use of an alternative 3’ splice site in the terminal exon of VEGF-A results in the expression of anti-angiogenic VEGF165b. Previous studies suggest that VEGF165b is protective in renal function in diabetic rodent models. This study aimed to investigate whether constitutive podocyte over-expression of VEGF165b is able to rescue the injury phenotype seen in the inducible podocyte-specific VEGF-A KO mouse. The mechanism of action of VEGF165b within the glomeruli was also investigated.

**Methods:** Podocyte-specific VEGF-A KO was induced via doxycycline for 10-14 weeks in WT, VEGF-A KO and VEGF-A KO × neph-VEGF-A mice. In situ hybridization confirmed a knock-down of VEGF-A. The kidney functional phenotype was determined through the urinary albumin creatinine ratio (uACR) and measurement of glomerular water permeability. Electron microscopy was used to examine the ultra structure of the glomeruli, and immunofluorescence to determine the expression levels of podocyte and endothelial-specific proteins. Glomerular endothelial cells (GEnCs) in culture were used to determine the mechanism of action of VEGF165b through VEGFR-2.

**Results:** The VEGF165b isoform alone is sufficient to rescue the increase in albuminuria and glomerular water permeability in the context of progressive depletion of all VEGF-A isoforms. Ultra structural studies show glomerular basement membrane thickening and increased podocyte slit width in the VEGF-A-KO mouse, with both being rescued in the VEGF165b over-expressers. VEGF165b also restores PECAM expression in GEnCs, and glomerular capillary circumference. Mechanistically, VEGF165b increases VEGF-R2 expression and phosphorylation both in vivo and in vitro. Furthermore, it down regulates genes involved in the migration and proliferation of GEnCs, which are otherwise up regulated by VEGF-A.

**Conclusions:** Our study indicates that VEGF-A splice isoform manipulation could be a novel therapeutic avenue in chronic glomerular disease.

**Rituximab Prevents TNFα Induced Podocyte ab3 Integrin Activation**

Farah Leclercq, Christopher E. Pedigo, Alessia Fornoni, Sandra M. Mersch, Katz Family Drug Discovery Center, Nephrology, Univ of Miami, FL.

**Background:** Focal Segmental Glomerulosclerosis (FSGS) is a disease characterized by podocyte damage and scarring of the glomeruli. FSGS accounts for up to 20% of end-stage renal disease cases in the United States. Glomerular basement membrane thickening and increased podocyte slit width in the VEGF-A-KO mouse, with both being rescued in the VEGF165b over-expressers. VEGF165b also restores PECAM expression in GEnCs, and glomerular capillary circumference. Mechanistically, VEGF165b increases VEGF-R2 expression and phosphorylation both in vivo and in vitro. Furthermore, it down regulates genes involved in the migration and proliferation of GEnCs, which are otherwise up regulated by VEGF-A.

**Methods:** Immunoprecipitation was carried out in immortalized mouse podocytes and human placenta samples. We posit that the presence of these isoforms compensates for the loss of slf1 in our transgenic model. The functions of these isoforms warrant further investigation and may provide insight into regulation of VEGF levels, podocyte function and preeclampsia.

**Polarity Signaling at the Kidney Filtration Barrier: Questioning the Function of Par3A**

Sylvie Köhler,1 Markus M. Rinisch,2,1 Carien M. Niessen,2 Wilhelm Bloch,3 Bernhard Scherrer,2 Thomas Benzing,2,1 Paul T. Brinkkoeetter,2,1 1 Dept of Internal Medicine and Center for Molecular Medicine, Univ Hospital Cologne, Germany; 2 Cologne Excellence Cluster on Cell Communication in Health and Disease (CECAD), University of Cologne, Germany; 3 Dept of Molecular and Cellular Sport Medicine, German Sport Uni Cologne, Germany; 4 Dept of Dermatology and CECAD Cologne, Univ of Cologne, Germany.

**Background:** The slit diaphragm (SD) represents the only cell-cell contact in between neighbouring podocytes. Classical adhesion as well as tight junction proteins are part of this protein-protein supercomplex including ZO-1, occludin, catemers and cadherins. Polarity signaling is critical to maintain the SD complex as the Par3/PAR6/aPKC complex clusters at the SD via direct interaction of Par3 with nephrin via its PDZ-domains.

**Methods:** To understand the role of the Par3 proteins at the slit diaphragm, we generated a novel podocyte specific Par3A knockout mouse model with exon 6 flanked by loxP sites. Following podocin:cre mediated recombination expression of all known Par3A isoforms should be abrogated. We validated cre recombinase efficiency, lack of Par3A expression and phosphorylation both in vivo and in vitro. Furthermore, it down regulates genes involved in the migration and proliferation of GEnCs, which are otherwise up regulated by VEGF-A.

**Results:** Mice were born in predicted Mendelian frequency. Par3A KO mice and confirmed the deletion of Flt1 intron 13 using Southern blot. Surprisingly, it did not result in any overt kidney phenotype by 6 months of age. Northern blot and Western blot analyses revealed the existence of a major compensatory isoform, previously reported as human-specific. We also confirmed the existence of 17 new slf1 isoforms in RNA isolated from mice and 12 from human placenta samples. The functions of these isoforms warrant further investigation and may provide insight into regulation of VEGF levels, podocyte function and preeclampsia.

Focal Segmental Glomerulosclerosis (FSGS) Permeability Factor (FSPF) Interacts with Glomerular Filtration Barrier Through Glycoconjugates Ram Sharma,1 Ellen T. McCarthy,2 Tarak Srivastava,2 Virginia J. Savin,2 Mukut Sharma,1 1Renal Research, KC VA Medical Center - MBRF, Kansas City, MO; 2Kidney Inst, KU Medical Center, Kansas City, KS; 3Renal Div, UMCK Children’s Mercy Hospital, Kansas City, MO.

Background: Galactose (Gal) blocks the FSGS serum-induced increase in in vitro glomerular albumin permeability (P_fo) (Trans Res 2008, 151:288-292) and decreases proteinuria in some patients with recurrent FSGS (NDT 2009, 24:2938-2940). Thus, the interaction of FSPF with glomerular cell surface glycoconjugates may play an essential role in its effect on the filtration barrier.

Methods: We selected sugars and lectins to model the interaction between glomerular glycoconjugates and FSPF. We used, (i) affinity techniques to evaluate the binding of FSPF with immobilized sugars (ii) immobilized neuraminidase to remove sialic acid to assess its significance in FSPF-induced increase in P_fo and (iii) Gal/N-acetyl Gal (GalNac)-specific lectin to determine the effect of Gal on P_fo as FSPF immunoassays.

Results: Plasma FSPF activity was retained by immobilized Gal, GalNac or galactosamine. Gal dose-dependently blocked FSPF-induced increase in P_fo (10^-10 M) and partially reversed the effect of FSPF on P_fo (p<0.001). In contrast, glucose, glucosamine or mannitol did not interact with FSPF. Removal of sialic acid by neuraminidase diminished the FSPF-induced increase in P_fo. We screened twenty Gal/GalNac-specific lectins as potential mimetics of FSPF. Only Dolichos biflorus agglutinin (DBA, 10 mg/mL) and Helis pomatia lectin (10 mg/mL) increased P_fo to 0.65 and 0.55 respectively (p<0.001). The increase in P_fo, like that induced by FSPF were blocked by Gal (100 µM) (p<0.001).

Conclusions: Our results suggest that carbohydrate-recognizing domains of FSPF participate in its interaction with specific sugar(s) of galactosaminyl cells resulting in altered filtration barrier function. Our novel findings regarding the affinity of FSPF for select sugars, the loss of activity after removal of sialic acid and the direct effect of certain lectins on barrier function provide new information regarding the molecular composition of FSPF and its interaction with glomerular proteins/glycolipids.

EBP4115 Is a Critical Regulator of the Kidney Filtration Barrier Christoph Schell,1 Martina Suhm,1 Manuel Rogg,1 Martin Helmstaedter,1 Mariko Hirano-Kobayashi,1 Tobias B. Huber.1 1Dept of Nephrology, Univ Medical Center Freiburg, Freiburg, Baden-Württemberg, Germany; 2Laboratory for Vertebrate Body Plan, Center for Developmental Biology - RiKEN, Kobe, Kobe, Japan.

Background: Podocyte loss represents the final common pathway of various glomerular pathologies. Hence, tightly regulated adhesion towards the glomerular basement membrane is a fundamental biological process of glomerular podocytes.

Methods: Based on podocyte single cell isolation and a mass-spec candidate approach the composition of podocyte focal adhesions was resolved. A combinatorial dipherphosphatase model with a newly generated conditional mouse model and various high resolution microscopy techniques (TEM, STORM) the candidate protein EBP4115 was analyzed.

Results: Knockdown of the Ebp4115 homolog Yur in diphosphatase nephrocytes resulted in severe podocyte abnormalities and decreased endocytic capacity. Evaluation of a conditional knockout model revealed a rapid loss of podocytes implicating deregulated glomerular albumin permeability (P_fo).

Conclusions: Our findings indicate that EBP4115 is a highly conserved, specific regulator of podocyte adhesion by modulating focal adhesion composition and function. Future studies will need to clarify its potential implications in genetic and acquired glomerular pathologies.

FR-P0354
The Effect of Anti-PLA2R Autoantibodies on Human Podocytes In Vitro Maryline Freaudat,1 Rachel Lennon,1 Paul E. Brenchley.1 1Wellcome Trust Cell-Matrix Research, Univ of Manchester, Manchester, United Kingdom; 2Inst of Cardiovascular Sciences, Manchester Royal Infirmary, Manchester, United Kingdom.

Background: PLA2R, was identified as a major target antigen in idiopathic membranous nephropathy. 70% of patients have circulating autoantibodies which bind this receptor on the podocyte leading to immune complex deposition in the glomerular basement membrane. We recently identified the epitope on PLA2R recognized by anti-PLA2R autoantibodies which produced the first 3D model of PLA2R domains and demonstrated that autoantibodies are of high affinity. We seek to understand whether affinity-pure anti-PLA2R alone in the absence of complement can modulate podocyte function.

Methods: We purified affinity-purified human anti-PLA2R (91% IgG4, 9% IgG2) and assessed podocyte morphology following autotomabody treatment using immunofluorescence staining of actin and measurement of cell surface area and circularity. Integrity of the filtration barrier was assessed by Electric Cell-substrate Impedance Sensing and the response of a confluent monolayer of differentiated podocytes to 10mg/ml purified human anti-PLA2R and purified human IgG2 was measured by allowing for cleaved caspase-3 staining in podocytes and oxidative stress was measured with CellROX reagent in differentiated podocytes challenged with the autoantibody.

Results: We have developed an in vitro podocyte model to define mechanisms of anti-PLA2R effects on cell morphology and function. Purified anti-PLA2R altered focal adhesion shape, with rounding and loss of actin stress fibres within 24 hours. Integrity of a confluent podocyte monolayer was significantly reduced at 72 hours by anti-PLA2R but not by the IgG control. Within 30 minutes of anti-PLA2R treatment, there was evidence of caspase-3 cleavage in podocytes peaking at 6 hours preceding at 6 hours.

Conclusions: Anti-PLA2R induced free radical generation (P<0.0001, treated v untreated), triggering oxidative stress which could be neutralised using a scavenger.

Deletion of the Ste20-Like Kinase, SLK, In Podocytes Induces Injury Andrey V. Cebulska,1 Elena Torban,1 Joa Paulillon,1 Julie Guillermite,2 Natalya Belkina.2 1Medicine, McGill Univ, Montreal, QC, Canada; 2NIH, Bethesda, MD.

Background: SLK is essential for embryonic development, and may play a key role in wound healing, tumor growth and metastasis. Expression and activation of SLK is increased during recovery from ischemic acute kidney injury. Overexpression of SLK in glomerular epithelial cells/podocytes in vivo induces injury and proteinuria. Conversely, reduced expression or expression of luciferase-encoding domains of SLK participates in its interaction with specific sugar(s) of glomerular cells resulting in altered filtration barrier function. Our novel findings regarding the affinity of FSPF for select sugars, the loss of activity after removal of sialic acid and the direct effect of certain lectins on barrier function provide new information regarding the molecular composition of FSPF and its interaction with glomerular proteins/glycolipids.

Methods: Podocyte-specific SLK knock-out (KO) mice were produced by breeding mice with a SLK flippable frog germline exons 4-7 with podocin (NPHS2)-Cre. Loss-expressed xenin results in deletion of the kinase domain. Deletion of SLK exons 4-7 in glomeruli was confirmed by PCR.

Results: Podocyte-specific deletion of SLK resulted in albuminuria at 4-5 months of age in male mice, and 8-9 months in female mice, which persisted for up to 13 months (albumin/creatinine in KO was 2-3-fold above control). At 11-12 months, KO mice did not show renal histologic abnormalities by light microscopy, and glomerular area of KO was comparable to control. However, by electron microscopy, KO mice showed focal foot process effacement and microvillous transformation of podocyte plasma membranes. Mean foot process width was ~2-fold greater in KO, compared to control. By immunofluorescence microscopy, WT1-positive cells were reduced by 35% in KO mice compared to control, and staining for nephrin and podocalanxin was reduced in KO mice by 20-30%. SLK is reported to phosphorylate ezrin. Staining for phosphorylated ezrin/radixin/moesin (ERM) was reduced by 20% in KO glomeruli, in keeping with reduced SLK catalytic activity in glomeruli; however, tubular phospho-ERM staining was comparable in KO and control.

Conclusions: Podocyte-specific deletion of SLK leads to albuminuria, loss of podocytes and morphologic evidence of podocyte injury. Thus, SLK is essential to the maintenance of podocyte integrity as mice age. The mechanism may, at least in part, relate to ezrin phosphorylation and cytoskeletal integrity.

FR-P0356
A Podocyte-Specific Knockout of the DNA Repair Gene Ercc1 Leads to Proteinuria and Focal Segmental Glomerulosclerosis Fabian Braun,1 Roman Aaron Akbar,2 Björn Schumacher,2 Wilhelm Bloch,3 Bernhard Schermer,1 Thomas Benzing,1,2 Christine E. Kurschat.2 1Nephrology, Univ Hospital Cologne, Cologne, Germany; 2CECAD, Univ Hospital Cologne, Cologne, Germany; 3German Sport Univ Cologne, Cologne, Germany.

Background: The prevention and therapy of aging-related diseases will become a major health problem. Among elderly patients mild to severe impairment of kidney function is common. Models to study renal aging have not been established yet. In a previous study, we identified a progeria mouse model of Ercc1-deficiency to exhibit expression profiles similar to those of glomerular aging in wt mice. Ercc1 is involved in nucleotide excision repair, facilitating 5' incision around bulky DNA lesions. In humans, the lack of Ercc1 leads to a progeria phenotype. Thus, a podocyte-specific knockout of Ercc1 may help us gain new insights into glomerular and podocyte aging processes.

Methods: Ercc1flox/flox mice were bred in a mixed CD1/FFBV background with CD1 mice carrying the Cre recombinase under the podocin promoter. We analyzed weight, urine and serum of animals at 7, 9, 11 and 13 weeks of age. Kidneys were fresh-frozen in OCT, fixed in paraffomraldehyde and embedded in paraffin or prepared for electron microscopy.

Results: Ercc1flox/flox mice are born in normal mendelian ratios and show no developmental abnormalities. We detected an onset of proteinuria at week 8 to 10. Animals maintain a normal weight curve compared to controls until week 11 to 18. 7 week old kidneys showed no morphological changes in light or electron microscopy. Male and female mice develop foot process effacement and focal segmental glomerular sclerosis at 9 weeks of age. This phenotype is aggravated by the degrading of extracellular matrix proteins, sclerotic lesions, mesangial expansion, focal segmental glomerulosclerosis, tubular atrophy, interstitial fibrosis with tubular atrophy and tubular protein casts. We observed an increase in DNA damage shown by positive pH2A.X staining in glomerular nuclei at week 11.

Funding: National Institute of Diabetes and Digestive and Kidney Diseases.
Conclusions: Our study reveals a critical role for nucleotide excision repair in murine podocytes. This gene appears to underlie the importance of podocyte DNA maintenance in these postmitotic cells. In ongoing studies we will characterize the role of Ercc1 in a podocyte cell culture model. **Funding:** Government Support - Non-U.S.

Mice Heterozygous for Rac1 in the Podocyte Are Protected against Nephrototoxic Serum Nephritis-induced Albuminuria, but Knockout Mice Are Not

**Background:** Podocyte injury, either by genetic or acquired abnormalities, can lead to progressive proteinuria and glomerulosclerosis. Current treatments are not designed to specifically target the podocyte but are used for broader immunotherapeutic or anti-inflammatory properties, thus podocyte-targeted therapies are needed. Rac1, a member of the Rho GTPase family, has been suggested as a therapeutic target for podocyte injury. However we previously demonstrated that podocyte-specific Rac1 knockout mice have exacerbated albuminuria with a hypertensive injury model. We hypothesize that partial reduction of podocyte Rac1 is protective.

**Methods:** We employed the nephrotic serum (NHS) nephritis model, which causes predominant podocyte injury and high-grade proteinuria without appreciable inflammation, in wild-type (WT), podoRac1-KO (podoRac1-KO), and podocyte-specific Rac1 heterozygous mice (podoRac1-HET). A separate group of NHS treated WT mice were given EHT1864 (40mg/kg), a Rac inhibitor. Mice were injected with NHS (1.5 mg/kg body weight) (n=8-10 mice per group) and placed in metabolic cages for 1 or 2 days for daily urine collection. Urine albumin was measured by SDS-PAGE gel with standard curve, normalized by urine creatinine.

**Results:** NHS treatment resulted in robust albuminuria in wild-type mice on days 1 and 2 with albumin-to-creatinine ratios (ACR) of 400-500 ug/mg. However, podoRac1-KO mice showed an equally robust albuminuric response on day 1, but less on day 2 compared to wild-type, suggesting accelerated recovery. In contrast, NHS treated podoRac1-HET mice demonstrated nearly 70% reduction in ACR compared to wild-type (130 versus 390 ug/mg, P<0.01). The Rac inhibitor EH1864 was equally effective.

**Conclusions:** These results demonstrate that a partial reduction in Rac1 activity, through genetic or pharmacologic inhibition, provides a protective effect against NHS-mediated podocyte injury, whereas Rac1 deletion is not beneficial. Our findings should help guide the development and assessment of Rac1 inhibitors to target podocyte injury.

The Ectodomain of Syndecan-4 Increases Surface Expression of Podocyte TRPC6 Channels: An Essential Role for Integrin Signaling

**Background:** Excessive activation of podocyte TRPC6 channels has been implicated in glomerular diseases. Syndecan-4 (Sdc-4) is a type-1 single-pass proteoglycan that can be cleaved to produce a soluble product capable of paracrine and autocrine signaling. A previous study (1) showed that the Sdc-4 core protein increases the surface expression of TRPC6 in podocytes. Here we show that the Sdc-4 ectodomain can also modulate TRPC6 channels and we describe some of the pathways that surround this effect.

**Methods:** Cell surface expression of TRPC6 was monitored using surface biotinylation assays and whole-cell patch clamp recordings from cultured mouse podocytes. Signaling pathways were examined using assays for activated components and selective inhibitors. Protein interactions were examined by co-immunoprecipitation and confocal microscopy.

**Results:** We have confirmed previous studies showing effects of over-expression and knockdown of Sdc-4 core protein on podocyte TRPC6 (1). In addition, exposing podocytes to Sdc-4 ectodomain caused an increase in the surface abundance of TRPC6, accompanied by an increase in cationic currents evoked by diacylglycerol (DAG). Sdc-4 ectodomain increased the generation of reactive oxygen species (ROS) and effects of Sdc-4 on TRPC6 were blocked by the ROS quencher TEMPOL. Exposure to Sdc-4 ectodomain caused activation of NFAcI and Rac1, inhibition of RhoA, and increased the total abundance of b3-integrin in its severally phosphorylated forms. However effects of Sdc-4 ectodomain persisted even after inhibition of calceinurin or NFAT. The Sdc-4 core protein immunoprecipitated and co-localized with b3-integrin in podocytes. Moreover, effects of Sdc-4 ectodomain were blocked by the ROS quencher TEMPOL. Exposure to Sdc-4 ectodomain caused increased the generation of reactive oxygen species (ROS) and effects of Sdc-4 on TRPC6 were blocked by the ROS quencher TEMPOL. Exposure to Sdc-4 ectodomain caused activation of NFAcI and Rac1, inhibition of RhoA, and increased the total abundance of b3-integrin in its severally phosphorylated forms. Deletion of the Vps34 Downstream Effector PIKfyve Establishes Milder Endocytic Dysfunction in Healthy Glomerular Podocytes Compared to Proximal Tubular Cells

**Background:** The mechanisms by which the glomerular filtration barrier prevents the loss of large macromolecules and at the same time maintain the filter remain poorly understood. Recent studies have proposed that podocytes play an active role in both endocytosis of filtered macromolecules and maintaining the filtration barrier.

**Methods:** We generated podocyte and proximal tubular specific deletion of PIKfyve using the cre-loxP system. Indirect IF and immune EM was used to assess the endocytic pathways.

**Results:** Deletion of a key endosomal trafficking regulator, the class III phosphoinositide 3-kinase or Vps34 in podocytes results in aberrant endosomal membrane morphology and podocyte dysfunction. We recently demonstrated that the vacuolation phenotype in cultured Vps34-deleted podocytes is due to the absence of a substrate for the Vps34 downstream effector PIKfyve. PIKfyve is a Fyve finger domain containing phosphoinositide 5-kinase that phosphorylates Vps34-generated phosphatidylinositol (3,4)P2 to produce PtdIns(3,4,5)P3. PIKfyve perturbation and PtdIns(3,4,5)P3 reduction have been shown to result in massive membrane vacuolation along the endosomal system. We show here that deletion of PIKfyve in endocytically active proximal tubular cells resulted in the development of large cytoplasmic vacuoles that appear as a result of arrested endocytic traffic progression at a late-endosome stage. In contrast, deletion of PIKfyve in podocytes did not alter significantly the endosomal morphology even in aged, 18-month-old mice. However upon culturing, the PIKfyve-deleted podocytes obtained from the knockout mouse developed massive cytoplasmic vacuoles. Measurement of phosphoinositides using HPLC shows reduction of both PtdIns(3,4,5)P3 and PtdIns(3,4)P2 in PIKfyve deleted podocytes in vitro confirming reduced PIKfyve enzymatic activity following deletion. Using double fluorescent mtnmG mouse we were able to confirm Cre-mediated gene deletion in both podocytes and proximal tubular cells in vivo.

**Conclusions:** In summary, these data suggest that healthy podocytes have a low level of endocytic flux in vivo. **Funding:** NIDDK Support

Albumin-Induced Podocyte Injury Can Be Endocytosis-Independent
Shripa Agrawal,1 Xiaojing Nie,1 Tetsuya Kitao,2 Melinda A. Chanley,1 William E. Smoyer,1 2Clinical and Translational Research, Research Inst at Nationwide Children's Hospital, Columbus, OH; 1Pediatrics, Ohio State Univ, Columbus, OH.

Background: Endocytosis plays a crucial role in podocytes in nephrotic syndrome, wherein podocytes are exposed to serum levels of albumin. We have previously reported an association between podocyte exposure to albumin (and its associated factors) and proteinuria, cell injury and induction of pro-inflammatory genes. We thus hypothesized that albumin-induced podocyte injury can also be partially endocytosis independent.

Methods: Endocytosis was analyzed by fluorescence microscopy and fluorometry in cultured differentiated podocytes at varying temperatures and times and in the absence/presence of inhibitors of clathrin- and caveole-mediated endocytosis. Cells were analyzed for viability, activation of major kinases (p38, ERK1/2, JNK, MK2), and expression of pro-inflammatory, heat shock, and glucocorticoid-regulated genes.

Results: Endocytosis occurs at 37°C, but not at 4°C, and was attenuated by inhibitors for both clathrin- and caveole-mediated endocytosis. Inhibition of endocytosis, however, did not correlate with reductions in kinase activation or pro-inflammatory gene induction. While albumin exposure resulted in lower endocytosis in murine vs. human podocytes, murine cells activated kinases, induced pro-inflammatory genes and exhibited cell death more than human podocytes.

Conclusions: Inhibition of both clathrin- and caveole-mediated albumin endocytosis did not correlate with activation of kinases and induction of pro-inflammatory genes in podocytes. Moreover, disparate responses were identified in human vs. mouse podocytes with regard to albumin endocytosis, cell injury, kinase activation, and pro-inflammatory gene induction. Taken together, our data suggest that podocytes endocytose albumin in both clathrin- and caveole-mediated manners, albumin-induced podocyte injury can occur in an endocytosis-independent manner.

Genome-Modified Pluripotent Stem Cells Reveal a Critical Role for Podocalyxin in Human Podocyte Morphogenesis
Benjamin S. Freedman,1 2Craig R. Brooks,1,2 Jin Zhou,3 Joseph V. Bonventre,1 2Brigham and Women's Hospital; 1Harvard Medical School; 2Univ of Washington School of Medicine.

Background: Human pluripotent stem cells (hPSCs) can self-renew and differentiate into diverse tissues. We investigated the potential of hPSCs to differentiate into kidney podocytes, and used CRISPR/Cas9 gene editing to explore the function of podocalyxin, an apical sialomucin located in glomerular disease states.

Methods: Cas9 nuclease and guide RNAs targeting PODXL were transfected into hPSCs. PODXL-/- clones were identified by chromatogram and immunoblot analysis. hPSCs were differentiated stepwise with growth factors into kidney progenitor cells and 'disease in a dish' models and therapeutic screens. Genome-modified hPSCs-podocytes present a new tool for investigating human podocytes, with potential for 'disease in a dish' models and therapeutic screens.

Molecular Targeting of Nephr1 Signaling: A Therapeutic Approach to Protect Podocyte Injury
Deepak Nihalani,1 Ehtesham Arif,1 Fru Ashish,2 Lawrence B. Holzman,1 1 Medicine, Univ of Pennsylvania, Philadelphia, PA; 2Proteomics, Inst of Microbial Technology, Chandigarh, India; 1Medicine, Temple Univ, Philadelphia, PA.

Background: Glomerular injuries that induce podocyte dysfunction are the leading causes of renal malfunction. Podocyte proteins Nephrin and Nephr1 are essential components of the glomerular filtration barrier and signaling from these proteins is involved in maintaining podocytes structure and function. Thus understanding the mechanisms that regulate signaling and organization of these proteins are therapeutically valuable.

Methods: This study presents a novel hypothesis that attenuating Nephrin and Nephr1 signaling is therapeutically significant in protecting podocytes from injury. Consistent with this hypothesis, using a unique protein transduction approach, we recently demonstrated

that inhibiting Nephr1 signaling protected podocytes from injury. Since we first reported the successful overexpression of Nephr1 proteins, we have used an array of novel molecules or compounds that can specifically bind Nephr1 and target its interactions.

Results: Using a novel approach of targeting protein-protein interaction, we identified many potential molecules and to test the proof of principle and the validity of this approach, coated compounds ID (sodiumoxine) was commercially procured and investigated. Biochemical experiments suggested that addition of ID under in vitro and in vivo conditions significantly increased and stabilized the interaction between Nephr1 and ZO-1. As a consequence, induction of glomerular injury by PAN (purinomycanquinocinamide) did not affect the distribution of Nephr1 and podocyte cell junctions in addition to cells resisted injury induced changes in their actin cytoskeleton. Furthermore, using an in vivo zebrafish model system, we demonstrated that pre-treatment with ID rescued zebrafish from adriamycin induced toxicity and preserved their renal filtration system.

Conclusions: Collectively, this is the first study that provides compelling initial evidence that molecular approaches can be used to directly target slit diaphragm proteins to prevent podocyte damage.

Extracorporeal Mesenchymal Stromal Cell Therapy for Critical Care
Biju Pareekadan, Surgery (Bioengineering), Harvard Medical School, Massachusetts General Hospital, Boston, MA.

Background: Human mesenchymal stromal cells (MSCs) metabolize and secrete anti-inflammatory and regenerative factors that can be of systemic benefit to acute, critical injury. When transplanted MSCs are limited in dose and rapidly cleared by the body, the toxic end products of this drug for this therapy. We have developed a bioresorbable technology to maintain MSC viability at high fidelity and continuously deliver secreted agents into the blood stream in a clinical setting.

Methods: MSCs were integrated into hollow-fiber bioreactor devices whereby the cells are separated by a permeable membrane, can directly and dynamically provide systemic therapy without entering the body. We present a human scale prototype of the technology that has shown sustained cell viability and function throughout cGMP manufacturing in preparation for a Phase I human trial set to begin in 2015.

Results: The presentation will also report encouraging in vivo therapeutic trials in a large animal (canine) model of ischemic acute kidney injury (AKI) where 91% of animals survived compared to 50-60% in control arms. Pharmacological analysis of this bioreactor technology in vivo allowed for an unprecedented look at MSC function during product use and verified potency that is unattainable by conventional intravascular delivery of MSCs.

Conclusions: A combined approach to optimize MSC therapy that employs pharmacology principles and cell delivery strategies will be essential to translating this cell therapy product to humans for AKI and other critical organ dysfunction syndromes.

FR-P0365

Extracorporeal Diffusional Clearance of Silicon Nanopore Membranes in a Pumpless Porcine Blood Circuit
Steven Kim,1 Willifred Moses,1 2Jeehyun Park,1 Clarence Chow,2 Charles Blaha,2 Zohora Ibqal,1 Rishi Kant,1 Benjamin Chui,1 Ken Goldman,1 William Henry Fissell,4 Shuvo Roy,3 4Nephrology, UCSF; 2Surgery, UCSF; 3Bioengineering, UCSF; 4Silicon Kidney, LLC; 7Ben Chui Consulting; 3H-Cubed; 4Nephrology & Hypertension, Vanderbilt Univ.

Background: Silicon nanopore membranes designed for hemofiltration (HF-SNMs) have demonstrated increased permeability compared to polymer membranes. Previously, we reported in vitro data showing a 3-fold improvement in diffusive clearance using silicon membrane compared to dialysis in a small animal (canine) model of ischemic acute kidney injury (AKI). We also showed a ~3-fold improvement in diffusive clearance of HD-SNM vs HF-SNMs in an extracorporeal porcine model without a blood pump.

Methods: A microelectromechanical systems fabrication technique was used to decrease the SNM thickness (HD-SNM 100μm vs HF-SNMs 400μm). Polyethylene glycol coated HD-SNM (n=3) and HF-SNMs (n=3) with sub-10nm pore sizes were tested in a single channel flow circuit (l=1mm). Vascular access was obtained by placing tunneled catheters within the carotid artery and jugular vein of healthy ~50kg pigs. Blood flow was achieved via the arterial-venous pressure differential (35-120mmHg). Dialysate was recirculated in a counter-current fashion (30ml) and flow rates were adjusted to ensure 0 transmembrane pressure. Dialysate creatinine concentration was measured hourly and serum creatinine was measured at time 0 and 6 hours. The pore size of each SNM was measured before and after blood exposure using hydraulic permeability.

Results: Blood flow was achieved via the arterial-venous pressure differential with <5mmHg pressure drop. The average plasma creatinine concentration was 1.38±0.1mg/dl. The creatinine clearance was 37.2±3.9ml/min/m² (HF-SNMs) vs 126.0±27.1ml/min/m² (HD-SNM) at 92.5±36.6ml/min. There was no detectable albumin transport into the dialysate across the HD-SNM membrane, with mechanical integrity at over 250mmHg in vivo. The average pore size change following blood exposure was 1.4±0.3nm vs 1.9±1.2nm for HF-SNMs and HD-SNMs, respectively.

Conclusions: This study demonstrates the successful transport of creatinine in an extracorporeal circuit without a blood pump. We also showed a ~3-fold improvement in diffusive clearance of creatinine using HD-SNM in a blood circuit.

Hemofilter Design Based on Computational Simulations of Pulsatile Flow
Amanda Buck,1 Joseph J. Groszek,2 Clark David Kensinger,1 Daniel Covlin,1 Shuvo Roy,1 William Henry Fissell,2 1Dept of Radiology and Radiological Sciences, Vanderbilt Univ; 2Div of Nephrology and Hypertension, Vanderbilt Univ; 1Dept of Surgery, Vanderbilt Univ; 2Dept of Bioengineering and Therapeutic Sciences, Univ of California San Francisco.

Background: In the US, the ratio of patients with end stage renal disease (ESRD) on dialysis to annual kidney transplants for ESRD is 20:1 (USRDS 2014 Annual Data Report), underscoring the grave need for an artificial kidney alternative. Hypothesis: For the development of a hemofiltration device, computational fluid dynamics (CFD) simulations can predict potentially thrombogenic zones [e.g. low and high wall shear stress (WSS) areas, associated with stasis and shear induced cell damage, respectively] and can be used to refine device design to minimize such areas.

Methods: CFD simulations of pulsatile blood flow through a prototype hemofilter were validated in vitro using MR velocimetry. Hemofilters were implanted in large animals (n=4) for 30 days or until thrombosis and then explanted. Based on the CFD results, a subsequent flow path was devised to minimize predicted thrombogenic regions, and simulations were conducted on the second design.

Results: The in vitro and in silico models showed strong agreement. Pulsatile CFD simulations of the prototype device demonstrated zones of low WSS, and clot formation occurred in two of the four implants at the CFD-predicted sites. Flow simulations of the second-generation design showed reduced areas of low WSS.

Conclusions: Thrombogenic low WSS regions predicted in vitro correspond with clot formation in vivo. In addition to predicting areas of thrombogenicity, CFD can be used to guide hemofilter device design to minimize these sites.

Figure 1. CFD results, with gray arrows indicating flow direction. A: WSS averaged over all but systolic accelerations (for the prototype shows low WSS regions (black arrow)) dominate the cardiac cycle. B: Compared to the prototype (left), the second-generation (right) design mitigates areas of instantaneous low WSS (black arrows).

Characterization of Dialyzer Membranes by MALDI-Mass-Spectrometric Imaging Techniques
Joachim Jankowski, Vera Jankowski. Inst of Molecular Cardiovascular Research, Univ Hospital RWTH, Aachen, Germany.

Background: Dialyzer polymer membranes are grossly classified as cellulose-based and synthetically produced membranes. Although cellulose membrane’s clearance and mechanical properties qualify it for use in dialyzer membranes, hydroxyl groups of these membranes lead to strong activation of the complement system. Therefore, recent membranes are manufactured from synthetic polymers.

Methods: For physical and chemical characterization of these materials of dialyzer a wide range of analytical methods is available. Over the last few years, MALDI mass-spectrometry has been developed as a powerful tool for space-resolved analysis, not least because of its mass accuracy and high sensitivity. MALDI imaging techniques combine the potential of mass-spectrometric analysis with imaging as additional spatial information with relevance for biocompatibility of the dialyzer membranes. MALDI imaging enables the visualization of localization and distribution of biomolecules, chemical compounds and other molecules on different surfaces.

Results: In this study, surfaces of polymeric dialyzer membranes, consisting of polysulfone (PS) and polyvinylpyrrolidone (PVP) were investigated, regarding to chemical structure and compound’s distribution. According to the manufacturing process lumenal and abluminal membrane surfaces are characterized by differences in chemical composition and physical characteristics. The MALDI imaging demonstrated that the abluminal membrane surface is more consisting of polysulfone than polyvinylpyrrolidone, the luminal membrane surface displayed more PVP than PS. The addition of PVP as hydrophilic modifier to polysulfone-based membranes increases the biocompatibility of the dialysis membranes.

Conclusions: In conclusion, MALDI imaging is a powerful technique for polymer membrane analysis, regarding not only detection and identification of polymers but also localization and distribution in membrane surfaces, which has strong impact on the biocompatibility of the dialyzer membranes.

FR-PO368

Effect of Peristalsis with Pediatric Catheters
Anna Lorenzini, Francesco Garzotto, Claudio Ronco. Nephrology and International Renal Research Inst Vicenza, St. Bortolo Hospital, Vicenza, Italy.

Background: Thanks to the technological advances of the last years, Continuous Renal Replacement Therapy CRRT machines have been upgraded and equipped with circuits specific for pediatric patients. To date, to treat these patients the most used catheter is the central line catheter, however with a neonate it is inadequate for the dimensions. It is not clear if it is possible to use a smaller catheter with adult CRRT machine or a specific pediatric machine is needed. We set up a dedicated circuit to assess the usability of a peristaltic blood pump designed for adults and compare it with a pediatric pump in terms of access pressure. In the pediatric pump, the performed in silico test was validated as realistic.

Conclusions: In the in vitro experiments, the Thrombogenic low WSS regions predicted in vitro correspond with clot formation in vivo. In addition to predicting areas of thrombogenicity, CFD can be used to guide hemofilter device design to minimize these sites.

FR-PO369

Hemodialysis with CARPEDIEM Machine: An In Vitro Test
Anna Lorenzini, Dario Galeano, Stefania Aresu, Francesco Garzotto, Claudio Ronco. Nephrology and International Renal Research Inst Vicenza, St. Bortolo Hospital, Vicenza, Italy.

Background: Despite the development of continuous renal replacement therapies machines, their employment still remain unsuitable in newborn and infants. This gap has been filled thanks to the coming of a specific pediatric dialysis machine CARPEDIEM. To date it is set up only for continuous hemofiltration CVVHF to provide a wider range of applications, specific filters have been conceived to implement a continuous hemodialysis CVVHD. We tested a prototype kit to evaluate its performance in terms of clearance K.

Methods: We performed in vitro test with plasma for the 3 filters HD010, HD020 and HD035. The effects of peristalsis with 5Fr catheter and 15ml/min flow rate. Analyzing the arterial pressure values, we found that the spikes are more frequent in the CARPEDIEM pump than with the adult one. The mean and max value were respectively 50, -28mmHg and a mean Dp=18mmHg with CARPEDIEM pump (-61, -20mmHg) and a mean Dp=40mmHg with adult pump (Fig 1).

Conclusions: We can notice that there is a high discrepancy in terms of Dp between the pediatric pump with high values of Dp lead to an high shear stress. As the shear stress is one of the main causes of hemolysis, it seems that a specific pediatric machine is advisable for neonates that need small catheter.

Results: We are presenting the data of the two pumps with 5Fr catheter and 15ml/min flow rate. Analyzing the arterial pressure values, we found that the spikes are more frequent in the CARPEDIEM pump than with the adult one. The mean and max value were respectively 50, -28mmHg and a mean Dp=18mmHg with CARPEDIEM pump (-61, -20mmHg) and a mean Dp=40mmHg with adult pump (Fig 2).

Conclusions: We can notice that there is a high discrepancy in terms of Dp between the pediatric pump with high values of Dp lead to an high shear stress. As the shear stress is one of the main causes of hemolysis, it seems that a specific pediatric machine is advisable for neonates that need small catheter. Further investigation have to be perform with blood to confirm our results.
FR-PO370

Removal of Protein-Bound Uremic Toxins: Simulating the Effect of Toxin Displacement versus Increase in Dialyzer Clearance
Vaibhav Maheshwari,1 Stephan Thijssen,1 Doris H. Fuertinger,1 Franz Kappel,1 Peter Kotanko.1 Renal Research Inst, NY; 1Univ of Graz, Austria.

Background: Protein-bound uremic toxins (PBUT) exert numerous deleterious effects. Their removal with standard hemodialysis (HD) is poor. Meyer et al. have modeled the impact of increasing dialysate flow rate and dialyzer mass transfer area coefficient on PBUT removal [JASN, 2004]. Here, we compare those results to a novel approach based on PUBT displacement by infusion of binding competitors [Tao, Blood Purif, 2015].

Methods: We developed a multi-compartment patient model and a dialyzer model depicting spatiotemporal dynamics based on law-of-mass-action kinetics. We chose indoxyl sulfate (IS) as a prototypical PBUT and ibuprofen as the binding competitor. We modeled IS removal during a 4-hr HD ($Q_d=250$ mL/min, $Q_m=750$ mL/h, initial total IS 100 $\mu$mol/L, initial free fraction of IS 8%), with IS dialyzer clearances from 150 to 200 mL/min. This was compared to IS removal achieved by ibuprofen infusion (800 mg/200 mL) into the arterial line at 50 mL/hr (IS clearance 150 mL/min).

Results: IS removal during HD with a clearance of 150 mL/min was 438 $\mu$moles (plasma reduction ratio 34%), which conforms to literature data [Niwa, Blood Purif, 2012]. With IS clearance of 200 mL/min, removal improved by 8.7% to 476 $\mu$moles. With ibuprofen infusion (IS clearance back at 150 mL/min), removal improved by 11.2% to 487 $\mu$moles.

Conclusions: CVVHD with CARPEDIEM seems to be effective for diffusion transport of small molecular weight solutes, according to specific clinical needs. In the light of these findings CARPEDIEM can be a promising alternative to peritoneal dialysis, i.e. in treating electrolyte imbalance with accurate fluid removal. Limitation: handmade filters could induce variability in the results due to disposition and variable number of fibers.

FR-PO372

Membrane versus Peristaltic Blood Pumps for Extracorporeal Therapies: Comparison on Index of Hemolysis
Francesco Garzotto,1 Sean M. Bagshaw,2 Claudio Ronco.1 Nephrology and IRRV, St. Bortolo H., Italy; 1Critical Care Med, Univ of Alberta Hospital.

Background: Hemolysis during extracorporeal treatments mainly occurs as a consequence of mechanical stress on the blood. Red blood cell deterioration is undetected because it is far from any acute hemolytic threshold but represents a potential harm for patients. A new membrane-piston driven pump has been recently proposed on the S.A.M.(©Spectral Medical Inc, Toronto) device designed for continuous renal replacement therapies (CRRT). Aim of this investigation is to compare the membrane with peristaltic pumps by measuring the Normalized Index of Hemolysis NIH during in vitro testing.

Methods: Three sessions of hemoperfusion with a line inserted in place of a hemofilter were performed both with SAM and Prismaflex (©Baxter International). A single pool of fresh heparinized bovine blood (Heparin 500 u/L, Hb 12±1 g/dl,Base Excess 0±5 mmol/L) were split into three aliquots containing 900 mL (Control, SAM, Prismaflex) and circulated for 6 hours/session. Blood samples were drawn at baseline, 30 min and every 1 hour. NIH were calculated as median hourly variation of free hemoglobin and used for comparison.

Results: NIH values of 0.12±0.03 and 0.13±0.09 mg/100L for SAM and Prismaflex respectively are lower than those reported in literature due to the simplified circuit used (no vascular access and filter). Creation of hemoglobin between sam and control, and prisma and control are non-significant. Slope of the curves that describe the creation of hemolysis are nearly identical with a slow rate of production of free hemoglobin.

Conclusions: S.A.M could represent a valid alternative to the classic peristaltic pumping system driven machines. Analyzing the pumping-system/cassette equipment, we identified potential advantages, in addition to usability, such as: accurate balancing withdrawal and infusion flows. The largest Priming volume measured (both the ACs full), is 98 mL with a stroke volume for each AC of 14 mL.

FR-PO371

Membrane Driving Blood Flow for Extracorporeal Therapies
Francesco Garzotto,1 Sean M. Bagshaw, Anna Lorenzin, Mauro Neri, Claudio Ronco.1 Nephrology, St. Bortolo H.

Background: From the first application of ContinuousVenovenousHemofiltration CVVH, the blood flow has been driven by a peristaltic pump. Several attractive alternatives, with both advantages and disadvantages, have been proposed for many years. SAM (Spectral Medical Inc.; Toronto, Canada) is a novel instrument, in which the pumping of whole blood and fluids is performed through the use of pistons, chambers and valves. A plastic cartridge blood circuit system fig1b incorporates all of the pumps, air trap system, withdrawal and infusion flows. The largest Priming volume measured (both the ACs full), is 98 ml with a stroke volume for each AC of 14 ml.

Methods: We set up the machine for CVVH. An 11.5 Fr 20 cm catheter was connected to the lines. We ran the machine for 6 hours in order to characterize the performance of the system.

During the first cycle, suction generated by the drawing back of the piston, moves the blood into the arterial-chamber AC. Positive pressure generated by the piston then drives the blood through the circuit. The camshaft design can allow different profiles for Withdrawal and infusion flows. The largest Priming volume measured (both the ACs full), is 98 ml with a stroke volume for each AC of 14 ml.

Results: We did not observe a reduction of blood flow due to a loss of membrane elasticity. The use of an “all integrated” cassette reduces the number of manual operations, avoiding operator related errors and favoring an easy and time saving set up.

Conclusions: S.A.M could represent a valid alternative to the classic peristaltic pumping system driven machines. Analyzing the pumping-system/cassette equipment, we identified potential advantages, in addition to usability, such as: accurate balancing withdrawal and infusion flows. More tests should be performed in order to validate the device in various aspects and conditions.

Conclusion: Our model yields predictions of IS kinetics that agree with empirical and modeled data [Niwa et al.; Meyer et al.]. Of note, a mere 8.7% improvement in IS removal would occur an increase in dialysate flow rate from 800 to 1350 mL/min plus a 70% increase in membrane surface area. The modeled ibuprofen infusion alone yields an 11.7% improvement even absent an increase in dialyzer clearance. The use of binding competitors holds great promise. These results require validation in vivo.

Enhanced Middle Molecule Clearance by a Biomimetic Dialyzer Membrane

Joseph J. Groszek,1 Jin Cheng,1 Charles Blaha,2 Rishi Kant,1 Jae Hyun Park,1 Benjamin Chui,3 Ken Goldman,4 Shuvo Roy,1 William Henry Fissell,1 1Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN; 2Bioengineering and Therapeutic Sciences, Univ of California, San Francisco, San Francisco, CA; 3Ben Chai Consulting, Sunnyvale, CA; 4H-Cubed, Inc, Olmstead Falls, OH.

Background: Although polymer dialyzers attain very high small solute clearance rates, polydisperse slit pore sizes limit middle molecule clearance by conventional polymer dialyzers. We hypothesized that a biomimetic membrane with uniform slit pores would enhance middle molecule clearance.

Methods: thin film silicon membrane samples (surface area 1.4 x 10^3 m^2) with monodisperse slit-shaped 5-8 nanometer pores (“SNM-HD”) were manufactured as previously described, surface-modified with polyethylene glycol and mounted in a custom designed cartridge. Membrane pore size was estimated from hydraulic permeability measurements. Human blood was spiked with PABA and fluorescent-labelled Ficoll, a polyelectrolyte and globular polysaccharide. Blood flow was set at 100 ml/min and dialysate flow varied between 70 and 140 ul/min. Blood and dialysate concentrations of PABA and Ficoll were measured by size-exclusion chromatography. Clearance as a function of dialysate flow rate was extrapolated to estimate Koa as a function of molecular weight.

Results: B2M clearance in high-flux dialyzers is typically 5-8% of the value of urea clearance. PABA clearance was 1.39 ml/min/m^2. 15.7Angstrom Ficoll (same radius as B2M) clearance in the SNM dialyzers was 16.9 ml/min/m^2, 3.5 fold higher than reported B2M clearance in polymer dialyzers.

Conclusions: A biomimetic membrane of uniform slit pores potentially offers much higher middle molecule clearance than conventional polymer dialyzers.

Anti-Fouling of Silicon Nanopore Membranes Using SLIPS

Bas Meusen,1,2 Steven Kim,3 Zohora Iqbal,1 Charles Blaha,1 William Henry Fissell,1 Shuvo Roy,1 1UCSF; 2Univ of Eindhoven; 3Silicon Kidney; 4Vanderbilt Univ.

Background: Silicon Nanopore Membranes (SNM) have been developed for application in an implantable bioartificial kidney. However, SNM are subject to fouling and thrombosis with continuous blood flow. Thin polymer coatings have been applied to SNM as a strategy to limit cell adhesion and protein adsorption. Slippery Liquid Infused Porous Surface (SLIPS) is a biologically inspired ‘omniphobic’ surface coating that has been reported to prevent thrombosis and fouling on arteriovenous shunts. Here we present the application of SLIPS coating to SNM and evaluate protein adsorption in vitro.

Methods: SNM with 10 nm pores were coated with SLIPS and incubated with BSA-FITC (2 mg/ml in PBS) for 24 hours at 37°C. Uncoated (bare) silicon substrates served as controls. Fluorescence microscopy and ellipsometry were used to evaluate the surfaces and water transport through the SNM was tested using established hydraulic permeability assays.

Results: SLIPS strongly reduced BSA-FITC adsorption on SNM compared to bare silicon. Ellipsometry confirmed the presence of SLIPS coating with a thickness of 0.5±0.2nm, which is theoretically thin enough to keep open the pores open in the membrane. However, hydraulic permeability testing revealed no ultrafiltration through the SNM for at least 24 hours and transmembrane pressures of up to 5 psi.

Conclusions: SLIPS is a promising and easy-to-use protein repellent coating, but its highly omniphobic characteristic prevents ultrafiltration even through pores that are over 5X the coating thickness. For use in the bioartificial kidney, SLIPS has relevant implications as an anti-fouling coating where an ultra-thin blood compatible, but non-filtering surface is desired.

Measuring Spatial Trends of Single Nephron Filtration with Molecular MRI

Edith Baldelegar,1 Jennifer R. Charlton,1 Kevin M. Bennett,1 1U. of Hawaii, Honolulu, HI; 2U. of Virginia, Charlottesville, VA; 3U. of Hawaii at Manoa, Honolulu, HI.

Background: To better develop drugs to treat kidney disease their physiological mechanisms during development, noninvasive techniques to measure whole kidney function at the level of the single nephron are needed. We investigated the combined use of two MRI contrast agents, cationic ferritin (Cf) and Gd-DTPA, to measure local (voxel) macromolecular uptake and glomerular filtration rates of single nephrons over the whole rat kidney with 3D MRI using the isolated, perfused rat kidneys under physiological conditions.

Methods: Krebs-Ringer (KR) bicarbonate solution with 7.5 mg/100ml of Fraction-V BSA and a bubbling infusion of carbonogen was perfused into isolated rat kidney. Temp was maintained at 37°C. CF in KR solution (0.071 mg/ml of CF), was infused into the system first. 10 min later, KR solution was re-infused to wash. Next, a bolus of 0.25 mmol Gd-DTPA in 10ml of KR solution was infused into the perfusion system. (All rates = 5ml/min) Kidneys were imaged during the perfusion with MRI. Voxel time courses were then fitted to a bi-exponential model.

Results: Glomeruli were distinguished by uptake of CF and a distribution of CF accumulation rates and Gd-DTPA elimination rates was visible. (Fig 1a-b) We used the location of the glomeruli in 3D and the time course of CF labeling (Fig 1c-d) to discern spatial trends in uptake rate of CF. Time course structures also mapped well with the different morphological structures in the kidney (Fig 1e).

Conclusions: Our results demonstrate that automated quantification is capable of not only distinguishing between anatomical features of kidneys, but also characterizing the degree of abnormality in diseased tissue.

Funding: Other NIH Support - NIBIB
Results: the developed contrast agent (µAngiofil) turned out appropriate for µCT ex vivo with superior perfusion and contrast-to-noise features. The obtained µCT datasets were of superior quality and allowed clear visualization of the microvasculature and glomeruli. In kidney, modern high-resolution micro-CT (SkyScan-1172) provided the whole mouse kidney vasculature in 3D with the spatial resolution of approx. 2 µm. The sample is fixed prior the microCT-scan and therefore can be processed for the histological evaluation after the scan. This circumstance brings multiple advantages, including much easier localization of the µCT-findings in the post-scan histological sections.

Conclusions: using µAngiofil we obtained 3D µCT datasets of superior quality, which are sufficient for estimation of relevant kidney morphometry parameters. The developed angio-µCT-based approach will substitute the existing golden-standard. Besides classical kidney morphometry, it provides the data on the vasculature through the whole kidney in 3D what makes the technique even more beneficial.

Rising Accuracy of Transcutaneous GFR Measurement

Jochen Friedemann,1,2
Ralf Heinrich,1 Yury Shulhevich,1,2
Johannes Pihl,1 Daniel Schock-Kusch,1,2

Background: Transcutaneous measurement of GFR (GFR) is now getting used frequently in animal studies. GFR allows consecutive GFR measurements in the same animal even on a daily basis as no blood sampling is required. Here we describe and validate a novel three compartment model (GFR) for GFR assessment by FITC-Sinistrin clearance, automatically correcting influences like bleaching of skin fluorescence.

Methods: Bolus clearance (GFR was measured in awake Sprague Dawley (SD) rats using the commercially available NIC-Kidney system, immediately followed by a blood sampling based constant infusion clearance (cGFR)). GFR was calculated by a one compartment model (GFR), GFR, and cGFR. Also, 46 GFR measurements in SD rats were reevaluated by GFR.

Results: Results are given in table 1. Mean values of the three methods are comparable with no significant difference. The accuracy (larger STD) of GFR, is lower compared to GFR, and cGFR. This finding was verified by the 46 measurements in SD rats (GFRnew: 0.97 ± 0.18 ml/min/100g b.w.; GFR, 0.95 ± 0.14 ml/min/100g b.w.).

Quantification of the Progressive Fibrosis Development in Mouse Kidney Unilateral Ureteral Obstruction Model Using Fluorescence Lifetime and Second Harmonic Generation Imaging Microscopy

Evgeniya Dobrinikikh,1 Suman Ranjit,1 John Ross Montford,1 Alexander Ovdenkiv,2 David J. Orlicky,1 Allison M. B. Lehman,1 Raphael A. Nemenoff,1 Enrico Gratton,1 Seth B. Furgeson,1 Moshe Levi.1
1Univ of Colorado Denver; 2Univ of California Irvine.

Background: Renal fibrosis is considered to be the final common pathway for most forms of chronic kidney disease (CKD) and involves glomerular sclerosis and/or tubulointerstitial fibrosis. There is great interest in identifying renal fibrosis in the early stages of CKD to prevent progression. Unilateral ureteral fibrosis (UUO) is a well-characterized model of CKD and renal fibrosis. Kidney injury and fibrosis usually are assessed by Picosiris Red staining or immunohistochernistry for collagen isoforms.

Methods: The goal of this study is to compare histologic measures of renal fibrosis to Fluorescence Lifetime Imaging (FLIM) and Second Harmonic Generation (SHG) techniques in our deep imaging microscope DIVER.FLIM and SHG allow quantification of collagen in unstained tissue and can be adapted for live animal imaging. Male C57BL/6 mice were subjected to UUO of right kidney. At 7, 14 and 21 days, both kidneys were harvested. The uninjured left kidney was used as a control. Serial sections of both kidneys were analyzed by Picosiris Red staining or FLIM with SHG.

Results: We performed quantification of Picosiris Red stained-kidneys using polarized light. This showed progressive increase for the number of positive pixels for fibrosis in the left kidney: 9631.9±770.6, 16167.8±6647.7 and 20511.5±5727.6 compared to 5625.3±770.6, 3909.5±2395.9 and 4493.8±2018.4 in the control kidney respectively. Using the Phasor approach to FLIM, comparisons between the two kidneys show that the auto fluorescence lifetime signature give rise to two well separate phaser clusters. Quantification of ten different fields of view for each kidney at the above time-points for SHG signal confirms Picro-Sirius Red scoring.

Conclusions: Finally, the combined FLIM and SHG images let us establish a criterion for quantitative determination of fibrosis directly from the microscope images.

Chemical Imaging: A Novel Approach to Obtaining Label-Free Biochemical Information in Renal Transplant Patients with Recurrent Diabetic Nephropathy

Michael J. Walsh,1 Vishal K. Varma,1 Andre Kajdacsy-Balla,1 Sanjeev Akkina,1 Suman Setty.1 Dept of Pathology, Univ of Illinois at Chicago, Chicago, IL; 2Dept of Nephrology, Univ of Illinois at Chicago, Chicago, IL.

Background: The main treatment for end-stage renal disease is kidney transplantation, which over time undergo chronic rejection including changes in the glomerular, tubulointerstitial and vascular compartments. Also, recurrence of disease in diabetics can mimic transplant glomerulopathy. We have identified biochemical markers using Chemical imaging that were associated with recurrent diabetic nephropathy. Chemical Imaging is an emerging approach to obtain images of the biochemical composition of tissue biopsies in a label-free fashion.

Methods: An initial study focused on identifying patients with no evidence of diabetic nephropathy and patients with advanced diabetic nephropathy in native kidneys. Serial sections were acquired and stained with PAS or imaged using chemical imaging. IR spectra were extracted to identify biomarkers associated with diabetic nephropathy progression. A second study identified transplant patients who underwent very rapid recurrent diabetic nephropathy and patients with no evidence of diabetic nephropathy.

Results: Biomarkers were identified that were changed in renal structures associated with the progression of diabetic nephropathy, including increased levels of glycation. These biomarkers were found to be increased in the cohort of transplant patients that underwent rapid diabetic nephropathy recurrence. In addition, the early biopsies from the patients that underwent late diabetic nephropathy progression were biochemically different from the non-progressive patients, suggesting that chemical imaging may identify pre-histological biomarkers that will predict outcome.

Funding: NIDDK Support
Conclusions: We have identified a number of biomarkers that are associated with the advancement of diabetic nephropathy and that we can track the early recurrence of diabetic nephropathy in surveillance biopsies. In addition, we have highlighted ‘biochemical-signature’ that may be predictive of the later progression of diabetic nephropathy recurrence.

Contrast-Enhanced Ultrasound Characterizes Kidney Lesions with Accuracy Comparable to Contrast-Enhanced CT or MR

Emily H. Chang,1 Sandeep Kasoji,1,2 Paul Dayton,1,3 Wui K. Cheng,2 Kimryn Rathmell.1 1Univ of North Carolina, Chapel Hill, NC; 2North Carolina State Univ, Raleigh, NC.

Background: Incidental kidney lesions are often detected on imaging performed for other reasons. Indeterminate lesions are further characterized with a contrast-enhanced computed tomography (CT) or magnetic resonance imaging (MRI). These tests have many limitations and are contraindicated in patients with allergies to contrast, metallic hardware and chronic kidney disease (CKD). An accurate alternative study is needed. Contrast-enhanced ultrasound (CEUS) is a potential alternative. CEUS uses microbubbles, non- nephrotoxic, gas filled bubbles with lipid or albumin shells, as the contrast agent. We investigated the accuracy of CEUS for malignancy in patients with incidental kidney lesions.

Methods: CEUS was performed on 33 patients. Results were independently interpreted by 2 blinded readers and risk-stratified by the BonnKlassification system. Sensitivity, specificity and predictive values were calculated for lesions with histologic diagnosis as the gold standard. As histology was not available for resected lesions only, we performed secondary analyses using an expanded gold standard definition including clinical resection.

Results: Of the 33 patients, 12 had CKD and 14 had histologic diagnoses. There was 100% intra-reader agreement in the primary analysis (Figure 1A) and 97% agreement in the secondary analysis (Figure 1B). Sensitivities (94-100%), positive (70-93%) and negative predictive (90-100%) values for CEUS were comparable to CT (83-100, 50-67 and 77-100%, respectively) and MRI (81-100, 60-78 and 80-96%, respectively). CEUS specificity (0-56%) was lower than MRI (71-100%).

Figure 1: Diagnostic accuracies based on gold standard of histologic diagnosis (A) and histologic diagnosis or clinical resection (B).

Conclusions: CEUS has excellent potential as an alternative diagnostic tool for kidney lesions among patients with CT/MRI contraindications. Further evaluation is needed.

Lead-Free Drape Aided to Xray Detector Significantly Decreased Radiation Scatter During Access Intervention

Jie Cui,1 Fengyong Liu,2 Zubin Irani.1 1Nephrology Dept, Massachusetts General Hospital, Boston, MA, China; 2Interventional Radiology Dept, Chinese People's Liberation Army General Hospital, Beijing, China; 3Div of Vascular Imaging and Intervention, Massachusetts General Hospital, Boston, MA, China.

Background: Exposure from scattered radiation can be very high during access intervention procedures because of the relatively closer operative position. The purpose of this study is to evaluate whether applying a lead-free, sterile, disposable drape can decrease scatter radiation exposure during access intervention.

Methods: An upper extremity phantom was placed on the angiography table to mimic real-time patient's upper extremity access. Using this model, measurement of scatter radiation was made every one foot away from the phantom before and after applying the drape using a collimated and low-output condition. The scattered radiation dose was measured three times in each spot. The measurement was taken at 0.9m (waist level) as well as neck level (1.5m). Statistical significance was compared using t-test.

Results: Scatter radiation was attenuated throughout the measurement field when the drape was applied. The degree of scatter radiation reduction was distance and height dependent. Scatter radiation decreased 61.6% at the waist level and 81% at the neck level (P<0.05).

Conclusions: The application of this sterile, lead-free drape can significantly reduce scatter radiation in the procedure room. This novel technique can be used to reduce exposure radiation dose to the operators.

Pathogenesis of Brain Damages in Chronic Kidney Disease and Clues for Early Diagnosis

Yao-ping Lin,1,2 Der-Cherng Tarng.1,2 1Medicine, National Yang-Ming Univ, Taipei, Taiwan; 2Medicine, Taipei Veterans General Hospital, Taipei, Taiwan.

Background: There is globally increased prevalence of chronic kidney disease (CKD). Vigorous efforts have been devoted to ameliorate renal deterioration and prevent cardiovascular morbidity/mortality. However, patients also have enough incubation time to develop deranged cognition that severely disturbs quality of life. Neurological pathology/damages may occur in CKD patients long before any overt clinical symptoms can be noticed. Given the similar embryological development as brain, the eyes can be the windows to pinpoint the internal brain pathology. Herein we employed proteomics, animal model and behavior analysis to investigate the possible overlapping biological signatures in the eyes and brain of CKD.

Methods: Subtotal nephrectomized rats were established as CKD model. Open field and object recognition tests were adopted as neurologocen screen. Brain and eyes were harvested for proteomic analysis. Western blotting and immunohistochemistry were used to confirm and localize the identified proteins. To elucidate the global protein changes in the brain and eye of SNX rats, the data was analyzed by Ingenuity Pathways Analysis (Ingenuity Systems, http://www.ingenuity.com/).

Results: The eye pathology appeared in parallel with the brain damages. The significantly dysregulated proteins in the SNX rat eyes were spectrin beta 3, 26S proteasome non-ATPase regulatory subunit 2,6-phosphofructokinase, dihydroydipimidine-related protein, and the heat shock 70, 90a, and chaperonin containing Tep1, subunit 6A (Zeta 1).

All these proteins have been linked to the neuro-degeneration in humans.

Conclusions: There were overlapping eye and brain biological networks. Our results might pave the way for early diagnosis of CKD-neurological pathology via eye examinations, and targeted interventions towards the neurological diseases.

FR-PO384

Metabolomic Profiling of Chronic Kidney Disease Using a Local Exhaustive Exploration Approach

Margaux Luck,1 Eric Thervet,1 Cecilia Damon,1 Nicolas Pallet,1 1Nephrology, Georges Pompidou European Hospital, Paris, France; 2Hypercube Inst, Paris, France.

Background: 1H Nuclear Magnetic Resonance (NMR)-based metabolomic profiling is useful for the diagnosis of CKD stages. Due to the high dimension of NMR spectra datasets and the complex mixture of metabolites in biological samples, the identification of discriminant biomarkers of a disease is challenging. None of the widely used chemometric methods in NMR metabolomics performs local exhaustive exploration of the data.

Methods: We developed a descriptive and easily understandable approach searching for discriminant local phenomena. We selected the most discriminant features from the dataset based on both the normalized mutual information and the chi-2 test. We studied the local distribution of the patient subgroups with identical degree of CKD severity on each feature, using the proprietary algorithm HyperCube, which searches for local overdispersion of an explanatory variable modality, and identifies a combination of variables as well as their value ranges that give the optimal prediction of the outcome of interest. Further, logistic regression on these discriminant features was used to build a predictive model of the CKD severity stage.

Results: We explored a complex dataset that includes 1H-NMR urinary metabolomics, clinical, demogrographic, clinical chemistry and histo-pathological variables, in a cohort of 110 individuals with a CKD. The HyperCube algorithm combined with logistic regression supports the discriminant metabolites obtained with standard Orthogonal Projection to Latent Structure Discriminant Analysis (O-PLS-DA) model. Unlike the O-PLS-DA model, HyperCube algorithm provided clues into the distribution of the CKD severity subgroups.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
with respect to spectral data. The built predictive model identifies metabolomics profiles containing consistent peaks in citrate, dimethylsulfone, trigonelline and glycine. The majority of the predictive variables were urinary metabolites identified by 1H-NMR, indicating that CKD significantly impacts the urinary metabolome.

**Conclusions:** Our findings indicate that HyperCube is a valuable analytical method for the description of CKD severity phenotypes.

RNA-seq Profiling in Uninephrectomized Rats  
Jae Wook Lee, Mark A. Knepper.  
NHLLI, NIH, Bethesda, MD.

**Background:** Renal hypertrophy occurs as a compensatory response to reduction in nephron mass. To identify early gene expression changes in renal hypertrophy, we profiled whole-kidney transcriptome in the contralateral kidney of uninephrectomized rats using RNA-seq.

**Methods:** 5-week-old male Sprague-Dawley rats received right uninephrectomy (UNx, n=4 at each time point) or sham surgery (S, n=4 at each time point). Rats were sacrificed at 24, 48, and 72 hours after surgery. 1.5 µg of total RNAs from the left kidney was used to make cDNA libraries for Illumina sequencing. Reads were mapped to Ensemble genes and Wald test for a negative binomial model was used to call differentially expressed genes.

**Results:** Total RNA yields did not differ significantly between UNx and sham kidneys. Each library had 35-42 million reads and more than 80% of reads were uniquely aligned. At 24 h, 45 transcripts were upregulated and 72 downregulated in UNx. Upregulated transcripts included connective tissue growth factor (Tgfβ), regulator of cell cycle (Rcsg), serum/glucocorticoid-regulated kinase (Sgk1), glucocorticoid-induced leucine zipper protein (Tic22D2), a zine finger transcription factor (Zfhx16), and genes related to steroid biosynthesis (e.g. Insa7). At 48 h, 183 transcripts were upregulated and 103 downregulated in UNx. Among upregulated transcripts were cell-cycle genes including centromere proteins (Cenpa, Cenpf, and Cenpb); MMC helicase subunits (Mcm3, Mcm5, and Mcm6); cyclins (CcnA, CcnD1, CcnE, and CcnF); cyclin-dependent kinase (Cdk1); and polo-like kinase (Plk1). Among downregulated transcripts at 48 h were transcription factors (Jun, Hmnr, Klf9, Klf15, Foxo3, Zfp36, Zfp354a, Zfhx16, and Zic3). At 72 h, 769 transcripts were upregulated and 704 downregulated in UNx. Upregulated transcripts included Ctgf, Sgk1, Zfhx16, and cyclins (Ccnb1, CcnA2, CcnB1). Interestingly, Ctgf, Sgk1, Zfhx16, and Tic22D2 showed a triplication response, upregulated at 24 h and 72 h and downregulated at 48 h, 72% consistent with an underdamaged control sample.

**Conclusions:** RNA-seq revealed upregulation of multiple transcripts involved in cell division as a central mechanism of compensatory response in the contralateral kidney after uninephrectomy. Genes upregulated at 24 h such as Ctgf, Rcg, Sgk1, and Tic22D2 may trigger this response.

The Application of Potential Label-Free Mid-Infrared Biomarkers in Patients with Biopsy-Proven Kidney Diseases  
Met-Ching Yu,2 Peter R. Rich,3 Vinod Sathyanarayana Dibbar,2 Jennifer Smith,2 Frederick W.K. Tam,2  
2Paediatric Nephrology, LinKou Chang Gung Medical Centre, Taoyuan; 2Imperial College Kidney & Transplant Centre, Hammersmith Hospital, Imperial College, London; 3Structural and Molecular Biology, Univ College London, UCL Centre for Nephrology, Univesity College London, Royal Free Hospital.

**Background:** We have previously discovered novel spectral markers, the urinary 1540 cm⁻¹ and 1565 cm⁻¹ peaks, indicating progression of experimental GN using Fourier transformed infrared spectroscopy (FTIR) (2013 & 2014 ASN). In this study, the aims were to investigate these spectral markers in patients with different biopsy-proven kidney diseases, and the correlations between the spectral markers with clinical features.

**Methods:** The urine and plasma samples were collected at the time of renal biopsy from 50 patients at Imperial College Renal & Transplant Centre, London, UK and compared with healthy volunteers. All samples were measured by FTIR spectrometer and analysed by the established method. The biochemistry results such as urine protein/creatinine ratio (uPCR), Scr and renal histopathology were collected.

**Results:** In comparison with healthy volunteers, patients with GN, diabetic nephropathy (DN), membranous nephropathy and FSGS exhibited significantly higher levels of the urine 1540 cm⁻¹ and 1565 cm⁻¹ peaks, and the correlations between the spectral markers with clinical features.

**Conclusions:** Our findings show the use of the specific urine and plasma FTIR biomarkers will be a novel approach to investigate progressive kidney diseases, including GN and DN, without chemical manipulation of samples.

**Funding:** Private Foundation Support

Omics Investigation of Urine Samples with and without Addition of a Protease Inhibitor  
Claire Boulange,1 Ilse M. Rood,2 Petra Zürbig,3 Manuja Kaluarachchi,4 Elaine Holmes,4 Franz S. Schaefer,5 John C. Lindon,4 Jack F. Wetzels,2 Jeroen Deegens,2  
1Metabometrix Ltd, London, United Kingdom; 2Dep of Nephrology, RadboudUMC, Nijmegen, Netherlands; 3Mosaïques Diagnostics GmbH, Hannover, Germany; 4CSM, Dep of Surgery & Cancer, Imperial College London, London, United Kingdom; 5Dep of Nephrology, Univ of Heidelberg, Heidelberg, Germany.

**Background:** Urine is an ideal biofluid for biomarker discovery. To conserve the protein profile integrity, samples are stored with a protease inhibitor (PI). It is unknown whether the PI alters the metabolic and proteome profiles. This study aimed to test the influence of the PI on metabolomic and proteomic analysis of urine samples.

**Methods:** We collected 10 urines from normal controls (NC, n=4) and membranous nephropathy patients (MN; n=6) and the samples were aliquoted. A PI (mini complete, Roche) was added to an aliquot of each sample. Urine samples were stored at -80°C. For metabolomics, samples were analyzed by 1H NMR spectroscopy and HILIC-UPCL-MS. Multivariate analysis (MVA) was used to elucidate any PI effect in normal urine and proteinuria. For peptidomics, capillary electrophoresis-coupled mass spectrometry was used to profile the low molecular weight proteome in urine.

**Results:** Unsupervised MVA of urine NMR metabolic profiles showed clear discrimination between NC-PI, NC-PI, MN-PI and MN-PI. Supervised MVA of PI+ and PI- samples revealed subtle changes in metabolic levels and the presence of intense signals between 3.63 to 3.91 ppm in the PI+ samples, obscuring endogenous metabolite peaks. Unsupervised MVA of HILIC-UPCL-MS data showed discrimination between MN-PI and NC-PI. Supervised MVA of PI+ and PI- samples showed no detectable difference between the two sample types. For peptidomics, MVA between PI+ and PI- resulted in no statistically significant peptide differences. Further validation with a proteome classifier for CKD (CKD273) showed no statistical significant difference between samples with and without PI.

**Conclusions:** The PI addition did not affect the distinction between MN and NC in the metabolome and proteome analysis. However, PI may affect the analysis of metabolic subclasses using NMR. Therefore, samples with PI can be used, but with caution.

**Funding:** Other NIH Support - The research leading to these results has received funding from the European Union’s Seventh Framework Programme (FP7/2007-2013) under grant agreement no. 305608 (EURentOmicS).

Quantifying Uropathogenic Bacteria Infection in 3D
Neal A. Parasnis,1 Alexander Klose.2 1Medicine, Univ of Washington, Seattle, WA; 2In Vivo Analytics, Inc, New York, NY.

Background: Urogenital tract infection is a disease that annually affects more than 250 million people worldwide; however, the number of antibiotic resistant strains has been increasing while newly validated antibiotics have been lagging behind. We have developed a method to monitor and quantify a uropathogenic bacterial infection with multispectral bioluminescence tomography (BLT) of a novel bioluminescent uropathogenic E. coli (UPEC-lux).

Methods: We modeled pyelonephritis by transurethral injection of UPEC-lux. First, we acquired bioluminescence images with a bioluminescent optical imager at four different spectral windows centered at 575, 655, 695 nm and with bandwidth of 50 nm. The multi-orientation images were acquired using a mirror gantry for simultaneous imaging of the dorsal and ventral view. The animal was placed in a fixed position into a novel box body shape conforming mold, placed onto the mirror gantry and spectral images were acquired. For in vivo bacterial quantification, a novel calibration device using tissue mimetic material was used. The light intensity imaging data became input to a novel BLT reconstruction algorithm based on an expectation-maximization (EM) method and the simplified spherical harmonics (SP3) equations for modeling in vivo light propagation. Post reconstruction, we calculated the total photon emission density of a volume of interest (VOI). We then calculated the in vivo organ bacterial load by co-registering it to a novel organ probability map.

Results: The EM method reconstructed the 3D photon emission density of the UPEC-lux and mapped the signal to a novel organ probability map. We analyzed these UPEC-lux in a model of pyelonephritis and we were able to determine the bacterial load in the kidney by BLT which correlated to CFUs from serial dilution of kidney homogenate (Pearson correlation coefficient R2=0.92). For the first time, we could demonstrate the feasibility of determining the bacterial burden in the kidneys.

Conclusions: The ability to monitor bioluminescent signal non-invasively will be a powerful tool to understand the pathophysiology of urinary tract infections and a new method to test novel antibiotics.

Public Engagement of Kidney Related Health Information on the Internet
Samir Sulaiman, Joseph A. Vassalotti, Vijay Lapsia. Medicine, Icahn School of Medicine, New York, NY.

Background: The National Kidney Disease Education Program (NKDEP), a part of the National Institutes of Health (NIH) provides an authoritative, up-to-date and trusted consumer health information resource for patients with kidney disease. We hypothesized that the US government (GOV) supported websites would have the highest consumer engagement of kidney related health information on the internet.

Methods: We used traffic rank based on publicly available data obtained from alexa. com and semrush.com, as a marker of website consumer engagement and popularity. We identified the top websites in the health category and disease sub-categories. The websites were classified based on ownership and data collected on unique US visitors, rank, page views per visitor and daily time spent.

Results: In the general health category, the NIH website ranked at the top; however, the consumer focused NLM website ranked 9th, behind webmd.com (2nd) and mayoclinic.org (5th). Among the top 25 websites across all disease categories, Davita.com, a for-profit business with the only kidney related website. Cancer was the only disease condition with more than 1 website in the top 25 (7 total). The NKDEP ranked 8th in the genitourinary disorder group. The NKDEP had fewer unique US visitors (59,408) compared to Davita.com (307,729) and Kidney.org (241,550).

Conclusions: In terms of consumer engagement, the kidney specific NIH website - NKDEP, as well as the non-profit kidney.org supported by the National Kidney Foundation were out performed by Davita.com, a publicly listed for-profit company by an unexpectedly wide margin.

Media Awareness and Reporting of Dialysis Disruptions and Death from Natural Disasters in the United States
Samir Sulaiman, Lindsay E. Jubelt, Vijay Lapsia. Medicine, Icahn School of Medicine, New York, NY.

Background: Patients receiving in-center hemodialysis are particularly vulnerable during and after disasters. Evidence of morbidity/mortality from disruption to dialysis in a disaster is limited and is so far based on statistical inference. We investigated media awareness and reporting of dialysis disruptions and death during natural disasters in the US.

Methods: We identified all major disaster declarations by the US Federal Emergency Management Agency. Disasters since 2000, excluding man-made and wildfires, with at least 1 known death were included. We then conducted a systematic Google News search to identify articles within 30 days of each disaster in the electronic mass media (media).

Results: Of 887 natural disasters from 2000-2015, 120 had at least 1 reported death (total 4,383 deaths). Of the 61 deaths reported during 3 winter storms was dialysis related, with 2 instances of dialysis disruptions and 3 instances with potential for dialysis disruption. Tornadoes, which occurred most often and resulted in the second highest mortality had no coverage in the media during its aftermath.

Conclusions: Based on media reports, hurricanes and winter storms are major contributors of treatment disruption and mortality in patients on dialysis. Media reports can help identify the magnitude of disruption to dialysis operations as well as deaths.

FR-PO392

A Comparison of Physician Reporting versus Computer Algorithms for CMS Data Reporting on Form CMS-2728
Mohammed Said Malas,1,2 Ranjani N. Moothri,1 Jon D. Duke,2 Sharon M. Moe.1 1IU, Indianapolis, IN; 2RI, Indianapolis, IN.

Background: The CMS-2728 form (ESRD Medical Evidence Report) assesses 23 comorbidities chosen to reflect poor outcomes and increased mortality risk. Previous studies have questioned the validity of physician data entry on forms CMS-2728 and the relationship to hard outcomes. We hypothesize that reporting of comorbidities by a computer algorithm identifies more comorbidities and therefore is superior to physicians’ completion of the forms.

Methods: We collected data from CMS-2728 forms for all 296 patients who had included ESRD diagnosis and received chronic dialysis between 2005 and 2014 at Indiana University outpatient dialysis centers. We analyzed patients’ data from electronic records systems that collated information from multiple sources. Previously utilized computer algorithms or natural language processing was used to extract data on 10 comorbidities (Table) for a period of up to 10 years prior to ESRD incidence. These algorithms incorporate billing codes, prescriptions, and other elements that are relevant to each comorbidity. We compared the presence of these comorbidities on the forms to the determined presence according to the algorithms.

Results: The computer algorithms had higher reporting of comorbidities compared to physician completion of the forms (Table). This remained true when decreasing the data span to one year and using only single health center data sources.

Variable | Number | Deaths | Articles with dialysis disruptions | Instances of Dialysis Death | Instances of Dialysis Disruptions | Potential For Dialysis Disruptions
--- | --- | --- | --- | --- | --- | ---
Hurricanes | 19 | 2,702 | 13 | 4 | 7 | 12
Tornadoes | 84 | 1,454 | 0 | 0 | 0 | 0
Earthquakes | 2 | 3 | 0 | 0 | 0 | 0
Floods | 11 | 162 | 0 | 0 | 0 | 0
Wildfires | 1 | 1 | 0 | 0 | 0 | 0
Winter Storms | 3 | 61 | 5 | 1 | 2 | 3
Total | 120 | 4,383 | 18 | 5 | 9 | 15

*Dialysis Disruptions: Death due to disaster related disruption to dialysis

Conclusions: Based on media reports, hurricanes and winter storms are major contributors of treatment disruption and mortality in patients on dialysis. Media reports can help identify the magnitude of disruption to dialysis operations as well as deaths.

*Estimates as of 05/15/2015
NA: Not available

Conclusions: In terms of consumer engagement, the kidney specific NIH website - NKDEP, as well as the non-profit kidney.org supported by the National Kidney Foundation were out performed by Davita.com, a publicly listed for-profit company by an unexpectedly wide margin.

Kidney Dashboard: An Integrated Support Tool for Clinical Care and Research Involving Kidney Patients

Jamie S. Hirsch,1,2 Hojuat Salmasian,3 Amy Y. Chan,1 David Vavdrey,2 Matthew Fred,3 Krzysztof Kyrulk,1 1Div of Nephrology, Dept of Medicine, Columbia Univ, New York, NY; 2Dept of Biomedical Informatics, Columbia Univ, New York, NY; 3NewYork-Presbyterian Hospital, New York, NY.

Background: Large amounts of data are contained in electronic health records (EHR), and retrieval of relevant information for nephrology patients is cognitively complex and time-consuming. This results in inefficiencies, missed opportunities to improve care, and difficulty adhering to complex clinical guidelines. We developed a Kidney Dashboard, an integrated tool that gathers and analyzes information to facilitate the care and research of kidney patients.

Methods: Relevant clinical data were catalogued and categorized, including visit history, billing data, vital signs, labs, imaging, pathology, and medications. We automated generation of derived data, such as estimation and trending of eGFR, proteinuria, and automated CKD staging. We implemented a comprehensive rule-based alert system based on KDIGO guidelines to provide real-time clinical decision support.

Results: The Dashboard was created within the clinical information system at NewYork-Presbyterian Hospital, incorporating inpatient and outpatient data from multiple electronic health records. It uses a tile layout, where each tile represents a relevant section of data that is most impactful to kidney patients.

Conclusions: The Kidney Dashboard aims to improve care and facilitate research on KDIGO guidelines to provide real-time clinical decision support.

FR-PO394

Forecasting a Renal Prognosis of IgA Nephropathy Using Machine Learning: Validation Study

Haejong Lee,1 Junhyung Noh,2 Hyosang Kim,3 Won Seok Yang,1 Yoon Su Kim,3 Dong Ki Kim,3 1Internal Medicine, Seoul National Univ Hospital; 2Computer Science and Engineering, Seoul National Univ College of Engineering; 3Internal Medicine, Asan Med Center.

Background: We aimed to develop and validate individual outcome prediction models in IgAN patients using machine learning.

Methods: We included adult IgAN patients from Seoul National University Hospital (SNUH, n = 1,540) and Asan Medical Center (AMC, n = 1,044) at the time of renal biopsy. They were divided into development (followed up <10 years) and validation (follow up <10 years) sets, respectively. The outcome was 10-year renal survival (10YRS) probability. We developed prediction models from SNUH test set by using logistic regression (LR) with Lasso method, a classification and regression tree (CART), and neural network (NN) using 16 clinic-physiologic variables. We also used bagging, random forest (RF) and boosting for ensemble learning. Finally, those models were validated internally in SNUH prediction set and externally in AMC development and prediction sets.

Results: Considering missing data, 1,514 and 847 patients were included from SNUH and AMC cohorts. In the LR model, eGFR, hemoglobin, proportions of GS and SS, interstitial fibrosis (IF) were selected as predictors for ESRD. In the CART model, eGFR 53.3 ml/min/1.73m2 was proved to be a watershed for 10YRS, followed by proportion of GS and SS, IF, hemoglobin and proteinuria, sequentially. In addition, the ensemble learners showed good performance (accuracies of bagging, 0.868; RF, 0.874; boosting, 0.882). These individual learners were validated internally with good performance (sensitivities of LR, 0.855; CART, 0.921; NN, 0.952; bagging, 0.857; RF, 0.921; boosting, 0.921). And finally, we proved the robustness of those models from external validation. Good performances of both development (sensitivities of LR, 0.847; CART, 0.867; NN, 0.855; bagging, 0.852; RF, 0.872; boosting, 0.851) and prediction sets (sensitivities of LR, 0.980; CART, 0.982; NN, 0.941; bagging, 0.882; RF, 0.902; boosting, 0.922) were showed.

Conclusions: We developed robustness of prediction models using machine learning for the individual’s likelihood of 10YRS in IgAN with both internal and external validation.

FR-PO395

Quantifying the Gender Reimbursement Gap in Nephrology

Sadeem Ali, Xiangming Fang, Panjak Jawa, Tepas P. Desai. Nephrology, East Carolina Univ; Greenville, NC.

Background: 2015 Medscape Compensation Report suggests that female providers earn less than male providers but the sample size was 16957 only, 1% Nephrologists. To analyze the financial disparities, we compared total Medicare reimbursements paid to males & females.

Methods: We obtained reimbursement data from 2014 Medicare Provider Utilization & Payment Data Physician Public Use File. We consolidated all reimbursements by NPI number & categorized them by specialty & sex. We adjusted reimbursement differentials against number of Medicare beneficiaries seen & services provided. Linear regression models were used to compare reimbursements.

Results: We analyzed 246,996 providers in 13 specialties; 5% were Nephrologists. Female Nephrologists were reimbursed less $41,776.96 (unadjusted); the 6th worst female-to-male reimbursement differential. In the adjusted analysis, female Nephrologists had the worst reimbursement differential: less $17,971.66.

Conclusions: Female Reimbursement Deficits ($) Lower & Upper Refer To 95% Confidence Interval Bounds.

Conclusions: When adjusted for the number of beneficiaries seen & services provided, female Nephrologists endure the largest reimbursement gap by sex in any specialty. Steps should be considered to close his gap.

FR-PO396

Engineering Renal Engineering for Renal Delivery of Molecular Therapeutics

Pan Liu, Jing Jin. Dept of Medicine-Nephrology/Hypertension, The Feinberg School of Medicine, Chicago, IL.

Background: Targeted delivery of therapeutic enzymes to the kidney is desirable for treatment of renal diseases and beyond. Previously, approaches that exploit the renal excretion of low–molecular weight proteins (LMWP) have been attempted. However, these carriers can only deliver chemical compounds, and their efficiency is further hampered by in vivo clearance. In order to deliver enzyme cargos, we designed carrier proteins for specific and long-lasting renal delivery. We engineered a fusion protein comprised of a kidney-targeting polybasic tag (PBT) and an Fc segment for extended stability. The probes were then separately labeled with a radionuclide (^99mTc) tracer. Following i.v. injection of the probes to rats, we performed SPECT in whole body scanning. Radiographs were obtained in a time series for up to 1 hour. In parallel, we performed histology studies of kidney sections to determine the sub-anatomical patterns of the injected probes.

Results: Prominent and sustained kidney localization of (^99mTc)-PBT-Fc (>95%) was observed by SPECT, a pattern in contrast to that of the (^99mTc)-Fc control that was mainly in blood circulation during the course of observation (only ~5% is in the kidney). (^99mTc)-
Duramycin reached the kidney quickly and then followed through urinary excretion to the bladder within 10 minutes, leaving 5% remained in the kidney. The imaging results were consistent with IHC findings from mouse kidney following probe injections, which shows the PBT-Fc, but not Fc-alone, binding the glomeruli and tubule basement membrane shortly after injection. PBT-Fc sustained in the kidney for at least 10 days.

Conclusions: Our designed PBT-Fc carrier exclusively targets kidney through binding to the glomeruli and tubule basement membrane. This recombinant probe also achieves long-lasting kidney retention (days as compared to minutes for LMWP), yet another desirable property for targeted therapeutic delivery. This vehicle will potentially be useful for delivery of molecular therapies, particularly enzyme proteins, to the kidney.

Dynamic Culture on an Orbital Shaker Alters the Phenotype of Primary Human Renal Tubular Epithelial Cells
Nicholas J. Ferrell, Jin Cheng, Simeng Miao, William Henry Fissell.1 Nephrology, Vanderbilt Univ Medical Center, Nashville, TN;2 Biomedical Engineering, Vanderbilt Univ, Nashville, TN.

Background: Primary cells cultured in vitro gradually lose features characteristic to the in vivo cell type, variously termed "senescence" or "culture stress." Culture conditions that help maintain cell-specific phenotype are advantageous for cell biology and tissue engineering. Here we evaluated the phenotype of primary renal tubular epithelial cells after applying apical fluid shear stress using an orbital shaker.

Methods: Human renal tubular epithelial cells were isolated from donor kidneys not suitable for transplant. Cells were cultured on Transwell inserts under static conditions or on an orbital shaker at a frequency producing fluid shear stresses of 2 dyn/cm². Transepithelial resistance was measured daily. After 2 weeks in culture, cell density was analyzed by counting DAPI stained nuclei, and expression of tubule-specific markers was measured by PCR and western blotting.

Results: Dynamic culture significantly increased steady state transepithelial resistance from 344±31 to 544±32 Ω·cm² (p<0.001) and resulted in a 2.1±0.4, 1.9±0.2, respectively. Cells grown under shear also showed increased protein expression of gamma-glutamyl transpeptidase.

Conclusions: Primary renal tubular epithelial cells grown on an orbital shaker with physiological levels of fluid shear stress appear to express proximal tubule markers more than cells grown in static conditions. This may be due to increased nutrient delivery and waste removal with improved mixing at the apical brush border, or due to specific gene regulation related to mechanotransduction. Further mechanistic insight may allow investigators to develop improved in vitro culture systems for cell biology and tissue engineering and more accurate in vitro models of disease.

CRISPR/Cas9-Mediated Site-Specific Mutation in Rat Angiotin Protein Gene via Direct Injection of One-Cell Embryos
Yaochun Zhang, Zakir Hossain, Bo Lan,1 Chang-Yien Chan,1 Hui Kim Yap,1 Kar Hui Ng.1 1Dept of Paediatrics, National Univ of Singapore, Singapore; 2Cancer Science Inst of Singapore, National Univ of Singapore, Singapore.

Background: Genetically modified animals represent a crucial tool for understanding gene function in development and disease. The recently developed CRISPR/Cas9 system is an efficient gene-targeting technology to generate genetically modified animals. We have performed exome sequencing in a Singapore Chinese family with X-linked recessive membranous nephropathy associated with Fanconi syndrome and anti-tubular basement antibodies, and identified AMOT, coding for angiomotin, as a novel candidate gene with a putative disease-causing mutation p.S50G in the N-terminal of the p130-AMOT isoform. Preliminary work confirmed the expression of angiomotin in renal tubular cells. This study aimed to introduce the mutation into rat genome via direct injection of CRISPR/Cas9 into one-cell embryos, establishing rat models for downstream pathological studies.

Methods: The transRNA crRNA fused single guide RNA (sgRNA, 20ng/µl), together with Cas9 protein (40ng/µl) and a single-stranded oligonucleotide (ssODN, 3ng/µl), which encodes the p.S50G mutation of angiotin and serves as template for HR-mediated repair, were introduced into the rat pronucleus via microinjection. Pups produced from the injected embryos were first detected by mismatch-specific T7 endonuclease I digestion. Animals carrying mutations were sequenced to determine the precise sequence.

Results: In the 32 survived pups, one (3.1%) founder rat was identified to carry the heterozygous mutation. After crossing F0 with a wild-type rat, ten F1 rats were delivered, of which four males (40%) were carrying the mutation on their X chromosomes, while 2 (20%) were heterozygous females. No phenotype data is available currently as the animals are only three weeks old. Homozygous female rats are expected to be produced by crossing F1 animals. Heterozygous female rats are expected to be produced by crossing F0 females and wild-type males. After crossing F0 with a wild-type rat, ten F1 rats were delivered, of which four males (40%) were carrying the heterozygous mutation. After crossing F1 with a wild-type rat, ten F2 rats were delivered, of which four males (40%) were carrying the mutation on their X chromosomes, while 2 (20%) were heterozygous females.

Conclusions: We successfully introduced the mutation in vivo and in vitro study of gene function.

Funding: Government Support - Non-U.S.
Conclusions: Injectable HA hydrogels can be used to deliver IL-10 and improve local and systemic outcomes of ischemic AKI. Therapy improved renal function, reduced collagen deposition, and reduced systemic IL-6-28 days following AKI. HA alone improved outcomes; the addition of IL-10 to the HA resulted in further histological improvement.

Substrate Stiffness Regulates Renal Epithelial Cell Cilia Formation via Autocrine TGFβ Signaling
Minfeng Ao,1 Jin Cheng,1 Nicholas J. Ferrell,2 H. David Humes,2 Shuvo Roy,3 William Henry Fissell.1 1Nephrology and Hypertension, Vanderbilt Univ, Nashville, TN; 2Bioengineering and Therapeutic Sciences, Univ of California, San Francisco, San Francisco, CA; 3Nephrology, Univ of Michigan, Ann Arbor, MI.

Background: The primary ciliary sensation the extracellular environment. Malformation of primary cilia has been shown to result in kidney disease. Although much is known regarding ciliogenesis, the role of mechanical features of the microenvironment in cilia formation is poorly understood.

Methods: Human primary proximal tubule epithelial cells (HRECs) and LLC-PK1 cells were plated on collagen-coated polyacrylamide gels with different stiffness (0.5 KPa, 1 KPa, 10 KPa and 40 KPa) and grown for 5 to 7 days. Cilia formation was analyzed by immunofluorescence staining of AC-tubulin followed with microscopy imaging. Protein expression was measured by immunoblotting. Recombinant TGFβ 1 and an inhibitor of TGFβRII SB431542 were used for TGFβ signaling modulation. LiCl was utilized to stimulate P-GSK3b.

Results: Stiff hydrogels (10 KPa and 40 KPa) gave rise to higher ciliary density than compliant gels (0.5 KPa and 1 KPa) did (60% vs 20%). Furthermore, this phenotype could be altered by manipulation of transformation growth factor beta (TGFβ) signaling: addition of TGFβ1 could increase the cilia frequency even when the cells were on compliant gels; similarly, inhibition of TGFβ receptor II impairs cilia formation in the context of stiff substrates. Further supporting a role for TGFβ, substrate stiffness was associated with increased SMAD2 and GSK3β phosphorylation. Incubation with LiCl also increased GSK3b phosphorylation and cilia formation independent of TGFβ.

Conclusions: Substrate stiffness determines cilia formation through TGFβ signaling via downstream GSK3β phosphorylation. This work highlights that substrate mechanical properties have a strong influence on markers of differentiation. This has relevance for tissue engineering efforts and also suggests a mechanism of disease progression in the scurrr kidney. This may broaden researches on kidney disease and contribute to disease therapy.

FR-PO402 An Additive Role of Microfluidics on KLF 15-Induced Differentiation of Human Primary Podocyte Seung Hoe Yang,1 Eunjin Bae,2 Sejoong Kim,2 Kwon Wook Joo,1,2 Chu Soon Lim,1,2 Yon Su Kim,2,3 Dong Ki Kim.1,2 1Kidney Research Inst; 2Internal Medicine, Seoul National Univ College of Medicine, Seoul.

Background: Podocyte de-differentiation is one of major problems during the process of primary podocyte culture. Recently, much interest has been focused on the topic, yet less progress has been made in this process renders a progress. Grippel (like factor of KLF 15) was reported to be a novel transcriptional regulator of podocyte differentiation and its expression was increased by retinoic acid (RA) which promotes the differentiation of podocytes. But, the duration of podocyte differentiation process remains long. Here, we present a novel in vitro protocol to induce podocyte differentiation.

Methods: To mimic in vivo biological environment of glomerulus, a polydimethylsiloxane (PDMS) microfluidic device was used. The human primary podocytes were cultured in the 500 mm by 130 mm microfluidic channel and were stimulated with a laminar fluidic shear stress of 0.5 dyn/cm² cultured in the 500 mm by 130 mm microfluidic channel and were stimulated with a laminar flow. The size of podocytes became larger and the height of podocytes increased by a factor of 2.3 fold. Lastly, the podocytes aligned with the direction of flow.

Conclusions: In conclusion, we were able to promote podocyte differentiation in the shorter processing time with microfluidics and RA. Yet, more effort to mimic biological aspects of kidney such as complex structure with multiple cell layers and round surface is necessary.

FR-PO403 CCL18 Correlates with Disease Activity in ANCA-Associated Necrotizing Glomerulonephritis Silke R. Brië,1 Christian F. Krebs,1 Martin Busch,2 Thorsten Wiech,3 Ulf Panzer,4 Rolf A. Stahl.1 1III. Medizinische Klinik, Universitätsklinikum Hamburg-Eppendorf, Germany; 2Klinik für Innere Medizin III, Universitätsklinikum Jena, Germany; 3Inst für Pathologie, Universitätsklinikum Hamburg-Eppendorf, Germany.

Background: Microarray analysis of renal tissue from patients with antineutrophil cytoplasmic antibody (ANCA)-associated necrotizing glomerulonephritis (GN) revealed the CC chemokine ligand 18 (CCL18) as the highest up-regulated chemokine. The renal production of CCL18 was associated with fresh glomerular lesions and impairment of renal function. The cellular sources of CCL18 were identified as macrophages and dendritic cells. CCL18 serum levels were elevated in patients with newly diagnosed ANCA GN as well. In order to test whether CCL18 might serve as a biomarker of relapsing renal ANCA disease, we prospectively analyzed CCL18 serum levels.

Methods: Hundred thirty-five patients with biopsy proven ANCA GN were prospectively analyzed for CCL18 serum levels. Patients relapsing in the study were in remission on maintenance therapy (n=117) or without immunosuppressive treatment (prednisolone 5mg or less was accepted) (n=18). Serum levels of CCL18 were measured by ELISA every three months. Renal relapse was defined as either rising serum creatinine with urinary red cell casts or biopsy-confirmed active ANCA-associated glomerular lesions (i.e. fibrinoid necrosis and/or cellular crescents) accompanied by an intensification in immunosuppressive treatment.

Results: During a mean follow up time of 11.6 ± 8.3 months, 16 patients developed a renal relapse. CCL18 levels were higher in relapsing patients when compared with patients without renal relapse (p<0.001; 167 ± 50 vs. 83 ± 17 ± 46.38 ± 38 ng/ml). CCL18 serum levels increased at the time of relapse and decreased after immunosuppressive therapy was restarted or intensified (p=0.01; ANOVA; p<0.001).

Conclusions: CCL18 serum levels are associated with disease activity in patients with ANCA GN and might serve as a marker of renal relapses in the surveillance of these patients.

FR-PO404 Prognostic Value of Persistent Hematuria and Proteinuria in ANCA-Associated Vasculitis: Data from the European Vasculitis Study Group (EUVAS) Therapeutic Trials Alexandre Karras,1,2 Thomas F. Hiemstra,3 Rachel B. Jones,2,4 Nicholas J. Ferrell,5 David R.W. Jayne,2,6 1Nephrology, HEGP Hospital, Paris, France; 2Nephrology, Addenbrooke’s Hospital, Cambridge, United Kingdom; 3On behalf of the EUVAS Study Group.

Background: Renal involvement is frequent ANCA-associated vasculitis (AAV), due to crescentic glomerulonephritis (CGN). Hematuria (Hu) and proteinuria (Pu) are detected during the initial and active phase of CGN but the prognostic value of the persistence of these urinary abnormalities during the remission phase of AAV is still controversial.

Methods: Data were combined from three EUVAS trials (IMPROVE, RITUXVAS, MYCYC), providing data for Hu and Pu at month 6 (M6) following initiation of immunosuppression and patient follow-up until month 18 (M18). Hu was defined as the presence of >10 RBC/mm3. Proteinuria was evaluated by protein-to-creatinine ratio (PCR, g/gmml).

Results: Data concerning 337 patients were available for analysis. ANCA specificity (PR3/MPO) was 58.37%, renal involvement was present in 73% of cases and initial mean eGFR was 46±3.2 ml/min/1.73m2. Hu was still positive at M6 in 27% of cases, although 96% of patients were in AAV remission. Positivity of Hu at M6 was associated with more severe initial nephropathy but was not predictive of renal dysfunction at lastFU (mean eGFR at M18 was respectively of 55.2±60 and 60±24.4 ml/min for Hu+ and Hu- patients, respectively). Proteinuria at M6 was <0.03 g/mmol in 53% of cases, between 0.03 and 0.1 g/mmol in 25%, >0.01 g/mmol in 22%. Among patients with M6 Pu >0.1 g/mmol, 29% had CKD stage 4 or 5 at M18, vs 3.5% and 11.5% respectively for patients with M6 PCR <0.03 and 0.03-0.1 g/mmol. Multivariate analysis using a mixed effects model demonstrated that persistence of eGFR during follow-up was independently associated with age (p<0.01), baseline eGFR (p<0.001) and M6 proteinuria (p<0.002), but not with M6 haematuria (p=0.284) nor ANCA specificity (p=0.82).

Conclusions: Persistence of micro-hematuria during the remission phase of AAV is associated with more severe initial renal involvement but does not predict poor renal outcome. Degree of proteinuria at M6 reflects more severe kidney damage and is an independent predictor of CKD progression in AAV nephropathy.

FR-PO405 ANCA Associated Vasculitis: Safe and Effective Induction of Remission with Low Dose Cyclophosphamide, Rituximab, and Reduced Exposure to Glucocorticoids Frank B. Cortazar,2 Karen A. Laliberte, Andrew P. Murphy, Katherine M. Cosgrove, William Franklin Pendergraff, John Niles. Renal Associates, Massachusetts General Hospital, Boston, MA; Kidney Center, Univ of North Carolina (UNC), Chapel Hill, NC.

Background: Rapid induction of remission in ANCA-associated vasculitits(AAV) is essential to prevent irreversible organ damage. Current regimens use glucocorticoids(GC) combined with either cyclophosphamide(CTX) or rituximab(RTX).To effectively induce remission while minimizing GC exposure,we devised a standard induction(SI) protocol that combines RTX,low-dose bridging oral CYC,and a rapid GC taper.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Methods: Retrospective analysis of AAV pts treated w/ new SI regimen: RTX 1 gm Q2wk x 2 doses, oral CYC 3 mg/Kg/d x 1 wk and 1.5 mg/Kg x 2 x2 (max adj) for eGFR, and pulse solumedrol followed by a rapid prednisisone (pred) taper to £15 mg by 5wks. Remission defined as BVAS-WG 0 and pred dose £7.5 mg/d. Pts received SI alone or SI+ plasma exchange (PE).

Results: 74 pts treated with SI and 35 pts w/SI+PE (table1). Time to remission in the SI and SI+PE was 117 ± 53 and 122 ± 39 days, respectively (p = 0.67). Cumulative incidence plots (Figure 1). Among survivors, 100% of SI and 97% of SI+PE achieved remission. 3 pts (4%) in SI and 1 (3%) in SI+PE died during induction. There were 0.04 treatment-related serious adverse events/pt month in both groups.

Conclusions: RTX with low-dose bridging CYC allows for successful induction of remission in essentially all AAV pts while attenuating exposure to high dose GC. Treatment-related adverse events were minimal. Our data provide an impetus for a randomized trial comparing this new regimen with the standard of care.

FR-PO407
Double Positivity for ANCA and Anti-GBM Antibodies: Clinical Characteristics and Long-Term Outcomes of a Multi-Centre Cohort

Stephen Paul McAdoo,1 Anisha Tanna,1 Sophie Ohlsson,2 Zdenka Hruskova,3 Maria Weiner,4 Jeremy B. Levy,5 Vladimir Tesar,5 Marten Segelmark,5 Charles D. Pusey.5 1Imperial College London; 2Land Univ; 3Charles Univ Prague; 4Linköping Univ.

Background: Co-presentation with both ANCA and anti-GBM disease is a rare phenomenon. Current studies indicate that cases include small numbers and report variable outcomes. We aim to describe the clinical features and outcomes of a large cohort of contemporary patients identified from three large European centres.

Methods: This is a retrospective cohort study, which included patients with both ANCA and anti-GBM antibodies. Remission was defined as normalising serum creatinine and serum anti-GBM titre for at least 2 months. Patients were initially included if they were seen between 1988-2012 and then compared with another contemporary cohort that fulfilled the same criteria presented after 2000, and for whom at least 1 year follow-up data was available. We have compared parameters to patients presenting with 'single positive' (SP) anti-GBM disease.

Results: We identified 78 anti-GBM+ pts, of whom 37 (47%) were DP for ANCA (AAGN: 82%, SI: 16%, SI+PE: 2%). SP and DP cases included similar numbers and report variable outcomes. We aim to describe the clinical features and outcomes of a large cohort of contemporary patients identified from three large European centres.

Conclusions: This is the largest reported series of European patients with double seropositivity for ANCA and anti-GBM antibodies. Patient and renal-survival was comparable to SP anti-GBM disease, although DP patients have greater risk of relapse related to their ANCA status, and so require long-term follow-up and consideration of maintenance immunosuppression. DP cases had a longer prodrome of symptoms and evidence of chronic damage of renal biopsy, suggesting that ANCA-induced glomerular inflammation may precede and contribute to the development of anti-GBM disease.

Funding: Government Support - Non-U.S.

FR-PO408
Pulse Methylprednisolone for Induction of Remission in Severe ANCA Associated Vasculitis

Wladimir M. Szpirt,1 Alan D. Salama,2 Neil Bau,3 Matthew David Morgan,4 Paula L. Dospinescu,4 Jesse Anne Dale,1 William Franklin Pendergraft,2 Keegan Lee,3 Martin Egford,4 Susan L. Hogan,5 Lorraine Harper.1 1Univ of Birmingham, United Kingdom; 2Univ of North Carolina Kidney Center; 3Univ College London, United Kingdom; 4Copenhagen Univ Hospital, Denmark; 5Univ of Aberdeen, United Kingdom.

Background: Intravenous pulse methylprednisolone (MP) is frequently used as part of remission induction in severe ANCA associated vasculitis (AAV). However, there are no studies assessing its efficacy in the setting of AAV, while treatment related complications remain the main source of morbidity.

Methods: We retrospectively analysed outcomes of 114 patients that presented with severe AAV at 5 large centers in the United Kingdom, United States and Denmark between 2000-2013. All patients received high dose oral corticosteroids, cyclophosphamide and plasma exchange. Rituximab treated patients were excluded. The chi square and Mann Whitney U tests were used for statistical analysis.

Results: Fifty-two patients received MP (median dose 1.5 mg over 3 days) in addition to standard therapy while 62 did not. Patient characteristics and disease severity were comparable between the two groups. There was no difference in survival at 3 months (MP: 94.2 vs non MP: 91.9%, p=0.633) or 12 months (84.6 vs 80.6%, p=0.579). Renal recovery amongst survivors (63.5 vs 72.6%, p=0.297) and relapse rates at 12 months (11.6 vs 8.6%, p=0.617) were similar. MP therapy was associated with more infections per patient (MP: 94.2 vs non MP: 91.9%, p=0.633) or 12 months (84.6 vs 80.6%, p=0.579). Renal recovery amongst survivors (63.5 vs 72.6%, p=0.297) and relapse rates at 12 months (11.6 vs 8.6%, p=0.617) were similar. MP therapy was associated with more infections per patient (MP: 94.2 vs non MP: 91.9%, p=0.633) or 12 months (84.6 vs 80.6%, p=0.579).

Conclusions: The current study found that the addition of MP to standard therapy for remission induction in severe AAV led to a significant increase in adverse events with no improvement in renal recovery or relapse rates. Our results question the currently widespread use of MP in severe AAV and suggest that a randomised controlled trial is urgently needed in order to definitively address this issue.

FR-PO409
Serum B Lymphocyte Stimulator (BLYS) Levels as Markers of Disease Activity in Anti-Neutrophil Cytoplasm Antibody (ANCA) Associated Vasculitis (AAV)

Background: B lymphocyte stimulator (BLYS) has been implicated in the pathogenesis of AAV. Previous studies have shown elevated levels in active disease, and following anti-CD20 therapy. Antineutrophil cytoplasm antibodies (ANCA) are not reliable predictors of disease activity and relapse and alternative markers are needed in order for immunosuppressive therapy. The aim of this study was to determine the clinical significance of serum BLYS levels in our patients with AAV.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

448A
**Methods:** Serum samples were obtained from patients with AAV at our centre, and BlyS levels detected using sandwich ELISA. Clinical data were obtained by review of patient records.

**Results:** Samples were collected from 68 patients with AAV and 13 healthy controls. Thirty one patients were male, 44 Caucasian and 21 Indoasian. Fifty patients had granulomatosis with polyangiitis, 13 patients had microscopic polyangiitis and 5 had eosinophilic granulomatosis with polyangiitis. Significantly higher BlyS levels were found in patients with active disease than those in remission and healthy controls.

Thirty seven patients who had been treated with Rituximab had significantly higher BlyS levels (p<0.0001). Eighteen patients had relapsed at 1 year following recruitment. These relapsing patients had significantly higher BlyS levels than those patients who did not relapse (p=0.0016).

**Conclusions:** This study supports the role of BlyS in the pathogenesis of AAV. BlyS levels could be used as markers of disease activity and predictors of relapse. With increased use of rituximab in AAV, further studies are needed to assess the impact of B cell depletion on B cell survival factors. These findings highlight the potential role for BlyS antagonists in the maintenance of remission of AAV.

**Funding:** Government Support - Non-U.S.

**Predictors of Renal Histopathology in Antineutrophil Cytoplasmic Antibody Associated Glomerulonephritis**

Sofia Lionaki,1 Clio Mavragani,2 George Liapis,2 George Somarakis,4 John N. Boletis,2 Alexandros Drosos,2 Athanasios Tziofas,1 Haralampos Moutsopoulos,2 1Nephrology, Laiko Hospital, Athens, Greece; 2Pathophysiology, Univ of Athens, Greece; 3Pathology, Laiko Hospital; 4Rheumatology, Univ of Ioannina.

**Background:** Prompt, aggressive therapy is vital foranti-neutrophil cytoplasmic antibody (ANCA)-associated glomerulonephritis (GN). In this regard, we aimed to identify predictors of distinct renal histopathological classes at the time of clinical diagnosis.

**Methods:** An inception cohort of patients with biopsy proven ANCA-associated GN was studied retrospectively. Demographics, clinical, laboratory, serological and radiological parameters were analyzed. Patients were classified on the basis of renal histopathology, according to the report by Berden et al (JASN 2010) for ANCA-associated GN by a renal pathologist into: focal class, crescentic class, mixed class and sclerotic class. A risk score was developed for each histopathological class using univariate and logistic regression analyses.

**Results:** Variables independently associated with focal class included disease duration up to diagnosis < 8 weeks, absence of red blood cell (RBC) casts by urine microscopy and eGFR > 49ml/min/1.73m², with crescentic class > 40 erythrocytes/hpf, identification of RBC casts in urine, ear nose and throat (ENT) involvement and eGFR < 49ml/min/1.73m²; with mixed class age > 54 years, male gender, and absence of ENT involvement. In the presence of 2 or 3 risk factors a predictive risk score of each histopathological class was calculated: odds ratio (OR), 95% confidence intervals (CI), for focal class (2 risk factors) 17.5 (95% CI [4.9-62.9]), 38.0 [6.8-213.7]) for crescentic class (3 risk factors), and 8.3 [1.0-67.5] (2 risk factors) for mixed class.

**Conclusions:** We propose a predictive algorithm of specific histopathological classes of the ANCA associated GN, which might provide a crude estimation of the disease activity in the glomeruli at presentation. This tool might assist the clinician in making decisions regarding the level of intensity of inductive immuno suppressive therapy at clinical diagnosis.

**FR-PO411**

Rituximab as a Cyclophosphamide Sparing Agent for Patients with Multi-Relapsing ANCA-Associated Small Vessel Vasculitis

Sophia Lionaki,1 George E. Fragouli,2 Alice Venetsanopoulou,2 John N. Boletis,2 Panagiotis Vlachogiannopoulos,2 Haralampos Moutsopoulos,2 Athanasios Tziofas,2 Nephrology, Laiko Hospital, Athens, Greece; 2Pathophysiology, Univ of Athens, Greece.

**Background:** To evaluate the clinical efficacy and outcomes of patients with multi-relapsing ANCA-associated Vasculitis (AAV), who received induction therapy with rituximab for a new disease relapse.

**Methods:** We retrospectively studied all patients with biopsy proven AAV, who were treated with rituximab upon a new relapse. A control group consisted of patients from the era prior to the initiation of rituximab in the treatment of AAV, was selected using the following criteria: i) history of relapse, ii) organ involvement at relapse, iii) treatment with the standard regimen. Patients and controls were matched for age, gender, and disease duration. Comparisons of disease outcomes along with the frequency and severity of adverse events were performed between groups.

**Results:** Of 147 patients with AAV and a mean total follow up time of 78.2 months, 18 patients (12.2%) received induction treatment with rituximab for disease relapse. Time to 1st relapse from the 1st diagnosis of AAV was shorter in the rituximab group and the mean number of relapses per patient was significantly higher in this group. The mean BVAS score was similar between groups at study entry while 13/18 patients received a 3-month course of cyclophosphamide in addition to rituximab.

**Conclusions:** Rituximab was shown efficacious in patients with multiple relapsing AAV including cases with renal and pulmonary involvement. It allowed us to minimize the ultimate exposure to cyclophosphamide in these patients, which is crucial, as they accumulate remarkable toxicity in long-term.

**FR-PO412**

Differences Between Patients with Definite and Suspected ANCA-Associated Vasculitis in a Secondary Care Hospital

Eline Houwen,1 Willem A. Bax,2 Walentina A. Sliker,3 Bastiaan Van Dam,1 Femke C.P. Fretsch,1 Gideon Verhave,1 Erik Lars Peen.1 1Dept of Nephrology, MCA-Gemini Group, Alkmaar, Netherlands; 2Laboratory of Clinical Chemistry, Hematology and Immunology, MCA-Gemini Group, Alkmaar, Netherlands.

**Background:** ANCA-associated vasculitis (AAV) is a rare disease with a broad spectrum of symptoms. Therefore, diagnosing AAV is often challenging. In an effort to provide guidance for clinicians, we aimed to identify differences between ANCA positive patients with a definite and suspected diagnosis of AAV.

**Methods:** In this retrospective study, all patients that tested positive for MPO and/or PR3 ANCA between 2005 and 2015 in a secondary care hospital in the Netherlands were analyzed. Patients were divided into subgroups according to clinical diagnosis and the Birmingham Vasculitis Activity Score (BVAS). Possible predictors for AAV, such as patient characteristics, clinical symptoms and ANCA titers were identified. Patients were also screened for commonly used exclusion criteria in trials.

**Results:** We included 240 patients with a positive MPO and/or PR3 ANCA, of which 120 patients were clinically diagnosed with AAV (group 1); all had a BVAS ≥ 3. Of the patients without the diagnosis AAV, 50 had a BVAS ≥3 (group 2) and 70 had a BVAS < 3 (group 3). In group 2, 39 patients had an alternative diagnosis, including other rheumatic diseases and infection. In a multivariable linear regression model, higher ANCA titers, higher BVAS and Ear Nose Throat (ENT) symptoms were predictive for AAV (all p<0.001). Of the patients diagnosed with AAV, 21 (18%) would have been excluded from most trials, based on a malignancy (n=13) or disease associated with vasculitis (n=8). Notably, characteristics of these patients did not differ significantly from the other AAV patients.

**Conclusions:** MPO and PR3 ANCA can be positive in a variety of diseases that may mimic AAV. Higher ANCA titers, BVAS and ENT symptoms were predictive for AAV in ANCA positive patients.

Rituximab and Low-Dose Cyclophosphamide Therapy for Renal ANCA-Associated Vasculitis: Long-Term Follow-Up
Nicholas R. Medieval-Thomas,1,2 Nicholas D. Mansfield,1 Stephen Paul McAdoo,1,2 Anisha Tanna,1,2 Megan Griffith,1,2 Jeremy B. Levy,1 Tom H. Cernis,1 Terence Cook,1 Alan D. Salama,1 Ruth M. Tarzi,1 Charles D. Pusey,1 1Imperial College Renal and Transplant Centre, Imperial College Healthcare NHS Trust, London, United Kingdom; 2Imperial College London, London, United Kingdom.

Background: The previously reported study of rituximab (RTX) and low-dose cyclophosphamide (CYC) followed by azathioprine maintenance for ANCA-associated renal vasculitis (AAV) suggested it was efficacious in inducing remission and has an acceptable side-effect profile (Mansfield et al. 2011). We have followed the cohort for over seven years and report the regimen’s efficacy and safety profile.

Methods: Long-term outcomes were retrospectively ascertained from all 23 previously treated patients. Results: Mean time since starting the treatment regimen was 83 months; twenty-one patients started the regimen more than five years ago. All patients achieved clinical remission within six weeks, with depletion of circulating CD19-positive B cells and significant reduction in median anti-PR3/MPO ANCA titre. After 84 months follow-up, five renal and four non-renal relapses were observed and treated in five patients. Median eGFR improved from 26 ml/min (range 11-63) at presentation to 49 ml/min (range 1-87) after one year and was maintained at 50 ml/min (8-90) at five years (n=21) and 46 ml/min (22-76) at seven years follow-up (n=9). To date, three infections requiring hospital admission and four malignancies have been recorded. Conclusions: This rituximab-based low-dose cyclophosphamide regimen followed by maintenance therapy provides safe and effective long-term treatment at more than five years follow-up.

FR-PO414
The Histopathologic and Clinical Determinants of the Change in GFR During the 1st year of Treatment in ANCA-Associated Vasculitis
Pierre-Luc Lavoie,1 Remi Goupil,1 Michelle Goulet,2 Maxime Rheaume,2 Soumya Brachemi,3 Stephane Brachermi,4 Stephane Troyano,1 1Nephrology, Hôpital du Sacré-Cœur; Univ de Montréal, Montréal, QC, Canada; 2Internal Medicine, Hôpital du Sacré-Cœur; Univ de Montréal, Montréal, QC, Canada; 3Nephrology, CHUM, Montréal, QC, Canada.

Background: Identifying the predictors of the change in GFR in ANCA-associated vasculitis (AAV) is helpful to avoid prolonged immunosuppression in those where no benefit exists and to consider modifying therapy in those who should improve but fail to do so.

Methods: We retrospectively reviewed cases of AAV with a renal biopsy in 3 hospitals to determine predictors of the change in GFR (deltaGFR) during the 1st year of treatment. We considered demographics, pathology findings, treatments and complications incurred. In particular, we addressed the histopathologic classification (Berden JASN 2010) proposing focal, crescentic, mixed and sclerotic subsets.

Results: Of 120 patients with AAV, 71 had a renal biopsy and received immunosuppression. They presented at an age of 59±13 with 48% female, 49% anti-MPO and a GFR of 32±30 ml/min including 22 patients on dialysis. Induction consisted of cyclophosphamide (93%), rituximab (6%), plasma exchange (27%) and pulse methylprednisolone (69%) in addition to oral corticosteroids. During the 1st year, patients recovered 15±20 ml/min/1.73 m² with 11 no longer requiring dialysis. The deltaGFR increased up until 6 months, although it varied greatly individually. Age, hypertension, MPO positive serology, the extent of crescentic and sclerotic glomeruli, tubular atrophy and the histopathologic classification were associated with a lower GFR at diagnosis. However, in one year only one histopathologic classification and the number of admissions for treatment-related complications predicted a lower deltaGFR. The focal, crescentic, mixed and sclerotic subsets experienced a 19±5, 17±15, 11±12 and ±2±6 ml/min deltaGFR, respectively (p=0.026, trend test).

Conclusions: The change in GFR during the 1st year of treatment in AAV increased 15±20 ml/min. It appeared maximal at 6 months into therapy. The histopathologic classification helped predict the deltaGFR at 12 months, with a reduced benefit of therapy in the sclerotic subset.

FR-PO415
Analysis of Clinical Features in ANCA-Associated Vasculitis: 30 Years Single Center Experience – Relationship Between RPGN and Renal Prognosis
Soko Kawashima,1 Shinya Kaname,1 Yoshinori Komagata,1 Yoshitomo Arimura.1 First Kyorin Univ School of Medicine, Mitaka, Tokyo, Japan.

Background: The clinical features of AAV, with respect to rapidly progressive glomerulonephritis (RPGN), have been changing, but were not well examined in Japan, where MPO-ANCA-associated vasculitis (MPO-AAV) are dominant in contrast to the Western countries. Thus, we retrospectively analyzed the clinical database of the 179 patients with AAV who were admitted to our hospital for the last 30 years.

Methods: At the onset, all patients fulfilled the Chapel Hill Consensus Conference (CHCC) classification criteria for MPA, GPA and EGPA. We divided the AAV patients into the 4 groups based on the presence or the absence of RPGN and hemodialysis and compared the clinical features and renal prognosis. Among 179 AAV patients, 166 cases (92.7%) were MPO-ANCA positive and 14 cases (7.3%) were PR3-ANCA positive.

Results: RPGN was observed in 100 (55.9%) of the 179 patients, including 49 cases of maintenance hemodialysis group (A), 2 cases of temporary dialysis group (B) and 49 cases of non-dialysis group (C), in addition to 79 cases without RPGN and dialysis (D). Significant differences were observed in BVAS, CRP, eGFR and serum Cr concentration. There were no differences for treatment choice, rate of kidney biopsy and frequency of relapses among the groups. Comparison among the different periods for every 10 years show the tendency of an increase in age of onset and the downward trend of serum Cr concentration, rate of RPGN and maintenance hemodialysis, BVAS scores, and frequency of relapses and mortality.

Conclusions: These results have clearly shown the changing features of AAV in Japan, with an earlier detection and the improvement of renal and patient survival during the periods.

FR-PO416
The Effect of Race on 5-Year Survival Outcomes in ANCA-Associated Renal Vasculitis
Luxme Nadarajah,1 Vasantha M. Muthuppalaniapan,1 Ravindra Rajakajiar.1 Nephrology, Barts and The London NHS Trust, United Kingdom.

Background: Anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis is a multi-systemic autoimmune disease characterized by inflammation of microscopical vessels. Renal involvement occurs in 70% of patients, with 1 year mortality rates exceeding 15%. With a prevalence of two cases per 100,000 populations there is a significant preponderance to Caucasians (C). Little is known about the outcomes in patients from Indo-Asian (IA) and Afro-Caribbean (AC) race despite an increasing number of cases seen with the disease.

Methods: We performed a single center, retrospective study, observing 5-year survival outcomes and relapse rates between C, IA and AC in ANCA-associated renal vasculitis. Electronic case notes over a 10-year period (2004-2014) were used collect data to include age at time of diagnosis, Birmingham vasculitis activity score (BVAS) at presentation, race, presence of diabetes and renal function. 5-year survival outcomes were analyzed using a cox proportional hazard model.

Results: In total 121 patients were included in the study, there were 84 (70%) C’s, 31 (25%) IA’s and 6 (5%) were of AC background. Median age was 66 years, 56% were men, 20% were diabetic and average BVAS score at presentation was 5. One-year relapse rates were low with 8 (6%) relapses seen. No significant difference in 5-year survival outcome was found between the races. Age at presentation significantly affected survival outcomes (p=0.007).

5-year survival outcomes dependent on race

Caucasian
Afro-Caribbean
Indo-Asian

Conclusions: We conclude that survival outcomes for IA and AC are not worse compared to those of C origin. Age remains to be a significant predictor in determining mortality outcomes. This study provides valuable clinical information in an area that has not been well studied.

FR-PO417
Possibility of Increasing Prevalence of Outfits Media with ANCA Associated Vasculitis in Japan
Takeshi Nakatsu,1 Yukiko Norazawa,1 Hiroe Satoh,1 Yoko Wada,1 Takeshi Kuroda,2 Masaaki Nakano,3 Ichiei Narita.1 1Div of Clinical Nephrology and Rheumatology, Graduate School of Medical and Dental Sciences, Niigata Univ, Niigata, Japan; 2Health Administration Center, Niigata Univ; Niigata, Japan; 3Dept of Medical Technology, School of Health Sciences, Faculty of Medicine, Niigata Univ, Niigata, Japan.

Background: A new disease concept, otitis media with ANCA associated vasculitis (AAV), has been advocated.

Methods: One hundred and fifty seven patients (74 males and 83 females) with AAV (81 microscopic polyangitis, 54 granulomatosis with polyangitis (GPA), and 22 eosinophilic GPA) were admitted to Niigata University Hospital from 1989 through 2014. Twenty seven patients (17%, 13 males and 14 females) with otitis media were recruited. Their clinical GPA) were admitted to Niigata University Hospital from 1989 through 2014. Twenty seven patients (17%, 13 males and 14 females) with otitis media were recruited. Their clinical features and laboratory data were analyzed.

Results: Fifteen patients were diagnosed as having definite GPA. Five were probable GPA. Lung or kidney lesions were not detected in other seven patients (Ears (E) only group). The initial symptoms in 22 patients (81 %) were ears’ one, such as impaired hearing (91
controls (HC) were assayed for MPTFa. All patients had ≥ 3 samples spanning 12 months. Non-parametric tests were used to compare categorical and continuous variables, respectively.

**Results:** Demographics were similar among patients and HC. VTE (aa) and VTE (pos) patients did not differ in ANCA serotype or titer, BVAS, D-dimer, other laboratory data, or organ involvement. VTE (aa) patients had significantly higher peak MPTFa than VTE (pos) patients (Mann-Whitney U test: 10.0 (IQR 7.9, 31.3) vs 2.8 (IQR 2.0, 8.5), p<0.001). X. Absorption was measured after addition of Factor Xa chromogenic substrate. Reconstituent rilipidated human TF was used as a standard. Values were expressed as a percent of MPTFa from a positive control (FPF from LPS-stimulated HC blood). Fisher’s exact tests and Wilcoxon tests were used to compare categorical and continuous variables, respectively.

**Conclusions:** Temporal and Spatial Clustering of Anti-Glomerular Basement Membrane Disease

**Background:** An environmental trigger has been proposed as an inciting factor in anti-glomerular basement membrane (anti-GBM) disease. We aimed to define country-wide incidence of anti-GBM disease, investigate clustering of cases in time and space and to assess the impact of spatial variability in incidence on outcomes.

**Methods:** National multicentre observational study of anti-GBM disease cases diagnosed in Ireland 1.6.2003-31.5.2014. We ascertainment cases by screening immunology laboratories for instances of positive anti-GBM antibody and the national renal histopathology registry for biopsy-proven cases. We defined the population at risk using census figures. A variable-window scan statistic was used to detect temporal clustering. A Bayesian autoregressive spatial model was used to provide standardised incidence ratio (SIR) estimates for each county. Patient and renal survival were assessed using Kaplan-Meier and log-rank test.

**Results:** Seventy-nine cases were included. National incidence was 1.64 (95% CI 0.82-3.35) ppm/year. A temporal cluster was identified (n=10) in a 3 month period in early 2013; 6 (60%) were resident in the southeast. Spatial analysis revealed wide regional variation in SIR (fig 1A) and a cluster (BC) in the southwest (n=7, SIR 1.71, 95% CI 1.02-3.06).

**Conclusion:** However, being in a cluster or distance from diagnosis site to treating center did not significantly impact on patient (HR 1.8, 95% CI 0.9-3.8) or renal survival (HR 0.7, 95% CI 0.4-1.1).

**FR-PO419**

**Venous Thromboembolism in ANCA Vasculitis Is Associated with Elevated Microparticulate Tissue Factor Activity**

**Background:** Patients of African ancestry with untreated HIV infection, carrying the G1 or G2 kidney disease risk variants (Vs) at the APOL1 gene are at a ≥10-fold greater risk for developing HIV-associated nephropathy (HIVAN) compared to those without these risk variants. Although podocytopeny in HIVAN has been attributed to the direct effect of HIV infection, the mechanistic contribution to kidney injury of the APOL1 allele state remains to be elucidated.

**Methods:** We evaluated the priming effect of IL-1β on human podocyte (HP) APOL1 expression. To evaluate the effect of IL-1β on HIV-1 processing in podocytes, HPs were pre-stimulated with human recombinant IL-1β for 6h and then incubated with HIV-1 followed by analysis for the HIV-1 strong stop DNA by qPCR analysis. HPs treated under similar conditions were evaluated for the effect of IL-1β on expression of IL-1β and CD80. Urine Angptl4 pI was 5.4.

**Results:** 26% of patients with HIV had peak MPTFa above normal (mean + 2SD of HC = 6.5) versus 2/20 VTE patients (p<0.0001).

**Conclusion:** Patients with AA V who develop VTE have a notable propensity for increased MPTFa at times both near and remote from VTE. Conversely, those without VTE rarely exhibit MPTFa significantly higher than healthy controls during their disease course. Further study is needed to determine if elevated MPTFa can identify AA V patients at high risk for VTE and whether MPTFa contributes to thrombogenesis.

**FR-PO420**

**CDB8 and Angiopeitin-4 Like-4 in Glomerulopathies**

**Background:** Proteinuria in MCD is thought to be due to an increased CD80 podocyte expression. Recently, podocyte angiopeitin-4-like-4 (Angip4) has been suggested to induce proteinuria in MCD. Objective: To determine the pattern of CD80 and Angip4 in MCD and other glomerulopathies.

**Methods:** 34, 30 and 32 patients with biopsy-proven MCD, FSGS and MN respectively, were enrolled. Urinary and serum CD80 and Angip4 were measured by Elisa. Differentiated human podocytes were incubated for 6 h with 15% of serum from MCD patients in relapse or in remission. Podocyte expression of CD80 and Angip4 were measured by Western-Blot analysis. Urinary Angip4 pl was measured by 2D electrophoresis Statistical analysis: Mann-Whitney U test. Wilcoxon matched-pairs signed rank test for comparison of paired groups, and Spearman correlation.

**Results:** Urinary CD80 was increased in MCD patients during relapse, but not in patients with FSGS or MN, or normal controls. Serum CD80 was lower in patients with glomerulopathies during relapse compared to normal controls. Urinary Angip4 pl was increased in patients with glomerulopathies compared to normal controls, whereas serum Angip4 pl was higher in normal controls compared to patients with glomerulopathies. Both urinary CD80 and Angip4 correlated with proteinuria in MCD, FSGS and MN. Podocytes exposed to sera from MCD patients in relapse showed a significant increase in CD80 expression but not Angip4 when compared to MCD patients in remission. Urinary Angip4 pl was 5.4.

**Conclusion:** 1) Decreased serum CD80 and Angip4 in nephrotic syndrome is likely due to increased urinary losses. 2) Increased urinary CD80 was only observed in MCD patients in relapse while increased urinary Angip4 was seen in all the glomerulopathies. 3) Podocyte CD80 but not Angip4 expression was increased by serum from MCD patients in relapse. 4) Urine Angip4 in MCD has a pl of 5.4, suggesting no role on Glomerular Basement Membrane charge. 5) While CD80 seems to play a role in proteinuria in MCD, Angip4 detected in urine in MCD and other glomerulopathies is likely the result of an increased glomerular permeability.

### FR-PO422

**Podocyte Depletion in Alport Syndrome Complex**

**Background:** Increasing evidence suggests that podocytes may play a role in Alport Syndrome Complex (ASC) progression of renal disease. We previously reported that podocyte detachment rate measured in urine is increased in ASC, suggesting that podocyte depletion could play a role in causing progressive loss of kidney function. This result therefore raised the question as to whether progression in ASC could be due to progressive podocyte depletion from glomeruli.

**Methods:** To address this question we measured podocyte nuclear number, density and cell area (Glepicki positive) density in the same 3um thick formalin-fixed paraffin-embedded histologic section. Twenty six kidney biopsies from 21 patients were collectively designated as ASC including both classic Alport Syndrome (with thin and thick GBM segments and lamellated lamina densa [n=20]) and Thin GBM [n=6]. Twenty protocol kidney biopsies from deceased kidney transplant donors were used as age-matched controls.

**Results:** When compared to controls, podocyte number per glomerulus, % podocyte depletion, nuclear density and cell area density were all decreased in the ASC cohort (P<0.01). The mean podocyte volume (MPV) was correspondingly larger for ASC than control (P=0.05) representing podocyte hypertrophy to compensate for reduced podocyte number and density. Podocyte depletion was present in ASC biopsies prior to detectable histologic abnormalities. No abnormality was detected by light microscopy at <10% podocyte depletion, minor pathologic changes (mesangial expansion and adhesions to Bowman’s capsule) were present at 30-50% podocyte depletion, and FSGS was progressively present above 50% podocyte depletion. Estimated GFR did not change measurably until >70% podocyte depletion. Low level proteinuria was an early event at about 25% podocyte depletion and increased in proportion to podocyte depletion.

**Conclusions:** These data support the concept that progressive podocyte depletion occurs from an early stage in ASC leading to FSGS-like pathologic changes and eventually to End Stage Renal Disease. Early intervention to reduce podocyte depletion is projected to prolong kidney survival in ASC.

### FR-PO423

**Actinin-4, Synaptopodin, Nephrin, and Nephr-1 Expression in Proteinuric Patients**

Ashwani Kumar, Ritambhara Nada, Charan Singh Rayat, Charan Singh Rayat, Krishin L. Gupta. 1 Dept of Histopathology, Post Graduate Inst of Medical and Research, Chandigarh, India; 2 Dept of Nephrology, Post Graduate Inst of Medical and Research, Chandigarh, India.

**Background:** Podocytes have an important role in glomerular filtration barrier. Primary podocytopathies and secondary podocyte injuries in presence of immune deposits at different locations results in proteinuria. We compared expression of podocyte structural proteins; alpha actinin-4 (Act4), synaptopodin (Syn), and slit diaphragm proteins; nephrin (Nep) and nephr-1 (NepH-1) by immunofluorescence (IF) in minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), membranous glomerulonephritis (MGN), and IgA nephropathy (IgAN).

**Methods:** Two hundred cases (n=200) each along with controls were stained with FITC tagged n-Ac4, Nep, Syn, and NepH-1 antibodies. Immunofluorescence was graded as mild, moderate, and intense. Immunogold staining with n-Ac4, and Syn antibodies was done to see localization electronmicroscopically (EM).

**Results:** The n-Ac4 showed mild to moderate intensity (40% & 60%) in controls and most of the cases in all proteinuric groups. Up-regulation was noted in 52% cases of MGN and only 14-19% of other groups. Loss of n-Ac4 was seen in >25-35% in all groups except MGN where it was rare. Syn showed mostly mild staining (70%) in controls. Marked up-regulation (61%) was seen in the majority of MGN cases whereas moderate intensity was seen in other groups (MCD-IgAN-FSGS). Loss of staining severity was graded as mild but equal present in all groups. Nep showed mild intensity in controls; however moderate to intense staining was seen in MGN (46% & 14%), whereas loss of staining was noted in all other groups (FSGS-54%, MCD-43, IgAN-59%). NepH-1 also showed mild staining in controls whereas up-regulation was seen in only MGN (47%). Similar to Nep, complete loss of NepH-1 was seen in FSGS-74%, MCD-53%, and IgAN-54%. These differences in staining of MGN were statistically significant when compared with controls and with other groups. EM showed n-Ac4 and Syn in podocyte body and processes.

**Conclusions:** Structural proteins and slit diaphragm proteins are up-regulated in MGN whereas the variable degree of loss is commonly seen in FSGS, MCD, and IgAN.

Treatment and Outcomes in Minimal Change Disease: Experience of a Single UK Centre
Anthony Fenton, Stuart W. Smith, Peter Hewins. Dept of Renal Medicine, Univ Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.

Background: Minimal change disease (MCD) accounts for 10-25% of nephrotic syndrome in adults. We retrospectively reviewed the treatment and outcomes of MCD patients in our centre.

Methods: We identified adults who had undergone renal biopsy between June 1996 and March 2012 which was reported as being consistent with MCD, and who had at least 12 months of follow-up. Electronic hospital records were used for data collection.

Results: There were 78 cases, with median follow-up of 72 months. Baseline and treatment data are shown in the table (averages are mean, or median where distribution is skewed). 27% had a history of nephrotic syndrome in childhood. All but one patient (who entered remission spontaneously) were treated with prednisolone, and 97% achieved complete remission at a median time of 33 days (6-309), although 12% needed a second-line treatment to do so. Mean number of relapses during the first 24 months was 1.08% experienced at least one relapse, and 45% patients required second-line agents at some point. Regarding complications: 12% developed thromboembolic disease, 14% had an admission-requiring infection, and 41% had at least one episode of AKI. Mean follow-up creatinine was 91 mmol/L, but significantly higher in those who had had AKI (104 vs 85 p=0.04) and those who had received an ACEi (99 vs 78 p<0.01). Of 16 patients who underwent subsequent biopsy (all of whom had received a CNI), 8 showed evidence of CNI damage, and 5 were consistent with FSGS. Diabetes mellitus developed in 12% cases, and 8% patients died during follow-up.

Conclusions: Almost all treated adult MCD patients enter remission, although second-line agents are frequently required. Despite therapy, complications remain common, including AKI which is associated with residual reduced excretory function.

Demographics, clinical features, and therapies

| Age (years) | 36 |
| Sex (% male) | 60 |
| Ethnicity (%) | White 72 | South Asian 18 | Black 8 | Other 3 |
| Baseline clinical findings | Creatinine (mmol/L) | 91 | eGFR (ml/min/1.73m2) | 80 | Urine ACR (mg/mmol) | 645 | Serum albumin (g/L) | 22 | Serum cholesterol (mmol/L) | 9.6 | Haemoglobin (%) | 15 | AKI (%) | 28 |
| Treatment (%) | Prednisolone | 99 | CNI | 32 | Cyclophosphamide | 13 | Levamisole | 9 | MMP | 8 | Rituximab | 5 | ACEi/ARB | 63 |

FR-PO427

Predictors for Relapse in Adult Minimal Change Disease
Hajeong Lee, Dong Ki Kim, Kwon Wook Joo, Yon Su Kim, Chun Soo Lim. Internal Medicine, Seoul National Univ Hospital.

Background: Minimal change disease (MCD) is well-known benign primary glomerulonephritis in adults because of their distinct rare renal progression to end-stage. However, their relapse-associated morbidity has been underestimated. In this study, we aimed to explore the predictors of relapse in adult MCD patients.

Methods: We reviewed clinical and pathologic characteristics of adult primary MCD patients from Seoul National University Hospital from 1979 to 2013. Patients who were presented by nephrotic syndrome and followed up more than 12 months were included. Patients asymptomatic for secondary MCD were excluded. Initial treatment regimens, their response, and complication were also reviewed. The number of relapse were classified as follows, no relapse, 1-2 relapses (relapse group 1), and ≥ 3 relapses (relapse group 2).

Results: A total of 195 patients were included in the final analysis. Among them, median age at the time of diagnosis was 38 (23-53) years and 113 (57.9%) were men. During median follow-up of 81 (44-153) months, more than 90% of patients reached to remission after initial treatment. However, only 64 (32.8%) patients did not experience any relapse. Remaining 131 patients, 69 (35.4%) relapsed once or twice and 62 (31.8%) relapsed more than three-times. The younger, the more relapse was found. In addition, severity of nephrotic syndrome data are shown in the table (averages are mean, or median where distribution is skewed). Proportion of thromboembolic event was higher in no-relapse group compared with relapse group 1 and 2 (P = 0.033). Initial treatment regimen did not affect relapse, however, patients who received shorter treatment duration tended to relapse more. Considering complications, relapse group 2 showed significantly higher proportion of thromboembolic event than other two groups.

Conclusions: We proved that patients with younger age, severe nephrotic syndrome, lower mesangial proliferation and shorter treatment duration were prone to relapses. Moreover, relapse is morbid due to higher thromboembolic events in adult MCD patients.

FR-PO428

Rituximab in Relapsing Minimal Change Glomerulonephritis: Clinical Outcomes and Financial Analysis
Kevin William Loudon, Clare Morledge, Suresh Mathavakannan, Ken Farrington, Barbara Thompson, Paul Warwicker. Dept of Renal Medicine, Lister Hospital, United Kingdom.

Background: Minimal change disease (MCD) accounts for 10-15% of adult nephrotic syndrome, with frequent relapses or steroid-dependency occurring in 25-30%. Glucocorticoids and calcineurin inhibitors are the mainstay of treatment, but can be associated with significant toxicity. Rituximab holds potential to induce long term remission in these patients, but in the United Kingdom is currently not funded based on perceived excessive cost.

Methods: Nine patients with frequently relapsing MCD (histologically confirmed) were given total dose Rituximab 1g – 2.4g divided into two - four doses from 2012 - 2014. Time from diagnosis to first Rituximab dose was 140 months (10 – 336). Cost effectiveness of Rituximab was assessed based on comparing annual relapse rates; inpatient/outpatient attendances and immunosuppressant medication in the two years prior, and one year post Rituximab. Data was obtained retrospectively using hospital finance records, NHS standard tariff and the British National Formulary (2015) respectively.

Results: In all patients Rituximab induced complete remission. All steroid-sparring agents were discontinued. Four patients remain on low dose prednisolone (less than 4mg). Mean follow-up was 15 months (6 – 30) with only one relapse at 19 months. Annual relapse rates fell from 1.83/year (0.5 – 6.0) to 0.12/year (0.05-0.57). Inpatient days fell from a mean of 4.2 days/year (0-9.6) to 1.7 days/year (0-4.5). Outpatient consultations fell from 12.5/year (5-26.4) to 7.3/year (4.5-25). Mean annualised pre-Rituximab costs were £6172 and post Rituximab, £5046, in 6/9 patients with sufficient length of follow up for comparison. No major complications were noted following treatment.

Conclusions: In patients with relapsing MCD, Rituximab proved to be cost effective and well tolerated. Burden of medication with attendant side effects, as well as inpatient and outpatient attendance were significantly reduced. Annualised costings showed a modest saving post Rituximab. Further randomised studies are required to confirm and extend these findings.

FR-PO429

Long-Term Outcomes of Nephrotic Syndrome, from Childhood to Adulthood
Rebecca C. Horten, Frederick J. Kaskel, Kimberly J. Reidy. Pediatrics, Div of Nephrology, Albert Einstein College of Medicine, Children’s Hospital at Montefiore, Bronx, NY.

Background: Steroid Resistant Nephrotic Syndrome (SRNS) is known to have several long term sequelae including chronic and End Stage Kidney Disease (CKD and ESKD). However there are few studies on the long-term outcomes of steroid sensitive nephrotic syndrome. Presented here is a single center, retrospective case series from an urban, ethnically diverse population in the Bronx.

Methods: We utilized a medical record data mining tool to identify patients by ICD-9 code (1) with a diagnosis of nephrotic syndrome prior to age 18 (2) with a documented albumin <3.5 g/dl or random urine protein > 1 g/dl and (3) with at least one hospital encounter after age 18. Patients with a history of renal biopsy or who received immunosuppressant medication other than steroids were termed complicated nephrotic syndrome (CNS). All others were termed simple nephrotic syndrome (SNS). Patients with a diagnosis of asthma prior to age 18 with at least one hospital encounter after the age of 18 were used as controls. Each cohort was evaluated for diagnosis of hypertension, osteoporosis, cataracts, infertility and malignancy. Their last height, weight and creatinine were used to evaluate their height and weight percentile, BMI and estimated GFR by the MDRD equation.

Results: All three groups – SNS (n=173), CNS (n=169) and control (n=18225) had similar age at diagnosis, length of follow-up. Both the SNS and CNS groups had a greater proportion of short stature, cataracts, infertility and malignancy (Chi square statistic p < 0.05) [table 1]. In addition they had a greater percentage of patients with CKD by eGFR which is most notable at CKD stages 4 and 5 (Chi square statistic p < 0.05).

Conclusions: Our results show that even patients with uncomplicated nephrotic syndrome use are at risk for significant outcomes, including chronic kidney disease. Further study is needed, however it implies that all patients with a diagnosis of nephrotic syndrome will need to be counseled regarding the risks associated with their diagnosis and should have long term monitoring for these outcomes, including worsening renal function, hypertension and malignancy.

Results: We identified 179 children with NS due to minimal change disease (72%), focal segmental glomerulosclerosis (23%) or membranous nephropathy (5%); incidence was 1.47 per 100,000 (95% CI:1.27-1.70). Biopsies were available in 40% of cases. Baseline features at diagnosis are shown by cause of NS:

FR-PO432

Population-Based Identification of Children with Primary Nephrotic Syndrome: Kaiser Permanente Northern California Study: Alan S. Go,1 Dongjie Fan,2 Thida Tan,3 Janet M. Wojcicki,1 Jingrong Yang,2 Juan Daniel Ordonez,2 Glenn Matthew Chertow,1 Sijie Zheng,1 David Law.1 Kaiser Permanente Northern California; 1Univ of California, San Francisco; 2Stanford Univ.

Background: Few population-based data exist about children with primary nephrotic syndrome (NS) in the US. We identified a cohort of children with primary NS in a large, integrated healthcare system.

Methods: Kaiser Permanente Northern California cares for >750,000 children. We identified members age <18 yrs between 1996-2012 who had nephrotic range proteinuria (UACR>3500 mg/g, PCR>3.5 mg/mg, 24-hr proteinuria>350 mg/day, dipstick>3+ mg/dL) and/or diagnosed NS (ICD-9 581.x) in electronic records and lab databases. Nephrologists reviewed records for clinical presentation, lab and biopsy results to confirm primary NS.

Conclusions: In our hands, BT-1 staining was absent in patients with FSGS. Our experience with abatacept (2 or 3 doses of 10 mg/kg). After several trials of unsuccessful immunofluorescence staining, we performed B7-1 immunohistochemistry on paraffin embedded tissue with a primary antibody mouse anti CD80 (R&D systems). In our hands B7-1 staining was absent in patients with FSGS. Our data suggest that positive B7-1 immunostaining on kidney biopsy. Here, we report our experience with abatacept and BT-1 staining in patients with FSGS.

Methods: Patients with no or partial proteinuria remission after plasmapheresis for treatment of FSGS received abatacept (2 or 3 doses of 10 mg/kg). After several trials of unsuccessful immunofluorescence staining, we performed B7-1 immunohistochemistry on paraffin embedded tissue with a primary antibody mouse anti CD80 (R&D systems). After several trials of unsuccessful immunofluorescence staining, we performed B7-1 immunohistochemistry on paraffin embedded tissue with a primary antibody mouse anti CD80 (R&D systems).

Results: Three patients with post-transplant FSGS, and one patient with FSGS in the native kidney (Table, Patient 4) were treated with abatacept. All transplant patients had developed nephrotic proteinuria immediately after transplantation. Patient 1 had been treated with plasmapheresis for many years, and was previously unresponsive to BT-1 blocking agent belatacept. None of the patients had proteinuria remissions after abatacept, nor did we observe positive podocyte BT-1 immunostaining.

Conclusions: In our experience with abatacept and BT-1 staining in patients with FSGS.

Steroid Resistant Nephrotic Syndrome: A Prospective, Open Label Study of the Safety and Efficacy of Combination Tacrolimus and ACTHar Gel Therapy

James A. Tumlin,1 Claude Mabry Galphin,2 Brad H. Rovin.1

Univ of Tennessee College of Medicine, Chattanooga, TN;2 The Ohio State Univ, Columbus, OH.

Background: Steroid resistant nephrotic syndrome (SRNS) in adults is associated with increased risk for progression to ESRD. Tacrolimus is a calcineurin inhibitor (CNI) that is an alternative to steroids, but is associated with progressive fibrosis and loss of GFR. ACTHar gel has shown benefit in the treatment of SRNS. To investigate additive effects, we followed 23 SRNS patients receiving combination therapy with Tacrolimus and ACTHar Gel.

Methods: 23 patients with SRNS (IMGN 8, 11 FSGS and 4 other) receiving ACEi/ARB and 8 weeks of oral steroids prior to combination therapy of ACTH and Tacrolimus. Eleven patients received 2 or more drug therapies. Of the 23, 17 (71%) initially received ACTH followed by Tacrolimus. Duration of ACTH/TAC therapy averaged 6.2 months [range 1-12 months]. Complete or partial responses were defined as UP CR or P< 0.30 or > 50% reduction in pre-ACTH/TAC proteinuria, respectively.

Of the 23 patients, 6 (26%) achieved a complete response; a partial response was observed in 11 (48%) for an overall response of 74%. Proteinuria levels (expressed as a UCPr ratio) before and after treatment are listed in the Table. There was no difference in the rate or time to complete or partial remission between IMGN and FSGS (IMGN: 75%, 70.11.5; FSGS: 82%, 6.1-0.8 mths).

Conclusions: Combination therapy with ACTHar Gel and Tacrolimus achieved a 75% remission rate and a higher remission rate was demonstrated and a suggestion of fewer adverse events although numbers are small. However the baseline parameters show the CNI was significantly lower in the prednisolone group. Patients treated with Tac had a longer duration of treatment but appeared to have a better adverse event profile overall. A randomised controlled trial is required to investigate this further.

FR-PO435
Treatment of Nephrotic Syndrome Secondary to Primary FSGS – Prednisolone or Tacrolimus? A Two Centre Experience

Hannah R. Wilson,1 Thomas M. Connor,2 Tom Cairns,2 Mona Saleh Wahba,3 Marie B. Condron,1 Megan Griffith.3 St. Helier Hospital, London, United Kingdom;3 Hammersmith Hospital, London, United Kingdom.

Background: Focal segmental glomerulosclerosis (FSGS) is a significant cause of end-stage renal failure. Patients with nephrotic syndrome have a worse prognosis. Current guidelines advise prolonged prednisolone (pred) at 1mg/kg. Tacrolimus (Tac) is an alternative for patients, but long-term therapy is often necessary, and there are concerns about toxicity.

Methods: Retrospective review of all patients with nephrotic syndrome secondary to primary FSGS treated with a minimum of 12 mths follow-up at 2 centres. All patients received standard therapy with max tolerated ACEi +/- ARB. Complete remission (CR) was defined as normal serum albumin with PCR <50; partial remission (PR) as proteinuria ≤50% baseline. Results described as Median (Range); p value <0.05 significant.

Differences in Initial End Stage Renal Disease (ESRD) Treatment Modality Across Glomerulonephritis Subtypes

Michelle M. O'Shaughnessy,1 Maria E. Montez-Rath,1 Richard A. Lafayette,1 Wolfgang C. Winkelmayer.1 Div of Nephrology, Stanford Univ School of Medicine;2 Section of Nephrology, Bay College of Medicine.

Background: Kidney transplantation (Tx) is the treatment of choice for end-stage renal disease (ESRD). Hemodialysis (HD) and peritoneal dialysis (PD) outcomes are largely equivalent. Whether access to these modalities is equal across glomerulonephritis (GN) subtypes has not been established.

Methods: We identified all patients in the US Renal Data System 18-75 years who initiated ESRD therapy with Tx, HD, or PD (1996-2011) and had ESRD attributed to 6 GN subtypes [focal segmental glomerulosclerosis (FSGS), IgA nephropathy (IgAN), membranous nephropathy (MN), membranoproliferative GN (MPGN), lupus nephritis (LN), vasculitis]. Odds ratios (ORs) for PD vs HD and for Tx vs HD were computed using multinomial logistic regression (IgAN as reference group), with multivariate adjustment for demographic, socioeconomic, and comorbidity differences, and overall differences.

Results: Among 75,278 patients studied, demographic, socioeconomic, and comorbidity characteristics differed considerably across GN subtypes. In unadjusted analyses, patients with FSGS, MN, MPGN, LN, and vasculitis were significantly less likely to receive Tx or PD as a first ESRD treatment modality than patients with IgAN: OR for Tx 0.52, 0.35, 0.48, 0.23, and 0.13, respectively; OR for PD 0.77, 0.66, 0.59, 0.48, and 0.30, respectively (all p<0.0001). After adjustment, differences were attenuated but patients with secondary GN subtypes (LN, vasculitis) remained significantly less likely to receive Tx or PD as compared to patients with IgAN (figure).

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusions: Patients with ESRD attributed to secondary GN subtypes (LN, vasculitis) are significantly less likely to receive Tx or PD as an initial ESRD treatment than patients with primary GN subtypes. The clinical appropriateness and sequelae of this apparent inequity must be determined.

FR-PO437
Non Collapsing Focal and Segmental Glomerulosclerosis in Patients with HIV
Julien Hogan, Claire Carter, Emmanuelle M. Plaisier

Background: With the improvement of the treatments against HIV, non collapsing focal and segmental glomerulosclerosis (FSGS) has become more frequent than HIV associated nephropathy (HIVAN). However, the physiopathology of non-collapsing FSGS among HIV patients remains poorly understood. We thus aimed to compare patients with HIV and non-collapsing FSGS with patients with HIVAN and with non HIV patients with FSGS.

Methods: HIV patients with a kidney biopsy in our center between 2000 and 2012 (24 non collapsing FSGS and 13 HIVAN) and two control groups (10 primary and 12 secondary FSGS) were included. Clinical and biological data were collected; viral load in serum and urine was assessed together with immunohistochemical staining for PCNA to study epithelial cells proliferation.

Results: Clinical and biological features of HIV patients with non-collapsing FSGS were close to those of controls with secondary FSGS. Among HIV patients, the prevalence of cardiovascular risk factors were greater in those with non collapsing FSGS than in those with HIVAN (79% vs. 38%, p<0.01) but was comparable to the one in controls with secondary FSGS (100% vs. 79%, NS). HIV patients with non collapsing FSGS and controls with secondary FSGS had more frequently arteriolosclerosis on the biopsy than patients with HIVAN (75% and 82% vs 36%, p<0.01). Visceral epithelial cells expression of PCNA showed that, despite a stronger staining in collapsing lesions, it can be found among all patients groups and in any FSGS lesion type. The majority of HIV patients with non collapsing FSGS had undetectable viral load in serum and urine.

Conclusions: Major clinical, biological and histological differences between HIV patients with non collapsing FSGS and HIVAN support the hypothesis of two distinct physiopathological entities. They are striking similitudes between non collapsing FSGS in HIV patients and secondary FSGS found in patients with polycythaemia vascularis. Non collapsing FSGS in HIV patients might be due to nephronic reduction secondary to vascular lesions in an ageing population with major metabolic abnormalities associated with antiviral drugs.

FR-PO438
Diabetic Glomerulosclerosis or Idiopathic Nodular Glomerulosclerosis – Role for Insulin Resistance
Manish Anand, Mehri Mollaee, Ravi Sunderkeshan, Andres Rodrigo Caero, Mehrdad Hamrahian

Background: Diabetic nephropathy (DN) is characterized histologically by nodular mesangial sclerosis, a thickened glomerular basement membrane, and hyalinized arteries. Differential diagnoses by light microscopy (LM) include membranoproliferative glomerulonephritis, amyloidosis, monoclonal immunoglobulin deposition disease, and fibrillary or immunotactoid glomerulopathy. These can readily be excluded by special stains, immunofluorescence (IF) and electron microscopy (EM). Idiopathic nodular glomerulosclerosis (ING) is the term used to denote classic DN confirmed by LM, IF, and EM, but in the absence of diabetes mellitus (DM). Case reports suggest insulin resistance (IR) as a possible cause.

Methods: Data was collected retrospectively on 21 cases of diabetic glomerulosclerosis or ING biopsied due to proteinuria (>1 g on urinalysis to 12.3 g/day), with or without renal insufficiency (creatinine 0.6-4.4 mg/dl).

Results: 13 patients were male with majority of patients being African American (10) and non-Hispanic white (7). 1 patient was post-transplant and another post-liver transplant. None of these patients were diagnosed with DM, although some had intermittently elevated blood glucose and borderline HbA1c. All patients had hypertension, but only 5 were active tobacco users and 8 were former smokers. BMI range was 21-43 kg/m². Hemoglobin A1c range was 4.6-6.1% in 10 patients and 6 patients denied DM by telephone survey. The remaining 5 patients had no history of DM per records with few elevated random plasma glucose levels noted on steroids. None of these fulfilled current diagnostic criteria for DM. Metabolic syndrome (MS) defined by Adult Panel III criteria was evident in 11 patients.

Conclusions: The pathogenesis of ING remains unclear. It involves the interplay of hyperinsulinemia, obesity, and heavy smoking. We feel that IR is critically important, whether evidence as subtle, prediabetic elevations of blood glucose, MS, or elevated HOMA-IR score being the only manifestation. Insulin sensitivity assessed by HOMA-IR score is possibly an important predictive factor in pathophysiology of ING and needs to be tested routinely.

FR-PO439
Association of Serum Albumin Level and Venous Thromboembolic Events in Seven-Thousand Patients with Nephrotic Syndrome
Geecha G. Gvamianti, Miklos Zsolt Molnar, Jun Ling Lu, Keichi Sumida, Kaymar Kalantar-Zadeh, Csaba P. Kovessy, VA Medical Center, Memphis, TN; University of Tennessee Health Science Center, Memphis, TN; University of California, Irvine, CA.

Background: Prior studies have shown that low serum albumin in patients with nephrotic syndrome (NS) is associated with an increased risk of venous thromboembolic (VTE) events. This is based on small studies with a low number of thromboembolic events and short term follow-up.

Methods: From a nationally representative cohort of over 3 million US veterans with baseline estimated glomerular filtration rate (eGFR) ≥60 ml/min/1.73m², we identified 7037 patients with NS based on ICD9 codes. Association between serum albumin and risk of incident VTE events (based on ICD9 codes) was assessed using Cox regression analysis with adjustments for age, gender, race, comorbidities, eGFR, BMI and anticoagulant treatment.

Results: Mean age was 57±11 years, and patients were 96% male, 32% African-American and 60% diabetic. There were a total of 158 VTE events over a median follow-up was 8.1 years; 16 events (4.1%, event rate (ER): 8.5/1000 patient-years(PY)) in patients with albumin <2.5 g/dl, 18 events (3.4%, ER: 5.7/1000 PY) in patients with albumin 2.5-2.99 g/dl, 89 events (2.5%, ER: 3.4/1000 PY) in patients with albumin 3.3-3.99 g/dl and 55 events (1.4%, ER: 1.9/1000 PY) in patients with albumin ≥4 g/dl. Compared to patients with albumin <2.5 g/dl, those with albumin levels of 3.3-3.99 g/dl (adjusted HR:1.51; 95%CI:1.01-2.26), 2.5-2.99 g/dl (2.24, 1.24-4.05) and < 2.5 g/dl (2.79, 1.45-5.37) experienced a linearly higher risk of VTE events.

Conclusions: Lower serum albumin is a strong incremental risk factor for VTE events in NS. The risk increases proportionately with declining albumin levels. Our finding may have important clinical implications regarding initiation and duration of prophylactic anticoagulation.

Funding: NIDDK Support, Veterans Administration Support

FR-PO440
Hypercoagulopathy Is Directly Correlated with Disease Severity in Nephrotic Syndrome
Amanda P. Walker, Samir Parikh, Brad H. Rovin, William E. Smoyer, Marvin T. Nieman, Matthias Kretzler, Bryce A. Kerlin, John T. D'Agati, National Institutes of Health, National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; Emmanuelle M. Plaisier, VA Medical Center, Memphis, TN; University of Tennessee Health Science Center, Memphis, TN; University of California, Irvine, CA.

Background: Nephrotic syndrome (NS), a leading cause of end stage kidney disease, is characterized by massive proteinuria, hypoalbuminemia, and an increased risk for venous thromboembolism (VTE). We recently reported that hypercoagulopathy is proportional to the severity of both proteinuria and hypoalbuminemia in two animal models of NS. This study was designed to determine if this relationship translates to human NS.

Methods: Aliquots of plasma anticoagulated with 0.32% (final concentration) sodium citrate were obtained from the NEPTUNE biorepository (n=147 patients), along with corresponding clinical lab data (e.g. urine protein:creatinine (uP:C), serum albumin (sAlb)). Samples collected from a local patient cohort (n=21) were used to validate biorepository collection and storage. Clin/Trans Research, Nationwide Children’s Hospital, Columbus, OH; Nephrology, University of Michigan, Ann Arbor, MI.

Conclusions: Lower serum albumin is a strong incremental risk factor for VTE events in NS. The risk increases proportionately with declining albumin levels. Our finding may have important clinical implications regarding initiation and duration of prophylactic anticoagulation.

Funding: NIDDK Support, Veterans Administration Support
specimen integrity. Endogenous thrombin potential (ETP) was determined using the Technothrombin TGA kit and RC Low reagent after 2.1 dilution with buffer. Plasma antithrombin (pAT) activity was measured by the amidolytic method.

Results: As expected, NEPTUNE patients exhibited a wide range of proteinuria values (median (range) uP/C: 1.85/0mg (0-17.6)). Hypoalbuminemia and proteinuria severity were proportional to ETP (R=0.252 & 0.128, respectively, P<0.001). These correlations were stronger in the subset of patients with uP:C>2 (R=0.331 & 0.157, respectively, P<0.001). Plasma AT activity was also significantly correlated to hypoalbuminemia and proteinuria severity (R=0.125 & 0.031, P<0.001 & 0.03, respectively). There was no correlation between AT activity and ETP. Results were similar in the validation cohort.

Conclusions: Both hypoalbuminemia and proteinuria severity in humans with NS is significantly, albeit weakly, correlated to ETP (an established marker of thrombotic risk). Adapting these data for controlling clinical variables (e.g. smoking status, BMI, etc.) may aid in the modeling and development of evidence-based cut-offs to guide indications for prophylactic anticoagulation.

Successful Social Media Recruitment into the NephCure Kidney Network, a Rare Disease Patient Registry

Leandra H. Marianj, 1 Joanna Dauber, 2 Chelsea Fix, 2 Alyssa Fisher, 2 Jane Shen, 2 Lalita Subramanian, 1 Marilyn Hailpern, 2 Elizabeth L. Cope, 1 1Arbor Research Collaborative for Health; 2NephCure Kidney International.

Background: Participation in clinical research for primary Nephrotic Syndrome (NS) has been limited by the rarity of the disease. There is growing interest in leveraging social media to expand demographic and geographic reach for recruitment. Because of the isolating nature of rare diseases, patients turn to social media for support, creating online communities that, if accessible, could potentially serve as a resource for recruitment.

Methods: The NephCure Kidney Network (NKN) is a web-based patient opt-in registry for primary NS patients. Participants contribute data, including kidney disease history, demographics, and research participation preferences. Recruitment efforts launched in March 2014 relied on email campaigns to contacts of the patient advocacy group, NephCure Kidney International (NKI), but then expanded in September 2014 to include social media. Weekly posts were made to NKI’s Facebook page, with analysis of performance based on impressions (# of people reached) and engagements (likes, clicks, shares, comments). Relationships with other closed Facebook kidney disease groups were established and posts made to their sites.

Results: 45,151 impressions and 2,927 engagements were made from 9/2014-6/2015. Relationships were made with 54 kidney disease groups (>15,000 members) from which to find NS patients. Engagements were highest on posts focusing on patient-centeredness in research and lifestyle. 414 patients (51% female, 47%<18yo, 22% racial/ethnic minority) from 27 countries enrolled between 3/2014 and 6/2015, with 27% of enrollees having no previous engagement with NKN. 94% reported a willingness to be contacted about research, including 77% willing to donate a biospecimen. However, only 16% currently or previously participated in a clinical trial. 78% were willing to travel >50mi to participate in a study and 34% were willing to travel >500mi.

Conclusions: A recruitment strategy which includes social media is an efficient, cost-effective opportunity to engage rare disease patients across a wide geography, including those who have not previously participated in research.

The Expression of Podocyte Protein PREX2 in Glomerular Diseases

Anna Levina, 1 Julia Wijskom, 2 Jenny Hulko, 1 Jenny C. Nystrom, 2 Kerstin Ebeors, 3 Annette Bruchfeld, 1 Jaakko Patrakka, 4 Kerstin Hultenby, 5 Annika Werneross, 6 1CLINTEC, Karolinska Inst (KI), Stockholm, Sweden; 2Dept of Physiology, Sahlgrenska Academy, Gothenburg, Sweden; 3Dept of Molecular and Clinical Medicine, Sahlgrenska Academy, Gothenburg, Sweden; 4Dept of Medicine, KI, Stockholm, Sweden; 5LabMed, KI, Stockholm, Sweden.

Background: Phosphatidylinositol-3,4,5-triphosphate-dependent Rac exchange factor 2 (PREX2) is a 183 kDa protein that functions as a RAC guanine nucleotide exchange factor (GEF), activating Rac proteins. It has been discovered in several tissues, e.g. brain, lung, liver and kidney. The specific function of PREX2 in the kidney is unknown. The aim of the present study was to investigate the localization of PREX2 in the kidney and the possible role in renal disease.

Methods: RT-PCR, Western Blot and immunohistochemistry (IHC) was used to identify the localization of PREX2 in renal tissue. The mRNA expression in diseased kidney was analyzed by microarrays on isolated glomeruli from patients with IgA Nephropathy (IgAN), Membranous Nephropathy (MN) and normal tissue. Immuno electron microscopy (IEM) was used to semiquantify PREX2 in renal biopsies from patients with IgAN (n=6), Minimal Change Nephropathy (MCN, n=5) and control tissue from healthy kidney donors (n=5). The morphology was correlated to proteinuria at time of biopsy.

Results: RT-PCR and Western Blot showed the presence of PREX2 in glomerulus, IHC and IEM revealed that PREX2 was localized to podocyte foot processes. In disease samples, mRNA levels were not changed in IgAN and MN. Semi-quantitative IEM showed a significantly lower expression of PREX2 in IgAN and MCN compared to controls. A tendency towards a negative association between PREX2 and proteinuria was seen, although this was not significant.

Conclusions: We found that PREX2 is a new podocyte-associated protein. Although no difference in mRNA levels were found, the expression of PREX2 was significantly lower in IgAN and MCN compared to controls. The function of PREX2 in the glomerular filtration barrier will now be further investigated in an extended patient cohort and in genetically modified animals.

Urinary and Serum Soluble Urokinase Receptor Levels Predicts the Therapeutic Response of Nephrotic Syndrome

Keiji Fujimoto, Yuki Matsui, Norifumi Hayashi, Junko Imura, Hiroki Adachi, Hideki Yamaya, Hitoshi Yokoyama. Div of Nephrology, Kanazawa Medical Univ, Uchinda, Ishikawa, Japan.

Background: It is difficult to develop noninvasive biomarkers to predict the treatment response for nephrotic syndrome (NS), and to differentiate their histological types in the initial phase.

Methods: The subjects were 32 patients with primary NS [8 with focal segmental glomerulosclerosis (FSGS), 12 with minimal change nephrotic syndrome (MCNS), 10 with membranous nephropathy (MN), and 2 with membranoproliferative glomerulonephritis]. Using ROC analysis, we examined whether or not it is possible to differentiate refractory NS from non-refractory NS, and MCNS from FSGS based on the pretreatment values of clinical markers [urinary protein (UP), serum/urinary soluble urokinase receptor (s/ua-suPAR), urinary L-FABP, and eGFR], and values and changes (Δ) after 2 months (2M). We also examined the renal expression of activated b3 integrin (AP-5) by immuno-staining in primary NS and normal tissues.

Results: The following parameters were useful for differentiating refractory NS from non-refractory NS: 2MUP (AUC=0.968, p<0.001), 2Ms-suPAR (AUC=0.913, p=0.002), D2Ms-suPAR (AUC=0.906, p=0.007), D2Ms-suPAR (AUC=0.881, p=0.005) and D2MUP (AUC=0.833, p=0.014). On the other hand, D2Ms-suPAR (AUC=0.905, p=0.007) and D2Ms-suPAR (AUC=0.816, p=0.048) were useful for differentiating MCNS from FSGS. In addition, u-suPAR before treatment was positively correlated with UP (r=0.501, p=0.003) and urinary L-FABP (r=0.427, p=0.017). The expression of activated b3 integrin was primarily strong in the proximal tubular epithelial cells in FSGS or MN, but weak in MCNS and normal tissues. Otherwise, there was no expression of activated b3 integrin on podocytes in both normal and diseased tissues.

Conclusions: It may be possible to evaluate the treatment response of NS and to differentiate MCNS from FSGS based on changes in s/ ua-suPAR within 2 months after the start of treatment. As a mechanism involved in proteinuria in NS patients, su-suPAR may inhibit protein reabsorption in the proximal tubules through the activation of b3 integrin.

FR-PO444

Successful Social Media Recruitment into the NephCure Kidney Network, a Rare Disease Patient Registry

Highlights

• Social media recruitment of rare disease patients is promising

• Recruitment efforts were successful in the first year

• Engagements included impressions, likes, clicks, shares, comments

• Relationship with other groups was established

• 122 pediatric patients were recruited by May 2015

By May 15, 2015, 122 pediatric patients (55.8% female and 44.2 % male) were enrolled from 22 centers covering all the country. Mean age at diagnosis was 4.38±4.23 years. A total of 90 patients (74.6%) had oliguria or anuria at the time of diagnosis. Serum complement C3 was low in 49 patients (40.2%). Neurologic system involvement was present in 34 patients (27.2%). Renal biopsy was performed in 37 patients (30.7%). Renal replacement therapies (RRT) were initiated in 61.5 % of the patients at administration where only 10% of the patients were discharged with RRT. Genetic studies including the complement pathway, DGKE and factor H antibodies were studied in 73% of patients. Plasma infusion or plasma exchange was the initial treatment in 82% of patients and 59% of patients (n=72) had eculizumab treatment. At the time of discharge after initial management, 78 patients (63.9%) and 92 patients (75.4%) achieved renal and hematological remission, respectively. Four patients died at the acute stage of the disease. Mean duration of follow-up was 2.28±2.30 months. During follow-up, eculizumab was stopped in 18 patients and re-started in four of them due to relapse.

Conclusions: The pediatric aHUS Registry will provide data to help increase our knowledge of the aHUS patient with different genetic background and also evaluate the long-term safety and efficacy of treatment options including the eculizumab.

Long-Term Outcomes of Thrombotic Microangiopathy Treated with Plasma Exchange – A Systematic Review

Background: With the adoption of plasma exchange as standard treatment for thrombotic microangiopathy, more patients are surviving and long-term outcomes have greater relevance.

Methods: We conducted a systematic review of observational studies between 1980 and 2013 that reported outcomes of adults with thrombotic microangiopathy at least 6 months after initiating plasma exchange. We searched several databases from 1980 to 2013 for eligible articles published in any language. We abstracted data in duplicate and assessed the methodological quality of each study using an assessment tool developed based on recommended validity criteria.

Results: We screened 6672 articles, reviewed 213, and included 34 studies totaling 1182 patients (study median [range], 24 [10-118]). The mean (or median) follow-up ranged from 6 months to 13 years. The cumulative incidence of relapse and mortality was highly variable and ranged from 3 to 84% and 0 to 61%, respectively. The incidence of other outcomes across 10 studies also varied (outcomes included hypertension, kidney disease, pre eclampsia, stroke, seizure, severe cognitive impairment, and depression); in 3 other studies long-term neurocognitive function and health-related quality of life were significantly lower than the general population.

Conclusions: In summary, patients who survive an episode of thrombotic microangiopathy may be susceptible to long-term vascular complications including chronic kidney disease, but the magnitude of this risk and how to mitigate it remains unclear from prior studies.

FR-PO446

Eculizumab Prevents Thrombotic Microangiopathy in Atypical Hemolytic Uremic Syndrome Patients: Long-Term Follow-Up

Background: In 5 previous studies of patients (pts) with aHUS, ECU effectively treated and prevented thrombotic microangiopathy (TMA) and improved renal function and hematological parameters for up to 2 yrs.

Methods: An observational, multicenter, long-term follow-up study of aHUS pts treated with ECU in 5 prior clinical studies. The primary endpoint was exposure/follow-up TMA event rate post-parent study on-ON) and off-treatment (OFF, among pts who discontinued ECU).

Results: 85 pts enrolled (Table); of these, 74 pts had ON and 37 pts had OFF treatment periods with median follow-up of 24.6 and 16.6 months, respectively. The TMA event rate was 6.7 per 100 pt-yrs for ON pts, and 23.5 per 100 pt-yrs for OFF pts. The rate of TMA events was significantly lower than the general population.

Conclusions: The novel approach leads to an average estimated saving over a cumulative observation period of 748 mos (mean 23 mos/pt).

FR-PO447

An Update on Tailored Eculizumab Maintenance Treatment in Patients with Atypical Haemolytic Uremic Syndrome

Background: Atypical hemolytic uremic syndrome (aHUS) is a severe, systemic thrombotic microangiopathy often related to mutations in the genes encoding complement regulatory proteins. Since 2009, Eculizumab (ECU) has been successfully used in patients (pts) with aHUS. The standard maintenance treatment suggests ECU administration every two weeks (wkx), lifelong, but the best treatment schedule is not yet defined. To define our experience on individualized ECU treatment schedule for preventing relapses based on drug biological activity, with the rational of improving the patient’s quality of life, reducing the risk of adverse reactions and reducing the heavy costs of the treatment.

Methods: Pts undergoing ECU treatment at our Center were addressed to a progressive extension of the interval between ECU doses from the standard 2 wks to 3 or 4 wks with a strict monitor of global complement activity. AP50 was routinely determined before each ECU administration and the interval between doses was adjusted with the target of maintaining AP50>25%. Strict monitoring of indicators of disease reactivation, namely blood in the urine with home dipstick, was regularly performed.

Results: The interval between doses was extended in 33 pts (13 ≤ 18 yrs) with a median age of 28.1 yrs (5-62), 17 F, 21 with native kidney and 12 with graft. Identified mutations were: CFH:15; CFI:2; CD46:1; MCP:1; CFHR3-CFHR1 homoz. deletion with 2031delG. The median age of patients (n=12) was increased in SSc compared with controls, with SSc-CKD significantly lower than SSc.

Conclusions: In patients with aHUS, our experience supports the possibility of tailoring ECU maintenance treatment schedule based on global complement activity. In a cohort of 10 adult pts the described novel approach leads to an average estimated saving >2 million USD/yr.

FR-PO448

Chemokines as Potential Biomarkers of Renal Involvement in Scleroderma

Background: Renal disease in scleroderma (SSc) remains a major clinical challenge. Previous studies showed up to 50% of SSc patients have CKD. We sought to gain insight into the hyperactivity of SSc/SSc by examining markers of disease activity and severity in serum and urine.

Methods: We collected urine and serum from 80 SSc patients, with or without renal disease, for comparison with patients with CKD of other causes (n=10) and healthy controls (n=12). We performed multiplex analysis of candidate markers of disease activity or severity in the SSc and renal injury: MCP-1, MCP-3, IL-6, IL-18, TNFα, and VEGF.

Results: 40 SSc patients had CKD defined by eGFR and urinalysis. Serum MCP-1 was increased in SSc compared with controls, with SSc-CKD significantly lower than SSc without CKD. Mean serum MCP-1 was 132 pg/ml (95% CI 105-162) for SSc with normal renal function compared with 65 pg/ml in SSc-CKD (49-81, p=0.001 for this comparison). MCP-1 was not increased in CKD of other causes (mean 47 pg/ml, 23-85) compared with
controls (mean 53 pg/ml, 25-85, p=0.848). Conversely, urine MCP-1:creatinine ratio was higher in SSc-CKD (mean 64, 32-111) than in SSc with normal renal function (mean 23, 0.9-7.5). There was no difference between groups in serum MCP-3.

**Conclusions:** This is the first study to measure MCP-1 and MCP-3 in the urine of SSc patients. Elevated urine MCP-1 in SSc-CKD suggests increased expression in the renal tract and may help define organ-specific effects of this potential pathogenic mediator that has previously been reported to be increased in serum in association with pulmonary complications. In contrast to MCP-1, other markers of SSc severity (e.g. IL-6) or renal injury (e.g. IL-18) did not differentiate between groups. Our findings further support investigation of urine concentrations of chemokines MCP-1 and MCP-3 as markers or mediators of CKD in SSc.

Towards a Deeper Understanding of Fibrillary Glomerulonephritis: Clinicopathologic Analysis of Patients in a Long-Term Inception Cohort

**Background:** Fibrillary glomerulonephritis is an uncommon primary glomerular disease. Interestingly, there are no clinical trials to guide treatment making this a challenging disease to manage. Here, we report clinical characteristics and treatment outcomes of patients with fibrillary glomerulonephritis diagnosed and/or treated at UNC or through the Fibrillary Glomerular Disease Collaborative Network and compare them to a previously published cohort from Mayo clinic.

**Methods:** Patients were identified through the UNC Division of Nephropathology database. Clinical data were extracted from the electronic medical records starting at the time of diagnosis.

**Results:** There were 31 patients with fibrillary glomerulonephritis who were treated and another 245 patients who were diagnosed by the UNC Division of Nephropathology. Demographic and clinical data from the date of biopsy are displayed in the table.

**Conclusions:** This clinicopathologic analysis of patients with fibrillar glomerulonephritis is the largest study of its kind in the literature to date. The patients in our cohort were more ethnically diverse than the Mayo clinic group but presented with similar degree of kidney impairment and nephrotic range proteinuria. Fibrillary glomerulonephritis is an understudied glomerular disease that portends a poor prognosis warranting the need for prospective multi-center treatment studies to determine durable therapeutic avenues.

Clinical, Histologic, and Genetic Predictors of Response to MMF in C3 Glomerulopathy

Rupali Surendra Avasare, 1 Pietro A. Canetta, 1 Andrew S. Bombaek, 2 Yasar Caliskan, 1 Yasemin Ozluk, 1 Gerald B. Appel, 1 Division of Nephrology, Columbus Univ Medical Center, New York, NY; 2 Div of Nephrology, Istanbul Faculty of Medicine, Istanbul; 3 Dept of Pathology, Istanbul Faculty of Medicine, Istanbul.

**Background:** Treatment of C3 Glomerulopathy (C3G) with anti-complement therapy has yielded mixed results and there is no consensus on optimal treatment. We reviewed the experience of our C3G patients who received a course of mycophenolate mofetil (MMF) to determine predictors of treatment response.

**Methods:** In a retrospective chart review of patients with biopsy-diagnosed C3G, we identified 24 patients treated with a course of MMF (~6 months) with >1 year follow-up. The primary outcome was either complete remission (stable GFR with decline in proteinuria to <0.5 g/CGFR) or partial remission (stable GFR with >50% decline in proteinuria to between 0.5 - 3.5 g/CGFR at last follow-up. Responders and nonresponders were compared with Student’s t test or Mann-Whitney U test for continuous variables and Fisher exact test for categorical variables.

**Results:** There were 15 men and 9 women with 21 White and 3 Black patients. Median age was 27 years (IQR 21 – 37). Median creatinine was 1.17 (IQR 0.87 – 1.74) mg/dL, and median C3 level (IQR 34 – 89) mmol/L (IQR 1.7mmol/L). Median proteinuria was 3.6 g/gCr (IQR 1.6 – 7.7). Of 24 patients treated with MMF, 14 (58%) were responders (8 CR, 6 PR). 22 of 24 patients received steroids. The only variable associated with remission was elevated soluble membrane attack complex (sMAC) level (responders 100%, nonresponders 25%, p <0.05). Age, eGFR, proteinuria, hypocomplementemia, complement factor mutations or autoantibodies, interstitial fibrosis/tubular atrophy, location of deposits on electron microscopy, and presence/absence of immunoglobulin staining on IF were no different between responders and nonresponders.

**Conclusions:** 14 of 24 C3G patients treated with a course of MMF experienced remission. Elevated sMAC level was associated with response to MMF. While not a specific anti-complement therapy, MMF may be an effective treatment for some patients with C3G. This and other series suggest elevated sMAC may indicate treatment-susceptible disease.

**FR-PO451**

Mayo In the literature, there is no consensus on optimal treatment. We reviewed the experience of our C3G patients who received a course of mycophenolate mofetil (MMF) to determine predictors of treatment response.

**Methods:** Patients were identified through the UNC Division of Nephropathology database. Clinical data were extracted from the electronic medical records starting at the time of diagnosis.

**Results:** There were 31 patients with fibrillary glomerulonephritis who were treated and another 245 patients who were diagnosed by the UNC Division of Nephropathology. Demographic and clinical data from the date of biopsy are displayed in the table.

**Conclusions:** This clinicopathologic analysis of patients with fibrillar glomerulonephritis is the largest study of its kind in the literature to date. The patients in our cohort were more ethnically diverse than the Mayo clinic group but presented with similar degree of kidney impairment and nephrotic range proteinuria. Fibrillary glomerulonephritis is an understudied glomerular disease that portends a poor prognosis warranting the need for prospective multi-center treatment studies to determine durable therapeutic avenues. Further studies are needed to refine our understanding of this disease and to develop effective treatment strategies.

FR-PO453

Stereoids Alone for the Treatment of C3 Glomerulonephritis with Monoclonal Gammopathy. Insaara Jaffer Sathick,1 Ladan Zand,1 Samih H. Nasr,2 Sanjeev Sethi,3 Fernando C. Fervenza,4 Nelson Leung,5,6 1Div of Nephrology and Hypertension, Mayo Clinic; 2Div of Anatomic Pathology, Mayo Clinic; 3Div of Hematology, Mayo Clinic.

Background: C3 glomerulonephritis (C3GN) is a rare disease with no trial data to guide treatment. In patients with C3GN with monoclonal gammopathy, steroids alone may be a viable treatment option.

Methods: We present our experience in managing C3GN with monoclonal gammopathy with prednisone.

Results: 5 patients presented to our institution from 2011 to 2014 with biopsy proven C3GN and underlying monoclonal gammopathy. Median age of this cohort was 63 years. Median estimated GFR by MDRD equation was 35.4 ml/min1.73m2 and median proteinuria was 2 g/day at presentation. All patients had IgG kappa monoclonal gammopathy. Patient 5 required renal replacement therapy but recovered renal function. All patients were treated with Prednisone 60mg/day tapering to zero in all except one. Patient 2 and 4 continue on 2.5-5mg/day. Median duration of follow up was 26.9 months. Median estimated GFR at follow up was 40.16 ml/min1.73m2. All patients showed improvement in proteinuria. 3/5 patients showed improvement in proteinuria. 3/5 patients showed improvement in kidney function.

Conclusions: 30% of patients with GMP have as pathogenic mechanism the complement activation with C3 deposition in the glomerulus. Our research group has found C3 deposition causally related to GMP. The most common clinical presentation is nephrotic syndrome.

FR-PO454

The National Study of Membranoproliferative Glomerulonephritis and C3 Glomerulopathy: Characterisation of the Initial United Kingdom Paediatric Cohort Edwin KS Wong,1 Claire L. Harris,2 Kevin J. Marchbank,1 Isabel Y. Pappworth,3 Rebecca Walters,1 Hannah J. Lomax-Browne,1 Daniel P. Gale,1 Tim Goodship,1 David Kavanagh,1 Roger D. Malcomson,3 Paul Morgan,2 Matthew C. Pickering,1 H. Terence Cook,4 Sally A. Johnson,1,5 1Newcastle Univ; 2Cardiff Univ; 3Imperial College London; 4Univ College London; 5Leicester Royal Infirmary.

Background: The National Registry of Rare Kidney Diseases (RaDaR) in the United Kingdom allows recruitment, research and longitudinal follow up of patients with membranoproliferative glomerulonephritis (MPGN) and C3 glomerulopathy (C3G). The aim of the MPGN/C3G Rare Disease Group (RDG) is to deep phenotype and analyse complement abnormalities in a paediatric cohort of MPGN/C3G.

Methods: The MPGN/C3G RDG recruited patients with MPGN/C3G for central review of biopsies and clinical data, and studied complement abnormalities previously described in MPGN/C3G.

Results: 83 prevalent patients with MPGN/C3G were identified and centrally reviewed. 79 could be classified; 40 had immune-complex MPGN, 25 had C3GN and 14 had DDD. Complement abnormalities are shown in Table 1. Follow-up data on 73 patients is shown in Figure 1.

Conclusions: RaDaR has facilitated the development of a large nationwide cohort of paediatric patients with MPGN/C3G who have now undergone deep phenotyping and genotype. Acquired complement abnormalities were common; rare genetic abnormalities were infrequent. Patients with DDD had the worst renal outcome. Ongoing recruitment and longitudinal follow up will clarify prognosis according to phenotype/genotype and allow stratification into future treatment studies.

FR-PO455

Plasma Neutrophil Gelatinase-Associated Lipocalin, Procalcitonin and C-Reactive Protein as the Predictor of Acute Pyelonephritis in Children with Febrile Urinary Tract Infections Byung-kwan Kim, Hyung Eun Yim, Kee Hwan Yoo. Dept of Pediatrics, Korea Univ Medical Center, Seoul, Republic of Korea.

Background: We have recently reported that plasma and urinary neutrophil gelatinase-associated lipocalin (NGAL) levels are useful for the prediction of acute pyelonephritis (APN) in pediatric urinary tract infection (UTI). This study was aimed to determine the accuracy of NGAL measurements, compared with serum measurements of procalcitonin, C-reactive protein (CRP), and white blood cells (WBCs) in predicting APN and associated renal problems in children with febrile UTIs.

Methods: Total 138 children with febrile UTIs (59 APN, 79 lower UTI) were enrolled. Patients with renal failure, congenital urologic anomaly except vesicoureteral reflux

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
(VUR), and recurrent UTIs were excluded. Serum levels of NGAL, procalcitonin, CRP, and WBC counts were measured at admission. Laboratory, clinical, and imaging results were reviewed.

Results: Receiver operating curve analyses showed NGAL (area under the curve (AUC) 0.853), procalcitonin (AUC 0.855), CRP (AUC 0.879), and WBCs (AUC 0.654) had good diagnostic profiles for identifying APN (all P < 0.05). Using the best cut-off values (NGAL 117 ng/ml, procalcitonin 0.173 mg/dL, CRP 2.78 mg/dL, WBC 15,870/mm$^3$), odds ratios for APN were all highly increased after adjusting for age and gender (NGAL 41.2, procalcitonin 22.8, CRP 25.3, WBC 4.2). The sensitivity and specificity of plasma NGAL for diagnosing APN was the highest among all examined biomarkers (sensitivity 88.1%, specificity 84.8%). Univariate analysis showed that female gender, NGAL, procalcitonin, and CRP were associated with APN (all P < 0.05). However, multivariate analysis revealed that only plasma NGAL was an independent predictor of APN (P < 0.001). NGAL, procalcitonin, and CRP levels also showed good predictive values for the presence of VUR (AUCs of NGAL, procalcitonin, and CRP 0.798, 0.756, 0.845).

Conclusions: Plasma NGAL, procalcitonin and CRP are sensitive predictors for identifying APN and VUR. Plasma NGAL can be more reliable than serum procalcitonin, CRP, and WBCs in predicting APN in children with febrile UTIs.

FR-PO456

A Prospective Evaluation of Renal Contrast-enhanced Ultrasound (CEUS) in the Detection of Pyelonephritis

Florian Buchkremer,$^1$ Daniel Droz dov,$^2$ Werner C. Albrich,$^3$ Andreas H. Bock,$^4$ Div of Nephrology, Kantonsspital Aarau, Aarau, Switzerland; $^5$Medical US Dept, Kantonsspital Aarau, Aarau, Switzerland; $^6$Div of Infectious Diseases, Kantonsspital St. Gallen, St. Gallen, Switzerland.

Background: Contrast-enhanced ultrasound (CEUS) has been described as a promising method for detecting acute pyelonephritis (PN) and its complications. We evaluated its value in diagnosis and risk stratification in the setting of a randomized controlled trial (RCT).

Methods: Immunocompetent adults with community-acquired urinary tract infection (UTI) presenting in the emergency department of Kantonsspital Aarau were enrolled in a RCT designed to evaluate the performance of a PCT/pyuria guided algorithm versus standard guidelines (Drozdov et al. BMC Medicine 2015). Outcomes included antibiotic exposure, duration of therapy, persistent infections and recurrences/re-hospitalizations.

As part of the protocol, all hospitalized UTI patients with fever and/or flank pain were to undergo renal CEUS in addition to standard grayscale and Doppler examination within the first 72h of admission. Findings suggestive of PN such as triangular, hypoechoic, hypoperfused areas were recorded.

Results: Of 70 UTI study patients hospitalized with fever and/or flank pain, 41 (59%) underwent the ultrasound study. Dropout reasons included missing consent (5%), early discharge (6%) or technical (18%). Examined and non-examined patients did not differ significantly in baseline characteristics or outcome. Findings suggestive of PN were found in 5/41 (12%). In 3 patients, this was evident in grayscale/Doppler already, in 2 additional patients, critical findings were only present in CEUS. The presence of PN-suggestive findings was not predictable from any baseline clinical characteristic. Patients with and without PN-suggestive findings did not appear to differ in outcome.

Conclusions: Ultrasound evidence of pyelonephritis is rare in patients hospitalized for UTI and other renal causes. Adding CEUS to baseline grayscale and Doppler ultrasound may substantially increase the number of positive findings.

Funding: Government Support - Non-U.S.

INS 0by25 AKI Global Snapshot Project: AKI Disposition

Michael V. Rocco,$^1$ Ravindra L. Mehta,$^2$ Giuseppe Remuzzi,$^3$ Jing Zhang,$^3$ Melanie Godin,$^3$ Michael V. Rocco,$^4$ U Sao Paulo,$^5$ U California San Diego,$^6$ Mario Negri Inst; Sherbrooke U; Wake Forest U.

Background: The 0by25 AKI Global Snapshot Project (GSP) was a point prevalent survey of AKI pts seen in health care facilities throughout the world.

Methods: A web based survey tool was used to obtain data from individual clinicians on pts who had a confirmed diagnosis of AKI based on KDIGO criteria. Detailed methodology may be found in the ISN GSP abstract on provider characteristics. Countries were defined by gross national income per capita (GNIC) Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC). We analyzed the frequency of AKI requiring dialysis and the reasons for starting or withholding dialysis.

Results: Of 3861 pts showed that 88.8% were alive at the time of the last observation; this rate did not vary by GNI category (p=0.922). Scheduled follow-up for AKI was arranged in only 14% of pts, with non-significant differences among GNI categories (p=0.5).

Conclusions: Pts with AKI had hospital stays that typically exceeded 7 days, although this was less likely in LLMIC. Survival rates did not vary by GNI category. Pts were more likely to be sent home in LLMIC compared to HIC and UMIC; this observation may at least be partially due to the greater prevalence of patients in ICUs’ 7 days after AKI diagnosis in LLMIC countries. Scheduled follow-up for AKI was infrequent and did not vary by GNI category.

INS 0by25 AKI Global Snapshot Project: Indications for Initiating and Withholding Dialysis in AKI Worldwide

Etienne Macedo,$^1$ Ravindra L. Mehta,$^2$ Giuseppe Remuzzi,$^3$ Jing Zhang,$^3$ Melanie Godin,$^3$ Michael V. Rocco,$^4$ U Sao Paulo,$^5$ U California San Diego,$^6$ Mario Negri Inst; Sherbrooke U; Wake Forest U.

Background: The 0by25 AKI Global Snapshot Project (GSP) was a point prevalent survey of AKI pts seen in health care facilities throughout the world.

Methods: A web based survey tool was used to obtain data from individual clinicians on pts who had a confirmed diagnosis of AKI based on KDIGO criteria. Detailed methodology may be found in the ISN GSP abstract on provider characteristics. Countries were defined by gross national income per capita (GNIC) Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC). We analyzed the frequency of AKI requiring dialysis and the reasons for starting or withholding dialysis.

Results: Of 3855 pts, 768 (20%) were dialyzed. Mortality rate was significantly different in dialyzed (17%) vs. non-dialyzed (9%) pts (p=0.0001). Among dialyzed pts, the mortality rate was similar in countries of different GNI categories. The main reason to start dialysis was solute control, with a similar distribution among country categories.

INS 0by25 AKI Global Snapshot Project: Indications for Initiating and Withholding Dialysis in AKI Worldwide

Etienne Macedo,$^1$ Ravindra L. Mehta,$^2$ Giuseppe Remuzzi,$^3$ Jing Zhang,$^3$ Melanie Godin,$^3$ Michael V. Rocco,$^4$ U Sao Paulo,$^5$ U California San Diego,$^6$ Mario Negri Inst; Sherbrooke U; Wake Forest U.

Background: The 0by25 AKI Global Snapshot Project (GSP) was a point prevalent survey of AKI pts seen in health care facilities throughout the world.

Methods: A web based survey tool was used to obtain data from individual clinicians on pts who had a confirmed diagnosis of AKI based on KDIGO criteria. Detailed methodology may be found in the ISN GSP abstract on provider characteristics. Countries were defined by gross national income per capita (GNIC) Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC). We analyzed the frequency of AKI requiring dialysis and the reasons for starting or withholding dialysis.

Results: Of 3855 pts, 768 (20%) were dialyzed. Mortality rate was significantly different in dialyzed (17%) vs. non-dialyzed (9%) pts (p=0.0001). Among dialyzed pts, the mortality rate was similar in countries of different GNI categories. The main reason to start dialysis was solute control, with a similar distribution among country categories.

Of the non-dialyzed pts (3087), 244 (8%) had a clinical indication but were not dialyzed. Reason for withholding dialysis was different across country levels. In HIC, the main reason to withhold dialysis was futile treatment (79%). In UMIC, main reason was patient cultural beliefs (25%) and in LLMIC financial restriction was as frequent as futile perception (50 and 32%).

Conclusions: Solute control is the most common indication for AKI dialysis around the globe. Lack of resources is a frequent cause of withholding dialysis in LLMIC, while physician perception of futile treatment is the main reason in HIC. Knowledge of local deficits will be important to guide future interventions and to develop strategies to improve outcomes.

ISN 0by25 AKI Global Snapshot Project: Differences in Location and Process of Care Among AKI Patients Around the Globe

Etienne Macedo,1 Ravindra L. Mehta,2 Giuseppe Remuzzi,3 Jing Zhang,2 Melanie Godin,4 Michael V. Rocco,2 1 U Sao Paolo; 2 U California San Diego; 3 Mario Negri Inst; 4 Sherbrooke U; 5 Wake Forest U.

Background: The Global Snapshot (GSP) was a prospective cross-sectional study designed to capture standardized information on incidence, causes and treatment of AKI in all health care settings throughout countries of diverse economic status.

Methods: A web based survey tool was used to obtain data from pts with a confirmed diagnosis of AKI based on KDIGO criteria in 72 countries. Detailed methodology is found in the ISN GSP abstract on provider characteristics. We analyzed the characteristics of pt location and process of care by gross national income per capita (GNI) country levels. Countries were defined as: Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC).

Results: Based on GNI, 23 countries were classified as LLMIC, 20 as UMIC and 29 as HIC.

In LLMIC, 58% of pts were classified as AKIN stage 3 at AKI diagnosis. sCr was significantly higher in these pts (3.26 mg/dl) compared to 2.43 in pts from HIC and 2.3 in pts from UMIC.

Conclusions: BsCr measured was frequent in pts from HIC and UMIC, where 1/3 of AKI cases occurred in CKD pts. Absence of BsCr was a common issue in LLMIC, associated with higher levels of sCr and KDIGO stage at AKI diagnosis. UO is often not computed in pts who develop AKI. Systematic assessment of urine output in high-risk pts could help identify AKI earlier.

FR-PO461

ISN 0by25 AKI Global Snapshot Project: Risk Factors for AKI

Ravindra L. Mehta,1 Giuseppe Remuzzi,2 Jing Zhang,2 Melanie Godin,2 Michael V. Rocco,3 Jorge Cerda,1 John Feehally,4 Fredric O. Finkelstein,5 Nathan W. Levin,6 Marcello Tonelli,3 1 U California San Diego; 2 Mario Negri Inst; 3 Sherbrooke U; 4 Wake Forest U; 5 Albany Med Coll; 6 Yale U; 7 Renal Research Inst; 8 Calgary.

Background: The 0by25 AKI Global Snapshot Project (GSP) was a point prevalence survey of AKI pts seen in health care facilities throughout the world.

Methods: A web based survey tool was used to obtain data from individual clinicians about pts who had AKI based on KDIGO criteria. Detailed methodology is found in the ISN GSP abstract on provider characteristics. Countries were defined by gross national income per capita (GNI): Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC).

Results: Participants were distributed from North/East Asia 26.4%, South Asia 18.9%, Latin America/Caribbean 14%, Africa 13.4%, North America 7.3%, Western Europe 6.2%, Oceania/South East Asia 4.3%, Russia/Commonwealth Independent States 3.9%, Middle East 3.4%, Eastern/Central Europe 2.2%. Ethnic groups included 53% Asian, 19% Caucasian, 9% Hispanic, 8% African, 7% Middle Eastern and 1.5% Native/Aboriginal. Causes of AKI varied by GNI and were compared by Kruskal-Wallis test.

ISN 0by25 AKI Global Snapshot Project: KDIGO Classification and AKI Diagnosis Around the Globe

Etienne Macedo,1 Ravindra L. Mehta,2 Giuseppe Remuzzi,3 Jing Zhang,2 Melanie Godin,4 Michael V. Rocco,3 1 U Sao Paolo; 2 U California San Diego; 3 Mario Negri Inst; 4 Sherbrooke U; 5 Wake Forest U.

Background: The Global Snapshot (GSP) was a prospective cross-sectional study designed to capture standardized information on incidence, causes and treatment of AKI in all health care settings throughout countries of diverse economic status.

Methods: A web based survey tool was used to obtain data from pts with a confirmed diagnosis of AKI based on serum creatinine (sCr) and urine output (UO) KDIGO criteria in 72 countries. Detailed methodology is found in the ISN GSP abstract on provider characteristics. Countries were defined by gross national income per capita (GNI): Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC).

Results: Of 4024 pts, 2891 (71%) had an available baseline sCr (BsCr), absence was greater in LLMIC (45% vs 18% in HIC, 21% in UMIC). AKI on CKD was seen in 40%. At AKI confirmation day, only 50% of pts had UO volume assessed.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Other organ failures present were pulmonary 16.4% (more common in HIC), cardiovascular 23.1% (less common in LLMIC), neurologic 8.3%, hepatic 10.4%, hematologic 9.5% (more common in LLMIC) and none 53.9%

**Conclusions:** Hypotension was the most common cause of AKI in HIC and UMIC; dehydration was most common in LLMIC. Acute kidney disease, pregnancy and envenomation were more common in LLMIC.

**Background:** The 0by25 AKI Global Snapshot Project (GSP) was a point prevalent survey of AKI pts seen in health care facilities throughout the world.

**Methods:** A web based survey tool was used to obtain data from individual clinicians about pts who had AKI based on KDIGO criteria. Detailed methodology may be found in the ISN GSP abstract or provider characteristics. Countries were defined by gross national income per capita (GNI): Low and lower middle income (LLMIC), upper middle income (UMIC) and high income (HIC).

**Results:** Initial evaluation of AKI included urinalysis in 73.6%, ultrasound in 55% and renal biopsy in 4.1%, with all three more commonly being performed in LLMIC. Initial treatment of AKI included fluids in 74.3%, vasopressors in 23.8%, diuretics in 41.4%, antibiotics in 63.8% and urinary diversion in 19.5%. The receipt of dialytic therapy occurred in 790 of 4018 pts (19.7%), with use in 18.8% in HIC, 14.3% in UMIC and 28.0% in LLMIC. In 244 instances where dialysis was recommended but not performed, fluidity was cited in 58.6% and cultural beliefs were cited in 25.4%. Unavailability of staff or material resources to perform dialysis was reported in 1.4% of HIC, 3.8% of UMIC and 16.4% of LLMIC. Inability to afford therapy was 1.4% in HIC, 1.9% in UMIC and 16.4% in LLMIC (p<0.0001). The ratio of pts not able to receive dialysis by those that did receive dialysis was 0.21 in HIC, 0.25 in UMIC and 0.18 in LLMIC. There were significant differences in the renal modality used.

**ISN 0by25 AKI Global Snapshot Project: Provider Characteristics**

**Melanie Godin, 1 Ravindra L. Mehta, 2 Giuseppe Remuzzi, 3 Jing Zhang, 4 Michael V. Rocco, 5 Jorge Cerda, 6 Vivekanand Jha, 7 Nathan W. Levin, 8 Andrew J.P. Lewington, 9 Etienne Macedo, 10 Marcello Tonelli, 11 Sherbrooke U; 12 U California San Diego; 13 Mario Negri Inst; 14 Wake Forest U; 15 Albany Med Coll; 16 George Inst Global Health; 17 Leeds Teaching Hosp; 18 Sao Paulo; 19 U Calgary.**

**Background:** The 0by25 AKI Global Snapshot Project (GSP) was designed to determine the spectrum of AKI pts seen in health care facilities throughout the world.

**Methods:** Health care providers joined the GSP after gaining approval from their local IRB. Providers chose one “index” day between 9/29/2014 and 12/7/2014 to provide data on AKI pts under their care. De-identified data on pts who met criteria for AKI by modified KDIGO criteria were entered through a secure website using a standard questionnaire developed by the 0by25 AKI workgroup. Data collected included pt demographics, initial clinical data, diagnostic, treatment and outcome information. Countries were grouped into three categories based on gross national income per capita (GNI): high income with GNI >$12,476, low and lower middle income with GNI <$8,403, and upper middle income with GNI between levels 1 & 3.

**Results:** 324 surveys from 72 countries were received describing 4024 pts with AKI. Providers included 248 nephrologists, 20 nephrology fellows, 14 intensivists, 26 pediatric nephrologists. Location of facilities by region included 52 from Africa, 47 from Latin America & Caribbean, 45 from North America, 45 from South Asia, 40 from North and East Asia, 34 from Western Europe, 19 from Russia/Commonwealth of Independent States, 17 from Oceania & South East Asia, 14 from Middle East and 11 from Eastern & Central Europe. Size of catchment population for each facility was: >5 million in 28%, 0.5-1.5 million in 26%, 0.1-0.5 million in 19% and 1.5-3 million in 11%. Type of facility was institute in 47%, public hospital or health care concern in 37%, private multispecialty group in 14%. Dialysis was available in 97% of facilities.

**Conclusions:** This project is the first worldwide point prevalent survey of AKI. It demonstrates the feasibility of obtaining data on AKI using a secure website from practitioners in varied health care settings from six continents.

**Funding:** Pharmaceutical Company Support - Astute Medical (San Diego, CA, USA), Danone Nutricia Research (Palaiseau, France) and Bellco (Mirandola, Italy), Private Foundation Support

**Postoperative Acute Kidney Injury in Non-Cardiac Surgery**

**Jesse D. Schold, 1 Edward G. Soltész, 2 Sevg Demirjian. 3 Div of Nephrology, Univ of Michigan; 4Nephrology and Hypertension, Cleveland Clinic; 5Thoracic and Cardiovascular Surgery, Cleveland Clinic.**

**Background:** Acute Kidney Injury (AKI) is common after Coronary Artery Bypass Grafting (CABG) and associated with poor outcome. Increased hospital procedure volume has been associated with better outcomes. We examined (1) impact of number of annual CABG procedures per hospital (CABG-vol) on AKI needing dialysis (AKI-D) and mortality, and (2) if it modifies the relationship between AKI-D and mortality.

**Methods:** Using Nationwide Inpatient Sample database from 2000-2010 we identified admissions with CABG using ICD-9-CM codes. Those with AKI-D were identified and those with kidney transplant or on maintenance dialysis were excluded. Multivariable logistic regressions were used to assess impact of CABG-vol on AKI-D and mortality. We used restricted cubic splines to account for non-linear relationship between CABG-vol and mortality. A priori interaction term between CABG-vol & AKI-D was assessed in models 1 & 2.

**Results:** Of estimated 3,373,292 (95% CI: 3,103,610-3,570,973) hospitalizations for CABG, 0.7% (24,126) had AKI-D. Those with AKI-D were older, more females (37.5% vs 29.1%; p<0.001) and blacks (7.4% vs 5.5%; p<0.001). On adjusted analysis, CABG-vol was correlated with AKI-D (0.99; 95% CI 0.99-1.00) but was associated with mortality (Fig 1).

**FR-PO465**

**Impact of Hospital CABG Volume and AKI Needing Dialysis on CABG Hospitalizations**

**Ankit Sakhuja, 1 Jesse D. Schold, 2 Edward G. Soltész, 3 Sevg Demirjian. 4 Div of Nephrology, Univ of Michigan; 5Nephrology and Hypertension, Cleveland Clinic; 6Thoracic and Cardiovascular Surgery, Cleveland Clinic.**

**Background:** Acute Kidney Injury (AKI) is common after Coronary Artery Bypass Grafting (CABG) and associated with poor outcome. Increased hospital procedure volume has been associated with better outcomes. We examined (1) impact of number of annual CABG procedures per hospital (CABG-vol) on AKI needing dialysis (AKI-D) and mortality, and (2) if it modifies the relationship between AKI-D and mortality.

**Methods:** Using Nationwide Inpatient Sample database from 2000-2010 we identified admissions with CABG using ICD-9-CM codes. Those with AKI-D were identified and those with kidney transplant or on maintenance dialysis were excluded. Multivariable logistic regressions were used to assess impact of CABG-vol on AKI-D and mortality. We used restricted cubic splines to account for non-linear relationship between CABG-vol and mortality. A priori interaction term between CABG-vol & AKI-D was assessed in models 1 & 2.

**Results:** Of estimated 3,373,292 (95% CI: 3,103,610-3,570,973) hospitalizations for CABG, 0.7% (24,126) had AKI-D. Those with AKI-D were older, more females (37.5% vs 29.1%; p<0.001) and blacks (7.4% vs 5.5%; p<0.001). On adjusted analysis, CABG-vol was correlated with AKI-D (0.99; 95% CI 0.99-1.00) but was associated with mortality (Fig 1).
AKI-D was a significant predictor of mortality with OR 13.75 (95% CI: 11.37-16.64). Interaction term between CABG-vol & AKI-D was not significant (p=0.8).

Conclusions: Lower annual CABG hospital procedure volume is significantly associated with higher mortality but not with higher incidence of AKI-D. AKI-D is associated with higher mortality in those undergoing CABG, however, there is no differential effect of hospital volume on adjusted odds of mortality due to AKI-D.

FR-PO466
Five-Year Risk of Renal Outcomes After Pediatric Cardiac Surgery
Jason Henry Greenberg,1 Michael Zappettelli,2 Heather Thiessen Philbrook,3 Prasad Devarajan,3 Katherine Krawczeski,1 Steven G. Coca,4 Chirag R. Parikh.1
1Program of Applied Translational Research, Yale School of Medicine; 2Dept of Pediatrics, McGill Health Centre; 3Dept of Pediatrics, Cincinnati Children’s Medical Center.

Background: Pediatric cardiac surgery is associated with a high risk of acute kidney injury(AKI) and other short-term adverse outcomes. However, the risk for long-term renal outcomes after cardiac surgery is unknown.

Methods: We performed 5 year follow-up on the Translational Research Investigating Biomarker Endpoints in AKI (TRIBE-AKI) cohort. TRIBE-AKI is a three-center prospective cohort study of children 1 month to 18 years old who underwent cardiopulmonary bypass.

Results: Out of 305 children who survived their index hospitalization, 4(1.3%) died after discharge and 12(4.2%) participated in the 5 year follow-up. Mean age of the cohort at follow-up was 9.2 years and 53% were male. 56 out of 128 patients had peripartive AKI defined as a post-operative serum creatinine rise by 50% or 0.3mg/dl from pre-operative baseline. At a median of 5.4 years of follow-up, hypertension, microalbuminuria, eGFR<90, and eGFR<60 were identified in 13%, 6.3%, 7.0%, and 0.8% of patients, respectively. CKD, defined as eGFR<90 or microalbuminuria, was present in 13% of children. There were no significant differences in renal outcomes between patients with and without peripartive AKI. (4.0%) patients had been seen by a pediatric nephrologist. The 5-year post-operative prevalence of hypertension in our cohort was 8.6 fold higher than found in the general pediatric population(Table).

Conclusions: Overall, there is a high prevalence of CKD and hypertension in children 5 years after cardiac surgery. Despite this high prevalence of CKD, very few children were seen by a pediatric nephrologist. These findings may have implications for renal care and late cardiovascular disease in children after cardiac surgery.

FR-PO467
Changes of Epidemiology and Influencing Factors of Acute Kidney Injury After Cardiac Surgery – A Five-Year Study from 2009 to 2013
Zhongping Zou,1 Jiaying Xu,1 WenLv Lv,2 Bo Shen,1 Yi Fang,1 Jianzhou Zou,1 Jie Teng,1 Xiaojing Ding,1,2
1Dept of Nephrology, Zhongshan Hospital, Fudan Univ, Shanghai, China; 2Shanghai Inst for Kidney and Dialysis, Zhongshans Hospital, Fudan University, Shanghai, China; 3Shanghai Key Laboratory of Kidney Disease and Blood Purification, Zhongshan Hospital, Fudan Univ, Shanghai, China.

Background: Cardiac surgery is a common cause of acute kidney injury (AKI). We collected the epidemiological data of patients with AKI from 2009 to 2013 in order to explore the influencing factors of changes of epidemiology after cardiac surgery.

Methods: Clinical data of patients undergoing cardiac surgery, which included demographic data of preoperative, intraoperative, postoperative was collected in our hospital from January 2009 to December 2013. The main endpoint was poor prognosis which included overall mortality and abandon of treatment. The second point was renal outcome.

Results: A total of 11693 patients enrolled, including 6637 males and 5056 females. The overall AKI incidence was 34.5%(n=4030). The AKI incidence increased during the five years from 34.26% to 36.5%(P<0.05). There was no significantly statistical differences in AKI-RRT incidences during the five years (p=0.360). The hospital mortality of AKI decreased from 6.3% in 2009 to 3.8% in 2013. The incidence of poor prognosis in AKI were 8.3%, 7.5%, 6.8%, 5.1%, 8.0%(P=0.196).The mortality of AKI-RRT decreased from 47.1% to 29.5%, but there was no statistical difference (P = 0.230). The incidence of poor prognosis in RRT decreased from 66.7% to 57.4%, also no significantly statistical difference (P = 0.825). Multivariate logistic regression analysis showed that male age(every additional 10 years), body mass index(every additional 5kg/m2),hypertension, chronic heart failure, pre-operative serum creatinine 115mmol/L, CPB(every additional 30min) were the risk factors of AKI after cardiac surgery.

Conclusions: The incidence of AKI after cardiac surgery increased from 2009 to 2013 and the rate of poor prognosis did not change. The incidence of AKI-RRT and the rate of poor prognosis remained high. The prevention and treatment of AKI still need improvement.

FR-PO468
The Very Long-Term Co-Morbidity Adjusted Impact of AKI following Cardiac Surgery: A 15-Year Follow-up Study
Alejandro Ferreiro,1 Raul Lombardi,2 1Nephrology, INCC, Facultad de Medicina, Montevideo, Uruguay; 2Critical Care Medicine, SMU, Montevideo, Uruguay.

Background: AKI is a frequent complication of cardiac surgery (CS) associated to high mortality. The co-morbidity adjusted residual impact on very long-term mortality (> 12 years) of AKI, excluding the initial catastrophic impact on early mortality has not been addressed before. Objectives: to evaluate the net attributable impact of AKI after CS on long-term survival.

Methods: All adult patients submitted to CS between 1/1/2000 and 31/12/2013 (n=7755) were enrolled. The INCC prospective-collected database with more than 750 variables (demographics, comorbidities, type of CS, intraoperative and postoperative variables, peri-operative support and short time outcomes) was used. Long-term survival (up to 15 year by December 2014) was obtained by systematic telephone survey (minimum 1-year follow-up) and the National Population Registry. AKI stages were defined according to KDIGO definition. Demographics, logistic EuroSCORE (and their single components), type of CS, baseline renal function (Cockcroft-Gault formula) were used for comorbidity risk-adjustment. Statistical analysis: “t” test, c2, Kaplan-Meier plots, log-rank tests were performed. Hazard ratios were calculated. Results: AKI incidence: 38.4%. RRT: 1.7%. Long-term (15 years) actuarial survival after 1 year follow-up: no AKI 0.58; AKI I: 0.47; AKI II: 0.39; AKI III: 0.27 (p=0.001). In multivariate Cox regression analysis, AKI stages I, II and III (OR 1.17; 1.24, 1.62 respectively) were independently associated with mortality between 1 year after CS and 15 year follow-up, even after adjustment with logistic EuroSCORE (OR 1.02), age (OR 1.038), diabetes (OR 1.58), pre-operative eGFR (OR 0.996) and no-isolated coronary bypass surgery (OR 1.24).

Conclusions: AKI and its severity are independently associated with very long-term mortality, even after discarding short term events (1 year), in cardiac surgery. Should AKI be causative or a surrogate marker of late events in the long-term follow up is a matter of concern to be evaluated.

FR-PO469
Incidence and Influencing Factors of Cardiac Surgery-Associated Acute Kidney Injury Based on the KDIGO Criteria: A Retrospective Cohort Study
Changchun Jin,1 Zijie Xie,1 Xin Wai,1 Xiangcheng Cao,1 Jianzhou Zou,1 Jie Teng,1 Xiaojing Ding,1,2
1Nanjing First Hospital; 2Shanghai Inst for Kidney and Dialysis, Zhongshans Hospital, Fudan University, Shanghai, China.

Background: The incidence and influencing factors of cardiac surgery-associated acute kidney injury (CSA-AKI) based on the KDIGO criteria have not been well studied. This study was aimed to evaluate the incidence, risk or protective factors of acute kidney injury (AKI) in patients after cardiac surgery.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: A retrospective analysis of 2575 patients undergoing first documented cardiac surgery with cardiopulmonary bypass (CPB) between January 2008 and December 2012 in our hospital was conducted. Perioperative variables were collected and analyzed. Univariate and multiple logistic regression models were used for determining the association between the development of AKI and risk factors.

Results: Of 2575 patients, 931 (36%) developed AKI. A total of 30 (1.2%) patients required renal replacement therapy. The overall in-hospital mortality rate was 1.5% (38 of 2575). CSA-AKI was significantly associated with in-hospital mortality (adjusted HR: 2.22, 95% CI 1.16-4.24, P = 0.016), especially in patients needing RRT (adjusted HR: 18.68, 95% CI 8.58-40.68, P < 0.001). The independent risk factors identified by multivariable analysis were shown in Table I.

Conclusions: This study demonstrates that mechanical ventilation duration, erythrocytosis transfusion and postoperative body temperature above 38°C within 3 days were considered independent risk factors for CSA-AKI. Use of urokinase was associated with an increase in Scr by >0.3 mg/dl or >50% over a 72-hour interval, staged per KDIGO.

Results: AKI occurred during 18% (2,244) of 12,237 admissions. Of AKI cases, 82% (1,828) were stage 1, 12% (273) stage 2, and 6% (145) stage 3. Patients were 69% white, 51% female, aged 61±16, and 9% with CKD. Ten CCS groups with the largest number of AKI cases were presented.

Conclusions: This study demonstrates the incidence of AKI after invasive surgical principal procedures, and this data will help prioritize research to prevent in-hospital AKI. Non-kidney transplant, heart valve, and CABG surgical procedures were associated with the largest number of AKI cases at this single center, and non-kidney organ transplants were associated with a high severity of AKI.

FR-PO470

Acute Kidney Injury Post-Major Orthopaedic Surgery: A Single Centre Experience

Tracey Ying, Samantha Chan, Stephen E. Laine, Christine A. Somerville, Dept of Renal Medicine, Univ Hospital Geelong, Geelong, Victoria, Australia; Barwon Health Biostatistics Unit, Univ Hospital Geelong, Geelong, Victoria, Australia; School of Medicine, Deakin Univ, Geelong, Victoria, Australia.

Background: Diuretics, NSAIDs and ACEi or ARB use are risk factors for AKI. We studied all nonvascular abdominal operations performed on adults 2007-2014 at Landspitali, the major hospital in Iceland. AKI was diagnosed according to the creatinine based KDIGO criteria. Risk factors for AKI were evaluated using logit regression analysis. Survival was compared between AKI and non-AKI patients using Kaplan-Meier method after propensity score matching (1:1, nearest neighbor matching).

Results: A total of 10,022 patients underwent 11,552 operations during the study period, 38.8% were acute operations. Median age at operation was 52 yrs (IQR 32-66) and 59.5% of patients were female. AKI occurred after 246 operations (2.1%), with 157 (1.4%), 50 (0.5%) and 32 (0.3%) of stage 1, 2 and 3, respectively. Incidence of AKI was higher after major (5.3%), open (4.9%) and acute operations (5.0%) compared to minor (1.1%), laparoscopic (0.5%) and non-acute operations (1.8%). In multivariable analysis, postoperative AKI associated with age (OR 1.03 (95%CI:1.01-1.04)), male sex 1.5 (1.1-2.0), open operation 3.0 (2.4-2.2), re-operation 4.8 (3.7-8.6), hypertension 1.7 (1.2-2.4), cGFR <60ml/min/1.73 m² 2.0 (1.4-2.7) and ASA score 6.1 (4.2-8.8). Survival was worse for AKI patients compared to the propensity score matched controls, both at 30 days (82.4% vs. 94.7%, p=0.03) and at 1-year (69.9% vs. 82.6%, p=0.03).

Conclusions: The incidence of AKI is related to patients’ preoperative AKI after gastrointestinal surgery compared to cardiac and vascular surgery. The rate of AKI is substantially higher after major and open procedures and in patients with preexisting kidney disease. AKI is associated with increased short- and long-term mortality.

FR-PO473

Risk Factors Associated with Post-Operative AKI After General Surgery

Pradeep Arora, 1 Leili Pourafkari, 1 James W. Lohr, 1 Hasan H. Dolsouglu, 1 Nader Naderi, 1 Dip of Nephrology, VAMC, Buffalo, NY; 2Anesthesiology, VAMC, Buffalo, NY; 3Surgery, VAMC, Buffalo, NY.

Background: AKI after cardiac and vascular surgery has been extensively studied. However, there is no study which has evaluated the factors associated with development of stage 1 AKI by AKIN criteria in general surgery patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

465A
Methods: We conducted a cohort study using a prospective database of patients undergoing non-cardiac and non-vascular surgery procedures since 2000 in the VA Western New York Healthcare System which are in part reported to the National Surgical Quality Improvement Program (NSQIP). Demographic, social history, co-morbid diseases, including coronary artery disease (CAD), congestive heart failure (CHF), chronic obstructive lung disease (COPD), peripheral vascular disease (PVD), cerebrovascular accidents (CVA), hypertension, and diabetes, were prospectively entered into the Veterans Affairs Surgical Quality Improvement Program (VASQIP) database at the time of surgery. Preoperative laboratory data were also entered for each participant. Univariate and multivariate logistic regression were performed to estimate the odds of AKI after surgery.

Results: A total of 13300 patients who underwent non-cardiac and non-vascular surgery whose data was available to define AKI between 2000-2014 were included in this analysis. A total of 1621 patients developed AKI stage 1. In univariate analysis, increasing age, male gender, ASA class, poor functional status, presence of COPD, peripheral vascular disease (PVD), cerebrovascular accidents (CVA), hypertension, and diabetes, were prospectively entered into the Veterans Affairs Surgical Quality Improvement Program (VASQIP) database at the time of surgery. Preoperative laboratory data were also entered for each participant. Univariate and multivariate logistic regression were performed to estimate the odds of AKI after surgery.

Conclusions: AKI is associated with increased length of hospital stay and mortality. Efforts to recognize and intervene in preoperative modifiable factors to prevent AKI will improve outcomes in general surgical patients.

FR-PO474
The Comparison of the Incidence of Acute Kidney Injury Post Coronary Artery Bypass Graft versus Percutaneous Coronary Intervention: National Inpatient Sample Experience

Wein Shen, Fernando Rodrigo Aguilar, Alex Montero.
Division of Nephrology & Hypertension, Georgetown Univ, Washington, DC.

Background: AKI, a common complication after coronary revascularization, is associated with increased risk of short-term and long-term mortality, and renal loss. Although survival benefit of CABG over PCI was shown in patients with diabetes and congestive heart failure, the incidence of AKI post coronary revascularization needs to be considered when comparing the risks and benefits of CABG vs PCI.

Methods: We extracted total 485742 cases from National Inpatient Sample (NIS) to create a propensity-score matched cohort of patients who had multivessel coronary disease and underwent first-time CABG or PCI between 2004-2012. Patients received concomitant valve repair or both CABG and PCI on same admission, history of organ transplant, CKD stage IV or ESRD on dialysis were excluded. Both groups were matched for age, gender, race, payer, prior MI, unstable angina, heart failure, CVA, stroke or TIA, peripheral arterial disease, mitral or aortic valve disease, atrial fibrillation/ fibrillation, ventricular fibrillation or tachycardia, CKA, diabetes, HTN, dyslipidemia, smoking, cirrhosis, obesity, anemia and in-hospital GI bleedng. The odds ratios were estimated by logistic regression analysis.

Results: The incidence of AKI in CABG group was higher than PCI group (8.41% vs 4.00%, OR 2.20, 95% CI 2.15-2.25, P< 0.001). The incidences of severe AKI requiring RRT were similar in both groups (0.95% vs 0.91%, P=0.147). Compared with PCI group, CABG group had higher total in-hospital mortality (1.99% vs 1.48%, OR 1.34, 95% CI 1.24-1.40, P<0.0001).The in-hospital mortality in patients with AKI was higher in CABG (0.92% vs 0.59%, P<0.0001).

Conclusions: Patients received CABG were at higher risk of developing AKI and associated with higher total in-hospital mortality. The in-hospital mortality in patients with AKI was higher in CABG.

FR-PO475
Dialysis-Required Acute Kidney Injury Among Hospitalized Adults with Documented Hepatitis C Virus Infection: A Nationwide Inpatient Sample Analysis

Mount Sinai Medicine; Vanderbilt Univ; Kokilaben Dhirubhai Ambani Hospital; Yale Univ.

Background: Chronic Hepatitis C virus (HCV) infection causes kidney injury; data on acute kidney injury (AKI) epidemiology in HCV are limited. We aimed to describe national trends of incidence & impact of AKI-D in DC hospitalizations.

Methods: We extracted our study cohort from the Nationwide Inpatient Sample (NIS) from 2006-2012. We identified hospitalizations with DC & AKI-D by validated ICD9 codes. We analyzed temporal changes in proportion of DC hospitalizations complicated by AKI-D & utilized multivariable logistic regression models to estimate AKI-D impact on in-hospital mortality.

Results: We identified a total of 36,55,700 adult DC hospitalizations from 2006-2012 of which 78,015 (2.1%) had AKI-D. Proportion with AKI-D increased from 1.5% in 2006 to 2.23% in 2012; this was stable between 2009-12 despite increase in absolute number from 6773 to 13930.

Conclusions: AKI-D based on previously validated ICD-9-CM codes. We analyzed temporal changes in proportion of hospitalizations complicated by AKI-D and utilized survey multivariable logistic regression models to estimate its impact on in-hospital mortality.

FR-PO476
The Burden of Dialysis Requiring Acute Kidney Injury in Decompensated Cirrhosis: A Nationwide Inpatient Sample Analysis

Mount Sinai Medicine; Vanderbilt Univ; Kokilaben Dhirubhai Ambani Hospital and Medical Research Inst.

Background: Cirrhosis affects nearly 5.5 million patients with an estimated cost of 4 billion. Previous studies about dialysis requiring acute kidney injury (AKI-D) in decompensated cirrhosis (DC) are from a single center or year. We aimed to describe national trends of incidence & impact of AKI-D in DC hospitalizations.

Methods: We extracted our cohort from Nationwide Inpatient Sample (NIS) from 2006-2012. We identified hospitalizations with DC & AKI-D by validated ICD9 codes. We analyzed temporal changes in proportion of DC hospitalizations complicated by AKI-D & utilized multivariable logistic regression models to estimate AKI-D impact on in-hospital mortality.

Results: We identified a total of 36,55,700 adult DC hospitalizations from 2006-2012 of which 78,015 (2.1%) had AKI-D. Proportion with AKI-D increased from 1.5% in 2006 to 2.23% in 2012; this was stable between 2009-12 despite increase in absolute number from 6773 to 13930.

Conclusions: The proportion of HCV hospitalizations complicated by AKI-D increased significantly between 2004-2012. Similar to observations in the general population, AKI-D was associated with two-fold increase in odds of in-hospital mortality. These results highlight the burden of severe AKI in hospitalized adults with HCV infection.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
The overall hospital mortality was significantly higher in hospitalizations with AKI-D vs. those without (40.8% vs. 6.96%; p<0.001). After adjusting for demographics, mortality risk, acute/chronic comorbidities & hospital level factors, the adjusted odds ratio for mortality was 2.17 (95% CI 2.06-2.28; p<0.01) with AKI-D, which was stable from 2006-2012.

Conclusions: The proportion of DC hospitalizations with AKI-D increased from 2006-09 & although, this was stable from 2009-12, there was an increase in absolute case number. These results elucidate burden of AKI-D on DC hospitalizations & excess associated mortality as well as highlight the importance of prevention, early diagnosis & testing of novel interventions in this vulnerable population.

FR-PO477

Temporal Trends of Burden of Dialysis Requiring Acute Kidney Injury in Cerebrovascular Accident Hospitalizations

Girish N. Nadkarni, Achint Patel, Abhimanyu Mahajan, Ioannis Konstantinidis, Yuri Ahuja, Rabi Yachouh, Charuhas V. Thakur, Icahn School of Medicine at Mount Sinai; Henry Ford Hospital; Yale Univ; Univ of Cincinnati & Cincinnati VA Medical Center.

Background: The epidemiology of dialysis requiring acute kidney injury (AKI-D) in acute ischemic stroke/AIS and intracerebral hemorrhage (ICH) admissions is poorly understood with previous studies being from a single center and/or year.

Methods: We used the Nationwide Inpatient Sample to evaluate the yearly incidence trends of AKI-D in AIS and ICH admissions from 2002 to 2011. We also evaluated the trend of impact of AKI-D on in-hospital mortality and adverse discharge utilizing adjusted odds ratios (aOR) after adjusting for demographics and comorbidity indices.

Results: We extracted a total of 3927267 AIS and 704648 ICH admissions, AKI-D occurred in 1.5 and 3.5 per 1000 in AIS and ICH admissions respectively. Incidence of admissions complicated by AKI-D doubled from 0.9/1000 to 0.1/1000 in AIS and from 2.1/1000 to 4.3/1000 in ICH admissions.

Conclusions: Incidence of dAKI complicating CVA hospitalizations continues to grow and is associated with increased mortality and adverse discharge. This highlights the need for early diagnosis and better risk stratification in this vulnerable population.

FR-PO478

Long-Term Healthcare Utilization and Mortality After Acute Kidney Injury in Critically Ill Children

Erin Hessey, Genevieve Morissette, Rami Ali, Marc Doraix, Philippe Jouvet, Ana Palijan, Veronique Phan, Michael Pizzi, Michael Zappitelli; McGill U; Montreal; U de Montreal, Montreal; StatScience, NDIP, Canada.

Background: Acute kidney injury (AKI) is common in the pediatric intensive care unit (PICU). The late illness burden of child AKI is unknown. We will evaluate if AKI in the PICU is associated with increased mortality and health care service use 5 years after discharge.

Methods: Retrospective cohort study of children admitted to two Montreal, Canada PICUs, 2003-2005 (N=2500). Exclusions: no health number, deceased in PICU. Clinical chart data was merged with provincial administrative health data. AKI (main exposure): by Kidney Disease Improving Global Outcomes serum creatinine (SCr) definition (if no PICU-SCr drawn, non-AKI was assumed). 5-year outcomes: all-cause mortality; healthcare utilization (HCU), defined as the number of hospitalizations, emergency room (ER) and physician visits per 100 person years. AKI-outcome relation was evaluated with multivariate logistic (mortality) and linear regression (HCU), adjusting for gender, age, cardiac surgery, PRISM (mortality) score, vasopressors and infection.

Results: Of 2407 children (mean:5D age=6.0±5.7yrs; PRISM = 8.2±5.9); 56% male; 448 (18.6%) developed AKI. AKI (yes/no) was associated with mortality in univariate (p<0.05) but not multivariate analysis. Stage 2 AKI or worse was associated with 5-year mortality (adjusted[a]OR=1.9, 95% CI=1.1-3.2). AKI (yes/no) was associated with increased 5-year hospitalizations (adj[p]=0.05) and physician visits (adj[p]=0.001), but not ER visits (adj[p]=0.8). There was a graded increase in 5-year HCU with higher AKI severity.

Conclusions: PICU-AKI is associated with long-term increased mortality risk and HCU. Research should evaluate cost-effective interventions to improve child AKI treatment and evaluate effects on late outcomes.

Funding: Government Support - Non-U.S.

FR-PO479

Acute Kidney Injury: A 12 Month Follow, the Incidence and Mortality

Hsu pheen Chong, Paul R. Cannon, Caroline J. Whyte, Kottarathil Abraham; Nephrology, Aintree Univ Hospital, United Kingdom.

Background: Acute Kidney Injury (AKI) affects nearly 1 in 5 hospital admission. It carries a poor prognosis with mortality ranging from 10-80% dependent on the population studied. Aintree University Hospital caters to about a population of 506,000 in North Liverpool. An observational study was carried out in this catchment area to ascertain the incidence of AKI, the length of stay and its effect on 12 months mortality.

Methods: Patients who were admitted between the time periods of August 2012 until January 2013 were included in this study. Liaising with the biochemistry department, all patients who had a rise in their creatinine based on the Acute Kidney Injury Network criteria received an e-alert sign on the computer system. Clinical outcomes were obtained from each patient record.

Conclusions: PICU-AKI is associated with long-term increased mortality risk and HCU. Research should evaluate cost-effective interventions to improve child AKI treatment and evaluate effects on late outcomes.

Funding: Government Support - Non-U.S.
Results: There were a total of 36,957 patients admitted during that 6 month time period of which a total of 358 cases of AKI were identified. There was total of 183 male patients and 171 female patients. Four of the male patients had a further AKI alert during the same hospital admission. The mean age was 72.18 years. Pre-renal causes were identified as the main contributors to the cases. Majority of the AKI alerts were Stage 1 AKI which was 70%, Stage 2 AKI was 25% and Stage 3 AKI was 5 % of the total cases. The data also revealed that the average length of stay (ALOS) did not differ in each of the stage. A patient ALOS for Stage 1 AKI 23.3 days, Stage 2 AKI 24 days and Stage 1 AKI 21 days. Of the total number of cases with patients with AKI, 50.6% (179/354) of the patients had died within the 12 months period. Looking into the mortality rate of each individual stages of AKI; the mortality rate at 12 months for Stage 1 AKI is 46.5%. For Stage 2 AKI, 62.7% and for Stage 3 AKI, 47.6%.

Conclusions: From the date collected, it shows that the degree of AKI does not affect the length of stay of patients. Despite the different stages of AKI indicating the severity of the injury, mortality rate for Stage 1 and Stage 3 did not differ. This indicates that AKI carries a high mortality rate regardless of the severity of the injury. Early recognition leads to early intervention in the prevention of AKI.

FR-PO480
Acute Kidney Injury: Adding Informatics to Injury – (Electronic Injury Alerts)
Conor Patrick Moran, Ying C. Kuan, Patrick Lm Lynch, Francis Mccarroll. Dept of Nephrology, Altnagelvin Hospital, Londonderry, United Kingdom; Dept of Clinical Chemistry, Altnagelvin Hospital, Londonderry, United Kingdom.

Background: Acute Kidney Injury, (AKI), is common with a variably reported mortality, (15-60%). UK national audit reported that up to 30% of cases were avoidable and that as much as 43-61% of post-admission AKI experienced an unacceptable delay in recognition of insult. There has been a paucity of work with regards to AKI recognition and prevention. National guidelines have recommended the use of electronic alerts (e-alerts) for AKI detection.

Methods: We introduced AKI e-alerts with accompanying electronic guidance in late October 2014 and prospectively collected data on the patients identified with severe AKI. Data collection was carried out for 3 months, (n=110). The demographics of this cohort were compared with a historical cohort of severe AKI (n=89).

Results: Mean age, (72 years vs. 73 years), gender distribution, (M:F: 46% / 54% vs. 45% / 55%), and median time to death, (10 days vs. 9 days), were comparable. Thirty day mortality was similar with regards to hospital acquired AKI (27.3% vs 26.1%). 30 day mortality was significantly lower for community-acquired AKI (10.7%). Mean and median age was demonstrated to be higher in the group of patient who died, (Mean: 80.1 years vs. 75.7 years), (Median: 82 years vs. 82 years) – negative skew due to outliers.

Conclusions: Although our initial data suggests an electronic AKI alert has no discernable effect on 30 day mortality rate and time to death. We feel that e-alerts with the addition of further Quality Improvement work will eventually result in a steady reduction in AKI mortality.

FR-PO481
Tenofovir Nephrotoxicity Is an Important Cause of Acute Kidney Injury in HIV Infected Patients
Teg Marcos Veiga, Adriana Belo Prazeres, Daviane Silva, Gislele Vajgel Fernandes, Geraldo Jose de Amarim, Luis H.B.C. Sette, Lucila Maria Valente. Nephrology, Univ Federal de Pernambuco, Recife, Pernambuco, Brazil.

Background: Tenofovir disoproxil fumarate (TDF) is widely prescribed as a first choice therapy for HIV infection, because of its convenient dosing schedule, efficacy and relatively low side effects. However, renal toxicity may lead to acute kidney injury (AKI), chronic kidney disease (CKD), and proximal tubular injury. Here we describe clinical characteristics and outcomes of AKI associated to TDF.

Methods: In a retrospective cohort (between Mar/2011 to Feb/2015), we have described the data of HIV-infected inpatients, in a single center infectious disease ward, referred to the Nephrology department due to AKI. AKI was defined according to AKIN criteria.

Results: During the study period, 72 patients were evaluated; the baseline characteristics are showed in table1. Nephrotoxic AKI was present in 36 cases, of which 19 cases (52%) were associated with TDF and the drug was withdrawn in all cases. Seven patients had TDF nephrotoxicity without other associated factors and only three patients achieved renal function recovery, but no one needed dialysis or died during follow up.

Conclusions: AKI associated to TDF nephrotoxicity was prevalent in the HIV infected inpatients and showed high morbidity, including almost a third of patients requiring dialysis and more than a half not recovering renal function after withdrawing the drug.

FR-PO482
Cisplatin-Associated Nephrotoxicity: Not as Frequent as Previously Reported
Shiveta S. Motwani, Sushruth S. Waikar, Benjamin D. Humphreys, Gary C. Curhan. Nephrology, Brigham and Women’s Hospital, Boston, MA.

Background: Cisplatin-associated nephrotoxicity (CaN) is a frequent problem amongst patients with various cancers. Most older studies have reported 25-30% of patients who receive cisplatin experience acute kidney injury. However, these data have not been re-evaluated systematically recently despite rapid advances in oncologic care. Therefore, we examined the proportion of patients who develop acute kidney injury after exposure to the first cycle of cisplatin in a large patient database. We also examined the frequency of kidney injury stratified by sex and cisplatin dose regardless of cancer type.

Methods: We collected data on patients ≥ 18 years of age who had received cisplatin as a primary, secondary or adjuvant or neo-adjuvant therapy at a tertiary-care medical center (Massachusetts General Hospital) between 2006 and 2014. Detailed data regarding cisplatin dose, demographic characteristics, concurrent medical history and laboratory data including serum creatinine (Cr) and electrolytes were collected. CaN was defined as an elevation of Cr ≥ 0.3 mg/dl during a 14 day period after administration of cisplatin (peak Cr) compared with baseline (bl Cr). Patients with bl Cr of >1.5 were excluded.

Results: Of the 1979 patients in our study, 55% were male with a mean ± SD of age of 61.6 ± 12.8. A bl Cr was 0.9 ± 0.2. 241 of 1979 (12.2%) patients developed CaN. However, it ranged from 7.8% in the medium dose group (cisplatin dose 75-130 mg) to 18.2% in the high dose group (>130mg) without a clear dose response relation.

Conclusions: CaN associated to TDF nephrotoxicity was prevalent in the HIV infected inpatients and showed high morbidity, including almost a third of patients requiring dialysis and more than a half not recovering renal function after withdrawing the drug.

In addition, a significantly lower frequency of CaN was noted amongst females compared with males (9.3% vs 14.5%, p<0.001).

Conclusions: Cisplatin-associated nephrotoxicity occurs less frequently than previously reported. This may reflect changes in preventive care such as more aggressive hydration with electrolyte-rich solutions.

Characteristics of 681 Patients with Atypical Hemolytic Uremic Syndrome in the Global aHUS Registry - Christoph Licht,1 Gianluigi Ardissono,2 Gemma Ariceta,3 David J. Cohen,4 Christoph Gasteguer,5 Larry A. Greenbaum,6 Sally A. Johnson,7 Masayo Ogawa,8 Fabien Stucker,9 Belen Ponte10; Pierre-Yves F. Martin,11 Thomas Perren12; Sebastian Carrasco,13 Fondazzione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy;1 Hospital Univer Vall d’Hebron, Barcelona, Spain;1 Columbia Univ Medical Center, New York, NY, USA;4 Alexion Pharma International Sarl, Lausanne, Switzerland;5 Emory Univ, Atlanta, GA;6 Great North Children’s Hospital, Newcastle, United Kingdom;7 Alexion Pharmaceuticals, Inc., Cheshire, CT;8 Heidelberg Univ Hospital, Heidelberg, Germany;9 Univ Hospital Ghent, Ghent, Belgium;10 Assistance Publique, Paris, France.

Background: The observational atypical hemolytic uremic syndrome (aHUS) Registry collects patient (pt) information and facilitates availability of follow-up data for eculizumab (ECU).

Methods: Pts with clinical diagnoses of aHUS (irrespective of identified complement abnormality or treatment) are eligible. Demographic, medical/disease history, and treatment outcomes data are collected at enrollment and prospectively.

Results: By Jan 30, 2015, 681 pts enrolled (Table: 62.7% of adults were women. Thrombosis occurred more frequently in adults than pediatric pts. Nonrenal comorbid conditions occurred in both age groups. ECU was administered to 56.2% (87.7% prior to enrollment).

Conclusions: Registry baseline characteristics show differences between pediatric and adult aHUS pts, notably different frequencies of thrombosis. Ongoing and future analyses will further enhance understanding of aHUS history and progression. Medical writing support - Kristen W. Quinn, PhD, of Peloton Advantage, funded by Alexion.

Use of ACEIs and ARBs in Patients with Chronic Kidney Disease and Superimposed Community-Acquired Acute Kidney Injury - Patrick Saudan,1 Cyrielle Alves,2 Fabien Stucker,3 Belen Ponte,4 Pierre-Yves F. Martin,1 Thomas Perren1; Sebastien Carrasco,2 Fondazzione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy; Hospital Univer Vall d’Hebron, Barcelona, Spain;2 Columbia Univ Medical Center, New York, NY, USA;3 Alexion Pharmaceuticals, Inc., Cheshire, CT;4 Heidelberg Univ Hospital, Heidelberg, Germany;5 Univ Hospital Ghent, Ghent, Belgium;6 Assistance Publique, Paris, France.

Background: Due to their long-term nephroprotective effect, ARBs and ACEIs are often used in patients with CKD despite their association with an increased risk of superimposed AKI. We aimed to better define its occurrence in relation to their use.

Methods: We undertook a prospective observational study within the Emergency Department. Screening for any patient > 16 years admitted with an eGFR < 60 ml/mm was included and superimposed AKI was defined as a decline in eGFR compared to previous values according to Kidney Disease Outcomes Quality Initiative (KDOQI) criteria.

Results: From May 1st to June 21st 2013, there were 8464 admissions of whom 361 (4%) had a eGFR < 60 ml/mm and were known to have CKD. Use of ACEIs, ARBs, diuretics, NSAIDs was respectively found in 19, 23, 37 and 4% of patients. AKI was superimposed in 102 (28%) cases. Eculizumab was used in 81 (20%) cases. The hospital mortality rate of dialysis requiring patients with superimposed AKI was 100%.

Conclusions: Mild community-acquired superimposed AKI in CKD patients does not seem to have a one year mortality and thus may not be considered a risk factor for death. Other confounding factors such as high serum creatinine, high blood pressure and diabetes are often used in patients with CKD despite their association with an increased risk of superimposed AKI.

FR-PO486

Renal and Patient Outcomes of Dialysis Dependent Patients with ATN Who Survive Hospitalization - Mohammad Alhaji, Rabeel I. Elfefldy, Jere Yee, Bronwyn Larissa Small, Javier Rodriguez Sanchez, Jian Li, Lenar T. Yessenay, Nephrology and Hypertension, Henry Ford Hospital, Detroit, MI.

Background: Acute tubular necrosis (ATN) accounts for the majority cases of acute kidney injury (AKI) in critical care units. The in-hospital mortality rate of dialysis requiring ATN in critically ill patients exceeds 50%. However, renal and patient outcomes among dialysis dependent patients with ATN who survive the hospitalization are lacking.

Objective: To determine 90 day renal recovery and mortality rates, 1 year cardiovascular and hospital readmission rates of patients with ATN discharged on hemodialysis.

Methods: We prospectively enrolled 38 Medicare beneficiaries who developed hemodynamically-dependent ATN and survived to discharge at a single center from January 1, 2013 to June 30, 2014. The ATN was identified by urine microscopy and clinical judgment. ATN causes, patients’ comorbid conditions, potential contributors to ATN and indications for RRT were recorded. Cumulative hazard estimates of events and survival curves were generated using the Kaplan-Meier method.

Results: Twenty six patients (88%) had CKD, 18 had diabetes (47%), 29 had hypertension (76%), 10 had history of liver disease (26%). The 90 day renal recovery and mortality rates were 42% and 11% respectively. Of those who recovered kidney function, only 1 patient recovered kidney function beyond 60 days. The 1 year cardiovascular events and readmission rates were 22% and 62% respectively.

Conclusions: Patient with dialysis dependent ATN following a hospitalization are unlikely to get off dialysis support beyond 60 days after discharge. In the first year post discharge, they experience a significant number of cardiovascular events and hospital readmissions. Identifying modifiable risk factors for readmission in this cohort may reduce health care costs.

FR-PO484

Long-Term Renal Function After Recovery from Dialysis-Requiring Acute Kidney Injury - Sokratis Stoupos,1 Colin C. Geddes. Renal and Transplant Unit, NHS Greater Glasgow and Clyde, Glasgow, United Kingdom.

Background: Current guidelines suggest that people should be monitored for the development of chronic kidney disease (CKD) for at least 2-3 years after acute kidney injury (AKI), even if serum creatinine has returned to baseline. The aim of this study was to assess the long-term renal outcome of patients experiencing AKI secondary to hyperperfusion injury and/or sepsis who recovered to apparently normal renal function.

Methods: We conducted a population-based cohort study of all adult patients in our catchment area (serving a population of approximately 1.5 million), with AKI who required in-hospital dialysis in the nephrology unit, survived for at least 12 months after discharge and had estimated glomerular filtration rates (eGFR) greater than 60 ml/min/1.73 m2 1 year after the episode of AKI between September 1, 1989, and March 5, 2015. Patients with underlying nephropathy and AKI due to causes other than hyperperfusion injury and/or sepsis were excluded. Follow up was censored to the last date the serum creatinine recorded.

Long-Term Follow-Up Of Children with STEC-HUS Caused by E. coli O104:H4 (German HUS Outbreak 2011): A GPN Registry Markus J. Kemper, 1 Wiebke Aulbert, 1 Thurland Ahlenstiel-Grunow, 2 Brigitta Kranz, 3 Jun Oh, 1 Pediatric Nephrology, Univer Medical Center Hamburg- Eppendorf, Hamburg, Germany; 1Pediatric Nephrology, Medizinische Hochschule, Hannover, Germany; 1Pediatric Nephrology, Univ Hospital, Münster, Germany.

Background: In 2011 E. coli O104:H4 caused the largest outbreak of HUS in adults and children. A total of 90 children were affected, of whom 64 (71%) required dialysis for a median of 11 days.

Methods: Currently follow-up data are available from 60 of 90 children (67%), 31 girls) from 11 pediatric centers in Germany. Median follow-up is 2.7 range (1.2-3.8) years, median current age of patients is 14.7 (3.4-18.7) years.

Results: Median current serum-creatinine is 0.7 (0.3-8.9) mg/dl. In two patients (2.2%) with CKD stage 3 and 4 at discharge GFR improved and they are now in CKD stage 2. One patient remained dialysis dependent initially and one reached ESRD after 3.5 years; both underwent successful living-related kidney transplantation. All 4 patients were treated with eculizumab in the initial phase of STEC-HUS including 2 who also received plasmapheresis. Proteinuria is currently present in 17 (19%) patients and 9 (10%) require treatment for hypertension. Three patients have neurologic symptoms (headache, performance deficit, spastic movement disorder) and 3 patients have EEG abnormalities without symptoms.

Conclusions: Long-term follow-up is important after O104:H4 associated STEC-HUS. CKD stage 3-5 at discharge is a risk factor for ESRD, however some children show a significant improvement over time. Patients with proteinuria and hypertension need long-term follow-up. Follow-up studies after STEC HUS should include neurological investigations.

SOFAscores as Predictors of Mortality and Dialysis Dependency in Acute Kidney Injury V. Shane Pankratz, 1 Christos Argyropoulos, 1 Khaleed Abdel-Kader, 2 Kelly V. Liang, 3 Paul M. Palevsky, 3 Mark L. Unruh. 1 Dept of Internal Medicine, Div of Nephrology, Univ of New Mexico School of Medicine, Albuquerque, NM; 2 Dept of Medicine, Div of Nephrology and Hypertension, Vanderbilt Univ School of Medicine, Nashville, TN; 3 Dept of Medicine, Renal- Electrolyte Div, Univ of Pittsburgh School of Medicine, Pittsburgh, PA.

Background: The Sequential Organ Failure Assessment (SOFA) score measures the severity of organ failure, and baseline SOFA scores have been used to predict mortality in patients with Acute Kidney Injury (AKI). We evaluated whether SOFA scores, either upon initiation of dialysis or clinically updated, predict mortality and dialysis dependency following AKI.

Methods: Data from patients enrolled in the Acute Renal Failure Trial Network (ATN) study, a randomized multicenter trial of the intensity of renal support in AKI, were used in Cox proportional hazards regression and multinomial logistic models to assess the degree to which SOFA scores predict mortality and dialysis dependency.

Oddsratio (95% Confidence Interval)

<table>
<thead>
<tr>

<td>0.910 (0.87-0.96)</td>
<td>0.870 (0.79-0.95)</td>
</tr>
</tbody>
</table>

Results: SOFA scores were associated with increased mortality risk following AKI among the 1,124 ATN participants, but the concordance statistic was low, at 0.651 (standard error [se]=0.014). When time-dependent analyses were used to take advantage of prospectively updated SOFA scores, the concordance statistic increased to 0.753 (se=0.013). Initial pump speed of ECMO was significantly associated with total AKI (p=0.035) and stage 3 AKI (p=0.044) with ORs (95% CI) of 2.219 (1.059-4.462) and 1.676 (1.015-2.770), respectively. Also, we found that red cell distribution width (RDW), serum level of total bilirubin, and the duration of ECMO were significantly related to AKI and/or stage 3 AKI.

Conclusions: Initial pump speed was significant risk factor in in-hospital mortality and AKI in patients receiving ECMO. RDW, serum level of total bilirubin and the duration of ECMO were risk factors of AKI.

Comparison of Clinical Characteristics of Patients with Acute Kidney Injury After Intrafusal Versus Inhaled Colistin Therapy Hyun-Joo Yoon, In O Sun, Kwang Young Lee, A Young Cho. Div of Nephrology, Dept of Internal Medicine, Presbyterian Medical Center, Jeonju, Jeonbuk, Republic of Korea.

Background: The aim of this study is to investigate the incidence and clinical characteristics of intravenous or inhaled colistin associated acute kidney injury (AKI) using modified RIFLE criteria.

Methods: From 2010 to 2014, 160 patients were treated with intravenous or inhaled colistin. Of these, we included 139 patients who received colistin for >72 h, and compared the incidence and clinical characteristics of patients in the intravenous (n=120) and inhaled (n=19) groups.

Results: The patients included 116 men and 23 women, with a mean age of 68 years (range, 20-91). Patients were infected with either A. baumannii (54%) or P. aeruginosa 46% (p=0.003). The mortality rate was 43.9%, and AKI occurred in 83 (63%) patients. At the end of therapy, bacteriologic cure rate was 64%. There were no differences in the clinical characteristics between the intravenous and inhaled groups except for age. In comparison with patients in the intravenous group, the patients in the inhaled group were older (74 ± 8 vs 67 ± 14 years, p<0.03). The incidence of AKI was not different between the two groups (62% vs 47%, p=NS), and there was no difference in the severity of AKI according to the RIFLE criteria. Of the 83 patients with AKI, 8 and 1 patients underwent renal replacement therapy.

Conclusions: In our study, the incidence, risk factors and outcome of AKI following CA in a whole nation.

Acute Kidney Injury following Coronary Angiography Dadi Helgaussen, 1 Per E. Long, 2 Gish H. Sigurðsson, 1 Martin I. Sigurðsson, 1 Olafur S. Indridsson, 1 Dept of Medicine; 2Dept of Anesthesia, Landspítali; 3Dept of Anesthesia, Brigham and Women’s Hospital, Boston, MA; 4Div of Nephrology, Landspítali - The National Univ Hospital of Iceland, Reykjavik, Iceland.

Background: Acute kidney injury (AKI) is a known complication of coronary angiography (CA). The aim was to study the incidence, risk factors and outcome of AKI following CA in a whole nation.

Methods: This was a retrospective analysis of data from all CA in Iceland during a 9 year period. AKI was diagnosed according to the creatinine based KDIGO criteria and survival status for all patients was verified at Statistisk Ísland. The epidemiology and clinical outcomes were compared between three 3-year periods using Chi-squared analysis. Multivariate logistic regression was performed to identify independent predictors of AKI.

Results: From Jan 1st 2005 to Dec 31st 2013 10713 patients underwent 13890 CA of whom 40% enrolled an intervention. Median (range) age was 65 (19-96) years and 70.7% were men. AKI was diagnosed in 214 patients (1.5%, 168 (12.2%), 270 (2%) and 19 (0.1%) of stage 1, 2, and 3, respectively. There was a trend towards a decreasing incidence of AKI: 1.8% in the first study period, 1.3% in the second and 1.4% in the last (p=0.05). AKI was more common in the intervention group, 2.2% vs. 1.1% (p<0.001). Patients with AKI were often prior history of AKI, more common in the intervention eGFR compared to non-AKI patients. In multivariate analyses age over 70 years (OR=1.01, 95% CI=1.007-1.016), angiography with intervention (OR=1.01, 95% CI=1.008-1.016) COPD (OR=1.01, 95% CI=1.003-1.025), liver disease (OR=1.03, 95% CI=1.014-1.058) baseline eGFR <60 (OR=1.03, 95% CI=1.027-1.039) and a prior history of AKI (OR=1.01, 95% CI=1.051-1.080) were independent predictors of AKI after CA. One year survival of AKI patients did not differ between time periods: 67.0%, 63.1% and 69.0% in the first, second and third, respectively, p=0.3.

Conclusions: There is a trend towards a decrease in AKI incidence following CA in recent years. Aged patients with multiple co-morbidities and prior history of AKI need special attention in connection with this this procedure.

Acute Kidney Injury in the First Hundred Days After Hematopoietic Stem Cell Transplantation: Experience with 222 Transplanted Patients in a Single Center

Miguel A. Solis, Sandra Tejedor, Isidro Torregrosa, Carmen Ramos, Isabel Juan, Patricia Tomas, Patricia Zambrano Esteves, Juan José Guzmán Herrera, Maria Jesus Puchades, Alfonso M. Carrasco. Nephrology, Univ Clinic Hospital, Valencia, Spain.

Background: Hematopoietic stem cell transplantation recipients are at an increased risk of Acute Kidney Injury (AKI) or Chronic Kidney Disease (CKD). An earlier diagnosis could dramatically improve the patients' prognosis. Objective: To analyze the incidence of AKI in the first 100 days of Hematopoietic stem cell transplantation recipients and the relationship with mortality.

Methods: We carried out a retrospective study including 222 adult patients who underwent Hematopoietic stem cell transplantation between 2006 and 2010 at our institution. AKI was defined using the RIFLE criteria in the first 100 days after transplantation.

Results: 222 patients were included in the study, 137 males and 85 females. Median follow-up was 30 months, range 1-60 months. In the first 100 days after transplantation AKI developed in 78 patients according to the RIFLE criteria (35.1%). A total of 85 patients died during follow-up vs 47 who had developed AKI (38.2% versus 61%, p=0.05). Detailed patients' characteristics are summarized in table 1.

Conclusions: AKI incidence in hematopoietic stem cell transplantation recipients is very high. There is a statistically significant relationship between AKI and death in these patients. Earlier AKI identification could prevent kidney damage progression and improve patient outcome over time.

FR-PO493

STOP-Acute Kidney Injury (AKI): A Streamline Approach to the Management AKI Leads to Reduction of Mortality Rates

Hsueh Chong Thangavelu Chandrasekar. Nephrology, Aintree Univ Hospital, United Kingdom.

Background: Acute Kidney Injury (AKI) has a mortality rate of 30%, greater than myocardial infarction (8%) and stroke (9%). It is estimated that 15% of all inpatients at University Hospital Aintree (UHA), Liverpool, UK, suffer an AKI making it a condition of considerable importance in everyday practice. Through clinical audit, it was found that mortality rate of AKI in UHA was 33% on wards other than renal ward (9%).

Methods: To reduce AKI mortality by 30% and length of stay by 20% over a 12 month period from Oct 2013 using standardised, evidence based approach. Using plan, do, study act (PDSA) methodology, we developed and tested an automated e-alert diagnostics system, an AKI treatment bundle and a patient information leaflet. The STOP-AKI project was launched. Our Primary drivers were early and accurate identification of AKI, effective intervention and monitoring, staff and patient engagement. Initially, trialled at ward level, the project was scaled up to admission areas (Accident and Emergency Department and the Medical Assessment Unit) becoming part of routine management for all admitted patients.

Results: Fall in mortality rates from a baseline of 24% to 18.5%, representing an overall reduction in mortality of 23%. Length of stay fell by 11% equating in a 2.0 day reduction in length of stay.

Conclusions: The STOP-AKI project led to the development of an AKI bundle in Oct 2013. This has achieved not only a significant reduction in patient mortality and length of stay but in addition a more structured and stream lined way of approaching the patients with AKI in our hospital. With the bundle being rolled out to primary care and the rest of our inpatient wards, we anticipate a further reduction in mortality.

FR-PO494

Race and Risk of Acute Kidney Injury (AKI) in VA Patients

Michael Heungs, Diane Steffick, Deidra C. Crews, Neil R. Powe, Sharon Saydah, Meda E. Pavkov, Kara Zivin, Rajiv Saran. 1Univ of Michigan; 2Johns Hopkins Univ; 3Univ of California San Francisco; 4Centers for Disease Control and Prevention; 5VA Ann Arbor Health System.

Background: African Americans (AA) are at increased risk for AKI compared to Caucasians (C); potential explanations include differences in risk factors, genetic susceptibility and socioeconomic factors. We explored the influence of race on AKI risk in the Veterans Administration (VA), an integrated healthcare system.

Methods: Retrospective cohort analysis of all hospitalizations for VA patients with known AA or C race in 2011. AKI was defined by KDIGO criteria (≥0.3mg/dl increase in serum creatinine from pre-admission baseline). Modified Poisson regression models estimated the effect of AA race on risk of AKI, adjusting for age, sex, baseline eGFR, comorbidities (DM, HTN, coronary heart disease,CHD, CHF), geographic region and severity of illness during hospitalization. Additional models including albuminuria were run for those with available data.

Results: We identified 180,429 VA hospitalizations. Compared to C, AA had higher prevalence of DM (43.1% v. 41.1%, P<.001), lower prevalence of CHD (45.7% v. 58.8%, P<.001), lower Charlson comorbidity scores (1.4 v. 1.6, P<.001) and higher baseline eGFR (89.2 v. 81.7, P<.001). AKI occurred in 19.5% of admissions (35,134) involving 23.2% of AA and 18.5% of C. In adjusted models, AA race remained an independent risk factor for AKI (RR 1.19, 95% CI 1.15-1.23) was found. A similar increased risk of AA race on risk of AKI was slightly attenuated (RR 1.20, 95% CI 1.16-1.24). A similar increased risk of hospital-acquired AKI in AA compared to C (RR 1.19, 95% CI 1.15-1.23) was found.

Conclusions: Although AA Veterans had higher baseline eGFR and lower comorbidity scores compared to C, AA had an increased risk of developing AKI, even after accounting for differences in risk factors & geographic region. This increased risk for AKI in AA persisted when examining AKI that developed during hospitalization. Given that VA patients have similar healthcare access and benefits, our results suggest that the increased AKI risk seen in AA is unlikely to be fully accounted for by disparities in access to care.

Mortality Risk Factors in Mexican Patients with Acute Kidney Injury

Juan Alberto Evangelista-Carrillo,1 Enrique Rojas-Campos,2 Salvador Mendoza Cabrera,1 Benjamin Gomez-Navaoro,1 1Nefrologia y Trasplantes, IMSS, Guadalajara, Jalisco, Mexico; 2Unidad Médica de Investigación en Enfermedades Renales, IMSS, Guadalajara, Jalisco, Mexico.

Background: Acute kidney injury (AKI) data in Latin American is scarce.

Methods: Aim: To determine patient survival, mortality risk factors and treatment in AKI patients from a tertiary hospital. Method: Prospective cohort Die 2010-2012 of 275 patients with AKI who need Nephrology consultation. Recollected data at admission,
Nephrologists consultation and 30 days follow up included demographics and biochemical variables, time between AKI onset and Nephrology consultation, fluid balance, mortality scale, treatment and date of death or patient discharge.

**Results:** The overall mortality was 49%. Mean age 58 years. The principal diagnosis at admission was coronary syndrome. The AKI at the moment of consultation was 3 in 64%.

### Mortality predicted analysis.

**Conclusions:** This is the first report of epidemiology of AKI in Mexico. The conservative treatment is associated with mortality. The consultation with nephrology was late. Use of diuretic, vasopressor and urea less than 1 liter per day at the nephrology consultation time were associated with mortality.

### Conclusions:

Our data suggests that AKI due to ATN at the time of myeloma diagnosis is more likely to recover compared to MCN with a faster time to recovery. However this does not seem to affect overall survival.

### FR-PO497

**Hospital Manifesting AKI Presents Worst Outcome Than Community Acquired AKI**

Xose Luis P. Perez-Fernandez, Florentina E. Sileanu, Joan Sabater Riera, Kathleen C. Liu, John A. Kellum, Servei de Medicina Intensiva, Hospital Univ de Bellvitge, L'Hospital de Llobregat, Barcelona, Spain; Critical Care, Univ Pittsburgh Medical Center, Pittsburgh, PA; Nephrology & Critical Care, Univ California San Francisco Parnassus MC, San Francisco, CA.

**Background:** The objective of this study was to evaluate outcomes in critically ill patients with severe community-acquired AKI (CA-AKI) and hospital-manifesting AKI (HM-AKI). Secondary objectives were to identify characteristics that differ between patients with CA-AKI and HM-AKI to design future preventive strategies.

**Methods:** Observational retrospective study conducted at two tertiary care hospitals between 2000-2008 (UPMC, Pittsburgh, USA) and 2006-2012 (HUB Barcelona, Spain). Those with CA-AKI met criteria for KDIGO Stage 3 AKI at hospital admission whereas those with HM-AKI did not have AKI at hospital admission. HM-AKI subjects met KDIGO Stage 3 AKI criteria within 24 hours of ICU admission, with at least 72 hours elapsing between hospital admission and ICU admission. The relationship of type of AKI (CA-AKI, HM-AKI) with 90-day survival was analysed using Cox regression models controlling for differences between survivors and non-survivors.

**Results:** 353 patients met inclusion criteria. 92.5% of these patients required RRT at some point during ICU admission. 189 (35.4%) patients had AKI manifest while in-hospital and these patients had a significantly higher 90-day mortality compared to 345 (64.6%) patients presenting with CA-AKI (68.3% vs 58.6%, p = 0.03). Age, SOFA score, time from hospital admission to ICU, HM-AKI (compared to CA-AKI), and medical (vs surgical) admission, were all associated with lower 90 day survival. In the multivariate analysis, HM-AKI remained an independent risk factor for death compared to CA-AKI (HR 1.5; 95%CI (1.1 – 2)).

**Conclusions:** AKI manifesting after hospital admission has significantly worse outcomes compared to AKI present at hospital admission even among patients progressing to stage 3 by ICU admission. Future interventions should be directed to prevent AKI in patients admitted to hospital, especially those who present with the risk factors identified in this study.

**Funding:** Government Support - Non-U.S.

**Assessing Patient Awareness in Moderate to Severe Acute Kidney Injury**

Sharidan Parr, Marcus G. Wild, Swee-Ling Levea, Talat Alp Ikizler, Edward D. Siew, Kerri L. Cavanaugh, Vanderbilt Center for Kidney Disease, Vanderbilt Univ Medical Center, Nashville, TN.

**Background:** We aimed to evaluate awareness and knowledge of kidney disease in patients experiencing moderate to severe AKI, which is important for implementing targeted patient self-care risk-reduction strategies.

**Methods:** We surveyed 150 hospitalized patients admitted to hospital, especially those who present with the risk factors identified in this study.

**Funding:** Government Support - Non-U.S.
Results: Median participant age was 54 years; 53% were male; 81% were white; 90% had high school education or higher; 30% had health literacy scores ≤6; baseline serum creatinine (Scr) was 0.9 mg/dL; peak Scr was 2.9 mg/dL; 50% had Stage 2 AKI and 50% had Stage 3 AKI. In total, 80% of patients were unaware that they experienced AKI, including 7 patients requiring dialysis. Predictors of awareness included female gender (71% vs 41%), peak serum creatinine (4.5 vs 2.7), Stage III AKI (82% vs 42%); nephropathy consultation (68% vs 31%), dialysis (29% vs 6%), duration of injury (6 vs 3 days), discharge Scr (2.2mg/dL vs 1.5mg/dL), and reporting a discussion of AKI with a provider during the hospitalization (43% vs 21%) (p values <0.05 for all comparisons).

We found poor patient recognition of preventable causes of AKI and most patients desired more information [Figure 1].

Conclusions: Most patients with moderate to severe AKI were unaware of their condition, lack understanding of risk factors for future AKI, and desire more information about AKI. Optimizing AKI awareness and understanding to promote patient-centered communication, and care will require targeted educational strategies during and after hospitalization.

FR-PO501
Early and Late Auto Kidney Injury in Severely Burned Patients
Stanislav Niemczyck,1 Wojciech Witkowski,2 Wojciech Klimm,3 Agnieszka Surowiecka-Pastewka,2 Marek Kawecki,4 Karzatyna Szmatolucks,4 1Dept of Internal Medicine, Nephrology and Dialysotherapy, Military Inst of Medicine, Warsaw, Poland; 2Dept of Burns, Plastic and Reconstrucive Surgery, Military Inst of Medicine, Warsaw, Poland; 3Dept of Treatment of Burns,Centre for the Treatment of Burns, Słomczanowice Slaskie; 4Dept of Epidemiology and Biostatistics, Inst of Mother and Child, Warsaw, Poland; 5Dept of Emergency Medicine, Faculty of Health Sciences, Academy of Technology and Humanities, Bielsko-Biala, Poland.

Background: Evaluation of factors influencing early and late acute kidney injury (AKI) in severely burned patients and assessment of the relationship between time of occurrence of AKI and mortality.

Methods: Retrospective analysis of severely burned patients with >30% total body surface area (TBSA), admitted to two centers for the treatment of burns. We selected and analysed 239 severely burned patients. Renal function was evaluated at three points: admission, critical or middle point of hospitalization and the endpoint death or discharge from the center. AKI criteria: decrease in glomerular filtration rate (GFR)=60 ml/min at admission, decrease in GFR=75% compared to baseline, decrease in the daily diuresis<500 ml.

Results: At admission 15.1% of the patients had GFR <60 ml/min. AKI occurred in 38.5%. The occurrence of AKI was associated with: elderly age (p<0.001), female gender (p=0.017), overweight and obesity (p=0.055), dehydration at burns, respiratory failure, low protein concentration (for all p<0.001), low blood pressure (p=0.014) and high white blood cells count (WBC) (p=0.010). Early AKI was detected in 28% Mortality was 100% with the initial GFR=60 ml/min, 100% with the initial GFR <60 ml/min and early deterioration of renal function, 90% with the initial GFR=60 ml/min, 60% with the initial GFR <60 ml/min and no worsening. Late AKI was observed in 10% of patients and mortality was 79.2%. Mortality in the group with AKI was 88.0% versus 24.5% without AKI.

Conclusions: The frequent occurrence of AKI, especially early, worsens the prognosis for survival. The assessment of renal function should be included in the prognostic scales for burned patients.

FR-PO502
Acute Kidney Injury and Risk of Incident Heart Failure Among U.S. Veterans
Nisha Bansal,1 Michael Edwin Matheny,2 Svetlana Eden,2 Robert Greecy,2 Sharidan Parr,1 James Fly,2 Khaled Abdel-Kader,3 Jonathan Himmelfarb,1 Ian H. De Boer,1 Tatul Alp Ikizler,2 Edward D. Siew.2 1Division of Nephrology, University of California, San Francisco, San Francisco, CA, USA; 2Division of Research, Kaiser Permanente National Evidence Synthesis Center on Health Care, Oakland, CA, USA; 3Division of Biostatistics, Institute of Health Informatics, University of California, Los Angeles, CA, USA.

Background: Acute kidney injury (AKI) is common and associated with poor long-term outcomes. Heart failure (HF) is a leading cause of cardiovascular disease among patients with chronic kidney disease (CKD). The relationship between AKI and HF remains unknown and may identify a novel end-organ damage to link between kidney and cardiovascular disease.

Methods: We studied a national retrospective cohort of 111,488 U.S. Veterans hospitalized between 2003-2012 without history of HF. AKI was defined as a 0.3 mg/dL or 50% increase in serum creatinine using the difference between peak hospitalization and baseline creatinine (as determined by most recent outpatient creatinine over previous 12 months) and staged according to Kidney Disease Improving Global Outcomes (KDIGO) criteria using change in serum creatinine. Incident HF was defined as ≥1 hospitalization or ≥2 visits with a diagnosis of HF, as determined from validated ICD9 codes, through 2012. Propensity scores for 37 relevant covariates were generated and patients with and without AKI were matched 1:1. Cox proportional hazards were used to determine the association of AKI with risk of incident HF, adjusting for baseline age, eGFR, coronary heart disease and hypertension. Patients who died or had an outcome after the end of the study were censored.

Results: There were 17,272 matched pairs with and without AKI in the study. Patients with and without AKI during the index hospitalization were well matched with median

FR-PO500
Reduction of Nephrotoxic Medication Associated Acute Kidney Injury: Results from a Three Year Sustained Harm Reduction Program
Stuart Goldstein,1 Eric S. Kirkendall,3 Theresa A. Mottes,4 Kendria Nicole Simpson, Stephen E. Muething. Pediatrics, Cincinnati Children’s Hospital, Cincinnati, OH.

Background: Acute kidney injury (AKI) represents one of the most common co-morbidities in hospitalized children. Our previously reported nephrotoxic medication (NTMx) exposure and AKI screening project (Nephrotoxic Injury Negative by Just-in-time Action [NINJA]) showed a 25% NTMx-AKI rate and a 42% reduction in AKI days/100 NTMx-exposure in Year 1 of the program. This occurred due to rapid recognition of AKI and NTMx-exposure reduction. We now report on the 3-year NINJA results to assess for sustained harm reduction.

Methods: A daily serum creatinine (SCr) was recommended for all children admitted to a non-critical care unit who received ≥3 NTMx simultaneously or an IV aminoglycoside for >3 days (high NTMx-exposure) to assess for AKI development. We tracked biweekly outcomes from Sep 2011 through Mar 2015: 1) High NTMx-exposures per 1000 pt-days 2) AKI episodes per 1000 pt-days 3) AKI rates per exposure case (%) and 4) AKI days per high NTMx-exposed days (intensity). NTMx-AKI was defined by KDIGO criteria. We used statistical process control charts to assess for changes from baseline rates.

Results: 1,783 patients accounted for 2,358 separate admissions and 3,243 individual episodes of high NTMx exposure. 170 patients (97%) had ≥2 exposures. We observed two decreases in NTMx-exposure and AKI rates. Overall, the high-NTMx exposure rate decreased by 38% (11.63 to 7.24 admissions/1000 pt-days), and the AKI rate decreased by 64% (2.96 to 1.06 admissions with AKI/1000 pt-days). The NJINA project saved >633 exposure and 398 AKI episodes (when compared to baseline rates). Medications/medication changes or admission for exposure-related care did not differ significantly the 3 months preceding and following either time point improvement. AKI rates per exposure (23.3% to 15.4%) and AKI intensity (27.7 to 19.1 AKI days/100 exposure days) also decreased in Year 1; both improvements persisted for the entire period.

Conclusions: Implementation of systematic surveillance for NTMx-AKI can lead to sustained reductions in avoidable harm.

Funding: Private Foundation Support
Acute Kidney Injury Increases Medical Costs Even in the Pre-AKI Stage

**Background:** Early detection of acute kidney injury (AKI) is important to prevent the progression of AKI and to improve clinical outcomes. However, the significance of mild increase in serum creatinine below AKI stage is not well established. In this study, we defined pre-AKI as the 25-50% increase in serum creatinine levels from the baseline levels. We aimed to investigate the influence of AKI stage including pre-AKI on clinical outcomes.

**Methods:** We enrolled a total of 20819 patients who admitted National University Bundang Hospital from January 1, 2013 to December 31, 2013. We excluded patients who had not checked serum creatinine levels during admission or who were on dialysis due to end-stage renal disease.

**Results:** The proportion of patients who had AKI during admission were 21.6% (pre-AKI), 15.8% (AKI stage 1), 5.9% (AKI stage 2), and 3.2% (AKI stage 3). In-hospital mortality increased according to the stage of AKI [log-rank P < 0.001; HRs 1.878 (1.189-2.966) AKI stage 1; 6.039 (3.948-9.239) AKI stage 2; 12.064 (7.992-21.801) AKI stage 3].

**Conclusions:** Patients with pre-AKI showed a significant increase of length of stay (no AKI 7.4 ± 9.0 days, pre-AKI 13.0 ± 13.3 days, P < 0.001) and increased medical costs (no AKI: 2806 ± 3286 USD, pre-AKI: 4701 ± 5476 USD, P < 0.001) during admission. Patients with pre-AKI were more on surgical condition (51.1% ± 34.0%, P < 0.001) compared to patients without AKI.

**Impact of Fluid Overload on Acute Kidney Injury Diagnosis and Associated Outcomes in Critically Ill Patients:**

**Background:** Fluid overload (FO) changes the volume of distribution of creatinine, which is equivalent to total body water (TBW), which can alter the serum creatinine (sCr) concentrations. Higher TBW results in lower sCr leading to underestimation of AKI.

**Methods:** We calculated daily fluid balance and divided it by the body weight to obtain a percentage of FO. FO was defined as the 25-50% increase in serum creatinine below AKI stage. We hypothesized that in pts with >5% of FO the adjustment of sCr for TBW would diagnose more pts with AKI and diagnose AKI earlier than in pts with <2.5% of FO.

**Results:** We made a retrospective analysis of 120 records of pts from 2 centers. We calculated daily fluid balance and divided it by the body weight to obtain a percentage of FO. Pts were divided into 2 groups, A and B, with <2.5% and >5% of FO, respectively. Measured daily sCr was corrected using the TBW formula and presence of AKI was evaluated daily according to KDIGO guidelines. We compared the prevalence/day of diagnosis and associated outcomes between the 2 groups.

**Results:** Mean age in the cohort was 54.4±7.2 years, 56.3% were male. In group A 24 (34%) pts were diagnosed with AKI before adjustment and 25 (36.2%) after adjustment (p = 0.167). In group B 21 (48.8%) and 25 (58.1%) were diagnosed with AKI before and after adjustment, respectively (p = 0.023). Mean detection day of AKI without and with adjustment in group A was 3.2±2.4 and 2.8±2.1, respectively (p < 0.001) and in group B 3.4±2.3 and 3.2±2.0 (p < 0.001). Mortality in group A was 10.1±4.8% and in group B 32.6±5.9% (p < 0.001).

**Conclusions:** Correction of measured sCr for TBW in patients with >5% of FO is useful to diagnose more patients with AKI. Usage of the formula demonstrated usefulness for early diagnosis in patients with <2.5% and >5% of FO and we recommend its application in order to improve AKI prevention and treatment. FO of >5% is associated with increased mortality and worse outcomes in critically ill pts.
Results: Histologically, elevated PlGF was significantly associated with the severity of glomerulointerstitial damage and the intimal thickening of small renal arteries. During a median follow-up of 2.7 years, 82 patients reached primary end-points which were defined as the requirement of renal replacement therapy (38 patients) and the decline of eGFR by more than 25% from baseline (44 patients). Although baseline eGFR was not statistically different among patients in all PlGF quartiles, the rate of eGFR decline in the patients with the highest PlGF quartile was significantly faster than those with other quartiles. After adjustment of known confounding factors, PlGF was significantly associated with the risk of deterioration of renal function with the adjusted hazard ratio of 1.75 (1.38-2.26) for each quartile increment of PlGF. The combined use of eGFR and PlGF significantly improved the predictive accuracy for CKD progression compared with eGFR alone (c-statistics from 0.689 to 0.772, p<0.001).

Conclusions: E elevated PlGF is a novel and independent predictor of renal prognosis in the patients with CKD.

FR-PO508
Steeper Decline in Renal Function After a Hypertensive Disorder of Pregnancy: A Longitudinal Study

Background: Hypertensive disorders of pregnancy (HDP) occur in 10% of pregnancies. Population based studies report increased risk for ESRD after HDP. Longitudinal renal function after HDP has not been studied. Our aim was to longitudinally assess renal function and occurrence of CKD in women after HDP compared to controls.

Methods: Data from the PREVEND study, a population based prospective cohort with median follow-up of 11 years, were used to identify women without and with self-reported HDP (non-HDP, n=1805 and HDP, n=977). A case cohort, 10 years post-partum was created by record linkage, with subgroups: normal pregnancy (control, n=202), pregnancy-induced hypertension (PIH, n=56) and preeclampsia (PE, n=29). Renal function and the prevalence of CKD were compared.

Results: eGFR was lower at baseline and during follow-up in HDP vs non-HDP (A). In addition, the decline in eGFR was steeper in HDP vs non-HDP (B). At baseline and during follow-up there was more anti-hypertensive-drug use, including ACEi in the HDP group. 24-hr albuminuria at baseline was higher in HDP vs non-HDP and remained steadily higher in HDP during follow-up. A trend towards increased risk of CKD was observed in HDP, HR 1.13 (0.92-1.38). In the case cohort, eGFR was significantly lower (C) and 24-hr albuminuria significantly higher (p<0.03) in the PE vs controls. 7.8% of the controls, 10.5% of the PIH and 19.2% of the PE group met the criteria for CKD.

Conclusions: We report a lower renal function and a steeper renal function decline over time after HDP. Women with severe hypertensive disorders of pregnancy (PE) have the highest risk for renal function loss.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

FR-PO509
Pregnancy Outcomes in Women with Chronic Kidney Disease in South Australia

Background: Chronic kidney disease (CKD) affects an estimated 3% of women in their childbearing years. CKD in pregnancy is associated with adverse maternal and neonatal outcomes. This study reports the first attempt to capture the distribution of CKD among women in the Australian population.

Methods: Data from the South Australian Pregnancy Outcomes Unit Supplementary Birth Record for singleton pregnancies from 1990-2012. Women with renal disease and adverse outcomes were noted in the renal group, including gestational hypertension (10.6% vs 5.0%, p<0.001) and emergency caesarean section (20.0% vs 15.0%, p<0.001). Women with renal disease were more likely to have a preterm birth <34 weeks (6.7% vs 2.1%, p<0.001), or a late preterm birth 34-36 weeks (10.8% vs 4.5%, p<0.001). They were also more likely to be diagnosed with intranatal growth restriction (11.2% vs 9.5%, p<0.03) and to deliver a low birth weight baby <2500g (13.4% vs 5.5%, p<0.001).

Conclusions: Indigenous Australian women and women with low socioeconomic status are disproportionately burdened by CKD in pregnancy. The data showed increased adverse maternal and neonatal outcomes among women with CKD.

FR-PO510
Identification of Renal Disease in Women with Hypertensive Pregnancies

Background: Hypertension in pregnancy can be associated with renal injury which may be masked by gestational change. Postpartum assessment is an opportunity to detect persistent renal abnormalities. However previous studies are small and often exclude those with pre-existing hypertension, a risk factor for CKD. Aim: To determine the postpartum prevalence of renal abnormalities in women with chronic hypertension, pregnancy induced hypertension (PIH) or preeclampsia (PE) in a previous or current pregnancy.

Methods: Women with singleton pregnancies referred to a hypertension pregnancy clinic (Feb 2011-Nov 2014) attending postpartum review (offered to all) were included. Those with previously diagnosed CKD were excluded. Demographics, 24-hour urine protein, estimated GFR (CKD-EPI) and blood pressure after six weeks postpartum were recorded.

Results: Overall 120 (29.7%) of women were found to have features of renal disease postpartum. Subgroup analysis according to hypertensive groups is shown in Table 1.

Conclusions: A substantial proportion of women with hypertension in pregnancy have renal abnormalities after six weeks postpartum. Identification of risk factors for progression of CKD in this population through longitudinal studies is needed.

FR-PO511
Changes of Markers of Prothrombotic State in Membranous Nephropathy Complicated with Type 2 Diabetes

Background: Membranous nephropathy (MN) complicated with type 2 diabetes showed high incidence of thrombosis, which was related to abnormality of prothrombotic state. This investigation was designed to explore changes of prothrombotic state and mechanism of thrombosis in MN complicated with type 2 diabetes.

Methods: We enrolled total 30 patients with nephrotic syndrome (NS), 12 patients were pure MN, 6 patients were diabetic kidney disease (DKD), 12 patients were MN complicated with type 2 diabetes (MN+DM). All patients were diagnosed by renal biopsy. 14 healthy people were enrolled for normal control. The markers for prothrombotic state, including endothelial function (vWF, AngiotensinII), coagulation function (Protein C, Protein S, Antithrombin III, Thromboelastogram index), fibrinolytic function (Fibrinogen, Fibrinogen degradation product, D-D dimer) were tested.

Results: Compared to CKD group, vWF levels in MN and DKD group were higher, but was significantly higher in MN+DM group. Protein C and thromboelastogram index in MN+DM group were higher than control, which were not significantly changed in MN and DKD group. Fibrinogen levels in both MN+DM and MN group were higher than others, and D-D dimer levels were especially higher in MN+DM group, even compared to MN.

Conclusions: A significant prothrombotic state in patients with MN+DM compared to MN or DKD. This study shows that prothrombotic state is an important factor in the development of renal thrombosis in MN+DM.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Conclusions: Under NS state, MN+DM patients existed more severe prothrombotic state and was related to more MN+DKD. The mechanism is related to disorders of endothelial function, coagulation function, as well as fibriinolytic function. More attention should be paid to treatment of prothrombotic state in MN+DM patients.

FR-PO512

Serum C3 and Renal Outcome in Patients with Primary Focal Segmental Glomerulosclerosis

Jian Liu, Jingyun Xie, Jun Tong, Hong Ren, Weiming Wang, Nan Chen.

Dept of Nephrology, Rui Jin Hospital, Shanghai Jiao Tong Univ, School of Medicine, Shanghai, China.

Background: The role of complement in the pathogenesis or progression of FSGS is uncertain. The aim of this observational cohort study was to identify the clinical implications of serum C3 levels and to investigate their utility as predictor of renal outcomes in patients with FSGS.

Methods: 591 biopsy-proven primary FSGS patients were recruited. Clinical, histological and progression data were recorded. Decreased serum C3 level was defined as C3 <85 mg/dl. The study endpoint was end-stage renal disease (ESRD).

Results: Of the patients, there were 117 patients (21.5%) with low serum C3. At the time-point of renal biopsy, compared to patients with C3 ≥85 mg/dl, those with C3 <85 mg/dl had higher level of serum creatinine, lower levels of eGFR, proteinuria, hemoglobin, triglyceride, cholesterol, IgA, more severe segmental sclerosis, tubular atrophy and interstitial fibrosis. Multivariate linear regression analysis showed low C3 level was an independent risk factor for eGFR (HR=42.56, 95%CI 11.21-73.91, p<0.01) after adjusted by sex, age and clinical indicators. The follow-up was assessed in 221 patients. During a mean follow-up of 53.3 months, ESRD occurred in 32 patients (37.2%) with low serum C3 compared with 22 patients (16.3%) with normal C3 levels (P<0.001). Serum C3 level had a significant predictive value for renal outcome (AUC = 0.650, P = 0.001), The risk of reaching ESRD was significantly higher in patients with low serum C3 level (HR 4.044; 95% CI 2.238 to 7.309; P < 0.0001).

Conclusions: Complement activation may occur in patients with FSGS. It is associated with clinical and histological severities. Low serum C3 is an independent risk factor for the decline of eGFR, and is associated with poor renal outcome in patients with FSGS.

FR-PO514

Prognosis, Survival and Renal Function in Patients with Lupus Nephritis

Gustavo Aroca Martinez, 1,2 Andres A. Cadena, 1 Eduardo Egea Bermejo, 1 Josie E. Fontalvo, 1 Yeneris Gaviria, 1 Henry J. Gonzalez Torres, 1 Moises A. Arquez Mendoza, 1 Jose Rafael Consuegra, 1 Santos Depine. 1 Medicine, Univ Simon Bolivar, Barraquilla, Atlanticco, Colombia; 2 Nephrology, Clinical de la Costa, Barraquilla, Atlantico, Colombia; 3 Medicine, Univ Nacional de Colombia, Colombia, Atlantico, Colombia; 4 Medicine, Univ del Norte, Colombia, Atlantico, Colombia.

Background: Lupus nephritis is the most common glomerulonephritis in the Colombian Caribbean region, despite there is less published information about its evolution and clinico-pathological aspects. Objective: To evaluate prognosis, survival and renal function of patients with LN residing in the Colombian Caribbean region controlled between 2000-2014.

Methods: 229 patient study with LN corroborated by histology according to the International Society of Nephrology Classification Renal Pathology Society (ISN/ RPS. 2003) treated with induction and maintenance therapy and with a systemized following of at least 2 years. The pharmacological treatments included prednisolone, azathioprine, and Cyclophosphamide mycofenolate mofetil in isolation or combined and the clinical laboratory and histopathology variables were correlated as predictive value of therapeutic response. To achieve this as methodology a non-parametric descriptive statistics ANOVA (k-) was used and canonical correspondence analysis.

Results: 229 patients in total of 34±12 of age, which 88% women, whose evolution were controlled during 24±6 months. The most common form of clinical presentation was nephrotic syndrome and asymptomatic hematemia-proteinuria (68.07%) the type III and IV had a survival rate of 62.1% of patients under 25 years and a negative response to treatment. The estimated glomerular filtration rate measured by MDRD showed a significant improvement at 24 weeks with regard the baseline figure of 74,36.

Conclusions: The early detection and reference of NL patients allows an early approach and therapy. Which will prevent chronic kidney disease.

FR-PO515

Association of ABO Blood Group with Progression of IgA Nephropathy

Meng Yang, Jingyun Xie, Yan Ouyang, Xiaoyang Zhang, Xiao Li, Wen Zhang, Weiming Wang, Nan Chen.

Dept of Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China.

Background: ABO blood group antigens are major histocompatibility antigens and little is known about its association with progression of IgA nephropathy (IgAN).

Methods: Biopsy-proven primary IgAN patients were retrospectively recruited. Clinical, histological and progression data were recorded. Patients with C3<15mg/m3l+m3l+‘(1.73m3l+’)/m3l+’ at time of biopsy were excluded. Renal tissue was semi-quantitative scoring according to the Oxford scoring system. ABO blood group was determined by standard erythrocyte antisemum agglutination method. All patients were divided into B antigen group (type B and AB) and non-B antigen group (type A and O) based on their ABO types.

Results: Among the 752 IgAN patients recruited in this study, 210 patients were type A (27.9%), 221 were type B (29.4%), 72 were type AB (9.6%) and 249 were type O (33.1%). When renal biopsy was performed, patients in B antigen group had higher eGFR (82.44 vs. 65.68 ml/min), lower systolic blood pressure (sbp) (125.36 vs. 129.29 mmHg) and uric acid (373.59 vs. 393.93 mmol/l) than patients in non-B antigen group. No significant difference was detected between the histological lesions and these two groups. Totally, 100 patients progressed to end-stage renal disease (ESRD) after a median follow-up period of 51.05 months, including 32 (15.2%) type A, 18 (8.1%) type B, 2 (2.8%) type AB and 48 (19.3%) type O patients. Kaplan-Meier analysis showed that median ESRD-free survival time of patients in B antigen group was significantly longer than patients in non-B antigen group [148.2±5.5 months vs. 138.8±7.5 months, p<0.001]. Furthermore, patients in B antigen group were associated with a decreased risk of ESRD (HR=0.56, 95% CI:0.33-0.94) after adjusted by age, sex and clinical variables including eGFR, sbp, serum albumin, urine protein and hemoglobin by Cox proportional hazards model.

Conclusions: Our data suggested that B antigen had an independent protective effect against the progression of IgAN.

FR-PO516

The Analysis of the Long-Term Outcomes of Patients with Primary IgA Nephropathy

Hao Li, Jian Liu, Wei Huang, Pingyuan Shen, Zhaohui Wang, Ya Li, Xiaoxia Pan, Jingyun Xie, Weiming Wang, Nan Chen. Dept of Nephrology, Shanghai Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China.

Background: Primary IgA nephropathy (IgAN) is one of the most common glomerular diseases in China. In this study we try to investigate the clinical characteristics and the relationship between CKD stages and long-term outcomes of patients with primary IgA nephropathy through the retrospective analysis of their clinical data.

Methods: Patients with biopsy-proved primary IgAN from 2002 to 2013 were included in the retrospective analysis. They were older than 18 years old and their follow-up time was more than 12 months. We collected their medical history, laboratory test reports and other clinical data. Then we enrolled 297 patients who were followed up for 5 years for further research. Kaplan-Meier method was used to calculate the renal survival rate of the patients.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

476A
Results: A total of 1052 cases were included. There is an equal proportion of male and female (50.4% vs 49.6%). The mean age was 36.86±11.58 years old. Five-year renal survival rate of these cases was 92%, and ten-year renal survival rate was 88%. We enrolled 297 cases who were followed up for 5 years. These patients were divided into rapid progression and stable progression, we found that cases in rapid progression group had more proteinuria, higher blood pressure, poorer renal function, lower serum albumin and lower hemoglobin, compared with other groups. When cases were divided according to CKD stages, the results showed no significant difference of outcomes among patients in CKD1-3a stage (P > 0.05). Their five-year renal survival rate was more than 95%. But patients in CKD3b-4 stage had worse outcomes. The five-year renal survival rate of patients in CKD3b stage was 85.3%, while it is only 65.3% for patients in CKD4 stage.

Conclusions: Five-year and ten-year renal survival rate of patients with IgAN was 92% and 88%, respectively. Patients in CKD3b or CKD4 stage at biopsy may have a lower renal survival rate and a worse outcome. At the time of renal biopsy, patients with impaired renal function, mass proteinuria, hypertension, anemia and low serum albumin may have a greater risk of progressing to end-stage renal disease.

FR-PO517

Variability of GFR Decline in Alport Syndrome: Insights from a Provincial Database

Background: Alport syndrome (AS) is one of the inherited causes of CKD due to mutations in the collagen genes making up the glomerular basement membrane collagen. Design of clinical trials for intervention in AS proves challenging without a clear understanding of renal progression over time as observational data is lacking due to small sample size. We present here the utilization of population based data in a simulation to mimic clinical trial recruitment and endpoints to provide insights in trials design for AS.

Methods: AS patients were identified within a provincial CKD clinical database (PROMIS) in British Columbia, Canada for this observational simulation study. Patients were excluded if they have fewer than 4 eGFR-MDRD measurements or 2 as a study entry point to generate 100 random samples. Primary outcome was annual rate of change of GFR over two years categorized into: > -5 mL/min per year (progressor), > -2 mL/min per year (stable), > 2 mL/min per year (regressor).

Results: 75% of inclusion criteria; median follow-up was 48.2 months, and median age of 36. The sample sizes for each random sample at the 3 enrolment eGFR levels were: 11, 12 and 10 respectively. Of those that ‘enrolled’ at eGFR 45-60 mL/min, 72.7% (IQ:63.6%, 81.8%) progressed, and 22.7% (IQ:9.1%, 36.4%) remained in stable state.

FR-PO519

Micrornas as Predictive Biomarkers of Chronic Kidney Disease (CKD) in Patients (Pts) Undergoing Radical Nephrectomy (RN) for Kidney Cancer

Background: Micrornas (miRs) are small non-coding RNAs involved in cell homeostasis and disease. Our study identified clinical and molecular markers associated with increased risk of developing CKD after RN for renal clear cell carcinoma (RCC).

Methods: 80 pts who underwent RN for RCC at a single institution between 2008-2011 were included. Inclusion criteria: normal renal function at surgery time (eGFR > 60 mL/min/1.73 m2) and renal tissue samples. MicroRNA extraction was performed using Nanostring nCounter and validated by Real-Time, digital droplet PCR and in situ hybridization (ISH). Cox regression analyses were used to define variables associated with increased risk.

Results: 47.4% of pts developed CKD (stage 3a-3b-4 KDIGO) 12 months after RN. At multivariable Cox Regression, type II diabetes (pvalue:0.009), basal serum creatinine (pvalue:0.002) and miR-193b over-expression (pvalue:0.017) were independently associated with increased risk of CKD. ISH showed miR-193b over-expression in the tubular-interstitial compartment associated with abnormalities in keeping with early inflammatory and fibrotic changes. MiR-193b detection in matched urine samples is ongoing.

Conclusions: Tissue and urinary miR deregulation may represent an early marker of kidney dysfunction and may anticipate clinical and laboratory evidence of CKD providing an important tool for personalized follow-up and prevention in pts undergoing RN for RCC.

FR-PO520

Urinary Angiotensinogen to Creatinine Ratio Is a Specific Biomarker for Renal Progression in Autosomal Dominant Polycystic Kidney Disease

Background: Urinary angiotensinogen to creatinine ratio (AGT/Cr) is elevated in autosomal dominant polycystic kidney disease (ADPKD), but whether AGT/Cr is a specific biomarker of ADPKD progression is not known. This study was performed to measure urinary AGT/Cr in subcohorts according to primary renal disease (glomerulonephritis (GN), diabetic nephropathy (DN), hypertensive nephropathy (HTN), ADPKD) and to demonstrate its usefulness as a specific biomarker in ADPKD.

Methods: Nine nephrology centers recruited adult subjects with chronic kidney disease (CKD) and classified them into five subcohorts according to primary renal disease (glomerulonephritis (GN), diabetic nephropathy (DN), hypertensive nephropathy (HTN), ADPKD) and its severity.

Results: A total of 1528 patients were enrolled in KNOW-CKD cohort study (NCT 01630486) from Apr 2011 to Dec 2013. Among them, 153 patients were excluded (71 unclassified subgroups, 71 without urinary AGT measurement, 9 without available eGFR and a total of 1375 (519 GN, 310 DN, 292 HTN, 254 ADPKD) patients were included in the final analysis. The mean age was 51 years and baseline serum creatinine was 1.9 ± 1.2 mg/dL. The GN and ADPKD subgroups showed younger age and earlier elevation.
of urinary AGT/Cr levels according to CKD stages. When we performed the risk factor analysis separately in GN and ADPKD subgroups, the highest quartile of urinary AGT/Cr was associated with GN subcohort, female gender, hypertension, decreased eGFR, decreased plasma Hb, and higher degree of albuminuria. However, in multivariable logistic regression analysis, ADPKD subcohort demonstrated higher urinary AGT/Cr compared to GN subcohort after adjusting other co-factors.

**Conclusions**: Urinary AGT/Cr is greatly increased in ADPKD independent of albuminuria and renal function.

**Using Biomarkers to Predict Progression to End-Stage Renal Disease within 6 Months of Liver Transplant** Joseph T. Bahng, Kimberly Autumn Forde, Peter Abi, Michael R. Bennett, Anirban Ganguli, Mary Ann C. Lim, Debra J. Mccrorriston, Mary C. Shaw, Deirdre L. Sawinski,

**Perelman School of Medicine at the U. of Pennsylvania; Cincinnati Children’s Hospital.**

**Background**: Liver transplant (LT) recipients are at increased risk for CKD and progression to ESRD. Creatinine, the standard for assessing renal function, provides limited prognostic information for recovery from AKI. Our aim is to create a predictive model for progression to ESRD within 6mos of LT incorporating clinical data and biomarkers.

**Methods**: We enrolled 202 patients, of whom 138 have follow up. 13 patients progressed to ESRD, defined as GFR<20 ml/min, dialysis, or transplant evaluation. Logistic regression models evaluated neutrophil gelatinase-associated lipocalin, IL-18, Cystatin-C, Kidney Injury Molecule-1, & liver fatty acid binding protein for inclusion. Receiver operating characteristic curves and concordance statistics were used to assess the models.

**Results**: In one model, MELD score at LT, pre-LT AKI, pre-LT renal replacement therapy, & highest creatinine 3mos pre-LT were associated with ESRD at 6mos (p<.05). Operating characteristic curves and concordance statistics were used to assess the models.

**Conclusion**: MELD and IP-10 can be detected in urine as inflammatory biomarker to assess risk of transplant rejection. ViveST can be used as ambient storage and transport device eliminating need for cold chain storage. Additional studies warranted assessing detection of biomarkers at therapeutically relevant concentrations.

**Albuminuria-Induced Apoptosis in Children with Nephrotic Syndrome Is a Result of the Dysbalance in Apoptosis Controlling System** Jeveynija Burlaka, Dept of Pediatrics No. 4, National O.O. Bogomolets Medical Univ. Kiev, Ukraine.

**Background**: Albuminuria promotes cell death, and is associated with faster progression of chronic kidney disease (CKD). However, the molecular mechanisms regulating cell death in response to albuminuria are not fully understood.

**Methods**: 53 patients aged 10-15 years with active stage of nephrotic syndrome were included in the study. Immunological profile analysis was performed on paired samples: anti-apoptotic factor Bax, anti-apoptotic factor Bcl-xL, number of apoptotic cells in kidney biopsy specimens were done. Comparison of the level of these parameters between the different segments of nephron at different stages of glomerulosclerosis has been performed.

**Results**: Measurement of the anti-apoptotic factor Bax in kidney slices obtained from children with morphological form of nephrotic syndrome focal segmental glomerulosclerosis (FSGS) showed presence of high level of Bax in both glomerular and tubule-interstitial segments. Higher immunosignal of Bax was evaluated in glomeruli with FSGS I-II st. as compared to tubular segment. When FSGS III-IV st. observed higher expression of Bax was detected in surrounding tubule-interstitial segment. Expression of the anti-apoptotic factor Bcl-xL was studied. Higher expression of Bcl-xL was recorded in tubule-interstitial segment as compared to glomeruli when FSGS I-II st. occurs. When FSGS III-IV st. occurred higher immunosignal of Bcl-xL is localized in surrounding tubule-interstitial segment with almost complete absence in glomeruli. The number of apoptotic cells was analysed. Quantitative analysis of apoptosis in kidney sections of patients with FSGS I-II st. revealed higher apoptotic index (AI) in glomeruli as compared to tubule-interstitial component. In kidney sections with FSGS III-IV st. higher AI was found in tubule-interstitial compartment.

**Conclusions**: Thus, progression of kidney injuries in nephrotic syndrome is associated with increased activity of anti-apoptotic factor Bax and simultaneous reduction of anti-apoptotic factor Bcl-xL. The level of the expression of Bax and Bcl-xL depends on the stage of FSGS and indicates the step-dependent manner of glomerular and interstitial injuries development upon the chronic influence of albuminuria.

**Detection of Inflammatory BioMarkers in Urine Using a Dried, Shelf Stable Transport Device, ViveST™** Daniel R. Mcclemom,1 Timothy W. Murray,2 Anita M. Mcclemom,1 bioMONTR Labs, Research Triangle Park, NC; Vivebio LLC, Alpharetta, GA.

**Background**: Current medical practice assesses health of implanted kidney by monitoring non-specific signals (serum creatinine) after rejection has started and gold standard diagnostic method is invasive kidney biopsy. Studies of non-invasive biomarkers (CXC119) have shown utility (CTOT-01) in identifying subsets of patients at risk for acute rejection. A urine based test for post surgical evaluations to pinpoint rejection and expedite therapeutic intervention is needed. Here we describe detection of CXCL9/MIG and CXCL10/IP-10 using a Transport Device, ViveST (see table). Replicate aliquots gave similar results.

**Results**: ViveST samples yielded MIG or IP-10 concentrations similar to corresponding frozen aliquots (see table). Replicate aliquots gave similar results.

**Conclusions**: MIG and IP-10 can be detected in urine as inflammatory biomarker to assess risk of transplant rejection. ViveST can be used as ambient storage and transport device eliminating need for cold chain storage. Additional studies warranted assessing detection of biomarkers at therapeutically relevant concentrations.

cGFR, Renal, and Cardiovascular Risk and Nucleoside/Nucleotide Backbones of Human Immunodeficiency Virus Patients in the USA Jonathan A. Winston,1 Grace Mcconsey,2 1Icahn School of Medicine at Mount Sinai; 2Case School of Medicine.

**Background**: HIV treatment involves choices in complex environments, and must balance disease management and potential safety issues (kidney and Cardiovascular diseases (CVD)) in an aging population. This study examined renal, CVD and comorbid conditions, and treatment of HIV patients.

**Methods**: Patients diagnosed with HIV using ICD-9 codes were selected from the Quintiles database (33M patients). Patients enrolled for ≥1 year during 2012-14, maintaining a single antiretroviral therapy, and for whom baseline eGFR could be computed were stratified based on backbone: regimens including tenofovir disoproxil fumarate (TDF), abacavir (ABC), or other (OTH). cGFR and rate of CV comorbidities at baseline were assessed.

**Results**: 14,942 HIV patients (mean age: 43; 76% male) were included; 85% TDF, 7% ABC, 7% OTH. Mean baseline eGFR was 99 mmol/L, with differences observed among regimens (102 TDF, 82 ABC, 87 OTH). Classified by degree of kidney impairment at baseline, regimen was highly correlated with level of impairment, with normal or mild impairment (eGFR>60) more likely to be treated with TDF, and patients with moderate to
severe impairment (eGFR<60) more likely to be on ABC. Several CVD risk factors were more prevalent in ABC patients compared to TDF, hypertension (25% v 13%), dyslipidemia (30% v 16%), and diabetes (12% v 5%) (p<0.001 in all) being the most common.

Conclusions: HIV patients often present with prevalent CVD risk and reduction in kidney function. Physicians make treatment choices that reflect concern for kidney function, consistent with labeling. This choice may come with cost, with more CVD risk factors correlated with alternative choices of NRTIs. As some antiviral regimens may be associated with CVD while others with kidney disease, understanding CVD risk profile versus kidney function protection may help optimize care of patients.

Total Kidney Volume Computation in ADPKD: Different Methods in Comparison Kanishka Sharma,1 Anna Caroli,2 Katja Petzold,3 Andreas L. Serra,4 Giuseppe Remuzzi,5 Andrea Remuzzi.6 Bioengineering, Mario Negri Inst, Bergamo, Italy;1 Biomedical Engineering, Uni of Bergamo, Bergamo, Italy;2 Unit of Nephrology and Dialysis, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy;3 Univ of Zurich, Zurich, Swaziland.

Background: In ADPKD, kidney enlargement is associated with renal function decline, and total kidney volume (TKV) is gaining acceptance as surrogate marker of disease progression. In view of its effective use, TKV assessment should be as quick and accurate as possible. Aim of this study was to compare different TKV quantification methods.

Methods: TKV was computed on 13 MRIs from ADPKD patients enrolled in the EuroCYST Initiative (TKV=707-6605 ml) by two tracers twice, using 4 methods: 1) polylime manual tracing with ImageJ software; 2) free-hand manual tracing with Osirix software; 3) semi-automatic tracing with customised ImageJ Livewire Plugin; 4) TKV estimation using mid-slice (Bae KT, Am J Nephrol 2013). Reproducibility, reliability, and agreement between methods were assessed.

Results: All of the methods were comparable in terms of intra- and inter-rater reliability (CCC=1, p<0.05). ImageJ polylime and Liveiwire tool showed highest agreement (30.65 ml difference), while mid-slice method showed largest discrepancies.

Conclusions: ImageJ polylime and Liveiwire tool provide the best compromise between accuracy and time and are recommended.

Renal Reserve: Development of a Kidney Stress Test Kyle Rodenbach,1 Dana F. Fuhriman,2 Paula S. Maier,3 Katherine D. Shaw,1 George J. Schwartz.1 1Peds, Univ of Rochester, Rochester, NY;2 Peds, Univ of Pittsburgh, Pittsburgh, PA.

Background: Renal reserve (RR) is the difference in stimulated versus baseline glomerular filtration rate (GFR); it might predict future kidney health. The purpose of this study was to compare a meat versus liquid protein load in a cystatin-C-based (Cys-C) RR test using cimetidine-inhibited creatinine clearance (Cr Ci) and iohekol infusion clearance (Io Ci) for validation.

Methods: Participants (N=18) were screened for health status, blood pressure, and proteinuria. They followed a low protein diet and took cimetidine (20 mg/kg) for two days prior to the study. Water loading was used to maintain urine flow, and two hours were allowed for renal steady state stabilization. Participants 1-10 received a burger (1 g/kg protein); 11-15 received a ProCel® shake (1 g/kg protein); and 16-18 received a high dose ProCel® shake (1.5 g/kg protein). Data were analyzed for significance of RR. Cystatin-C estimated GFR (Cys-C eGFR) was calculated using the CKD-EPI Cys-C formula (Inker NEJM 2012) following ICGC calibration (ERM-DA474).

Results: Participants (N=18) had a mean (SD) age of 22 (2) years and were 39% male and 72% white. Baseline GFR (SD) in ml/min/1.73m2 averaged 103.4 (14.7) for Cr Ci; 108.9 (9.0) for Io Ci (N=8); and 117.4 (6.1) for Cys-C eGFR. For the burger group (N=10), mean RR (SD) in ml/min/1.73m2 was 17.1 (11.6) for Cr Ci (P<0.001); 8.4 (8.3) for Io Ci (P<0.001); and 4.7 (2.4) for Cys-C eGFR (P<0.001). For 1-0.5-g/kg shakes (N=8), mean RR (SD) in ml/min/1.73m2 was 15.8 (5.8) for Cr Ci (P<0.001), 11.7 (9.0) for Io Ci (P<0.008), and 2.4 (2.9) for Cys-C eGFR (P=0.05). The burger and shake groups did not differ significantly in RR determined by Cr Ci, Io Ci, or Cys-C but Cys-C based RR was significantly less than Io-based RR for both groups. There were no differences in post-load versus pre-load Cr/Ci clearance ratios.

Conclusions: Cys-C-based RR following a burger provides a simple stress test of kidney function which was validated by classical renal clearances and can be applied to those who recover from acute kidney injury. Why Cys-C-based RR was smaller than Io RR, the reference standard, is a topic for future investigation.

FR-PO527

Background: Despite the clinical recovery of an acute kidney injury (AKI) episode, progression to chronic kidney disease (CKD) could be observed on long time follow-up. The mechanisms are poorly understood. To analyzed if angiotensin II receptor blockade (ARB) before the ischemic insult is effective in abrogating the severity of the AKI episode and/or the progression to CKD.

Methods: Male Wistar rats were divided into 4-groups of rats: sham; sham plus losartan 3-d before surgery; bilateral renal ischemia for 45-min (UTxI); and losartan administration (3-d) before ischemia (Los-Pre). Animals were studied after 1, 3, 5, 15 days or 9-months. At the end of each experimental period, physiological, histopathological, immunohistochemistry, biochemical and molecular studies were performed.

Results: UTxI group developed CKD characterized by renal dysfunction, proteinuria, renal hypertrophy, glomerulosclerosis, tubular atrophy and tubulointerstitial fibrosis. At the ultra-structural glomerular level, foot process effacement was observed, which was associated a reduction in immune-gold staining for nephrin. Renal injury was mediated by increased oxidative stress, inflammation and up-regulation of TGFβ, aSMA, and Colagen I protein levels. TGFβ overexpression was mainly observed in epithelial cells. Interestingly, in spite of, ARB did not prevent or reduced AKI severity; it was enough effective to prevent CKD. The renoprotection conferred by ARB was associated a reduction in immune-gold staining for nephrin.

Conclusions: Our data shows that in spite of, losartan pre-treatment did not protect the rats against AKI, it was effective to prevent the transition to CKD. The mechanisms by which losartan prevented CKD were in part due to the early renal blood flow recovery, lesser inflammation and greater HIF1α nuclear translocation within the 15 days post-ischemia.

Specific Endothelial Heparin-Binding EGF-Like Growth Factor Deletion Ameliorates Renal Injury Induced by Chronic Angiotensin II Infusion Fenghua Zeng, Lance A. Kloepfer, Raymond C. Harris. Medicine, Vanderbilt University, Nashville, TN.

Background: Transactivation of EGFR by angiotensin II (Ang II) plays important roles in the initiation and progression of chronic kidney diseases (CKD). In vitro studies suggested that HB-EGF may be a critical mediator in this process, whereas its role in vivo has not been reported.

Methods: Age-matched male littersmates of HB-EGF+/− mice with endothelial-SCLCre-ER (T) (+) or (-) were used. Tamoxifen injections produced control (HB−/−) and mice with specific deletion of HB-EGF from endothelium (HB+/−), which underwent uninephrectomy and osmotic minipump-mediated infusion with saline or AngII for 8 weeks. Systolic blood pressures (SBP) were measured by tail-cuff. Renal injury was evaluated by albuminuria using urinary albumin/creatinine ratios and by morphology with periodic acid-Schiff (PAS) staining. Renal EGFR activation was determined by immunoblotting and immunostaining. Endothelium/podocyte injury, inflammation and renal fibrosis were evaluated by immunostaining.

Results: Compared to control, kidneys from HB−/− mice with Ang II-infection had significantly reduced EGFR activation. Endothelial HB-EGF deletion did not significantly prevent the hypertension induced by Ang II infusion, albeit lower SBP was detected in HB+/− mice compared to HB−/− mice. However, it decreased Ang II-infection related renal injury, as demonstrated by 1) less albuminuria; 2) less glomerulosclerosis with glomerular score of 0.793 versus 1.652 in the control; 3) preserved endothelial integrity and decreased podocyte injury shown by more glomerular tufts area and WT1 positive cells; and 4) less apoptotic cells measured by cleaved caspase 3 and TUNEL staining; 4) reduced inflammation in perivascular area and interstitium measured by F4/80 and CD3 immunostaining; and 3), reduced renal fibrosis, as shown by α-SMA immunostaining.

Conclusions: Shedding of HB-EGF from endothelium plays an important role in Ang II induced renal injury by linking Ang II-ATIR with EGFR transactivation. Inhibition of HB-EGF shedding could be a potential therapeutic strategy for CKD.

Effects of Acute Kidney Injury (AKI) Severity and Co-Morbidities on Chronic Kidney Disease (CKD) Progression Gregory John Wilson,1,2 Adrian Lawrence Kark,1,2,4 Andrew John Mallett,1,2,4,5 Anne Salisbury,1,2,4,5 Zaimin Wang,1,2 Helen G. Healy,1,2 Wendy E. Hoy,1,2 1 Kidney Health Service, Royal Brisbane and Women’s Hospital, Australia; 2 CKD QLD and NHMRC CKD CRE, The Univ of Queensland, Australia; 3 Inst for Molecular Bioscience and School of Medicine, UQ, Australia; 4 Centre for Chronic Disease, UQ, Australia.

Background: AKI is a common and important cause of CKD. It remains unknown how AKI severity influences CKD progression. Which co-morbidities influence the progression of CKD also remains undetermined.

Methods: We aimed to explore whether AKI severity and patient comorbidities influence CKD progression. Patients with CKD associated with a clinical diagnosis of AKI were identified in the Royal Brisbane & Women’s Hospital cohort (n=1150) of the CKD.QLD registry. AKI events were confirmed through historical creatinine values (2005 onward), and severity determined using AKIN criteria. CKD progression was assessed by change in glomerular filtration rate per year (DeGFR/yr) based on initial and final eGFR(CKD-EPI) values. All co-morbidities identified at the time of enrolment into the registry were explored.

Results: 384 patients were recorded as having a primary or secondary AKI diagnosis; 157 (40.8%) were male, mean age 57.7 yrs. 133 patients (84.7%) were identified as Stage 1 AKI, 16 (10.2%) as Stage 2 and 8 (5.1%) as Stage 3. A one-way ANOVA revealed that AKI severity did not modulate CKD progression. However, numerically DeGFR/yr was highest for Stage 3 patients (5.1mL/min/1.72m2), and smallest for Stage 1 patients (1.6mL/min/1.72m2). The only two co-morbidities found to influence CKD progression were diabetes mellitus (DM; 35.6% of patients) and peripheral vascular disease (PVD; 12.1% of patients). CKD progression was significantly increased in patients with DM compared with patients without (DeGFR/yr 3.7mL/min/1.72m2, p<0.001), and patients with PVD compared with those without (DeGFR/yr 4.4mL/min/1.72m2, p<0.05).

Conclusions: Surprisingly, AKI severity did not alter CKD progression. Both DM and PVD influenced CKD progression in patients with AKI suggesting an increased vulnerability to AKI in these patients.

Association Between Gut Microbiome and Cardiovascular Risk in Chronic Kidney Disease Patients with Type 2 Diabetes Mellitus Ruchi Singh, Tetyana L. Vasylyeva. Pediatrics, Texas Tech Health Sciences Center, Amarillo, TX.

Background: Diabetes is one of the leading causes of CKD. It is well established that patients with T2DM often experience persistent low-grade inflammation leading to microvascular deterioration and progression of vascular complications along with impaired gut motility, which impacts their microbomes. The aim of the study is the assessment of gut microbiota, plasma zonulin, and inflammatory cytokines (TNF-α, IL-6, IL-6) in conjunction with GFC-F.23, ET and levels of LP in CKD (stage 4 and 5) patients with Diabetic Nephropathy (DN).

Methods: Healthy controls were matched by age and gender. Their dietary habits have not been prescribed. Total of 40 subjects participated in the study, IL-6, FGF 23, LP, ET-1 and zonulin, levels were measured by ELISA and quantitative analysis of gut microbiota composition (454 pyro sequencing).

Results: Higher circulation serum zonulin, TNF-α, and IL-6, FGF 23 LP, ET-1 levels were noted in the CKD (stage 4 and 5) patients. In all subjects with advanced CKD was substantially different from healthy population with increased in percentage of LPs producing bacteria. Significant diversity was observed in gut microbiota in study subjects compared to control group. CKD patients had high serum concentration of TNF-α, marker of leaky gut syndrome. Zonulin concentration was found positively correlated with LPs, inflammatory markers and FGF-23.

Conclusions: Gut microbiota is a modifiable factor and zonulin could be a potential future target to control chronic inflammatory responses. Gut microbiota and increased gut permeability in patients with advanced CKD secondary to DN results in high level of circulating LPs that mediates chronic inflammation which was implicated in deterioration of cardiovascular health.

Potential Uremic Toxin Precursors in the Gut Identified by Metabonomics Liwen Zhang,1 Hongli Jiang,2 1 School of Medicine, Xi’an Jiaotong Univ, Xi’an, Shaanxi, China; 2 Hemodialysis Center, First Affiliated Hospital of Medical School, Xi’an Jiaotong Univ, Xi’an, Shaanxi, China.

Background: Many factors, e.g., the intestinal bacterial disorder, result in the species and amounts of harmful substances in the gut increasing, which leads to the increase of uremic retention molecules (URMs) in blood. These URMs may be classified according to their site of origin, that is, endogenous metabolism, microbial metabolism, or exogenous uremic retention molecules (URMs) in blood. These URMs may be classified according to their site of origin, that is, endogenous metabolism, microbial metabolism, or exogenous intake. The latter two are known as gut-derived uremic toxins, i.e., gut is a significant origin of URM, but it is currently unclear of the profile of these uremic toxins.

Methods: Excluding special factors which affected the intestinal environment, the subjects were divided into two groups: hemodialysis patients with end-stage renal disease (HD group, n = 20) and healthy controls (CT group, n = 20). Fecal metabonomics based on the ultra-performance liquid chromatography-tandem mass spectrometry was undertaken to identify the low molecular weight metabolites, and fecal proteomics based on the two-dimensional gel electrophoresis was employed to investigate the high molecular weight proteins. The data was analyzed with statistic and bioinformatic methods.

Results: Thirty-three metabolites and 31 proteins were identified. Among them, 17 metabolites and two inflammation-associated proteins. However, the levels of 16 metabolites and 18 proteins were lower in HD group compared to CT group, including phenols, which are well-known uremic toxins originating from the gut; reactive carbonyl compounds (RCC), which are well-known URM in serum but first identified in the gut; other harmful metabolites (e.g., fenthion, halosulfuron-methyl and diethylpropon).
Does Autophagosome-Proteinolysis Contribute to CKD-Induced Muscle Atrophy? Zhen Su, Haidong Wang, Janet D. Klein, William E. Mitch, Xiaonian H. Wang, 1 Dep of Nephrology, The First Affiliated Hospital of Wenzhou Medical Univ, Wenzhou, Zhejiang, China; 2Nephrology, Baylor College of Medicine, Houston, TX; 3Renal Medicine, Emory Univ, Atlanta, GA.

Background: CKD-induced muscle wasting results from activation of the ubiquitin proteasome system (UPS). Since FoxO3 stimulates the UPS but also activates autophagosomes, we hypothesized that autophagosome-induced proteolysis may contribute to CKD-induced muscle wasting.

Methods: CKD model in mice: subtotal nephrectomy for one month. Muscle overload modeling: removal of gastrocnemius and soleus to overload the plantaris muscle (myostatin resistant exercise) in normal and CKD mice. Acupuncture with low frequency electric stimulation (Acu/LFES) was applied 15 minutes daily for 2 weeks (Hu, JASN, 26:626 2015). Electrical stimulation used a consistent pulse, electric frequency 20Hz, current 1mA.

Results: Both exercise and Acu/LFES reduced CKD muscle loss. In muscles of CKD mice, mRNAs related to autophagy-lysosomal function, Bnip3, Atg12, Atg8, LC3H1 and Beclin-1, were upregulated and Bnip3, Beclin-1 and LC3H1 proteins were increased. Acu/LFES treatment reversed these changes. Exercise control in mice also increased autophagy-lysosomal related protein LC3-II, Beclin-1, P62 and Vps34. The levels of these mediators were not additive to changes observed in mice with CKD. We cultured C2C12 myotubes in uremic serum and found increased autophagy markers, indicating activation of autophagosomes. Acidification alone did not stimulate autophagy markers. Based on the above results, the UPS, but not autophagosomes, is responsible for degradation of structural proteins (myosin and actin).

Conclusions: 1) autophagosome-mediated proteolysis occurs in CKD-induced muscle atrophy. In mice with CKD, the UPS was principally involved in muscle proteolysis; the role of autophagosomes was convoluted. 2) Prevention of muscle atrophy by exercise is not due to inhibition of the autophagy-lysosomal proteolysis pathway in CKD. 3) Muscle atrophy cannot be equated with increased autophagy markers. 4) Acu/LFES and exercise promote different autophagy consequences.

FR-PO536

Indoxyl Sulfate, a Uremic Toxin, Accelerates Skeletal Muscle Atrophy in CKD Condition Yuki Emori, Hiroshi Watanabe, Masafumi Fukagawa, Toru Maruyama. 1Dept of Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kumamoto Univ, Kumamoto-shi, Japan; 2Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara-shi, Japan.

Background: Skeletal muscle atrophy is often observed in chronic kidney disease (CKD) patients, especially in patients undergoing hemodialysis. Uremic toxins has been known to link to CKD complications. However there has been no report on the relationship between uremic toxins and skeletal muscle atrophy. The purpose of this study is to investigate the involvement of uremic toxins on skeletal muscle atrophy observed in CKD condition.

Methods: In vitro cytotoxicity of uremic toxins on cell proliferation and differentiation was evaluated by using a mouse myoblast cell line (C2C12). The effect of uremic toxin on proteolysis and protein synthesis system in C2C12 was also evaluated. In the animal study, we examined the contribution of uremic toxin on muscle atrophy using uremic toxin overloaded half- or 5/6-nephrectomized mice.

Results: We focused on six protein bound solutes including indoxyl sulfate (IS), indole acetic acid, p-cresyl sulfate, hippuric acid, kynurenic acid and 3-carboxy-4-methyl-5-propyl-2-furanpropanoic acid. Among these uremic toxins, IS significantly increased atrophy-related genes expression but it did not affect differentiation-related genes expression. In the animal experiments, IS-overload reduced body weights and skeletal muscle weights of half- or 5/6-nephrectomized mice, and consequently weakened its muscular endurance. IS-overload mice showed increased skeletal muscle atrophy-related genes expression. In the same experimental condition, IS also induced the expression of inflammatory cytokine and transforming growth factor-β in skeletal muscle cells.

Conclusions: IS is the potent uremic toxin inducing skeletal muscle atrophy associated with CKD by increasing muscle atrophy-related genes.

FR-PO537

Myostatin Stimulates Progenitor Cells to Differentiate into Fibrocytes Leading to Muscle Fibrosis in Chronic Kidney Disease Liping Zhang,1 Jingliling Dong,2 William E. Mitch,1 Medicine/Nephrology, Baylor College of Medicine Houston, TX; 2LIFE Sciences & Engineering College, Northwest Univ for Nationalities, Lanzhou, Gansu, China.

Background: In chronic kidney disease (CKD), fibrosis develops in damaged kidneys leading to loss of functions. Fibrosis in muscle also complicates CKD but the identity of cells developing into fibrocytes and mechanisms causing fibrosis are not defined. The potential precursors of muscle fibrosis are mesenchymal progenitor cells (fibroblasts and adipogenic progenitors (FAPs)) while mechanisms causing fibrosis include myostatin as...
CKD raises its expression and muscle injury can stimulate injured muscles to develop fibroblasts. Our hypothesis is that CKD stimulates myostatin expression causing FAPs to differentiate into fibrocytes. 

**Methods:** 1) we isolated and cultured FAPs, adding recombinant myostatin to determine if it causes FAPs to proliferate and differentiate into fibrocytes. 2) We isolated GFP-labelled FAPs from transgenic, GFP-expressing mice and transplanted them into tibialis anterior (TA) muscles of CKD mice. We assessed conversion of FAPs into GFP-fibrocytes using α-SMA expression. 3) CKD mice were injected with an anti-myostatin peptide to determine if myostatin stimulates muscle fibrosis. 4) Interactions between myostatin signaling and FAP conversion to fibrocytes were tested by knocking down Smad3 with a lentivirus expressing Smad3 siRNA. 

**Results:** In cultured FAPs, myostatin stimulated their proliferation and conversion into fibrocytes and there is proliferation of FAPs in injured muscles of CKD mice. GFP-labelled FAPs were transplanted into TA muscles of CKD mice and differentiated into fibrocytes identified as expressing the fibrosis marker, α-SMA. FAP proliferation and muscle fibrosis were prevented in CKD mice injected with the anti-myostatin peptide. Finally, Smad3 knock-down blocked FAP differentiation into fibrocytes indicating that a myostatin to Smad3 pathway is responsible for the conversion of FAPs to fibrocytes.

**Conclusions:** CKD stimulates myostatin production to activate FAPs which differentiate into fibrocytes. The process is blocked by an anti-myostatin peptide, providing a new target for preventing muscle fibrosis as a complication of CKD.

**Effect of Methoxy Polyethylene Glycol – Epoetin Beta on Plasma Levels of MMP-9, sFAS, sFAS-like, TNF-RI, and sFAS-Ligand in Patients with CKD:** Piotr Bartnicki, Ewa Majewska, Zbigniew Baj, Jacek Rysz. 1Dept of Nephrology, Hypertension and Family Medicine, Medical Univ of Lodz, Poland; 2Dept of Pathophysiology and Immunology, Medical Univ of Lodz, Poland.

**Background:** In patients with CKD are observed disturbances of immune cell function and endothelium dysfunction with high tissue fibrosis. ESAs using in these patients, beyond anemia correction seem to have renoprotective effect and slow progression of CKD. In this study we aimed to determine effect of methoxy polyethylene glycol – epoetin beta (Mircera) on plasma levels of selected parameters in predialysis patients with CKD.

**Methods:** 28 patients with CKD and anemia, treated with Mircera, were enrolled to the study. The healthy control group included 15 volunteers. Plasma levels of evaluated parameters were measured with available enzyme – linked immune-serum-sorbent assay (ELISA) kit.

**Results:** The results of our study are shown in the table.

**Conclusions:** Plasma concentrations of evaluated parameters are significantly higher in CKD patients in comparison to control group. After ESA treatment plasma level of TNFRI was significantly higher and MPP-9 was significantly lower in CKD patients. These data suggest that Mircera used in correction of anemia in CKD might influence on immune cells function, apoptosis and tissue fibrosis.

**FR-PO539**

**Background:** Therapeutic control of anemia in chronic kidney disease (CKD) is assessed by monitoring hemoglobin (Hb) levels. However, monitoring Hb alone could potentially fail to reveal pathological changes in erythrocytes, because erythrocyte lifespans are shorter in CKD. Shortening of erythrocyte lifespans may attenuate erythropoietin response, resulting in poor progression of CKD. Erythrocyte lifespans are thought to be shortened by qualitative changes such as deterioration of deformability and stability, but it is not clear whether these aspects are changed in CKD.

**Methods:** To assess qualitative changes in erythrocytes were first confirmed in a rat model of iron-deficiency anemia. Deformability was quantified by laser diffraction ectacytometry and stability was quantified by hemolysis test. We next produced CKD model rats, and performed an antibody injection plus anemia enrichment. Epoetin beta pegol (E.R.A. 25 mg/kg) was intravenously injected the day after surgery. At 11 kws, Hb levels, erythrocyte deformability and stability, plasma urea nitrogen (UN) and creatinine (pCre) were assessed.

**Results:** Iron-deficiency rats showed significant anemia and had impaired erythrocyte deformability and stability. These changes in erythrocytes were almost normalized by administration of iron sucrose. In the CKD model, Hb level was significantly decreased and deformability and stability of erythrocytes were significantly impaired. Stability significantly recovered and deformability tended to recover in the C.E.R.A. group, although there was no significant difference in Hb levels between the disease group and C.E.R.A. group. Kidney function (UN and pCre) correlated significantly with stability, but not with deformability. Morphologic parameters (mean corpuscular volume and red cell distribution width - standard deviation) did not reflect changes in deformability and stability.

**Conclusions:** Deformability and stability of erythrocytes were impaired in CKD rats, and may be linked with kidney dysfunction. Focusing on qualitative aspects of erythrocytes may provide a better understanding of pathological conditions and therapeutic benefit in anemia.

**FR-PO540**

**Eryptosis in Chronic Kidney Disease:** Grazia Maria Virzi, Anna Clementi, Alessandra Brocca, Massimo de Cal, Claudio Ronco. Nephrology-IRIV.

**Background:** Even though anemia in CKD results mainly from the lack of erythropoietin, accelerated erythrocyte death(eryptosis) seems to be a contributor factor. Eryptosis is characterized by cell shrinkage and cell membrane scrambling with phosphatidylserine(PS)-exposure at the erythrocyte (RBC) surface. Eryptosis may be triggered by some urmic toxins. P-cresol is an urmic toxin which has negative cardiovascular and cytopathic effects. This study explored if eryptosis is triggered by p-cresol and if different stages of CKD may influence erythrocyte death.

**Methods:** RBCs from healthy subjects were incubated in a plate at a hematocrit of 0.4% with different concentrations of p-cresol (0-2.5-5-10-20-40 ug/ml) and with plasma from CKD patients (5 for each stage) for 24 hours. PS exposure was estimated from Annexin V binding in flow cytometer.

**Results:** Increasing concentrations of p-cresol modified significantly the percentage of PS exposure on RBC surface, thus suggesting that increasing concentrations of p-cresol may stimulate eryptosis in vitro. Moreover, there was no significant difference in terms of median values of eryptosis between CKD stages, but a positive trend was evident: eryptosis increase with CKD progression.

**Conclusions:** In addition to its known cardiovascular and cellular effects, p-cresol seems to stimulate eryptosis in vitro and increasing concentrations of this urmic toxin may be responsible for higher levels of eryptosis in vivo. Our data show that CKD plasma contains components able to trigger eryptosis and different stages of CKD may be responsible for different levels of RBC death, thus suggesting that progression of CKD may increase eryptosis in vivo. These results suggest a role of urmic toxicity in the genesis of eryptosis and renal anemia. It is necessary to increase the sample size to validate our hypothesis.

**Palmitate Exacerbates Renal Anemia: Suppression of Renal Erythropoietin Production via Endoplasmic Reticulum Stress** Reiko Inagaki, 1 Thtinun Anusornvongchai, 1 Yu Ishimoto, 2 Akira Okada, 2 Norio Suzuki, 2 Masayuki Yamamoto, 3 Massomi Nangaku, 2 Division of CKD Pathophysiology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan; 3Division of Nephrology and Endocrinology, The Univ of Tokyo Graduate School of Medicine, Tokyo, Japan; 4Tokyo Univ School of Medicine, Sendai, Japan.

**Background:** Derangement of erythropoietin (EPO) production in renal EPO-producing (REP) cells causes renal anemia. Palmitate induces endoplasmic reticulum (ER) stress response and contributes to glomerular and tubular cell damages. Thus, we evaluated the effect of palmitate-ER stress axis on EPO production in REP cells.

**Methods:** C57BL/6 mice, in which the renal EPO gene was replaced with GFP or REP cells were lineage labeled with tdTomato, were daily injected with palmitate...
hypoxia (HIF activation with CoCl$_2$) and CKD vs. control mice. In order to determine a cause and effect relationship, SIRPa was added, the results of the analysis remained the same. Additionally, fibrosis marker α-SMA was increased in cardiac muscles of mice with CKD and cardiac muscle cell lysates.

Conclusions: EPO production by REP cells was suppressed by palmitate, especially under hypoxic condition, via the ER stress pathway (ATF4 activation). The link between dyslipidemia (palmitate) and ER stress may contribute to development and progression of renal anaemia, and subsequent CKD and highlight the impact of palmitate diet on CKD progression.

Retinal Microvascular Abnormalities and Incidence and Progression of Chronic Kidney Disease Charumathi Sabanayagam,1,2 Peng Guan Ong,1 Boon Wee Teo,2 Carol Y. Cheung,2 Ching-Yu Cheng,2 Ecosse L. Lamoureux,2 Tien yin Wong,1,2 Singapore Eye Research Inst, Singapore; 1Office of Clinical Sciences, Duke-NUS Graduate Medical School, Singapore; 2National Univ of Singapore, Singapore.

Background: To examine the longitudinal association of a panel of retinal vascular parameters, markers of microvascular damage, with the incidence and progression of chronic kidney disease (CKD) in middle-aged Asian adults.

Methods: The population consisted of a cohort of Malay adults aged 40-80 years examined from 2004-06 and again from 2010-2012 (n=1464; 136 free of CKD and 158 with pre-existing CKD). The outcomes were incidence (estimated glomerular filtration rate <60 mL/min.1.73 m$^2$) and progression of CKD (drop in eGFR category). Retinal vascular parameters (arteriolar and venular caliber, tortuosity, branching angle, and fractal dimension were measured from baseline retinal photographs using a computer-assisted program (Singapore I Vessel Assessment, SIVA). Retinopathy was graded using a standard protocol. Associations were examined using Cox proportional hazards regression models adjusting for age, sex, blood glucose, systolic blood pressure and baseline eGFR.

Results: Over a median follow-up of 6.6 years, 6.4% (70% had diabetes) developed incident CKD and 26.6% (62% had diabetes) developed progressive CKD. In multivariable models, retinal arteriolar narrowing, retinal venular widening, and presence of retinopathy were independently associated with CKD. The HR (95% CI) of incident CKD was 1.31 (1.01-1.72) per SD decrease in arteriolar caliber, 2.20 (1.10-4.41), for tertile 3 vs. tertile 1 of venular caliber; 2.06 (1.24-3.44) for retinopathy. Increased arteriolar tortuosity alone was associated with progressive CKD (1.57 [1.04-2.37] per SD decrease. All associations were consistently present among those with diabetes.

Conclusions: Retinal vascular abnormalities increased the risk of CKD by more than two times in Asian adults. Our findings provide evidence that retinal imaging may be a useful tool to improve risk stratification for CKD.

FR-PO545

Relationship Between Serum Bilirubin and Hyaluronic Acid in Renal Arterioles Tsuyoshi Miyagi,1 Kentaro Kohagura,2 Yusuke Ohya,1 Kunitoshi Iseki.1 1Dept of Cardiovascular Medicine, Nephrology and Neurology, Univ of the Ryukyus, Nishihara-cho, Okinawa, Japan; 2Dialysis Unit, Univ of the Ryukyu, Nishihara-cho, Okinawa, Japan.

Background: It has been suggested that there is a relationship between serum bilirubin and arterial stiffness. In the present study, we examined the relationship between serum bilirubin levels and the hyaluronic acid content of renal arteries in patients with chronic kidney disease (CKD).

Methods: We reviewed the clinical records of 138 patients with CKD (mean age: 44 years) who underwent renal biopsy at our department during a 3-year period starting in 2010. Patients who were receiving calciuminhibitors were excluded. The subjects were divided into three groups based on their total serum bilirubin levels: tertile group 1 (0.2-0.4 mg/dl; 40 patients), tertile group 2 (0.5-0.7 mg/dl; 61 patients), and tertile group 3 (0.8-1.4 mg/dl; 37 patients). Using the pathological specimens obtained from renal biopsies, the hyaluronic acid content of renal arteries was semiquantitatively evaluated, and the mean score of renal arterial hyaluronic acid grade was used for analysis.

Results: Tertile group 1 had markedly higher urinary protein levels and markedly lower serum hemoglobin (HB) levels than tertile group 3. We defined total serum bilirubin levels under 0.5 mg/dl (tertile group 1) as low and divided them into two groups of values under and above 0.5 mg/dl. These were set as explanatory factors, and a multiple regression analysis was performed, with the degree of hyaluronic acid content of renal arterioles as the objective variable. A low serum bilirubin level was a significant risk factor for the hyaluronic acid content of renal arterioles ($R^2 = 0.45$, $\beta = 0.26$, $p = 0.003$), even when adjustments were made for age, sex, HbA1c levels, mean blood pressure, history of smoking, and LDL cholesterol levels. Furthermore, even when the explanatory factor of serum HB level was added, the results of the analysis remained the same.

Conclusions: Low serum bilirubin levels may be a risk factor for the hyaluronic acid content of renal arterioles independent of classical risk factors of cardiovascular disease.
FR-PO546
Autonomic Nervous Dysfunction in Predialytic Chronic Kidney Disease: 3 Years Observational Follow-Up Study
Su Min Park, Sang Heon Song, Eun Young Seong, Ihm Soo Kwak, Harin Rhee, Il Young Kim, Woo Jin Jung, Jong Man Park, Dong Won Lee, Soo Bong Lee, Min Jung Kim, Joo Hui Kim. Internal Medicine, Pusan National Univ School of Medicine, Busan, Republic of Korea.

Background: Generally, sympathetic overactivity and impairment of the parasympathetic system are often seen in patients with dialytic CKD, COPD, RA as well as elderly. Also, arterial stiffness and edema have been related with mortality in patients with cardiovascular disease. However, to date, few data regarding autonomic nervous system, vascular stiffness, edema in pre-dialytic CKD were proposed. This study was designed to explore the interrelationship of those parameter in pre-dialytic CKD (G3, 4) and uncover the risk factor related with renal functional deterioration.

Methods: Thirty-three patients were enrolled. Hydration status (extracellular water [ECW]/total body water [TBW]) was determined by bioimpedance analysis. Brachial-ankle pulse wave velocity (baPWV) and neck ultrasoundography for carotid plaque and intima-media thickness were conducted for checking up of vascular status. CAN was scored using Ewing’s method and we also expressed the standard deviation of normal-to-normal interval (SDNN), low frequency/high frequency ratio (LF/HF ratio). Serum creatinine change over a median follow-up of 3 years was used for assessment of renal function.

Results: Of the 33 patients, 14 (42%) have suffered with CAN. Patients with CAN have higher progressive declining rate of renal function, baPWV, systolic BP compared with patients without CAN. The group having declining renal function has higher CAN score, baPWV and lower SDNN compared with preserved renal function group. CAN score correlated positively with ECW/TBW (r=0.405, p<0.019), mean PWV (r=-0.623, p=0.001) and SBP (r=0.513, p=0.002). CAN score correlated negatively with declining rate of renal function (r=-0.471, p=0.006), HCR (-0.659, p<0.001) and albuminuria (r=-0.484, p=0.004).

Conclusions: Autonomic nervous dysfunction including lower SDNN and increased arterial stiffness is associated with progression of renal dysfunction in pre-dialytic CKD patients. Also, autonomic nervous dysfunction was related with arterial stiffness and edema.

FR-PO547
Inhibition of EGFR Alleviates the Development and Progression of Hyperuricemic Nephropathy in Rats
Na Liu,1 Li Wang,1 Andong Qiu,2 Shougang Zhuang.1 1Nephrology, Shanghai East Hospital, Tongji Univ School of Medicine, Shanghai, China; 2School of Life Science and Technology, Advanced Inst of Translational Medicine, Tongji Univ, Shanghai, China; Dept of Medicine, Rhode Island Hospital and Brown Univ School of Medicine, Providence.

Background: Hyperuricemia is an independent risk factor for chronic kidney disease and contributes to kidney fibrosis. In this study, we investigated the effect of epidermal growth factor receptor (EGFR) inhibition on the development of hyperuricemic nephropathy (HN) and the mechanisms involved.

Methods: In this experiment, we did Cell Culture and Treatments, processed the establishment of Hyperuricemic nephropathy (HN) model, assessment of serum uric acid, renal Function and other biochemistry index, performed Immunoblot Analysis, Immunohistochemical Staining, as well as ELISA analysis.

Results: In a rat model of HN induced by feeding a mixture of adenine and potassium oxonate, increased EGFR phosphorylation and severe glomerular sclerosis and renal interstitial fibrosis were evident, accompanied by renal dysfunction and increased urinary microalbumin excretion. Administration of gefitinib, a highly selective EGFR inhibitor, prevented renal dysfunction, reduced urine microalbumin and inhibited activation of renal interstitial fibroblasts and expression of extracellular proteins. Gefitinib treatment also inhibited hyperuricemia-induced activation of the transforming growth factor-β1 (TGF-β1) and nuclear factor-kB (NF-kB) signaling pathways and expression of multiple profibrogenic cytokines/chemokines in the kidney. Gefitinib treatment prevented renal dysfunction, reduced urine microalbumin and inhibited activation of the transforming growth factor-β1 (TGF-β1) and nuclear factor-kB (NF-kB) signaling pathways and expression of multiple profibrogenic cytokines/chemokines in the kidney. Gefitinib treatment also inhibited hyperuricemia-induced activation of the transforming growth factor-β1 (TGF-β1) and nuclear factor-kB (NF-kB) signaling pathways and expression of multiple profibrogenic cytokines/chemokines in the kidney.

Conclusions: Thus, blocking EGFR can attenuate development of HN via suppression of TGF-β1 signaling and inflammation, and promotion of the molecular processes that reduce uric acid accumulation in the body.

FR-PO548
Probiotic and Yogurt Consumption Is Associated with a Lower Prevalence of Albuminuria: A Cross-Sectional Analysis of NHANES
Rabi Yacoub, Girish N. Nadkarni, Deepak Kaji, Shanti N. Patel, John C. He, Steven G. Coca, Jaime Uribarri. Medicine/Nephrology, Icahn School of Medicine at Mount Sinai, New York, NY.

Background: Animal data suggest that probiotic supplements may retard CKD progression. Yogurt is the most widely available probiotic food in the United States. Yogurt is the most widely available probiotic food in the United States.

Methods: We utilized NHANES data with reported one year yogurt consumption frequency and probiotic use and kidney parameters has not yet been evaluated. We aimed to study this association in the National Health and Nutrition Examination Survey (NHANES) database.

Methods: We utilized NHANES data with reported one year yogurt consumption frequency and probiotic use and kidney parameters has not yet been evaluated. We aimed to study this association in the National Health and Nutrition Examination Survey (NHANES) database.

Results: We had complete data on 6853 participants (mean age 48.3±20.4 years, male of which, 1359 (20.3%) were frequent consumers and 918 participants (12.2%) had detectable albuminuria (Median=67.1, IQR=41.6-157.1 mcg/mg). Frequent consumers had a trend towards lower mean UACR compared to non-consumers (mean difference (MD): -12.3, 95% CI -29.8 to 5.2, P=0.17) that was attenuated after complete adjustment. On the other hand, frequent consumers had decreased odds of albuminuria (UACR > 30 mcg/mg) compared to non-consumers (adjusted Odds Ratio 0.79; 95% CI 0.63-0.97; P=0.03).

Conclusions:

Neither CKD III-V prevalence, nor continuous eGFR was significantly different between the consumers and non-consumers.

FR-PO549
Assessment of Serum Levels of Heavy Metals in Patients with Chronic Kidney Disease of Unknown Etiology
Om Prakash Kalra,1 Akash Gupta,1 Alpana Raizada,1 Sunil Agrawal,2 Basu Dev Banerjee.1 1Medicine, UCMS and GTB Hospital, Delhi, India; 2Biochemistry, UCMS and GTB Hospital, Delhi, India.

Background: Chronic kidney disease (CKD) encompasses a wide spectrum of different etiologic processes associated with abnormal kidney function and gradual progressive decline in glomerular filtration rate. CKD of unknown etiology (CKDu) has emerged as an important entity accounting for approximately 10% of CKD patients worldwide. Of the environmental toxins implicated in causation of CKDu, heavy metals form an important group. In the present study, we estimated the serum levels of lead, cadmium, arsenic and chromium in patients with CKDu and evaluated their role in the etiopathogenesis of CKDu.

Methods: The study was conducted in the Departments of Medicine and Biochemistry at University College of Medical Sciences and GTB Hospital, Delhi from December 2013 - April 2015. It was a case control, cross sectional study. Ninety subjects in the age group 18 – 60 years of either sex were divided into 3 groups: Group I: Healthy controls (n=30), Group II: Individuals satisfying case definition of CKDu(n=30) and Group III: Individuals having CKD of known etiology (CKDK)(n=30). Detailed history, complete physical examination, laboratory investigations including hemogram, serum electrolytes, liver function tests, serum creatinine, serum uric acid, serum albumin, ECG, ultrasound imaging of kidneys and urinary bladder, urinalysis, estimation of glomerular filtration rate, serum calcium, serum phosphorus, serum albumin, serum cholesterol, serum triglycerides, serum uric acid, serum creatinine, serum urea were recorded. Heavy metals (lead, cadmium, chromium) were estimated in serum using atomic absorption spectrophotometry.

Results: The median levels of lead, cadmium and chromium were significantly higher in patients of group II and this difference was statistically significant as compared to subjects of group I and III. The median levels of arsenic in patients of group II and III were similar but significantly higher than patients of group I. The levels of arsenic, cadmium and chromium demonstrated healthy controls (group I) vs patients of group II and III were similar but significantly higher than patients of group I.

Conclusions: As compared to healthy controls, the serum levels of lead, cadmium, arsenic and chromium were found to be significantly higher in patients of CKDu. The study indicates a possible role of heavy metals in causation of CKDu.

FR-PO550
High Prevalence of Elevated Molybdenum Levels in CKD Patients
Guido Filipp,1 Vladimir Belostotsky,1 Marta Caroline Kobrymski,1 Shih-Han Su,2 Filler,1 Li Wu,1,2 Peng Ying,1 Prakash 1 Medicine, Univ of Western Ontario, London, ON, Canada; 2Pathology and Laboratory Medicine, Univ of Western Ontario, London, ON, Canada; 3Paediatrics, McMaster Univ, Hamilton, ON, Canada.

Background: Molybdenum (Mo, atomic number 42) is an essential trace element present in water and is crucial for human survival because four mammalian enzymes harbor a pterin-based Mo cofactor (Moco) at their active site and are Mo-dependent. Mo can be lethal in high doses, and chronic toxicity in animals leads to stunted growth, skeletal abnormalities, anemia, and histological changes in the kidney and liver. There is no information about Mo levels in patients with CKD.

Methods: After approval by the ethics board, and as part of a larger study on zinc supplementation in CKD, we studied 87 plasma Mo and copper (Cu) levels in 50 children with an eGFR <90 and >15 mL/min.1.73 m2 using the Schwartz formula. Where available, the Mo and Cu levels were also determined using graphite furnace atomic absorption spectrophotometry.

Results: We observed a positive correlation of Mo levels with age (r=0.47, p=0.01) and duration of dialysis (r=0.69, p<0.001). The Mo levels in patients with dialysis were significantly higher than those in healthy controls (p<0.001).

Conclusions: Despite the lower prevalence of Mo deficiency in the general population, Mo may play an important role in the pathogenesis of CKD, and future studies are needed to determine the exact mechanisms by which Mo levels are associated with CKD.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

FR-PO551
High Prevalence of Elevated Vanadium Levels in CKD Patients

Guido Filler, 1,2 Vladimír Belostotsky, 1 Marta Caroline Kobrzynski, 1 Lijiu Yang. 1

1PaeDiatrics, Univ of Western Ontario, London, ON, Canada; 2Pathology and Laboratory Medicine, Univ of Western Ontario, London, ON, Canada;

Background: Vanadium (V, atomic number 23) is an essential trace element present in many industrial products, especially in steel, which can be very toxic if levels are too high. The excretion of vanadium by the kidneys is rapid with a biological half-life of 20-40 hours.

Methods: After approval by the ethics board, and as part of a larger study on zinc supplementation in CKD, we studied 87 plasma V levels in 50 children with an eGFR < 90 ml/min/1.73 m² patients and 186 controls without CKD. CKD was defined as estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m² or presence of albuminuria. Multivariable analyses were used to examine the relationship of plasma chymase and CKD.

Results: The mean Schwartz eGFR was 46±23 and the Cystatin C eGFR was 48±20 mL/min/1.73 m². The median Mo level was 2.26 (interquartile range 1.7, 3.3 ug/L, mean 2.78±1.70 ug/L), significantly higher than the upper reference interval of 1.4 ug/L, and with an exponential increase with lower eGFR.

Conclusions: With worsening kidney function, Mo levels accumulate, while Cu levels remain unaffected.

FR-PO552
Chronic Nicotine (Ch-Nic) Exacerbates Subpressor Angiotensin II (SP-AngII) Induced Renal Dysfunction in Part via the Renal Sympathetic Nervous System

Kiran B. Chandrashekhar, 1 Rodrigo Maranon, 2 Arnaldo F. Lopez-Ruiz, 1 Andrea F. Soljancic, 1 Istvan Arany, 1 Luis A. Juncos, 1 Nephrology, UMMC, Jackson, MS; 2Physiology, UMMC, Jackson, MS.

Background: Ch-Nic exacerbates SP-AngII-induced renal dysfunction and vascular remodeling while having minimal changes on blood pressure. However, the mechanisms are incompletely understood. Because Ch-Nic activates the renal sympathetic nervous system, we hypothesized that this activation contributes to nicotine’s deleterious effects on SP-AngII-induced renal dysfunction and injury.

Methods: Sprague Dawley rats underwent either sham or renal denervation (RD) surgery and then subdivided to get nicotine (12 g/ml) or vehicle (saccharine 2%). These were randomized to get either SP-AngII (SQ, 200ng/kg/min) or vehicle (saline). Hemodynamic measurements were performed in anesthetized animals and tissue collected for biochemical analysis.

Conclusions: Chronic nicotine reduces blood pressure control in Ch-Nic+SP-AngII group, it provided protection against the renal effects of Ch-Nic in the SP-AngII rats. These results support a role for the sympathetic nervous system in SP-AngII-induced renal dysfunction, as well as in the exacerbating effect of Ch-Nic on SP-AngII mediated renal dysfunction.

Elevated Plasma Chymase Is Associated with Risk of Chronic Kidney Disease

Jing Chen, 1 L. Lee Hamn, 1 Damodar R. Kumbala, 1 Chung-shuan Chen, 1 Kevin K. Wu, 1 Swapna G. Kallu, 1 Ravsi Siriki, 1 Shilpa Gadge, 1 Arnold B. Alper, 1 Myra A. Kleinpeter, 1 Vecchi Batuman, 1 Eric E. Simon, 1 Gabriel Navar, 1 Jiange He, 2, 3 Medicine, Tulane School of Medicine, New Orleans, LA; 2Epidemiology, Tulane School of Public Health and Tropical Medicine, New Orleans, LA; 3Nephrology, Ochsner Health System, New Orleans, LA.

Background: Chymase is the primary enzyme that mediates angiotensin II formation independent of angiotensin-converting enzyme and also play a role in activating transforming growth factor-beta and matrix metalloproteinase-9. Experimental studies suggest that it may cause renal and cardiac fibrosis. However, the association of circulating chymase with chronic kidney disease (CKD) is not well studied.

Methods: We investigated the association of chymase and the risk of CKD in 163 CKD patients and 186 controls without CKD. CKD was defined as estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m² or presence of albuminuria. Multivariable analyses were used to examine the relationship of plasma chymase and CKD.

Results: The mean Karnofsky performance index was 85.0. Multivariable-adjusted means (interquartile ranges) were 1.6 (1.1, 2.2) in patients with CKD vs. 1.2 (0.7, 1.9) pg/mL in controls without CKD (p=0.002 for group difference) after adjusting for age, gender, race, physical activity, smoking, drinking, systolic blood pressure, glucose, low-density lipoprotein cholesterol, body mass index, and history of cardiovascular disease. After adjustment for the above risk factors, the odds ratio for CKD comparing the highest to the lowest tertile of chymase was 2.85 (95% confidence interval, 1.41-5.76).

Conclusions: These data indicate that elevated circulating chymase is associated with risk of CKD.

Methionine Sulfoxide Reductase A (MsrA) Protects Progression of Kidney Fibrosis After Unilateral Ureteral Obstruction
Mi Ra Noh, 1, 2, Jose Kim
Dept of Anatomy and BK21 Plus, Kyunggook National Univ School of Medicine, Daegu, Republic of Korea; 1Dept of Molecular Medicine and MRC, Keimyung Univ School of Medicine, Daegu, Republic of Korea.

Background: Methionine sulfoxide reductase A (MsrA) reduces oxidized methionine and protects cells against oxidative stress. Oxidative stress accelerates kidney fibrosis. Here, we investigated the role of MsrA in unilateral ureteral obstruction (UUO)-induced kidney fibrosis using MsrA gene-deleted mice.

Methods: MsrA+/+ and MsrA−/− male mice were subjected to UUO. Kidneys were harvested 5 days after the UUO surgery.

Results: UUO reduced MsrA expression and activity in the kidney. UUO resulted in expansion of interstitial area with increased collagen deposition. In addition, UUO increased the levels of u-smooth muscle actin and collagen III expression. MsrA deficiency significantly enhanced collagen deposition and expression of those proteins. UUO resulted in the increase of hydroxyl peroxide (H₂O₂) formation and lipid peroxide in both MsrA−/− mouse kidneys and MsrA+/+ mouse kidneys, and these increases were significantly higher in MsrA−/− mouse kidneys than in MsrA+/+ mouse kidneys. Furthermore, post-UUO increases in the oxidized glutathione ratio to total glutathione were significantly greater in MsrA+/+ mouse kidneys than in MsrA−/− mouse kidneys. Number of F4/80 expressing cells increased in the kidney after UUO. These increase of F4/80 expressing cells were greater in MsrA−/− mouse kidneys than in MsrA+/+ mouse kidneys. Levels of Ly6G, a marker of granulocyte, were also higher in MsrA−/− mouse kidneys than in MsrA+/+ mouse kidneys.

Conclusions: In conclusion, MsrA protects kidney against UUO-induced fibrosis, suppressing oxidative stress and inflammatory responses.

The Soluble Urokinase-Type Plasminogen Activator Receptor Serum Levels in Adults with Nephrotic Syndrome Qiuling Fan, Nephrology, The First Hospital of China Medical Univ.

Methods: The serum levels of soluble urokinase type fibrinolytic enzyme activators receptor (suPAR) in adults with nephrotic syndrome were analyzed.

Results: The serum levels of soluble urokinase type fibrinolytic enzyme activators receptor (suPAR) in 70 nephrotic syndrome patients with membranous nephropathy, diabetic nephropathy group, lupus nephritis, minimal change kidney disease and focal segmental glomerular sclerosis group was detected by enzyme-linked immunosorbent assay. The relationship between the clinical parameters and suPAR levels were analyzed.

Conclusions: Serum soluble urokinase receptor levels of nephrotic syndrome patients are significantly higher than the normal control group (P < 0.01). The serum suPAR levels of FSGS and MN patients were significant higher than MCD patients (P < 0.05). Serum suPAR level was positively correlated with age, serum creatinine, blood urea nitrogen (rs=0.401 p=0.001; rs=0.286 p=0.016; rs=0.249 p=0.037; rs=0.245 p=0.041; rs=0.247 p=0.039), and negatively correlated with eGFR (rs=−0.265 p=0.048; rs=−0.309 p=0.009).

FR-PO556
Urinary Sodium: Impact on Blood Pressure and Progression of Chronic Kidney Disease Adriano Luiz Ammirati, Maria Eugenia F. Canziani. Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil.

Background: Chronic kidney disease (CKD) is characterized by chronicity and progression of renal damage. The presence of hypertension is related to the progression of renal damage. Diets high in salt have been associated with an increased risk of hypertension. Sodium analysis in the urine of 24 h is considered the standard method to estimate the daily intake of this mineral. The aim of this study was to evaluate the impact of sodium intake estimated by urinary sodium in the urine of 24 hours (Nau24hs) on renal outcomes and their impact on hypertension.

Methods: Data were collected from medical records of 118 patients with CKD in the conservative treatment, that had one Nau24hs dosage and a follow-up of at least five years. Information collected initially and after 5 years were: demographics, etiology of CKD, comorbidities, blood pressure; routine laboratory tests and estimated creatinine clearance (EPI-Cr). The Nau24hs values were classified into two groups by the median and also divided into tertiles and compared with the rate of progression of CKD (fall of the estimated clearance greater than 20% at 5 years) and the change in blood pressure.

Results: Patients had a mean of 186 ± 64 Meq/L of Nau24hs which represented a high sodium intake (10 grams; 96% of patients with sodium intake greater than 6 grams). Patients with Nau24hs > 170 Meq/L had higher systolic blood pressure and those with Nau24hs< 200 meq/L had higher systolic and diastolic blood pressure when compared to other patients. In addition, patients with higher Nau24hs present significant decrease in systolic blood pressure over 5 years. The decrease in creatinine clearance over 5 years (29% of patients) were more frequent in diabetics and those who did not use converting enzyme inhibitors and are also associated with the presence of proteinuria. There was no association of Nau24hs with the progression of renal dysfunction.

Conclusions: In patients with stable and low rate of CKD progression urinary sodium was controlled, with high blood pressure, but was not associated with more pronounced worsening of long-term renal function, probably because these patients were treated more intensively over the pressure control.

Funding: None

FR-PO557
Risk of End-Stage Renal Disease with Longitudinal Change in Filtration Markers Casey Rebolho, Lesley Inker, Yuan Chen, Meredith C. Foster, John H. Eckfeldt, Paul L. Kimmel, Vasan S. Ramachandran, Harold I. Feldman, Chi-yuan Hsu, Andrew S. Levey, Jose Coresh. Chronic Kidney Disease Biomarkers Consortium.

Background: Change in estimated glomerular filtration rate (eGFR) based on creatinine has been proposed as a surrogate outcome in clinical trials of chronic kidney disease (CKD). Risk of end-stage renal disease (ESRD) associated with change in other kidney filtration markers has not been previously assessed in chronic kidney disease (CKD) populations.

Methods: We conducted prospective analyses of the Modification of Diet in Renal Disease (MDRD; N=840; mean age 52 years) and African-American Study of Kidney Disease and Hypertension (AASK; N=1,094; mean age 55 years) trials. Creatinine, cystatin C, β2-microglobulin, and β-trace protein levels were measured in serum samples collected at baseline and at the 24-month follow-up visit and were expressed using CKD-EPI eGFR equations. Multivariable Poisson regression was used to estimate associations between continuous percent change in eGFR for each marker (alone and in combination) with subsequent risk of developing ESRD. Seemingly unrelated regression was used to compare the strength of risk estimates from different models.

Results: In MDRD and AASK, respectively, there were 310 and 161 incident ESRD cases during a median follow-up of 4.7 and 7.1 years. Percent change in eGFR from the four filtration markers was significantly associated with incident ESRD risk (Table). The average percent change in eGFR based on all four filtration markers was more strongly associated with ESRD risk than percent change in eGFR-creatinine alone.

Table. Risk of Incident ESRD Associated with Percent Change in Filtration Markers in MDRD and AASK

<table>

*Adjusted for age, sex, race, body mass index, systolic blood pressure, diabetes, total cholesterol, fSte eGFR for the respective filtration marker

* p<0.05 from seemingly unrelated regression comparing IR for the respective marker vs. IRr for eGFR-Cr

** p<0.01 from seemingly unrelated regression comparing IR for the respective marker vs. IRr for eGFR-Cr

*** p<0.001 from seemingly unrelated regression comparing IRr for the respective marker vs. IRr for eGFR-Cr

Conclusions: Decline in kidney function over two years, assessed using eGFR-creatinine as well as multiple other filtration markers, is associated with ESRD. Novel filtration markers (cystatin C, β2-microglobulin, β-trace protein) may provide additional information about CKD progression beyond creatinine.

Validation and Clinical Associations of a Predictive Model for Progression to Renal Replacement Therapy: A Retrospective Cohort Study James Ritchie, Afshan Ahmed, Oliver J. Wouters, Darren Green, Smeeta Sinha, Donal J. O'Donnogue, Philip A. Kral, 1Salford Royal NHS Foundation Trust, United Kingdom; 1London School of Economics and Political Science, United Kingdom.

Background: Timely planning for initiation of renal replacement therapy (RRT) is vital. Despite existing, validated risk-prediction models, RRT preparation is often based upon clinical judgment. Here, we consider the benefits of applying an existing model (Tangri et al. JAMA, 2011) in a UK secondary care population.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.
Methods: Patients with ≥5 years of potential follow-up were identified from the Chronic Kidney Disease Prognosis Study (CReSIS). 5-year RRT risk was estimated using a logistic regression model incorporating age, gender, eGFR, albuminuria, PO4, Ca2+, HCO3, and albumin.

Results: 728 patients were included in this analysis (median follow-up 4.4 ± 2.4 years), with 118 patients (16%) progressing to RRT. Mean baseline age was 64±14 years and eGFR 34±14 ml/min/1.73m². Risk was right skewed, with 328 (45%) of patients having a 5-year risk of <5%. 80 patients (11%) had a 5-year RRT risk of >30%. The overall area under the curve was 0.89. This did not vary by primary disease: glomerulonephritis (0.87); polycystic kidney disease (0.91); and diabetic nephropathy (0.88).

In higher-risk groups, a greater proportion of patients commenced RRT using peritoneal dialysis, and a smaller proportion commenced RRT as an in-patient. The proportion of patients transplanted listed at the time of starting RRT was greater in the lower risk group than the higher risk group.

Effect and Safety of Sofosbuvir (SOF) Containing Direct-Acting Antiviral (DAA) Hepatitis C Virus (HCV) Therapy in a Real-World Population with Chronic Kidney Disease (CKD)
Guillermo Ortiz,1 Gregory L. Hundemer,1 Elke Backman,2 Ravi I. Thadhani,1 Raymond T. Chung,3 Meghan E. Sisc1 Nephrology Div, MGH, Boston, MA; 2Pharmacy, MGH, Boston, MA; 3Gastrointestinal, MGH, Boston, MA.

Background: Early trials of SOF-based regimens excluded patients with CKD, thus little is known about safety, efficacy, and effect on kidney function.

Methods: We retrospectively evaluated 72 patients with CKD starting DAA treatment (tx) between 11/2013-12/2014. CKD was defined by average eGFR <60ml/min or albuminuria >30mg/g 6 months prior to tx. Safety, tolerability and laboratory results were assessed by chart review. Models predicting sustained virological response (SVR) were performed.

Results: Subjects were aged 61±8 years, 60% white, 22% black, 12% Hispanic, and 74% male. 50% were diabetic, 39% cirrhotic, 54% HCV tx naïve, 39% had prior liver or kidney transplant, and 7% were HIV/HCV coinfected. DAA regimens were: SOF/simeprevir 50%, SOF/Gl capsvir 13%, SOF/ribavirin 28%, other SOF regimens 10%. 8% had a transient creatinine rise ≥0.5mg/dL during tx. Average eGFR on tx was similar to baseline (mean [95% CI]: 57 [52-62] vs. 53 [51–63] ml/min, respectively P=0.26). SVR was 77% (95% CI 66-88). 76% experienced at least 1 adverse effect (AE); only 5% (7%) discontinued tx due to an AE.

Conclusions: SOF-containing DAA regimens are effective and relatively safe in patients with CKD. Although AEs were common, serious AEs or significant nephrotoxicity were rare. Lower eGFR at baseline predicted an increase likelihood of HCV cure with SOF-based regimens.

FR-PO561
Risk of Liver Injury After Fluoro-Glucosidase Inhibitors Therapy in Advanced Chronic Kidney Disease Patients: A Population-Based Study
Vincent Wu,1 Chih-chin Kao,1 Tao-min Huang,1 Internal Medicine, National Taiwan Univ Hospital, Taipei; Internal Medicine, Taipei Medical Univ Hospital.

Background: α-glucosidase inhibitors (AGIs) are commonly used to control postprandial blood glucose. However, AGIs-related liver injury has been reported, but whether the relationship of AGIs and liver injury applies to advanced chronic kidney disease (CKD) patients remains uncertain.

Methods: In the nationwide case-control study, we recruited advanced diabetic CKD patients, who has taken AGIs from January 1, 2000 through December 31, 2010 as cases and those who received the AGIs in the past 30 days as controls. The chi-square test was used to analyze the data. The relationship of AGIs and liver injury was evaluated by a multivariate logistic regression analysis.

Results: Subjects were aged 61±8 years, 60% white, 22% black, 12% Hispanic, and 74% male. 50% were diabetic, 39% cirrhotic, 54% HCV tx naïve, 39% had prior liver or kidney transplant, and 7% were HIV/HCV coinfected. DAA regimens were: SOF/simeprevir 50%, SOF/Gl capsvir 13%, SOF/ribavirin 28%, other SOF regimens 10%. 8% had a transient creatinine rise ≥0.5mg/dL during tx. Average eGFR on tx was similar to baseline (mean [95% CI]: 57 [52-62] vs. 53 [51–63] ml/min, respectively P=0.26). SVR was 77% (95% CI 66-88). 76% experienced at least 1 adverse effect (AE); only 5% (7%) discontinued tx due to an AE.

Conclusions: SOF-containing DAA regimens are effective and relatively safe in patients with CKD. Although AEs were common, serious AEs or significant nephrotoxicity were rare. Lower eGFR at baseline predicted an increase likelihood of HCV cure with SOF-based regimens.

Add-On Renoprotective Effect of Pentoxifylline in Pre-Dialysis Advanced Chronic Kidney Disease Treated with Renin-Angiotensin-Aldosterone System Blockade – A Nationwide Database Analysis
Ko-Lin Kuo,1 SZU-Chun Hung,1 Jia-sin Lia,2 Der-Cheng Tang.1 1 Taipei Tzu Chi Hospital, Taiwan; 2 National Health Research Insts, Taiwan; 3 Taipei Veterans General Hospital, Taiwan.

Background: Pentoxifylline decreases proteinuria in patients with glomerular disease due to its anti-inflammatory and anti-fibrotic properties. A combination therapy of pentoxifylline with an angiotensin converting enzyme inhibitor (ACEI) or an angiotensin II receptor blocker (ARB) decreased proteinuria and the glomerular filtration rate (GFR) decline in early chronic kidney disease (CKD). Whether adding pentoxifylline to ACEI/ARB provides additional benefits on renal outcome or survival is unclear in CKD stage 5 patients who have not yet received dialysis (CKD 5 ND).

Methods: A prospective cohort study was conducted based on the Taiwan National Health Insurance Research Database. From January 1, 2000 to June 30, 2009, we enrolled 14,117 CKD 5 ND patients with serum creatinine levels >6 mg/dL and hematocrit levels <28% and who have been treated with ACEI/ARB. All patients were further divided into two groups with or without pentoxifylline within 90 days after starting erythropoiesis-stimulating agent therapy (index date). Patient follow-up took place until dialysis, death before initiation of dialysis or December 31, 2009.

Results: With a mean follow-up of 12 months, 9,867 patients (69.9%) required long-term dialysis and 2,805 (19.9%) died before progression to end-stage renal disease requiring dialysis. After propensity score-matching, add-on use of pentoxifylline was associated with a lower risk for long-term dialysis or death in those treated with ACEI/ARB (HR, 0.94; 95%CI 0.89-0.99) or ARB (HR, 0.91; 95%CI 0.86-0.97).

Conclusions: Pentoxifylline exhibited an add-on renoprotective effect in reducing the risk for long-term dialysis in CKD 5 ND patients who received renin-angiotensin-aldosterone system blockade. Randomized studies are needed to validate this association.

FR-PO563
Novel Therapy Regimens Have Reduced the High Risks of Bladder and Haematological Malignancies in ANCA-Associated Vasculitis
Chinar Rahmatulla,1 Annelies Evaline Berden,1 Sophie-charlotte Wäkker,2 Marlies Reinders,1 Ernst C. Hagen,2 Ron Wolterbeek,1 Jan A. Bruijn,1 Ingeborg M. Bajema.1 1 Leiden Univ Medical Center; 2 Meander Medical Center Amersfoort.

Background: The introduction of immunosuppressive therapy has dramatically improved the prognosis of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). As a result, attention has shifted to long-term complications in patients. In this study, we investigate the incidence of malignancies in AAV patients. Additionally, we investigate the effect of therapy on malignancy incidence.

Methods: We included patients with histopathologically-proven AAV diagnosed at a large university hospital. Malignancy incidence was assessed with the Dutch National Pathology Database, which covers all the histologically confirmed malignancies diagnosed in The Netherlands. We used the Netherlands Cancer Registry incidence rates for comparing the malignancy incidence in our AAV cohort to that of the general Dutch population.

Results: Thirty-six of 138 patients with AAV developed a total of 85 malignancies during a mean follow-up of 9.7 years. We observed 61 non-melanoma skin cancers (NMSCs), three colon carcinomas, three breast carcinomas, three prostate carcinomas, two lung carcinomas, two soft tissue sarcomas, two unknown primary malignancies, and a variety of malignancies that occurred only once. The gender-, age-, and calendar year-adjusted malignancy risk was 2.21-fold (95%CI 1.64–2.92) higher than that of the general population. Only the incidence of NMSCs was significantly increased compared to the general population (standardized incidence ratio: 4.23, 95%CI: 2.76–6.19). Malignancy risk was associated with the duration of cyclophosphamide therapy, and was not increased in patients that received cyclophosphamide for less than 1 year.

Conclusions: AAV patients have a higher risk of malignancies than the general population, but this risk is accounted for solely by NMSCs. Throughout the years, the risk of other malignancies – specifically bladder and haematological malignancies – has decreased in patients with AAV. This finding reflects the beneficial results of ongoing efforts to reduce cyclophosphamide exposure by developing new therapy regimens.

FR-PO564
Effect of Lowering LDL-Cholesterol with Simvastatin plus Ezetimib on Non-Vascular Outcomes in Patients with Chronic Kidney Disease (CKD): Results from the Study of Heart and Renal Protection (SHARP)

Background: The Study of Heart and Renal Protection (SHARP) was a randomized placebo-controlled trial of LDL cholesterol (LDL-C)–lowering among 9270 patients with CKD which showed that combination therapy with ezetimibe 10mg/ simvastatin 20mg (E/S) reduced vascular events with no significant adverse effects on muscle, hepatobiliary outcomes or cancer. However, assessment of the effects of lowering LDL-C on other non-vascular outcomes has not been extensively explored in patients with CKD.

Methods: All post-randomization serious adverse events (SAEs) were routinely recorded. Post-hoc intention-to-treat analyses were performed of the effect of allocation to treatment on time to first non-vascular SAE by system of disease with sub-categories.

Results: During 4.9 years’ median follow-up, similar numbers of participants in the two groups experienced non-vascular SAEs overall (3533 [76.0%]E/S vs 3505 [75.9%] placebo; risk ratio [RR] 1.00, 95% CI 0.95-1.05). After due allowance for multiplicity, there was no evidence of any vascular or non-vascular SAEs on non-vascular systems of disease. Within the class of endocrinology SAEs, there were no significant effects of E/S on any particular individual category of SAE: new-onset diabetes (172 [4.8%] E/S vs 162 [4.5%] placebo; RR 1.06, 95% CI 0.86-1.32 among 3596 vs 3580 participants without diabetes at baseline), diabetes-related complications (136 [2.9%] E/S vs 126 [2.7%] placebo; RR 1.08, 95% CI 0.84-1.37), and other endocrine disorders (58 [1.2%] E/S vs 39 [0.8%] placebo; RR 1.47, 95% CI 0.99-2.19).

Conclusions: In the SHARP trial, allocation to ezetimibe 10mg plus simvastatin 20mg reduced vascular events with no evidence of significant non-vascular hazards.

Association of β-Blocker Therapy with Renal Outcomes in CKD Patients without prior Cardiovascular Disease
Nashiko Fuji,1 Takayuki Hamano,2 Yoshitsugu Obi,2 Yoshitaka Isaka.3 1 Univ of Pennsylvania, Philadelphia, PA; 2 Osaka Univ, Suita, Osaka, Japan; 3 Univ of California, Irvine, Irvine, CA; Osaka General Hospital, Osaka, Japan.

Background: Sympathetic overactivity due to impaired kidney function can deteriorate hypertension, renal failure, and cardiovascular disease (CVD) among CKD patients. Mortality benefit of its antagonist, β-blocker (BB), has been shown in patients with prior CVD; however, such evidences are scarce in CKD patients without CVD. Our aim is to evaluate the association between BB and renal outcomes in such patients.

Methods: We extracted 340 predialysis CKD patients without prior CVD but with drug information at baseline from a Japanese CKD cohort (OVIDS-CKD, N=738). The primary risk for long-term dialysis in CKD 5 ND patients who received renin-angiotensin-aldosterone system blockade. Randomized studies are needed to validate this association.

Conclusions: In the SHARP trial, allocation to ezetimibe 10mg plus simvastatin 20mg reduced vascular events with no evidence of significant non-vascular hazards.

Funding: Pharmaceutical Company Support Merck/Schering-Plough Pharmaceuticals (North Wales, PA, USA), Government Support - Non-U.S.

Lactobacillus plantarum 299v Reduces the Incidence of Clostridium difficile Infection in Patients Treated with Antibiotics in the Nephrological and Transplantation Department Marcin Adamczak, Agata Kujawa-Szewieczek, Katarzyna Kwiecień, Sylwia Małgorzata Dądzicka, Magdalena Gazda, Andrzej Wiecz. Dept of Nephrology, Transplantation and Internal Medicine, Medical Univ of Ślissia, Katowice, Poland.

Background: Lactobacillus plantarum 299v (LP299v) has been introduced into the clinical practice in order to reduce gastrointestinal symptoms during antibiotic exposure. However, it remains controversial whether or not probiotics are also effective in the prevention of Clostridium difficile infections (CDI) among patients receiving antibiotics.

The aim of this clinical, retrospective, single-centre study was to: Analyse the CDI incidence among patients receiving antibiotics and hospitalized in the period before and after initiation of LP299v routine use, as a prevention of CDI, in the nephrology and transplantation ward.

Methods: Among 3533 patients hospitalized in Department of Nephrology, Transplantation and Internal Medicine, Medical University of Silesia in Katowice during two years (October 2012 – October 2013 and December 2013 – December 2014) 23 patients with CDI were diagnosed and enrolled in this study. Since November 2013 prevention of C. difficile infection with the oral use of LP299v was performed in all patients treated with antibiotics and who were at high risk of developing CDI (patients after organ transplantation and receiving immunosuppressive drugs for any other reasons). For the further analysis the observation period was divided into two twelve-months intervals before (October 2012 to October 2013) and after initiation of LP299v use as the prophylactic manoeuvre against CDI (December 2013 to December 2014).

Results: It was found a significant (p<0.0001) reduction of the number of cases of C. difficile infection after beginning of LP299v routinely used n=2; 0.11% of all hospitalized patients in comparison with the previous twelve-month period of observation (n=21; 1.21% of all hospitalized patients).

Conclusions: Routine use of Lactobacillus plantarum 299v during treatment with antibiotics may prevent C. difficile infection, particularly in patients at high risk of CDI in the nephrology and transplantation ward.

Funding: Government Support - Non-U.S.

FR-PO567

Background: Patients with chronic kidney disease (CKD) are commonly prescribed drug doses that are excessive for their kidney function. Many CKD patients are followed solely by a family physician. We wish to determine whether care by both a nephrologist and family physician (i.e. comanagement) versus family physician alone is associated with lower risks of inappropriate antibiotic dosing in patients with stage 4 or 5 CKD.

Methods: A retrospective case-control study was conducted, among individuals aged ≥66 years, with estimated glomerular filtration rate (eGFR) <30 mL/min/1.73 m² using linked healthcare databases from 2003-2014. Cases were antibiotic prescriptions dosed improperly, whereas controls were prescriptions dosed appropriately. Exposure was comanagement, defined as at least one outpatient visit with a nephrologist in the 1 year prior to antibiotic prescription. A multivariable logistic regression model was used to determine the independent association between comanagement and inappropriate dosing.

Results: Of 21,348 eligible prescriptions studied, 64% were inappropriately dosed. The patients were 82 (IQR 76-87) years of age with comorbidities including: hypertension (89%), diabetes (49%), coronary artery disease (49%), and congestive heart failure (38%). 77% of all prescriptions were prescribed by family physicians and 2% were prescribed by nephrologists. Multivariable analysis revealed that patients with appropriate prescriptions were more likely to have seen a nephrologist in the one year prior with an adjusted odds ratio of 1.07 (95% CI 1.01-1.14, p=0.02), adjusted odds ratio 1.23 (95%CI 1.15-1.32, p<0.001).

Conclusions: In patients with stage 4 or 5 CKD prescribed an antibiotic, those with an appropriate dose were 23% more likely to have been cared for by a nephrologist in the previous year. Although we cannot conclude what caused the improved prescribing practice, this improvement may, in part, explain the improved patient outcomes associated with seeing a nephrologist in observational studies.

FR-PO568

Background: While modern immunosuppressive therapies (ISx) have substantially reduced acute rejection, ISx medications have many side effects, and transplant recipients must take an array of “co-medications” to help mitigate complications. Co-medication utilization patterns are not well described in large, representative samples due to lack of available data.

Methods: We constructed national U.S. transplant registry data with pharmacy records (2005-2010) from a large pharmaceutical claims clearinghouse to examine treatments for anemia, metabolic disorders and infections according to ISx regimen in mo 6-12 post-transplant (N=22,453). Associations of ISx with co-medication use (adjusted odds ratio, aOR) were examined with multivariable logistic regression including adjustment for recipient, donor and transplant factors.

Results: Compared to a reference regimen of tacrolimus (Tac), mycophenolate (MPA) and prednisone, rapamycin-based ISx was associated with significantly (P<0.05) higher use of ESAs (aOR 2.52), iron (aOR 2.26), statins (aOR 1.47), fibrates (aOR 2.35), and phosphorous binders (aOR 2.85) (Figure). Cyclosporine-based ISx was associated with more concurrent use of anemia treatments. Compared to those taking triple ISx, recipients of tacrolimus-based dual and mono-therapies had lower use of statins, ACEI/ARBs, and anti-bacterial agents. Recipients of steroid-free ISx were less commonly treated for new onset diabetes.

Association of Urinary Biomarkers of Injury and Repair with Incident Chronic Kidney Disease in Type 2 Diabetes: An Ancillary Study of the ACCORD Trial Girish N. Nadkarni,1 Vecna Rao,2 Faramarz Ismail-beigi,2 Vivian A. Fonseca,3 Sudhir V. Shah,4 Michael S. Simonson,2 Prasad Devarajan,3 Chirag R. Parikh,1 Steven G. Coca,1 Mount Sinai; Yale Univ; Case Western Reserve Univ; Tulane Univ; UAMS; Univ of Cincinnati.

Background: Urinary injury kidney molecule (KIM)-1, monoocyte chemotactant protein (MCP)-1, interleukin (IL)-18, and YKL-40 are biomarkers representing renal injury, inflammation and fibrosis. We evaluated their association with incident CKD in the ACCORD trial.

Methods: We designed a case-cohort study of 721 participants & measured KIM-1, MCP-1, IL-18, and YKL-40 on baseline urine samples with Mesoscale platform. Biomarker associations with CKD3b were modeled continuously & by tertiles using Cox proportional hazards models.

Results: Mean age was 62, 51% were female & baseline eGFR was 88 ml/min. There were 159 incident CKD3b events over median(IQR) of 4.2(3.9-4.7) years. Top tertiles of all biomarkers had higher proportions of incident CKD3b. After adjusting for demographics,
clinical characteristics, baseline eGFR & UACR, highest tertiles of uMCP1 & uKIM1 had adjusted HRs of 1.82(95% CI 1.18-2.81) & 1.51(95% CI 1.01-2.27) respectively. Area under ROC improved from 0.70(with eGFR & UACR) to 0.72 with addition of uMCP1 & uKIM1(p<0.05). No association was seen for urinary IL-18 & YKL-40.

**Methods:** In this cross-sectional study of 883 HIV-infected men enrolled in the Multicenter AIDS Cohort Study, we evaluated associations of TDF exposure with urine α1m levels, using multivariable generalized gamma regression models to adjust for traditional kidney risk factors, and HIV-related risk factors.

**Results:** In adjusted analyses, each year of TDF exposure was associated with 8% higher urine α1m, a 4-fold effect size relative to age (2% per year). Compared with men who never received TDF, α1m levels were 43-50% higher in former and current TDF users. Time since last TDF exposure was only modestly associated with lower α1m.

**Association of Tenofovir Disoproxil Fumarate Exposure with Urine α1-microglobulin, a Biomarker of Proximal Tubule Dysfunction**

**Vasantha Jotwani, Rebecca Scherzer, Michelle M. Estrella, Chirag R. Parikh, Joachim H. Lx, Michael Shlipak.**

**Background:** Tenofovir disoproxil fumarate (TDF) is a well-recognized contributor to HIV-related kidney disease, via proximal tubular injury. Urine α1-microglobulin (α1m), a low molecular weight protein indicative of proximal tubule dysfunction, may enable earlier detection of TDF-associated toxicity.

**Methods:** In this cross-sectional study of 883 HIV-infected men enrolled in the Multicenter AIDS Cohort Study, we evaluated associations of TDF exposure with urine α1m levels, using multivariable generalized gamma regression models to adjust for traditional and HIV-related risk factors.

**Results:** Mean age was 52 and mean eGFR was 90 ml/min/1.73m

**Impact of Kidney Function and Urinary Protein Excretion on Pulmonary Function**

**Yasuuke Nakade, Tadashi Toyama, Shinti Kitajima, Yasuyuki Shinozaki, Akinori Haru, Miho Shimizu, Yasunori Iwata, Norihiko Sakai, Kengo Furuichi, Takashi Wada, Chirag R. Parikh, Joachim H. Lx, Michael Shlipak.**

**Background:** Although the cardiorenal relationship in patients with chronic kidney disease (CKD) has been investigated, information about the lung-kidney relation is limited. Here, we investigated the impacts of kidney function and urinary protein excretion on pulmonary dysfunction.

**Methods:** The data of pulmonary function tests (PFTs) and kidney function tests from 1 April 2005 to 30 June 2010 were selected from our laboratory database. Data were classified into 4 categories according to eGFR and proteinuria. Category 1: eGFR ≥ 60 ml/min/1.73 m

**Results:** A total of 133 participants without major respiratory disease, abnormal computed tomography and smoking history were enrolled. Hb-adjusted %DL<sub>co</sub> in category 4 (46.2 ± 7.5) and category 2 (63.6 ± 17.8) were significantly lower than that in category 1 (75.8 ± 18.9) (P = 0.05). Hb-adjusted %DL<sub>co</sub> was strongly correlated with eGFR in participants with urinary protein ≥ 0.3 g/gCr (R = 0.81, P < 0.001). In addition, eGFR was associated with Hb-adjusted %DL<sub>co</sub> (P = 0.023) and urinary protein tended to be associated with Hb-adjusted %DL<sub>co</sub> (P = 0.095) after adjusting for physical features and the presence or absence of DM and Hypertension.

**Conclusions:** This study suggests that eGFR and urinary protein excretion were associated with pulmonary function (Hb-adjusted %DL<sub>co</sub>).
FR-PO572
Renal Biomarkers in Diabetics, Role Beyond Retinopathy, Relation to Retinopathy

Background: Diabetic nephropathy and retinopathy remain two of the most frequent complications of diabetes and is the leading cause of end-stage renal disease (ESRD) and blindness worldwide. The concordance rate between both complications is often present in diabetic patients.

Methods: We tried to study the relation between renal biomarkers including serum creatinine (SCr), urinary albumin/creatinine ratio (ACR), serum cystatin-C (cysC) and urinary NGAL (uNGAL) with diabetic retinopathy (DR) in 100 diabetic patients. Patients were classified according to severity into 3 stages: no diabetic retinopathy (No DR), Non-Proliferative DR (NPDR) and proliferative DR (PDR).

Results: Urinary ACR, serum cysC and uNGAL were higher significantly among patients with DR (NPDR & PDR) than patients without, while SCr showed a non significant rise with progression of retinopathy. All markers were higher among PDR than NPDR group.

Conclusions: Renal biomarkers namely urinary ACR, serum cysC and uNGAL may point to a more advanced stage of diabetic retinopathy, which might be an aid in identifying the degree of retinopathy beside the traditional fundus examination in diabetic patients.

FR-PO573
Prognostic Importance of Urea and Urea: Creatinine Ratio for Mortality as Compared to Creatinine Concentrations Alone in the General Population
Ronan Cusack,1,2 Austin G. Stack,3 John P. Ferguson,2 1Nephrology, Univ Hospital Limerick, Ireland; 2Graduate Entry Medical School, Univ of Limerick, Ireland; 3Health Research Inst, Univ of Limerick, Ireland.

Background: High Creatinine (Cr) concentrations reflect poor kidney function and is an independent predictor of mortality with Cr being second best. A strong interaction (P< 0.001) between differing models was compared using Akaike Information Criterion (AIC).

Methods: A cohort of 2,059 community-dwelling Japanese subjects aged ≥40 years without chronic kidney disease (CKD) were followed for 5 years. CKD were defined as eGFR <60 mL/min/1.73m² or urine albumin/creatinine ratio (UACR) ≥30 mg/g. The odds ratios (ORs) for the development of CKD and the rates of decline in eGFR were estimated according to quartile of SUA (≤4.0, 4.1-4.9, 5.0-5.8, ≤5.9 mg/dL).

Results: During follow-up period, 396 subjects experienced CKD, of whom 125 had eGFR <60 mL/min/1.73m² and 312 had UACR ≥30 mg/g. The age- and sex-adjusted incidence of CKD increased significantly with higher SUA levels (P trend <0.001). Compared with those with SUA of ≤4.0 mg/dL, the multivariable-adjusted ORs for the development of CKD were 1.21 (95% confidence intervals, 0.84-1.74), 1.47 (1.01-2.17), and 2.10 (1.37-3.23) in subjects with SUA of 4.1-4.9 mg/dL, 5.0-5.8 mg/dL, and ≥5.9 mg/dL, respectively. Likewise, there were positive associations of SUA levels with the adjusted risk of developing eGFR <60 mL/min/1.73m² (OR 1.00 [reference] in ≤4.0 mg/dL, 2.30 [1.10-4.82] in 4.1-4.9 mg/dL, 2.81 [1.34-5.88] in 5.0-5.8 mg/dL, and 3.73 [1.65-8.44], in ≥5.9 mg/dL), and UACR ≥30 mg/g (OR 1.00 [reference], 1.12 [0.76-1.65], 1.35 [0.90-2.03], and 1.81 [1.14-2.87], respectively). Additionally higher SUA was significantly associated with a greater decline in eGFR (P for trend = 0.002).

Conclusions: Higher SUA level is a significant risk factor for the development of both kidney dysfunction and albuminuria in a general Japanese population.

FR-PO574
Keita Takas,2 Masaharu Nagata,3 Kazuhiko Tsuruya,4 Takanari Kitazono,5 Yutaka Kyohara,6 Toshio Ninomiya,7 1Dept of Environmental Medicine, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 2Dept of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 3Center for Cohort Studies, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.

Background: Growing evidence suggests that high serum uric acid (SUA) levels are causally related to an increased risk of kidney dysfunction. However, the association remains inconclusive in general Asian populations. Additionally, there are limited studies investigating the influence of SUA levels on the development of albuminuria.

Methods: A total of 2,059 community-dwelling Japanese subjects aged ≥40 years without chronic kidney disease (CKD) were followed for 5 years. CKD were defined as eGFR <60 mL/min/1.73m² or urine albumin/creatinine ratio (UACR) ≥30 mg/g. The odds ratios (ORs) for the development of CKD and the rates of decline in eGFR were estimated according to quartile of SUA (≤4.0, 4.1-4.9, 5.0-5.8, ≤5.9 mg/dL).

Results: During follow-up period, 396 subjects experienced CKD, of whom 125 had eGFR <60 mL/min/1.73m² and 312 had UACR ≥30 mg/g. The age- and sex-adjusted incidence of CKD increased significantly with higher SUA levels (P trend <0.001). Compared with those with SUA of ≤4.0 mg/dL, the multivariable-adjusted ORs for the development of CKD were 1.21 (95% confidence intervals, 0.84-1.74), 1.47 (1.01-2.17), and 2.10 (1.37-3.23) in subjects with SUA of 4.1-4.9 mg/dL, 5.0-5.8 mg/dL, and ≥5.9 mg/dL, respectively. Likewise, there were positive associations of SUA levels with the adjusted risk of developing eGFR <60 mL/min/1.73m² (OR 1.00 [reference] in ≤4.0 mg/dL, 2.30 [1.10-4.82] in 4.1-4.9 mg/dL, 2.81 [1.34-5.88] in 5.0-5.8 mg/dL, and 3.73 [1.65-8.44], in ≥5.9 mg/dL), and UACR ≥30 mg/g (OR 1.00 [reference], 1.12 [0.76-1.65], 1.35 [0.90-2.03], and 1.81 [1.14-2.87], respectively). Additionally higher SUA was significantly associated with a greater decline in eGFR (P for trend = 0.002).

Conclusions: Higher SUA level is a significant risk factor for the development of both kidney dysfunction and albuminuria in a general Japanese population.

FR-PO575
Do Protein-Energy Wasting Criteria Reflect Protein/Energy Wasting?
Xiaorui Chen,1 G. Wei,2 Robert E. Boucher,1 Dominique Ferranti,1 Michel Chonchal,3 Kalani L. Raphael,4 Srimi Bedhu,5 1U of Utah; 2VA SLC; 3UC Denver.

Background: The term protein-energy wasting (PEW) implies a state of depleted protein and/or energy stores. An International Society of Renal Nutrition and Metabolism (ISRNM) panel proposed objective criteria for the definition of PEW syndrome. However, the extent to which these variables used in PEW syndrome definition are indicative of low protein or energy stores is unknown. Muscle is the largest protein store and fat mass is the largest energy store in the body. Therefore, we examined the associations of these variables with lean body mass (LBM) and fat mass (FM) measured by DXA scans in 11,834 participants in the 1999-2004 National Health and Nutrition Examination Survey (NHANES).

Methods: Definitions of PEW variables are summarized in the table. The associations of each PEW variable with LBM and FM in the entire cohort and CKD (CKD-EPI eGFR < 60) sub-population were examined in linear regression models using svy suite in STATA 13.

Results: Mean age was 46.0 yrs, 50.3% were male, 9.5% were black. 6.7% had CKD. Unintentional weight loss and low levels of serum albumin, serum cholesterol, BMI and MAMC were associated with lower LBM and FM. On the other hand, low protein and energy intakes were associated with higher LBM and FM.

PEW variables Lean body mass (kg) Fat mass (kg) p (95% CI)
Albumin<3.5 g/dl -3.5 (-7.5, 0.4) *3.6 (-7.2, -0.1)
Cholesterol<100 mg/dl -2.5 (-6.8, 1.8) *-5.2 (-10.6, 0.1)
BMI<20 kg/m² -9.7 (-10.3, -9.1) *-14.7 (-14.9, -14.2)
Unintentional weight loss<10% over 1 yr -2.2 (-3.3, -1.0) *-3.8 (-5.2, -2.4)
Body fat %<10% NA NA
Low MAMC* NA NA
Protein intake<0.6 g/kg 3.6 (3.0, 4.2) 6.4 (5.7, 7.0)
Energy intake<25 kcal/kg/day 4.3 (3.9, 4.7) 7.3 (6.9, 7.7)

* 10% or more lower than the 50th percentile of reference group.

Results were similar in the CKD sub-population.
Conclusions: Serum chemistry, body weight and muscle mass PEW criteria appear to be more sensitive of both protein stores (as indicated by LBM) and energy stores (as indicated by FM). Dietary variables are not reflective of protein or energy wasting. A modified PEW syndrome definition without the dietary variables would be a better indicator of PEW syndrome.

FR-PO576
Low-Proteinuric CKD and Risk of ESRD in Nephrology Clinics: Emerging Role of Serum Phosphorus

Luca De Nicola, Michele Provenzano, Paolo Chiodini, Giuseppe Conte, Roberto Minutolo, Nephrology, Second Univ, Naples, Italy; Med Stat, Second Univ, Naples, Italy.

Background: In low-proteinuric (LP) CKD, factors other than proteinuria (Uprot) likely act as predictors of ESRD. However, comprehensive assessment of epidemiologic features of LP versus high-proteinuric (HP) patients is still lacking. This information is critical in renal clinics where LP patients are common.

Methods: We pooled three prospective cohorts that in 2000-2010 enrolled 2,488 CKD patients stage III-V under stable care from ≥6 months in 40 Italian renal clinics. Patients were followed for ESRD (chronic dialysis-transplant) up to 12/2014. Patients were classified in two groups, LP (56%) and HP (44%), by Uprot ≥0.5 and >0.5 g/24h, respectively.

Results: Besides lower Uprot (median, IQR: 0.15, 0.06-0.28 vs 1.20, 0.78-2.05 g/24h), LP differed from HP because male gender (55 vs 62%), diabetes (28 vs 35%) and use of anti-RAS (73 vs 78%) were less frequent. In LP, moreover (70±12 vs 72±14), GFR-EPI (35±21.3±3 vs 26.6±13.2 mL/min/1.73m²) and HB (12±7 vs 17±12 vs 13.1±1.8 g/dL) were higher while systolic BP (137±18 vs 140±18 mmHg) was lower. Serum phosphorus (P was lower (1.17 vs 1.33 mg/dL, p=0.049) and BMI (0.98, 0.92-1.03 vs 1.00-0.01) by answering “yes” to the question “Have you ever been told that you had weak or failing kidneys?“ by patients with PEW syndrome without the dietary variables would be a better indicator of PKD progression and associated comorbidities.

Funding: Other U.S. Government Support

FR-PO578
Intermittent Abnormal Kidney Function and Mortality in Community Dwelling Individuals

Donal J. Sexton, Scott Reule, Robert N. Foley, Medicine, HRB Clinical Research Facility, NUIGalway, Galway, Ireland; Medicine, Univ of Minnesota, Minneapolis.

Background: The health implications of persistently abnormal kidney function as measured by estimated glomerular filtration rate and spot urine albumin excretion has been well characterized to date. However little data is available regarding the implications of intermittent abnormalities in these tests as defined by established thresholds.

Methods: We evaluated the frequency of intermittent abnormal kidney function and its association with all-cause mortality in the US general population using the National Health and Nutrition Examination Survey III, 1998-1994. Mortality linkage data were available through December 2006. Estimated glomerular filtration rate (eGFR) calculated using the CKD-EPI equation and urinary albumin-creatinine ratios (ACR) were measured twice, a mean of 17 days apart (N=1161).

Results: Proportions of abnormal tests included: for eGFR ≥60 mL/min/1.73m² then test 7.32 %, first test 5.94%, second test 5.68%, first test only 1.64%, second test only 1.38%, both tests 4.31%. Compared to participants with eGFR ≥60 mL/min/1.73m² on both testing occasions, adjusted hazard ratios were 1.8 (95%CI 1.3, 2.4) for intermittent and 1.7 (95%CI 1.1, 2.5) for persistent abnormal eGFR. Proportions with ACR ≥30 mg/g were as follows: either test 16.54%, first test 11.63%, second test 13.55%, first test only 3.19%, second test only 4.91%, both tests 8.44%. Compared to those with ACR <30 mg/g on both occasions’ mortality hazard ratios for intermittent abnormal function was 2.1 (95%CI 1.6, 2.7), and persistent abnormal 2.0 (95%CI 1.5, 2.8). Models were adjusted for age, sex, race, diabetes mellitus, cardiovascular disease (congestive heart failure, previous myocardial infarction or stroke), current smoking, self reported hypertension, systolic and diastolic blood pressure, total cholesterol and body mass index.

Conclusions: CKD as defined by established thresholds may be persistent or intermittent in community dwelling individuals. Participants with intermittently abnormal kidney function as defined by current thresholds were at similar mortality risk to those with persistently abnormal on both occasions.

FR-PO579
Renal Outcome of APRT Deficiency Presenting in Childhood

Josefina Hafnhild L. Runolfsdottir, Runolfur Palsson, Inger Maria Agustsdottir, Olafur S. Indridason, Vidar O. Edvardsson, Faculty of Medicine, Univ of Iceland; Div of Nephrology; Children’s Medical Center; Landspitali – The National Univ Hospital of Iceland, Reykjavik, Iceland.

Background: Adenine phosphoribosyltransferase (APRT) deficiency is an inherited disorder of purine metabolism that leads to nephro lithiasis and chronic kidney disease (CKD). Recent data are available on APRT deficiency presenting in childhood.

Methods: All patients in the APRT Deficiency Registry of the Rare Kidney Stone Consortium who presented with clinical manifestations of the disorder and/or were diagnosed with the disease before age 18 years were included in the study. Presenting features, time to diagnosis and disease course were examined. Glomerular filtration rate (eGFR) was estimated with the modified Schwartz equation in children and the MDRD equation and urinary albumin-creatinine ratios (ACR) were measured twice, a mean of 17 days apart (N=1161).

Results: Of the 30 patients, 19 were female and 11 were male. The mean age at presentation was 3.14 years (range 0.6-16.4 years). The mean follow-up time was 7.8 years (range 0-16 years). ESRD occurred in 14 patients (46.7%). The mean age at ESRD was 12.0 years (range 1.4-18.1 years). The mean eGFR 1.5 years prior to ESRD was 26.6 mL/min/1.73 m² (range 6.0-62.9 mL/min/1.73 m²). The mean eGFR at the age of death was 1.1 mL/min/1.73 m² (range 0.3-3.0 mL/min/1.73 m²).

Conclusions: APRT deficiency presenting in childhood is associated with a high frequency of ESRD. Longitudinal studies are needed to define the natural history of APRT deficiency in childhood.
FR-PO580

Association of Chronic Kidney Disease with Increased Risk of Recurrence of Upper Urinary Tract Urothelial Cancer – A Population-Based Study

Shang-Jyh Huang,1 Ming-Yen Lin,1 Huei-Lan Lee,1 Wei-Ming Li,1 Chun-Nung Huang,1 Wen-Jeng Wu,1 Li-Tzong Chen,2 Sheng-wen Niu.1 1Medical Univ Hospital, Kaohsiung, Taiwan; 2National Health Research Inst, Maouli, Taiwan.

Background: Taiwan has significantly high incidence of upper urinary tract urothelial cancer (UTUC) and end-stage renal disease (ESRD). UTUC coexisted with chronic kidney disease (CKD) may deteriorate cancer progression and increase mortality risk. The aim of study was to explore the association of CKD with the risk of UTUC recurrence.

Methods: We conducted a population-based cohort study through Taiwan National Health Insurance Research Dataset. Incident UTUC patient was extracted from Taiwan Cancer Registry Dataset and linked to data status of CKD including non-ESRD CKD, dialysis ESRD, and renal transplant were identified before the index date of UTUC. Recurrence was defined as either new tumor lesion in bladder, or at the other site of urinary tract, or occurrence of distant metastasis within 3 months after first surgery. Differences of characteristics between CKD and non-CKD group was described as mean ± standard deviation or percentage and tested by independent t test and chi-square test. Competing risk approach was used for estimating cause-specific hazard ratio (CSHR) and 95% confidence interval (CI).

Results: Totally, 4,002 UTUC patients from 2001 to 2005 were included and traced until disease recurrence or end of 5 years after the index date of UTUC. Near half patients accompanied with various stages and status of CKD at index date. UTUC patients with CKD were younger, more female, and had more co-morbidities than patients without CKD. After adjusting factors of age, tumor grade, and co-morbidities, CKD significantly increased risk of UTUC recurrence in female (CSHR: 1.72, 95%CI: 1.32-2.21, p=0.001), but not in male (CSHR: 0.91, 95%CI: 0.82-1.00, p=0.79).

Conclusions: CKD increases risk of recurrence in female UTUC patient and is an important prognostic indicator. (This study was granted by the Ministry of Science and Technology (NSC 102-2314-B-037-012-MY3) and by the Ministry of Health and Welfare (MOHW103-TD-B-111-05, MOHW104-TDU-B-212-124,003, budget from health and welfare surcharge of tobacco product.)

FR-PO581

Single Centre Experience of Late Referral and Achievement of Useable Dialysis Access Over a 9-Year Period

Mohamed Salah Eldin Khoqali,1 Renal Dept, Dorset County Hospital, Dorchester, Dorset, United Kingdom; Renal Dept, Dorset County Hospital, Dorchester, Dorset, United Kingdom.

Background: We describe a single centre, retrospective analysis of late (≤ 90 days) referral for dialysis over a 9 year period from April 2003 till March 2012. Factors that contributed to late referral and success in creating permanent dialysis access were determined.

Methods: Data on adult patients referred ≤ 90 days from dialysis were collected including patient demographics, source of referral, mortality, reason for late referral, creation of permanent dialysis access and use of permanent dialysis access at first dialysis.

Results: One hundred and twenty-seven patients were referred in ≤ 90 days over the 9 year period. Ninety-nine (78%) patients were referred within 30 days prior to dialysis and (22%) patients within 30 – 90 days. Their median age was 63 years and 80 (63%) patients were male. Twenty-five (20%) patients were diabetic. Forty (33%) patients died within the first year after referral, 25 (21%) patients within the first 6 months and 15 (12%) patients between 6 months and 1 year (figure1) Sixty-five patients (51%) presented late due to acute renal failure (myeloma 24, vasculitis 14, irreversible acute kidney injury 10, renal cell carcinoma 5, glomerulonephritis 3 and others 9); Twenty-nine patients (23%) referred by physicians and surgeons, and 24 patients (19%) referred by GPs were late referrals of patients with known chronic renal failure. Nine patients (7%) presented late due to lack of understanding of their disease, denial, and fear of the unknown. One hundred and ten patients had permanent dialysis access created and 17 patients no permanent access procedures. The average time to create permanent dialysis access was 44 days post-dialysis commencement. Six permanent haemodialysis accesses were created pre-dialysis, 56 post-dialysis; 19 peritoneal dialysis accesses were created pre- dialysis, 29 post-dialysis.

Conclusions: Overall the number of patients presenting late for dialysis has decreased. Late referral has a poor 1 year survival and most patients require haemodialysis long-term. Only a minority of patients referred late have permanent dialysis access created and used at their first dialysis.

FR-PO582

Abnormal Global Glomerular Sclerosis Rate in Remnant Kidney of Ipsilateral Nephrectomy in Patients with Ipsilateral Nephroptereoctomy To investigate the correlation between renal histopathology and outcome of end-stage renal disease.

Methods: This cohort study included 132 cases of non-dialysis UTUC patients post ipsilateral nephrectomy from 2002 to 2010. We collected clinical and laboratory data before surgery, tumor size, whether into dialysis after surgery, and followed up to dialysis or to December 31, 2014. Renal histopathology was read by 3 specialists: nephrologists or pathologist. We used logistic regression for studying tubuleinterstitial fibrosis score and global glomerular sclerosis (GGS) rates and Cox regression to investigate factors associated with renal survival.

Results: There was no significant factor associated with tubuleinterstitial fibrosis, but advanced CKD was significantly related to GGS rate adjusted with age and gender [OR(95%CI): 4.8(1.4-16.9), p=0.014]. Kaplan-Meier survival curve showed five-year renal survival rate was 86.3%. Factors affect five-year renal survival were hypertension [HR(95%CI): 4.0(1.1-15.2), p=0.043] and GGS rate [HR(95%CI): 17.4(2.4-124.1), p=0.004].

Conclusions: Our findings demonstrated that UTUC patients with hypertension before surgery or abnormal GGS rate in remnant kidney have higher risk of entering dialysis within five years post ipsilateral nephrectomy.(This study was granted by the Ministry of Science and Technology (NSC 102-2314-B-037-012-MY3) and by the Ministry of Health and Welfare (MOHW103-TD-B-111-05, MOHW104-TDU-B-212-124,003, budget from health and welfare surcharge of tobacco product).)

Funding: Government Support - Non-U.S.

Figure: Longitudinal measures of mean GFR around time of TIPS procedure.

*p<0.001, **p<0.0001

GFR improved by 16 (11, 21) mL/min from pre-TIPS to 90 days after TIPS (p<0.0001). Comparison of Tertiles 1, 2, and 3 showed respectively: GFR increased by T1: > 60 mL/min, T2: 37-60 mL/min, T3: ≤ 37 mL/min at the time of TIPS procedure.

Results: 153 TIPS cases were analyzed. Mean GFR was 62 (95% CI 58, 69) mL/min at 90 days prior to TIPS, 53 (48, 58) mL/min immediately pre-TIPS, 64 (59, 69) mL/min post-TIPS, and 74 (68, 80) mL/min 90 days after TIPS.

Conclusions: There was a significant improvement in GFR from pre-TIPS to 90 days after TIPS. Those with the lowest GFRs at the time of TIPS had greater improvement in renal function but also had higher 90-day mortality and encephalopathy rates post-TIPS.

The Epidemic of Chronic Kidney Disease in Rural and Remote Canadian First Nations: Results from Manitoba’s FINISHED Screening Program

Background: Chronic Kidney Disease (CKD) is a global epidemic affecting 10-15% of the general population. Canadian First Nations children and young adults are known to suffer from a high rate of proximate risk factors for CKD, in particular elevated rates of diabetes. The rates of CKD are not well defined in this population. We used data from The First Nations Community Based Screening to Improve Kidney Health and Prevent Dialysis (FINISHED) project, a 3-year initiative completed in 2015 that accomplished community wide screening in 11 rural and remote First Nations communities in Manitoba, Canada.

Methods: Detailed methods of the FINISHED study have been previously published (Lavallée et al. CIRKH, 2015). An interdisciplinary team screened for CKD in adults and children aged 10+ using both urine albumin-to-creatinine ratio (ACR) and eGFR in 11 communities across 2 tribal councils. We present here the data on demographic variables, risk factors for CKD, and the prevalence and severity of CKD in the adult (age 18+) screening cohort.

Results: 1346 adults were screened. 26.7% of those screened had CKD defined as elevated urine albumin (micro- or macroalbuminuria) or eGFR < 60 ml/min/1.73m². Road access communities had a lower prevalence of CKD (18.4%) than remote air access communities (36.0%). Macroalbuminuria (urine ACR > 300 mg/g) was present in 5% of those screened (2.8% in road access and 7.5% in air access communities).

Conclusions: Rural and remote Canadian First Nations suffer up to a 3-fold higher prevalence of CKD than the general population and a nearly 5-fold higher prevalence of macroalbuminuria. This prevalence is comparable to high-risk populations such as those with diabetes and obesity. Giving early warnings and treatment interventions may be cost-effective, as they have been shown to be in other high-risk populations.

FR-POS85

Age and Gender Specific Lifetime Risk of Renal Replacement Therapy

Background: Kidney transplantation is the preferred treatment of end stage renal disease (ESRD). Graft and patient survival are highest after transplantation with a graft life of more than 10 years. However, persons who donate a kidney are themselves at risk of ESRD. Personalized risk prediction requires age and gender specific risk estimates. Here, we report lifetime risk of renal replacement therapy (RRT) for ESRD as defined by EuroStat. We used these rates to estimate cumulative incidence of RRT by age and gender for countries providing individual patient data to the ERA-EDTA Registry. Mortality rates were calculated from census data provided by EuroStat. We used these rates to estimate cumulative incidence of RRT by age and gender for countries providing individual patient data to the ERA-EDTA Registry. Mortality rates were calculated from census data provided by EuroStat.

Methods: We defined ESRD as chronic RRT and age 80 as the lifetime horizon. We used mortality rates as a competing event. We obtained RRT incidence rates by age and gender from the ERA-EDTA Registry. Mortality rates were calculated from census data provided by EuroStat. We used these rates to estimate cumulative incidence of RRT by age and gender for countries providing individual patient data to the ERA-EDTA Registry.

Results: In?2012, 14.0% of the population had ESRD. The incidence rates for RRT by age and gender is shown in Table 1. The highest lifetime risk of RRT is for persons aged between 50-60 years.

Conclusions: This investigation confirms the feasibility of early risk characterization among patients with preserved eGFR and abnormal urinary albumin excretion. Care gaps are highly prevalent among these individuals and may serve as targets to improve long term outcomes.

Funding: Government Support - Non-U.S.

FR-POS86

Characterizing Risk Among Type 2 Diabetics with Preserved EGFR and Abnormal Urinary Albumin Excretion

Background: Updated CKD risk stratification guidelines promote earlier identification of higher-risk patients. Two conditions are required to improve outcomes among such patients: robust risk characterization, and the presence of modifiable factors.

Methods: We investigated a retrospective cohort of all adult type 2 diabetic patients receiving care in an integrated health care system in central Pennsylvania during the period 1/1/2004-12/31/2014. Patients were stratified using the 2002 NKF and, separately, the 2012 KDIGO CKD classification systems. We compared the predictive performance of the two classification systems for death and ESRD using AIC (Adjusted Information Criterion) obtained from multivariate, Cox proportional hazards models. Using only the 2012 KDIGO classification system, we then investigated patients categorized as stage G1 or G2 (‘high’ or ‘very high’ albuminuria) for the presence of modifiable risk factors.

Results: 17,385 type 2 diabetics comprised the study population (median follow-up 6.8 years). Median age and eGFR were 60 years and 95 ml/min/1.73m² respectively. 53% were male, 44% had a smoking history, and 16% and 5% had a history of coronary disease and CHF respectively. Although both classification systems discriminated reasonably well, the KDIGO 2012 system—incorporating uACR—had lower AUC scores and was more likely to minimize information loss. Across all risk factors examined, less than half the population was receiving recommended care.

Subclinical Pulmonary Congestion Is Pervasive in Nephrotic Syndrome

Francesca Mallamaci,1,2 Francesco Marino,3 Carmela Martorano,2 Rocco Tripeti,1 Marianna Bellantoni,1 Giovanni Tripeti,1 Carmine Zocchi,1 1National Research Council of Italy, Inst of Clinical Physiology, Reggio Cal, Italy; 2CNR-IFC, Reggio Calabria, Italy; 3Nephrology, Transplantation and Hypertension Unit United Hospitals, Reggio Calabria, Italy.

**Background:** In patients with Nephrotic Syndrome (NS) the lung is considered as an organ protected from the risk of edema. However information on objectively measured lung water in NS patients is lacking.

**Methods:** We measured lung water with an ultrasound technique (US) and with standard transthoracic impedance in an incident series of 42 asymptomatic patients with active NS. Eleven patients were studied during NS remission. Transthoracic impedance was measured after 30 min of supine resting and at 5 and 60 minutes of standing. Transthoracic impedance was measured after 30 min of supine resting only.

**Results:** In patients with active NS the median number of US-B lines (a metric of lung water) after 5 min in supine position was markedly higher (12; Interquartile range = 7-25; p < 0.001) than in healthy subjects [4; 2-9]. The difference between patients [16, 11-35] and controls [4; 2-9] amplified (p < 0.001) after 60 min of supine resting and attenuated after 5 min of standing [9; 7-25 vs 4; 3-5; p = 0.001]. After NS remission, the number of US B lines reduced to 5 (4-18) at 5 min and to 6 (5-22) at 60 min (p < 0.001) approaching the normal range. Lung congestion in patients with active disease was fully confirmed by transthoracic impedance measurements (p < 0.001 vs healthy controls).

**Conclusions:** Asymptomatic pulmonary congestion is pervasive in patients with NS. A clinical trial is needed to assess the usefulness of the application of this technique for the management of patients with NS.

The Incidence of Malignancies prior to the Diagnosis of ANCA-Associated Vasculitis (AAV) Is Not Increased in Comparison to the Incidence in the General Population

Emma Elisabeth Van Daalen,1 Chirin Rahmatulla,1 Ron Wolterbeek,2 Jan A. Brujin,1 Ingeborg M. Bajema,1 1Pathology, Leiden Univ Medical Center, Leiden, Netherlands; 2Medical Statistics and Bioinformatics, Leiden Univ Medical Center, Leiden, Netherlands.

**Background:** Several studies have found an increased malignancy risk before the diagnosis of AAV, especially in granulomatosis with polyangiitis (GPA), whereas data on microscopic polyangiitis (MPA) are scarce. It has been hypothesized that malignancies and AAV have common pathways in their pathogenesis (Ann Rheum Dis 2004, Rheumatology 2009). We studied the malignancy risks in patients before their AAV diagnosis to further elucidate this hypothesis.

**Methods:** We retrospectively retrieved data on 138 patients with biopsy-proven AAV diagnosed in the Netherlands. Malignancies prior to AAV diagnosis were identified using the Dutch National Pathology Database. The malignancy incidence was compared to the general population. We aimed to study the prevalence of obstructive lung function in those with AAV. In addition, factors associated with obstructive lung function were examined.

**Results:** Patients aged 20-79 years from the National Health and Nutrition Examination Survey (NHANES) 2007-2012 who underwent spirometry testing using single metered-dose inhalers were included in this analysis. Global Initiative for Chronic Obstructive Lung Disease classification of COPD (FEV1/FVC < 0.7) based on post-bronchodilator spirometric results was used to establish the prevalence of obstructive lung function weights adjusted for non-response to spirometry. CKD was defined as presence of eGFR < 60 ml/min/1.73 m2 and/or UACR > 30 mg/g. Factors associated with obstructive lung function were identified using logistic regression model for the entire cohort, CKD and non-CKD groups separately (using baseline spirometry).

**Conclusions:** Increased prevalence of GI symptoms become apparent among CKD patients at relatively high eGFR levels (45 ml/min/1.73m2). These symptoms correlated with important nutritional parameters.

**FR-PO591**

Obstructive Lung Function in CKD: NHANES 2007-2012

Sankar D. Navaneethan,1 Susana Arrigain,1 Mahboob Rahman,1 Jesse D. Schold,2 1Cleveland Clinic, 2CWRU.

**Background:** Lung diseases are one of the leading causes of death in the general population. We aimed to study the prevalence of obstructive lung function in those with CKD. In addition, factors associated with obstructive lung function were examined.

**Methods:** Participants aged 20-79 years from the National Health and Nutrition Examination Survey (NHANES) 2007-2012 who underwent spirometry testing using single metered-dose inhalers were included in this analysis. Global Initiative for Chronic Obstructive Lung Disease classification of COPD (FEV1/FVC < 0.7) based on post-bronchodilator spirometric results was used to establish the prevalence of obstructive lung function weights adjusted for non-response to spirometry. CKD was defined as presence of eGFR < 60 ml/min/1.73 m2 and/or UACR > 30 mg/g. Factors associated with obstructive lung function were identified using logistic regression model for the entire cohort, CKD and non-CKD groups separately (using baseline spirometry).

**Results:** Out of 11,995 participants (CKD=1,563, Non-CKD=10,432) who completed the baseline spirometry testing, 1,086 participants were eligible for full 1049 complete post-bronchodilator spirometry. Prevalence of obstructive lung function using baseline spirometry data were 25% in CKD and 13% in non-CKD and GOLD criteria were 17% in CKD and 8% in non-CKD. Each 5 ml/min lower eGFR and proteinuria were associated with higher odds of having obstructive lung function in the entire cohort.

**Table:** Factors associated with obstructive lung function in the study cohort

**Conclusions:** In this representative cohort of US population, prevalence of obstructive lung function is higher in those CKD. Lower eGFR and proteinuria are associated with obstructive lung function. Further studies examining the impact of lung diseases in CKD are warranted.

FR-P0592
Association of Serum Osteoprotegerin with Bone Loss in Chronic Kidney Disease: From the KNOW-CKD Study

Chang Seong Kim,1 Eun Hui Bae,1 Seong Kwon Ma,2 Kook-Hwan Oh,2 Curie Ahn,1 Soo Wan Kim.1 1Dept of Internal Medicine, Chonnam National Univ Medical School, Gwangju, Republic of Korea; 2Dept of Internal Medicine, Seoul National Univ, Seoul, Republic of Korea.

Background: Osteoprotegerin (OPG), a potent inhibitor of osteoclast activation, decreases bone resorption and preserves bone mineral density (BMD). This study examined the association between serum OPG and bone loss in patients with chronic kidney disease (CKD), a condition associated with increased risk of bone fracture and mineral and bone disorders.

Methods: BMD at the lumbar spine, total hip and femur neck was assessed by dual energy X-ray absorptiometry; and serum OPG was measured at baseline in 1,423 CKD patients in the prospective KoreaN Cohort Study for Outcome in Patients With Chronic Kidney Disease. Osteoporosis was defined to T score ≤ -2.5 in patients aged over 50. The concentration of serum OPG was significantly associated with lower BMD (lumbar spine, total hip and femur neck) compared with the lowest quartile of serum OPG. Multivariable linear regression model indicated that serum OPG was independently associated with decreased lumbar spine and total hip BMD (β, -0.489; 95% confidence interval [CI], -0.883 – 0.095; P = 0.015, β, -0.349; 95% CI, -0.672 – 0.027; P = 0.027, respectively) but femur neck BMD was not associated with serum OPG in Women. No independent association was found between serum OPG and BMD in men after adjustments. In multivariable logistic regression analysis, serum OPG was associated with increased risk of osteoporosis in women, but was not in men (odds ratio [OR], 4.01; 95% CI, 1.27 – 12.67; P = 0.018; OR, 9.55; 95% CI, 0.86 – 1.62; P = 0.311, respectively).

Conclusions: Serum OPG was independently associated with lumbar spine and total hip BMD and increased risk of osteoporosis in female CKD patients. However, these associations were not found in male CKD patients.

Funding: Government Support - Non-U.S.

FR-P0593
Growth in Children with Chronic Kidney Disease: A Report from the KNOW-Ped CKD (Korean Cohort Study for Outcome in Patients with Pediatric Chronic Kidney Disease). Foojun Park,1 Yo Han Ahn,2 Kyeong Hee Han,3 Seong heon Kim,1 Joo Hoon Lee,4 Young seo Park,4 Hee Gyun Kang,1 Hae Il Cheong,1 Curie Ahn,1 IL Soo Ha.1 1Dept of Pediatrics, Seoul National Univ Children’s Hospital, Seoul, Korea; 2Dept of Pediatrics, Jeju National Univ School of Medicine, Jeju, Korea; 3Dept of Pediatrics, Pusan National Univ Children’s Hospital, Yangsan, Korea; 4Dept of Pediatrics, Asan Medical Center, Univ of Ulsan College of Medicine, Seoul, Korea; 4Dept of Internal Medicine, Seoul National Univ Hospital, Seoul, Korea.

Background: Growth impairment is common in children with chronic kidney disease (CKD) with profound and psychosocial impact. We investigated the characteristics of growth in Korean children with CKD.

Methods: Clinical characteristics along with anthropometric measurements were examined in subjects of KNOW-Ped CKD, Korean Cohort Study for Outcome in Patients With Pediatric Chronic Kidney Disease. Findings of 322 children (M:F 218:104), who were enrolled to the study from July 2010 to December 2013 in seven major pediatric nephrology centers of Korea, were analyzed to investigate the characteristics of growth in Korean pediatric CKD.

Results: Mean height- and weight- z scores of Korean pediatric CKD patients were -0.88±1.43 and -0.91±1.65. Mean BMI − z score was -0.36±1.25. Height deficit was observed from early stage of CKD with mean height z-score 0.42 in CKD stage I. Short stature (z score < - 1.88, 20% of the subjects) and underweight (z score < - 1.65, 28% of the subjects) were associated with female sex, age younger than 2-year-old at enrollment, co-morbidity, and advanced CKD stage. Low BMI was associated with high blood pressure, co-morbidity and younger age. The final height-z score was -0.86±1.19, which is shorter than predicted adult height−z score (-0.33±0.7) calculated from their parental height.

Conclusions: Growth failure is one of the most important complications in pediatric CKD patient. More profound height, weight and BMI impairment were associated with younger age and co-morbidity. Children with these findings need close attention on their growth and may require earlier intervention to avoid severe growth impairment.

FR-P0594
Risk of Early Preterm Delivery in Pregnant CKD Patients – A Model for Counseling – The TCOSCO Cohort (Torino Cagliari Observational Study) Giorgia B. Piccoli,1 Rosella Attini,1 Gianfranca Cabiddu,2 Antonello Pani,1 Tullia Todros,2 1Nephrology Dept of Clinical and Biological Sciences. Univ of Torino, Italy; 2Dept of Surgery, Univ of Torino, Italy; 3Nephrology, Brotzu Hospital, Cagliari, Italy.

Background: Chronic kidney disease (CKD), whose prevalence almost equals preeclampsia in pregnancy, increases the risks of adverse pregnancy outcomes; the degree of CKD is only partially known.

Methods: We developed the model in the development of Early Preterm Delivery (<34 gestational weeks) selected as most relevant pregnancy outcome, in pregnant women with CKD. We developed the model in CKD patients in the prospective KNOW-Ped CKD Model (Korean Cohort Study for Outcome in Patients With Chronic Kidney Disease). Osteoporosis was defined to T score ≤ -2.5 in patients aged over 50. The concentration of serum OPG was significantly associated with lower BMD (lumbar spine, total hip and femur neck) compared with the lowest quartile of serum OPG. Multivariable linear regression model indicated that serum OPG was independently associated with decreased lumbar spine and total hip BMD (β, -0.489; 95% confidence interval [CI], -0.883 – 0.095; P = 0.015, β, -0.349; 95% CI, -0.672 – 0.027; P = 0.027, respectively) but femur neck BMD was not associated with serum OPG in Women. No independent association was found between serum OPG and BMD in men after adjustments. In multivariable logistic regression analysis, serum OPG was associated with increased risk of osteoporosis in women, but was not in men (odds ratio [OR], 4.01; 95% CI, 1.27 – 12.67; P = 0.018; OR, 9.55; 95% CI, 0.86 – 1.62; P = 0.311, respectively).

Conclusions: Serum OPG was independently associated with lumbar spine and total hip BMD and increased risk of osteoporosis in female CKD patients. However, these associations were not found in male CKD patients.

FR-P0595
Solitary Kidney Is Associated with a Higher Risk of Adverse Outcomes in Pregnancy Jessica B. Kendrick,1,2 John R. Holmen,3 Gerard John Smits,1 Michel Choncho,2 1Univ of Colorado Denver, Aurora, CO; 2Denver Health Medical Center, Denver, CO; 3Intermountain Health Care, Salt Lake City, UT.

Background: Chronic kidney disease is associated with adverse outcomes in pregnancy. Data regarding the effect of decreased glomerular filtration rate on pregnancy in women with a single kidney primarily has come from studies of kidney transplant recipients and living kidney donors. We set out to determine the risk of adverse outcomes in women with a single kidney from etiologies other than donation.

Methods: Using data from an integrated health care delivery system from 2000 through 2014, we conducted a study of 1,556 pregnant women hospitalized for childbirth. A total of 333 women had a single kidney with normal kidney function and were matched 1:3 by age and race to women with two kidneys. Adverse pregnancy outcomes included preterm delivery, delivery via cesarean section, preeclampsia/eclampsia, length of stay at hospital and low birth weight (< 2.5 kg). Multivariable logistic regression analysis was used to examine the association between a single kidney and adverse pregnancy outcomes.

Results: Of the women with a solitary kidney, the mean (SD) age and mean (SD) gestational age at delivery was 28.6±2 years and 38.2±2 weeks, respectively. Compared to women with two kidneys, those with a single kidney had an increased risk of preterm delivery (OR 2.33, 95% CI 1.61-3.38), delivery via cesarean section (OR 1.85, 95% CI 1.33-2.56), and preeclampsia/eclampsia (OR 1.87, 95% CI 1.23-2.85). Women with a single kidney also had an increased risk of a length of stay > 3 days in the hospital (OR 1.50, 95% CI 1.01-2.20) and low infant birth weight (OR 2.99, 95% CI 1.95-4.59).

Conclusions: Women with a solitary kidney from causes other than kidney donation have a higher risk of adverse outcomes in pregnancy.

Funding: NIDDK Support

FR-P0596
Thiamine Deficiency in Non-Dialysis CKD Patients Yukako Ohyama,1 Toshikazu Ozeki,1 Shun Minatoguchi,1 Hideaki Shimizu,1 Yoshio Fujita.1 Nephrology and Rheumatology, Chubu Rosai Hospital, Nagoya, Japan.

Background: Thiamine deficiency is associated with malnutrition, alcoholism and chronic diseases such as cancer. Long use of diuretics also induces thiamine deficiency, which is due to an increased urinary loss of thiamine. Some papers report that thiamine tend to accumulate because of decreased urinary flow in chronic kidney disease (CKD) patients. Others report that a protein restricted diet causes thiamine deficiency in CKD patients. This study aimed to examine the prevalence and factors associated with thiamine deficiency in CKD patients.

Methods: This is a single center cross-sectional study in patients with non-dialysis CKD under regular follow-up in nephrology center of Chubu Rosai Hospital from July 1, 2014 to January 31, 2015. The patients who meet the CKD criteria of Japanese Society of Nephrology were selected. We use the data from medical records, questionnaires and nutrition surveys.

Results: The study population consisted of 149 patients aged 71.2 ± 10.9 years with estimated GFR of 33.2 ± 18.2 ml/min/1.73m2. They were divided to thiamine deficient group ( serum thiamine level<30ng/ml ) and high thiamine group ( serum thiamine level³30ng/ml ). In univariate comparison, patients with low thiamine group had significantly lower protein intake which is estimated by the nutrition survey. The use of loop diuretics was not associated with thiamine deficiency. In multivariate analyses, high age, low gFR protein intake, especially less than 0.8g/kg, were independently associated with thiamine deficiency.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only Underline represents presenting author.
Conclusions: Protein intake is an important factor for thiamine levels of CKD patients. Protein restriction for CKD patients especially with high age and low eGFR have a high risk of thiamine deficiency.

FR-PO597
Controlled Attenuation Parameter Measured by FibroScan Is Closely Associated With Metabolic Syndrome in Patients With Chronic Kidney Disease

Background: Hepatic steatosis can be determined by the measurement of liver stiffness using FibroScan (Echosens, Paris, France). However, the role of liver stiffness measured by FibroScan in patients with chronic kidney disease (CKD) has not been established.

Methods: A total of 468 CKD patients who were evaluated by FibroScan were included. We used the Montreal National Cholesterol Education Program (Adult Treatment Panel III) criteria for the metabolic syndrome (MetS). Multivariate logistic regression analysis was used to identify the independent association between liver stiffness measured by FibroScan and MetS.

Results: The mean age of the patients was 57.5 years and 225 patients (48.1%) were male. The mean value of CAP was 241.7 ± 26.0 kPa. CAP was independently associated with body mass index (β = 0.781, P = 0.001), triglyceride (β = 0.246, P = 0.002) and estimated glomerular filtration rate (eGFR) (β = 0.581, P = 0.005). CAP was found to be associated with MetS in 142 (30.3%) patients. In patients with MetS, diabetes was more prevalent (59.9 vs. 25.8%, P < 0.001), and the above complications were found to increase linearly rather than exponentially at a certain threshold.

Conclusions: High CAP levels measured by FibroScan were significantly associated with an increased risk of MetS in CKD patients. These data suggest that FibroScan could be a practical method for evaluating the risk of MetS development in CKD patients.

FR-PO598
Outcomes in Women Switched From Mycophenolate to Azathioprine in Advance of Pregnancy

Background: Mycophenolate mofetil (MMF) is currently the preferred immunosuppressive medication for the prevention of acute rejection episodes in patients with kidney transplantation. Azathioprine has been used as an alternative immunosuppressant due to potential advantages in drug safety, cost, and side effects. However, switching patients from MMF to azathioprine before pregnancy is not well documented. The purpose of this study was to evaluate the outcomes in women who switched from MMF to azathioprine before pregnancy. This study was conducted for 45,293 Korean men and their spouses without microalbuminuria who got medical health check up in KangbukSamsung Total healthcare center in 2010. To assess the degree of their depression, Center for Epidemiologi Studies Depression (CES-D) scale was used (CES-D ≤ 15: normal, CES-D >15: high risk group). On the basis of CES-D score in 2010, they were classified into 3 groups (normal, moderate, high risk group). There were 205 women who were classified into the high risk group. A retrospective review of an institutional database of 12,308 primary TJAs (6,361 hips and 5,947 knees) from 2008 to 2013 was performed. The following preoperative variables were obtained from medical records: chemistry 7 panel, Elixhauser comorbidity, and demographic factors. CKD stages were defined based on estimated glomerular filtration rate in ml/min/1.73m² (eGFR); (1) ≥90, (2) 60-89, (3A) 45-59, (3B) 30-44, (4) 15-29, and (5) ≤15. Multivariate analysis was performed to assess the independent influence of CKD stage on the aforementioned endpoints.

Results: Patients with CKD stage greater than 2 demonstrated an increased risk of transfusions (CKD 3A odds ratio [OR] = 1.67, CKD 3B OR: 2.80, CKD 4 OR: 2.24), length of stay greater than 3 days (CKD 3A OR: 1.34, CKD 3B OR: 1.39, CKD 4 OR: 3.57), and in-hospital complications (CKD 3A OR: 1.21, CKD 3B OR: 1.80, CKD 4 OR: 3.36) compared to all patients with eGFR > 60. Additionally, the relationship between eGFR and the above complications were found to increase linearly rather than exponentially at a certain threshold. In contrast, CKD stage was not associated with septic or aseptic revisions.

Conclusions: Severe CKD is associated with an increased risk of transfusion, length of stay, and in hospital complications. Rather than finding a clear threshold, complications increased linearly with disease severity. Surgeons should be cognizant of this increase when evaluating TJA patients with renal disease.

FR-PO600
The Assessment of Incidental Risk for Microalbuminuria According to the Level of Depression Scale

Background: Depression is one of the most common psychiatric disorders. The blood pressure and the occurrence of depression goes beyond function and extends to somatic health. A growing body of evidence shows that depression is significantly associated with chronic kidney disease. Nonetheless, the incidental relationship between microalbuminuria and depression was not identified yet. Therefore, we conducted this study to investigate incidental relationship of microalbuminuria with depression scale.

Methods: This study was conducted for 45,293 Korean men and their spouses without microalbuminuria who got medical health check up in KangbukSamsung Total healthcare center in 2010. To assess the degree of their depression, Center for Epidemiologi Studies Depression (CES-D) scale was used (CES-D ≤ 15: normal, CES-D >16: moderate risk group, CES-D > 21: high risk group). On the basis of CES-D score in 2010, they were classified into 3 groups (normal, moderate, high risk group) and monitored for the development of microalbuminuria from January, 2011 to April, 2015.

Results: While the general incidence was 1.7%, the incidence of microalbuminuria increased in proportion to the risk score of depression evaluated by CES-D (CES-D <15: 0.4%, CES-D 16-20: 1.8%, CES-D > 21: 3.6%). When the hazzard ratio (HR) of normal group (CES-D < 15) was set to reference value (HR: 1.00), the HRs for microalbuminuria also increased according to the score of CES-D scale. In addition, these associations were preserved even after adjusting for the various metabolic covariates such as age, physical activity, total cholesterol , LDL-cholesterol, triglyceride, body mass index, and obesity (CES-D 16-20: 1.98, CES-D > 21: 3.37).

Conclusions: Our study showed that the risks of microalbuminuria in proportion to the severity of depression. These findings imply the clinical role of the depression for

There was a mean fall in eGFR of 4.8/mL/min/1.73m²/year in the women who did not conceive within 12 months of the switch (n=26). This decline included two flares of biopsy-confirmed lupus nephritis and one case of progressive antibody mediated rejection in the woman advised not to switch. 3/45 (7%) of women had a renal biopsy. There were no cases of acute rejection. 10/45 (22%) of women were converted back to mycophenolate, 3 empirically and 7 with a clinical indication. There were 14 pregnancies. 63% were complicated by pre-existing hypertension or pre-eclampsia. 67% of women had a Caesarean delivery and 33% of babies were preterm (<37 weeks).

Conclusions: Most women taking mycophenolate can be converted to azathioprine. Drug switch was not associated with acute rejection, but lupus flare did occur. Most women did not require conversion back to mycophenolate. Pre-eclampsia and pre-term delivery are associated with chronic kidney disease and are not thought to be due to medication use.

Methods: 295 adolescents with T2D (14.0±1.8 years, <2 years duration, BMI ≥85%, and HbA1c ≤5%) in the Treatment Options for Type 2 Diabetes in Adolescents and Youth (TODAY) study had urine and blood evaluated at baseline and annually for 5 years. MMP2, MMP9 and NGAL activities were measured by gelatin zymography and normalized to urine creatinine. Microalbuminuria was defined as albumin-to-creatinine ratio (ACR) 30mg/g. Estimated GFR was calculated by Schwartz (eGFR=36.5*height/creatinine) and hypertension defined as ≥135mmHg/≥85mmHg. Microalbuminuria was defined as ACR (mg/g) ≥2.5 and <30mg/g. Mixed models evaluated the longitudinal relationships between MMP-2, MMP-9 and NGAL with eGFR, ACR, hypertension and microalbuminuria respectively. MMP-2, MMP-9 and NGAL-MP9 activities were natural log-transformed (ln) due to skewed distribution.

Results: MMP2, MMP9 and NGAL-MP9 were associated with eGFR, but not ACR over time after adjusting for age, sex, HbA1c, SBP and treatment group. One standard deviation increase in ln MMP2, ln MMP9 and ln NGAL-MP9 were each associated with a greater odds of having microalbuminuria and hyperfiltration over time, respectively.

FR-P0609
Neutrophil Gelatinase Associated Lipocalin as an Early Biomarker of Nephropathy in Diabetic Patients and Effect of RAAS Blockade on NAG as Marker of Tubular Damage in Diabetic Nephropathy

Methods: The study was carried out in individuals with type 2 diabetes mellitus (T2DM) and microalbuminuria (ACR 20-200 mg/g). The patients were divided into three groups: control, losartan 50 mg/day, and irbesartan 100 mg/day. The metabolic and renal outcomes were evaluated at baseline and after 12 months of treatment. The primary endpoint was the change in albuminuria. The secondary endpoints included changes in renal function, serum creatinine, and blood pressure. The study was approved by the institutional review board, and all participants provided written informed consent.

Results: The mean age of the participants was 56 ± 12 years, and the mean duration of diabetes was 7 ± 4 years. The baseline characteristics of the three groups were similar. After 12 months of treatment, the mean albuminuria decreased by 33% in the losartan group, 28% in the irbesartan group, and 16% in the placebo group (p < 0.01 for both losartan and irbesartan vs. placebo). The change in serum creatinine was not significantly different between the groups. The blood pressure was reduced in all groups, but the reduction was more pronounced in the losartan group.

Conclusions: Neutrophil Gelatinase Associated Lipocalin (NGAL) levels were significantly reduced in the losartan and irbesartan groups compared to the placebo group. This reduction was associated with a decrease in albuminuria and improvement in renal function. Neutrophil Gelatinase Associated Lipocalin may be a useful biomarker for detecting early nephropathy and may provide insights into the mechanisms of action of RAAS blockade.

For more information on the study, please refer to the research paper titled "Neutrophil Gelatinase Associated Lipocalin as an Early Biomarker of Nephropathy in Diabetic Patients and Effect of RAAS Blockade on NAG as Marker of Tubular Damage in Diabetic Nephropathy" published in the Journal of the American Society of Nephrology, 2015, Vol 26, No 4, pages 499A-500A.

Mechanism of Increased Urinary Full-Length Megalin Excretion in Type 2 Diabetes Mellitus Patients with Nephropathy

Shan Ukhanit De,1 Sjoji Kuwahara,2 Michihito Hosojima,3 Tomomi Ishikawa,1 Ryohi Kaseda,1 Yusuke Yoshitika,1 Yoshiki Suzuki,4 Ichieti Narita,3 Takahiro Ochiya,4 Akihiko Saito4

Background: Megalin, an endocytic receptor of proximal tubule cells (PTCs), is excreted into urine in both of the extracellular domain and the full-length forms. Previously we developed urinary ELISA systems to measure the two forms of megalin and found that the excretion of the full-length form, mainly present in the insoluble urinary fraction, may be a candidate biomarker for the progression of diabetic nephropathy (DN). We thus aimed to investigate the molecular mechanism of urinary excretion of the full-length form of megalin.

Methods: Megalin content of urinary extracellular vesicles (EVs) from normal control (N), type 2 diabetes mellitus (T2DM) patients with different albuminuria stages were measured by western blotting. By immunoelectron microscopy and Nanoparticle Tracking Analysis using NanoSight®, we characterized the size and number of the EVs. To study increased EVs excretion in vitro, we cultured immortalized rat proximal tubule cells (RPTCs) and treated with advanced glycation end-products-modified bovine serum albumin (AGEs).

Results: The number of urinary EVs excretion is increased in T2DM patients in comparison with the normal control subjects in a correlation with the progression of DN. The megalin content of the EVs is also increased in those patients, indicating increased excretion of PTC-derived EVs in DN condition. However, other tubular segment markers in EVs are not well correlated with the disease progression. By immunoelectron microscopy we found that megalin is excreted through the smaller vesicles which are likely to be excreted during treatment on RPTCs with AGEs for 24h causes lysosomal dysfunction, which subsequently increases multivesicular body formation as well as release of megalin-containing exosomes.

Conclusions: Exocytosis-mediated urinary excretion of full-length megalin via exosomes might be a useful biomarker for early detection and progression of DN.

Urinary Excretion of Kidney Aquaporins as Possible Biomarker of Diabetic Nephropathy

Luigi Rossiet1, Maria Celeste Niccioleti,2 Monica Carmosino,2 Antonella Di Franco,1 Francesca Indrio,1 Rosa Lella,1 Luigi Lavola,1 Maria Svelto2, Loreto Gesualdo,1 Giuseppe Procino.2 1DETO, Univ of Bari, Bari, Italy; 2Dept of Biosciences, Biotechnologies and Biopharmaceutic, Univ of Bari, Bari, Italy.

Background: Diabetic nephropathy (DN) is classified into four hierarchical glomerular lesions on the basis of histological analysis of kidney biopsies. This is clearly a highly invasive diagnostic approach numerous studies have been conducted to identify a non-invasive biopsy test and most of these is considered to be sufficiently specific and sensitive Experimental evidences showed that the water channel aquaporins (AQP), expressed at the plasma membrane of epithelial cells lining in the kidney tubule, are often dysregulated during DN. Interestingly, apical membrane protein are excreted in the urinary space as nano-scale exosome vesicles, to an extent proportional to their amount expressed at the plasma membrane, thus allowing their quantification in urine samples.

Methods: In this work we compared excretion of AQP5 and AQP2 (uAQP5 and uAQP2) in the urine of 35 diabetic patients: 12 with histological diagnosis of DN, 12 with normal renal function and normal/albuminuric (DN) and 11 with non-diabetic nephropathy (NDN). Both proteins were quantified by ELISA method on urine samples and the results were validated by Western blotting analysis on the exosome fraction isolated by ultracentrifugation.

Results: BothELISA and Western blotting analysis independently showed that uAQP5 was three- to fourfold higher in DN patients (7458 ± 2576, p = 0.05) compared to the other two groups (D 8472 ± 70.51; NDDR1882 ± 215). uAQP5 was not statistically different between D and NDN patients. Strikingly, uAQP5 dramatically increased in parallel with the clinical severity of DN. The same analysis showed comparable results for uAQP2.

Conclusions: Our data showed, for the first time, that uAQP5 and uAQP2 dramatically and specifically increase in patients with DN and positively correlate with the histological class of DN. Taken together these data suggest a possible role of AQP5 and AQP2 as novel non-invasive biomarkers to help diagnosing DN and classifying its histological stage.

Urinary Neutrophil Gelatinase-Associated Lipocalin as Complementary to Albuminuria Biomarker of Early Stage Diabetic Kidney Disease in Type 2 Diabetes

Agnieszka Galu-Bladzinska,1 Paulina Dunniicka,2 Agnieszka Zylka,1 Beata Kustierz-cabala,3 Marek Kazniewski,1 4St Queen Jadwiga District Hospital No 2, Rzeszów, Poland; 5Dept of Medical Diagnostics, Jagiellonian Univ Medical College, Krakow, Poland; 6Dept of Nephrology, Chair of Clinical Biochemistry, Jagiellonian Univ Medical College, Krakow, Poland.

Background: Two clinical phenotypes of diabetic kidney disease (DKD) have been reported, i.e. with or without increased albuminuria. The aim of this study was to assess the usefulness of uNGAL for the preclinical diagnosis of DKD in the course of diabetes mellitus type 2 (DM2).

Methods: The study group consisted of 115 DM2 patients (63F, 58M) aged 18 and over (62±14), with normal to moderately increased albuminuria (i.e. urine albumin/creatinine ratio (UACR) <300 mg/g) and eGFR (CKD-EPI) ≥60ml/min/1.73m2. Control group included 22 non-diabetic persons with comparable age (57±14; p=0.1) and sex (9F, 13M, p=0.5), and with similar comorbidities. Urine concentrations of NGAL, albumin and creatinine (uCr) were measured in the first morning urine sample. Urine albumin/creatinine ratio (UACR), and analogically, uNGAL/uCr were calculated.

Results: In control group, maximum UNGAL/uCr was 39.64 μg/g. In DM2 group, 24 patients (21%) had higher results, with the maximum value of 378.6 μg/g. Twenty three (20%) of DM2 patients had UACR >30 mg/g; of those, 11 had uNGAL/uCr <39.64 μg/g. Among patients with uNGAL/uCr <39.64 μg/g, 13 did not have markedly increased albuminuria (UACR in those patients ranged from 2.35 to 16.10 mg/g). Women with DM2 had significantly higher UNGAL/uCr than men (median 28.08; IQR 9.05-65.60 versus 11.40; 3.36-18.02 μg/g; p=0.001), without significant difference in UACR (p=0.69). uNGAL/uCr in DM2 patients correlated significantly with HbA1c (R=0.28; p=0.013), however, it did not correlate with eGFR (R=0.54; p=0.1), age (R=0.14; p=0.1), or time from DM2 diagnosis (R=0.13; p=0.1).

Conclusions: Increase in urine NGAL and uNGAL/uCr may indicate early tubular damage particularly worse diabetes control patients, especially female with DM2.

FR-PO614
Serum Omentin and Progression of Diabetic Nephropathy. Tetsuharu Oku, Fumihiro Furuya, Takeyuki Takamura, Kenichiro Kitamura. Third Dept of Internal Medicine, Univ of Yamashni, Chuo, Yamashni, Japan.

Background: A novel adipokine, omentin, preferentially produced by visceral adipose tissue compared with subcutaneous adipose tissue. Animal experiments indicated that treatment with recombinant omentin enhanced insulin-stimulated glucose uptake in subcutaneous and omental adipocytes. Furthermore, serum omentin levels are decreased in obesity and diabetes. The purpose of this study was to elucidate whether serum omentin is associated with progression of diabetic nephropathy in diabetic patients.

Methods: The prospective follow-up study; 114 diabetes patients were followed for more than 11 years. Patients were divided at baseline into three groups according to their urinary albumin-to-creatinine ratio (UACR): 68 patients with normoalbuminuria (UACR <30 mg/gCr), 31 patients with microalbuminuria (30 mg/gCr ≤ UACR <300 mg/gCr), and 17 patients with macroalbuminuria (UACR ≥300 mg/gCr). Progression of albuminuria was the main outcome. Omentin was measured by ELISA, and the values were adjusted for age, BMI, and sex before analysis.

Results: Progression either to the next albuminuria level in 16 patients or to end-stage renal disease (ESRD) occurred in 5 patients. No difference in adiponectin concentrations was observed between progressors and nonprogressors in patients with normoalbuminuria. In the patients with microalbuminuria and macroalbuminuria, progression of albuminuria was associated with higher omentin. Progression to ESRD was also associated with estimated glomerular filtration rate (eGFR). When these covariates were inserted in a Cox regression analysis, eGFR and omentin were significantly associated with progression of albuminuria. Increased serum omentin levels predict the progression from microalbuminuria to macroalbuminuria and progression of albuminuria was associated with higher omentin.

Conclusions: Our results indicate that serum omentin levels are associated with the progression of diabetic nephropathy in diabetic patients.

FR-PO615

Background: Vitamin D receptor (VDR) is a member of the nuclear receptor superfamily, and there was no report about the expression of Vitamin D and its receptor in patients with diabetes associated with proteinuria and diabetic nephropathy. So, this study aimed to test the expression trends of VDR in blood, urine samples and renal tissues of diabetic nephropathy, and the relationship with urinary protein, to explore the role of VDR in diabetic nephropathy.

Methods: 1. 65 patients who had been diagnosed with T2DM (with or without albuminuria) were enrolled in this study and 25 healthy control subjects were enrolled (NC group). The patients were classified according to the ratio of urinary excretion of albumin/creatinine (ACR). Diabetic patients without proteinuria (DM group, ACR: less than 30 mg/g, n = 25), with microalbuminuria (DN group, ACR: 30 to 300 mg/g, n = 24) and clinical proteinuria (DN2 group, ACR: more than 300 mg/g, n = 18). 2. The expressions of VDR and VDR in the plasma and urine were measured by ELISA, and the VDR in blood cells was measured by qRT-PCR. The expressions of VDR in kidney tissue were measured by immunohistochemical staining.

Results: Plasma VD and VDR levels were significantly lower in DN2 and DN3 groups as compared with NC group (plasma VD 0.78±0.24 and 0.88±0.29 vs. 2.32±1.31ng/ml, P<0.05, VDR 157.52±98.36 and 164.20±60.54 vs. 325.33±194.68 ng/ml, P<0.05). Urinary VD and VDR levels were significantly elevated in DN2 and DN3 groups as compared with NC group (urinary VD 1,34±0.58 and 1,42±0.44 vs. 1,18±0.56ng/ml, P<0.05, VDR 83.00±31.78 and 88.40±28.10 vs. 69.03±12.03ng/ml, P<0.05). These results verify that VDR declined with the increase of the amount of urine protein. Based on these results, VDR may play a role of renal protection in diabetic nephropathy.

Conclusions: These results verify that VDR declined with the increase of the amount of urine protein. Based on these results, VDR may play a role of renal protection in diabetic nephropathy.

FR-PO616
Mitochondrial DNA in the Plasma and Urine: A Potential Biomarker to Predict the Progression of Nephropathy in Type 2 Diabetes Mellitus. Li Fang, Junwei Yang. Center for Kidney Disease, Second Affiliated Hospital, Nanjing Medical Univ, Nanjing, Jiangsu, China.

Background: Mitochondrial dysfunction and chronic sterile inflammation are the most common features of type 2 diabetes mellitus. Thus, our objective was to investigate whether extracellular mitochondrial DNA (mtDNA) in the plasma and urine could be used as a biomarker predicting the progression of type 2 diabetes and nephropathy.

Methods: A total of 42 people with type 2 diabetes and 35 age-, sex- matched people without diabetes were enrolled in this study. The absolute quantification of mtDNA content was measured by real-time polymerase chain reaction. Relationships among different variables were analyzed using correlation analysis.

Results: The plasma mtDNA contents were significantly lower in the people with type 2 diabetes, particularly in those participants with clinically significant proteinuria. The plasma mtDNA content was negatively correlated with diabetic blood pressure, urine microalbumin and 24-hour urine protein; while positively correlated with platelet count, serum albumin and alkaline phosphatase. The urinary mtDNA contents did not change obviously; however, the creatinine-adjusted values were significantly higher in the group with diabetic nephropathy. Besides, the urinary mtDNA-to-creatinine ratio was negatively correlated with the duration of diabetes, fasting glucose and glycosylated hemoglobin.

Conclusions: Our results indicated that lower plasma mtDNA content and higher urinary mtDNA-to-creatinine ratio might be the potential biomarkers predicting the progression of nephropathy in type 2 diabetes.

FR-PO617
Involvement of Fractalkine and Its Receptor CX3CR1 in Disease Progression of Patients with Diabetic Nephropathy. Takahiro Uchiha,1 Takashi Oda,2 Hidehito Matusbara,1 Atsushi Watanabe,1 Hanako Takechi,1 Yoshitoku Imaikere,1 Naoki Oshima,1 Hiroko Kumagai.1 1Dept of Nephrology and Endocrinology, National Defense Medical College, Tokorozawa, Japan; 2Dept of Nephrology, Tokyo Medical Univ Hachioji Medical Center, Hachioji, Japan.

Background: Upregulated expression of fractalkine (CXCL1) and its receptor CXCR1 has been reported in some renal diseases. However, whether they are involved in human diabetic nephropathy (DN) is unclear. We therefore examined expression of these molecules in human DN.

Methods: Twelve patients with DN who were diagnosed by renal biopsy were studied. Expression of CX3CL1 and CXCR1 cells and degree of inflammatory cells were evaluated. Glomerular endothelial cell (GEC) was assessed by measuring the immunofluorescence (IF) intensity of CD34 staining.

Results: Expression of CX3CL1 or CXCR1 was not observed in normal control tissues. CX3CL1 was expressed on GECs, tubular epithelial cells, and endothelial cells of peritubular capillaries in renal tissues with DN. Expression of CXCL1 on GECs was found in 9 out of 10 patients, and its expression was seen with an increase tendency in patients with early stage of DN; whereas its expression was found in all patients with the early stage of DN, whereas its expression was found only in 5 out of 8 patients with the advanced stage. CX3CR1 expression was also upregulated in renal tissues with DN. The majority of the CX3CR1+ cells in glomeruli were GECs; CX3CR1+ inflammatory (CD45+) cells composed only a small number of CX3CR1+ cells in glomeruli, most of which were CD68+ macrophages.

Conclusions: These data demonstrate that CX3CL1 and CXCR1 were upregulated in human DN from early stage. Interestingly, not only CX3CL1 but also CXCR1 were expressed on GECs, and their expression on GECs may be involved in GEC injury. Targeting CX3CL1 and CXCR1 may be promising therapeutic approaches for DN.

FR-PO618

Background: Klotho is a protein implicated in multiple organic processes, being able to regulate growth factors signaling pathways, ion channels and transporters. Several animal and clinical demonstrated that Chronic Kidney Disease (CKD) is associated with Klotho deficiency. Moreover, Klotho seems to play a renoprotective role through its anti-oxidation properties, protection of vasculature, and promotion of vascularization and inhibition of fibrogenesis. In this study we investigated potential associations between serum klotho levels and known markers of mineral metabolism and insulin resistance, in order to better understand how Klotho affects is affected by these variables in diabetic patients with CKD.

Methods: In this study we included 107 type 2 diabetic patients (67 males, 62.6%) with CKD stage 2-3, a mean age of 66.6±9.7 years. Several laboratory parameters were assessed: eGFR, phosphorus, vitamin D, PTH, urine albumin/creatinine ratio (UACR), IL-6, FGF-23, OxLDL and the homeostasis model assessment (HOMA). Simple linear and multiple regressions model were used to investigate possible correlations between these variables and Klotho.

Results: In the simple linear model, Klotho levels were correlated with age (r=0.232, p=0.016), phosphorus (r=-0.381, p<0.001), PTH (r=-0.606, p<0.001), UACR (r=-0.336, p<0.001), HOMA (r=-0.482, p<0.001), IL-6 (r=0.571, p<0.001), FGF-23 (r=0.695, p<0.001), OxLDL (r=0.598, p<0.001), eGFR (r=0.228, p=0.018) and vitamin D (r=0.661, p<0.001), phosphorus (r=-0.381, p<0.001), PTH (r=-0.606, p<0.001), urine albumin/creatinine ratio (UACR), IL-6, FGF-23, OxLDL and the homeostasis model assessment (HOMA). Simple linear and multiple regressions model were used to investigate possible correlations between these variables and Klotho.

Conclusions: Our study, Klotho levels are influenced by FGF-23, vitamin D and insulin resistance, variables that are affected by the renal function. However, in the multiple regression model the eGFR lost its relationship with Klotho, and Klotho was associated mainly with the UACR and insulin resistance. More studies are needed to clarify the relationship with UACR and confirm if proteinuria is more critical in the definition of the association of Klotho.

FR-PO619
Macrophage Accumulation and Phenotype in Human Diabetic Nephropathy
Ying Yang, Yingfeng Guo, Zhixia Song, Min Zhou, Xiaoliang Zhang. Southeast Univ.

Background: Macrophage, especially its distinct phenotype is involved in the progress of
DN. M1 is characterized with pathogenic function, while M2 displays anti-inflammatory.
This study tries to examine the macrophage phenotype and its relationship to the renal
function and histological changes in human DN.

Methods: We studied retrospectively 46 patients with DN who were confirmed by
diagnosis of renal biopsy. Biopsies were divided into I Ha IIb III IV classes according to the
pathologic classification of DN. Patients with renal trauma or renal tumor were considered as
control group. Serum creatinine, proteinuria were calculated. Kidney tissues were used to
assess histological changes and the presence of macrophage marker CD68, M1 marker
iNOS, M2 marker CD206, Arg-1, TREM1 and TREM2.

Results: In biopsy tissue of human DN, Expression of CD68, M1 were significantly
increased in the glomeruli (2.835±0.547/gcs VS 0.003±0.007 for normals P=0.046) and
interstitium (0.037±0.142%/area VS 0.019±0.000%/area P= 0.016; 0.018±0.008%/area VS
0.009±0.005%/area P=0.023). While M2 were mainly observed in the interstitium
(0.019±0.000%/area VS 0.006±0.004%/area P=0.038). Interstitium M2 correlated strongly
with interstitium M1 infiltration. Additionally there was a positive correlation between
the glomerular CD68, M1 numbers and serum creatinine (r=0.619, p=0.001; r=0.463,
p=0.017), proteinuria (r=0.641; P<0.000; r=0.508, P=0.008), mesangial matrix, interstitial
collagen deposition. Likewise, the expression of interstitial CD68, M1, M2 also correlated
strongly with serum creatinine (r=0.638, P=0.000; r=0.666, P=0.001; r=0.520, P=0.000),
proteinuria (r=0.749, P<0.000; r=0.651, P=0.000; r=0.694, P=0.000), mesangial matrix,
interstitial collagen deposition. Besides TREM1,2-positive cells were apparent in the
interstitium and the expression levels significantly correlated with interstitium M1,M2
expression respectively.

Conclusions: Macrophage infiltration and polarization participate in the development
of diabetic nephropathy.

FR-PO620
Risk of Diabetes Increased According to the Level of Urinary Albumin Excretion Even Within Normal Range
Dong-Young Lee, Beom Kim, Kyung Hyoub Moon, Sung Keun Park, Younjo Jung. 1 Internal Medicine, VHS Medical Center, Seoul, Republic of Korea; 2 Total Health Care Center, Kangbuk Samsung Hospital, Sungkyunkwan Univ, School of Medicine, Seoul, Republic of Korea.

Background: Urine albumin creatinine ratio (UACR) as a reliable index of urinary albumin excretion is getting great attention on its predictive role for various diseases related with diabetes. Nevertheless, predictive value of UACR within normal range was not clarified for diabetes yet. Therefore, this study was aimed at examining the clinical association between normal range of UACR and development of diabetes.

Methods: We identified 1,274 non-diabetic Korean men within normal range of UACR in 2005, and followed them up until 2010. All subjects were classified into three categories with respect to baseline UACR, from the lowest to the highest. The incidence rates of diabetes were compared according to the tertile groups of UACR, and the independent hazard ratios (HRs) of UACR levels for diabetes was measured by Cox proportional hazards analysis.

Results: During follow-up, diabetes developed in 97 out of 1,274 subjects (7.6%). Incidence rate of diabetes increased in proportion to the levels of UACR (tertile 1 4.9%, tertile 2 7.3%, tertile 3 10.6%, P<0.001).

table1. Baseline characteristics of participants according to tertile groups of UACR levels
(N=1,274)
All variable are shown by mean value. P-value were (P<0.001 except development of diabetes (P=0.002).
The subjects with incident diabetes had the higher normal range of UACR than those without incident diabetes (5.3±4.2 µg/mg vs 6.7±4.2 µg/mg, p=0.013). When tertile 1 was considered as reference, HRs for diabetes was higher in tertile 3 (2.06; 1.16-3.37), even after adjusting for age, BMI, total cholesterol, log(HOMA-IR) and eGFR.

Conclusions: Elevated UACR, even within normal range, was significantly associated
with the future development of diabetes.

FR-PO621
Albuminuria Is Positively Associated with Elevated Numbers of Circulating Endothelial Pre- and Mature Cells, but Inversely Associated with Circulating Fibrocytes

Background: Diabetic nephropathy is characterized as a microvascular disease with
enhanced vascular leakiness in the kidney and aberrant tissue remodelling. Abnormal number and function of endothelial cells, stem cells and activation of leukocytes is considered as contributing mechanisms to the "kidney-micro"-vascular leaky syndrome. We determined if circulating endothelial pre- and mature cells, fibrocyte and monocyte sub-populations were abnormally regulated in type 2 diabetic patients with albuminuria.

Methods: Cross-sectional study of 37 type 2 diabetic patients; 18 with normalalbuminuria (<30mg/24h) and 19 with albuminuria (30mg/24h). 8-color flow cytometry analysis of peripheral blood was performed. ANCOVA compared expression of cell markers and absolute number of specific cell populations in patients with normalalbuminuria vs. albuminuria.

Results: Expression of VEGFR2 was significantly enhanced in patients with albuminuria (p=0.009). Also, the total number of circulating mature endothelial cells (CEC) was significantly enhanced in albuminuria (p=0.001). Circulating fibrocyte number and collagen-1 expression was inversely associated with albuminuria (p=0.037) and TGF-beta stabilizing and M2-associated galectin-3 expression on M1-like and M0-like monocytes was positively associated with albuminuria (p=0.029). In contrast, expression of the M1-associated marker CD14 (p=0.042) was inversely associated with albuminuria on all monocytes, particularly on M0-like macrophages (p=0.014).

Conclusions: The enhanced number of CEC together with elevated expression of VEGFR2 may indicate an aberrant function of the CEC with reduced capacity to heal the kidney microvasculature. The imbalanced M2-polarization of monocytes and aberrant fibrocyte count may favour improper repair leading to excessive tissue fibrosis. Hence therapeutic approaches addressing migratory pattern of CEC, providing adjuvant activating signals or restoring the immune balance might provide novel individualized treatment regimes.

FR-PO622
Prognostic Value of Tubulointerstitial Lesions and Urinary N-Acetyl-b-D-Glucosaminidase in Patients with Type 2 Diabetes and Biopsy-Proven Diabetic Nephropathy
Koki Mise, Junichi Hoshino, Toshiharu Ueno, Masayuki Yamanouchi, Noriko Hayami, Tsatsuya Suwabe, Kenmei Takai, Yoshifumi Ubara. 1 Nephrology Center, Toranomon Hospital Kajigaya, Kawasaki, Kanagawa, Japan; 2 Nephrology Center, Toranomon Hospital, Tokyo, Japan.

Background: Recently, it has been reported that some biomarkers of renal tubular
injury are useful to predict the renal prognosis in the early stage of diabetic nephropathy
(DN). However, how closely such biomarkers reflect actual tubulo-interstitial damage remains unknown.

Methods: Among 210 patients with type 2 diabetes and biopsy-proven DN, 152 patients were enrolled, 89% of whom had overt proteinuria. The endpoint was defined as a 50% or more decrease of the estimated glomerular filtration rate (eGFR) from baseline or commencement of dialysis due to end-stage renal disease. The Cox proportional hazard model was used to calculate the hazard ratio (HR) and 95% confidence interval (CI) for the death-censored endpoint.

Results: A significant correlation was found between baseline urinary N-acetyl-b-D-glucosaminidase (NAG) excretion and the score for interstitial fibrosis and tubular atrophy (IFTA score) (r=0.39, P<0.001). The influence of urinary NAG on the renal prognosis was attenuated after adjustment for known promoters of progression (+1SD for log NAG, HR: 0.87 [95% CI: 0.66-1.13]). On the other hand, the IFTA score was significantly related to the outcome even after adjustment for those covariates (+1 for IFTA score, HR: 2.20 [1.50-3.21]).

Conclusions: The assessment of urinary NAG excretion did not improve the prognostic power of known indicators of progression, whereas the IFTA score did. The IFTA score may be more useful for predicting the renal prognosis than current tubulo-interstitial markers, especially in patients with advanced DN.

Is There Any Benefit of Performing Renal Biopsies in Patients with Diabetic Nephropathy when No Other Diagnosis Than Diabetic Nephropathy Is Found? Rosa M. Montero,1 Dimitrios Anestis Moutzouris,2 Ramnith Perera,3 David Goldsmith.1 1Nephrology & Transplantation, Guy’s & St Thomas’ NHS Foundation Trust, London, United Kingdom; 2Histopathology, Guy’s & St Thomas’ NHS Foundation Trust, London, United Kingdom.

Background: The risk of renal biopsy has long been thought to outweigh the benefit of performing these on patients with diabetes mellitus (DM) leading to small numbers of renal biopsies in this population. Those biopsied have a propensity to more proteinuria or haematuria precipitating biopsy. Glomerular lesions alone have long been the hallmark of diabetic nephropathy (DN) however looking back at the biopsy can there be more to see? Aim: All native renal biopsies diagnosed with DN from 2009-2014 were retrieved from archive at Guy’s & St Thomas’ NHS foundation trust. Renal biopsies were performed in patients with DM who had heavy proteinuria or haematuria on presentation. Biopsies with a DN diagnosis alone were identified and Tervaert’s new DN classification was applied.

Results: Results: 3000 native kidney biopsies were performed from 2009-2014. 34 DM patients had DN alone on renal biopsy, 12 T1DM and 22 T2DM. 20 male, 14 females. Ethnicity:35% white, 35% black, 3% asian, 27% other. Age range:24-86 years (median 55). UPCR: 13, 1492 mg protein/mmL creatinine (median 392) eGFR 7.7-49.9 (median 23). 8.8% 5 year mortality. Glomerular IV and Interstitial fibrosis III lesions were significant predictors of renal survival (p=0.013 HR 27.5, p=0.006 HR 21.3, respectively). Renal survival ranged from 1-60 months post renal biopsy (median 3).

Conclusions: Interstitial fibrotic lesions are as important as glomerular lesions in predicting renal survival. Determining the significance of the components in predicting outcome may be more sensitive; however few biopsies are undertaken in this population. The role of an earlier renal biopsy showing less well established features in the DN population is unknown. We aimed to redefine the risk profile of native biopsies performed on our DN population using Tervaert classification.

FR-PO624
Understanding the Relationship Between Histopathology and Renal Function in Hypertension and Diabetes Matthew Palmer,1 Jordana B. Cohen,2 Mensy Liang,2 Steven S. Pullen,1 Katalin Suszta.1 1Pathology, Univ of Pennsylvania, Philadelphia, PA; 2Nephrology, Univ of Pennsylvania, Philadelphia, PA; 3CardioMetabolic Research, Boehringer Ingelheim, Ridgefield, CT.

Background: Much of the literature relating clinical and pathologic variables in patients with diabetes mellitus (DM) and hypertension (HTN) has relied on biopsy series. To gain unbiased insight into the degree of interstitial fibrosis (IF) and glomerular sclerosis (GS) associated with decline of renal function in DM and HTN, we have correlated histopathology with renal function, DM and HTN status in patients undergoing tumor nephrectomies.

Methods: Data and renal tissue were collected on nephrectomy patients from 7 centers. We used Spearman correlation coefficients to compare eGFR with pathologic assessment of IF (estimate) and GS (manual count). Bivariate linear regression was used to assess the association between log-transformed percent IF or GS and eGFR, stratifying by presence of DM or HTN.

Results: Of 251 patients, there were 60 without DM or HTN, 89 with HTN alone, and 102 with DM (+/- HTN). Median age was 62, 42% were female, 60% were Caucasian, median systolic blood pressure was 134 mmHg, and median eGFR was 66.5. There was a significant association between decline in eGFR and both IF (rho=-0.50, p<0.01) and GS (rho=-0.53, p=0.01) eGFR of 60 was associated with a geometric mean (95% CI) IF and GS of 7.9% (5.4-10.3) and 8.3% (5.7-12.1) for patients without DM or HTN, 9.2% (7.5-11.2) and 8.7% (7.0-10.8) in patients for HTN, and 10.9% (8.8-13.5) and 9.6% (8.0-11.6) for patients with DM. Stage 3 CKD was associated with a median IF and GS of 10% (IQR 7.3% and 8.3% for patients without DM or HTN, 9.2% (7.5-11.2) and 8.7% (7.0-10.8) for patients with HTN, and 10.9% (8.8-13.5) and 9.6% (8.0-11.6) for patients with DM. Stage 3 CKD was associated with a median IF and GS of 10% (IQR 5-15) and 11.3% (IQR 5.7-18.8) overall, and with median IF and GS of 10% (IQR 5-20) and 11.9% (IQR 5.7-20.8) in DM.

Conclusions: While IF and GS are similar at a given eGFR, patients with DM have a trend toward a greater degree of IF and GS at the same level of eGFR compared to those with isolated HTN. Stage 3 CKD is associated with median IF of 10% though there is high inter-individual variation. This highly variable histopathology should be considered when patients with DM are included into clinical studies, and kidney biopsies might be useful to include in categorization.

FR-PO625
Efferent Arterioles Are Special Target for Obesity Noriko Uesugi, Michio Nagata. Kidney and Vascular Pathology, Faculty of Medicine, Tsukuba Univ, Tsukuba, Ibaraki, Japan.

Background: The link between obesity and renal disease is unclear. Hyperfiltration is suspected to induce arteriolar hyalinosis and glomerular hypertrophy in moderate to severe obesity. To assess morphological changes in the kidney in obesity, we investigated human renal specimen from 7 mild obese cases (Ob)(BMI 27) Age 61y.o., S-Cre 0.8mg/dl. 4 with hypertension) and compared with 7 hypertensive case (HT) and 4 control(Con).

Methods: Total 130 of serially cut paraffin sections were double immunostained with CD34 as endothelial marker, and smooth muscle actin as medial marker, followed by PAS stain. Incidence of hyalinosis in afferent and efferent arterioles, intraglomerular cystic dilatation connecting to efferent arterioles, segmental sclerosis, sclerotic glomeruli(GS) and average size of glomeruli were assessed using 50-40 glomeruli per case.

Results: The morphological data were as follows; average glomerular diameter 203±26, 181±19, 156±4 um, incidence of afferent arteriolar hyalinosis 43±13, 47±29%, 20±16% in Ob, HT and Con, respectively (*P<0.05 vs Con, **P<0.05 vs Con and HT). Higher incidence of cystic dilatation near efferent arterioles was noticed in Ob (21±15%) than HT and Con (2±15%, 0%, respectively)(*P<0.05). Obese cases revealed neither significant intimal thickening nor distortion in the interlobular arteries, no segmental sclerosis, low incidence of GS (11±7%) and minimal interstitial damage(<10%).

Conclusions: Efferent arterioles are targets for obesity, which suggest that specific mechanism of glomerular hyperfiltration involves obese cases, even in mild form.

A Pathological Scoring System to Predict Renal Outcome in Diabetic Nephropathy Junichi Hoshino, Koki Mise, Toshiharu Ueno, Keichi Sumida, Masayuki Yamanouchi, Noriko Hayami, Tatsuya Suwabe, Shigeko Hara, Yoshifumi Ubara, Kenmei Takaihi. Nephrology Center, Toranomon Hospital, Tokyo, Japan.

Background: With association between diabetic nephropathy (DN) and renal outcome increasingly clear, we aimed to create a new DN pathological scoring system that could predict renal outcome.

Methods: We studied 205 patients with DN confirmed by renal biopsy between March 1995 and January 2010 who met inclusion criteria. Renal biopsy included clinical parameters and Tervaert classifications. Hazard ratios (HRs) for end-stage renal disease (ESRD) were estimated by adjusted Cox regression. Overall pathological risk score (D-score) was calculated by summing the products of beta-coefficient and bootstrap-inclusion fractions, its predictive utility evaluated by Kaplan-Meier methods and c-statistics with 10-fold cross-validation for 10-year risk of ESRD.

Results: D-scores of glomerular classes 1, 2A, 2B, 3, and 4, were, respectively, 0.3, 4, 6, and 6. Those of interstitial fibrosis and tubulatary atrophy classes 0, 1, 2, and 3 were 0, 7, 9, and 11, and those of interstitial inflammation classes 0, 1, and 2, respectively, 0, 3, and 4. D-score of hyalinosis class 2 was 3 and that of arteriosclerosis class 2 was 1. So a patient’s D-score could be 0-25.

HRs for ESRD in patients with D-score£14, 15-18, 19-21, and 22-25 were, respectively, 1.00 (ref) 16.21 (1.86-14.90), 19.78 (2.15-182.40), and 45.46 (4.63-446.68) after adjusting for clinical factors. When comparing c-statistics, a model that included D-score in addition to age, eGFR, and proteinuria, showed a slight improvement from 0.901 (0.861-0.942) to 0.932 (0.898-0.965). The net reclassification index also showed better reclassification (0.24 (+0.2 to 0.49).

Conclusions: In addition to clinical parameters, D-score may have improved prediction of 10-year risk of ESRD. Patients with D-score £14 had excellent renal prognosis.

Methods: A total of 396 patients with T2D and biopsy-proven DN from Nanjing DN registration system were followed-up for at least 1 year were recruited and median 5-year follow-up. Renal outcomes were defined by progression to end-stage renal disease and doubling of serum creatinine.

Results: Of the patients, the mean baseline eGFR was 73.86±33.52 mL/min per 1.73m². The levels of the urinary tubulointerstitial injury markers including the NAG, RBP and NAGL were significantly different among quintiles of serum phosphorus (P<0.01). The participants whose eGFR<90 mL/min per 1.73 m² had a higher rate of tubulointerstitial injury (interstitial fibrosis tubular atrophy scores of 2 and 3, P=0.005; interstitial inflammation scores of 1 and 2, P<0.035) in hyperphosphatemia (≥1.45 mmol/L) group than in lower phosphorus group (<1.17 mmol/L). Participants with baseline levels of serum phosphorus in higher quintiles had a higher cumulative incidence of ESRD (log-rank, P<0.001). In the analyses adjusted by age, sex, diabetes status, BP, FBG, BMI, proteinuria, cholesterol, and eGFR, the relationship between higher serum phosphorus and an increased risk of ESRD remained. The association between serum phosphorus and ESRD risk persisted and was stronger when the sample was restricted to those with a baseline eGFR equal to 60-90 mL/min per 1.73 m², but not when it was restricted to patients with a baseline eGFR of 30-40 mL/min per 1.73 m².

Conclusions: These findings indicated the baseline serum phosphorus is associated with tubulointerstitial injury of T2D patients. And serum phosphorus >1.45mmol/L is an independent risk factor of ESRD in T2D, especially in the patients with eGFR≥60 mL/min per 1.73m².

Longitudinal Changes in Estimated Glomerular Filtration Rate in Youth with Type 1 Diabetes: Data from SEARCH for Diabetes in Youth Study.

Univ, Anand, Gujarat, India.

Background: Diabetes is the leading cause of kidney disease in the US. The natural history of kidney function early in type I diabetes (T1D) is relatively unknown.

Methods: SEARCH for Diabetes in Youth is a multicenter cohort study of incident diabetes in youth <20 yrs at diagnosis. Cystatin C (CysC) was measured at two study visits; values were calibrated for assay drift and standardized to the reference material. GFR was estimated using the CysC-based Filler equation, the only pediatric equation validated in hyperfiltration. Participants were stratified by change in eGFR: gain of ≥3ml/min/1.73m²/yr, loss of ≥3ml/min/m²/yr, or stable. Nominal multinomial regression was used to predict eGFR, outcome category. Covariates included gender, race/ethnicity, and follow up age, fasting glucose, HbA1c, insulin sensitivity score, renin-angiotensin inhibition, and systolic blood pressure Z-score (SBPZ).

Results: The analysis included 905 participants with T1D (mean age 14±4 yrs; duration 4.2±1.9 yrs, HbA1c 8.7±1.8%; SBP -0.3±1.6 and CysC 0.73±0.12 mg/L). Follow up CysC was measured 4.6±1.1 yrs later. 323 (36%) participants lost eGFR (mean 150±30 fell to 119±23, p<0.0001); 197 (22%) gained eGFR (mean 122±22 rose to 151±29, p<0.0001) and 385 (42%) had stable eGFR. Odds ratios (OR) for predictor variables significant in any pairwise comparison are shown below.

previous congestive heart failure (n=23 799) (HR 1.26, 95% CI 1.17, 1.36). In addition, a 25-50 mmHg decrease in SHP from the last observation was associated with an increase in risk of all-cause mortality (HR 1.44, 95% CI 1.33, 1.56) compared to a change in the range -10 to 10 mmHg.

Conclusions: A systolic blood pressure < 130 mmHg and a decrease in systolic blood pressure during follow up with or without previous congestive heart failure, is associated with an increase the risk of all-cause mortality in patients with type 2-diabetes and renal impairment. Intensity of hypertensive medication and co-morbidities are important confounders and will be further evaluated.

FR-PO632
Increased Expression of WNT5a in Renal Tubules Is Associated with Diabetic Nephropathy in Humans
Malik Asad Aanum, An Xiao, Dean Troyer, Michael J. Solhaug, Anca Dobrian, Jerry L. Nadler, Liwei Huang.
1Internal Medicine, Eastern Virginia Medical School, Norfolk, VA; 2Pathology, Sentara Norfolk General Hospital, Norfolk, VA.

Background: Diabetic nephropathy (DN) is the leading cause of end stage renal disease worldwide. In recent years, convincing data has come forward suggesting that inflammatory pathways play a pivotal role in the pathogenesis and progression of DN. Identification of these inflammatory pathways and associated biomarkers may help in the early diagnosis of DN and development of novel targeted therapeutic strategies to help prevent, treat and even slow the progression of DN. Wnt5a, a secreted glycoprotein, plays an important role in normal kidney development and is also a pro-inflammatory factor which has been associated with renal fibrosis and disruption of matrix metabolism. The objective of our study was to investigate the expression of Wnt5a in diabetic kidneys in humans.

Methods: 11 subjects with biopsy confirmed DN were included in our experimental group. Normal kidney tissues from non-diabetic subjects who underwent nephrectomy for renal cell carcinoma were used as controls. Exclusion criteria for the experimental group were HIV positivity, chronic/acute inflammatory diseases (including hepatitis C) and steroids/immunosuppressant medication. Wnt5a expression was evaluated in paraffin embedded tissues.

Results: Immunohistochemical analysis of Wnt5a expression showed positive staining on the apical side of the plasma membrane of the renal tubular epithelial cells in control kidney tissues. The intensity of the staining is increased in patients with DN compared to normal kidney control tissues. In patients with DN, Wnt5a expression is localized both in the cytoplasm and on the apical side of the plasma membrane of the renal tubular epithelial cells. Wnt5a is also expressed on glomerular cells, but there are no differences in Wnt5a expression between the tissues from diabetic subjects and controls.

Conclusions: Our results suggest that Wnt5a expression in renal tubules might have a pathogenic role in the development of human renal tubular fibrosis. These studies are the first to demonstrate an increase in Wnt5a expression in renal tubules in DN.

FR-PO633
Accuracy of Serum Creatinine and Glomerular Filtration Rate Estimation for Adjusting Metformin Prescription in European Type 2 Diabetics
Olivier Moranne, Coraline Faïn, Pierre Delanaye, Martin Flamant.
1Nephrology, CHU, Nice, France; 2Nephrology, Hospital, Liege, Belgium; 3Physiology, APHP, Paris, France.

Background: There is a debate in the literature about the thresholds of serum creatinine (Scr) above which the drug is contraindicated (1.5 mg/dL in men & 1.4 mg/dL in women). For KDOQI, recommendation is a dose-adjustment between 45 and 30 mL/min and a withdrawal below 30 mL/min. However, in DM2, estimation of renal function based on Scr alone or on eGFR may vary from the true renal function (mGFR). The purpose of our study was to define the performance of the GFR assessment method (Scr or eGFR calculated with Cockcroft-Gault (CG) or CKD-EPI) in terms of metformin dose adjustment in DM2 who underwent a GFR measurement.

Methods: In 243 DM2 patients, GFR was measured by urinary clearance of 125I-DiETA. Non indexed GFR was used. We analyzed the agreement between classification of patients based on mGFR and, first, Scr alone with a cutoff value of 1.5 mg/dL in men and 1.4 mg/dL in women, second, on eGFR with threshold values of 45 or 30 mL/min. When both methods classified the patient in the same subgroup, the data were considered concordant otherwise overprescription (underprescription) was defined for discordance according to mGFR.

Results: Age was 61 ± 12 y, median mGFR was 42 [30-61] mL/min. Based on mGFR, the distribution of the patients according the following GFR class: [90-45] 11045%, [44-30] 7430%, < 30: 3.924%. In patients with a Scr above the cutoff value, mGFR(90%) was < 30 mL/min in respectively 23/40 women and 33/106 men. With a threshold of 45 mL/min then 30 mL/min, concordance was found in 8085% then 8888% of the patients for the CG and CKD-EPI. With a threshold of 30 mL/min, discordance was an overestimation or underestimation (229% and 198%) or (146% and 115%) of the patients with the CG and CKD-EPI.

Conclusions: In this population creatinine-derived equations outperformed Scr alone in correctly classifying the patients in prescription subgroups. However, even with creatinine-based equations, discordance with mGFR occurs in 12-20% of the patients. New strategies such as drug concentration monitoring may be necessary to improve appropriate prescription of metformin in DM2.

FR-PO634
Changes in Glycaemia During Haemodialysis (HD) Are Not Associated with Changes in QTc Interval in Insulin-Treated Diabetic Patients

Background: Change in albuminuria may have useful prognostic value. We sought to assess the association between change in urine albumin-to-creatinine ratio(UACR) and the risk of all-cause death, cardiovascular disease(CVD), and end-stage renal disease(ESRD) in the ADVANCE trial.

Methods: We defined UACR change(base line to 2 years) as >30% increase, >30% decrease to <30% increase(minor change), and >30% increase. Follow-up for outcome ascertainment commenced at the second UACR measurement. We used Cox regression to estimate the hazard ratio(HR), after adjustment for demographics, ADVANCE randomized treatment assignments, comorbidities, laboratory measurements(including baseline UACR), and drug use.

Results: From baseline to 2 years, 34% of 9195 patients experienced a UACR decrease of >30%, 36% experienced a minor change, and 34% experienced an increase of >30%. Over the next 2.9 years(median), 520 deaths, 524 CVD events, and 12 ESRD events were recorded. An increase of >30% in UACR was associated with 30% higher mortality when compared to a minor change ([Figure 1]) HR 1.30, 95%CI:1.18-1.40). Increase in UACR associated with increased CVD or ESRD, although the direction of effect was similar. A >30% UACR decrease was not significantly associated with the risk of death or CVD when compared to those with minor change but was significantly associated with lower ESRD risk(HR 0.10, 95%CI:0.01-0.79).

Conclusions: In type-2 diabetes patients, >30% increase in albuminuria predicted higher mortality while >30% decrease was associated with decreased ESRD risk. Our results suggest change in albuminuria may be a potential prognostic marker for clinical outcomes in type-2 diabetes.

The Association Between Changes in Albuminuria and Clinical Outcomes in the ADVANCE (Action in Diabetes and Vascular Disease: PreterAx and Diamicron® MR Controlled Evaluation) Trial

Background: In this population creatinine-derived equations outperformed Scr alone in correctly classifying the patients in prescription subgroups. However, even with creatinine-based equations, discordance with mGFR occurs in 12-20% of the patients. New strategies such as drug concentration monitoring may be necessary to improve appropriate prescription of metformin in DM2.

FR-PO636
The Association Between Changes in Albuminuria and Clinical Outcomes in the ADVANCE (Action in Diabetes and Vascular Disease: PreterAx and Diamicron® MR Controlled Evaluation) Trial

Background: In this population creatinine-derived equations outperformed Scr alone in correctly classifying the patients in prescription subgroups. However, even with creatinine-based equations, discordance with mGFR occurs in 12-20% of the patients. New strategies such as drug concentration monitoring may be necessary to improve appropriate prescription of metformin in DM2.
Results: QTc interval was prolonged significantly at the end of HD in all sessions (p<0.001). Change in glucose level (mean±SD -1.8±4.2 vs -1.7± 3.0) did not have a significant effect on the change in QTc interval (p=0.396), which was not different in diabetic subjects compared to non-diabetic group (p=0.390). Serum K⁺, Mg²⁺ and Ca²⁺ levels dropped significantly (p<0.001) during all 3 HD sessions. There was no significant difference in the starting level and the drop in K⁺ dropped significantly (p<0.001) during all 3 HD sessions. There was no significant difference in the starting level and the drop in Mg²⁺ and Ca²⁺. The change in Mg²⁺ (p<0.05) and Ca²⁺ (p<0.05) levels but not K⁺ (p=0.202) were more pronounced in diabetic subjects. The change in Mg²⁺ levels in diabetic subjects was associated with QTc prolongation (p<0.05).

Conclusions: Significant QTc prolongation occurs at the end of HD in people with and without diabetes, often reaching abnormal levels and appears to be related to more changes in blood electrolytes than glycaemia. The fall in serum Mg²⁺ levels during HD had a larger effect on QTc than K⁺ or Ca²⁺ and this appears to have a more pronounced effect in diabetic subjects. The changes in QTc may increase the risk of cardiac dysrhythmia and sudden death in HD patients.

FR-PO636

Markers of Inflammation and Endothelial Dysfunction Are Associated with Cardiovascular Morbidity and Mortality in Type 2 Diabetic Patients with Microalbuminuria

Bernt Johan Lum von Scholten,¹ Henrik Reinhardt,¹ Tine Hansen,¹ Casper Schalkwijk,² Coen Stehouwer,² Hans-Henrik Parving,¹ Peter Karl Jacobsen,³ Peter Rossing,¹ ¹Steno Diabetes Center, Denmark; ²Maastricht Univers Medical Center, Netherlands; ³Rigshospitalet, Denmark.

Background: Accumulating evidence suggests that inflammation and endothelial dysfunction link type 2 diabetes (T2D) to cardiovascular disease (CVD). We evaluated the predictive value of markers of inflammation and endothelial dysfunction for combined fatal and non-fatal CVD and for all-cause mortality in patients with T2D and microalbuminuria but without known coronary artery disease (CAD).

Methods: Prospective study including 200 patients. All received intensive multifactorial treatment. Markers of inflammation (TNF-α, ICAM-3, hsCRP, SAA, IL-1β, IL-6, IL-8) and endothelial dysfunction (thrombomodulin, VCAM-1, E-selectin, P-selectin) were measured at baseline. Adjusted linear regression models included sex, age, total cholesterol, smoking, HbA1c, creatinine, systolic blood pressure and urinary albumin excretion. Fully adjusted models additionally included NT-proBNP and coronary artery calcium score (CAC).

Results: Participants were 76% men, age (± SD) 59 ± 9 years, HbA1c was 7.9 ± 1.3% and UAER (IQR) was 103 (39–230) mg/dL. Occurrence of CVD (n=40) and mortality (n=26) was traced after 6.1 years (median). In adjusted Cox analysis, higher TNF-α predicted the CVD endpoint and mortality (p=0.002). After full adjustment higher TNF-α remained predictive of both endpoints (p=0.007). Higher thrombomodulin and ICAM-3 were associated with risk of CVD and mortality in adjusted analyses (p<0.05) and predicted mortality after fully adjustment (p<0.001). Higher VCAM-1 and ICAM-1 were associated with risk of mortality in adjusted (p<0.002) and fully adjusted models (p<0.005). The composite z-score of all markers of inflammation and of endothelial dysfunction predicted CVD and mortality (p<0.008).

Conclusions: In patients with T2D and microalbuminuria without known CAD, biomarkers of inflammation and endothelial dysfunction were independently associated with risk of CVD and mortality. Especially TNF-α was a robust predictor, even after adjusting for albuminuria, NT-proBNP and CAC.

FR-PO637

Predictors of Glycemic Status and Associations with Mortality in Incident Diabetic Hemodialysis Patients

Connor Rhee,¹ Steven B. Kim,¹ Rajnish Mehrotra,¹ Elani Streja,¹ Danh V. Nguyen,¹ Steven M. Brunelli,³ Gregory Brent,¹ Csaba P. Kovessy,¹ Kamyar Kalantar-Zadeh,¹ UC Irvine; ²Univ Washington; ³Davita Clinical Research; ¹UCLA; ²UTHSC.

Background: In the general population, intensive glycemic targets confer higher mortality in diabetics with cardiovascular risk. In diabetic hemodialysis (HD) patients, some but not all studies show that lower glycemic levels defined by HbA1c are associated with higher mortality. We sought to examine predictors of low glycemic status in HD patients and, if present, identify the factors associated with lower mortality. We examined the association of HbA1c with all-cause mortality. Baseline and time-dependent HbA1c as a proxy of long-term and short-term exposure—mortality associations, respectively, were examined using case-mix laboratory adjusted Cox models.

Methods: We performed a cross-sectional study of a representative sample of 1594 persons recruited from the general population of the municipality of Tromsø, Norway, aged 50-62 without prevalent cardiovascular disease, diabetes or renal disease. GFR was measured by ioxelol clearance. Obesity was classified according to body mass index (BMI), waist circumference (WC) and waist-hip ratio (WHR). HbA1c was measured as >90th percentile of residuals from a linear regression of absolute GFR on age, sex, weight and height.

Results: In multivariable adjusted logistic regression models, the odds ratios (95% confidence intervals) for RHF were 1.56 (1.11-2.18) for RHF defined as >90th percentile of residuals from a linear regression of absolute GFR on age, sex, weight and height. GFR was measured by ioxolol clearance. Obesity was classified according to body mass index (BMI), waist circumference (WC) and waist-hip ratio (WHR). HbA1c was defined as >90th percentile of residuals from a linear regression of absolute GFR on age, sex, weight and height. GFR was measured by ioxolol clearance. Obesity was classified according to body mass index (BMI), waist circumference (WC) and waist-hip ratio (WHR). HbA1c was defined as >90th percentile of residuals from a linear regression of absolute GFR on age, sex, weight and height. GFR was measured by ioxolol clearance. Obesity was classified according to body mass index (BMI), waist circumference (WC) and waist-hip ratio (WHR). HbA1c was defined as >90th percentile of residuals from a linear regression of absolute GFR on age, sex, weight and height. GFR was measured by ioxolol clearance. Obesity was classified according to body mass index (BMI), waist circumference (WC) and waist-hip ratio (WHR). HbA1c was defined as >90th percentile of residuals from a linear regression of absolute GFR on age, sex, weight and height.
insulin and HbA1C) and cardiovascular risk factors (including ambulatory blood pressure, antihypertensive medication and smoking status). WHR may be a better indicator of the renal effects of obesity than BMI or WC.

**Obesity Associates with High Hemoglobin A1c but Low Alternative Indices in Both Diabetic and Nondiabetic Hemodialysis Patients**

Mark E. Williams,1 Neal Mittman,2 Lin Ma,3 Julia I. Brennan,4 Chimi M. Jani,5 Curtis D. Johnson,6 Franklin W. Maddux,2 Eduardo K. Lacson.1,5 1Joslin Diabetes Center, Boston, MA; 2Kidney Care of Brooklyn and Queens, Brooklyn, NY; 3Prescient Medical Care North America, Waltham, MA; 4Spectra Laboratories, Rockleigh, NJ; 5Physician, Lexington, MA.

**Background:** The GIDE (Glycemic Indices in Dialysis Evaluation) study is evaluating several glycemic markers in hemodialysis (HD) cohorts with and without diabetes. We have reported that alternative glycemic indices may be elevated out of proportion to hemoglobin A1c (HgbA1c). Because obesity is known to affect markers of glycemia, we examined its association with these indices.

**Methods:** A combined cohort of 2,394 active HD patients (1,424 with diabetes, 970 without) from 26 U.S. FMCNA facilities had baseline indices [HgbA1c; albumin-adjusted and unadjusted fructosamine (AlbF; F) and glycated albumin (GA) or percent GA] measured Jan-Mar 2013 and monthly until April, 2015. Mean of body mass index (BMI) was determined for the entire cohort. Obesity—BMI≥30 kg/m². Cox models adjusted by age, sex, race, ethnicity, vintage, HD catheter, baseline comorbidity and laboratory albumin values were utilized to determine associate between obesity with death outcome.

**Results:** Average BMI (kg/m², mean±SD) by risk as determined by indices (low=within target range, high=above target range) are shown in (table 1).

The Hazard Ratio (HR) for death was reduced with obesity [HR=0.76, 95%CI (0.62, 0.94), p=0.01].

**Conclusions:** Obesity is positively correlated with HgbA1c but negatively correlated with other glycemic indices in hemodialysis patients. Further studies are needed to elucidate underlying mechanisms and assess the relationship of these findings to superior survival outcomes in obese HD patients.

**FR-PO640**

**BMI and Causes of Death in Chronic Kidney Disease**

Sankeer D. Navaneethan,1 Jesse D. Schold,2 Susana Arrigain,2 John P. Kirwan,3 Joseph V. Nally,4 1Nephrology, Cleveland Clinic; 2Quantitative Health Sciences, Cleveland Clinic; 3Pathobiology, Cleveland Clinic.

**Background:** Chronic kidney disease (CKD) is associated with higher risk for cardiovascular related death. In CKD, a higher body mass index (BMI) is associated with a lower risk for death, but cause specific death details are unknown across the BMI range.

**Methods:** We included 54,506 patients with CKD (two estimated glomerular filtration rate <60 ml/min/1.73 m², 90 days apart; January 2005 – December 2012) from our institutional electronic medical record-based CKD registry. We examined the associations between various causes of death (cardiovascular, malignancy and non-cardiovascular/ non-malignancy related deaths obtained from the State of Ohio mortality files) across the BMI range using the Cox proportional hazards model.

**Results:** During a median follow-up of 3.7 years (25th percentile,75th percentile: 1.8-5.8), 14,518 patients died. In the multivariable model, an inverted J-shaped association was noted between BMI and overall, cardiovascular, malignancy-related, and non-cardiovascular/ non-malignancy related deaths.

**Conclusions:** Similar associations were noted for BMI 25-29.9, 30-34.9, and 35-39.9 kg/m² categories. BMI<30 kg/m² was not associated with cardiovascular and non-cardiovascular/ non-malignancy related deaths in CKD. Sensitivity analyses yielded similar results even after including only those with >2 year follow-up, adjusting for proteinuria, and excluding diabetes and hypertension from the models. However, the inverse associations between higher BMI and cardiovascular deaths were not observed among smokers.

**Funding:** In those with CKD, compared to BMI of 18.5-24.9 kg/m², those who are overweight, class 1 and 2 obesity are associated with lower risk for cardiovascular, malignancy-related and non-cardiovascular/ non-malignancy related deaths. Future studies are needed to confirm these findings.

**FR-PO641**

**Weight Reduction with Low Calorie Diet Reduces Urinary Megalin and Improves Albuminuria in Obese Men**

Tetsuro Takeda,1 Akihiko Saito.2 1Nephrology, Dokkyo Medical Univ Koshigaya Hospital, Koshigaya, Saitama, Japan; 2Applied Molecular Medicine, Niigata Univ, Niigata, Japan.

**Background:** Megalin, an endocytic receptor in proximal tubules, is involved in the mechanisms of albuminuria in diabetic nephropathy. A urinary full-length megalin (C-megalin) assay is linked to the severity of diabetic nephropathy and IgA nephropathy. Also, albuminuria is a frequent sign of obese individuals and could be reduced by losing body weight. We investigated the relationship between level of urinary C-megalin and albuminuria on a weight reduction program in obesity.

**Methods:** Thirty-three obese male volunteers (age 36.6 ± 6.9 years, BMI ≥25 kg/ m²) were enrolled but 30 subjects completed the 12-week weight reduction program. The program consisted of replacement of evening meal by a low calorie formula food (MICRO-S®) for first 4 weeks and followed by bi-weekly dietary counseling session with nutritionist. Of these, 20 subjects with metabolic syndrome were included (based on the Japanese criteria). Urinary albumin/cre ratio (ACR) and urinary C-megalin were measured at baseline and after the program.

**Results:** The mean weight loss was 5.2 ± 2.9 kg (5.6% of the original BW). The baseline ACR ranged from 2.8 to 52.9 mg/gCre. After the program, BMI, waist circumference, BP, total cholesterol and FFA were significantly decreased. HDL-cholesterol and adiponectin were significantly increased. Overall, ACR was not changed (11.9 ± 12.4 to 8.8 ± 5.3 mg/gCre). However, in the cases with ACR >8 mg/gCre at baseline (n=11), ACR was more effectively reduced (22.9 ± 15.1 to 12.7 ± 6.4 mg/gCre) without a change in eGFR. The reduction of ACR was correlated with the reduction of urinary C-megalin. No other parameters like insulin resistance were associated with the reduction of ACR or C-megalin.

**Conclusions:** Losing BW with a formula food is effective in reducing urinary ACR in obese men. This improvement of ACR is related to the reduction in urinary C-megalin. Since albumin is excreted into urine by its increased glomerular leakage and/or decreased proximal tubular reabsorption via megalin and cubilin, our observations suggest that megalin metabolism in proximal tubules may determine albuminuria in obesity.

**Funding:** Pharmaceutical Company Support - CCF CKD registry creation was supported by an unrestricted grant from Amgen to the Department of Nephrology and Hypertension at Cleveland Clinic

FR-PO642
Obesity Management in Patients with Chronic Kidney Disease (CKD): A National Survey
Christopher Lawrence,1 Helen L. MacLaughlin,2 Ken Farrington,1 Andrew H. Frankel.1 1Lister Hospital, United Kingdom; 2Kings College London, United Kingdom; 3Imperial College London, United Kingdom.

Background: Obesity contributes to the development and progression of CKD and may be a barrier to, or increase risks of, transplantation. Evidence for how the renal multi-disciplinary team (MDT) should proceed is limited and sometimes counterintuitive i.e. association of increased weight and better survival on hemodialysis. The study assessed approaches to obese patients with CKD across the UK and describes the availability of, and extent of co-working with, bariatric services.

Methods: An online survey tool was designed and sent by the British Renal Society to UK renal clinical directors and dieticians. The survey focussed on patients with CKD stage ≥ 3, with proteinuria and co-existent Obesity stage II (BMI > 35kg/m²) as these patients are most likely to progress to ESRD.

Results: 58/71 (82%) of UK units responded with respondents split between dieticians (53%) and nephrologists (47%). Most respondents (78%) thought the prevalence of obesity has increased over the last decade. There was no consensus on the BMI cut off for kidney transplantation: 30%, 16%; £35, 71%; £40, 12%; none, 2%. The most common actions for initial obesity management were: to provide education/motivation (81%); dietetic referral (69%) and test fasting glucose and lipids (43%). Therefore only 33% would refer to bariatric services. The main perceived barriers to weight loss were: lack of patient motivation (79%); no funding (60%); lack of services (53%). 54% of renal units co-locate with bariatric services. Only 35% of renal units can refer directly to local/regional bariatric service, the remainder were uncertain of referral pathways (27%) or relied on primary care physicians to refer. Only 5 units (9%) have a joint care pathway for obese patients with CKD undergoing bariatric surgery.

Conclusions: The response to obesity in CKD falls short of National (NICE) guidelines. The increasing prevalence of obesity is a challenge to the renal MDT. Strategies to tackle this include wider recognition of the problem; identifying and sharing best practice and co-working with, bariatric services.

FR-PO643
Effects of Renin-Angiotensin Blockade (RASB) on the Components of Early Intersitial Expansion in Patients (pts) with Type 1 Diabetes (TID) Zarah Khan, Michael Mauer, Maria Luiza A. Caramori. Medicine and Pediatrics, Univ of Minnesota, Minneapolis, MN.

Background: Intersitial expansion is important for GFR loss in the later stages of a variety of disease processes, including diabetic nephropathy (DN). The Renin-Angiotensin System Study (RASS; NEJM 2009;361:40) considered whether RASB with enalapril or losartan compared to placebo could slow progression of early DN lesions over 5 years (yrs) in 285 normoalbuminuric (NA), normotensive (NT), normal GFR T1D pts. RASS found no treatment benefit of RASB on DN lesions but observed an unexpected ~50% increase in the arterial collagen (Col), Int cells (C), peritubular capillaries (PTC) and undefined Int space (S) [Vv(Int/Cortex)]. However, possible effects of RASB on individual Int components, i.e., Int collagen (Col), Int cells (C), peritubular capillaries (PTC) and undefined Int space (S) were not assessed. Here we report these additional studies.

Methods: Baseline and 5-yr renal biopsies from 21 RASS pts (52% males), from a single research center, 7 from each treatment group, with a wide range of change in Vv(Int/Cortex), mean age of 34±10 yrs, and TID for 11±4 yrs were selected. These pts were matched for age and sex, and selected for electron microscopic (EM) measurements of the fractional volume (Vv) of each of the Int components by masked unbiased random sampling and laborious morphometric point counting methods. Renal volume (RV) was measured by ultrasound and calculated using the kidney’s length, width, and anterior-posterior diameter by the formula L×W×P÷0.523.

Conclusions: RASS found that NA, NT, normal GFR TID pts had surprisingly rapid increases in Vv(Int/Cortex) which was un influenced by RASB. Here, using EM morphometric analyses, we showed that RASB also did not affect Int composition, since the Vv of each component at 5 yrs was not different from baseline in any of the groups.

Liraglutide Improves Glycemic and Blood Pressure Control and Preserves Renal Function and Left Ventricular Function in Patients with Type 2 Diabetes Mellitus with Renal Impairment Takeyuki Hiramatsu, Akiko Ozeki, Kazuki Asai, Akinori Hobo, Hideaki Ishikawa, Shunji Furuta. Nephrology, Konan Kosei Hospital, Konan, Aichi, Japan.

Background: Diabetes mellitus(DM) is a progressive multifactorial disease associated with cardiovascular complications. To prevent progression of systemic cardiovascular complications in DM patients, glycemic control is important. However using of anti-diabetic agents was restricted in patients with renal impairment. In this study, we examined the efficacy and safety of the glucagon-like peptide analogue, liraglutide to treat type 2 DM patients with renal impairment.

Methods: Twenty type 2 diabetes patients with renal insufficiency (Age; 65.4y, DM duration:11.9y, eGFR;21.6ml/min/1.73m²) were enrolled. Anti-diabetic agents were switched to liraglutide from others. Prior to liraglutide therapy, 9 patients used insulin, 8 used oral antidiabetic agents, and 3 were only diet therapy. During 24 months liraglutide use, we examined the change of blood pressure and renal function. Echocardiography was examined at baseline and 24 months after liraglutide initiation.

Results: Hemoglobin A1c, and systolic/diastolic blood pressure levels were gradually decreased with liraglutide use. Renal function indicated by eGFR was not changed (table1), and the slope of the reciprocal of serum creatinine was improved after use of liraglutide (p<0.001). Moreover Liraglutide induced ameliorating left ventricular function(LVMI and EF).

FR-PO645
Do SGLT2 Inhibitors Affect GFR and Albuminuria in Diabetic Patients? A Systematic Review and Meta-Analysis Lubin Xu, Yang Li, Peng Xia, Limeng Chen. Dept of Nephrology, Peking Union Medical College Hospital.

Background: SGLT2 inhibitors are a new class of antihyperglycemic drugs that lower blood glucose levels by inhibiting renal reabsorption of glucose. SGLT2 inhibitors can have potential renoprotective capacities through modulation of tubuloglomerular feedback and alleviation of hyperfiltration. However, there are also concerns about deleterious effects on renal function caused by volume depletion.

Methods: We performed this systematic review and meta-analysis to assess the effects of SGLT2 inhibitors on estimated GFR (eGFR) and urinary albumin/creatinine ratio (ACR) in diabetic patients. We conducted a systematic search of PubMed, Embase, Cochrane Central Register of Controlled Trials and Sinomed through April 2015 to identify published randomized double-blind controlled trials of SGLT2 inhibitors reporting renal outcomes. Two reviewers worked independently to extract data and assess the quality of included studies. Random effects model were used in data synthesis.

Results: We retrieved 2279 studies, 53 of which met the predefined criteria. Among included studies, 33 studies examined short-term effect with follow up less than 26 weeks, and 20 studies examined long-term effects with follow-up longer than 48 weeks. 4 studies included subjects with CKD 2-4. SGLT2 inhibitors did not cause statistically significant changes in eGFR (mean change, -0.19 ml/min/1.73m², 95% CI, -0.86 to 0.47) or in ACR (mean change, -2.76 mg/g, 95% CI, -6.75 to 19.23).

No adverse events were seen.

Conclusions: These findings suggest that liraglutide therapy for type 2 diabetes patients with renal impairment was safe and effective for decreasing glucose levels and blood pressure. Moreover it preserved renal function and improving left ventricular function.

FR-PO645
Do SGLT2 Inhibitors Affect GFR and Albuminuria in Diabetic Patients? A Systematic Review and Meta-Analysis Lubin Xu, Yang Li, Peng Xia, Limeng Chen. Dept of Nephrology, Peking Union Medical College Hospital.

Background: SGLT2 inhibitors are a new class of antihyperglycemic drugs that lower blood glucose levels by inhibiting renal reabsorption of glucose. SGLT2 inhibitors can have potential renoprotective capacities through modulation of tubuloglomerular feedback and alleviation of hyperfiltration. However, there are also concerns about deleterious effects on renal function caused by volume depletion.

Methods: We performed this systematic review and meta-analysis to assess the effects of SGLT2 inhibitors on estimated GFR (eGFR) and urinary albumin/creatinine ratio (ACR) in diabetic patients. We conducted a systematic search of PubMed, Embase, Cochrane Central Register of Controlled Trials and Sinomed through April 2015 to identify published randomized double-blind controlled trials of SGLT2 inhibitors reporting renal outcomes. Two reviewers worked independently to extract data and assess the quality of included studies. Random effects model were used in data synthesis.

Results: We retrieved 2279 studies, 53 of which met the predefined criteria. Among included studies, 33 studies examined short-term effect with follow up less than 26 weeks, and 20 studies examined long-term effects with follow-up longer than 48 weeks. 4 studies included subjects with CKD 2-4. SGLT2 inhibitors did not cause statistically significant changes in eGFR (mean change, -0.19 ml/min/1.73m², 95% CI, -0.86 to 0.47) or in ACR (mean change, -2.76 mg/g, 95% CI, -6.75 to 19.23).

No adverse events were seen.

Conclusions: These findings suggest that liraglutide therapy for type 2 diabetes patients with renal impairment was safe and effective for decreasing glucose levels and blood pressure. Moreover it preserved renal function and improving left ventricular function.
Effects of Statins on Diabetic Kidney Disease in Patients with Type 2 Diabetes

**Background:** Renoprotective properties of statins have received much attention; however, a recent large cohort study found no beneficial effect of statins on diabetic kidney disease (DKD). Furthermore, whether there are differences among statins in their effects on the risk of ESKD remains unclear. The aim of this study is to compare effects of 4 statins on progression of DKD.

**Methods:** This was a single-center historical cohort study of Japanese adult ambulatory patients with type 2 diabetes. We studied 412 patients who were newly prescribed one of the following 4 statins: pravastatin, rosuvastatin, atorvastatin and pitavastatin, and had estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73 m². The control group, 946 patients without prescription history of statins were enrolled. Two outcomes were defined: 1) annual decline in eGFR and 2) progression to a more advanced stage of albuminuria. To adjust for the effects of confounding factors, we used the propensity score (PS) as the covariate. PS was estimated using a multinomial logistic regression model that included 18 clinical parameters. Furthermore, to take into account the varying number and spacing of eGFR measurements, and the variable follow-up period for each individual, we conducted the linear mixed-effects model regression analysis. The intercept and slope were treated as random effects.

**Results:** During the median follow-up period of 5.3 years (range, 2.0–8.6 years), the adjusted eGFR decline (± standard error) in the control group (1.6 ± 0.1 mL/min/1.73 m²/year) was significantly slower than that in rosuvastatin (2.4 ± 0.2, p<0.001), atorvastatin (2.6 ± 0.3, p<0.001) and pitavastatin group (2.3 ± 0.3, p=0.036), but not in pravastatin group (1.7 ± 0.2, p=0.780). Next, during the median follow-up period of 4.2 years (range, 0.1–8.5 years) for 138 patients who showed progression of albuminuria stage, the adjusted hazard ratio (vs. control group) for the albuminuria progression was 0.85 (p=0.690), 0.86 (p=0.067), 1.01 (p=0.980), and 0.69 (p=0.462) in pravastatin, rosuvastatin, atorvastatin and pitavastatin group, respectively.

**Conclusions:** Statins may have no beneficial effect on the progression of DKD. Instead, some statins are likely to be associated with faster renal function decline.

FR-PO648

Glucose Targets for Preventing Diabetic Kidney Disease and Its Progression: A Meta-Analysis

**Background:** Diabetes is the leading cause of end-stage kidney disease (ESKD). Blood pressure lowering and glucose control are considered central to protection of kidney function in diabetic nephropathy, however the optimal target range for blood glucose levels among patients with diabetes remains unclear. We evaluated the benefits and harms of intensive versus standard glycemic control for preventing the onset and progression of kidney disease.

**Methods:** Using standard Cochrane methods, we did a systematic review and meta-analysis of randomized controlled trials that evaluated intensive versus standard glycemic control administered to adults and children with type 1 or type 2 diabetes with or at risk of kidney disease. Intensive glycemic control was defined by a treatment targeting an HbA1c < 7.0% or fasting plasma glucose levels < 120 mg/dL. Effect sizes were calculated using a random-effects model. Studies were critically appraised using Cochrane methods.

**Results:** 10 studies involving 28,885 participants were eligible for inclusion. In studies at low risks of bias, intensive glycemic control had uncertain effects on doubling of serum creatinine (0.79, CI 0.34–1.87) and end-stage kidney disease (1.21, CI 0.12–11.98). Tight glycemic control reduced the onset (0.82, CI 0.71–0.93) and progression (0.56, CI 0.36–0.87) of microalbuminuria. In absolute terms, treating 1000 patients with tight glycemic control for 1 year might prevent 7 experiencing new-onset albuminuria and 22 with worsening microalbuminuria.

**Conclusions:** Intensive glycemic control among adults with diabetes had very uncertain effects on developing of ESKD and progression of kidney failure, while providing small clinical benefits on the onset and progression of microalbuminuria.

Results: The model predicts that finerenone is an effective treatment option for DKD patients, primarily by virtue of reduced risk of end-stage renal disease (ESRD) and renal death. It reduced the risk reductions [ARR] of up to 9.7% and 9.3%, respectively, for advanced DKD, i.e. macro-albuminuria and CKD3/4 and increased health-related quality of life, and that it would generate cost savings on renal replacement therapy (up to $19,100 for advanced DKD). From a clinical outcomes perspective the optimal time point to begin finerenone treatment appears to be 6 months after patients have progressed to either macro-albuminuria or CKD stage 3, as represented by both phase II clinical trials. Reduced CV events and CV mortality, however, are greatest (ARR of up to 3.8% and 4.5%, respectively) when finerenone treatment is started in early disease states, as represented by the phase 3 trial population “FIGARO”.

Conclusions: Treatment with the MRA finerenone appears to be of significant benefit to patients and the healthcare system, particularly if initiated in advanced stages of DKD.

FR-PO650
Independent Association of Systolic Blood Pressure and Hemoglobin A1c Levels on Clinical Outcomes in Diabetic Patients with Normal Kidney Function

University of Tennessee Health Science Center, Memphis, TN; University of California, Irvine, CA; VA Medical Center, Memphis, TN.

Background: Systolic blood pressure (SBP) goal of <140 mmHg is recommended for majority of patients with diabetes mellitus (DM). It is however unknown if glycemic control modifies the association of uncontrolled hypertension (HTN) with mortality and morbidity in DM patients.

Methods: We examined 894,661 US veterans with DM and baseline eGFR > 60 ml/min/1.73m² (mean age 66.6±10.9 years, 97% males, 17% African-Americans). The association of mutually exclusive combined categories of hemoglobin A1c (A1c: <6.5, 6.5-6.9, 7.0-7.9, 8.0-8.9, 9.0-9.9, and ≥10%) and SBP (<120, 120-129, 140-159, 160-179, ≥180 mmHg) with the risk of all-cause mortality, incident CKD, coronary heart disease (CHD), and stroke was examined in Cox models adjusted for baseline characteristics, statin use, and co-morbidities, using patients with A1c 6.5-6.9% and SBP of 120-139 mmHg as referent.

Results: A total of 221,983 (25%) patients died, and 178,628 (20%), 43,374 (5%) and 7,415 (1%) patients developed incident CHD, and stroke, respectively, during a median follow up of 7.4 years. SBP displayed a U-shaped association with mortality in each A1c category. Conversely, SBP >120-139 mmHg was associated with a monotonous increase in the risk of CKD, CHD and stroke in all A1c categories. A1c levels were linearly associated with worse outcomes for all end points and in all SBP categories.

Conclusions: SBP above 120-139 mmHg and higher A1c levels were associated with higher mortality and morbidity in diabetic patients, independent of each other. Tight glycemic control may reduce mortality and morbidity across all SBP categories in patients with normal kidney function.

High Acid Diets Increase Urinary Nitrogen Excretion and May Decrease Muscle Mass in Obese Diabetics

Lynda A. Frassetto, Umesh Masharani, Anthony Sebastian. UCSF, San Francisco, CA.

Background: We have previously shown that decreasing dietary acid loads with bicarbonate supplements lowers urinary nitrogen (N) excretion in postmenopausal women. Here we examined whether we could lower urinary N excretion in obese diabetics by increasing plant food intake (“Paleo diet”) compared with a “usual” acid diet (America Diabetes Association diet).

Methods: 12 obese well controlled type 2 diabetics (7 Paleo, 5 ADA) were enrolled in a 21 day no-weight loss controlled metabolic diet study. Daily protein intake per 2500 kcal averaged 116 g on the Paleo and 127 g on the ADA diets (p=0.7). Fasting arteralized blood and 24-hour urine samples were collected at baseline (pre, days -2 to 0) and the last 3 diet days (on, +19 to 21). Each subject’s tests were averaged by period, and the group averages analyzed by one-way ANOVA and between groups by t-test. Urinary N excretion was adjusted per 70 kg. Body composition [total (T), fat free mass (FFM), kg] was measured by bioimpedance (BIS).

Results: Mean±SD. ADA or Paleo pre-on; a, p<0.05; Δ Paleo vs Δ ADA: b, p<0.1; c, p<0.05; d, p<0.01.

Both groups had equally modest nonsignificant declines in weight.

Conclusions: The higher acid diet had significantly greater loss of fat free mass associated with a greater loss of urinary urea and ammonium. A plant based low acid weight loss diet may be better in maintaining lean body mass compared to a usual acid diet.

Clinical Benefit of Pre-Dilution On-Line Hemodiafiltration for Removal of Low-Molecular-Weight Proteins and Fibrob mast Growth Factor-23 in Diabetic Patients

1Hashimoto Clinic, Kanagawa, Japan; 2Urology, Kitasato Univ, Kanagawa, Japan; 3Organ Transplant Medicine, Kitasato Univ, Kanagawa, Japan; 4Medical Engineering and Technology, Kitasato Univ, Kanagawa, Japan; 5Chemical Science and Technology, Hosei Univ, Tokyo, Japan.

Background: Increased concentration of fibroblast growth factor 23 (FGF-23) is reportedly associated with increased risk of cardiovascular complication and mortality in dialysis patients. Therefore, there is a possibility that reduction of FGF-23 levels may improve prognosis of dialysis patients with elevated its levels. We compared the removal performance of low-molecular-weight proteins (LMWP) and FGF-23 between pre-dilution on-line hemodiafiltration (HDF) and hemodialysis (HD) with super high-flux dialyzer.

Methods: The study involved 31 patients (15:HDF, 16:HD, 4 hrs, Qd:600 mL/min).

Results: A total of 221,983 (25%) patients died, and 178,628 (20%), 43,374 (5%) and 7,415 (1%) patients developed incident CHD, and stroke, respectively, during a median follow up of 7.4 years. SBP displayed a U-shaped association with mortality in each A1c category. Conversely, SBP >120-139 mmHg was associated with a monotonous increase in the risk of CKD, CHD and stroke in all A1c categories. A1c levels were linearly associated with worse outcomes for all end points and in all SBP categories.

Conclusions: SBP above 120-139 mmHg and higher A1c levels were associated with higher mortality and morbidity in diabetic patients, independent of each other. Tight glycemic control may reduce mortality and morbidity across all SBP categories in patients with normal kidney function.

FR-PO653
Comparison of Removal Performance of Small- to Large-Molecular-Weight Substances Between Pre-Dilution On-Line Hemodiafiltration and Hemodialysis with Super-High-Flux Dialyzer

Kenji Sakurai, Takeshi Saito, Fumi Yamauchi, Hiroimi Hosoya, Yositaka Kurthara, Daisuke Iishi, 1Hashimoto Clinic, Sagamihara Kanagawa, Japan; 2Urology, Kitasato Univ, Sagamihara Kanagawa, Japan.

Background: In pre-dilution on-line hemodiafiltration (HDF), net dialysate flow rate is reduced, because replacement fluid accounts for 30 to 50% of total dialysate flow (Qdtotal). Therefore, removal efficiency of small-molecular-weight substances by diffusion is reduced, whereas that of low-molecular-weight proteins (LMWPs) by convection is
improved. In hemodialysis (HD) using super high flux dialyzer, the increased blood flow rate (Qb) increases amount of internal filtration, thereby improving the removal efficiency of LMWPs. In this study, we compared the removal efficiency of small- to large-molecular-weight substances between HDF and HD to verify the superiority of HDF.

**Methods:** The study involved 62 patients (31: HD, 31: HDF). Super high flux dialyzers for HD and high-performance hemodiafilters for HDF were used. Qd was 500 mL for HD and Qdtot was 600 mL/min for HDF. Replacement fluid volume for HD was 44.4 ± 10.6 mL/session. Qb was 256 ± 23, 257 ± 25 mL/min and Treatment time was 4.1 ± 0.2, 4.0 ± 0.1 hours in HD and HDF, respectively. Removal rates (RR) of b2-microglobulin (b2-M; 11.8 kDa), pro-OP (ProPRL; 23 kDa), o1-microglobulin (o1-M; 33 kDa) and a1-acid glycoprotein (a1-AGP; 44 kDa) were measured. 

**Results:** The performance of HDF in removing LMWPs was superior to that of HD and there was no significant difference in Kt/V in both modes. An increased concentration by HDF greatly contributed to improved removal of LMWPs and appropriate control of dialysate flow rate improved the removal efficiency for small molecular substances to the level achieved by HD.

**The Effect of Increasing Kt/V in the HEMO Study on Levels of Non-Urea Solutes**

**Timothy W. Meyer; Tammy L. Solerte; Tariq Shafi; Tanushree Banerjee; Neil R. Powe; Thomas H. Hostetter.**

**Background:** In the HEMO study, outcomes were no better in patients randomized to “high dose” thrice weekly hemodialysis providing spKt/V$_{urea}$ 1.73 than in those randomized to “standard” hemodialysis providing spKt/V$_{urea}$ 1.32.

**Methods:** This study assessed whether “high-dose” treatment lowered levels of non-urea solutes. Solutes were measured by LC/MS/MS in plasma samples obtained at least 3 months after randomization in 1281 HEMO subjects.

**Results:** Ref.

Increasing Kt/V$_{urea}$ caused statistically significant but only modest reductions in the levels of trimethylamine oxide, phenylacetylglutamine, and symmetric dimethylarginine. Mathematical modeling showed that limited reduction in the levels of these solutes was a predictable consequence of the intermittency of treatment. Their reduction ratios with standard treatment are high and the increased intensity of treatment reflected by a 30% increase in Kt/V$_{urea}$ in HEMO’s high dose arm could not remove much more solute. Remarkably, increasing Kt/V$_{urea}$ in HEMO caused no reduction in the levels of asymmetric dimethylarginine or p-cresol sulfate, two solutes which have been associated with cardiovascular disease in dialysis patients. Modeling showed that stability of their plasma levels could be accounted for by increased solute production accompanying the increase in Kt/V$_{urea}$ and/or the presence of non-dialytic clearance.

**Conclusions:** Levels of non-urea solutes may fall only slightly or not at all when Kt/V$_{urea}$ is increased above standard levels for thrice weekly treatment. Treatments that are more effective in reducing solute levels may be required to improve outcomes.

Quality Control and Improvement Union of Hemodialysis Centers: A New Management Model
Jiangying Gan, Mei Wang. Dept of Nephrology, Peking Univ People’s Hospital, Beijing, China.

Background: With the increasing incidence of end stage renal disease (ESRD) in China, more dialysis facilities are needed. There are huge variations of patient care staffing levels and quality of care. How to maximize the utilization of existing health resources, optimize the management of hemodialysis patients and improve quality control are important issues. The aim of this study was to investigate the feasibility and effects of quality control and improvement union comprised of best hospitals and basic hospitals on patients’ medical quality control and improvement.

Methods: The HD union was constructed and specific measures were determined including, 1) Quarterly continuous quality improvement (CQI) meetings, 2) education based on typical cases including: extensive discussions, guidelines and latest research results introductions, 3) lectures focusing on key questions, 4) opening green channel and construction of two-way referral system. Paired t-test was used to compare the differences of medical parameters of each hemodialysis center before and two-years after construction of HD union.

Results: The leading center of HD union was the HD center from Peking University People’s Hospital. Cooperating centers were other eight centers from class three and class two hospitals. After quarterly CQI meetings, all union members learned how to do medical quality control and improvement, constructed standards and procedures for diagnosis, cure and nursing of their HD center, established the institutions of lab exam and regular round quality control and improvement, constructed standards and procedures for diagnosis, cure and nursing of their HD center, established the institutions of lab exam and regular round quality control and improvement.

Conclusions: Quality control and improvement union of hemodialysis centers is an effective integrated management model in Beijing, China. The quality control and improvement of basic hospitals by balancing the technical advantages of grade A class three hospitals and basic hospitals.

Feasibility of Mindfulness Meditation Training During Dialysis for Patients with Chronic Kidney Disease and Effect on Tolerability of Sessions
James C. Wasserman,1 Daniel Schupack,2,3 Andrew E. Williams,4 Paul K. Han,4 George K. Dreher,1 Mary Bitterauf,4 1Div of Nephrology, Maine Medical Center, Portland, ME; 2Center for Outcomes Research and Evaluation, Portland, ME; 3Maine Medical Center, Portland, ME; 4Maine Medical Center Research Inst, Portland, ME; 5MaineHealth, Falmouth, ME.

Background: Hemodialysis (HD) for CKD entails ≥12 h of weekly treatment, creating significant distress for patients. Mindfulness-Based Stress Reduction (MBSR) has effectively helped patients with other chronic diseases cope with distressing symptoms and treatments. An abbreviated form of MBSR (Mindfulness Meditation Training, MMT) was incorporated into HD sessions to explore its feasibility, acceptability and potential effects on distress.

Methods: 12 patients were randomly assigned to MMT during HD or usual care. The MMT group underwent weekly 1-h individual sessions during HD for 4 wk. Within-session change in affective response was assessed with the Self-Assessment Manikin, validated measure of emotional valence, arousal and dominance. Anxiety, depression, self-rated health and coping skills were also assessed with validated measures. Patient perceptions were assessed with qualitative interviews at study’s end.

Results: In qualitative interviews, patients reported improved tolerability of HD session length, positive intention to continue meditation and no significant issues with MMT sessions or home practice. There were no significant between-group differences in affective response, anxiety, depression, self-reported health or coping skills at baseline or in change over time. Retention rate was 91.7% overall and 83.3% for the MMT group.

Conclusions: MMT appears to be a feasible and acceptable intervention for CKD patients during HD, although effectiveness remains to be demonstrated. Small sample size and low baseline distress levels in the study population limited the power to establish effects of MMT. Further research is needed to determine if abbreviated MBSR is sufficient to benefit tolerability of HD in this population. Focus on patients with higher baseline distress levels in future research would increase the likelihood of observing clinical benefit.

Fluid Management Parameters Are Associated with Dialysis Recovery Time in Conventional Hemodialysis
Wael F. Hussein,1,2 Rohini Arrarnreddy,1,2 Marc Reiterman,1 Sumi J. Sun,1 Brigitte Schiller,1,2 1Dept of Medicine, Div of Nephrology, Stanford Univ, Palo Alto, CA; 2Satellite HealthCare, San Jose, CA.

Background: Longer dialysis recovery time (DRT) is associated with increased mortality and shorter time to hospitalization. We studied the association of fluid management and hemodynamics with recovery time in conventional hemodialysis (HD) patients.

Methods: Self-reported DRT, obtained by asking “How long does it take you to recover from a dialysis session?”, was recorded for 2,689 patients undergoing thrice weekly adequate HD in 46 centers in 3 states. Ordinal logistic regression was used to study the association between patient and dialysis characteristics with DRT. Statistical adjustments were made for demographics, comorbidities and body weight.

Results: Forty-three percent of patients were female, 20% were black, median age and vintage were 63 and 3.3 years, median dialysis session length was 203 min (IQR: 180–220). DRT in categories of immediate recovery: <0 to ≤ 2 hours (hrs), > 2 to ≤ 6 hrs, > 6 to ≤ 12 hrs, and > 12 hrs, were reported in 27%, 28%, 17%, 9%, and 20% of the patients respectively. In multivariable analysis, longer DRT was associated with female gender, non-black race, lower serum albumin, chronic heart failure, cerebrovascular disease, missed dialysis sessions, higher pre-dialysis systolic blood pressure and larger UF volume. Ultrafiltration rates (UFR) were divided into three categories: <10, 10 to 13, and >13 ml/kg/hr. Compared to the lowest UFR category, UFR >13 ml/kg/hr was associated with longer DRT; OR of 1.16 (95% CI 0.99 – 1.36) and 1.28 (95% CI 1.06 – 1.54) in the unadjusted and the adjusted analyses respectively. IDH was associated with longer DRT in the unadjusted (per 10% higher frequency, OR 1.04 [95% CI 0.01 – 0.17]) and adjusted analyses (OR 1.03 [95% CI 1.00 – 1.07]).

Conclusions: Long DRT affects a large proportion of HD patients. Optimizing UFR and controlling IDH are critical measures to improve quality of life for these patients.

FR-PO660
Different Adsorptive Properties of Hemodialysis Membranes May Cause Selective Depletion of Plasma Proteins
Jan Mares, Lukas Kiellberg. Nephrology, Charles Univ, Plzen, Czech Republic.

Background: During hemodialysis (HD) session, plasma proteins are adsorbed to the surface of HD membrane. The resulting biofilm affects both dialyzer permeability and biocompatibility. The aim of this study was to analyze its composition in different HD membranes.

Methods: Twelve long-term HD patients were assigned to 4h HD with three different dialyzers in a cross-over design: ethylene-vinyl-alcohol/EVAL (KF-201-1.8C, Asahi KASEI), polysulfone (F8 HPS, Fresenius), and vitamin E-substituted polysulfone (VIE-18, Asahi Kasei). After HD session, the biofilm was eluted with acetic acid. Obtained proteins (200 µg) were separated by 2-dimensional electrophoresis and fractions showing distinct abundance across groups were identified by tandem mass spectrometry. Blood was sampled along the session to enable subsequent confirmatory studies (ELISA). Data are given as means ± SEM, statistical significance was calculated by ANOVA (general linear model).

Results: The amount of protein eluted from KF dialyzers was higher than from F8 or VIE: 42±9.6, 9±3.3, and 12±6.9 mg, (p<0.001), respectively. Totally, 305 protein fractions were detected, 235 common to all eluates. In 48 fractions, spot intensities varied between groups suggesting different adsorption (p<0.05). Among them, 11 individual plasma proteins were identified: mannose-binding lectin associated protein 1 (MASP1 p=0.012), clusterin (p=0.003), retinol-binding protein 4 (RBP4, p=0.018), α1-microglobulin (AMBP, p<0.001), complement factor H (CFH, p=0.004) and its related proteins 1, 2, 5 (FHR, p<0.001), α2-macroglobulin β, (p=0.001), and complement C3 (C3, p=0.004). The highest abundance bound less FCN2, MASP1, and clusterin but more AMBP, CFH, and FHRs than polysulfone membranes. The most prominent difference was established in FCN2, it was therefore selected for a confirmatory study. It showed a sustained decline of plasma FCN2 levels at all timepoints during HD with F8 but not KF dialyzers (-40±3.6% and 111±5.3% of pre-dialysis levels, respectively (p<0.001).

Conclusions: Different HD membranes show variable binding characteristics for particular plasma proteins. It can be responsible for their increased clearance and temporary depletion as demonstrated in case of ficolin-2.

Mathematical Model of Protein Transport and Plasma Refilling in Hemodialysis
Bengt Lindholm, 1 Mauro Pietribiasi, 1 Małgorzata Debowska, 2 Alicja Wojcik-Zaluska, 2 Wojciech T. Zaluska, 2 Jacek Waniowski, 2 1 Baxter Novum & Renal Medicine, Karolinska Inst, Stockholm, Sweden; 2 Inst Biocybernetics & Biomedical Engineering, Warsaw, Poland, Rehabilitation and Physical Therapy, Med Univ Lublin, Lublin, Poland; 3 Nephrology, Medical Univ Lublin, Lublin, Poland.

Background: Mathematical modeling offers a way to estimate quantities we cannot access directly during hemodialysis (HD). Here we propose a whole-body model of vascular refilling describing water and protein shifts across the capillary membrane during HD. The model was applied to reproduce profiles of plasma volume and serum total protein concentration in patients (pts) undergoing HD.

Methods: The double-compartment model (vascular and interstitial space) was based on balance equations of protein mass and water volume in each compartment. The net transport across the capillary wall is the sum of the flow through the membrane’s pores and lymphatic flow. The capillary membrane is described according to the three-pore theory. Two transport parameters of the model, the relative number of large pores (LpP) and the total permeability surface area product (LPs) of the capillary membrane, were estimated from volumetric data and blood samples collected in 20 stable, non-diabetic pts during 60 HD sessions.

Results: LPs and LP were estimated to 10.0 ± 8.4 mL/min/mmHg and 0.062 ± 0.041. The model predicted profiles of plasma volume and serum total protein concentration with a average root-mean-square error < 2%, with larger errors only in pts with very high initial drop in blood volume. When increasing the assumed value of interstitial/serum protein ratio from 0.3 to 0.6, while the total refilling rate remained similar, the value of individual pore fluxes changed so that filtration through large pores at its peak was 40% smaller and absorption through small and ultrasmall pores was 80% and 60% higher, respectively.

Conclusions: The model proposes a mechanistic interpretation of fluid transport processes induced by ultrafiltration during HD. The estimated values of individual flows through each kind of pore and protein absorptive represent the relative importance of these not-measurable quantities on total vascular refilling.

Effect of Computationally-Optimized Vibration on Clearance of Solutes During In Vitro Hemodialysis
Katherine N. Gharibian, 1 Susan J. Lewis, 1 Joseph L. Bull, 2 John J. Pitre, 3 Bridget A. Scoville, 3 Thomas Velenosi, 2 Brad URR, 3 Detlef Krieter, 2 H. Santhosh, 1 Mauro Pietribiasi, 1 Christoph Wanner, 2 Thomas Koerner, 2 Craig Boggs, 3 Brad Lemke, 3 Krieter, 2 1 Dept. of Molecular Medicine, Biocybernetics & Biomedical Engineering, Warsaw, Poland; 2 Inst Biocybernetics & Biomedical Engineering, Warsaw, Poland; 3 Dept. of Biomedical Engineering, Univ of Michigan, Ann Arbor, MI.

Background: In vitro studies demonstrated that the addition of vibration enhances dialytic clearance of solutes by a median of 18% during CVVHD. In this study, we applied computational fluid dynamics to determine vibration’s effects during hemodialysis and validated them using an in vitro hemodialysis model.

Methods: Based on predictions of a computational fluid dynamics model, two vibration settings (120 Hz/0.176 mm/ 360 Hz/0.0755 mm) were selected and applied to a F8 dialyzer (1.8 m² Fresenius) during in vitro hemodialysis using blood-dialysate flow rates of 300/600 mL/min, respectively. Mean transmembrane clearances were analyzed for six solutes: urea, creatinine, gentamicin, vancomycin, indoxyl sulfate and hippuric acid. Albumin, free hemoglobin, and LDH concentrations were measured after 4 hours of dialysis with applied vibration to assess blood and dialyzer integrity.

Results: A one-way ANOVA showed no significant difference between the control group and non-control vibration groups in solute clearance: urea, (F(1,27)=1.801, p=0.184; creatinine, F(2,27)=2.525, p=0.099; gentamicin, F(2,23)=0.273, p=0.763; vancomycin, F(2,23)=0.003, p=0.997; indoxyl sulfate, F(2,33)=0.390, p=0.680; hippuric acid, F(2,23)=0.398, p=0.675. Four hours of vibration had no significant effect on blood and dialyzer integrity as measured by concentrations of albumin (F(1,22)=0.185, p=0.735), hemoglobin (F(1,22)=1.038, p=0.319) and LDH (F(1,22)=0.185, p=0.672).

Conclusions: Although vibration has been shown to enhance solute clearance in clinical settings, in this study, vibration did not significantly enhance solute clearance in an in vitro hemodialysis model using flow rates typically seen with intermittent hemodialysis.

Sevelamer Hydrochloride Improves Oxidative Stress in Maintenance Hemodialysis Patients
Serenzeh Shariati, 1 Bahar Gurlekdemirci, 1 Cihat Burak Sayin, 1 Emre Tutar, 1 Zeynep Bal, 1 Fatma Nurhan ozdemir Acar. 1 Dept. of Nephrology, Baskent Univ Faculty of Medicine, Ankara, Turkey.

Background: Oxidative stress plays a key role in the pathogenesis of cardiovascular diseases. Superoxide dismutase (SOD) and malondialdehyde (MDA) are well-known antioxidant enzymes that detoxifies advanced glycation end products (AGEs). We thought that avoiding calcium intake and through pleiotropic effects, sevelamer hydrochloride might be a differential influence in terms of oxidative stress. The aim of this study is to evaluate the effects of phosphate binders (PBs) on the components of the oxidative stress and clinical and biochemical parameters including pulse wave velocity in our maintenance hemodialysis (MHD) patients.

Methods: A total of 111 patients (mean age: 52.2 ± 14.3 years; mean duration of dialysis: 9.7 ± 4.8 years) undergoing maintenance hemodialysis and using the same PBs at least one year were enrolled into the study. Patients were divided into two groups according to usage of PBs as sevelamer based PB (group 1: n= 1; and calcium based PB (group 2: n=27). Biochemical parameters were assessed from monthly clinical visits. Serum AGE, MDA and SOD levels were determined by ELISA method. Pulse wave velocity (PWV) was determined by the SphygmoCor system.

Results: Groups were similar in means of demographic characteristics and URR levels. Patients in group 1 had significantly lower AGE (p: 0.018), higher MDA (p: 0.027) and SOD (p: 0.012) levels. Although both baseline and first year PWV values were similar in two groups, PWV values significantly decreased in group 1 (p=0.001) where increased in group 2 (p=0.021) in the second year analysis. In linear regression analysis, serum AGE levels were detected as the unique predictor of DPWV (p: 0.005). For each 1 mL/min of increased level of AGE resulted in 0.53 cm/sec of increased level of PWV (p=0.005, CI: 0.016-0.089).

FR-PO665
Conclusions: Despite similar phosphorus levels and dialysis adequacy, sevelamer decreased serum levels of phosphate, calcium, and parathyroid hormone. This study demonstrates the beneficial effects of sevelamer in reducing serum levels of these parameters, which are known to be risk factors for cardiovascular disease in patients with ESRD. Sevelamer may be a useful addition to the treatment regimen of patients with ESRD to improve their overall health outcomes.

Association Between Depressive Symptoms and Dependency with Mortality in Hemodialysis Patients
José Ramón Gómez, Óscar Gomez, Ana M. Rivas, E. P. Salinas, and M. J. García

Background: Depression is a common issue in chronic kidney disease and is associated with adverse outcomes, including mortality. The aim of this study was to determine the association between depressive symptoms and dependency with mortality in hemodialysis patients.

Methods: A retrospective cohort study was conducted in a hospital affiliated dialysis unit in Spain. The study included all patients who started hemodialysis between January 2010 and December 2015. Depressive symptoms were assessed using the Beck Depression Inventory (BDI). Dependency was assessed using the Karnofsky Performance Status (KPS) scale. The primary outcome was mortality. The secondary outcomes were depression and dependency.

Results: A total of 600 patients were included in the study. The mean age was 55.7 ± 13.9 years, and 40.3% were women. The mean BDI score was 7.2 ± 7.0, and 17.5% of patients had a BDI score of ≥11 (moderate to severe depression). The median KPS score was 80. The median follow-up time was 28 months. During the follow-up period, 120 patients died, and 70 were considered depressed (BDI ≥11).

Conclusion: Depressive symptoms and dependency are associated with mortality in hemodialysis patients. Early identification and treatment of depressive symptoms and dependency may improve patient outcomes.

FR-PO667
Protein Biofilm and Its Relation to Dialyzer Permeability for MLL-Assisted Protein Biofiltration
Borna Vahdati, M. B. Hanley, N. M. Johnson, T. M. Webster, and J. M. Miller

Background: Protein biofilm formation on dialyzers is a significant issue in chronic dialysis patients. The aim of this study was to investigate the protein biofilm formation and its relation to dialyzer permeability.

Methods: Dialyzers were collected from patients on hemodialysis and subjected to proteomic analysis. The protein content of the biofilm was determined using mass spectrometry. The dialyzer permeability was measured using the diffusion coefficient of albumin.

Results: The protein content of the biofilm was significantly higher in FX and Xevonta dialyzers compared to Polyflux. The diffusion coefficient of albumin was significantly lower in FX and Xevonta dialyzers compared to Polyflux.

Conclusion: Protein biofilm formation is a significant issue in chronic dialysis patients. The protein content of the biofilm is significantly higher in FX and Xevonta dialyzers compared to Polyflux. This may explain the lower dialyzer permeability observed in FX and Xevonta dialyzers.

FR-PO668
Limitations of Access Recirculation due to a Low Access Flow Rate on Molecule Clearance

Background: Access recirculation is a common issue in patients on hemodialysis. The aim of this study was to investigate the limitations of access recirculation due to a low access flow rate on molecule clearance.

Methods: A model was developed to simulate the effects of access recirculation on molecule clearance. The model was validated using clinical data from a hemodialysis center in Germany.

Results: The model showed that a low access flow rate significantly limited the access recirculation. This limitation led to a decrease in molecule clearance, which was most pronounced for larger molecules.

Conclusion: Access recirculation is a significant issue in patients on hemodialysis. A low access flow rate limits the access recirculation, which significantly limits molecule clearance.

Acknowledgments: This study was supported by Baxter Healthcare Corporation. The authors declare no conflicts of interest.

Protective Effects Of Intravenous L-Carnitine (LC) Administration on Development of Cardiomyopathy in Hemodialysis (HD) Patients

Takushi Uchino,1, Jyunichiro Hashiguchi,1 Satoshi Funakoshi,1 Hiroshi Ichiinose,1 Osamu Sasaki,1 Kenji Sawasaki,1 Miki Yano,1 Yutaka Morii,1 Kazunori Utsunomiya,1 Yoko Obata,1 Tomoya Nishino,1 Miwa Shirahama,1 Takashi Harada,1 Nagasaki Kidney Center, Nagasaki, Japan; 2Nagasaki Univ. School of Medicine, Nagasaki, Japan.

Background: Due to loss via dialyzer patients on maintenance HD often suffer from dialysis-related carnitine deficiency, causing various clinical symptoms. Carnitine Consensus Conference in 2003 convened by The National Kidney Foundation had reported that the level of evidence was “moderate” for cardiomyopathy. Recent studies have shown that L-carnitine can improve left ventricular (LV) function in HD patients. In this study we aimed to investigate whether intravenous administration of LC can prevent the development of cardiomyopathy in HD patients as assessed by M-mode ultrasound cardiography (UCG).

Methods: Thirty-eight HD patients without reduced left ventricular function were treated with intravenous administration of 1000 mg/body of LC at the end of every HD session for 12 months. M-mode UCG assessments were undergone in all subjects at the three points; 1 year prior to the treatment, the start of LC administration and year after the treatment.

Results: As shown in Figure 1, average 5%FS (fractional shortening) significantly declined during 1 year before the start of LC, then stabilized after the treatment, suggesting LC administration might protect the progression of LV contraction impairment. Average early diastolic filling velocity (E)/ atrial filling velocity (A) ratio showed similar pattern, suggesting LC treatment could be protective in LV diastolic disorder. LC treatment also might delay LV hypertrophy progression.

Conclusions: Intravenous LC administration can be a candidate therapy for protection of the development of cardiomyopathy in HD patients.

Symptoms and Quality of Life Among Patients Receiving HD

Mark L. Unruh,1 Kim J. Cox,2 Stephen H. A. Hernandez,2 Sanah Parvez,2 Mark Parshall,2 1Div of Nephrology, Univ of New Mexico; 2College of Nursing, Univ of New Mexico.

Background: Health-related quality of life (HRQOL) assessment is a required condition of coverage for HD providers, but standard measures may not adequately reflect the impact of symptoms and treatment on QOL for patients receiving HD or the concerns that matter most to them. The purpose of this qualitative study is to more fully characterize patients’ perspectives on the symptoms and treatment experiences affecting their QOL.

Methods: We conducted semi-structured interviews with a diverse sample of 50 HD patients (48% Female; 42% Hispanic; 30% American Indian; 14% Black; 12% Non-Hispanic White) to elicit their experiences with diagnosis and treatment of ESRD and the impact of symptoms and treatment on QOL for patients receiving HD or the concerns that have the greatest impact on their QOL.

Results: Participants recalled that the initial diagnosis of ESRD was received with shock and denial. Over time, patients reported that QOL was associated with “taking control” of some features of their treatment. Common symptoms associated with HD, such as cramping and fatigue, were described as potentially manageable when patients were able to participate in decisions about fluid removal and scheduling of HD treatments. Patients who formed a partnership with their providers to negotiate fluid removal reported fewer episodes of severe cramping and improved QOL. Similarly, being able to choose among a variety of days and shifts for HD treatment enabled patients to manage fatigue, work hours, travel, and attendance at social events. These factors were critically important to the QOL in our relatively young sample (median age = 53; median duration of HD treatment = 4 years).

Conclusions: This is one of the largest and most diverse qualitative studies of symptoms among patients undergoing HD. There were few differences in symptoms or the impact of treatment on QOL among racial and ethnic groups. Findings highlighted the importance of fluid management and fatigue to patient experience.

Longitudinal Measures of Protein Carbamylation and Mortality on Dialysis

Sahir J. Kalim,1 Anderson H. Berg,2 Rayhnuma Ahmed,1 Joshua Wibecan,1 Caitlin A. Trottier,1 S. Ananth Karumanchi,2 Ravi I. Thadhani.1 1MGH; 2Bid.

Background: Single time-point measures of carbamylation have recently been associated with mortality in dialysis patients. This study investigated whether repeated measurements of carbamylation over time, allowing calculation of the rate of change, improved on mortality prediction.

Methods: In a nested case-control study, we measured % carbamylated albumin (C-Alb, a measure of carbamylation load) in a cohort of incident hemodialysis patients. 122 subjects who died within 1 year of starting dialysis (cases) were randomly selected and matched for demographics to 244 individuals who survived at least 1 year on dialysis (controls). C-Alb was assayed within 14 days of dialysis initiation and every 90 days for 1 year or until death. Logistic regression quantified case-control differences.

Results: In adjusted models, there was no case-control difference in day14 C-Alb (P=0.83) and, as expected, carbamylation decreased in both groups with dialysis initiation. By day 90, unit increase in C-Alb was predictive of 1-year mortality (OR 1.7, 95%(CI 1.1-2.8; P=0.02) despite no differences in Kt/V. Final C-Alb (last measure taken at study completion or preceding death) was a stronger mortality predictor than C-Alb from any other time point (OR 2.4, 95%(CI 1.4-4.0; P=0.003). A smaller % decrease in C-Alb between any 2 time points carried an increased mortality risk (e.g. C-Alb from day 14 to final =21% in cases vs. -35% in controls; OR 1.6, 95%(CI 1.2-2.0; P=0.002). Sensitivity analysis showed follow up time did not bias the results.

Conclusions: C-Alb decreases with dialysis initiation. Smaller decreases in C-Alb over time, resulting in persistently high carbamylation, may herald increased mortality risk during year 1 of dialysis. Because dialysis intensity and amino acid therapy reduce carbamylation, the utility of C-Alb as a therapeutic guide should be investigated.

Recruitment Challenges in the Blood Pressure in Hemodialysis Pilot Study

Jennifer J. Gassman,1 Dana Miskulin,1 Philip Zager,2 David W. Ploth,3 Manisha Jham,2 Lavinia A. Negrea,2 Mahboob Rahman,3 1Cleveland Clinic; Tufts; 2UMM; 3DCI; MUSC; 4Univ of Pittsburgh; 5Case Western.

Background: The optimal BP target in hemodialysis (HD) patients is unknown. The Blood Pressure in Dialysis (BID) Pilot Study is an ongoing NIDDK/Dialysis Clinic Inc. funded multi-center randomized trial treating hypertensive HD patients to a standardized predialysis systolic BP (SDUSBP) of 110-140 vs. 155-165 mm Hg. To assess feasibility and safety and inform the design of a full-scale trial.

Methods: We consented 281 participants who entered baseline from December 2011 to January 2015. We randomized 126 participants. Achievement of the SDUSBP goal was assessed by determining 2-week running mean SDUSBP in each patient. Participants are followed for 12 months. BP was measured at each dialysis session, home, and ABPM. BP and medications were backtitrated until predialysis SDUSBP was greater than 155 mm Hg. Outcomes include protocol adherence, SDUSBP adherence and left ventricular mass by MRI. To recruit, we identified hypertensive patients, 125 approached for consent refused. Reasons for refusal included perception of study being burdensome 34 (27%) and reluctance to change medications/goals 10 (8%).

Results: Of the 281 participants who entered the baseline period 155 (56%) were not randomized, 38(25%) changed their minds, 9(6%) unlikely to adhere, 6(4%) had contraindications to MRI, 6(4%) could not perform required procedures, and 65(24%) were
Unable to achieve the lower limit goal of a SDUSBP >155 mm Hg despite backtitration. Retention has been excellent. Patient characteristics are balanced between treatment arms. There is good separation between arms.

**Conclusions:** We anticipate that a Phase III BID clinical trial will require >1200 participants. MRI will be eliminated and the protocol will be simplified. Routine BPAs run higher than SDUSBP and too low a BP was the primary reason for failure to randomize. The anticipated revised protocol will facilitate recruitment and randomization. Clinical sites should plan to enroll twice the number that need to be randomized to achieve the randomization target in the full-scale study.

**Association of Time-Averaged Concentration of Hemoglobin with Mortality: Results from a Large U.S. Hemodialysis Cohort**

Hanie Zhang, Stephan Thijssen,3 Peter Kotanko,1,12 Renal Research Inst, New York, NY; 1Icahn School of Medicine at Mount Sinai, New York, NY.

**Background:** In hemodialysis (HD) patients the time averaged concentration of hemoglobin (HbTac) can be estimated from pre- and post-HD hemoglobin (Hb) levels. It has been suggested that Hb tac may be an appropriate indicator for anemia management (Siga, Int Urol Nephrol 2014). However, the association between Hb tac and mortality has not yet been evaluated.

**Methods:** We analyzed Hb data obtained by Crit-Line™ monitor (CLM) in chronic HD patients. A 6-month baseline period with at least 10 CLM measurements preceded a 12-month follow-up during which outcomes were noted. We used Hb values from HD sessions following a short interdialytic interval. Hb tac was computed as follows (Kripler, NDSCG 2000): Hb tac = 0.5 × Hb post + 0.3 × 1.28. We defined Hb post as the average of Hb between minutes 5 to 20 from the start of the CLM recording, and Hb post as the average of Hb between minutes 5 to 20 from the end of the CLM recording. The relation between Hb tac during baseline and mortality was explored by spline analysis of hazard ratio (HR).

**Results:** We studied 982 patients (figure 1A) with a total of 19,142 CLM measurements. Average Hb tac was 10.72 g/dL (SD 0.81, range 7.27 – 14.62 g/dL). The mortality rate during follow-up was 11.6 per 100 patient-years. The minimal HR (figure 1B) was 0.82 at Hb tac of 10.87 g/dL. The solid line represents mean HR, the dotted lines 95% confidence interval.

**Conclusions:** Hb tac is associated with mortality, levels around 10.9 g/dL are associated with the lowest mortality risk. Studies are required to further explore methods to estimate Hb tac based on Hb measurements by the CLM and the usefulness of Hb tac as an indicator of anemia control.

**Development and Validation of a Predictive Mortality Risk Score in Chinese Incident Maintenance Hemodialysis Patients**

Xi Yao,1 Fang Han,2 Jin Li,2 Haiyan Wang,2 Yanan Jin,2 Yan Li,2 Li Wang,2 Yiwu Yang,3 Hanjie Zhang1

**Background:** We aimed to predict 2-Year all-cause mortality in incident maintenance hemodialysis (MHD) patients by using available clinical and laboratory data, and to establish a risk scoring model.

**Methods:** Data of incident MHD patients were from Zhejiang Dialysis Quality and Management Center(ZDQM) during the period from January 2008 to June 2012. All patients were >18 years old and survived at least 3 months after starting dialysis treatment, who were followed up for two years. Patients were randomly divided into training dataset (60%, n=2551) and validation dataset (40%, n=1784). The predictive model was developed by using a logistic regression model according to the clinical data in training dataset. The risk model were tested by using the area under the receiver operating characteristic (ROC) curve. The risk scoring model for 2-Year mortality was set up according to the coefficient and rank of variables in the risk model.

**Results:** In our predictive model, predictors were age, causes of end stage kidney disease (ESRD), vascular access, history of cancer, serum albumin and serum total calcium. The area under the ROC curve of predictive model in training dataset was 0.767, Hosmer-Lemeshow Chi-test, P=0.925, which was highly discriminatory when applied to validation dataset(ROC=0.732), and the sensitivity and specificity were 71.5% and 64.2%, respectively. The risk scores of low, intermediate, high and very high mortality risk strata were <9, 9–13, 14–17 and >18 points, respectively. Observed and predicted mortality risk in the training dataset and validation dataset had a significantly linear relationship (R2=0.989 and 0.984) across risk strata.

**Prediction of Changes in Serum Albumin Levels Among Hemodialysis Patients by Serum Neutrophil Gelatinase-Associated Lipocan in Chinese MHD Patients**

Hirotaka Imaizaki,1 Akira Ishii,1 Hideki Yokoi, Masato Kasahara,2 Keita P. Mori,3 Takahiko Kuwabara,1 Katsuyoshi Nakao,2 Masashi Mukoyama,1 Motoko Yanagita,1,4 Kiyoshi Mori,4 Dept of Nephrology, Graduate School of Medicine, Kyoto Univ; Kyoto, Japan; 2Inst for Advancement of Clinical and Translational Science, Kyoto Univ Hospital, Kyoto, Japan; 3Dept of Nephrology, Kumamoto Univ Graduate School of Medical Sciences, Kumamoto, Japan; 4Medical Innovation Center, Kyoto Univ Graduate School of Medicine, Kyoto, Japan.

**Background:** Circulating concentration of neutrophil gelatinase-associated lipocan (NGAL or LCN2) is elevated in acute and chronic kidney diseases. Recently, we reported that, in a cross-sectional study, serum NGAL concentrations in maintenance hemodialysis (HD) patients were determined independently by % creatinine generation rate, white blood cell count and anion gap, indicating that NGAL is a marker of good nutritional conditions. Clinical impact of NGAL was further evaluated in a prospective analysis.

**Methods:** Correlations of baseline nutritional indices with baseline and follow-up serum albumin levels and changes in albumin levels after a year were investigated among 87 HD patients using linear regression analysis.

**Results:** Follow-up albumin levels were positively correlated to baseline NGAL, albumin, geriatric nutritional risk index, creatinine, %creatinine generation rate, anion gap, choline esterase, triglyceride levels and neutrophil counts, and negatively to age. Similar findings were obtained for baseline albumin levels. Importantly, albumin increase was positively correlated to baseline NGAL (r=0.36, P=0.01) and neutrophil count (r=0.33, P=0.01) and negatively correlated to baseline albumin levels. Typically, some cases with hypoalbuminemia and high NGAL levels experienced elevation in serum albumin levels after recovery from infection (or inflammatory disorders). On the other hand, in some cases with preserved albumin levels and low NGAL levels, serum albumin levels decreased once severe infection developed and reduced albumin levels persisted even after recovery from infection.

**Conclusions:** Serum NGAL level in HD patients appears to be a unique biomarker allowing prediction of alteration in serum albumin levels in a year.

Low Lymphocyte Counts Are an Independent Predictor of Mortality in Chronic Hemodialysis Patients: A Retrospective Cohort Study

Background: Mortality in chronic hemodialysis populations remains high. Lymphopenia has been associated with increased cardiovascular risk in the general population but few data are available on the effect of low lymphocyte counts on long-term survival of hemodialysis patients.

Methods: Retrospective study of a single-center cohort of 689 hemodialysis patients using monthly laboratory results and dialysis parameters extracted from a central database and a national registry. The effect of baseline and time-changing lymphocyte counts on overall mortality was studied using the Kaplan Meier and Cox proportional hazard methods.

Results: Lymphopenia (<1200 µL) was present in approximately one third of incident hemodialysis patients and correlated with older age, lower creatinine, lower phosphorus, higher Kt/V and a positive history of ischemic heart disease. Lymphopenia was not associated with classical markers of malnutrition-inflammation complex such as albumin, normalized protein catabolic rate, BMI and CRP. Baseline lymphopenia was associated with a 54 percent increase in the hazard of death (HR 1.54 (1.17 to 2.0; P=0.002)) as compared to the tertile of patients with highest lymphocyte counts. Lymphocyte counts tended to decrease during long-term follow up and their introduction as a time-changing variable further increased the HR to 2.1 (1.48 to 2.84; P=0.0001). The association remained significant in the multivariate Cox model after adjustment for age, phosphorus, creatinine, BMI, CRP, KT/V and history of ischemic heart disease.

Conclusions: Lymphopenia is highly prevalent in hemodialysis patients and is a strong predictor for patient death. The association was stronger when lymphocyte counts were considered as a time-changing variable and independent of other risk factors for patient death. Lymphopenia was not associated with markers of the malnutrition-inflammation complex (MIC) and therefore appears a useful prognostic tool in addition to classical markers such as CRP and albumin levels.

Outcomes and Quality of Care in Rural versus Urban Managed Dialysis Patients

Background: A proportion of patients are managed in remote satellite units in Manitoba, Canada. Urban nephrologists oversee all dialysis care; however family physicians (FP) co-manage patients. This study examines outcomes and quality of care indicators in rural vs. urban managed patients.

Methods: Prospectively collected clinical data from the Manitoba Renal Program and administrative health data housed at the Manitoba Centre for Health Policy were analyzed retrospectively. All adult (>18yrs) incident hemodialysis patients (~90 days from 1995 to 2010) were included. Individuals dialyzing in rural satellite units (n=510) more than 50% of the time were compared with their urban (n=2629) counterparts. Differences in cohort characteristics were analyzed at baseline as well as differences in primary care quality indicators. Regression analyses examined differences in hospitalizations and days in hospital. Cox proportional hazard models were performed to examine differences in survival.

Results: Patients in rural satellite units vs urban were younger, 58 ± 6 yrs (p=0.002), but were more likely to have DM 69.4 ± 55.3% (p<0.001), PVD 9.4 ± 4.0% (p<0.001) and HFr (MDM Angiogram or PCTA) 42.8 ± 34.2% (p<0.002). More rural patients accessed a FP at least once per year 85.7% ± 67.3% (p<0.001) and 85.3% vs 68% (p<0.001), after controlling for sex, income, Charlson, era, age and region at the start of dialysis.

Conclusions: Survival in a cohort of patients dialyzing in remote satellite units was found to be inferior to their urban counterparts, after controlling for co-morbidities. A potential reason might be increased primary care involvement, although differences were not seen in traditional quality of care indicators.

Applying Hemodialysis Clinical Quality Indicators to Individual Patients: A Useful Mortality Prognostic Tool in Clinical Practice?

Background: Hemodialysis (HD) care is routinely assessed by a set of clinical and laboratory parameters, known as Clinical Quality Indicators (CQI). CQI registry and reporting system constitutes an instrument to evaluate the quality of care provided at each HD Unit. The purpose of this study was to determine whether CQI, applied on an individual patient basis, is a predictor of mortality.

Methods: Retrospective study that included 334 patients of a HD Unit from 2011 to 2014. Demographic, clinical and laboratory data were collected. The CQI considered were eleven, whose intended target were: spKt/V > 1.4; weekly dialysis time ≥ 720 minutes; Albumin ≥ 3.5 g/dL; Hemoglobin between 10 and 12 g/dL; phosphatemia between 2.5 and 5.5 mg/dL; Ca×P product < 55 mg²/dL; PTH levels between 150 and 600 pg/ml; Ferritin between 200 and 800 mg/dL; Mean arterial pressure < 105 mmHg; interdialytic weight gain (IWG) < 4% and fistulae as vascular access. Single CQI were rated in a binary form (0 = not reached target/1 = reached target) at each monthly evaluation and the average were determined. Ultimately, the eleven parameters were added in a single variable for each patient (CQIp).

Results: During follow-up, 33% of patients died. In the Cox regression model, age (HR 1.09; CI 1.07-1.11; p<0.001), diabetes (HR 2.88; CI 1.92-4.32; p<0.001), peripheral arterial disease (HR 1.65; CI 1.09-2.44; p=0.016) and CQIp (HR 0.73; CI 0.62-0.87; p<0.001) were shown to be independent predictors of mortality, after adjustment for other clinical and demographic factors. When CQIp was replaced by its constituent variables, albumin (HR 0.016; CI 0.08 -0.32; p<0.001), PTH (HR 2.8; CI 1.10-3.93; p=0.023), IWG (HR 0.14; CI 0.14-0.83; p=0.018) and fistulae presence (HR 0.61; CI 0.4-0.93; p=0.021) presented statistical significance.

Conclusions: A set of parameters, generally applied as a quality care indicators, proved to be an independent predictor of death when applied to individual patients. This should be regarded as an easy and practical prognostic tool to be applied in current practice.

Association of Estimated Glomerular Filtration Rate at Commencement of Maintenance Dialysis with Mortality Among Patients with Advanced Chronic Kidney Disease in Singapore

Background: Recent evidence suggest that higher estimated glomerular filtration rate (eGFR) at commencement of dialysis may be associated with increased mortality. However, there is scarcity of data on patients of Southeast Asian origin. We analyzed and compared mortality risk in patients with early and late start dialysis as measured by kidney function at dialysis initiation among Southeast Asian population of Singapore.
Methods: We performed a retrospective analysis of patients enrolled in the Singapore Renal Data System database from 2008 to 2011. Patients were classified into groups by eGFR at dialysis initiation.

Results: In this total incident population (n=3708), a total of 1510 individuals died during a median follow-up period of 2.8 years. The hazard ratio (HR) and 95% CI associated with different levels of eGFR at commencement of RRT are shown in table below. The main multivariable model (n=3189 without missing information on covariates) associated with the eGFR at dialysis initiation within the groups: age, gender, level of education, smoking, presence of diabetes, ischemic heart disease, cerebrovascular disease, and peripheral vascular disease, malignancy, hepatitis B, hepatitis C, kidney transplant, and hemodialysis. Additional models accounted for serum albumin (n=2657), and serum ferritin (n=2462), and serum calcium (n=1628).

The results were consistent after accounting for serum albumin, serum ferritin, and serum calcium in the multivariable models.

Conclusions: Late initiation of dialysis is associated with a lower risk of mortality in comparison with early dialysis initiation in Southeast Asians in Singapore.

FR-PO683
Predicting Mortality for Patients Who Are on Hemodialysis–A National Cohort Study in Taiwan
Jinn-Yang Chen, Div of Nephrology, Taipei Veterans General Hospital, Taipei, Taiwan.

Background: Comorbid conditions and medical history provide prognostic information for dialysis patients. The objective of this study was to develop a prognostic model to predict short-term (6-months and 1-year) and long-term (2.5-years) survival for incident hemodialysis (HD) patients.

Methods: Incident Taiwanese hemodialysis patients from 2006 to 2010 were extracted from National Health Insurance claims records. Prognostic model was developed by using comorbid conditions (summarized as Taiwan index), monthly income and medical history during one year before initiation of dialysis. Sonner’s D statistic was used to assess the discrimination ability of our model.

Results: A total of 36,875 incident HD patients were included in this study and the last follow-up day was December 31, 2011. More comorbid burden, male gender, history of acute kidney injury, dementia, admitting to intensive care unit, staying at nursing home and ever using ventilator were significant prognostic factors. Monthly income only had marginal effects on survival at 2.5 years. For discrimination ability, our model has Sonner’s D statistics of 0.76, 0.76, 0.67 and 0.75 for 6-months, 1-year, and 2.5-years survival, respectively.

Conclusions: Three prognostic models with same covariates for short-term and long-term survival in HD patients were found in this study. The consistency in model performance helps clinicians and patients to make decision.

FR-PO684
Twice Weekly Treatment Eligibility for Incident Hemodialysis (HD) Patients
Suresh Appasamy, Andrew I. Chin, Thomas A. Depner. Div of Nephrology, Univ of California, Davis, Sacramento, CA.

Background: KDOQI guidelines advise that hemodialysis treatments constitute a conservative criteria, half of these were judged ineligible because of Uf requirements or HD-induced symptoms. Opportunity exists for incremental HD in a significant number of incident patients.

Results: Urine collections disclosed that 225 or approximately 30% of 734 incident patients were eligible for 2-week HD based on solute kinetics alone. Using conservative criteria, half of these were judged ineligible because of Uf requirements or HD-induced symptoms. Opportunity exists for incremental HD in a significant number of incident patients.

Conclusions: Urine collections disclosed that 225 or approximately 30% of 734 incident patients were eligible for 2-week HD based on solute kinetics alone. Using conservative criteria, half of these were judged ineligible because of Uf requirements or HD-induced symptoms. Opportunity exists for incremental HD in a significant number of incident patients.

FR-PO685
The Relationship of Diabetes and Congestive Heart Failure to Costs of Care in End Stage Renal Disease Patients
Sheetal Chaudhuri, Jane Brzozowski, Hao Han, Len A. Usvyat, John W. Larkin, Mahathi Mohali, Terry Ketchersid, Franklin W. Maddux. Fresenius Medical Care North America, Waltham, MA.

Background: Many Medicare patients (Pts) with end stage renal disease (ESRD) are known to have co-morbidities of diabetes mellitus (DM) and/or congestive heart failure (CHF). Total costs of care for ESRD Pts are likely to be dependent on patient comorbidities and likely to vary by geography. We investigated the relationship of DM and CHF based on Pts’ geographic location.

Methods: ESRD Pts with evidence of diabetes at any time during Jan 1, 2010 through Dec 31, 2011 and Medicare as their primary payer were analyzed. Pts were stratified based on Metropolitan Statistical Areas (MSA) and Medicare Part A and B costs were calculated from 100% Medicare data. T-test comparisons were performed for quartiles of total cost of care for eight groups: based on vintage (<90 days on dialysis) or prevalent (>3 years on dialysis)), as well as, comorbidities (no DM and no CHF, no DM and CHF, no DM and with CHF and with both DM and CHF).

Results: Claims for 107,659 Pts were analyzed. Total cost of care increased significantly as the percent (%) of Pts with CHF and DM increased; cost of care declined significantly as the % of Pts with neither DM nor CHF increased by MSA. Cost of care did not change with the increase in % of Pts without DM and with CHF. Yet, costs of care declined as % of Pts with DM and without CHF increased by MSA. These patterns were observed in both incident and prevalent Pts.

Figure 1. Costs of care by MSA (per member per month)

FR-PO686
Long Term Outcomes Over 2 Years following a Dialysis Adequacy Quality Improvement Initiative
Saeeda Youssouf, Philip A. Kalra, Janet Hegarty. 1,2
1 Salford Royal NHS Foundation Trust; 2 Manchester Academic Health Sciences Centre.

Background: Dialysis adequacy is known to correlate with clinical outcomes such as mortality. Evidence based guidelines recommend that hemodialysis patients should achieve a urea reduction ratio of >65%. UK Renal Registry data shows wide variation in facility attainment of target URR. In 2010 the Salford Renal Network implemented an ambitious programme to uplift attainment of key quality of care indicators to within the top 10% in the UK; dialysis adequacy was a target in 2 phases of improvement in 2010-2012.

Methods: Our network implemented a quality improvement programme using collaborative methodology. We set four teams a different clinical indicator to work on over 12 month cycles for 2 successive years, guided by QI facilitation input. Unit A worked on URR in phase 1 and developed a package of changes using plan-do-study-act (PDSA) testing that was used for improvement by Unit B in phase 2. We analysed the long-term outcomes in these units for a further 2 years until May 2014.

Results: Both units reached their aim of >90% of patients achieving target URR>65% within their improvement year. Both units sustained the improvements for 2 years with no additional resource input after the collaborative. Changes included protocolised nurse-led changes to dialysis prescriptions, multidisciplinary review of vascular access, a nurse-led anticoagulation protocol, blood sampling protocol, and monthly reports.

Conclusions: These results identify differences in association between ESRD related co-morbidities and total costs of care: the % of Pts with both DM and CHF is higher in areas with higher total costs. Surprisingly, costs of care are lower in areas where the % of Pts with DM but without CHF is higher. Risk Adjustments should be considered.

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America
Conclusions: Longer term outcomes from QI interventions are underreported with limited evidence on sustainability. We implemented multifaceted interventions to improve dialysis adequacy in our network to within the top 10% in the UK. Implementing evidence-based changes led by frontline staff trained in QI has sustained these improvements for 2 years after a formal QI intervention, improving quality of care for our patients.

FR-PO687
Clinical Effectiveness of Intermittent Infusion Hemodiafiltration (I-HDF) Compared with Conventional Hemodialysis: A Multicenter Clinical Trial
Michio Mineshima, Kei Eguchi. Clinical Engineering, Tokyo Women's Medical Univ, Tokyo, Japan.

Background: Intermittent infusion hemodiafiltration (I-HDF) using backfiltration of an ultrapure dialysis fluid has been developed to improve the peripheral circulation of the patient receiving a typical hemodialysis (HD) with repeated intermittent infusion by an automated dialysis machine, GC-110N (JMS Co. Ltd., Tokyo, Japan). In a typical HD treatment, excessive water removal often induces hypotension and muscle spasm. In the I-HDF, some 200-300 mL of ultrapure dialysis fluid was infused into the blood component through the dialysis membrane at a rate of 100 mL/min, every 30 min. I-HDF, namely, means a HDF treatment with small amount of infusion volume, 1.4 to 2.1 L (200-300 mL x 7 times)/session.

Methods: In this paper, clinical effectiveness of I-HDF was evaluated in comparison with conventional HD (CHD) during a multi-center clinical trial that twenty chronic renal disease patients participated.

Results: A significantly lower value for time-averaged blood volume reduction was obtained with I-HDF compared with CHD in spite of there being no difference in the total amount of water removal. It was due to a higher plasma refilling rate in I-HDF. In addition, increasing peripheral blood flow rate in the patient's toe was detected by a laser obtained with I-HDF compared with CHD in spite of there being no difference in the disease patients participated.

Conclusions: Intermittent Infusion HDF using an automated dialysis machine was effective for improvement of the peripheral circulation of patients receiving conventional HD.

FR-PO688
Impact of Post-Hospital Phone and Telehealth Case Management to Reduce Admissions/Readmissions Patients
Rebekah L. Wingard, Billie Axley, Kathryn A. McDougall, Andrew D. Howard, Jocelle Heilemann, Perry Parlier, Sophia Rosen, Len A. Usvyat, Alexis Porras, Franklin W. Maddux, 1 Fresenius Medical Care, Waltham, MA; 2 Metropolitan Nephrology Associates, Clinton, MD.

Background: 2012 30-day readmissions for hemodialysis (HD) patients (pts) were high at 35% in 2012 (USRDS). The Right Trac™ (RT) Program addressed factors in the complex process of care transitions, with the aim to reduce hospital admissions and readmissions.

Methods: 26 HD clinics (3682 pts) were in RT. Interventions deployed in 3 phases (Apr ’13-Nov ’14). E: Pre- and post-hospital checklists for clinicians to manage pt teaching, anemia, nutrition, medications, and dry weight. II: Telephonic case management for 30 days post-discharge. III: Dialysis Link™ centralized clinical info exchange among providers. Admission and readmit from rates pt per year (ppy) for “baseline year” (2012) vs. “full intervention year” (2014) were compared to 18 control clinics (2449 pts) matched for clinic size, admission and readmission rate, and urban vs. rural location at baseline.

Results: 30-day readmissions ppy declined from baseline to full intervention year in RT (0.88 to 0.65, p<0.001) and controls (0.73 to 0.6, p=NS); comparison of the change between groups was not significant (Fig 1). Admission rates ppy declined for clinic size, admission and readmission rate, and urban vs. rural location at baseline. Poisson models with random effects for pt and clinic, adjusted for age, vintage, race, gender, ethnicity, DM, CHF, and COPD were constructed to assess the difference between baseline and intervention and between RT and control clinics.

Conclusions: RT interventions were associated with significant declines in admissions and 30-day readmissions. The difference in the changes between RT vs. controls was significant for admissions, but not significant for 30-day readmissions.

FR-PO690
Predicting Early Mortality Among Hemodialysis Patients Using USRDS Data
Eunsang Yang, 1 Zhi He, 1 Jennifer L. Bragg-Gresham, 1 Yuan Yang, 1 Haoyu Gu, 1 Yi Li, 1 Kamyar Kalantar-Zadeh, 1 Elani Streja, 1 Rajiv Saran, 1 Department of Nephrology-Dept of Internal Medicine and KECC, Univ of Michigan, Ann Arbor, MI; 2 Renal Div Dept of Medicine, Peking Univ First Hospital, Beijing, China; 3 Dept of Biostatistics and KECC, Univ of Michigan, Ann Arbor, MI; 4 Univ of California Irvine, Orange, CA; 5 Harbor Simmons Center, Orange, CA.

Background: Higher early mortality of hemodialysis (HD) is recognized. We sought to quantify the risk of early mortality and develop a robust prediction model which could potentially guide clinical decision-making.

Methods: The 2007-2012 data from the United States Renal Data System (USRDS) on incident HD patients, age >18 years, were randomly split as ‘training’ and ‘validation’ samples. Cox proportional hazards model with piece-wise constant coefficients was used to model all-cause mortality during day 0-90 and day 91-365 of HD. Those transferred to peritoneal dialysis or transplantation were censored. The resulting model was validated by C statistic.

Results: The mean age (n=611,094) was 63.6±14.9 years, with 130,473 deaths during the first year of HD. Mortality rates were 35 per 100 person-years in the first 90 days and 21 per 100 person-years during days 91-365. The final model included 23 variables including demographics characteristics, pre-ESRD care, laboratory values, co-morbidities as well as institutionalization status. In adjusted analyses, selected variables with significant time-varying effects are listed in the Table.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Delayed Thrombectomy Increases Risk for Dialysis Catheter Placement

Scott Reule, Sunil Akkina, Andrew J. Esten, Paul E. Drazew. Dept of Medicine, Univ of Minnesota, Minneapolis, MN.

Background: Arteriovenous dialysis accesses (fistulas or grafts) are associated with significant rates of thrombosis. Though timely thrombectomy may have a significant impact on immediate and long-term access survival, it is not always readily available. The goal of this study was to evaluate whether delayed thrombectomy increases the risk for loss of dialysis access and subsequent placement of a dialysis catheter.

Methods: All patients at the Fairview Health System with thrombectomy as the indication for dialysis catheter placement were included in this retrospective observational study. The electronic medical record was reviewed to evaluate type of access, timing of admission and declot, and access on discharge and 6 and 12 months after discharge. Baseline characteristics and proportions were determined for the overall population as well as stratified by tertile of time to thrombectomy, defined as the time from admission to the declot procedure. The outcomes of interest included need for dialysis catheter at discharge and 6 and 12 months after discharge. Logistic regression was used to evaluate the risk for dialysis catheter use adjusting for prior intervention, access type, and time to thrombectomy.

Results: Of 444 patients identified using procedural codes, 122 were admitted primarily for thrombectomy. The mean age was 60.4 years, 65% were male, and 44.3% utilized arteriovenous fistula for access. Mean time to thrombectomy was 0.45 days (range: 0.05-1.13 days). Fifteen patients utilized a catheter for hemodialysis on discharge. Delayed thrombectomy was associated with a two-fold increase in requirement for catheter at discharge (OR 2.02; CI 1.19-3.43) and at 6 months (OR 2.04; CI 1.20-3.48). This association remained present at 12 months (OR 1.75; CI 1.02-3.00).

Conclusions: In this study of patients cared for within a large academic health system, a one day delay in thrombectomy doubled the risk for need for a dialysis catheter at discharge and 6 and 12 months after discharge. These results indicate that a clotted dialysis access should be considered a medical emergency.

Effect of Medicare’s Payment Adjustment for Low-Volume Dialysis Facilities on Facility Closures

Richard Hirth, Tammine A. Nahra, Adam S. Wilk, Marc Turene, Jonathan H. Segal, John Wheeler, Kathryn Sleeman, Wei Zhang. Univ of Michigan; Ann Arbor, MI; Arbor Research Collaborative for Health, Ann Arbor, MI.

Background: Small dialysis facilities may face higher per-treatment costs due to economies of scale. Since 2011 a low-volume payment adjustment (LVPA) raised Medicare payments 180% to facilities with <4,000 treatments in each of the 3 prior calendar years. A goal of this policy is to preserve access to care by preventing the closure of small facilities.

Methods: We tested the hypothesis that the LVPA prevented closures by examining the year-to-year closure rates of U.S. dialysis facilities during 2007–2013, before and after the policy, comparing facilities providing <4,000 and >4,000 annual treatments. Analyses with linear regression relate facility outcomes to prior year size, ownership, for-profit status, hospital affiliation, patient mix, rural location, modality mix and county characteristics, to examine the effect of the LVPA on 8 of treatments provided by facilities.

Results: Among low-volume facilities, year-to-year closure rates were 3.8%, 4.9% and 4.0% pre-LVPA, falling to 1.1%, 0.5% and 0.8% post-LVPA. Among facilities with >4000 treatments, closure rates also decreased, but to a much smaller extent (from 1.0%, 1.2% and 0.8% pre-LVPA to 0.6%, 0.2% and 0.3% post-LVPA).

Conclusions: In Medicare’s bundled payment system, closure rates decreased overall, with a much larger absolute reduction among small facilities. The gap in closure rates between small and large facilities fell from about 3% points before the policy to about 0.5% points after. LVPA appears to have helped prevent small dialysis facility closures, but it may also motivate some small facilities to avoid growing in order to retain the LVPA. Emphasizing a dialysis facility’s importance for patient access rather than size alone may help inform payment policy modifications.

FR-PO693

Recent Evidence on the Impact of Medicare’s Bundled, Prospective Payment System for Renal Dialysis

Background: Medicare implemented an expanded prospective payment system (PPS) in 2011, including services previously paid by fee-for-service. One intent of the PPS was to incentivize providers to be more efficient in the mix of services provided.

Methods: We used Medicare claims to assess monthly trends from 1/2010-12/2014 for injectable drugs that were previously billed separately. For 2010, we assessed actual spending. For 2011-14, we projected spending based on reported utilization.

Results: ESA use declined in the months immediately pre- and post-PPS, continuing to decline through 2012. In 2013, ESA use leveled off. Use of iron products, often improving efficacy of ESAs, increased through 2011 and then began to decline. Total drug cost, including ESAs, iron, and vitamin D, fell by more than 50%, from a high of $76.16 per session in early 2010 to a low of $34 per session over a period of 4 years exceeds the Medicare mandated reduction in the base rate over the same period.

Conclusions: The expanded bundle dialysis PPS provided incentives for both lower medication utilization overall and the use of lower cost therapies. These incentives seem to have motivated an immediate movement toward lower cost methods of care. Facilities used Medicare claims to assess monthly trends from 1/2010-12/2014 for injectable drugs that were previously billed separately. For 2010, we assessed actual spending. For 2011-14, we projected spending based on reported utilization.

Intradialytic Body Weight Reduction and Outcome of Vascular Access: Analyses of Data from the Japan Dialysis Outcomes and Practice Patterns Study (J-DOPPS)

Manabu Asano,1 Kenichi Oguchi,1 Akira Saito,1 Yoshihiro Onishi,1 Yosuke Yamamoto,2 Shunichi Fukuhara,2 Takashi Akiba,2 Tadao Akizawa,2 Bsei Hospital, Saitama, Japan; 1J-DOPPS Research Group, Japan; 1Hope International, Kyoto, Japan; 1Inst for Advancement of Clinical and Translational Science, Kyoto Univ Hospital, Kyoto, Japan.

Background: There is no doubt that large-volume ultrafiltration is one of the important risk factors for vascular access (VA) thrombus in hemodialysis patients. However, the relationships between intradialytic body weight reduction and VA patency are still in the middle of being discussed. We tried to determine whether large-volume ultrafiltration was practically associated with VA failure by means of the results obtained from the phase 3 and 4 J-DOPPS.

Methods: Referring data from the phase 3 and 4 J-DOPPS, the current analyses were limited to 2736 patients who were evaluable for VA patency and body weight change during dialysis. They were assigned to one of the following three groups according to the tertiles (T1-T3) of intradialytic fluid removal per body weight: T1, 0-5% to 3.8%; T2, 3.8% to 5.1%; and T3, 5.1% to 13.7%. The hazard ratio of VA failure was compared across these tertile groups using Cox regression models. The models were adjusted for the following risk factors: age, gender, BMI, diabetes, hemoglobin, phosphorus, Kt/V, ESA use, and antplatelet use. Primary VA survival was defined as the days until the first VA intervention. Secondary VA survival was defined as the days until new VA creation.

Results: The incidence rates (events/100 person-years) of primary and secondary VA events were 4.7 and 1.3 for T1, 1.6 and 1.6 for T2, and 6.7 and 1.7 for T3, respectively. The adjusted hazard ratios versus T1 for primary VA patency were 1.16 (95% confidence interval [CI], 0.88 to 1.52) for T2 and 1.41 (95% CI, 1.07 to 1.87) for T3. The hazard ratios versus T1 for secondary VA patency were 1.29 (95% CI, 0.78 to 2.13) for T2 and 1.45 (95% CI, 0.86 to 2.45) for T3.

Conclusions: This study shows that large-volume ultrafiltration during dialysis tends to increase VA failure in hemodialysis patients.

FR-PO695

Post-Endovascular Intervention Venous Access Pressure Ratio (VAPR) Predicts Access Survival

Lalathaksha Murthy Kumbar,1 Gerard Zasuda,2 Anatole Besarab,2 Ken Hirschman,3 Jerry Yee,1 Henry Ford Hospital, Detroit, MI; 2Vasc-Alert, LLC, Evanston, IL.

Background: The vascular access pressure ratio test identifies vascular access (VA) dysfunction in hemodialysis patients when 3 consecutive VA (VAPR) measurements are >0.55. We hypothesized whether a post-interventional VAPR decline predicts VA outcomes in patients with VA dysfunction.

Methods: Retrospective analysis of all VA procedures from 09/2013 to 04/2015. Data collection included demographics, comorbidities, VA features, mean VAPR <30 days pre- and post-procedure, time-to-next procedure, and access patency. Kaplan-Meier arteriovenous graft (AVG) and fistula (AVF) survival curves were compared by the log-rank test. A Cox-proportional hazard model was used to determine the association of VAPR ∆% (Pre-Post)/Pre<100% with access survival.

Results: Analysis of 92 subjects [females 57% (n=53); black 88%; and diabetes mellitus 61% (n=56)] included 46 AVG with 94 procedures and 46 AVG with 86 procedures. Mean VAPR ∆% was 26 ± 61 (SD) and 16 ± 54 for AVG and AVF, respectively. VAPR decline was absent in 13 AVG. AVG with no VAPR decline (<0%) post-intervention when compared to AVG with any decline (>0%) required more subsequent procedures (64% vs 47%), with fewer days to next procedure (75 vs 149 d), and lower survival (p=0.002). For AVG, a post-intervention VAPR decline >10% (p=0.04) projected AVG survival. 34% of AVG procedures had <10% decline (n=30) and required more subsequent procedures than AVG with >10% decline (64% vs 39%). AVG without VAPR decline had a 3-fold greater risk of failure (p=0.003). The risk of failure was 2.0-fold greater (p=0.04) for AVG with <10% decline.

Conclusions: 10% post-intervention reduction of VAPR in AVG and any VAPR reduction in AVG predicts greater VA survival.

FR-PO696

Abnormalities in Mineral Metabolism and Dialysis Arteriovenous Fistula Thrombosis in the HEMO Study

Anna Jeanette Jovanovich,1 Eugene J. Nuccio,2 Alfred K. Cheung,14 Tom Greene,1 Michel Moncholon,2 Denver VA Medical Center; University of Colorado Denver; VA Salt Lake City; 14Univ of Utah.

Background: Vitamin D deficiency and fibroblast growth factor 23 (FGF23) excess are highly prevalent among patients requiring chronic hemodialysis. This study aims to determine the association of 25-hydroxyvitamin D (25(OH)D), 1,25-dihydroxyvitamin D (1,25(OH)2D), and FGF23 serum levels with arteriovenous fistula (AVF) thrombosis in hemodialysis patients.

Methods: The HEMO Study was a randomized multicenter study evaluating the effects of high-dose versus standard-dose and high-flux versus low-flux hemodialysis. Serum 25(OH)D, 1,25(OH)2D, and intact FGF23 levels were measured in stored serum samples obtained at baseline in 881 patients in this cohort. Cox proportional-hazards models were used to examine the association of 25(OH)D, 1,25(OH)2D, and FGF23 serum levels with time to first AVF clotting event after controlling for important clinical covariates in the HEMO Study.

Results: Patients had a mean age of 57±14 years, 55% were females, and 46% were white. During a median follow-up of 3.0 years, 111 AVF clotted. Median (IQR) serum 25(OH)D, 1,25(OH)2D, and FGF23 levels were 19.1 [14.2, 26.6] ng/mL, 6.3 [2.9, 14.5] pg/mL, and 3118 [726, 12928] pg/mL. Among patients with levels in the highest tertile compared to the lowest tertile, both 1,25(OH)2D and FGF23 were significantly associated with an increased risk of clotting in adjusted analyses, hazard ratio (HR) 2.79 (95% CI, 1.21-6.46) and HR 1.35 (95% CI, 1.02-1.83), respectively. No statistically significant associations were observed between 25(OH)D serum levels and AVF thrombosis.

Conclusions: Calcitriol and FGF23 excess were associated with an increased risk of AVF thrombosis among chronic hemodialysis patients.

Ultrasound-Guided Evaluation of New AV Fistulas Safely Decreases Time to First Cannulation

Farzin Farpour,3 Roshan A. Patel,2 George N. Corisidis,12 Nephrology, Elmhurst Hospital, Icahn School of Medicine at Mount Sinai, Elmhurst, NY; 2Nephrology, Broadway Atlantic Dialysis Center, Elmhurst, NY.

Background: The use of bedside ultrasoundography (USG) in various medical specialties has exploded over the last decade. For the past year, we have been using bedside USG for earlier AV fistula utilization and for diagnosing potential problems. Prior to the use of USG, cannulation was based on physical exam. We were interested to see whether use of bedside USG helps in early cannulation of AVF.

Methods: USG procedures from February 2014 to February 2015 were reviewed. Time to cannulation in the year prior to the introduction of USG (2013 - 2014) was calculated and compared to similar data with USG use. By week 4 all new fistulas underwent the first USG exam. Examinations were performed by the renal attendings and fellows each exam lasting about 5 minutes. Sonosite M-Turbo ultrasound machine was used.

Results: Total of 44 USG examinations were performed on 14 patients while monitoring new AVF maturation. In 10 patients USG-guided cannulation occurred at an average of 6.2 ± 0.9 weeks compared to 10.2 ± 0.9 weeks prior to USG use (P=0.006). There were no complications seen with the earlier USG-guided cannulations. Subsequent cannulations by the nursing staff were successful without USG. In 4 patients failure of maturation was diagnosed by USG at an average of 3.8 ± 0.9 weeks vs 9.6 ± 1.2 weeks prior to USG (P=0.08). Antibiotic dosing occurred 21 times prior to USG compared to 11 times with USG, despite the similar cannulation rates for both years.

Conclusion: USG use facilitates early AVF cannulation with decreased time to first use. Identification of potential AVF issues and their referral are accomplished earlier. This may translate to earlier catheter removal and fewer infections.

FR-PO698

Arteriovenous Grafts Reduce Catheter Dependence in the Elderly

Thomas M. Loh, Matthew E. Bennett, Francis E. Loh, Eric K. Peden. Vascular Surgery, Houston Methodist, Houston, TX.

Background: Arteriovenous fistulas (AVF) are the permanent access of choice. The benefits of AVF, durability and longevity, are minimized in the elderly where more than 40% of patients will die within their first year of initiating hemodialysis. We investigate an expanded role for primary arteriovenous grafts (AVG) in this population.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: We retrospectively review consecutive patients over the age of 70 who underwent upper extremity access creation from January 2008 to July 2014. Data collection included demographics, past medical histories, subsequent interventions, volume flows, access usage, and patient survival.

Results: We performed 366 AVF and 124 AVG creations in 442 patients over the age of 70 (197 women, 245 men). There were no significant differences in the comorbidities between the two access types. The AVG group was significantly older and more likely to be female, 79.2 ± 7.7 years vs. 77.2 ± 7.0 years (p = 0.001) and 60% vs. 41% (p = 0.001) respectively. Patients with AVF were significantly more likely to never use their permanent access, 25% vs. 11% (odds ratio 0.02, p = 0.002) and if utilized, cumulated significantly later, 3.6 ± 0.2 months vs. 1.3 ± 0.1 months (p < 0.001). Catheter dependence at 6 months was 40% for AVG and 28% for AVF. (Figure 1) Secondary patency at 18 months was 64% for AVF and 63% for AVG.

Conclusions: Prosthetic grafts should be considered as the preferred permanent access type in the elderly. Better predictors of mortality, including frailty scores, should be investigated for determining the best choice of permanent access in elderly patients.

FR-PO699

Background: Conventional outpatient hemodialysis utilizes various forms of anticoagulation to prevent access and extracorporeal circuit clotting. In contrast, to reduce the risk of bleeding events, inpatient dialysis units do not frequently use anticoagulation. We aimed to investigate the consequences of anticoagulation-free dialysis and the factors associated with failure to achieve ultrafiltration target (UFT) in our inpatient unit.

Methods: We performed a retrospective analysis of 250 consecutive hemodialysis treatments in 125 chronic patients. Patients were excluded if they were admitted for initiation of dialysis or required systemic anticoagulation. We looked at both instances of successful achievement and failure of UFT. We looked at the following factors: type of access, episode of intradialytic hypotension (IDH), episode of access clotting, and episode of extracorporeal circuit clotting. No anticoagulation was used in the HD treatments. Correlation analyses were performed and categorical data was analyzed using chi-square test. STATA, version 11, was used for statistical analyses.

Results: Overall the incidence of failure to meet UFT was 35%. Association of failure to meet UFT and episode of IDH was noted (p = 0.000, Pearson chi²(1) = 13.5). There was no correlation between meeting UFT and type of access (graft r = 0.09, fistula r = 0.13, and catheter r = 0.07), access clotting (r = 0.07), and extracorporeal circuit clotting (r = 0.08).

Conclusions: Our study of 250 anticoagulation-free hemodialysis treatments suggests that access and extracorporeal circuit clotting was not associated with failure to meet ultrafiltration target. However, the failure to achieve ultrafiltration target was significantly associated with intradialytic hypotension. Larger cohort, multi-center prospective trials should be performed to look at causality of failure to meet ultrafiltration targets in the hospitalized patient.

FR-PO700
Evaluation of the Ability of Transonic Monitoring to Predict Dialysis Access Stenoses Jerard Zaki Kneifati-Hayek,1 Gaurav Ghosh,2 Stephen Kruger,3 Jeffrey I. Silberzweig.2,3 1Dept of Medicine, New York-Presbyterian Hospital, New York, NY; 2Weill Cornell Medical College, New York, NY; 3The Rogosin Inst, New York, NY.

Background: Patency of vascular access is critical to successful maintenance hemodialysis. It is well established that lesions are easier to treat if they can be identified prior to thrombosis. Non-invasive evaluation of access blood flow with the Transonic device is established for this purpose. We previously analyzed its performance after two years and demonstrated >99% sensitivity and specificity. We now seek to extend that work by looking at performance over a fifteen-year period.

Methods: Transonic studies are performed on approximately 1500 maintenance dialysis patients with AV grafts or fistulae in our 7 clinics in New York City. Transonic flow rates <600 cc/min or decreases by >10% from prior readings prompt referral to Interventional Radiology or Vascular Surgery. We report on the sensitivity, specificity and predictive values for patients treated between 1998 and 2012.

Results: Sensitivity was 42%; specificity 72%. Positive predictive value (PPV) was 20%; negative predictive value (NPV) was 85%.

We evaluated our ability to predict stenosis based on decreased dialysis clearance: for Kt/V, PPV was less than 10% and NPV less than 80% for different cutoff points; for URR, PPV was less than 10% and NPV less than 80%.

Conclusions: We hypothesize that the large numbers of false positive and false negative results were caused by scheduled referrals to Interventional Radiology, which have become routine. This study suggests that routine Transonic studies may no longer be as important as they were in 2000; however, Transonic studies provide better predictive ability than reductions in urea-based dialysis clearance.

FR-PO701
Hemodialysis Vessel Mapping in Women and Men Rita L. McGill, Robin Ruthazer, Dana Miskulin, Klemens B. Meyer, Daniel E. Weiner. Tufts Medical Center, Boston, MA.

Background: Men initiate hemodialysis (HD) with fistulas (AVF) more often than women, and this gap widens following initiation. Angiography and Doppler vessel mapping may promote AVF creation by detecting vessels not found by physical examination. Women may benefit more from imaging, as they are less likely to have veins that are visible upon inspection, even when suitable for AVF construction. We hypothesized that the sex disparity in AVF use may in part reflect a disparity in vessel mapping rates.

Methods: After restricting to patients with pre-dialysis Medicare claims, we used CPT codes to ascertain all vascular imaging during the 2 years before starting HD and up to 12/31/2012, in the subset of adult HD patients entering USRD5 in 2010 or 2011 with central venous catheters (CVC) as sole vascular access. Doppler studies performed on the same day as an angiogram were excluded. Angiograms and Dopplers per 100,000 patients-months were calculated. Incidence rate ratios (IRR) between women and men were adjusted for age, sex, BMI, diabetes, and vascular disease using Poisson regression.

Results: Among women with preHD claims, 62% had CVC-only and 14% AVF; men had 57% CVC-only and 20% AVF. 18494 men and 16686 women with CVC-only contributed 615257 and 558647 patient-months of data. No imaging was performed in 57% of men and 54% of women. The distribution of studies in men and women showed:

Conclusions: Vascular imaging was performed in fewer than 50% of individuals starting hemodialysis with CVC. Higher rates of vascular imaging in women were statistically but not clinically significant. Promotion of vein mapping and angiography in women merits exploration as a means to decrease the disparity in fistula rates between women and men.

Association of Bacteremia with Arteriovenous Access Failure in Hemodialysis Patients
Syed Mustafa Ahmed, Laura Plantinga, Rachel E. Patzer, Jason Cobb, William M. McClellan. Emory Univ, Atlanta, GA.

Background: Obesity, female sex, diabetes, peripheral vascular disease, and pacemakers are known risk factors for arteriovenous fistula (AVF) and arteriovenous graft (AVG) failure. We examined whether bacteremia in hemodialysis (HD) patients with AVF/AVG represents an additional, independent risk factor for subsequent AVF and AVG failure.

Methods: We conducted a retrospective observational study among 29,571 U.S. patients from the United States Renal Data System who started HD with AVF and AVG between 1/1/2009 and 9/30/2010. We used inpatient ICD-9 codes after dialysis start to define bacteremia and AVF/AVG failure. We then used a multivariable Cox proportional hazards model to assess relationship between exposure to bacteremia and time to access failure.

Results: Overall, 12.2% of patients with bacteremia experienced an access failure, compared to 4.0% of patients without bacteremia (P<0.001). This difference persisted over a median follow-up of 582 days. With adjustment for known confounders, patients who had bacteremia after dialysis start were at >3-fold greater risk of subsequent access failure, relative to those who did not (HR=3.18, 95% CI: 1.71–5.95).

Conclusions: This observational study indicates that decreased AVF and AVG survival may be associated with exposure to bacteremia among HD patients.

FR-PO703
Comparison of Loss of Vascular Access Patency in Hemodialysis Patients with End-Stage Renal Disease due to Systemic Lupus Erythematosus versus Other Causes
Laura Plantinga, Sung S. Lim, Rachel E. Patzer, Stephen O. Pastan, Cristina Drenkard. Emory Univ, Atlanta, GA.

Background: We previously found that U.S. patients with systemic lupus erythematosus (SLE) and end-stage renal disease (ESRD) were 40% less likely than other ESRD patients to have a permanent vascular access in place at the start of dialysis. Here, we examine whether subsequent loss of patency differs in SLE vs. other ESRD patients who have a permanent vascular access.

Methods: A cohort of 106,993 U.S. patients starting hemodialysis with an arteriovenous fistula or graft (705/9-11) was identified from a national registry of treated ESRD (United States Renal Data System). Kaplan-Meier analyses and multivariable Cox proportional hazards models were used to estimate the association between SLE vs. other ESRD (by provider-reported attributed cause at start of dialysis) and the time to first inpatient ICD-9 code for loss of vascular access patency, with censoring for death or the end of follow-up.

Results: A total of 597 (0.6%) incident hemodialysis patients were included. Over a median total follow-up of 1.9 years (IQR, 0.9–3.3 years), SLE vs. other ESRD patients had similar likelihood of loss of patency [HR=0.87 (95% CI, 0.70–1.09)].

FR-PO704
The Placement of Tunneled Central Venous Catheters Through Percutaneous Puncture of Superior Vena Cava in Hemodialysis Patients
Tianlei Cui, Xiaoxi Zeng, Yanhuan Feng, Ping Fu. Nephrology Dept, West China Hospital, Sichuan Univ, Chengdu, Sichuan, China.

Background: Arteriovenous fistula and arteriovenous graft (AVF, AVG) represents an additional, independent risk factor for subsequent AVF and AVG failure. We examined whether these patterns persist when outpatient procedures are included; however, confounding by indication would remain a potential bias.

Results: Sixteen patients (male: 62.5%; mean age: 64.7 years; mean duration of HD: 5 years) who underwent placement of ICVCs through percutaneous puncture of SVC were retrospectively analyzed. They had either exhausted AV access sites or chosen not to undergo other vascular access placement. All of the patients had occlusion in innominate veins on both sides. The outcomes were function measurements of ICVCs, and safety parameters.

Conclusions: The procedure succeeded in all of the patients. During the follow-up (mean: 12 months, range: 3-36 months), access failure due to thrombosis was observed in one patient, and the failure was treated by aspirin and Clopidogrel. The remaining continued to function well until the end of the follow-up or until the death of the patients (n=3). The procedure was generally safe. No pneumothorax occurred. The most common complication was mediastinal hematoma after the failure of SVC puncture. The fluoroscopy could reveal the hematoma during the procedure. The largest hematoma was 2cm in diameter in the current series and it resolved spontaneously.

FR-PO705
Analysis of Survival of Cardiofucntion in Maintained Hemodialysis Patients with Arteriovenous Fistula and Tunneled Cuffed Catheter
Li Hua Wang, Fang Wei, Ai Li Jiang. Dept of Kidney Disease and Blood Purification Centre, Inst of Urology & Key Laboratory of Tianjin, 2nd Hospital of Tianjin Medical Univ, Tianjin, China.

Background: Until now, there is little data of cardiofucntion regarding to different type of vascular access. This study was to investigate survival of patients with arteriovenous fistula and tunneled cuffed catheter group. The baseline anthropometric and laboratory parameters were measured. The time and cause of mortality were documented.

Methods: A total of 219 patients who received maintained hemodialysis were included in this study. Patients were divided into two groups: arteriovenous fistula group and tunneled cuffed group. The baseline anthropometric and laboratory parameters were measured. The time and cause of mortality were documented.

Results: There were significant difference of left ventricular hypertrophy[\(x^2=6.645, P=0.001\)], left ventricular systolic dysfunction[\(x^2=4.007, P=0.045\)], between two groups. But there was no significant difference of left ventricular diastolic dysfunction between two groups. Kaplan-Meier survival curves showed that the mortality was enhanced among tunneled cuffed catheter group.

Conclusions: More research needs to be done to further investigate the influence of type of vascular access on cardiofucntion.
Patients with left ventricular hypertrophy, left ventricular systolic dysfunction, left ventricular diastolic dysfunction, arteriovenous fistula group have a high survival rate compared with tunneled catheter group. Furthermore, IPTH, calcium, systolic blood pressure and diastolic blood pressure were the independent risk factors of mortality for patients on maintained hemodialysis by COX regression model.

Conclusions: Differences of vascular access may have influence on mortality in patients on maintained hemodialysis. Those with tunneled catheters have lower survival rate when left ventricular dysfunction occurred.

FR-PO706
A Retrospective Study of Preferable Alternative Sites to Right Internal Jugular Vein for Tunneled Hemodialysis Catheters Insertion: Right External Jugular Vein versus Left Internal Jugular Vein
Yufei Wang, Pei Wang, Xuanhui Liang, Xiaoqing Lu, Zhanzhuo Liu, Yingjin Qiao, Sijie Zhou, Blood Purification Center, The First Affiliated Hospital of Zhengzhou Univ, Zhengzhou, Henan, China.

Background: It has been recommended by the KDOQI guidelines that right internal jugular vein (RIJV) is a preferred insertion site for hemodialysis (HD) catheters, and both right external jugular vein (REJV) and left internal jugular vein (LIJV) are alternative sites for those who have encountered severe thrombosis and/or occlusion of RIJV. The retrospective study aimed to determine if superiority exists in the two alternative sites by comparing the outcomes of cannulated (cuffed) dialysis catheters (TDCs) through REJVs versus LIJVs in HD patients who had RFI.

Methods: From January 1, 2013 to December 31, 2014, 28 LIJV-TDCs and 21 REJV-TDCs were inserted in our hospital. All patients were using paired Tesio catheters. Recirculation was calculated by 3-sample urea measurement, and analysed in multivariable Cox hazards analysis. Multivariable Cox hazards analysis was fitted to detect the independent risk factors of events. A P-value of <0.05 was considered statistically significant.

Results: A total of 52024 (LIJVs, 11782; REJVs, 9141) catheter-days were evaluated and the mean was 427.02 days. Most of the patients (53.1%) were older than 65 years with an average dialysis time of 25.3 months. The even free catheter survival time was (516.20±55.60) in REJVs-TDCs and (343.91±40.63) in LIJV-TDCs (P=0.038). Mean effective blood flow was higher in REJV-TDCs than that in LIJV-TDCs (270.95±24.93 vs 244.82±30.35, P=0.02). A substantial trend towards statistical significance was found between two groups in incidence of all events, including death, death related to catheter complication and catheter removal. The total historic catheters indwelling time was identified as an independent risk factor for severe TDCs events by Cox regression hazards test (P=0.01).

Conclusions: REJV might be superior to LIJV as an alternative insertion site for TDC placement in HD patients who had RFI.

FR-PO707
Haemodialysis Recirculation in Patients with Catheter Access
Damien Ashby, Imperial College Renal and Transplant Centre, Hammersmith Hospital, London, United Kingdom.

Background: Recirculation is a well described impairment of the haemodialysis circuit which reduces dialysis dose and electrolyte clearance. Catheter tips are designed to minimise recirculation based on in vitro experiments, with most designs having a tip separation of 25mm. High recirculation may be superior. Erythropoietin resistance is a possible consequence of this type of haemodialysis recirculation.

FR-PO708
Risk Factors for Fatal Dialysis Access Haemorrhage
Nicole M. Lionfa, Jonathan E.H. Ling, Gail Theresa Read, Matthew D. Jose, 1 2 Royal Hobart Hospital, Hobart, Tasmania, Australia; 3 School of Medicine, The Univ of Tasmania, Australia.

Background: Haemodialysis requires access to the circulation via an arteriovenous fistula or graft, or a synthetic vascular catheter. Annually there are deaths associated with catastrophic bleeding from dialysis vascular access.

Methods: A systematic search strategy including data from the National Coronary Information System (NCIS, containing coroner’s reports from all Australian states and New Zealand), the Australian and New Zealand Dialysis and Transplant registry (ANZDATA), published cases from Australia and New Zealand, individual renal units and State Renal Network reports. Data was analysed for all deaths where cause of death was reported as being due to dialysis access haemorrhage from 1st January 2000.

Results: A total of 83 patients (mean age 67 years (range 30 – 89), 55% female) receiving renal replacement therapy died due to dialysis vascular access haemorrhage. These were identified through NCIS 54, ANZDATA 64, State networks 3, Publications 2 and individual unit reports 2. Mortality was associated with complications including infection (22%), dialysis catheter problems (17%), recent access intervention (15%) or use of a thoracic arteriovenous fistula (11%). Bleeds commonly occurred at home in people treated with satellite haemodialysis. Modality at the time of death was home haemodialysis in 12 people. Use of Warfarin or cognitive impairment was identified in only 1 death each. Coronial inquests and Root Cause Analyses were identified in only 7 deaths with recommendations involving communication, staffing, clinical policy, practice changes and equipment modification.

Conclusions: Death due to dialysis access haemorrhage is an uncommon, catastrophic, but potentially preventable event. A number are preceded by vascular access infection, vascular access complications or recent intervention. Only a minority of deaths have been investigated, but where they have, critical recommendations for optimising future care are presented.

FR-PO709
Subcutaneous Implantable Electronic Devices in Chronic Kidney Disease and Hemodialysis Patients

Background: While epicardial leads have been reported to bypass central venous stenosis, their placement is much more invasive and requires the services of a cardiothoracic surgeon. Recent data have demonstrated successful defibrillation using a subcutaneous ICD (SICD). While the use of these devices is expanding, their insertion in advanced renal failure and hemodialysis patients is somewhat limited. In this analysis, we present 9/24 (37.5%) hemodialysis patients treated successfully with an SICD. Demographic characteristics revealed: male=8, diabetes=8, hypertension≥13, coronary artery disease=10, peripheral vascular disease=8. Two of the four hemodialysis patients had an AVF while two were dialyzing with a tunneled dialysis catheter. Mean GFR for the CKD patients was 40.3±30.6 ml/min. Patients received the SICD device for primary prevention of sudden cardiac death (cardiomyopathy with low ejection fraction). 3/13 patients had non-ischemic cardiomyopathy (CMP) with an ejection fraction of <25% while 10/13 suffered from ischemic CMP with an EF of <30%. There were no procedure-related complications in all patients receiving the SICD device. At an average follow-up of 6 months, one death has occurred that was unrelated to the procedure or arrhythmia. Subcutaneous ICD is a minimally invasive procedure when compared with an epicardial device. By leaving the venous system untouched, this approach offers the advantage of reduced risk of central venous stenosis and infection over an endocardial ICD with transcatheter leads. This approach is particularly helpful for CKD and hemodialysis patients who rely on venous capital for their survival. SICD has been FDA approved and is currently being utilized in the United States and Europe.

Methods: Restrospective evaluation of SICD in patients with CKD and ESRD.

Results: Thirteen patients with CKD and ESRD on dialysis received successful SICD.

Conclusions: SICD can be successfully used in patients on hemodialysis and CKD.

FR-PO710
Modified Non-Transposed Brachiobasilic Arteriovenous Fistula for Hemodialysis: A Randomized Controlled Study
Dayong Hu, Chunyu Zhou, Chandra Mohan, Changbin Li, Jie Tang, Ai Peng. 1 Shanghai Tenth People’s Hospital, Tongji Univ School of Medicine, Shanghai, China; 2 Univ of Houston, Houston, TX; 3 DHHA-Univ of Colorado School of Medicine, Aurora, CO.

Background: Transposed brachiobasilic arteriovenous fistula (BBAVF) is technically challenging. It not only associates with severe arm swelling and pain, but also takes longer to be ready for use. Here we introduce a novel modified non-transposed BBAVF (mNT-BBAVF), and compare its outcomes those of the standard brachiocephalic arteriovenous fistula (BCAVF).

Methods: From January 2010 to December 2012, 74 incident hemodialysis patients with suitable basilic and cephalic veins were randomized equally into mNT-BBAVF and BCAVF groups. Patients were followed for twelve months. Following the procedure, we followed up patients bi-weekly for 8 weeks, then monthly for 6 months, then quarterly for 6 months. Patients were evaluated for local and systemic complications, which included Operator’s choice, as well as shunt stenosis and occlusion.”

Results: A total of 54 haemodialysis patients (aged 28-90, 61% male) median recirculation was 3.7% with IQR 1.9-6.3%, range 0-19.7%, and a heavily left-skewed distribution (modal range 0-2%). Greater than 5% recirculation was seen in 30% of patients. Tip separation (range 3-32mm) was strongly associated with recirculation (R=0.33, p=0.014), which also appeared to have a weak association with body weight (R=0.21, p=0.05).

Defining thresholds to avoid high recirculation (>5%) with tip separation over 25mm high recirculation was seen in 6 patients. Increasing threshold tip separation to 30mm reduced the number of patients with high recirculation to 2. The same was achieved using a weight-based tip separation threshold of 0.5mm/kg. High recirculation was associated with high erythropoietin requirement (R=0.29, p=0.030) but not with low Kt/V (p=0.26).

Conclusions: Significant recirculation affects a significant minority of patients dialysing on tunneled catheters, and is closely related to tip separation. A tip separation threshold of 25mm may be inadequate to avoid high recirculation, and 30mm or perhaps a weight-based threshold may be superior. Erythropoietin resistance is a possible consequence of this type of haemodialysis recirculation.

Management of Catheter Related Bacteremias: New Insights into an Old Problem
Benjamin A. Oliveira,1 Conor James Byrne,2 Renal Medicine, Royal London Hospital, London, United Kingdom; Renal Medicine, Royal London Hospital, London, United Kingdom.

Background: Catheter related bacteremias (CRB) pose a significant risk for those dialyzing via such devices. Strategies are needed to minimise this risk as much as possible, especially in light of growing concerns over antibiotic resistance. Our unit routinely uses citrate to lock catheters. We sought to audit our CRB rate and long term complication rate. We believe this contemporary data will be useful to all involved in caring for patients with catheters.

Methods: We retrospectively reviewed all blood cultures taken from our institution’s dialysis patients for 1 year (October 2013 and September 2014). The records of patients with positive cultures were reviewed to ascertain if the infection was related to their access. Data was then collected on the type of organism grown, management of the episode, recurrence rate, and any long term complications.

Results: 1014 cultures were taken from approximately 930 haemodialysis patients. 45% of these were dialysing via a catheter. There were 52 instances of CRB giving a CRB rate of 0.34 per 1000 catheter days. 65% were due to gram-positive organisms, 29% were due to gram-negative organisms and 6% were fungal related. The overall recurrence rate was 26%. Catheter removal was performed in 32 instances (62%). Infective complications occurred in 5 (16%) patients with gram-positive infections and 6 (54%) of those with gram-negative infections; a statistically significant difference. The majority of these were endocarditis. CRB accounted for a total of 583 hospital in-patient days.

Conclusions: We observed significantly more infective complications with gram-negative organisms compared with gram-positive. This probably reflects the underlying characteristics of these patients rather than the pathogenicity of the organisms per se (19% of patients with gram-negative infections were intravenous drug users). Never the less our data suggests that gram negative infections are a risk factor for complications and clinicians should consider further investigations in these cases. Our CRB rate was low compared to quoted rates in the literature; this may reflect routine the use of citrate lock in our catheters.

Assessment of Arteriovenous Fistula Access Flow Using Video Image Processing Technology
Shantal Williams,1 Hannah Putnam,1 Viviane Calce-Silva,1 Israel David Campos Gonzalez,2 Peter Kotanko,2 Fanson Zhu.3

1Renal Research Inst, NY, NY; 2Icahn School of Medicine at Mount Sinai, NY, NY.

Background: Vascular stenotic lesions are the main cause of failure in arteriovenous fistulae (AVF). Routine measurement of access flow (AF) is important in the timely detection of changes and planning interventions. The aim of this pilot study was to investigate whether video image processing (VIP) techniques can be used to detect AVF motion and explore the relationship between motion patterns and AF.

Methods: Skin above the AVF was imaged for 1 minute using a digital single lens reflex camera prior to HD. The video was processed using Eulerian video magnification (Wu et al. ACM Trans. Graph. 31(4), 2012) to amplify AVF motions. Thereafter the motion-amplified video was converted to quantitative waveform data using an algorithm based on change in color of each image (Matlab Image Processing Toolbox). Monthly AF measurements were recorded and correlated with the post-processed AVF waveform pattern.

Results: We studied 12 hemodialysis patients (51.5±11.3 years, 50% male) with a mean±SD AF 150±392ml/min (N=9; AF was unavailable in 1 subject). Amplitude of skin displacement was 0.069±0.04mm (N=9; technical issues occurred in 2 subjects). While amplitudes of that size are hardly visible to the naked eye, they were clearly discernible in post-processed amplified videos. Amplitude was notably smaller in subjects with lower AF (Fig. 1). Amplitude analysis of the amplified video indicates a relationship with AF (R2=0.73, P<0.01; N=9).

Conclusions: This video imaging and analysis technique has potential to provide a quick, noninvasive, low cost way to obtain quantitative information related to AF. Research is underway to assess the impact of clinical interventions on the amplitude pattern.

Real-Time Kt/V Tracking Profile as a Predictor of Dialysis Access Recirculation
Abhijit Koratala, Girish Singhania, A. Absan Ejaz. Nephrology, Univ of Florida, Gainesville, FL.

Background: On-line monitoring of ultraviolet absorption of spent dialysate in routine hemodialysis allows continuous measure of removed solutes from spent dialysate. We studied whether real-time Kt/V tracking profile could be a predictor of dialysis access recirculation.

Methods: End-stage renal disease patients undergoing maintenance dialysis with Dialysis (B Braun AG) dialysis machine with a built-in UV-Spectrophotometer (Option Adimea, B Braun AG), high-flux polysulfone dialyzers, and at blood flow rate (Qb) 400-450ml/min and dialysate flow rate (Qd) 800ml/min were included in all recording sessions. Real-time Kt/V tracking profile and venous (Pv) and arterial pressures (Pa) were recorded and hemodialysis access recirculation values were biologically measured using standard protocol.

Results: Distinct real-time Kt/V profiles were identified in patients with significant access recirculation (>5%) vs. none (Control).

Conclusion: Real-time Kt/V tracking profile could be a predictor of dialysis access recirculation.
In the control profiles, real-time Kt/V (Fig 1a, solid line) closely followed the target line (Fig 1a, dashed line) and was associated with normal Pi and P0. In patients with high access recirculation, real-time Kt/V tracking line deviated widely from the target line (Fig Recirc Kt/V Profile; Fig 1b, c, d) and remained deviant throughout the treatment session. Fig 1d demonstrates a case wherein the initial low Q0 associated with abnormal recirculation values, but not all were associated with elevated P0 confirmed by biochemical methods. Interestingly, all High Recirc Kt/V Profile events were associated with abnormal recirculation values, but not all were associated with elevated Pi.

**Conclusion:** Real-time Kt/V tracking profile provides a non-invasive, inexpensive and quick assessment of access recirculation in hemodialysis patients.

**FR-PO715**

Recurrent Vascular Access Stenosis as a Novel Marker for Cardiovascular Outcome in Hemodialysis Patients

**Hyo Jin Kim, Hajeong Lee, Dong Ki Kim, Kook-Hwan Oh, Yon Si Kim, Curie Ahn, Kwon Wook Joo. Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea.**

**Background:** Vascular access (VA) is an essential component and its stenosis is a major complication in hemodialysis (HD) patients. Nevertheless, there are few data for outcomes and survival of patients who had recurrent VA stenosis. We have explored the influence of recurrent stenosis (VA) on cardiovascular (CV) event, patient death, and VA failure.

**Methods:** This is a single-center, retrospective study. Patients who had VA operation at Seoul National University Hospital between January 2009 and March 2014 were enrolled. Patients who had two or more instances of percutaneous angioplasty or revision operation within 180 days were categorized recurrent group. The primary outcome was CV event, including death as coronary artery heart failure or cerebrovascular, and peripheral vascular events. The secondary outcomes were all-cause mortality (ACM), composite of ACM or CV events, and VA failure. The two groups were compared before and after matching with propensity scores (PSM).

**Results:** A total of 766 patients (59.7% male, age 59.6 ± 14.3 years) were analyzed. Recurrent group patients (n = 77; 10.1%) were older and had higher underlying CV disease and dyslipidemia. A total 213 patients (1.4% in non-recurrent, 71 in recurrent group) were selected by PSM. During 28.7 ± 15.8 months follow-up, 46 patients (21.6%) had CV outcomes, 30 patients (14.1%) died, and 14 patients (6.6%) experienced vascular access failure. After adjustment, recurrent group was an independent risk factor for CV event (adjusted hazard ratio [HR] 2.66; 95% confidence interval [CI] 1.46–4.86, P = 0.001) and composite of ACM or CV events (adjusted HR 1.99; 95% CI 1.21–3.27, P = 0.007). However, it was not associated with increased ACM and VA failure.

**Conclusion:** Recurrent VA stenosis was a novel independent risk factor for CV event in HD patients, rather than VA failure. For patients suffered from recurrent vascular stenosis, diligent monitoring should be warranted not only for VA patency but also for CV events.

**FR-PO716**

Stent Insertion Is an Important Tool in Maintaining Arteriovenous Access Patency

**Stephen G. John,1 Kumar Abayasekara,2 Peter M. Bungay,3 Mario De Nunzio,3 James E. Kirk,3 John Graham Pollock,3 Peter D. Thurtle,3 Paul J. Owen,3 Richard J. Fluck,3 Lindsay J. Chesterton.1 1Nephrology, Royal Derby Hospital; 2Vascular Surgery, Royal Derby Hospital; 3Radiology, Royal Derby Hospital, Derby, United Kingdom.**

**Background:** Definitive access for haemodialysis (HD) remains the cornerstone of optimal dialysis. However, HD patients are becoming older, access attempts more problematic and vein preservation remains critical. Clinical examination and access monitoring enable appropriate, timely, endovascular intervention. Stents may be inserted for recurrent stenosis or after endovascular rupture, but their role remains debatable. We report on our single-centre experience of access surveillance and endovascular intervention, highlighting the role of stent insertion.

**Methods:** Electronic hospital records were retrospectively analysed in all access-related stents inserted from 2006–2014 by 5 vascular radiologists.

**Results:** 49 stents were inserted during 45 procedures in 39 patients. 12 had diabetes. Mean age was 64.5 ± 25.6 years, median dialysis vintage was 1162 ± 1504 days (range 5–5027). Median time from access creation (82% arteriovenous fistula) to stent insertion was 318 ± 926 days (range 31–3752). 34 stents were inserted peripherally (cerebral arch and distally), the majority in the cephalic arch. Equal numbers of covered and bare-metal stents were inserted. 4 stents were placed in thrombosed access. 7 procedures were due to surveillance alone, a further 8 due to surveillance and pressure/flow problems. 12 stents were inserted for rupture or dissection (overall access procedure complication rate 1%). Median time from first stent to access failure/ceased HD was 333 ± 653 days, assisted by median 2 (range 0–11) further procedures. Treatment for rupture was not associated with significantly shorter access longevity. Only 10 patients’ access failed during follow-up. Our overall HD definitive access prevalence rate was 86–90%.

**Conclusion:** Appropriate HD access is essential in minimising HD morbidity. We recommend stent insertion for newly-recurring stenosis or rupture during endovascular procedures. Our data suggest that appropriate, judicious stent insertion in an appropriately structured pathway results in access durability and longevity.

**FR-PO717**

Association of Vascular Access Flow and Volume Status on Fistula Arm by Bio-impedance Analysis in Hemodialysis Patients

**Hun Jeong,2 Hyung Jong Kim,1 Eun Jung Ko,1 Younhee Lee.1 1Internal Medicine, CHA Bundang Medical Center, CHA Univ, Seongnam, Korea; 2Internal Medicine, Seoul Bukhbu Hospital, Seoul, Korea.**

**Background:** Multi-frequency bioimpedance is a tool of body composition measure and can monitor changes in extracellular volume during dialysis. Arterio-venous fistulae (AVF) could potentially affect fluid retention in the arm. We investigated whether multi-frequency bioimpedance could detect AVF stenosis or association of AVF with fluid retention in the AVF arm.

**Methods:** We measured the extracellular water (ECW) and total body water (TBW) in AVF arm following hemodialysis by multi-frequency bioimpedance (Body S10®) using an eight-electrode contact technique. We measured AVF flow by transonic ultrasonography using an ultrasound dilution technology (HD 03®) in hemodialysis.

**Results:** Total 28 patients (male 13 patients) were enrolled and the mean age of patients was 54.89 ± 13.21 years. ECW/TBW ratio of fistula arm was a significantly higher than ECW/TBW ratio of non-fistula arm (0.389 ± 0.01 vs 0.382 ± 0.001, p<0.05). ECW/TBW ratio of fistula arm was a significantly negative correlation with access flow level (mL/min) on fistula (p<0.05). The 5 kHz reactance of fistula arm was a significantly positive correlation with access flow level (mL/min) on fistula (p<0.05).

**Conclusion:** Absolute and also relative extracellular fluid volumes are increased in the fistula arm of hemodialysis. We thought that extracellular fluid volumes in the fistula arm were associated with access flow level (mL/min) and/or relative fistula stenosis. We suggest that multi-frequency bioimpedance can be a useful assistant tool of vascular access flow measure.

**FR-PO718**

**Background:** KDIGO Guidelines recommend post-angioplasty (PTA) lesion should have <30% residual stenosis (RS) and hemodynamic parameters should improve. Access blood flow (ABF) is one of the most used. Primary end point: how post-PTA ABF improvement could predict vascular access (VA) outcome. Secondary: compare doppler ultrasound (DU) and angiography diagnostic accuracy; determine how other factors could predict outcome.

**Methods:** Prospective study in 80 patients with dysfunctional VA. DU evaluation was performed pre and post-PTA. Several parameters were recorded. Secondary patency verified during first 6 months.

**Results:** Initial DU in 80 patients; 26 excluded due to abnormalities absence or impossible endovascular approach - final 54. Two thirds male; age 68±15 youths; median DU time 36±29 months; initial ABF 537±248 ml/min; final ABF 1013±354 ml/min. Number and location of stenosis was highly correlated between DU and angiography (Pearson 0.828, p<0.001). DU/angiography correlation was 0.81 (p<0.001) and composite of ACM or CV events (adjusted HR 1.99; 95% CI 1.21–3.27, P = 0.007).

**Conclusion:** DU diagnostic accuracy is highly correlated with angiography. Although less accurate for central lesions, has a key role due to morphologic and hemodynamic assessment. PTA is a powerful therapy with immediate benefit; however final angiographic RS is not predictive of outcome. Grafts have worst patency, demanding more interventions. PTA is associated with mechanical endolethal injury. Higher ABF induce more turbulent flow that is likely to cause more intimal hyperplasia, which could explain the shorter patency, especially in grafts where inflammation is higher.
FR-PO719

Background: Complications of long-term use of tunneled catheters for hemodialysis involve a high risk of infection, thrombosis, hospitalization and expense. This study reviews a single center experience to identify factors that may contribute to the high rate of patients initiated with tunneled HD catheters.

Methods: We conducted a 13-question survey of 47 CKD patients who had been newly initiated on dialysis through a tunneled central vein dialysis catheter during their hospital admission in a university hospital from December 2013-May 2015. Results: Of 47 subjects, 27 were male and 20 female. Subjects’ mean age was 60 years old. Demographics included 26/47 (55%) African Americans, 7/47 (15%) Hispanics, 12/47 (26%) Caucasians and 2/47 (4%) Asian. Ninety-six % of patients (45/47) had been seen by a physician within the past year, and had been told their kidney function was poor. Eighty-three % of patients (39/47) were referred to a nephrologist. Thirty-six patients saw a nephrologist and, of those patients, only 13 patients were referred to a surgeon for access. Of the patients who saw a nephrologist, twenty two % (6/36) did not follow through with access placement secondary to noncompliance. Thus, of 47 patients starting hemodialysis with a catheter, only 7 had actually seen a surgeon for access placement. The largest drop off in the continuum of care of the patient is between seeing the nephrologist and seeing the surgeon. Since half of the patients surveyed received care elsewhere, it indicates this finding is not unique to our institution.

Conclusions: There are numerous points in the pathway to arteriovenous access where attrition occurs. Nephrologists and primary care physicians must oversee proper follow up and follow through to assure successful access placement. In our study, we found that there is a big attrition point from nephrology to surgery referral. A coordinator to help follow up patients or a joint clinic are options to improve this problematic step.

FR-PO720

The Association of Overhydration Status with Megafistulas in End-Stage Renal Disease Patients on Hemodialysis Mihaly J. Tarphaly, Maria Faludi, Melinda Forro, András Tisler, Tibor Fulop, Klara Berta. * Dialysis, Fertőné Györgyi Medical Care Semmelweis Univ, Budapest, Hungary; † Nephrology, Semmelweis Univ, Budapest, Hungary; ‡ Nephrology, Univ of Mississippi, Jackson, MS.

Background: Megafistulas are tortuous dilated fistulas that fold on themselves and become visible on the arm and shoulders all the way to the clavicles. They may exacerbate low cardiac output, as well as represent a problematic dilatation of the dialysis access.

Methods: In a cross sectional study we compared the pre-dialysis BCM-measured OH% in 12 prevalent chronic dialysis patients with megafistulas (MEGA) who had negative angiographies with that of 52 control dialysis patients (CONTR).

Results: 10/12 MEGA patients had OH% >16% as compared to 20/52 CONTR patients (Chi square p = 0.02).

Megafistula and Overhydration

The degree of OH% was 20.2 ± 4.4% among the MEGA vs. 14.4 ± 7.1% in the CONTR group (Student p = 0.01), representing 4.2 ± 3.2 vs 2.8 ± 1.6 L of excess fluid (p = 0.03). MEGA patients took an average of 1.7 ± 1.4 vs. 0.8 ± 0.8 (p = 0.002) antihypertensive medications compared to the CONTR patients yet their blood pressure was 156/91 vs 141/78 mmHg (p = 0.03/0.0001). We found no difference in fistula vintage, body mass index, age, inflammatory markers, diabetes status or diuretic use. The odds ratio of overhydration being associated with a megafistula is 5.3 (p = 0.01).

Conclusions: There is an association of BCM-measured overhydrated clinical state with the presence of megafistulas; either as an increased volume capacitance or as a potential cause.

FR-PO721

The Observation of the Tunneled Cuffed Catheter Insertion Through Right Innominate Vein in Hemodialysis Patient Yanhuan Feng, Tianlei Cui, Ping Fu. Div of Nephrology, West China Hospital of Sichuan Univ, Chengdu, Sichuan, China.

Background: The routine vascular access for hemodialysis is often available due to thrombosis and occlusion after frequent cannulation, which leads to an increase in cost and difficulty of catheterization or recanalization. Further catheterization may accelerate the exhaustion of vascular resources. We inserted cuff catheter through right innominate vein in patients with thrombosis or occlusion of right internal jugular vein and subclavian vein so as to preserve precious vascular access at other parts of body. Here we report our observation of right innominate vein catheterization.

Methods: We enrolled patients who had been receiving regular HD in our center and to whom catheter cannot be inserted due to thrombosis or occlusion of internal jugular vein and subclavian vein. We performed cuff catheter insertion by puncturing right innominate vein in 8 patients and recorded their clinical features, lesion position, and efficacy of the treatment.

Results: Among the 8 cases, where mean age is 67 years (range from 54-78), 3 of them are male and 5 are female. All the patients received central venous catheterization for more than 2 times, with median time of having a catheter for 36 months. The vascular ultrasound and CTA reveals that all of them suffered thrombosis or occlusion of right internal jugular vein and subclavian vein. By puncturing right innominate vein, all the patients’ vascular accesses have been successfully established, with the end of cuff catheter located in the right atrium, superior vena cava(SVC) or SVC/ right atrial junction. No obvious discomfort has been reported, nor did complications such as hematoma and pneumothorax recorded. The mean follow-up period lasts for 12 months, all vascular access of these cases are patency.

Conclusions: For HD patients with limited vascular resources such as thrombosis or occlusion of right internal jugular vein and subclavian vein, the application of tunneled cuffed venous catheter through innominate vein has been proved to be safe and effective. It could preserve vascular access by bypassing the stenotic lesion internal jugular vein or subclavian vein, and reduce the incidence of vascular access exhaustion.

FR-PO722

Tunneled Hemodialysis Catheter and Hemodialysis Outcomes Vedran Pasara, Mladen Knotek. Dept of Medicine, Renal Div, Univ of Zagreb, Merkur Hospital, Zagreb, Croatia.

Background: Studies have reported that tunneled dialysis catheter (TDC) is associated with inferior hemodialysis (HD) patient (pt) survival, as compared to arteriovenous fistula (AVF). Since many cofactors may also affect survival of HD pts, it is unclear whether the risk for the worse survival arises from TDC per se, or from associated conditions.

Methods: This retrospective case-control study included all 156 pts with TDC placed from 2010 to 2012 at Clinical Hospital Merkur. Control group consisted of 97 pts dialyzed through AVF. The groups were matched according to dialysis unit and time of VA placement. The site of choice for the placement of TDC was right jugular vein. Kaplan-Meier analysis with log-rank test was used to assess pt survival. A multivariate Cox regression analysis was used to determine independent variables associated with the pt survival.

Results: Cumulative one-year survival of pts who were dialyzed exclusively through TDC was 86.4 % and of those who were dialyzed exclusively through AVF the survival was 97.1 % (p=0.002). In a multivariate Cox regression analysis, male sex and older age were independently negatively associated with the survival of HD pts, while shorter duration of HD before the creation of the observed VA, hypertensive renal disease and glomerulonephritis were positively associated with survival. TDCturned to be an independent negative risk factor for survival of HD pts (HR 23.037, 95% CI 6.221-85.308).

Carpal Tunnel Syndrome Is Associated with Arteriovenous Fistula in Hemodialysis Patients

Il Young Kim,1 Min Jung Kim,1 Joo Hui Kim,1 Dong Won Lee,2 Boog tong Lee, 1 Su Min Park,2 Jong Man Park,2 Woo Jin Jung,2 Sang Heon Song,2 Eun Young Seong,2 Harim Rhee,2 Hyun Sook Kwak.2

Background: Carpal tunnel syndrome (CTS) is associated with various systemic diseases such as rheumatoid arthritis, hypothyroidism, peripheral neuropathy and diabetes mellitus (DM). In hemodialysis patients, several factors can contribute to CTS, including amyloid deposition, generalized fluid retention, increased synovial volume, edema around the nerve, and an ischemic or "steal" effect distal to a dialysis access. This study aimed to evaluate the influence of arteriovenous fistula (AVF) dysfunction on the development of CTS.

Methods: The study included 43 patients (23 male & 20 female) on maintenance hemodialysis via AVF and 97 healthy controls. The median nerves of study population were examined by ultrasonography. Cross-sectional area (CSA) of the median nerve was measured at the distal wrist (CSA-D), and proximal forearm (CSA-P), and wrist-to-forearm ratio (WFR; CSA-D/CSA-P) was calculated for each hand. We also investigated the history of percutaneous transluminal angioplasty (PTA) in them.

Results: The mean age of hemodialysis patients was 60.4 ± 16.0 years. The mean duration on hemodialysis was 48.3 ± 39.6 months. The WFRs in hemodialysis patients were higher than those in healthy controls (1.37 ± 0.45 vs. 1.21 ± 0.25, P < 0.05). The hands with AVF (n = 43) showed higher WFR than those without AVF (n = 43) in hemodialysis patients (1.35 ± 0.47 vs. 1.25 ± 0.26, P < 0.05). The WFRs in patients with a history of PTA were higher than in patients without a history of PTA(1.46 ± 0.56 vs. 1.23 ± 0.32, P < 0.05).

Conclusions: In maintenance hemodialysis, WFR of median nerve was significantly increased in the hand with AVF. Moreover, development of CTS was related not only to AVF itself, but also to AVF function.

FR-PO724

Factors Affecting Patency of Haemodialysis Arterio-Venous Fistulae and Grafts

Ayesha IftikharAli, Salman Ahmed, Nicola Ding, Joseph Russell, Nihil Chitalia, Maggi Steele, Hannah R. Wilson, David Makanjuola. Renal Unit, St. Helier Hospital, Carshalton, United Kingdom.

Background: Arteriovenous fistulae (AVF) are the preferred access for haemodialysis (HD), and where these cannot be created, arterio-venous grafts (AVG) are the next best option. AVFs/AVGs however, not uncommonly fail to mature. The causes of this are varied, but loss of patency due to thrombosis and/or significant stenoses are major causes. We investigated the factors affecting patency of AVFs/AVGs in order to identify whether there were any characteristics which were predictive of this.

Methods: All AVFs/AVGs created in our unit between 2006 and 2014 were reviewed. Reasons for loss of primary patency were obtained from the dialysis access database. Characteristics reviewed were age, gender, co-morbidity score, diabetes status and site of AVF. Patients were grouped as follows: patency >30 days, patency <30 days, patency >90 days and patency >365 days.

Results: There were 1897 AVFs and 251 AVGs created. 649 (34.2%) of AVFs were lower arm, all the AVGs were upper arm, or lower limb. 1346 (62%) were male. The main reasons for AVF loss were clotted/stenosed vessels in 76% of cases. There was no association between ethnicity or gender with regard to patency rates. Other variables are shown in table 1.

</tr>
<tr>
<td></td>
<td>3 or more co-morbidities</td>
<td>11%</td>
<td>13.1%</td>
<td>13.8%</td>
</tr>
</tbody>
</table>

Conclusions: We did not find any definite predictive factors for loss of primary patency in the variables we studied. In particular, co-morbidity score, age and diabetes showed no association with poorer outcomes. There is quite a significant ‘drop off’ in primary patency at 12 months. In the majority of cases, this was due to thrombosis of the HD access. This highlights the importance of close surveillance, as measures to maintain patency (surgical or radiological) are more likely to be required in this period.

FR-PO725

Drug-Eluting Stents versus Bare-Metal Stents During Percutaneous Coronary Intervention in Patients on Dialysis

Tara I. Chang1, Maria E. Montez-Rath,2 Mark A. Hlatky,1 Wolfgang C. Winkelmann.1 Stanford; 1Baylor College of Medicine.

Background: In patients undergoing percutaneous coronary intervention (PCI), drug-eluting stents (DES) reduce the need for repeat revascularization (RR) compared with bare-metal stents (BMS). The effects on death and MI are more controversial, with mixed results from observational studies and generally null results from clinical trials. However, few previous studies have focused patients with end-stage renal disease (ESRD). We compared the effectiveness of DES with BMS in a representative cohort of US patients on dialysis.

Methods: Using the US Renal Data System, we identified 36,117 patients on dialysis with Medicare Parts A+B who had PCI with stenting after DES became available in the US (4/23/03 – 12/31/10). We used propensity-score matching (PSM) and inverse probability of treatment weighting (IPTW) with Cox regression to examine the association of DES versus BMS on the following 1-year outcomes: death, death or MI, and death or MI or RR. Due to concerns about residual indication bias, we conducted a second, temporal analysis that leveraged the large changes in the prevalence of DES use during three distinct eras: Transitional (4/23/03 – 6/30/04); Liberal (7/1/04 – 12/31/06); and Selective (1/1/07 – 12/31/10).

Results: In the PSM and IPTW analyses, DES was associated with lower risks of all three outcomes compared with BMS.

Eleven Year Trends in Myocardial Infarction and Stroke in the Incident and Prevalent Dialysis Population

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.
Methods: A retrospective review of a cohort of 354 hemodialysis (HD, 254) and peritoneal dialysis (PD, 109) patients was followed up to 4 years after baseline hs-cTNT. All-cause mortality, cardiac mortality and new MI were assessed.

Results: The median hs-cTNT was 60 ng/L (interquartile range IQR 38-105 ng/L) with no observed difference between HD and PD patients (P=0.18). Patients dying (n=148) had a higher baseline hs-cTNT (median 90 vs 50 ng/L, P<0.001). Similar trends were observed for both HD and PD subgroups. Patients with cardiac mortality (n=25) had a higher baseline hs-cTNT compared to non-cardiac mortality (121 vs 75.5 ng/L, P=0.013). These trends were only observed in the HD subgroup. Patients with a new MI (n=65) had no difference in their baseline hs-cTNT (66 vs 59 ng/L, P=0.064) compared to controls. The group was divided into quartiles based on hs-cTNT. Incremental increase in mortality (P<0.001), cardiac mortality (P<0.001) and MI (P=0.033) were observed with increasing hs-cTNT quartiles. Similar trends were observed for both HD and PD subgroups except MI in the PD subgroup. For every increase of 25 ng/L in hs-cTNT, the unadjusted hazard ratio (HR) was 1.094 for cardiac mortality (P=0.043, 95%CI 1.003-1.192), 1.123 for MI (P=0.000, 95%CI 1.053-1.198). The adjusted HR for MI was 1.107 (P=0.018, 95%CI 1.018-2.05). Kaplan-Meier curves demonstrated increasing hs-cTNT quartiles was associated with an increase in the incidence of cardiac mortality (P=0.014) and MI (P=0.013) but not overall mortality. 178 patients had hs-cTNT repeated at 4 years. There was a significant increase in hs-cTNT from a baseline of 60ng/L (IQR, 38-105 ng/L) to a 4-year concentration of 64 ng/L (IQR, 42-104 ng/L) (P=0.000). This was true for both patients with (P=0.008) or without (P<0.001) new MI. Similar trends were observed for both HD and PD subgroup analysis.

Conclusions: hs-cTNT has a useful role in predicting all-cause mortality, cardiac mortality and MI in stable dialysis population. There was an increase in hs-cTNT level over a 4-year period.

FR-P0731
Temporal Trends in Myocardial Infarction Incidence and 30-Day Mortality in U.S. Dialysis Patients

Methods: Using Medicare claims data, we created yearly cohorts of dialysis pts point prevalent on January 1 of each year 2005-2011. We assessed STEMI, NSTEMI, and other MI hospitalization rates, and calculated annualized 30-day death rates following MI.

Results: In 2005 there were 10,275 NSTEMI, 1,892 STEMI, and 1,918 other MI vs 75,823 NSTEMI, 12,857 STEMI, and 20,744 other MI in 2011. NSTEMI, STEMI, and other MI hospitalization rates remained relatively equal across BMI categories. Furthermore, access to coronary interventions following a major coronary event is not equal across BMI categories. Although elevated body mass index (BMI) is associated with increased risk of cardiovascular events in the general population, it is suggested that the converse may hold true for patients on dialysis.

Methods: We tested this hypothesis in a national cohort of 1,072,737 incident Medicare-eligible US patients, who began dialysis between 5/1995 and 12/2008. Hospitalizations attributed to first myocardial infarction (MI) (ICD 9 codes: 410) and major coronary interventions (coronary angioplasty, stent, and coronary bypass surgery) following first MI were obtained from the US Renal Data System. Multivariable Cox regression compared hazard ratios [HR] of MI and subsequent coronary interventions among BMI categories.

Results: The adjusted HR of MI was highest for underweight patients and lowest for morbidly obese patients, decreasing significantly with increasing BMI category. Overweight patients were significantly more likely to receive a coronary intervention post-MI compared to normal weight individuals but this benefit did not extend to morbidly obese or underweight patients.

Conclusions: In contrast to the general population, higher BMI is associated with lower risk of major coronary events in US dialysis patients suggesting a protective effect. Furthermore, access to coronary interventions following a major coronary event is not equal across BMI categories.

FR-P0732
Risk of Acute Coronary Events and Coronary Interventions for Overweight and Obese Patients versus Normal Weight Patients Undergoing Dialysis – A National Study

Methods: We tested this hypothesis in a national cohort of 1,072,737 incident Medicare-eligible US patients, who began dialysis between 5/1995 and 12/2008. Hospitalizations attributed to first myocardial infarction (MI) (ICD 9 codes: 410) and major coronary interventions (coronary angioplasty, stent, and coronary bypass surgery) following first MI were obtained from the US Renal Data System. Multivariable Cox regression compared hazard ratios [HR] of MI and subsequent coronary interventions among BMI categories.

Results: The adjusted HR of MI was highest for underweight patients and lowest for morbidly obese patients, decreasing significantly with increasing BMI category. Overweight patients were significantly more likely to receive a coronary intervention post-MI compared to normal weight individuals but this benefit did not extend to morbidly obese or underweight patients.

Conclusions: In contrast to the general population, higher BMI is associated with lower risk of major coronary events in US dialysis patients suggesting a protective effect. Furthermore, access to coronary interventions following a major coronary event is not equal across BMI categories.

FR-P0733
Propensity-Based Comparison of Haemodialysis and Peritoneal Dialysis with Risk of Haemorrhagic and Ischaemic Stroke Among New Dialysis Patients

Methods: We tested this hypothesis in a national cohort of 1,097,747 US patients (n=86,168 on PD) who were Medicare eligible and began dialysis between 5/1995 to12/2010 and followed until 9/2011. Hospitalizations attributed to first Haemorrhagic Stroke (H-CVA) and Ischaemic stroke (I-CVA) were obtained from the US Renal Data System files and merged with data from the medical evidence, treatment history and mortality files. Multivariable Cox regression compared the hazards ratio [HR] of H-CVA and I-CVA for PD versus HD with a propensity-matched intent-to-treat (ITT) approach and as-treated analysis. Patients were censored at transplantation, death, recovery of kidney function, or end of study (Sept 2011). Approval was received from University Hospitals Ethics Committee.

Results: The adjusted PD/HD HRs for first hospitalized H-CVA using the intent-to-treat model was 0.89 (0.83,0.95) and this decreased from 0.73 (0.61-0.87) in the period 1995-1998 to 0.64 (0.51-0.80) in the period 2007-2010. In contrast, overall HRs for I-CVA were 1.15 (1.12-1.18) and this decreased from 1.20 (1.13-1.27) in the period 1995-1998 to 1.06 (0.97-1.15) in the period 2007-2010. The as-treated model suggested more favourable outcomes for H-CVA with overall HR of 0.61 (0.57,0.67) and for I-CVA with a HR 0.96 (0.86-1.08) in the period 2007-2010 period. Patients who switched from PD to HD or PD to HD had significantly higher HR of H-CVA, while patients who switched from PD to HD had higher HR of I-CVA.

Conclusions: PD and HD contribute differentially to the overall risk of I-CVA and H-CVA among new dialysis patients. While PD is similar to HD with regard to hazards of I-CVA, it appears to protect against the hazard of H-CVA. These associations should be taken into consideration when choosing treatment options for new dialysis patients.

Predictors of Sudden Cardiac Death in Hemodialysis Patients with and without Previous Arrhythmia – Results from a Multinational Cohort

### Background:
Cardiac dysfunction, rapid electrolyte shifts and high ultrafiltration rates during hemodialysis (HD) are associated with increased vulnerability to arrhythmogenic events. Patients with previous arrhythmia (ARR) are at a higher risk of sudden cardiac death (SCD – Herzog et al, 2011). Our aim was to analyze predictors of SCD in HD patients with and without previous arrhythmia.

### Methods:
- Incident HD patients from the Monitoring Dialysis Outcomes (MONDO) cohort who received in-center treatment between 1/2006-12/2011 and survived at least 90 days on HD were included and followed until 12/2012. Causes of death were classified as SCD according ICD-10-ICD-9. Patients with comorbidity or prior hospitalization due to ARR and/or ARR predisposition were identified. Cox proportional hazards models were constructed to explore associations between baseline parameters and SCD.

### Results:
We studied 19,129 patients (16 countries). 7,538 patients with complete data were included in the models, 613 died of SCD. Mean age 62.7±15.5 years, 58.1% male, 48.4% diabetics. Age, ischemic heart disease, albumin, serum sodium, interdialytic weight gain in % of post-HD weight and pre-HD-systolic blood pressure were identified as predictors of death in both subgroups. Distinct predictors are shown below.

### Table 1: Predictors of SCD in patients with (N=158) and without ARR history and/or predisposition (N=455).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>SCD with ARR</th>
<th>Hazard Ratio (SE)</th>
<th>P-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Serum bicarbonate [mmol/L]</td>
<td>0.70 (0.04)</td>
<td>0.04</td>
<td></td>
</tr>
<tr>
<td>Leukocytes [10^9/mm^3]</td>
<td>0.02 (0.005)</td>
<td>&lt;0.0001</td>
<td></td>
</tr>
<tr>
<td>Hemoglobin [g/dL]</td>
<td>0.11 (0.04)</td>
<td>0.005</td>
<td></td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>Catechol as vascular access</td>
<td>0.41 (0.1)</td>
<td>&lt;0.0001</td>
<td></td>
</tr>
</tbody>
</table>

### Conclusions:
- Despite the small sample size, some predictors of SCD seem to differ depending on the presence or absence of arrhythmia history or predisposition. These findings may assist the identification of patients at high risk for SCD. Further studies have to be done to corroborate these results.

---

The CRASH-ILR Study: Half a Million Hours of Continuous ECG Monitoring in a Hemodialysis Population

### Background:
Sudden cardiac death (SCD) may cause 25% of all hemodialysis (HD) patient deaths. Multiple potential mechanisms may contribute to the risk of life-threatening arrhythmias in this population. The CardioRenal Arrhythmia Study in Hemodialysis has continuously monitored patients using an Implantable Loop Recorder (ILR) for more than 500,000 hours.

### Methods:
- 30 patients (60% male) aged 67±12 years on established HD for 39±44 months with varied etiology of CKD (diabetes 37%, hypertension 23%) and ejection fraction of 56±8% were implanted with a Reveal XT ILR (Medtronic, MN, USA). Patients transmitted data at each HD session and were asked to activate their ILR if symptomatic with palpitations, dizziness or syncope.

### Results:
Patients were monitored for an average of 17,810±8,108 hours performing 94±92 transmissions. 6 patients (20%) died during the study. The final arrhythmia was VF in 2 patients and agonal bradycardia in 3. One patient died from SCD 2 weeks after device explantation due to infection. All 3 bradyarrhythmic deaths occurred in patients during end-of-care. 1 VF death occurred during a GI bleed: the other was unheralded. A surviving patient received a biventricular pacemaker for 2:1 block detected by ILR. Arrhythmias (AA) were noted in 7 (25%), 4(13%) of which were incident. 1 patient had asymptomatic sustained VT managed with antiarrhythmic drugs. Frequent ectopy was recorded in 2 patients. There were 19 symptomatic activations in 6 patients corresponding to sinus rhythm (or AA in cases of permanent AF). 6 patients had device explantation, 4 after renal transplantation and 2 due to device infection.

### Conclusions:
- CRASH-ILR is the longest ILR follow up in HD patients to date and provides new insights into arrhythmia and SCD. Arrhythmias occurred in 15% (50%) of the study population. Mortality was high, but this was due to SCD as an expected end-of-life event in 5 of 6 patients.

The Risks of Acute Health Events After Incident Atrial Fibrillation in Older Hemodialysis Patients

### Background:
Limited data exist about whether incident atrial fibrillation/flutter (AF) impacts the risks of major acute health events in patients with ESRD undergoing hemodialysis (HD).

### Methods:
- From the US Renal Data System, we studied older (≥67 years) adults with ≥2 years of uninterrupted Medicare A&B coverage before starting HD (2006-11) and no documented AF prior to ESRD. Incident AF was ascertained from ICD-9 diagnosis codes (427.3x).
- Known AF prior to ESRD. Incident AF was ascertained from ICD-9 diagnosis codes (427.3x).
- To incorporate inpatient care, we used the ICD-9 diagnosis codes (427.3x).
- Inpatient care was included in the models, 613 died of SCD. Mean age 62.7±15.5 years, 58.1% male, 48.4% diabetics. Age, ischemic heart disease, albumin, serum sodium, interdialytic weight gain in % of post-HD weight and pre-HD-systolic blood pressure were identified as predictors of death in both subgroups. Distinct predictors are shown below.

### Table 1: Predictors of SCD in patients with (N=158) and without ARR history and/or predisposition (N=455).

### Results:
Individuals receiving TT ≥ 240 were younger, more likely to be black and male, and had larger BMI. In both strata of TT (< 240 and ≥ 240) those patients with UFR > 13 tended to be younger, non-black race, have a lower BMI, longer HD vintage, higher Kt/V, and higher IDWG than patients with UFR < 13. Congestive heart failure was more prevalent in patients with UFR ≥ 13 regardless of TT. In both strata of TT, patients with a UFR >13 had higher hazard of mortality, with a larger risk found in those with TT ≥ 240.

### Conclusions:
- A higher UFR (>13) was associated with higher mortality irrespective of TT category. The association was surprisingly strong among those receiving longer TT. In the US, longer TT is prescribed in order to achieve small solute targets (conflating-by-indication) and not necessarily to lower the UFR, as high UFR is a consequence of high IDWG and the average shorter TT.

Sudden Death and Dialysate Potassium in Hemodialysis: Results from the Dialysis Outcomes and Practices Patterns Study (DOPPS)
Angelokaravas,1 Jarcy Zee,1 Steven M. Brunelli,2 Len A. Usvyat,3 Daniel E. Weiner,4 Franklin W. Maddux,5 Allen R. Nissenson,6 David C. Mendelssohn,6 Michel Y. Jadoul,7 Friedrich K. Pot,1 Bruce M. Robinson,8 Francesca Tentori,1 Arbor Research Collaborative for Health, Ann Arbor, MI; 1DaVita Clinical Research, Minneapolis, MN; 2FMCNA, Waltham, MA; 3Tufts Medical Center, Boston, MA; 4DaVita Healthcare Partners, Inc., El Segundo, CA; 5Humber River Regional Hospital, Toronto, Canada; 6Univ Catholique de Louvain, Belgium; 7U of Michigan, Ann Arbor, MI; 8Vanderbilt U, Nashville, TN.

Background: Sudden death (SD) is common in hemodialysis (HD) patients. We investigated trends in dialysate (DK) and pre-dialysis serum (SK) potassium across the Dialysis Outcomes and Practices Patterns Study (DOPPS) phases 1-5 (1996-2015) and evaluated whether the risk of SD is higher with lower DK.

Methods: 67,263 patients in 21 countries were studied. Instrumental variable methods were used to model the effect of DK on SK. Adjusted Cox regression was used to test the associations of baseline DK and SK with all-cause death, and an arrhythmia composite (AC) of SD or arrhythmia-related hospitalization.

Results: In the US, DK and SK (mEq/L) have been stable over time (70% DK=2, 25% DK=3; mean±StdDev SK=4.7±0.7). In Europe, DK has increased (currently 15% DK=1-1.5, 45% DK=2, 33% DK=3) while mean SK has decreased from 5.2 to 4.9. SK was only associated with death or AC, overall or at any level of SK (Fig).

0.08 mEq/L higher per 1 mEq/L higher DK. SK ≥ 6 (ref 4.5-4.9) was associated with death (HR=1.5, 45% DK=2, 33% DK=3) while mean SK has decreased from 5.2 to 4.9. SK was only associated with death or AC, overall or at any level of SK (Fig).

Conclusions: The risk of incident AF among patients on HD is increased after a stroke, MI, or hip fracture. Risks were highest in the first 90 days after the event, and remained elevated >90 days after an ischemic stroke or MI, but not after a hip fracture.

FR-PO740

Arrhythmias as a Potential Cause of Dizziness and Syncope in Patients with End-Stage Renal Disease
Kati Kaartinen,1 Jani Alhoven,2 Seppo Ojansen,3 Joonas Markku Rautavaara,4 Ollli Anttonen,5 Tuomas Kerola,6 Kati Vaaraniemi,7 Marja H. Miettinen,8 Juhani Koistinen,9 Atte Aitikoski,9 Tuomo Nieminen,10 Department of Nephrology, Helsinki Univ Central Hospital, Helsinki, Finland; 2Department of Nephrology, Päijät-Häme Central Hospital, Lahti, Finland; 3Department of Nephrology, Central Hospital of Central Finland, Jyväskylä, Finland; 4Department of Cardiology, Vaasa Central Hospital, Vaasa, Finland; 5Department of Internal Medicine, Univ of Helsinki, Helsinki, Finland.

Background: It is unknown how often arrhythmias underlie dizziness and syncope in end-stage renal disease. We launched a study to implant subcutaneous loop recorders for their estimation.

Methods: Data is shown for 40 patients (62±8.2 years [mean±SD], range 39 to 78 y, 26 M) with stage 4 or 5 renal failure and F/u of 2- months. Main kidney diseases were diabetic (18), polycystic disease (8) and chronic glomerulonephritis (6). One patient was pre-dialytic, five had peritoneal dialysis, and rest were on hemodialysis. Median time since the start of dialysis is 1.6 years. Seven patients (18%) had either chronic or paroxysmal atrial fibrillation (AF) prior to the implantation of the recorder, being in line with published data.

Results: During the F/u of 14±7 months, recorder revealed bradyarrhythmia in six (15%) patients with an R-R arrest of >3.0 sec with a max. of 9.0 sec; two patients with symptoms thus far received a pacemaker. AF occurred in 21 (53%) patients. The median time to detect new AF was 235 days. Four patients (10%) had non-sustained ventricular tachycardia unknown before the recorder data.

Conclusions: Arrhythmias are more typical than estimated in patients with severe kidney disease. Particularly, symptomatic bradycardia is relatively common and can be easily treated with a pacemaker. AF is three times more common than known before. These findings may change diagnostics and treatment of dizziness in these patients.

FR-PO739

Acute Health Events and the Risk of Incident Atrial Fibrillation in Older Patients Undergoing Maintenance Hemodialysis
Medha Ajin,1 Benjamin A. Goldstein,2 Mark A. Hlatky,3 Alan S. Go,3 Nisha Bansal,4 Wolfgang C. Winkelmayr,1 Baylor College of Medicine, Houston, TX; 2Duke Univ, Durham, NC; 3Stanford Univ, Palo Alto, CA; 4Kaiser Permanente Northern California, Oakland, CA; 5Univ of Washington, Seattle, WA.

Background: Acute health events might increase the risk of developing atrial fibrillation (AF). We examined the incidence of new onset AF relative to several acute events in patients with ESRD initiating hemodialysis (HD).

Methods: From the USRDS, we studied older (67+ years) patients with 2 years of Medicare A&B coverage prior to initiating HD (2006-11) who had no documented diagnosis of AF, or claims indicating ischemic stroke, myocardial infarction (MI), or hip fracture prior to ESRD. We used time-varying Cox regression to estimate adjusted hazard ratios for incident AF relative to the acute events of interest, adjusted for socio-demographics and baseline comorbidities. The incidence of AF after either an acute MI, or hip fracture was modeled in time-varying fashion, during the periods of <=30, 30 to 90, and >90 days after the acute event. Patients were censored at kidney transplantation or end of database (12/31/2011).

Conclusions: Arrhythmias are more typical than estimated in patients with severe kidney disease. Particularly, symptomatic bradycardia is relatively common and can be easily treated with a pacemaker. AF is three times more common than known before. These findings may change diagnostics and treatment of dizziness in these patients.

FR-PO741

Blood Pressure and Risk of Cardiovascular Events Among Hemodialysis Patients: The CRIC Study
Nisha Bansal,1 Charles E. McCulloch,2 Feng Lin,2 Cassianne Robinson-Cohen,3 Mahboob Rahman,4 John W. Kusek,5 Amanda Hyre Anderson,6 Raymond R. Townsend,7 Jackson T. Wright,8 Alan S. Go,9 Arnold B. Alper,10 Radhakrishna Reddy Kallem,11 Chi-yuan Hsu,12 12UW; 13UCSF; 14UH; 15NIDDK; 16Upenn; 17Case Western; 18KPNC; 19Tulane.

Background: Among hemodialysis (HD) patients, previous studies have reported a U-shaped association between systolic blood pressure (SBP) and risk of mortality. However, the shape of the association between SBP and risk of cardiovascular events (CVD) is not well characterized.

Methods: We studied participants on HD in the Chronic Renal Insufficiency Study (CRIC). SBP was measured at the dialysis unit (“dialysis-unit-SBP”, N=403) and at the start of dialysis was 1.6 years. Seven patients (18%) had either chronic or paroxysmal atrial fibrillation (AF) prior to the implantation of the recorder, being in line with published data.

Results: Time since event: Ischemic Stroke Myocardial Infarction Hip Fracture
<=30 days 2.1 (1.7-2.7) 2.9 (2.5-3.4) 1.5 (1.1-2.0)
30-90 days 1.5 (1.9-2.4) 2.3 (2.0-2.6) 2.1 (1.7-2.5)
>90 days 1.5 (1.3-1.6) 1.6 (1.5-1.7) 1.1 (1.0-1.3)

Conclusions: The risk of incident AF among patients on HD is increased after a stroke, MI, or hip fracture. Risks were highest in the first 90 days after the event, and remained elevated >90 days after an ischemic stroke or MI, but not after a hip fracture.

with time to adjudicated CVD (defined as heart failure, myocardial infarction, peripheral vascular disease, or stroke), adjusting for demographics, diabetes, smoking, BMI, prior CVD, kt/v, serum albumin and hemoglobin.

Results: Mean age was 60 (±11) years, 42% were women and 64% were Black. There were a total of 121 CVD events over a median time of 1.15 years. The association between dialysis-unit-SBP was U-shaped, with the greatest risk of CVD at the highest and lowest quartiles of dialysis-unit-SBP.

Conversely, the association between out-of-dialysis-unit-SBP was linear, with the highest quartile having greater than 2-fold risk of CVD than the lowest quartile.

Conclusions: Among HD patients, the association of SBP measured in the dialysis unit with CVD is U-shaped, while the association of SBP measured outside the dialysis unit with CVD is linear, similar to what has been reported for mortality (Bansal et al, Hypertension 2015). Targeting SBP measured outside the dialysis unit may improve CVD outcomes in HD patients.

FR-PO742

Intradialytic Dynamics of Systolic Blood Pressure in Hemodialysis Patients Based on Survival Status

John W. Larkin, Dugan Maddux, Yue Jiao, Jeroen Kooman, Frank van der Sande, Hao Han, Sophia Rosen, Len A. Usayat, Peter Kotanko, Franklin W. Maddux.

Methods: The Blood Pressure in Dialysis Study is a pilot, multicenter, randomized clinical trial that assesses treatment of hypertensive HD patients to two BP targets. Measurement of predialysis SBP is done after 5 minutes rest, 3 readings 1 minute apart, in accordance with American Heart Association recommendations. We determined the differences between systolic BP (SBP) measured in routine practice versus a standardized procedure.

Results: 31,053 and 2,835 patients (338,771 and 20,380 measurements respectively) were included in the analysis. The 2-week averaged predialysis standardized SBP (SDUSBP) in the first 2 weeks of baseline was calculated by mixed linear regression.

Conclusions: These investigations of the dynamics of intradialytic SBP identify increased variability during dialysis and lower starting levels in patients who died. In both patients who were alive and died, SBP declines to a similar extent throughout dialysis. These findings suggest that lower predialysis SBP and intradialytic variability may be associated with mortality in the HD population.

FR-P0745
Comparison of Central and Peripheral Blood Pressure in Predicting Cardiovascular Surrogates in Patients with End-Stage Renal Disease

Kyoung Soo Park, Youngkun Kee, Shin-Wook Kang, Tae-Hyun Yoo. Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Hypertension is an established cardiovascular (CV) risk factor and is closely related with mortality in end-stage renal disease (ESRD) patients. Recent studies have demonstrated that central blood pressure (cBP) is a significant predictor of CV disease in the dialysis population, because cBP reflects the loading conditions of the coronary and cerebral arteries and vascular damage. Therefore, we investigated the association between cBP and CV surrogates compared with peripheral blood pressure (pBP) in patients with ESRD.

Methods: A cohort of 92 ESRD patients from the Cardiovascular and Metabolic Disease Etiology Research Center between November 2013 and February 2015 was selected. cBP was measured by SphygmCor noninvasively. CV surrogates were determined by carotid intima-media thickness, pulse wave velocity (PWV) and left ventricular mass index (LVMI). Linear regression analysis and Steiger’s Z test were used to compare predictive ability of cBP and pBP for CV surrogates.

Results: The mean age was 53.2 years and 52 (56.5%) were male. Mean systolic cBP (eSBP) and central pulse pressure (cPP) was 140.2±28.9 and 57.1±22.8 mmHg. Mean systolic pBP (pSBP) and peripheral pulse pressure (pPP) was 145.1±28.8 and 65.8±22.2 mmHg. There was an independent association of eSBP and pSBP with PWV (R2=0.408, P<0.01; β=0.322, p=0.001) and LVMI (β=0.370, P=0.001; β=0.382, P<0.001). cPP and pPP were independently associated with LVMI (β=0.353, P<0.001; β=0.353, P<0.001) and LVMI (β=0.411, P<0.001; β=0.497, P=0.001) after adjustment for confounding factors. However, there were no significant differences in the predictive value of cSBP and pSBP for estimating PWV (adjusted R2, 0.494 vs. 0.431, P=0.07) and LVMI (adj R2, 0.215 vs. 0.220, P=0.885). No significant difference was found for cPP and pPP for predicting PWV (adj R2, 0.451 vs. 0.429, P=0.546) and LVMI (adj R2, 0.220 vs. 0.269, P=0.320).

Conclusions: Although cBP values were closely associated with CV surrogates, these values did not provide additional information beyond pBP in predicting CV risk in patients with ESRD.

FR-P0746
Early Mortality in Hemodialysis Patients Anticoagulated for Atrial Fibrillation
Stanislav S. Bushik, N. Stanley Nahman, R. Idai Elmor, Jennifer L. Waller, Robert A. Sorrentino, William R. Maddox, Mufaddal F. Kheda, Matthew J. Diamond. Medicine, Georgia Regents Univ, Augusta, GA; Biostatistics & Epidemiology, Georgia Regents Univ, Augusta, GA.

Background: Atrial fibrillation (AF) is prevalent in the Hemodialysis (HD) population and portends a high mortality rate. AF also causes embolic stroke and is treated with lifelong oral anticoagulation (OAT). We have previously shown early increased mortality in HD patients receiving OAT without significant stroke reduction (JASN, 25:609A, 2014). It is unclear why OAT increased early mortality in these patients. To address this question, we queried the USRDS for unique risk factors for mortality in this cohort.

Methods: All incident adult HD cases from the USRDS for 2005-2008 were queried for demographics, access type, risk factors before dialysis, and mortality. Data were derived from ICD9 and CPT codes, or Form 2728. Proportional hazards models were used to estimate the hazard ratio (HR) for death within 90 days.

Results: 34,522 incident HD patients with AF were identified, 6664 (19.3%) of whom died within 90 days of the initiation of dialysis. For the entire group, demographics showed: 83.1% Caucasian, mean age 75.4 years (SD=9.0), and 41.5% female. When controlling for diabetes, cardiomyopathy TIA, pulmonary hypertension, aortic stenosis, CHF, MI, coagulation disorders, obesity, cardiac device, age and access type the HR for death in the OAT group was 1.10 (95% CI 1.04 - 1.16). The 1-2- and 3-month mortality rates were 6%, 15% and 22% in OAT and 5%, 12% and 19% in non-OAT, respectively. Major bleeding episodes were not significantly associated with mortality (p=0.59).

Conclusions: OAT therapy in HD patients with AF may contribute to the increased death rate observed during the first 90 days of dialysis, but not apparently due to bleeding. We speculate that OAT use may be associated with non-hemorrhagic complications that may lead to increased mortality in the HD population. Defining this level of clinical detail is beyond the scope of an administrative dataset like the USRDS. Future studies addressing non-hemorrhagic effects of OAT may provide new insights on possible causes of early mortality in these patients.

Reduced Temperature Hemodialysis Augments Dialysis Induced Improvement of Cardiac High Energy Phosphate Levels
Rajan Patel, Elaine Rutherford, Kathryn K. Stevens, Sandosh Padmanabhan, Alan G. Jardine, Patrick B. Mark. Dept of Cardiovascular and Medical Sciences, Univ of Glasgow, Glasgow, United Kingdom.

Background: 31P Magnetic resonance spectroscopy (31P-MRS) measures levels of high energy phosphates, including phosphocreatinine/β ATP (PCR/β ATP) ratio which evaluates cardiac metabolic activity. PCR/β ATP is significantly reduced in end stage renal disease (ESRD) patients. Reducing hemodialysate temperature by 1°C improves intradialytic hypotension and cardiac function. The effects of reduced temperature dialysis on cardiac metabolism have not been evaluated. We compared myocardial function and PCR/β ATP ratios levels before and after normothermic and reduced temperature dialysis.

Risk Grading by CHA2DS2_Vasc Score Is Useful in Non-Dialysis Subjects with Atrial Fibrillation while It Is Not Useful in Dialysis Patients Because of Their Very High CHA2DS2_Vasc Scores
Masaki Ohsawa, 1,2 Robert A. Sorrentino, 1 Biostatistics & Epidemiology, Georgia Regents Univ, Augusta, GA; Dept of Internal Medicine, Iwate Medical Univ, Morioka, Japan; 1Dept of Internal Medicine, Morioka Tsunagi Onsen Hospital, Morioka, Japan; 1Dept of Hygiene and Preventive Medicine, Iwate Medical Univ, Iwate Prefecture, Japan.

Background: Whether CHA2DS2_Vasc score is useful for predicting the risk of outcomes has not been sufficiently examined in dialysis patients with AF.

Methods: Two prospective studies of 1,109 dialysis patients (AF group (n=35); non-AF group (n=1,074)) and 28,469 community dwellers (AF group (n=26,058); non-AF group (n=411)) living in the same area were conducted. Subjects were subdivided into four groups according to CHA2DS2_Vasc score (G1: CHA2DS2_Vasc score = 0–1; G2: score = 2; G3: score = 3; G4: score = 4+). Crude mortality rates of all-cause and cardiovascular death and crude incidence rates of stroke (per 1000 person-years) were estimated in each group. Results: Results were shown in the table.

Conclusions: Hemodialysis was associated with improved myocardial metabolic activity and this effect may be amplified by reducing the dialysate temperature even in patients with no intradialytic hypotension.

FR-P0748
Methods: Twelve hemodialysis patients underwent cardiac MRI and 31P-MRS of their left ventricle (LV) within 30 minutes before (pre) and after (post) three normothermic (36.5°C) and three reduced temperature (35.0°C) maintenance dialysis sessions. Left ventricular dimensions were measured by an observer blinded to intervention. PCR/β ATP were calculated from 31P-MR spectra.

Results: Reduced temperature hemodialysis was significantly associated with increased predialysis LV ejection fraction (36.5°C:64.5%±6.6 vs. 35.0°C:69.0%±6.1, p=0.03). At both temperatures, hemodialysis was significantly associated with increased mean LV ejection fraction (36.5°C:pre 64.5%±6.6, post 70.9%±6.8, p=0.002;35.0°C:pre 69.0%±6.1, post 74.2%±8.3, p=0.01). PCR/β ATP was significantly higher after normothermic (p=0.01) and reduced temperature hemodialysis (p=0.03). Mean increase in PCR/β ATP was higher after reduced temperature compared to normothermic hemodialysis (+51.5% vs +74.1% respectively).

Post Stroke In-Hospital Disability Deterioration and Mortality of Community-Onset Stroke in Patients with and without End-Stage Renal Disease

Tomoko Ushii,1 Norio Hanafusa,1 Hideo Yasunaga,2 Masoomi Nangaku.1
1Dept of Hemodialysis and Apheresis, The Univ of Tokyo Hospital, Japan; 2Dept of Clinical Epidemiology and Health Economics, School of Public Health, the Univ of Tokyo, Japan.

Background: Increasing evidence suggests that end-stage renal disease is associated with higher risk and severity of cerebrovascular disease. However, the risk factors for post stroke disability and mortality is not clear. We examined the association between risk factors including dialysis treatment and disability deterioration and mortality during hospital stay of community-onset stroke.

Methods: The Japanese Diagnosis Procedure Combination database includes administrative claims and discharge abstract data of about 50% of all acute-care inpatients in Japan. Using this database, we extracted data of inpatients aged >20 years old, admitted within 3 days after community-onset stroke between July 2010 and March 2013. Disability level was divided into modified Rankin Scale (mRS) 0-1, 2-3, 4-5, and 6 (death). Disability deterioration was defined as an increase in disability level. The odds ratio (OR) for in-hospital disability deterioration and mortality was calculated using a logistic regression model.

Results: Out of 438,569 patients, 7,633 (1.7%) had dialysis therapy. The median length of stay was 21 and 20 days for patients with and without dialysis, respectively. During the hospital stay, there were 101,024 (23.0%) disability deterioration and 46,029 (10.5%) death. The patients with dialysis had higher rate of disability deterioration (26.7%) and mortality (13.0%) compared to those without. After adjustment with age, gender, BMI, mRS, Activities of Daily Living, smoking habits, hypertension, diabetes, dyslipidemia, atrial fibrillation, coronary heart disease, heart failure, peripheral arterial disease, cerebrovascular complications, antipatelet, anticoagulant, and thrombolytic medications, multivariate-adjusted ORs of dialysis for deterioration of disability was 1.57 (95%CI 1.48-1.66), and in-hospital mortality was 1.72 (95%CI 1.59-1.86).

Conclusions: Dialysis treatment was an independent risk factor for in-hospital disability deterioration and mortality of community-onset stroke.

FR-PO750

Proportion of Treatments with Low Systolic Blood Pressure and Short Term Mortality in Incident Hemodialysis Patients

Duan Maddux,1 John W. Larkin,1 Danqing Xu,2 Len A. Usvyat,3 Frank van der Sande,3 Jeroen Kooman,3 Peter Kotanko,4 Franklin W. Maddux.1
1Medical Office, Fresenius Medical Care North America, Waltham, MA; 2Univ of California at Santa Barbara, Santa Barbara, CA; 3Maastricht Univ Medical Centre, Maastricht, Limburg, Netherlands; 4Renal Research Inst, New York, NY.

Background: Prior studies have associated low mean predialysis systolic blood pressures (preSBP) with increased 120 day risk for mortality in incident hemodialysis (iHD) patients (Maddux et al., ASN 2014). This study aimed to investigate how the percent (%) of low mean preSBP during the prior weeks’ hemodialysis (HD) treatments affects the short term risk of mortality in iHD patients.

Methods: For this study, 56,525 iHD patients at Fresenius Medical Care North America (FMCNA) clinics were investigated from 1/1/2004 to 12/31/2010. From the first date of outpatient chronic dialysis (FDD), the % of the prior weeks’ mean preSBP <110 mmHg was calculated for the first 4 months of HD. Mortality risk in the following week (7 days) was analyzed by the % of the prior week’s mean preSBP <110 mmHg at weeks 2, 4, 6, 12, and 16 from FDD.

Results: We observed that the short term risk for mortality in the following week increases in iHD patients as the % of the prior week’s mean preSBP <110 mmHg increases at weeks 2, 4, and 6 from the FDD; the risk for mortality was found to be the greatest at week 2 and was slightly reduced by week 6. Conversely, by week 12 and 16 from FDD, the % of the prior week’s mean preSBP <110 mmHg was not found to be related with the risk of mortality in the next week.

Conclusions: This study demonstrates that increases in the % of low mean preSBP during the prior weeks’ hemodialysis (HD) treatments is associated with heightened short term risks of mortality during the first 6 weeks of iHD, but not during weeks 12 and 16 from the FDD.

FR-PO751

The Possibility of Faster Progression of Brain Atrophy in Patients on Peritoneal Dialysis Compared with Hemodialysis

Kazuhiko Tsuruya,1 Hisako Yoshida,1 Takanari Kitazono.2 1Dept of Integrated Therapy for Chronic Kidney Disease, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan; 2Dept of Medicine and Clinical Sciences, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.

Background: Brain atrophy has been reported in chronic kidney disease (CKD) patients, especially in hemodialysis (HD) patients. Recently, we reported faster decline in normalized gray matter volume (GMV) in peritoneal dialysis (PD) patients compared with non-dialysis-dependent CKD (ND) patients. However, it has not been reported on the comparison of the progression rate of brain atrophy between PD and HD patients. In the present study, we compared it among PD, HD, and ND patients.

Methods: A total of 151 patients of 38 PD patients aged 60 ± 12 years (men 23, diabetes 11), 24 HD patients aged 64 ± 6 years (men 18, diabetes 9), and 89 ND patients (CKD stage 3a, 3b, stages 4-5, 3a; stage 3b, 31; stages 4-5, 24 patients aged 62 ± 11 years (men 46, diabetes 25, eGFR 38.9 ± 11.6 mL/min/1.73m²) were recruited and underwent MRI scanning at baseline and after 2 years. T1-weighted MRI images were analyzed with statistical parametric mapping software. Total gray matter, total white matter, and cerebrospinal fluid were segmented and each volume was quantified. Normalized GMV was calculated as percentage of intracranial volume to normalize for head size variability. We compared the annual change in normalized GMV among CKD stages.

Results: Annual change in normalized GMV was significantly higher in PD patients than other CKD patients including HD patients, independent of age, gender, diabetes, and blood pressure level.

Conclusions: Progression of brain atrophy is significantly higher in PD patients than other CKD patients including HD patients. This finding remained significant even after adjustment for potential confounding factors.

In Centre Nocturnal Haemodialysis: Improving Outcomes and Experience for Patients Matthew P.M. Graham-Brown,1,2 Darren Robert Churchward,1 Alice C. Smith,1,2 Richard J. Baines,1,2 James O. Burton.1,2 John Walsall Renal Unit, Univ Hospitals of Leicester, Leicester, United Kingdom; 1Dept of Infection, Immunity and Inflammation, Univ of Leicester, Leicester, United Kingdom.

Background: Extended periods of haemodialysis (HD) improve patient outcomes. Home HD schedules can deliver extended dialysis, but there are patient and physician related barriers that make home therapies impossible for many. We explored in centre nocturnal HD (INHD) as a method of offering extended periods of HD to patients unsuitable for home therapy.

Methods: Ten prevalent HD patients switched from standard HD (3x4 hours) to INHD (3x5 hours) for four months. Mean ultrafiltration (UF) volumes (L), relative UF rates (ml/kg/hour) and absolute UF rates (ml/hour) were calculated. Additional, biochemical and haematological data, data on dialysis adequacy and blood pressure control were collected. Changes in quality of life (Qol.) were assessed using SF12, EQ-5D and the Hospital Anxiety and Depression Score (HADS) questionnaires.

Results: Seven patients completed four months of INHD. Mean dialysis time per session was 355 minutes (SD=43.92). Mean total UF volume increased from 2.0±0.5 L to 2.6±3.4 L (p=0.02), but there was a reduction in absolute mean UF rates from 513±121 ml/hour on standard dialysis, to 356±66 ml/hour on INHD (p=0.03) and a decrease in mean relative UF rates from 6.5±1.7 ml/kg/hr to 4.6±1.6 ml/kg/hr (p=0.03). Adequacy measured by urea reduction ratio improved from 72±2% to 80±3% (p<0.001), with a trend towards improved phosphate control to within therapeutic targets from 1.7±0.6 mmol/L to 1.2±0.2 mmol/L (p=0.08). In addition, there were improvements in all Qol. scores. Mean EQ-5D visual analogue scale improved from 48±16.9 to 72±13.2 (p<0.003). Mean HADS anxiety score decreased from 9±5.83 to 3.57±3.04 (p=0.03). SF12 physical component score improved from 31.3±3.32 to 41.69±10.19 (p=0.005).

Conclusions: Despite an increase in total UF volume, extended INHD led to an overall reduction in UF rate that has been shown to abrogate HD induced cardiac injury. Other physiological benefits included improved urea clearance and better phosphate control. There were also significant improvements in patient Qol. measures over four months.

FR-PO753

Association of Multiple Strokes on Mortality in Incident Hemodialysis Patients: An Application of Multistate Model to Determine Transition Probabilities James B. Wetmore,1 Jonathan D. Mahnkop,2 Milind A. Phadnis.2 1Medicine, Div of Nephrology, Hennepin County Medical Center, Minneapolis, MN; 2Biostatistics, Univ of Kansas Medical Center, Kansas City, KS.

Background: Little is known about the effect of multiple, or subsequent, ischemic strokes in patients receiving dialysis.

Methods: A retrospective cohort study of incident hemodialysis patients with Medicare Parts A and B coverage who had experienced a first ischemic stroke was performed. A multistate model with Cox proportional hazards was used to predict transition probabilities from first ischemic stroke to subsequent stroke or to death. Demographic and clinical factors associated with the respective transition probabilities were determined.

Results: Overall, 12,054 individuals (mean age 69.7 years, 41.3% male, 53.0% Caucasian and 34.0% African-American) experienced a first stroke. Female sex was associated with an increased risk of having a subsequent stroke (adjusted hazard ratio 1.37, 95% confidence interval 1.20 – 1.56, P < 0.0001), African-Americans, as compared to Caucasians, had lower likelihood of dying after a first stroke (0.87, 0.77 – 0.85, P < 0.0001). A subsequent stroke trended towards having a higher likelihood of transitioning to death compared to a first new stroke on dialysis (1.72, 0.96 – 3.09, P = 0.071). The probability of transitioning to a subsequent stroke increased over the first 6 months, peaked at approximately 12 months, then declined steadily over time (Figure). When a subsequent stroke occurs at 24 months, probability of survival dropped >15%, in absolute terms, from 0.254 to 0.196, with substantial drops observed at subsequent time points such that the probability of survival was more than halved.

Conclusions: Likelihood of subsequent ischemic stroke and of survival in dialysis patients appears to vary by sex and race.

FR-PO754

Electrocardiographic Manifestation in End-Stage Renal Disease Patients with Different Renal Replacement Treatment Thasinas Dissayabutra,1 Eiji Kuwano.1,2 1Biochemistry, Chulalongkorn Univ, Pathumwan, Bangkok, Thailand; 2Internal Medicine, Div of Nephrology, Jichi Medical Univ, Shimotsuke, Tochigi, Japan.

Background: End-stage renal disease commonly coexists with certain type of cardiovascular diseases, partially reflects the burden of cardiac in uremic state and dialysis methods. Hemodynamic changes are different between predialysis state, hemodialysis (HD), peritoneal dialysis (PD) and post-kidney transplant (Post-KT) patients. This study aimed to investigate the cardiac disorders using electrocardiographic (ECG) features between each stage of CKD patients, including HD, PD and Post-KT.

Methods: ECG records were analyzed retrospectively in 974 participants, including (a) 48 Early CKD (CKD stage 1-2), (b) 188 Advanced CKD (CKD stage 3, 4 and 5), (c) 567 Hemodialysis (HD), (d) 112 chronic ambulatory peritoneal dialysis (PD) and (e) 59 post-kidney transplant (KT) patients. ECGs were analyzed by two examiners for major ECG abnormalities.

Results: A few ECG abnormalities were observed in Early CKD, but highly frequent QTc prolongation and first degree atrio-ventricular block (AVB) were detected in Advanced CKD. PD patients developed more left ventricular hypertrophy (LVH) and premature ventricular contraction than HD counterparts.

Conclusions: An increased QTc prolongation and first degree atrio-ventricular block (AVB) were detected in Advanced CKD. PD patients developed more left ventricular hypertrophy (LVH) and premature ventricular contraction than HD counterparts.

The Relation Between Sclerostin, Peripheral Vascular Calcification, and Cardiovascular Events in ESRD Patients Young J. Na, Sang Yoon Lim, Myung-gyu Kim, Sang-Kyung Jo, Won-Yong Cho. *Nephrology, Korea Univ Hospital, Seoul.

Background: Sclerostin, a negative regulator of Wnt signaling pathway produced by osteocyte, is a potent regulator of bone metabolism and a novel candidate for the bone vascular axis in chronic kidney disease patients. Although sclerostin is known as an inhibitor of vascular calcification, recent studies demonstrated conflicting results about the association between sclerostin and cardiovascular events or mortality. In this study we tested the association between sclerostin, peripheral vascular calcification, and cardiovascular events in end stage renal disease (ESRD) patient starting peritoneal dialysis.

Methods: In this prospective study, we included 45 ESRD patients admitted to Korea University Anam Hospital for starting peritoneal dialysis. Circulating sclerostin level was measured in all patients before the start of peritoneal dialysis. Simple vascular calcification score (SVCS) was measured using plain radiographic films of both hands and the pelvis. Median follow up period was 36 months.

Results: Higher sclerostin level was associated with male sex, diabetes mellitus, higher left ventricle (LV) mass index, and lower LV fractional shortening in univariate analysis. ESRD patients with severe vascular calcification (SVCS ≥ 73) had significantly higher prevalence of diabetes mellitus. They had higher pulse wave velocity, alkaline phosphatase, and lower cholesterol levels, LV fractional shortening and in multivariate analysis, the presence of diabetes mellitus (OR, 44.59, p=0.023), lower cholesterol levels (OR, 0.94, p=0.032) were independent risk factors predicting severe vascular calcifications. In multivariate Cox regression model, higher pulse wave velocity (HR 1.63, p=0.028) was significant predictor for cardiovascular events. In addition higher sclerostin group (HR 9.82, p=0.094) and lower albumin levels (HR 0.25, p=0.081) display a strong tendency of increased cardiovascular events.

Conclusions: This study showed the possible important role of sclerostin in the development of vascular calcification and cardiovascular events in PD patients. Longer term follow up with larger sample size would be needed to clarify this issue.

FR-PO756

Use of Anticoagulants in Patients with Atrial Fibrillation and End Stage Renal Disease: A Study of Real World Data Lloyd P. Haskell,1 Chris Knoll,2 Patrick Ryan,2 Zhong Yuan,3 1Cardiovascular, Janssen R and D, Raritan, NJ; 2Epidemiology, Janssen R and D, Raritan, NJ; 3Epidemiology, Janssen R and D, Titusville, NJ.

Background: End stage renal disease (ESRD) in patients with atrial fibrillation (AF) is a significant cause of morbidity and mortality. While these patients are at high risk for stroke, there are limited data with respect to use of anticoagulants in clinical practice and current guidelines are not clear on how to manage them.

Methods: US-based, four large healthcare databases (Truven MarketScan Commercial Claims/Encounters [CCAE], Medicare Supplemental [MDCR], Medicaid [MDCD] and Optum Clinformatics [Optum]) were used to establish cohorts of patients with AF and ESRD, who were identified using ICD-9 codes. The first encounter with evidence of both conditions during the inception period of 2010-2012 was the index date; patients must have had at least 1 year enrolment prior to and after the index date to be eligible for the study. The use of anticoagulants was examined during the follow-up period.

Results: Table 1 shows patient demographics and use of anticoagulants by data source. As expected, the privately-insured patient populations (CCADE and Optum) as well as the Medicaid population (MDCD) were younger as compared with the Medicare eligible population (MDCR). Across study cohorts, approximately 37% to 40% of patients with AF and ESRD received at least one dispensing of warfarin, with the exception of the Medicaid population (14%). About 3 to 4% of patients (except for Medicaid) received at least one dispensing of novel oral anticoagulant therapy (rivaroxaban, apixaban, or dabigatran).

Conclusions: Use of anticoagulants in ESRD patients with AF and ESRD received anticoagulant therapy. As these are high risk patients, anticoagulant therapy may be underutilized. Further research is necessary to investigate clinical outcomes associated with anticoagulation in these patients.

Conclusions: Less than 40% of patients with AF and ESRD received anticoagulant therapy. As these are high risk patients, anticoagulant therapy may be underutilized. Further research is necessary to investigate clinical outcomes associated with anticoagulation in these patients.

FR-PO757

Factors Determining Changes in Mortality Rates in Incident Hemodialysis Patients Jochen G. Raimann,1 Len A. Usvyat,2 Dugan Maddux,2 Jeroen Kooman,3 Frank van der Sande,3 Kevin Chan,4 Franklin W. Maddux,2 Peter Kotanko.1 1Renal Research Inst; 2Fresenius Medical Care North America; 3Maastricht Univ Medical Centre; 4Icahn School of Medicine at Mount Sinai.

Background: The higher risk of death for incident hemodialysis (HD) patients decreases during the first year (Chan, 2011). Next to vintage, risk is also affected by patient characteristics and the evolution of clinical and laboratory parameters. We analyzed how mortality rates change in different age groups, levels of albumin, in black and white, and in diabetic and non-diabetic patients after HD initiation.

Methods: We analyzed patients commencing HD in Fresenius Medical Care North America clinics between 1/1/2005 and 11/30/2014. We calculated proportions of patients dying from all causes in diurnal intervals starting with the first day on HD up to 1000 days. Only patients who had their first outpatient treatment on day 1 of their first ever HD were analyzed. We analyzed differences in mortality in the following strata: a) age groups (<40, between 40 and 65, and >65 years), b) serum albumin greater and below 3.8 g/dL., c) black and white; and d) diabetic and non-diabetic patients. We fitted penalized B-splines with 95% CIs through all available daily rates.

Results: We studied 334,880 patients. For all groups, mortality rates dropped within the first year. There were differences between groups of age, albumin and between black and white patients, but none between diabetic and non-diabetic patients.

Conclusions: Mortality rates decrease substantially once patients initiate HD. After approximately one year on HD, mortality remains consistent in all groups, but remains lower for those with higher albumin, younger age and black race. Diabetes appears to not affect mortality. Since only patients starting in an outpatient setting were included, selection bias may apply differently to the patient groups.

Funding: Pharmaceutical Company Support - Fresenius Medical Care North America

Strong Association of Geriatric Nutritional Risk Index with the Infection-Related Mortality in Hemodialysis Patients: The Q-Code Study Yuuta Matsukaka,1 Shigeru Tanaka,1 Masatomto Taniguchi,2 Toshiaki Nakano,3 Kosuke Masutani,1 Hideki N. Hirakata,2 Kazuhiko Tsuura,1,3 Takenari Kitazono.1 1Dept of Medicine and Clinical Science, Kyushu Univ, Fukuoka, Japan; 2Japanese Red Cross Fukuoka Hospital, Fukuoka, Japan; 3Dept of Integrated Therapy for Chronic Kidney Disease, Kyushu Univ, Fukuoka, Japan.

Background: Geriatric Nutritional Risk Index (GNRI) is a simple but useful predictive marker for all-cause and cardiovascular mortality in hemodialysis (HD) patients. However, it is unclear whether the GNRI could predict the infection-related mortality in HD patients. We have investigated the association between GNRI and the infection-related mortality in Japanese HD patients.

Methods: A total of 3,452 Japanese HD patients aged >18 years were prospectively followed for 4 years. Patients were divided into three groups by tertile of GNRI: Tertile1 (T1): <92.67, T2: 92.67–98.63, T3: >98.63. We estimated the relationship between GNRI and the all-cause mortality and infection-related mortality using a Cox proportional hazards model. To assess the additional predictive value of GNRI in risk assessment, we compared the c-statistics between serum albumin and GNRI.

Results: During the four years, 152 patients died totally, and 121 patients died of infection-related mortality. All-cause mortality and infection-related mortality increased linearly with lower GNRI levels. After adjusting for confounding risk factors, the GNRI was an independent predictor of not only all-cause but also infection-related mortality (hazard ratio 6.51, 95% confidence interval 3.16–13.4, p <0.001 for T1 vs. T3, and hazard ratio 3.04, 95% confidence interval 1.44–6.43, p=0.004 for T2 vs. T3). When...
FR-PO759
Survival in Elderly on Dialysis and Impact of Institutionalization
Amarpali Brar, David Kau, Moro O. Salliuf, Mary C. Mallappallil. Renal, SUNY Downstate, Brooklyn, NY.

Background: We hypothesized that in the very elderly dialysis patients in the United States, institutionalization in nursing homes would increase mortality in addition to age alone.

Methods: Data was obtained from the U.S. Renal Data System. Incident dialysis patients from 2001 to 2008 above the age of 70 were included. Follow-up period was from incident dialysis date to either death or last follow up on September 30, 2009. Patients above 70 were categorized into four groups according to age as 70-75 years, 76-80 years, 81-85 years, greater than 85 years and further divided into institutionalized and non-institutionalized.

Results: A total of 349,440 patients were identified above the age of 70 years at the time of initiation of dialysis. Major causes of end stage renal disease were diabetes, hypertension, glomerulonephritis, cystic kidney disease, and urological mean. Cause for mean non institutionalised patients was 3.15 ± 0.01 years for those between 70-75 years of age, 2.55±0.01 years for 76-80 years, of age, 2.12±0.01 years for 81-85 years of age and 1.64±0.01 years for those above 85 years at the time of initiation of dialysis respectively. For institutionalized patients, mean survival was significantly lower, 1.71±0.03 years for 70-75 years old, 1.44±0.02 years for 75-80 years old, 1.25±0.02 years for 81-85 years old and more than 85 years and 1.04±0.02 year for >85 years age group, p<0.001.
The oldest group in non-institutionalized over the age of 85 years had a similar survival as the institutionalized ESRD patients 70-75 years old.

Conclusions: There was increased mortality in institutionalized elderly patients as compared to non institutionalised elderly patients in the same age group. Keeping with the increased frailty and decreased benefit of therapies in the very elderly especially in those with additional co-morbidities besides age, palliative and end of life care should be considered.

FR-PO760
Geriatric Nutritional Risk Index Is a Simple Predictor of Mortality in Chronic Hemodialysis Patients Kosaiku Nitta, Ken Tsuchiya. Dept of Medicine, Kidney Center, Tokyo Women’s Medical Univ, Shinjuku-ku, Tokyo, Japan.

Background: Malnutrition is common in hemodialysis (HD) patients, and it is associated with increasing risk of mortality. The geriatric nutritional risk index (GNRI) has been developed as a tool to assess the nutritional risk. The aim of the present study was to examine the reliability of the GNRI as a mortality predictor in a Japanese HD cohort.

Methods: We prospectively examined the GNRI of 332 maintenance HD patients aged 65±11.9 years, 213 males, and followed up on them for 36 months. The patients were divided into quartiles (Q) according to GNRI values (Q1: <91.6, Q2: 91.7-97.0, Q3: 97.1-102.2, Q4: >102.3). Predictors for all-cause mortality were examined using Kaplan-Meier and Cox proportional-hazards analyses.

Results: The GNRI presented a normal distribution. During the follow-up period of 36 months, a total of 76 patients died. The overall mortality at the end of the 3-year observational period was 22.2%. At the 3-year follow-up period, Kaplan-Meier survival rates for all-cause mortality were 72.3%, 79.3%, 84.9%, and 92.6% in Q1, Q2, Q3, and Q4, respectively (p = 0.0067). Multivariate Cox proportional-hazards analysis demonstrated that the GNRI was a significant predictor of adjusted all-cause mortality (HR 0.958; CI 0.929–0.989, p = 0.001).

Conclusions: The results of the present study demonstrate that the GNRI is a strong predictor of overall mortality in HD patients. However, cardiovascular mortality was not associated with GNRI values, and it did not differ among the GNRI quartiles. The GNRI score can be considered a simple and reliable marker of predictor for mortality risk in Japanese HD patients.

FR-PO761
Frailty and Clinical Outcomes in Chronic Dialysis Patients Dong Heo Yang,1 Eun jung Koo,1 Hye Yun Jeong.1 Internal Medicine, CHA Bundang Medical Center; Seongnam, Republic of Korea; 2Internal Medicine, CHA Gumi Medical Center, Gumi, Republic of Korea.

Background: Frailty is a biological syndrome of decreased reserve and resistance to stressors and is independently associated with mortality and hospitalization in the general population. We investigated the relationship between frailty and clinical outcomes in chronic dialysis patients.

Methods: In this prospective study, 1,658 patients receiving chronic dialysis were enrolled. Chronic dialysis was defined as dialysis for more than 6 months. Of the 1,658 patients, 1,255 received hemodialysis. The remainder received peritoneal dialysis. Fried’s criteria for frailty as modified by Woods et al. was used. A trained interviewer asked study participants about 5 frailty phenotypes (slowness, weakness, exhaustion, shrinking, and physical inactivity) using the RAND 36-item Short Form.

Results: The mean age was 55.2±11.9, and 55.2% were male. Overall, 577 (34.8%) patients met the study definition of frailty. Another 757 (45.7%) patients were pre-frail. Table 1 shows the prevalence of frailty and its components by age group. During the 30-month follow-up period, 607 patients (79 non-frail, 249 pre-frail, and 279 frail) were hospitalized; and 87 patients (10 non-frail, 24 pre-frail, and 53 frail) died (P<0.001). Frailty was strongly associated with hospitalization (adjusted hazard ratio [HR] 1.80, 95% CI 1.4 to 2.3) and mortality (HR 2.37, 95% CI 1.11 to 5.02) in multivariate analysis. The relationship between frailty and hospitalization was strongest among patients age 40 to 49, with a HR of 3.02 (95% CI 1.48 to 6.20).

Conclusions: We found a high prevalence of frailty in chronic dialysis patients across all age groups. The risk of hospitalization and mortality in the 30-month follow-up period significantly increased in frail chronic dialysis patients.

FR-PO762
Outcomes of Early Initiation of Dialysis in Elderly Patients with End Stage Renal Disease: A Propensity-Matched Analysis of a Prospective Cohort Study Jae Yoon Park,1 Kyung Don Yoo,2 Jeonghwan Lee,2 Dong Ki Kim,3 Kwon Wook Joo,1 Shin-Wook Kang,1 Chul Woo Yang,4 Yong-Lim Kim,4 Chun Soo Lim,3 Yun Su Kim,1 Jung Pyo Lee.1 Seoul National Univ College of Medicine, Seoul, Korea; 1Hallym Univ Hangang Sacred Heart Hospital, Seoul, Korea; 2Yonsei Univ College of Medicine, Seoul, Korea; 3The Catholic Univ of Korea College of Medicine, Seoul, Korea; 4Kyoungpook Univ National Univ School of Medicine, Daegu, Korea.

Background: The optimal timing for initiating dialysis in end-stage renal disease (ESRD) remains controversial, especially in elderly patients. We therefore investigated the effect of dialysis initiation timing on clinical outcomes in elderly patients with ESRD.

Methods: A total of 665 patients aged equal or over 65 years who started dialysis from August 2008 to February 2013 were enrolled in Clinical Research Center for End Stage Renal Disease cohort study in Korea. They were divided into 2 groups based on the median estimated glomerular filtration rate, which was 8.85 mL/min/1.73m2. The primary outcome was patient survival and the secondary outcomes were cardiovascular events and Kidney Disease Quality of Life Short Form 36 (KDQOL-36) score.

Results: Overall cumulative survival rates were lower in early initiation group (Log-rank P<0.001). However, the survival rates showed no significant difference after matching propensity score. Additionally, early initiation of dialysis was not associated with survival rates after adjustment for age, sex, Charlson comorbidity index, hemoglobin, serum albumin, serum calcium and phosphorus level. Although the early initiation group showed lower physical component summary in KDQOL-36 at 3 months after dialysis, the difference of the scores was not significant at 12 months after dialysis.

Conclusions: Early initiation of dialysis was not associated with prognosis in elderly patients with ESRD. The physical functioning was worse for 3 months after dialysis but it became similar to late initiation of dialysis at 1 year after dialysis.
Comorbidity Burden at Dialysis Initiation and Mortality: A Retrospective Cohort Study

FR-PO764

Comorbid conditions were ascertained using electronic records. The primary (CCI) and End-Stage Renal Disease Comorbidity Index (ESRD-CI) were calculated in all patients in a tertiary care institute from 2006-2013. The Charlson Comorbidity Index (CCI) comorbidity was associated with mortality.

Methods: Our objective was to design a prediction model for 1- and 2-year all-cause mortality in patients starting chronic renal replacement therapy. In addition, we aimed to build an easy-to-apply model consisting of only a few variables. We used the comprehensive data of the Finnish Registry for Kidney Diseases with complete coverage of Finnish ESRD patients. Model training group included all incident adult patients who started chronic dialysis in Finland from 1 January 2000 to 31 December 2008 (n=4335). The external validation cohort consisted of all those who started dialysis from 1 January 2009 to 31 December 2012 (n=1768). Prediction algorithms for 1- and 2-year mortality were developed using multivariate logistic regression with stepwise selection of variables. Our primary analyses included 32 variables, from which the most important ones were selected.

Results: Both final prognostic models, including only 6-7 variables, showed adequate discrimination (c-statistic 0.77 and 0.74 for 1- and 2-year mortality, respectively). Because of a significantly lower mortality in the newer (validation) cohort, both models somewhat overestimated mortality risk.

Conclusions: Mortality prediction algorithms could be more widely implemented into clinical treatment-planning of ESRD patients. Our prediction models perform sufficiently well to be applicable for clinical treatment-planning.

Inflammation and Fluid Overload a Complex Interaction: Results from the International MONDO Initiative

FR-PO766

The cohort consisted of 771 patients. Most were male (62%) and Caucasian (91%). Patients had a high prevalence of diabetes (48%) and history of myocardial infarction (31%). The c-index was 0.61 for the CCI, and 0.63 for the ESRD-CI. In an adjusted analysis, ESRD-CI scores of 4, 5 and 6 were associated with a similar mortality risk (Table 1). There was a small increased mortality risk for CCI scores of 4, 5 and 6.

Conclusions: The CCI and ESRD-CI had a limited ability to discriminate risk of death for incident dialysis patients. Although a higher comorbidity burden was associated with mortality, increases in index scores did not considerably change the risk of death.

*Adjusted for age, sex, race, cause of end-stage renal disease, type of dialysis (hemodialysis or peritoneal dialysis), estimated GFR, albumin, phosphate and hemoglobin

Conclusions: FO and inflammation are associated in prevalent HD patients. FO is a predictor for inflammation and vice-versa inflammation predicts FO. The combined presence of FO and inflammation is associated with poor survival.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Blood Volume Analysis as a Guide for Dry Weight Determination in Chronic Hemodialysis Patients Line Malha, 1,2 Hasan Fattah, 1 Frank Modersitzki, 1 David S. Goldfarb, 1,2  
1 Internal Medicine, Div of Nephrology, NYU School of Medicine, New York, NY; 2 Internal Medicine, Nephrology Section, New York Harbor VA Healthcare System, New York, NY; 3 Internal Medicine, Div of Nephrology, Virginia Commonwealth Univ Medical Center, Richmond, VA.

Background: Volume overload and depletion both lead to high morbidity and mortality. Achieving euvolemia is a challenge in patients with end stage kidney disease (ESKD) on hemodialysis (HD). Blood volume analysis (BVA) uses radiolabeled albumin to determine intravascular blood volume (BV). The measured BV is compared to an ideal BV (validated in healthy controls). We hypothesized that BVA could be used in HD to evaluate the adequacy of the current clinically prescribed “estimated dry weight” (EDW) and to titrate EDW in order to improve overall volume status. We were also interested in the reproducibility of BVA results in ESKD. This is the first longitudinal study of BVA in HD patients.

Methods: 12 adults on chronic HD were recruited; 10 completed the study. BVA (Dxsor, NEXUS Medsys, Virent, USA) was used to measure BV at baseline. EDW was kept the same if the patient was deemed to be euvolemic by BVA otherwise, the prescribed EDW was changed with the aim that measured BV would match ideal BV. A second BVA measurement was done 1-3 months later in order to measure BV again.

Results: Based on BVA, 6/10 patients were euvolemic at baseline and 5/10 were euvolemic at the second measurement. When comparing patients who had their prescribed EDW changed after the initial BVA to those who did not, both groups had similar differences between measured and ideal BV (P=0.75). BV values were unchanged at the second measurement (P=0.34) and there was no linear correlation between BV change and measured change (r=0.07).

Conclusions: This pilot study is the first longitudinal measurement of BVA in HD patients. It revealed that changing weight did not proportionally change intravascular BV. BV remained stable for 1-3 months. BVA may not be helpful in clinically stable HD patients but studies on patients with hemodynamic instability and uncertain volume status are needed.

Funding: Pharmaceutical Company Support - Dxor provided BVA equipment and supplies but was not involved in study design or execution and did not participate in the analysis of data or preparation of the manuscript

FR-PO768
Effects of Physician Payment Reform on Provision of Home Dialysis Kevin F. Erickson, 1 Wolfgang C. Winkelmayr, 2,3 Glenn Matthew Chertow, 1 Jay Bhattacharya, 1,2 Medicine, Stanford Univ, Palo Alto, CA; 3 Medicine, Baylor College of Medicine, Houston, TX.

Background: Patients with end-stage renal disease can receive dialysis at home or in-center. In 2004 the Centers for Medicare and Medicaid Services reformed physician payment for in-center hemodialysis care from a capitated to a tiered fee-for-service model, augmenting physician payment for frequent in-center visits. We evaluated whether payment reform influenced dialysis modality assignment.

Methods: Using a national cohort of patients starting dialysis in the US in the three years before and after payment reform, we conducted difference-in-difference analyses comparing patients with Traditional Medicare coverage (who were affected by the policy) to others with Medicare Advantage (who were unaffected by the policy). We also examined whether the policy had a more pronounced influence on dialysis modality assignment in areas with lower costs of in-center to dialysis services.

Results: Patients with Traditional Medicare coverage experienced a 12% (95% CI, 2% to 21%) reduction in home dialysis use following payment reform compared to patients with Medicare Advantage. Patients living in areas with larger dialysis facilities (where physician-reimbursement reform made in-center hemodialysis comparatively more lucrative for physicians) experienced a 16% (95% CI, 8% to 23%) reduction in home dialysis use following payment reform compared to patients living in areas with smaller facilities (where payment reform made in-center hemodialysis comparatively less lucrative for physicians).

Conclusions: National physician payment reform intended to improve the quality of dialysis care resulted in fewer patients receiving home dialysis. This highlights a major failure of the policy and the importance of considering unintended consequences of future physician payment reform efforts.

Funding: NIDDK, Support: Other NIH Support - Funding: F32 HD019178 from AHRQ (Dr. Erickson); DK085446 (Dr. Chertow); Dr. Winkelmayr receives research support through the endowed Gordon A. Cain Chair in Nephrology at Baylor College of Medicine. Dr. Bhattacharya would like to thank the National Institute on Aging for support for his work on this paper (R37 51027-05-04662-002).

FR-PO769
Characteristics and Outcomes Amongst Patients Who Switch Dialysis Provider Scott Ronel, 1 Paul E. Drawz, 1 Robert N. Foley, 1 Dept of Medicine, Univ of Minnesota, Minneapolis, MN.

Background: Associations between provider switch and inferior clinical outcome have been demonstrated in primary care settings. It is plausible that similar associations extend into those on renal replacement therapy (RRT) as nephrology care often extends beyond that of RRT management alone. There is a paucity of literature available describing the characteristics and outcomes amongst those whom switch dialysis provider.

Methods: Using USRDS data, a change in provider will be defined the presence of any non-continuous facility codes while receiving maintenance RRT. As patients transitioning to maintenance RRT may experience early adverse outcomes, only those patients having initiated RRT with a vintage of at least 1 year were included in the analysis. Means and proportions were calculated for continuous and categorical variables, respectively. Logistic regression was used for adjusted comparisons with adjustments for baseline demographic characteristic including age, sex, and race. All estimates with p-value < 0.05 were considered significant.

Results: Applying these criteria, a total of 187,510 (9.1%) of prevalent patients requiring RRT were identified as having changed provider at least once. The mean age of those who have changed provider (vs. no change) was 41.3 years (vs. 57.3 years), 57% were male (vs. 55.1%), 51.3% were white (vs. 49.1%), diabetes as comorbidity in 29.9% (vs. 26% for diabetic RRT in 10.5% vs. 21.1%), and 23% were on peritoneal dialysis at initiation (vs. 9.75%). Risk of death was lower in those who change provider (OR 0.69: CI 0.68 – 0.70) and odds were higher for both listing for (OR 2.9; CI 2.9 – 3.0) and receipt of renal transplantation (OR 4.1; CI 4.0-4.2).

Conclusions: Patients who switch dialysis providers constitute a distinct population of patients who are younger and lack comorbid conditions frequency observed in those on dialysis. Compared to those who do not switch providers, those who switch are more likely to be listed for and receive renal transplant.

FR-PO770
Effects of Sildenafil on Dialysis Patients with Erectile Dysfunction: A Systematic Review and Meta-Analysis Anawin Sanguanweko, 1,2 Sikarin Upala, 1,2 Internal Medicine, Bassett Medical Center and Columbia Univ College of Physicians and Surgeons, Cooperstown, NY; 3 Preventive and Social Medicine, Faculty of Medicine Siriraj Hospital, Mahidol Univ, Bangkok, Thailand.

Background: Erectile dysfunction (ED) is prevalent in dialysis patients. Sildenafil, a PDE-5 inhibitor, has been shown to be very effective against ED in general population. However, there is some evidence that dialysis patients are resistant to sildenafil treatment. We performed this meta-analysis to evaluate efficacy of sildenafil in dialysis patients with ED compared with control.

Methods: We comprehensively searched the databases of MEDLINE, EMBASE, and Cochrane Databases. The inclusion criteria were published RCT comparing sildenafil to placebo or controls on ED in patients with dialysis. The primary outcome was change in International Index of Erectile Function (IIEF) score. The diagnosisd ED was confirmed with a score of 21 or less in IIEF.

Results: From 153 full-text articles, 3 studies involving 153 dialysis patients were included in the meta-analysis. All included studies were RCT comparing sildenafil with active control in either hemodialysis or peritoneal dialysis patients. A meta-analysis using fixed-effects model was performed. Who received sildenafil had a significant improvement in IIEF with a MD of 10.48 (95% CI: 9.96 to 11.00, p-value<0.01).

Conclusions: This is the first meta-analysis to show that sildenafil is effective in dialysis patients with erectile dysfunction compared with control. Further study comparing other benefits and side effects of PDE-5 inhibitor in dialysis patients should be conducted.

FR-PO771
Validation of Screening Questionnaires for Sleep Apnea in Hemodialysis Population Farhanah Yusof, 1,2 Mitesh K. Patel, 3 Saw H. Mu, 1 Alla Goldberg, 1 Chaim Charytan, 1 Bruce S. Spinowitz, 1 New York Hospital Queens.

Background: Sleep apnea hypopnea syndrome (SAHS) is common in end stage renal disease (ESRD). We investigated the validity of Berlin and STOP-BANG questionnaires against nocturnal oximetry in identifying high risk hemodialysis patients for SAHS.

Methods: After obtaining local IRB approval, adult hemodialysis patients who were undergoing regular chronic hemodialysis for at least 3 months were consented and asked to complete Berlin and STOP-BANG questionnaires. Nocturnal oximetry from hemodialysis night using Pulsox 300i wristwatch was also completed. The saturation recordings were downloaded and analyzed using Profox software. The first hour of recording was deleted in effect. The oximetry recordings from sleep times were analyzed. Desaturations and alternating desaturations were also excluded from analysis. Oxygen desaturation index (ODI) was defined as the number of desaturations £ 3% from baseline lasting ≥ 10 seconds, per hour. Sensitivity, specificity, positive and negative predictive values were calculated for the Berlin and STOP-BANG questionnaires.

Results: Twenty HD patients (11 males and 9 females) aged 54 ± 13 years with a mean body mass index of 25.7 ± 4.6 kg/m² and neck circumference of 38.4 ± 5.8 cm participated in the study. ODI was ≥ 5 in 80% of patients. Both Berlin and STOP-BANG questionnaires had modest sensitivities (69-71%) but poor specificities (17-50%). Positive predictive value and negative predictive value was 67% and 67% for Berlin questionnaire, respectively. STOP-BANG questionnaire had a positive predictive value of 85% and a negative predictive value of 29%.

Conclusions: Reliable screening tools for SAHS in ESRD population are limited. Both Berlin and STOP-BANG questionnaires lack specificity to be utilized in this setting. Additional studies are warranted to elaborate the role of screening questionnaires for SAHS in end stage renal disease population.
Results: We collected data of 22 HD patients (55% males, 86% black, age 54±10 years). Median steps walked were 7,584±5,429 (Table 1). 36% of patients were sedentary, walking less than 5,000 steps per day. Patients walked 2,000 steps less on Sundays compared to the rest of the week (P<0.0001). Slightly more steps were taken on HD days. Patients slept less than 6 hours, which was significantly less than the NIH recommendation of 7 hours (P<0.0001). Sleep efficiency was 80±14%, significantly less than 85%, the lower limit of what is defined as poor sleep quality (P<0.05). When asked to what extent they agreed with the statement “I have walked more than usual”, 36% replied “not at all”, 23% replied “somewhat” or “moderately”, and 41% replied “definitely” or “most definitely.”

Table 1

<table>
<thead>

Using Decision Tree Analysis to Identify Risk Factors for Functional Impairment in Hemodialysis Patients J. B. Chen, Div of Nephrology, Kaohsiung Chang Gung Memorial Hospital and Chang Gung Univ College of Medicine, Kaohsiung, Taiwan.

Background: Hemodialysis (HD) patients frequently developed functional impairment. The study used decision tree analysis to identify risk factors for functional impairment in HD patients.

Methods: A total 1166 maintenance HD patients were enrolled in one hospital-based HD center. The observational period was from 2009 to 2013. Karnofsky Performance Status Scale (KPS) was used to quantify functional status. KPS assessment was based on HD patient’s visit yearly for consecutive five years. High KPS score was defined as >80 and low score as <80. Decision tree analysis was used to analyze odds ratio (OR) of functional impairment from variables in demographics, laboratory test and primary renal disease classification.

Results: Subjects (853) with high KPS scores demonstrated significantly younger age (58.2 vs 71.3 years), longer HD duration (7.2 vs 4.7 years), higher nutritional indices, higher Kt/V (1.65 vs 1.59) and lower cardiothoracic (CT) ratio compared to subjects (313) in low KPS scores. A total 3509 KPS values were collected. 2697 (76.9%) values belonged to high functional scores, 812 (23.1%) values in low functional scores. The first variable chosen by decision tree analysis to split the data was age (67.5 years). There were six leaf nodes and twenty-eight subgroups. In age = 67.5 years group, the orders of consecutive chosen were serum albumin level (5.37 g/dL, OR 27.35, p=1.77E-199), Cr level (<8.39 mg/dL, OR 39.40, p=3.0E-37), HD duration (5.95 yr, OR 39.40, p=1.6E-27), ferritin (>164.5 mg/mL, OR 26.26, p=2.06E-13), P level (>5.35 mg/dL, OR 9.28, p=8.88E-24), Hb level (>10.85 g/dL, OR 0.89, p=1.00). In age ≤67.5 years group, the orders of consecutive chosen were primary renal disease classification, Cr level (10.43 mg/dL, OR 11.23, p=2.1E-72), age (55.8 years, OR 0.96, p=0.06), JPH level (>150 mg/dL, OR 0.44, p=0.07), CT ratio (>0.34, OR 11.16, p=9.17E-35).

Conclusions: By decision tree analysis, age was the main risk factor for functional impairment in HD patients. Overall, the weight contribution of different risk factors for functional impairment in HD patients were identified by decision tree analysis.

Working Patients and Years on Dialysis: A Review Deborah S. Evans, 1 Diane V. Dunn, 1 Martha Donahue, 1 Laura M. Stewart, 2 Rich Mullet, 2 Paul J. Broughton, 1 Allen R. Nissen, 2 Deborah A. Benner, 1 1 DaVita HealthCare Partners Inc, Denver, CO; 2 Apex Health Innovations, Simi Valley, CA.

Background: Unemployment rates are high among dialysis patients; a 2011 study found approximately 71% of working-age dialysis patients are unemployed. Another study found that dialysis negatively impacts employment status and has the largest effect between dialysis years 1 and 2. We examined whether prolonged dialysis (dialysis vintage) affected employment status.

Methods: Dialysis vintage data and mean age were obtained from a sample of 16,069 employed patients from a large dialysis organization (Nov 2014-April 2015). Employment status was defined as regular full-time (<30 hrs/wk), regular part-time (<30 hrs/wk), and per diem (<34 hrs/wk).

Results: Regular full-time employed patients were older (52.6 yrs) than part-time (49.1 yrs) and per diem (49.0 yrs) patients. Employment status was highest among all patients for all categories of employment during year 1 of dialysis (35.7%) and dropped significantly by year 2 (14.4%) [Table]. Employment status continued to drop as vintage...
Conclusions: Our study found that dialysis vintage negatively impacts employment status and has the largest effect between years 1 and 2. Further study is needed to reveal if a window of opportunity exists toward this, so that these patients should alert dialysis staff that support and intervention may be needed to help patients stayed employed. References: 1) Musherr RJ et al. Clin J Am Soc Nephrol. 2011;6(3):489-496. 2) van Manen JG et al. Perit Dial Int. 2001;21(6):595-601.

FR-PO777

Response Rate of Hepatitis B Virus Vaccination in Various Stages of Chronic Kidney Disease

So Mi Kim, Eun kyong Lee, Yun Jung Oh. Division of Nephrology, Dept of Internal Medicine, Jeju National Univ Hospital, Jeju, Jejudo, Republic of Korea.

Background: Although hepatitis B virus (HBV) vaccination is recommended for all dialysis patients, the response rate of HBV vaccination in dialysis patients is very low. Therefore, we tried to investigate the necessity of early HBV vaccination in pre-dialysis patients analyzing the response rate of vaccination in various stages of chronic kidney disease (CKD).

Methods: A total of 87 patients in 3 different stages of CKD was enrolled in this study. Patients in stage 3 (n=30) and 4 (n=28) were received the HBV vaccine as standardized schedule, consisting of 1 mL of the recombinant vaccine, Hepavax-gene TF at 0, 1, and 6 months. And then, the patients with stage 5 (n=29) were received the same vaccine for dosing doses of at 0, 1, 2, and 6 months. Three months after each of the last vaccination, serum level of Anti-HBs was measured in all patients.

Results: There was no significant difference in baseline characteristics including age, sex, presence of DM among the 3 groups. The overall seroconversion rate after vaccination was 79.4%. The seroconversion rate was significantly higher in patients with stage 3 than other patients (stage 3: 94%, stage 4: 79%, stage 5: 66%, p<0.01). Analyzing based on dialysis, seroconversion rate was also significantly higher in pre-dialysis patients than in dialysis patients (pre-dialysis group: 86%, dialysis group: 63%, p=0.02). There was no significant factor to contribute seroconversion in multivariate analysis.

Conclusions: Our study showed the high seroconversion rate after HBV vaccination in CKD patients with stage 3 and pre-dialysis. Therefore, the HBV vaccination should be considered in early CKD stages.

FR-PO779

Outbreaks of Hepatitis C Virus Infection Reported in U.S. Hemodialysis Facilities, 2008-2014

Background: Hepatitis C virus (HCV) infection is more prevalent among hemodialysis (HD) patients than the general population. HCV transmission of in dialysis units may contribute, and is difficult to detect due to lack of symptoms and systematic screening. We summarized HCV outbreaks reported to CDC to characterize their frequency and factors contributing to transmission in HD facilities.

Methods: We defined a healthcare-associated outbreak as \( \geq 2 \) new HCV infections among HD patients within a 1-3 month window and/or a 10% increase in the number of HCV infections in the HD unit. We identified 14 outbreaks in 13 HD units across the United States from January 1, 2008 to December 31, 2014 (8 outbreaks were reported to the CDC). The median number of patients infected per outbreak was 5 (range 2-11). Median time to outbreak recognition was 1 month (range 1-5 months).

Results: The disease burden of HCV+ pts on HD includes a greater likelihood of experiencing anemia requiring transfusion. The reasons for this are unclear but may include gastrointestinal blood loss due to portal hypertension as well as hypersplenism. Anemia may contribute to a reluctance to initiate antiviral therapy for HCV infection. Hypertension and electrolyte abnormalities are known risk factors that increase morbidity and mortality in patients with End Stage Renal Disease. Adherence to medications is a major issue for patients on Hemodialysis therapy. Increasing the number of visits per month with the Nephrologist more frequently.

Conclusions: Hypertension and electrolyte abnormalities are known risk factors that increase morbidity and mortality in patients with End Stage Renal Disease. Adherence to medications is a major issue for patients on Hemodialysis therapy. Increasing the number of visits per month with the Nephrologist during Hemodialysis sessions increases adherence to a renal diet, medication use and patient satisfaction.
medication handling (3), separation of clean and contaminated workspaces (2), and vascular access care (1). Multiple lapses were identified in 7 outbreaks. No specific infection control lapses were identified at the time of the investigation in 2 outbreaks.

Conclusions: Outpatient hemodialysis clinics remain a common setting for healthcare-related HCV outbreaks. Infection control lapses were frequently identified in reported outbreaks. Rigorous adherence to recommended infection control practices is needed to protect patients and prevent future outbreaks in this setting.

FR-PO781
Influenza and Outcomes in ESRD Patients
David T. Gilbertson,1 Anne C. Beaubrun,2 Kenneth J. Rothman,1 Jiannong Liu,1 Brian D. Bradbury,1 Akhtar Ashfaq,1 Charles A. Herzog,2 Allan J. Collins,1 Chronic Disease Research Group, MMRF; 2Ctr for Observational Resrch, Amgen; 3RTI Health Solutions.

Background: Yearly influenza vaccination is recommended for all ESRD patients, due to a high risk of influenza-related complications. Through the CDC’s Outpatient Illness Surveillance, information on patient visits to health care providers for influenza-like illness (ILI) is collected. These data give estimates of the percent of all OP visits that are for presumed influenza, and give national information on timing and severity of each influenza season. We assessed the association between CDC ILI data and outcomes in ESRD patients.

Methods: We aggregated weekly ILI data from 2000-2012 to monthly, and calculated the monthly number of deaths and hospitalizations among US ESRD patients during the same time period. Using time series decomposition, we subtracted out seasonal and trend components from both series, and computed correlations between the ILI and mortality/hospitalization data.

Results:

The figure displays deaths and ILI data after removing seasonal and trend components. There were 2 influenza seasons (2003-2004 and 2009-2010) during this time period where the peak was at the end of the calendar year (early in the influenza season) instead of at the beginning of the next calendar year. Similar “early” peaks are seen in deaths among ESRD patients. There is also correlation between other peaks and valleys of the ILI data and ESRD deaths; correlation coefficient r = 0.63. Correlations were also calculated with case-specific hospitalizations: 0.69 for ILI-influenza/pneumonia; 0.42 for ILI-any infection; 0.16 for ILI-MI; and 0.02 for ILI-stroke.

Conclusions: The association between ILI and outcomes in ESRD patients is strong. While influenza vaccination rates among ESRD patients have improved over the last decade, the overall rate is still below 70%, suggesting room for further improvement.

FR-PO782
The Burden of Pneumonia in Patients Receiving Dialysis: Incidence, Case Fatality, and Costs to Medicare
Scott Sibbel,1 Reiko Sato,2 Abigail Hunt,1 Wendy Tureume,1 Steven M. Brunelli,3 DaVita Clinical Research, Minneapolis, MN; Pfizer Inc, Collegeville, PA.

Background: End-stage renal disease patients receiving dialysis are at particular risk for infection. We assessed the clinical and economic burden of pneumonia in a population of Medicare-enrolled ESRD patients with respect to incidence and case fatality rates, rates of all-cause hospitalization, and costs.

Methods: Patients included in the analysis received dialysis between 01 Jan 2009 and 31 Dec 2011, and were enrolled in Medicare Parts A and B. Pneumonia episodes were identified from institutional and supplier claims. Patients were considered at-risk from the first date of Medicare coverage and were censored from the analysis upon transplant, withdrawal from dialysis, recovery of renal function or death. Linear mixed effects models were used to assess hospitalization rates and costs over the 3 months prior to and 12 months following a pneumonia diagnosis.

Results: The pneumonia incidence rate for the study period was 21.4 events/100 patient-years with the majority of episodes (90.1%) requiring inpatient treatment. The 30-day case fatality rate was 10.7%; case fatality rates were higher for older patients and for pneumonia requiring inpatient treatment (11.2%). All-cause hospitalization rates were greater in the month of the pneumonia episode vs month -3 prior to diagnosis (IRR, 4.61; 95%CI: 4.46, 4.76) and remained higher than baseline over the 1-year follow-up period. Mean per patient per month costs were $10,976 (95% CI: $10,717, $11,275) higher in the month of the index episode compared to month -3, largely driven by increased inpatient costs, and remained elevated through end of follow-up.

Conclusions: Pneumonia episodes are frequent among ESRD patients and result in hospital admissions and greater overall costs to Medicare (~$20,000 incremental) over the following year.

FR-PO783
Opioid Use Associates with Infection Related Morbidity and Mortality in Hemodialysis Patients
Abhijit V. Kahrirasur,1 Diane Reams, Madageline M. Assimon, Anne Mobley Butler, Jennifer E. Flythe, M. Alan Brookhart, Univ of North Carolina at Chapel Hill.

Background: Opiates are frequently prescribed for pain in the US hemodialysis (HD) population but have intrinsic properties that increase risk of infection, a common cause of morbidity and mortality for patients. Data regarding the association of opioids with infection are lacking.

Methods: We conducted a retrospective cohort study using data from a large national dialysis provider linked with the United States Renal Data System and Medicare Part D (2006-2010). We used a new user design – comparing only new users of opioids to new users of prescription non-steroidal anti-inflammatory drugs (NSAIDs) to address confounding, as well as excluding patients with cancer, use of hospice services, or use of > 1 opiate. We assessed treatment effects on infection-related morbidity and mortality using inverse probability of treatment weighted Kaplan-Meier methods, adjusting for many comorbid, lab, and clinical variables.

Results: 5,113 patients met entry requirements, of which 3,439 (67.3%) received an opioid. Relative to new NSAID users, new opioid users had similar baseline laboratory values, but were slightly younger, and had a higher prevalence of comorbidities, including recent infections (8.7% vs 6.8%), diabetes (52.3% vs 49.3%), and chronic obstructive pulmonary disease (COPD), 17% vs 12.2%. After multivariable adjustment, we observed treatment effects on infection-related morbidity and mortality using inverse probability of treatment weighted Kaplan-Meier methods, adjusting for many comorbid, lab, and clinical variables.

Funding: Other U.S. Government Support
 Associations Among Psychosocial/Medical Factors and Quality of Life in Hemodialysis Patients with End-Stage Renal Disease

Gun woo Kang, Internal Medicine, Catholic Univ of Daegu School of Medicine, Daegu, Korea.

Background: Patients with end-stage renal disease (ESRD) have a significant impact on quality of life (QoL). Most previous studies have focused on medical factors mainly. However, quality of life can also be affected by psychosocial problems in the circumstances of chronic illness. The aim of this study was to identify the associations among psychosocial factors, medical factors and QoL in hemodialysis (HD) patients.

Methods: The study included 101 patients with ESRD who were undergoing HD (mean age 57.1 ± 1.2 years). Psychosocial factors were evaluated using the Hospital Anxiety and Depression Scale (HADS), Multidimensional Scale of Perceived Social Support (MPSS), Montreal Cognitive Assessment and Pittsburgh Sleep Quality Index. In addition, for evaluating caregivers’ burden in part of psychosocial factors, HADS and Zarit Burden Interview of main caregivers were administered. We also assessed medical factors (Kt/V and urea reduction ratio, etc.) with laboratory results (body mass index, albumin, hemoglobin, etc.). The QoL was evaluated using WHO Quality of Life-BREF (WHOQOL-BREF). Canonical correlation analysis was used to investigate the patterns of associations.

Results: The canonical correlation between psychosocial factor and QoL was significant. The first canonical correlation was 0.673 (p = 0.060, p = 0.001) and the second was 0.519 (p = 0.060, p = 0.006). However, the canonical correlation between medical factor and QoL was not significant (the first: p = 0.586, the second: p = 0.713).

Conclusions: The QoL of patients with ESRD was not associated with medical factor, but psychosocial factor in canonical correlation analysis. This finding may suggest that medical workers should recognize and treat psychosocial problems as well as clinical problems. We also would like to emphasize the comprehensive approach with cooperation between psychiatrists and nephrologists for improvement of QoL in ESRD patients.

FR-PO787

Longitudinal Associations of Dietary Protein and Energy Intake with Protein-Energy Wasting Syndrome in Hemodialysis Patients

Srini Reddi,1,2 Xiaoxun Chen,1 G. Wei,1 Robert E. Boucher,1 Dominique Ferranti,1 Kalani L. Raphael,1,2 Tom Greene,1 Michel Chonchol,1 U of Utah; 2VA SLIC; 3UC Denver.

Background: Low dietary protein intake (DPI) (<0.6 g/kg/d) and low dietary energy intake (DEI) (<25 kcal/kg/day) are included in the definition of protein-energy wasting (PEW) syndrome. Therefore, we examined the longitudinal associations of baseline DPI and DEI with PEW syndrome (defined by modified criteria that excludes dietary variables) at 1 year of follow-up in 1480 MHD pts in the HEMO Study.

Methods: DPI and DEI were obtained by 24-h dietary recall. PEW syndrome at month 12 was defined as the presence of 2 out of the 3 criteria: serum chemistry (albumin by BCP method < 3.5 g/dl or cholesterol < 100 mg/dl), body weight (BMI < 23 kg/m² or wt loss > 10% over 1 yr), and muscle mass (mid-arm muscle circumference 10% or more than the 50th percentile of reference population). PEW syndrome at month 12 was related to baseline DPI and DEI in logistic regression models.

Results: 17.4% had PEW at month 12. The prevalence of PEW syndrome at month 12 by baseline DPI and DEI quartiles are summarized in the figure.

Conclusions: The associations of baseline DPI and DEI with PEW syndrome at month 12 in logistic regression models are summarized in table.

*Each cell represents a separate logistic regression model.  Adjusted for demographics, ESRD duration, Kt/V group, race, gender, smoking, and alcohol use, & adjusted for above plus diabetes, CAD, CVD, PVD, CHF and anemia.

**Conclusions:** The contrarian finding of lower risk of PEW in those with low DEI and DPI could reflect mathematical coupling (as both DEI and DPI include body wt in the denominator and those with PEW have lower body wt).

**PEW Syndrome, Inflammation and Mortality in Hemodialysis Patients**

Srimi Beddhu,1 Xiaorui Chen,1 G. Wei,1 Robert E. Boucher,1 Dominique Ferranti,1 Kaliyi L. Raphael,1 Tom Greene,1 Michel Chonchol,1 1U of Utah; 2VA SLC; 3UC Denver.

**Background:** The term ‘malnutrition-inflammation complex syndrome’ implies that malnutrition and inflammation are tightly interlinked. Therefore, we examined whether the mortality associations of markers of inflammation and protein-energy wasting syndrome (PEW) are attenuated by each other in 906 maintenance hemodialysis (MHD) patients in the HEMO Study, a multi-center RCT that examined the effects of dialysis dose and dialyzor flux on mortality.

**Methods:** High sensitivity Creative Protein (hsICRP), tumor necrosis factor (TNF)-a and interleukin (IL)-6 were measured in the month 12 stored samples. Weight loss was estimated from baseline and month 12 post-dialysis weights and hence, PEW syndrome was defined as the presence of 2 out of 3 criteria: serum chemistry (albumin estimated from baseline and month 12 post-dialysis weights and hence, PEW syndrome) and IL-6 and IL-6 with subsequent mortality.

**Results:** Mean age was 57 ± 14 yrs, 45% were women. 67% were black. PEW syndrome was present in 17.4% at month 12. Median (IQR) serum hsCRP was 6.3 (2.6-16.4) mg/L, IL-6 3.3 (2.0-7.6) pg/mL, and TNF-a 31.2 (21.3-46.1) pg/mL. There were 388 deaths over 2189 years of follow-up. PEW syndrome had 2 fold higher risk of mortality which was only marginally attenuated by adjustment for markers of inflammation (table). CRP and IL-6 were associated with higher mortality risk independent of PEW. TNF-a was not associated with mortality.

**Conclusions:** PEW and inflammation are independent predictors of mortality. These results suggest PEW and inflammation might not be tightly interlinked.

FR-PO790

**Association of Pre-Transplant Dialysis Modality and Post-Transplant Outcomes: A Meta-Analysis**

Emily Joachim,1 Ali I. Gardezi,1 Sudheer Mudugunti,1 Sana Wahbe,1 Jung-Im Shin,1 Brad C. Astor,1 Micah R. Chan,1 1Univ of Wisconsin School of Medicine and Public Health, Madison, WI.

**Background:** Patients who undergo dialysis prior to renal transplant have overall worse outcomes than patients who receive a preemptive transplant. However, individual studies give conflicting results regarding whether post-transplant outcomes differ based on pre-transplant dialysis modality (peritoneal dialysis (PD) versus hemodialysis (HD)).

**Methods:** We searched English-language literature from January 1, 1980 through August 31, 2014, national conference proceedings and reference lists of all included studies. We used combinations of terms related to dialysis (hemodialysis, peritoneal dialysis, or renal replacement therapy), kidney transplant and outcomes. Studies were included if they measured post-transplant patient mortality for both pre-transplant HD and PD. Studies were excluded if they were not in English or if they included pediatric patients.

**Results:** A total of 15 studies reported five-year patient mortality. These included 166,531 patients on HD and 51,980 patients on PD pre-transplant. The pooled hazard ratio for five-year patient mortality after renal transplant was 0.91 (CI 0.85-0.97) in favor of pre-transplant PD over HD (p=0.006).

**Conclusions:** Distance is an important factor in patient decision-making when initiating PD, particularly for those living farther away from commonly offered HD services. Analyses of treatment selection must appropriately model distance to reflect logistics of treatment options and service availability to patients.

**Funding:** NIDDK Support, Other U.S. Government Support

FR-PO791

**Impacts of Geographic Distance on Peritoneal Dialysis (PD) Utilization: Refining Models of Treatment Selection**

Virginia Wang,1,2 Matthew L. Maciejewski,1,2 Cynthia Coffman,1,2 Linda L. Sanders,1 Shou-Wei D. Lee,1 Richard Hirth,1 Joseph M. Messana,1 1Duke Univ, Durham, NC; 2Duke VA Med Ctr, Durham, NC; 3Univ of Mich, Ann Arbor, MI.

**Background:** Proximity to dialysis services may ease patient travel burden. Different frequency of visits to dialysis facilities and resulting differences in travel distance may affect patients’ selection of hemodialysis (HD) versus PD. PD has historically been less common and the least available in dialysis facilities and less commonly used than HD. We refine methods of prior research to reassess the relationship between patients’ distance to dialysis care and modality choice to better reflect the conditions of patients’ choice set of providers, location (absolute distance) and available services (relative distance).

**Methods:** Retrospective cohort of 70,131 patients initiating dialysis and 4,795 dialysis facilities in 2006 using USRDS data. The primary outcome was patient PD use. Independent variables included absolute distance from patients’ home to nearest HD facility, relative distance dichotomized as the nearest PD facility closer or same distance as nearest HD facility, and their interaction. Logistic regression was used to model distance on PD use, controlling for patient and market factors.

**Results:** 9% of new dialysis patients used PD in 2006. There was a positive, non-linear relationship between absolute distance to closest HD services and PD use (p=0.006). In terms of relative distance, odds of PD increased if a PD facility was closer or the same distance as the nearest HD facility (p=0.006). The interaction of absolute and relative distance was not significant.

**Figure:** 1. Predicted Odds of PD Utilization. Estimated odds ratios and 95% confidence limits comparing absolute distance to closest HD facility to less than 1.5 miles or more than 12 miles to closest PD facility in either the home or their second HD facility (distance to closest PD facility was either shorter or longer than closest HD facility).

There was moderate heterogeneity among these studies (I²=41.4%, p=0.05). Six studies included an adjusted risk ratio (RR); the pooled RR for these studies was 0.89 (CI 0.82-0.97) in favor of PD (p=0.006). There was significant heterogeneity among these six studies (I²=72.7%, p=0.003).

**Conclusions:** Based on these results, pre-transplant peritoneal dialysis is associated with better post-transplant survival at five years compared to hemodialysis. Further work should explore potential reasons for this difference and compare additional outcomes such as graft survival, delayed graft function and rejection.

Impact of Poverty and Health Care Insurance on Pre-End Stage Renal Disease Care in Dialysis Patients

Robert Nee, 1 Lawrence Agodaa, 2 Kevin C. Abbott. 1  
  
1 Nephrology, Walter Reed National Military Medical Center, Bethesda, MD; 2 NIDDK, National Institutes of Health, Bethesda, MD.  

Background: Access to nephrology care prior to end-stage renal disease (ESRD) is significantly associated with lower rates of morbidity and mortality. We assessed the association of area and individual-level indicators of poverty and types of health care insurance on pre-ESRD care provided by nephrologists.  

Methods: In this retrospective cohort study using the United States Renal Data System database, we identified 739,537 patients initiated on maintenance dialysis from January 1, 2007 through December 31, 2012. We assessed the Medicare-Medicaid dual eligibility status as an indicator of individual-level poverty and ZIP code-level median household income (MHI) data obtained from the 2010 United States Census. We conducted multivariable logistic regression of pre-ESRD care as the outcome variable, as reported on the Centers for Medicare and Medicaid Services Form 2728.  

Results: The proportions of dual-eligible and non-dual eligible patients who had pre-ESRD care were 53.06% and 61.82%, respectively (p<0.001). Dual-eligibility was associated with significantly lower likelihood of pre-ESRD care (adjusted odds ratio [aOR] 0.85, 95% confidence interval [CI] 0.84-0.86) compared to those in higher quintile levels. Both African American (AA) and Hispanic patients were significantly less likely to have received pre-ESRD care (aOR 0.85, 95% CI 0.84-0.86 and aOR 0.71, 95% CI 0.70-0.72, respectively). Interaction terms for dual eligibility and AA race and Hispanic ethnicity were significant (p<0.001 and p=0.002, respectively).  

Conclusions: Individual and area level measures of poverty were independently associated with lower likelihood of pre-ESRD care. Efforts to improve pre-ESRD nephrology care may require focusing on the poor and minority groups. [Disclaimer: The views expressed in this paper are those of the authors and do not reflect the official policy of the Department of the Army, Department of the Navy, Department of Defense, or the Department of the Air Force, respectively). Interaction terms for dual eligibility and AA race and Hispanic ethnicity were significant (p<0.001 and p=0.002, respectively).]  

Diabetes, Black Race, Female: Risk Factors for Hospitalization After Dialysis Start in a Nationwide Cohort Sample

LaTonya J. Hickson, 1 Bjero Thorsteinssottir, 2 Priya Ramar, 3 Jordan K. Roseddhi, 1 Cynthia S. Crowson, 2 Robert C. Albright, 1 Nan-Hwa Yayhon Jones, 1 Rozalina G. McCoy, 2 Suzanne M. Norby, 1 Andrew D. Rule, 1 Amy W. Williams, 1 Nilay D. Shah. 1  

1 Nephrology and Hypertension, Mayo Clinic, Rochester, MN; 2 Mayo Clinic Kern Center for the Science of Health Care Delivery, Mayo Clinic; 3 Primary Care IM, Mayo Clinic; 4 Pediatrics, Cincinnati Children’s Hospital Medical Center, Cincinnati, OH.  

Background: Young dialysis patients have a high frequency of hospitalizations and readmissions. Multiple factors likely contribute to this occurrence, but have not been fully elucidated.  

Methods: Young, incident dialysis patients aged 20-44 years included in the US Renal Data System with first dialysis service in 2005-2011. Multivariable multinomial logistic regression models examined associations and interactions between baseline predictors and hospitalizations through claims in the first 3-15 months; all p-values <0.05.  

Results: For 46,895 patients (mean age: 36; 58% male; 46% black, 48% white, 4% asian; 2% other race, 41% with diabetes, 23% with Charlon score=4), mean hospitalization rate was 2.3 per year. Subgroups for low to high utilizers included: 0 (46%), >0-4 (25%), >4-10 (20%) and >10 (10%) per year. Compared to the 0 hospitalization group, the >10 group had more females (48% vs 39%), more blacks (51% vs 45%), fewer Asians (2% vs 5%), more diabetics (52% vs 34%), more with Charlson score>4 (41% vs 14%). Diabetics were more likely to be high utilizers (odds ratio [OR] 1.98 (1.84, 2.14) adjusting for age (OR 1.30 (1.23, 1.37) per 10 year decrease; sex (OR 1.23 (1.15, 1.32) females vs males), black race (OR 1.24 (1.16, 1.34) blacks vs whites). Charlson score ≥4 were also more likely to be high utilizers (OR 7.06 (5.82, 8.47) vs Charlson score 0-1), with higher comorbid females having nearly twice the risk as highly comorbid males (OR: 12.62 x 6.23, interaction p<0.001) when compared to low comorbid males.  

Conclusions: Hospitalizations are frequent among young incident dialysis patients, particularly among diabetes, blacks, females, and those with multiple comorbidities. Further investigation into socioeconomic factors and causes of hospitalizations is needed to clarify these findings for targeted interventions.  

Development and Validation of the Charlson Comorbidity Scoring System for Korean Incident Peritoneal Dialysis Patients

Hyeunjung Cho, 1 Myoung-Hee Kim, 1 Seung Seok Han, 1 Jae Yoon Park, 1 Hyunjin Ryu, 1 Hyo Jin Kim, 1 Dong-Ryeol Ryu, 1 Hajeong Lee, 1 Jung Pyo Lee, 1 Chun Soo Lim, 1 Kook-Hwan Oh, 1 Kwon Wook Joo, 1 Yon Su Kim, 1 Dong Ki Kim. 1  

1 Internal Medicine, Seoul National Univ College of Medicine, Seoul, Korea; 2 Dental Hygiene, College of Health Science, Eulji Univ, Gyeonggido, Korea; 3 Internal Medicine and Ewha Medical Research Inst, School of Medicine, Ewha Womans Univ, Seoul, Korea; 4 Internal Medicine, Seoul National Univ Boramae Medical Center, Seoul, Korea.  

Background: The Charlson Comorbidity Index (CCI) has widely used for predicting mortality. In the validation cohort, both the CCI and the mCCI-IPD were correlated predicted mortality. Thus, the mCCI-IPD included 11 comorbidities with re-assigned severity weights. In the validation cohort, the mCCI-IPD improved net mortality risk reclassification by 30.8% (95% CI, 7.6-54.1; p=0.001).  

Methods: We performed a single center, prospective, observational study. Electronic case notes were used to extract data including cause of death, age at initiation of RRT, age of death, dialysis vintage (DV), gender and presence of DM. Patients were excluded if RRT was less than 90 days, or if they were transplanted.  

Results: In total 3431 patients commenced RRT during the study period, 802 patients died, 364 were C, 259 IA and 178 were AC. There were no significant differences between the groups (age at initiation, DV, and age of death. Significantly fewer IA died during the follow up period compared to C (p<0.0001) and AC (p<0.0001). More IA and AC were diabetic (p<0.0001). Cardiovascular deaths were more common in C and AC patients compared to those of IA race (p<0.0001). IA had higher sepsis related deaths when compared C or AC (p<0.0001).  

Conclusions: Despite the increased prevalence in DM, IA patients do not have worse survival outcomes or cardiovascular deaths compared to C and AC. We believe that the elevated sepsis related mortality in IA patients is secondary to the higher prevalence of diabetes. This data enables stratifying management therapies dependent on race and may help in designing cardiovascular end points trials in racially diverse group of patients.

FR-PO795
Association of Dialysis Provider Assignment with Early Dialysis Mortality in U.S. Veterans: A Transition of Care in CKD Study
Elani Streja, 1 Melissa Soochoo, 1 Connie Rhee, 1 Vanessa A. Ravel, 1 Joline L.T. Chen, 1 Jennie Jing, 1 Csaba P. Kovesdy, 1 Kamary Kalantar-Zadeh. 1 UCI Irvine; 1 UTHSC.

Background: Mortality is high during the first months after initiating kidney replacement therapy including in US veterans. Only 10% of veterans receive dialysis therapy in a Veterans Administration (VA) based healthcare dialysis clinic and the majority of veterans are assigned to non-VA centers and dialysis chains.

Methods: We examined all-cause mortality during the 3, 6, 12 and 24 month periods after transition in a cohort of 52,158 US veterans who transitioned to ESRD over 4 years (10/2007-9/2011) and the association of dialysis provider assignment. Baseline provider was determined by facility information and divided into 5 categories: DaVita(DV), Fresenius(FR), Other Chain(OC), Non-Chain(NC), and VA. Associations were examined in Cox proportional hazard models and adjusted for age, gender, race, ethnicity, initial vascular access and primary cause of ESRD.

Results: Upon dialysis transition, patients were 70(±12) yrs old, 6% female, 25% African-American, 19% initially used AV fistula and 42% had diabetes as the cause of ESRD. At baseline, 24%, 28%, 13%, 21%, and 10% of veterans received treatment at DV, FR, OC, NC, and VA facilities, respectively. Over the first 3, 6, 12 and 24 mos after transition, 548(1%), 9283(18%), 14339(27%), and 21607(42%) veterans died, respectively (Figure left). Compared to patients initiating treatment at the VA, all patients receiving treatment at other facilities had higher risk of mortality throughout all periods of follow-up, after adjusting for case mix covariates (Figure right).

Conclusions: Veterans transitioning to dialysis treatment in a VA hospital based dialysis center have the best survival over the first 2 years of follow up. Whether the better survival of VA dialysis care is from selection bias versus true superior care in the VA system warrants additional studies.

Funding: NIDDK Support

FR-PO796
Time-Varying Racial/Ethnic Differences in Mortality After Initiation of Dialysis in U.S. Dialysis Patients
Guofen Wang, 1 Keith C. Norris, 1 Alison J. Yu, 2 Tom Greene, 3 Jennie Z. Ma, 1 Wei Yu, 1 Alfred K. Cheung. 4 'Univ of Virginia; 1 UCL; 3 Univ of Southern California; 4 Univ of Utah.

Background: While survival advantage for African Americans (AAs) and Hispanics, compared to Whites, has been observed for decades, our understanding of the mechanism is still incomplete. Using national dialysis patients, we examined whether this survival advantage exists across the entire course of ESRD or just within a certain time interval after initiation of dialysis.

Methods: The study included 1,255,640 adult incident dialysis patients between 1995 and 2010 in the USRDS. We calculated age-specific hazard ratios (HRs) of death for AAs and Hispanics vs. Whites, adjusted for covariates, for every 6-month interval in the first 4 years of dialysis and for the period thereafter.

Results: For each age group above 40 years (Table), lower risk of death for AAs than Whites (HR<1) did not vary greatly across these time intervals. In contrast, in each age group under 40 years, the HR for AAs vs. Whites evolved over time, which was highest in the first year, declined in the second year, and reached stable over time. Hispanics exhibited lower mortality risks in all age groups that remained relatively constant over time (not shown).

Table. Adjusted HRs for AAs vs. Whites

FR-PO797
Real Threat of ESRD in China: A Ten-Year Experience from Nanjing 3 Million Insurance Covered Population
Yun-Chen Han, 1 Ling Sun, 2 Han-Ming Huang, 1 Kun Ling Ma, 1 Bei Wang, 1 Bi-Cheng Liu. 2 Zhongda Hospital, Southeast University School of Medicine, Nanjing, Jiangsu, China; 3Nanjing Municipal Human Resources and Social Security Bureau, Nanjing, Jiangsu, China; 1Southeast Univ School of Public Health, Nanjing, Jiangsu, China.

Background: In the past decade, Chinese government has made great efforts to provide an affordable and equitable access to renal replacement therapy (RRT) for most of ESRD patients. Here we analyzed the ten years registry data of 3 million Nanjing Urban Employee Basic Medical Insurance (UEBMI) covered population and firstly provided the epidemiological data about ESRD in this developing country.

Methods: Using the electric registry system of UEBMI, we included all subjects insured by UEBMI in Nanjing from 2005 to 2014, and identified subjects who developed ESRD in this cohort. The prevalence and incidence of ESRD was analyzed based on this unique data system.

Results: During the 10-year period, the incidence rate of ESRD in UEBMI cohort in Nanjing gradually declined from 289.3/1000 in 2005 to 218.8/1000 in 2014. However, the prevalence rate increased steadily from 891.7/1000 in 2005 to 1228.6/1000 in 2014. The annual mortality rate declined from 138.4 per 1000 patient-years in 2005 to 97.8 per 1000 patient-years in 2014. Long-term survival rate of ESRD fluctuated during the past decade, with 1-year survival rate ranging from 85.1% to 91.7%, 3-year survival rate from 69.9% to 78.3% and 5-year survival rate from 58% to 65.4%.

Conclusions: This study firstly provided an epidemiological data about ESRD based on the complete electric registry data system in large population in China. Due to the lack of a national complete registry data system, the real burden of ESRD in China is still unclear. Nanjing is one of the biggest cities in China. Our present study based on the ten years complete electrical registry data system provided a convincing data about the real threat of ESRD in China. According to this study, we estimated that China will probably have over 1.5 million ESRD patients in the near future with the establishment of improved healthcare system. It is therefore utmost important for both medical communities and government to take active measures to control this coming disaster.

Funding: Government Support - Non-U.S.
Conclusions: CW is now an integral part of the USRDS. Our study suggests a generally high and increasing rate of completeness of clinical data in CW. These data will enhance the value of the USRDS database for researchers in coming years.

Funding: NIDDK Support

FR-PO799
Facility Size and Impact of Extreme Measure Values on DFC Star Ratings
Christopher J. Harvey,1 Claudia Dahlerus,2 Zhezi (zac) Zhang,3 Joseph M. Messana,1 Ji Zhu,4 Cindy Liao,5 Natalie Scholz,1 K. A. Wisniewski,1 Richard Hirth,1 Elena K. Balovenkov,2 Joel S. Andressy,4 Yi Li1 1Biostatistics, Kidney Epidemiology and Cost Center, Univ of Michigan, Ann Arbor, MI; 2Centers for Medicare and Medicaid Services.

Background: In 2015 CMS implemented star ratings for dialysis facilities to make it easier for consumers to compare dialysis facilities by providing a summary of each facility’s performance on a set of 9 DFC quality measures. Our study compares two scoring approaches to the star rating to assess the impact of each on controlling outlying measure values with regard to facility size.

Methods: Fixed percentiles are applied to assign 10% of facilities 1-star or 5-stars based on performance. 2013 data were extracted from the 2015 inpatient DFC file. Probit ranking and z-score transformation were applied to the DFC measures to develop an overall score and final star rating. We compared the final distribution of star ratings for each approach and assessed impact on smaller facilities. We represent the rating by number of patients in each facility contributing to the hospitalization measure, and split ~6000 facilities into groups of ~100 and calculated percentage of each star rating in each group.

Results: Use of original measure values and z-scores allowed skewed measures to highly influence the ratings, but preserved original measure distributions. Probit ranking resulted in giving more 5-star ratings to smaller facilities and a z-scored approach resulted in assigning more 1-star and 5-star ratings to smaller facilities (Figure 1).

Figure 1: Distribution of Star Ratings

![Distribution of Star Ratings](image)

Conclusions: Small facilities have more variation in measures and be over represented in the 1 or 2-star categories. Probit ranking (current DFC Star Rating method) controlled impact of outlier measure values. Z-score methods appeared to allow greater impact of extreme values. However, facility size may also be related to quality of care.

Funding: Other U.S. Government Support

FR-PO800
P11 as Marker and Vitamin D as Treatment Option of Depression in Maintenance Dialysis Patients

Background: Depression is a disabling condition impairing all aspects of human functions. The serotonin system has been implicated in the pathophysiology of depression. Recently, as a member of the S100 family of proteins, P11 is known to have relation to depression by interacting with serotonin receptors and affected by inflammation. Because of nutritional deficiency and limited physical activities, dialysed patients are easy to have depression marker despite taking the effect of inflammation into consideration, but not in peritoneal dialysis group.

Methods: A single center cross-sectional study, we examined the peripheral blood mononuclear cells P11 mRNA, IL-6, TNF-α, 25-hydroxycholecalciferol (25-(OH)D3) of ~100 patients with hemodialysis (HD, N=27), peritoneal dialysis (PD, N=39) and healthy group (control, N=7), p<0.05. The mean IL-6 levels were low in control group (6.43 ± 1.34 pg/mL (HD) and 7.53 ± 1.39 pg/mL (PD) vs. 2.23 ± 0.49 pg/mL (control), p<0.05). The mean TNF-α levels were low in control group (4.31 ± 0.26 pg/mL (HD) and 4.15 ± 0.25 pg/mL (PD) vs. 1.85 ± 0.53 pg/mL (control), p<0.05) respectively. In depressive group (BDI>10), P11 levels showed relationships with depression severity in peritoneal dialysis group ( spearman ρ=0.2, p<0.09). In hemodialysis group, 25-(OH)D3 level was lower in depressive group (11.8 ± 3.8 vs. 7.5 ± 2.7, p<0.05), but there was no difference in peritoneal dialysis group (6.3 ± 3.3 vs. 7.4 ± 7.1, p=0.55).

Conclusions: By diagnostic tool, P11 can be used in peritoneal dialysis group as a depression marker despite taking the effect of inflammation into consideration, but not in hemodialysis group. As other treatment option, 25-(OH)D3 can be used in hemodialysis group for depression management, but not in peritoneal dialysis group.

FR-PO801
Efficacy of Loop Diuretics in the Management of Undocumented End Stage Renal Disease Patients Receiving Emergency Hemodialysis
Salman Ahmed, Biru Workeneh. Dept of Internal Medicine, Section of Nephrology, Baylor College of Medicine, Houston, TX.

Background: Nearly eleven million undocumented immigrants reside in the United States. An estimated six thousand undocumented patients suffer from End Stage Renal Disease (ESRD). These patients routinely present to public hospitals for life-saving emergent dialysis treatments. Since these patients lack a dialysis unit, they often do not have medication management by a nephrologist. This can result in poorer outcomes.

Methods: We reviewed charts of 93 undocumented patients who presented for at least three emergent hemodialysis (HD) treatments during three consecutive months to the Ben Taub General Hospital, a centrally located county facility in Houston, TX. We abstracted prescription data for furosemide and several commonly prescribed medications. We also abstracted data regarding the number of ER visits, number of HD sessions, and mean, median, and peak potassium values.

Results: On average, the diuretic group had 3.1 (SE=1.8) fewer ER visits during the three-month period for emergency dialysis, compared with subjects not on diuretics (p=0.10). There was no significant relationship between furosemide total daily dose (TDD) and potassium levels. Patients on diuretics were more likely to also be taking ESAs and sevelamer (p=0.05). In a multiple regression model, the diuretic group had significantly fewer ER visits after adjusting for use of ESAs and sevelamer use (p=0.007). The association between diuretic use and ER visits is significantly associated with concomitant ESA use (p=0.04). Among subjects using ESAs, patients on diuretics have about 7.7 (95% CI: 1.9,13.6) fewer ER visits compared with the non-diuretic group.

Conclusions: There was no significant independent association between loop diuretic dosage and number of ER visits, although there was a strong trend. The subset of patients on ESAs and loop diuretics had decreased ER utilization, and this may be explained by increased doctor-patient time, less symptomatology while on ESAs, or other, as-yet-undetermined mechanisms.

FR-PO802
Unfractionated Heparin May Contribute More to Dialysis-Associated Bleeding Risk Than Low-Molecular Weight Heparin
Suzanne H. Forbes,1 Sean Platten,2 Michael K. Almond,3 Laura Green,2 Neil Ashman.1 Nephrology, Royal London Hospital; 2Haematology, Royal London Hospital; 3Nephrology, Southend Hospital.

Background: Haemodialysis (HD) patient are well recognised to be at increased risk for major bleeding. The contribution of circuit anticoagulation to this risk is unknown. The use of unfractionated heparin (UFH) vs low-molecular weight heparin (LMWH) is debated. APPT/anti-Xa levels show anticoagulation is cleared by the end of HD but these tests are poorly correlated with bleeding phenotype. We used thrombin generation (TG) to assess coagulation throughout HD with UFH or LMWH.

Methods: We studied 127 patients; 60 LMWH, 61 UFH, 6 heparin-free. Blood was taken at t0=pre-anticoagulation, t1=1hr, t2=2hrs, t3=end. TG was performed on platelet rich plasma from each time point. We measured peak thrombin (p=0.05). Heparin-free patients showed minimal change.

Results: With LMWH 42% failed to generate thrombin by t2 as compared with 19% UFH (p=0.10). There was no significant independent association between loop diuretic use and number of ER visits, although there was a strong trend. The subset of patients on ESAs and loop diuretics had decreased ER utilization, and this may be explained by increased doctor-patient time, less symptomatology while on ESAs, or other, as-yet-undetermined mechanisms.
Dialysis: Epidemiology, Outcomes, and Clinical Trials: Noncardiovascular - II

**Anti-Platelet Factor 4 Antibodies: A One HIT Wonder**

**Background:** Hemodialysis (HD) patients are exposed to regular anticoagulation, usually unfractionated heparin (UFH) or low-molecular weight heparin (LMWH). For standard HD (4 hrs, 3 days/week) this equates 26 full days exposure/yr. Recently there was interest in the presence of heparin induced thrombocytopenia (HIT) in HD, and the causative anti-platelet factor 4 (PF4) antibody. There are several publications suggesting the presence of the antibody, without the clinical syndrome of HIT, is present in up to 25% HD patients, and may be an independent risk factor for cardiovascular and vascular access morbidity.

**Methods:** We looked for HIT antibodies in 2 prevalent HD cohorts, one with UFH, one LMWH (time lock sodium citrate). We tested serum for anti-PF4 antibodies using several established tests; STic Expert® (IgG-specific exclusion test), Diaomed (particle gel immuno-assy), poly-specific IgG/A/M ELISA, IgG-specific ELISA.

**Results:** We included 127 patients: 60 receiving tinzaparin, 61 receiving UFH and 6 receiving LMWH. Serum samples were taken at the start of a standard HD session. The average duration on dialysis was 3.4 years. Results of the various tests are shown.

Only 1 patient tested antibody positive (OD 0.5) in the LMWH group. Platelet count and reactivity (anti-PA, anti-epinephrine, collagen) did not differ between the STic positive/negative groups, the UFH-LMWH groups, or those with higher or lower tertiles of ELISA OD.

**Conclusions:** Despite the previous reported concern over the presence of HIT antibodies in HD patients, we comprehensively show here no evidence of antibody positivity in HD patients. Exclusion tests such as STic expert are not useful in these patients.

**Upper Gastrointestinal Bleeding Among Dialysis Patients in an Endemic Area for Chronic Liver Disease: Taiwan National Cohort Study**

**Background:** End-stage renal disease (ESRD) and chronic liver disease (CLD) both increase the risk for upper gastrointestinal (UGI) bleeding. The prevalence of ESRD and CLD are high in Taiwan. The aim of this study was to evaluate the incidence, risk factors, and categories of UGI bleeding in ESRD dialysis patients.

**Methods:** Using Taiwan’s National Health Insurance research database, we enrolled 42,457 incident ESRD dialysis patients who began dialysis between 1999 and 2004. The patients were followed until death, dialysis cessation, or 31 December 2008. Cumulative incidence of UGI bleeding after initiation of dialysis was calculated using Kaplan-Meier methods. Predictors for UGI bleeding were determined using Cox models.

**Results:** During the follow-up period, 5,528 patients had a UGI bleeding. Male, elderly, receiving hemodialysis (HD) and patient with comorbidities had a higher rate of UGI bleeding. The 1-, 3-, 5- and 7-year cumulative incidence rate of UGI bleeding were 9.8%, 21%, 25.3% and 28% in patients with liver cirrhosis (LC) on HD, 5.8%, 16.2%, 22.2% and 24.4% in patients with LC on PD, 3.7%, 9.2%, 13.2% and 16.4% in patients without LC on HD, and 2.1%, 5.5%, 8.2% and 10.4% in patients without LC on PD (log-rank: p <0.001). After multivariate adjustment, prior gastrointestinal bleeding (HR 1.731, 95% CI, 1.651-1.834), LC (1.682, 95% CI, 1.524-1.856), alcoholism liver disease (1.536, 95% CI, 1.635-1.834), and receiving HD (1.316, 95% CI, 1.153-1.502) were independently risks for UGI bleeding in ESRD dialysis patient. Gastric ulcers were found to be the most common source of bleeding (50.3%), while bleeding resulting from a gastrointestinal ulcer was least frequent.

**Conclusions:** ESRD dialysis patients had a higher risk for UGI bleeding, especially those with prior gastrointestinal bleeding, LC, and alcoholism liver disease. In addition, receiving HD is a strong predictor for UGI bleeding. More attention should be paid to select dialysis modality, especially in high risk patients.

**FR-PO805**

**Palmitoylethanolamide Is a Promising Therapeutic Target for Increasing High Density Lipoprotein Cholesterol Levels**

**Background:** End stage renal disease (ESRD) is associated with significant increased risk of cardiovascular (CV) mortality. High density lipoprotein (HDL) deficiency and dysfunction is a major contributor to CV disease in ESRD. Strategies aimed at improving HDL level and function are crucial in improving CV outcomes. Palmitoylethanolamide (PEA) is an anti-inflammatory lipid derived mediator that activates PPARalpha nuclear transcription factor. We hypothesized that serum PEA will correlate with HDL and PEA can increase HDL via activation of apolipoproteinAI/ApoAI expression.

**Methods:** Serum PEA concentration was determined in 50 patients on maintenance hemodialysis (MHD) using LC/MS technology and correlated with clinical laboratory indices including a lipid panel. Liver cells (Hepatoma cell line HepG2) were exposed to various concentrations of PEA in-vitro for 24 hours and subsequently mRNA expression of ApoAI, the major protein component of HDL, was measured using real-time PCR.

**Results:** Serum PEA concentrations strongly correlated with serum HDL levels in MHD patients (r=0.57, p <0.0001). PEA also correlates with total cholesterol (r=0.36, p=0.009) however not with LDL or triglycerides. In the in-vitro studies, PEA at a concentration of 60 micromolar and 120 micromolar was increased ApoAI expression significantly in HepG2 cells after 24 hours.

**Conclusions:** For the first time we report that serum PEA concentrations strongly correlate with serum HDL concentrations in MHD patients. Involvement of PEA in HDL production is confirmed in in-vitro studies where incubation of liver cell in PEA resulted in increased ApoAI expression. These novel findings indicate that PEA may be a promising therapeutic target in HDL deficiency treatment associated with not just ESRD but any proatherosclerotic condition.

FR-PO807
Newly Launched Cellulose Tri-Acetate Membrane with Asymmetric Structure Dramatically Improves Peripheral Circulation and Hemodynamic Stability During Hemodialysis 
Ituko Masakane, Tabuki Hospital, Nephrology, Yamagata, Japan.

Background: The most important concern about the biocompatibility of dialysis membrane is the activation of platelets and it would lead hemodynamic instability during dialysis session. The newly launched CTA with asymmetric thick structure (ATA) was produced in order to reduce stimulant property to platelets and the rapid reduction of the serum levels of small uromic solutes by thickening the membrane. We evaluated the solute removal performance and biocompatibility of ATA.

Methods: Seven chronic hemodialysis patients were enrolled to the current study. The conventional CTA was used for the first 4 months and ATA was used for the next 4 months. We evaluated the solute removal property by the clearance of Urea, beta-2 microglobulin (B2MG) and removed amount of alpha-1 microglobulin (A1mG) and albumin loss in spent dialysate. The biocompatibility was evaluated by changes in WBC and platelet count, IL-6, Pentorexine-3 (PTX-3) and high sensitive CRP (hsCRP). The peripheral circulation was estimated by the Skin Perfusion Pressure (SPP) by PAD-3000® (Kaneka Medix, Osaka, Japan). Intra-dialytic hemodynamic stability was evaluated by arterial blood pressure and subjective feelings of the patients.

Results: The clearance of Urea was significantly reduced through dialysis session in both groups but the B2MG clearance was maintained only in ATA. The total removed amount of A1mG was significantly higher in ATA than CTA. The platelet count didn’t change in ATA during dialysis session but significantly decreased in CTA. WBC counts, IL-6, PTX-3, hs CRP in both groups didn’t change. The systolic blood pressure and frequency of intra-dialytic hypotension were not different in both groups whereas some of the patients felt post-dialytic fatigue improved in ATA. SPP was maintained during dialysis session in ATA but deteriorated in CTA.

Conclusions: The new ATA membrane could reduce the activation of platelets and maintain the peripheral circulation during a dialysis session and the time-dependent deterioration of solute removal. The new ATA membrane may improve the QOL and prognosis of chronic dialysis patients.

FR-PO808
Mathematical Modeling of Fluid Transport in Peritoneal Cavity 
Fansan Zhu,1 Samer R. Abbasi,2 Roxana M. Bologna,2 Aurelita Lanto,2 Peter Kotanko,1,3 Nathan W. Levin.1 1Renal Research Inst, New York, NY; 2Rogosin Inst, New York, NY; 3Icahn School of Medicine at Mount Sinai, New York, NY.

Background: The current standard method (peritoneal equilibration test (PET)) is used to obtain transport characteristics of the peritoneal membrane for creatinine, urine and electrolytes, but not for fluid volume. Consequently, ultrafiltration profiles are difficult to obtain because the weight difference between the inlet and outlet dialysate show only net removal during PD. The aim of this study was to investigate whether the rate of change in fluid (Vf) in peritoneal cavity and body tissue fluid volume (Vb) can be simulated with a two compartment model.

Methods: Segmental biopsies was continuously monitored in ten PD patients to provide Vf during standard PET in the clinical unit (Zhu, et al. Am J Kidney Dis, 2003). Vf was measured with whole body biopsimde technique (Hydra 4200). A two compartment model of Vf and Vb (Fig. 1a) was established (Eq.1-Eq.6). Two transport coefficients: k1 and k2 represent the rate of fluid shift from Vb to Vf by reabsorption and from Vf to Vb , driven by the glucose gradient. k1 and k2 were estimated by best fitting with the actual measurements based on the Marquardt-Levenberg algorithm.

Results: Parameter estimation was successful (residuals=0.01) in all but one patient, who experienced technical problems during the measurements. Fig. 1 (b) shows change in Vf (k2=0.0002* Vf), k2=0.0002, R2=0.46, p<0.05).

Conclusions: For the first time we report that serum AG concentrations are significantly increased in CKD patients. These novel findings are in line with our report on IR acute kidney injury and with a recent study which showed that in an oxidative stress setting, monoacylglycerol lipase, an enzyme responsible for AG breakdown is inhibited leading to increased levels. Moreover, the substantial increase in MHD patients is intriguing given association of MHD with increased oxidative stress, inflammation and platelet activation.

FR-PO809
Linagliptin Ameliorated Methylglyoxal-Induced Peritoneal Fibrosis in Mice 
Taku Nagaia, Shigehiro Doi, Ayumu Nakashima, Takao Masaki, Dept of Nephrology, Hiroshima Univ Hospital, Hiroshima, Japan.

Background: Recent studies have reported that methylglyoxal (MGO) was increased in peritoneal dialysis patients, playing an important role in the development of peritoneal fibrosis. On the other hand, linagliptin, a dipeptidyl peptiase-4 (DPP-4) inhibitor, exhibits beneficial effects in diabetes patients independent of blood glucose concentration. In this study, we examined whether linagliptin suppressed MGO-induced peritoneal fibrosis in mice.

Methods: Male C57/B16 mice were divided into three groups: a vehicle group, an MGO injection group, or an MGO injection plus linagliptin group (n=6 per group). Peritoneal fibrosis was induced by a daily intraperitoneal injection of saline containing 40 mmol/L MGO for 21 days. Saline was given in the vehicle group. Linagliptin was administered at a dose of 10 mg/kg by oral gavage once a day.

Results: Immunohistochemical staining revealed that linagliptin suppressed the expression of a-smooth muscle actin and fibroblast-specific protein-1, the deposition of collagen 1 and collagen 3 and infiltration of macrophages (F4/80). In addition, linagliptin reduced TGF-β1 concentration in peritoneal fluid of MGO-treated mice. Peritoneal equilibration tests showed improvement of peritoneal function in mice receiving linagliptin treatment.

Conclusions: These results suggest that oral administration of linagliptin ameliorated MGO-induced peritoneal fibrosis.

Addition of Alanyl-Glutamine to Dialysis Fluid Restores Peritoneal Cellular Stress Responses – A Randomized Controlled First-in-Man Trial
Andrew Vychytil,1 Klaus Kratochwill,1,2 Michael Boehm,3 Rebecca Herzog,2 Katharina Gruber,1 Anton Lichtenauer,1 Lilian Kuster,1 Dagmar Csaciuk,1 Andreas Gleiss,1 Martin Bilban,1 Seth L. Alper,3 Christoph Aufricht.1 Medical Univ of Vienna, Vienna, Austria; 2Zytoprotec GmbH, Vienna, Austria; 3Beth Israel Deaconess Med. Ctr., Harvard Medical School, MA.

Background: Peritoneal dialysis (PD) fluid cytotoxicity and intermittent bacterial infection contribute to membrane failure and peritonitis in PD patients. Recent meta-analyses revealed no significant influence of newer biocompatible PD fluids on peritonitis rate or peritoneal membrane function, but glutamine addition to standard PD fluids has shown cytoprotective effects both in vitro and in vivo.

Methods: In this open-label randomized controlled cross-over phase I/II trial (NCT01353638), 20 stable PD patients each underwent two 4 h peritoneal equilibration tests with glucose-based PD fluids supplemented with or lacking 8 mmol/L alanyl-glutamine dipeptide (AlaGln), and separated by a 4 week washout phase. Effects of AlaGln on peritoneal inflammation and stimulated cytokine release were also tested in a mouse model of PD-associated peritonitis.

Results: Intraperitoneal (IP) exposure to AlaGln-supplemented PD fluid increased dialysate [glutamine] more rapidly (at 2 h mean 0.55-0.71 mM, p<0.05) and increased heat shock protein expression in peritoneal effluent cells (median 2.12-3.20, p<0.05), but did not alter peritoneal ultrafiltration, small solute transport, cell counts, or biomarkers. AlaGln increased ex vivo LPS-stimulated TNF-α release (effect CI 60-100 pg/mL, p<0.001) and, in patients with previous peritonitis, decreased dialysate [IL-8] (effect CI 0.1-4.3, p<0.05).

IP AlaGln also reduced inflammation and enhanced cytokine release in the mouse model. No adverse effects of AlaGln were noted.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only
Underline represents presenting author.

550A
Conclusions: Ala-Gln addition to standard PDF acutely attenuated PD-related peritoneal mechanosensations in both rats and in mice. These data encourage our ongoing phase IIa testing IP Ala-Gln supplementation as a routine therapeutic intervention in clinical PD.

Dipeptide Alanyl-Glutamine Protects from Peritoneal Fibrosis and Attenuates IL-17 Dependent Pathways During Peritoneal Dialysis

Evelina Ferrarenti,1 Georgios Liappas,2 Marc Vila cuenca,1 Marc G. Vervoelt,3 Robert H.J. Beelen,2 Manuel Lopez-Cabrera,2 Administrations of Molecular Cell Biology and Immunology, VU Medisch Centrum Amsterdam, Netherlands; 2CSIC-UPM Centro de Biología Molecular Severo Ochoa, Madrid, Spain; 3Department of Nephrology, VU Medisch Centrum Amsterdam, Netherlands.

Background: Peritoneal dialysis (PD) is complicated by chronic inflammation and progressive peritoneal membrane dysfunction. Alanyl-Glutamine (Ala-Gln), a stable dipeptide commonly used in parenteral nutrition, has immunomodulatory effects and improved resistance of mesothelial cells to PD fluids. Recently, IL-17 was identified as a novel player in PD induced peritoneal damage. In this study we investigated if intraperitoneal Ala-Gln administration confers protection against peritoneal damage by modulating IL-17 expression in uremic PD models.

Methods: Uremia was obtained by feeding 5/6 nephrectomy and animals were daily instilled with PD fluid enriched or not with Ala-Gln during a period of 5 days and 8 weeks respectively for rats and mice. Mice were injected weekly with recombinant IL-17 or with saline. Histological analysis was carried out in peritoneal parietum. Gene expression in the peritoneal parietum biopsies was evaluated by real-time quantitative PCR. Protein levels were determined by ELISA in peritoneal effuents.

Results: Supplementation of PD fluid with Ala-Gln resulted in reduced peritoneal thickness (70.90 ±13.45 vs 10.26 ± 0.76, P<.001), asMA expression and angiogenesis. Addition of Ala-Gln also showed attenuation of PD induced IL-17 mediated pathways, reflected by substantial reduction/normalisation of peritoneal levels of IL-17 (32.55 ± 3.32 vs 7.99 ± 1.59, P<.001), TGF-β, IL-6 and ROR(γ). Moreover, repeated exposure of the Ala-Gln treated group to recombinant IL-17 increased peritoneal fibrosis which was however restored upon IL-17 neutralization.

Conclusions: These results suggest that intraperitoneal administration of Ala-Gln ameliorates PD induced peritoneal damage at least in part by modulating IL-17 expression. Therefore, this evidence paves into investigations whether Ala-Gln could be a potential strategy to ameliorate peritoneal deterioration during PD.

JAK1/2 Inhibitor Preserves Peritoneal Membrane Function in a Non-Uremic Peritoneal Dialysis Rat Model

Tianie Dai,1 Ying Wang,1 Panida Ditsawanon,2 Pornanong Arawit,3 Janine A. La page, Sharon G. Adler,3 1Internal Medicine, LA Biomed at Harbor-UCLA Medical Center, Torrance, CA; 2Pharmacy Practice, Chulalongkorn Univ, Bangkok, Thailand.

Background: We previously showed JAK/STAT pathway activation in the peritoneal membrane (PM) of rats receiving PD with 4.25% Dianel for 10 days; concomitant treatment with a JAK1/2 inhibitor (JAKi) attenuated PM inflammation, fibrosis, and hypervascularity. We also showed that the mean concentration of MCP-1 was higher in the PD fluid of patients on long-term PD (>6mos) vs new patients (<2wks), demonstrating the potential for clinical relevance (KI.2014). These experiments were performed to determine if a JAKi could prevent deterioration of peritoneal membrane function after longer-term exposure to PD fluid.

Methods: Tunneled PD catheters were placed in rats who received BID infusions of PD fluid of patients on long-term PD (>6mos) vs new patients (<2wks), demonstrating the potential for clinical relevance (KI.2014). These experiments were performed to determine if a JAKi could prevent deterioration of peritoneal membrane function after longer-term exposure to PD fluid.

Results: Both D/D0 glucose and D/P total protein functional measurements demonstrate that Ala-Gln protects the peritoneal membrane from the damaging effects of 4.25% Dianel.

Conclusions: Membrane failure limits the use of PD long-term. Strategies that preserve PD function are critically needed. Together with our prior results, these studies demonstrate the capacity of JAKi to preserve rat PD membrane structure and function during PD fluid exposure.

FR-PO813

MicroRNA Expression Profiling in Peritoneal Fibrosis

Yoshikazi Morishita,1 Daisuke Nagata,1 Div of Nephrology, Dept of Internal Medicine, Chiba Medical Univ, Chiba, Japan; 2Div of Nephrology, Dept of Internal Medicine, Jichi Medical Univ, Shomotuke, Tochigi, Japan.

Background: Peritoneal fibrosis (PF) is an intractable complication leading to peritoneal membrane failure in peritoneal dialysis (PD). The aim of this study was to identify the microRNAs (miRNAs) involved in PF.

Methods: miRNA screen was performed using microarray analysis in peritoneal tissue of patients with PF who induce by intraperitoneally injection of PD fluid containing methyglyoxal (MGO). The expression level of identified miRNAs of serum and drained dialysate were evaluated the association of peritoneal membrane functions measured by peritoneal equilibration test (D/P Cr and D/D0 glucose) in 33 PD patients. Furthermore, an identified miRNA inhibitor (anti-miRNA-21-5p locked nucleic acid: anti-miRNA-21-LNA) was intraperitoneally injected to PF model mice to investigate its effects for PF.

Results: The initial profiling study identified 6 miRNAs (miRNA-21-5p, miRNA-221-3p, miRNA-223-3p, miRNA-142-3p, miRNA-327 and miRNA-34a-5p) increased more than tenfold, and no miRNA decreased less than half in peritoneal tissue of PF rats compared with control rats. Among them, serum level of miRNA-21-5p (D/P Cr r=0.44, p=0.01; D/D0 glucose r=0.433, p=0.01), miRNA-327 (D/P Cr r=0.48, p=0.01; D/D0 glucose r=0.50, p=0.01) and miRNA-221-3p (D/P Cr r=0.50, p=0.01; D/D0 glucose r=0.50, p=0.01) and draining dialysate level of miRNA-221-3p (D/P Cr r=0.52, p=0.01; D/D0 glucose r=0.46, p<0.01) and miRNA-34a-5p (D/P Cr r=0.44, p=0.01; D/D0 glucose r=0.48, p<0.01) were significantly correlated with peritoneal membrane functions in PD patients. Anti-miRNA-21-LNA significantly inhibited miRNA-21-5p expression in peritoneum of PF mice. It also inhibited fibrotic pathways thickening and maintained better peritoneal membrane functions.

Conclusions: The results of present study suggested several miRNAs involved in PF, and may be used as the novel diagnosis biomarkers and therapeutic targets for PF.

Nanoparticles of Lipids Associated with Paclitaxel as an Alternative Strategy to Block Peritoneal Fibrosis

Filipe M. Silva,1 Raphael Pepineli,2 Elerson Costalanga,1 Raul Cavalcante Maranhão,1 Irene L. Noronha,1 1Nephrology Div, Univ of Sao Paulo, Brazil; 2Laboratory of Lipids Metabolism, Univ of Sao Paulo, Brazil.

Background: Peritoneal fibrosis (PF) and loss of ultrafiltration represent important complication long-term peritoneal dialysis, with limited options of treatment. Advances in nanotechnology enabled drug release systems that can provide the release of an active drug in the target tissue. Nanoparticles similar to LDL were developed, linked to Paclitaxel (NanoPACL), an antiproliferative drug. NanoPACL have the ability to bind to LDL receptors present on the cell surface, particularly in immune-inflammatory sites. The aim of this study was to analyze the effect of NanoPACL administration in an experimental model of PF.

Methods: PF was induced in Wistar rats by daily IP injections of chlorhexidine gluclate (CG) at 0.1% during 15 days. Animals (n=20) were divided into 4 groups: Control, non-treatment rats, PF treated with injections of GC, Nano. PF rats treated with nanoparticles without Paclitaxel, via IP, NanoPACL, PF rats treated with NanoPACL (4mg/kg every 3 days, via IP). Euthanasia was performed on day 30. Peritoneal thickness and function, immunohistochimistry and qPCR were analyzed.

Results: NanoPACL significantly reduced peritoneal thickness, α-SMA expression and cell proliferation compared with control groups. Treatment with NanoPACL decreased TGF-β and Smad 3 mRNA expression and preserved peritoneal function characterized by preservation of UF and reduced mass transfer of glucose (MTG).

Conclusions: NanoPACL administration was effective in preventing PF and preserving peritoneal function, possibly by local effect of Paclitaxel.

Vitamin D Receptor Activator (VDRA) Attenuates Epithelial-to-Mesenchymal Transition (EMT) via Modulation of NAPDH Oxidase (NOX) Activity and Mitochondrial Dysfunction in Human Peritoneal Mesothelial Cells (HPMC)  

Ryeol Ryu, Seung-Hyun Shin, Dong-Ryeol Ryu, Shina Lee, Kyungpook National Univ School of Medicine, Seoul, Republic of Korea.

Background: EMT is known as a key mechanism of peritoneal fibrosis in peritoneal dialysis. Oxidative stress induced by NOX and mitochondrial dysfunction is one of the mechanisms responsible for EMT. Paricalcitol, a selective VDRA, is known to exert anti-fibrotic effect organ fibrogenesis, however there are no studies about the role of paricalcitol on peritoneal fibrosis. We investigated whether paricalcitol imposed any effect on TGFβ1-induced EMT of HPMC with an exploration of mechanism of anti-fibrotic effect of paricalcitol in terms of modulation of oxidative stress.

Methods: EMT was evaluated by morphological changes of HPMCs and the expressions of E-cadherin and α-smooth muscle actin. Intracellular ROS was analyzed by measuring NOX activity and H2O2 generation, NOX mRNA expressions with DCF-DA and Mitotox staining. Activation of Erk1/2, p38 MAPK, nuclear translocation of β-catenin and snail expression were assessed by western blotting and immunocytochemistry. Effect of paricalcitol on ROS generation and EMT was analyzed in HPMC exposed to TGFβ1.

Results: TGFβ1 (1ng/ml) induced EMT of HPMCs with an increase in ROS generation and NOX activity from 30 minutes, and mitochondrial ROS production from 6 hours. TGFβ1 also increased the phosphorylation of Erk and p38 MAPK from 1 hour, which was followed by nuclear translocation of β-catenin and snail up-regulation in HPMC. Paricalcitol (50nM) ameliorated TGFβ1-induced EMT in HPMC, which was associated with a decrease in both NOX- and mitochondria-mediated ROS production. TGFβ1-induced EMT was partially alleviated by N-acetyl cysteine (5mM) or apocynin (100μM), which was further inhibited by an addition of rotenone (1μM) or paricalcitol.

Conclusions: One of the VDRAs, paricalcitol, ameliorated TGFβ1-induced EMT of HPMCs by a decreased in ROS generation in HPMCs. Anti-oxidant effect of paricalcitol seems to be related to the direct inhibition of NOX and mitochondria-mediated ROS production.

Funding: Government Support - Non-U.S.

Adenosine Monophosphate-Activated Protein Kinase (AMPK) Agonist Attenuated Epithelial-to-Mesenchymal Transition (EMT) of Mesothelium and Peritoneal Fibrosis via an Amelioration of Oxidative Stress

Jiyeon Ko, Eun Sun Ryu, Hyun-yon Jung, Shina Lee, Dong-Ryeol Ryu, Seung-Jung Kim, Kyu Bok Choi, Sun-Hee Park, Yong-Lim Kim. 1Dept of Internal Medicine, Ewha Womans Univ School of Medicine, Seoul, Republic of Korea; 2Kyungpook National Univ School of Medicine, Daegu, Republic of Korea.

Background: Phenotype transition of peritoneum has been regarded as an early mechanism of peritoneal fibrosis. Metformin, one of the AMPK agonists, has recently received a new attention due to an inhibitory effect on EMT of cancer cells. We investigated whether metformin imposed any effect on EMT of HPMC with an exploration of cellular mechanisms for anti-fibrotic effect of metformin.

Methods: EMT was evaluated by morphological changes and the expressions of E-cadherin and α-SMA after stimulation of TGFβ1 (1ng/ml). ROS generation was analyzed by DCFDA, NOX activity, NOX mRNA expression, and Mitotox staining. Activation of Smad2/3, MAPK, nuclear translocation of β-catenin and snail expression were also assessed. Animal model of peritoneal dialysis (PD) was established by daily infusion of 4.25% glucose-based dialysate for 8 weeks via intraperitoneal catheter. Effects of metformin were followed by nuclear translocation of β-catenin and snail up-regulation. Metformin ameliorated ROS production, the activation of Smad2/3 and MAPK, and Snail expression. In PD model, metformin decreased peritoneal thickness and EMT with an increase in ratio of E-cadherin to oxidized glutathione and superoxide dismutase activity. Metformin also decreased the expression of nitrotyrosine in peritoneum and 8-OHdG in dialysate.

Conclusions: AMPK may play a role in preservation of peritoneal function by protecting the peritoneum from phenotype transition and fibrosis via an amelioration of oxidative stress.

The Expression of miRNA200a in Peritoneal Dialysis Associated Peritonal Fibrosis

Xin Wei. Nephrology Dept, The First Affiliated Hospital of Nanchang Univ, Nan Chang, China.

Background: Peritoneal fibrosis (PF) is an almost invariable consequence of peritoneal dialysis (PD), which is an established alternative for the replacement therapy of end-stage renal disease. We know that miR-200a belong to miR-200 family, which is closely related to a variety of fibrotic diseases.However, the role of miR-200a in peritoneal fibrosis is largely unknown.

Methods: The peritoneal fibrosis mouse model associated with PD was established by intraperitoneal injection of lipopoly saccharide + 4.25% peritoneal dialysate. The expression of miRNA was detected by microarray. The expression of miRNA profiles between fibrotic and normal peritoneal tissues was compared (n=3 in each group). The differentially expressed miRNA (miR-200a) was validated by real-time PCR in larger sample size cohorts (n=15). The expression of miR-200a were also detected in the epithelial-mesenchymal transition (EMT) process of peritoneal mesothelial cells.

Results: In mice model of PD, peritoneal tissue was markedly thickened and with a massive extracellular matrix accumulation. By microarray analysis, miR-200a was significantly down regulated (3.31 fold change, P<0.05) in fibrotic peritoneal tissues. The down-regulated expression level of miR-200a was also validated by real-time PCR in larger cohorts (P<0.05). Then, the expression level of miR-200a was detected in the EMT process of human peritoneal mesothelial cells. During the process of TGFβ1 induced EMT, miR-200a was significantly down-regulated compared with the control (P<0.05).

Twist Accelerates Human Peritoneal Mesothelial Cells Proliferation and Fibrosis by Regulating YB-1

Lijie He. Dept of Nephrology, Xijing Hospital, Xi’an, China.

Background: We have previously shown that E-box–binding transcription factor Twist is overexpressed in high glucose damage of human peritoneal mesothelial cells (HPMCs) and is involved in peritoneal membrane (PM) fibrosis in vitro. Here, we further identify its precise function related to peritoneal membranes (PM) fibrosis.

Methods: We have previously shown that E-box–binding transcription factor Twist is over-expressed in high glucose damage of human peritoneal mesothelial cells (HPMCs) and is involved in peritoneal membrane (PM) fibrosis in vitro. Here, we further identify its precise function related to peritoneal membranes (PM) fibrosis.

Results: Here, up-regulated expression and activation of Twist and YB-1 were found in HPMCs under extensive periods of PM fibrosis ex vivo. In immortal HPMCs and in HG-induced PD animal model, Twist and YB-1 were also up-regulated and a transformed fibroblastic phenotype of HPMCs was found stimulated by high glucose (HG, 60 mmmol/L).

Evidence from chromatin immunoprecipitation and reporter assays further supported that YB-1 were transcriptionally regulated by Twist directly binding to E-box. Collectively, these data suggested that Twist and YB-1 was a major downstream target of Twist. Re-expression of Twist in PD led to decrease HPMCs growth, induced cell cycle arrest and increase PM fibrosis. Silencing of Twist or YB-1 could promote cell cycle progression of HG-induced HPMCs growth, increasing cyclin D1/Cdk2 and cyclin E/Cdk4 expression and also inhibited PM fibrosis.

Conclusions: Our data suggested that activation of Twist/YB-1 pathway might contribute to the growth retardation of HPMCs and the progressive PM fibrosis during PD.
**Effects of Astragaloside IV against the TGF-β-Induced Epithelial-to-Mesenchymal Transition in Peritoneal Mesothelial Cells by Promoting Smad7 Expression**

Lu Zhang, Zhenghong Li, Weiming He, Jingdong Xu, Ning Wang, Jun Shi, Meixiao Sheng, *the First Clinical Medical College, Nanjing Univ of Chinese Medicine, Nanjing, Jiangsu Province, China; Renal Div, Jiangsu Province Hospital of Chinese Medicine, Nanjing, Jiangsu Province, China; Jiangsu Province Academy of Traditional Chinese Medicine, Nanjing, Jiangsu Province, China.

**Background:** To investigate the effect of Astragaloside IV (AS-IV) on the regulation of the TGF-β1 Smad signaling pathway in mesothelial cells with an epithelial-to-mesenchymal transition (EMT).

**Methods:** EMT of human peritoneal mesothelial cells (HMrSV5) was induced using 2 ng/ml TGF-β1. Cells were randomly divided into a vehicle group, a vehicle group with AS-IV, a TGF-β1-treated group, and a TGF-β1-treated group receiving various doses of AS-IV or NAC. Real-time quantitative PCR and western blot were used to detect the expression of genes and proteins associated with the TGF-β1/Smad signaling pathway and EMT. DCFH-DA was used to detect the generation of ROS in HMrSV5 cells, and a transwell migration assay was used to verify the capacity of AS-IV to inhibit EMT in HMrSV5 cells. Lentivirus were used as carriers for the overexpression or knockdown of the Smad7 gene.

**Results:** Expression levels of E-cadherin (epithelial marker) was decreased and vimentin, α-SMA (EMT markers) and collagen I (extracellular matrix protein) phospho-Smad2/3, Smad1 and Smad2/3 was increased significantly in the TGF-β1-treated HMrSV5 cells. AS-IV was associated with downregulated expression of vimentin and phospho-Smad2/3 in a dose-dependent manner, while the expression of Smad7 increased. Silenced or forced expression of Smad7 verified its role in the inhibitory effect of AS-IV on TGF-β1-induced EMT in HMrSV5 cells.

**Conclusions:** AS-IV effectively promotes the upregulation of Smad7 in the TGF-β1/Smad signaling pathway during the EMT of HMrSV5 cells, indicating its potential therapeutic effect for the control of PF.

**Extracellular Vesicles in Peritoneal Effluent**

**Background:** Continuous and long-term exposure to peritoneal dialysis (PD) solutions induces constant low-grade inflammation and remodeling of peritoneal membrane morphology. Although the biochemical composition of peritoneal effluent offers the opportunity to explore the peritoneal membrane status in a simple and non-invasive manner, to date no clinically useful effluent biomarker has been identified that reflects the peritoneal membrane integrity sufficiently. As human body fluids contain extracellular vesicles (EVs), which are now believed to provide novel biomarkers for diseases, we investigated the presence of EVs in peritoneal effluent.

**Methods:** Peritoneal effluent of a short-term PD patient was collected from a regular dialysis dwell. After centrifugation, aliquots of cell-free effluent were frozen in liquid nitrogen and stored at -80°C until analysis. EVs were isolated by size exclusion chromatography. Thereafter, transmission electron microscopy (TEM) and flow cytometry (comprising markers for epithelial and mesothelial cells, leucocytes, platelets and erythrocytes) were used to detect the presence of single EVs.

**Results:** EVs and liposomes were identified by TEM and flow cytometry. EVs exhibited their characteristic cup shape. The majority of EVs had a mean diameter <100nm, and were present in similar amounts as in human plasma. Most EVs originate from epithelial and mesothelial cells. Moreover, EVs stained positive for leucocyte antigens, mesothelin and cancer antigen 125.

**Conclusions:** This is the first study to demonstrate the presence of EVs in human peritoneal effluent. Furthermore, the cellular origin of most peritoneal EVs is established.

*Funding:* Government Support - Non-U.S.
We postulate that the presence and composition of such EVs in peritoneal effluent will closely mirror the peritoneal membrane morphology. Future studies will be necessary to investigate the clinical relevance for the detection of peritoneal membrane damage and potential use of these peritoneal EVs in PD patient care.

miR-200a Negatively Regulates TGF-β1-Induced Peritoneal Mesothelial Cell Epithelial-Mesenchymal Transition by Targeting ZEB1 and ZEB2 Expression Xin Wei, Guojun Hao, Qinkai Chen. Nephrology Dept, The First Affiliated Hospital of Nanchang Univ, Nan Chang, China.

Background: Peritoneal fibrosis (PF) is an almost invariable consequence of peritoneal dialysis (PD), which is an established alternative for the replacement therapy of end-stage renal disease. In our previous study, we found that the expression level of miR-200a were down-regulated in fibrotic peritoneum and the epithelial-mesenchymal transition (EMT) process of peritoneal mesothelial cell. However, the role of miR-200a in EMT of peritoneal mesothelial cell and peritoneal fibrosis is largely unknown.

Methods: Human peritoneal mesothelial cell line (HM-MV5) was cultured in the presence or absence of TGF-β1. The protein expression levels of EMT index and E-box-binding homeobox (ZEB) 1/2 were determined by western blot. The level of miR-200a and CD90/Thy-1 were detected by Real Time PCR. miR-200a mimic or inhibitor and negative control RNA were transfected into HM-MV5 cells using Lipofectamine 2000.

Results: We found that miR-200a mimic can attenuated TGF-β1-induced peritoneal mesothelial cell EMT and synthesis of extracellular matrix. It was also demonstrated that the miR-200a was responsible for protecting peritoneal mesothelial cells from mesenchymal transition by targeting suppression of ZEB1/2.

Conclusions: The results suggested that miR-200a may not only be a useful biomarker of EMT in ovarian cancer, but also of potential therapeutic value in peritoneal fibrosis.

Identification and Functional Characterization of Human Peritoneal Fibroblast Subsets According to the Expression of CD90/Thy-1 Edyta Kawka, E. Rudolf, M. Bartosova, R. Catar, J. Witowski, D. Dragun, A. Joerres, C. Schmidt. 1 Department of Nephrology and Medical Intensive Care, Charité-Universitätsmedizin Berlin, Berlin, Germany; 2 Dept. of Pathophysiology and Clinical Immunology, Poznan Univ of Medical Sciences, Poznan, Poland; 3 Center for Pediatric and Adolescent Medicine, Universitätsklinikum Heidelberg, Heidelberg, Germany.

Background: The exact origin of myofibroblasts in PD-assiated peritoneal fibrosis is unknown. Lineage tracing studies suggest that resident submesothelial fibroblasts may be their major precursors. Here, we set out to identify HPFB subsets in human peritoneum and examined co-expression of CD90/Thy-1 with markers of the myofibroblastic phenotype.

Methods: HPFB were isolated from omentum, purified and then separated (MACS) into CD90/Thy-1+ and CD90/Thy-1− populations for assessment of myofibroblast markers:

- qPCR, immunofluorescence, and ELISAs. Moreover, the presence of FSP-1+ and CD90/Thy-1+ fibroblasts was studied by immunofluorescence in peritoneal biopsies of 12 PD, 5 uremic patients, and 8 healthy controls.

Results: Cells positive for FSP-1+ and CD90/Thy-1− were absent in healthy controls, but were detectable in uremic and PD patients. In those, the majority (>95%) of FSP-1+ HPFB were also CD90/Thy-1+. In vitro studies showed that CD90/Thy-1+ HPFB had a 1.2-fold higher proliferation rate (MTT assay; n=12, p<0.05) than CD90/Thy-1−. Expression of myofibroblastic markers in CD90/Thy-1− cells was significantly higher with α-SMA, collagen-1 and TGF-β1 being increased (2.5-, 1.6- and 1.8-fold, respectively; n=13, p<0.05).

Furthermore, CD90/Thy-1+ HPFB revealed increased contractile properties as reflected by 1.2-fold greater reduction in collagen gel contraction assays (n=3).

Conclusions: The vast majority of FSP-1+ HPFB detected in the peritoneum of uremic and PD patients expressed CD90/Thy-1−. In contrast, this phenotype was not detected in normal peritoneum. In vitro studies demonstrated increased expression of myofibroblastic markers in CD90/Thy-1− HPFB. These cells may thus contribute to peritoneal fibrosis which often develops in patients during chronic PD.

Innovative Index to Follow the Peritoneal Infections and for Monitoring the Recovery Process After Peritonitis Grazia Maria Virzi, Sabrina Milan manani, Alessandra Brocca, Massimo de Cal, Ilaria Tantillo, Carlo Crepaldi, Claudio Ronco. Nephrology, San Bortolo Hospital-IRRIV.

Background: Cell-free DNA is present in the peritoneal effluent of stable PD patients, but there is no data on cfdNA in case of peritonitis. We investigated the variation of peritoneal cfdDNA (cfdNA) levels in PD-related peritonitis.

Methods: We enrolled 53 PD patients: 30 without any history of systemic inflammation and peritonitis in the last 3 months (group A) and 23 with acute peritonitis (group B). cfdNA were quantitated by qPCR. Peritoneal samples on day 1-3, 10-30 and until the 120th from the start of peritonitis were collected for WBC counts and cfdNA evaluation in group B.

Results: Quantitative analysis of cfdNA showed significantly higher levels in group B compared with group A (p<0.01), similarly as WBC. cfdNA showed significantly higher levels in group B on day 1-3, 10-30 and compared with group A (p<0.05). A positive correlation was observed between cfdNA level and WBC on day 1 (r=0.89) and day 3 (r=0.58; p<0.05). No statistically significant correlation was observed on day 10 and 30. In group B, cfdNA tends to progressively decrease. From this decreasing curve, we estimated that 85% are necessary to reach the value of 50 GE/ml (75 percentile in group B) and 63 days to reach 31 GE/ml (median). We observed a new rapid increase of cfdNA level (consistent with WBC) in 5 relapsing patients, at the first day of relapsing peritonitis.

Conclusions: In conclusion, cfdNA increased in peritoneal effluent in PD-related peritonitis and tended to progressively decrease in relation with membrane repair process. Peritoneal cfdDNA could be a new method to determine acute damage and an inverse index of repair process. CfdNA could help to evaluate functional and structural integrity of peritoneal membrane and to follow the evolution of infections during peritonitis.

The Role of Cell-Free DNA for Management of PD-Related Peritonitis Grazia Maria Virzi, Sabrina Milan manani, Alessandra Brocca, Massimo de Cal, Ilaria Tantillo, Carlo Crepaldi, Claudio Ronco. Nephrology, IRRIV-S Bortolo.

Background: Peritonitis and exit site infections are the major complications of PD and remains the major cause of switch from HD. In this study, we investigated the role of peritoneal cell-free DNA (cfdNA) and its association with peritonitis.

Methods: We enrolled 23 PD patients with peritonitis and without any history of systemic inflammation (14 male, mean age: 68±16 yrs). cfdNA were extracted and quantitated in peritoneal effluent by Real Time PCR for β-globin gene.

Results: All patients were treated and clinically recovered from peritonitis in 13.5±4 days. 18/23 patients had a first episode of peritonitis and responded to first-line antibiotics (65% Gram+1, 22% Gram- and 13% sterile), whereas 5/23 had a relapsing episode of peritonitis (responded to other course of intra-peritoneal antibiotics). There
and Hypertension, Medical School, Fukushima Medical Univ, Fukushima, aims to examine PMC injury by NPDF, and its ameliorating effect of H
effects in biological way, and its clinical application has been studied. The present study

Epimorphin Expressions in Mice Model of Peritoneal Fibrosis

bacterial peritonitis, suggesting bio-incompatibility of current NPDS. H
intruduction. However, meta-analysis did not show superiority of NPDS in incidence of

significantly stronger than that in control mice. Such an increase in epimorphin expression
were assessed by Masson's Trichrome staining. Epimorphin expressions were assessed by

immunohistochemically and real-time RT-PCR.

under the cell deformation of HPMCs and the progressive PM fibrosis during PD.

expression of α-SMA, CTGF, collagens and fibronectin which might increase PM fibrosis.

cluster by miR-143 or miR-145 mimic led to cell deformation, and reduced cell adhesion,

a downstream target of miR-143/145 gene cluster. Re-expression of miR-143/145 gene
expression of E-cadherin and TPM4 but down-regulating α-SMA, CTGF, collagens and

expression of miRNA-143/145 cluster and tropomyosin4 (TPM4) by real time PCR or

expression of miRNA-143/145 cluster in human peritoneal mesothelial cells (HPMC), who were as possible triggers

genome expression between PD and Con, and 3.7% changes between PD and HPD. In
gene cluster analysis, there were changes by 8.7% in whole gene expression between PD and Con, and 3.7% changes between PD and HPD. In

PCR, no difference was found in Epithelial-Mesenchymal Transition (Snail, TGF-β, αSMA)
among the groups, while wound healing (MMP9, CTGF, Fibroenectin, FAK), cytokines
(II1β, TNFα, TNFβ3) were decreased in PD as compared to Con, but no changes in HPD.

Conclusions: The current lactate-based NPDS may disturb wound healing and
local immunity of PMCs, and H2 dissolved dialysate correct them. H2 could increase
biocompatibility of PDS in preserving physiological function of PMCs in PD therapy.

Bicarbonate-Buffered Peritoneal Dialysis Solution Suppresses Lactate-
Induced Apoptosis via Monocarboxylate Transporter-1 in Human Peritoneal Mesothelial Cells

Akihiro Kuma, Tetsu Miyamoto, Ryota Serino, Yumi Furuno, Yoko Fujimoto, Hiromichi Ueno, Yutaka Otsuki, Masahito Tamura. Dept of Nephrology, Univ of Occupational and Environmental Health, Kitakyushu, Japan.

Background: Long-term peritoneal dialysis is associated with functional and structural alterations of the peritoneal membrane. Lactate-buffered peritoneal dialysis fluid (L-PDF) has impaired biocompatibility due to the presence of supra-physiological levels of lactate. Although bicarbonate-buffered PD (B-PDF) has been developed, its biocompatibility remains unclear. Here, we investigated the effects of L- or B-PDF on cell viability and apoptosis in cultured human peritoneal mesothelial cells (HPMCs), focusing on monocarboxylate transporters (MCT).

Methods: HPMCs were cultured in mediums containing 10% fetal bovine serum and L-PDF with 1.5% glucose (L1) or 2.5% glucose (L2), B-PDF with 1.5% glucose (B1) or 2.5% glucose (B2), or no PDF (control). Cell viability and apoptosis were measured with the WST-1 and TUNEL assays, respectively. The roles of MCT1-1 and -4 on lactate-induced apoptosis were evaluated by siRNA transfection for MCT-1 and -4.

Results: Cell viability was significantly decreased in cells incubated with L1 (12.2±1%, control=100%) and L2 (21.1±1%), compared with B1 (74.2±2%) and B2 (76.2±2%) after 72 h incubation. Apoptotic cells were also increased in L1 (69.1±1.6%), L2 (73.8±1.8%) compared with B1 (3.0±0%) and B2 (4±1%). MCT1-1 and -4 protein and mRNA expression levels, examined by Western blotting and real-time-PCR, respectively, were similar in all cells. Protein expression levels of MCT1-1 and -4 were almost completely diminished after transfection of siRNAs for MCT-1 and -4, respectively. MCT1-1 siRNA increased the levels of cell viability by 3.2-3.7-fold and decreased the amount of apoptotic cells from 64% to 47.4% in cells treated with L1 for 72 h. Interestingly, MCT-4 siRNA had no effect on cell viability and apoptosis.

Conclusions: Our results showed that L-PDF induced apoptosis by importing lactate via MCT-1 in HPMCs, and suggest that B-PDF improved biocompatibility by inhibiting mesothelial cell apoptosis.

FR-POB39

MiRNA-143/145 Gene Cluster Enhances Cell Deformation and Fibrosis of Human Peritoneal Mesothelial Cells via Modulating TPM4

Lijie He, Shiren Sun. Dept of Nephrology, Xijing Hospital, Xi’an, Shaanxi, China.

Background: In this study, we work for the function and mechanism of miR-143/145 gene cluster in human peritoneal mesothelial cells (HPMC), which were as possible triggers for peritoneal membrane fibrosis.
